Editorial Preface

From the Desk of Managing Editor...

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Editorial Board

Editor-in-Chief

Dr. Kohei Arai - Saga University

Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation

Associate Editors

Alaa Sheta

Southern Connecticut State University

Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems

Domenico Ciuonzo

University of Naples, Federico II, Italy

Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things

Dorota Kaminska

Lodz University of Technology

Domain of Research: Artificial Intelligence, Virtual Reality

Elena Scutelnicu

"Dunarea de Jos" University of Galati

Domain of Research: e-Learning, e-Learning Tools, Simulation

In Soo Lee

Kyungpook National University

Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning

Krassen Stefanov

Professor at Sofia University St. Kliment Ohridski

Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design

Renato De Leone

Università di Camerino

Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming

Xiao-Zhi Gao

University of Eastern Finland

Domain of Research: Artificial Intelligence, Genetic Algorithms

CONTENTS

Paper 1: An Empirical Internet Protocol Network Intrusion Detection using Isolation Forest and One-Class Support Vector Machines

Authors: Gerard Shu Fuhnwi, Victoria Adedoyin, Janet O. Agbaje

PAGE 1 – 6

Paper 2: Ensemble Security and Multi-Cloud Load Balancing for Data in Edge-based Computing Applications

Authors: Raghunadha Reddi Dornala

PAGE 7 – 13

Paper 3: Converting Data for Spiking Neural Network Training

Authors: Erik Sadvovsky, Maros Jakubec, Roman Jarina

PAGE 14 – 20

Paper 4: A Secure and Scalable Behavioral Dynamics Authentication Model

Authors: Idowu Dauda Oladipo, Joseph Bamidele Awotunde, Mathew Nicho, Jemima Omotola Buari, Muyideen Abdulaheem, Tarek Gaber

PAGE 21 – 32

Paper 5: Visualization of AI Systems in Virtual Reality: A Comprehensive Review

Authors: Medet Inkarbekov, Rosemary Monahan, Barak A. Pearlmutter

PAGE 33 – 42

Paper 6: Symbol Detection in a Multi-class Dataset Based on Single Line Diagrams using Deep Learning Models

Authors: Hina Bhanbhro, Yew Kwang Hooi, Worapan Kusakunniran, Zaira Hassan Amur

PAGE 43 – 56

Paper 7: The Spatial Distribution of Atmospheric Water Vapor Based on Analytic Hierarchy Process and Genetic Algorithm

Authors: Fengjun Wei, Chunhua Liu, Rendong Guo, Xin Li, Jilei Hu, Chuanxun Che

PAGE 57 – 68

Paper 8: Detection of Tuberculosis Based on Hybridized Pre-Processing Deep Learning Method

Authors: Mohamed Ahmed Elashmawy, Irraivan Elamvazuthi, Lila Iznita Izhar, Sivajothi Paramasivam, Steven Su

PAGE 69 – 76

Paper 9: Automated CAD System for Early Stroke Diagnosis: Review

Authors: Izzatul Husna Azman, Norhashimah Mohd Saad, Abdul Rahim Abdullah, Rostam Affendi Hamzah, Adam Samsudin, Shaarmila A/P Kandaya

PAGE 77 – 83

Paper 10: The Current State of Blockchain Consensus Mechanism: Issues and Future Works

Authors: Shadab Alam

PAGE 84 – 94

Paper 11: A Novel Approach for Identification of Figurative Language Types in Devanagari Scripted Languages

Authors: Jatinderkumar R. Saini, Preeti Sagar, Hema Gaikwad

PAGE 95 – 103

Paper 12: Machine Learning Model for Automated Assessment of Short Subjective Answers

Authors: Zaira Hassan Amur, Yew Kwang Hooi, Hina Bhanbro, Mairaj Nabi Bhatti, Gul Muhammad Soomro

PAGE 104 – 112

Paper 13: Sentiment Analysis in Indonesian Healthcare Applications using IndoBERT Approach

Authors: Helmi Imaduddin, Fiddin Yusufida A'la, Yusuf Sulisty Nugroho

PAGE 113 – 117

Paper 14: The Medical Image Denoising Method Based on the CycleGAN and the Complex Shearlet Transform

Authors: ChunXiang Liu, Jin Huang, Muhammad Tahir, Lei Wang, Yuwei Wang, Faiz Ullah

PAGE 118 – 125

Paper 15: Comparing Scrum Maturity of Digital and Business Process Reengineering Groups: A Case Study at an Indonesia's State-Owned Bank

Authors: Gloria Saripah Patara, Teguh Raharjo

PAGE 126 – 134

Paper 16: Adaptive Learner-CBT with Secured Fault-Tolerant and Resumption Capability for Nigerian Universities

Authors: Bridget Ogheneovo Malasowe, Maureen Ifeanyi Akazue, Ejaita Abugor Okpako, Fidelis Obukohwo Aghware, Arnold Adimabua Ojugo, Deborah Voke Ojie

PAGE 135 – 142

Paper 17: A Yolo-based Violence Detection Method in IoT Surveillance Systems

Authors: Hui Gao

PAGE 143 – 149

Paper 18: Towards Automated Evaluation of the Quality of Educational Services in HEIs

Authors: Silvia Gaffandzhieva, Rositsa Doneva, Mariya Zhekova, George Pashev

PAGE 150 – 165

Paper 19: Machine-Learning-based User Behavior Classification for Improving Security Awareness Provision

Authors: Alaa Al-Mashhour, Areej Alhogail

PAGE 166 – 178

Paper 20: Collateral Circulation Classification Based on Cone Beam Computed Tomography Images using ResNet18 Convolutional Neural Network

Authors: Nur Hasanah Ali, Abdul Rahim Abdullah, Norhashimah Mohd Saad, Ahmad Sobri Muda

PAGE 179 – 185

Paper 21: An Enhanced Algorithm of Improved Response Time of ITS-G5 Protocol

Authors: Kawtar Jellid, Tomader Mazri

PAGE 186 – 194

Paper 22: Design and Application of an Automatic Scoring System for English Composition Based on Artificial Intelligence Technology

Authors: Fengqin Zhang

PAGE 195 – 205

Paper 23: An Efficient Deep Learning with Optimization Algorithm for Emotion Recognition in Social Networks

Authors: Ambika G N, Yeresime Suresh

PAGE 206 – 215

Paper 24: Improved Drosophila Visual Neural Network Application in Vehicle Target Tracking and Collision Warning

Authors: Jianyi Wu

PAGE 216 – 226

Paper 25: Earth Observation Satellite: Big Data Retrieval Method with Fuzzy Expression of Geophysical Parameters and Spatial Features

Authors: Kohei Arai

PAGE 227 – 234

Paper 26: Virtual Route Guide Chatbot Based on Random Forest Classifier

Authors: Puspa Miladin Nuraida Safitri A. Basid, Fajar Rohman Hariri, Fresy Nugroho, Ajib Hanani, Firman Jati Pamungkas

PAGE 235 – 241

Paper 27: Approaches and Tools for Quality Assurance in Distance Learning: State-of-play

Authors: Silvia Gaffandzhieva, Rositsa Doneva, Senthil Kumar Jagatheesaperumal

PAGE 242 – 253

Paper 28: Efficient Parameter Estimation in Image Processing using a Multi-Agent Hysteretic Q-Learning Approach

Authors: Issam QAFFOU

PAGE 254 – 262

Paper 29: Design and Implementation of an IoT Control and Monitoring System for the Optimization of Shrimp Pools using LoRa Technology

Authors: José M. Pereira Pontón, Verónica Ojeda, Víctor Asanza, Leandro L. Lorente-Leyva, Diego H. Peluffo-Ordóñez

PAGE 263 – 272

Paper 30: An Overview of Vision Transformers for Image Processing: A Survey

Authors: Ch.Sita Kameswari, Kavitha J, T. Srinivas Reddy, Balaswamy Chinthaguntla, Senthil Kumar Jagatheesaperumal, Silvia Gaffandzhieva, Rositsa Doneva

PAGE 273 – 289

Paper 31: Multimodal Contactless Architecture for Upper Limb Virtual Rehabilitation

Authors: Emilio Valdivia-Cisneros, Elizabeth Vidal, Eveling Castro-Gutierrez

PAGE 290 – 295

Paper 32: Attitude Synchronization and Stabilization for Multi-Satellite Formation Flying with Advanced Angular Velocity Observers

Authors: Belkacem Kada, Khalid Munawar, Muhammad Shafique Shaikh

PAGE 296 – 303

Paper 33: Hussein Search Algorithm: A Novel Efficient Searching Algorithm in Constant Time Complexity

Authors: Omer H Abu El Hajjia, Arwa H. F. Zabian

PAGE 304 – 309

Paper 34: Testing the Usability of Serious Game for Low Vision Children

Authors: Nurul Izzah Othman, Hazura Mohamed, Nor Azan Mat Zin

PAGE 310 – 317

Paper 35: Cybersecurity Advances in SCADA Systems

Authors: Bakil Al-Muntaser, Mohamad Afendee Mohamed, Ammar Yaseen Tuama, Imran Ahmad Rana

PAGE 318 – 328

Paper 36: Model Classification of Fire Weather Index using the SVM-FF Method on Forest Fire in North Sumatra, Indonesia

Authors: Darwis Robinson Manalu, Opim Salim Sitompul, Herman Mawengkang, Muhammad Zarlis

PAGE 329 – 337

Paper 37: Prediction of Cryptocurrency Price using Time Series Data and Deep Learning Algorithms

Authors: Michael Nair, Mohamed I. Marie, Laila A. Abd-Elmegid

PAGE 338 – 347

Paper 38: Advances in Value-based, Policy-based, and Deep Learning-based Reinforcement Learning

Authors: Haewon Byeon

PAGE 348 – 354

Paper 39: Scalable Blockchain Architecture: Leveraging Hybrid Shard Generation and Data Partitioning

Authors: Praveen M Dhulavvagol, Prasad M R, Niranjan C Kundur, Jagadisha N, S G Totad

PAGE 355 – 363

Paper 40: Detection of Herd Pigs Based on Improved YOLOv5s Model

Authors: Jianquan LI, Xiao WU, Yuanlin NING, Ying YANG, Gang LIU, Yang MI

PAGE 364 – 370

Paper 41: The Impact of Cyber Security on Preventing and Mitigating Electronic Crimes in the Jordanian Banking Sector

Authors: Tamer Bani Amer, Mohammad Ibrahim Ahmed Al-Omar

PAGE 371 – 380

Paper 42: Research on the Local Path Planning for Mobile Robots based on PRO-Dueling Deep Q-Network (DQN) Algorithm

Authors: Yaoyu Zhang, Caihong Li, Guosheng Zhang, Ruihong Zhou, Zhenying Liang

PAGE 381 – 387

Paper 43: Prostate Cancer Detection and Analysis using Advanced Machine Learning

Authors: Mowafaq Salem Alzboon, Mohammad Subhi Al-Batah

PAGE 388 – 396

Paper 44: Application of Improved Ant Colony Algorithm Integrating Adaptive Parameter Configuration in Robot Mobile Path Design

Authors: Jinli Han

PAGE 397 – 407

Paper 45: Simulation of Logistics Frequent Path Data Mining Based on Statistical Density

Authors: Fengju Hou

PAGE 408 – 413

Paper 46: Simulation Analysis of Hydraulic Control System of Engineering Robot Arm Based on ADAMS

Authors: Haiqing Wu

PAGE 414 – 420

Paper 47: Enhanced Transfer Learning Strategies for Effective Kidney Tumor Classification with CT Imaging

Authors: Muneer Majid, Yonis Gulzar, Shahnawaz Ayoub, Farhana Khan, Faheem Ahmad Reegu, Mohammad Shuaib Mir, Wassim Jaziri, Arjumand Bano Soomro

PAGE 421 – 432

Paper 48: A Hybrid Metaheuristic Model for Efficient Analytical Business Prediction

Authors: Marischa Elveny, Mahyuddin K. M Nasution, Rahmad B. Y Syah

PAGE 433 – 440

Paper 49: A Mechanism for Bitcoin Price Forecasting using Deep Learning

Authors: Karamath Ateeq, Ahmed Abdelrahim Al Zarooni, Abdur Rehman, Muhammd Adna Khan

PAGE 441 – 448

Paper 50: Research on Improving Piano Performance Evaluation Method in Piano Assisted Online Education

Authors: Huayi Qi, Chunhua She

PAGE 449 – 459

Paper 51: Methodological Insights Towards Leveraging Performance in Video Object Tracking and Detection

Authors: Divyaprabha, M. Z Kurian

PAGE 460 – 474

Paper 52: Pairwise Test Case Generation using (1+1) Evolutionary Algorithm for Software Product Line Testing

Authors: Sharafeldin Kabashi Khatir, Rabatul Aduni Binti Sulaiman, Mohammed Adam Kunna Azrag, Jasni Mohamad Zain, Julius Beneoluchi Odili, Samer Ali Al-Shami

PAGE 475 – 483

Paper 53: Campus Network Intrusion Detection Based on Gated Recurrent Neural Network and Domain Generation Algorithm

Authors: Qi Rong, Guang Zhao

PAGE 484 – 492

Paper 54: Dynamic Modelling of Hand Grasping and Wrist Exoskeleton: An EMG-based Approach

Authors: Mohd Safirin Bin Karis, Hyreil Anuar Bin Kasdirin, Norafizah Binti Abas, Muhammad Noorazlan Shah Bin Zainudin, Sufri Bin Muhammad, Mior Muhammad Nazmi Firdaus Bin Mior Fadzil

PAGE 493 – 499

Paper 55: Research on Semantic Segmentation Method of Remote Sensing Image Based on Self-supervised Learning

Authors: Wenbo Zhang, Achuan Wang

PAGE 500 – 508

Paper 56: Mechatronics Design and Robotic Simulation of Serial Manipulators to Perform Automation Tasks in the Avocado Industry

Authors: Carlos Paredes, Ricardo Palomares, Josmell Alva, José Cornejo

PAGE 509 – 517

Paper 57: Integrating Transfer Learning and Deep Neural Networks for Accurate Medical Disease Diagnosis from Multi-Modal Data

Authors: Chamandeep Kaur, Abdul Rahman Mohammed Al-Ansari, Taviti Naidu Gongada, K. Aanandha Saravanan, Divvela Srinivasa Rao, Ricardo Fernando Cosio Borda, R. Manikandan

PAGE 518 – 528

Paper 58: An Integrated Instrument for Measuring Science, Technology, Engineering, and Mathematics: Digital Educational Game Acceptance and Player Experience

Authors: Husna Hafiza R. Azami, Roslina Ibrahim, Suraya Masrom, Rasimah Che Mohd Yusoff, Suraya Yaacob

Abstract—With the increasing reliance on web-based applications and services, network intrusion detection has become a critical aspect of maintaining the security and integrity of computer networks. This study empirically investigates internet protocol network intrusion detection using two machine learning techniques: Isolation Forest (IF) and One-Class Support Vector Machines (OC-SVM), combined with ANOVA F-test feature selection. This paper presents an empirical study comparing the effectiveness of two machine learning algorithms, Isolation Forest (IF) and One-Class Support Vector Machines (OC-SVM), with ANOVA F-test feature selection in detecting network intrusions using web services. The study used the NSL-KDD dataset, encompassing hypertext transfer protocol (HTTP), simple mail transfer protocol (SMTP), and file transfer protocol (FTP) web services attacks and normal traffic patterns, to comprehensively evaluate the algorithms. The performance of the algorithms is evaluated based on several metrics, such as the F1-score, detection rate (recall), precision, false alarm rate (FAR), and Area Under the Receiver Operating Characteristic (AUCROC) curve. Additionally, the study investigates the impact of different hyper-parameters on the performance of both algorithms. Our empirical results demonstrate that while both IF and OC-SVM exhibit high efficacy in detecting network intrusion attacks using web services of type HTTP, SMTP, and FTP, the One-Class Support Vector Machines outperform the Isolation Forest in terms of F1-score (SMTP), detection rate (HTTP, SMTP, and FTP), AUCROC, and a consistent low false alarm rate (HTTP). We used the t-test to determine that OCSVM statistically outperforms IF on DR and FAR.

Keywords—HTTP; SMTP; FTP; ANOVA F-test; AUCROC; OC-SVMs; FAR; DR; IF

I. INTRODUCTION

Network Intrusion can be referred to as an unauthorized penetration of a computer in an establishment or an address in one's assigned domain [1]. The nature and types of network intrusion have evolved over the years and become more rampant in recent years [2].

An intrusion can be passive or active. In passive intrusion, the penetration is gained stealthily and without detection, while in active intrusion, changes to network resources are affected. Intrusion can either come from an insider or an outsider. By insider, we mean an employee, customer, or business partner. Outsider means someone not connected to the organization. Network intrusions can occur in different ways. Some announce their presence by defacing the website, while others are malicious, with the goal of siphoning off data

until it's discovered. Some redirect users who are unaware of their website through cracking passwords or mimicking your website [1]. Sometimes, intruders absorb network resources intended for other uses or users, which can lead to a denial of service [3]. These unauthorized penetrations on the digital network are imperil on many occasions the security of networks and their data [4].

Network security breaches are rapidly increasing and result in a significant amount of loss to organizations, and often leads to a loss of confidence in them from their unaware customers that have fallen victims. The IBM report shows that the average cost of a data breach has risen 12 percent over the past five years to 3.92 million dollars per incident on average [5]. This is more than the cost of a breach caused by a system glitch or human error.

Many researchers have carried out research and projects on network intrusion detection [6], [7], [8]. Wang and Battiti identified intrusions in computer networks with principal component analysis [9]. Liao and Vemuri used a k-nearest neighbour classifier for intrusion detection [10]. Gaffney and Ulvila evaluated intrusion detectors using a decision theory approach [11]. But this area still longs for more work as a result of the rapid rise in network intrusion. Therefore, we need to design an efficient algorithm that can successfully defend against network intrusions in an ever-evolving threat landscape. To achieve proactive security control, organizations must put in place a good network security infrastructure and leverage the potential of machine learning, which has the capability of automatically and continuously detecting network intrusions. This will help block intruders and prevent them from achieving their goals. The remainder of this paper is organized as follows: In Section II, we briefly review some related work in anomaly detection based Network Intrusion Detection. Section III gives a description of the algorithms used in this paper. Section IV analyzes the empirical evaluation, where we review the data sets used, evaluation metrics description, results, and result discussion. Section V covers the conclusion.

II. RELATED WORK

Liu and Ting [23] focused on using an Isolation Forest to detect anomalies that have many applications in the areas of fraud detection, network intrusion, medical and public health, industrial damage detection, and so on. The goal here is to build a tree-based structure that isolates anomalies

rather than profiles anomalies like in the previous methods such as classification-based methods [12], and clustering-based methods [13]. Their proposed method, called Isolation Forest, builds a collection of individual tree structures that recursively partition a given data set, where anomalies are instances with a short path length on the trees. The anomaly score is used to determine instances that are anomalies, and has values between 1 and 0, with a score close to 1 being an anomaly and vice versa. The authors compared their results with other methods for anomaly detection techniques [14] like ORCA, LOF, and RF on real-world data sets with high dimensions and large data sizes using the metric AUC (Area Under the Curve) and run times. [15] proposed a hybrid of SVM and decision trees in classifying attacks of different forms of intrusion in knowledge discovery and data mining 1999 (KDDCUP99) data.

In [16], Sarumi et al. compared SVM and Apriori using Network Security Laboratory Knowledge Discovery and Data Mining (NSL-KDD) data and the University of South Wales NB 2015 (UNSW NB-15) dataset. From their results, they concluded that SVM outperformed Apriori in terms of accuracy, while Apriori showed a better performance in terms of speed.

In [17], Farnaaz and Jabbar proposed a detection intrusion system using random forest. Experimental results were conducted on the NSL-KDD dataset. Empirical results show that the proposed model achieved a low false alarm rate and a high recall. Similarly, [18], [19], [20], and [21] applied machine learning techniques for network intrusion detection systems.

All the above mentioned papers discuss intrusion detection methods without any statistics to compare their results, attacks using web services, and no user guidance for using the proposed algorithms. To overcome this, one can look at the statistical significance of the various evaluation metrics based on the different machine learning algorithms proposed by them and also change the various parameters in the machine learning algorithms to observe their performance.

This paper compares the performance of One-class SVM and Isolation Forest machine learning algorithms in network intrusion using a two-sample t-test and parameter alternation to provide some guidance on these algorithms' usage to new researchers in this field. Our approach can also guide evaluating and analyzing these techniques in solving intrusion detection problems. Also, this method can overcome one of the main challenges of intrusion detection techniques, accurate representative labels for normal and abnormal instances, which is a significant concern. To overcome this challenge in most intrusion detection problems, our approach can be used as a pre-labeling technique and then supervised anomaly detection techniques to solve intrusion detection problems. Overall, our empirical results demonstrate the potential of Isolation Forest and One-Class SVM and provide valuable insights for future research in this field.

III. METHODS

This section presents the intrusion detection approach used in this paper. These approaches include the ANOVA F-test, the Isolation Forest, the One-Class Support Vector Machines, and the two-sample t-test.

A. ANOVA F-test

The ANOVA F-test, or Analysis of Variance F-test, is a statistical technique used to compare the means of two or more groups to determine whether significant differences exist. It is commonly employed in feature selection or variable ranking tasks, where the goal is to identify the most relevant features or variables for a particular analysis or model.

Applying the ANOVA F-test to a dataset can rank features based on their F-statistic or p-value. Features with high F-statistic values or low p-values are considered more relevant, as they exhibit significant differences between the groups or classes. These relevant features can then be selected for further analysis or modeling, while less informative features can be discarded to reduce dimensionality and improve computational efficiency. In the case of web network intrusion detection, the ANOVA F-test can be used to identify the most discriminative features that differentiate between normal network traffic and malicious intrusion attempts. By selecting the most significant features, it is possible to improve the performance and efficiency of intrusion detection systems by focusing on the most relevant information and reducing noise or irrelevant variables.

B. Isolation Forest (IF)

IF has been applied in different scenarios. Isolation Forest is an unsupervised learning algorithm for anomaly detection that works on the principle of isolating anomalies, instead of the most common technique of profiling normal points [22] and [23]. It is different from other distance and density based algorithms (see Fig. 1). The underlying assumption for this algorithm is that fewer instances of anomalies result in a smaller number of partitions (shorter path length) and the instances with distinguishable attribute values are more likely to be separated in early partitioning [24]. This implies that data points that have a shorter path length are likely to be anomalies. The necessary input parameters for building Isolation Forest algorithm are the subsampling size, the number of trees, and the height of the tree [24]. The subsampling size was suggested to be smaller for the machine learning algorithm to function faster and yield a better detection result [25]. We can use log to base 2 (number of data points) to get the depth of trees needed, but the path length converge before $t = 100$. [25].

Algorithm 1: $iForest(X, t, \psi)$
Inputs: X – input data, t – number of trees, ψ – subsampling size
Output: a set of t $iTrees$
1: Initialize Forest
2: set height limit $l = \text{ceiling}(\log_2 \psi)$
3: for $i = 1$ to t do
4: $X' \leftarrow \text{sample}(X, \psi)$
5: $Forest \leftarrow Forest \cup iTrees(X', l)$
6: end for
7: return Forest

Fig. 1. Algorithm 1.

C. One-Class Support Vector Machines

One-Class Support Vector Machines (OC-SVMs) [26] are a natural extension of SVMs. One-Class SVM is an unsupervised learning technique capable of differentiating test samples from a particular class from other classes. The One-Class SVM works on the basics of minimizing the hypersphere of one

class in the training set and then considers every other class not within the hypersphere as anomalies or outliers. In order to identify suspicious observations, an OC-SVM estimates a distribution that encompasses most of the observations and then labels as “suspicious” those that lie far from it with respect to a suitable metric. This model uses different kernel functions or hyperspheres: linear, radial basis, sigmoid, and polynomial.

D. Two Sample t-test

The two-sample t-test, also known as the independent samples t-test or unpaired t-test, is a statistical hypothesis test used to compare the means of two independent groups to determine if there is a significant difference between them. The test assumes that the data is normally distributed and that the variances of the two groups are equal (although there are modifications available if this assumption does not hold). In order to compare the performance of IF and OCSVM with the ANOVA F-test, we used a two-sample t-test to test whether there is a significant difference between the mean performances of DR, FAR, F_1 score, AUCROC, and precision. The null hypothesis (H_0) for the two-sample t-test states that there is no significant difference between the mean performances of the two models, while the alternative hypothesis (H_1) states that there is a significant difference, unlikely to have occurred by chance, between the mean performances of the two models.

IV. EMPIRICAL EVALUATION

A. Data Description

The NSL–KDD dataset is an improved version of the KDD99 dataset, in which a large amount of data redundancy has been removed [27]. This dataset has the same attributes as the KDD99 having 41 features that are labeled as either normal or attacks using different web services (http, smtp, ftp, etc.). The NSL–KDD dataset repository has two files: KDDTrain.txt and KDDTest.txt. Table I shows the attack categories using different services and the number of data points per category in the NSL–KDD train and test datasets. The NSL–KDD dataset has 125973 data points in the training dataset and 22544 in the testing dataset.

TABLE I. THE ATTACK TYPES (CLASS) USING DIFFERENT INTERNET PROTOCOLS (HTTP, SMTP AND FTP), THE NUMBER OF RECORDS IN THE NSL-KDD TRAINING AND TESTING DATASET

Attacks using different Internet Protocol	No. of records		Attack Types (class)
	Training	Testing	
Normal	45,078	7,291	Normal traffic data
HTTP	2,289	1,180	Worm, Land, Smurf, Udpstorm, Teardrop, Pod, Mailbomb, Neptune, Process table, Apache2, Back
SMTP	284	316	Ipsweep, Nmap, Satan, Portsweep, Mscan, Saint, WarezClient, Worm, SnmpGetAttack, WarezMaster,
FTP	648	48	Imap, SnmpGuess, Named, MultiHop, Phf, SPy, Sendmail, Ftp_Write, Xsnoop, Xlock, Guess_Password

B. Data Pre-processing

The NSL-KDD dataset has 41 features, each representing an attack type described in Section 4.1 and an attack category (class feature). These features are both numeric (38 features) and categorical (3 features). The categorical features are protocol_type (3 types), service (70 types), and flag (11 types) that need to be converted to numeric features. We want to extract the most popular attacks caused by using different internet protocols (the service feature). These widespread attacks use web services (internet protocols) such as hypertext transfer protocol (HTTP), simple mail transfer protocol (SMTP), and file transfer protocol (FTP). After extracting the various internet protocols, the attack types (class) feature is labeled with a numeric type, starting with Normal, labeled as 0 and 1 for the different attack types.

Using ANOVA F-test feature elimination, the most relevant features with the highest F-statistic values in the dataset are identified, eliminating the least important features. These features are src bytes (number of data bytes transferred from source to destination in a single connection), dst bytes (number of data bytes transferred from destination to source in a single connection), and duration.

C. Confusion Matrix

The performance of machine learning techniques can be evaluated using different parameters. These parameters are calculated using True Positive (TP), False Negative (FN), False Positive (FP), and True Negative (TN) as shown in the confusion matrix [28] in Table II. The following parameters are used to evaluate our proposed approach.

1) *Detection Rate (DR)*: It is the ratio between the total number of attacks detected by the NIDS and the total number of attacks present in the dataset [17] which can be calculated using the formula:

$$DR = \frac{TP}{TP + FN}$$

2) *Precision*: This measures the fraction of examples predicted as attacks that turned out to be attacks, which can be calculated using the formula:

$$Precision = \frac{TP}{TP + FP}$$

3) F_1 *Score*: It is the harmonic mean of the fraction of examples predicted as attacks that turned out to be attacks (precision). It can also be described as the ratio between the total number of attacks detected by the NIDS and the total number of attacks present in the dataset (the detection rate) which can be calculated using the formula:

$$F_1 \text{ Score} = \frac{2 * TP}{2 * TP + FN + FP}$$

4) *False Alarm Rate (FAR)*: It is the fraction of non attacks that are misclassified as attacks, which can be calculated using the formula:

$$FAR = \frac{FP}{FP + TN}$$

TABLE II. CONFUSION MATRIX: A CONTINGENCY CONTAINING FOUR METRICS, TRUE POSITIVE (TP), TRUE NEGATIVE (TN), FALSE POSITIVE (FP), AND FALSE NEGATIVE (FN).

Attack		Predicted Class	
		Yes	No
Actual class	Yes	TP	FN
	No	FP	TN

5) *Receiver Operating Characteristic (ROC) Curve*: The Receiver Operating Characteristic (ROC) curve is a graphical representation used to evaluate the performance of binary classification models in machine learning. It is created by plotting the ratio between the total number of attacks detected by the NIDS to the total number of attacks present in the dataset (detection rate) against the fraction of non-attacks that are misclassified as attacks (False Alarm Rate) at various classification threshold levels. The area under the curve (AUC) of the ROC quantifies the overall performance of the classification model. AUC values range from 0 to 1, with a value of 0.5 representing a random classifier and a value of 1 indicating a perfect classifier. A higher AUC value suggests a better-performing classification model.

A good NIDS should have high detection rates, precision, AUCROC, F_1 score but low FAR.

Most machine learning algorithms are evaluated using predictive accuracy, but this is not appropriate for network intrusion detection because it mostly involves imbalanced data. In terms of imbalanced data, we mean that the proportion of data points in each class is not approximately equal. The evaluation metrics adopted in this paper for evaluation and comparison of our models are standard AUC (Area under curve). The area under the receiver operating curve gives an average measure of performance across all possible classification thresholds.

D. Experimental Results

All experiments were performed in Python with alternating parameters for Isolation Forest (Sklearn) and One-class support vector machines (Sklearn) using the Intel(R) Core(TM) i7-10510U CPU at 1.80 GHz and 2.30 GHz processor with 16 GB of RAM. Training and testing of the Isolation Forest took four seconds, while it took 40 seconds to train the One-Class support vector machine model on the three selected features from the NSL–KDD dataset. The experimental results for One-class support vector machines and Isolation Forest on different performance metrics are shown in Table III and Table IV respectively.

E. Discussion of Results

In Table III, the polynomial kernel outperformed the other kernels on HTTP and SMTP subsets with high DR, F_1 Score, AUCROC, Precision, and low FAR. On the other hand, in Table III, the sigmoid kernel performed much better than the different kernels on the FTP subset.

In Table IV, isolation forest with 100 estimators on the HTTP subset achieved the highest DR, F_1 Score, AUCROC,

Precision, and low FAR. The SMTP and FTP subset performs best on the evaluation metrics with 50 estimators. Generally, both Isolation Forest and One-class support vector machines didn't perform well on the FTP subset, having very high FAR and low DR, F_1 Score, AUCROC, and Precision. It is evident in Table III and IV that the one-class support vector machines outperform Isolation Forest on all subsets, that is, HTTP, SMTP, and FTP having high DR, F_1 Score, and low FAR. Statistical analysis of overall performance on the one-class support vector machines and Isolation Forest results used a two-sample t-test with two-tailed probability to determine if each model's DR and FAR score on the test data yielded statistically significant differences ($p < 0.05$). In the HTTP, SMTP, and FTP, the one-class support machines had a significantly different DR, and FAR score ($p < 0.001$), which showed that our hypothesis was accepted.

Our approach improved detection capabilities on selected attack types when compared to other models and benchmarks in related work. The RFE process identified several key features highly relevant to network intrusion detection. These features align with our expectations and prior research [18], [20], and [25], confirming the importance of specific traffic characteristics in detecting malicious activities. The combination of IF, OC-SVM and ANOVA F-test not only improved the model's performance but also reduced the complexity of the model by eliminating redundant and irrelevant features.

The practical implications of our findings are significant for the field of network intrusion detection. The improved detection rates offered by our approach can help security practitioners identify and respond to cyber threats more effectively. Additionally, reducing false positives and negatives can minimize the operational overhead of manually investigating false alarms. Furthermore, our approach demonstrates potential scalability and adaptability for different network environments and evolving cyber threats.

V. CONCLUSION AND FUTURE WORK

The experiments performed on the NSL-KDD network intrusion data show that One-class support vector machines had the overall best performance in terms of DR and FAR scores over the Isolation Forest, with the best performance obtained by tuning the default parameters in both algorithms. Also, the number of estimators in Isolation Forest is comparable; using 100 and 50 estimators outperformed 200 estimators.

Therefore, One-class support is a good model for network intrusion detection by changing the default parameters in Sklearn. Also, polynomial or sigmoid kernel functions could be the best kernels to choose when using One-Class SVM on network intrusion data. Because of the usage of feature selection, the computational cost decreases (four seconds for Isolation Forest and forty seconds), and our experimental results indicate that our proposed approach increases the DR, F_1 score, AUCROC, and precision and decreases FAR for three types of attacks. We equally compared one-class support vector machines and Isolation Forest selected attack types using a two-sample t-test and found that our proposed approach (with fewer features) is promising. For future work, we will experiment with deep learning approaches like GANs and autoencoders since they are capable of handling data of higher

TABLE III. ONE-CLASS SVM PERFORMANCE MEASURE ON NSL–KDD TEST

Ensemble Security and Multi-Cloud Load Balancing for Data in Edge-based Computing Applications

Raghunadha Reddi Dornala
Cloud Architect, USA

Abstract—Edge computing has gained significant attention in recent years due to its ability to process data closer to the source, resulting in reduced latency and improved performance. However, ensuring data security and efficient data management in edge-based computing applications poses significant challenges. This paper proposes an ensemble security approach and a multi-cloud load-balancing strategy to address these challenges. The ensemble security approach leverages multiple security mechanisms, such as encryption, authentication, and intrusion detection systems, to provide a layered defense against potential threats. By combining these mechanisms, the system can detect and mitigate security breaches at various levels, ensuring the integrity and confidentiality of data in edge-based environments. The multi-cloud load balancing strategy also aims to optimize resource utilization and performance by distributing data processing tasks across multiple cloud service providers. This approach takes advantage of the flexibility and scalability offered by the cloud, allowing for dynamic workload allocation based on factors like network conditions and computational capabilities. To evaluate the effectiveness of the proposed approach, we conducted experiments using a realistic edge-based computing environment. The results demonstrate that the ensemble security approach effectively detects and prevents security threats, while the multi-cloud load balancing strategy with edge computing to improve the overall system performance and resource utilization.

Keywords—Edge computing; cloud computing; dynamic load balancing; fog computing; multi-cloud load balancing

I. INTRODUCTION

With the rapid advancement of edge computing and cloud technology, the aviation industry has witnessed significant transformations in flight management systems. These systems now rely on distributed edge computing infrastructure and leverage multiple cloud service providers for improved performance and reliability [1]. To ensure secure and efficient operations, ensemble security and multi-cloud load balancing techniques have become crucial in managing flight management cloud applications [2]. Ensemble security integrates multiple security measures and protocols to protect flight management systems from cyber threats. As edge computing extends the attack surface, incorporating diverse security mechanisms becomes essential [3]. It can include encryption, authentication, access control, intrusion detection systems, and advanced threat intelligence to safeguard critical flight data and systems [4].

In addition to security, effective load balancing across multiple cloud providers is paramount for flight management cloud applications [5]. Load balancing distributes incoming

network traffic across various cloud instances to optimize resource utilization, reduce latency, and enhance system scalability [6]. Multi-cloud load balancing ensures that flight management systems can efficiently utilize cloud resources, handle sudden traffic spikes, and deliver a seamless user experience. Ensemble security and multi-cloud load balancing are intricately linked in edge computing environments [7]. Organizations can dynamically distribute traffic based on security policies and performance metrics by integrating security measures with load-balancing algorithms [8]. It allows flight management cloud applications to balance the workload efficiently across different cloud providers while ensuring data confidentiality, integrity, and availability [9].

This study explores the challenges and opportunities associated with ensemble security and multi-cloud load balancing in the context of flight management cloud applications. We will discuss the essential requirements, potential solutions, and benefits of adopting these techniques in the aviation industry. Furthermore, we will examine real-world use cases and best practices for implementing ensemble security and multi-cloud load balancing to enhance the safety and performance of flight management systems in edge computing environments. By leveraging ensemble security and multi-cloud load balancing with the integration of edge computing with task scheduling, the aviation industry can fully utilize edge computing capabilities while maintaining robust security measures. It ensures flight management systems' safe and efficient operation and opens up new possibilities for advanced applications, such as real-time analytics, predictive maintenance, and intelligent decision-making.

The paper's organization is as follows: Section II presents the literature survey by explaining the existing models and their drawbacks. Section III explained the Intrusion Detection and Prevention System with Multiple Loads Balancing. Section IV introduced edge computing with cloud computing. Section V presented the parameters used to analyze the performance of the proposed approach. Section VI introduced the conclusion for the overall work.

II. LITERATURE SURVEY

Kuppusamy et al. [10] proposed a combined dynamic model that integrates the reinforced optimization approach to increase the scheduling performance in Fog computing. The experiments are conducted using the FogSim simulator to create the data and an available tool that manages energy efficiency by using the resources in fog computing. The proposed system mainly focused on addressing the schedule

with less cost and analyzing the CPU processing time and assigned memory. Simulation results show that the proposed model performance is increased by 12% to 15% in terms of CPU usage and 6% to 11% of less energy usage for solving job scheduling issues. Jango et al. [11] proposed the two-phase scheduling model consisting of a Bi-factor approach, which classifies the task based on end date and preference scheduling using the advanced Jellyfish Algorithm (ADS). The parameters are measured based on the speed, capacity, task size, complete tasks, and total VM used for resource provisioning fog combined cloud platform. The model was tested on real-time and average datasets considering the small and high workload based on the assigned task. The performance is measured using QoS parameters that reduce the cost and other metrics. K. Cao et al. [12] introduced the edge-based integrated model that deploys the cloud application in heterogeneous servers that estimate the response time from data centers. The proposed model can process both offline and online phases. An edge-based optimized model is executed offline, and the online mobility-based gaming system is developed to overcome the issues. Results show that the response time is improved by 48.57% from the base station. J. Al-Jaroodi et al. [13] proposed a distributed model that combined with cloud and fog-integrated sCPS, named PsCPS. The proposed integrates the multiple clouds, fogs, and sCPS subsystems to provide better services to face many challenges for combining. R. Deng et al. [14] proposed a fog-cloud integrated model that reduces power consumption and measures transmitting delay. The proposed model primarily focused on resolving the workload assignment issue by allocating work between the fog and cloud with minimal usage and artificial service delay. The problem is divided into three sub-issues assigned to sub-systems and solved. The simulation results show that fog computing can significantly improve cloud computing efficiency in terms of bandwidth and dissemination latency. M. Guo et al. [15] introduced the delay-based workload allocation (DBWA) that solves the issues based on energy efficacy and delay-undertake workload allocation issues in IoT-integrated systems. The proposed approach would be improved if the Lyapunov drift-plus-penalty theory was adopted. Finally, the proposed approach obtains better performance in terms of efficient allocation. G. Qu et al. [16] proposed the Deep Meta Reinforcement Learning-based Offloading (DMRO) algorithm that merges various parallel DNNs with Q-learning to make fine-tuned learning approach to solve the adaptive decision-making in the dynamic platform. The proposed approach improved the offloading by up to 18.1%. A. Yousafzai et al. [17] proposed an effective integration-based measurement offloading system. The proposed approach needs the program borders at edge servers that lately combine applications. The outcome saves 45.45% of runtime and 85.45% of energy consumption. The proposed system finally obtained the resource-exhaustive IoT application processing in mobile edge computing (MEC). V. Mohammadian et al. [18] discussed various issues in the cloud load balancing model—the existing approach aimed to find the under-loaded and overloaded nodes and balanced loads. Various issues are identified and solved by the proposed approach in cloud computing. The proposed model obtained better results in terms of fault detection and integrated the

simulation tools considered into the account. A. Pandita et al. [19] introduced several scheduling approaches in cloud computing regarding fault tolerance. Several advantages and disadvantages are discussed in the comparison. In cloud computing, the researchers firmly designed an effective fault tolerance system. E. Gures et al. [20] provide the dynamic load balancing approach to solve the generic issue in cloud computing. Various solutions are discussed to solve the load balancing issue. A comparative analysis uses various load-balancing models and analyzes the performance. M. T. Sandikkaya et al. [21] proposed a novel security model (NSM) to secure the PaaS Providers over malicious behavior based on neighbors. The NSM is not like an intrusion detection system, which focuses on processors' usage and challenging resource access. Finally, the NSM approach analyzes the malicious traffic among 100k requests. Several classifiers are used to classify the malicious threads and show better accuracy. O. Sohaib et al. [22] propose a novel 2-tuple fuzzy semantic group selection method that relies on a technology-organization-environment (TOE) system and employs an approach for ordering preference by resemblance to ideal solution (TOPSIS). The TOPSIS is used to help small-to-medium-sized operations assess and make decisions on online e-commerce.

III. INTRUSION DETECTION AND PREVENTION SYSTEM WITH MULTIPLE LOADS BALANCING

An Intrusion Detection and Prevention System (IDPS) mainly focused on detecting and preventing the unauthorized users or malicious activities within a computer network. The following steps involved in IDPS:

1) *Data collection*: The IDPS collects network traffic and system log data to analyze for potential threats. This can include network packets, log files, and system events.

2) *Traffic monitoring*: The IDPS monitors network traffic in real-time or analyzes stored data to identify suspicious patterns or anomalies. This can be done using several signature-based and anomaly detection.

3) *Signature-based detection (SBD)*: SBD is mainly compared with the network traffic over system-generated database events, known as attack signatures. If any similarity is identified, then the intrusion is a better one.

$$\text{Match} = \text{Compare}(\text{Signature}, \text{Network Traffic}) \quad (1)$$

4) *Anomaly detection*: Anomaly detection identifies deviations from normal patterns of network traffic or system behavior. Statistical analysis or machine learning algorithms are often used to detect anomalies.

$$\text{Anomaly} = \text{Compare}(\text{Statistics}, \text{Network Traffic}) \quad (2)$$

5) *Behavior-based detection*: Behavior-based detection establishes a baseline of normal behavior for the network or system and identifies deviations from that baseline. It can involve monitoring user activity, network connections, or system processes.

$$\text{Deviation} = \text{Compare}(\text{Baseline}, \text{Network}) \quad (3)$$

6) *Alert generation:* When a potential intrusion is detected, the IDPS generates an alert or notification to notify system administrators or security personnel. The alert may contain information about the detected threat, its severity, and recommended actions.

7) *Response and prevention:* Based on the severity of the threat, the IDPS may take automated actions to prevent or mitigate the intrusion. This can include blocking suspicious network traffic, terminating malicious processes, or initiating security measures to protect the network.

8) *Logging and reporting:* The IDPS maintains logs of detected threats, alerts, and responses for future analysis and reporting. These logs can help in understanding attack patterns, identifying vulnerabilities, and improving security measures.

It's important to note that the specific equations or algorithms used in each step may vary depending on the implementation and technology used in the IDPS. The equations mentioned above are generalized representations to illustrate the concept.

IV. EDGE COMPUTING WITH CLOUD COMPUTING

Edge computing and cloud computing are two distinct paradigms in computing that serve different purposes and offer unique advantages. However, combined, they can create a robust and efficient computing ecosystem. This section discussed how edge computing and cloud computing work together to enhance the overall computing experience. The cloud platform provides multiple services to users based on the usage of computing resources, data storage, and cloud application over the internet. All these applications and resources are deployed in cloud data centers provided by the cloud service provider (CSP). Users can leverage these resources on demand without needing local infrastructure, reducing costs and improving scalability. Fig. 1 explains the step-by-step process of proposed approach with functionalities.

Fig. 1. Proposed system architecture.

On the other hand, edge computing brings computational capabilities closer to the data source or end-users. It involves performing data processing and analysis at the network's edge near the data source rather than sending all data to the cloud for processing. It reduces latency, minimizes bandwidth usage, and enables real-time decision-making, making it ideal for time-sensitive applications and services.

When edge computing and cloud computing are combined, they form a hybrid computing architecture that takes advantage of the strengths of both approaches. For example, sensors, smartphones, and IoT devices can perform initial data processing and filtering at the edge before selectively sending relevant data to the cloud for further analysis or storage. This method reduces the data sent to the cloud, saving bandwidth and allowing faster response times and more efficient resource utilization. The cloud is crucial in this hybrid architecture by providing a centralized and scalable infrastructure for advanced analytics, machine learning, and storage. The data from edge devices can be processed and analyzed in the cloud using sophisticated algorithms and models, taking advantage of the vast computing resources available. The insights and results can be returned to edge devices for immediate action or decision-making.

This edge and cloud computing combination is precious in various industries and applications. For example, edge computing can handle real-time sensor data processing in autonomous vehicles, while the cloud can perform high-level analytics and provide over-the-air updates. In healthcare, edge devices can collect patient data and perform initial analysis, while the cloud can store and process the data for long-term monitoring and research.

A. Load Balancing in Cloud Computing

Load balancing is an essential aspect of cloud computing that helps to optimize resource utilization, improve performance, and ensure the high availability of apps and services. Cloud computing is the delivery of computing resources such as virtual machines, storage, and applications via the internet. Load balancing distributes incoming network traffic across multiple servers or helps to avoid overloading and ensure efficient resource utilization. The primary goal of load balancing in cloud computing is to distribute workload evenly among servers or resources so that no single resource becomes overburdened while others remain underutilized. By evenly distributing the workload, load balancing helps to achieve optimal resource utilization, improve response times, and increase the overall throughput of the system.

Load balancing mechanisms in cloud computing can be categorized into two main types: static and dynamic load balancing. Static load balancing involves distributing the workload evenly based on predefined rules or static configurations. It is suitable for situations where the workload remains relatively constant and predictable. However, in dynamic and unpredictable environments, dynamic load balancing techniques are more effective. Dynamic load balancing utilizes various algorithms and techniques to monitor the system's workload continuously and adjust the distribution of requests accordingly. These techniques take into account factors such as server capacity, response time,

network latency, and current resource utilization to make intelligent decisions about workload distribution. Some popular dynamic load balancing algorithms include Round Robin (RR), Weighted Round Robin (WRR), Least Connections (LC), and Adaptive Load Balancing (ALB).

Load balancers also monitor the health and availability of servers and can automatically reroute traffic away from faulty or overloaded servers, ensuring high availability and fault tolerance. Cloud service providers often offer load balancing services as part of their cloud infrastructure offerings. These load balancers are typically provided as managed services, which means that the service provider takes care of the underlying infrastructure and maintenance, allowing users to focus on their applications and services.

B. Multi-Cloud Load Balancing Model

Round-robin (RR) and Consistent Hashing (CH) are two different algorithms used for load balancing in distributed systems. However, they can also be combined to achieve load balancing with Consistent Hashing.

Round-robin is a simple load balancing algorithm that distributes incoming requests evenly among a set of servers in a cyclic manner. Each request is assigned to the next available server in the rotation. This ensures that each server receives an equal number of requests over time.

For a given request i ($0 \leq i < M$), the server index is calculated as follows:

$$\text{server}_{\text{index}} = i \bmod N \quad (4)$$

Here, "mod" represents the modulo operation. The request is then sent to the server with the corresponding index.

Consistent Hashing is a more advanced load balancing algorithm that provides scalability and minimizes the redistribution of requests when a server is added or removed from the system. It uses a hash function to map each request to a specific server in the system based on the request's key or identifier.

To combine Round-robin with Consistent Hashing for load balancing, we can follow these steps:

Step 1: Initialize a list of servers.

Step 2: Assign each server a unique identifier or key.

Step 3: Create a hash ring to represent the distribution of keys across the servers.

Whenever a request comes in, apply the Consistent Hashing algorithm to determine the server responsible for serving that request.

Step 4: If the server is available and can handle the request, forward it to the server.

If the server is unavailable or overloaded, use Round-robin to select the next available server in the rotation and forward the request to that server.

Step 5: Continue the Round-robin rotation for subsequent requests until a server becomes available again.

Periodically update the hash ring and redistribute the keys when adding or removing servers from the system. By combining Round-robin with Consistent Hashing, we achieve both load balancing and the ability to scale the system dynamically without significant redistribution of requests. Round-robin ensures that the servers receive an equal share of requests, while Consistent Hashing minimizes the impact of adding or removing servers on the overall distribution of requests. This combined approach provides a balanced and efficient load balancing mechanism, ensuring optimal utilization of the server resources in a distributed system.

C. Task Scheduling for Multiple-Cloud

Organizations have increasingly turned to multi-cloud environments in recent years to meet their diverse computing needs. Multi-cloud refers to using multiple cloud service providers simultaneously, allowing businesses to leverage the strengths of different platforms and avoid vendor lock-in. However, managing and optimizing tasks across multiple clouds can be complex and challenging. Task scheduling is a critical aspect of managing cloud resources effectively. It involves determining when and where tasks or workloads should be executed to ensure efficient resource utilization and meet performance objectives. In multi-cloud environments, task scheduling becomes even more intricate as organizations must consider cost, performance, data locality, and compliance across multiple cloud providers. Multi-cloud task scheduling primarily aims to assign tasks to the most appropriate cloud resources based on various criteria, such as workload characteristics, resource availability, and user-defined policies. It involves making intelligent decisions to balance workload distribution, maximize resource utilization, minimize costs, and optimize performance across multiple clouds.

Several key challenges must be addressed to achieve effective task scheduling in a multi-cloud environment. These challenges include:

1) *Heterogeneity*: Each cloud provider offers different virtual machine types, pricing models, and service-level agreements. Task scheduling algorithms must account for this heterogeneity and make informed decisions about resource selection.

2) *Interoperability*: Ensuring seamless communication and data transfer between cloud providers is crucial. Task scheduling mechanisms should consider data locality and network latency to minimize data transfer costs and enhance performance.

3) *Scalability*: Multi-cloud environments often involve a large number of tasks and resources. Task scheduling algorithms must scale efficiently to handle the increased complexity and volume of scheduling decisions.

4) *Dynamicity*: Cloud environments are dynamic, with fluctuating workloads and resource availability. Task scheduling mechanisms should be adaptable and able to handle workload variations and changes in resource availability in real time.

5) *Cost optimization*: Multi-cloud environments introduce cost considerations due to varying pricing models and resource utilization. Task scheduling algorithms should minimize costs while meeting performance objectives and user-defined policies.

Addressing these challenges requires the development of intelligent task-scheduling algorithms and frameworks specifically designed for multi-cloud environments. These algorithms should consider workload characteristics, resource availability, performance requirements, and cost constraints to make optimal scheduling decisions.

D. Ensemble Security and Multi-Cloud Load Balancing

Ensemble Security and Multi-Cloud Load Balancing are two important concepts in the field of cloud computing and network security.

E. Ensemble Security

Ensemble Security refers to a comprehensive approach to securing computer networks and systems by using a combination of security measures and tools. The term "ensemble" implies the integration and coordination of various security components to create a stronger and more effective security system.

In ensemble security, multiple security mechanisms are employed to protect against a wide range of threats and vulnerabilities. This paper mainly used the mechanisms which includes intrusion detection and prevention systems (IDPS), data encryption. By combining these different security measures, organizations can create a layered defense system that provides multiple barriers against potential attacks.

The advantage of ensemble security is that it offers defense in depth, meaning that if one security measure fails, others can still provide protection. Additionally, ensemble security enables organizations to leverage the strengths of different security tools and technologies, thereby enhancing overall network security posture.

F. Multi-Cloud Load Balancing (MCLB)

In cloud computing, MCLB is a technique that distributes incoming network traffic across multiple cloud service providers (CSPs) or regions within a single CSP. Load balancing improves application performance, optimizes resource utilization, and ensures cloud-based services' high availability and scalability.

In a multi-cloud environment, organizations may choose to deploy their applications and services across different CSPs to take advantage of each provider's unique capabilities and to mitigate the risk of vendor lock-in. Multi-cloud load balancing allows organizations to distribute the incoming traffic across these different cloud environments, ensuring that the workload is evenly distributed and that no single cloud provider becomes overloaded.

Load balancers serve as go-betweens for users or clients and cloud resources. Incoming requests are intelligently distributed based on factors such as server capacity, latency in the network, and specific to application requirements. This helps in optimizing resource utilization, preventing

bottlenecks, and ensuring that the applications remain accessible and responsive. By implementing multi-cloud load balancing, organizations can achieve higher fault tolerance, improved performance, and scalability across multiple cloud environments. It also provides flexibility in managing and scaling resources based on changing demands and enables efficient utilization of cloud resources.

V. EXPERIMENTAL RESULTS

The experiments are conducted on flight management applications which can take Lakhs of requests from the user and managed by the proposed multi-cloud management system with high security. The total requests are analyzed by the proposed model is 10k, 20k and 30k requests. The performance metrics are given below:

1) *Response time (RT)*: It measures the time taken to process a request and provide a response to the client.

$$RT = \text{Complete time} - \text{request time} \quad (5)$$

2) *Throughput (TP)*: It represents the number of requests processed per unit of time.

$$TP = \text{Total} \frac{\text{Requests}}{\text{Time}} \quad (6)$$

3) *Utilization (UTL)*: It indicates the percentage of resources being used by a server or a load balancer.

$$UTL = \left(\frac{\text{Resource used}}{\text{Total Resource capacity}} \right) * 100 \quad (7)$$

4) *Error rate (ER)*: It measures the percentage of failed requests or the number of requests resulting in errors.

$$ER = \left(\frac{\text{Number of failed requests}}{\text{Total number of requests}} \right) * 100 \quad (8)$$

TABLE I. ANALYSIS OF PERFORMANCE METRICS FOR LIST OF ALGORITHMS FOR 10K REQUESTS FOR 10K FILES

Algorithms	RT (Sec)	TP (request/sec)	UTL (%)	ER (%)
Least Response Time (LRT)	56.45	67	56	32
IP Hash	51.23	76	61	28
MCLB	45.67	81	67	21

Table I shows the performance of several existing and proposed algorithms based on the given metrics. These metrics mainly shows the huge impact on final outcomes. The proposed model MCLB mainly focused on managing the load balancing among the servers and providing the security for the processing data. For every one request one file is requested by the users. The encryption and decryption is implemented at the data owners end to provide the high end security for the data. The MCLB improved with the integration of Edge computing obtained the performance in terms of given metrics. The total requests processed by the MCLB are 10k requests for 10 files. Fig. 2 shows the performance of algorithm based on the given parameters.

Fig. 2. Performance metrics for list of algorithms for 10k requests.

TABLE II. ANALYSIS OF PERFORMANCE METRICS FOR LIST OF ALGORITHMS FOR 20K REQUESTS

Algorithms	RT (Sec)	TP (request/sec)	UTL (%)	ER (%)
Least Response Time (LRT)	66.45	76	63.4	34.5
IP Hash	61.23	83	65.2	31.2
MCLB	65.67	85.5	69.34	22.2

Table II shows the performance of list of algorithms based on several parameters such as response time (RT) which is high for LRT and low for MCLB. The throughput is low for LRT and high for MCLB which is more efficient. The utilization of resources is high for MCLB and low for LRT. Finally the error rate (ER) shows the low rate for MCLB and high for LRT. Fig. 3 shows the overall performance for 20k requests.

Fig. 3. Performance metrics for list of algorithms for 20k requests.

TABLE III. ANALYSIS OF PERFORMANCE METRICS FOR LIST OF ALGORITHMS FOR 30K REQUESTS

Algorithms	RT (Sec)	TP (request/sec)	UTL (%)	ER (%)
Least Response Time (LRT)	73.55	78.8	64.4	31.5
IP Hash	66.23	84.1	66.2	26.2
MCLB	68.67	86.3	70.34	18.2

Fig. 4. Performance metrics for list of algorithms for 30k requests.

Table III shows the comparison between LRT, IP Hash and MCLB. The existing model LRT shows the low performance in terms of high RT (Sec), low TP and utilization of resources and high error rate. The proposed approach MCLB shows the better performance in terms of parameters given in Table III. Fig. 4 shows the overall performances for all the algorithms for 30k requests sent by various users present in VMs.

VI. CONCLUSION

Modern cloud computing and network security rely heavily on ensemble security and multi-cloud load balancing. Ensemble security combines multiple security measures to form a robust defense system, whereas multi-cloud load balancing optimizes resource distribution while improving application performance and availability in various cloud environments. The combination of edge computing and cloud computing provides a powerful computing model that takes advantage of the advantages of both paradigms. It allows efficient data processing, lowers latency, increases scalability, and enables real-time decision-making. Organizations can create a robust and flexible computing ecosystem that meets the diverse needs of today's rapidly evolving technological landscape by combining edge computing and cloud computing.

Converting Data for Spiking Neural Network Training

Erik Sadovsky, Maros Jakubec, Roman Jarina

Department of Multimedia and Information-Communication Technologies-FEIT,
University of Zilina, Zilina, Slovak Republic

Abstract—The application of spiking neural networks (SNNs) for processing visual and auditory data necessitate the conversion of traditional neural network datasets into a format suitable for spike-based computations. Existing datasets designed for conventional neural networks are incompatible with SNNs due to their reliance on spike timing and specific preprocessing requirements. This paper introduces a comprehensive pipeline that enables the conversion of common datasets into rate-coded spikes, meeting processing demands of SNNs. The proposed solution is evaluated on Spike-CNN trained on Time-to-First-Spike encoded MNIST and compared with the similar system trained on the neuromorphic dataset (N-MNIST). Both systems have comparative precision; however the proposed solution is more energy efficient than the system based on neuromorphic computing. Since, the proposed solution is not limited to any specific data form and can be applied to various types of audio/visual content. By providing a means to adapt existing datasets, this research facilitates the exploration and advancement of SNNs across different domains.

Keywords—SNN; rate coding; spike timing; data conversion; MNIST

I. INTRODUCTION

Spiking Neural Networks (SNNs) have emerged as a highly promising research direction, bridging the gap between neuroscience and machine learning. By emulating the behaviour of biological neurons and their asynchronous communication through discrete spikes, SNNs offer a compelling computational framework for modelling and understanding neural processes [1], [2]. However, a significant obstacle in fully realizing the potential of SNNs lies in the lack of dedicated databases specifically designed for their training and evaluation.

In contrast to conventional neural networks that are trained using readily and widely available datasets such as MNIST or ImageNet (which are widely used in computer vision and pattern recognition fields among many others), SNNs require special data representations that capture the temporal dynamics of neural processing in a form of spikes. The precise timing of the spikes becomes crucial for encoding and processing information, necessitating a departure from traditional data formats [3]. Consequently, substantial research efforts are currently focused on developing comprehensive databases tailored explicitly for SNN training and evaluation.

Despite notable progress in the field of SNNs, the development of specialized databases for training and testing remains an ongoing research challenge. Currently, only a

limited number of publicly available datasets, such as the Spiking Neural Network Architecture (SNA), N-MNIST [4], DVS Gesture [5], and N-TIDIGITS [6], have been specifically designed for SNNs. These datasets enable training and testing of SNNs across various tasks, including decoding neural activity, image classification, gesture recognition, and speech recognition.

The availability of dedicated datasets is crucial for advancing the field of SNNs, as they serve as the foundation for training and evaluating network performance. However, existing datasets for SNNs (usually recorded using a specialized neuromorphic device) are limited in size and diversity, hindering the exploration of SNN capabilities across different domains and applications. This limitation underscores the pressing need to develop methodologies for converting and adapting conventional datasets into formats suitable for SNN training.

Our objective is to explain a processing pipeline for converting amplitude-based data into time/rate encoded spikes and compare a performance of SNN trained on such data with the performance of the SNN trained on specialized neuromorphic dataset. Such conversion process involves the transformation of input data into spike-based representations that preserve the temporal information necessary for accurate neural computation. This conversion necessitates careful consideration of various factors, including spike encoding schemes, spike rates, and the representation of spike timing. Moreover, it is essential to ensure that the converted data maintains the underlying structure and statistical properties of the original data to guarantee meaningful and reliable training of SNNs. By bridging the gap between conventional data formats and SNNs, our work aims to empower researchers and practitioners to overcome the limitations imposed by the scarcity of SNN-specific databases.

In this paper, we propose specifically an approach to converting image data (conventionally represented by pixel intensity values in matrix form) into spike-based representations incorporating temporal encoding techniques. We study and evaluate the proposed approach on MNIST dataset. To prove our concept, we compare the performance of developed SNN architectures trained on the spike-converted MNIST database with ones trained using the N-MNIST database, created by capturing MNIST images using neuromorphic Dynamic Vision Sensor (DVS) camera [7]. N-MNIST is a widely used benchmark dataset for evaluating the performance of SNN models in various tasks.

This paper is organized as follows. Section II introduces Spiking Neural Networks (SNNs) and emphasizes the need for new databases. Section III provides an overview of SNNs applications developed on the N-MNIST database. Section IV outlines the proposed methodology, including data conversion, database description, and network settings. Section V presents the results, demonstrating the effectiveness of SNNs trained on the newly acquired database. Finally, Section VI concludes the paper by summarizing the findings, discussing research implications and limitations, and providing recommendations for future studies.

II. SPIKING NEURAL NETWORK – THEORETICAL BACKGROUND

Despite the enormous efforts of scientists and evidently great progress in information and cognitive science, the human brain, with its billions of interconnected neurons, remains an enigmatic engine capable of complex cognitive processes. In recent years, there has been a surge of interest in developing computational models that emulate the functionality of biological neural networks. While traditional Artificial Neural Networks (ANNs) have been successful in numerous applications in diverse domains, they fall short in capturing the temporal dynamics and binary nature of spiking neurons observed in biological systems.

Spiking neural networks present a promising alternative to ANNs, providing a more biologically realistic approach to modelling neural computation. By communicating through discrete binary events known as spikes, SNNs mimic the action potentials observed in real neurons. This temporal coding scheme enables SNNs to capture the dynamics and synchronization observed in biological neural systems, opening new avenues for understanding brain function and developing advanced cognitive computing systems.

A. Neuronal Dynamics in SNNs

The core of a SNN lies in the dynamics of its constituent spiking neurons. Unlike traditional ANNs, which operate using real-valued activations, SNNs leverage the binary nature of spiking neurons to encode and process information through time.

1) *Integrate and fire model*: The Integrate and Fire (IF) [8] model represents a fundamental building block of SNNs. In this simplified model, the membrane potential of a neuron, denoted as V , integrates the input spike trains it receives. Once the membrane potential surpasses a threshold voltage, the neuron generates an output spike. The dynamics of the membrane potential in the IF model can be described as:

$$\frac{du}{dt} = R \cdot I(t), \quad u < V_{th} \quad (1)$$

where u denotes the membrane potential, the derivative du/dt represents the rate of change of the membrane potential, R is the membrane resistance, $I(t)$ represent the input spike train, and V_{th} is the threshold voltage.

2) *Leaky integrate and fire model*: The Leaky Integrate and Fire (LIF) model builds upon the IF model by incorporating the concept of leakage. In biological neurons,

the membrane potential gradually decays towards a resting potential due to ion leakage. The LIF model accounts for this phenomenon by including a leakage term in the dynamics of the membrane potential. The LIF model can be expressed as:

$$\tau_m \frac{du}{dt} = -(u - u_{rest}) + R \cdot I(t), \quad u < V_{th} \quad (2)$$

where τ_m represents the membrane time constant, u_{rest} is the resting potential. Fig. 1 provides a visual representation of the key elements and parameters characterizing a LIF neuron.

Fig. 1. LIF neuron characterized by membrane potential V , membrane time constant τ , input $I(t)$, and synaptic weight w .

B. Impulse Coding

Impulse coding is a fundamental aspect of SNNs, as it involves the transformation of data into an impulse-based format that enables efficient processing within these networks. The objective of impulse coding is to preserve relevant information while generating a stream of spikes. However, determining the importance of specific information and developing a unified approach to impulse coding remains a complex and context-dependent challenge. The following subsections briefly discuss three mechanisms of impulse coding in SNNs, namely rate encoding, temporal encoding, and population coding.

1) *Rate encoding*: Rate encoding, also known as rate coding, is a widely studied and utilized method of encoding information in SNNs. It's based on the assumption that the average firing rate of neurons over a specific time interval carries the desired information. By modulating the firing rate of neurons, different stimuli can be represented. The rate encoding approach offers a straightforward and intuitive method for representing information using spikes.

The strength of the stimulus representation is believed to increase with the firing rate. However, the precise mapping between firing rate and stimulus intensity can vary depending on the neural population and the specific encoding scheme employed. The rate encoding method provides a reliable means of representing information in SNNs and has been successfully applied in various applications.

2) *Temporal encoding*: Temporal encoding is another mechanism employed in impulse coding, which focuses on the precise timing of spikes to represent information. Instead of relying solely on the firing rate, temporal encoding

emphasizes the temporal order and precise timing of individual spikes. The relative timing of spikes across multiple neurons can convey specific features or patterns of stimuli.

In temporal encoding, the timing of spikes within a spike train carries the information, such as the duration between spikes or the occurrence of specific spike patterns. The brain has the remarkable ability to decode and interpret these temporal patterns to extract meaningful information. Temporal coding offers a rich representation that captures fine-grained details of stimuli and enables precise temporal processing in neural networks.

3) *Population encoding*: In addition to rate encoding and temporal encoding, population encoding has been introduced as a third category of impulse coding. Population encoding involves the joint activity of multiple neurons to encode information. Rather than relying on the individual firing rates or precise timing of spikes, population encoding considers the collective behaviour of a group of neurons.

The underlying principle of population coding is that the combined activity of a population of neurons carries information that cannot be represented by individual neurons alone. By analysing the distributed patterns of activity across the population, specific features or stimuli can be decoded. Population coding provides a powerful mechanism for encoding complex information and has been observed in various biological sensory systems.

III. RELATED WORK

In recent years, several studies have investigated a variety of SNN approaches, using the N-MNIST database, a widely used benchmark dataset for performance evaluation (see Section IV for details on N-MNIST). He et al. [9] compared the performance of the feedforward SNNs and recurrent neural networks (RNNs). The authors modified the N-MNIST database by compressing individual spiking events along the temporal axis and utilized the leaky integrate and fire (LIF) model as the spiking neuron model. Their findings indicated that SNNs generally outperformed conventional RNNs in terms of accuracy. However, with the adaptation of loss functions and the incorporation of Long Short-Term Memory (LSTM) networks, RNNs achieved competitive accuracy with SNNs. This study highlighted the advantage of SNNs in processing features represented by a sparse set of spikes. Another approach by Cohen et al. [10] introduced the method of inverse synaptic kernels for training SNNs on N-MNIST. The authors constructed a spiking neural network with a hidden layer comprising up to 10,000 neurons and achieved a high classification rate of 92.87% on the N-MNIST test subset. This work demonstrated the potential of leveraging biologically inspired principles to further enhance the performance of SNNs.

Wu et al. [11] proposed a novel architecture by incorporating a population of neurons in the output layer of a convolutional SNN. The output spike sequence from this layer represented population coding, which improved the discriminative capabilities of the network. The experiments conducted on the N-MNIST and DVS-CIFAR10 databases showed remarkable accuracies of 99.53% and 60.5%,

respectively. This study highlighted the effectiveness of population coding in visual recognition tasks using SNNs.

For event-based features as (SNN input data), Ramesh et al. [12] introduced the Event-Based structural Descriptor (EBD) that captures a spatio-temporal structure using a log-polar grid and applied it to various computer vision problems, including N-MNIST classification. They proved the efficacy of event-based representations in capturing spatiotemporal information and leveraging it for robust classification in SNN frameworks. Their classifier achieved a high accuracy of 97.95% on the N-MNIST test subset.

Addressing the challenges associated with SNN training, Shrestha et al. [13] explored the non-differentiability of the spike generation function and proposed a solution for converting existing databases into spike-based representations. They introduced the SLAYER algorithm, inspired by backpropagation, enabling the training of both feedforward and convolutional SNNs. The N-MNIST database was used to demonstrate the algorithm's effectiveness and the conversion process from image-based to spike-based representations.

Table I summarizes the accuracy achieved by various approaches on the N-MNIST dataset, providing a comprehensive performance comparison of the state-of-the-art SNN-based methods.

TABLE I. PERFORMANCE COMPARISON OF THE STATE-OF-THE-ART METHODS ON THE N-MNIST DATASET

Authors	Method	Accuracy (%)

The Spiking Heidelberg Digits (SHD) and the Spiking Speech Command (SSC) [23] datasets are both audio-based classification datasets that provide input spikes and output labels for different spoken digits and commands. Both of these datasets were created using a software conversion that was based on mathematical models of inner auditory system.

The IBM gestures dataset [24] contains spike trains of gesture movement recordings under different illumination conditions. It is one of the most popular real world scenario datasets for training SNNs.

IV. METHODS

In this section, we present a comprehensive methodology that enables the conversion of various datasets into temporal-encoded spikes suitable for SNN processing. The proposed approach combines techniques of data preprocessing, feature extraction, and network configuration to ensure the compatibility of the converted spikes with the SNN architecture.

A. Datasets

1) *MNIST*: MNIST is a standard database consisting of grayscale images of handwritten digits. It contains 60,000 training images and 10,000 test images, with each image having a size of 28×28 pixels. One of the advantages of using this database is that it requires minimal data preprocessing since most machine learning libraries have built-in support for MNIST. Although MNIST is not encoded in spikes, it can be utilized for SNN development in such a way that classical ANNs are first trained on MNIST and then converted to SNNs. It should be noted that MNIST does not include a separate validation set. If needed, a few samples from the training set have to be separated for such a purpose.

2) *N-MNIST*: Neuromorphic MNIST (N-MNIST) [4] is a spike-based representation of the MNIST database. It captures the dynamics of handwritten digits using a Dynamic Vision Sensor (DVS) camera. N-MNIST consists of the same number of samples as MNIST. Each sample is encoded as a binary file, storing pixel index (x, y), event type (ON or OFF), and the event timestamp. The events represent changes in light intensity. N-MNIST provides dynamic sequences with a duration of 300 ms and a resolution of 34×34 pixels. The motion in N-MNIST is inspired by the saccadic eye movement, featuring rapid movements in three directions lasting 100 ms each. This database enables the exploration of SNNs and their performance on tasks involving temporal information, serving as an alternative to static image-based databases.

B. Conversion Procedure: Transforming Data for Effective SNN Training

The first step for enabling SNN training on the MNIST dataset is to encode the data samples into time-distributed spike sequences.

The conversion pipeline consists of the following steps:

- Loading the image data
- Preprocessing the image data
- Scaling the image data
- Converting the image data into spike sequences
- Saving the converted spike sequences for later use in training

To implement this spike encoding procedure, several libraries written in Python have been used: *Pytorch* and *Pytorch-vision* for MNIST loading, *snnTorch* library for

temporal encoding and *h5py* library for saving the converted spike sequences.

The next step was to preprocess the image data to be compatible with the *snnTorch* library. One main preprocessing step was to scale the image values between 0 and 1. This step was mandatory as it was a requirement from the *snnTorch* library. One can do multiple preprocessing operations step such as resizing, rotating, etc, at this step.

The scaled values of the data are then used as an input for the spike generation module of the *snnTorch* library (this module enables to use several encoding schemes, either of rate or temporal types). The simulation time of the temporal encoded samples may be specified to a desired value.

The output from the spike generation module is an array of discrete values 0 and 1, in which value of 1 represents a spike. The array is a two-dimensional array of [T, U] size, in which the first dimension represents the simulation time index and the second one corresponds to the feature number, T is the total number of simulation time steps, and U represents the number of features (which matches SNN input layer size).

The final step is to save the generated spike data for the later use in SNN training. A common practice in neuromorphic datasets is to save the data in the form of arrays that correspond to: coordinates (x,y), spike times, and labels. Each event (spike) has a coordinate that corresponds to the index of the input neuron firing a specific spike, and a timestamp. In addition, a label is assigned to the whole sample. We have followed this common practice and reformulated the encoded spike data into corresponding arrays as mentioned above.

In our experiments, we have chosen a temporal encoding scheme, because of lower number of spikes needed to carry the information. This encoding scheme belongs to the group of temporal encoding schemes. As opposed to the rate encoding schemes, temporal encoding schemes contain a smaller number of spikes. In rate encoding schemes the average number of spikes represents the information. However, in temporal encoding schemes, the precise timing of a single spike carries the information. There are several temporal encoding schemes available. [25]. In this experiment, we applied the Time-to-First-Spike encoding procedure (T2FS) [26]. In the case of T2FS, the information is carried in the time of the first spike from the beginning of the simulation. It was experimentally proven, that tactile systems (e.g., at the fingertips) use a similar scheme to encode and transmit information about touch. Also, it has been suggested that the first spike carries twice as much information compared to rate encoding [27].

Lower number of spikes has a positive impact on overall hardware requirements, especially on the size of the batch in GPU. Also, this lower number of spikes reflects lower requirements for energy if a SNN processing this dataset would be implemented on hardware. The simulation time of samples was set to 30 ms as opposed to 300 ms simulation time of N-MNIST samples. The shorter sample time was selected to investigate the ability of SNNs to process samples with short sample time.

The encoding procedure of the *spikegen* module returns a multi-dimensional array with values 0 and 1. Note, due to

differences between input structure of the library used for SNN training with converted samples and the output structure of the *spikegen* module, the structures need to be reorganized to fit each other. The proposed pipeline block diagram is shown in Fig. 2.

Fig. 2. Proposed pipeline block diagram.

C. Baseline System

The Spiking Convolutional Neural Network (SCNN), that is similar to the structure published in [13] was chosen as a baseline architecture. The architecture of the baseline system is shown in Table II.

The baseline model was trained on N-MNIST. The output layer of the model uses the rate encoding method, where the neuron with a higher spike rate is selected as the neuron representing the class. The neurons were trained to spike 60 times for the representing (true) class and 10 times otherwise (false class). The simulation time of SNN was 300 ms. The trained SNN was able to classify samples with processing delay of 150 ms. Although the process was more biologically plausible, its computational cost may be a disadvantage.

TABLE II. THE ARCHITECTURE OF THE BASELINE SYSTEM

Layer	Parameters
Input	34×34×2
Conv1	12 kernels (5×5)
Delay1	-
Pool1	2×2
Delay2	-
Conv2	64 kernels (5×5)
Delay3	-
Pool2	2×2
Delay4	-
Fc1	10

D. The Proposed System

As an alternative we propose an approach using a software conversion of the MNIST dataset that may be widely available and without the need of a specialized hardware (in contrast to N-MNIST).

The proposed architecture is again a SCNN similar to the baseline, except the input layer. The size of the input layer corresponds with the size and format of the MNIST image data. The structure of the model consists of convolutional layers followed by pooling. After each layer also a time delay

layer is applied. The delay layer is used as a special layer in SNNs. The SCNN output layer is a spiking fully connected layer with 10 neurons corresponding with the number of classes to be recognized. The whole architecture is shown in Table III.

The proposed system was trained from scratch for 80 epochs. The time of the whole training process was around 2.5 hours (using NVIDIA RTX 2060TI with 6GB of GPU memory). We used the Adam optimizer with starting learning rate of 0.001. The learning rate parameter was modified by the *ReduceLROnPlateau* learning rate scheduler, which modified the value of the learning rate based on criteria. The batch size of both train and test subsets was set to 32.

To implement and train the proposed SCNN on the converted MNIST dataset we applied the *Pytorch* library along with the *slayerPytorch* library that includes an implementation of SNN training using *Pytorch*. SNNs implemented using this library consists of Spike Response Model spiking neurons. The architecture is trained using the Spike SLAYER algorithm. This algorithm uses a surrogate gradient approach to overcome difficulties with training SNNs. This library contained all building blocks to create a SNN. This includes special layers that were made of spiking neurons, spike processing and the surrogate gradient method. There are more parameters that were needed to be configured. Most of these parameters were related to the *slayerPytorch* library and were used to control the simulation of SNN. We used similar parameters as the baseline, except that our samples had different simulation length. Note, our proposed model was trained for temporal encoding, where a lower number of spikes were needed for the model to classify a sample than in the case of the rate encoding that was used in the baseline.

TABLE III. ARCHITECTURE OF THE MODEL

Layer	Parameters
Input	28×28
Conv1	12 kernels (5×5)
Delay1	-
Pool1	2×2
Delay2	-
Conv2	64 kernels (5×5)
Delay3	-
Pool2	2×2
Delay4	-
Fc1	10

V. EXPERIMENTAL RESULTS AND DISCUSSION

The trained architecture was able to achieve accuracy of 98.79% on the MNIST test set. The changes in accuracy and loss during the training process are shown in Fig. 3 and Fig. 4.

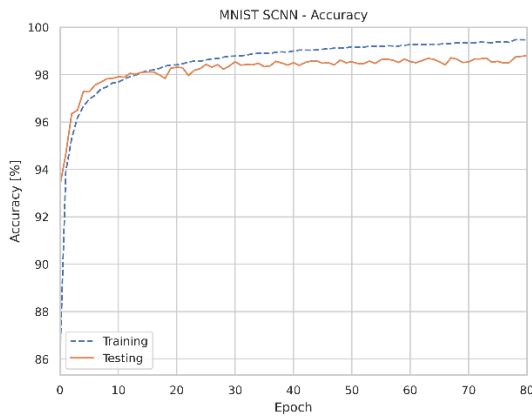

Fig. 3. Accuracy on subsets during the training process.

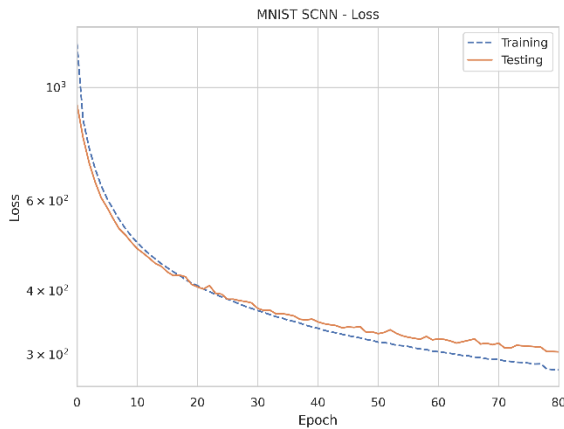

Fig. 4. Loss of the model during the training process.

The accuracy of the baseline system on the N-MNIST test set was 99.2%. The performance of the baseline system is comparable with other systems trained on N-MNIST and published. Although, the accuracy of our trained model was not higher than the baseline system, it is still a competitive number.

The improvement of our model is in spike efficiency. Our trained model was able to classify MNIST samples with only average of 27 spikes on the output layer during the simulation time. The baseline system for N-MNIST used 150 spikes on average during the simulation time. Our proposed system uses a more energy-efficient temporal encoding method, while the baseline system used rate encoding. Also, the number of spikes that are on the input of the SNN is lower. Baseline system for N-MNIST used around 4100 spikes on average, while our system used only 784 spikes. When encoding an image, the spikes are first occurring on the indexes of pixels with higher brightness intensity, while spikes on indexes of pixels with lower brightness intensity occur later. Note, each represented pixel contains only one spike. This means, that for MNIST images with a resolution of 28x28 pixels only 784 spikes occur for each image. Such a number of spikes are much smaller than in the case of the N-MNIST dataset, in which each sample around 4100 spikes on average.

Our proposed model is more energy efficient not only on the input spikes, but also on the output spikes. The comparison

of the baseline system and our proposed system is summarized in Table IV.

TABLE IV. COMPARISON OF THE BASELINE SYSTEM AND OUR PROPOSED SYSTEM

	Baseline system	Proposed system
Dataset	N-MNIST	MNIST (converted with the proposed pipeline)
Encoding	Rate encoding	Temporal encoding
Number of spikes on input (average)	4100	784
Number of spikes on output	150	27
Accuracy	99.2%	98.79%

Although our experiments are carried out on MNIST benchmark dataset, the methodology we present is versatile and applicable to other image datasets as well as to diverse data modalities, including audio or biological signals (e.g. in the form of spectrograms).

VI. CONCLUSION

In this paper we have presented a software conversion process that uses an energy efficient temporal encoding method to convert static image data into a format of spikes distributed in time. The proposed method was compared with a baseline method that used a specialized hardware for converting the same dataset. The baseline system used rate encoding. The functionality of the proposed method was examined on SNN that used a similar architecture to the baseline system. The results of the proposed solution in terms of accuracy were competitive with the baseline. However, the SNN trained using the proposed temporal encoding needs a significantly lower number of spikes in both input and output spike trains to correctly classify the dataset.

We envisage that the proposed pipeline will not only facilitate improved training and testing of SNNs but also inspire the development of larger datasets that cover a broader application domain. Through these efforts, we attempt to unlock the immense potential of SNNs and neuromorphic computing while advancing our understanding of brain-inspired computation.

The future improvements for the proposed pipeline may be in experiments with more datasets to be converted into spike trains and then used for training SNNs. The length of samples in time may play a role in the accuracy of the trained model and would need to be further investigated.

Abstract—Various authentication methods have been proposed to mitigate data breaches. However, the increasing frequency of data breaches and users' lack of awareness have exposed traditional methods, including single-factor password-based systems and, two-factor authentication systems, to vulnerabilities against attacks. While behavioral authentication holds promise in tackling these issues, it faces challenges concerning interoperability between operating systems, the security of behavioral data, accuracy enhancement, scalability, and cost. This research presents a scalable dynamic behavioral authentication model utilizing keystroke typing patterns. The model is constructed around five key components: human-computer interface devices, encryption of behavioral data, consideration of the authenticator's emotional state, incorporation of cross-platform features, and proposed implementation solutions. It addresses potential typing errors and employs data encryption for behavioral data, achieving a harmonious blend of usability and security by leveraging keyboard dynamics. This is accomplished through the implementation of a web-based authentication system that integrates Convolutional Neural Networks (CNNs) for advanced feature engineering. Keystroke typing patterns were gathered from participants and subsequently employed to evaluate the system's keystroke timing verification, login ID verification, and error handling capabilities. The web-based system uniquely identifies users by merging their username-password (UN-PW) credentials with their keyboard typing patterns, all while securely storing the keystroke data. Given the achievement of a 100% accuracy rate, the proposed Behavioral Dynamics Authentication Model (BDA) introduces future researchers to five scalable constructs. These constructs offer an optimal combination, tailored to the device and context, for maximizing effectiveness. This achievement underscores its potential applications in the realm of authentication.

Keywords—Behavioral authentication; keystroke dynamics; human-computer interface; two-factor authentication

I. INTRODUCTION

Stolen credentials remain the most frequent means by which hackers commit data breaches. In general, 80% of hacking-related breaches involve brute force or stolen credentials, and 37% of all breaches involve the use or theft of credentials [1]. Ensuring data protection and privacy through effective and efficient authentication methods is not only a priority for individuals, organizations, and countries but also a context for promoting incremental and radical innovation. Data-protection authorities must acquire new technologies and

use them effectively to regulate personal information practices so as to meet present and future challenges, for the technology advances in step with the security threats [2-3]. Hence, cybersecurity attacks have been increasing exponentially and rendering existing detection mechanisms insufficient [4]. Cyber-criminals exploit security flaws to access users' data and privileges [5], and, in turn, tactics such as authentication serve to restrict and control access to unauthorized users [6].

More than 555 million passwords have been obtained through data breaches and exposed in the public domain [7]. Some 27% of those surveyed in a Google poll admitted attempting to guess the passwords of others, 17% of whom claimed to have succeeded [8], and, according to one report, 80% of hacking incidents are enabled by stolen and reused login information, 81% of which at the company level are caused by the many poor passwords among the 300 billion in use [9]. Verizon's 2022 Data Breach Investigations Report identified passwords as a frequent weak link in cybersecurity, with 80% of all data breaches worldwide again being associated with passwords [10].

Multifactor authentication (MFA) can block more than 99.9% of account compromise attacks [11], and two-factor authentication (2FA) is currently among the primary mechanisms for defending against password attacks [12], especially those involving phishing and password reuse [13]. Biometric authentication (BA) based on keystrokes is considered more reliable than these traditional means of authentication because of its novelty and low intrusiveness [14]. A National Bureau of Standards study found keystroke dynamics (KD) to be a reliable and accurate BA method, achieving at least 98% accuracy [15].

The overwhelming focus in the scholarship for several decades has been on the legal and technological dimensions of the challenges associated with data protection [2]. Among the world's privacy and security laws, the European Union General Data Protection Regulation (GDPR), adopted in 2016 and enacted on May 25, 2018, is the strongest [16], and a crucial aspect of compliance with this regulation is adequate authentication and authorization [17]. Accordingly, biometrics generated through KD has become a viable option to authenticate users for both security and surveillance purposes [18] given the minimal implementation cost of KD and lack of a need for special hardware since the gathering of typing data

is reasonably straightforward, requiring no additional effort by the user [19].

Accordingly, we propose a scalable dynamic behavioral authentication model incorporating future trends in information systems, specifically, trends in or toward (1) devices, (2) dynamic encryption standards, (3) assessing the emotional state of the authenticator, (4) the ubiquitous access to and usage of devices, and the option to (5) incorporate emerging technologies and solutions for low cost and increased functionality. The result, validated based on these five constructs, is a cost-effective and non-intrusive MFA system method to augment users' authentication and ensure data security while efficiently handling their typing errors [19]. The use of keystrokes itself validates the model owing to its simplicity and its ability to integrate seamlessly with passwords. Simply put, KD is an extremely useful method for BA because it is extremely difficult to impersonate [20].

The main contributions of this paper are:

- a dynamic behavioral authentication model incorporating five scalable constructs namely HCI devices, encryption, user profiles, ubiquitous, and the options for cost effective applications,
- scalability in all five constructs of the model that offers multiple avenues for future research on combinations of the components of the constructs,
- a secure and efficient authentication system based on users' unique key-typing patterns with an error-correction feature,
- a cost-effective way to implement BA compared with other methods (which may require a combination of hardware and software),
- alignment of the proposed system with the relevant data protection and privacy regulations (e.g., the GDPR) to assist organizations with compliance.

In the remainder of the paper, Section II presents our justification for using 2FA and MFA and our analysis of attacks followed by a review of the research on the application of behavioral authentication in KD. Section III presents the methodology and Section IV discusses the application of KD and the resulting model. We discuss our conclusions in Section V.

II. LITERATURE REVIEW

The following discussion surveys current issues relating to password authentication, the use and usability of multifactor authentication, the ease of password attacks, and behavioral authentication methods.

A. Challenges in Password Authentication

Password-based authentication has been fraught with multiple issues. Firstly, the resilience of diverse operating environments is considered a significant technical challenge for future biometric systems. [21]. Secondly, the endeavor to develop efficient and secure biometric authentication systems that can withstand impersonation attacks, guarantee the non-reversibility of biometric templates, and safeguard the privacy

of personal information is critical [22]. Thirdly, the challenge lies in establishing appropriate policies and laws to prevent the indiscriminate use of biometric data [23]. From a keystroke recognition perspective, there is a necessity for the development of technology to enhance accuracy [24]. Lastly, a majority of the current research on keystroke dynamics revolves around free text (emphasizing n-graphs). This not only poses challenges in improving accuracy but also frequently requires a substantial amount of time to construct user models [25]. The suggested research surmounts these constraints by achieving a 100% accuracy enhancement and employing the Homomorphic Public Key Encryption technique for training and predicting encrypted data. This approach guarantees privacy while expediting training without sacrificing usability.

However, this can be enhanced through multifactor authentication systems that combine passwords, biometrics, and OTP verification [26]. The study [27] observed that, to control access to data, most systems rely on usernames and passwords for authentication, which are both convenient and insecure because they can be quickly entered into an online application or service [28]. Since the human capacity for information processing is limited, users face difficulties in remembering and matching their passwords and, therefore, often use either easy-to-guess passwords or complex passwords that are hard to remember [29]. Many internet applications, such as remote logins, for government organizations, private corporations, database management systems, and school systems are based on password authentication, but the current internet environment is vulnerable to replay, guessing, modification, stolen verifier, and other types of attacks [30]. Regardless of the complexity of a password string, passwords are considered a weak form of authentication because they can be shared, stolen, forgotten, or hacked [31]. Despite several major problems that have been identified with alphanumeric passwords, they are still used to protect both low-sensitivity and highly sensitive information [29] and remain the most widely used method of end-user authentication [32]. Since password-based user authentication methods provide only partial protection from hackers and intruders, additional authentication should be applied [33].

B. Multifactor Authentication (MFA)

MFA has emerged as a substitute mechanism to increase security by demanding that users provide more than one factor of authentication (i.e., in addition to a password) [32]. This layered approach to authentication provides more robust protections for users and minimizes the risks of breaching security [5] because a hacker must penetrate multiple layers of security to gain access to an MFA-enabled system. The various types of MFA present various security issues but combining them with password-based authentication systems can greatly improve the credibility of a user's login and complicate access for intruders [34].

Factors such as "what the user knows" (inherent), "what the user has" (possession), and "what the user is" (biometric) have served as additional authentication methods [32]. In this regard, biometric features unique to individuals, ranging from physiological characteristics (e.g., fingerprints and iris, hand, and face patterns) to behavioral characteristics (e.g., KD,

mouse movements, gait, and handwriting), have served to identify users [3]. Many such biometric approaches tend either to be expensive or to place heavy demands on computer hardware, making them inappropriate for most users [35].

C. Review of Authentication Methods

Human interface devices such as keyboards and mouse have been used extensively to help users interact with computer devices to increase their productivity. In this respect, the analysis of computer users' typing behavior (i.e., KD) is described as a behavioral biometric (BB) that can be analyzed and measured to improve cyber defenses [36]. The analysis of KD through BB (Fig. 1) focus on human-computer interaction (HCI) involving mouse movements and keyboard strokes [37]. The method proposed concentrates on a subcategory of HCI, wherein the innovative secure authentication approach relies on users' behavioral patterns manifested through keystrokes.

While extensive and valuable research on KD has facilitated authentication systems, challenges relating to the current user-authentication features include: -

- the increased use and introduction of HCI devices,
- the need to secure a behavioral and biometric database through relevant encryption standards,
- the ubiquitous and universal nature of devices that require cross-platform functionality,
- users' input errors during UN and PW entry linked to emotional states and secure web forms that restrict genuine access after a limited set of related errors,
- the availability of machine learning- and web-based solutions and hardware for authentication mechanisms, and
- biometric systems that can be forced on victims (unconsciously or under duress).

Fig. 1. Classification of behavioral biometrics [adapted from 37].

A lightweight, web-based secure authentication system that can be seamlessly integrated into multiple browsers based on behavioral KD meets these challenges. Research on KD using the keyboard and/or mouse in the literature includes authentication studies using ML, a combination of machine learning (ML) and web-based solutions, and hardware tokens. A Google Scholar title search using “keyboard dynamics” and “user authentication” generated seven relevant results, and a further search for these phrases anywhere in articles published since 2016 generated 62 results. These search results indicate that academic researchers exploring the application of KD in systems and device authentication (Table I) have been focusing on:

- the use of ML techniques for enrollment and verification with KD from live users and publicly available datasets based on keyboard and/or mouse dynamics with a near-zero error rate,
- proposing and experimenting with web-based applications that incorporate KD, mouse dynamics, a combination thereof, a combination of KD and biometrics, and behavioral features to achieve an accuracy of 97.96%,
- methodologies and experimental applications using KD and a combination of KD and mouse dynamics with hardware and software to achieve an accuracy of 97%, and
- Client-server KD systems requiring both hardware and software, along with peripherals like sensors, cameras, and hardware tokens.

D. Behavioral Authentication using ML

Several studies have described the successful or near-successful use of keystroke and/or mouse dynamics for authentication with public data sets as well as live users, mostly from a back-end server perspective. The author in [38] created a system using an ML classifier beginning with a support vector machine (SVM) room for each user that accesses data from 34 user environments and was able to accept real users with an extremely low error rate (nearly 0%). These findings demonstrate that a one-class SVM may serve as a tool for the continuous user analysis and validation of button dynamics through the formulation of plans and the choice of the proper kernel parameter. With histogram gradient boosting as the primary classifier for the training and testing phase on a keystroke benchmark dataset, [19] achieved 97.96% average accuracy and an average equal error rate (EER) of 0.014 across all subjects, thus outperforming all previous advances in both ML and deep learning approaches. The researcher in [39] used the confidence interval and k-means clustering to demonstrate the success of trajectory dissimilarity, achieving a higher accuracy rate, 96%, than other techniques. While trajectory dissimilarity uses KD for the usernames confidence interval and k-means clustering uses KD for passwords, another significant finding from the study is the use of the former to protect users from account lockout attacks (i.e., exploiting the lock-out of accounts after a defined number of incorrect password attempts).

TABLE I. REVIEW OF EXPERIMENTAL RESEARCH USING KEYBOARD AND / OR MOUSE DYNAMICS

	Author	ML	Live users	Public dataset	Error-correction method	Web-based	Accuracy (%)	Error rate

*Natural language processing; **Portable hardware token. EER = equal error rate; FAR = false accept rate; FRR = false reject rate; FER = failure to enroll rate

Quimatio, Njike, and Nkenlifack [40] proposed an authentication method based on three bagging ensembles formed by an SVM, K-nearest neighbor (KNN), and decision tree classifiers, the outputs of which were merged using the CMU dataset to achieve 95.65% accuracy. Kar, Bamotra, Duvvuri, and Monahan [41] proposed KD for authentication by taking a dataset of 51 users who typed a password in eight sessions on alternate days to record fluctuations in their moods and implemented anomaly-detection algorithms based on distance metrics and ML algorithms, such as artificial neural

networks (ANNs) and convolutional neural networks (CNNs), to classify the users with 95.05% accuracy with an ANN with Negative Class.

Other studies of these issues include that of Raul, Shankarmani, and Joshi [42], who proposed combining non-conventional features with the conventional time-based features for user identification in static KD using ML classifiers and observed improvements in the false reject rate (FRR), false accept rate (FAR), and EER; their five ML algorithms determined that the logistic regression method

achieved 90.50% accuracy. Shi, X. Wang, Zheng, and Cao [43] proposed a user authentication method based on KD and mouse dynamics involving comparison of all of the representative time windows and dimensionality-reduction targets of the KD features to determine the parameters for ensuring the robustness of the algorithm and, using real-world setting, the HCI dataset achieved 89.22% accuracy in authenticating users, thus demonstrating the effectiveness of the algorithm. X. Wang, Shi, Zheng, Zhang, Hong, and Cao [44] presented a user authentication method that relies on scene-related and user-related features for user identification: first, features are extracted based on keystroke and mouse movement data; next, scene-related features are obtained that have a low correlation with scenes; lastly, scene-related and user-related features are fused to ensure their integrity. This proposed method has the advantage of improving user authentication accuracy in hybrid scenes, with an accuracy of 84%. Alshanketi, Traore, and Ahmed [31] presented an algorithm for handling typing errors in mobile keystroke BA combining timing- and pressure-based features. They used the random forest algorithm to classify and differentiate between trusted users and impostors based on a profile built for each user.

Researchers have also used ML to measure the error rates as success factors in authentication. Piugie, Di Manno, Rosenberger, and Charrier [45] proposed an approach based on the transformation of behavioral biometrics data (i.e., time series) into a 3D image that retains all of the characteristics of the behavioral signal and assists in training images based on CNNs and evaluates the performance of the system in terms of the EER based on a significant dataset, and they demonstrated the efficiency of the proposed approach on a multi-instance system. Mao, Wang, and Ji [46] combined keystroke content with keystroke time as the feature vector using a CNN to process the feature vectors and then input the normalized vector into the bi-LSTM network for training; they then tested this approach on an open data set and achieved an FRR, FAR, and EER of 3.09%, 3.03%, and 4.23%, respectively. Stragapede, Delgado-Santos, Tolosana, Vega-Rodriguez, Guest, and Morales [47] took into account the emotional and physical state of the authenticator and proposed a novel transformer architecture to model free-text KD performed on mobile devices using a publicly available Aalto mobile keystroke database, and they achieved experimental results that outperformed the current state-of-the-art systems, with an EER of 3.25% from only five enrollment sessions of 50 keystrokes each.

Jadhav Kulkarni, Shelar, Shinde, and Dharwadkar [3] proposed an ML-based authentication model that uses the static approach of keystroke dynamics to recognize and authenticate users accessing the system based on their unique keystroke profiles with respect to the flight, dwell, press, press-to-press, and release-to-release time and achieved an FAR and an FRR of 1% and 4%, respectively. Gupta, Khanna, Jagetia, Sharma, Alekh, and Choudhary [35] proposed a high-efficiency authentication system combining two methods to make keystroke biometrics less susceptible to forgery and more usable and reported that the system efficiently implemented secure authentication with the advantage of ease of

implementation since all that is required is the installation of software on any workstation. Yang et al. [55] focused on the text entered by the user and proposed contents and keystroke dual attention networks (ML) with pre-trained models for continuous authentication to address user-inputted “text” during keystrokes as an important asset beyond traditional KD characteristics, and their model achieved state-of-the-art performance on two datasets.

E. Web-based Behavioral Authentication

The research on various aspects of authentication systems has included web-based authentication, web-based keystroke authentication, portable tokens, and parametric approaches. Beginning with the first of these, to date, researchers have looked at web-based authentication. Thus, Bhattacharya, Trivedi, Obaidat, Patel, Tawar, and Hsiao [48] constructed a 2FA scheme for web users based on real-time KD by employing the KNN classification algorithm and achieved 87% accuracy over 146 testing samples and a recall value of 0.95, thus addressing the false-negative issue. Kang and Kim [49] used mouse dynamics and KD to identify personalized repeated user interface (UI) sequences with an Apriori algorithm based on the keystroke-level model of the HCI domain and validated the effectiveness of the system in complementing normal authentication through access testing with commercial applications that require intensive UI interactions.

Siti Rahayu, Guan, and Yusof [33] proposed an authentication system using KD in three stages—enrollment, verification/retraining, and client/server connection—and achieved a low error rate with just five users. Rahman [50] introduced a novel method utilizing KD as an additional validation layer in web-based applications such that users were prompted to type five words after registering their username and password (UN-PW), with the extracted features stored as a JSON object in the database. Vasyil, Sharapova, Ivanova, Denis, and Yulia [51] developed a web-based authentication system based on users’ keystroke features and suggested merging KD with other human features to achieve greater precision in authenticating users. Zaidan, Salem, Swidan, and Saifan [27] developed a web-based application for use in the study of the factors affecting KD in mobile systems that extracts and stores features such as the characters typed, key-hold latency, up-down latency, down-down latency, and overall latency; they then tested factors such as the device used for typing, the knowledge of the text, the mood of the user, and the complexity of the password on this dataset and achieved positive results. Boakye Osei, Opanin Gyamfi, and Okoe Alhassan [52] proposed a web-based keystroke login system using features such as dwell, flight, and locate to minimize error rates. Though the system achieved lower error rates than previous systems, it was limited to web-based formats and QWERTY keyboards. Aliksieiev, Strelitskiy, Gavva, Gorelov, and Synytsia [53] used a web-based application to gather and analyze users’ keystroke information based on a calculation of digraph timings and employed a non-parametric test to compare multiple datasets for situations in which distribution is difficult to determine and the sample is small.

From a cloud environment perspective, [54] used a combination of static authentication, click color-based dynamic authentication, and behavioral biometrics (keystroke with cryptographic encryption and a hashing technique) to achieve 96% accuracy and a decrease in false positives with an error rate of 3%. In [18] author developed a unique way to perform KD-based authentication with a keyboard and an array of pressure sensors that serves to develop unique user profiles that improve the suggested system's efficiency and, using a real-world dataset, achieved a 97% success rate in experiments. Using a natural language processing method, [56] introduced a portable hardware token for MFA using keystrokes to enhance authentication, but the proposed algorithm, though simple, achieved relatively low accuracy, but with a relatively high error rate. So, they suggested applying ML and considering close keystrokes to reduce authentication errors. ML techniques, especially CNN, have been effectively employed in behavioral authentication using gait recognition to extract high-level features from the input data [57]. Likewise, the random forest classifier and support vector machine have been utilized in behavioral authentication involving touch behavior (such as finger pressure, size, and pressure time) while tapping keys on smartphones. This approach achieved an accuracy of 97.80% employing just 25 features [58].

This review of the literature on KD reveals two major aspects of authentication, namely the use of multiple devices (KD and/or mouse dynamics, including touch screens) and the extensive use of ML and web-based solutions in authentication. However, there is a lack of emphasis on the applicability of Behavioral Authentication (BA) across different devices, the potential for scalability in encryption standards, the influence of various emotional states of users on behavioral data errors, cross-platform compatibility, and the need to incorporate upcoming applications and solutions for cost efficiencies. In this regard, a validated secure and scalable model can offer multiple alternatives for the five constructs.

The experiment phase of research centers on keystroke dynamics as a behavioral biometric, propelled by both the user's frequent utilization of this parameter and their proximity to the computing device. While biometric parameters can encompass both physiological and behavioral traits, behavioral aspects, such as the user's gait, interaction with the graphical user interface, haptic responses, programming style, registry access, system call logs, and mouse dynamics, offer advantages like persistent security, post-login authentication, ease of behavioral data collection, and the absence of a requirement for specialized hardware [37]. The evaluation metrics, namely FAR, FRR, ERR, and FER, are all zero due to the 100% acceptance rate. As a result, these evaluation metrics are not elaborated upon in the subsequent section. Additionally, the experimental results establish a foundation for the forthcoming model, which can be employed for future research endeavors. In terms of the number of users, researchers have extensively used ML classifiers on publicly available databases for error reduction and conducted experiments using live keystrokes with numbers of users ranging from five to hundreds in which the data revealed no change in effectiveness, even with few users.

III. METHODOLOGY

The discussion of the research methodology here includes the proposed framework (Fig. 2) and the methods employed during the development of the proposed system.

A. KD Authentication Framework

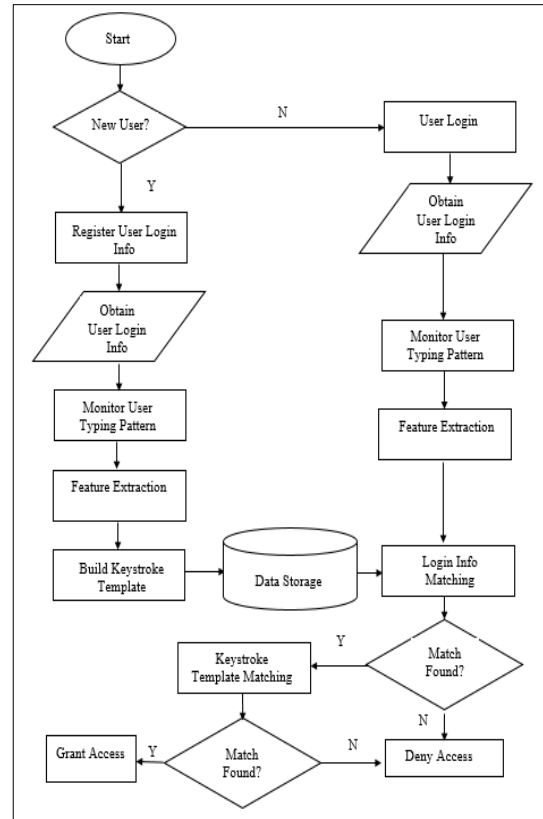

Fig. 2. Proposed framework.

B. Methods Employed

The method is a static approach that involves checking users' data during authentication. The experimental process starts with the training and testing phase and concludes with measures to handle errors. This section describes the environment under which our system was developed and evaluated.

1) *Experiment environment:* The system was developed using Python Programming 3.12 prerelease (2028-10 PEP 693) windows version running on a Laptop with specification (Core i5 with Intel Processor and 16 GB of RAM with Window 10 Operating version (Box 1).

2) *Dataset description:* The data were collected from five users. Each one was asked to type in the word "P@ssw0rd" in 10 trials. From each trail, four features (key press, key release, the characters typed by the user, and the total number of keys typed by the user) were extracted. Then three statistical features (average, mean and standard division) were added to each user's features. So, the total dataset used consists of 800 features (5x10x4x3).

3) *Classifier description:* In the classification phase, the CNN algorithm was used as follows. The features, extracted above, have been added at the fully connected layer of the CNN model. This further improved the classification accuracy.

Box 1 Python parameters

Python-CNN parameters tuning	Learning rate =
0.01, 0.001, 0.0001	
Neuron count= 8, 16, 12,	
Layer depth = 1, 2, 3,	
Kernel size = 8, 16, 12,	
Loss function = L2 loss, Binary cross-entropy,	
Epoch = 20, 50, 100	
Number of Hidden layers =2 Output layer=1	
Total number of layers =3	

4) *Security of the data:* Since the behavioral keystroke data from the five users is stored on a server, users are unable to modify the application due to encryption. The system utilizes keystrokes to ascertain whether a user is a legitimate individual or an imposter, both during the session and even after logging into the program. The Paillier cryptosystem algorithm, that comes under the category of the Homomorphic Public Key Encryption technique was utilized in the keystroke analysis training to predict encrypted data, ensure both privacy and accelerate training without compromising usability. It assumes a public key encryption technique that supports the following homomorphic property, as demonstrated by the equation: $E(m_1).E(m_2)$. This property can be stated as $E(m)^k = E(k.m)$ for various identical ciphertexts. For notation, we use the letter E to designate an encrypted value. For example, E(x) stands for the encryption of x, and (C) represents the encryption of the distance indication C.

a) *Training phase:* The training phase incorporates the enrollment and registration of new users, who are prompted to a sign-up page, thus enabling the system to acquire and store their data. This phase includes the following processes:

- Registering and Obtaining Users' Login Information: Every unique user signs up with a preferred UN-PW (with a minimum length) that is stored in the database.
- Monitoring Users' Typing Patterns: After registration, users are required to type a sequence of characters three times at various speeds while the system monitors their typing rhythm.
- Feature Extraction: Once users register, specific features are extracted while they are typing, including key press (how long a key is held down), key release (how quickly a pressed key is released), the characters typed, and the total number of keys typed.
- Building a Keystroke Template: After extraction of the behavioral features, the data are structured in an array to store the extracted features of each character independently of the other characters. To build a keystroke template, the fastest keystroke data typed serve as the upper bound and the slowest as the lower bound.

- Data Storage: After these features have been extracted and the template has been built, they are stored in the database along with users' UN-PWs for deployment to authenticate them when they try to log into the system.

b) *Testing phase:* The testing phase occurs during the login of existing users using the credentials registered in the enrollment process through the sign-up interface. This phase includes the following processes:

- Obtaining Users' Login Information: Each user must type in the previously chosen UN-PW, and the data are collected mainly for matching with the stored behavioral characteristics.
- Monitoring Users' Typing Patterns and Feature Extraction: As in the training phase, users are prompted to type a sequence of characters twice so that the system can extract matching keystroke data.
- Login Information and Keystroke Template-matching: The system matches the UN-PW to the pre-registered data stored in the database. If the data do not match, the user is given three more tries and then, if still unsuccessful, locked out. Authentication is ensured only after matching of the username, password, and behavioral keystroke data. If the average keystroke provided does not fall within the bounds described in 3.2.1, the user is prompted to try again in like manner as in the case of the UN-PW.

c) *Error handling:* Users may make mistakes when entering their passwords, thereby compromising the accuracy of the authentication system. To prevent this outcome, the keystroke data for each letter are gathered and stored separately based on how the letter is typed. This information is then organized into an array and stored in the database. If a user attempts to correct a mistake by deleting a character using the backspace key, the keystroke datum for the last letter entered is removed from the array.

IV. IMPLEMENTATION, RESULTS AND MODEL

A. Implementation

A web-based application served to implement the system, the main components of which are (1) a server-side programming language (NodeJs) for back-end functions, (2) a front-end language (HTML and CSS) for user interface, (3) a database (MongoDB) for storing users' profiles and keystroke data, (4) JavaScript for extracting keystroke data, and (5) a web browser. As the flow chart (Fig. 2) shows, the proposed system consists of two phases, registration (training) and login (testing). The following discussion describes each of these phases in turn.

1) *User registration:* As discussed, access to the system requires a login ID for every user (Fig. 3). The login data are collected and stored during the registration process. In this phase, data such as first and last name, username, email, and password are collected, as the figure shows, and then stored in the database.

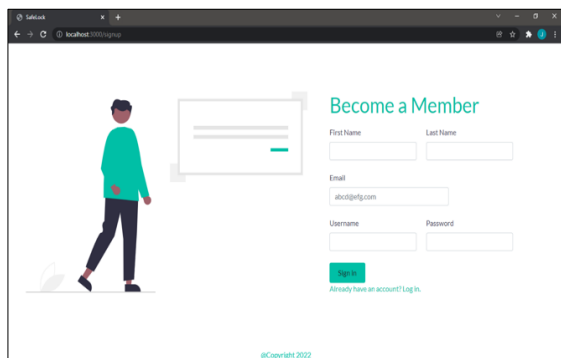

Fig. 3. User registration page.

2) *Generation of the keystroke template*: Once the login ID has been documented and stored in the database, the user is prompted through a screen as shown (Fig. 4).

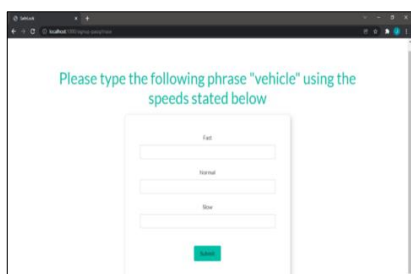

Fig. 4. Keystroke collection page.

Users are asked to type a randomly generated word in order to build a keystroke template. The features described above, such as the press and release of keys, which letters are typed, and the total number of characters typed, are extracted while the user types the word and stored independently in separate arrays. The keystroke data for the first letter occupy the first index of the array, the data for the second letter occupy the second index, and so on, as shown (Fig. 5).

Fig. 5. Keystroke parameters.

The keystroke time KT , also referred to as the dwell time, is based on the user's typing rhythm for each letter of the randomly generated word and computed as

$$KT = K_{release} - K_{press}$$

where K_{press} is how long the user presses a key, $K_{release}$ is the time the user releases the pressed key, and $KT_{average}$ is the keystroke time of the phrase typed computed as the summation of the difference between the key press and key release times divided by the overall number of characters typed:

$$KT_{average} = \frac{\sum(K_{release} - K_{press})}{total\ number\ of\ letters\ typed}$$

Users are required to type the randomly generated word at various speeds as shown (Fig. 5) so that the system can collect their keystroke data at various speeds. The keystroke data at these speeds provide the bounds for each user's keystroke values, with the fastest keystroke serving as the lower bound and the slowest as the upper bound.

3) *Data storage*: Users' login ID and keystroke data are collected and stored in the database as shown (Fig. 6).

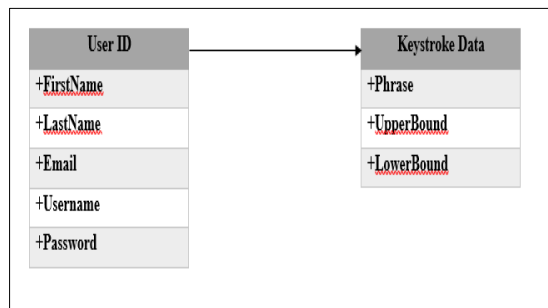

Fig. 6. Database model.

After users enter their login information on the registration page, the data are saved in the database, including the upper bound, the cumulative keystroke data, and the phrase used to log in. To minimize security risks, sensitive data, such as users' passwords and keystroke timing, are encrypted before storage in the database.

4) *User verification*: This process consists of the verification of users' login ID and keystroke timing as shown (Fig. 7).

a) *Login ID verification*: Once users try to access the system after registration, they are required to type in the credentials that they previously supplied, including the UN-PW, as shown in Fig. 7. Once the mandatory login data have been provided, the system matches the username and encrypted password by decrypting the latter to cross-check with the stored password hash for successful authentication, after which users are directed to the keystroke verification page.

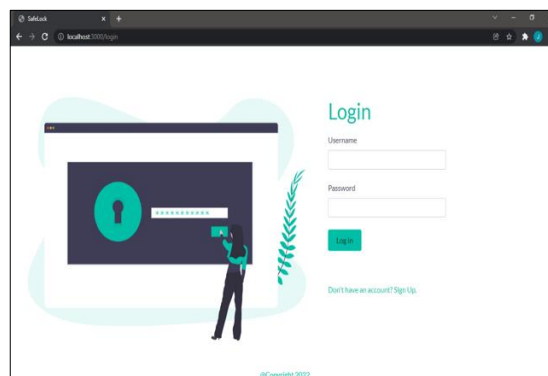

Fig. 7. Login ID verification.

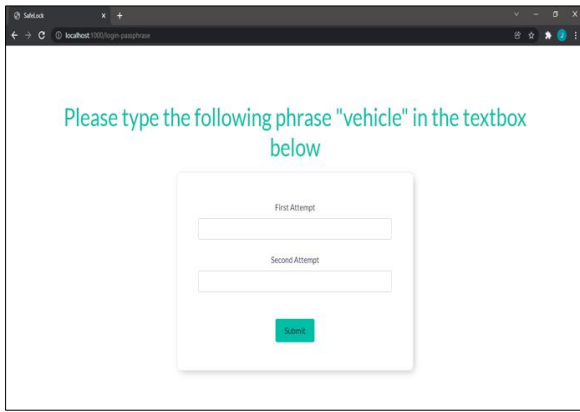

Fig. 8. Keystroke verification page.

b) *Keystroke timing verification:* On this form (Fig. 8), the user is required to enter the given phrase twice. During this process, the system computes the keystroke data for each letter typed and, once the user completes typing the first word or phrase, the average keystroke data. The process is then repeated with a second word or phrase. Once the user submits these data, the average of the keystroke data of the two words or phrases is computed and compared with the upper and lower keystroke bounds stored in the database, and the user is given access only if the average falls between them.

5) *Error handling:* Users are bound to make mistakes when typing. In keystroke-based systems, these mistakes can affect the accuracy of the system, but they can be managed efficiently. For example, in a situation in which a user types a sequence of characters, accidentally types a wrong character, and attempts to correct the error by tapping the backspace key. However, this attempt does not solve the problem of the mistyped character because the backspace key can be considered a character as well and the keystroke timing can be computed together with other characters. The proposed system incorporates an error-handling feature that deletes the last keystroke data accumulated after the backspace key is typed (Fig. 9).

Fig. 9. Error handling using backspace.

B. Results and Discussion

To enroll in the system, each user types three words or phrases at fast, normal, and slow speeds. Taking into account the emotional state of authenticators, a rapid typing speed

indicates that they are in a hurry or excited, while a slow speed indicates feelings of tiredness or illness. This approach, then, establishes ranges of possible values for users' keystroke timing in order to authenticate them regardless of their emotional state. During the typing process, event listeners (key down and key up) served to capture the key press and the key release times. The system is designed so that, when users make mistakes and press the backspace character, instead of adding the last character typed, it deletes the last character from the array as shown (Fig. 10). This feature renders our system privacy-protected, as personal behavioral data is deleted when no longer required.

In the experiment, the system grants access to all users who have connected to it provided that their typing times fall within their ranges. Conversely, if the keystroke time is not within their ranges, users are not granted access. However, the system can also grant access to another entity if the stored behavioral values fall within the range (using the same UN-PW), and this feature can be enhanced by increasing the number of words/phrases (Fig. 8) entered into the systems as shown in Table II. Based on these features of our model, it can be noted that there is a time limit imposed on the storage of personal data, fulfilling one of the privacy protection requirements.

▶ (2) ['v', 'e']	signup-passphrase:95
▶ (2) [0.009, 0.029]	signup-passphrase:103
average:0.019	signup-passphrase:108
▶ (3) ['v', 'e', 'h']	signup-passphrase:95
▶ (3) [0.009, 0.029, 0.017]	signup-passphrase:103
average:0.018333333333333333	signup-passphrase:108
▶ (4) ['v', 'e', 'h', 'e']	signup-passphrase:95
▶ (4) [0.009, 0.029, 0.017, 0.021]	signup-passphrase:103
average:0.019	signup-passphrase:108
▶ (3) ['v', 'e', 'h']	signup-passphrase:86
▶ (3) [0.009, 0.029, 0.017]	signup-passphrase:87
▶ (4) ['v', 'e', 'h', 'i']	signup-passphrase:95
▶ (4) [0.009, 0.029, 0.017, 0.016]	signup-passphrase:103
average:0.017750000000000002	signup-passphrase:108

Fig. 10. Error handling using backspace.

The example presented in the figure is of the lower-bound keystroke values and corresponding upper-bound values for five users. User_a is granted access as long as the keystroke values provided at login fall within the range of 0.019 to 0.022, and this applies to other selected users as well. However, if user_c logs into the system as user_a, access is still granted because the keystroke times for user_a and user_c are similar. This method should always complement the usual UN-PW authentication method.

TABLE II. KEYSTROKE TIME VARIATION

User	User_a	User_b	User_c	User_d	User_e
Lower Bound	0.019	0.015	0.019	0.023	0.016
Upper Bound	0.022	0.020	0.023	0.026	0.019

In the error-handling approach, the last character typed and its corresponding keystroke are deleted once the backspace key is pressed. However, in rare cases, a user holds a character down for too long and causes it to duplicate, resulting in a key down time for each duplicated character but only one key up time for all of them. This arrangement renders the algorithm inefficient because the user's effort to delete the duplicated characters removes the data for other characters typed as well. Therefore, the user is required to delete all of the characters and start typing over again or refresh the page.

C. The Behavioral Dynamics Authentication Model

Five major constructs that directly influence the security of the authentication mechanism were developed based on the comprehensive review of the literature and were validated in the authentication experiment: the HCI devices, the encryption standard for the behavioral data, users' emotional state at the time of data entry, the seamless cross-platform transferability of the authentication mechanism, and the cost-effectiveness of the authentication mechanism (Fig. 11). Since the emergence of the keyboard, the HCI interface domain has advanced to support specialized devices that incorporate virtual or augmented reality and wearable technologies. Similarly, any authentication mechanism must take into account emerging trends in cryptology, including encryption algorithms. The accuracy of authentication depends on the emotional state of the authenticator as reflected in login errors. In other words, consideration of users' dominant emotional state during authentication can mitigate unauthorized authentication as well as authentication errors and recourse to the "forget your password?" option. For security of authentication mechanisms in a cross-platform domain, incorporating options for multiple operating systems authentications into the mechanism ensure seamless and secure operations. With the rapid application of AI in securing information system entities, and the emergence of innovative web applications taking into account the dynamic adoption of these into authentication mechanisms can ensure a balanced cost-security feature.

The system achieved 100% model validation with just five users by taking into account only one feature of each of the five constructs. This result demonstrates the economic feasibility and potential scalability of the model for future research involving experiments with various combinations of the constructs.

The main findings of the present study include:

- 1) The introduction of five constructs that offer an optimal combination ensuring efficient and effective behavioral authentication across all computer usage contexts.
- 2) The assessment of KD simulation to showcase the capability of KD in accurately authenticating even with just five users,
- 3) The demonstration of achieving a 0% rate for both FAR and FRR, and
- 4) The feasibility of encrypting behavioral data to enhance data protection.

Fig. 11. The behavioral dynamics authentication model (BDAM).

V. CONCLUSION

Authentication processes that employ behavioral dynamics can ensure seamless and secure authentication through an optimal combination of HCI devices, data encryption, users' emotional states, cross-platform functionality, and the appropriate selection of solutions. We demonstrated the feasibility of constructing a secure, scalable, and dynamic behavioral authentication model, as described in this study. Our experimental results involved keystroke behavioral data collected from a computer system utilizing a web-based solution. We employed a CNN classifier and incorporated an error-correction feature. Remarkably, we achieved 100% accuracy in our authentication model with just five users. The web-based keystroke authentication system uniquely identifies users by integrating the UN-PW with their keyboard typing patterns, storing the keystroke data for each character typed independently, based on the bound value of the largest and smallest keystroke values recorded. For error handling, once the backspace key is triggered during typing, the keystroke data for the last character typed is deleted, and, when the keystroke data acquired during the process do not fall within the bounds established for a user, access to the system is denied; otherwise, access is granted.

The limitations of the research described here, also present avenues for future study to improve authentication systems. First, regarding the error-detection phase, the researchers considered only the backspace key, though some users also use the delete key, and taking this additional feature into account could enhance the speed of genuine authentication. Second, the system receives input in the form of mouse dynamics and touchscreen dynamics for laptops, tablets, and smartphones, but, while the focus here is on KD, the addition of touchscreen dynamics along with KD can add an additional security layer (potentially as an option) to touchscreen-enabled devices.

Third, changes in the environment and variation in the emotional state of the authenticator can render authentication challenging.

Future research can address the limitations by considering the following aspects. Firstly, researchers could replicate the study across various contexts, encompassing diverse environmental conditions similar to those encountered during authentication. Secondly, by accounting for users' cultural differences, extending the research to encompass subjects from multiple cultural backgrounds can enhance the robustness of the findings. Thirdly, given the substantial potential of ML in this domain, experimenting with different classifiers can yield those that ensure efficiency and effectiveness. Lastly, since the proposed model's versatility allows replication with diverse construct combinations and its scalability accommodates future trends in devices, security concerns, user behavior, and technologies, researchers could strive to pinpoint the optimal set of construct variables for enhancing authentication security and performance.

Abstract—This study provides a comprehensive review of the utilization of Virtual Reality (VR) in the context of Human-Computer Interaction (HCI) for visualizing Artificial Intelligence (AI) systems. Drawing from 18 selected studies, the results illuminate a complex interplay of tools, methods, and approaches, notably the prominence of VR engines like Unreal Engine and Unity. However, despite these tools, a universal solution for effective AI visualization remains elusive, reflecting the unique strengths and limitations of each technique. The application of VR for AI visualization across multiple domains is observed, despite challenges such as high data complexity and cognitive load. Moreover, it briefly discusses the emerging ethical considerations pertaining to the broad integration of these technologies. Despite these challenges, the field shows significant potential, emphasizing the need for dedicated research efforts to unlock the full potential of these immersive technologies. This review, therefore, outlines a roadmap for future research, encouraging innovation in visualization techniques, addressing identified challenges, and considering the ethical implications of VR and AI convergence.

Keywords—Virtual Reality (VR); Artificial Intelligence (AI) Visualization; VR in AI Visualization; Human-Computer Interaction (HCI)

I. INTRODUCTION

Artificial intelligence (AI) systems have advanced quickly in recent years, with applications ranging from robotics and autonomous vehicles to machine learning and natural language processing [1]. As these systems become more complex, effective visualisation methods are becoming increasingly important [2]. Primarily, it fosters an understanding of AI operations, demystifying the 'black box' nature of these systems into interpretable processes [3]. This increased transparency aids not only in understanding the system's operations but also in spotting errors or inefficiencies, thus, paving the path for necessary improvements. Visualization also plays a pivotal role in enhancing the trust and transparency of AI systems, by illuminating the decision-making pathways of these technologically advanced systems [4]. Lastly, visualization is a key player in education [5], converting abstract AI concepts into tangible, clear forms. Thus, it stands as an indispensable tool in making intricate AI models more understandable, trustworthy, and user-friendly.

Virtual reality (VR), with its immersive and interactive capabilities, offers a promising platform for visualizing AI systems [6]. Users can experience and interact with AI systems in an immersive and interactive environment via VR, and visualization techniques can aid users in better grasping and analyzing the data produced by AI systems.

The real-world significance of comprehending AI systems

cannot be overstated. In sectors like healthcare, finance, and transportation, misinterpretations or biases stemming from obscure AI predictions can lead to severe consequences, including misdiagnoses, financial inaccuracies, and transportation mishaps [7, 8]. Proper visualization tools can mitigate these risks by illuminating the decision-making processes, ensuring more accurate and safer AI-driven outcomes. Moreover, a transparent understanding of AI systems can bolster trust among end-users, a crucial factor for the widespread adoption and societal acceptance of these technologies [9]. The economic implications are profound; AI systems that are both effective and trusted can revolutionize industries, driving innovation and efficiency [10].

The immersive experience of VR can offer new possibilities to make Convolutional Neural Networks (CNNs) more human-understandable by depicting them in 3D environments [11]. However, according to [12], this field is still relatively unexplored and has two main challenges. First, rendering large, popular architectures like ResNet50 is currently not feasible with existing tools, which often restrict CNNs to linear structures without splits or joints. Additionally, the number of visible layers may be limited due to computational limitations or constraints with the interaction design. Second, current tools do not offer a flexible and convenient interface for developers and researchers to visualize custom architectures. To fully realize the potential of VR for understanding and interacting with CNNs, more research and development are needed in this field. Despite the potential benefits of visualizing AI systems in VR, research in this area has been limited. While various studies have investigated the use of VR for visualizing AI systems, a comprehensive review or meta-analysis has yet to consolidate the present state of knowledge in this field.

This comprehensive literature study is intended to give an in-depth overview of the present state of knowledge about the viability of virtual reality technology for visualizing AI systems. We anticipate that the findings of this review will offer valuable insights that can guide future research in the domain of VR-based AI visualization. The review highlights the potential and limitations of existing VR engines and visualization methods, thereby identifying key areas of focus for further development and innovation. This study provides a basis for understanding the challenges currently faced in this field, such as handling complex data and managing cognitive load within VR environments. It also underscores the need for further exploration into the ethical implications of integrating VR and AI technologies. Thus, it presents a roadmap to shape the evolution of AI visualization tools, encouraging the development of more intuitive, user-friendly, and ethically

responsible solutions.

The main objectives of this review are to synthesize the findings from the literature, identify major themes and trends in the field, and offer suggestions for further investigation. In order to achieve these objectives, the following research questions are proposed:

- RQ1: How have different combinations of Virtual Reality techniques and AI systems been employed in the study of AI visualization in virtual reality, and which tools and frameworks have been most commonly utilized?
- RQ2: What are the diverse visualization and interaction techniques used for understanding, interpreting, and explaining complex AI models, and how do these methods enhance the exploration and representation of AI systems?
- RQ3: What are the potential applications, challenges, and technical considerations in utilizing VR technology for AI visualization, and how have these been addressed in various domains and studies?

By addressing these research questions, we aim to contribute to the existing knowledge on utilizing virtual reality technology in the visualization of AI systems and present an up-to-date overview of the relevant literature.

This paper is organized as follows: Section II begins with a comprehensive overview of the research methods employed. This encompasses the search strategy adopted, inclusion and exclusion criteria applied, study selection process, and methods of data extraction and synthesis, all focusing on the literature related to AI visualization in VR. Following this, Section III elaborates on the findings of the review, examining the array of VR techniques and AI systems in use, as well as the applied visualization and interaction techniques. It also discusses the potential applications and implementation challenges that VR technology faces in AI data visualization. Within this section, a discussion subsection synthesizes the literature, emphasizing the dynamic interplay of tools, methods, and approaches, and pointing out research gaps and challenges. Finally, Section IV concludes the paper, reflecting on the current state of the field and offering recommendations for future endeavors in VR and AI visualization.

II. METHODS

This comprehensive review examined research published in English in peer-reviewed journals or conference proceedings on the visualization of AI systems in VR but eliminated studies that still need to meet these requirements. By the type of AI system represented in VR, studies were categorized for synthesis in order to find common themes and trends and provide a thorough overview of the current state of the art.

A. Search Strategy

An exhaustive search was conducted in this comprehensive literature review to identify relevant studies on visualizing AI systems in virtual reality. The following databases were searched: IEEE Xplore, Scopus, Web of Science, Springer, and Google Scholar. The search strategy included relevant keywords and subject headings related to visualization techniques

and virtual reality AI systems,¹ and was limited to articles published in English, without a time restriction. Additionally, reference lists of identified articles were manually scanned for potential additional studies. The most recent results were obtained through a search performed on January 8, 2023. All identified articles were imported into Mendeley's reference management software for further analysis and screening.

B. Inclusion and Exclusion Criteria

Studies were included in this comprehensive review if they met the following criteria:

- published in a peer-reviewed journal or conference proceeding,
- focused on the visualization of AI systems in virtual reality, and
- provided empirical data, such as case studies, experiments, or user evaluations

while studies were excluded if they:

- were not published in English,
- focused solely on AI systems or virtual reality, but did not specifically address the visualization of AI systems within VR environments, or
- lacked sufficient methodological detail.

C. Study Selection

Fig. 1 presents a flow diagram illustrating the literature search and selection process of this comprehensive review. Guided by a well-defined research strategy, we aimed to ensure the exhaustiveness and relevance of the included studies. The process began with the identification of 940 records from an extensive search of multiple databases. The Publish or Perish tool was employed as an additional filter at this stage to refine search results and ensure the quality of the selected studies [13]. This tool enabled a more precise assessment of the articles, leading to the inclusion of studies that held significant influence in the field and strong relevance to the research questions. Consequently, 915 records were disregarded due to irrelevance or non-compliance with inclusion requirements.

The remaining 25 works underwent a full-text assessment to determine their suitability for the review. Subsequently, seven works were excluded for various reasons, including insufficient data, a lack of focus on visualization of AI systems in virtual reality, or other criteria-based factors. Ultimately, the final research included 18 papers, laying a robust foundation for synthesizing and assessing the state of knowledge on the visualization of AI systems in virtual reality.

¹The specific search query was: ("virtual reality" OR "VR") AND ("artificial intelligence" OR "AI") AND ("visualization" OR "visualisation" OR "display" OR "mapping" OR "interpret*" OR "explain*")

D. Data Extraction and Synthesis

We organized and summarized the included studies in detail in Table I (in Appendix) for analysis.

The synthesis process involved extracting key information from each study, such as reference, publication type, year of publication, VR engine/framework, features, and code availability. Each study is concisely outlined in the table, highlighting its primary goals and outcomes. The review's objective is to discern recurring patterns, shared aspects, and distinctions among the studies, thereby providing in-depth insight into the current state of knowledge regarding virtual reality's role in AI system visualization.

The table encompasses a diverse range of studies, including conference proceedings, journal articles, and tool development projects, all focusing on the visualization of AI systems in virtual reality. Most studies utilize widely-known VR engines, such as Unity and Unreal Engine, for frontend visualization, and backend machine learning frameworks like TensorFlow, PyTorch, and Caffe2. These studies explore features like network architecture, layer design, feature maps, and user interaction. Some also provide code availability, fostering further exploration and development by the research community.

By compiling information from these studies, the review presents a full overview of current research on the visualization of AI systems in virtual reality. It points out key advances and identifies areas requiring more research, ensuring a robust and in-depth understanding of the topic and laying the groundwork for future investigations.

Fig. 1. Flow diagram of the literature search and selection process.

E. Study

The characteristics of each study, such as reference, publication type, year, features, VR engine/framework, and code availability, have been thoroughly analyzed and are presented in Table I. The table offers a comprehensive overview of the current research on the visualization of AI systems in virtual reality. By examining the characteristics of these studies, we aim to identify common themes, trends, and areas where further research is needed. This organized presentation of study characteristics in Table I allows for a clear understanding and comparison of the key aspects of the included works, facilitating a comprehensive synthesis of the existing knowledge in this field.

During the study selection process, we identified several studies that appeared to meet the inclusion criteria but were eventually excluded:

- 1) In [14], the authors excluded due to similarity to [11].
- 2) In [15], the authors Excluded due to significant overlap in content and authorship with [11].
- 3) In [16], the authors excluded due to its focus on visual data mining and representation of data and symbolic knowledge within VR spaces for classification tasks, rather than AI system visualization in VR.
- 4) In [17], the authors excluded because it focused on the simulation of autonomous and intelligent vehicles in virtual reality, rather than on the visualization of AI systems in VR.
- 5) In [18], the authors excluded as its main focus was on creating a virtual simulation environment for autonomous vehicles to learn obstacle avoidance using deep learning, rather than directly addressing the visualization of AI systems in VR.
- 6) In [19], the authors excluded as it involves virtual reality and deep learning, its primary focus is on pedestrian crossing behavior in the presence of automated vehicles rather than on the visualization of AI systems in VR.
- 7) In [20], the authors excluded as the paper is related to the broader field of AI and virtual reality; it does not specifically focus on the visualization of AI systems in VR. Instead, it presents a framework for detecting cybersickness in VR environments using machine learning models and explainable AI techniques. The goal of this research is to detect, analyze, and mitigate cybersickness in real-time for standalone VR headsets.

These studies were excluded to ensure a complete and unbiased perspective on the topic in our comprehensive review.

III. RESULTS OF SYNTHESSES

A. Virtual Reality and AI Systems (RQ1)

Different combinations of VR techniques and AI systems have been used in the study of AI visualization in virtual reality.

For example, [11] utilized the Unreal Engine for creating 3D scenes dedicated to neural network visualization. They used TensorFlow as their AI system to provide detailed information for neural networks and permit the adjustment of training parameters. Similarly, [12] employed the Unity game engine with OpenXR support for immersive visualization and interaction with convolutional neural networks (CNNs). Their AI system of choice was PyTorch, a deep learning framework designed to interconnect with Unity for dynamic visualization and interaction with custom CNN architectures.

Unity, as a gaming engine, was a common choice among researchers. For instance, [21] used Unity to create a virtual reality environment for visualizing deep neural networks built using the Caffe framework. The research [22] and [23] both utilized Unity in their research, illustrating its dual functionality. They used Unity for creating virtual reality environments and developing deep convolutional neural network models. Furthermore, they employed Unity Barracuda to define these neural network models, demonstrating that Unity can also serve as a host for AI systems. [24] paired Unity with the Oculus Quest VR headset and used TensorFlow and Keras

machine learning frameworks to define a CNN model for image classification.

The study [25] and [26] both used VR technology, with the latter also leveraging Unity and Steam VR, for deep learning model development. Their chosen AI system was deep learning neural networks defined using TensorFlow and Keras. It [27] and [28] also relied on Unity for virtual reality techniques, with the latter using TensorFlow as the AI system.

In some studies, the focus was primarily on the VR techniques utilized, with less emphasis placed on the specific AI systems implemented. For instance, [29] leveraged Open VR, which supports a range of consumer head-mounted displays (HMDs) including Oculus Rift and HTC Vive, yet they did not detail the AI systems used. Similarly, [30] employed an array of VR tools including an Oculus Rift headset, a Leap Motion '3D mouse', and a Microsoft Kinect sensor, but did not disclose the AI systems integrated with these tools. In another instance, [31] mentioned the use of explainable AI and clustering algorithms, but they did not specify the exact software libraries or frameworks employed, emphasizing the variance in the level of detail provided across different studies. In summary, a range of combinations of virtual reality techniques and AI systems are evident in the literature. Unity stands out as a common choice for VR, with TensorFlow being frequently paired as the AI system. This diversity underscores the flexibility and adaptability of these technologies in visualizing AI systems in virtual reality.

Beyond the specific visualization of AI systems in VR, broader AI applications in VR have also been extensively reviewed. For instance, [32] offers a comprehensive review of AI applications in VR, providing a wider perspective on how these two technologies can be combined to create interactive and immersive experiences.

B. Visualization and Interaction Techniques (RQ2)

Visualizing and interacting with complex AI models is crucial for understanding, interpreting, and explaining them. A variety of techniques are used to this effect, as evidenced by the following literature.

Interactive 3D visualization is a recurring technique used for exploring deep learning network layers at various levels of detail. The study [11] utilized this approach, enabling users to interact with each neuron in the network. Similarly, [12] used 3D rendering of Convolutional Neural Networks (CNNs), representing the computational graph as a connected conveyor system and optimizing the rendering of large architectures. They also allowed users to move, scale, and interact with CNN layers, offering a display of weight distributions, classification results, and feature visualizations. Expanding on these concepts, [33] delve into the merger of intricate networks and VR technology, creating interactive three-dimensional representations of large-scale datasets. Their approach is applied to a range of network types, including gene-gene interaction networks, social networks, and neural networks, demonstrating the broad applicability of these visualization techniques.

Visualization techniques can also involve more specialized approaches. For instance, [21] utilized interpretation modules, occlusion analysis, and virtual walkthroughs of network layers,

with real-time manipulation of input images for interaction. This study [24] employed 3D force-directed graphs and real-time color changes to represent neural network parameters, with direct manipulation and sonification for auditory feedback as interaction techniques.

Certain studies use more straightforward visual representations, such as [22], who rendered 2D images with the gray colormap using matplotlib, though interaction techniques were not explicitly discussed. The research [25] used a direct physical approach, visualizing interactions by moving concrete objects with hands and showcasing real-time test dataset results.

The research [26] and [27] presented network architecture, filters, and feature maps, with user interaction as the interaction technique. [34] visualized feature maps, filter responses, and saliency maps in 2D layers, while offering menu navigation, grabbing and moving objects, and selecting layer properties as interaction techniques.

The study [29] utilized an immersive node-link visualization based on VR, with neurons spatially arranged in circles, and interactive elements controlled through the spatial input devices included with the Head-Mounted Display (HMD). They also included a virtual travel technique (flying) for user positioning.

In cases such as [31], immersive parallel coordinates plots were used for visualization, although interaction techniques were not specified. The study [30] used immersive visualizations with SL Linden Scripting Language (LSL) and OpenSim, employing natural interaction techniques with commercial hardware.

Finally, [23] combined 3D visualization methods provided by TensorSpace.js and NeuralVis with conventional 2D visualization techniques such as Grad-CAM, while employing the Mixed Reality Toolkit and DXR for interaction.

In summary, a broad range of visualization and interaction techniques have been employed to illuminate and explore AI models. These methods offer different ways of understanding and interacting with AI systems, enriching our ability to interpret and utilize these complex models.

C. Application and Implementation (RQ3)

The utilization of VR technology for data visualization has vast potential, yet it is not devoid of challenges. For example, the complexity and high dimensionality of modern datasets can often make visualization difficult [6, 30]. Additionally, issues surrounding the scalability and adaptability of these visualization techniques to accommodate larger, more intricate architectures are prevalent [12].

Moreover, the cognitive load brought about by the complexity of the data and the VR environment itself is another concern. This has led to the call for more intuitive and user-friendly visualization tools to simplify the learning process and boost understanding [22, 24, 26, 27].

Moreover, the limitations of current tools and technologies present considerable technical challenges. For example, [22] pointed out the lack of support for large datasets in VR platforms and the limited resolution of existing VR display technology. The need for high-quality graphics and processing

power, along with the potential for motion sickness in VR environments, create substantial obstacles [35]. The study [12] say that in sensitive applications such as medicine and law enforcement, black-box systems such as neural networks will need to become more transparent in order to comply with regulations and earn the public's trust. This is compounded by the difficulties in understanding and representing the depth of images and models, as noted by [32]. These intersecting technical and ethical considerations necessitate careful attention and innovative problem-solving in the continued development and implementation of VR visualization tools for AI systems.

A recent study by [33] provides a practical example of VR-based model visualization in the context of gene-gene interactions between human sex chromosomes and other human chromosomes. The authors detail the entire process of model development, from data collection to the final display of the model in a VR environment. The study also outlines specific software and hardware requirements, including the use of Python libraries, Unity 3D software, and Meta Quest 2 hardware. Despite the technical challenges involved, the study underscores the value of VR technology in enhancing the visualization and interpretation of complex network data.

Notwithstanding these challenges, promising applications of VR for data visualization have been demonstrated across various domains. For instance, VR has proven effective in interpreting and understanding complex AI structures, such as deep learning models and convolutional neural networks [11, 12, 21, 26, 27]. The application of VR in these areas offers potential enhancements in explainability and interpretability of complex AI and machine learning systems [11, 21].

D. Discussion

The synthesis of the literature reveals a dynamic interplay [11, 12] of tools, methods, and approaches in utilizing VR for the visualization of AI systems. The widespread adoption of versatile VR engines like Unreal Engine and Unity [21–23] underlines the necessity for flexible and universally embraced foundations. These engines are compatible with an array of AI systems, including but not limited to ML platforms like TensorFlow, Caffe2, and PyTorch [24–26], showcasing their capacity to integrate with diverse technologies seamlessly.

The assortment of visualization and interaction techniques in the literature reflects the importance of intuitive and engaging methods for representing complex AI models. Interactive 3D visualization, immersive node-link visualization, and other specialized approaches illustrate the richness of techniques currently employed. However, the diversity of these methods underscores a potential research gap, as the lack of standardization could hinder collaborative efforts and delay the development of best practices.

Despite the widespread application of VR in AI visualization across various domains, significant challenges persist [35]. These include the high dimensionality and complexity of modern datasets, the cognitive load imposed by the VR environment, and the limitations of current tools and technologies. Thus, another research gap emerges: the need for more user-friendly, intuitive, and adaptable tools that can accommodate complex and high-dimensional AI models.

Moreover, the increasing integration of these technologies into our everyday lives necessitates a focus on ethical considerations. Several studies highlight the need for responsible and considerate use of AI and VR technologies, revealing another research gap that calls for more research into ethical guidelines or principles for this field.

Therefore, future research efforts must continue to innovate visualization and interaction techniques, address identified challenges, consider ethical implications, and fill the existing research gaps [33]. Moreover, it is crucial that subsequent studies continue exploring the potential of VR for AI visualization across diverse application domains, while seeking to reduce the cognitive load and enhance user experience.

IV. CONCLUSION

The application of Virtual Reality (VR) in the realm of Artificial Intelligence (AI) visualization represents a burgeoning frontier in Human-Computer Interaction (HCI). As this comprehensive review elucidates, the field is characterized by a rich interplay of tools, techniques, and methodologies, with VR engines like Unreal Engine and Unity at the forefront. However, the absence of a universal solution for AI visualization emphasizes the inherent complexities and challenges of this domain. The myriad of visualization techniques, while showcasing the field's innovative spirit, also points to a lack of standardization, potentially hampering collaborative advancements.

Challenges such as managing high data complexity and cognitive load, coupled with the limitations of current tools, remain significant hurdles. These challenges, however, also pave the way for future research opportunities, emphasizing the need for more intuitive and adaptable solutions.

In conclusion, the application of VR in AI visualization is an evolving field marked by significant potential and substantial challenges. The research reviewed here provides a solid foundation for future studies, pushing forward a deeper understanding and more effective use of AI systems through immersive technologies. Nonetheless, substantial gaps exist in the current research that need to be addressed to further advance this promising field.

<p>The paper describes an application aimed at enhancing the comprehensibility of neural networks through interactive 3D visualization. The app allows users to visualize the layers of a convolutional neural network and observe the classification process, providing greater transparency and opacity of AI systems for both experts and non-experts. The prototype will be improved based on feedback and evaluation, with plans to support additional model types and data formats, as well as integration with augmented reality headsets. Future enhancements will include the addition of user interfaces for displaying neuron results, and support for standard exchange formats such as ONNX.</p>						
[12]	Journal	Tool Development, Research	2022	Unity/ PyTorch	Network architecture, Layer design, Feature maps, User interaction	Available
<p>This work introduces an open-source software for the immersive visualization of popular CNN architectures using Python and the Unity game engine, allowing users to freely navigate a 3D environment in desktop or VR mode. The software offers feature maps, activation histograms, weight histograms, and feature visualizations to facilitate a greater understanding of CNNs. The authors address the issue of making the visualization of large-scale models feasible in VR by developing a Pytorch module that enables the optimized visualization of nearly any computational graph, including branches and joints, in Unity. This software is made for both experienced developers and researchers, as well as those who are new to the field of deep learning. In a use case study, the authors trained the architectures CovidResNet and CovidDenseNet using three distinct training strategies on the Caltech101 and SARS-CoV-2 datasets to produce models with varying generalization abilities. Using visualization software, the authors determined that CNNs memorized images based on high-frequency patterns and proposed new measures to make it more difficult for the network to memorize images. The ability to visualize popular, cutting-edge architectures raises new issues for future research, such as considering machine learning problems with 3D input data and visualizing statistical variations in network characteristics. The authors propose clustering the channels based on the cross-correlation of their filter outputs in order to further improve the presentation of the feature space and to illustrate the semantic connections between channels.</p>						
[35]	Journal	Survey	2016	—	—	—
<p>The article explores the potential of integrating ANNs with VR to create immersive and interactive experiences. The primary objective of the review is to investigate the possible benefits of combining ANN and VR, discussing various algorithms and training functions related to ANN and their role in solving VR development and interfacing problems. The authors address the importance of data visualization in VR, highlighting how VR can enable effective data interaction and manipulation. They discuss the use of ANN for creating VR spaces and dimensionality reduction techniques, such as clustering and neural networks, which can enhance the efficiency of VR systems. The paper also presents several applications of ANN in VR, including facial expression detection, human body tracking, face detection, data visualization, and speech recognition. The authors argue that the integration of ANN and VR can lead to the development of powerful systems capable of a wide range of applications, creating intelligent virtual environments. In conclusion, the authors emphasize the potential benefits of combining ANN and VR technologies, and how their synthesis can contribute to more responsive and stimulated tracking and analysis of events in various fields, ultimately transforming existing practices and conventions.</p>						
[21]	Journal	Tool Development	2022	Unity/ Caffe2	Network architecture, Layer design, Feature maps, User interaction	—
<p>The paper discusses the use of VR technology for visualizing and interpreting DNNs. The authors developed a plugin for the Caffe framework in the Unity gaming engine to create and visualize a VR-based AlexNet architecture for an image classification task. The interactive model allows users to navigate through the network and select connections to understand the activity flow of particular neurons. An interpretation module based on the Shapley values algorithm was used to analyze the network's decisions. The authors suggest that VR-based visualization can provide a more immersive and accessible way to explore and interpret DNN models, which can help improve their decision-making processes. They also suggest possible future work, including developing a formal quantification method for interpreting network decisions.</p>						
[22]	Journal	Research	2022	Unity/ Barracuda	—	—
<p>The article discusses using VR in deep learning and data visualization. The authors propose a VR platform using Unity for developing deep convolutional neural network models for image classification. The article describes the methodology used to create a CNN for recognizing human activities (HAR), which involves using the Barracuda package developed by Unity Labs and the ONNX format for transferring machine learning models. The article concludes that VR can be an effective tool for designing deep learning applications and is suitable for classifying images in various scientific sectors.</p>						
[24]	Conference	Tool Development	2021	Unity / Python	NN visualization: node-link approach, User interaction	—
<p>This study introduces a virtual reality interface for interacting with artificial intelligence. The interface lets users operate neural networks using virtual hands and offers audible feedback on the loss, accuracy, and hyperparameters in real time. The system's goal is to give a creative and user-friendly interface for interacting with AI, which may facilitate the understanding of the principles behind training neural networks. The study suggests several future directions, including enhancing the system's pedagogical benefits, looking at designs for larger neural networks, and experimenting with new forms of sonification to enhance the user experience.</p>						
[25]	Journal	Research	2021	—	—	—
<p>This paper presents a deep learning model development environment based on VR technology for image classification. The proposed DNN environment allows users to build neural networks by moving concrete objects with their hands, automatically transforming these configurations into a trainable model and providing real-time test dataset results. The study highlights the significance of interactive technology in addressing challenges in understanding and analyzing neural networks. The system aims to bridge the gap between professionals in different disciplines, offering a new perspective on the model analysis and data interaction. The results demonstrate that the proposed DNN method outperforms traditional PCA and SVM methods in classifying environmental landscape images. The paper also discusses the implementation of real-time image processing algorithms on FPGAs, emphasizing the advantages of using large memory and embedded multipliers.</p>						

TABLE I. INCLUDED STUDIES

Ref	Venue	Type	Year	VR Engine/Framework	Features	Code
[26]	Conference	Tool Development	2019	Unity and STEAM VR/ TensorFlow	Network architecture, Feature maps, User interaction	Available
<p>This paper investigates the potential of VR for visualizing CNNs for individuals who are new to machine learning. Because neural networks are so complicated, the authors present a VR-based visualization method to help people who aren't experts understand how CNNs work. The study emphasizes the role of virtual reality in creating an immersive and engaging environment that increases learning motivation while reducing distractions.</p> <p>An exploratory study was conducted with 14 participants, most of whom had little knowledge of CNNs. The results showed that the VR visualization method was easy to use, helped people learn, and made them more interested in learning about CNNs. Participants found the VR environment more comfortable, fun, and exciting than traditional desktop visualizations. Some participants noted that the immersive nature of VR helped them focus better on the complex architecture of CNNs.</p> <p>The authors suggest doing a follow-up study comparing how well VR visualization works with traditional desktop visualisation. This would help us learn more about how immersive environments affect how well people learn. The study also gives ideas for improving VR visualisation by letting users move and resize individual visualization elements to make the structure fit their needs and preferences. This research adds to the growing interest in using VR in schools and workplaces to help people learn and understand difficult ideas.</p>						
[27]	Conference	Tool Development	2022	Unity /—	Network architecture, Feature maps, User interaction	—
<p>The work aims to develop a VR application to visualize CNNs for machine learning beginners. The authors identified the need for an interactive and immersive visualization tool to aid in understanding CNNs, which can be complex and challenging for beginners. They conducted a proof-of-concept study with five participants and used the thinking-aloud method to evaluate the clarity of the VR environment. The study found that the VR environment was intuitive and helpful for users to understand the CNN components. However, some users found it difficult to understand the relationship between the input layer and feature maps. In addition, the visualization of the pooling layers did not stand out from the feature maps in their form of presentation. The authors plan to enhance the prototype based on the evaluation and conduct a user study to further evaluate its effectiveness.</p> <p>In conclusion, the study found that the VR environment was intuitive and helpful for users to understand the CNN components, but some areas need improvement. The authors plan to enhance the prototype and conduct further studies to evaluate its effectiveness. This work has important implications for machine learning, as it provides an interactive and immersive visualization tool to aid in understanding complex CNNs, which can lead to better learning outcomes for beginners.</p>						
[29]	Conference	Tool Development	2020	Open VR/ —	Network architecture, Feature maps, User interaction	—
<p>The article describes a new tool for visualizing ANNs using node-link diagrams in immersive virtual reality. The tool is targeted towards machine learning experts and was evaluated through an expert review. The results of the review showed that the tool was perceived as helpful in a professional context, which supports the hypothesis that node-link visualization can improve the workflow of machine learning experts. While more evaluation is needed, the authors are optimistic that their visualization tool could be actively used by experts in the field.</p>						
[28]	Conference	Research	2021	Unity/ TensorFlow	—	—
<p>This paper explores and proposes using visualization technology for deep learning and VR research projects, opening up new avenues for exploration in the field. The paper presents an outline of deep learning visualization research and case studies of deep learning visualization research using VR. The paper also identifies challenges that need to be addressed for effective visualization using VR, such as evaluation methods, high-quality operability, a wide range of customizability, scalability, and special support for beginners. Case studies and an overview of deep learning visualization research using virtual reality are presented in this paper.</p> <p>The research presented in this paper provides evidence that VR technology has the potential to enhance the way humans interact with deep learning models by providing insights into the processes of model construction and training. Significant difficulties are highlighted, and potential solutions are proposed, such as the use of new evaluation criteria and gamification to simplify deep learning for newcomers. Further, the paper argues that the proposed method's scalability and adaptability are crucial for experienced users and programmers. Overall, the paper shows the potential of virtual reality technology in deep learning research, and the authors suggest that implementing functions to customize filters and visualize results in real-time is essential for practical application.</p>						
[34]	Journal	Research	2022	Unity/ TensorFlow	Network architecture, Layer design, Feature maps, User interaction	Available
<p>In this study, the authors developed an interactive VR environment for constructing and analyzing deep learning models for biomedical image classification. The authors found that their proposed tool effectively enabled non-experts to understand and organize the structure of deep learning models and allowed users to build more accurate models and troubleshoot existing models faster when compared to a state-of-the-art drag-and-drop alternative. The authors also found that users enjoyed the experience in virtual reality significantly more, which they suggest can partially explain the higher objective scores, as positive emotions help with information retention. The authors argue that their interface achieved better outcomes through intuitive affordances for user actions, immersion, and ease of use.</p> <p>While introducing virtual reality presents challenges in educational and professional applications, such as cost, design, and physical limitations, the authors designed their VR environment to mitigate some risks. A more comprehensive VR platform could benefit expert use in the future, with improvements such as adding more layer types, developing new UI elements for fine-tuning layer properties, and enabling nonlinear model designs. The authors also suggest that improved visualization techniques and more explanatory elements could improve their tool's demonstrational benefit and interpretability. They conclude that future 3D/4D data visualization work can benefit from more straightforward navigation and a more accessible computational approach. Their proposed VR environment could be directly applied to cross-domain applications in biomedical image classification, providing sufficient benefits in understanding and prototype development.</p>						
[31]	Journal	—	2021	—	—	—
<p>The paper presents a refinement of the Immersive Parallel Coordinates Plots (IPCP) system for Virtual Reality (VR) and integrates data-science analytics, including explainable AI (XAI) methods, to enhance the visualization of multidimensional datasets in VR. The enhancements aim to automate part of the analytical work and assist users in pattern identification in complex datasets.</p> <p>The focus on visualization of multidimensional datasets and the integration of XAI methods in a VR environment aligns with the main focus of your systematic review, which is the visualization of AI systems in virtual reality.</p>						

TABLE I. INCLUDED STUDIES

Ref	Venue	Type	Year	VR Engine/Framework	Features	Code
[6]	Journal	Survey	2023	—	—	—
<p>The paper presents a systematic literature review on visualization in VR. It analyzes various techniques used in different domains and their collaboration. The review found that there is a growing body of research on immersive visualizations across various problem domains. However, only a few studies focus on creating standard guidelines for VR, and each study either provides an individual framework or relies on traditional 2D visualizations. Game engines are widely used, but they are not suitable for critical scientific studies. The paper mentions two examples of AI visualization in VR: Gradient-weighted Class Activation Mapping (GradCAM) for Deep Reinforcement Learning (DRL) algorithms and Caffe2Unity for visualizing neural networks. The review highlights the need for further research and alternative approaches to address design challenges, develop standard guidelines for VR, and ensure the accuracy and effectiveness of 3D visualizations.</p>						
[30]	Conference	Tool Development	2014	—	—	—
<p>The authors leverage commercial software development for virtual environments such as video games or virtual worlds and focus on developing scientific data visualization tools within such environments. They develop immersive visualizations of highly dimensional data sets using general-purpose visualization techniques and scripts. They propose using natural interaction techniques in immersive virtual reality with inexpensive commercially developed hardware.</p>						
[23]	Conference	Tool Development	2021	Unity/ Unity Barracuda	—	—
<p>The paper presents an interactive visualization system for DL models in an immersive environment. The immersive environment allows for unlimited displays and visualization of high-dimensional data, making it possible to analyze data propagation through layers and compare multiple performance metrics. The proposed system addresses the challenge of limited display area in desktop environments and aims to make the analysis of complex DL models more accessible for non-experts. The prototype system received positive feedback from machine learning engineers, but they viewed the visualization technology as a unique introduction to the immersive environment. Future work includes improving system design, evaluating usability, comparing performance with existing desktop systems, and exploring the benefits of immersive visualization in DL model analysis. The ultimate goal is to develop hybrid systems that complement existing tools rather than replacing them.</p>						
[33]	Conference	Tool Development	2022	Unity/ Python	Network manipulation, Real-time evaluation, User interaction	—
<p>This paper investigates the integration of complex networks and VR technology to create interactive 3D visualizations of large-scale data. This methodology is applied to various types of networks including gene-gene interaction networks, social networks, and neural networks. The authors illustrate the process of developing a VR-based visualization model using a biological dataset. They highlight both hardware and software requirements for implementing such VR visualizations. Examples from literature showcase the successful application of VR technology in understanding intricate relationships in these networks. The authors predict an increase in the use of VR technology for data visualization, particularly with the emergence of Metaverse concepts. As future work, they plan to develop a large-scale gene-gene interactions dataset and a VR interactive application to provide an efficient model for specialists to interact with large-scale data.</p>						
[32]	Journal	Survey	2023	—	—	—
<p>This comprehensive literature review investigates the application of AI methods in VR solutions, given the scarcity of such studies. The analysis involved locating and evaluating relevant documents from various databases, with a particular focus on AI's contributions to VR applications. The study observed that machine learning, specifically in the subfields of neural networks, deep learning, and fuzzy logic, is the most prevalent AI technique employed in VR. The application of AI in VR revealed multiple advantages, including high algorithmic efficiency and precision, especially in human-machine interaction and intelligent robotics. The study also revealed numerous real-world application fields such as emotion interaction, education, agriculture, transport, and health. However, the review highlighted several limitations, such as high computational cost and dataset dependence. This paper emphasizes the potential for future research focusing on finding new VR applications incorporating AI technologies, alongside a stronger emphasis on AR.</p>						

Symbol Detection in a Multi-class Dataset Based on Single Line Diagrams using Deep Learning Models

Hina Bhanbhro¹, Yew Kwang Hooi², Worapan Kusakunniran³, Zaira Hassan Amur⁴

Computer and Information Science Department, Universiti Teknologi,
PETRONAS Seri Iskandar, Perak Darul Ridzuan, Malaysia^{1, 2, 4}

Faculty of Information and Communication Technology, Mahidol University, Thailand³

Abstract—Single Line Diagrams (SLDs) are used in electrical power distribution systems. These diagrams are crucial to engineers during the installation, maintenance, and inspection phases. For the digital interpretation of these documents, deep learning-based object detection methods can be utilized. However, there is a lack of efforts made to digitize the SLDs using deep learning methods, which is due to the class-imbalance problem of these technical drawings. In this paper, a method to address this challenge is proposed. First, we use the latest variant of You Look Only Once (YOLO), YOLO v8 to localize and detect the symbols present in the single-line diagrams. Our experiments determine that the accuracy of symbol detection based on YOLO v8 is almost 95%, which is more satisfactory than its previous versions. Secondly, we use a synthetic dataset generated using multi-fake class generative adversarial network (MFCGAN) and create fake classes to cope with the class imbalance problem. The images generated using the GAN are then combined with the original images to create an augmented dataset, and YOLO v5 is used for the classification of the augmented dataset. The experiments reveal that the GAN model had the capability to learn properly from a small number of complex diagrams. The detection results show that the accuracy of YOLO v5 is more than 96.3%, which is higher than the YOLO v8 accuracy. After analyzing the experiment results, we might deduce that creating multiple fake classes improved the classification of engineering symbols in SLDs.

Keywords—Single line diagrams; engineering drawings; synthetic data; symbol detection; deep learning; augmented dataset

I. INTRODUCTION

An engineering drawing (ED) is an illustration of a schematic that demonstrates the operation or construction of an electrical system, procedure, or plant facility [1]. Engineering designs comprise of technical drawings such as mechanical or architectural blueprints, electrical circuits, and drawings [2]. In many different businesses, there is an increasing need for establishing digital systems for processing and analyzing these representations [3]. With such a framework, connected businesses will have the unusual opportunity to make extensive use of diagrams to direct their future practices.

A single-line diagram uses lines and symbols to represent the logical flow of power through physical processes and plant components. Although these components resemble each other in form and shape, they are highly asymmetrical in nature, which makes these documents complex [1]. Distinct power distributions are represented by lines of variable thickness, and each sign stands for a different component such as a

transformer, generator, motor, switch, etc. [4]. A typical SLD diagram may have over 50 different symbols, making it an information-rich visual representation. While placing a purchase order or even when project teams are scheduling their work, these drawings are carefully inspected in order to estimate the numbers of various pieces of equipment [5]. When symbols on SLD diagrams are functionally different but visually identical, as in Fig. 1, this process can become considerably more difficult and complex. As a result, distinguishing one symbol from another can be both crucial and difficult. Misreading or omitting any material can also cause severe internal disagreements and be damaging to the progress of a project.

Scientists, on the other hand, are looking into solutions for a power system to transform the conventional power system that existed before into an intelligent power system. The fusion of a power system with artificial intelligence is getting closer and closer as new technologies, like artificial intelligence, arise [6]. It is a common duty in modern businesses and academia to include artificial intelligence technology in power system dispatching software to speed up the process of creating circuit diagrams for power systems. A fundamental document in the power system, the principal wiring diagram of the power station is also commonly needed for viewing and change by the power system's dispatching users [7]. The current power dispatching system relies heavily on the work expertise of dispatchers for the creation and upkeep of station wiring diagrams, which not only raises the danger of safety mishaps in the power grid system but also drives up the cost of wiring diagram maintenance [8, 12]. Therefore, one difficulty facing the contemporary power sector was how to employ artificial intelligence technology to automatically build the station wiring diagram.

Generative models have also undergone significant progress and have been successfully used in numerous areas. One of those is the Generative Adversarial Networks (GAN), which has emerged as a well-known and frequently employed technique for producing content. Ian Goodfellow first introduced GANs in 2014 [9]. We will go over our GAN-based approach to solving the issue of imbalanced classes within the context of Methods section. Another difficult issue that affects a wide range of fields, including engineering drawings [10], is the under-or over-representation of one or more classes of symbols in the diagrams in the dataset [11].

Fig. 1. A part of single line diagram.

It is logical to presume that construction industries have these designs for their on-going projects in a readable electronic format that can be edited with cutting-edge software. However, many businesses continue to maintain these designs as paper copies or in digitized form, particularly for their older projects. Therefore, digitizing these drawings in a way that makes information extraction simple and accessible, may be advantageous [13]. This can make it simple to correct previous designs when the plant's components have been replaced over time owing to maintenance. As a result, project teams will find it simpler to keep track of their instrumentation inventory during the building phase and to create a library of up-to-date drawings for maintenance during the post-installation phase with the help of digitized and updated SLD diagrams. The following restrictions are communicated through the contextualization and digitization of complicated SLDs:

A. Size

According to an estimate in [11], a typical SLD page consists of approximately 50 distinct types of shapes including symbols, connectors, and text. To depict a specific segment of a power system, it may be necessary to utilize anywhere between 100 to 500 pages.

B. Asymmetrical Components

Apart from the typical challenges of classical machine vision such as variations in lighting, scale, and pose, technical drawings utilize equipment symbols that conform to different standards across various industries. Consequently, assembling a precisely labeled dataset that can be employed for symbol classification is a complex undertaking, as mentioned in reference [14]. It is crucial to have a comprehensive assortment of precisely defined symbols that lack symmetry to effectively employ advanced deep learning methods for symbol recognition.

C. Connecting Lines

Connecting lines that indicate the logical and physical relationships between symbols are abundant and knotted in complex SLDs. As a result, it is difficult to apply digitization techniques based on thinning [15] or vectorizing [15]. The artwork for line identification are represented by lines of various

styles and thicknesses. Furthermore, sophisticated Engineering Drawings (EDs) adhere to rule sets for application-based connectivity. This means that based on a standard that cannot be stated or inferred from the use of the physical lines connecting the symbols, two symbols may or may not be connected. As a result, contextualization is more difficult to implement than when it is applied to simpler drawings, like circuit diagrams [16]. This opens up several intriguing options, such as incorporating human expert knowledge through human-machine interaction into a potential solution. Another avenue would be interactive learning [17].

D. Labels

Symbols, connectors, and other text characters may overlap; however, symbols and annotations in a variety of scripts and styles are used to distinguish between symbols exhibiting comparable characteristics, to indicate connectors, and to clarify additional information. Symbols with an overlap in drawing sheets are difficult to separate, as demonstrated by techniques like those used by Cao et al. [18] and Roy et al. [19]. Three further challenges have been identified once all of the text elements have been found: As seen in Fig. 1, various lengths and sizes are used to represent text strings that describe symbols and connectors. Additionally, it can be challenging to connect symbols and connectors to their matching text, and text interpretation mistakes could lead to some information being misunderstood.

E. Samples with Inconsistent Occurrence

Inconsistent appearance of symbols within the diagrams is another major issue towards digitization. Deep learning models perform better with large amounts of samples, while in SLDs, symbol frequency is highly imbalanced which creates a class imbalance problem due to the dominance of the majority classes over the minority classes. Hence, deep learning models can be biased towards the majority classes.

A range of methods, especially from the field of machine vision, must be applied to overcome these obstacles. These include symbol detection and localization, as well as feature extraction. The fact that recent advancements in deep learning and machine vision, particularly in the recognition and classification of objects, have not been put to the test against such challenging real-world situations, must be noted [21].

In this article, particularly, the YOLOv8 model for object identification and MFCGAN for class balancing are thoroughly examined. To extract symbols from drawing images, this study aims to use SLDs to create a dataset for model training. The dataset contains 22 different classes of symbols various shapes and sizes.

We were unable to locate a study that assesses a significant amount of deep learning-based detection algorithms that have been particularly designed for the problem domain of single-line symbol identification while taking into account key variables including Precision, Recall, and F1.

The following are the main contributions of this study:

- Symbols in SLD images are classified using YOLOv8, the latest variant of YOLO model.

- Mixed-quality single-line symbols are synthetically generated using MFC-GAN.
- A GAN-based solution is provided for enhancing the quantity of minority classes to handle the class imbalance problem; along with an expansion of the YOLOv5 training set using newly generated synthetic data.
- We suggested an experimental setup using MFC-GAN for creating synthetic images.
- The accuracy of symbol identification and recognition in Single Line Diagrams (SLDs) is enhanced by using a YOLOv5-based network for object detection.

According to experiments, the *IoU* and performance of the model can be enhanced through the use of synthetic image data generated using different GANs.

The remainder of this paper is structured as follows: In Section II, we delve into the landscape of existing research within the relevant domain, examining both the challenges that have been encountered and the solutions that researchers have put forth in this realm. Moving forward to Section III, we intricately explore the proposed methodology and perform an in-depth analysis of the dataset. Moreover, within this section, we provide a comprehensive exposition of the detection model. The outcomes of our dataset construction and symbol detection are meticulously presented in Section IV. Subsequently, we engage in a thorough discussion of the results in Section V. Lastly, we draw this study to a conclusion in Section VI.

II. RELATED WORK

This section covers recent accomplishments made by the research community in this domain. We discuss single-line engineering drawings, different deep learning techniques used for digitizing the engineering drawings, later we present GANs and discuss the general architecture and recent advancements made to improve the performance of GANs.

A. Single Line Diagrams

In various papers, including [1-4], the problem of recognizing and grouping symbols present in single-line diagrams (SLD) has been raised. The challenge of digitizing SLD, where the aim is to summarize the link between the numerous symbols, served as the inspiration for several of these works. The study in [22] provides an overview of numerous strategies created to digitize ED. In earlier research, including [23-26], symbols were recognized using classifiers that were traditionally based on machine learning and fed hand-crafted characteristics.

SLD digitization has notably drawn a lot of business interest due to the wide range of applications that may be made from a digital output, such as security evaluation, graphic simulations, or data analytics [27]. There are certain strategies developed expressly to handle the digitization of SLDs in the literature. More than 30 years ago, Furuta et al. [48] and Ishii et al. [28] published research on developing software to enable fully automated P&ID digitization. These techniques are currently ineffective due to incompatibility with hardware and software requirements. About ten years later, Howie et al. [29,

30] suggested a semi-automatic technique for localizing symbols of interest using the templates of the symbols as input. Gellaboina et al.'s [49] description of the most recent method for symbol identification uses an iterative learning strategy based on recurrent training of a neural network (NN) with the Hopfield model. This method was developed to pinpoint the most frequently occurring symbols in the artwork that also displayed a prototype pattern. Deep learning models were utilized [31] to build one-line diagrams automatically while generating core power systems.

B. Symbol Detection Using YOLO

Object detection can identify the sort of object present in an image or video and pin-point its location at the same time. In photos and videos, object detection expresses the location information as X and Y coordinate values. Additionally, the width and height values—which represent the object's size—are utilized as label information. Typically, the width and height data are expressed as bounding boxes using the X and Y coordinates.

Recent studies have employed deep neural networks to perform symbol spotting. For instance, researchers in [34] employed the YOLO 32, [33] model to identify symbols in floor plan diagrams. In another study [10], symbol detection was reformulated as a semantic segmentation problem, which led to the development of a pixel-level approach for symbol detection. Researchers are using YOLO for the goal of symbol recognition and classification as a result of the one-stage detection method's growing popularity and success [11]. To do this, the authors of [12] suggested transforming a construction image into a region adjacency network, where each node represented a connected component in the image. These nodes were then categorized using a YOLO. The YOLO and CNN-based technique was put forth in [13] and used to categorize symbols in [14].

Recent research has confirmed the effectiveness of YOLO variants in detecting complicated engineering components [35]. For instance, one-line symbols in substation diagrams were localized and categorized using YOLOv3. The model correctly identified 97% of the symbols. YOLO algorithms demonstrated encouraging results in detecting the symbols in electrical circuits despite the lack of suitable datasets [20]. Additionally, YOLO variations were used to accurately classify hand-drawn electric symbols with a 95% accuracy [11]. To the best of our knowledge, the work detailed here is the first attempt at localizing and matching symbols in a zero-shot method despite the very extensive literature that already exists in this field.

Since 2012, two primary types of deep learning-based object detection models have emerged: one-stage detectors and two-stage detectors, as described in research [32]. Understanding the concepts of region proposal and classification is essential to comprehend the distinction between the two categories. Region proposal refers to an algorithm that quickly identifies possible object locations, while classification is the process of categorizing objects based on their specific type. Although two-stage detectors are better at accurately detecting objects, their slow prediction time restricts their real-time detection ability. To address this issue,

one-stage detectors have been proposed that perform both classification and region proposal simultaneously, resulting in faster object detection. The one-stage detector is a technique that produces results by simultaneously executing classification and region proposal.

As depicted in Fig. 2, upon inputting the image to the model, the Convolutional Layer is employed to extract its features and perform classification. Simultaneously, a region proposal is conducted to generate the output. Models like YOLO, RetinaNet, RefineDet, etc. are good examples [37].

Fig. 2. One-stage model for object detection.

One of these one-stage detectors is YOLO, which integrates the region proposal and classification stages into a single operation. This means that it predicts the position and type of an object simultaneously by treating the bounding box and class probability as a single problem. YOLO divides the image into grids of a predetermined size to forecast the bounding box for each grid, and then trains the bounding-box confidence score and grid cell class score, as mentioned in reference [38].

The YOLO processing procedure is depicted in Fig. 2. First, an $S \times S$ grid area is created from the input image. The number of bounding boxes anticipated in each grid cell is equal to the number of bounding boxes that correspond to the area where an object is located. This can be denoted as (x, y, w, h) , where (x, y) denotes the center point coordinates of the bounding box, and (w, h) denote its width and height.

Second, the confidence, which stands for the box's dependability and is determined similarly to Equation (1). The IoU (Intersection over Union) is used to determine it by computing the ratio of the overlapping area between the predicted and ground truth bounding boxes divided by the probability $Pr(\text{Object})$, which represents the likelihood of an object being present in the grid.

$$Pr(\text{Object}) \times IoU^{\text{truth}} \quad (1)$$

The probability of C classes is then determined for each grid and Equation (2) is shown.

$$Pr(\text{Class}_i | \text{Object}) \quad (2)$$

In this instance, what is strange is that YOLO does not classify the number of classes (background) as an input to a neural network model, although the existing Object detection does [38]. YOLO divides the input image into grids in this manner, performing classification and bounding box calculations for each grid at the same time.

C. Synthetic Data Generation Using GANs

Several studies in the past decade have explored the challenge of identifying symbols in architectural floor plans. To overcome the scarcity of training data available for neural networks, the authors recommended employing a Generative Adversarial Network (GAN) to generate synthetic training data.

Ian Goodfellow first introduced generative adversarial networks (GAN) in 2014. (Goodfellow et al., 2014). These are regarded as generative models that can produce original content. The Generator (G) and the Discriminator (D) are two competing models (such as CNNs, neural networks, etc.) that make up GANs [39]. The discriminator is a classifier that gets input from both the generator and the training set (genuine content). (Fake input). The discriminator will learn how to differentiate between real input samples and bogus input samples during the training phase. However, the generator is trained to provide samples that accurately reflect the fundamental properties of the original data. (Replicating original content). The GAN model is shown in Fig. 3.

Fig. 3. Architecture of generative adversarial networks.

Equation (3) demonstrates that the value function is employed to perform adversarial training of both models G and D .

$$\min_D \max_G V(D, G) = E_{x \sim p_{\text{data}}(x)} [\log D(x)] + E_{z \sim p_z(z)} [\log(1 - D(G(z)))] \quad (3)$$

Where x is a sample from the real training data, $P_{\text{data}}(x)$ is the probability distribution over the real data, the probability distribution over the noise vector z is referred to as P_z , and the outcome of the generator function G (or generated images) is denoted as $G(z)$. GANs are at the forefront of image generation quality, as per [39].

GANs have been effectively used to solve a variety of issues, including speech synthesis, segmentation, and image production [40]. They have also been successfully used in recent years to address issues with class imbalance. The class mismatch is widespread throughout numerous industries, including banking, security, and health [6]. The issue arises when one or more classes are unequally or excessively represented in the dataset. When dealing with imbalanced datasets, a conventional supervised learning algorithm tends to favor the majority class [41].

By including conditional probabilities in the value function, supervised GANs offer an improvement over the basic GAN architecture. This gives the user more control over the samples that are created and introduces the diversity that is required to supplement synthetic input data for datasets with class

imbalance. Examples of this kind are AC-GAN [10], CGAN [9], and vanilla GAN [8]; even though the literature demonstrates that these models, particularly in extreme situations, can be significantly impacted by class disparity [11].

III. RESEARCH METHODOLOGIES

We present our method for recognizing the end-to-end symbols from intricate engineering drawings in Section III A. The dataset utilized for the tests will be covered in detail in the subsection that follows. Data exploration and pre-processing will be part of this. The specifics of our suggested approach to dealing with a class imbalance in these drawings are provided in Section IV.

Machine learning is commonly used to classify symbols and texts. Fig. 4 shows a conceptual model for digitizing engineering drawings that includes the essential phases. Such a framework will be extremely useful in fields where schematics can be turned into knowledge.

We determine the characteristics and variety of the created minority samples for our image-generating experiment after each run. In classification studies, we add created minority samples from trained models to the training data. (MFCGAN). The classification performances on the minority classes are then provided after a YOLO classifier has been trained on the expanded dataset.

A. Overview of Symbol Detection Framework

We first look for the areas of an engineering diagram that might contain interesting symbols and attempt to extract all the components from drawing. The next step is to locate and count the interesting symbols that originate from these zones of interest. The vast array of shapes and structures that these symbols emerge in drawings is the task's main problem. Furthermore, as stated in Section I, we cannot anticipate identical depictions of a specific component on all drawings. Additionally, there are a great number of different components and elements that are frequently used in these diagrams. As a result, it is not viable to use a fully supervised technique, training thoroughly to recognize and classifying every single type of object that could be seen in such images.

Information about the symbols that appear in an engineering drawing can be found in a variety of ways, including:

- 1) A table of legends listing the names of the components represented by the different symbols.
- 2) A table with numbers that represent the index of a component and the name of the object it represents.
- 3) There is no tabular data linking the names of objects to the appropriate diagrams.

In the current study, we focus on the first form of drawing, in which the component name and drawing image are both provided. We go into great detail on the various parts of the suggested framework in the sections that follow.

Fig. 4. Schematic of model for digitization of SLDs.

B. Summary of SLD Dataset

For the study in this paper, we chose to employ Single Line Diagrams (SLDs), as shown in Fig. 1. The engineering partner gave a set of 800 sheets for review. These diagrams contain a variety of symbols of varied sizes and dissimilar (asymmetrical) nature, as shown in Fig. 5.

The dataset is suitable for evaluation because the SLDs have a variety of attributes. The numerous electrical system components and connectivity information can be seen schematically represented on the SLD sheets. It is a representation of electrical apparatus and power flow movement, frequently in the form of symbols (represented as various kinds of lines).

In many industries, these diagrams can be found as paper documents or digital photographs. Evaluating and analyzing these materials requires a lot of experience, knowledge, and time [15]. Furthermore, misreading these publications can have disastrous repercussions. For instance, if an engineer needs to modify a wire in an electrical system after installation, they must first verify the associated SLD diagram and decide what safety precautions to take. Therefore, it's important to comprehend these designs correctly.

Fig. 5. Example of asymmetrical symbols found in SLDs.

The original data's big SLD sheets are 7500x5250 pixels in size. To expedite training, we divided the sheet into a 6x4 grid, resulting in 24 patches of sub-images that were minuscule in comparison to the original images (1250x1300).

The data generated by the annotation is kept in a file that corresponds to the 22 different classes. The width and height of the symbols that the bounding boxes enclose, as well as the center x and y values of the bounding boxes, were recorded as data. The collection of 800 images includes 12,500 samples, which represent 22 different types of symbols. The initial sample is severely imbalanced, as shown in Fig. 6.

A deep learning model needs to be fully annotated to be ready for training. To do this, we used the LabelBox program to annotate the set of SLD photos, as shown in Fig. 7. Twenty two different symbols in the total collection were annotated. Using the LabelBox tool to record the classes of the associated symbols and their locations is a simple approach for annotating a diagram.

In some instances, the distinctions between the symbols can be very significant. For instance, the dataset contains 1340 instances of generator symbols but only 99 and 117 instances of each disconnect and load symbol. Although delta and capacitor are present in the sample more than 800 times each, inductor and voltmeter are only present 203 and 212 times respectively. Three symbols that were significantly underrepresented overall were not included in the first trial (i.e. appears only once or twice in split sets).

Fig. 6. Sample distribution in the original SLD dataset.

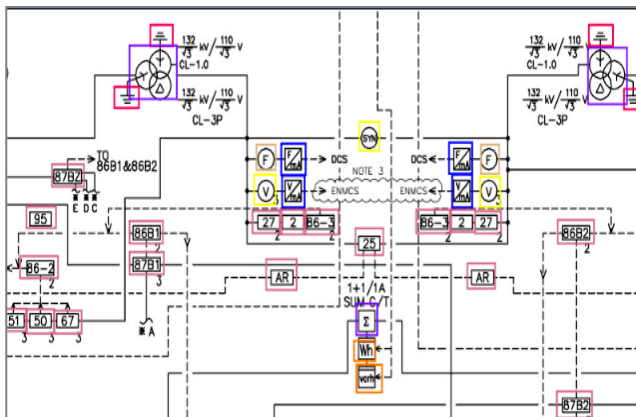

Fig. 7. An SLD annotated using labeling tool.

C. Symbol Detection

The YOLO approach was favored due to two key reasons. Firstly, it has a simple architecture that enables the prediction of multiple bounding boxes and class probabilities simultaneously using a single convolutional neural network. Secondly, YOLO is known for its high speed in comparison to other object detection techniques, which is essential for practical use in testing SLDs that contain an average of 50 engineering symbols.

1) *YOLOv8 architecture*: At the time this paper was being written, Ultralytics was actively working on YOLOv8 as they addressed community concerns and added new features. Glenn Jocher, the creator of YOLOv8, also discussed the developer-friendly features of YOLOv8 [54]. YOLOv8 comes with a CLI that enables training a model easier, in contrast to other models where chores are separated across numerous executable Python files. The addition of new convolutional layers and YOLOv8's Anchor Free Detection are further features of the software.

Since they may represent the distribution of the boxes from the target benchmark but not the distribution of the custom dataset, anchor boxes were a notoriously difficult component of older YOLO models. YOLOv8 is an anchor-free model, in contrast. In other words, rather than predicting an object's offset from a known anchor box, it predicts the object's center directly. To expedite Non-Maximum Suppression (NMS), a challenging post-processing procedure that sorts through candidate detection following inference, anchor-free detection decreases the number of box predictions [51, 55].

Using Equation (4), the bounding box's position is determined:

$$U_{x,y}^y P_{x,y} * IOU_{Ground Truth}^{Predicted} \quad (4)$$

According to Equation (4), x and y denote the yth bounding rectangle of the xth grid. The probability value assigned to the yth bounding box of the xth grid is $U_{x,y}$. If the yth bounding box contains an object, then $P_{x,y}$ is assigned a value of 1; otherwise, it is assigned a value of 0. The IoU between the predicted class and the actual ground truth is referred to as the $IoU_{groundtruth}$, and a greater IoU typically corresponds to more accurate predicted bounding boxes.

The bounding box, categorization, and confidence loss functions are combined to form the YOLOv8 loss function. The total loss function of the YOLOv8 is represented by Equation (5) [42]:

$$loss_{YOLOv8} = loss_{boundingbox} + loss_{classification} + loss_{confidence} \quad (5)$$

The stem's primary construction block, C2f, took the place of C3, and the first 6x6 conv is now a 3x3. Below is a diagram summarizing the module, where "f" represents the number of features, "e" represents the rate of growth, and CBS is a block made up of a conv, a BatchNorm, and a SiLU later. All of the

bottleneck's outputs are concatenated in C2f. C3 merely utilized the output of the previous bottleneck.

The first conv's kernel size was changed from 2x2 to 3x3, but the bottleneck remains the same as in YOLOv8. We might infer from this data that YOLOv8 is beginning to return to the ResNet block that was established in 2015. Features are directly concatenated in the neck without being forced to have the same channel dimensions. By doing this, the parameters count and tensor size as a whole are decreasing. YOLOv8 enhances photos while you're training online. The model views a slightly different variety of the images it has been given at each epoch.

2) *Multi-fake class generation*: Class imbalance has been a subject of extensive research, and various techniques have been developed, ranging from simple data augmentation and sampling to more sophisticated approaches like GAN [56]. In this study, we are utilizing MFC-GAN to generate more classes to handle the imbalance problem.

Our goal is to adopt a method similar to the MFC-GAN approach introduced in [57] to tackle the problem of class imbalance in the dataset of engineering symbols, specifically at the classification level.

The very little and occasionally subtle differences between the various classes of symbols led to the selection of this paradigm. We may train the discriminator using the MFC-GAN model to categorize both actual and false symbols, which allows for more precise discrimination across cases, as seen in Fig. 8.

By conditioning the generator on attribute labels, control generation was accomplished. Numerous studies involving various sample sizes in the minority classes, notably the goatee and eyeglass classes, were conducted. The MFC-GAN model is trained from scratch for each run, and samples are created following the end of the training.

Fig. 8. Framework design for multi-fake class GAN.

The discriminator network for this study is built with four convolutional layers with two-stride spacing and uses batch normalization in between layers. Leaky ReLu with an alpha of 0.2 is used to activate all convolution layers, and the Sigmoid function is employed as the activation function in the final layer.

The classifier model generates a 2xN soft-max output for N classes and shares the discriminator layers with it. The generator is constructed using five transpose convolution layers

with a stride of two and one linear layer. All the layers except the last one are activated using Leaky ReLu, and the final layer is activated using a sigmoid function. Batch normalization is applied between adjacent layers.

The generator of the GAN model takes a noise vector with a size of 100 as input along with symbol label encoding, which is similar to the input of most GAN models. The label encoding is important for class-specific generation, which is a significant aspect of our experiment.

The generator produces a 64x64 image of greyscale symbols. A batch size of 100 and a learning rate of 0.001 were used, which were selected through experimentation. Both the discriminator and the generator employed spectral normalization. Eq. (6), (7), and (8) will be used to train the suggested model.

$$L_s = E[\log P(S=real|X_{real})] + E[\log P(S=fake|X_{fake})] \quad (6)$$

$$L_{cd} = E[\log P(C=c|X_{real})] + E[\log P(C' = c' |X_{fake})] \quad (7)$$

$$L_{cg} = E[\log P(C=c|X_{real})] + E[\log P(C=c|X_{fake})] \quad (8)$$

Where L_s denotes the chance that the sample is real or fraudulent and is used to determine the sampling loss. The losses for classification of both the generator and discriminator are calculated using L_{cd} and L_{cg} . The set of created images is called X_{fake} , and X_{real} represents the training data.

3) *Architecture of YOLOv5*: In this study, the YOLOv5 algorithm was utilized, which is one of the most recent variations of the YOLO algorithm [44]. This algorithm is a speedy and effective system for identifying objects and locating them instantly. Since the symbols present in SLDs have a high degree of similarity, rapid detection is also necessary, which the YOLOv5 algorithm can fulfill. The system was built using the PyTorch deep learning framework, which has excellent detection performance and has simplified the process of training and testing specialized datasets. The YOLOv5 algorithm comprises three components: the head, the neck, and the backbone [45].

For our investigation, we opted to utilize the YOLOv5 detection model because of its straightforwardness and transparency. YOLOv5 created CSPDarknet, which formed the core of the network [58], by combining Darknet with the cross-stage partial network (CSPNet) [43]. CSPNet addresses the issue of recurrent gradient information in large-scale backbones by integrating gradient changes into the feature map, which decreases the model's parameters and FLOPS (floating-point operations per second). This ensures inference speed and accuracy while also reducing model size, which is crucial for accurate and speedy recognition of sperm cells. Furthermore, the YOLOv5 incorporates a path aggregation network (PANet) [59] as its neck to improve information flow. PANet employs a novel feature pyramid network (FPN) architecture with an enhanced bottom-up methodology to increase low-level feature propagation. Adaptive feature sharing connects the feature grid to each feature level, ensuring that the downstream subnetwork receives meaningful data from every feature level. In addition, PANet enhances precise

localization signals at lower levels, considerably improving the object's location accuracy. The head of YOLOv5, the YOLO layer, generates three different sizes of feature maps to enable multi-scale prediction, allowing the YOLO model to handle small, medium, and large objects [58].

The CSPNet provides the framework for this algorithm. Because of the simplified model of CSPNet, fewer hyperparameters and FLOPS are produced, and the disappearing and ballooning gradient issues caused by complex neural networks are addressed. These enhancements improve the effectiveness and accuracy of object recognition inference. CSPNet has various features, including multiple convolutional layers, three convolutions in four CSP blocks, and spatial pyramid sharing. The CSPNet is responsible for extracting features from an input image, pooling and convolving that data to create a feature map. Consequently, in YOLOv5, the backbone serves as a feature generator [60].

The neck or core segment of YOLOv5 is referred to as the PANet. Its main function is to collect all the features obtained from the backbone, maintain them, and send them to the deeper layers to perform feature fusions. These feature fusions are then passed on to the head for object recognition, allowing the output layer to be aware of the high-level characteristics.

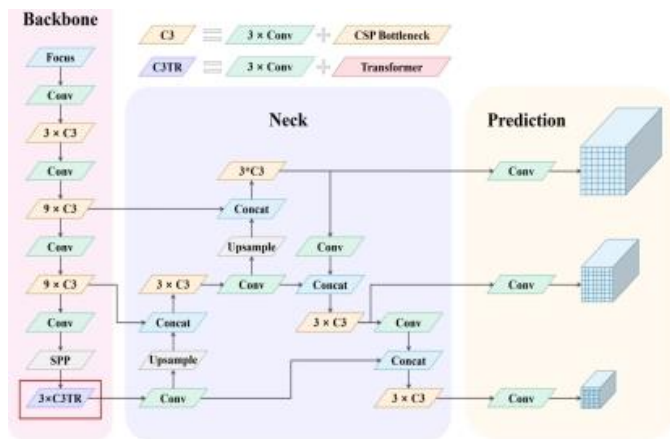

Fig. 9. Network architecture of YOLOv5 model.

The YOLOv5's head is responsible for identifying objects. It places bounding boxes and a class probability score around the target item, which is determined by 1x1 convolutions. The overall architecture of YOLOv5 is depicted in Fig. 9.

The position of the bounding box is established using Equation (9):

$$U_x^y = P_{x,y} * IOU_{Predicted}^{Ground Truth} \quad (9)$$

Equation (9) demonstrates that the yth bounding box of the xth grid is defined by x and y. The yth bounding box of the xth grid has probability value. $P_{x,y}$ equals 1 when a subject is present within yth bounding box; otherwise, it is equal to 0. The $IOU_{Ground Truth}$ is the IoU that exists among the predicted class and the actual data. Higher IoUs are related to more accurate predicted bounding boxes.

The loss function of YOLOv5 is produced by merging the bounding box, classification, and confidence loss functions.

The combined loss function of YOLOv5 is shown in Equation (10) [46].

$$loss_{YOLOv5} = loss_{bounding\ box} + loss_{classification} + loss_{confidence} \quad (10)$$

Equation (11) is used to determine the $loss_{bounding\ box}$.

$$loss_{bounding\ box} = \lambda_{if} \sum_{a=0}^{b^2} \sum_{c=0}^{d^2} E_{a,c}^g, h_g(2-k_a k_{na}) [(x_a - x'_a)^2 + (y_a - y'_a)^2 + (w_a - w'_a)^2 + (h_a - h'_a)^2] \quad (11)$$

Equation (11) uses h' and w' to denote the width and height of the target item, while x_a and y_a denote the coordinates of the target object in an image. Lastly, the indicator function (λ_{if}) shows whether the bounding box contains the target object.

The $loss_{classification}$ method is shown in equation (12):

$$loss_{classification} = \lambda_{classification} \sum_{c=0}^{b^2} \sum_{c=0}^{d^2} E_{a,c}^g \sum_{CCc1} L_a(c) \log(LL_a(c)) \quad (12)$$

$loss_{confidence}$ is determined using Equation (13):

$$loss_{confidence} = \lambda_{confidence} \sum_{c=0}^{b^2} \sum_{c=0}^{d^2} E_{a,c}^{Confidence} (c_i - c_1)^2 + \lambda_g \sum_{c=0}^{b^2} \sum_{c=0}^{d^2} E_{a,c}^{Confidence} (c_i - c_1)^2 \quad (13)$$

In Equations (12) and (13) show the symbols that represent confidence and signify the category loss coefficient λ , classification loss coefficient, and confidence score.

IV. RESULTS AND EXPERIMENTS

This section can be separated into two experiments and should present a clear and accurate depiction of the experimental findings, their analysis, and the conclusions that can be drawn from the experiments.

There were two experiments done. The initial test was created to assess a complete method for identifying symbols in engineering drawings. In this context, the aim is to enhance the overall efficiency of analyzing a collection of drawings by detecting and identifying symbols, which is an important task as symbols make up a significant portion of these drawings. This can aid in completing other tasks, such as detecting text, pipelines, etc. The second experiment is different from the first, as it concentrates on using GAN-based methods to deal with the problem of class imbalance.

A. Symbol Detection Using YOLOv8

The SLD sheets in our dataset had a size of about 7500x5250 pixels. To avoid using computationally expensive training data, the SLDs were divided into 24 patches by multiplying their original width by 6 and their original height by 4. The resulting patch size was approximately 1250x1300 pixels. The annotations for the entire SLD were used to retrieve data for each patch's annotations, as described in the preceding section.

Symbols that spanned multiple patches were excluded from the training phase. After extensive testing, the third version of the YOLO framework was selected as it showed better detection rates for small objects compared to the previous versions. It should be emphasized that, when compared to the

entire image size, the technical symbols in our dataset are relatively small.

To conduct the experiment, the researchers utilized a recent version of YOLO architecture. Initially, they configured the total number of classes to be 22 in all three YOLO layers, and then adjusted the number of filters to 3 (referred to as Class_{no} 5), where Class_{no} represents the complete number of classes present in the dataset.

The dataset was divided into two sets: training set with 640 SLDs and test set with 160 SLDs, with a ratio of approximately 80:20. A pre-trained YOLO network was used and fine-tuned on our dataset by adjusting all layers. YOLO was implemented using PyTorch. To enhance object detection for various object sizes, it was observed that changing the input size during training is effective [47]. In this study, the network input size was modified to 416x416 after every 10 batches, and the training stopped after 10,000 batches. The learning rate was 0.001, and the batch size was 64.

During the testing phase, the model input size was increased from 416x416 to 2400x2400. This enabled us to perform symbol detection on the original SLD images instead of integrating detection from the SLD patches, thereby simplifying the symbol detection process for an entire SLD diagram in one step. To evaluate the model, we experimentally set the Intersection over Union (IoU) threshold to 0.5 and compared the detected symbols with the ground truth. A Python-based front-end was developed utilizing OpenCV and other libraries to analyze and display manual errors.

B. Training Evaluation of YOLOv8

1) *Computer hardware configuration:* GPU computing is a preferred choice for processing deep learning on a PC [50], and therefore, strong hardware support is required for deep learning networks. The training and generation processes were conducted on a GPU workstation that ran on Linux, CUDA 11.1, Python 3.8, and PyTorch 1.8.0, and was equipped with an Nvidia A40 4 48 GB GPU.

C. YOLOv8 Detection Results

The training phase produced an accuracy of 96%, while the testing phase produced an accuracy of 95.9%, with 11987 out of 12500 symbols in the test set correctly detected and recognized. The loss matrix for the training and validation sets indicates that the most of the instances of the classes were identified and detected accurately, indicating that symbols with sufficient training instances were correctly identified. An example output from the proposed methods is shown in Fig. 10, with different symbols highlighted in different colors.

In this case, the identified symbols were labeled with numbers, and the labels predicted by the models were noted down to compare them with the actual labels later. These symbols comprised various electrical components like switches, generators, motor, re-lays, inductors, as well as input/output labels such as "label_to" and "label_from".

Table I in the paper contains details about the number of symbols in both the training and testing datasets, with columns labeled "No. of Training Samples" and "No. of Testing

Samples". It also displays the accuracy achieved for each class in the testing set, along with the number of symbols that were correctly identified, listed under "Correctly Detected Samples" or "Class Accuracy".

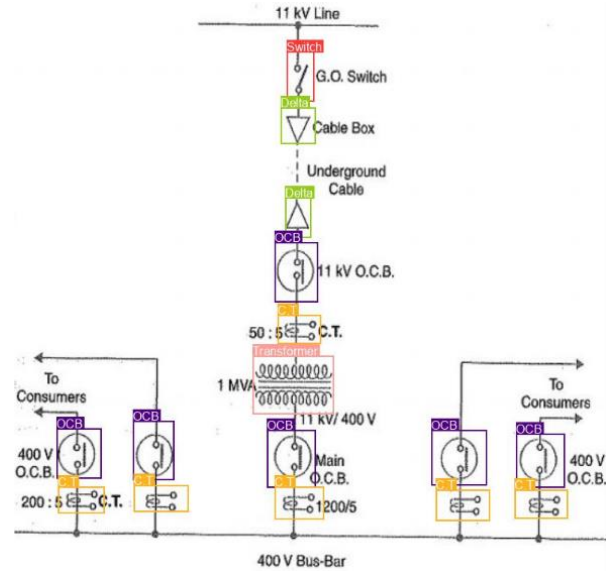

Fig. 10. Symbol detection using YOLOv8.

TABLE I. YOLOV8 DETECTION RESULTS BASED ON ORIGINAL SLD DATASET

Symbols	No. of Training Samples	No. of Testing Samples	Class Accuracy
Fuse	400	80	100%
Circuit Breaker	300	52	100%
Drawout Circuit Breaker	600	190	99%
Capacitor	601	20	99%
Generator	940	400	100%
Transformer	305	50	97%
Voltmeter	182	20	94%
Ammeter	550	190	100%
Disconnect	89	10	94%
Switch	501	115	100%
OCB	509	290	100%
C.T	309	80	100%
Ground	515	140	100%
Diode	310	30	98%
Drawout Fuse	679	110	100%
Inductor	185	18	98%

The results of the study show that most instances (11987 out of 12500) were accurately detected and identified. Fig. 10 displays different symbols from various SLD diagrams and how they can be accurately recognized regardless of their orientation. Some symbols, such as transformers, OCB, C.T, ground, and delta components, have various orientations, but the suggested approach can correctly detect and identify them. Even in situations where the text overlaps, resistors and ground

symbols are accurately detected, demonstrating the approach's resilience to innate visual issues, at least in this context, as opposed to conventional methods.

The round-shaped motor symbol in the testing set was misclassified as a generator symbol in all five instances due to their similarity. It is expected that increasing the number of training examples for this symbol, as well as other symbols in the majority class (such as switch, relay, C.T, inductor, voltmeter, load, etc.), would improve their detection rates.

To conclude, based on the results presented in Table I, it can be inferred that the detection rate for the symbols load, resistor, and motor was very low. This could be attributed to the fact that there were only a few training samples for these symbols. The complexity of the problem notwithstanding, the average accuracy of the remaining 22 symbols in the dataset was above 95%, which is a positive result, although these symbols were excluded.

D. MFC-GAN for Sample Generation and Symbol Detection

The purpose of this study is to evaluate a GAN-based model that can tackle the class imbalance problem in the dataset, which is a classification problem as opposed to a recognition task like in the first experiment. The main aim of this experiment is to utilize the MFC-GAN model to generate more symbols, which can then be added to the training set to improve classification accuracy.

Experiment 2 made use of a dataset that was very similar to the one utilized in Experiment 1, with all symbols being resized to 64x64 grayscale images. The problem was framed as a supervised learning task, where the goal was to learn a function $f(x)$ that maps a given engineering symbol instance (x_i) to its corresponding class (y_i). In this case, the 22 symbols in the dataset were represented as a discrete set of classes denoted as Y , where y_i belongs to Y . The dataset suffered from severe class imbalance, as previously mentioned, with some instances such as the angle choke valve being present in less than 0.01% of the dataset.

In this experiment, the MFC-GAN model was employed in two stages, namely the GAN training stage and the classification stage for this experiment. The purpose was to address the issue of class imbalance in the dataset. The MFC-GAN model was initially trained using all the samples in the dataset, with a focus on the symbols with the least representation. These symbols included fuse, circuit breaker, drawout circuit breaker, capacitor, generator, transformer, voltmeter, ammeter, disconnect, and switch. The numbers of occurrences of these symbols in the training set were 48, 344, 790, 1340, 821, 355, 212, 740, 99, and 616 respectively. The model underwent training only once on this dataset, and the generated samples were obtained after the training. To improve the learning of minority instance structure while training, the less represented classes were resampled.

Using the MFC-GAN model trained on the least represented symbols in the dataset, symbols from the minority class were generated. Eight symbols with the least representation were selected. To create a balanced dataset, 80% of the original dataset was used for training, and the remaining 20% was kept for testing. The artificially generated symbols

were added to the training set, providing more than 4,000 additional synthetic samples for each minority class. This allowed the dataset to be rebalanced by increasing the prevalence of the least represented symbols.

Our goal is to evaluate the effectiveness of the synthesized symbols by comparing the performance of a classification model trained before and after the inclusion of these symbols in the training set.

The experiment employed a four-layer CNN classification model, consisting of three convolution layers with 32, 64, and 128 outputs, respectively. The kernel sizes for these layers were 3x3, 2x2, and max-pooling. The fourth layer was a fully connected layer with 256 units, which represented the 22 symbol classes, and fed into a 22-way Soft-max out-put. The model was trained using SGD with 64 batches and a learning rate of 0.001. The model's classification performance was assessed using standard measures like true positive rate, balanced accuracy, G-mean, and F1-Score, with the aim of comparing the model's performance before and after incorporating the generated symbols into the training dataset.

1) Results: Fig. 11 displays a comparison between the original symbols in the diagram and the symbols generated by the MFC-GAN model.

Fig. 11. Original SLD samples compared with MFC-GAN generated samples.

The comparison between the MFC-GAN generated symbols and the original symbols of the diagram is depicted in Fig. 11. The generated symbols by MFC-GAN were found to be more accurate and precise compared to symbols generated by other methods. The generated samples had clear symbol traits and distinct categories formed in each instance. Moreover, these high-quality samples resulted in an improved performance of the classifier. For example, Table III shows that for the angle disconnect, which had only 99 instances of the class, the accuracy improved from 0 to 94%. Similarly, seven out of eight minority classes demonstrated similar improvements. However, the MFC-GAN model did not improve the baseline in the load and inductor classes. It was observed that certain symbols such as OCB, capacitor, voltmeter, and ammeter exhibited significant similarity despite being uniquely generated, which hindered the classifier's ability to classify the load and inductor classes. This

observation was further supported by the low precision data in Table III for these classes.

Fig. 12. Sample distribution in MFC-GAN generated dataset.

In this study, MFC-GAN models were able to produce occurrences of minority classes that were significantly underrepresented in the dataset, as demonstrated in Fig. 12. Both subjective and objective methods were used to evaluate the generated samples, including an assessment of the classifier's performance before and after incorporating the samples into the training sets. The results showed an improvement in performance across several commonly used evaluation parameters. However, it should be acknowledged that the class imbalance issue can only be addressed to some extent by MFC-GAN, and other strategies may need to be explored and utilized.

The study categorizes the outcome of classification predictions into four groups based on the relationship between the predicted output and the actual value: True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN). To assess the efficacy of defect detection, the study calculates the precision, recall, and F1 score of the model for different types of faults. Precision rate, which measures the accuracy of detection findings, is computed by dividing the number of symbols expected to be positive by the total number of symbols predicted to be positive. Recall rate, which gauges the thoroughness of detection findings, is calculated by dividing the number of samples expected to be positive by the total number of samples that actually have a positive value. Precision and recall are given in Equations (14) and (15):

$$\text{Precision} = \frac{TP}{TP + FP} \quad (14)$$

$$\text{Recall} = \frac{TP}{TP + FN} \quad (15)$$

To evaluate classification problems, it is essential to take into account both the accuracy of identification and the completeness of detection. The model is evaluated using the F1 score, which considers both precision and recall. Equations (16) and (17) express accuracy as the number of symbols that are correctly identified.

$$\text{F1-score} = \frac{2}{\frac{1}{\text{Precision}} + \frac{1}{\text{Recall}}} = \frac{2 \cdot \text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \quad (16)$$

$$\text{Accuracy} = \frac{2}{\frac{1}{\text{Precision}} + \frac{1}{\text{Recall}}} = \frac{2 \cdot \text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \quad (17)$$

The results of the detection data are shown in Table II. The attributes represent the actual class, and each row represents the predicted category. The total number of symbols for each category is calculated by adding up the numbers in each column. The predicted category and the total number of predicted symbols for that category are shown in each row. Our proposed method can accurately detect the majority of single line-based engineering symbols. In this study, the precision of symbol detection for all types is over 95%, the average recall rate is 93.67%, and the F1 score is above 0.9. The average frame detection time is 0.074 seconds, while the average recall and precision rates are 90.67% and 0.074 seconds, respectively.

TABLE II. SYMBOLS GENERATED USING MFC-GAN

Symbol Name	Symbol	Original Instances	Generated Instances
Fuse		480	2380
Circuit Breaker		344	2400
Drawout Circuit Breaker		790	1800
Capacitor		821	2011
Generator		1340	2219
Transformer		355	2200
Voltmeter		212	2587
Ammeter		740	2500
Disconnect		99	1900
Switch		616	1800
OCB		799	1800
C.T		389	2178
Ground		655	2100
Diode		340	2291
Drawout Fuse		589	2408

Iron-core Inductor		750	1950
Load		117	1701
Motor		541	1870

V. DISCUSSION

This section may be divided into two subsections which provide comparisons and conclusive remarks on the experiments.

A. Comparison with Different Data Augmentation Techniques

Table II displays the frequency of the different classes in both datasets. After generating synthetic SLD images using MFC-GAN, it can be observed that the new samples are approximately balanced. However, to address the issue of class imbalance, the original dataset could be improved by including additional distinct and separate photos.

TABLE III. YOLOV5 CLASSIFICATION PERFORMANCE OF SYMBOLS ON AUGMENTED DATASET

Metric	Switch	Relay	Motor	Generator	Load	Inductor	Fuse	Resistor
Precision	1.00	1.00	0.85	0.89	1.00	1.00	1.00	1.00
Recall	0.94	0.89	0.92	1.00	1.00	0.90	0.91	0.87
F1-score	0.89	0.94	0.91	0.95	0.88	0.90	0.92	0.91
Accuracy	1.00	0.98	0.99	1.00	1.00	1.00	1.00	1.00

We conducted an experiment to test the accuracy and performance of YOLOv8 in various conditions and configurations using 800 images, and an example of the detection results can be seen in Fig. 13. The accuracy testing and performance of the experiment using images from our datasets are displayed in Table IV. YOLOv5 is generally more accurate than its recent version. Group 2, which is the augmented dataset, had the highest average accuracy of 96% when using YOLOv5, with only five detection errors. YOLO's performance can be improved by utilizing a large dataset that includes both real and synthetic images generated by GANs. When a deep learning-based method is trained on a small and insufficient dataset, it may result in overfitting and difficulties in mapping the object [52]. Adding noise or generating fake images during training can make the process of learning the input image from the output image easier, reducing general errors, and enhancing the training component [53]. Thus, to improve item identification accuracy, it is necessary to include synthetic images in addition to actual photographs.

B. Missed Detection

Table V presents the outcomes of the evaluation of the model on the SLD components dataset, revealing that there were a total of 52 instances where the SLD components were either absent or wrongly classified as some other symbols. Out of these occurrences, eight symbols were misclassified, while the remaining 46 symbols were not detected entirely. This issue can be attributed in part to the nature of some drawings, where symbols are nearly completely obscured by text and comments. The Intersection over Union (IOU) metric in Table V confirms that these missed symbols have a zero IOU, indicating that they were not detected by the model.

TABLE IV. COMPARISON OF YOLOV8 AND YOLOV5 CLASS ACCURACY

Dataset	Accuracy	Wrong Detection	Missed Detection
Original	95%	8	46
Augmented	96.3%	3	2

Fig. 13. Symbols detected in augmented dataset.

After conducting a visual inspection of the data in Table V, some symbols were found to be mislabeled. Specifically, when reviewing the results for the switch representation, it was observed that the algorithm had predicted the correct class for symbols with an incorrect label. However, for some symbols, the algorithm had predicted the wrong class label.

TABLE V. SYMBOLS MISSED OR OVERLOOKED BY THE CLASSIFIERS

Class	No of Sample Occurrence		Predicted Sample Class		IOU	
	YOLOv8	YOLOv5	YOLOv8	YOLOv5	YOLOv8	YOLOv5
Disconnect	2	5	Switch	Ground	0.50	0.91
Load	1	3	-	Fuse	0.56	1.00
Inductor	2	4	-	-	-	0.00
Voltmeter	-	16	-	-	-	0.00
Diode	-	10	-	-	-	0.00
Circuit Breaker	-	8	-	-	-	0.00

VI. CONCLUSION AND FUTURE RECOMMENDATION

In this study, we proposed a system for analyzing and processing complex engineering drawings. Our approach achieved more than 96% accuracy in recognizing symbols on the drawings, based on extensive testing on a large collection of SLD sheets provided by an industry partner. We utilized advanced bounding-box detection techniques, which

demonstrated high accuracy in identifying symbols from 22 different categories, despite some of these symbols having only minor differences. To address class imbalance in the symbol dataset, we suggested a GAN-based model. Our experiments showed that our system could generate realistic engineering symbols, and adding this synthetic data to the training set improved classification accuracy. According to the experimental results, the proposed GAN model was capable of learning from a smaller amount of training in-stances.

The subsequent emphasis of this study will be on the application of GANs to the creation of symbols in a schematic environment. In future development, an integrated system will be created using the recommended methods to enable thorough analysis and processing of technical diagrams like SLD. This approach will make it much easier to perform additional tasks such as line detection or text localization. Furthermore, future work will involve combining Explainable AI (XAI) and other GAN methods such as WGAN, CycleGAN, PCCGAN, and StyleGAN with other detection techniques.

ACKNOWLEDGMENT

We appreciate Yayasan UTP FRG (YUTP-FRG), grant number 015LC0-280, and Computer and Information Science Department of Universiti Teknologi PETRONAS for providing funding and support for this research.

Abstract—The inversion of water vapor spatial distribution using ground-based global navigation satellite systems is a technique that utilizes the propagation delay of satellite signals in the atmosphere to retrieve atmospheric water vapor information. To further promote the accuracy of the information obtained by this method, a satellite system is designed to solve the spatial distribution of atmospheric water vapor based on chromatography technology and genetic algorithm. Firstly, the accuracy of the empirical air temperature and pressure model to calculate the zenith statics delay is analyzed. To optimize the global weighted average temperature model, a model that considers the decreasing rate of atmospheric weighted average temperature and a model based on the linear relationship between surface heat and weighted average temperature are proposed. The idea of removal interpolation restoration is introduced to achieve regional interpolation of atmospheric precipitable water. Finally, in response to the problem of multiple solutions in the current water vapor chromatography equation, a genetic algorithm based chromatography method is put forward to achieve the solution of atmospheric water vapor spatial distribution. The experimental analysis shows that the average root mean square error and average absolute error of the design method of the research institute are 1.78g/m³ and 1.41g/m³, respectively, which can realize the calculation of atmospheric water vapor density distribution with high accuracy.

Keywords—Global navigation satellite system; spatial distribution of water vapor; genetic algorithm; chromatography technology

I. INTRODUCTION

The atmosphere is a crucial carrier of the earth's gas and water cycle, providing oxygen for humans and animals, carbon dioxide for plant photosynthesis, and water for all life [1]. Through the greenhouse effect, the atmosphere maintains a suitable temperature on the Earth, and through the absorption of harmful rays by ozone, protects earth's organisms from harm. Water vapor is an important component of the atmosphere, mainly concentrated in the lower atmosphere. It has an important impact on the atmospheric greenhouse effect and circulation [2,3]. The atmosphere water vapor has complex temporal and spatial changes, and accurately measuring, modeling, and predicting the content

and changes of water vapor is of great importance for studying the greenhouse effect and climate change. With the continuous expansion of Global Navigation Satellite System (GNSS) and its related fields, GNSS technology used to study the atmosphere water vapor spatial distribution (AWVSD) has made significant progress [4,5]. To achieve a more accurate solution of water vapor distribution, research is conducted on the estimation of atmospheric precipitable water volume (PWV) based on GNSS technology, and the idea of removal interpolation restoration is introduced to optimize the accuracy of the calculation. In terms of three-dimensional water vapor chromatography, a chromatography manner with genetic algorithm (GA) is proposed to address the problems in the chromatography equation.

The gap between research and existing national and international research: Currently, there are generally four main methods for calculating atmospheric water vapor content. The first method is direct calculation using measured sounding data. Sounding data are relatively old, objective and accurate, so they are often used to verify other calculation methods. However, due to the limited number of sounding stations, it is not possible to describe the spatiotemporal distribution of regional water vapor in detail, especially for areas with uneven terrain loads and stations. The second is to use remote sensing data to invert the atmospheric water vapor content, a new technology that has been developed and widely used in recent years, but whose measurement accuracy still needs to be improved. The third is to establish the relationship between the water vapor content and the surface meteorological elements for the calculation. The calculation is simple and the results are ideal, but this greatly increases the number of stations. Fourth, NCEP/NCAR reanalysis data is currently the most widely used method for calculating water vapor content. Gridded data can compensate for the shortcomings of insufficient stations in calculating the spatial distribution of water vapor, but the coarse grid affects the fine analysis and its applicability is not high enough. The method developed by the Research Institute is an improved method based on the use of remote sensing data to invert the atmospheric water vapor content, ensuring high accuracy in the spatial distribution of water vapor with fewer stations.

Motivation and potential benefits of the research: Over the past century, the global climate has undergone a significant change characterised by global warming, and the warming of the climate system has become an indisputable fact. And global warming has also led to more frequent natural disasters caused by extreme weather events, with extremely high losses for society. Extreme precipitation often leads to more severe flood disasters. Detecting water vapor in real time and controlling its spatiotemporal changes, as well as studying its interaction with precipitation, is of great research importance for precipitation forecasting. However, traditional water vapor detection methods have drawbacks such as high operational costs, large station requirements and insufficient accuracy. The use of GNSS to invert the spatial distribution of water vapor has good performance, but the accuracy needs to be improved. Research is underway to improve this technology to achieve high performance water vapor spatial distribution detection.

The main contributions and impacts of the research include:

1) Using different model expressions, different practical resolutions, and different spatial resolution modeling data, the impact characteristics of different modeling factors on the accuracy of empirical temperature and pressure models were studied. A temperature and pressure model based on segmented practical ideas was constructed, and the accuracy of calculating ZHD estimates for different ZHDs in measured meteorological parameters was evaluated within the context of de Qianqiu.

2) The weighted average temperature decline rates for different height intervals were obtained and analyzed, and a CPT2wh model was established. At 1 × Provide the average value, annual amplitude, and semi-annual amplitude of Tm decline rate on a grid point. The proposed model effectively improves the lack of elevation correction in Tm estimation and significantly improves the accuracy of Tm estimation for stations with large elevation differences.

3) A new method for detecting the spatial distribution of water vapor based on genetic algorithm and Analytic Hierarchy Process has been proposed. This method does not need to rely too much on the conditions of the Moon Lake, prior information and external meteorological data, and converts the inverse problem of the matrix into the function optimization problem, which effectively solves the ill conditioned problem of the equation.

4) A GNSS-PWV spatial interpolation method based on the idea of removal interpolation recovery is proposed. This method does not require the surface measured meteorological data of the station to be measured, nor does it require regression analysis of the observed data, which can effectively avoid the issue of elevation correction in PWV interpolation.

The research and work can address the shortcomings of traditional methods of spatial detection of water vapour and provide more accurate detection results. The data will be useful as a guide for government planning and regional responses to climate change.

The specific content of the study is divided into three parts:

The first part is the literature review section, which analyzes the current research status at home and abroad, and explores the key points that need to be overcome in the research.

The second part is the methodology section, which mainly introduces the technologies required for the AWVSD calculation method designed by the research institute, and makes improvements to address the limitations of related technologies.

The third part is the experimental analysis section, which mainly analyzes the performance of the research institute's design methods.

II. RELATED WORKS

The amount of water content in clouds is an important parameter for studying the impact of clouds on climate. Many scholars have used different methods to calculate and analyze the AWVSD characteristics. Shi et al. used the HYSPLIT platform to simulate the Lagrangian trajectory of air envelopment in East China during the summer monsoon. It investigated four different periods during its seasonal migration from south to north [6]. Huang et al. used radio temperature measurement data from 2012 to 2017 to establish an empirical model of atmospheric weighted average temperature (Tm) in Guilin, China. Then, they used observation data from 11 GNSS stations in Guilin to study the spatiotemporal characteristics of GNSS derived PWV under heavy rain from June to July 2017 [7]. Lee et al. found in their observation of the time process of H2O2 generation in condensate droplets that it was typically generated from droplets smaller than 10 microns [8]. Tan et al. obtained the land surface temperature (LST) of Dongting Lake (China) from Landsat 7 data, and discussed its relationship with land cover (LULC) type. The outcomes denoted that LST varied greatly among different LULC types, with higher LST in building areas and lower LST in other areas. Water bodies played a critical supervision role in reducing LST [9].

GNSS technology was gradually developing and becoming a focus of research for scholars. Pan et al. considered the advantages and disadvantages of remote sensing technology and Global Navigation Satellite System Interferometric Reflection (GNSS-IR) in trajectory recognition of water content (VWC), and proposed a point surface fusion method with GA combined with backpropagation neural network (GA-BP) for GNSS IR and MODIS data to raise the accuracy of VWC estimation [10]. Zheng et al. used the signal-to-noise ratio of navigation satellite signals to invert sea level based on observation data from MAYG on the east coast of Africa from 2017 to 2019 [11]. LÜ et al. used Differential Interferometric Synthetic Aperture Radar (InSAR) and pixel offset tracking to gain the line of sight displacement and near-field range displacement of the M6.9 earthquake in Menyuan, Qinghai from SAR images. At the same time, they obtained high-speed displacement waveforms of 16 GNSS stations through historically accurate point positioning schemes and inverted the seismic fracture process [12]. Lewen et al. conducted

monitoring of changes in the spatial environment of the line of sight based on global and regional GNSS reference station networks for inversion of tropospheric and ionospheric parameters [13].

GA is an efficient, parallel, and global search method. Jalali Z et al. used GAs and constant development manners to optimize the exterior walls of an office building. The SPEA-2 algorithm was utilized for multi-objective optimization [14]. Garud et al. extensively reviewed the applicability of artificial neural networks (ANN), fuzzy logic (FL), and GA, as well as their hybrid models, using AI for effectiveness prediction. Besides, some literature on predicting solar radiation using ANN, FL, GA, and their hybrid models has been summarized [15]. Shariati et al. collected a database of 1030 datasets to intelligently predict the strength of concrete containing slag and fly ash as partial substitutes for cement [16]. Abualigah et al. proposed an efficient task scheduling optimization method based on a multiverse optimizer and genetic algorithm (MVO-GA). MVO-GA was utilized to improve the effect of task transmission through cloud networks, provide appropriate transfer decisions, and rearrange transfer tasks with the efficiency weights collected in the cloud [17].

Based on the above literature analysis, there are various methods for calculating and analyzing the AWVSD, but the accuracy of the obtained AWVSD analysis methods still needs to be improved. To this end, the study utilizes GNSS technology to estimate atmospheric PWV, and then uses GA algorithm for water vapor chromatography. A solution model for AWVSD based on Analytic Hierarchy Process (AHP) and GA is obtained.

III. A SOLUTION MODEL FOR AWVSD BASED ON AHP AND GA

Water vapor can effectively absorb solar longwave radiation and surface infrared radiation, thereby providing insulation for the entire Earth system. Its content in the atmosphere has complex spatial and temporal variations, constantly affecting weather characteristics and climate environments around the world. Therefore, the accurate measurement, modeling and prediction of water vapor levels and changes are of great importance for the study of the greenhouse effect and climate change. At the same time, an in-depth understanding of the spatiotemporal changes of water vapor plays an important role in improving the accuracy of weather forecasting and conducting disaster weather warnings. When electromagnetic waves pass through the Atmosphere of Earth, they are affected by the ionospheric delay and the flow delay, which will lead to the extension of the electromagnetic wave propagation practice and the bending of the propagation path. Therefore, monitoring and studying the distribution of water vapor in the atmosphere is of great importance for services such as radio communications, navigation, positioning and timing. In order to improve the accuracy of information obtained from current water vapor spatial distribution inversion techniques, research has been carried out on key technologies for obtaining atmospheric precipitable water and tomographic inversion of atmospheric water vapor density, with a focus on ground-based GNSS inversion. Firstly, the empirical air temperature and pressure model is analyzed

to calculate the accuracy of the zenith Statics delay. In order to optimize the global weighted average temperature model, the model of worrying about the decline rate of the atmospheric weighted average temperature and the model based on the linear relationship between the surface heat and the weighted average temperature are proposed. And introduce the idea of removal interpolation restoration to achieve regional interpolation of atmospheric precipitable water. Finally, in response to the problem of multiple solutions in the current water vapor chromatography equation, a genetic algorithm based tomography method is proposed to achieve the solution of atmospheric water vapor spatial distribution.

1) *GNSS-PWV spatial interpolation based on the idea of removal interpolation recovery*: In the GNSS solution model, each satellite signal corresponds to a tropospheric delay, and directly estimating them will result in rank deficiency in the equation. The convective delay is modeled as the sum of zenith directional delay (ZTD) and the product of atmospheric horizontal gradient and their corresponding projection functions. The calculation method of ZTD is shown in equation (1).

$$STD = m_h(ele) \times m_w(ele) \times ZWD + m_\Delta(ele) \times \cot(ele) \times [G_{NS} \cos(azi) + G_{WE} \sin(azi)] \quad (1)$$

In formula (1), *STD* means the total delay of tropospheric oblique path; m_h stands for the dry mapping function; m_w stands for the wet mapping function; m_Δ expresses the atmospheric horizontal gradient mapping function; G_{NS} and G_{WE} express the atmospheric horizontal gradient in the north-south and east-west directions respectively; *ele* and *azi* indicate the satellite altitude angle and azimuth angle respectively; *ZWD* denotes the zenith wet delay; *ZHD* means the zenith statics delay. Usually, atmospheric precipitable water vapor (PWV) and integrated water vapor (IWV) are utilized to characterize the information of atmospheric water vapor content. The conversion relationship between the two is shown in equation (2).

$$IWV = \rho_w \times PWV \quad (2)$$

In equation (2), ρ_w means the density of liquid water. ZWD and PWV's conversion relationship is shown in equation (3).

$$\left\{ \begin{array}{l} PWV = \Pi \cdot ZWD \\ \Pi = \frac{10^6}{\rho_w \times R / m_w \times (k_2' + k_3 / T_m)} \end{array} \right. \quad (3)$$

In equation (3), Π means the conversion factor; R denotes the general gas constant; m_w indicates the molar mass of wet air; k_2' and k_3 express the atmospheric refractive index constants; T_m means the atmospheric weighted average temperature. The process of inverting PWV through ground GNSS is shown in Fig. 1.

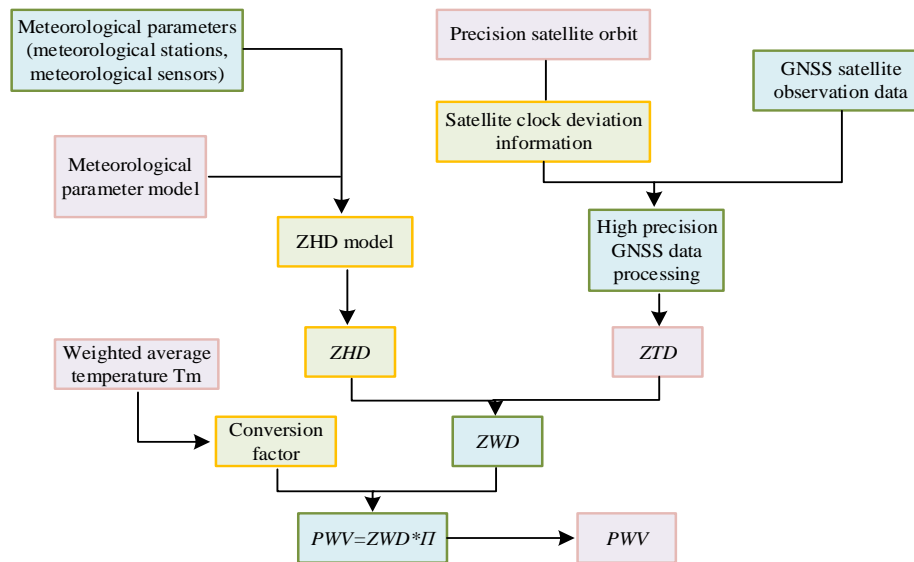

Fig. 1. Process of PWV inversion based on ground GNSS.

After obtaining the GNSS station ZWD, it is necessary to use conversion factors to obtain the atmospheric PWV. It is a function of the weighted T_m , and accurately obtaining T_m is the useful way to improving the accuracy of GNSS-PWV. To this end, the GPT2w model is applied to calculate T_m . When using GPT2w to calculate T_m , the study first selects the four model grid points closest to the desired station, and uses the model coefficients stored in external grid files to calculate the T_m estimates of the four grid points. Then, the interpolation algorithm is used to interpolate the T_m estimates of the four grid points to gain the T_m estimates of the station to be measured. However, during the research, it is found that the GPT2w model lacks elevation correction when calculating T_m , which limits the accuracy of the model in some cases, especially on the waiting points with significant elevation differences from the GPT2w grid points. For this purpose, the study adopts the index of virtual temperature, temperature decreasing rate, and water vapor pressure (WVP) decreasing factor to adjust the pressure, temperature, and WVP accordingly. At the same time, it applies the vertical T_m decline rate to the GPT2w model. Considering the limitations of the relationship between T_m and surface temperature (T_s) used globally, a GGTm T_s model is established using GGOSAtmosphere and ECMWF data. By providing high-precision T_m - T_s relationships on global grid points, more accurate T_m estimation can be achieved.

GNSS technology is used to gain PWV, which has become an important data source for meteorological departments. However, due to environmental and economic factors, GNSS stations are often scattered and have large distances, which limits the analysis of AWVSD in certain applications. Therefore, research is conducted on spatial interpolation of GNSS-PWV. It has a closed connection between water vapor and terrain, so it needs to consider the impact of terrain factors on PWV interpolation. To address the above issues, a method based on the idea of removal interpolation restoration is

proposed for spatial interpolation of GNSS-PWV. The interpolation method is shown in Fig. 2.

Using the coordinates and time information of the measuring station, the GPT2w model can calculate meteorological parameters, and use these two parameters to estimate the ZWD of the measuring station. The calculation method is shown in equation (4).

$$ZWD = 10^{-6} \times \left(k_2' \times k_3 / T_m \right) \times \frac{R / m_d \times g_m}{(\lambda + 1)} \times e \quad (4)$$

In equation (4), m_d means the molar mass of dry air; g_m indicates the average gravity; e and λ denote the WVP and the decline rate of WVP respectively. After obtaining ZWD, it is converted into PWV using a conversion factor. The conversion method is shown in equation (5).

$$PWV = \frac{m_w \times g_m}{m_d \times p_w \times (\lambda + 1)} \times e \quad (5)$$

Using the GPT2w model, the PWV estimation at the corresponding time of the station calculated by using the above formulas (4) and (5) is denoted as GPT2w_PWV. The PWV true value obtained by using GNSS technology to high-precision process the observation data is denoted as GNSS_PWV. Firstly, it calculates the difference between the two types of PWVs based on PWV_residual. Then, the interpolation algorithm is used to interpolate the PWV_residual of the GNSS station to obtain the difference of the desired station. Finally, the obtained difference and its GPT2w_PWV are interpolated into the PWV of the station to be tested. This method achieves interpolation without the need for surface meteorological observation data and regression fitting processes, and considers the influence of elevation issues on PWV interpolation. The distribution and elevation of GNSS stations are shown in Fig. 3.

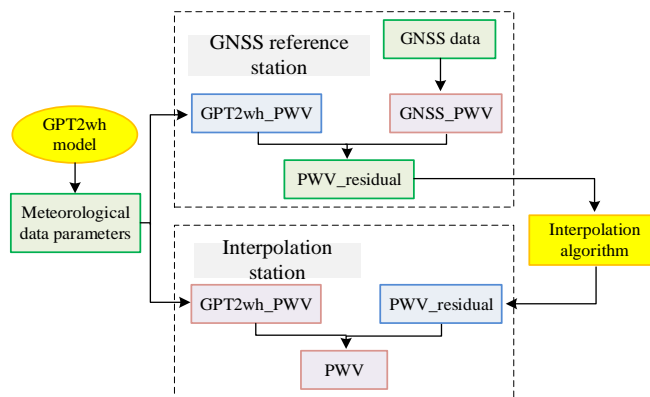

Fig. 2. Interpolation method process.

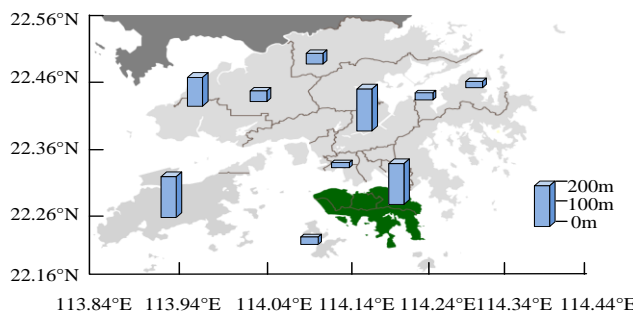

Fig. 3. Distribution and elevation of GNSS stations.

Based on the above content, research has estimated PWV in the atmosphere using the GPT2w model and Tm-Ts model. However, GNSS stations are often scattered and have large distances, which limits the analysis of AWWSD in some applications. Research conducts the spatial interpolation of GNSS-PWV to improve the accuracy of existing PWV interpolation methods.

2) *GA-based 3D water vapor AHP algorithm*: Through GNSS observation data and meteorological information, precise PWV of the station can be obtained, while PWV is only the water vapor content in a unit low area column that runs through atmosphere. It is the average water vapor content in the zenith direction of multiple rays on the oblique path near the station, and cannot accurately show the variation in water vapor space, thereby limiting its application in meteorology such as weather forecasting. A GNSS water vapor tomography (WVT) manner is put forward, which uses optimization methods for equation solving to avoid matrix inversion, but relies heavily on constraint equations and external observation data. The parameters of the water vapor chromatography method based on genetic algorithm are: the population size is 200, the crossover probability is set to 0.8, the Choice function is Roulette, the crossover function is Intermediate, and the mutation function is adaptive feasibility.

Chromatography techniques (CT) refer to the method of inverting the spatial distribution of parameters using integrated observations from different positions and directions within the study area. In GNSS 3D WVT, the oblique path water vapor content (SWV) generated by the GNSS satellite

signal passing through the tomography area is the observed measurement, and the WVD in each grid is the desired parameter. The WVT observation equation is established by calculating the intercept within each grid, as shown in equation (6).

$$SWV^q = \sum_{i=1}^n d_i^q \cdot x_i \quad (6)$$

In equation (6), q indicates the satellite ray number for WVT; n means the total number of tomographic grids; d_i^q means the intercept of the q th satellite ray passing through the i th grid, and x_i refers to the WVD value within the i tomographic grid. The equation diagram is shown in Fig. 4.

Due to the fixed position of GNSS stations in the chromatography area, satellite signals will vary with their altitude and azimuth angles. When constructing the observation equation for water vapor chromatography, these SWVs passing through the side of the chromatography study area are defined as invalid satellite rays, and only the effective satellite rays passing through the top of the chromatography area are selected. It collects all available WWVs for water vapor chromatography and constructs a water vapor chromatography equation set using equation (7).

$$y_{m \times 1} = A_{m \times n} \cdot x_{n \times 1} \quad (7)$$

In equation (7), y means the matrix containing all SWVs; m expresses the total number of SWVs that can be used for water vapor chromatography; A indicates the matrix

containing the intercept of satellite rays passing through the grid, where the number of never passing through the grid is 0. x means the matrix composed of all the parameters to be solved, and n means the total number of WVD in the grid to be solved. For some small-scale water vapor tomographic regions, the vertical layering of the tomographic grid is almost parallel, and the mutual exchange of water vapor densities in each layer of the grid may not affect the overall results, which leads to the multiplicity of observation equations. In addition,

the limited number of GNSS stations in the tomographic region often leads to uneven and insufficient distribution of GNSS satellite signal rays in the tomographic region. Furthermore, there is a case where the coefficient matrix A is rank deficient. Therefore, in addition to the observation equation, the study also constructed horizontal, vertical and top-level constraints. The geometric diagrams of the first two constraint equations are shown in Fig. 5.

Fig. 4. Graphical representation of GNSS three-dimensional WVT observation equation.

Fig. 5. Geometric diagram of horizontal and vertical constraint equations.

Equation (8) is established by using distance dependent Gaussian weighting function.

$$w_1^i x_1 + w_2^i x_2 + \dots + w_{i-1}^i x_{i-1} - x_i + w_{i+1}^i x_{i+1} + \dots + w_l^i x_l = 0 \quad (8)$$

In equation (8), l indicates the total amount of grids in the same horizontal layer; x_l denotes the atmospheric WVD of the l th grid; w_l^i expresses the horizontal weight coefficient of the l th grid in the horizontal layer relative to the i th grid, and d is the distance between the center points of the corresponding two grids. The vertical constraint equation is shown in equation (9).

$$x_i = x_{i+1} \cdot e^{(h_{i+1} - h_i)/h} \quad (9)$$

In equation (9), h is the height of the water vapor chromatography area. For top level constraints, research suggests that the top level region of the tomographic model has very little water vapor, so the WVD of all top level tomographic grids is directly constrained to be 0. Synthesizing three constraints and using the least square (LS) method can obtain the atmospheric WVD solution as shown in equation (10).

$$x = (A^T P A + B^T P B)^{-1} \cdot (A^T P y) \quad (10)$$

In equation (10), B denotes the coefficient matrix of the constraint equation. For the 3D WVT method based on GA, it needs to primarily construct the tomography equation, and then the idea of optimization equation is used to solve it. The calculation method is shown in equation (11).

$$\min f(x) = (y - Ax)^T P (y - Ax), x \in R^+ \quad (11)$$

In equation (11), the x value that minimizes $f(x)$ is the result of water vapor chromatography. After the tomographic equation is obtained, a fitness function is constructed, and then some groups representing the approximate value of the grid WVD are randomly generated. Then, according to the fitness value of the grid WVD, the grid density estimation value of the subsequent generations is selected as the parent. After selection, a new grid WVD approximation solution is formed by using the group of parents mentioned above to calculate new offspring through crossover and mutation. It calculates the fitness value of the approximate value of the WVD of each group of grids. When the fitness value of a group meets the requirements or reaches the number of searches, the GA algorithm stops searching, or continues to iterate circularly. The specific process of GA based water vapor chromatography method is shown in Fig. 6.

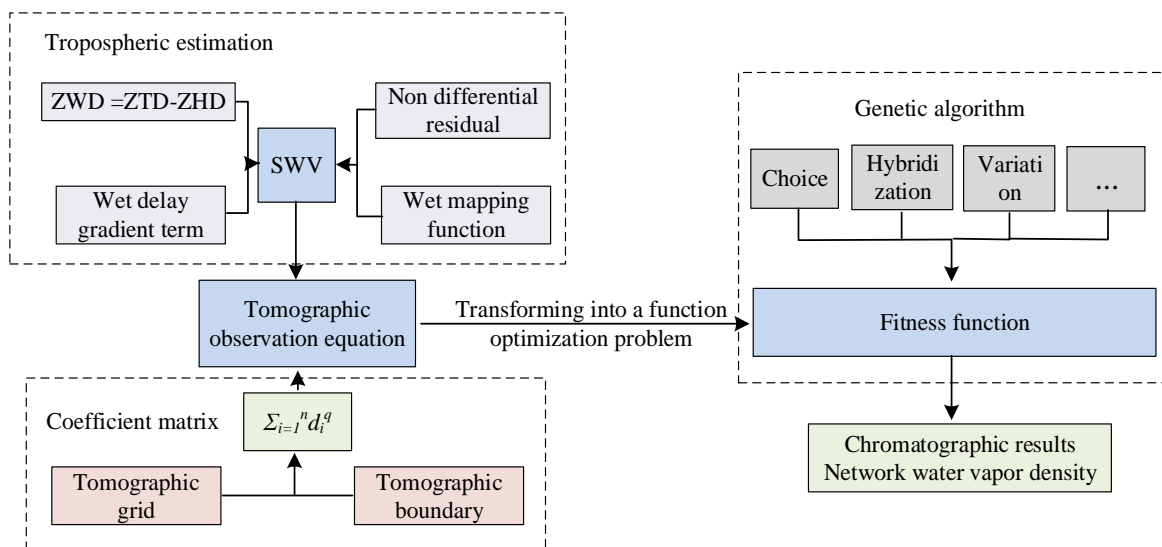

Fig. 6. Flow chart of water vapor chromatography method based on GA algorithm.

Based on the above operations, x that minimizes the value of the fitness function is obtained, that is, the best solution of equation (11), from which the distribution information of atmospheric WVD over the tomographic area is obtained.

IV. RESULTS AND DISCUSSION

The purpose of the performance evaluation is to measure the good or bad results of the research work in order to further identify and optimize the performance differences between different models. In order to achieve a more accurate solution of water vapor distribution, research will be carried out on the estimation of atmospheric precipitable water volume (PWV) based on GNSS technology, and the idea of removal interpolation restoration will be introduced to optimize the accuracy of the calculation. In terms of three-dimensional water vapor chromatography, a chromatography method based on genetic algorithm is proposed to solve the problems in the chromatography equation. To test the detection performance of the water vapor spatial distribution detection method developed by the research institute, a series of experiments were designed to test the model improvement effect and detection accuracy. When GPT2w model was applied to work out Tm, the study used a decreasing rate to adjust and optimize it vertically. Here, the optimized model was named GPT2wh. To test the improvement effect of the model, the accuracy of GPT2wh was verified by using Tm calculated from sounding station data. The experiment selected 459 sounding stations containing meteorological profile information for more than half a year in 2020, and used the two improved models before and after to obtain the daily Tm values of the corresponding stations from 0 to 12 o'clock. Bias and RMSE were used as statistical variables for comparative analysis, as shown in Fig. 7.

In Fig. 7, for the GPT2wh model, the accuracy of most sounding stations was better than 5K, with a proportion of 88.45%; For the GPT2wh model, stations with an accuracy of 5K accounted for 76.45%. Compared to the GPT2w, the maximum improvement of RSME by the GPT2wh model was

7.35K, from 11.35K to 4.00K. The mean RMSE of the GPT2wh model was 3.83K, which was 0.33K less than that of the GPT2w, and the accuracy was improved by about 8%. The different colors in Fig. 7(a) and 7(b) could distinguish between different types of stations, with positive and negative Bias stations, respectively. This was mainly due to the height difference between the sounding station and its four model grid points, while the GPT2wh model included a Tm decay rate that could be vertically corrected for Tm, with significant reductions in positive and negative bias values. The mean deviation of the GPT2wh model was 0.32K and the mean deviation of the GPT2w model was 0.94K. Based on the contents of Fig. 7, the improved model gave a more accurate Tm value.

To further test the performance of the two models, statistical analysis was conducted on the height difference between each sounding station and its corresponding model nodes, and the trend curve of the two indicators changing with the height difference was plotted in Fig. 8.

In Fig. 8, the RMSE and Bias values of the GPT2w increased with the increase of height distinguish, while the GPT2wh could get stable RMSE and Bias in different height difference ranges. The average bias of the GPT2w model varies widely at different altitudes, from 0.32k to 10.34k; the average bias of the GPT2wh model is relatively stable and small. As the altitude difference increases, the average RMSE of the GPT2w model increases significantly, while the GPT2wh model can achieve smaller and smaller RMSE. It can be seen that the GPT2wh model has limited improvement in Tm when the height difference is small, while the improvement effect on Tm is more significant when the height difference is large. This indicated that the improved model could well promote the accuracy of height difference method station estimation Tm. And as the height difference increased, the promotion of the GPT2wh became more significant.

To validate the effectiveness of the PWV spatial interpolation method proposed by the research institute, station cross validation and grid point PWV interpolation

using GNSS station PWV were used to compare the interpolation accuracy of the entire region. Firstly, different interpolation schemes were used for comparison: the first group of schemes did not take into account of the influence of elevation factors on PWV interpolation, and directly used IDW, Kriging, and TPS. The second group added the GPT2wh model on top of the first group, while the third group used the 3DRing and 3DTPS algorithms that considered elevation factors. Adding the GPT2wh model on top of the third group formed the fourth group of schemes. By comparing the PWV interpolation schemes mentioned above, the impact of elevation factors on the PWV interpolation results has been verified, and the effectiveness of using the removal interpolation restoration idea for PWV interpolation in different situations has been evaluated. The RMSE distribution of daily station cross validation for different schemes is shown in Fig. 9.

In Fig. 9, the first group of schemes showed the worst with a larger RMSE, while the third group considered the elevation factor and reduced the RMSE of the interpolation results. Based on the idea of removal interpolation recovery, after adding the GPT2wh model, the second group effectively reduced the RMSE value compared to the first group and the fourth group compared to the third group. Based on the content of Fig. 9, this idea could effectively improve the interpolation accuracy of PWV. In the results of Kriging and 3DKriging, the interpolation algorithm that adds elevation factors can improve the accuracy of PWV interpolation for most stations, but some stations do not show significant improvement, especially for stations located at 113.84° E

and 22.26° N. Because when the HKNP station is the desired station, its elevation is no longer within the elevation range of the other 11 reference stations, and the elevation is relatively large. Even if the influence of elevation factors is taken into account in 3DDrilling, 11 reference stations cannot provide sufficient and reliable elevation reference information for the HKNP station, resulting in a small improvement in PWV interpolation accuracy. The second highest station is HKST. Although its elevation is significantly different from most of the survey stations, its elevation is included in the elevation range of 11 reference stations. Therefore, using Kriging for PWV interpolation accuracy crossover, while using 3DKriging can better improve the PWV accuracy of the HKST survey station. Through analysis, it can be concluded that the accuracy of 3DDrilling interpolation of PWV depends largely on the selection of reference stations, often requiring the elevation range of reference stations to cover as much as possible the elevations of all stations to be measured. The same problem exists for 3DTPS. The PWV interpolation method, which is based on the idea of removal interpolation restoration, can effectively solve the above problems. For the HKNP station, the RMSE of Kriging GPT2wh interpolated PWV is 1.58m, which is 4.45m better than the RMSE of Kriging; the RMSE of TPS-GPT2wh interpolated PWV is 1.43m, which is 2.97m better than the RMSE of TPS. Compared to PWV interpolation using 3DDrilling and 3DTPS, Kriging-GPT2wh and TPS-GPT2wh not only improve the accuracy of HKNP for special height stations, but also perform better for all other stations.

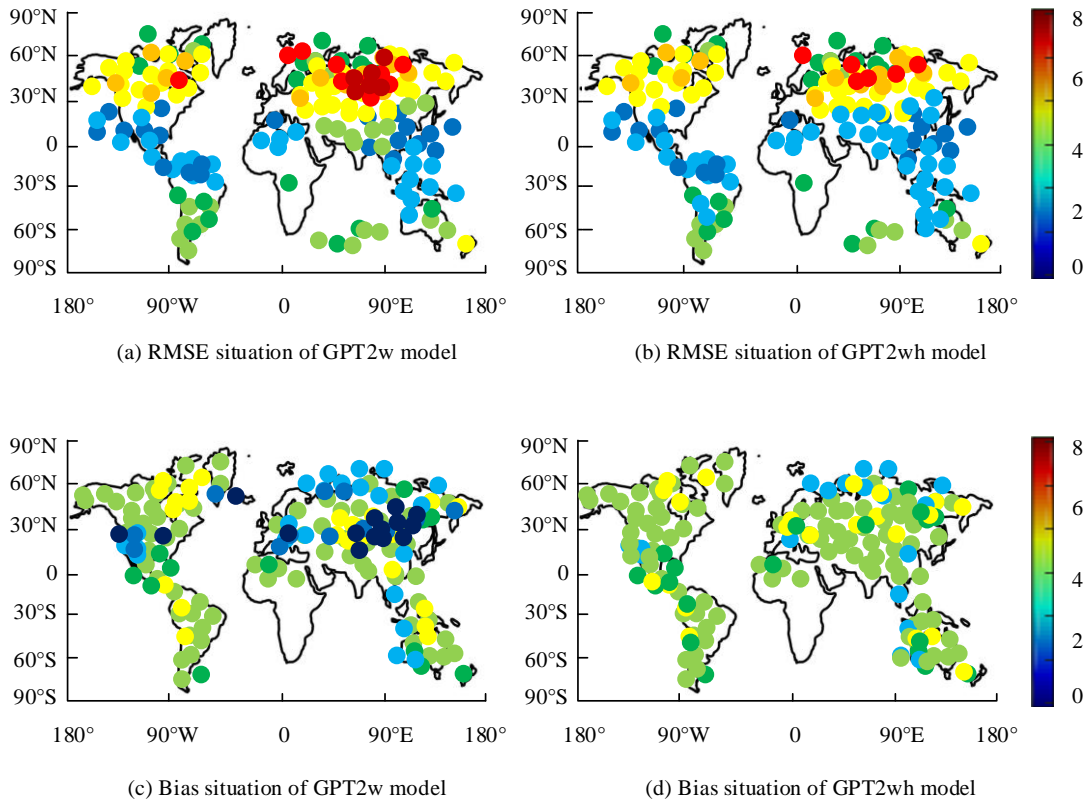

Fig. 7. Bias and RMSE scatter plots of the GPT2w model before and after improvement.

To further verify the accuracy of each interpolation method, the PWV of each grid point interpolated by ten methods was statistically compared with the PWV provided by ECMWF. The statistical information of grid points for different interpolation methods is listed in Table I.

In Table I, the grid point PWV verification results were similar to the station cross validation results. The accuracy of grid point verification results was better than that of station cross validation, regardless of MAE, RME, or CRE. This was because of the overall difference in PWV obtained from ECMWF grid data and GNSS data.

The LS method was the most commonly used solution method for 3D WVT, and a large amount of experiments demonstrated that this method could obtain high-precision atmospheric WVD. To assess the GA algorithm's accuracy based tomography method designed by the research institute, the results were compared with those of LS. In the experiment, linear regression and box chart were used to analyze the atmospheric water vapor density distribution of the two methods. The chart included experiments under all weather conditions, as shown in Fig. 10.

In Fig. 10 (a), the scatter distribution and regression line of atmospheric WVD showed a good linear relationship between the two chromatographic methods. The beginning point and

slope of the regression equation were 0.534 and 0.9542, respectively. Fig. 10(b) showed the distribution of the difference in atmospheric WVD between the two chromatography methods, with Q1 and Q3 being $-0.83\text{g}/\text{m}^3$ and $0.61\text{g}/\text{m}^3$, respectively, indicating that the proportion of the difference in atmospheric WVD calculated by the two chromatography methods within $1\text{g}/\text{m}^3$ exceeded 50%. The upper and lower limits of the box plot were $2.73\text{g}/\text{m}^3$ and $-2.88\text{g}/\text{m}^3$, respectively. The outlier only accounted for 3.21%. From the content of Fig. 10, the atmospheric density outcomes obtained by the GA based tomography method were consistent with that obtained by the LS method, which proved that this method could achieve high precision solution of AWVSD. The RMSE and MAE obtained by comparing the genetic algorithm based tomography results with sounding data and ECMWF data were $1.45/1.24\text{g}/\text{m}^3$ and $1.35/1.01\text{g}/\text{m}^3$, respectively, while the RMSE/MAE obtained by comparing the least squares tomography results with sounding data and ECMWF data were $1.46/1.24\text{g}/\text{m}^3$ and $1.37/1.15\text{g}/\text{m}^3$, respectively. Overall, it can be seen that both the genetic algorithm based tomography and the least squares tomography methods can provide good atmospheric water vapor results compared to the reference values in both sunny and rainy experiments, and the statistical results of the former are better than those of the latter.

Fig. 9. RMSE distribution of various PWV interpolation methods in different year product days.

TABLE I. COMPARISON OF GRID POINT STATISTICAL INFORMATION OF DIFFERENT INTERPOLATION METHODS

Interpolation method	Sunny day(mm)			Rain(mm)		
	MAE	RMSE	CRE	MAE	RMSE	CRE
IDW	2.459	2.966	0.462	2.455	2.967	0.471
IDW-GPT2wh	1.640	2.045	0.193	1.643	2.045	0.196
Kriging	2.537	3.012	0.472	2.533	3.023	0.471
Kriging-GPT2wh	1.470	1.801	0.141	1.481	1.803	0.143
3DKriging	1.820	2.203	0.217	1.812	2.204	0.220
3DKriging-GPT2wh	1.587	1.896	0.160	1.592	1.892	0.162
TPS	2.873	3.324	0.692	2.882	3.312	0.693
TPS-GPT2wh	1.630	1.923	0.168	1.631	1.935	0.169
3DTPS	1.978	2.375	0.245	1.974	2.348	0.243
3DTPS-GPT2wh	1.699	2.004	0.182	1.698	2.003	0.181

Fig. 10. Linear regression and box plot of chromatographic results obtained from two chromatographic methods.

To further test the performance of the tomography method (Method 1) designed by the research institute, three-dimensional WVT experiments were conducted under different weather conditions using GNSS observation data offered by the Hong Kong Satellite Positioning Reference Station Network SatRef, and three-dimensional water vapor information was obtained under different weather conditions. Compare Method 1 with the currently popular centralized chromatography method, and the specific results were shown in Table II. The comparison methods included: GNSS WVT with consideration for boundary signals and vertical constraints (Method 2), a robust adaptive WVT (Method 3), WVT with fusion of ECMWF grid data (Method 4), and water vapor distribution tomography based on Kalman filtering (Method 5).

In Table II, regardless of whether it is sunny or rainy, the RMSE values of water vapor chromatography density for Method 1 were lower than those for the other four methods. During the entire chromatographic experiment, the average RMSE and MAE values of Method 1 were 1.78g/m³ and 1.41g/m³, respectively. According to the comprehensive table, Method 1 could obtain higher precision atmospheric WVD values. The meteorological profile data provided by radiosonde stations can be used to calculate water vapor

density values, which are studied as reference values to evaluate the accuracy of water vapor tomography methods based on genetic algorithms. Due to the daily launch of radiosonde balloons at 0:00 and 12:00 UTC, the study chose to compare the water vapor chromatography results of the corresponding time periods under sunny and rainy conditions. During the rainy period from August 9, 2022 to August 15, 2022, the atmospheric water vapor density calculated from radiosonde data and the results of water vapor tomography based on genetic algorithms will vary with altitude. It is found that the atmospheric water vapor density decreases with increasing altitude; the atmospheric water vapor profile obtained by the genetic algorithm based tomography method is in agreement with the atmospheric water vapor profile obtained by radio sounding. In absolute terms, the agreement is better in the upper atmosphere. Considering the relative error, the corresponding values for tomographic grids with heights greater than 5km and less than 5km are 31% and 15%, respectively. This is because the water vapor density value in the upper atmosphere is relatively small, and small differences between sounding data and tomographic results can also lead to significant relative errors; the proportion of the atmospheric water vapor content within 5km of the Earth's surface exceeds 90%.

TABLE II. COMPARISON OF WATER VAPOR CHROMATOGRAPHY RESULTS OF VARIOUS METHODS

Project		Method 1	Method 2	Method 3	Method 4	Method 5
Sunny day	RMSE	1.84	2.01	1.98	2.22	2.31

V. CONCLUSION

The amount of water content in clouds not only has a significant impact on the growth of cloud droplets and the formation and intensity of precipitation, but also serves as a predictive parameter for global climate data simulation and an important parameter for studying the impact of clouds on climate. To achieve a more accurate solution of AWVSD, research was conducted on estimating PWV based on GNSS technology, while introducing the idea of removal interpolation restoration to optimize the accuracy of the calculation. In three-dimensional water vapor chromatography, a chromatography method based on GA was proposed to address the problems in the chromatography equation. Through experimental analysis, the accuracy of most sounding stations in the GPT2wh model was better than 5K, with a proportion of 88.45%, which was more accurate than the Tm value obtained before improvement. The first group of schemes displayed the worst with a larger RMSE, while the third group considered the elevation factor and reduced the RMSE of the interpolation results. Based on the idea of removal interpolation recovery, after adding the GPT2wh model, the second group effectively reduced the RMSE value compared to the first group and the fourth group compared to the third group. This idea could effectively improve the interpolation accuracy of PWV. The average RMSE and MAE values for Method 1 were 1.78g/m³ and 1.41g/m³, respectively. The tomography method designed by the research institute could obtain higher precision atmospheric WVD values. The detection method for water vapor spatial distribution proposed by the research institute needs to be further improved and refined. Further research and work are needed after this proposal:

Step 1: Various empirical meteorological parameter models have been studied and constructed, but with the continuous enrichment and improvement of analytical data and spatial resolution of meteorological data, more dense meteorological grid parameter models need to be provided. In future research work, it is necessary to further consider how to reasonably sample global grid points, refine the positional relationship between the desired points and grid points, and improve the accuracy of spatial distribution research.

Step 2: A stable 3D water vapor chromatography algorithm and program have been developed, but the efficiency and automation level of the program still need to be improved. Subsequent research content needs to achieve automated batch processing of GNSS observation data, automated mapping,

and comparative verification of sounding data.

Step 3: The study area selected by the Research Institute is the Hong Kong region, which has a large number of GNSS stations and a small geographical area. However, the research has not explored how to achieve water vapor spatial distribution detection in areas with large areas and sparse GNSS stations. In the future, regional water vapor spatial inversion can be achieved by exploring reasonable grid partitioning strategies, multi-source observation data fusion and other means.

ACKNOWLEDGMENT

The research is supported by: R&D center of building energy saving engineering technology of Shandong Huayu University of Technology, No.: 2019-03.

Abstract—The disease, tuberculosis (TB) is a serious health concern as it primarily affects the lungs and can lead to fatalities. However, early detection and treatment can cure the disease. One potential method for detecting TB is using Computer Aided Diagnosis (CAD) systems, which can analyze Chest X-Ray Images (CXR) for signs of TB. This paper proposes a new approach for improving the performance of CAD systems by using a hybrid pre-processing method for Convolutional Neural Network (CNN) models. The goal of the research is to enhance the accuracy and Area Under Curve (AUC) of detection for TB in CXR images by combining two different pre-processing methods and multi-classifying different manifestations of the disease. The hypothesis is that this approach will result in more accurate detection of TB in CXR images. To achieve this, this research used augmentation and segmentation techniques to pre-process the CXR images before feeding them into a pre-trained CNN model for classification. The VGG16 model managed to achieve an AUC of 0.935, an accuracy of 90% and a 0.8975 F1-score with the proposed pre-processing method.

Keywords—Tuberculosis; CNN; pre-processing; CXR images; augmentation; segmentation

I. INTRODUCTION

Tuberculosis, also known as TB, is an infectious disease brought on by the bacterium *Mycobacterium tuberculosis*. Although it mostly affects the lungs, it can also have an impact on the kidneys, the spine, and the brain.

When an infected individual coughs, sneezes, or talks and another person inhales the bacteria, TB is transmitted through the air. It is crucial to remember that TB cannot be transmitted via innocuous touch such as handshakes or sharing of utensils. Chronic cough, chest pain, blood in the cough, exhaustion, fever, night sweats, and weight loss are some of the signs of TB. Yet, some TB patients may not even exhibit any symptoms [1]. Although TB is a treatable and curable illness, a lengthy antibiotic treatment regimen is necessary. TB can be fatal if neglected.

According to the World Health Organization (WHO), tuberculosis (TB) is one of the top 10 causes of death worldwide. In 2020, there were an estimated 10 million new cases of TB globally with an estimated 1.5 million deaths from TB in 2020. The global TB treatment success rate was 85% in 2019 and disproportionately affects vulnerable populations,

such as people living in poverty, people who use drugs, and prisoners [2].

Chest X-rays and CT (Computed Tomography) scans are two different medical imaging techniques used to diagnose and monitor various conditions related to the chest, such as lung diseases. However, considering the disproportionality of TB affecting impoverished areas, chest X-rays have the advantage regarding its cost, availability, convenience and quick results [3].

Sputum microscopy, Chest X-rays (CXR), and culture in solid and liquid media can all be used to diagnose and find TB. CXR, one of the most popular and cost-effective imaging tests worldwide, can be utilized for TB early detection [3]. Although CXRs are helpful for making an early diagnosis, radiologists may encounter difficulties, such as the inability to tell TB from other symptoms in some situations [4], [5].

Computer aided diagnosis (CADx) and computer aided detection (CADE) systems also known as CAD systems, have been shown to improve the accuracy of medical diagnoses, reduce false positives and false negatives, and potentially reduce the time needed for interpretation. However, like any diagnostic tool, CADE/x systems are not infallible and must be used in conjunction with clinical judgment and expertise. Overall, CADE/x systems are a valuable tool in modern medicine, helping medical professionals to make more accurate diagnoses and improve patient outcomes [6]. A CAD system traditionally consisted of four main stages; pre-processing, segmentation, feature extraction and classification [7].

To optimize the system and produce higher accuracy, a wide variety of techniques and algorithms can be applied at each step, in various combinations [8]. Classifiers make the final determination regarding the patient's health state among the four stages of a CAD system. Information from earlier stages is compressed and filtered to acquire the information that is most pertinent to the patient's health and is then fed to classifiers [9]. Machine learning emerged in the field of computer science that enabled computers to classify data without being explicitly programmed. As the field of machine learning (ML) research developed, many classification algorithms, including Decision Trees, Support Vector Machines (SVM), Genetic Algorithms (GAs), and Fuzzy Algorithms (FA), flourished [10-12]. However, Convolutional

Neural Networks (CNNs), perhaps more significantly, have recently demonstrated their reliability [13].

CNN is a deep learning technique which makes it ideal for big data. The arrangement of the visual cortex in the brain served as the model for CNN construction. It is made up of multiple layers of linked neurons that work in a hierarchical fashion to interpret information ranging from basic features like edges and corners to more intricate forms and patterns. [14].

The objective of this research is to investigate the effects of combining two main methods of pre-processing methods such as shear, zoom and flipping for augmentation and the robustness of U-Net mask for segmentation on the training set of a pre-trained CNN classifier in hopes to a high accuracy and AUC with the proposed method of pre-processing on binary and multi-classification. Hence, being able to classify different types of manifestations of TB in CXR images.

The literature review is discussed in Section II. Section III describes the chest X-ray dataset that is used and the proposed methodology for pre-processing, the performance measurements are also explained in this section. Section IV discusses the experiments conducted and results obtained by applying the proposed methodology on the CXR dataset and the comparison with other papers. Finally, the proposed research work is concluded.

II. RELATED WORK

To identify any lung-related disease on CXRs, Computer Assisted Diagnosis (CAD) has been extensively used. Methods involving machine learning alternatives to CNN have been researched as CAD systems. Some methods of TB detection make use of the segmentation of the lungs. Here, scientists attempt to separate the heart or lung structures before assessing them for any anomalies. Other research implements augmentation methods onto the CXR images, changing the parameters of the images within a designated range before feeding it into the machine learning model to achieve more reliable results.

Related works show research on other models used aside from CNN with pre-processing for detection of TB in CXR images. Antony B. et al. [15] attempted eliminating background noise by applying two segmentation methods, the CANNY algorithm and a median filter on 662 images. The results reported only an 80% accuracy as the highest accuracy while using a K-NN classifier in his paper, the highest accuracy among the other two classification methods (SMO and SLR).

To detect Tuberculosis in patients, Muhathir [16] used the K-NN classification method and HOG feature extraction technique. The results indicate that 70.90% of positive cases were correctly identified, with 234 out of 330 samples, while 72.72% of negative cases were correctly identified, with 240 out of 330 samples. The study shows that using the K-NN and HOG feature approach, the X-ray Set TB can be classified with an accuracy of 71.81% when using cross-validation.

Three alternative deep-learning models—AlexNet, ResNet-18, and DenseNet121—were tested in Jared et al. [17] study to

see which was most effective in identifying tuberculosis (TB) in CXR. For their training set, the researchers used 180,000 images, but they made no mention of data pre-processing. According to the findings, DenseNet121 had the highest accuracy (91%), with an Area Under Curve (AUC) ranging from 0.94 to 0.96. Although Jared et al. [17] did not rely on augmented photos to increase the size of the dataset, the high accuracy and AUC were probably caused by the numerous training images employed.

For the purpose of TB identification in CXR pictures, Syeda et al. [18] developed an ensemble model using the pretrained deep-learning models VGG-16, VGG-19, ResNet50, and GoogleNet. The ensemble's accuracy was 86.7% with an AUC of 0.92 after training on 600 images and 200 more; however, if any pre-processing techniques were used, the accuracy might have been enhanced with a bigger data set and variance to prevent overfitting problems.

Gordienko et al. [19] reported an increase in accuracy and loss after segmentation of 247 TB CXR images with a U-Net CNN and Bone Shadow Exclusion and using them for training a self-made seven-layer CNN. No reports of augmentation have been applied to the image, and with a low number of images overfitting could occur. It has only been reported that the test accuracy has increased, and the test loss has decreased.

Erdal [20] proposes and compares in his study, three methods of segmentation: bounding box, lung mask with black background and lung mask with white background. AlexNet, VGG16 and VGG19 deep-learning architecture were utilized for feature extraction and a Random Forest algorithm for classification. Accuracy reached 88.3% and AUC reached 0.93 as reported. Erdal [20] also reported that the lack of contrast enhancements and augmentation have acted as a limitation in his research.

Only using the Montgomery County (MC) TB CXR images dataset, with 138 images total of both abnormal and normal CXR images, Mustapaha & Serestina [21], have managed to multiply the total images up 5000 images through augmentation. Through their proposed CNN model a 87.1% accuracy was achieved.

Oposing previous studies that have utilized segmentation as a pre-processing technique for lung segmentation before feeding the images to the training model, such as the studies done by Erdal [20] and Gordienko et al. [19], Ahsan et al. [22] displayed that it is possible to achieve a comparable accuracy using the VGG-16 model without pre-processing segmentation. An accuracy of 80% was reached by the VGG-16 model and an accuracy of 81.25% when partial augmentation was applied.

Marcio et al. [23] combined the Montgomery, Shenzhen and PadChest CXR datasets with a total of 290 images, generating the training and test datasets using a HDF5 dataset generator, then applied augmentation. Marcio et al. [23] tested out three different pretrained CNN models being AlexNet, GoogleNet and ResNet50, achieving results between 0.78 and 0.84 AUC.

Similarly, Eman et al. [24] has used Montgomery and the Shenzhen Datasets and has used augmentation to multiply the dataset images up to 2040 images. However, Eman et al. [24]

have explored a more specialized and advanced array of CNN models; ConvNet, Exception, ResNet50, VGG16 and VGG19. All CNN models have achieved an accuracy above 87% and a maximum of 90% and an AUC of 0.91.

To summarize the presented related work, it can be concluded that there is emphasis on augmentation for improving classification models, while sometimes in other related works there is neglect of preprocessing. However, the benefits of segmentation in combination with augmentation remain unexplored as it is deemed more time-consuming and difficult, particularly when dealing with big or complicated data sets [22]. Addressing this underutilization of segmentation alongside augmentation is key to unlocking their full potential for classification performance.

The main contribution of this research is to develop a hybrid pre-processing method to enhance data quality by reducing noise and outliers, while normalizing data for more effective CNN learning. This study demonstrates that combining segmentation and augmentation as pre-processing enhances model accuracy.

III. METHODOLOGY

A. Datasets

The data sets that will be used during the experimental stage are all obtained from online open-source image databases:

1) *Shenzhen dataset*: The dataset was collected in collaboration with Shenzhen No. 3 People's Hospital, Guangdong Medical College, Shenzhen, China. It contains 662 cases of chest X-rays, including 326 normal cases and 336 tuberculosis cases [25].

2) *Montgomery (MC) dataset*: The dataset was collected from the Department of Health and Human Services in partnership with Montgomery County, Maryland in the United States. The group consisted of 138 frontal chest radiographs from the Montgomery County Tuberculosis Screening

Program, of which 80 were normal and 58 were tuberculosis [25].

The datasets were divided into training/validation dataset and test dataset with a respective ratio of 80:20.

B. Flowchart

The flowchart in Fig. 1 outlines the process of training a VGG16 CNN model for image classification. The training dataset is pre-processed with ZCA, normalization, U-net segmentation, and augmentation techniques in that specific order before being used to train the model. The validation dataset is used to monitor model performance during training, and the test dataset is used for prediction and calculating model performance metrics.

C. Data Pre-Processing

Image resizing to 227x227, Mean Normalization and Standardization were applied to the set before segmentation and augmentation. Regarding segmentation, U-net CNN segmentation is being utilized for the pre-processing segmentation.

1) *Normalization and ZCA*: Normalization is used to scale the pixel values of an image to a range between 0 and 1. This is done to ensure that the pixel values are in a consistent range and to prevent the dominance of certain pixel values. Normalization is often done by dividing each pixel value by the maximum pixel value in the image [26]. ZCA is used to remove the correlation between the different color channels in an image. This is important because the color channels may be correlated, which can lead to redundant information and increased computational complexity. ZCA whitening transforms the image data so that each pixel value is uncorrelated with every other pixel value. This is done by performing eigenvalue decomposition of the covariance matrix of the pixel values and then transforming the data using the eigenvectors [27]. Both normalization and ZCA are useful for improving the performance of machine learning models on image datasets.

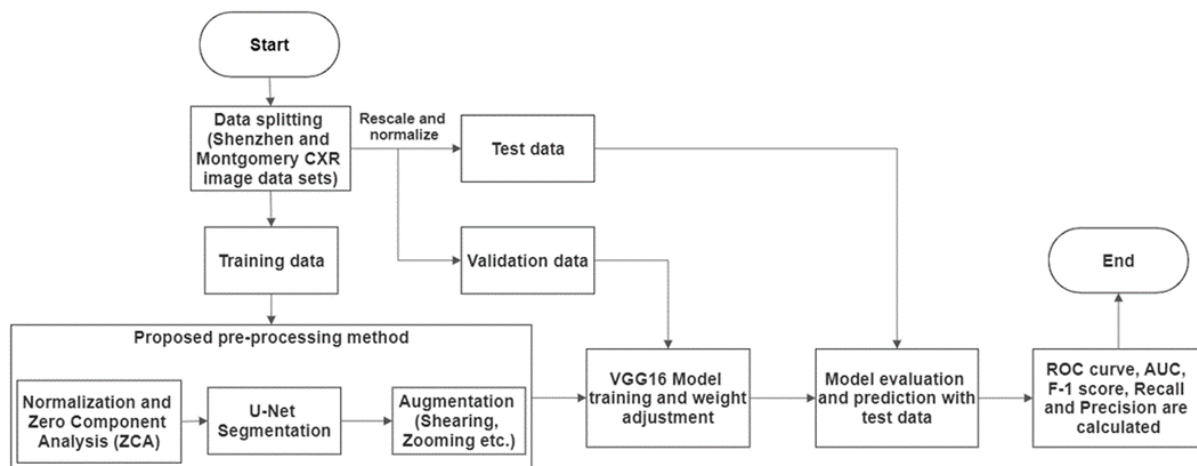

Fig. 1. Flowchart of simulation including the proposed method.

2) *U-net segmentation*: U-net CNN is a CNN designed for segmentation of biomedical images. What makes U-net stand out from other general convolutional neural networks is that general CNNs need to focus on image classification in biomedical cases, hence they require the user to identify the presence of a disease and localize the area of said disease. U-net eliminates this issue by applying classification to each pixel and can distinguish and localize borders by itself [28]. This method of segmentation could help eliminate the need for manual segmentation.

An expanding path and a contracting path make up the U-Net architecture. The contracting path is composed of convolutional layers followed by max-pooling layers, much like a conventional convolutional neural network. This path's goal is to minimize the spatial dimensionality of the input image while capturing its context.

The segmented image is localized using the expanding path, and the low-resolution feature maps created by the contracting path are upsampled. This path concatenates the corresponding feature maps from the contracting path with transposed convolutions to increase the spatial dimensionality of the features. This process is repeated several times to recover the original resolution of the input image.

The U-Net architecture also incorporates skip connections, which connect feature maps from the contracting path to feature maps from the expanding path. These connections aid in protecting the input image's small features, which can be lost during down sampling. That is where it gets its U shape from as seen in Fig. 2.

Many image segmentation tasks, including medical picture segmentation, cell segmentation, and object detection, have proven to be successful when using U-Net. It works particularly effectively in cases when the input images are tiny and the borders of the items that need to be divided are clearly defined [28].

3) *Augmentation*: Several transformations of augmentation were applied to the segmented images to increase the dataset's variability. The following augmentations were performed:

- Rescale transform every pixel value from range [0,255]
- Random rotations were applied up to 0.2 radians.

- Random shifts were applied to the width and height dimensions up to 0.1.
- Random shearing was applied for a maximum shear of 0.2.
- Zoom range up to 0.2.
- Horizontal and vertical flips.

D. VGG16 CNN Classifier

The VGG-16 architecture consists of 16 layers, including 13 convolutional layers, and three fully connected layers. It uses small 3x3 convolutional filters with a stride of 1 pixel, and max pooling layers with a 2x2 filter and stride of 2 pixels, which helps reduce the spatial dimensionality of the features.

The output of the last convolutional layer is flattened and fed into the fully connected layers, which perform classification on the input image. The final layer uses SoftMax activation to produce a probability distribution over the image classes.

Object detection, picture segmentation, and style transfer are just a few of the computer vision applications for which the VGG-16 architecture has been extensively employed as a pre-trained model [29]. Its popularity is a result of its efficiency and simplicity, which make it a reliable benchmark model for comparison with other designs.

1) *Fine-tuning*: The VGG-16 CNN model's weights are pretrained on a massive image dataset known as ImageNet. ImageNet is mostly comprised of natural and colorful pictures of animals and food, which deviates from what monochromatic Chest X-rays are. Fine-tuning the pretrained weights of the VGG-16 can be accomplished by unfreezing the weights of the 5th block of layers of the model. The unfreezing will increase the computation time needed for training the model, but it might result in more optimized weights [30].

2) *ADAM optimizer*: In order to calculate the difference between a neural network's predicted and actual output during training, the Adaptive Moment Estimation (ADAM) optimizer utilizes a loss function [31]. The optimizer then modifies the neural network's weights in accordance with the gradient of the loss function relative to the weights. Table I displays the hyperparameters used during experimentation.

Fig. 2. The U-Net architecture displayed with the arrows denoting different operations [28].

TABLE I. HYPERPARAMETERS USED DURING EXPERIMENTATION

Hyperparameter	Values considered
Batch size	32,64
Number of epochs	30,40,50
Learning rate	0.001, 0.0001, 0.00001
Embedded dropout rate	0.3,0.5,0.7
Embedded activation function	Sigmoid
Optimizer	ADAM
Number of unfrozen layers	4 layers (5 th block)

E. Performance Evaluation Metrics

1) *Confusion matrix*: A confusion matrix is a table used to evaluate the performance of a classification algorithm by comparing the predicted and actual values of a dataset as seen in Table II. The matrix is organized into rows and columns, with each row representing the instances in a predicted class, and each column representing the instances in an actual class. The diagonal of the matrix represents the instances that were correctly classified, while the off-diagonal elements represent the instances that were misclassified.

The confusion matrix provides a useful way to visualize the performance of a classifier, and it can be used to calculate various metrics such as accuracy, precision, recall, and F1 score.

TABLE II. CONFUSION MATRIX

Actual values	Predicted values	
	Yes (Predicted class)	No (Predicted class)
Yes (Actual class)	True Positive (TP)	False Negative (FN)
No (Actual class)	False Positive (FP)	True Negative (TN)

- True Positive (TP): Number of patients correctly classifies as having TB.
- True Negative (TN): Number of patients correctly classified as not having TB.
- False Positive (FP): Number of patients incorrectly classified as having TB.
- False Negative (FN): Number of patients incorrectly classified as not having TB.

2) *Accuracy*: Accuracy of the model can be calculated from the confusion matrix by the following mathematical equation:

$$Acc = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

3) *Precision*: Precision measures how many of the model's positive predictions were right. A high precision indicates that the model made few incorrect positive predictions and is a good indicator of how well the model detects positive cases. The precision mathematical equation is as follows:

$$P = \frac{TP}{TP + FP} \quad (2)$$

4) *Recall*: The model's recall evaluates how successfully it detects positive cases out of all actual positive cases. A high recall indicates that the model is good at recognising positive examples, whereas a low recall indicates that the model is missing many positive cases. The recall mathematical equation is as follows:

$$R = \frac{TP}{TP + FN} \quad (3)$$

5) *F1 score*: The F1-score is a measure of the balance between precision and recall. The F1-score is a useful metric for evaluating the overall performance of a binary classification model, especially when the classes are imbalanced. The F1-score equation is as follows:

$$F1 = \frac{2(Recall * Precision)}{(Recall + Precision)} \quad (4)$$

6) *ROC curve and AUC*: An ROC (Receiver Operating Characteristic) curve is a plot used to visualize the performance of a binary classification model. It is created by plotting the true positive rate (sensitivity) against the false positive rate (1-specificity) at different classification thresholds, as seen in Fig. 3.

AUC (Area under the ROC Curve) is a valuable metric for evaluating the performance of binary classification models and is commonly used in a variety of machine learning applications. AUC represents the area under this curve, which ranges from 0 to 1. A perfect classifier would have an AUC of 1, while a random classifier would have an AUC of 0.5.

Fig. 3. ROC curve - A plot of true positive rate vs false positive rate.

IV. RESULTS AND DISCUSSION

A. Experiments

A total of three experiments have been conducted in this study to observe the effects of the hybridization of the pre-processing methods, such as no segmentation and augmentation (experiment 1), with segmentation only (experiment 2) and with augmentation and segmentation (experiment 3), where the results are discussed in terms of the confusion matrix and the other performance measures

discussed in Section III. The test data set consists of 160 CXR images with 80 TB positive cases and 80 normal cases.

B. Proposed Pre-Processing Method Performance

The hybridized pre-processing method used in experiment 3 has achieved a higher performance in comparison to experiment 1 and 2, as seen in the metrics achieved in the confusion matrix in table 3 and the performance measures in table 4, with an accuracy of 90%, a recall of 87.5%, a precision of 92.11% and a F1-score of 0.8975. Regarding the AUC shown in Fig. 4, out of the 3 experiments the proposed method has produced the best ROC curve and an AUC of 0.935, followed by 0.89 from experiment 2 and 0.87 from experiment 3, as seen from the confusion matrix table in Table III and the performance metrics table in Table IV.

C. Result Discussion

In this section, the discussion will progress from a baseline with no preprocessing to segmentation alone, and finally to the combined use of both techniques, the study systematically highlights their individual and joint impacts on model accuracy. This approach effectively highlights the research's

focus on demonstrating the effectiveness of segmentation and the combination of both segmentation and augmentation.

The first experiment has an accuracy of 82.5% and an AUC of 0.87 and does not use segmentation or augmentation. For the performance of the model, this approach is regarded as the standard. The input data is supplied straight to the CNN model without segmentation or augmentation, which may cause the data to be overfitted or underfitted.

The accuracy and AUC of the second experiment, which only uses segmentation, are 86.25% and 0.89, respectively. This method significantly outperforms the baseline method in terms of accuracy, proving that segmentation can increase the quality of the input data used to train the CNN model.

The third experiment involves both segmentation and augmentation and achieved 90% accuracy and an AUC of 0.935. This method shows the highest accuracy and AUC compared to the other two experiments. The combination of both segmentation and augmentation techniques could have helped the model to isolate important features and improve the robustness of the model.

Fig. 4. ROC curves of experiment 1 (top left), experiment 2 (top right) and experiment 3 (bottom middle).

TABLE III. THE CONFUSION MATRIX OF EXPERIMENT 1-3 REPRESENTED IN NUMBER OF IMAGES

Experiment No.	Confusion matrix			
	True positive	True negative	False positive	False negative
1	56	76	4	24
2	64	74	6	16
3	70	74	6	10

TABLE IV. PERFORMANCE MEASURES CALCULATED FROM THE CONFUSION MATRIX

Experiment No.	Performance measures			
	Accuracy	Recall	Precision	F1-score
1	82.5%	70%	93.33%	0.8000
2	86.25%	80%	91.43%	0.8533
3	90%	87.5%	92.11%	0.8975

TABLE V. OVERALL CLASSIFICATION ACCURACY AND AUC COMPARISON WITH PREVIOUS RESEARCH WORK

Reference	CNN model	Dataset	Pre-processing	Overall Accuracy Rate and AUC
Proposed pre-processing method	VGG-16	Shenzhen and Montgomery	Augmentation and U-Net segmentation	90% and 0.935
Syeda et al. [18]	Ensemble (VGG-16, VGG-19, ResNet50 and GoogleNet)	Shenzhen and Montgomery	None	86.7% and 0.92
Ahsan M et al. [22]	VGG-16	Shenzhen and Montgomery	Augmentation	81.25% and 0.89
Erdal [20]	Ensemble (VGG-16, VGG-19, AlexNet, Random Forest)	Shenzhen	Manual segmentation	88.3% and 0.92

D. Comparative Analysis

The overall accuracy rate and AUC comparison of the various pre-processing methods from previous work is represented in Table V. For a valid comparison, the author has compared the proposed pre-processing method with other applications of pre-processing from the related works in Section II. It's crucial to maintain the experimental parameters as consistently as feasible.

The proposed pre-processing method, which included VGG-16, augmentation, and U-Net segmentation, achieved the maximum accuracy of 90% and AUC of 0.935, illustrating the efficiency of these techniques in improving the model's ability to generalize and detect essential traits in CXR images. Syeda et al.'s [18] technique showed lower accuracy and AUC even when employing multiple architectures, demonstrating that augmentation and segmentation are still beneficial and necessary in improving model performance.

As demonstrated by Ahsan M. et al.'s [22] method, augmentation alone was unable to improve model performance with a small data set size. While manual segmentation is useful as shown by Erdal [20], it is time-consuming and error-prone, and U-Net's ability to segment major features in images makes it more effective and robust for CAde systems.

V. CONCLUSION

In conclusion, the results of the study have shown that applying both segmentation and augmentation techniques can lead to better performance measures in terms of accuracy, AUC, recall, precision, and F1-score when classifying TB related CXR images compared to using only one or none of these techniques.

Augmentation has become a popular technique in recent years, and for good reason. It allows for the creation of a large and diverse training set without the need for additional data collection efforts, which can be time-consuming and costly. However, augmentation alone may not always be sufficient, particularly when dealing with complex images with intricate features or objects.

Furthermore, while manual segmentation can be effective in capturing important details in the images, it is not robust or flexible enough to be widely used in computer-aided detection systems. The rise of automatic segmentation methods such as U-Net has made segmentation more viable as a pre-processing technique for image analysis tasks. Overall, the findings suggest that researchers consider using both segmentation and augmentation techniques as pre-processing methods when developing CAde systems.

ACKNOWLEDGMENT

The authors would like to thank Ministry of Higher Education (MOHE), Malaysia and Universiti Teknologi PETRONAS for supporting this work through a Research Grant, FRGS, (Ref: FRGS/1/2022/TK07/UTP/02/4) and Cost Centre, (015MA0-159).

Abstract—Stroke is an important health issue that affects millions of people globally each year. Early and precise stroke diagnosis is crucial for efficient treatment and better patient outcomes. Traditional stroke detection procedures, such as manual visual evaluation of clinical data, can be time-consuming and error-prone. Computer-aided diagnostic (CAD) technologies have emerged as a viable option for early stroke diagnosis in recent years. These systems analyze medical pictures, such as magnetic resonance imaging (MRI), and identify indicators of stroke using modern algorithms and machine learning approaches. The goal of this review paper is to offer a thorough overview of the current state-of-the-art in CAD systems for early stroke detection. We give an examination of the merits and limits of this technology, as well as future research and development directions in this field. Finally, we contend that CAD systems represent a promising solution for improving the efficiency and accuracy of early stroke diagnosis, resulting in better patient outcomes and lower healthcare costs.

Keywords—Stroke diagnosis; CAD system; machine learning; deep learning

I. INTRODUCTION

Stroke, also known as cerebrovascular illness, is the third highest cause of death in Malaysia. In 2019, there were 47,928 fatalities, 443,995 common cases, and 512,726 DALYs lost due to stroke. [1] According to a White Paper on Acute Stroke Care in Malaysia by the Galen Centre for Social Health and Policy, commissioned and funded by Boehringer Ingelheim (Malaysia), only 21% of stroke patients were able to be treated at a medical facility within three hours of the onset of symptoms, while the median time from the onset of stroke symptoms to arrival at a hospital was seven hours or more [2]. Stroke is a disease that arises when an artery or blood vessel becomes clogged or ruptured, resulting in decreased blood flow and oxygen delivery to the brain which leads to temporary or permanent failure in humans; an untreated stroke can result in death [3]. Strokes are classified into two types: ischemic and hemorrhagic as shown in Fig. 1. Ischemic strokes are caused by artery blockages or occlusions caused by plaque build-up along the inner lining of the arteries. This kind of stroke occurs in more than 80% of cases, typically abruptly and without warning. Hemiparesis is the most common symptom of an ischemic stroke, which occurs when one side of the body suddenly becomes weak or unable to move. Hemorrhagic stroke is caused mostly by the rupture of cerebral blood vessels, aneurysms, or physical trauma. More than half of people who survive this type of stroke will have a serious

disability. Both the effects of a stroke and the recovery process are particular to each individual. However, only 107 neuroradiologists were supposedly available to treat patients, with at least one of them in every state hospital in our country where it is very critical and limited. Also, the traditional method of analyzing clinical data for stroke diagnosis involves manual visual inspection, which is a time-consuming process. Unfortunately, delayed stroke diagnosis and treatment can lead to brain cell death, as individuals become disabled due to a lack of oxygen and blood flow.

Technological developments in healthcare have led to various enhancements in disease diagnostics. Medical Imaging, which includes Cone Beam Computed Tomography (CBCT), Computed Tomography (CT), and Magnetic Resonance Imaging (MRI), is one of them. This technology is capable of producing specific images of a particular area based on the imaging techniques used. To diagnose stroke patients, radiologists use CT and MRI scans. However, detecting irregularities in the images can be challenging since recent research has shown that the patient's life can potentially be saved if treatment is initiated within the first six hours of a stroke. This period is referred to as the "Golden hours." [4] MRI is a medical imaging technology that employs a powerful magnet, radio waves, and computer to create highly detailed images without the use of radiation. According to Nouf Saeed Alotaibi's research in 2022, MRI is currently the most precise imaging test for brain medical imaging when compared to other technologies like CT scans or X-rays. Magnetic resonance imaging (MRI) is increasingly being used in the diagnosis and treatment of acute ischemic stroke due to its high sensitivity and relatively high specificity in detecting abnormalities that occur after such strokes [5]. The MRI process involves using T1, T2, Flair, DWI, and Black Blood sequences to gather data that must be obtained within 6 hours after the stroke that referred to as the "golden hour of stroke."

Some researchers have developed computer-aided diagnosis (CAD) systems for MRI to address the limitations of manual visual inspection for stroke diagnosis. These systems analyze MRI images using algorithms and machine learning approaches to detect anomalies associated with acute ischemic stroke. CAD systems can save time and minimize the strain on neuroradiologists by automating the analysis procedure. Furthermore, CAD systems may improve the accuracy of stroke diagnosis, resulting in earlier treatment and better patient outcomes. CAD systems for MRI stroke diagnosis are often divided into phases. MRI images are first pre-processed

to reduce noise and artefacts. Following that, feature extraction techniques are used to identify key image characteristics associated with strokes. Finally, a machine learning system is trained on a collection of MRI pictures with established stroke diagnoses to identify fresh images as normal or suggestive of acute ischemic stroke. Recent research has demonstrated that CAD systems can detect acute ischemic stroke in MRI images with great accuracy. In one study, for example, a CAD system was shown to have a sensitivity of 93% and a specificity of 95% in diagnosing acute ischemic stroke in brain MRI data. Another study discovered that a CAD system could distinguish between acute and chronic ischemic strokes with 95% accuracy. Overall, CAD systems for MRI stroke diagnosis have the potential to increase the efficiency and accuracy of stroke diagnosis, thereby shortening treatment time.

In conclusion, in the past few years, CAD systems have demonstrated great potential in enhancing the speed and precision of stroke diagnosis as well as enabling prompt and efficient treatment. This review paper aims to present a thorough summary of the latest diagnosis methods and system algorithms in CAD systems, with the goal of achieving early stroke detection. The purpose of this paper is to examine the application of these systems in modern stroke treatment research and showcase the latest developments in this area. Furthermore, this review will delve into the advantages and disadvantages of CAD systems and investigate the obstacles and prospects for additional research and enhancement. And lastly, our hope is to contribute to global efforts to enhance stroke diagnosis and treatment by conducting a critical assessment of the latest advancements in CAD systems for the early detection of stroke.

Fig. 1. Comparison of Ischemic and Hemorrhagic stroke [4].

II. MEDICAL IMAGING MODALITY FOR STROKE DIAGNOSIS

Modern advancements have resulted in a variety of methods for treating and diagnosing early stroke. These include a variety of approaches for diagnosis and assessment that doctors can use to provide the best therapy possible depending on the patient's medical history. The first step in diagnosing a stroke patient is determining if the patient is suffering from an ischemic or hemorrhagic stroke so that appropriate therapy may begin. The initial test is a CT scan or an MRI of the head for the early diagnosis of stroke.

A. Magnetic Resonance Imaging (MRI)

MRI has been the primary neuroimaging modality in several specialized clinics for critical-stage stroke in recent years, allowing pathophysiological evaluation of critical-stage stroke. In the brain, MRI can differentiate between white matter and grey matter and can also be used to diagnose aneurysms and tumours [3] [5]. MRI is the preferred imaging modality for diagnosis and therapy in the brain. Due to its sensitivity, accuracy, extension, and age, MRI is the most instructive imaging technique. Besides DWI and SWI, one of the sequences that latest in MRI is BB sequence (Black Blood Sequence) compared to conventional sequence: T1, T2 and Flair. Apart from DWI and SWI, one of the most recent MRI sequences for stroke is the BB sequence (Black Blood Sequence), as opposed to the conventional sequences: T1, T2, and Flair. Fig. 2 shows a comparison of brain lesions in BB sequence with CE T1, where study shows that BB-based automatic detection is more sensitive than MP-RAGE of CE T1 and has greater potential benefits in terms of automated CNN-based detection. MRI black blood imaging (BB) suppresses intraluminal blood signal throughout the field of view without reducing the signal strength of tiny abnormal region or lesion, allowing human readers to detect brain lesions [6]. Fig. 2 shows the comparison of the same lesion in different modalities; BB sequence and CE-T1 sequence of MRI.

Fig. 2. Left, lesion in the Black Blood sequence (BB). Right, corresponding axial conventional Contrast-Enhance T1 slice with identical lesion. [6].

B. Computed Tomography (CT)

A CT scan is a diagnostic imaging process that produces pictures of the interior of the body using X-rays and computer technologies. It displays comprehensive views of every bodily component, including the bones, muscles, fat, organs, and blood vessels. The X-ray beam in CT moves in a circle around the body. This allows for many views of the same organ or structure and gives far more information. Hence, CT is the most effective imaging modality for acute ischemic stroke because of its availability, low cost, and quick acquisition time [7, 8]. CT also act as a standard in the early examination of acute stroke patients because it can readily and quickly see cerebral hemorrhages (as shown in Fig. 3) [9]. Dynamic contrast-enhanced (DCE)-CT is also utilized in clinical practice to improve image resolution and to examine the microvasculature of brain structures and other organs. In DCE-CT imaging, an iodine-based contrast agent is administered intravenously into the patient's body, affecting the measured X-ray absorption in tissues, and leading in contrast enhancement in the produced picture. At last in this section, Fig. 4 illustrated the three different samples of modalities including CT, Flair and DWI of MRI images.

Fig. 3. CT scans against MRI scans for stroke detection. (A, B) A hemorrhage may be plainly observed in a patient's CT scan (A; white arrow), although it is less visible in an MRI scan (B; white arrow). (C, D) An ischemic infarct is just faintly visible in a C. [9].

Fig. 4. Sample of CT images, MRI Flair and DWI sequences images [10].

III. STROKE DIAGNOSIS SYSTEM

Modern stroke detection devices, such as computed tomography (CT) and magnetic resonance imaging (MRI), may aid an experienced radiologist in determining if a patient has suffered a stroke; however, if a general radiologist makes an incorrect diagnosis, the patient may miss the best time for treatment. As a result, improving the quality of the diagnostic picture is crucial for assisting the physician in making an accurate diagnosis or image identification. In terms of stroke risks, different computer-aided diagnostic (CAD) systems have been created to help physicians diagnose and treat stroke patients. These methods enabled the identification of early cerebrovascular accident (CVA) symptoms and contributed to increased diagnosis accuracy for acute strokes. A notable trend is machine learning research and end-to-end system design for computer-aided stroke diagnosis and classification. Hence, there are already some important papers and developed systems for the binary classification of stroke presence or absence and hemorrhagic or ischemic stroke [11].

A. Computer-aided Diagnosis System (CAD)

The CAD technique has been used in medical imaging for illness diagnosis, prognosis, treatment decision assistance, and therapeutic monitoring. Manual segmentation in MRI takes a long time because specialists must examine several pictures of the brain taken in different orientations using different pulse

sequences [10]. Moreover, there is the possibility of inter- and intra-observer biases. These limitations can be overcome by semi-automated and automated machine learning-based CAD systems for identifying and segmenting ischemic stroke lesions, enabling high-throughput image screening for faster, reproducible, and more sensitive detection of ischemic stroke lesions. The automated delineation of the precise topology of stroke lesions allows for quantitative evaluations of infarct size and/or salvage ability, which is important for prognosis and therapeutic decision-making. A typical stroke CAD system consists of distinct sequential stages as referred to in Fig. 5.

Fig. 5. Overview of typical Computer-Aided Diagnosis (CAD) system for end-to-end stroke detection.

Apart from that, several methodologies have been used to assess the performance of CAD systems in preparation for commercialization. Methods such as leave-one-out, cross-validation, hold-out, and resubstituting are examples of these techniques. The pattern recognition process in classical and current CAD medical algorithms typically consists of three major phases; however, completion of all three steps is not required. These processes are as follows: pre-processing of medical pictures, including segmentation and identification of areas of interest (ROI), extracting automatically produced or hand-engineered features from human specialists, and data categorization according to those characteristics in Fig. 5. Current CAD algorithms can offer output data without going through all of these processes; this became feasible with the development of neural networks with several hidden layers. [12]. There are also several types of processing phase in CAD as shown in Fig. 6.

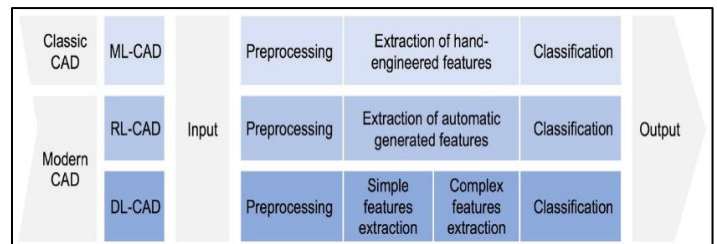

Fig. 6. Several types of processing phases in CAD including ML-CAD(Machine Learning based), RL-CAD(Representation Learning based) and DL-CAD(Dep Learning based) [12].

B. Machine Learning Technique

Watershed segmentation is a segmentation technique that uses gradients. The watershed transformation considers the size of the image's gradient as a topographic surface. The water flow line, which indicates the region's borders, corresponds to pixels with the maximum gradient magnitude intensity (GMI). Water is placed on any pixel that is surrounded by flowing stream water that flows naturally down to the minimal local average intensity. Pixels flow into the same shape as the segment's catchment basin. The watershed transform has a severe disadvantage in that it has a propensity to over-segment the picture. To evade this constraint, the object's position must be inferred using instance markers, which can guide the selection of a subset of these basins. [13]

Fuzzy C-Means (FCM) is an excellent data analysis, pattern recognition, picture segmentation, and fuzzy modelling algorithm [13]. It is a well-known soft clustering method and one of the most promising fuzzy clustering methods. Fuzzy clustering algorithms are preferable because they can more intuitively describe the link between input pattern data and clusters [14]. It is more flexible than the analogous hard-clustering approach in most circumstances, as it uses a membership function to connect each pattern to each cluster. Clustering, but not partitioning, is the result of such algorithms. A hybrid technique involving the K-means and FCM algorithms was proposed, which enhanced the accuracy in diagnosing brain infarct with lower processing costs (Fig. 7 to 9 [10]).

Fig. 7. Original DWI sample image.

Fig. 8. Morphological binary image from sample image in Fig. 7.

Fig. 9. Orange marking on detected infarct.

The K-Means algorithm is a clustering approach that is used to identify the optimal answer by continually decreasing the distance of components from their cluster centre and increasing the cluster. Since the k-performance algorithm is reliant on the beginning value of the cluster centre, strategies must be tested numerous times for varied results with different initial cluster centres [15]. The primary drawbacks of this approach are that the number of clusters is unexpected and that it is sensitive to the initial cluster centres. To circumvent this constraint, a statistical calculation or cluster verification approach is necessary [13]. Hence, the overview comparison in pros and cons of these 3 techniques are shown in Table I.

TABLE I. OVERVIEW COMPARISON SEGMENTATION TECHNIQUES (FCM, K-MEANS, WATERSHED) [10] [14] [15]

Segmentation Technique	Advantages	Disadvantages
Watershed Transform [10]	Several areas are segmented at the same time. It produces a complete contour of the images and avoids the need for many contours to be joined.	Over segmentation could be easily obtained.
Fuzzy C-Means [14]	Defines a distinct border for the split region.	Sensitive to noise.
k-Means [15]	If k is kept small, it is faster to compute than hierarchical clustering.	The exact number of clusters is unknown.

As for image classification in medical imaging, especially for stroke, Support Vector Machines (SVM) are classified as a classification technique, whereas it can be used in both classification and regression situations. It is capable of handling a large number of continuous and categorical variables. SVM is also classified as one of the supervised learning classification techniques that builds a hyperplane (or series of hyperplanes) in a higher-dimensional space to classify. SVM iteratively develops ideal hyperplanes, which are used to minimise errors. SVM's core notion is to determine the maximum marginal hyperplane (MMH) that optimally allocates a dataset into classes, as shown in Fig. 10. SVM was utilised to appropriately identify them as benign tumours, malignant tumours, or healthy brains. Support Vector machines (SVMs) have substantial computational advantages [16].

Fig. 10. Support Vector Machines techniques (SVM) [16].

Random-forest classification is a prominent supervised classification approach. Random forest classifiers are trained classifiers that are used to outline the borders of feature space points that belong to various classes, with the purpose of minimizing the margin between classes (like a SVM classifier) [17]. The random forest is made up of a few decision trees that have been trained to accept input values (feature vectors) and assign membership values to the lesion or background groups as illustrated in Fig. 11. The random forest's final predictions are formed by averaging the results of each individual tree, which tends to over fit the training data, but the random forest may reduce that issue by averaging the prediction results from multiple trees. As a result, random forests outperform single decision trees in terms of predicting validity. A study recommended that dense conditional random fields (CRF), which are frequently used as a post processing step to generate more spatially contiguous segmentations, be implemented as an optimizer in system [18]. The features used for training in RF-based multilayer cascaded RFs are still based on independent voxels and their neighbours, whereas in dense CRFs, the inference process implicitly assumes conditional independence between voxels, which may lose correlation constraints between directly adjacent voxels.

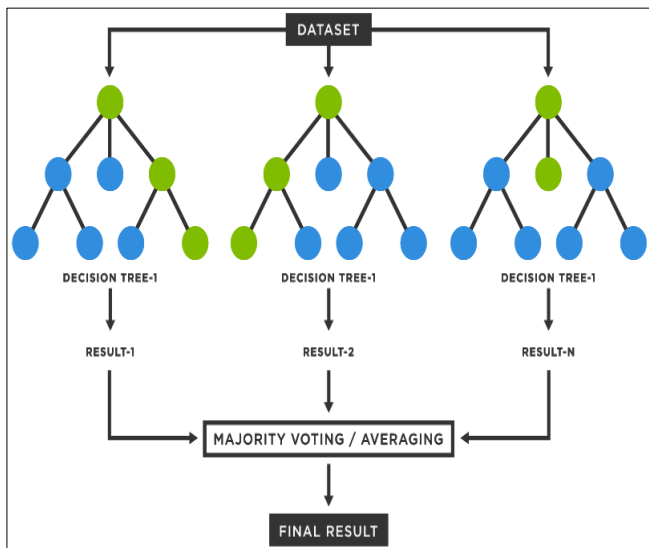

Fig. 11. Random Forest techniques (RF) [19].

C. Deep Learning Technique

Deep learning algorithms have consistently demonstrated transformative performance in a variety of tasks, most notably medical image analysis as shown in Fig. 12. Convolutional neural networks have been particularly successful in identifying and classifying patterns in medical images, leading to improved diagnosis and treatment planning. Additionally, deep learning models can also assist in predicting patient outcomes and detecting anomalies that may be missed by human observers. Convolutional neural networks are now a deep learning technique commonly used in computer vision tasks like radiography. It is designed to learn spatial information by backpropagation, utilizing numerous building blocks to achieve exceptional results in image identification. Deep learning models along with the application of CNN are being considered as methods for imaging acute ischemic strokes. Illustrated by a convolutional neural network (CNN), systematically pulls measurements from many samples in order to acquire more sophisticated abstract features for classification, recognition, and segmentation, enabling intelligent MRI interpretation [20]. It computed neural network characteristics and developed code for use in CNN input stages and passing signals with geometric detail. The visual cortex field interacts with individual cortical neurons belonging to the scanning field but does not transmit CNN weak signals. CNN nodes are linked, but not all-to-all links in a geometrical framework. In the image processing input layer, nodes are assigned to generate spectrum ranges for scanning components and shapes. All comparable structures and images (the kernel) are derived. The picture was transmitted to MRI outputs through kernel signals [7].

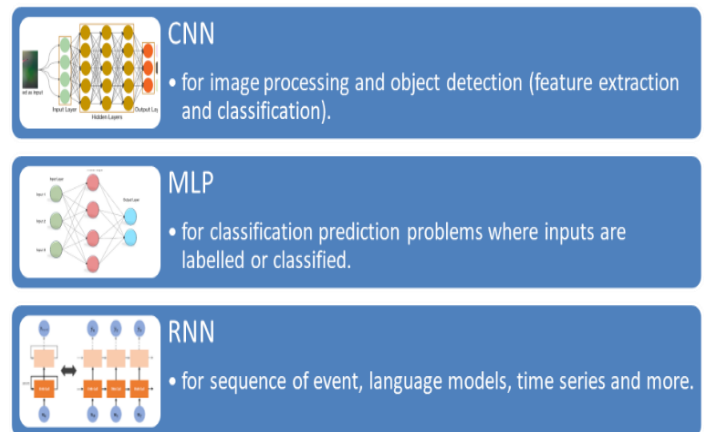

Fig. 12. Deep learning algorithm.

IV. RESULTS AND DISCUSSION

This section provides an inventory of findings from a variety of recent research initiatives that have used ML and DL approaches to construct early stroke diagnostic systems based on MRI data. We shed light on the findings of these research by thorough classification and theme analysis, uncovering recurring trends, diverse outcomes, and methodological variances as shown in Table II. The given results included a wide range of performance parameters, highlighting accomplishments in sensitivity, specificity, and diagnostic accuracy. Notably, we investigate how dataset sizes,

architectural choices, feature extraction approaches, and pre-processing procedures affect the effectiveness of these systems. We provide a panoramic picture of the state-of-the-art in ML and DL-powered stroke detection by aggregating these findings, revealing the shared discoveries that contribute to the progress of this critical medical application.

Drawing on the findings of Yannan Yu and colleagues' work, the core approach used focuses on the use of deep learning U-Net for determining Final Ischemic Stroke patients [21]. The findings of this study demonstrate a dichotomy of results, defined into two separate categories: minor instances (n = 32), with a dice score coefficient (DSC) of 0.58 (0.31-0.67), and major instances (n = 67), with a DSC of 0.67 (0.29-0.65). Furthermore, Hyuna Lee and colleagues conducted remarkable work on stroke detection, utilizing a variety of methodologies such as Logistic Regression, Support Vector Machine (SVM), and Random Forest. The findings of this comprehensive method show that Logistic Regression has a sensitivity parameter of 75.8%, while SVM and Random Forest both have a noteworthy 72.8% sensitivity [22].

Yusuf and colleagues also made significant contributions, exploring hemorrhagic and ischemic stroke using deep learning CNN approaches, especially improved MobileNetV2 and EfficientNet-B0 models. In stroke detection, the updated MobileNetV2 model obtains a remarkable accuracy of 96% (: 0.92), whereas the modified EfficientNet-B0 model achieves 93% (: 0.86). Not content with diagnosis, they expand their investigation towards vascular territorial categorization, revealing outstanding accuracy rates of 93% (0.895) using the modified MobileNetV2 model and 87% (0.805) using the modified EfficientNet-B0 CNN model [11].

Meanwhile, Sercan and colleagues focus their work on brain tumour and ischemic and hemorrhagic stroke lesion studies, using deep learning capabilities through the CNN-D-UNet architecture. Their sophisticated technique yields precision levels of 0.99 and accuracy levels of 0.989 for brain tumours, while precision and accuracy levels for brain stroke lesions are commendably documented at 0.986 and 0.985, respectively [23].

Adriell adopts a more specialised approach, concentrating just on hemorrhagic stroke segmentation using the Mask R-CNN technique and fine-tuning it to get results with a remarkable accuracy of 99.72% 0.24 and sensitivity of 99.97% 0.06 [24]. Fathia's research focuses on ischemic stroke and employs a trinity of deep learning techniques - CNN, U-Net, and Fine Tuning. Their efforts were rewarded with an average accuracy of 99.77% and a Dice Coefficient of 55.77% [25].

Finally, a notable work released in 2023 by Hongyu Gao and colleagues explores the landscape of Acute Ischemic stroke using a repertory of CNN, SVM, and Random Forest approaches. Significantly, the results highlight the CNN classifier's dominance, with an exceptional area under the curve (AUC) of 0.935, validating its usefulness in the domain [26].

TABLE II. OVERVIEW OF THE COMPARISON BASED ON RECENT RESEARCH

Author	Type of lesion	Technique used	Result parameter
Yannan Yu, 2020 [21]	Final Ischemic Stroke Lesions	U-Net	Minimal (n = 32): DSC=0.58(0.31-0.67) Major (n = 67): DSC= 0.48 (0.29-0.65)
Hyuna Lee, 2020 [22]	Stroke	Logistic regression SVM Random Forest	Sensitivity Logistic Regression = 75.8%, p: 0.02 SVM = 72.7%, p: 0.033 Random Forest = 75.8%, p: 0.013
Yusuf Kenan Cetinoglu 2021 [11]	Hemorrhagic and Ischemic stroke	CNN Modified MobileNetV2 EfficientNet-B0	Modified MobileNetV2: 96% (κ : 0.92) - EfficientNet-B0: 93% (κ : 0.86)
Sercan Yalçın 2022 [23]	Brain Tumor Ischemic and hemorrhagic stroke	CNN D-UNet	Brain Tumor: Precision: 0.99, Accuracy: 0.989 Brain Stroke: Precision: 0.986, Accuracy: 0.985
Adriell Gomes Marques 2022 [24]	Hemorrhagic stroke segmentation	Mask R-CNN Fine-tuning	Acc: 99.72 ± 0.24 Sen: 99.97 ± 0.06
Fathia ABOUDI, 2022 [25]	Ischemic Stroke	CNN U-Net Fine-tuning	Average precision: 99.77% Dice Coefficient: 55.77%
(Hongyu Gao 2023) [26]	Acute Ischemic Stroke (Endovascular Thrombectomy)	CNN SVM RF	CNN: CTP and PWI (0.902 vs. 0.928; p = 0.557)

V. CONCLUSION

In conclusion, this study found that the development of automated CAD systems for systematic stroke identification and measurement of stroke extent is necessary, which has significant therapeutic and diagnostic consequences. Eventually, this will result in better and more prompt stroke care, as well as lower patient morbidity and mortality. Advances in neuroimaging acquisition techniques, as well as the use of machine learning, are critical to this goal. In this review study, we conducted a thorough search for several image analysis approaches used to diagnose stroke lesions using MRI data. In this work, we looked at the most recent methods for segmenting and classifying cerebral stroke on MRI images, with an emphasis on machine learning approaches. This study found that by combining machine learning models and cognitive systems, brain infarcts may be recognized more efficiently and with greater accuracy on MRI in real-world clinical circumstances, which will aid in clinical

decision-making. Moreover, the limits of various methodologies as well as potential remedies are examined. We hope that this work will be a helpful resource for scholars in the subject as well as a source of ideas and inspiration.

ACKNOWLEDGMENT

The study is funded by Universiti Teknikal Malaysia Melaka (UTeM) through the Grant, No: PJP/2022/FTKKE/S01887. The Current State of Blockchain Consensus Mechanism: Issues and Future Works

Shadab Alam

College of Computer Science & IT, Jazan University, Jazan, Saudi Arabia

Abstract—Blockchain is a decentralized ledger that serves as the foundation of Bitcoin and has found applications in various domains due to its immutable properties. It has the potential to change digital transactions drastically. It has been successfully used across multiple fields for record immutability and reliability. The consensus mechanism is the backbone of blockchain operations and validates newly generated blocks before they are added. To verify transactions in the ledger, various peer-to-peer (P2P) network validators use different consensus algorithms to solve the reliability problem in a network with unreliable nodes. The security and reliability of the inherent consensus algorithm used mainly determine blockchain security. However, consensus algorithms consume significant resources for validating new nodes. Therefore the safety and reliability of a blockchain system is based on the consensus mechanism's reliability and performance. Although various consensus mechanisms/algorithms exist, there is no unified evaluation criterion to evaluate them. Evaluating the consensus algorithm will explain system reliability and provide a mechanism for choosing the best consensus mechanism for a defined set of problems. This article comprehensively analyzes existing and recent consensus algorithms' throughput, scalability, latency, energy efficiency, and other factors such as attacks, Byzantine fault tolerance, adversary tolerance, and decentralization levels. The paper defines consensus mechanism criteria, evaluates available consensus algorithms based on them, and presents their advantages and disadvantages.

Keywords—Blockchain; consensus mechanism; consensus algorithm; data security; distributed systems; bitcoin

I. INTRODUCTION

The concept of blockchain revolves around the decentralized recording of digital transactions, eliminating the need for a central authority. These transactions are structured as blocks, which undergo encryption and validation by the majority of participating nodes before being appended to the blockchain. Initially introduced without standardized applications, the Blockchain methodology gained prominence with the advent of Bitcoin in 2008, credited to Satoshi Nakamoto [1]. Originally intended to circumvent the reliance on financial institutions, this innovation aimed to enable direct peer-to-peer transactions among participants. Bitcoin's success in achieving this objective set a precedent, demonstrating how businesses beyond the financial sector could conduct transactions without the intervention of a centralized third party. The structure comprises interconnected data blocks, each encapsulating transactions organized within branches of a Merkle tree, all cryptographically linked to the preceding block [2].

The blockchain operates as a ledger, capturing the complete transaction history in a chronological sequence due to the arrangement of blocks [3]. Among the most pivotal functions within the blockchain are verification and security, which are realized through a dedicated technique known as a consensus algorithm [4]. This algorithm is paramount in the blockchain system, primarily responsible for upholding its credibility, safety, and overall integrity. The consensus mechanism's efficacy directly influences critical aspects such as the stability, throughput, and accessibility of the blockchain system [5]. Within the network, nodes collaborate as validators of transactions, thereby upholding the integrity of the data. Including a block in the chain necessitates the consensus of the majority of nodes, confirming the accuracy of both the transactions contained within the block and the block as a cohesive entity. The foundation of this determination lies in a consensus algorithm implemented at the blockchain level, ensuring the precision of the data. Based on the level of access, blockchain networks can be categorized into two distinct types: private and public [6].

In contrast to public blockchains, which anybody may access and interact with, private blockchain can only be accessed by machines that have been allowed access. A consensus method in the blockchain can force the system's dispersed nodes to debate whether a transaction or block is valid. It allows for the eventual writing of valid data into the blockchain when the nodes have reached a consensus. In a distributed scheme, obtaining consensus between uncertain nodes has been discussed as a "Byzantine" problem in which a herd of army generals has cordoned off the city. Specifically, there is a clash between generals as some choose to attack, and others want to withdraw from the town. The town, assaulted by several generals, would collapse. Therefore, they should agree on whether to attack or retreat [7].

Similarly, the blockchain algorithm's major challenge in distributed ambiance is to achieve consensus [8][9]. Generally, the blockchain is decentralized because of a centralized node for noticing and checking every transaction. It creates a necessity to design and develop protocols or methods that specify all the transactions are legitimate. For this reason, the consensus algorithm is believed as the soul of every blockchain. In a decentralized or distributed environment, the consensus is a crucial issue that defines the mechanism to approve or refuse a block by every agreed node [10]. Once the new block is allowed by every network member, it is then attached to the blockchain [11]. As discussed, the blockchain's primary issue is how to achieve consensus between members of the network. Every algorithm has implemented a broad

spectrum of consensus algorithms with many strengths and weaknesses. The number of current consensus algorithms can create a fuss in choosing and applying them. Therefore, it is necessary to recognize various performance evaluation criteria that include every aspect of the consensus algorithm, besides the profound understanding of current algorithms' limitations for attaining consensus between peers and guaranteeing data security in the blockchain [12]. The main goal of this paper is to present criteria for evaluating the efficiency or the performance of widely known blockchain consensus algorithms and further review and evaluate the existing consensus mechanisms based on these identified parameters.

The subsequent sections of this article are organized as follows: Section II presents the pertinent background research in this domain. Section III offers a concise overview of the prevailing consensus techniques within the realm of blockchain technology. The approach taken to evaluate these consensus algorithms is expounded upon in Section IV. Section V presents a comprehensive analysis of the challenges and limitations inherent in these algorithms, accompanied by suggestions for potential avenues of further exploration. Section VI delves into the existing gaps and research challenges, while the conclusive Section VII provides a comprehensive summary encapsulating the entirety of this study.

II. RELATED WORK

The origins of consensus algorithms can be traced back to concepts of credibility and reliability in distributed algorithms, exemplified by the Byzantine General Problem. In 1999, Castro and Liskov introduced Practical Byzantine Fault Tolerance (PBFT), a novel consensus approach aimed at mitigating trust-related concerns. PBFT fosters trust among participating stakeholders and facilitates efficient data exchange while minimizing latency. Following this, the Proof of Work (PoW) concept emerged in the same year, drawing inspiration from PBFT's principles, and was proposed as a means of validating transactions within open distributed systems. Subsequently, the PoW concept laid the foundation for the operational model of Satoshi's Bitcoin cryptocurrency [1]. PoW involves solving complex puzzles, its functionality hinging on the value in relation to the targeted hash cost. When the cost is lower, a block is mined and subsequently appended to the blockchain.

While doing the literature review on the consensus algorithms, this article identified literature related to consensus and studies associated with comparing the consensus algorithm. To review the metrics and criteria, a systematic review of the consensus algorithms has been done. G. T. Nguyen and K. Kim reviewed the Blockchain consensus algorithms applied in some well-known applications at this time [13]. Bach et al. (2018) present a comparative study of algorithmic steps, scalability, methods, and security risks of popular consensus algorithms. Authors in [14] tested that none of the deterministic consensus protocols could guarantee a mechanism in a decentralized system. Still, Paxos can not only assure steadiness but also the security of the network. As per [15], there is no doubt that Paxos is demanding and challenging to implement and understand, but the modern training standard

allows us to achieve a consensus algorithm whenever required [16]. Paxos is the group of protocols for attaining consensus in the network of unreliable or defective processes [17]. Ferdous et al. (2020) analyze a wide range of consensus algorithms employing comprehensive taxonomic properties and investigate the consequences of the different problems that are still widespread in consensus algorithms. They also provided detailed literature on cryptocurrencies belonging to various class consensus algorithms [18]. Alsunaidi and Alhaidar thoroughly analyzed Blockchain technology, focusing on well-known consensus algorithms to identify the characteristics and variables affecting performance and security [19]. Panda et al. presented a thorough analysis of the distributed consensus processes in accordance with the kind of blockchain used. It also does a comparative analysis of the consensus protocols [20]. Sharma and Jain cover the different consensus methods, how they operate, and their applications. Additionally, it looked at blockchain technology, including its benefits and drawbacks [21].

Meneghetti et al. (2020) presented a comprehensive survey of the PoW techniques, attacks, and their current use in cryptocurrency consensus algorithms. They also analyzed some known attacks on these consensus algorithms and then presented them in a coordinated manner according to their core ideas [22]. The consensus algorithm can resolve common problems, such as harmonization among dispersed systems [23]. Consensus algorithms used in the blockchain can determine the legitimacy of distributed transactions in cryptocurrencies. Moreover, it is also used in authorizing the uniqueness of a front-runner of the distributed task. The consensus algorithm ensures reliability amongst state machine replicas and, later on, harmonizes them. The stack of 32 consensus algorithms is sorted into two significant types: proof-based and vote-based [13]. This study illustrates the advantages and disadvantages of all kinds and contrasts them, established on obtrusive characteristics.

Simultaneously, the limits and upcoming growth in technology are also discussed [13],[24]. Yang Xiao et al. (2020) survey provides comprehensive literature on blockchain consensus algorithms. The analysis is done concerning performance, fault tolerance, and vulnerabilities. At the same time, there is also an emphasis on their use cases. Bamkan et al. (2020) comprehensively examined the resources accessible on the consensus algorithms in light of their traits, motivations, and present difficulties [25]. This paper defines the criteria for consensus evaluation as throughput, profitability, degree of decentralization, and vulnerabilities and evaluates the existing blockchain consensus mechanisms based on these criteria [6].

Further, article [2] presents some open issues and challenges in implementing various consensus mechanisms with their virtues and drawbacks. In-depth research on blockchain technology has been done by examining its design, including a range of consensus algorithms and the options for security and data privacy within the blockchain discussed in this article [26]. A survey of the leading consensus mechanisms on blockchain solutions is done in this paper and highlights each one's properties. Additionally, it distinguishes between probabilistic and deterministic consensus procedures [27]. Some other studies also presented a brief review of

consensus algorithms, but these studies are not comprehensive, like [28] surveys highlighting the latest studies in blockchain and consensus algorithms. This paper adds theory and information that may be utilized to choose an appropriate consensus algorithm. It will aid scholars in their continued study of consensus in the context of private blockchain [29]. According to this article, the Byzantine consensus may need to be rethought in light of the blockchain environment, which also looks at prominent blockchain consensus algorithms [30]. Lashkari & Musilek [31] presented a very detailed analysis of existing blockchain consensus algorithms. Ferdous et al. [32]

surveyed the consensus algorithms being used in cryptocurrencies. Lina Ge et al. (2022) surveyed the PoS-based consensus algorithms and compared them with their advantages and disadvantages [33]. Xiong et al. [34] reviewed the widely used main consensus algorithms, the possible scenarios in which they can be suitable, and their relative disadvantages. Jain & Jat [35] survey some prominent consensus algorithms, reviews the key features and parameters, and compare the presented consensus algorithms based on these.

TABLE I. COMPARATIVE STUDY OF RELATED RESEARCH WORK

Ref	Year	Idea of Paper	Comments
[13]	2018	It reviews the Blockchain consensus algorithms applied for various applications.	None
[19]	2019	The author thoroughly analyzed Blockchain technology, focusing on well-known consensus algorithms to identify the characteristics and variables affecting performance and security.	It is recommended that one of the leading consensus algorithms for public Blockchain networks be improved by introducing a lightweight mechanism.
[20]	2019	This paper presented a thorough analysis of the distributed consensus processes. In accordance with the kind of blockchain used, it also does a comparative analysis of the consensus protocols.	None
[21]	2019	This paper covers the different consensus methods, how they operate, and their applications. Additionally, we looked at blockchain technology, including its benefits and drawbacks.	None
[25]	2020	This survey comprehensively examined the resources accessible on the consensus algorithms in light of their traits, motivations, and present difficulties.	It examined protocols' use cases while analyzing them in terms of fault tolerance, performance, and vulnerabilities.
[6]	2020	This paper defines the criteria for consensus evaluation as throughput, profitability, degree of decentralization, and vulnerabilities and evaluates the existing blockchain consensus mechanisms based on these criteria.	None
[2]	2020	It outlines several unresolved problems and difficulties in implementing various consensus processes and their advantages and disadvantages. The proposed poll would guide blockchain academics and developers as they consider and create the next consensus mechanisms.	None
[26]	2020	In-depth research on blockchain technology has been done by examining its design, which includes a range of consensus algorithms and the options for security and data privacy within the blockchain discussed in this article.	None
[27]	2020	A survey of the leading consensus mechanisms on blockchain solutions is done in this paper and highlights each one's properties. Additionally, it distinguishes between probabilistic and deterministic consensus procedures.	It aims to create a hybrid consensus algorithm relying on communication lines that are only partially synchronized and reaching an agreement on just allowing for one-hop neighbor voting.
[28]	2020	This survey highlights the latest studies in blockchain and consensus algorithms.	None
[29]	2020	This paper adds theory and information that may be utilized to choose an appropriate consensus algorithm. It will aid scholars in their continued study of consensus in the context of private blockchain.	To determine the actual performance indicators of the consensus employed, additional study can be conducted by adjusting the number of loads and peers and assessing it using some benchmarks.
[30]	2020	According to this article, the Byzantine consensus may need to be rethought in light of the blockchain environment, which also looks at prominent blockchain consensus algorithms.	None
[31]	2021	Presented a very detailed analysis of existing blockchain consensus algorithms.	It does not consider the attacks on consensus algorithms.
[32]	2021	It surveys the consensus algorithms being used in crypto-currencies.	It does not consider the attacks on consensus algorithm and consider only crypto-currencies.
[33]	2022	Survey on consensus algorithm for Proof of Stake (PoS)	Discussed only PoS-based consensus algorithm
[34]	2022	Presents the review of main consensus algorithms being widely used, the possible scenarios in which they can be suitable, and their relative disadvantages.	It does not consider the attacks on consensus algorithms.
[35]	2022	This paper surveys some prominent consensus algorithms, reviews the key features and parameters, and compares the presented consensus algorithms based on these.	A limited no of consensus algorithms are taken and further does not consider the attacks on consensus algorithms in detail.
Our Review	2023	Our paper conducted a detailed review of the maximum prominent blockchain consensus algorithm. It further compared these consensus algorithms based on performance and security attack criteria.	Other articles have either covered the security attacks or performance analysis but have not combined both approaches.

Recent surveys on consensus algorithms have examined the limitations and future work of various consensus algorithms. Nonetheless, there is a gap in the existing analysis of the consensus algorithm. The current literature does not provide enough criteria for a comprehensive and comparative analysis of consensus algorithms. Henceforth, this paper aims to provide a complete and detailed analysis of existing and recent consensus algorithms concerning throughput, scalability, latency, and energy efficiency. Table I present a comparative study of previous related and current research work and highlights the significance of the recent research work.

This paper also takes other factors, including attacks, Byzantine fault Tolerance, adversary tolerance, and decentralization levels. Besides comparison, this paper presents the advantages and disadvantages of consensus algorithms. The analysis results are shown in tabular formats, visually illustrating these algorithms in a meaningful way.

III. PARAMETER FOR EVALUATION

This sub-division will discuss different parameters that categorize consensus algorithms [2].

A. Blockchain Type

Blockchain can be categorized into three primary classes: private, public, and consortium. These classifications are indicative of the governance structure among participants and the specific nature of the blockchain.

B. Scalability and Attacks

In decentralized systems, scalability plays a vital role. In terms of scalability, consensus algorithms are separated, like ELASTICO and Proof of Trust, but PoW is non-scalable.

C. Adversary Tolerance

It quantifies the blockchain's ability to withstand malicious operations. Additionally, it gauges the stability of the blockchain network during catastrophic events. Research has demonstrated that the consensus algorithm exhibits the highest level of tolerance towards adversaries.

D. Throughput

Throughput in the consensus algorithm means how long it takes to confirm the transactions in a blockchain network [36]. It further suggests that the extreme throughput is an absolute rate at which the blockchain can authorize transactions [37].

E. Energy Consumption

Out of the various factors or criteria that disturb the blockchain consensus algorithm's valuation is power utilization. There is a variation in consensus algorithms' energy consumption that cannot be experimentally evaluated due to varied heterogeneous limitations [38].

F. 51% Attack

A 51% attack is commonly known as an assault on a blockchain, typically targeting bitcoins, executed by a group of miners wielding over 50% of the network's mining hash rate or computational power [6]. Usually, these types of threats cannot be evaded theoretically [39]. Blockchain protocols strive to elevate the costs associated with this attack to deter it, although a complete resolution remains elusive.

G. Double Spending Attack

A double-spend is a unique problem related to digital currencies that works when one user spends the digital assets more than once [40]. Since there is no centralized authority to control transactions, the attacker will attempt to generate a regular contract to contain it in a block. Then he will try to outspread the deceitful branch of the system he had shaped until the deceitful branch is confirmed and accepted as the precise branch that consists of the fraudulent transaction [41].

IV. REVIEW OF EXISTING CONSENSUS ALGORITHM

In simple language, the term consensus means harmony or concord. The consensus algorithm will authorize an agreement among all the nodes, thereby guaranteeing reliability and trust between the unidentified peers. The consensus algorithm also ensures that each block in the existing chain involves every peer node across the system [38]. That enables distinctness and clarity in the added processes or transactions, which defines a mutually beneficial network for every node. It is worth noting that once the block gets verified, it's practically impossible to eliminate or alter them. The consensus algorithm erases all the non-member intermediaries to guarantee the accuracy of the transaction [3]. However, once the consensus involving chain transactions obtains a global status, all nodes or peers become reliable for the blockchain structure. It eventually helps in the authentication of the untrustworthy and uncertain network associated with the self-contradictory person. However, in this part, we will present the utmost significant consensus algorithms commonly utilized in the blockchain system, with their disadvantages and benefit in general.

A. Proof of Work (PoW) [1]

It was presented by Nakamoto and later applied to Bitcoin [1]. Subsequently, this was endorsed by other cryptocurrencies, which include Ethereum, Dogecoin, Monero, and last but not least, Litecoin. It has a high algorithmic cost with a clear quorum design. Hash is a difficult and random mathematical formulation used to confirm the saved operation within blocks [42]. To achieve consensus in a network, miners strive against each challenging computational puzzle. Such puzzles are challenging to solve, but the result can be promptly verified once they are solved. Once the miner found the solution to the new block, it is broadcasted to the network. In turn, all other miners will confirm and verify that the solution is accurate, and then the block may be confirmed [43][2]. The PoW algorithm's benefit is that it comes with a significant amount of security, a decentralized framework, and a permissible level of scalability. On the contrary, it has some disadvantages, including lesser throughput, high block creation time, the inadequacy of energy, dependencies on specialized hardware, high computation cost, and comprehensive bandwidth [9], [19].

B. Proof of Stake (PoS) [33]

It arose as a substitute for PoW, originally used as a consensus algorithm in blockchain technology, and was applied to validate and add new blocks to the chain. PoW requires enormous amounts of energy, which is the main reason for PoS establishment. For this reason, the authors suggested light-weighted consensus protocols for lower-power IoT communication channels [44]. PoS is based on the concept

that individuals can confirm or excavate block transactions according to how many coins they retain [45]. The miners will obtain no award besides the transaction fee in these methods. If the full node is chosen to build a new block, then the lender will gain a proportion of those operations [6].

C. Distributed Proof of Stake (DPoS) [46]

It was introduced by Daniel Larimer [47]. A key feature of this algorithm is its emphasis on decentralization. DPoS structures the network more efficiently, granting each delegate ample time to publish on every node [2]. This approach finds utility in private blockchains due to its semi-centralized characteristics. Within this method, potentially malicious miners are subject to capping based on specific parameters such as intervals and block sizes [9].

D. Practical Byzantine Fault Tolerance (PBFT) [48]

PBFT deals with the byzantine issue of the distributed nodes that can cause 33% of work damage because of chain faults. PBFT is the capability of a distributed network to reach an adequate consensus despite malignant nodes in a system failure or the broadcast of incorrect information. PBFT aims to safeguard against disastrous system failure by decreasing the effect of the malignant nodes [49]. The advantage of this method is its high throughput and energy efficiency. On the other hand, specific points like scanty or no scarce constraints quantifiable for being scalable and network delays while stating every node poll are some of its disadvantages.

E. Proof of Importance (PoI) [50]

In PoI, a miner's application-specific integrated circuit chips are deployed to enhance computing power. It works when any more family of coins has a strong possibility to mine the next block. PoI compensates users with more transactions and the user with a considerable net stake in tackling these restrictions. PoI was first established in the NEM design [50]. In PoI, each node is allocated a significant value. A node carrying out a transaction with a node with great significant worth is, in all probability, to mine the next block even though the node has less stake than another node. It is considered an improvement over the PoS algorithm [2].

F. Proof of Capacity (PoC) [51]

It was introduced in 2015 by Dziembowski. As the name implies, PoC's dynamics revolve around selecting a miner node based on the available memory capacity of an external hard disk. The node with a larger storage capacity can precompute and retain a greater number of solutions for the impending problem before actual mining begins. This approach effectively addresses the intricate challenges associated with node management within the Proof of Work framework, subsequently alleviating broader difficulties. PoC entails the strategic utilization of hard drive resources, encompassing the storage and computation of results on the hard drive prior to the commencement of the mining process.

G. Proof of Burn (PoB) [52]

This method is a substitute for attaining a deal in the blockchain network. This algorithm node in the network has to lose or scorch cryptocurrency to obtain the mining entitlement to the permitted source. This method is less like Proof of Work,

but the only difference is where the belongings are in the form of cryptocurrency rather than the computing power of a node. The loss of coins reflects the node's longer commitments to stay sincere in the system as it has lost real coins to increase the mining entitlement [2].

H. Delegated Byzantine Fault Tolerance (DBFT) [2]

It can be derived that DBFT monitors the conventional phases of the DPoS protocol in the start-up phase. In this method, the consensus is obtained using a superannuated BFT method by adding extra steps [2]. Here the user will vote and select members to add the new role in the chain based on bulk voting of more or equal to 66% affirmative from the members [42]. It should be noted that fault tolerance of delegated Byzantine is very rarely prone to confront delays from the PBFT, but restricting the number of votes can jeopardize the decentralization of the network [4].

I. Reliable, Replicated, Redundant, And Fault-Tolerant (RAFT) [53]

This method is a Substitute for the Paxos protocol. This method is more straightforward and, at the same time, provides safety and privacy with add-on features[2]. The consensus in this method is reached by choosing a delegate, and then this delegate will be accountable for copying the logs every time the latest user accesses the network. Heartbeat notes will operate as an interfering signal for marking the presence of the forerunner [2]. Each node will have a time-out for the signal's arrangement if it will not get the message before its lapse. After this, there will be a process of selecting the new leader, or else time will reset.

J. Proof of Activity (PoA) [54]

One more consensus algorithm, PoA, was developed by Bentov et al. in the year 2014 [55]. The authors mentioned this algorithm as a union of PoS and PoW. It is a safer algorithm countering Bitcoin's potential assaults and has even ignorable sanctions concerning the network communication and storage area. Nevertheless, through PoS structured protocols, shareholders may engage in downward price spirals; for that reason, the coins that they maintain will produce revenue commensurate to real commerce taking place [2].

K. Proof of Authentication (PoAH) [56]

It is a consensus algorithm aimed at a lightweight and sustainable blockchain for building a lightweight decentralized security system to circumvent central dependencies. PoAH is a cryptographic verification mechanism that is a replacement for the PoW algorithm. This consensus algorithm is appropriate for private and permissible blockchain and makes blockchain application-specific. Besides securing the system, PoAH maintains sustainability and scalability.

L. Proof of PUF-Enabled Authentication (PoP) [57]

It is a comprehensive algorithm that effectively manages both data and device security aspects. This innovative approach combines the utilization of physical unclonable functions (PUF), which serve as integral hardware security components. These PUFs contribute to the system's ability to offer advantages in terms of latency, scalability, and energy consumption. The mechanism involves incorporating a

cryptographic hash of all previously processed data along with the involvement of any device incapable of generating the PUF key in a uniquely generated manner within the PUF module. This integrated approach ensures the robust handling of both data and security keys. In comparison to Proof of Work (PoW), PoP demonstrates a notable increase in speed, while in contrast to Proof of Authority and Hashpower (PoAH), it exhibits a slightly elevated latency.

M. Rock-Scissors-Paper (RSP) [58]

To achieve consensus and avoid attacks by the malicious participant, this algorithm uses three balance variables: Rock, scissors, and Paper. RSP does not directly address the problem of variable difficulty; instead, it proceeds with the consensus based on the device's specification. Furthermore, computations can be performed quickly and easily using a high specification of computing devices. This consensus algorithm reduces the power utilization that is required to limit the maintenance and processing cost.

N. Proof of Research (PoR) [18]

It is a hybrid consensus algorithm that combines Proof of Stake (PoS) with Proof of BOINC (Berkeley Open Infrastructure for Network Computing). This innovative approach is facilitated by Gridcoin, a cryptocurrency that individuals can acquire through the contribution of their computational resources to the BOINC project. PoR bears similarities to PoS, allowing individuals to become investors by possessing a designated quantity of Gridcoin and engaging in the minting process.

O. Proof of Stake Velocity (PoSV) [18]

It is an innovative consensus algorithm crafted to address the challenges encountered within the Proof of Stake framework. PoSV introduces a hybrid approach that integrates seamlessly with conventional PoS algorithms. The fundamental premise of PoSV lies in the concept of stake velocity, which mirrors the concept of money velocity in economics. The core principle driving stake velocity is the augmentation of stake circulation during the PoS consensus process. Investors can actively enhance this stake flow by engaging in the consensus mechanism, thereby staking their cryptocurrency as a dynamic alternative to passively holding it offline. This strategic involvement substantially enhances the security measures and

mitigates the issue of inadequate participant engagement often observed in conventional PoS systems.

P. Proof of Familiarity (PoF)[59]

This consensus algorithm is designed to integrate various healthcare stakeholders' medical conclusions. PoF guarantees stakeholders' medical results' privacy and integrity by utilizing previously-stored results using blockchain. Proof of familiarity uses a two-layer security measure to preserve the identity of stakeholders. It first stores stakeholders' identities locally, and then the hash of these are stored in the blockchain.

Q. Proof of Trust (PoT) [60]

Consensus protocol integrates a confidence dimension to satisfy the service sector's practical criteria, i.e., fixing the unfaithful activities that exist so frequently in a transparent, public service network, together with the reward steps. PoT consensus utilizes random logic algorithms to maximize block node unpredictability using time signs and digital signatures. A credibility evaluation of the crowdsourcing membership involved will be done automatically by the improved algorithm. The validity, equity, and stability can be obtained by the PoT.

R. Proof of Luck (POL) [61]

PoL is a blockchain consensus algorithm that uses a random number generator on a trusted execution environment (TEE) platform to select a consensus leader. This allows for fair mining while also enabling quick transaction validation, deterministic confirmation times, and low energy consumption, among other benefits.

S. Leased Proof of Stake (LPoS) [61]

It represents a variant of the PoS consensus mechanism. Notably employed within the Waves platform, this distinctive PoS approach facilitates token holders in "leasing" their tokens to complete nodes, thereby earning a share of the rewards. On conventional PoS networks, individual nodes contribute new blocks to the blockchain. Within the LPoS framework, users have the flexibility to actively operate a full node or alternatively lease their stake to a full node. This engagement in the LPoS ecosystem yields rewards for the participants.

Table II illustrates the comparison of various consensus algorithms on defined parameters.

TABLE II. ANALYSIS OF CONSENSUS ALGORITHMS

Consensus Algorithms	Byzantine fault Tolerance	Adversary tolerance	Decentralization level	Node identity	Throughput(tps)	Scalability	Latency	Energy efficiency	51% Attack	Double spending Attack	Trust
PoW [62]	50%	<25%	Decentralized	Permissionless	Low	High	High	No	Vulnerable	Vulnerable	Untrusted
PoS [33]	50%	<51%	Semi-Centralized	Permissionless	Low	High	Medium	Yes	Vulnerable	Difficult	Untrusted
DPoS[46]	50%	<51%	Semi-Centralized	Permissioned	High	High	Medium	Yes	Vulnerable	Vulnerable	Trusted
PBFT[48]	<=33%	<33%	Decentralized	Permissionless	High	Low	Low	Yes	Safe	Safe	Semi-trusted
PoI[50]	50%	N/A	Decentralized	Permissionless	Low	High	Medium	Yes	Safe	Safe	Untrusted
PoC[51]	NA	NA	Decentralized	Permissioned	Low	High	High	Fair	Vulnerable	Vulnerable	Semi-trusted
PoB[52]	NA	<25%	Decentralized	NA	Low	Low	High	No	Vulnerable	Vulnerable	Untrusted
DBFT[2]	NA	<33%	Semi-Centralized	Permissionless	High	High	Medium	Yes	Vulnerable	Vulnerable	Semi-trusted
RAFT[53]	>50%	<50%	Decentralized	Permissionless	High	High	Low	Yes	NA	Safe	Trusted
PoA[54]	>50%	N/A	Decentralized	Permissionless	High	High	Low	No	Vulnerable	Vulnerable	Trusted
PoAh[56]	N/A	N/A	Decentralized	Permission-based	N/A	High	low	low	No known attacks	No known attacks	Trusted
PoP[57]	N/A	N/A	Decentralized	Permissioned	N/A	high	low	low	No known attacks	No known attacks	Trusted
PoR[18]	50%	<51%	Semi-Centralized	Permissionless	Medium	low	medium	medium	Vulnerable	difficult	Untrusted
PoSV[18]	50%	<51%	Semi-Centralized	Permissionless	high	medium	low	low	Vulnerable	difficult	Untrusted
RPS[58]	N/A	N/A	Decentralized	Permissioned	N/A	N/A	N/A	low	No known attacks	No known attacks	Trusted
PoF[59]	N/A	75%	Decentralized	Permissioned	medium	high		low	No known attacks	No known attacks	Trusted
PoT[60]	>50%	N/A	Decentralized	Permissioned	high	high	low	medium	safe	safe	trusted
PoL[61]	N/A	<25%	Decentralized	N/A	high	high	low	yes	safe	safe	trusted
LPoS[61]	N/A	<51%	Decentralized	Permissioned	high	high	high	yes	No known attacks	No known attacks	Semi-trusted

V. ANALYSIS OF CONSENSUS ALGORITHM

The foundation of blockchain rests on a secure and dependable architecture that stems from consensus mechanisms. Different consensus algorithms are applied to specific applications due to the unique demands of each domain. For instance, some domains require swift transaction processing, while others prioritize minimal computational power consumption. The consensus algorithm assumes a pivotal role within the blockchain framework. It operates on the premise that consensus is crucial to achieving unanimous agreement among network nodes during the process of block authentication [63]. The consensus algorithm strives to strike a balance among miners, assigning them equal weight to facilitate arriving at a resolution or decision by the majority of miners.

However, while this approach suits controlled environments, it proves inadequate for public blockchains as it exposes vulnerabilities to Sybil attacks. These attacks involve an individual creating multiple identities to manipulate the blockchain's functioning. In a decentralized ecosystem, a single block's addition is the responsibility of a single participant. The user selection process can be either random or based on specific criteria. Nevertheless, relying on random selection leaves the system susceptible to potential breaches.

Since blockchain is a decentralized network, no single node can handle the entire network. That is why blockchain has

endorsed a distributed consensus method to implement the data's uniformity and trustworthiness [64]. PoW [62] is based on the idea that nodes are less likely to attack the network as long as they invest a significant amount of computational effort. In a PoW blockchain, miners must perform computationally intensive tasks to add a block, making it nearly impossible for Sybil attacks to occur. PoW operates through a process called mining, where nodes perform calculations until the correct result is found. In the case of Bitcoin, the mining process involves searching for a random number, or nonce, that generates the correct hash for a block header. Therefore, the miners should be able to carry out specific tasks to calculate the figure. Once the miner overcomes the issue, all the other nodes are responsible for confirming that the response is accurate. Because of the more utilization of energy in PoW, its rendering becomes ineffective in the lower-powered application. Moreover, the nodes that take part in the block's authentication shall not correspond to enhancing the transactions of a block that makes PoW non-scalable [65].

PoS-Proof of Stake creates division among its users based on stake [33]. Any node with a definite volume of stake in their blockchain could be the miner. This algorithm also reassumes that any extra stake user will be less susceptible to a network attack. When any node turns out to be a miner, it will assign a particular quantity of its stack; therefore, a network holds this volume to ensure the user is trustworthy and permissible to do the mining. PoS needs significantly less computing energy, so

Proof of Stake has a very low power utilization than PoW. The only problem with PoS is that the mining procedure always aims at its richest member because they own a more significant stake over the rest of the nodes. DPoS, or Delegated Proof of Stake, is an additional consensus method projected to improve PoS [46]. In this method, only limited members are accountable for validating the blocks rather than only transferring this responsibility to stakeholders. The main advantage of DPoS is quick transactions because fewer nodes participate. Moreover, the selected nodes are capable enough to fine-tune the size of the block and the intervals. Fraudulence can be dealt fastly since substituted nodes are replaced with ease. One more type or alternative of PoS is TaPoS (Transaction as Proof of stake) [66]. Contrary to PoS, in which only a limited number of nodes can assist the security of a network, in TaPoS, each node secures the network. The disadvantage of PoS is the accumulated stack age, although the node is not linked to the network. PoA is projected to compensate nodes based on what activity does and their network ownership [67].

PBFT is projected to aim at asynchronous situations to help in solving BG (byzantine general) problems [48]. This method presumes that beyond two-thirds, all nodes are genuine, and beneath this are malevolent. A front runner gets selected by every block of the family, and then this front runner or leader's job is to validate a block. Another alternative to the BFT is Delegated BFT (DBFT), which works like a DPoS in which only a few nodes are accountable for authenticating and generating the block. One more protocol that is quite similar to PBFT is SCP (Stellar Consensus Protocol). SCP is carried out based on a method or algorithm named FBA (Federated Byzantine Agreement) [68]. The only alteration between PBFT and PCA is that PBFT entails a contract from widely held nodes, whereas SCP depends on a subsection of the nodes, which are considered very important. Table III below presents a concise comparison based on their respective advantages and disadvantages.

TABLE III. COMPARISON OF CONSENSUS ALGORITHMS BASED ON THEIR ADVANTAGES AND CHALLENGES

Consensus Algorithms	Advantages	Challenges
PoW [62]	*Extensive power of decentralization *Extra protected network	*High drafting power (expensive) * High electricity utilization
PoS[66]	*Energy efficient & faster processing * Improved rewards & more significant stakes	*Less decentralization than PoW *Less security than PoW
DPoS[46]	*accelerated processing than PoW and PoS * Enhanced recompenses allocation and energy efficient	*More prone to attacks and is less decentralized *Affluent people control the network
PBFT[48]	*Capable of doing transactions devoid of confirmation *Substantially reduce energy	*Elevated volume of connection between nodes *Difficult in the message's authenticity and is prone to Sybil assaults.
PoI[50]	*Quick and power-efficient *no particular hardware is required for mining.	N/A
PoC[51]	*larger drive sizes	N/A
PoB[52]	*PoB enforcement can be tailored *The power of burnt coins diminishes fractionally every time a fresh block is mined	*Source waste (the burnt coins are lost) *Huge risk protocol, no coin retrieval assurance
DBFT[2]	*Provides perfect decisiveness *Quick transaction delivery	*Prone to 51% attack *Still believed centralized
RAFT[53]	*Could endure catastrophe of up to half of the nodes *Structure clarity and robustness	*Present execution can ensure liveness for one Byzantine failure
PoA[54]	*High security & low transaction fee *Eliminates 51% attack in the blockchain network	*Requires a significant number of assets in the mining phase *Participants can double-sign transactions
PoAh[56]	*Appropriate for private as well as permissioned blockchain *Maintains system sustainability and scalability	N/A
PoP[57]	*PoP is highly scalable *Runs noticeably faster, consumes fewer resources and uses less energy.	N/A
PoF[59]	*The integrity of a medical conclusion.*Privacy of participants	N/A
PoSV[18]	*Raise the overall security of the system *Counter the lack of participant issues in PoS	*Less decentralization than PoW
PoR[18]	*Faster and Energy efficient	*Less security than PoW
RPS[58]	*Efficient power consumption and economical maintenance cost.*Fast processing time	*Specification of devices can result in the polarization of the computing devices.
PoT[60]	*highly scalable*ensures the performance and consistency of the consensus process.	N/A
PoL[61]	*Extensive power of decentralization.*low-latency transaction validation.	*Attacker may confront a limited number of TEEs
LPoS[61]	*Energy efficient & faster processing *Improved rewards & more significant stakes	*Less decentralization than PoW *Less security than PoW

VI. OPEN ISSUES AND RESEARCH CHALLENGES

Some of the open issues and research challenges are emphasized in this section.

A. Overhead

Blockchain introduces significant overhead in terms of traffic, encompassing factors such as storage size, heightened implementation costs, legal compliance considerations, and deficits in information and organization. It presents a substantial challenge, particularly with regard to escalating energy consumption.

B. Cross-compliant Hybrid Alternative (CHA)

Although many providers favor creating consensus solutions based on particular use case requirements, consensus mechanisms still need to handle various requirements. As a result, the CHA class is anticipated to witness a large variety of consensus mechanisms [31].

C. Hybrid Consensus Algorithms

A single particular type of consensus algorithm frequently has more restrictions in practical application scenarios. Examples include the PoW algorithm's resource consumption issue and the PBFT algorithm's difficulty applying only to consortium and private chains, not public ones. The goal of maximizing strengths and avoiding weaknesses can thus surely be achieved by combining the advantages of multiple algorithms into one. Additionally, this offers a fresh concept and point of reference for advancing consensus algorithms in the future [34].

VII. CONCLUSION

Recent surveys on consensus mechanisms have analyzed the performance and application set-ups, limitations, and future work of various consensus algorithms. Nonetheless, there is a gap in the existing analysis of the consensus algorithm. This paper provides a complete and detailed analysis of current and recent consensus algorithms based on throughput, scalability, latency, and energy efficiency. Further, this paper also evaluates the consensus algorithms based on 51% attacks, Byzantine fault Tolerance, adversary tolerance, and decentralization levels. Besides comparison, this paper presents the advantages and disadvantages of consensus algorithms to understand existing research challenges clearly. This comparison also highlighted the resource requirements for choosing a suitable consensus algorithm for a resource constraint environment. The analysis results have been presented in tabular formats, visually illustrating these algorithms in a meaningful way. These evaluations reflect that PoAh, PoP, PoT, and PoI are promising approaches that have high Byzantine fault Tolerance, and no known attack has been reported till now against these consensus mechanisms. This article has further highlighted the open issues and research challenges affecting the consensus mechanism. These open issues and research challenges can be further researched in detail for future research.

A Novel Approach for Identification of Figurative Language Types in Devanagari Scripted Languages

Jatinderkumar R. Saini, Preety Sagar, Hema Gaikwad

Symbiosis Institute of Computer Studies and Research, Symbiosis International (Deemed University) Pune, India

Abstract—Poetry can be defined as a form of literary expression that uses language and artistic techniques to evoke emotions, create imagery, and convey complex ideas in a concentrated and imaginative manner. It is a form of written or spoken art that often incorporates rhythm, meter, rhyme, and figurative language to engage the reader or listener on multiple levels. There is no automated system that can identify figures of speech (FoS) in poetry using Natural Language Processing (NLP) methods. In this research paper, the authors categorized four types of FoS: व्रत्या अनुप्रास (Type of alliteration), छेकानुप्रास (Type of alliteration), अन्तल्यानुप्रास (Rhyme), and पुनरुक्ति (Repetition) using two custom algorithms, Koshur and Awadhi (KA and AA), developed specifically for three different language corpora of poems (Koshur (K), Awadhi (A), and Hindi (H)). To evaluate the effectiveness of these algorithms, the authors conducted tests on three languages using four distinct approaches: with stopwords without optimization, with stopwords with optimization, without stopwords without optimization, and without stopwords with optimization. Authors have put lots of effort into identifying FoS in not only one single language but in three Devanagari scripted languages. This research work is the first of its kind. The average accuracy without stopwords was not up to the mark. The authors then optimized both algorithms and again tested them on the same corpora with or without stopwords, resulting in a significant increase in accuracy.

Keywords—Figures of speech (FoS); natural language processing (NLP); Koshur; Awadhi

I. INTRODUCTION

India is renowned for its rich cultural heritage and vast literary traditions. With twenty-two scheduled languages, the country boasts a remarkable diversity of literature, and poetry stands out as one of its prominent forms of expression. Indian poetry, rooted in ancient times, has flourished through the ages, reflecting the myriad influences of its diverse regions and communities.

Poetry is characterized by its unique use of language, employing words and phrases chosen for their sound, texture, and connotation, as well as their literal meaning. Poets often strive to capture the essence of an experience or emotion, using vivid imagery and metaphorical language to paint a picture or evoke sensory impressions. While poetry can take many forms and styles, ranging from traditional structures like sonnets and haikus to free verse and experimental formats, it is united by its emphasis on creative expression, aesthetic beauty, and the power of words. It explores themes such as love, nature, human experiences, social and political issues, and the mysteries of existence. To acquire a deeper knowledge of a given poetry, we

might focus on numerous elements. These aspects include Emotion (Rasa), voice, diction, imagery, figures of speech, syntax, sound, rhythm, and verse meter [1]. These unfold the poem's actual theme, meaning, or feelings. The figure of speech (FoS) is one such element that creates a mesmerizing effect and produces magic. They are considered the ornaments used for the beautification of the poems.

This is a maiden attempt by the authors of this research paper to identify four different forms of figures of speech (FoS), namely व्रत्या अनुप्रास 'Type of alliteration', छेकानुप्रास 'Type of alliteration', अन्तल्यानुप्रास 'Rhyme' and पुनरुक्ति 'Repetition' (which is an implicit type of alliteration) on three different language corpora Koshur, Awadhi, and Hindi, implemented in two different algorithms Koshur and Awadhi algorithm (KA and AA) and later optimized with and without stopwords. All three languages, Koshur Awadhi, and Hindi are based on the Devanagari script.

Kashmiri or commonly referred to as 'Koshur', is a branch of the Indo-Aryan language in the linguistic landscape of India spoken by about seven million people from the state of Jammu and Kashmir, India. The Perso-Arabic script, the Sharda script, and the Devanagari script are the three main scripts used to write Koshur [2,3]. The Perso-Arabic script is considered the official script of Koshur, and Devanagari is used by Kashmiri Hindus for literature purposes [4]. The pioneers of literature, the Kashmiri poets, brought freshness and sweetness to the poems using this script [5]. The corpora considered in this research paper were Koshur poems written in Koshur Devanagari script.

Awadhi is spoken in twenty districts of India and eight districts of Nepal [6]. Awadhi is a language spoken in the Awadh region of Uttar Pradesh and some parts of north India. Awadhi is one of the dialects of Hindi, and it has 38 million native speakers [7]. But very less research work has been performed on the Awadhi language. Prominent texts like Ramcharitmanas, one of the most important religious texts in the world, is written in Awadhi. The Epic Ramcharitmanas is traditionally divided into several major kaandas or books, that deal chronologically with the major events in the life of Rama—Bala Kaanda, Ayodhya Kaanda, Aranya Kaanda, Kishkindhaa Kaanda, Sundara Kaanda, Lanka Kaanda, and Uttara Kaanda. Ramcharitmanas has seven Kaanda such as the other text like Hanuman Chalisa and Padmavat are also written in Awadhi. [8][9][10]. Today, the world is rapidly heading towards digitization. e-Books are easy to publish, handle and promote. All the important ancient books and texts are being digitized.

Hindi is the official language of India and holds a significant place in the country's cultural and literary heritage. Hindi belongs to the Indo-Aryan language family and shares roots with other languages, such as Sanskrit. Poetry in Hindi is a rich and diverse art form that has flourished for centuries. It encompasses various forms and styles, including Bhakti poetry, Ghazals, Doha, and Geet. Each form has its unique structure, rhythm, and thematic focus.

Automated identification of four types of FsoS in Devanagari scripted three major languages, Koshur, Awadhi, and Hindi, are first of its kind, and hybridization of two separate algorithms further improved the performance. No such work, as per authors' best-known knowledge, is seen with special reference to three languages. The author's contribution to this research covers the following items: -

- Identification of four different FsoS, using two different algorithms and their implementation on three different language corpora.
- Optimization of algorithms with and without stopwords.
- Comparison of both KA and AA algorithms considering accuracy and execution time taken by each algorithm.

The remaining sections of the paper are organized as follows: Section II gives a detailed literature review of the work. Section III explains the methodology used along with the algorithms. Section IV shows the interpretation of the results. Section V concludes the work and discusses its future scope.

II. LITERATURE REVIEW

A thorough literature review was done to gather information about the present state of the research effort in the field of Natural Language Processing (NLP) which is a branch of Artificial Intelligence and Machine Learning, and work done in FoS in poetry. Research in poetry and nearby segments like poetry generation, sentiment analysis, text classification, meter classification, etc., has been seen in many Indian and foreign languages like Marathi, Punjabi, Hindi, Arabic, Chinese, Persian, etc., but still, many Indian regional languages are either completely absent or badly represented on the NLP map. Although authors can find some work in the Hindi language, but Koshur and Awadhi language are ones in which very little or no study has been done.

According to Chopra et al. [11] NLP is a field of study in computer science, artificial intelligence, and linguistics that investigates how computers interact with human or natural languages. NLP is primarily concerned with human-computer interaction. NLP was also felt necessary because computers could access much information recorded or stored in natural language. Saini and Kaur [1] worked on poetry characteristics such as diction, rhyme, and rhythm, setting it apart from other genres of literature. These factors were experimented with, to attempt an automatic system for categorizing poetries based on emotional states tested to develop a system for categorizing poetries based on the Indian concept of 'Navrasa.' Kushwah and Joshi [12] investigated Hindi poetry based on 'Chhand',

one of the properties of Hindi poems. They created an algorithm that detects the presence of 'Rola Chhand' in any poem provided as input. A few poems are available in digital form, but their poetic properties are not aimed at, and their algorithm focuses on one such property.

Audichya and Saini [13] worked on producing automatic metadata for 'Chhand' based on the stanzas of the poems. They also provided superior techniques for metadata creation and procedures for 'Muktak Chhands'. It was the first time that not only rules of the 'Chhands' were identified but also were confirmed and modelled from the standpoint of computational linguistics. Audichya and Saini [14] worked on identifying three Hindi figures of speech using NLP. They also created a systematic structure of types and sub-types of Hindi FoS. Bafna and Saini

The study [15] recovered tokens from two corpora using two different methodologies. To count and contrast extracted tokens, BaSa, and Zipf's law were employed. Further token comparison between the two approaches is accomplished. They used both Hindi and Marathi poems and prose. To demonstrate that Hindi and Marathi behave similarly for NLP operations, common tokens from corpora of Marathi and Hindi poetry and prose were identified. It was established that BaSa outperforms Zipf's law. Kaur and Saini [16] worked on creating a content-based classifier for Punjabi poetry. After going through the pre-processing layer, more than 2,034 poems and 31,938 tokens were separated and weighted using the term frequency (TF) and term frequency-inverse document frequency (TF-IDF).

Pal and Patel [17] classified poetry based on nine different types of Rasas like Shringar, Hasya, Rudra etc., and used a mix of part-of-speech and emotion-based features to classify poems into different types. In research by Lone et al. [18], a Kashmiri-to-English Machine Translation System was presented, as well as it highlighted various features of the Kashmiri language. Their method was built on machine intelligence, and it can learn various translation rules from a series of translated input words by employing Long Short-term Memory (LSTM) architecture for deep sequence learning. The paper also reports difficulties and challenges associated with the work. Mir and Laway [19] worked on Word Sense Disambiguation (WSD) System for Kashmir Language; they designed Sense Annotated Corpus for Kashmiri Language and WSD Data Set. Ahmad and Syam [20] developed a Parts-of-Speech tagger (POS) in Perso-Arabic script for the Kashmiri language with an accuracy of 80.64%. Rasool et al. [21] opened the doors to the creation of a powerful multilingual machine translation system that includes Kashmiri as one of the languages. The aim of the researcher here is to incorporate Kashmiri into UNL (Universal Networking Language) framework. In this work, a selected Kashmiri corpus is analysed to UNL using IAN, and subsequently, Kashmiri expressions are generated from UNL expressions using EUGENE. Gilkar et al. [22] proposed a POS rule-based tagger for Kashmiri written in the Nastaliq script. The authors tried to create an automatic tagger for Kashmiri corpora using a rule-based and stochastic (hybrid) tagging approach. Aabid et al. [23] presented an Automatic Recognition System (ARS) that allows computers to understand natural

speech for recognizing Kashmiri digits zero (sefar) to nine (nov) spoken in isolation by different male and female speakers. In study by Ramakrishna et al. [24] Kashmiri palatalized consonants were examined, which were related to, the i-matra vowel and palatalized in Kashmiri phonology. For the purpose of analysing Kashmiri voice data.

Firdaus et al. [25] explained that poem writing is a way to express ideas, thoughts, and feelings using artful language. Writing poetry is a skill that is taught in schools. There are hardly any students who are interested in poetry. Less appealing is the poetry writing process used in schools. As a result, the purpose of this study is to demonstrate an original way to write poetry using the "Atafora" technique by fusing students' sensory experiences with a metaphorical figure of speech. Malik et al. [26] discussed the figures of speech in the songs from Rose's album "R". The study's objective was to characterize four different types of figures of speech used in the two-track lists of the R album: (a) comparative figures of speech, (b) contradiction figures of speech, (c) affirmation figures of speech, and (d) satirical figures of speech. This study used a qualitative research design and an analytical framework. The -R- album's two songs with the title "On the Ground and Gone" that use figure of speech are the study's source of data. Krishna et al. [27] stated that poets frequently use figurative language to convey their thoughts and emotions. Poetry that captures the attention of the readers will be enhanced by figurative language. Paradox is frequently used in figurative poetry to emphasize the poem's message. This study focuses on the implications of paradox in the poem by Rudyard Kipling. The authors used the descriptive qualitative method to examine Rudyard Kipling's chosen poems' figure of speech. The study discovered 17 paradoxes, including seven rhetorical paradoxes, seven social paradoxes, two logical paradoxes, and one philosophy of science contradiction. Maula et al. [28] identified the figurative language in Lady Gaga's album titled "Always Remember Us This Way" using descriptive qualitative research. Wati et al. [29] discussed the comparative figurative language in the poems from Emi Suy's poetry collection titled Ibu Menanak Nasi hingga Matang Usia Kami. The anthology was published in 2022, served as the study's data source. Heuristic reading, a first-level semiotic reading technique, and Hermeneutic reading, a second-level structuralism-semiotic technique, was used for data collection and data analysis purpose, respectively. Naaz et al. [30] discussed different tools such as Text2Matr, RPaGen, and FoSCal. The Text2Matr tool offers a chanda-related observation, including chanda type detection and classification, rhythm determination, chanda correctness verification, etc. For an input Hindi poetry, the RPaGen tool provides rhyme pattern(s). The tool FoSCal, used for generating alankara scores, and the tool's FoSCal uses the pattern created by RPaGen for alankara rating. Mahdi et al. [31] explained that poets use a wide range of writing strategies when creating new poems. This paper discussed the use of personification, symbolism, and figure of speech such as Simile and Metaphor in British love poems and lyrics. Nidi et al. [32] discussed the personification figure of speech and its general meaning. The two varieties of personification FsoS prosopography and prosopopeia are used. The author has used the poems by Robert Frost.

Setiani et al. [33] stated that poetry is a literary form that includes stanzas, lines, rhythms, and rhymes. Denotative and connotative meanings are frequently utilized in poetry. Denotative means emotional feeling of the word, and connotative means figurative language. Hutaurok et al. [34] mentioned the importance of figures of speech. The personification and apostrophe create pictures in the mind of reader or listener, and pictures help to convey the message faster than words. Sayakhan et al. [35] Figurative language is used frequently in ordinary conversation, popular music, television, and commercial topics as well as in classic works like Shakespeare and the Bible. The author has specially discussed two figures of speech such as personification and apostrophe. A person is just mentioned in an apostrophe, whereas with personification, inanimate objects are given human characteristics.

While performing the literature review the authors found few papers on FoS but no papers were found in Koshur and Awadhi.

Therefore, the gap with the authors was huge, the reason behind this gap is mainly that the languages are highly resourceless, it is tedious to work with such resourceless languages and researchers have to face lots of difficulties as no initial work has been carried out before.

To address this significant gap, the authors have embarked on developing FoS algorithms. The research question then becomes: How can the development of FoS algorithms alleviate the challenges posed by the lack of resources in these languages and contribute to narrowing this gap?

For the above mentioned research question authors have worked on the objectives like development, optimization and implementation of FoS algorithms for Devanagari scripted languages.

III. METHODOLOGY

To identify FsoS in three different languages, authors developed the logic represented in Fig. 1. The input to the flowchart was the poems in all three languages. The entered poems then need to be tokenized on the basis of sentences, words, and letters, and accordingly, rules were applied as per the type of FoS identified.

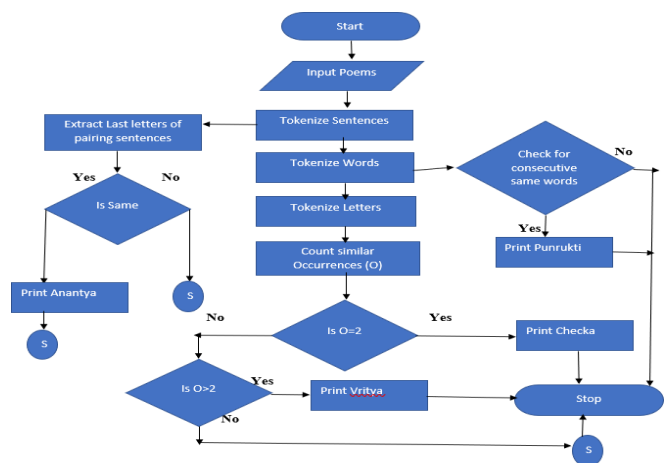

Fig. 1. Logical representation.

TABLE I. SUMMARY OF FoS, TRANSLITERATION, TRANSLATION, DEFINITION, AND EXAMPLE

FoS- N	T	RST	D	H	E	K	A
त्रया अनुप्रास	Vrity Anupras (VA)	Type of Alliteration	consonant word repeats more than once.	चारुचंद्र की चंचल किरणें, खेल रहीं हैं जल थल में	Serve Fast food with fast speed	यि छु म्योन वतन यि छु चोन वतन	बंदउ गुरु पद पदुम परागा सुरुचि सुबास सरस अनुरागा
छेकानुप्रास	Cheka Anupras (CA)	Type of Alliteration	The same letter used repeatedly but only 2 times	फूले फले राष्ट्र दिन-रात मेरा	My country, my nation is blooming	वदुन रिवुन पँतिम ति बार याद छुम में याद छुम	जो सुमिरत सिधि होइ गन नायक करिबर बदन
अन्त्यानुप्रास	Anantya Anupras (AA)	Rhyme	Rhyming pattern at the end of lines	बुंदेले हरबोलों के मुँह हमने सुनी कहानी थी।खुब लडी मर्दानी वह तो झाँसी वाली रानी थी	On the fifteenth of May, in the jungle of nool, In the heat of the day, in the cool of the pool	सुमरन पनन्य दिचोनम, लोलुक निशान वेसिये।रँछरुन तोगुम न रोवुम, ओसुम न बान वेसिये	एहि महँ रघुपति नाम उदारा। अति पावन पुरान श्रुति सारा
पुनरुक्ति अलंकार	Punrukti (PU)	Repetition	one word used twice consecutively without changing its meaning	मीठा-मीठा रस टपकता	milky-milky chocolate, covered with coffee beans.	जिंदगी हुँद मोदुर-मोदुर फरागथ.	बार बार रघुबीर सँभारी। तरकेउ पवनतनय बल भारी॥

Legends- FoS N-FoS Name,, T-, Transliteration , RST-Roman Scripted Translation, D-Definition, H Hindi, ,E-English-Koshur ,A-Awadhi

TABLE II. METADATA OF THREE DIFFERENT LANGUAGE POEMS

S.No.	Attributes	Koshur	Awadhi	Hindi

2	NoP	17	7	17
3	CS	341	340	353
4	ExT	2096	2819	1716
5	ExSW	510	264	862

Legends-Corpus Type- CT, DA-Different Authors, RAM-Ramcharitmanas, ABV-Poems of Shri Atal Bihari Vajpayee, NoP-Number of Poems, CS-CorpusSize, ExT-Extraction of tokens, ExSW-Extraction of Stop Words.

To detect or identify the figures of speech in Koshur, Hindi, and Awadhi, authors need detailed descriptions of all four types of FoS and their rules. Table I shows the definitions and examples of FoS in all four languages.

The Table II above shows the details of corpus used. Well-known poems from three different languages were taken. Awadhi poems were extracted from different kaand of epic Ramcharitmanas where one kand represents one section. Throughout the paper, the authors used the word section in place of kand. For Hindi, poems of Shri. Atal Bihari Vajpayee ji had been taken, and poems of different authors were extracted for Koshur. The selection of Koshur poetry was made in order to include a variety of poems, including those about love, nature, patriotism, and other topics. For the implementation of the algorithm, lines of the poems were considered as Units of Measurement (UoM). In Awadhi, 40-50 lines were taken from each section. For Hindi and Koshur, seventeen poems were considered having 353 and 341 lines, respectively. Tokenization is a process of breaking sentences into words. After applying the tokenization process, the extracted words were 2819, 1716, and 2096 for Awadhi, Hindi, and Koshur, respectively. In NLP, stopwords are words that have less relevance and do not carry valuable information. The authors extracted 264, 862, and 510 stopwords in Awadhi, Hindi, and Koshur. Awadhi and Koshur are low-resource languages, and there are various challenges, such as the non-availability of linguistic documents like dictionaries, wordnet, thesaurus,

stopwords list, POST etc. So, the extraction of stopwords was also a challenge for the authors.

As all three languages support the Devanagari script, the Hindi stopwords list has been taken as the benchmark. To identify Koshur stopwords, the authors have considered three lists of stopwords from three different languages (Hindi, English, and Punjabi). Some new words were also added to the list that were fetched from credible sources. For the identification of Awadhi stopwords, the authors have referred list of Hindi stopwords and modified them according to the Awadhi language. The authors also contributed new words from the literature of Awadhi.

IV. RESULT AND DISCUSSION

The authors developed two different algorithms, one for the Koshur language and another for Awadhi. Both algorithms were then implemented and tested on the corpus with stopwords and without stopwords. Optimization of algorithms was also done to improve the performance. Algorithms developed for the Koshur language were implemented in Hindi and Awadhi, and the algorithms developed for the Awadhi language were implemented in both Koshur and Hindi.

The performance of the Koshur and Awadhi algorithms on a corpus with stopwords and without optimization is shown in Table III. Table IV shows the performance of both algorithms with stopwords and with optimization.

The performance of the Koshur and Awadhi algorithms on a corpus without stopwords and without optimization is shown in Table V and Table VI shows performance without stopwords with optimization.

Fig. 2 shows the average accuracy of two algorithms with stopwords, with and without optimization. Fig. 4 show the result of the Koshur and Awadhi algorithms without stopwords, with and without optimization. The dark shades represent the result of Koshur algorithm and light shades represent the result of Awadhi algorithm.

The authors' observation on Fig. 2 is that both algorithms have increased the performance after optimizing the existing

code and removal of the extra loops and unwanted instructions from the code. Fig. 3 displays the time taken by the algorithms.

There are four types of approaches considered by the authors the names are WSWWO-With Stopwords With Optimization, WSWWO-Without Stopwords Without Optimization, WOSWOO-Without Stopwords With Optimization, WOSWOO-Without Stopwords Without Optimization. The graph shows the relation between ET and the approaches. The time taken by the algorithms before optimization was little high than the time taken after optimization. The orange colour line shows with stopwords with optimization, and blue colour represents with stopwords

without optimization.

(a) Without optimization.

(b) With optimization.

Fig. 2. (a,b) Koshur and Awadhi algorithm accuracy with stopwords.

Fig. 3. ET taken by algorithms with stopwords.

The observation related to Fig. 4 is that after removing the stopwords, the accuracy reduces noticeably. The stopwords are words that do not make semantic sense and are unwanted for processing. As we know that poets use figurative language for writing poems and create a magical effect, but when we remove the stopwords, this effect breaks the rhythm of the poem, and hence code is not able to catch the particular FoS. So our contribution is improvised algorithms that increased the accuracy of the previous algorithms without stopwords up to a great extent. Fig. 5 displays the execution time taken by both the algorithms.

The algorithms after optimization showed the difference in timing. The optimized algorithms were taking less time than the algorithms without optimization.

Fig. 6 show the accuracy of individual FoS named VA, CA, AA, and PU. The blue, pink, and green colours represent

Koshur, Awadhi, and Hindi languages. The Koshur algorithm with stopwords was giving 100% accuracy in Hindi and Koshur languages for VA FoS. The same algorithm was giving 100% accuracy in Awadhi in CA FoS. The accuracy for AA and PU FoS in Hindi was 94.11% and 93.30, which was the highest among all three languages. The same algorithm, when used on corpus without stopwords, was giving 100% results in Koshur and Hindi for VA FoS. The CA and AA FoS scored 94.11 % accuracy in Awadhi and Hindi. The 92.30% accuracy was received in Awadhi and Hindi languages for PU FoS.

(a) VA

(b) CA

(c) AA

(d) PU

Fig. 7. Application of Awadhi algorithm for four FsoS.

Similarly, Fig. 7 show the individual accuracy of FoS named VA, CA, AA, and PU. The dark red, violet and orange colours are used for Koshur, Awadhi, and Hindi. While implementing the Awadhi algorithm on corpora with stopwords, the authors recorded 100% accuracy in VA and PU FoS in Koshur, Hindi, and Awadhi languages, respectively. For CA and AA, the accuracy was 98.80 % and 98.63% in Awadhi. The Awadhi algorithm without stopwords provided 100% accuracy in VA in Awadhi and Hindi. The same algorithm gives 100 % results in Hindi for CA and AA FoS. For the Koshur language, 85.71% accuracy was scored in PU FoS.

After analyzing the results the authors derived that the initial implementation of both algorithms performed less accurately on datasets without stopwords compared to datasets that included stopwords. The disparity in accuracy was quite noticeable. However, after applying optimization techniques to both the KA and AA algorithms, there was a significant enhancement in accuracy for both types of datasets – with and without stopwords. The optimization process played a crucial role in enabling the authors to achieve higher accuracy levels for their algorithms, even when stopwords were removed from the text. This underscores the effectiveness of the optimization in improving the algorithms' performance across different types of textual data.

V. CONCLUSION AND FUTURE SCOPE

The Koshur, Awadhi, and Hindi corpora were used by the authors of this research study to identify four different forms of figures of speech. Two algorithms, KA and AA, were applied by the authors on a corpus with and without stopwords. Authors then improved the algorithms' performance and applied them again on a corpus with and without stopwords.

Both the algorithms before optimization, when implemented on corpora without stopwords, showed low accuracy compared to corpora with stopwords. The difference in the accuracy was quite noticeable. After implementing optimized algorithms (both KA and AA), a significant increase in accuracy can be seen on the corpus without stopwords and with stopwords as well. Optimization helped authors to increase the accuracy of algorithms even after removing the stopwords.

This accomplishment offers a tangible solution to the stark resource limitations these languages confront. The optimized algorithms exhibit a capacity to extract meaningful insights from text, compensating for the lack of extensive linguistic resources. Consequently, the development of these FoS algorithms not only provides a means to navigate the complexities of resource-scarce languages but also contributes significantly to narrowing the existing accuracy gap between corpora with and without stopwords.

In the future, the work will be extended for other Devanagari scripted languages, and the identification of more FoS can be explored and tested.

Abstract—Natural Language Processing (NLP) has recently gained significant attention; where, semantic similarity techniques are widely used in diverse applications, such as information retrieval, question-answering systems, and sentiment analysis. One promising area where NLP is being applied, is personalized learning, where assessment and adaptive tests are used to capture students' cognitive abilities. In this context, open-ended questions are commonly used in assessments due to their simplicity, but their effectiveness depends on the type of answer expected. To improve comprehension, it is essential to understand the underlying meaning of short text answers, which is challenging due to their length, lack of clarity, and structure. Researchers have proposed various approaches, including distributed semantics and vector space models. However, assessing short answers using these methods presents significant challenges, but machine learning methods, such as transformer models with multi-head attention, have emerged as advanced techniques for understanding and assessing the underlying meaning of answers. This paper proposes a transformer learning model that utilizes multi-head attention to identify and assess students' short answers to overcome these issues. Our approach improves the performance of assessing the assessments and outperforms current state-of-the-art techniques. We believe our model has the potential to revolutionize personalized learning and significantly contribute to improving student outcomes.

Keywords—Natural language processing; short text; answer assessment; BERT; semantic similarity

I. INTRODUCTION

Semantic similarity is a technique used to determine whether two separate texts have the same meaning. It is a crucial task in natural language processing (NLP) and can be applied to a range of downstream applications, such as text classification, summarization, and question-answering systems (QAS). In the early days of text similarity research, the emphasis was often on comparing lengthy texts, such as news articles, large corpora, and documents. Compared to lengthy writings, short texts have unique characteristics that pose challenges to traditional approaches for measuring similarity. First, short texts have a shorter form, which means that traditional approaches such as knowledge-based, and corpus-based which rely on examining common terms in two texts to determine similarity often lack statistical evidence to support them [1]. Second, short writings frequently use colloquial language and contain numerous typographical and grammatical errors. Third, due to the huge volume of short messages produced, they tend to be ambiguous and noisy [2]. Consequently, it is difficult to use traditional text similarity

methods for short texts. There are three main methods for calculating the similarity of short texts. The first method is word-level semantic-based, which looks at the words in the texts and finds pairs of similar words. It then calculates the similarity of the whole text based on the similarity of these word pairs. The second method is semantic modeling-based, which looks at the overall structure of the texts and compares the two models to see how similar they are. The third method is deep learning-based, which converts the short texts into "word embeddings" and calculates how close the words are to each other using cosine similarity [3]. Other approaches such as convolutional neural networks (CNN) and recurrent neural networks (RNN) can take a long time to train due to their sequential processing of information. However, most of the supervised work in NLP is done using a human-annotated corpus. This approach involves two steps: first, candidate phrases are extracted using a heuristic method, and then a classification model is trained to determine whether the phrase is from an answer or a sentence [4-5]. Other deep learning approaches such as pre-trained sentence transformers, like GPT-1, BERT, XLNet, Roberta, and ELECTRA, have been incredibly successful because they can learn a universal language representation from vast amounts of unlabeled text data. Moreover, the transformer learning model has led to a lot of progress in machine learning. It uses a sequence-to-sequence architecture and an attention mechanism to determine the significance of words in a sequence. This mechanism imitates the way humans read and think. Transformer-based models use a feature extraction technique that creates a vector for each word in the sequence based on its relevance to the other words. The aim of this study is to evaluate students' short subjective answers with the help of a multi-head attention transformer learning model based on the BERT language model, which is a promising method for improving the accuracy of student assessment. Student assessment is a crucial aspect of classroom instruction, involving evaluating students' knowledge, understanding, and skills to inform instruction and support student learning. Various forms of assessment, including quizzes, exams, projects, and presentations, serve to measure student progress and identify areas where additional support is needed [6-7]. By providing feedback to both students and teachers, effective assessment practices can help ensure that students are meeting learning goals and enable teachers to tailor instruction to meet the needs of individual students.

The key contributions of this study are:

- 1) To develop a BERT-based transformer learning model that utilizes multi-head attention to accurately identify and assess students' short answers in personalized learning.
- 2) To evaluate the effectiveness of the proposed transformer learning model in improving the accuracy of assessments compared to current state-of-the-art techniques.
- 3) To investigate the challenges of assessing short answers using machine learning methods, such as transformer models with multi-head attention, and propose solutions to overcome these issues.
- 4) To contribute to the field of NLP and personalized learning by developing an advanced technique for understanding and assessing the underlying meaning of short text answers.

The paper is structured as follows:

Section II provides a comprehensive review of the related literature, Section III elaborates on the proposed method, Section IV presents the results and corresponding discussions, and presents the implications and suggested solutions, and Section V concludes the paper.

II. RELATED WORK

The purpose of the literature review is to examine the various machine learning methods and techniques that are utilized in short text semantic similarity. In order to achieve this objective, we have meticulously analyzed 20 studies to provide a comprehensive overview of the related work.

The field of natural language processing (NLP) is experiencing an increasing use of deep learning techniques. Various attention-based neural network models, including Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), and Bidirectional Encoder Representations from Transformers (BERT), have captured the attention of numerous researchers. In the domain of short text semantic similarity (STSS), Wang et al. [8] conducted a study in the field of short text semantic similarity. They utilized a Convolutional Neural Network (CNN) to classify short text and identify related words. The authors also used external knowledge and Jaro-Winkler similarity to understand the conceptual meaning of words and detect grammatical errors in sentences, respectively. The research conducted by Shih et al. [9] resulted in the development of a short answer grading system that utilizes a Convolutional Neural Network (CNN). Their CNN model operates as a text classifier to interpret Chinese language responses submitted by students. The authors' use of binary classification methods enabled the grading of answers as either correct or incorrect with relative accuracy. This system has the potential to revolutionize the grading process of short answer responses in the Chinese language.

Furthermore, the DE-CNN model introduced by Xu et al. [10] represents a significant advancement in the area of short-answer comprehension. By utilizing multiple embedding layers, the authors were able to gain a deeper understanding of the context and underlying concepts within short answers. The attention embedding layer further enabled the extraction of concept representations, enhancing the model's accuracy and

effectiveness. These findings have implications for the development of future deep-learning models designed for short-answer comprehension. Moreover, the CNN model proposed by Perera et al. [11] represents a significant contribution to the field of web-based question-answering systems. By focusing on factoid questions with short answers, the authors were able to develop a model that effectively identifies irrelevant answers. However, it is worth noting that the model's inability to answer the complete factoid question set highlights a need for continued research in this area. Future studies may consider building on this work to enhance the accuracy and effectiveness of web-based QAS models. The character-level CNN developed by Surya et al. [12] also represents a promising approach to short-answer comprehension. By relying solely on character-level data, the model can learn to identify key information without any prior knowledge of language or semantics. Nevertheless, the challenges faced by the authors in scoring short answers highlight the need for continued research in this area. Future studies may consider developing novel tools and strategies to enhance the effectiveness of short-answer scoring in the context of character-level CNNs. The approach proposed by Liu et al. [13] represents a novel approach to mining and comprehending global features from a short text. By combining the strengths of both CNN and LDA, the authors were able to develop a method that effectively captures both local and global features. This approach may have significant implications for natural language processing tasks, particularly in the context of short text comprehension. The SVMCNN model developed by Hu et al. [14] represents a promising approach to short-text classification. By combining the strengths of both CNN and SVM, the authors were able to develop a more robust model capable of accurately classifying short text data. Moreover, by training the model on the Twitter social platform using TensorFlow, the authors demonstrated the applicability of their method to real-world scenarios. This study may have important implications for the development of more effective short-text classification methods.

Moreover, the LSTM model proposed by Yao et al. [15] represents a novel approach to short text similarity calculation. By utilizing cosine similarity and backward propagation, the authors were able to develop a more accurate and robust model capable of measuring the similarity between short texts. This method may have important implications for various natural language processing tasks, such as information retrieval and question-answering systems. The approach taken by Zhou et al. [16] represents an innovative method for short-text classification using both RNN and CNN. By combining semantic features extracted from both types of neural networks, the authors were able to develop a more comprehensive and effective model for Chinese short-text classification. This study may have important implications for various natural language processing tasks, such as sentiment analysis and document classification. The study conducted by Hassan et al. [17] sheds light on the challenges involved in measuring similarity among short texts and proposes a potential solution using RNN and Tf-IDf vectors. The findings of this research could be beneficial for improving the performance of short text classification and similarity tasks in various fields, such as social media analytics, customer service, and content analysis.

The use of RNNs to generate vector representations of short text is a promising approach for improving the accuracy and efficiency of natural language processing tasks. The evaluation of the model on a standard benchmark dataset like DSTC provides a reliable way to assess its performance and compare it with other models. The research conducted by Lee et al. [18] contributes to the ongoing efforts to develop effective and scalable solutions for processing short text in various domains, such as social media, e-commerce, and customer service.

Furthermore, Mozafari et al. [19] introduced a BERT-based answer selection model (BAS) to capture both the syntactic and semantic information in short question-answer pairs. The model employs pre-trained BERT embeddings to encode the input text and utilizes a binary classification approach to predict whether a given answer is correct or not. The authors evaluated the performance of their proposed model on several benchmark datasets and achieved state-of-the-art results in short answer selection tasks. Wijaya et al. [20] leveraged the BERT model to devise an automated grading system for short answers in the Indonesian language. The study employed Cohen's Kappa to assess the inter-rater reliability among student answers, and the model demonstrated high accuracy in grading the short answers. These findings suggest that the proposed approach holds promise for implementation in educational contexts, where efficient grading mechanisms are essential.

Luo et al. [21] explored the use of the BERT model for grading short answers, similar to the study by Wijaya et al. [20]. However, they utilized a different dataset for training the model, which was the short answer scoring V2.0 dataset. In addition, the study used the regression task function to check the linearity between answers, and found that the BERT model achieved high accuracy in grading short answers. These results indicate the potential of the BERT model in improving the efficiency of grading mechanisms in educational settings. However, further research is needed to investigate the generalizability of these findings across different languages and domains. In the study, Alammary et al. [22] introduced the use of BERT models for short text classification in Arabic. The researchers explored different versions of BERT models and evaluated their effectiveness in classifying Arabic short texts. Furthermore, the study compared the performance of the Arabic BERT models with their English counterparts. This research has significant implications for natural language processing tasks in the Arabic language and can lead to the development of more effective and accurate models for Arabic text classification. Heidari et al. [23] developed a short answer grading system for Indonesian students using domain-independent subjects such as biology and geography. The study employed the BERT model to detect word embeddings from sentences and analyze the contextual information for improved grading accuracy. By integrating domain-specific knowledge into the model, the proposed approach demonstrated high accuracy in grading short answers, suggesting its potential use in educational contexts for efficient and reliable grading. Gaddipati et al. [24] highlighted the distinctions between transformer-based language models such as BERT, GPT, GPT2, and ELMO. Unlike ELMO and GPT, BERT utilizes a transformer mechanism and extracts contextual embeddings in

a bidirectional manner. The model is trained on large-scale datasets such as Book Corpus and Wikipedia, which consist of 800M and 2500M words, respectively. Overall, the study sheds light on the unique features and capabilities of these advanced language models. Furthermore, Zhu et al. [25] developed a BERT-based framework for grading short answers, which incorporated CNN and capsule networks, as well as a triple-hot loss strategy to encode key sentences. The approach was tested on a dataset of student short-answer responses and yielded superior results compared to other state-of-the-art methods. These findings indicate that the proposed framework has the potential to significantly improve the accuracy and efficiency of grading mechanisms in educational settings. In addition to the classification of ASAG systems, Burrow et al. [26] also identified several limitations in these systems. One of the main limitations identified was the inability of existing ASAG systems to handle complex or open-ended questions. Another limitation was the reliance of ASAG systems on pre-defined rubrics, which can limit the flexibility of the grading process. The authors suggested that future research should focus on addressing these limitations and developing more sophisticated ASAG systems that can handle a wider range of questions and provide more accurate and flexible grading mechanisms.

On the other hand, Mohler et al. [27] proposed a different approach for grading short answers using lexical semantic similarity. The authors argue that deep learning techniques, such as the ones used in BERT and other transformer-based models, may not be the most effective method for grading short answers because they rely on large amounts of training data. Instead, Mohler et al. utilized a method based on semantic similarity to assess the quality of short answers. By comparing the semantic features of the correct answer and the student's answer, the system was able to assign a score that reflected the level of correctness. This approach may be particularly useful for assessing short answers in domains where training data is limited, and where deep learning models may not be effective. Ye et al. [28] leveraged the BERT model to generate context-sensitive representations and combined it with the GCN model to classify short text. The study demonstrated that the proposed approach achieved high accuracy in classifying short text, indicating its potential application in various natural language processing tasks. By incorporating both contextual and graph-based information, the proposed method may provide a more comprehensive understanding of the meaning of the short text.

III. METHODOLOGY

A. Data Collection

This study utilizes the computer science dataset, developed by Mohler et al. [27], which comprises 2443 student answers and 87 questions from 12 assignments in the field of computer science. The dataset includes both, the questions and reference answers, as well as the student responses, and was designed to evaluate the effectiveness of models in grading student answers by comparing them to the evaluator's desired answer. The dataset has been graded by human evaluators who are experts in the field of computer science, and the grading scale ranges from 0 (not correct) to 5 (totally correct). Table I provides a detailed overview of the dataset used in this study. It contains a total of 87 questions and 2442 student responses, which are

distributed across 12 different assignments. The number of questions in each assignment varies. The grading of each student response is done by two human graders, and the average of their scores is used as the standard score for each response.

TABLE I. MOHLER DATASET FOR THE ASSESSMENT

Institute	University of North Texas
Class/domain	Introductory computer science class
Course	Data structure
Assignments	12 assignments
Questions	87
Answers	2442
Score by human evaluators	0-5
Data collection	WebCT online learning environment
Type of questions	Open-ended

Additionally, it is worth noting that the dataset used in this study exhibits a bias toward correct answers. The dataset comprises both very short and very long answers. However, to ensure a fair evaluation, we have only included answers containing 10-20 words from the test dataset, which is considered an ideal size for short answers. Fig. 1(a) and Fig. 1(b) present the score assigned by human evaluators which is inconsistent, and Fig. 1(b) illustrates the biased nature of the dataset toward correct answers.

Fig. 1. (a) Distribution of grades and (b) Histogram of scores assigned by human evaluators [29].

Table II illustrates the sample example from the dataset which contains questions, teacher answers, student answers, and scores assigned by teachers.

TABLE II. ILLUSTRATES THE SAMPLE EXAMPLE FROM THE DATASET

	Sample of questions, teacher answers, and student answers	Grades
Question. Teacher answer.	What is a variable? A location in memory that can store a value.	
Student answer:	A block of memory that holds a specific type of data.	5,5
Student answer:	A pointer to a location in memory.	3,5
Question. Teacher answer.	What is a pointer? A variable that contains the address in memory of another variable.	
Student answer:	A pointer holds a memory location.	5,4
Student answer:	Is a reference call to the place in memory where the object is stored.	3,4

B. Pre-processing

Before training and testing our machine learning model, we performed several pre-processing steps on the dataset to ensure that the text data was in a clean and normalized format. One issue we encountered was that many of the student answers contained spelling errors and unnecessary punctuation, which can introduce noise and sparsity into the dataset and negatively impact the performance of our model. To address this issue, we implemented techniques such as spell-check and punctuation removal to clean and normalize the text data. These steps involved identifying and correcting misspelled words, and removing unnecessary punctuation marks that may interfere with our analysis. Additionally, we also performed other pre-processing steps as mentioned in Fig. 2 such as removing stop words and converting text to lowercase to further enhance the quality and consistency of the data. By carefully pre-processing the dataset, we were able to significantly improve the accuracy and effectiveness of our machine-learning model, and ultimately generate more reliable and informative results. The following algorithm 1 mentions the pre-processing steps applied to the dataset (see Fig. 2).

Pseudocode of Pre-processing Dataset	
Input:	<ul style="list-style-type: none"> A dataset with text entries that contain spelling errors and or punctuation.
Output:	<ul style="list-style-type: none"> A cleaned dataset with the same text entries, but with all spelling errors and punctuation removed.
Steps:	<ol style="list-style-type: none"> Load the dataset into a list. Define a function to remove punctuation from a given text. Define a function to remove spelling errors from a given text. Loop through each entry in the dataset and apply the following cleaning steps: <ol style="list-style-type: none"> Remove punctuation from the entry using the punctuation removal function. Remove spelling errors from the entry using the spelling error removal function. Append the cleaned entry to a new list of cleaned data. Return the new list of cleaned data.

Fig. 2. Cleaning of the dataset.

C. BERT-Multi-Head Attention Model

BERT is a transformer-based model that utilizes bidirectional processing and attention mechanism to understand language. Several versions of the BERT model such as Roberta, KeyBERT, M-BERT, and SBERT have been introduced. We used the BERTbase-uncased model as it has shown the best performance on NLP tasks. This model can encode various languages but utilizes the default English vocabulary. The architecture of the BERT model with tokens is shown in Fig. 3, where E1-EN generates the input tokens, and T1-TN are output tokens that categorize phrases using binary representations and deliver them to the C-label. BERT employs a masked language modeling technique that predicts incoming words based on the surrounding context. This technique changes 15% of the words in a sentence presented in Fig. 4 where 80% are converted to "mask" tokens, 10% to random words, and 10% to their previous representations. BERT evaluates the accuracy of its predictions and fine-tunes accordingly. Compared to an implementation of BERT that operates without masking, BERT coverage is slower but reaches a higher threshold. The next sentence prediction (NSP) examines whether the two sentences are connected logically, providing contextual information for both sentences.

Fig. 3. BERT language model.

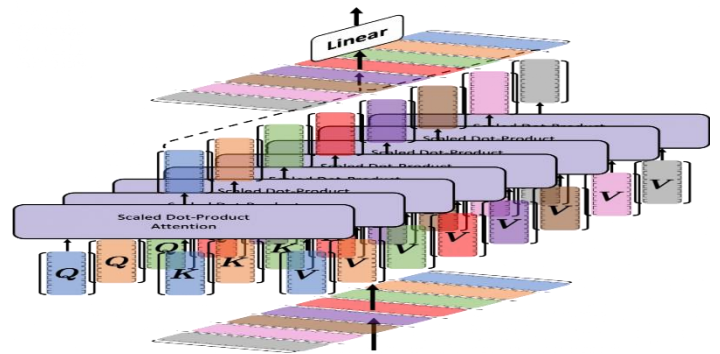

Fig. 5. Multi-head attention.

Fig. 4. BERT model with and without masked language modeling.

It uses a transformer-based architecture to process text data and learn contextual representations. One of the key components of transformer architecture is multi-head attention. Multi-head attention is a type of attention mechanism that allows the model to attend to different parts of the input sequence simultaneously. In the case of BERT, multi-head attention is used in both the encoder and decoder components of the transformer architecture. The BERT multi-head attention model consists of three components: query, key, and value matrices as shown in Fig. 5. These matrices are used to compute the attention scores, which determine how much attention each token in the input sequence should receive. The query matrix represents the current token that is being processed, while the key and value matrices represent all the other tokens in the sequence. The multi-head attention mechanism in BERT involves splitting the query, key, and value matrices into multiple heads. Each head has its own set of parameters and is trained to attend to a different part of the input sequence. This allows the model to capture different aspects of the input sequence and learn more complex relationships between the tokens. The output of the multi-head attention mechanism is computed as the weighted sum of the values, where the weights are determined by the attention scores. The attention scores are computed by taking the dot product of the query matrix and the key matrix and then applying a SoftMax and linear function to normalize the scores. The resulting attention vector is then multiplied by the value matrix to obtain the output. The BERT multi-head attention model also includes a layer normalization step after the output is computed. Layer normalization ensures that the output has a mean of zero and a standard deviation of one, which helps to improve the stability and performance of the model.

The implementation method utilized the BERT multi-head attention model, a monolingual model solely evaluated on the English dataset. The process involved setting up sentence transformers on a dataset and fine-tuning the model through a question-answer task. The results were evaluated using statistical approaches. Fine-tuning the model ensured that it could accurately understand the context of the given task, making it suitable for various natural language processing applications. Additionally, the implementation method applied the attention mechanism to highlight the answers that best matched the teacher's answer. This approach enabled the model to provide more accurate responses and perform better in question-answering tasks. Fig. 6 presents a visual representation of the implementation process. By following this process, the model can be optimized for specific tasks, resulting in better performance. It is worth noting that this implementation method is limited to the English language, as BERT is a monolingual model. However, there are other models available that support multiple languages. Overall, the BERT multi-head attention model is a powerful method for natural language processing tasks and has been widely adopted in various applications, including chatbots, sentiment analysis, and language translation.

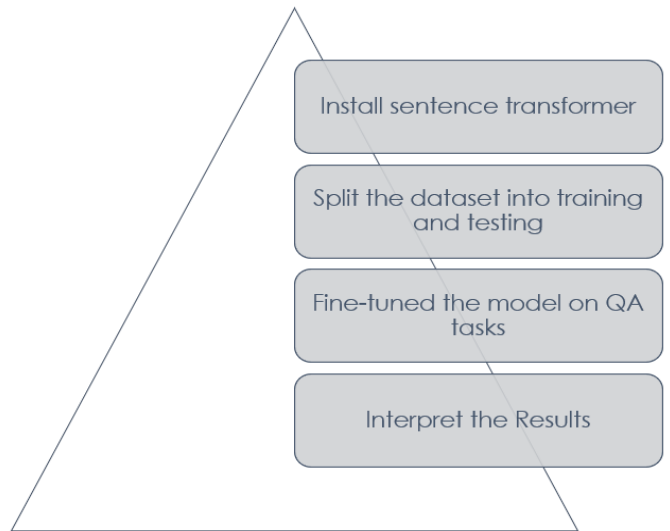

Fig. 6. Implementation details.

D. Training and Testing

To evaluate the performance of our approach, we utilized the BERT multi-head attention model. We randomly split the Mohler dataset into 70% training and 30% testing data, ensuring that the split was representative of the entire dataset. We trained the model for 1000 iterations, using different training and testing data for each iteration to improve the generalization of the results. The cosine similarity feature was trained using isotonic, linear, and non-linear (ridge) regression models, and the performance was compared to previously established models such as Mohler et al. [27]. Following training, we evaluated the model by testing it on the unseen test data. The similarity scores of the test data were input through the trained regression model, resulting in predicted grades that were compared to the desired scores. We calculated the Root Mean Square Error (RMSE) and Pearson correlation to evaluate the model's performance. Our utilization of the BERT multi-head attention model allowed us to effectively analyze and evaluate the performance of our approach on the Mohler dataset. The results of this study could have significant implications for future natural language processing applications, particularly those that require accurate grading of written responses.

IV. RESULTS

A. Feature Extraction

In the feature extraction, we use the pre-trained embeddings from each transfer learning model and assign them to the tokens of every word in all the answers. To create answer embeddings, we use the Sum of Word Embeddings (SOWE) method, as shown in Eq. (1). Here, a_{ij} denotes the j -th answer vector of question q_i , and w_k represents the vector of the k -th word in the answer a_{ij} . By applying this method, we obtain a single vector that represents each answer in a high-dimensional hypothesis space. The resulting sentence embeddings have the same size as the word embeddings. This approach allows us to capture the semantic and syntactic properties of each answer and create a compact representation of it.

$$a_{ij} = \sum_{k=1}^{n_j} w_k \quad (1)$$

In this equation, " a_{ij} " represents the vector of the j th answer of the question " q_i ", " w_k " represents the vector of the k th word in the answer " a_{ij} ", and " n_j " represents the number of words in the answer " a_{ij} ". The equation calculates the sum of the word embeddings for each word in the answer to create a single vector representing the entire answer. To create a Question-Answering model using BERT, the tokenizer utilizes two special tokens, namely [CLS] and [SEP]. These tokens serve the purpose of encoding the sentence sequence. The [CLS] token is a classification token, whereas the [SEP] token separates the Key and response answer, as exemplified below. The sequence of sentences is then passed as a token input to the BERT model for training [32,35]. The model generates high-dimensional embeddings for input tokens, which are then used to predict the grades within a specified range. An example of BERT embeddings is given below.

Question: What is a variable??

Key Answer: A location in memory that can store a value.

Student Answer: a block of memory that holds a specific type of data.

[CLS] and [SEP]: [CLS] a location in memory that can store a value [SEP] A block of memory that holds a specific type of data

Token ids of both responses:

[101, 10408, 1996, 9896, 1998, 5468, 1995, 3558, 2770, 2051, 1012, 102, 270, 2019, 9896, 2006, 103, 3563, 102]

Example of Response pair and Token Id's

Additionally, the multi-head attention mechanism is utilized to visualize the relationships between words. The lines that are darker in color indicate a closer relationship between words at layers 1,2,3,4.

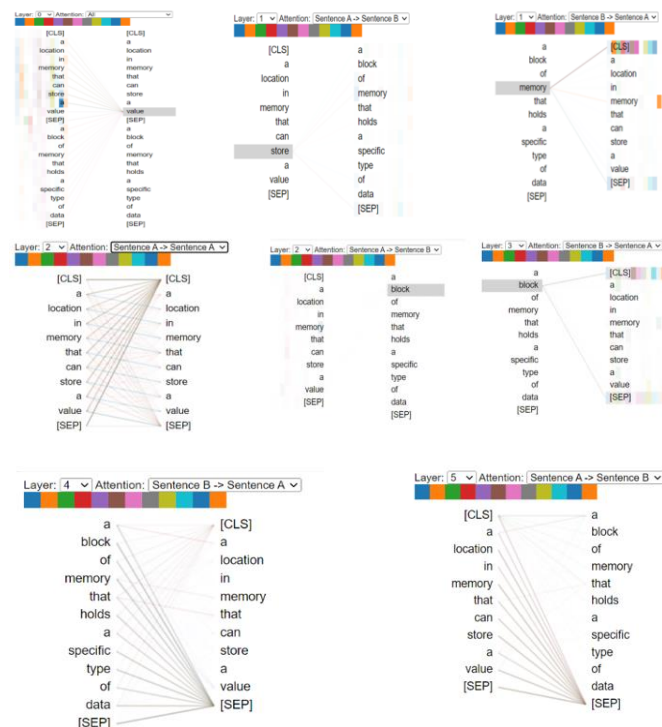

Fig. 7. BERT-based multi-head attention model for layers 0, 1, 2, 3, 4, 5

The findings obtained from the BERT-based multi-head attention model are extremely encouraging (see Fig. 7). Layer 0 has highlighted the importance of the [CLS] and [SEP] tokens, as they effectively emphasize the embeddings from the text. Layer 1 has shown a strong correlation between the words "store" and "memory," indicating that they are related. In layers 2, 3, and 4, words such as "block," "value," "memory," "type," and "hold" also share strong embeddings, indicating their interconnectedness. Moreover, the relationship between student and teacher responses has also been established, as their embeddings show strong correlations. Layer 0 also performed self-attention with multi-heads to determine the relationships between different parts of the answer itself. The multi-head attention module utilized teacher-to-teacher, teacher-to-student, and student-to-student attention to determine the strong impact

of different words. This approach has proved to be highly effective in identifying the key components of the response and the underlying relationships between them. The results obtained through this model have significant implications for natural language processing, particularly in the field of language understanding and interpretation. The multi-head attention mechanism can be used to improve the accuracy of machine translation, question-answering systems, and text classification algorithms, among others. Overall, the BERT-based multi-head attention model has demonstrated its ability to capture complex relationships between different components of natural language text. This approach has the potential to revolutionize the field of natural language processing and enable more accurate and efficient analysis of text data.

B. Automated Scoring

To evaluate student answers, we employed text similarity techniques that match the embeddings of teacher answers to student responses. We used Python programming with Spyder IDE to implement this process. After extracting the embeddings using the BERT-multi-head attention model, we used four similarity methods to obtain a similarity value, which we used as a scoring rubric. These four methods are the longest common subsequence (LCS), cosine coefficient (SC), Jaccard coefficient (JC), and Dice coefficient (DC). Additionally, we chose these methods as they are commonly used in Natural Language Processing (NLP) and provide reliable results for text similarity comparisons.

$$Score = \frac{(Score(sim)*answer\ score)+(Score(keymatch)*answer\ score)}{2} \quad (2)$$

Example to calculate the similarity of teacher and student answers:

Teacher answer: a location in memory that can store a value.

Student answer: a block of memory that holds a specific type of data.

$$Sim_{lcs} = \frac{2*40}{58*40} = 0,81633 \quad sim(cosine) = \sqrt[6]{9*6} = 0,81650 \quad score(keymatch) = 6/9 = 0,66667$$

$$Sim_{jaccard} = \frac{6}{9} = 0,66667 \quad Simdice = \frac{2*6}{9+6} = 0,80000$$

To determine the score for each student response, we derived a scoring rubric by averaging the similarity values obtained through two different methods: the String-based method and the keyword-matching technique. The String-based method involves comparing the strings in the form of embedding values of the teacher's and student's answers to identify common sub-sequences and measure their similarity. On the other hand, the keyword matching technique involves identifying the presence of specific keywords in the student's answer that are expected based on the question or prompt.

In the previous example, we obtained a similarity score of 0.66667. However, it should be noted that we have multiple references available, and we select the highest similarity score among them. In this case, the highest similarity score is 0.85714.

$$Score = \frac{(0.81633*4)+(0.85714*4)}{2} = 3.34695$$

Therefore, we consider this score as the final similarity score for the response in question. This approach helps to ensure that the students receive a fair and accurate evaluation, as we consider all available references and select the most appropriate one.

C. Comparative Evaluation

Our model's performance was evaluated using RMSE and Pearson correlation scores, and we conducted a comparative analysis of our model's performance with various pre-trained models, such as ELMO, GPT, and GPT2, as reported by Gaddipati et al. [24], on the Mohler dataset. We further compared our model's performance with other approaches and showed that the BERT-multi-head attention method outperformed other techniques in terms of effectiveness. Table III displays the Root Mean Square Error (RMSE) and Pearson correlation (ρ) results of various Pre-trained transfer learning models on the Mohler Dataset.

Table IV compares the performance of different models and approaches on the Mohler dataset. The models are evaluated based on their RMSE (Root Mean Square Error) and Pearson correlation scores. The results for the BOW (Bag of Words) approach with SVMRank, achieve an RMSE of 1.042 and a Pearson correlation score of 0.480. The results for the tf-idf approach with SVR, which performs slightly better than the BOW approach with an RMSE of 1.022 and a Pearson correlation score of 0.327. The results for the tf-idf approach with LR (Logistic Regression) and SIM (Semantic Information), which outperforms the previous two approaches with an RMSE of 0.887 and a Pearson correlation score of 0.592. Furthermore, the results for three different word embedding models - Word2Vec, GloVe, and FastText; all of these models use SOWE (Sum of Word Embeddings) and Verb phrases features, and they achieve RMSE values ranging from 1.023 to 1.036 and Pearson correlation scores ranging from 0.425 to 0.465. The results for deep learning models - ELMo, GPT-2, and Roberta; ELMo uses a 5-layer BiLSTM (Bidirectional Long Short-Term Memory) with max-pooling and achieves an RMSE of 0.875 and a Pearson correlation score of 0.655. GPT-2 uses a 12-layer Transformer and achieves an RMSE of 0.911 and a Pearson correlation score of 0.610. Roberta uses a 24-layer Transformer and achieves the best performance among all the models with an RMSE of 0.851 and a Pearson correlation score of 0.692. Results of our BERT-based model (our approach) with Multihead Attention as the feature has RMSE value as 1.990, which means that on average, our model's predictions deviate from the actual values by 1.990 points. The Pearson correlation coefficient is 0.773, which indicates a strong positive correlation between our model's predicted scores and the actual scores. Overall, the RMSE value of 1.990 is higher than the RMSE value of the RoBERTa model (0.851), which indicates that our model has a higher prediction error than RoBERTa. However, the Pearson correlation coefficient of our model (0.773) is higher than that of RoBERTa (0.692), indicating that our model's predicted scores are more strongly correlated with the actual scores than RoBERTa's predictions.

TABLE III. A SUMMARY OF THE RESULTS OBTAINED BY VARIOUS APPROACHES ON THE MOHLER DATASET IS PRESENTED

Model	Isotonic regression		Linear regression		Ridge regression	
	RMSE	P	RMSE	p	RMSE	P
ELMO [24]	0.978	0.485	0.995	0.451	0.996	0.449
GPT [24]	1.082	0.248	1.088	0.222	1.089	0.217
GPT2 [24]	1.065	0.311	1.077	1.075	1.079	0.269
BERT-multi-head attention Our model	1.089	0.456	1.990	0.773	1.536	0.876

TABLE IV. COMPARISON WITH OTHER METHODS

Model	Features	RMSE	Pearson Correlation
BOW [29]	SVMRank	1.042	0.480
Tf-idf [30]	SVR	1.022	0.327
Tf-idf [31]	LR+SIM	0.887	0.592
Word2Vec[33]	SOWE + Verb Phrases	1.025	0.458
Glove [34]	SOWE + Verb Phrases	1.036	0.425
FastText[35]	SOWE+Verb Phrases	1.023	0.465
ELMO [24]	5-layer BiLSTM +max-pooling	0.875	0.655
GPT-2 [24]	12-layer transformer	0.911	0.610
Roberta[36]	24-layer transformer	0.851	0.692
BERT (our approach)	Multihead Attention	1.990	0.773

D. Model Implications

One of the primary challenges is the limited availability of training data for short answers. Short answers are usually context-dependent and diverse in nature, making it difficult to generate large amounts of high-quality training data. Additionally, there is often ambiguity and variation in short answers, which makes it challenging for machine learning models to accurately evaluate them. Another challenge is the need for efficient methods to encode short answers and generate embeddings that can be used for similarity matching. Transformer models with multi-head attention have shown promise in this regard, but there is a need for further research to optimize their performance for short answer evaluation. Furthermore, there is a need for developing robust methods to handle outliers, exceptions, and edge cases that are often encountered in short answer assessment. This requires careful consideration of the characteristics of short answers and the

design of models and algorithms that can handle such situations effectively [36-40]. To overcome these challenges, potential solutions include utilizing data augmentation techniques to generate more diverse training data, developing novel algorithms and models specifically tailored for short answer assessment, and leveraging domain-specific knowledge and expertise to enhance the performance of machine learning models. Additionally, the use of ensemble methods and human-in-the-loop approaches may improve the accuracy and reliability of short answer evaluation.

V. CONCLUSION AND FUTURE WORK

This study aimed to assess short subjective answers using a BERT-based multi-head attention model and string-based methods such as cosine co-efficient, longest common subsequence, Dice coefficient, and Jaccard coefficient to score the answers. Additionally, we compared the performance of the BERT multi-head attention model with former approaches using isotonic, linear, and ridge regression. The findings suggest that the BERT multi-head attention model outperforms other approaches, indicating its effectiveness in understanding and assessing the underlying meaning of short answers. Our study highlights the potential of machine learning methods in improving the efficiency of personalized learning, particularly in the assessment of open-ended questions. Overall, this study contributes to the growing body of research on NLP techniques and their applications in the education domain. Further research can explore the generalizability of our proposed model in different educational settings and subject domains.

Abstract—The rapid growth of application development has made applications an integral part of people's lives, offering solutions to societal problems. Health service applications have gained popularity due to their convenience in accessing information on diseases, health, and medicine. However, many of these applications disappoint users with limited features, slow response times, and usability challenges. Therefore, this research focuses on developing a sentiment analysis system to assess user satisfaction with health service applications. The study aims to create a sentiment analysis model using reviews from health service applications on the Google Play Store, including Halodoc, Alodokter, and klikdokter. The dataset comprises 9,310 reviews, with 4,950 positive and 4,360 negative reviews. The IndoBERT pre-training method, a transfer learning model, is employed for sentiment analysis, leveraging its superior context representation. The study achieves impressive results with an accuracy score of 96%, precision of 95%, recall of 96%, and an F1-score of 95%. These findings underscore the significance of sentiment analysis in evaluating user satisfaction with health service applications. By utilizing the IndoBERT pre-training method, this research provides valuable insights into the strengths and weaknesses of health service applications on the Google Play Store, contributing to the enhancement of user experiences.

Keywords—Application; healthcare; IndoBERT; sentiment analysis

I. INTRODUCTION

In the present age of digital advancements, a myriad of applications has emerged to cater to diverse facets of human life, spanning across desktops, tablets, and smartphones. This surge in demand has created lucrative business prospects, resulting in the proliferation of mobile applications aimed at resolving everyday challenges [1]. Regrettably, not all applications boast commendable features and functionalities, including the healthcare applications readily available on the Google Play Store. Consequently, there arises a pressing need for a system capable of comprehensively analyzing application reviews to enhance their overall performance. While opinions and ratings serve as primary means for gathering feedback on an app's usability, ratings alone may not consistently provide reliable insights [2]. Furthermore, ratings fail to offer a comprehensive understanding to improve the user experience aspect. Thus, the examination of customer reviews becomes crucial for gaining deeper insights and understanding [3]. User experience entails the intricate narrative surrounding a user's interaction with the app, while opinions delve into their underlying thoughts and emotions. Users possess the freedom to express their evaluations in various textual forms, resulting

in a less structured review dataset, which in turn poses greater challenges in handling and analysis [4].

Sentiment analysis, commonly referred to as opinion mining, is a technique that aims to classify user sentiment based on polarity [5]. It encompasses a wide array of objectives, methodologies, and types of analytics. In the domain of sentiment analysis, three main methodologies are employed: machine learning (ML), hybrid learning, and lexicon-based approaches [6]. Among these, supervised learning emerges as the most popular and widely utilized ML approach. This methodology involves training the model using labeled data to predict outputs, while also incorporating additional unlabeled inputs for enhanced performance [7].

In the context of sentiment analysis, it is important to acknowledge that certain languages, such as English and Chinese, benefit from being considered high-resource languages, as they have readily available datasets accessible to the academic community. However, the majority of languages face challenges due to limited data collection and a lack of published research, including Indonesian [8]. Previous research on sentiment analysis of Indonesian text has explored the efficacy of machine learning models like Support Vector Machine (SVM) and Naïve Bayes, demonstrating their effectiveness in addressing this issue [9]. Nevertheless, the integration of pre-training using language models has emerged as a promising approach across various natural language processing tasks [10], [11]. One significant drawback of conventional language models is their unidirectional nature, which imposes limitations on the available architecture for pre-training. To overcome this limitation, a novel technique called Bidirectional Encoder Representations from Transformers (BERT) has been proposed to enhance the fine-tuning-based approach [12].

A number of previous studies have explored sentiment analysis in the context of Indonesian language, employing various approaches ranging from traditional machine learning classifiers to deep learning-based algorithms such as IndoBERT. For instance, sentiment analysis using random forest algorithms demonstrated promising results, achieving an average out-of-bag (OOB) score of 0.829 [13]. Similarly, research focused on emoticons and emoticon categories utilized classification-based machine learning algorithms like naïve Bayes and support vector machines [14]. Sarcasm data classification was also conducted using random forest classifiers, naïve Bayes, and support vector machines [14]. Furthermore, Word2Vec was employed as an alternative to hand-crafted features for sentiment analysis of hotel reviews in

Indonesian, with the conclusion that optimal accuracy can be achieved by simultaneously increasing vector dimensions and the amount of data [15]. IndoBERT, which outperforms both multi-Indonesian lingual BERT and Bert, has demonstrated superior data processing capabilities. The research involved data collection, data preprocessing, and fine-tuning of IndoBERT. Hoax detection classification was completed using pre-trained BERT models, with multilingual BERT for general purposes and IndoBERT specifically tailored for Indonesian. The fine-tuned IndoBERT model, trained on an Indonesian monolingual corpus, exhibited enhanced performance compared to the original BERT and improved multilingualism [16].

However, performing this analysis manually is quite difficult; hence we propose performing Indonesian language analysis using the IndoBERT algorithm, which was built exclusively to evaluate Indonesian language material. The primary objective of this research is to develop a sentiment analysis system for healthcare application reviews on the Google Play Store using the IndoBERT approach. Additionally, the system aims to assist users in selecting health service applications that offer optimal functionality and facilities. The proposed methodology involves leveraging IndoBERT as a pre-training model, renowned for its effectiveness in processing Indonesian language data. The data utilized in this research is sourced from the Google Play Store, making it a novel and previously unexplored area of investigation.

II. METHODOLOGY

The research conducted in this study encompasses several stages. Firstly, review data was collected by scraping the Google Play website, followed by manual labeling of the obtained data. The labeled data was then preprocessed to ensure cleanliness and suitability for classification. The dataset was subsequently divided into three parts: training data, validation data, and testing data, with a distribution ratio of 70:10:20. The next step involved creating a classification model using IndoBERT, and adjusting hyperparameters to optimize its performance. Lastly, the model was evaluated using the testing data, employing various parameters such as accuracy, precision, recall, and F1-score. For a comprehensive overview of the research design, please refer to Fig. 1.

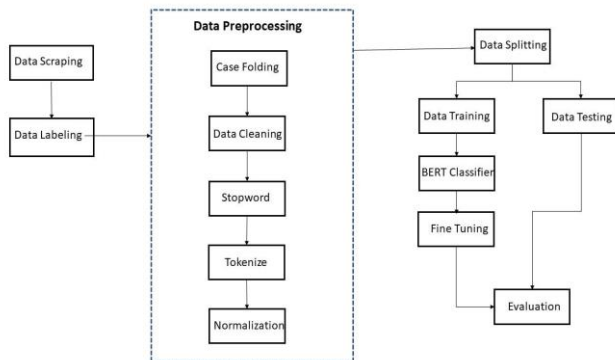

Fig. 1. Research design.

A. Data Scraping and Labeling

The dataset utilized in this research was obtained from the Google Play website. Data collection was performed using scraping techniques, employing the Python programming language and the Google-play-scraper library. The authors specifically collected review data from healthcare applications such as Alodokter, Halodoc, and Klikdokter, amassing a total of 9.310 user reviews in September 2022. To avoid the biases data, we removed any personally identifiable information (PII) from the reviews.

As the data was initially unlabeled, a manual data labeling process was conducted to facilitate the subsequent classification task; it is a very important process because the deep learning model will learn from the pattern of the given dataset.

The dataset was divided into two classes: positive and negative class. Following the completion of the labeling process, the dataset comprised 4.950 positive reviews and 4.360 negative reviews, so the dataset used is quite balanced. Detailed information regarding the datasets used in this study can be found in Table I.

TABLE I. DATASET

No	Class	Data
1	Positive	4.950
2	Negative	4.360
	Total	9.310

B. Preprocessing Data

Preprocessing is a crucial step in converting raw data into a format suitable for classification input [17]. This process involves five stages, namely case folding, data cleaning, stopword removal, tokenization, and normalization [18]. Case folding denotes a textual transformation operation that converts all capital letters within a string to a lowercase, to render the comparison and processing of text more consistent. Data cleansing constitutes a critical preprocessing step for natural language processing (NLP) pipelines. NLP involves manipulating and analyzing human language; hence the quality of the input data can substantially influence the performance and efficacy of NLP systems. This process aims to prepare the classification input by eliminating unwanted elements. Various actions are performed during data cleaning, such as removing unique characters, usernames, hashtags, punctuation, emojis, and excessive spaces, resulting in a dataset containing only words.

The next phase is known as the stopword process and entails removing common words that appear frequently but have no significant meaning. In computational linguistics and textual data analysis pipelines, function words considered uninformative are frequently used. These terms, known as stopwords, are eliminated prior to subsequent processes because they contribute marginally to the semantic content. Typically, they contain high-frequency words such as "the," "is," "and," "a," "an," "in," "of," etc. The precise stopword lexicon varies based on the objective of natural language processing and the examined language. The rationale behind the eradication of stopwords is the reduction of the dimensionality of textual data, which can accelerate processing

and improve the efficacy of specific natural language processing techniques, such as text categorization and information extraction. By removing these common terms, the emphasis transfers to more informative content words that can provide more meaningful distinctions. To accomplish this, a stop-list dictionary containing these words is compiled. Therefore, data containing stop list terms are removed to improve sentiment analysis performance.

Following this, the tokenization process is applied to convert each data entry into individual tokens, where each token typically corresponds to a single word [19], [20]. Lastly, data normalization is performed to address the presence of non-standard words commonly found in Google Play reviews. This conversion of non-standard words into standard ones is essential for improving classification performance

C. Data Splitting

After the data enters preprocessing, it will be divided into three parts: training data, validation data, and testing data [21]. Each part serves a different function: data training is used to create models, data validation reduces overfitting, and data testing evaluates the created models. The proportion of data sharing is 70% for the training set, 20% for the validation set, and 10% for the test set.

D. BERT Fine Tuning

BERT is a pre-training model that has undergone extensive training on a vast amount of data. The process of creating a BERT model involves two key steps: pre-training and fine-tuning. During pre-training, the model is trained on unlabeled data using various pre-training tasks. Subsequently, the BERT model is fine-tuned using labeled data from downstream tasks, starting with the pre-trained parameters. Despite commencing with the same pre-trained parameters, each downstream task results in a well-tuned model [12]. Fig. 2 illustrates the fine-tuning process on the pre-trained BERT model. The versatility of the BERT technique has been demonstrated through various studies aimed at addressing research gaps. For instance, researchers have successfully improved accuracy with transformer-based models when dealing with large, complex documents [22]. Additionally, BERT-based text classification has been enhanced by incorporating additional sentences and domain knowledge [23]. Notably, the impact of these improvements has been particularly evident in high-resource languages like English.

Fig. 2. BERT fine tuning.

To train pre-training models effectively, it is crucial to use specific languages. Since our dataset consists of user reviews in Indonesian, it necessitates pre-training models tailored for the Indonesian language. As a result, the BERT-based model has undergone significant enhancements, leading to the development of IndoBERT [24]. This improved version is built upon the Indonesian vocabulary, achieved by modifying the Huggingface framework. IndoBERT has been meticulously trained on an extensive dataset comprising over 220 million words, sourced from various Indonesian platforms, including Indonesian Wikipedia, news articles from Kompas, Tempo, Liputan6, and Korpus Web Indonesia. The training process involved running IndoBERT through 2.4 million steps or 180 epochs, taking approximately two months to complete. The positive attributes of IndoBERT motivated us to utilize this model for classifying Indonesian app reviews. For this study, we specifically employed "IndoBERT-base-p1," which represents one variant of the IndoBERT model [8].

E. Evaluation

Evaluation is a technique used to determine a model's classification aptitude. This study's model evaluation employs a confusion matrix that generates true positive (TP), false positive (FP), false negative (FN), and true negative (TN) values. Multiple metrics, including accuracy, sensitivity, specificity, and precision, as well as the F1-Score, are employed to evaluate the implemented model. The accuracy formula has been shown in equation (1), the recall formula has been shown in equation (2), the precision formula has been shown in equation (3), and the F1-Score formula has been shown in equation (4).

$$Accuracy = \frac{TP+TN}{TP+FP+FN+TN} \quad (1)$$

$$Recall = \frac{TP}{TP+FN} \quad (2)$$

$$Precision = \frac{TP}{TP+FP} \quad (3)$$

$$F1 - Score = \frac{2 \times (Precision \times recall)}{recall+precision} \quad (4)$$

III. RESULT AND DISCUSSION

This research utilizes IndoBERT transfer learning, a technique that leverages a pre-trained model to address new problems of a similar nature. In this study, we employ IndoBERT as the pre-trained model, which stands for Indonesia Bidirectional Encoder Representations from Transformers, built using the PyTorch framework. IndoBERT is a transformers-based model, derived from Bert Base with 12 hidden layers, tailored specifically for monolingual Indonesian language tasks [25].

The investigation utilized a dataset comprising 9.310 samples, which were categorized into three subsets: training, validation, and test data. Fig. 3 illustrates the data labeling, with 4.950 samples carrying a positive label and 4.360 samples carrying a negative label. It is evident that positive or "good" reviews constituted 53.2% of the data, while negative reviews accounted for 46.8%.

Fig. 3. Review category proportions.

The author employed 10 epochs for the training process. Observing the results, it becomes evident that utilizing 10 epochs yields commendable accuracy, depicted by a noticeable upward trend in the curve. Additionally, this study utilized a learning rate of 1e-6, as a parameter for Adam's optimizer. This parameter was chosen based on experimental induction. It is worth noting that the appropriate learning rate varies from case to case, as learning rates that are too large or too small can lead to suboptimal solutions. The learning rate typically ranges from 0 to 1, with higher values facilitating faster training but not necessarily guaranteeing more optimal results. Therefore, careful selection of the learning rate value is vital to achieve the best possible outcomes. Fig. 4 illustrates the training results against the dataset, showcasing the performance curve in relation to the chosen parameters.

According to Fig. 4, the curve exhibits a pronounced upward trend to the right, suggesting a well-trained model. Additionally, the model trained with the new dataset undergoes evaluation to determine its performance against the dataset. To assess the model's effectiveness, a confusion matrix is employed in this study. The evaluation of the model against the testing data is depicted in Fig. 5.

According to the observations from Fig. 3, the model demonstrates excellent predictive capabilities. Notably, the values for true positive and true negative are significantly higher than those for false positive and false negative. The study's results indicate an impressive accuracy score of 96%, an F1-Score of 95%, a Recall of 96%, and a Precision of 95%.

Fig. 4. Training history.

Fig. 5. Confusion matrix.

This study employs a different methodology than previous studies, such as Pandesenda et al., who conducted sentiment analysis on Alodokter data extracted from the Google Play Store in 2020 [26]. This procedure employs Fast Large-Margin, which yields an accuracy of 92.33%. Mehta et al., using Bidirectional LSTM, identify healthcare sentiment analysis from Twitter data with an accuracy of 80.88% in a separate study [27]. A comprehensive overview of these comparisons can be found in Table II.

TABLE II. COMPARISON WITH OTHER STUDIES

No	Researchers	Method	Accuracy
1	Pandesenda et al.,	Fast Large-Margin	92.33%
2	Mehta et al.,	Bidirectional LSTM	80.88%
3	Our Study	IndoBERT-base-p1	96%

The reasons for specific projections in the context of sentiment analysis are critical for various reasons. (1) Sentiment analysis provides interpretability, bridging the gap between the model's sophisticated computations and human perception of emotion. (2) Users and stakeholders have a right to know why certain decisions are being made, especially when those decisions impact their experiences or choices. (3) Domain experts can provide insights into why certain linguistic patterns may carry particular sentiment connotations in the given language or culture. The limitation of this research is that the model was trained using IndoBERT, which is specifically designed for Bahasa Indonesia content and has not been tested with other languages.

IV. CONCLUSION

In conclusion, this study focused on conducting sentiment analysis of Indonesian text using the transfer learning technique with the IndoBERT pre-trained model. The research was based on a dataset containing 9.310 reviews, each labeled as either positive or negative. During the training process, 10 epochs were used along with Adam's optimizer, employing a learning rate of 1e-6. The evaluation of the model yielded impressive results, with a high accuracy score of 96%, an F1-Score of 95%, a Recall of 96%, and a Precision of 95%. These findings underscore the effectiveness of transfer learning with IndoBERT as a robust approach for sentiment analysis of Indonesian text. If the dataset used increases, with reference to the current high accuracy value, there is a possibility that the performance will decrease but not significantly.

By contributing to the advancement of natural language processing research for the Indonesian language, this study holds significant value. The applications of this technique are diverse and can prove beneficial in areas like opinion mining, social media analysis, and market research. To further enhance the model's capabilities, future research may explore parameter optimization and evaluation with larger and more diverse datasets, thereby increasing its generalizability.

ACKNOWLEDGMENT

The author expresses gratitude to the Universitas Muhammadiyah Surakarta for providing research support, enabling the completion of this study. This research is fully funded by Riset Muhammadiyah (RisetMu).

Abstract—Medical image denoising plays an important role for the noise in the medical images can reduce the visibility, thereby affecting the diagnostic results of the doctors. Although good results have been achieved by the well-known deep learning-based denoising methods for their strong ability of learning, the loss of structural feature information and the well preservation of the edge information have not attracted considerable attention. To deal with these problems, a novel medical image denoising method based on the improved CycleGAN and the complex shearlet transform(CST) is proposed. The CST is used to construct the generator to embed more feature information in the training process and the denoising process is modeled to adversarial learn the mapping between the noise-free image domain and the noisy image domain. With the mechanism of the recurrent learning from the CycleGAN, the proposed method does not need the paired training data, which obviously speeds up the training and is more convenient than other classical methods. By comparing with five state-of-the-art denoising methods, experiments on the open dataset fully prove the accuracy and efficiency of the proposed method in terms of the visual quality and the quantitative PSNR, SSIM, and EPI.

Keywords—Medical image; image denoising; CycleGAN; complex shearlet transform

I. INTRODUCTION

Medical imaging techniques play the vital role in modern disease diagnosis, for they are the disruptive tools to observe the internal structure and functional information of human body. For example, the computed tomography(CT) can show the clear structure of the fracture [1] and the PET can effectively detect and distinguish the cancer or the normal metabolism of the lung [2]. Though great success has been achieved, the main challenge comes from the possible noise or artifacts during imaging procedure, which may result in the unexpected diagnostic errors, even the death. For example, the noise will largely affect the results of image reconstruction [3]. Thus, the effective denoising methods are highly needed to be the fundamental and mandatory step of the medical imaging pre-processing or the further applications.

Nowadays, many advanced denoising methods have been proposed, all of which can be generally divided into four categories: the filter-based methods [4], the model-based methods [5], the multi-scale geometric transform-based methods [6] and the deep learning-based methods [7, 8]. For the filter-based methods, they typically implement the low-pass filters to replace the noisy or suspected pixel by their

locally averaging value or energy in the neighboring region. The Gaussian filter, median filter and diffusion filter are the common methods in the early days. However, these methods are easy to produce the results with low contrast. Then, the bilateral filter [9], non-local filter [10], guarding filter [11], the block matching and 3D collaborative filtering (BM3D) [12] are successively proposed. They improve the denoising results, but are limited to the great diversity of the noise and the setting of the parameters, such as the height and width of the searching window. The model-based methods treat the denoising process to be a special mathematical model, for example, G. Gilboa et al. proposed to use the partial differential equations to describe the evolution of an image in time, and the solution of these equations are adapted to remove the noise and preserve the details [13]. Usually, the good results can be obtained, but the computational complexity is too high to implement in the real time application.

In recent years, for the low computational complexity and the superior properties in the frequency domain, a large number of work under the multi-scale geometric transform-based methods have been popularly reported, which decompose the noisy images into multi-resolution and different directions in each scale and then do the operations on the coefficients by the threshing scheme, considering the correlation of them, or the combination with the filters. According to the proposed time, the commonly used decomposition tools include the wavelet transform, curvelet transform, contourlet transform, non-subsampled contourlet transform, shearlet transform, non-subsampled shearlet transform [14, 15]. For example, A. Halidou et al. reported a new review on the wavelet transform based medical image denoising methods, which compare the performance of the typical wavelet, such as the discrete wavelet, Harr wavelet, and Dual-Tree complex wavelet [16]. P. S. Negi and D. Labate proposed a novel denoising method based on the discrete shearlet transform for CT images [17] and X. He et al. proposed the medical image denoising methods based on the non-subsampled version of the shearlet transform [18]. They decompose the input image into sub-images with different frequency bands and perform the denoising process for each sub-image separately, and then recompose the denoising sub-images into the results. It not only has good denoising effect and fast speed, but also has strong robustness, and can be applied in practical scene. A very good review of the multi-scale geometric transform-based methods on different image modalities can be found in [19, 20]. The benefits of the multi-

scale geometric transform-based methods are obvious since the features can be easy to capture in different scales, but they usually suffer from the disadvantages that the operations on the transformed coefficients may not match the distribution of the specific noise in different scales and directions. Though some typical models are proposed to alleviate the drawback, such as the generalized Gaussian distribution model in the wavelet and shearlet domain [21, 22], the Hidden Markov Model in the wavelet, NSCT and shearlet domain [23-25], Gaussian scale mixture model [26], the results are still not satisfying.

With the great breakthrough of the deep learning theory, it has been popularly applied in the medical imaging processing domain, such as the image U-net model for the super-resolution [27], the convolutional long short-term deep network for recognition of human action [28], and the graph resnet for motor imagery classification [29], as well as the image denoising. For example, K. Zhang et al. construct the "FFDNet" model for image denoising based on the conventional neural network [30], W. Li et al. proposed to use the fast and flexible deep convolutional neural network(FFCNN) to remove the Gaussian noise [31] and K. Zhang et al. designed beyond Gaussian denoiser by the residual learning of deep CNN [32]. R. S. Thakur et al. compared the different performance of the state-of-art image denoising methods using convolutional neural networks in [33]. Recently, the good denoising results have been obtained by the generative adversarial network (GAN) model for it models the denoising task to be the game between the noisy image and denoising image, which is implemented by the learning strategy on the generative and the discriminator network [34]. Furthermore, to suppress the influence of the diversity of the noise and control the sampling variables, the conditional generative adversarial networks (CGAN) is proposed for removing the noise of the low-dose CT images [35]. The deep learning-based methods outperform the other methods for their strong representation and generalization ability of the deep level features. Though great success has been achieved, the deep learning-based methods also suffer from some obstacles, such as the large amount of training data, the selection of the pooling functions for the specific model and the unpredictable interpretability of the deep features.

On the other hand, comprehensively considering the advantages and disadvantages of the above methods, simultaneously using the multiscale feature and the deep features may be a good way to deal with their drawbacks. Very recently, some impressive works have been reported in this domain. For example, Z. Lyu et al. constructed the "NSTBNet" model based on the non-subsampled shearlet transform and a broad convolutional neural network to remove spatially variant additive Gaussian noise [36], C. Gu et al. combine the GAN and LSTM models for 3D reconstruction of Lung Tumors from CT Scans[37], Q. Song et al. proposed the multimodal sparse transformer network (MMST) to remove the external noise in the task of the automatic speech recognition by using the mechanism of sparse self-attention [38] and B. Jiang et al. constructed the so-called "EFFNet" model for image denoising by enhancing the transformed

frequency features with dynamic hash attention [39]. Inspired by the above work, a novel image denoising method based on the complex shearlet transform and the cycle-consistent adversarial networks (CycleGAN) is developed to improve the denoising performance.

The main contribution of this research work is as follows:

Firstly, a simplified but efficient cycle-consistent adversarial network is constructed. Compared with other deep learning models, it does not need a large amount of pairwise training data with labels. So, the accuracy and robustness, stability is high.

Secondly, the image denoising is modeled to be the problem of the adversarial learn; the mapping between the noise-free image domain and the noisy image domain. As the state-of-the-art multiscale representation tool, the complex shearlet transform is employed to construct the image generator, which is able to preserve the significant and important characteristics well.

Finally, five state-of-the-art denoising methods are conducted to prove its effectiveness and accuracy. Experimental results demonstrate it produces the best denoising results both in the qualitative and quantitative analysis.

The paper is structured into several sections. Section I introduces the background of the denoising methods. Section II describes the related work on the CycleGAN and the CST. Section III presents the details of the whole proposed method. Section IV conducts the experiments and discussions. Section V finally presents the conclusion and discusses the further plan.

II. THE RELATED WORK

A. The CycleGAN

The CycleGAN model is a very typical model to deal with the problem of the image to image translation in the vision and graphics domain, whose goal is to train a useful mapping between the source domain and the target domain without the paired or aligned input-output data set.

According to [40], the principle of the CycleGAN is based on two core concepts: the basic GAN model and the Cycle Consistency Loss. The GAN is used to generate images in the target domain similar to the given training data, while the cycle consistency loss encourages the generated images to be returned to the original images in the source domain.

As shown in Fig. 1, the CycleGAN consists of two mappings functions G and F, and their associated discriminators D_x and D_y . Different from the GAN, CycleGAN contains two generators and two discriminators, where one generator converts the data from the source domain to the target domain and the other generator converts it back to the source domain. The discriminators are used to determine whether the transformed data are true or false in the two directions.

Fig. 1. The structure of the CycleGAN model.

For the training process, a generator and a discriminator network are trained separately in each domain. The purpose of the discriminator is to determine whether the generated data is realistic, while the generator is to generate a more realistic data to deceive the discriminator. The input of the generator is the data from the source domain and the output is the data from the target domain. The output of the discriminator is a probability value that indicates whether the data is real or generated.

During the training process, the generator is encouraged to generate more realistic data by calculating the difference between the output of the generator and the data in the target domain. Two cycle consistency losses are used to regularize the outputting mapping.

B. The Complex Shearlet Transform

As state-of-the-art multi-scale geometric transform tool, the complex shearlet transform is especially suitable to represent the local feature of the images by using the phase and amplitude information. It has many unique characteristics. For example, the different discrete shearlet transform, the CST is proposed with strict mathematical theory guarantee to meet the Parsval frame. Furthermore, though it has the similar property of shift invariance with the non-subsampled shearlet transform, it has the simpler implementation and higher computational efficiency. In addition, the CST has stronger direction selectivity.

Actually, the discrete implementation of the CST is realized by using the Laplace pyramid for multi-resolution analysis, and the multi-scale partition filters to get the directions. How to implement the CST is not the research hotspot in this paper, more details can be found in [41]. Fig. 2 shows an example of the CST.

(c) the high-pass sub-bands at the first and second level

Fig. 2. An example of the CST.

III. THE PROPOSED METHOD

The main purpose is to make the full use of the advantage of the CycleGAN, that is, its training does not require one-to-one image samples. Only the two types of image domains are ok. Specifically speaking, for the proposed method, it does not need the sample labels to guide the training process, but only the set of images containing noise and without noise are required. It greatly enhances the generalization and makes the network more effective to avoid the overfitting phenomena in learning the mapping from the noise-containing image domain to the noise-free image domain.

A. The Whole Process

The proposed model is shown in Fig. 3.

Fig. 3. The process of the proposed model.

As shown below, it mainly consists of two generators and two discriminators; X, Y is noisy images in the X and Y domain, respectively. Images in the X domain can be generated by the generator G, and then reconstructed back to X domain by generator F. Similarly, images in the Y domain can be generated by the generator F, and then reconstructed back to the Y domain by the generator G. The discriminators Dx and Dy play a discriminatory role to ensure the migration of the images.

B. The Process of Image Generation

The CycleGAN model is proposed to solve the image translation problem, so two generators are needed to realize

the transformation between two domains. However, For the image denoising problem, the aim is mainly to solve the mapping from noise-containing to noise-free without caring about the mapping from noise-free to noise-containing, so the two styles of the generators in CycleGAN are simplified in our method, and a separate noise extractor is used to realize the mutual transformation between noise-containing and noise-free images [42].

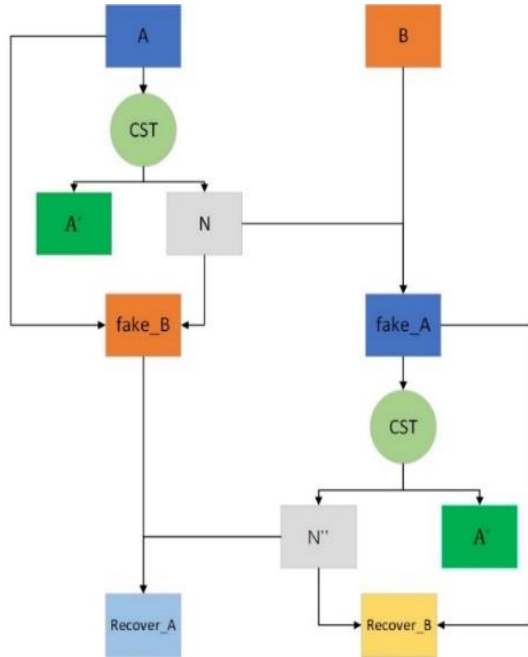

Fig. 4. The procedure of the image generation.

As shown in Fig. 4, there are six types of images involved in the generating procedure, and the CST is used to produce them to input more feature information in the training. Firstly, let A be the noisy sample image in the dataset and B be the noiseless sample; then, A is input through the CST extractor to get the noise component N, the noise image A is subtracted from the noise component N to get the denoised image fake_B, the noiseless image B is added to the noise component to get the generated noise image fake_A. The fake_A is passed through the CST noise extractor again to get the noise component N', fake_A is subtracted from the noise component N' to get the secondary noisy image. The noisy image B is added with the noise component to get the generated noisy image fake_A', the noise component N' is obtained by passing fake_A' through the CST noise extractor again, the noisy image recovered_B is obtained by subtracting fake_A' from the noise component N', the noisy image recovered_B is obtained by adding fake_B with the noise component N', and the noisy image recovered_A is obtained by adding fake_B with the noise component N'. recovered_A, and the noise-free sample image A is outputted by the CST noise extractor to predict the noise component in the noise-free image, and the ideal output value should be 0.

C. The Loss Function

In the proposed method, three models are needed to update the parameters, i.e. the noise extractor G, discriminator DA and discriminator DB. According to the basic CycleGAN, the

loss of the two discriminators consists of the discriminant error to determine whether the image is real or the generated. And the loss of the generator is composed of three losses, i.e. the loss_GAN, loss_identity and loss_cycle. In our method, the discriminant error is also maintained, and in order to improve the stability of the model and speed up the training, a new denoising loss (noted as loss_denoise) is added to the training of the model. More details on the calculation of the losses can be found in the following description.

1) Consistency loss is obtained from the final output images of A and the generator G, and the final output images of B and generator F. In an ideal state, the final output images between A and B should be identical, so the difference between them is used to be the consistency loss.

2) The adversarial loss is the opposite to the discriminatory loss of the discriminator, which represents the ability of fake_A and fake_B to deceive the discriminator. So, the correct judgment of the discriminator is used to be the adversarial loss.

3) The cyclic consistency loss is obtained from the images recovered_A and recovered_B generated by adding noise and removing noise from the generated images fake_A and fake_B again and the original images A and B. Recovered_A and recovered_B should be similar to A and B respectively to the maximum extent in order to ensure the noise is successfully removed without affecting other information. Therefore, the difference between them is used to be the cyclic consistency loss.

4) The denoising loss similar to it is in the general image denoising model. Thus, the difference between the noise-containing image after passing through the noise extractor and the noise-free image is used to be the denoising loss.

The calculation of the four types of losses can be divided into two categories, one is to calculate the error, and the other one is to calculate the difference between two images, which can be represented by the Mean Squared Error (MSE) and Mean Absolute Error (MAE) in the following equations.

$$MSE(y, y') = \frac{\sum_{i=1}^n (y_i - y'_i)^2}{n} \quad (1)$$

As the calculation of the adversarial loss and the discriminator loss needs to be compared with the output of the discriminator, so y in Equation (1) is the target value with 0 or 1, y' is the output of the discriminator, and n is the number of a batch in the training, which is calculated uniformly for the output of the whole batch.

$$MAE(u, u') = \frac{\sum_{i=1}^n |u_i - u'_i|}{n} \quad (2)$$

For the other type of loss, it is necessary to compare the magnitude of the difference between the two images, so a pixel-by-pixel comparison is required. In Equation (2), u is the real image, u' is the generator-generated image, and n is the number of a batch in training.

After obtaining the four losses, the loss $loss_G$ of the noise extractor model can be obtained by Equation (3) to (7).

$$Loss_A = (loss_indentifyA + loss_indentifyB) * a \quad (3)$$

$$Loss_B = (loss_GANA + loss_GANB) * b \quad (4)$$

$$Loss_C = (loss_cycleA + loss_cycleB) * c \quad (5)$$

$$Loss_D = loss_denoise * d \quad (6)$$

$$Loss_G = Loss_A + Loss_B + Loss_C + Loss_D \quad (7)$$

In the above equation, a, b, c and d are the weighting coefficients.

After the CST, the low-frequency sub-band images usually contain few noise components, so the $loss_denoise$ accounts for a relatively small proportion of the loss, and it mainly relies on the consistency loss to ensure that the original image information is not lost. For high-frequency sub-band images, they contain more noise components. Thus, the $loss_denoise$ ratio should be adjusted upward to focus on noise removal, and the ratio of the other losses should not be adjusted downward too much, ensuring that the high-frequency details of the texture in the image not be removed by any mistake.

IV. THE EXPERIMENTS AND DISCUSSION

A. Experiment Setting

The experimental platform is the CentOS Linux with Intel Xeon Silver and the NVIDIA Tesla P100. All the codes are implemented by the PyTorch and OpenCV.

The peak signal-to-noise ratio (PSNR), structural similarity index measure (SSIM), and edge preservation index (EPI) are used to be the performance metrics. To save space, how to compute them can be found in [43, 44].

The experiments are designed to be two parts: training the CycleGAN denoising model and verifying the effectiveness of the denoising algorithm. According to [32, 33], the deep learning-based methods outperform the traditional methods, such as the Wiener filtering, polynomial regression, or the wavelet denoising, so the proposed method is compared with five state-of-the-art denoising methods, i.e. the NSST-BM3D model [18], the FFDNet model [30], the FFCNN model [31], the GAN model [35] and the NSTBNet model [36]. The parameters, such as the size of the convolutional layer, the network depth, are set to be the same as they are reported in the corresponding literature. For the implementation of proposed model, the basic structure of the CycleGAN is used get the best performance by tuning the parameters according to [40].

All the images can be downloaded from the public data set LIDC-IDRI [45], and 5000 images are selected in the

experiments. All of them are added the 10%, 15%, 20%, 25%, and 30% Poisson noise [46].

B. Results and Discussion

Table I shows the average PSNR values obtained by the different methods under the five noise levels of 10%, 15%, 20%, 25%, and 30%. It can be seen that the proposed method gets the best value. Compared with NSST-BM3D, FFCNN, and FFDNet, the improvements are more obvious when the noise is at the higher level. Compared with NSTBNet and GAN, the PSNR values are also higher.

TABLE I. THE PSNR VALUE OF DIFFERENT METHODS

Level	NSST-BM3D	FFCNN	FFDNet	NSTBNet	GAN	CycleGAN
10%	29.84	30.02	30.10	30.13	30.20	30.38
15%	28.01	28.18	28.29	28.36	28.39	28.63
20%	26.15	26.22	26.30	26.35	26.38	26.44
25%	25.12	25.24	25.28	25.30	25.31	25.44
30%	23.43	23.51	23.64	23.66	23.71	23.95

TABLE II. THE SSIM VALUE OF DIFFERENT METHODS

Level	NSST-BM3D	FFCNN	FFDNet	NSTBNet	GAN	CycleGAN
10%	0.872	0.875	0.875	0.882	0.875	0.891
15%	0.801	0.796	0.806	0.813	0.807	0.876
20%	0.762	0.763	0.776	0.783	0.784	0.794
25%	0.706	0.723	0.724	0.735	0.740	0.755
30%	0.663	0.703	0.710	0.715	0.719	0.723

TABLE III. THE EPI VALUE OF DIFFERENT METHODS

Level	NSST-BM3D	FFCNN	FFDNet	NSTBNet	GAN	CycleGAN
10%	0.94	0.95	0.95	0.96	0.97	0.98
15%	0.90	0.89	0.91	0.92	0.91	0.94
20%	0.83	0.846	0.86	0.87	0.87	0.89
25%	0.80	0.82	0.83	0.85	0.84	0.86
30%	0.70	0.71	0.73	0.75	0.77	0.81

Table II and Table III show the average SSIM and EPI values of different methods at the five different noise levels, respectively. The CycleGAN value is higher than that for the other methods. When the noise level increases, its advantages will slowly manifest, especially when the noise level is 20% and 25%, the SSIM is significantly higher than the other methods and when the noise level is 20%, the EPI get the best value.

The reason is that during the training process, the denoising extractor in the proposed method makes full use of the CST features via the low-pass and high-pass sub-bands coefficients. The consideration of the geometric and structural features of the source can be well maintained in the final result and guarantee the good value of the SSIM and EPI.

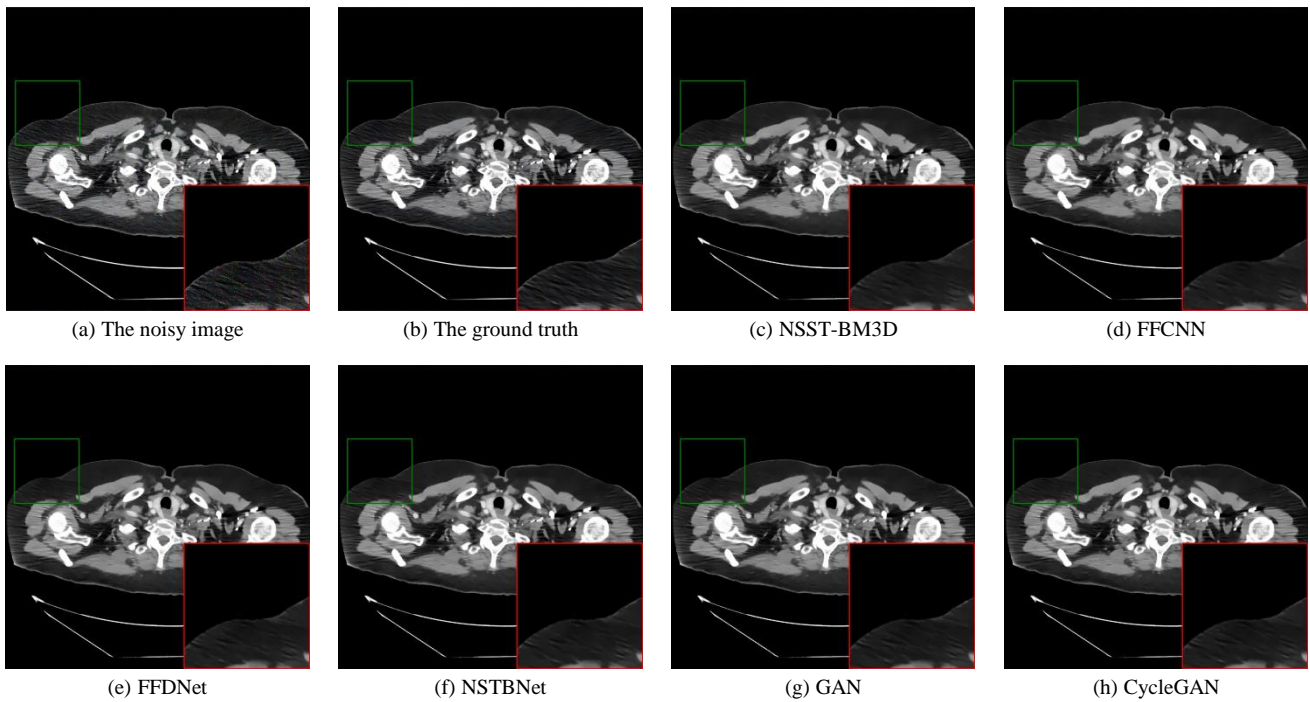

Fig. 5. The denoising results at the 10% noise level.

Fig. 6. The denoising results at the 15% noise level.

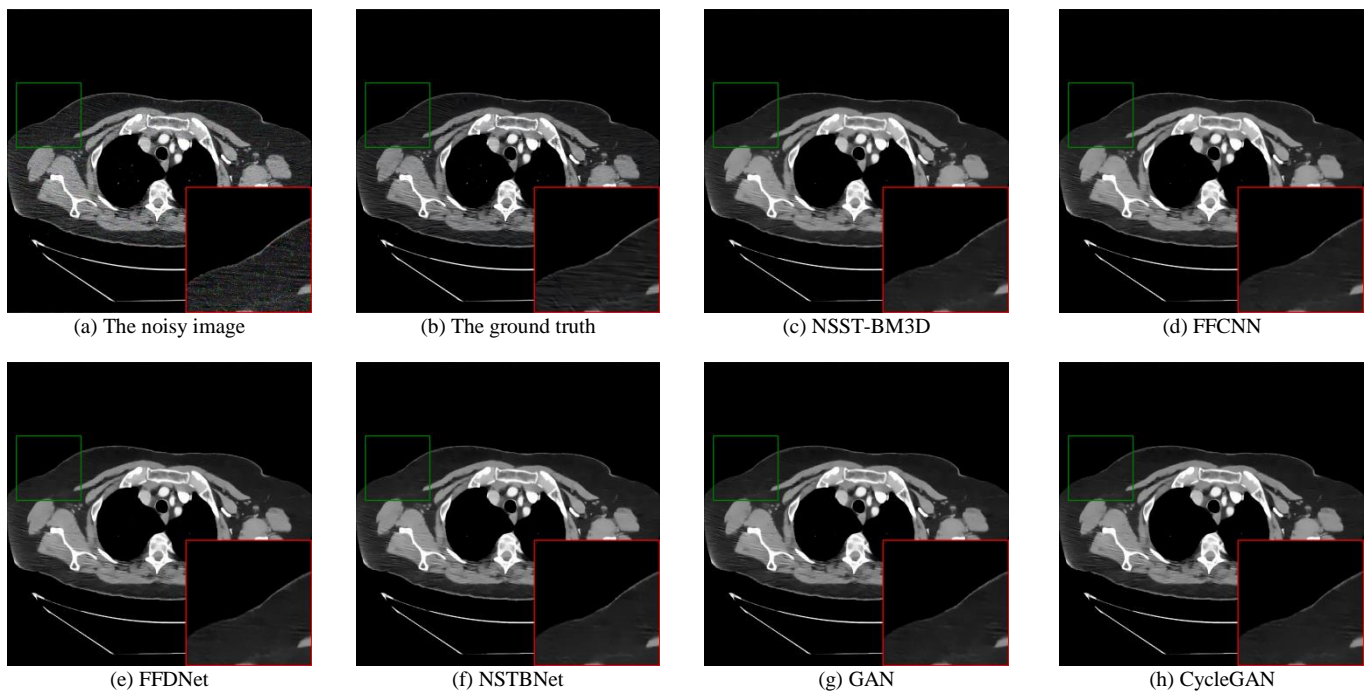

Fig. 7. The denoising results at the 20% noise level.

In Fig. 5 to Fig. 7, the visual results of the different methods are shown. Due to space limitations, only three groups of the experimental images are presented. The area marked by the red squares is enlarged at the same location. Compared with the ground truth and noisy images, the results of the CycleGAN method are more clear and they perform better in maintaining more feature details than other methods. According to the enlarged area, the details can be compared. The edge part of CycleGAN denoising image is more smooth and clearer, and the detail part is almost equivalent to it is in the ground truth.

Medical image denoising is very important in kinds of medical imaging processing tasks. After the optimization, the proposed model can be applied into the object detection, segmentation, and classification tasks enabled by the denoising techniques mentioned in this paper.

V. CONCLUSION

An effective medical image denoising method based on the improved CycleGAN model and the complex shearlet transform is proposed. The main idea is to use the multi-scale decomposition property of the CST and the principle of the recurrent learning of the GAN. The advantages mainly locate at the strong ability of the extracting the important structure and edge information of the noisy images and training an effective cycle GAN model. Compared with five state-of-the-art denoising methods on the open dataset, the validity and accuracy are fully demonstrated.

In future, we will discuss with some medical experts to implement more experiments on the data from different imaging modalities, such as the MRI, PET and Ultrasound, and consider their feedback to validate the effectiveness.

Comparing Scrum Maturity of Digital and Business Process Reengineering Groups: A Case Study at an Indonesia's State-Owned Bank

Gloria Saripah Patara, Teguh Raharjo

Faculty of Computer Science, Universitas Indonesia, Jakarta, Indonesia

Abstract—Bank XYZ, an Indonesia's state-owned bank, has been conducting business and digital transformation throughout its organization. Based on a recent McKinsey survey, less than 30% of organizations succeed in transformation. Fast changing business requirements and various technology-based initiatives enforce the organization to employ an Agile methodology and Scrum, to cope with the situation. Group Grp-DGT and Grp-BPR are two groups in Bank XYZ that manage their projects using Scrum. Grp-DGT develops digital projects, whereas Grp-BPR develops Business Process Reengineering (BPR) projects. Scrum maturity in both groups needs to be appraised to promote sustainability in the long run. Comparing Scrum maturity between digital and BPR projects has not been done in the previous works, especially in a state-owned bank in Indonesia. This research will help the organization through the research output which are Scrum maturity level at both groups and proposed recommendations to improve Scrum practices. The other organizations can benefit from the recommendations as well. Scrum maturity model (SMM) is used to appraise the practices, while Agile Maturity (AMM) is used to calculate the maturity rating. From this research, it is found that Grp-DGT has reached maturity level 5 (optimizing), whereas Grp-BPR is still at level 1 (initial). Based on assessment results and Scrum guides, the recommendations are then drafted. There are 15 recommendations proposed to Grp-BPR to reach level 2 and onwards.

Keywords—Transformation; scrum; digital project; BPR project; scrum maturity model; agile maturity model

I. INTRODUCTION

Business transformation has become a catch-all term for years now. It refers to how organizations reach their fullest potential. It aims to improve overall performance by generating more revenue, reducing operational expenses, and improving both customer satisfaction and productivity among employees [1]. Business processes are reengineered to be more efficient and optimized in terms of the way customer performs their financial transactions. In line with this business transformation, digital transformation has been progressing in organizations. It utilizes cutting-edge technologies to boost the current operations and to create new business opportunities [2–5]. Based on McKinsey survey [6], there are more than 80% organizations that have undertaken efforts to apply digital transformation in the past five years, and less than 30% succeed it. To win these transformations, the organizations have to manage their projects effectively. Agile project management fits the condition. It has been used in business

process improvement [7, 8]. It is rapid and adaptive to change, builds effective communication among all stakeholders, brings customer into the team, and promotes a self-managed team. It also delivers software rapidly and incrementally to compete with fast-changing market [9–11].

Bank XYZ has been aggressively performing both transformations through its two groups (or divisions in other organizations). Those groups are Digital Group (Grp-DGT) and Business Process Reengineering Group (Grp-BPR). Grp-DGT is a group developing digital projects, whereas Grp-BPR is a group developing BPR (Business Process Reengineering) projects. Bank XYZ needs Scrum maturity assessment as a part of evaluation of the current software development process in both groups. This gap raises two questions: What is the current maturity level of Bank XYZ? How does Bank XYZ improve its level? To answer these questions, this research intends to compare Scrum maturity level in Grp-DGT and Grp-BPR. It also recommends improvement in Scrum practices based on the assessment results. These recommendations can be used to support product delivery sustainability in the long run.

There are few previous case studies in Indonesia that conduct Scrum maturity assessment. Scrum maturity model (SMM) is used to perform an assessment to Scrum practices in a telecommunication company [12], an education technology startup [13], and two software development companies [14, 15]. They proposed recommendations to the organizations based on assessment results. Panjaitan et al. [14] discussed the results and the recommendations in a thorough approach. In addition, Scrum maturity level can also be compared between two groups as conducted in research [16] and [17]. Setiawan et al. [16] compared Scrum practices in a Corporate Strategy group and an Information Technology (IT) group at a telecommunication company, whereas Zelfia et al. [17] compared an IT group and a temporary unit at a state-owned bank. Comparing groups in a state-owned bank that develop digital and BPR projects has not been done previously.

Problem identification and root cause analysis are performed through direct observation and semi-structured interview. Literature study is then performed to find previous related case studies to be used as theoretical foundation and research instrument's drafting guidelines. This research will combine Scrum maturity model (SMM) and Agile maturity model (AMM) to appraise the Scrum practices and to calculate key process area (KPA) rating respectively.

Elicitation is performed by administering an online questionnaire to the respondents. Then, recommendations are proposed based on assessment results. Conclusion, limitations, and future work are also described.

This paper is constructed as follows. Section II depicts an overview of Agile methodology, Scrum framework, and Scrum maturity model. Section III explains about the research methodology utilized in this study. Section IV describes the results and the discussion related to this study's purpose including proposed recommendations for the organization. Section V shows the conclusion of this study's result, limitations, and suggestion for the future study.

II. LITERATURE REVIEW

A. Agile Methodology

Agile is a way of thinking based on values, governed by principles, and manifested in numerous practices. Based on the circumstances, agile practitioners favor certain practices over others. Agile software development was formalized in 2001 through the Agile Manifesto [9, 18].

There are four values in the Manifesto, and they are promoted in software development process [9, 14, 18–22]. Those values are (1) individuals interacting to arrive at solutions, (2) focus on delivering well-functioning software, (3) customer and developers collaborating constantly, and (4) emphasizing on responding to requirement change.

Twelve principles were derived from the values, to clarify them [9, 18, 20–22]. Those principles are (1) prioritizing customer satisfaction, (2) receiving requirements change, (3) delivering well-functioning software constantly, (4) daily interaction and collaboration between business people and developers, (5) motivating individuals to build the project, (6) using face-to-face conversations to share information to and within development team, (7) project progress is evaluated through a well-functioning software, (8) development sustainability is achieved when the sponsors, developers, and users maintaining their pace constantly, (9) constant focus to technical excellence and good design, (10) simplifying things to maximize outcome and impact, (11) self-organizing teams promotes the best designs, specifications, and architectures, and (12) the team gives thought on how to be more effective, then calibrates and consequently adjusts its behavior.

Fig. 1 illustrates the interconnection among values, principles, and practices of the Agile Manifesto.

Fig. 1. The interconnection among the values, principles, and practices of the agile manifesto.

Despite the term “agile” becoming popular after the Manifesto, the viewpoints and methods have been practiced for many years before that [9, 11]. It is a superset term covering various techniques and frameworks. Fig. 2 shows the relationship among Agile and the other related terms. It is depicted as a superset term pointing to all kinds of approaches which meet the values and principles of the Agile Manifesto. Agile and the Kanban Method are shown as subsets of lean because they practice the same concepts, such as attention to value, incremental delivery, and effective process [9]. Based on a recent survey mentioned in [13, 17], Scrum is the most popular Agile approach among other approaches.

Fig. 2. Agile and other approaches [9].

B. Scrum Framework

Scrum is a simple and nimble framework that aids people, teams, and organizations in achieving goals and creating value by employing flexible approaches to solve complex problems. Empiricism and lean thinking are the foundation of Scrum. Empiricism means that the team constantly learns and improves from their past wrongdoings. Decisions and changes are made based on what the customer really needs, rather than what the developers think the customer needs. Whereas lean thinking focuses on providing benefit to the customer and assumes that anything else is inessential.

There are three primary ideas or pillars of empirical process: transparency, inspection, and adaptation [23, 24]. According to Schwaber et al. [24], transparency is mirrored through Scrum's artifacts that are visible to those performing the task. On the other hand, inspection and adaptation are implemented through four formal events in an iteration.

In Scrum, the product is delivered using an iterative, incremental approach to manage risks and to optimize predictability [24]. Commitment, courage, focus, openness, and respect are Scrum values. People's proficiency over these values determines the success of Scrum utilization throughout its process. As mentioned in [23], the process is categorized into five phases: (1) initiation, (2) planning and estimation, (3) implementation, (4) review and retrospective, and (5) release.

Based on Schwaber et al. [24], there are three roles in a Scrum development team who collectively focus their effort on a common goal, that is a product goal. The roles are

Product Owner (PO), Scrum Master (SM), and developers (DEV). VMEDU [23] categorized these three roles as core roles, and added business stakeholders, supporting services, vendors, and Scrum guidance body as non-core roles. An ideal team usually comprises of 5-9 members, 1 PO, 1 SM, and 3-7 DEVs. The team is self-organized, and each member has their own responsibilities.

The PO is the voice of business stakeholders and accountable for ensuring that the value is delivered through product increments. He or she articulates prioritized business requirements which are managed in the product backlog. The product backlog, including its items, must be visible, transparent, and understandable to the developers. The developers have specific skills to build the product. They are accountable for drafting a plan and backlog for Sprint. They also ensure deliverables quality through a Definition of Done and adapt their plan daily to meet the Sprint Goal. The Scrum Master is an individual who enables the team and the entire organization to understand what Scrum is, both theory and practice. He or she is also accountable for ensuring a proper work environment by removing impediments, so the developers can focus on delivering a high-value increment [23, 24].

Sprint is the centre of Scrum, where the team turned the business requirements into value. Fig. 3 illustrates Scrum flow for a Sprint. It is timeboxed for one to four weeks. When a Sprint concludes, it is immediately followed by a new Sprint. There are four events contained in a Sprint: Sprint planning, Daily Scrums, Sprint reviews, and Sprint retrospectives. In Sprint planning, the team discusses why this Sprint is valuable, what can be delivered, and how the selected work can be delivered. The Sprint backlog is defined in this event. Sprint goal, the selected product backlog items, and the delivery plan are part of Sprint backlog. Sprint goal is inspected daily through a Daily Scrum. The developers can synchronize their tasks, discuss potential problems, and plan for the next tasks. Definition of Done (DoD) is adhered during development. The developers then will demo the increment to stakeholders in a Sprint review event. The purpose is to obtain a review on the increment and discuss what to do next according to the current environment. The Sprint is concluded in the Sprint retrospective where future improvements are discussed [24].

Product backlog, Sprint backlog, and increment are the three artifacts mentioned in [24]. Information transparency to all team members is promoted through these artifacts, so they can be inspected, and an adaptation can be performed accordingly. A product backlog consists of ordered business requirements which are called product backlog items (PBIs). This artifact is changed based on the review or discussions with the stakeholders. The collection of PBIs which are selected to be delivered in a Sprint is called a Sprint backlog. The developers update and add more information into it along the Sprint. It must be completed to meet the Sprint goals. Increment is a delivered value which consists of the selected PBIs that have been completed in a specific Sprint. It is a steppingstone to the product goal.

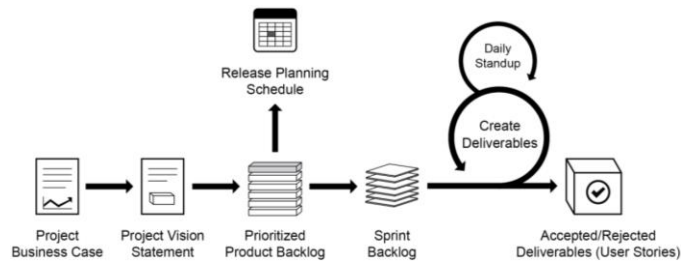

Fig. 3. Scrum flow for a sprint [23].

C. Scrum Maturity Model

According to Hutabarat et al. [25], a maturity model in a project management is a continuous process to recognize, evaluate, apply, and reassess the opportunities to improve constantly in project implementation. It is one of the organization success factors which has many types of projects, programs, and portfolios. In line with that, [14, 15] added that maturity model is a technique to evaluate the maturity level and development process capability. It continuously directs and enhances the organization's development process to avoid project failures.

The SMM refers to two maturity models, which are the AMM and the capability maturity model integration (CMMI) [12, 14]. The AMM links the Agile software development practices to maturity levels to make it simple, comprehensible, and applicable. It is designed based on Agile software development values, practices, and principles [26]. Fig. 4 depicts the AMM from an initial level to sustained level. At the initial level, an organization has not defined Agile development process clearly. At the explored level, the organization has shown more structured and complete software development practices than the first level. When an organization has practices related to customer relationship management, pair programming, communication, testing, and software quality, then it has reached the defined level. The improved level can be reached when an organization has collected of development process detailed measurement and has practiced software quality measurements. Finally, at the sustained level, an organization constantly enhances their processes through surveys and do not hesitate to have innovative initiatives [14, 26].

The CMMI is a process model that explicitly states what an organization should do to define, comprehend, and encourage behaviors that guide to improved accomplishment [27]. CMMI-DEV V1.3 mentioned that CMMI has five maturity levels: (1) Level 1 - Initial, (2) Level 2 - Managed, (3) Level 3 - Defined, (4) Level 4 - Quantitatively managed, and (5) Level 5 - Optimizing. The processes are usually ad hoc and disordered at level 1. A stable environment is usually not provided to support processes. Level 2 can be achieved when the processes are managed and performed according to documented plan. An organization achieves level 3 when processes are well described and comprehended, and are well explained in standards, procedures, tools, and techniques. At level 4, quantitative objectives for quality and process performance are established by the organization, and then utilizes them as barometer for projects management. The objectives are drafted and proposed based on the requirements

elicited from the business stakeholders. Finally, at level 5, an organization pays attention to constantly enhancing process performance through incremental and innovative processes, and technological refinement [28].

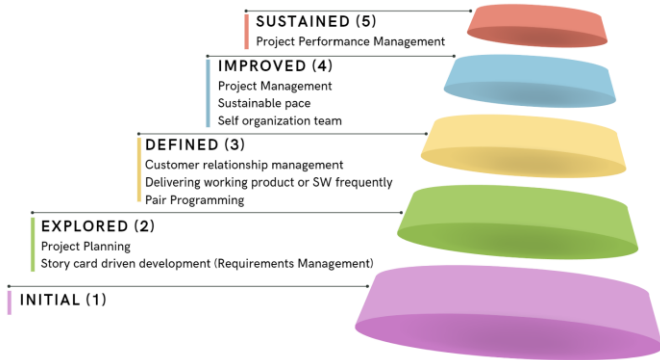

Fig. 4. Agile maturity model staged representation.

The SMM uses the same five levels as in CMMI. Its primary purpose is to guide organizations on promoting self-improvement and client’s active involvement. In addition, it also helps organizations to adopt Scrum on a staged approach by providing list of goals, objectives, practices, and metrics for every level [29]. Table I describes goals and their objectives at every level, starting from level 1 (Initial) to level 5 (Optimizing).

TABLE I. GOALS AND OBJECTIVES OF SCRUM MATURITY MODEL

Level	Code	Goals and Objectives
1 – Initial	L1	-
2 – Managed	L2.1	Basic Scrum Management
	L2.1.1	• Scrum Roles Exist
	L2.1.2	• Scrum Artifacts Exist
	L2.1.3	• Scrum Meetings Occur and are Participated
	L2.1.4	• Scrum Process Flow is Respected
	L2.2	Software Requirements Engineering
	L2.2.1	• Clear Definition of Product Owner
L2.2.2	• Product Backlog Management	
L2.2.3	• Successful Sprint Planning Meetings	
3 – Defined	L3.1	Customer Relationship Management
	L3.1.1	• Definition of Done exists
	L3.1.2	• Product Owner available
	L3.1.3	• Successful Sprint Review Meetings
	L3.2	Iteration Management
	L3.2.1	• Sprint Backlog Management
	L3.2.2	• Planned iterations
	L3.2.3	• Successful Daily Scrum
L3.2.4	• Measured Velocity	
4 – Quantitatively managed	L4.1	Unified Project Management
	L4.1.1	• Unified Project Management
	L4.2	Measurement and Analysis Management
L4.2.1	• Measurement and Analysis Management	
5 – Optimizing	L5.1	Performance Management
	L5.1.1	• Successful Sprint Retrospective
L5.1.2	• Positive Indicators	

III. RESEARCH METHODOLOGY

A. Research Stages

The objective of this research is to assess the level of Scrum maturity practices and propose recommendations for Bank XYZ’s software development process.

This research is designed to use an explanatory sequential mixed-method approach. As illustrated in Fig. 5, its stages start from problem identification to drafting suggestions for future work. The research problem is identified through an observation and semi-structured interview with a Scrum Master from group Grp-DGT and a Scrum Master from group Grp-BPR. Scrum maturity assessment has never been done in both groups, and these Scrum Masters also agreed that the assessment needs to be done to evaluate the current process. Literature study is then performed to obtain previous case studies with the same research questions. At this stage, theoretical foundations are acquired. The next stage is to construct the assessment questionnaire which is used as the research instrument. It is constructed based on SMM assessment questions. After the elicitation process, the data is analyzed using KPA rating formula from AMM. Maturity level at each goal is interpreted using this rating. The assessment result is used to find Scrum practices that need to be improved, and to draft proposed recommendations based on those findings. As the final stage, the author concludes the research and gives suggestions for future work.

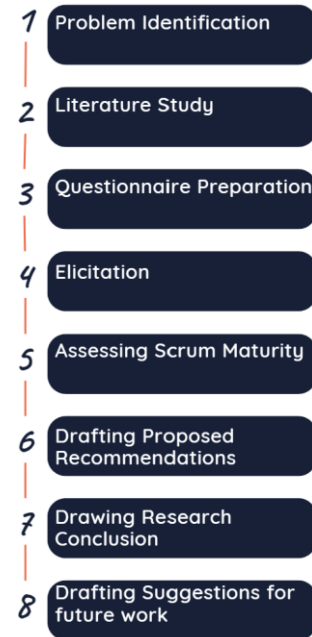

Fig. 5. Research stages of scrum maturity assessment at bank XYZ.

B. Instrument

This research uses a questionnaire as an instrument to collect data from respondents. The questionnaire is drafted based on SMM assessment questions explained in Yin et al. [29]. As described in Table II, there are 91 Scrum practices in total that will be assessed. All practices are transposed into questions which can be responded to as ‘Yes’, ‘Partially’, ‘No’, and ‘N/A’ (not applicable).

TABLE II. DETAIL COUNT OF ASSESSED SCRUM PRACTICES ON THE QUESTIONNAIRE

Goal/ Objective Code	Count	Goal/ Objective Code	Count	Goal/ Objective Code	Count
L2.1	28	L3.1	9	L4.1	1
L2.1.1	3	L3.1.1	3	L4.1.1	1
L2.1.2	9	L3.1.2	2	L4.2	2
L2.1.3	10	L3.1.3	4	L4.2.1	2
L2.1.4	6	L3.2	22	L5.1	11
L2.2	18	L3.2.1	8	L5.1.1	5
L2.2.1	5	L3.2.2	6	L5.1.2	6
L2.2.2	7	L3.2.3	5		
L2.2.3	6	L3.2.4	3		
Total of Assessed Scrum Practices	28 + 18 + 9 + 22 + 1 + 2 + 11				91

C. Elicitation

The questionnaire is drafted and distributed using Google Form. The questionnaire respondents are selected using purposive sampling technique. It is used to obtain data from the ones who understand the research problem [30]. There are four respondents who will fill out the questionnaire. They are two Scrum Masters who involved in digital projects and two Scrum Masters who involved in BPR projects.

D. Maturity Assessment

The appraisal of Scrum practices is performed using a questionnaire to obtain how practices are implemented in the projects. Data collected from the questionnaire will be analyzed using the KPA rating which is used in AMM [26]. The term “process area” in AMM is on a par to term “goal” in SMM. KPA rating can be calculated using equation as shown in (1).

$$R = \frac{\sum(Y_n) + \frac{1}{2} \sum(P_n)}{\sum(T_n) - \sum(NA_n)} \times 100\% \tag{1}$$

Where:

R = KPA rating

Y_n = ‘Yes’ responses

P_n = ‘Partially’ responses

T_n = Total assessed Scrum practices

NA_n = ‘N/A’ responses

Calculated KPA rating can be interpreted based on following categories [26]:

- 1) *Fully achieved*: 86% to 100% practices in the assessed KPA have been applied and proofs can be provided.
- 2) *Largely achieved*: 51% to 85% practices in the assessed KPA have been applied and proofs can be provided.
- 3) *Partially achieved*: 16% to 50% practices in the assessed KPA have been applied and some proofs can be provided.
- 4) *Not achieved*: 0% to 15% practices in the assessed KPA have been applied and a little or no proof can be provided.

IV. RESULT AND DISCUSSION

Scrum maturity assessment results are discussed for each level, starting from level 2 to level 5. KPA rating interpretation that will be mentioned along the discussion is coded as F (Fully Achieved), L (Largely Achieved), P (Partially Achieved), and N (Not Achieved). Scrum Masters who filled out the assessment questionnaire are also coded as X1 and X2 for the ones seated in group Grp-DGT. While Scrum Masters seated in group Grp-BPR are coded as Y1 and Y2.

A. Groups Assessment Result – Scrum Maturity Level 2

Basic Scrum Management (BSM) and Software Requirements Engineering (SRE) are two goals in Scrum maturity level 2. Table III shows the maturity level assessment results on first mentioned goal. KPA rating obtained for Grp-DGT is 95.53%. Scrum practices in four objectives listed in the table below are applied to more than 86.00% or applied almost entirely in project development. So, it can be said that BSM goal reaches Fully Achieved. On the other hand, KPA rating for Grp-BPR is 80.97%. Scrum practices in the listed objectives are applied to more than half of them, but it’s still lower than 86.00%. It means that the rating is interpreted as Largely Achieved.

TABLE III. ASSESSMENT RESULT OF BASIC SCRUM MANAGEMENT

Objectives	Grp-DGT		Grp-BPR	
	X1 (%)	X2 (%)	Y1 (%)	Y2 (%)
Scrum Roles Exist	100.00	100.00	50.00	100.00
Scrum Artifacts Exist	100.00	100.00	77.78	100.00
Scrum Meetings Occur and are Participated	90.00	100.00	60.00	81.25
Scrum Process Flow is Respected	83.33	91.67	83.33	91.67
Rating per Scrum Master	92.86	98.21	69.64	92.31
Rating per group	95.53		80.97	
Interpretation	Fully Achieved		Largely Achieved	

As shown in the Table IV, both Grp-DGT and Grp-BPR scored the same result for Software Requirements Engineering (SRE) goal assessment. The KPA rating is 94.44% which means that Scrum practices in three objectives listed in the table below are applied more than 86.00% or applied almost entirely in project development. So, it can be said that the rating for both groups in SRE goal can be interpreted as Fully Achieved.

TABLE IV. ASSESSMENT RESULT OF SOFTWARE REQUIREMENTS ENGINEERING

Objectives	Grp-DGT		Grp-BPR	
	X1 (%)	X2 (%)	Y1 (%)	Y2 (%)
Clear Definition of Product Owner	100.00	90.00	100.00	100.00
Product Backlog Management	85.71	100.00	85.71	92.86
Successful Sprint Planning Meetings	91.67	100.00	100.00	91.67
Rating per Scrum Master	91.67	97.22	94.44	94.44
Rating per group	94.44		94.44	
Interpretation	Fully Achieved		Fully Achieved	

B. Groups Assessment Result – Scrum Maturity Level 3

Customer Relationship Management (CRM) and Iteration Management (IMG) are the goals in Scrum maturity level 3. Table V shows the maturity level assessment results on first mentioned goal. KPA rating obtained for Grp-DGT is 91.66%. Scrum practices in three objectives listed in the table below are applied to more than 86.00% or applied almost entirely in project development. So, it can be said that CRM goal reaches Fully Achieved. Whereas KPA rating for Grp-BPR is 94.44% which means that Scrum practices in the listed objectives below are also applied to more than 86.00% or almost entirely in project development. So, the rating can be interpreted as Fully Achieved.

TABLE V. ASSESSMENT RESULT OF CUSTOMER RELATIONSHIP MANAGEMENT

Objectives	Grp-DGT		Grp-BPR	
	X1 (%)	X2 (%)	Y1 (%)	Y2 (%)
Definition of Done exists	100.00	100.00	100.00	100.00
Product Owner available	100.00	100.00	100.00	100.00
Successful Sprint Review Meetings	62.50	100.00	87.50	87.50
Rating per Scrum Master	83.33	100.00	94.44	94.44
Rating per group	91.66		94.44	
Interpretation	Fully Achieved		Fully Achieved	

As shown in the Table VI, assessment result for goal IMG scored slightly different at 87.74% for Grp-DGT and 87.91% for Grp-BPR. It means that Scrum practices in three objectives listed in the table below are applied more than 86.00% or applied almost entirely in project development. These ratings can be classified as Fully Achieved.

TABLE VI. ASSESSMENT RESULT OF ITERATION MANAGEMENT

Objectives	Grp-DGT		Grp-BPR	
	X1 (%)	X2 (%)	Y1 (%)	Y2 (%)
Sprint Backlog Management	68.75	75.00	75.00	81.25
Planned iterations	100.00	91.67	83.33	90.00
Successful Daily Scrum	100.00	100.00	100.00	100.00
Measured Velocity	100.00	100.00	100.00	100.00
Rating per Scrum Master	86.84	88.64	86.36	89.47
Rating per group	87.74		87.91	
Interpretation	Fully Achieved		Fully Achieved	

C. Groups Assessment Result – Scrum Maturity Level 4

Two goals in Scrum maturity level 4 are Unified Project Management (UPM), and Measurement & Analysis Management (MAM). Table VII shows the maturity level assessment results on first mentioned goal. KPA rating obtained for Grp-DGT is 100.00% which is undoubtedly interpreted as Fully Achieved. It means that Scrum practices in an objective listed in the table below are applied entirely in project development. On the contrary, KPA rating for Grp-BPR only reaches 75.00%. Scrum practices in the listed objective are applied to more than half of them, but it's still lower than 86.00%. It means that UPM goal reaches Largely Achieved. Grp-BPR's rating is a bit contrast compared to Grp-DGT's perfect rating.

TABLE VII. ASSESSMENT RESULT OF UNIFIED PROJECT MANAGEMENT

Objectives	Grp-DGT		Grp-BPR	
	X1 (%)	X2 (%)	Y1 (%)	Y2 (%)
Unified Project Management	100.00	100.00	100.00	50.00
Rating per Scrum Master	100.00	100.00	100.00	50.00
Rating per group	100.00		75.00	
Interpretation	Fully Achieved		Largely Achieved	

Assessment result for MAM goal is shown in Table VIII. Grp-DGT scored 100.00%, whereas Grp-BPR scored 87.50%. It means that Scrum practices in the objective listed in the table below are applied entirely in Grp-DGT's project development. Whereas Grp-BPR applies more than 86.00% or applies almost entirely in project development. These KPA ratings can be interpreted as Fully Achieved. Despite having the same interpretation, a Scrum Master in Grp-BPR didn't perfectly satisfy with the practices.

TABLE VIII. ASSESSMENT RESULT OF MEASUREMENT AND ANALYSIS MANAGEMENT

Objectives	Grp-DGT		Grp-BPR	
	X1 (%)	X2 (%)	Y1 (%)	Y2 (%)
Measurement and Analysis Management	100.00	100.00	100.00	75.00
Rating per Scrum Master	100.00	100.00	100.00	75.00
Rating per group	100.00		87.50	
Interpretation	Fully Achieved		Fully Achieved	

D. Groups Assessment Result – Scrum Maturity Level 5

There is only one goal in Scrum maturity level 5, that is Performance Management (PMG). Table IX shows that the KPA rating obtained for Grp-DGT is 91.66% which means that Scrum practices in two objectives listed in the table below are applied to more than 86.00% or applied almost entirely in project development. So, it can be said that PMG goal reaches Fully Achieved. Whereas KPA rating for Grp-BPR is 75.00% which means that Scrum practices in the listed objectives are applied to more than half of them, but it's still lower than 86.00%. So, the rating can be interpreted as Largely Achieved.

TABLE IX. ASSESSMENT RESULT OF PERFORMANCE MANAGEMENT

Objectives	Grp-DGT		Grp-BPR	
	X1 (%)	X2 (%)	Y1 (%)	Y2 (%)
Successful Sprint Retrospective	90.00	100.00	100.00	80.00
Positive Indicators	75.00	100.00	75.00	50.00
Rating per Scrum Master	83.33	100.00	86.36	63.64
Rating per group	91.66		75.00	
Interpretation	Fully Achieved		Largely Achieved	

KPA rating and interpretation of each goal is shown in Table X. Grp-DGT ratings are more than 85% for all Scrum maturity goals. It means that Grp-DGT assessed as Fully Achieved overall or Scrum practices are applied almost entirely in project development. Whereas Grp-BPR has three goals with KPA rating less than 86.00%, namely goal BSM, UPM, and PMG. It means that Grp-BPR needs further improvement to reach Fully Achieved overall.

TABLE X. ASSESSMENT RESULT SUMMARY

Level	Goals and Objectives	Grp-DGT	Grp-BPR
		Rating (Int.)	Rating (Int.)
2	Basic Scrum Management	95.53 (F)	80.97 (L)
	• Scrum Roles Exist	100.00 (F)	75.00 (L)
	• Scrum Artifacts Exist	100.00 (F)	88.89 (F)
	• Scrum Meetings Occur and are Participated	95.00 (F)	70.62 (L)
	• Scrum Process Flow is Respected	87.50 (F)	87.50 (F)
	Software Requirements Engineering	94.44 (F)	94.44 (F)
	• Clear Definition of Product Owner	95.00 (F)	100.00 (F)
	• Product Backlog Management	92.85 (F)	89.28 (F)
	• Successful Sprint Planning Meetings	95.83 (F)	95.83 (F)
3	Customer Relationship Management	91.66 (F)	94.44 (F)
	• Definition of Done exists	100.00 (F)	100.00 (F)
	• Product Owner available	100.00 (F)	100.00 (F)
	• Successful Sprint Review Meetings	81.25 (F)	87.50 (F)
	Iteration Management	87.74 (F)	87.91 (F)
	• Sprint Backlog Management	71.87 (L)	78.12 (L)
	• Planned iterations	95.83 (F)	86.66 (F)
	• Successful Daily Scrum	100.00 (F)	100.00 (F)
	• Measured Velocity	100.00 (F)	100.00 (F)
4	Unified Project Management	100.00 (F)	75.00 (L)
	• Unified Project Management	100.00 (F)	75.00 (L)
	Measurement and Analysis Management	100.00 (F)	87.50 (F)
	• Measurement and Analysis Management	100.00 (F)	87.50 (F)
5	Performance Management	91.66 (F)	75.00 (L)
	• Successful Sprint Retrospective	95.00 (F)	90.00 (F)
	• Positive Indicators	87.50 (F)	62.50 (L)

TABLE XI. CURRENT VS EXPECTED MATURITY

Code	Objectives	Current (%)	Expected (%)
L2.1.1	Scrum Roles Exist	75.00	86.00
L2.1.2	Scrum Artifacts Exist	88.89	86.00
L2.1.3	Scrum Meetings Occur and are Participated	70.62	86.00
L2.1.4	Scrum Process Flow is Respected	87.50	86.00
L4.1.1	Unified Project Management	75.00	86.00
L5.1.1	Successful Sprint Retrospective	90.00	86.00
L5.1.2	Positive Indicators	62.50	86.00

As illustrated at Fig. 6, there are four objectives that will be discussed further as their ratings are below the expected rating which is equal to or more than 86.00%. Those objectives are (1) Scrum roles exist, (2) Scrum meetings occur and are participated, (3) Unified project management, and (4) Positive indicators. Whereas there are three objectives that exceed the expected rating: (1) Scrum artifacts exist, (2) Scrum process flow is respected, and (3) Successful Sprint retrospective.

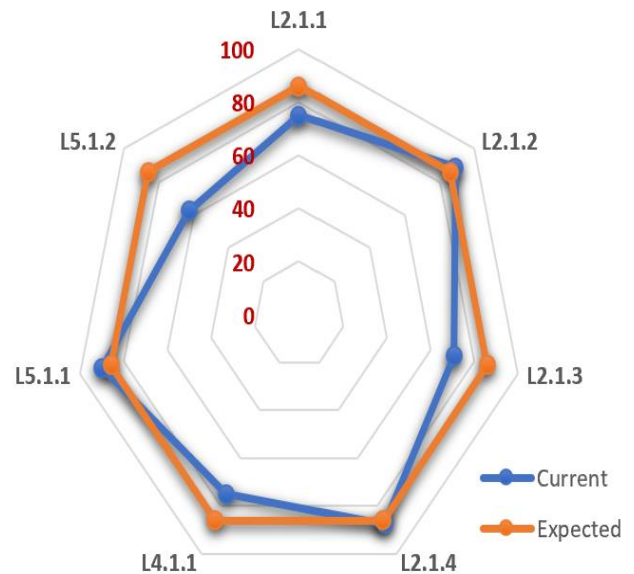

Fig. 6. Comparison of the current and expected maturity.

E. Scrum Practice Recommendation

Improvement recommendations are proposed to Grp-BPR because the assessment found that there are three SMM goals that don't reach Fully Achieved. The goals that need improvement regarding the application of the Scrum practices are Basic Scrum Management (BSM), Unified Project Management (UPM), and Performance Management (PMG). These goals are spread at SMM level 2, level 4, and level 5. Table XI describes seven objectives of the mentioned goals. Three objectives from BSM goal, one objective from the UPM goal, and two objectives from PMG goal. The rating of each objective is compared against the expected rating.

Table XII describes recommendation of improvement that can be done by Grp-BPR to reach Fully Achieved overall. The recommendations are based on SMM questionnaire responses, Scrum Guide [24], SBOK Guide [23], and A Guide to Scrum and CMMI [27].

TABLE XII. RECOMMENDATION OF IMPROVEMENT

Goals	Objectives	Recommendation
Basic Scrum Management	Scrum Roles Exist	Product Owner (PO) is a person who collect requirements from business stakeholders. He or she must ensure the team comprehends the value they are going to deliver. PO must be appointed as the project starts. He or she must know the responsibilities of a PO.
		Developers are people who build and deliver value collectively. They work based on business requirements written in a product backlog. The role must exist and staffed as the project starts.
	Scrum Meetings Occur and are Participated	Release planning is held optionally to obtain commitment over an increment delivery plan. Responsibilities, needed resources, and activities are discussed at this event.
		In release planning event, Scrum Master (SM) and PO must be present.
		Daily Scrum is one of the events that occurred in a Sprint. Developers discuss their task progress and its impediments.
		This event must be held daily on workdays to inspect progress toward Sprint goal and adapt the Sprint backlog as needed.
		Developers must attend Daily Scrum event, whereas PO and SM can attend it as developers, if they are working on Sprint backlog.
		In Sprint review event, the team presents the increment that they have built to the stakeholders. This event must be held once every Sprint.
		Sprint retrospective is held to discuss on how to better the next Sprint, in terms of the value's quality and process effectiveness. This event must be held once every Sprint.
		SM and developers must attend Sprint retrospective, whereas PO isn't mandatory to attend it.
Unified Project Management	Unified Project Management	All projects must adhere to the entire goals, objectives, and practices described in Scrum Maturity Level 2 and 3. Project Management Office (PMO) can enforce procedures to support the adherence.
Performance Management	Positive Indicators	SM coaches the team to successfully perform their tasks. SM should also remove the impediments throughout the project. Servant leadership style helps boosting the team's growth and energy level in their Scrum journey.
		A survey, at least once every Sprint, can be conducted to obtain the team's satisfaction level. This survey can also be part of Sprint retrospective.
		A survey can be conducted to obtain the stakeholders' satisfaction level. This survey can also be part of Sprint review.
		SM must ensure Scrum process has been adhered. Proper planning and task estimation should promote a work-life balance. Extra working hours must be minimized.
		SM must promote a psychologically save environment for the team. Constructive criticism and discussions in every event are welcome.

V. CONCLUSION

This research aimed to compare the Scrum maturity between two groups at Bank XYZ, namely Digital Group (Grp-DGT) and Business Process Reengineering Group (Grp-BPR). Based on assessment result, the recommendations for improvement are proposed to better Scrum practices at both groups. The following conclusions are drawn according to the research:

1) Group Grp-DGT has reached Scrum maturity level 5 (optimizing). KPA ratings of SMM goals are interpreted as Fully Achieved overall. Whereas Grp-BPR is still at level 1 (initial). Goal "Basic Scrum management" appraised as Largely Achieved with rating 80.97%. There are two objectives in this goal that don't meet the minimum rating to be appraised as Fully Achieved. Moreover, goal "Unified project management" and "Performance management" are also appraised as Largely Achieved with the same rating 75.00%.

2) Proposed recommendations for Scrum practices improvement are aimed for Grp-BPR due to its three goals are appraised as Largely Achieved. Deeper into the objective's rating, there are only four out of seven objectives whose ratings are below 86%. The recommendations are then drafted according to SMM questionnaire responses ("partially" and "no") in these four objectives. There are 15 recommendations in total for three goals consisting of nine recommendations for "Basic Scrum management", one recommendation for "Unified project management", and the last five recommendations for "Performance management". These recommendations can be used to improve Scrum practices in Bank XYZ, specifically at Grp-BPR group.

This research output can be used by Bank XYZ as a part of evaluation of the current project development process in Grp-DGT and Grp-BPR groups. Bank XYZ is also able to use it to tackle current problems in the other projects or initiatives that are not covered in this research or proposed by other groups. It would also provide aid in increasing Scrum maturity level of the next projects or Sprints in Grp-DGT and Grp-BPR groups. The other organizations, as required, would also benefit from the research output by applying the recommendations to those specific objectives.

VI. LIMITATIONS AND FUTURE WORK

This research utilized Scrum maturity model (SMM) to perform assessment to project development process at Grp-DGT and Grp-BPR groups of Bank XYZ. The elicitation was performed using a purposive sampling technique where there were four respondents participating, two respondents seated as Scrum Master at Grp-DGT, and the other two respondents seated as Scrum Master at Grp-BPR. The distributed questionnaire has 91 questions in total. There were 15 recommendations to improve four objectives that were found below the expected KPA rating.

There are some limitations of this research: (1) using only questionnaire to collect data, (2) proposed recommendations of improvement are based on SMM questionnaire responses

and Scrum guides, (3) risk impact of the unrealized Scrum practices is not investigated or being the part of the research questions, and (4) scope of study is limited to Bank XYZ.

Based on those limitations, it is suggested for the future researchers to do these works: (1) combining questionnaire, interview, and other data collection techniques to enhance the quality of the assessment results, (2) drafting the recommendation based on the combination of Scrum guides and Scrum expert judgment, (3) investigating risk impact of the unrealized Scrum practices, and (4) extending the case study scope by including some selected financial institutions.

Abstract—The post covid-19 studies have reported significant negative impact witnessed on global education and learning with the closure of schools' physical infrastructure from 2020 to 2022. Its effects today continues to ripple across the learning processes even with advances in e-learning or media literacy. The adoption and integration therein of e-learning on the Nigerian frontier is yet to be fully harnessed. From traditional to blended learning, and to virtual learning – Nigeria must rise, and develop new strategies to address issues with her educational theories as well as to bridge the gap and negative impact of the post covid-19 pandemic. This study implements a virtual learning framework that adequately fuses the alternative delivery asynchronous-learning with traditional synchronous learning for adoption in the Nigerian Educational System. Result showcases improved cognition in learners, engaged qualitative learning, and a learning scenario that ensures a power shift in the educational structure that will further equip learners to become knowledge producer, help teachers to emancipate students academically, in a framework that measures quality of engaged student's learning.

Keywords—Adaptive blended learning; computer-based test; fault tolerant design; resumption capabilities; Nigeria; FUPRE

I. INTRODUCTION

Learning is simply the process that leads to the alteration in the capability of a system causing a change in behaviour as it tries to accomplish tasks [1]. Learning thus, must yield a change or alteration in a system [2]–[4]; and thus, must equip and re-position the learner with a better knowledge to deal with task(s) at hand [5]. These changes may yield acquired skillsets, modified values, improved preferences and attitude, and new knowledge cum understanding for a learner [6]–[8] – all of which essentially improves a learner's experience and performance [9]–[11], and grants him/her the capability of new data readily, made available for future use in varying/similar instances of tasks [12]. Learning is a lifelong skillset acquired in a bid to accomplish a task over and over again [13], [14]. Learning modifies the behaviour of a learner system as it acquires the requisite skills and knowledge, which is therein stored and retrieved on demand access for use to

resolve challenges as well as assess risks, explore cum exploit challenges and opportunities [15], [16].

The covid-19 pandemic era witnessed a global lockdown of many public infrastructures with the following events namely: (a) closure of schools [17], (b) adoption of social distancing as a means to curb and reduce the spread [18], [19], (c) the migration and mobility pattern of residents from one place to another [20], and (d) adoption of nose-masks in public places [21], [22]. The post-covid-19 studies report that: (a) conventional schools were shut down to curb its widespread propagation, (b) enforcement of school shutdown resulted in various impact on the learning process for over 1.6 billion students, (c) short-term disruptions in the learning timeframe with significant negative impacts, and (d) these impacts rippled across the learning-verse, a variety of long-lasting effects in the formation of learner [23], [24].

The adoption of ICT has further bolstered and revolutionized the learning process with e-learning variants [25] as a means to help learners creatively contribute to knowledge creation (a hard feat to obtain in traditional schools with classroom settings). e-Learning today involves use of ICT-based services and electronic media-formats that can be replicated within medium that cuts across a variety of platforms in the learning process [26]. While, e-learning offers many benefits, the negative impacts of covid-19 era on education includes: (a) adoption of social distancing to curb the spread of the pandemic [27], (b) lessened migration of residents from one place to another, (c) adopting nose-masks in public places/gathering, and (d) closure of schools. Studies have reported that the covid-19-era – had significant negative-impact on the learning prospects of over 1.6 billion learners globally; and where such effects are not properly handled, may have long-lasting effects on the formation of such students.

The implications is: (a) non-access to physical infrastructure for learning, (b) yielded increased learning inequality and losses resulting from the stratified Internet access [28], [29], (c) learning disparities resulting from digital revolution/integration across a variety of learning platforms in

Nigeria (uLesson etc.), (d) the learner psychomotor and cognition health stability to adjust to blended, ICT-rich-learning paradigm as a new reality, and (e) learner adaptabilities to new complex logistics in these new paradigm, and other costs [30]–[32]. These, are determined through formative and summative testing.

II. METHODS AND MATERIALS

A. Computer-based Testing

Taking into account the changes already in place, there is a need to ensure that today's students are competent in science and technology. (Ojugo et al. [33] and Durojaye et al. [34]). The goals of science education must thus be: (a) to ensure basic science-tech literacy to enhance daily living of residents in our society today, (b) prepare learners for further training in science-tech, (c) develop skills and attitudes to prepare us for technological growth, (d) to improve learner creativity and innovation, (e) to enhance user-friendly interaction of various careers and provide knowledge applications. Fagbola et al. [35] Poor performance in science-tech can be attributed to: (1) the nature of the subject, (2) curriculum design, (3) teacher/learner characteristics, (4) the teaching style, and (5) disjointed teaching to meet examination deadlines.

To enable teachers and students harness unrestricted online access to resources in order to contribute and share knowledge with the rest of society, it is necessary to change these attitudes regarding education alongside summative testing based on CBT [36]. Technology integration with CBT is not the only thing that's going to get you into a knowledge era; rather, it leans more on the attitude of both the teacher/learner, and the requisite changes made via a paradigm shift by the teaching method as enabled by ICT. It is necessary for teachers to take on the basic issues, as well as questions about this and other topics such as: (a) teacher's literacy and awareness in mixed learning; (b) how teachers navigate a new technology together with their expectations around CBT [37].

B. Testing and Attitudinal Types

In order to enhance students' mastery of essential content, the pedagogical test is a way in which teachers use as part of their preparation for teaching feedback on continuing education and training. This also covers a wide range of formal and informal assessment methods and procedures used by teachers during the learning process in order to change the whole teaching and learning process through participatory learning, which are intended to improve learning results and retention of skills acquired throughout education [38]. Qualitative feedback for students/teachers that focuses on the content and performance is also involved, in addition to scores. Employed as assessment method, its practice presents students with clear learning targets, examples and models of strong and weak projects, regular descriptive feedbacks, the ability for self-assessment and track learning as well as set goals [39], [40].

Conversely, periodic quizzes, end-of-unit summative test, end-of-course tests and standard tests – all provide an overview of student performance at this point in time. They shall be used to assess the programme's content [41] in a

formative manner and to grade it. Albazar [42] mention the seven-principles of formative test as: (a) clarifies what good performance is about with set goals, criteria and expected standards, (b) it facilitates the development of self-assessment in learning, (c) provides quality content and engaged learnings, (d) encourages teachers and activates peer-dialogue around learning, (e) encourages positive motivational beliefs and self-esteem, (f) offers opportunities for bridging the gap between existing and desired performance, and (g) collects data for teachers that can be used as a tool for designing education and training [43], [44].

An attitude type refers to the expression of a favorable or unfavorable opinion about an individual, place, thing or event. The person's view of the target and how to talk or do things may also be referred to an attitudinal type [45], [46]. When we think about a person or something, it also means the feeling, attitude, position etc. It's a tendency or orientation in particular for the mind toward certain things [47], [48]. It refers, to the quadratic equation, to the attitude of students and teachers towards mathematics and science and technology education [49]–[51].

Iskandarov [52] Test is a *short* exam, which is grouped into formative and summative. The end of a course test is summative; while, the periodic test taken in an ongoing course is formative. To fulfil these two purposes, approximation tests are carried out to obtain a number of data on the programme's effects as well as diagnostic data for its deficiencies [53]. The Nigerian Teacher Institute groups testing into assessment methods as thus: (a) out-of-class, (b) open-book and (c) closed-book. These impact the attitude of the learner as it predisposes a learner to respond in a certain way. Younis et al. [54] attitude encompasses a range of affective behaviour with cognitive, psychomotor dimension that is measured via a self-report instrument. Attitude is a powerful motive in realization of a learner's expected goal(s).

C. Study Motivation

These challenges include (and not limited to) [55]–[57]:

1) *Paradigm shift*: The covid-19 era caught many societies, completely unprepared with the adoption/adaptation of ICT into education with Nigeria as case in point. With this shift and reform, parents and teachers had to switch their roles to become facilitators (that they were unprepared for).

2) *Questions framework*: The stratification of Internet access portends and presents network administrator(s) of the system that new questions must be uploaded onto the ensemble from time to time – to increase the pool of questions from which test-questions are drawn. Since the process is accomplished via scripting – a measure of error is unavoidably introduced with the addition of more contents onto the CBT platform.

3) *Resumption feat*: Most CBTs in administering questions – are pooled from their offline repository which are often clogged. A major issue in adopting e-learning with CBT capability is the lack of resumption ability with the learning management system (LMS) especially in lieu of physical infrastructure downtime, power outage and network failure.

4) *Poor integrity delivery outcome on the learning setting:*

The impact of the covid-19 era birthed the sudden need to adapt online teaching/learning [58], and also challenged the readiness of schools on paradigm shift to digital revolution readiness [59]. This forced adoption/adaptation of blended learning (i.e. e-learning that combines both a(synchronous) learning settings). These learning settings differed in terms of time, and the place of teaching/learning activities [60]. However, some of the challenges in the learning setting has been found to include: anonymity and social presence gaps, learning modalities, lower satisfaction, technophobia, lower cognitive achievement, disengaged participation in class of learners, fluency and slower interaction resulting from videoconferencing in e-learning [61]–[63].

D. *Proposed Adaptive Architecture for the Learner-centric Computer-based Testing (AdACoBaTe)*

Fig. 1 leverages on Dominic and Francis [26] model for e-learning as extended by [64] – which then provisions a test-based framework, which classifies learners into test groups, and proposed corresponding methods using the Sarasin model based on their learning styles namely: (a) visual learners who gain new facts and knowledge via visual inputs, (b) auditory learners who learn by listening to a teacher or teaching medium, and (c) kinesthetic/tactile learners learn via experiments and exploration (using Montessori means); however, both Hidayat and Utomo [65] commented that when a teacher is aware of the three types of learning styles outlined in Felder Silverman's 32-variant classroom activities they become more sensitive to designing exercises for improving teaching learning processes.

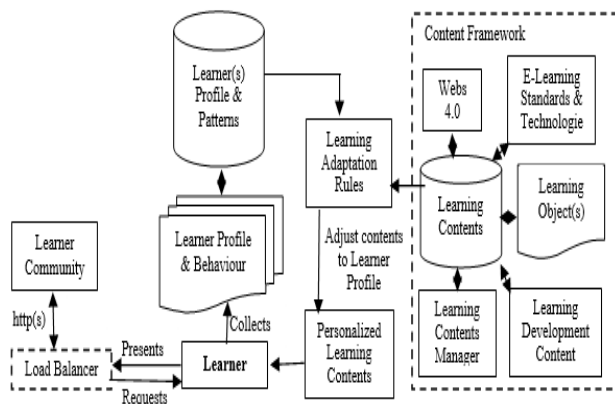

Fig. 1. AdACoBaTe: proposed adaptive content-based testing with resumption capabilities.

The workings of the ensemble is thus:

1) *The Learner Profiling Component* is that which directly interacts with the learner. It performs these tasks as thus: (a) all request and response are via HTTP/HTTPS format, (b) all request from the learning process is transmitted to a load balancing server that balances traffic on the basis of planned data structure and algorithm, (c) it collects data about learners profile and their learning behaviors, then sends them on to an adaptation model stored in a repository where they can be

formed patterns and adapted rules., and (d) it responds to learners with personalized learning contents provided by the adaptation model [66], [67].

2) *The Adaption Component* is the main processor for the experimental adaptive e-learning system. It performs these tasks: (a) it stores all learners profiles and their learning patterns into a repository, (b) it simplifies task(s) by responding to each learner, (c) it captures the browsing history, pattern and behavior of learners, and updates the captured data in its knowledge-base – helping the model to keep up with each learner and to transition between the learner profiles, (d) it uses its data content repository (or knowledge-base) about the learner’s profile to adjust the adaptation rules (and module) for each learner; And thus, identifies best learning style, learning path and learning contents suited for each identified learner, (e) it builds the personalized learning contents and hands them off to the learners’ model to present to a learner, and (f) it retrieves all contents required from the content model [68].

3) *Personalized Learning/Test-based Content* retrieves the learner’s profile and (a) provide adaptive contents from model, (b) retrieve the personalized learner’s questions in lieu of learned contents, and (c) stores them as temporary session to ease access to the contents and ensure that as the knowledge-base grows, performance is not degraded with the increase in users and the system shift between profiles [32]. Fig. 2 and 3 – show the state diagram of the ensemble as each learner log-in onto the CBT-system with resumption capabilities and fault tolerant design [69].

Fig. 2. Algorithm for randomized adaptive learner-based content with resumption capabilities for AdACoBaTe.

4) *The Content Component* – performs these tasks: (a) acts a repository for all the learning objects developed by a tutor cum administrator – allowing them to add/delete

questions to the pool, add/delete students list to an exam as well as monitor and manage the examination process, (b) ensures that a learner-content is based on the learning styles ratio as agreed in [70] and as suggested (i.e. visual 40%, kinesthetic 40%, and audio 20%), (c) develop contents using the latest web-tech (i.e. web 4.0 used to generate learner contents), and (d) use learning content development, management tools, and learning standards [71], [72] to proffer a system that is compatible, portable, can be ported to other systems of varying operating systems, shareable and interoperable with other e-learning systems. The preferred learning content ranges is as thus: (a) visual learning style consists of lecture materials, video lessons, animations etc, (b) kinesthetic consist of simulations, online quizzes, discussion forum, online compilations and question banks etc, and (c) audio consists of audio materials and accounts for 20-percent of learning styles.

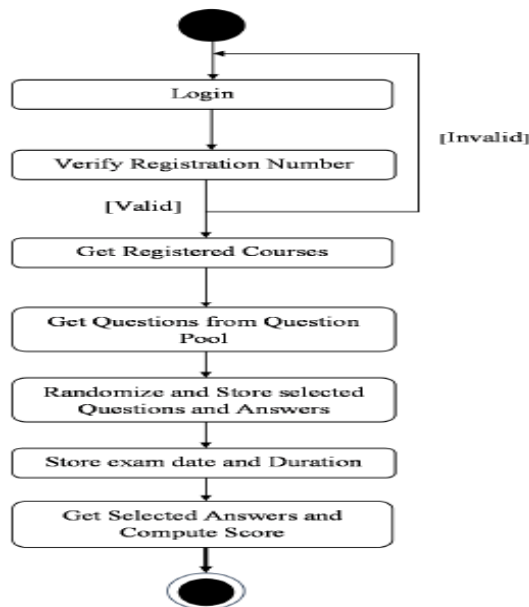

Fig. 3. Learner login with CBT access on AdaCoBaTe.

In order to prevent cheating and negligence on the part of students, a randomised question set is generally given for each student in an examination. System interfaces are easy for new computer users to use as they can navigate on a keyboard with their own set of keys. The proposed system is tolerant of failures because if there are incidents of network disruption, component failure or power outage during a test, the student's progress can be quickly restored.

a) Fault tolerance: Prior to the point of power-, component- and network-failure, system shall be capable of recover from a fault and resume the examination. Faults that occur during exams are recovered by the system. A student will not re-start the entire exam in such a case. System achieves this by tracking the entire exam, and allowing the user to resume an examination prior to the point of failure.

b) Power failure: The ensemble during examination shall be able to store each selected selection made by the student in its database and a copy will also be retained for temporary session storage. The CBT tracks client system IP-address during exams. With power fault, a user will be disconnected for an extended period pending the restore of power. If the IP address is not changed, student can re-log in and continue on the same system soon as power is restored to the machine. Also, prior to power failure, the client agent will initiate a countdown from the remainder time saved in the database. Ensemble retrieves the queries that have been entered in the database and divides them into various sets of questions, options or chosen answers.

c) Network fault: With a network fault, the client agent must not be able to send a student's newly selected answer to the orchestra if his or her computer has been disabled for an exam. To restore the network, system operation will be interrupted on the client side. The ensembles are keeping an eye on that idle time during the exam. The ensemble will give a student reallocation of idle time if it is beyond the 500-seconds threshold. Once network is back up, students are allowed to continue with their examinations from where they were before a technical failure occurred.

III. RESULTS AND DISCUSSION

A. Ensemble Performance Evaluation

Divayana [70] design seeks to ensure in e-learning systems such as public ethics, quality, accountability, nationalism etc. He categorized these feats into 10-dimensions as supported by Ojugo et al. [73]. We recast interaction with the system as a 9-dimension feat: (1) design effectiveness, (2) availability of video conference, (3) CBT readiness, (4) technical support, (5) teacher/learner use of system, (6) availability time, (7) the availability of resources, (8) the completeness of resources, and (9) data security. He used Eq. (1) to analyse the effectiveness of the learning style(s) and categorized into 4-percentiles: (a) high ranges from 81-100%, (b) sufficient from 61-80%, (c) moderate from 50-60%, and (d) poor falls below 50%.

Both categories high and sufficient – implies the learning design does not require any revision. Moderate requires some form of revision; while, the category poor implies a complete revision of the learning design. Thus, evaluation for both experts and participants yields the Table I and II respectively.

$$EP = [F/N] * 100 \quad (1)$$

Table I shows high and sufficient category ranging above 85% for all the evaluated variables by the various experts. The implication of which, is that these components do not require revisions of any kind. However, the data security component can be improved upon and agrees with [74].

TABLE I. EXPERTS' EVALUATION ON LEARNING / CBT DESIGN

Features	Experts' Evaluation Scores				
	1	2	3	4	5
Design Effectiveness	0.89	0.96	0.91	0.89	0.92
Availability of Video Conference	0.91	0.87	0.91	0.94	0.89
CBT Integration	0.75	0.89	0.79	0.89	0.91
Technical Support	0.85	0.90	0.92	0.88	0.91
Effective Usage of Framework by Teacher/Learner	0.92	0.92	0.86	0.85	0.90
Duration & Resumption Capacity	0.91	0.90	0.93	0.98	0.89
Reliability of contents	0.89	0.89	0.78	0.69	0.93
Completeness of resources	0.79	0.91	0.87	0.91	0.96
Data Security	0.76	0.67	0.88	0.95	0.89

TABLE II. PARTICIPANTS' EVALUATION ON LEARNING / CBT DESIGN

Features	Participants' Scores		
	σ	μ	+Di
Design Effectiveness	0.27	0.94	0.89
Availability of Video Conference	0.27	0.87	0.89
CBT Integration	0.23	0.82	0.73
Technical Support	0.33	0.90	0.95
Effectives Use by Teacher/Learner	0.28	0.81	0.78
Duration and Reciprocity	0.38	0.81	0.72
Reliability of contents	0.31	0.80	0.86
Completeness of resources	0.29	0.93	0.76
Data Security	0.13	0.85	0.72

Table II shows participant evaluation with mean, standard deviation and dyadic interaction between participants and the system. It yields a mean effectiveness in the ensemble use with over 90%, and a dyadic interaction that is above 70%. Also the relationship on the interaction between the participants and the e-learning platform cum system is sufficient.

B. Result Findings

The resulting resumption capability allows student's time to be recovered soon as fault is rectified. The system records the last activity during connectivity loss, and restores the time spent on it. If loss exceeds a threshold of 500 seconds, time is restored only if it persists. Ensemble resumes activities via automatic retrieval of remainder time, question-set and selected choices as in Fig. 2. The IP address and hostname of the client system, assigned to the user's registration number during the exam, shall also be used to restart the learner's session from the same device if and when the power is lost. This agrees with [75], [76].

Furthermore, the complexity with which examinations are scheduled is eliminated by using a series of simultaneous tests. The database is filled with a list of registered courses for each student. A student is entitled to write any scheduled course(s) registered, once the course schedule has been set. An algorithm for random selection of questions, is implemented

to avoid the same sequence of questions and answers being assigned to students. Eq. (2) is used to validate the algorithm so that the probability a student gets the same sequence of questions with the same sequence of choices is denoted by $P(R)$:

$$P(R) = \frac{Q \cdot S}{N \cdot Q! \cdot \pi_1^Q C_i!} \quad (2)$$

Where Q is the number of exam's question is Q , C_i is the number of choices for Q_i (where $i=1...Q$), the number of students is S , and the total number of questions stored in the database for this exam is N (where $Q \leq N$).

C. Discussion of Findings

We model the AdaCoBaTe ensemble to resolve the issues of fault-tolerance and resumption capability to reduce the effect of the occurrence of faults that may occur from power, network and physical infrastructure failure(s) – that may disrupt or terminate an examination. This can result in timing out that will eventually supposedly log out a user. To restore lost time, the system would monitor client computer connectivity to a server in order to solve this problem. System will restore the clock to when a student has last been in touch with this server if connectivity is lost for more than 500 seconds. In addition to restoring the rest of the period, if an exam is restarted, question set and selected choices are restored. This agrees with [77]–[79].

The algorithm for random selection of questions, its random distribution and random choice of responses – were developed and used. In general, it reduced examination malpractice as is corroborated by Fig. 2. A database is kept of the randomized question sets and selected answers, which are assigned to students when examinations resume. The random algorithm uses inbuilt-PHP shuffle function to ensure that sets of randomly selected questions are distributed normally. A comparison of the features of the proposed system to some popular online testing systems has been carried out. Automated resumption of tests will facilitate the adoption of Web based examinations by institutions that do not require uninterrupted power or Internet connection. This agrees with [80]–[82].

Further research can be poised toward the application of this study to online exams with descriptive questions, and not just multi-choice questions, and seek new means to track all assigned questions (alongside the selected choices as database size grows larger and for larger examinations). Also, to advance its security also, further studies can propose live image capture for students undertaking the exams as a means to detect impersonation when the exam is strictly online/web-enabled.

IV. CONCLUSION

To reposition education as a key integral facet of the society as recovery strategies against the impacts of covid-19 pandemic – requires strong policies, which will yield unexpected high-end results. And though, the impact in Nigeria (on a grander-scale) was not as projected – the shocks and disruptions as experienced with covid-19, still raises important educational concerns that only new reforms can

answer and help with national recovery. The questions raised as reflection of the local realities vis-à-vis implementation of platforms to exchange experiences will in turn, foster effective strategies cum policies to help repair the wreckage impacted on the society by covid-19 – and mitigate future pandemic. This CBT ensemble can be implemented on a Campus-Intranet design to help curb the issues of privileged control as well as security risks that comes with its access via the Internet. This intranet-based design mode will also curb the issues of interoperability. The personalized delivery outcome on the e-learning setting seeks to minimize the effects of anonymity and social presence gaps, advances an improved learner satisfaction with the tailored content delivery, improved cognition, and better engaged participation in class of learners.

A Yolo-based Violence Detection Method in IoT Surveillance Systems

Hui Gao

College of Computer and Information Engineering
Xinxiang University
Xinxiang 453000, Henan, China

Abstract—Violence detection in Internet of Things (IoT)-based surveillance systems has become a critical research area due to their potential to provide early warnings and enhance public safety. There have been many types of research on vision-based systems for violence detection, including traditional and deep learning-based methods. Deep learning-based methods have shown great promise in ameliorating the efficiency and accuracy of violence detection. Despite the recent advances in violence detection using deep learning-based methods, significant limitations and research challenges still need to be addressed, including the development of standardized datasets and real-time processing. This study presents a deep learning method based on You Only Look Once (YOLO) algorithm for the violence detection task to overcome these issues. We generate a model for violence detection using violence and non-violence images in a prepared dataset divided into testing, validation, and training sets. Based on accepted performance indicators, the produced model is assessed. The experimental results and performance evaluation show that the method accurately identifies violence and non-violence classes in real-time.

Keywords—Violence detection; IoT; surveillance systems; Yolo; deep learning

I. INTRODUCTION

The use of Internet of Things (IoT) based surveillance systems has elevated significantly in the past few years, particularly for detecting and preventing violent incidents in public spaces[1–3]. Violence detection in IoT-based surveillance systems has become a critical research area due to its potential to provide early warnings and enhance public safety[4,5]. These systems can process and analyze real-time data from sensors and cameras, enabling quick and efficient identification of violent incidents [6].

There have been significant advances in violence detection technologies in IoT-based surveillance systems in recent years [7,8]. There has been significant research on vision-based systems for violence detection, including traditional and deep learning-based methods [9,10]. Traditional methods, such as motion detection, background subtraction, and object tracking, have been widely used for violence detection in surveillance systems [6,11,12]. However, these methods have limitations in terms of accuracy and robustness, particularly in complex and cluttered environments.

Recent studies have shown that deep learning-based model, like recurrent neural networks (RNNs), convolutional neural networks (CNNs), and YOLO, is able to significantly improve

the accuracy and efficiency of violence detection in vision-based systems [13–15]. These models can process and analyze image and video data, extract complex features, and identify violent events in real time.

Despite the recent advances in violence detection, using deep learning-based methods has shown great promise in ameliorating the efficiency and accuracy of violence detection [13,16]. Nevertheless, significant limitations and research challenges still need to be addressed, including the development of standardized datasets and real-time processing algorithms. According to these challenges, the lack of standardized datasets leads to generating inaccurate model for violence detection. Moreover, it is required to address an efficient model to perform in real-time requirement. This makes comparing the different models' performances challenging and limits their generalizability. Addressing this challenge is essential to advance the field and ensure the accurate and efficient detection of violent events in surveillance systems.

To deal with the research challenge in this work, the YOLO algorithm is utilized for the violence detection task in order to overcome these issues. The most recent object identification technique, YOLO, is highly accurate and quick in detecting several items in a picture. We generate a model for violence detection using violence and non-violence images in a dataset that has been divided into testing, validation, and training sets. Based on accepted performance indicators, the produced model is assessed. The system can be taught to recognize violence patterns and accurately identify violence and non-violence classes in real time.

The rest of this paper is structured as follows; Section II presents literature review. Section III discuss about the methodology. Experimental results and performance evaluation presents in Section IV Finally, the paper concludes in Section V.

II. LITERATURE REVIEW

This section presents the literature review and related works on the violence detection research domain. Ullah et al. [3], in IoT-based industrial surveillance networks, this research presented an edge vision technique with AI assistance for violence detection. The technique uses cloud computing, edge devices, and deep learning-based algorithms to analyse video data and identify possible real-time risks. Some important features are custom datasets for training, cloud computing and

edge device integration, and real-time notifications for possible risks. The method successfully detects violent occurrences with low false-positive rates and high accuracy. The method's drawbacks include the sizeable computational resources needed for in-the-moment data processing and analysis, as well as the hefty infrastructure expenditures.

AIDahoul et al. [17] rendered a method for violence detection utilizing a Convolutional Neural Network-Long Short Term Memory (CNN-LSTM) based IoT node. The suggested method utilizes a custom dataset for training the CNN-LSTM model, which analyzes the video data captured by the IoT node to detect violent events. The system can process and analyze data in real-time, quickly detecting potential threats. The key features of the proposed method include the use of a CNN-LSTM model for violence detection, the integration of IoT devices for data capture, and the ability to perform real-time analysis of data. The study found that the proposed approach achieved high levels of accuracy in detecting violent events with low false-positive rates. One limitation of the proposed approach is the potential for high power consumption by the IoT node when processing and analyzing data. The authors also note that the performance of the system may vary based on environmental factors and the specific application scenario.

In [18], the research presented a weakly supervised method for detecting violence in surveillance footage. In order to identify probable violent occurrences without needing manual annotation of the training data, the technique employs a Convolutional Neural Network (CNN) model to categorise video frames as violent or non-violent. The approach's main characteristics are using CNN models for classification and weakly supervised learning, eliminating the requirement for annotated training data. The study discovered that the proposed strategy outperformed earlier state-of-the-art approaches in achieving high accuracy in identifying violent incidents. The approach may still need some manual annotation, the authors point out, in order to operate at its best.

Abdali et al. [19] developed a CNN and Long Short-Term Memory (LSTM) model-based real-time violence detection method. To analyse video frames in real time and pinpoint violent situations, the proposed technique combines the advantages of CNN and LSTM. The approach's primary characteristics include real-time video processing, a bespoke training dataset, and highly accurate violent event detection with low false-positive rates. According to the study, the suggested solution beats current approaches in terms of processing speed and accuracy, making it appropriate for use in practical applications. The approach could involve a lot of computational power, and further study is needed to improve it for various settings and environments.

III. METHODOLOGY

This section discusses the details of the procedures in our methodology. This method consists of dataset description, dataset set preparation, Yolo algorithm, and training of the Yolo model. The corresponding details explain in the following sections.

A. Description of the Dataset

The dataset includes 3333 images of resolution 416 x 416 pixels with the annotated objects. The annotations include bounding boxes around people and objects of interest and labels indicating whether the object is associated with violent behavior. The dataset includes examples of different types of violence, including fights, weapons, and attacks. The dataset is intended for use with the YOLO (You Only Look Once) algorithm, a popular object detection algorithm known for its speed and accuracy.

B. Dataset Preparation

This study's provided dataset for violence detection has undergone several pre-processing and augmentation procedures. Pre-processing refers to the process of preparing the data for machine learning tasks. In this dataset, pre-processing included resizing all images to a resolution of 416 x 416 pixels, the input size required by the YOLO algorithm. Additionally, the dataset was converted to the YOLO format, which involves creating text files that contain the bounding box annotations and labels for each image.

Augmentation procedures are utilized to enhance the dataset's diversity and size artificially, improving the model's performance by making it more robust to variations in the input data. The dataset was augmented using various techniques, such as random scaling, random horizontal flipping, random rotation, and random translation. These techniques were applied to each image and corresponding annotations to create new training samples with slightly different characteristics.

Random horizontal flipping involves randomly flipping each image horizontally, which increases the diversity of the dataset and helps prevent overfitting. Random scaling involves randomly scaling each image by a factor of 0.25 to 2.0, which helps the model learn to recognize objects at different scales. Random translation involved randomly shifting each image horizontally and vertically by up to 20% of its width and height, respectively, which helps the model learn to recognize objects in different positions. Random rotation involves randomly rotating each image by up to 10 degrees, which helps the model learn to recognize objects from different angles.

All of these pre-processing and augmentation procedures were performed to enhance the diversity and quality of the dataset, which is able to lead to better performance and generalization of the violence detection model.

C. YOLO Algorithm

YOLO (You Only Look Once) is an object detection algorithm that simultaneously forecasts class probabilities and bounding boxes for objects in an input image. It is a popular algorithm due to its real-time detection capabilities and high accuracy. The YOLO algorithm consists of two main components: a post-processing algorithm and a convolutional neural network (CNN). The CNN takes an input image and outputs a set of bounding boxes along with their class probabilities. The post-processing algorithm selects the most probable bounding boxes and discards the others.

YOLO has several versions, with YOLOv5 being the latest and most advanced version. YOLOv5 is faster and more

accurate than previous versions, thanks to several improvements, including using a backbone network architecture, improved feature extraction, and a more efficient post-processing algorithm. Fig. 1 demonstrates the architecture of YOLOv5 network. The backbone of YOLOv5 is called CSPDarknet, which stands for Cross Stage Partial Network. It is a modified version of the Darknet architecture used in previous versions of YOLO. CSPDarknet is composed of a series of convolutional layers that extract features from the input image. It is designed to be computationally efficient while still producing high-quality feature maps.

The neck of YOLOv5 is called PANet, which stands for Path Aggregation Network. It is a feature fusion module that combines features from different scales and resolutions. The PANet module uses a top-down pathway to aggregate features from high-resolution feature maps and a bottom-up pathway to aggregate features from low-resolution feature maps. The resulting feature maps are then fused to form a single feature map with rich information from multiple scales.

The head of YOLOv5 is called YOLOLayer. It is responsible for predicting class probabilities and bounding boxes for objects in the input image. YOLOLayer uses anchor boxes to predict the location and size of objects in the image. It also uses a softmax function to forecast the probability of each object belonging to a particular class. The final output of the YOLOLayer is a bounding box set with associated class probabilities.

The procedure in the YOLOv5 algorithm is based on the following steps:

1) *Input image*: YOLO takes an input image of size (width, height, channels) and resizes it to a fixed size (416x416x3) before feeding it to the network.

2) *CNN architecture*: The CNN architecture of YOLOv5 consists of a backbone network and several detection heads. The backbone network is based on CSPDarknet53, a variant of Darknet53. The detection heads are responsible for predicting bounding boxes and class probabilities.

3) *Feature extraction*: The feature extraction process is carried out by the backbone network, which generates feature maps of various resolutions. The feature maps are then fed to the detection heads.

4) *Bounding box prediction*: The detection heads predict a bounding box set for each feature map. The bounding boxes are represented as (x, y, w, h), where (x, y) is the center of the box, w is the width, and h is the height.

5) *Class probability prediction*: The detection heads also predict class probabilities for each bounding box. The class probabilities represent the probability that the object inside the bounding box belongs to a particular class.

6) *Non-maximum suppression*: After predicting bounding boxes and class probabilities, YOLOv5 applies non-maximum suppression to eliminate duplicate detections. Non-maximum suppression selects each object's most probable bounding box and discards the others.

In summary, YOLOv5 is a state-of-the-art object detection algorithm that utilizes a CNN to forecast class probabilities and bounding boxes for objects in an image. It has several improvements over previous versions, making it faster and more accurate. The algorithm consists of a backbone network, detection heads, and a post-processing algorithm that applies non-maximum suppression.

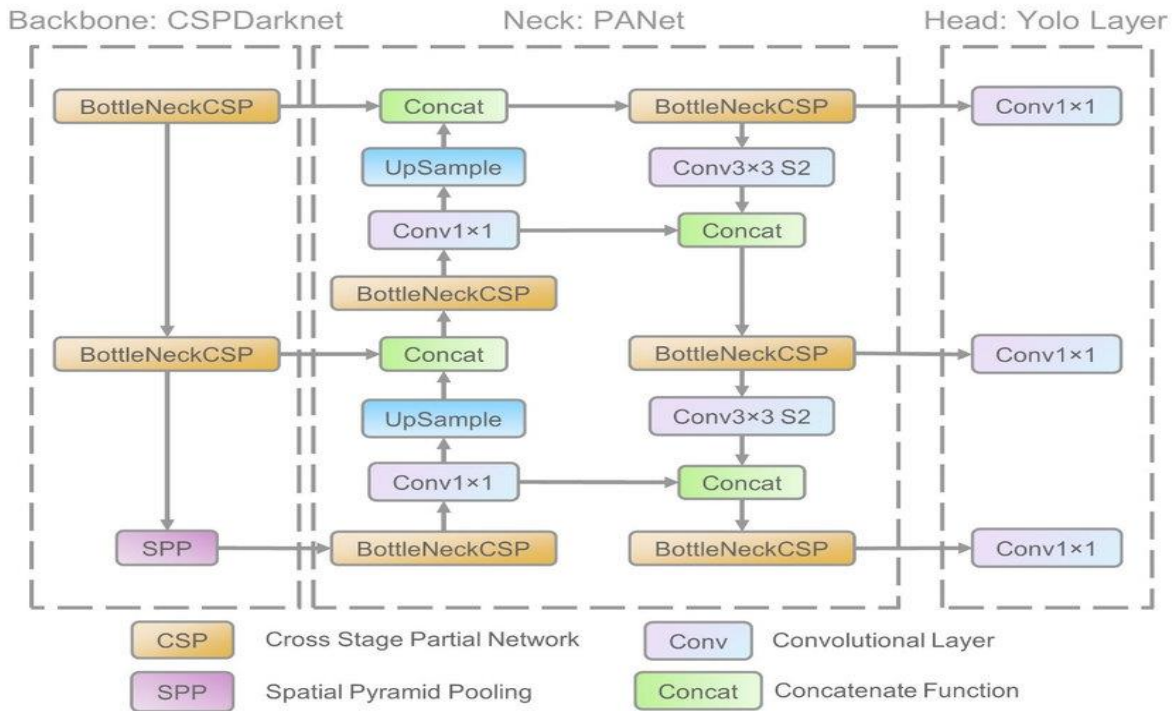

Fig. 1. The architecture of Yolov5 network [20].

D. Training the YOLOv5 Model

Training a YOLO (You Only Look Once) model for violence detection involves preparing the dataset, selecting a pre-trained model, fine-tuning it, and evaluating its performance. The first step discussed in section 3.2 is to prepare the dataset by resizing the images, annotating them with bounding boxes around the violent objects, and saving the annotations in a format the YOLO model can understand. Next, a suitable pre-trained YOLO model for violence detection must be selected for YOLOv5.

In the fine-tuning step, the pre-trained YOLO model is trained on the dataset, and its performance is assessed on the validation set. Hyperparameter tuning is able to be carried out to optimize the performance of the model. The batch size, learning rate, and number of epochs are some of the hyperparameters that can be tuned. Once the model is fine-tuned, its performance is assessed on the test set utilizing metrics such as F1 score, recall, and precision. If the model's performance is unsatisfactory, additional violent images can be added to the dataset, or the hyperparameters can be further tuned.

For training purpose, the dataset consisting of 2300 training samples, 662 testing samples, and 334 validation samples serves as the foundation for training the model YOLO model for violence detection using the given dataset of 2300 training samples, 662 testing samples, and 334 validation samples. Table I shows the proportion of each training, validation and testing sets. In the initial stage, the dataset is preprocessed to ensure consistency and compatibility with the YOLOv5 architecture. This involves resizing all images to a uniform input size, often in the form of squares, to facilitate streamlined processing. Annotations for each image are also processed to provide accurate bounding box coordinates and class labels corresponding to violent actions. These annotations are crucial for training the model to recognize and classify violence instances. The YOLOv5 model is then initialized with pre-trained weights, typically on a large-scale dataset, leveraging knowledge learned from a broad range of objects and features. Fine-tuning is performed on the violence detection dataset, allowing the model to adapt its features and parameters specifically for identifying violent actions. During training, the model iteratively adjusts its parameters by comparing predicted bounding boxes and class probabilities to the ground-truth annotations. This optimization process, often implemented using techniques like stochastic gradient descent, seeks to minimize the disparity between predictions and actual annotations.

To ensure the model generalizes well to new, unseen data, the training process employs techniques such as data augmentation. This involves applying transformations to the images, such as rotations, flips, and color variations, to expose the model to diverse scenarios it may encounter in real-world surveillance situations. Additionally, the training dataset is shuffled to prevent the model from memorizing the order of

samples. Throughout training, the model's performance is regularly evaluated using the validation dataset. Metrics like mean average precision (mAP) are calculated to assess the model's ability to precisely localize and classify violent actions. Training continues until the model's performance plateaus or shows satisfactory convergence.

TABLE I. POTATION TESTING, VALIDATION, AND TRAINING SETS

Set name	No. of samples	Set proportion (%)
<i>Training</i>	2300	70%
<i>Validation</i>	662	20%
<i>Testing</i>	334	10%

IV. EXPERIMENTAL RESULTS AND PERFORMANCE EVALUATION

The experimental findings and performance assessment of the suggested Yolov5 for violence detection on customized datasets are presented in this part: one research used to fall, no-fall, and half-classless films in a bespoke dataset. Utilizing various input image sizes, training datasets, and object detection thresholds, the study assessed Yolov5's performance. Fig. 2 demonstrates some examples of experimental results.

The experimental results and model performance evaluation for the YOLOv5 model for violence detection can be measured by various metrics such as Mean Average Precision (mAP), recall, and precision. Precision is the ratio of true positive detections to all of the model's positive detections. The formula for precision is:

$$Precision = \frac{TP}{TP+FP} \quad (1)$$

The ratio of precise positive detections to all positive cases in the dataset determines recall. The recall is the proportion of real positives to all real positives in the dataset. It displays the capacity of model to detect positive samples reliably. The formula for the recall is,

$$Recall = \frac{TP}{TP+FN} \quad (2)$$

In precision and recall, where TP is the number of true positives (correctly detected violence), FP is the number of false positives (non-violences detected as anomalies), and FN is the number of false negatives (violence not detected by the algorithm). Based on obtained results, Table 2 presents performance measurements for the average precision rate for each class.

A popular performance metric, the mAP, accounts for memory and accuracy at different confidence levels. It returns a single scalar number summarising the model's overall detection performance as the average accuracy over a range of recall values. Fig. 3 illustrates performance metrics for generated Yolov5-based violence detection model.

Fig. 2. Experimental results.

TABLE II. AVERAGE PRECISION RATES BY CLASSES

Set name	Validation set	Testing set
<i>Violence</i>	93%	91%
<i>Non-Violence</i>	89%	90%
<i>All</i>	91%	91%

Fig. 3. Illustration of performance metrics for generated YOLOv5-based violence detection model.

V. CONCLUSION AND FUTURE WORKS

A promising area of research that can improve public safety is using deep learning-based approaches for violence detection in IoT-based surveillance systems. This study presented the YOLO algorithm to address the issues related to violence detection. We utilize YOLOv5 as an advanced object identification technique that can quickly and accurately detect multiple objects in an image. We create a model for violence detection using images of violent and non-violent scenes divided into testing, validation, and training sets. The model's performance is evaluated using standard performance indicators. Our system can learn to recognize patterns of violence and accurately differentiate between violent and non-violent classes in real time. Therefore, the proposed method in this study is based on an efficient and fast deep learning architecture named as YOLOv5 network. This network, as previous studies proved and indicated, it is very effective in real-time detection algorithms. Inspiring of this, we also adopted YOLOv5 algorithm and generated a model to deal with violence detection. As our experimental results indicated, the proposed method present accurate results and provide satisfy in real-time requirement. Future work could focus on improving the robustness of the model by addressing various environmental factors that may affect violence detection accuracy. Additionally, the development of larger datasets with diverse scenarios can improve the generalizability of the model. Finally, further investigation could explore the integration of multiple sensors and modalities, such as audio and motion sensors, to enhance the accuracy and reliability of violence detection systems.

Towards Automated Evaluation of the Quality of Educational Services in HEIs

Silvia Gaftandzhieva¹, Rositsa Doneva², Mariya Zhekova³, George Pashev⁴
University of Plovdiv "Paisii Hilendarski", Plovdiv, Bulgaria^{1,2,4}
University of Food Technology, Plovdiv, Bulgaria³

Abstract—The provision of educational services with high quality is a matter of concern to all stakeholders in higher education (academic staff, administration, students, etc.). According to many researchers, student satisfaction is an indicator of service quality in higher education institutions (HEIs), and evaluating the quality of educational and administrative services from students is an effective tool for improving the quality of HEIs. To ensure a competitive benefit over other educational institutions, HEIs leadership should take measures leading to improved student feedback on the quality of the provided administrative and education services, seek ways to exceed student expectations and provide high-quality services. Due to the great importance of the opinion of students on the quality of the services offered, many HEIs develop and use tools to assess student satisfaction with the quality of the services in the HEI. Little researched in the literature is the issue regarding the need to develop tools for HEIs leadership allowing survey results analysis, tracking trends over the years and comparing HEIs results. Based on a detailed analysis of developed questionnaires for evaluating the quality of services, this paper explores the possibilities of automation of the overall process for conducting questionnaire surveys of student's satisfaction with the quality of services. As a result, a software prototype of a tool to automate the entire process for assessing student satisfaction is proposed - from questionnaire modelling, survey organizing and conducting to the analysis of the collected data. The developed tool allows governing bodies in HEIs to make informed decisions to improve the quality of services and to compare the results with those of competing universities.

Keywords—Quality assurance; higher education; educational services; administrative services; data analysis

I. INTRODUCTION

Quality assurance is a developmental process in the European Higher Education Area (EHEA). Standards, criteria and performance indicators are the starting point in the quality evaluation process at a given time. The implemented quality assurance methodologies of evaluation agencies assess whether or not HEI achieve threshold standards, focus on identifying or promoting HEIs excellence and formulate recommendations for quality improvement. In turn, excellence models set goals for institutions to exceed minimum expectations [1].

Due to the global growth of the higher education sector, HEIs are facing significant challenges to undertake sustainability initiatives in teaching, research and development and administrative services. High competition forces HEIs to review their policies, procedures and marketing guidelines to

ensure that they provide quality educational services and globally recognized education [2-3].

HEIs aim to produce services related to teaching, research and public service [4], divided into two main groups- administrative and educational services. The primary purpose of the administration in the HEI is to enable the performance of the main functions by providing support, integration, coordination, supervision, service of the learning processes, scientific research and public services. Regardless of differences in the specific nature of administrative work, all forms of administrative work can be considered a service. When considering administrative work as a service provision, there are two main groups of users: internal (academic and non-academic staff and students) and external (funding organizations, industry representatives, prospective students and individuals interacting with HEIs). Examples of administrative services offered to students are career guidance services, counselling, participation in internship programs, accommodation in dormitories, and administration of the training conducted [5-8]. On the other hand, teachers provide academic services in a university environment that are directly related to the training provided in the academic disciplines [6]. Gupta and Kaushik [9] note that services have characteristics that distinguish them from products, and assessing their quality can be challenging.

According to Al-Ababneh and Alrhaimi [10], there is no single model of the education quality management system. Even though the effectiveness of higher education management depends on external factors arising in the educational system management, HEIs leadership responds to the educational process effectiveness and the quality of the services provided. It requires the implementation of innovative management methods based on modern information technologies.

The development of technologies in the period of globalization and the industrial revolution 4.0 has had a formidable impact on how organizations from various sectors, including HEIs, perform their daily work [11]. In the digital transformation process, HEIs should invest funds to develop their infrastructure to ensure prestige, meet minimum standards, and use technology to answer the students growing needs. When implementing new solutions, HEI management often must resolve conflicts with existing academic or administrative systems or procedures and staff antipathy to technological innovation. Managing and addressing all these challenges is critical to maintaining the quality of services offered and the effectiveness of HEIs [12]. For this reason, HEIs leadership should integrate all actions for quality

assurance into the management process in HEIs. Improving quality may require changes in various areas, such as human resource management, finance and budget, infrastructure, administrative services, etc. Therefore, to achieve the set goals, it is necessary to consider the assurance and evaluation of the quality of services as tools for the strategic development of HEIs [13]. During the transition from traditional to mixed learning, imposed by the Covid-19 pandemic, problems are emerging in terms of ensuring and maintaining the quality of education, including the compliance of educational programs with the requirements of the labour market, the expectations of students and their families, digital transformation of the educational process and economic stability of institutional networks [14–18].

All stakeholders (academic staff, administration, students, the general public, etc.) are concerned about assuring quality educational services. Quality management in higher education requires understanding the needs of all stakeholders [9], [19–21] and adopting and implementing strategic plans to enable higher education to reply to the needs of external (employers) and internal users (students and teachers) [22-23]. Kazeroony [24] believes many factors explain the need for restructuring strategies to deliver quality education, including the ever-changing characteristics of learners, technological advances and economic reasons. According to Bernhard, due to the demand for quality services, most academic institutions worldwide have undergone a significant transformation [25]. Kettunen believes that the only way to improve stakeholder confidence in the education system is by integrating a plan for quality education services into the overall institutional governance framework and implementing quality assurance systems [26-27].

The service quality in HEIs cannot be examined without considering the student as the primary user of the offered educational and administrative services. Student satisfaction significantly affects the sustainability and development of HEIs, and therefore HEIs leadership should focus on providing better service quality [28-29].

The process of providing quality services is focused on meeting student expectations, continuous improvement and sharing responsibilities [30]. This process ensures HEIs have done well and supported students throughout their training as much as possible. Arokiasamy and Abdullah underlined the need for HEIs to provide a well-rounded university experience due to the potential impact of student satisfaction on HEI competitiveness, student retention, and efforts to attract new students in a highly competitive higher education market [31]. HEI leadership should consider that prospective students gather information about the HEI by contacting current graduates and visiting the website and social media pages. The great satisfied students are more loyal to their HEI and spread positive comments and recommend the HEI to others [32]. Therefore, to ensure that an HEI has a competitive advantage over other HEIs, management should do activities to improve student feedback on the quality of administrative and educational services, seek ways to exceed student expectations and provide high-quality services [33–38]. Students' perspectives on the quality of educational services can be seen as a basis for

adapting marketing efforts to answer student needs [6] and improve institutional performance [39].

According to many researchers, student satisfaction is an indicator of service quality in HEIs, and students' evaluation of the quality of educational services is an effective tool for improving the quality of HEIs [7], [31], [37], [40–52].

Based on a detailed analysis of developed questionnaires for evaluating the quality of services, this paper explores the possibilities of automation of the overall process for studying student satisfaction with the quality of services. Section II reviews different factors contributing to student satisfaction. Section III discusses various methods and tools used to measure student satisfaction. Section IV presents the developed prototype of a software tool for surveys conducted. Section V presents the results, which allows HEIs to make informed decisions to improve the quality of services and compare the results of their HEIs with those of competing universities. Section VI, conclusion, discusses the contributions, limitations of the study and plans for future research.

II. QUALITY OF SERVICES IN HEIS

Kara and DeShields [53] suggest HEIs recognizing the importance of student evaluation of quality services would, in most cases, meet the student's needs to a great extent. Several empirical studies have been conducted over the years on the factors contributing to student satisfaction. Douglas, Douglas and Barnes found [54] the quality of learning resources was not a determining factor. According to the results of other studies, the quality of resources is a vital component of the quality of educational services [55-56]. The quality of resources is a multidimensional construct evaluated by indicators for support teaching, learning and research activities in HEIs. Such indicators include lecture facilities, laboratory facilities, library services and access to information and communication technology (ICT) infrastructure and digital resources [57-58]. According to Arambewela and Hall, teaching style, innovative provision of knowledge, faculty support and feedback influence students' satisfaction [59]. Other researchers also point to innovative changes in curricula [60] and teaching methods [61] as determinants of student satisfaction. Muhsin, Nurkhin, Pramusinto, Afsari and Arham [62] also explored the relationship between university governance, teaching quality and student satisfaction and concluded that teaching quality, teaching facilities and good university governance have a positive and significant impact on student satisfaction. Tuan cites the services provided by the administrative staff, the know-how, skills and attitude of the academic and non-academic staff as leading factors in student satisfaction [63]. Similar are the main aspects influencing the quality of services in HEIs identified by Sultan and Wong [64] - academic environments, academic and non-academic staff. Another group of researchers identified technological, learning, executive and psychological environment as the main factors for student satisfaction [51], [65]. Kara, Tanui and Kalai identified learning facilities, availability of textbooks and library environment as determinants of student satisfaction [66]. Other researchers point to understanding and effective communication between students and staff within the education environment as a leading factor in determining service quality

and student satisfaction [2], [46]. According to Vinogradova, Kulyamina, Vasileva, Bronnikova and Vishnyakov, many factors can influence the formation of consumer expectations, such as the student's own needs, life experience, public opinion, the state of the educational organization, current information on the labour market [67]. According to Hoque, Akhter, Absar, Khandaker and Al-Mamun [29], among the main factors that influence student satisfaction are the comfortable of lecture halls, service timely provision, the capacity of non-academic staff to solve problems, experienced lecturers for teaching and research, and the focus of university management on students.

III. APPROACHES AND TOOLS FOR QUALITY ASSURANCE AND ASSESSMENT

The difficulties in identifying the quality dimensions make challenges in developing models and tools for evaluating the quality of services in higher education [13] and using industry models for service quality evaluation. Due to their limitations, imposed mainly by the centrality of student learning services, industry models can be used with partial success [19] and therefore have to be adapted to reflect the specifics of higher education.

Total quality management (TQM) is a widely used model for improving the performance of service providers and customer satisfaction. Companies that implement TQM [68] transform their organisational culture by engaging all their members to contribute to improving products, processes and services. Many HEIs implement TQM to respond to market pressures while producing high-quality results and striving for self-improvement due to their social contribution [69-70]. Some researchers are sceptical about its applicability in HIEs [71] before the identity and characteristics of education [72-74]. However, many scholars have found that TQM can address stakeholder expectations and challenges in HIEs [75].

The interest in developing models for assessing service quality began in the 1980s. In the beginning, research focused primarily on developing industrial models for evaluating customer satisfaction, such as the perception model customer-perceived service quality [76], SERVQUAL [77] and SERVPERF [78].

Marsh [79-80] proposed the SEEQ tool allowing students to assess the quality of teaching, content and learning in nine areas – Teaching/Course Value, Instructor Enthusiasm, Organization of Presentations and Materials, Group Interaction, Student-Teacher Interaction, Scope, Exams/Assessment, Tasks/Reading Materials, and Workload.

Parasuraman, Zeithaml and Berry [81] proposed a model for measuring service quality based on a multiple-item scale. SERVQUAL is based on the view that the evaluation of the service quality of customers is fundamental, and service quality is closing the gap between service expectations and perceptions. Researchers outline ten dimensions of service quality: Reliability, Responsiveness, Competence, Access, Courtesy, Communication, Trust, Security, Customer understanding and Tangibility. Dimensions in the model are defined as a measure of how well the level of service provided reply customer expectations. To overcome some difficulties in

evaluation, researchers proposed an updated version of the model in 1988. The updated version has five dimensions [77]: Tangible assets (physical facilities, equipment, staff, etc.), Reliability (the ability for reliable service provision), Responsiveness (willingness to serve and assist customers quickly), Security (employees' ability to inspire trust and confidence, politeness and awareness), Empathy (providing individual attention to customers). The evaluation is done through a questionnaire containing 22 questions to assess the five dimensions of the service, allowing for evaluating the customers' expectations and the service provider's performance. Due to its flexibility and ability to be adapted to sector-specific requirements, the proposed model is widely used to assess the quality of services in industries from various sectors, including retail, banking, healthcare and education [82–90]. According to several researchers, the SERVQUAL model is the most well-known and commonly used model for evaluating the quality of services in higher education, incl. from students [9], [39], [91–105].

Tan and Kek [91] used SERVQUAL to assess student satisfaction in Singapore and concluded that some cultural factors should be considered when developing the assessment questionnaires.

Dado, Taborecka-Petrovicova, Riznic and Rajic [92] used SERVQUAL to study the service quality in HEIs in Serbia. They conclude there is a significant gap between student expectations and perceptions. Legcevic, Mujic and Mikrut [94] also used SERVQUAL to identify the gap between students' expectations and perceptions of educational services in Croatia. The survey results show that the negative difference in service dimensions can be used as a guideline for planning and allocating resources to improve the quality of educational services. Over the years, researchers have developed several modified versions of the tool adapted for evaluating the quality of services in HEI.

Aghamolaei and Zare [106] proposed a modified version of the SERVQUAL instrument that allows the evaluation of the quality of educational services by students. The questionnaire measures perceptions and expectations of students from the service in five dimensions – Confidence, Responsiveness, Empathy, Reliability and Tangibility. Study results were analysed using SPSS13 software using descriptive statistics, paired t-test, Wilcoxon, Friedman and ANOVA. Using the proposed tool, 350 students evaluated the service quality.

Zafiroopoulos and Vrana [107] developed a modified version of the model to assess the quality of services in HEIs in Greece from students and teachers. The evaluation study shows no significant differences in how students and academic staff perceive the quality of education.

The HEQUAL tool (based on SERVQUAL) [108] allows students to evaluate the quality of services in HEIs. Students complete a questionnaire with 27 indicators divided into five groups: teaching and course content; administrative services; academic facilities; university infrastructure; support services. The creators underline the possibility of expanding the functionality of the service quality assessment tool by all stakeholders – academic staff, support and administrative staff.

Donlagić and Fazlić [13] developed a service quality assessment tool based on SERVQUAL. The proposed questionnaire contains 25 questions for each scale: one to measure the expectations of students and one to measure their perception of the services provided. The questions cover all dimensions of the SERVQUAL model – tangible assets (four questions for equipment, infrastructure, interior, teaching materials, etc.), reliability (six questions for reliably providing the service, such as allowing student problems, claims and requests), responsiveness (three questions related to the provision of quick service to students), assurance (six questions to evaluate the knowledge and politeness of the academic and non-academic staff and their ability to express trust and confidence) and empathy (six questions for the individual attention given to students). Each question is rated on a 7-point Likert scale. HEIs leadership can use the results of the service quality evaluation as input for planning and strategy setting.

Hassan and Yusof proposed a modified version of SERVQUAL that allows the study of the difference between expectations and satisfaction of students with the quality of educational services [109]. The sub-dimensions of education service quality are Reliability, Assurance, Empathy, Responsiveness, Tangibles (program and service quality), Communication, Knowledge/Expertise, Systems/Secondary Services, Social Responsibility and Development. The authors used a questionnaire to collect the data and a t-test and discriminant technique for results analysis.

Guillén Perales [110] proposed an approach to assess the impact of the primary variable on service quality and determined its significance from students. The evaluation is in two stages. In the first stage, quality evaluation of the service is carried out based on the feedback collected from the students, using a modified version of the SERVQUAL model for this purpose. In the second stage, evaluators should compare the results obtained by students and academic staff. The proposed approach was tested for service quality evaluation by 580 students. The results reveal the most significant dimensions of service quality identified by students. The comparison of the results with those of the academic staff showed notable differences in quality evaluation.

Rizos, Sfakianaki and Kakouris [111] discussed the differences between students' perceptions and expectations of the quality of administrative services. They explored the quality of administrative services of an HEI by assessing student satisfaction in the TQM context. The developed questionnaire follows the SERVQUAL model. It contains 22 questions to research perceptions and expectations regarding the quality of administrative services adapted for the educational environment, divided into five dimensions: Tangibility, Reliability, Responsiveness, Assurance and Empathy. With the proposed tool, the quality evaluation of administrative services of 5 HEIs in Greece was carried out based on primary data from 104 students. The obtained results make it possible to formulate recommendations for importance and effectiveness.

Rozak et al. [18] proposed a model for evaluating the quality of educational services in HEIs based on the SERVQUAL model. Following the proposed model, the

authors developed a questionnaire with 25 closed-ended questions on two scales: one to measure students' expectations regarding the quality of educational services and the other to measure student satisfaction. The collected data is analysed using numerical and statistical analysis techniques and tools such as SPSS. The validity and reliability of each of the items of the model dimensions are measured using the reliability test and the qualification of Cronbach's alpha scores. The collected data should be analysed using descriptive statistics. Using this tool, 236 students evaluated the service quality in Russia and Indonesia.

Hoque, Akhter, Absar, Khandaker, and Al-Mamun [29] developed an instrument to measure student satisfaction with service quality in private universities in Bangladesh based on the SERVQUAL model. The questionnaire developed to collect primary data contains 43 questions – 4 for demographic characteristics, 21 for quality of service, 10 for student satisfaction and 8 for student loyalty to the university. All these questions require a response on a 5-point Likert scale. During the pilot study, 229 students filled in the questionnaire. Primary data were analysed using AMOS 22 and structural equation modelling (SEM).

Ganbold, Park and Hong [112] proposed an approach for evaluating students' requirements regarding the quality of educational services in HEIs based on three models – SERVQUAL, KANO and TIMKO. The evaluation takes place in three phases. During Phase 1, using SERVQUAL, a measurement factor is determined to assess the quality of the educational service. The respondents' perceptions of service quality are classified using a two-dimensional quality classification scheme applying the KANO model. During the last phase, the degree of satisfaction and dissatisfaction of the students is calculated based on the TIMKO equation. This approach provides a satisfactory level of quality indicators to improve student satisfaction based on the PCSI index and ultimately allows HEIs leadership to develop a student satisfaction strategy. The tool was experimented with, to determine the degree of student satisfaction with higher education services in Mongolia and identify the quality characteristics that can improve student satisfaction based on the Potential Customer Satisfaction Improvement Index (PCSI).

The IPA importance-performance analysis is an exciting addition to the existing service quality measurement models [113-114]. According to this model, consumer satisfaction is a function of two components – the importance of the product to the customer and its performance by the service provider. IPA is a diagnostic tool that can identify attribute importance and a product or service benefits to satisfy customer needs [114, 115]. As it diagnoses the main disadvantages and sets the priorities using this tool, companies can overcome the shortcomings of SERVQUAL and discover their strengths and weaknesses. IPA uses a matrix in which one axis measures supplier performance, and the second axis measures customer importance [116]. Due to its simplicity and usefulness in making significant management decisions, IPA is used to evaluate service quality in various fields [117], including higher education [118]. Some researchers fault the model before the applied methods of dividing the quadrants and

evaluating the results. As a result, some modifications have been proposed [113], [119–121].

Researchers doubt the SERVQUAL model because perceptions and expectations are measured together after consumers use the service. On the one hand, this may subconsciously change expectations, and on the other hand, evaluating the service before submitting give often a different result [122-123].

According to Cronin and Taylor, the relationship between expected and received quality is not an appropriate approach for evaluating service quality, and they suggest considering it as a predictor of the service quality only perceptions [78]. The developed SERVPERF model includes 22 items to measure customer satisfaction with service. According to researchers [83], [124] SERVPERF outperforms SERVQUAL in selecting the most effective service quality model in developing countries.

As a result of research, Abdullah [125] researched the general applicability of the SERVPERF model in HEIs. He proposes a modified version for assessing student satisfaction with the services offered. HedPERF includes 49 quality indicators specific to higher education (13 from the SERVPERF model), divided into six dimensions – Non-academic aspects, Access, Academic aspects, Clarity, Reputation and Programmatic issues. Since it is based on SERVPERF, it also assesses service quality as a performance function. The tool was tested for validity and reliability by conducting an empirical study. As disadvantages of the model, researchers point to the overlapping of questions, the emphasis on administrative aspects, its limitations for evaluating other services, and the small number of HEIs in which HedPERF has been tested [88], [126].

Shaik, Lowe and Pinegar [127] proposed a tool to measure the quality of distance learning from students. The developed DL-sQUAL tool allows assessment of the quality of 23 services, divided into three areas – Quality of training services, Management and administrative services and Communication. Based on the evaluation results, administrators can identify services that need to be improved and opportunities for staff training. According to its creators, only administrators of distance learning can use the DL-sQUAL to assess the strengths and weaknesses of the services offered.

Hussain and Birol [6] developed a tool to evaluate student satisfaction with service quality based on SERVQUAL and SEEQ. They suggest three dimensions for quality evaluation: service quality (non-academic services), learning quality (academic services) and student satisfaction. The first two dimensions (non-academic and academic services) are considered multidimensional constructs and independent learning variables, and satisfaction is the dependent learning variable. Service quality is assessed in five areas (tangibility, reliability, responsiveness, confidence and empathy) and learning quality in nine areas (Learning values, Instructor enthusiasm, Course organization, Breadth of coverage, Group interaction, Individual understanding, Examination/assessment rules, Tasks and Workload). The proposed questionnaire contains 59 questions – 22 for service quality (based on SERVQUAL), 33 for learning quality (based on SEEQ), and 4

for student satisfaction. All these questions require a response on a 5-point Likert scale. A pilot study of the tool was conducted in Cyprus involving 330 students. The authors use means, standard deviation and frequencies, reliability analysis, exploratory factor analysis and regression analysis for results analysis.

Adapting the so-called "360-degree feedback" for evaluating the human resources management of a given company has been created as a tool for quality evaluation of management activities in HEIs [128, 129]. The teachers, students and graduates give feedback based on criteria defined according to the evaluated object (curriculum, processes, disciplines, etc.). Each stakeholder evaluates only these criteria for which (s)he has the necessary knowledge or experience.

Kara, Tanui and Kalai [66] explored the relationship between educational quality service and student satisfaction and developed an instrument to evaluate educational quality service and student satisfaction. The questionnaire contains 64 questions – 26 for academic resources, eight for administrative services, 22 for teaching and eight for social services offered. All these questions require a response on a five-point Likert scale. Using the questionnaire, the authors evaluate the quality of services in eight universities in Kenya by collecting primary data from 1062 students. They used factor analysis, descriptive statistics and regression analysis for data analysis.

Based on Harvey and Green's [130] quality framework, Kivistö and Pekkola [4] underlined a possible understanding of the dimensions of quality in HE administration – quality as exclusivity/excellence, quality as perfection/consistency, quality as fitness for purpose, quality as value for money, quality as transformation. According to them, the main tools for ensuring the quality of administrative services are regulations and action plans, administration audits, conducting periodic surveys among the users of administrative services (academic staff, non-academic staff, students, external stakeholders), analysis of quantitative data for financial and human resources and cost measurement, performing benchmarking and conducting internal forums for open dialogue and sharing of experience on the use of administrative services.

Vnoučková, Urbancová and Smolová [131] evaluated key internal quality management processes from students and identified factors for effective internal quality process management. They offered a tool for the quality of the management process evaluation in five key areas – leadership and strategic planning, focus on students and stakeholders, measurement of student learning outcomes, human resources planning and education process management. The authors used a quantitative study (filling in questionnaires) and a qualitative study within the target groups to collect data for evaluation. Students rated all indicators in the questionnaire on a five-point Likert scale. Primary data from the questionnaires are analysed using descriptive statistics and bivariate statistical methods.

According to Lestari and Khusaini [46], analytical tools can support HEIs in fulfilling their vision and mission. They are suitable for measuring student satisfaction and can be used to evaluate the quality of educational services. They offer a tool for assessing student satisfaction with the quality of academic

and non-academic administrative services and the availability of educational facilities. The evaluation is going on a proposed model with indicators in 5 areas – Reliability, Responsiveness, Confidence, Empathy and Physical evidence. The primary data for conducting the study were collected by filling in questionnaires from 184 students who evaluated the indicators using a five-point Likert scale. The survey results are analysed by comparing the differences in expectations and satisfaction in using the service, conducting a matched pairs test using SPSS and showing in a Cartesian diagram.

Prima and Saputra [132] considered the level of satisfaction of customers as a measure of the quality of services in HEIs. They propose a service quality assessment model based on previous research in the field [133] with ten dimensions (reality, responsiveness, competence, access, courtesy, communication, reliability, security, customer understanding/knowledge and tangibility) divided into five main areas – Reliability, Responsiveness, Assurance (competence, courtesy, security), Empathy (access, communication and understanding of the customer) and Tangibility.

Mastoi, Xin Hai and Saengkrod [3] explored the level of student satisfaction with the quality of administrative services, educational services, support facilities and physical environment. Based on an extensive literature review and qualitative data collection from interviews conducted with students and faculty, they identified five main dimensions of HESQUAL that were considered independent determinants for evaluating a dependent variable for overall student satisfaction – administrative quality, physical environment quality, the primary educational quality, the quality of the support facilities and the transformative quality. They collected the data for conducting the study from 500 questionnaires, did results analyses in SPSS and used multiple linear regression analysis to evaluate the role played by each factor in predicting student satisfaction.

Amoako and Asamoah-Gyimah [51] explored the factors contributing to student satisfaction with educational services and the quality assurance of services offered by HEIs. They offered two instruments – to evaluate the overall satisfaction of teachers and students from the quality of services. The questionnaire for students was developed based on previous research by Stukalina [65] and contains 19 questions divided into three dimensions - Technological environment (assesses the availability, adequacy and access to modern technologies in the context of their studies), Learning Environment (assesses the situation in the classroom and the teaching approach), The psychological environment (evaluates belonging to the academic family). The developed instrument assessed the satisfaction with educational services of 1500 students in Ghana. Researchers used Analysis of Moment Structures (AMOS) to validate the tool and test the hypotheses.

Montemayor [134] studied the ongoing procedures, prevailing practices and beliefs, conditions for existing relationships, perceived effects, and developmental trends. This process goes beyond simple data collection and tabulation. Primary data for the study were collected using a questionnaire and survey results were processed with SPSS v. 23.

Lian and Putra [11] proposed a methodology for evaluating the effectiveness and role of educational administration in HEIs in the digital era. They suggested a quantitative approach to measure data for efficacy and a qualitative approach to analyse the data according to the role. For the quantitative analysis, a questionnaire was developed to evaluate the administration with questions in four areas – goal achievement (effectiveness of the set goals), system (availability of resources and the connection with the external environment), strategic groups (level of satisfaction) and competitive values (criteria for success with educational administrative factors such as educational facilities, infrastructure, finance and environment). Each question requires a response on a five-point Likert scale. Qualitative research is conducted through observations, literature studies and interviews. The proposed approach has been used to evaluate the effectiveness of educational administration at PGRI Palembang University, Indonesia.

Vinogradova, Kulyamina, Vasileva, Bronnikova and Vishnyakov [67] identified criteria and indicators for evaluating educational services and developed a methodology for measuring the quality of educational services in HEIs. They proposed 33 quantitative indicators for quality evaluation, divided into five areas – Educational programs (10), Teaching staff (6), Educational technologies (6), Material and technical provision of the educational process (5), and Management of education processes (6). They define weights and formulas for calculating the score for each area and indicator. Based on the indicators' scores, they calculate a composite factor of the quality of educational services as considered the area weight in the calculation formula). In this way, the composite coefficient makes it possible to evaluate the quality of educational services in quantitative terms, the maximum value of which is 1. The proposed methodology allows objective evaluation and helps the HEIs leadership to take measures to improve the quality of educational services.

Krymets, Saienko, Bilyakovska, Zakharov, and Ivanova [23] proposed an approach to determining the requirements for the quality of education from the perspective of administrative staff, students and employers, developed based on stakeholder theory and TQM. The approach involves a survey with sets of questions for different stakeholder groups – Administrative/support staff (14 items), Teaching staff (19 items), Students (26 items), and Industry (15 items). They developed four frameworks with requirements to meet the needs of all users of educational services and to ensure the evaluation of the overall quality of higher education. Each question requires a response on a five-point Likert scale. For each statement, employer respondents rated both the expectations of graduates and the actual student performance in the workplace. The survey results were processed with Statistica 22.0 using basic analysis methods – Cronbach's α to check the reliability of the constructed sets of questions and Pearson's correlation to assess the reliability of perception and stakeholder requirements analysis.

Tran [135] offered a tool to assess students' perception of the quality of educational services with 22 questions divided into five areas – Educational services (four for admission services, transfer, fees, etc.), Facilities and equipment (four for classrooms, equipment, teaching aids, level of safety and

hygiene), Educational environment (five for attitude, enthusiasm and correctness of teachers during educational activities), Educational activities (four for training activities), Development and progress of students (five for evaluating learning results). All questions require a response on a five-point Likert scale. During the pilot evaluation, the authors used SPSS software for results analysis.

Hai [136] investigated the factors influencing student satisfaction with service quality in HEIs. To conduct the study, Hai collected data from 396 students. During structured discussions, participants are presented with a list of factors and asked to give their opinion on the listed factors and add some missing factors. Hai used SPSS 20, Cronbach's Alpha reliability coefficient, EFA, CFA and SEM for results analysis.

The results show that six factors influence student satisfaction with the quality of services – teaching staff, facilities, serviceability, educational activities, student support activities and educational programs.

Assiri [137] explored the most significant technical, human, economic, social and administrative obstacles and requirements to make suggestions for using e-government to improve the quality of education services in Saudi Arabia. He developed a tool to identify difficulties in implementing e-administration in HEIs from the perspective of employees and teachers.

Table I summarizes the criteria and the evaluation target (Expectation/Satisfaction) of the studied models for quality evaluation. The comparison proves that many factors affect the quality of the services offered in the education system.

TABLE I. COMPARISON OF STUDIED MODELS

Approach Authors	Criteria	Expectations/Satisfaction
Students Evaluations of Educational Quality (SEEQ) Marsh 1982, 1987	Training/Course Value Enthusiasm of Instructors Organization of Presentations and Materials Group Interaction Student-Teacher Relationship; Exams/Assessments, Assignments/Reading Materials, Workload.	Satisfaction
SERVQUAL Parasuraman, Zeithaml и Berry 1985, 1988	Reliability, Responsiveness, Competence, Access, Courtesy, Communication, Trust, Security, Customer Understanding and Tangibility.	Expectations and satisfaction
Modified SERVQUAL models - Tan, Kek 2004; Dado et al., 2011; Legcevic et al., 2012; Aghamolaei, Zare,2008; Zafiroopoulos & Vrana, 2008	Confidence, Responsiveness, Empathy, Reliability and Tangibility.	Expectations and satisfaction
HEdQUAL Icli & Anil, 2014	Teaching and Course content; Administrative services; Academic facilities; University infrastructure and support services.	Expectations and satisfaction
Donlagić & Fazlić, 2015	Tangible assets (equipment, infrastructure, interior, teaching materials, etc.) reliability (reliable service delivery, resolution of student problems, claims and requests), responsiveness (quick service), confidence (knowledge and courtesy of academic and non-academic staff, expression of trust and confidence) and empathy (given individual attention).	Expectations and satisfaction
Hassan & Yusof 2015	Reliability, confidence, empathy, responsiveness, tangibles (program and service quality), communication, knowledge (expertise), systems (secondary services), social responsibility and development.	Expectations and satisfaction
Rizos et al., 2022	Tangibility, reliability, responsiveness, confidence and empathy.	Expectations and satisfaction

Tran et al., 2022	Educational services (4 indicators), Facilities and equipment (4 indicators), Educational environment (5 indicators), Educational activities (4 indicators), and Development and progress of students (5 indicators).	Satisfaction
Hai, 2022	Faculty, Facilities, Service capacity, Educational activities, Student support, and Educational programs.	Satisfaction
Assiri, 2023	Technical, Human, Economic, Social and administrative obstacles and requirements for using e-government.	Satisfaction

Several test evaluations of the quality of services in specific HEIs have been carried out using the developed tools. Part of these surveys was organized using software solutions for surveys, such as Google Forms. The conduction of similar surveys with such tools has some disadvantages – the possibility of providing access to the survey questionnaire to external persons, manual data processing when detailed analysis of results is necessary, difficulties in tracking trends in assessments, etc.

Few studies have addressed the issue of monitoring the results of conducted studies [138-139]. None of the considered tools automates the overall process of evaluating student satisfaction, comparing results of individual HEIs and generating recommendations that can support HEIs leadership in decision-making. To ensure the high quality of the services, it is vital HEIs leadership not only to conduct periodic surveys, the results of which should be made public, but also to implement tools that analyse results and present them in a summarized form and allow them to make informed decisions to improve the quality of the services offered. Based on the results, HEIs leaders can identify weaknesses and take measures to improve problem areas to answer the needs of students and ensure student satisfaction with the quality of service provided by the institution's employees.

Despite the various factors, all models have a two-level hierarchical structure and require evaluation on a defined scale (in most cases five- or seven-point Likert scale). This fact enables HEIs leadership to search for solutions to automate the whole process of evaluating the quality of services in HEIs, from conducting surveys, and survey results analysis to the generation of evaluation reports.

IV. SOFTWARE TOOL PROTOTYPE

Automating the overall process for evaluating the quality of educational services from students requires the design, development and implementation of a software tool that allows:

- modelling of a questionnaire for evaluating the quality of educational services, including assigning weights to evaluated indicators;
- provide an opportunity for students to fill in questionnaires;
- generation of reports with the survey results for a specific HEI;
- generation of recommendations for improving the quality of educational services offered in HEIs;
- generation of reports for comparing the results of different HEIs.

The project for a software tool for evaluating student satisfaction with the quality of services offered includes the following six subsystems:

- Subsystem 1: Conceptual modelling of questionnaires (areas, indicators, weights) for quality evaluation;
- Subsystem 2: Modelling and managing quality evaluation procedures in specific HEIs;
- Subsystem 3: Evaluation of the quality of services by students according to the modelled questionnaire;
- Subsystem 4: Modelling of report templates for summarizing the evaluation results;
- Subsystem 5: Generation of reports (for individual HEIs and summary reports) for evaluating the quality of services in HEIs;
- Subsystem 6: Generating recommendations for improving the quality of services.

The developed software prototype UQCS is an online tool for evaluating the quality of educational services in HEIs by students. The tool generates recommendations and reports with evaluation results, allowing HEIs leadership to make informed decisions for improving the quality of services.

Fig. 1. The UML diagram of the university quality control system (UQCS).

The UML diagram shows (see Fig. 1) the main actors in the system (Student, Administrator and HEIs leadership) and the use cases they can perform. The use cases are:

- UC1: Create new questionnaire;
- UC2: Set question weights;
- UC3: Publish questionnaire;
- UC4: Fill out questionnaire;
- UC5: Generate reports.

Administrators can create a new questionnaire (UC1) by specifying the questions that will be included in the questionnaire and setting the weights for all questions (UC2) that determine how much each question contributes to the overall score of the questionnaire. Once the Administrators create the questionnaire and set the weights of the questions, they can publish the questionnaire so that students can start

filling it out (UC3). The Student can complete the questionnaire by answering questions and submitting their answers (UC4). Administrators and HEIs leadership can generate reports summarizing the evaluation results and recommendations (UC5). They can use these reports to track the quality of education at the university and identify areas where HEIs leadership can make improvements. The management of HEIs can review the evaluation results and the generated recommendations and compare the achievements of the HEI they manage with those of other universities. The arrows between the actors and use cases show the relationships between them. For example, the arrow from Student to UC4 shows that the Student can perform the Fill out questionnaire use case.

Subsystem 1 allows the administrator to create questionnaires that evaluate the quality of services provided in HEIs and assign weights to each question to reflect its importance. Using this subsystem, the administrator can model all the questionnaires considered in Section III. These are just a few of the screens that users see in Subsystem 1.

- *Questionnaire preview screen*: Users see this screen to preview a questionnaire before it is published. They can see how the questionnaire will look and how the questions will be presented;
- *Questionnaire publishing screen*: Users see this screen to publish a questionnaire. Once a questionnaire is published, it will be available for students to fill in.

Insert University

Phone:

Fig. 2. Insert form for university data.

Subsystem 2 allows administrators to create and manage quality assessment procedures for specific HEIs. The performed procedures can include different stages, such as distributing questionnaires, collecting responses, processing responses, and generating reports. The subsystem is sending emails to HEIs leadership about the organized survey. Users see the *Questionnaire creation screen* when they want to create a new questionnaire. They can enter the title of the questionnaire, add questions, and preview the questionnaire before publishing it. Fig. 2 shows the screen for insert of data for a new University in the Database.

Subsystem 3 allows students to fill in questionnaires to assess the quality of services provided in the HEI. The questionnaires are distributed within the quality assessment procedures created in Subsystem 2. After completing the questionnaire, the student's answers are recorded in the system database. Each student can fill in the questionnaire only once.

The database UCQS contains the following tables:

- *Questionnaire Table* – stores information about the questionnaires created by the administrators;
- *Question Table* – stores the questions associated with each questionnaire;
- *Student Response Table* – stores the responses of students to each question;
- *University Table* – stores information about different HEIs.

Fig. 3 the most significant part of the Python code using Flask that provides an HTTP API for the main functions of the "University Quality Control" system. This API allows users to create questionnaires, submit student responses, and retrieve results and recommendations.

```
from flask import Flask, request, jsonify
app = Flask(__name__)
# Sample data storage (you should use a database in a real application)
questionnaires = []
responses = []
# Endpoint to create a new questionnaire
@app.route('/api/questionnaires', methods=['POST'])
def create_questionnaire():
    data = request.get_json()
    title = data.get('title')
    description = data.get('description')
    questions = data.get('questions')
    if not title or not description or not questions:
        return jsonify({'message': 'Incomplete data. Title, description, and
questions are required.'}), 400
    questionnaire = {
        'title': title,
        'description': description,
        'questions': questions
    }
    questionnaires.append(questionnaire)
    return jsonify({'message': 'Questionnaire created successfully.'}), 201
# Endpoint to submit student responses
@app.route('/api/responses', methods=['POST'])
def submit_response():
    data = request.get_json()
    questionnaire_id = data.get('questionnaire_id')
    student_id = data.get('student_id')
    responses = data.get('responses')
    if not questionnaire_id or not student_id or not responses:
        return jsonify({'message': 'Incomplete data. Questionnaire ID, student ID,
and responses are required.'}), 400
    response = {
        'questionnaire_id': questionnaire_id,
        'student_id': student_id,
        'responses': responses
    }
    responses.append(response)
    return jsonify({'message': 'Student response submitted successfully.'}), 201
# Endpoint to retrieve questionnaire results
@app.route('/api/questionnaires/<int:questionnaire_id>/results',
methods=['GET'])
def get_questionnaire_results(questionnaire_id):
    questionnaire = next((q for q in questionnaires if q['questionnaire_id'] ==
questionnaire_id), None)
    if not questionnaire:
        return jsonify({'message': 'Questionnaire not found.'}), 404
    # Calculate results based on responses (you'll need to implement this logic)
    results = calculate_questionnaire_results(questionnaire_id)
    return jsonify(results), 200
# Endpoint to generate recommendations
```

```
@app.route('/api/questionnaires/<int:questionnaire_id>/recommendations',
methods=['GET'])
def get_recommendations(questionnaire_id):
    questionnaire = next((q for q in questionnaires if q['questionnaire_id'] ==
questionnaire_id), None)
    if not questionnaire:
        return jsonify({'message': 'Questionnaire not found.'}), 404
    # Generate recommendations based on results (you'll need to implement
this logic)
    recommendations = generate_recommendations(questionnaire_id)
    return jsonify(recommendations), 200
def calculate_questionnaire_results(questionnaire_id):
    return {'questionnaire_id': questionnaire_id, 'results': {'question1': 4,
'question2': 3}}
def generate_recommendations(questionnaire_id):
    return {'questionnaire_id': questionnaire_id, 'recommendations':
['Improve teaching methods', 'Enhance student support']}
if __name__ == '__main__':
    app.run(debug=True)
```

Fig. 3. Part of software code.

In the beginning, the necessary modules are imported, including Flask, and an instance of the Flask application is created. Lists in memory (questionnaires and answers) are used for temporary data storage. In a real-world application, you need to use a database to store the data. Here we define four API endpoints using the @app.route() decorator: /api/questionnaires: POST endpoint to create a new questionnaire; /api/responses: POST endpoint to submit student responses; /api/questionnaires/<questionnaire_id>/results: GET endpoint to retrieve questionnaire results; /api/questionnaires/<questionnaire_id>/recommendations: GET endpoint to generate recommendations. The create_questionnaire() endpoint allows the administrator to create a new questionnaire by providing a title, description, and a list of questions. The submit_response() endpoint allows students to submit their responses to a specific questionnaire by providing the questionnaire ID, student ID, and responses. The get_questionnaire_results() endpoint retrieves the results for a specific questionnaire, calculated based on the submitted responses. The get_recommendations() endpoint generates recommendations for improving the quality of services based on the results of a specific questionnaire. The calculate_questionnaire_results() and generate_recommendations() are sample functions representing the logic for calculating questionnaire results and generating recommendations. You should replace them with the actual implementation based on your requirements. The if __name__ == '__main__': block runs the Flask application in debug mode.

Fig. 4 is a part of the Python Flask code that verifies the student user using a simple username and password combination. In a real-world application, one would typically use a more secure authentication mechanism such as JWT (JSON Web Tokens) or OAuth2. We import the necessary modules, including Flask, and create an instance of the Flask app. We use an in-memory dictionary (student_credentials) to store the student usernames and passwords. In a real-world application, you should use a database and securely hash the passwords. We define a route /login using the @app.route() decorator. This route expects a POST request with a JSON payload containing the username and password. The login() function handles the login request. It checks if the provided username and password match the credentials stored in

student_credentials. If the login is successful, the function returns a JSON response with a success message and an authentication token. In this example, we are using a simple string as the token, but in a real application, you should use JWT or a similar authentication token mechanism. If the login fails (incorrect username or password), the function returns a JSON response with an error message.

```
from flask import Flask, request, jsonify
app = Flask(__name__)
# Sample student credentials (replace with actual credentials or use a
database)
student_credentials = {
    #...
}

Fig. 4. Part of software code for verification.

Subsystem 4 allows users to create report templates that summarize the results of evaluating the quality of services. We used Jasper Reports Server as a reporting tool to implement Subsystem 4, which involves modelling report templates with evaluation results. Using JasperSoft Studio, we designed four report templates and defined their corresponding parameters (see Table II).

TABLE II. A LIST OF DEVELOPED TEMPLATES OF REPORTS

Template	Parameter	Visualized data
Detail results of HEI	Survey ID HEI ID Survey period	Average scores by evaluated indicators (questions)
Summarized results of HEI	Survey ID HEI ID	Average scores by evaluated areas
HEIs ranking	Survey ID Survey period	Calculated average grades of HEIs
Detail HEIs ranking	Survey ID Survey period	Calculated average grades of HEIs for each evaluated area

During this stage, we designed SQL queries and data adapters to retrieve evaluation results from the UQCS database and populate the elements of report templates. After the user input parameter values, JasperSoft Studio fills in all data storage elements of templates with data retrieved from the UQCS database stored from Subsystem 3. The calculation of average scores is embedded in the developed document templates. The formula used considers both the grades given by the students on each indicator (question) and the assigned weights.

Subsystem 5 allows users to generate reports to assess the quality of services provided in HEIs. They can generate reports for an individual HEI or a group of HEIs. Subsystem 5 can run all developed templates (developed within Subsystem 4) stored in the Jasper Report Server. For this to be possible, a connection is required between Subsystem 3 (that store the evaluation results) and the Jasper Report Server. Based on this integration, the subsystem passes data to Jasper Reports Server for report generation. To enable report generation from the UQCS, a mechanism to trigger the report generation based on user requests has been implemented in Subsystem 5. Before report generation, the user must select the name of the report template and submit parameter values. The value of the HEI ID parameter is passed by the UQCS tool to eliminate the possibility of generating a report with the results of another HEI. The user must input values for other parameters (Survey ID and Survey period) as select sequentially values from drop-down lists. After receiving parameter values, JasperReport Server retrieves data from the UQCS database, calculates the results and fills in the report template with data. Then, JasperReport Server returns a completed report to the UQCS tool. The UQCS display reports on the screen and allows users to download them in the desired format (e.g., HTML, DOCX, XLSX, PDF, CSV) and share it with different stakeholders. Fig. 5 presents a part of the Python Flask client code that interacts with the Jasper Reports Server to generate and download a report.

```
import requests
app = Flask(__name__)
# Function to generate and download a report from Jasper Reports Server
def generate_report(report_template, parameters):
    jasper_server_url = 'http://jasper_reports_server_url'
    username = 'your_jasper_username'
    password = 'your_jasper_password'
    # Authenticate with Jasper Reports Server
    auth_url = f'{jasper_server_url}/jasperserver/rest_v2/login'
    auth_data = {'j_username': username, 'j_password': password}
    auth_response = requests.post(auth_url, data=auth_data)
    if auth_response.status_code != 200:
        return 'Authentication Failed.', 401
    # Generate the report
    report_url =
f'{jasper_server_url}/jasperserver/rest_v2/reports/{report_template}'
    headers = {'Authorization': f'Basic {auth_response.text}',
              'Content-Type': 'application/json'}
    report_response = requests.post(report_url, headers=headers,
    json=parameters)
    if report_response.status_code != 200:
        return 'Report Generation Failed.', 500
    # Download the report
    download_url = report_response.json()['outputResource']['uri']
    download_response = requests.get(download_url, headers=headers)
    if download_response.status_code == 200:
        # Save the report to a local file
        with open('generated_report.pdf', 'wb') as file:
            file.write(download_response.content)
        return 'Report Generated Successfully.', 200
    else:
        return 'Report Download Failed.', 500
# .... Some code omitted
```

Fig. 5. Part of software code for interaction with Jasper Reports Server.

The Flask client code provides an endpoint /generate_report that triggers the generation and download of a report from the Jasper Reports Server. The generate_report() function handles

the interaction with Jasper Reports Server. It performs authentication using the provided username and password and generates the report using the specified report template and parameters. The trigger_report_generation() route demonstrates how to trigger the report generation. Replace your_report_template_name with the actual name of the report template on Jasper Reports Server, and value1 and value2 with the required parameters. The generated report is saved locally as generated_report.pdf.

Subsystem 6 allows HEIs leadership and the administrator to generate recommendations for improving the quality of services provided. The recommendations are based on the results of the quality assessment. The Subsystem selects all evaluated areas with a result score of less than four and generates a recommendation for it. The recommendation is generated using Google Bard Artificial Language Model and the Python bardapi Library (see Fig. 6). This subsystem makes use of the following screens:

- *Questionnaire results screen:* Users see this screen to view the results of a questionnaire. They can see how students responded to the questions and the overall score of the questionnaire.
- *Recommendations screen:* Users see this screen to view recommendations for improving the quality of services based on the results of a questionnaire.

```
import bardapi
def generate_recommendations(areas, scores):
    """
    Generates recommendations for improving the quality of services in a
    university based on the evaluated areas and scores.
    Args:
        areas: A list of areas.
        scores: A list of scores for each area.
    Returns:
        A list of recommendations.
    """
    recommendations = []
    for i in range(len(areas)):
        if scores[i] < 4:
            recommendation = "Improve " + areas[i]
            explanation = bardapi.generate_explanation(areas[i])
            recommendations.append((recommendation, explanation))
    return recommendations
```

Fig. 6. Some of the code of the recommendations generator.

This would return the following example list of recommendations (see Fig. 7):

```
[("Improve instructional quality", "The instructional quality can be improved by hiring more qualified professors, providing more resources for students, and creating a more supportive learning environment."), ("Improve student-faculty interaction", "The student-faculty interaction can be improved by creating more opportunities for students to interact with professors, providing more support for student-led initiatives, and creating a more welcoming and inclusive environment."), ("Improve curriculum", "The curriculum can be improved by making sure that the courses are relevant to the needs of students, providing more opportunities for hands-on learning, and ensuring that the curriculum is aligned with the university's mission.")]
```

Fig. 7. Example list of recommendations for instructional quality improved.

V. RESULTS

The software tool UQCS was tested to assess the quality of services in three universities. After completing questionnaires created using Subsystem 1, users generated some reports with the evaluation results.

Here are some screenshots of reports generated by a user with the role “HEIs leadership” during the pilot testing of the tool. Data for experimenting were collected from completed questionnaires for evaluating the quality of services in nine areas (Instructional Quality, Student-faculty Interaction, Curriculum, Support Services, Campus Environment, Value for money, Quality of life, Student diversity, Career opportunities) by students from three universities. The Likert scale values for each question are on a scale of 1 to 5, with 1 being strongly disagree and 5 being strongly agree. The total score for each university is calculated by adding up the Likert scale values for all 10 evaluated areas.

Fig. 8 presents the generated report with summary results of one HEI who participated in the experiment. It shows the calculated average marks for each evaluated area and the overall student satisfaction mark. Based on the results, the HEI leadership can gain insights into which areas the university shows poor results and make informed decisions for improving the quality of services in these areas.

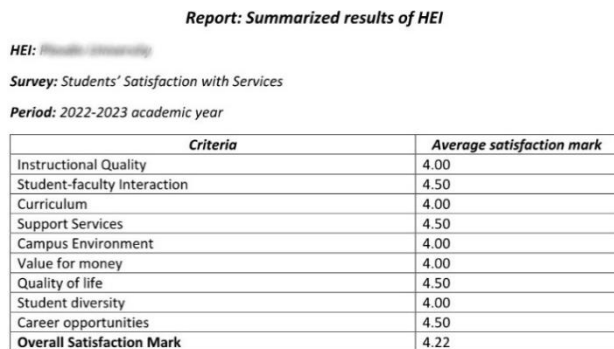

Fig. 8. Summarized results of HEI.

Fig. 9 shows a generated report with calculated overall satisfaction marks of all HEIs who participated in the experiment. The calculated scores allow the results of HEIs to be compared and their leaders to make informed decisions to improve the quality of services, which will lead to a rise in the ranking and an increase in the prestige of the HEI.

Fig. 9. HEIs ranking.

Fig. 10 shows a generated report with recommendations for improving the quality of services in one of the evaluated universities.

Recommendations for Improving Educational Service Quality

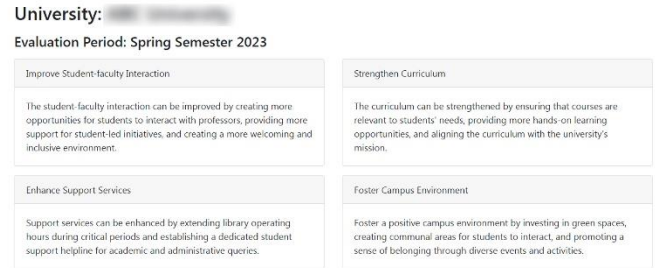

Fig. 10. Generated recommendations.

VI. CONCLUSION

The proposed approach automates the overall process for measuring student satisfaction with the quality of educational and administrative services in HEIs. The developed tool automatically analyzes the collected data. HEIs leadership can use it to generate summary reports with survey results allowing them to track the satisfaction of their students and compare the results with those of competing higher education institutions. The summarized results, and the recommendations generated by the tool, allow managers to make informed decisions to improve the quality of services. The results of the experimental testing of the developed prototype of the software tool prove its applicability to support the HEIs leadership in making decisions for improving the quality of the offered educational services.

The conducted research also has some limitations. Since it has been tested with students from a small number of universities, it does not allow making general conclusions about the overall student satisfaction with the quality of educational and administrative services in higher education institutions.

In the future, the tool's functionalities will be expanded by:

- enriching the set of report templates with the results of conducted studies, including for comparative analysis across multiple HEIs, enabling institutions to benchmark their performance against others;
- extending the report generation capabilities to allow users to customize report templates, select specific data points, and choose visualizations for more tailored insights;
- improving the user interface and experience of the UQCS tool to make it more intuitive and user-friendly for both administrators and HEIs leadership;
- implementing data validation and cleaning mechanisms to ensure that the input data for evaluations is accurate and consistent, leading to more reliable results;
- integrating machine learning models to predict potential areas of improvement based on historical data and trends;
- strengthening the security aspects of the system, including encryption of sensitive data, role-based access

control, and secure communication with external servers;

- optimizing the software architecture to ensure scalability as more HEIs adopt the tool and the user base grows;
- implementing a feedback mechanism within the tool to collect user suggestions and experiences, driving continuous enhancements.

ACKNOWLEDGMENT

Machine-Learning-based User Behavior Classification for Improving Security Awareness Provision

Alaa Al-Mashhour, Dr.Areej Alhogail

Department of Information Systems-College of Computer and Information Science, King Saud University Riyadh, Saudi Arabia

Abstract—Users of information technology are regarded as essential components of information security. Users' lack of cybersecurity awareness can result in external and internal security attacks and threats in any organization that has several users or employees. Although various security methods have been designed to protect organizations from external intrusions and attacks, the human factor is also essential because security risks by "insiders" can occur due to a lack of awareness. Therefore, instead of general nontargeted security training, comprehensive cybersecurity awareness should be provided based on employees' online behavior. This study seeks to provide a machine-learning-based model that provides user behavior analysis in which organizations can profile their employees by analyzing their online behavior to classify them into different classes and, thus, help provide them with appropriate awareness sessions and training. The model proposed in this paper will be evaluated and assessed through its implementation on a sample dataset that reflects users' online activities over a specific period to measure the model's accuracy and effectiveness. A comparison between six classification techniques has been made, and random forest classification had the best performance regarding classification accuracy and performance time. After users are classified, each group can be provided with the appropriate training material. This study will stimulate additional research in this area, which has not been widely investigated, and it will provide a useful point of reference for other studies. Additionally, it should provide insightful information to help decision-makers in organizations provide necessary and effective security awareness.

Keywords—Machine learning; user behavior analysis; cybersecurity; classification; security awareness

I. INTRODUCTION

The internet plays a significant role in many aspects of our lives, and many daily tasks have been digitalized and are required to be completed online. Besides this, the number of users and employees with varying levels of security knowledge and different backgrounds who are required to work online has increased, which has, in turn, influenced organizations' security requirements. Because of this, every organization now has internal cybersecurity and data and asset safety as a priority. Organizations that handle sensitive information assets can operate effectively, locally, and globally, exchanging information quickly and seamlessly among their employees, partners, suppliers, and customers. Indeed, many organizations now rely on online information exchange to keep their operations running smoothly in

collaboration with other parties. However, confidential information is becoming increasingly vulnerable to internal and external security attacks [1]. Although hardware and software-based technologies have been implemented, such as firewalls, proxy servers, and antivirus software, these solutions have not significantly reduced security attacks.

Security attacks or breaches, when they are carried out successfully in organizations, affect inside assets or data. However, the consequences are frequently financial and reputational, undermining customer trust. Applying technical control and systems in this regard is essential. Still, technical controls are only the first line of defense in cybersecurity, and they cannot prevent insiders with elevated access from violating security policies. Many previous studies in this field have discussed the human factor in cybersecurity and the significant role that employees can play in information security breaches. This has increased organizational focus on human threats [2,3].

As a result, many organizations have started to provide cybersecurity awareness training to their employees to make them conscious of cybersecurity threats or any other related issues. Awareness sessions and training are critical to ensuring that staff members act responsibly and are aware of the potential consequences of their online behavior [4]. Due to the importance of cybersecurity awareness inside an organization, various studies have reported that they can become considerably more secure against both internal and external security threats with improved security awareness programs [5–7]. Ryu et al. [8] outlined that a strong awareness program is essential to guarantee that employees properly comprehend their respective internet technology (IT) security duties and roles to safeguard the IT resources delegated to them. Therefore, to reach this level of awareness and responsibility in this regard, awareness sessions on cybersecurity's importance are vital to ensuring the enhancement of the security culture within an organization.

Many employers provide cybersecurity awareness sessions and frequently send out relevant material and emails, as will be viewed in Section II. Nevertheless, these conventional methods are ineffective because tailored and targeted security awareness materials based on the needs and knowledge of employees is required as the level of awareness varies greatly among employees.

This study proposes a machine-learning-based model that enables organizations to analyze users' online behavior,

activities, and actions to target them with appropriate security awareness materials. First, we will investigate six machine learning (ML) classification models to select the most appropriate classifier based on the performance measurements and how accurate each classifier is in forming each user class. We will go through several phases to train and test the models. Additionally, for added validation, we will conduct a cross-validation test to ensure accurate results.

Furthermore, based on the comparison results obtained through the performance calculation using confusion matrix, accuracy, F1, and other measures, including performance time, the best classification technique will be used to classify users into three classes and subsequently target them with suitable awareness sessions. The user classes are the malicious, suspicious, and normal (which require the fewest targeted awareness sessions) behavior classes.

Users' online behavior can reveal much about their knowledge level about cybersecurity and what type of security threats they may cause for their organization, as well as what type of security awareness training must be provided to them. Therefore, we used a dataset, which will be discussed later, that consists of web links that users have visited to show their web-behavior. After user classification, the organization can choose the suitable cyber security awareness materials and session content for each user's class, and it will be saved for subsequent users in the backend database to be sent again by the machine to each particular class without any human interaction.

The proposed model can be implemented as a plug-in for the security operations center dashboard. Therefore, in addition to having the ability to monitor network traffic, endpoints, logs, and security events, the organization will also be able to classify its employees into specific classes to send them classified training materials and take the required action in this regard. In addition, these classes can benefit decision-makers in assessing the organization's weaknesses regarding employees' behavior to define new awareness strategies, IT usage policies, and, if required, new tasks and responsibilities.

The remainder of this paper is organized as follows: The literature review will take place in Section II. Section III comprises the proposed methodology. Section IV presents the result, then a discussion and comparison of the results achieved in Section V, followed by the conclusion Section VI, which concludes the proposed model and presents directions for future work.

II. LITERATURE REVIEW

The use of Internet technology (IT) has increased dramatically since its advent. The rapid increase in internet traffic has led researchers to consider the significance of cybersecurity, and research on the values and methods of cybersecurity awareness has attracted substantial attention. Nevertheless, only a few studies have been conducted on the use of machine learning in cybersecurity awareness. This section covers background knowledge and related work regarding the proposed method.

As we are looking to enhance the user awareness level due to its importance, In fact, traditional training methods, such

as classroom discussions and exercises, have demonstrated their efficacy in increasing trainee awareness and, consequently, their ability to detect issues such as phishing or hacking attempts [9]. However, due to the high cost and number of trainees, traditional class sessions are rendered insufficient and cannot provide the information that individual employees need. Bernaschina et al. [10] studied some security training sessions that concentrated on phishing emails. At the end of each session, the trainees were given a survey to complete the evaluation of usefulness of the previous session as a learning opportunity. These trainees reported that they already had prior knowledge of phishing emails, which demonstrates that nontargeted sessions that are not based on specific behavior lead to the wastage of both time and money, as well as a reduction in benefits for the organization and its employees. Therefore, targeted sessions based on behavior analysis must be created.

Crume et al. [9] found that targeted employee awareness programs based on web behavior can aid in preventing the misuse of an organization's assets. Furthermore, implementing this training will result in numerous benefits for organizations, including improved resource utilization, employee knowledge and performance, and organizational policies and procedures.

Current research on awareness has tended to focus on analyzing users' behaviors based on qualitative data collected through interviews, scales, questionnaires, and surveys. User behavior analysis related to cybersecurity awareness, however, focuses on analyzing users' activities, such as accessing websites and files and user identity. User behavior analysis has successfully identified usage patterns that may indicate unusual or anomalous internet behavior.

A study carried out by Gartner has been mentioned in the work of Kumar and Singh [12] that defined user behavior analysis as outlining and incongruity recognition, which depends on a variety of analytic methodologies, typically combining fundamental analytical methods. Examples of this are policies that influence signatures, pattern recognition, mapping, basic rules of statistics, and advanced analytics tools. However, these methods do not provide accurate data regarding users' real online behavior.

As shown in some of the previous research on the impact of online behavior, this emphasizes the need for organizations to target their employees with specific awareness sessions based on an analysis of those behaviors. Targeted security awareness refers to the provision of training based on the threat that some employees' online behavior may pose. These employees can be identified using behavioral analysis of each user within an organization, using a range of qualitative and quantitative data. Multiple scales are used to assess employee awareness. For example, a Portuguese healthcare institution case study assessed employees' professional awareness of information security by assessing their attitudes and behavior related to cybersecurity [13]. The study consisted of applying and validating scales, such as the risky cybersecurity behaviors (RScB) scale, which is a questionnaire for employees that evaluates behaviors that may lead to poor cybersecurity practices and human vulnerability within enterprises, particularly in healthcare organizations. The RScB

scale has a score range of 0 to 120, with higher values indicating riskier behavior, which is frequently associated with a lack of cybersecurity awareness.

Moreover, in this regard, several machine-learning techniques, such as sequence clustering, can be used to analyze and study user behavior, such as grouping web users with common interests and behaviors. For example, clustering analysis creates a user cluster from web log files. For instance, Facebook’s machine-learning algorithms track every user’s activity on the network to predict their interests, recommend articles, and post notifications on the news feed based on the user’s previous behavior [14].

Fong Tsai showed [16] how collaborative filtering recommendations, which are widely used in recommendation systems on shopping websites, form cluster ensembles. This assumes that people who share the same preferences on certain items also tend to share the same choices on other items. Therefore, clustering based on user logs is done to identify users with similar choices, and it provides recommendations based on the preferences of these “similar neighbors.”

Jiang et al. [17] demonstrated that different machine-learning techniques can be used to extract meaningful data from a huge dataset, including extracting information to analyze user behavior. Callara and Wira [15] suggested an algorithm for user classification based on their dataset and found that it could distinguish 108 groups of users with similar online behavior, which meant they could classify each group with similar behavior as a separate group. They proved that classification techniques are useful in analyzing and labeling test data into known types of classes. Hence, employers can benefit from this classification by providing awareness sessions suited to each class to enhance their employee’s level of security knowledge and keep their assets safe.

Efficient classification techniques have been used by Niranjana and Nitish [11] to enable users to distinguish between phishing and normal websites, classify users as normal users or criminals based on their social media activities (crime profiling), and prevent users from running malicious code by labeling them as “malicious.” However, classifying users into two categories only offers limited options. Concerning the provision of security awareness sessions, a larger number of categories is needed to be more accurate and provide what is needed based on user experience and behavior.

III. METHODOLOGY

The user classification model is a multi-classification problem that aims to classify users into three classes based on the analysis results of their online behavior. To achieve the desired goal of classifying users based on their online behavior and delivering dedicated awareness material to them, a machine-learning-based classification model has been proposed. Assume D , a dataset of website instances, where domain d_i is defined using a set of n features, $F = \{f_1, f_2, \dots, f_n\}$, and each domain $d_i \in D$ is either malicious, suspicious, or normal behavior. The supervised machine-learning algorithm must be trained using D so that the resulting model M can

classify a new domain d_{new} that has not been seen before by M .

The research process has three main phases. The data are collected from users’ records and then prepared using data cleaning and preprocessing. Subsequently, the researchers take various steps to evaluate the classification methods to construct the most effective model of user behavior classification. A diagram describing the workflow of the research procedure is shown in Fig. 1.

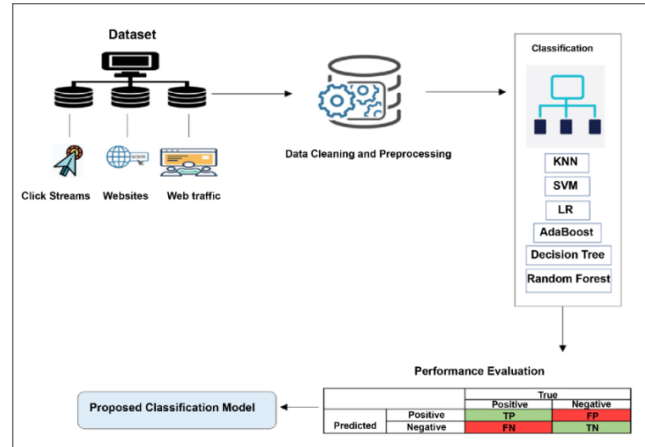

Fig. 1. Security awareness provision based on the user behavior model framework.

A. Data Description

The dataset that was used in this study is from Irvine’s Machine Learning Repository of the University of California [19]. The same dataset was used to investigate and validate the observations. It is an imbalanced multivariate dataset by nature, which has 8,118 instances, each with nine integral forms of attribute characteristics. The data are classified into three user classes to help provide suitable security awareness sessions. These data contain website references/sources which are legitimate or malicious besides the normal references.

Therefore, the dataset contains 8,118 website instances, of which 4,602 are authentic, 2,670 are malicious, and 846 are suspicious. The nine distinct features provided in the dataset that can be used to classify any website as malicious or authentic are server form handlers (SFH), popup window, SSL final state, request URL, URL anchor, web traffic, URL length, domain age, IP address, and the labeled class. They are briefly described in Table I.

B. Model Description

Six well-known classifiers were compared in a supervised learning environment with prior knowledge of the output target set. The classifiers were K nearest neighbor (KNN), support vector machine (SVM), logistic regression (LR), adaptive boosting (AdaBoost) classifier, decision tree classifier, and the random forest classifier. Chosen algorithms have been selected as they are commonly used by researchers and in practice for user classification in different fields, as in the work of Kotsiantis *et al.*, [42], Osisanwo *et al.*, [43], and other studies mentioned in this work [11,15,16,17,34,34]. They are described in the following subsections.

TABLE I. DATASET ATTRIBUTES DESCRIPTION

Feature	Description
SFH	SFHs that contain an empty string or “about: blank” are considered doubtful because action should be taken based on the submitted information. In addition, if the domain name in an SFH is different from the domain name of the webpage, then this reveals that the webpage is suspicious because the submitted information is rarely handled by external domains.
Popup window	This is considered a feature, particularly when the website is asking the users to submit any information through a popup window. It is unusual to find a webpage that requests personal information from users via a popup window.
SSLfinal stated	SSL is used to secure communication between a web browser and a web server. This turns a website’s address from HTTP to HTTPS. The “S” stands for “secure.”
Request URL	A request URL examines whether the external objects contained within a webpage, such as images, videos, and sounds, are loaded from another domain.
URL anchor	An anchor is an element defined by the <a> tag. This feature is treated exactly like a “Request URL.”
Website traffic	This feature measures the popularity of the website by determining the number of visitors and the number of pages they visit.
URL length	A URL length can show whether a URL is a suspicious or phishing URL, where specific calculations should be made to determine whether it is a safe URL or a suspicious or phishing URL.
Domain age	Most phishing websites exist for only a short period.
IP address	If an IP address is used that is different from the domain name in the URL, such as “ http://125.98.3.123/fake.html ,” then someone is trying to steal their personal information. Sometimes, the IP address is even transformed into hexadecimal code, as shown in the following link: “ http://0x58.0xCC.0xCA.0x62/2/paypal.ca/index.html .”
Class	This is the class of the domain (malicious behavior = -1, suspicious behavior = 0, and normal behavior = 1).

1) *The KNN classifier*: This is among the most basic classifiers. It works based on a supervised training method, and its technique is based on similarity. The KNN algorithm can perform regression and classification, and it is nonparametric by nature, as it does not make assumptions regarding non-available data. The basic principle is measuring the Euclidean distance from the new point to the nearest previous points, which are the KNNs. The class that has the nearest neighbors is assigned to the given query point.

2) *Support Vector Machine (SVM)*: This machine-learning classification method uses supervised learning, and it is based on the margin or decision boundary, as the SVM selects the optimal margin for classification. However, in this research, we applied the SVM one-vs-Rest (OvR) method of multiclass classification, which was used to create a multiclass SVM classifier. Here, for each class, we created three OvR classifiers. Each classifier should predict a class probability, and the data will be assigned to the highest-probability class.

3) *Logistic Regression (LR)*: This approach works based on the probabilistic prediction of any specified variable and performs the estimation of parameters related to the logistic model. We classified data into more than two classes.

Therefore, we had $y = \{0, 1 \dots n\}$. A one-vs-all strategy was used, in which we trained three distinct binary classifiers, each designed to recognize a specific class. Subsequently, we used these classifiers to predict the correct class.

4) *AdaBoost*: This approach can perform both classification and regression. The working mechanism is based on the meta-estimation and ensemble method. Through this method, weak learning is converted into stronger learning. In the beginning, it uses a basic learning method model and performs repetitive adjustments of the data distribution to increase the accuracy of the next model based on the existing model performance.

5) *Decision tree*: This is a tree-type classifier, and it has nodes, branches, and leaf nodes. The internal nodes are the dataset and features, whereas the branches represent the decision-making rules, and the leaf is the outcome. Thus, it is fundamentally a graphic illustration depicting all possible outcomes of a problem and its conditions. The classification and regression tree algorithm is used to form the tree structure. It is nonparametric by nature and classifies nonlinear data efficiently. It classifies each branch using the decision rules.

6) *Random forest*: The random forest approach is extremely efficient, and its training requires little time. Its accuracy and other performance measures are very high, even when datasets are large or contain missing data. It has parallel decision trees. Thus, it is a type of bagging ensemble. For the classification task, the output is considered the data found at the bottom of the node, while for the implementation of the regression, the mean of all the trees is considered the final output. Let the trees be denoted by $h_1(x), h_2(x), \dots$. AdaBoost, $h_k(x)$; the training data are given as X, Y , and the margin function can be defined as the equation given below:

$$\text{mg}(X, Y) = \text{av}_k I(h_k(X) = y) - \max_{j \neq y} \text{av}_k I(h_k(X) = j) \quad (1)$$

The classification models are implemented on an unbalanced dataset. Each classifier is trained and tested on the dataset.

C. Feature Importance

Feature importance refers to techniques that calculate a score for all the input features for this model—the score represents the importance of each feature. In other words, it indicates strategies for valuing input features depending on their predictive power for a target variable (rank features based on their effect on the model’s prediction.). Feature importance is essential in the context of understanding the data that go into a model, model improvement, or model simplification, which means, in the case of reducing the model dimensionality, high-scoring features could be kept, and the features with the lowest scores could be deleted because they were not necessary.

Because of the points, feature importance scores are a critical component in predictive modeling, as they provide enlightenment of the data and the model. Let D be a dataset of m classes; a represents a feature that takes V possible values $\{a_1, a_2, \dots, a_v\}$ in D . Let D_v be the subset of samples from D that takes the value of a_v for feature a , and let p_i be the

probability that a sample belongs to class i . In the proposed model, the following measures are used: information gain, gain ratio, Gini index, and Pearson product—moment correlation coefficient. These measures have been chosen because they are easy to understand and execute, have light computational requirements, and are frequently successful with various datasets. They are described as follows [19, 20]:

1) *Information gain*: This metric identifies the features that provide the most information about a class and must highlight that entropy plays a crucial role in measuring information gain. Entropy measures the uncertainty of the data. From a different perspective, entropy measures how difficult it is to guess the label of a random sample from a dataset, where low entropy indicates that the data labels are quite uniform, and high entropy indicates that the labels are in confusion [21]. Information gain computes the difference between the entropy before and after a split and specifies class element impurity. The information gain metric investigates the information content of messages; the information gain can be determined by separating dataset D by features, as follows:

$$\text{Gain}(D, a) = \text{Ent}(D) - \sum_{v=1}^V \frac{|Dv|}{|D|} \text{Ent}(Dv) \quad (2)$$

where $\text{Ent}(D)$ is the entropy. By dividing D based on feature a , a high information gain value indicates that the archived data is of greater purity.

2) *Gain ratio*: The gain ratio attempts to reduce the bias of information gain by introducing a normalizing term known as intrinsic information (II). II is the level of difficulty in guessing the branch in which a randomly selected sample is placed. The feature gain ratio is calculated as Gain ratio = information gain/II, which means mathematically:

$$\text{Gain_Ratio}(D, a) = \frac{\text{Gain}(D, a)}{IV(a)}, \quad (3)$$

where $IV(a)$ denotes the intrinsic value of a feature a and is calculated as follows:

$$IV(a) = - \sum_{v=1}^V \frac{|Dv|}{|D|} \log_2 \frac{|Dv|}{|D|} \quad (4)$$

3) *Gini Index*: This is also known as Gini impurity and measures the degree or probability of a variable being incorrectly classified when randomly selected. It measures the dataset impurity. If all the elements in a class belong to a single class, then it can be called pure. In the calculation of impurity, the weight of the feature based on the class label has been calculated. The degree of the Gini index varies between 0 and 1, and a lower Gini index means a higher dataset purity [22]. It can be calculated as follows

$$\text{Gini}_{index}(D, a) = \sum_{v=1}^V \frac{|Dv|}{|D|} \text{Gini}(Dv) \quad (5)$$

where

$$\text{Gini}(D) = 1 - \sum_{i=1}^m P_i^2 \quad (6)$$

4) *Mattheus correlation coefficient*: Brian W. Mattheus developed the Mattheus correlation coefficient (MCC) in 1975 using Karl Pearson's phi coefficient, and it has become a widely used metric for evaluating the effectiveness of machine-learning techniques, with extensions for multiclass cases [23]. It has a value range between [-1 and 1] that measures the strength and direction of the relationship between two variables as a strong correlation, no correlation, or an inverse relationship.

5) *Kappa*: Cohen's kappa builds on the idea of measuring the concordance between the predicted and true labels, which are regarded as two random categorical variables [24]. Two categorical variables can be compared by constructing a confusion matrix and determining the marginal row and column distributions. Therefore, we can begin using Cohen's kappa indicators as ratings of the dependence (or independence) between the model's prediction and actual classification.

In the multiclass case, the calculation of Cohen's kappa score is as follows [25]:

$$K = \frac{c \times s - \sum_k^K p_k \times t_k}{s^2 - \sum_k^K p_k \times t_k}, \quad (7)$$

where

- $C = \sum_k^K C_{kk}$ the total number of elements correctly predicted
- $S = \sum_i^K \sum_j^K C_{ij}$ the total number of elements
- $p_k = \sum_j^K C_{kj}$ the number of times that class k was predicted (column total)
- $t_k = \sum_j^K C_{ki}$ the number of times that class k was predicted (rows total)

D. Data Preprocessing

The original data must be preprocessed to remove irrelevant and redundant log entries. The following preprocessing techniques were applied to the collected data before they were trained and analyzed. Each technique is described next.

1) *Check and remove null or missing entries*: This step is considered one of the most essential steps in data cleaning. All missing data are identified and then removed. It should also clean the data of all irrelevant information, such as "Nan," "n/a," or any other irrelevant values having a number in the URL attribute. These are removed using Python Regex. Empty entries are removed as well.

2) *Data normalization and standardization*: The process in which the data is cleaned is known as data normalization. This cleaning makes the data regular for all the values of features, which leads to improved segmentation. It removes all the unstructured and redundant data to provide logical data storage. This type of data management is considered particularly crucial for large databases. The raw data hinder the achievement of high efficiency. This problem is dealt with

through data normalization. All the feature values are compressed between [0, 1]. The mean is shifted to 0, and the standard deviation is maintained at 1, so the data can be standardized and easily manipulated. Most machine-learning algorithms display noticeable increments in efficiency after the implementation of normalization.

E. Principal Component Analysis (PCA)

Essentially, the algorithm follows the data relationships to a base field and then sequentially applies mathematical functions in the data in different columns and rows along this path to generate the final feature [26]. The performance of classification algorithms may be compromised because of redundant or highly correlated features. Thus, we implemented dimensionality reduction using PCA, as it reduces the size of the feature space while retaining a significant amount of the information [27]. In this regard, many studies have indicated that PCA is less noise-sensitive than other dimension reduction methods [28, 7].

F. Experimental Setting

The proposed model was implemented using Python and Pandas library. A personal computer was used for this experiment, with the following specifications: operating system: macOS Monterey; chip: Apple M1 Pro; total number of cores (processors): eight (six performance and two efficiency); and OS Loader, version: 7459.141.1. In addition, the programming language Python was used.

Based on the parameter settings, the performance of various algorithms can vary. In this work, the algorithms were run using the following parameters:

1) *KNN model classifier*: $K = 5$, weights = “uniform”, algorithm = “auto” “fit method is `model1.fit(X_train,y_train)`, leaf_size = 30, $p = 2$ (Euclidean distance), metric = “minkowski”.

2) *SVM classifier*: The regularization parameter is set to 1, with a linear kernel, no class weights, and a shrinking heuristic.

3) *LR classifier*: The norm of the penalty = L2. No class weights, fit intercept is set to true, maximum iterations = 100, and for multi_class = “auto”.

4) *AdaBoost classifier*: integer value = 42.

5) *Decision tree classifier*: Decision tree classifier (random_state = 42) with no maximum depth, which means nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples, and the splitter is the “best”.

6) *Random forest classifier*: One hundred trees, with no maximum depth and a minimum number of splits = 2.

The experiments were designed using different machine-learning and data-analytics libraries, including scikit-learn [29], Numpy [14], and Pandas [31]. Six machine-learning algorithms (described previously) were employed along with the PCA-based feature importance measure with reduced dimensions. Standard 10-fold cross-validation [32] train/test trials were run by partitioning/splitting the entire dataset into training and testing (proportions of 70% and 30%). We

ensured that the test data contained a fair distribution for all classes. The following experiments were designed with consistent classifier configurations:

1) *Train* and test the seven machine-learning algorithms over the individual datasets.

2) *Train* and test the five machine-learning algorithms over the PCA-based dimension-reduced datasets using a 10-fold CV to compare the performances.

G. Performance Measures

After performing classification, its performance and results must be gauged without specific markers. Therefore, to evaluate a classifier’s capabilities, various performance measures can represent the classification quality of different classifiers on any given data. This provides a deeper insight into the classification techniques’ efficiency than that which using basic accuracy percentages can achieve. The performance evaluation is accomplished using performance metrics such as confusion matrix, precision, recall, and F1 score, as well as basic accuracy. Brief descriptions of each of the performance measures are as follows:

1) *The confusion matrix* represents the relationship between the actual and predicted values. The following briefly describes the confusion matrix with its four basic elements:

2) *True Positive (TP)*: A vector that gives a count of correctly classified data (presence of condition). Mathematically, this can be calculated by $TP/(TP+FP)$.

3) *False Positive (FP)*: A vector that gives the incorrect classification of data (e.g., the detection of a condition that is not present). Mathematically, this can be calculated by $TN/(TN+FN)$.

4) *True Negative (TN)*: A vector that shows the number of correctly classified data that do not possess the condition (absence of condition).

5) *False Negative (FN)*: A vector that gives the count of wrongly classified data (detected the absence of a condition when it was present).

a) *Accuracy*: The most basic and extensively relied upon measurement is accuracy, as calculated in Eq. 8 below. It represents the accuracy of the classification results and is the fraction or percentage of a classifier’s total correct identifications against the classifier’s total outcomes, both correct and incorrect.

$$\text{Accuracy} = \frac{\text{Correctly classified samples}}{\text{total number of classifications}} \quad (8)$$

b) *Precision*: This measurement tells us how precise the classifier results are. It gives the percentage of correctly identified positive outcomes against total positive outcomes, which includes false positives.

c) *Recall*: Recall measures the sensitivity of the classifier. It gives the recognition rate of a classifier. A recall is the proportion of correct positive outcomes against the total number of actual positives present in the dataset. Therefore, it includes false negatives.

d) *F1 score*: The F1 measurement is an amalgamation of both precision and recall. It is essentially the subjective average of both, namely the recall and precision values. It provides more precise estimations of incorrect outcomes than accuracy when the dataset is imbalanced.

e) *Receiver operating characteristic (ROC) area*: The ROC metric is used to evaluate the quality of multiclass classifiers. The true positive rate is typically plotted on the Y axis and the false positive rate (FPR) on the X axis. For multiclass problems, ROC curves can be plotted by comparing one class against the others. Applying this OvR to each class will give results in the same number of curves as classes. The ROC score can also be calculated separately for each class. ROC values range between 0 and 1. A model with 100% incorrect predictions has a value of 0.0 while one with 100% accurate predictions has a value of 1.0.

f) *Precision-recall curve (PRC) area*: PRC can be referred to as the relationship between precision and recall (sensitivity) and is regarded as a more suitable metric for unbalanced datasets. PRC can be calculated by integrating the piecewise function. Consequently, the PRC tends to intersect significantly more frequently than the ROC. The primary distinction between the two is that the number of true negative results is not factored into the PRC because the precision-recall curves are only affected by true positives in most cases. The PRC is generally a tortuous curve, fluctuating upwards and downwards [33].

IV. MODEL RESULTS

In this model, we were looking to classify users into three classes using each of the six best classifiers regarding the performance measurements that were applied to their evaluation and selection. Each classifier was trained and tested separately to evaluate it in a different portion of the dataset for each classification model with different testing options. We had 70% of the dataset for training and 30% for testing the model besides applying PCA to the dataset. In addition, we performed cross-validation to improve the effectiveness and accuracy of the classification.

A. ML Classification Results

The following Table II and Table III, illustrate the classification performance of the six classifiers used in this work. The tables show the evaluation measure for all six classification models trained on 70% of the dataset and tested on 30%.

TABLE II. PERFORMANCE MEASURES FOR THE SIX CLASSIFICATION MODELS TRAINED ON 70% OF THE DATASET

Classifier	KNN	SVM	LR	AdaBoost	Decision tree	Random forest
Accuracy	93.54%	88.21%	86%	96.07%	95.40%	96.58%
Recall	93.5%	88%	86%	96.1%	95.5%	96.6%
Precision	93.6%	87%	85%	96.1%	95.6%	96.6%
F1 measures	93.6%	87%	85%	96.3%	95.5%	96.6%
MCC	88%	80%	76%	93%	91%	94%
Time (seconds)	1.25	0.01	0.03	0.02	0	0.13

TABLE III. PERFORMANCE MEASURES FOR THE SIX CLASSIFICATION MODELS TESTED ON 30% OF THE DATASET

Classifier	KNN	SVM	LR	AdaBoost	Decision tree	Random forest
Accuracy	92.89%	88.%	87%	95.8%	94.62%	96.09%
Recall	92.8%	88.8%	87%	95%	94.6%	96.1%
Precision	93%	88.4%	85%	95%	94.7%	96.1%
F1 measures	93%	88.4%	86%	95%	94.6%	96.1%
MCC	87%	81%	77%	92%	91%	93%
Time (seconds)	0.56	0.01	0.01	0.01	0	0.05

As presented in the tables previously, we can see that all the classifiers have been applied to evaluate each classifier's performance. Training data helps construct a machine-learning model and teaches it what the expected outcomes should look like, while the model examines the dataset repeatedly to understand its characteristics and optimize its performance. In contrast, after a machine-learning model is constructed using the training dataset, it must be tested to evaluate the performance of each classifier to select the optimal classifier from those included.

Table II and Table III show the training and testing results regarding the performance matrix evaluation. Comparing the results of all classifiers using part of the dataset, the final results show that the best accuracy is for the random forest classifier, although some of the classifiers, such as AdaBoost and decision tree, have results close to the random forest classifier. Additionally, the LR classifier achieves the lowest accuracy value in both testing and training the model compared to the other classifier models. In this study, AdaBoost was a combination of J48 and decision tree, where the J48 algorithm is closer to the random tree algorithm even in the time it requires for execution. J48 is an algorithm that C4 (one of the decision tree classifiers) employs to generate a decision tree (an extension of ID3). Also referred to as a statistical classifier [30], the J48 algorithm is used to classify various applications and produce accurate classification results, to produce more accurate and fairer comparison results.

The random forest algorithm has the highest accuracy but requires significantly more time to generate a model than the decision tree and AdaBoost algorithms. Besides measuring each classifier's accuracy, because we have an imbalanced dataset, another measurement could assist us in deciding which classifier would perform the best and enable us to have more accurate evaluation results.

We also considered MCC because this indicator is viewed as an effective solution to overcoming the class imbalance issue [34]. In the evaluation, we also considered the F1 measurement, as it is widely used in most application areas of ML, particularly in multiclass cases [35]. Because we had close results for accuracy and time for some of the classifiers, for additional evaluation indicators, we added MCC results to the previously presented tables as well as included them and the F1 results in selecting the best classifier for this proposed

model. The random forest classifier has the highest MCC and F1 result among all the machine-learning classifiers.

B. Feature Importance

Next, to understand to what degree each feature contributes to model prediction, which will affect its performance and accuracy in the model, we analyzed feature importance using the four-feature importance measures. The following Fig. 2 shows each feature’s rank and score; the scores represent the “importance” of each feature. A higher score indicates that the feature will have more impact on the model used to predict a particular variable.

Fig. 2. Top four features and their corresponding weights using information gain, gain ratio, Gini index, and correlation coefficient.

The results show that the top four features are SFH, SSL_final_state, popup window, and requested_URL.

C. PCA

PCA, in this context, is the concept of reducing the number of variables of the dataset while retaining as much information as possible. Accuracy naturally suffers when a dataset’s variables are reduced, but the aim of dimensionality reduction is to sacrifice a little accuracy in return for greater simplicity because machine-learning algorithms can analyze data much quickly and easily with smaller data sets as there are fewer extraneous variables to process. Table IV and Table V. show the results of applying PCA to each classification model.

TABLE IV. PERFORMANCE MEASURES WITH PCA (70% TRAINING DATASET)

Classifier	KNN	SVM	LR	AdaBoost	Decision tree	Random forest
Accuracy	95%	86%	85%	97%	95%	98%
Recall	95%	86%	85%	97%	95%	98%
Precision	95%	86%	85%	97%	96%	98%
F1 measures	95%	86%	85%	97%	95%	98%
MCC	93%	79%	77%	95%	93%	96%
Time (seconds)	1.27	0.42	0	0.56	0	0.19

TABLE V. PERFORMANCE MEASURES WITH PCA (30% TESTING DATASET)

Classifier	KNN	SVM	LR	AdaBoost	Decision tree	Random forest
Accuracy	93%	85%	85.18%	95%	93%	96%
Recall	93%	85%	85%	95%	94%	96%
Precision	93%	90%	89%	95%	94%	96%
F1 measures	93%	86%	86%	95%	94%	96%
MCC	87%	79%	78%	92%	89%	93%
Time (seconds)	0.58	0.2	0.1	0.10	0.03	0.07

According to the previous presented tables (Table IV and Table V), we can see the improvement in accuracy when the PCA was applied to the dataset because of dimensionality reduction where the redundant and irrelevant data have been removed; in other words, the data that have no significant effect on the classification results have been removed. Additionally, the improvement in the MCC results is noticeable.

For further investigation, and as the final results of all six classifiers were similar, a 10-fold data split was constructed, as shown in the following Fig. 3, to understand how the algorithms performed.

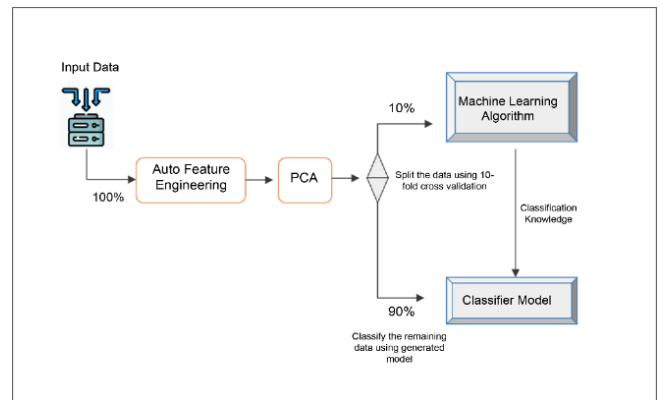

Fig. 3. Cross-validation process model.

The classifier constructed nine identical instances of the dataset and then split the data in each of these instances into 10% for training and 90% for testing. Each of these nine instances was trained/tested with a unique split. Finally, the result from each of these instances was combined into a final result. Because nine combinations of 10% of the data were used to classify the data, a reasonably realistic result could be obtained using this 10-fold cross-validation split.

Using cross-validation emphasizes that, as previous Fig. 4 and Fig. 5 shown, although all the classifier results are similar to each other, the random forest classifier shows the best performance regarding all performance measures and, in particular, the lowest FPR (2.2%), with incorrectly classified instances of 4% in the cross-validation test.

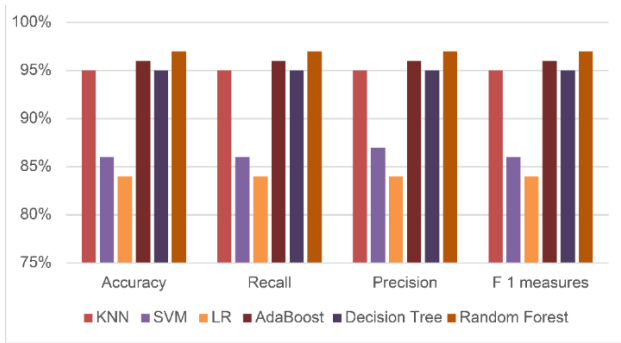

Fig. 4. Cross-validation.

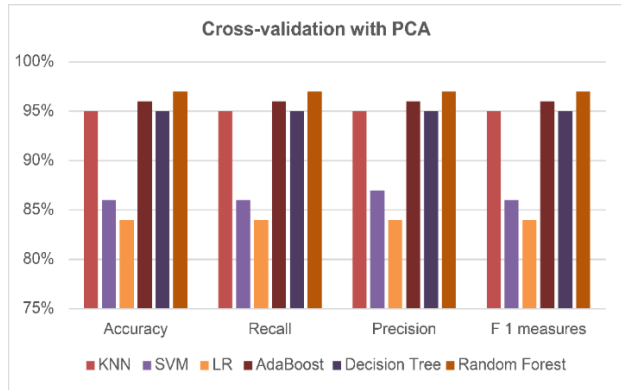

Fig. 5. Cross-validation with PCA.

D. Proposed Model

This study aimed to propose a model that can assist organizations in providing dedicated and targeted cybersecurity awareness sessions to their employees based on an analysis of their online behavior. The problem at hand was formulated as a multiclass problem. We differentiated between three classes: malicious, suspicious, and normal. Based on influential features and the best-performing classifier we identified, we propose an ML-based classification model. Fig. 6 shows the proposed model.

The dataset was first fed into the classifier, which was then used to extract features. Following that, a few preprocessing techniques were applied to ensure that the dataset was clean. After that, we applied the machine-learning classification models to the dataset.

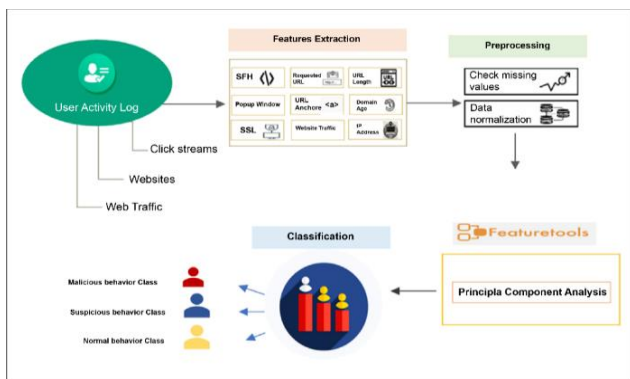

Fig. 6. Machine-learning-based classification model.

The Kruskal–Wallis test was used to compare the performance of the various models in the study. The Kruskal–Wallis test is a nonparametric statistical test that is computed based on the rank and the sum of ranks. The null hypothesis assumes that the performance measures of the models are drawn from the same distribution and that any differences are due to chance.

The hypothesis of the test is given below:

H_0 : The performances of the models are equal (i.e., there are no statistically significant differences in model performances).

H_A : At least one model performance is different (i.e., there are statistically significant differences in model performances).

1) *Test statistics*: The test statistic of the Kruskal–Wallis, H measures the differences among the performance of the groups and is given by the following:

$$H = \frac{12}{N(N+1)} \left(\sum \frac{R_i^2}{n_i} \right) - 3(N+1)$$

where n_i total number of observations in the model i
 R_i the sum of the ranks of model i
 N the total number of observations across all models.

The Kruskal–Wallis test statistic approximates a chi-square distribution with $k-1$ degrees of freedom, where k is the number of groups (models).

The observations for the test are obtained from the classification accuracy of each of the models from 10-fold cross-validation. Hence, this ensures that each classifier used is evaluated on the same splits of the dataset via the 10-fold cross-validation. These observations (classification accuracies from the 10-fold cross-validation) are provided in the appendix below. The Kruskal–Wallis test is then used to compare whether there is a statistically significant difference among the performance of these models. All analyses were implemented using Python software.

2) *Test results*: The test statistics and the associated p -values are given below in Table VI.

TABLE VI. TEST STATISTICS AND THE ASSOCIATED P-VALUES

	H statistics	p -value
Training set	45.4512	1.1745×10^{-8}
Testing set	48.9979	2.2215×10^{-9}
PCA with Training set	49.0362	2.1818×10^{-9}
PCA with Testing set	49.3816	1.8544×10^{-9}

Decision Rule

Reject H_0 if the p -value ≤ 0.05 ; else, fail to reject H_0 .

Because the p -value associated with any of the H statistics is less than 0.05, we reject H_0 . Hence, enough evidence

supports the alternative hypothesis that at least one of the model performances is different. Therefore, there are statistically significant differences in model performances.

3) *Post hoc statistical test: Dunn’s Test with the Holm–Bonferroni Correction:* Given that the Kruskal–Wallis test showed evidence of statistically significant differences in model performance, the Dunn’s test with Holm–Bonferroni p-value correction was conducted to ascertain which pairs of models differ significantly from each other.

Dunn’s test is a nonparametric pairwise post hoc test used to compute the rank-based Z-values for pairs of the models and convert these values into p-values. The Holm–Bonferroni correction is then applied to these p-values to control for family-wise error rate (FWER). FWER refers to the probability of committing at least one type I error among the pairs of comparisons. All computations are conducted using Python.

4) *Hypothesis:* The hypothesis of this test for each of the pairs of models is as follows:

H_0 : There is no statistically significant difference between the pair of models compared.

H_A : There is a statistically significant difference between the pair of models compared.

5) *Decision rule:* Reject H_0 if the Holm–Bonferroni Adjusted p-value ≤ 0.05 ; else fail to reject H_0

AdaBoost	Random Forest	1	Not significant
Decision Tree	Random Forest	0.000047	Significant

The results above show that there exists at least one instance where pair of models are statistically different regarding performance.

V. DISCUSSION

Currently, user behavior is one of the most critical factors in organizations' cybersecurity, and it can put the organization's safety, data, assets, reputation, and individuals at risk. Thus, providing cybersecurity training for users or employees plays a vital role in improving their attitude and behavior when online, particularly when the training is directed and targeted based on user needs and deficiencies.

Due to the large number of attributes and high volume of online data, we employed machine-learning techniques in the context of providing cybersecurity awareness by analyzing online user behavior. In this context, the main objective was the enhancement of people's cybersecurity awareness through the provision of targeted cybersecurity awareness programs that would lead to a decrease in cybersecurity issues and intrusions inside an organization.

Although user behavior analysis and the use of machine-learning techniques for analyzing user behavior are not new, the novelty of this paper lies in the fact that it is among the first few research that analyses human online behavior and applies ML to target employees with suitable awareness materials, the primary objective of this study differed from those of previous models and other studies. The concept of user behavioral analysis has been included previously in a number of fields and domains, such as marketing applications, to adopt new and efficient marketing strategies that are based on user data (i.e., utilizing recorded information of the past activities of potential clients in data-based behavioral marketing) [36]. It has also been included in recommendation systems by predicting user interests from a user's last browsing and searching activities, for example, by recommending specific articles for readers or an item of clothing during shopping [34].

Moreover, ML is used to classify users, such as on social media. It can be applied to building a practical system for detecting fake identities by using server-side clickstream models to group users with similar clickstreams into clusters or analyze user browsing behavior on specific websites [35], including e-commerce, education, and healthcare. The aim is the personalization or targeting of users with advertisements based on their browsing behavior. Thus, the application of machine-learning techniques helps classify users with a high degree of accuracy. In the security domain, its value has been proven in the fight against fraud and other applications [37]. Moreover, ML is used in the detection of phishing emails using algorithms. This can automate the detection of phishing emails using a variety of techniques, including deep-learning detectors that automate the process [38], where deep-learning algorithms have produced impressive results with unstructured data such as email data [39].

This proposed model can aid organizations in maintaining the security of their assets and data, as we include the human factor by enhancing the awareness levels of their employees regarding cybersecurity threats by providing appropriate

training and awareness based on the analysis of their online behavior that may help the organization in classifying users based on the analysis results.

Ryu et al. [18] and many others demonstrated the importance of personal security factors in this area. They showed the significance of raising awareness of the importance of security in industries. As a result, regardless of the type of security system in place, considering the importance of employees' online awareness and behaviors is critical.

Many other researchers [34–36] have shown that a strong awareness-raising program is required to ensure that employees understand their respective IT security duties and roles to protect the IT resources delegated to them. However, these studies achieved low accuracy in measuring users' online awareness; for example, questionnaires or surveys were published to a general audience, and the analysis was performed based on their answers [33]. This approach fails to analyze employees' actual online behavior that reflects their cybersecurity knowledge. As a result, the awareness content that is subsequently provided is not suitable for each individual.

In this study, we applied several machine-learning classifications to the same dataset with the same percentage split: 70% for training the model and 30% for testing the model. Thereafter, we compared the final results of the performance measures among all classifiers to determine the best one. The results demonstrated that the random forest classifier was the best option to choose with the best results, and it could be applied for analyzing user behavior inside the organization. Random forest achieved the highest accuracy rate in both training and testing sets of the whole dataset with different methods of testing and different measures that have been used, which are the accuracy, MCC, and F1 measures.

For the AdaBoost, decision tree, and random forest classifiers, the accuracy rates were similar. Therefore, we included the MCC and F1 measurements to ensure a more accurate comparison, rather than just taking into consideration the FPR and which classifier had the lowest FPR. PCA was also applied to the concept of reducing the dimensionality of the dataset used in the model, and cross-validation was used to validate each classifier.

Theoretically, when considering the computational costs of the random forest classifier, the complexity of the test time of a random forest of size T , which is the number of trees to build, and the maximum depth D is $O(T \cdot D)$, which is 0 by default and is the unlimited depth of the tree. Another important disadvantage is the memory space required for random forest classification, which is calculated by $O(2^D)$ [33]. This experiment showed that the running time to build the model is 0.23 s, on average, and the time required to test the model on 5,683 instances of training data is 0.11 s. Additionally, the time required to build the model is 0.19 s, and the time required to test the model on the supplied test set is 0.09 s for 2,435 instances.

Random forest showed its effectiveness in the classification process, as it did in many previous works, such

as in Android malware classification [40], where it performed very well with an accuracy of over 99%. In general, the samples were correctly classified, and the highest number of misclassified cases resulted from samples from the malicious class being mistakenly assigned to the benign class.

Moreover, Farnaaz and Jaber [41] used random forest classification to detect intrusions on a system, where the random forest classifier was used to classify four types of attacks. According to empirical findings, the proposed model was effective, with a low false alarm rate and a high detection rate.

Thus, the experimental results conclude that users can be successfully classified based on their online behavior to target them with the correct awareness materials using a machine-learning-based model.

VI. CONCLUSION

The causes of and methods for preventing security issues and risks to any organization are continually changing as a direct result of the ongoing evolution of cybersecurity threats. In addition, individuals' knowledge levels, technical skills, and levels of awareness regarding cybersecurity vary, which is one of the reasons for the difficulty in controlling their online behavior and the associated risks. Because of this, the measurement and analysis of online behavior are now absolutely necessary for any organization that wants to protect its assets from both internal and external breaches of security. A substantial number of earlier studies have established a clear connection between online users' actions and various problems and dangers related to cybersecurity. Regardless of the security technology in place, the most reliable indicator of potential vulnerabilities in an organization or network is users' actions when they are online. Providing directed and dedicated awareness sessions and training regarding cybersecurity is essential in any organization, and this must be managed appropriately.

In this study, we proposed a machine-learning-based model that can assist organizations in providing targeted awareness sessions to their employees based on an analysis of the employees' behaviors. The model will classify the users into three classes: malicious, suspicious, and normal behavior. This classification will ultimately increase awareness of particular behaviors. It may enable organizations to target each employee segment with appropriate sessions and training, increasing the effectiveness of resources.

To achieve this objective, a machine-learning model can be applied to identify patterns in users' web activities and, as a result, classify users according to their activities in virtual spaces. The primary goal of the proposed model is to help organizations target users with sessions of security awareness that are specific and tailored to their needs. Raising awareness can be automated based on specific behaviors, which may result in an effective process that saves organizations time and money. Six well-known machine-learning algorithms, namely KNN, LR, SVM, AdaBoost, decision tree, and random forest classifiers, were trained and tested independently on a user behavior records dataset by splitting the dataset into a 70% training dataset and a 30% testing dataset. The random forest

classifier showed superior performance among all the classifiers regarding the accuracy, F-measure, and the MCC measure. While applying PCA, the model also demonstrates a high accuracy rate, low FPR, high recall, and precision, as well as high F-measures.

Furthermore, as this model is based on machine learning, Machine learning methods at some point also have limitations, as when applied to security that can result in amplified nuances. They can give false positives and false negatives, causing them to miss detection, or insiders can corrupt the dataset, which will lead to wrong outcomes or corruption of the model itself. Furthermore, hackers are also learning machine learning and applying them to their hacking procedures and fishing for loopholes to exploit.

This model has the potential to undergo further development by automatically learning user classes to set up appropriate awareness sessions and training without human intervention. In subsequent research, an improved feature analysis might be included with the goal of making the model more precise. Another potential development would be the incorporation of additional user behavior categories. In addition, a monitoring strategy can be used to observe user behavior. Management can be notified if there is no change in the manner in which users conduct themselves while online. In the future, we plan to increase the number of classes for classifying users and the amount of automated content to be sent to each class to enhance the model's value to organizations.

Abstract—Collateral circulation is an arterial anastomotic channel that supply nutrient perfusion to areas of the brain. It happens when there is an existence of disruption of regular sources of flow due to an ischemic stroke. The most recent method, Cone Beam Computed Tomography (CBCT) neuroimaging is able to provide specific details regarding the extent and adequacy of collaterals. The current approaches for collateral circulation classification are based on manual observation and lead to inter and intra-rater inconsistency. This paper presented a 2-class automatic classification that is recently growing very fast in artificial intelligence disciplines. The two classes will differentiate between good and poor collateral circulation. A pre-trained convolutional neural network (CNN), namely ResNet18, has been used to learn features and train using 4368 CBCT images. Initially, the dataset is prepared, labeled and augmented. Then the images were transferred to be trained using the ResNet18 method with certain specifications. The algorithm performance was then evaluated using metrics in terms of accuracy, sensitivity, specificity, F1 score and precision on the CBCT images to classify collateral circulation accurately. The findings can automate collateral circulation classification to ease the limitations of standard clinical practice. It is a convincing method that supports neuroradiologists in assessing clinical scans and helps neuroradiologists in clinical decisions about stroke treatment.

Keywords—Collateral circulation; CBCT; ResNet; convolutional neural network; classification

I. INTRODUCTION

Stroke disease is one of the causes that lead to short or long-term disability in developed countries. Stroke disease is also one of the top causes of mortality in the world [1]. Worldwide, over 5.5 million annual mortality rate has been reported, while 50% became disabled as a result of their strokes [2]. Women had poorer post-stroke outcomes and were more likely to experience a stroke in their lifetime [3]. In 2019, the low-income group had a higher age-standardized stroke-related death rate than the high-income group [4]. Most strokes are often caused by the obstruction of pathways by both the brain and heart. The impact of stroke can be minimized by early detection of warning signs [5],[6]. Stroke disease is divided into two categories or groups: hemorrhagic stroke and ischemic stroke [6]. Most ischemic strokes will occur due to an unpredicted obstruction in the blood flow to several areas of

the brain. Lack of oxygen and nutrients for the cells in those areas of the brain will cause the cells death [5] and lead to other serious problems such as blood vessel ruptures, also known as a hemorrhagic stroke when the brain tissue is bleeding [7]. Although thrombectomy carries inherent risks, it should only be performed in stroke disease patients with certain signs, which are a large penumbra and small infarct, along with collateral circulation [1,2].

In the case of acute brain ischemia, cerebral collateral circulation plays a vital role in compensatory mechanisms [8]. As a result of a failure of the primary arteries, the cerebral collateral circulatory system acts as a secondary network of vessels pathway that maintains cerebral blood flow [9]. Good collateral circulation and a lower likelihood of hemorrhagic transformation should improve endovascular treatment for acute ischemic stroke [10]. Extending the therapeutic time window after ischemia and boosting collateral blood flow perfusion are essential components of treating ischemic stroke [6]. It has been shown that good collateral circulation makes a significant difference in the functional outcome [11] and recurrence risk of stroke patients suffering from different causes and receiving medical or endovascular treatment. Several features have been investigated to diagnose the conditions of collateral circulation and compare findings with stroke disease patients. Assessment of ischemic stroke of collateral circulation is actively investigated. As collateral circulation is critical in the assessment of penumbra presence and volume, which are critical factors in the severity and time course of ischemic strokes, the status of collateral circulation is critical [11], [12]. Fig. 1 shows the collateral circulation view in the human brain. However, rather than measuring the actual anatomical connections, these approaches assess the general condition of collaterals.

Imaging modality technique using Magnetic Resonance Imaging (MRI), Computerized Tomography (CT) [13], X-ray, CBCT, etc., provides precise details regarding the flow of blood to the various parts of the brain [14]. Then, when the imaging surveys have been completed, a comprehensive neurological examination must be undertaken [15]. These characteristics determine whether the underlying brain parenchyma survives in comparison to an arterial lesion. Cone Beam Computed Tomography (CBCT) is one of the most

popular techniques for assessing many diseases, especially the collateral circulation in the brain [16]. CBCT is considered an advanced imaging technology that provides accurate and three-dimensional (3D) images for assessing hard tissue, soft tissue, and bone [17],[18]. As a result of its advantages over conventional CT, CBCT is increasingly used in acute strokes and neurovascular image-guided procedures [19], including strokes and nerve damage. Fig. 2 shows an example of CBCT images.

Fig. 1. Collateral circulation in the human brain.

Fig. 2. CBCT image.

In recent years, machine learning specifically deep learning has become increasingly popular. Deep learning is a type of learning technique that employs multi-layered neural networks [15]. It has shown promising results in retrieving useful information from medical images and signals [20]. This research demonstrated an analysis framework to classify collateral circulation accurately for ischemic stroke patients into two classes: good and poor. The proposed method has been chosen to capture complex, non-homogeneous structures and tiny-size images. The aim is to discover the utilization of deep learning techniques to automate the classification of collateral circulation on CBCT images.

II. RELATED WORK

A. Collateral Circulation Scoring

Collateral circulation is an alternative network vessels that carries blood to the same destination tissue [21]. It serves as an auxiliary vascular system and plays a crucial role in preventing cerebral ischemia when the primary vascular pathways are partially obstructed [22]. Table I presents the state-of-the-art evidence suggesting that the combination of neuroradiology expertise and artificial intelligence holds promise in facilitating timely and accurate disease diagnosis.

TABLE I. COLLATERAL CIRCULATION GRADING SYSTEMS

Author	Modality	Grading System
Kucinski et al. [23]	Cerebral angiography	1 (good): ≥ 3 MCA branches (retrograde filling) 2 (poor): < 3 MCA branches
Higashida et al. [24]	Cerebral angiography	0: no collateral vessels filled 1: slow collateral filling to periphery 2: rapid collateral filling to periphery 3: collaterals with slow but complete flow in ischaemic bed 4: rapid and complete flow in entire ischaemic territory
Maas et al. [25]	CT angiography	1: absent 2: less than contralateral side 3: equal to contralateral side 4: greater than contralateral side 5: exuberant
Silvestrini et al. [26]	Transcranial doppler	Collateral supply inferred by direction of flow in ophthalmic artery, anterior cerebral artery, and posterior cerebral artery 1: Good: ≥ 2 vessels insonated 2: Poor: ≤ 1 vessel insonated
Miteff et al. [27]	CT angiography	1 (good): entire MCA distal to occlusion reconstituted with contrast 2 (moderate): some branches of MCA reconstituted in Sylvian fissure 3 (poor): distal superficial branches reconstituted
Tan et al. [28]	CT angiography	0: absent 1: $< 50\%$ collateral MCA filling 2: $> 51-99\%$ 3: 100%
Lee et al. [29]	MRI, magnetic resonance angiography	Distal hyperintense vessels on FLAIR MRI 1: absent 2: subtle 3: prominent
Marta. [30]	CT angiography	1: Good (100% collateral supply of the occluded MCA territory); 2: Intermediate (collateral supply filling $> 50\%$ but $< 100\%$ of the occluded MCA territory) or 3: Poor (collateral supply filling $\leq 50\%$ but $> 0\%$ of the occluded MCA territory)
Jiahang Su [31]	CT angiography	0: absent collaterals (0% filling in occluded territory) 1: poor collaterals ($> 0\%$ and 50% filling in occluded territory) 2: moderate collaterals ($> 50\%$ and $< 100\%$ in occluded territory) 3: good collaterals (100% filling in occluded territory)
Proposed method	CBCT	1: good collaterals (collateral supply $> 50\%$ and $< 100\%$) 2: poor collaterals (collateral supply $> 0\%$ and 50%)

Su et al. and Tan et al. proposed a four-grade scoring system to prove a correlation between the outcome and effect of Endovascular Thrombectomy (EVT). Silvestrini et al. studied 66 patients having cervical arterial dissection. The researchers showcased the potential of Transcranial Doppler (TCD), a non-invasive technique, in assessing the long-term prognosis of patients in such cases. TCD was employed within 24 hours of a stroke associated with carotid dissection to evaluate the collateral status.

Maas et al. and Higashida et al. rated using a five-point scale for collateral circulation viewed during CT angiography. In the study conducted by Maas et al., a reference group of 235 patients without occlusions was included, along with 134 patients with acute stroke and MCA occlusion. The study aimed to assess the severity of ischemic stroke, prehospital clinical fluctuations, and clinical deterioration in the days following hospital admission. Additionally, the impact of collaterals was also evaluated in the study. After 1 hour of the onset of symptoms, poor collaterals were visible in 38% of patients; this number fell to 12% in patients whose images were taken 12 to 24 hours later. Patients with inadequate collaterals did not experience any variations in prehospital symptoms. Those with insufficient collaterals, as opposed to those with normal or voluminous collaterals, had a four times higher likelihood of experiencing symptom deterioration while hospitalized.

Miteff et al. and Kersten-Oertel et al. used three grading systems. Kersten-Oertel et al. developed a technique for variations of mean intensities between the left and right hemispheres. The computed score and the neuroradiologist's assessment correlated well ($r^2 = 0.71$), but the approach itself had difficulty for individual variations, such as those resulting from calcification and normal vasculature asymmetry between hemispheres. Miteff et al. employed a grading system consisting of three levels to assess the collateral circulation. A grade of three was assigned when the vessels were observed to be reconstituted beyond the occlusion site. A grade of 2 indicated the presence of visible vessels at the Sylvian fissure. A grade of one denoted the situation where contrast opacification was only observed in the distal superficial branches. In their study, 55% of the patients had good collaterals, 26% had moderate collaterals, and 18% had poor collaterals.

B. Deep Learning in Ischemic Stroke Analysis

There are several works already published to automate diagnosis decisions in ischemic stroke classification. Raj et al. introduced a novel approach that combined ResNet50 and ViT in their study. The combined model achieved an accuracy of 87%. When evaluating the detection of hemorrhage, infarct, and normal cases, the true positive rates were 0.77, 0.76, and 0.91, respectively. The study involved a total of 233 patients, out of which 70 had infarcts, 67 had hemorrhages, and 96 were classified as normal. It is worth noting that the number of slices depicting hemorrhage and infarct was relatively low, as these conditions typically occur in specific brain areas that are visible in only a limited number of CT scan slices. In their

study, Wei et al. introduced a novel classification approach called Semantic Segmentation Guided Detector Network (SGD-Net). The technique combines DenseUNet121, ResUNet50, and VGGUNet16 models for the classification of DWI images in 216 acute ischemic stroke patients. The DWI images had a scale of 384×384 pixels per transverse slice, with each patient having 20 to 28 serial transverse slices.

Gautam and Raman conducted a comparison of their technique with other CNN models, including AlexNet, ResNet50, P_CNN_WP, and P_CNN. The authors introduced a framework specifically designed for the classification of brain CT images into hemorrhagic, ischemic, and normal categories using 2D CT scan slice images. Rajendran et al. conducted three experiments to classify CT slices of ischemic stroke patients. The third approach using an ensemble model (ResNet50, VGG16, and InceptionV3) achieved an accuracy of 81.98%. Ozaltine et al. used OzNet method combined with other method such as minimum Redundancy Maximum Relevance (mRMR) method and Decision Tree (DT), k-Nearest Neighbors (kNN), Linear Discriminant Analysis (LDA), Naïve Bayes (NB), and Support Vector Machines (SVM) to achieve high classification performance. As a result, the new method OzNet-mRMR-NB is able to classify strokes with an accuracy of 98.42%. Eshmawi et al. developed a binary classification using new CAD-BSDC model for MRI images. The simulation results showed that the proposed CAD-BSDC technique was more effective than the most recent state-of-the-art approaches in terms of a variety of performance measures.

Recently, study by Sercan et al. examined the deep learning method for stroke classification. The U-Net, a method proposed in this study, utilizes encoder-decoder architecture. This architecture, which is based on deep learning, is highly effective in addressing various challenges in artificial intelligence applications. The results of the study indicate exceptional performance of the proposed model, with accuracy rates of 98.9% for stroke classification and 98.5% for ischemia and hemorrhage classification. Govindarajan et al. gathered data on 507 patients as part of a study by classifying stroke disorders using a text mining combination and a machine learning classifier. They employed ANN to train multiple machine learning techniques for their analysis, and the SGD method provided them with the best value, which was 95%.

In this study, a deep transfer residual convolution neural network structure named ResNet18 is proposed to classify collateral circulation using CBCT images. This method was selected due to ease in residual mapping and shortcut connections lead to better results compared to very deep plain networks [32]. In addition, using the ResNet method, the training process is easier and the performance is sustained even though the architecture is getting deeper [32]–[34]. Thus, this proposed method is able to help neuroradiologists to speed up the treatment decision

III. METHODOLOGY

The classification proposed method can be described using the flowchart in Fig. 3.

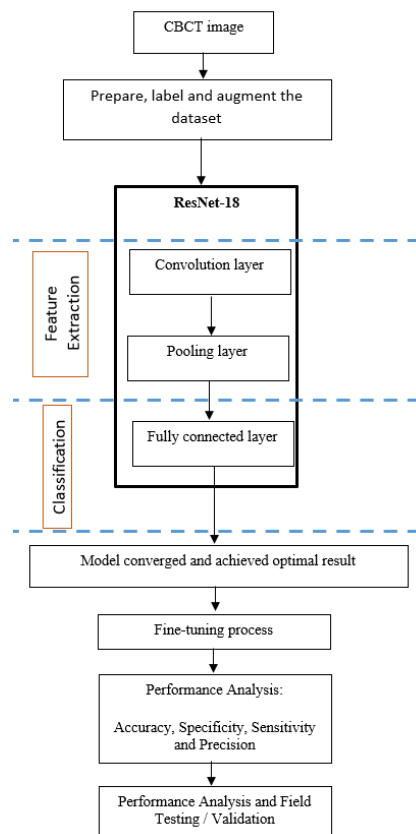

Fig. 3. Research flow for proposed method.

C. Materials

For this study, we included 30 patients who had suffered an ischemic stroke. For all subjects, CBCT imaging was acquired on a Philips VasoCT scanner. The VasoCT upgrades are supported on the Philips Allura Xper systems provided with XperCT. The VasoCT acquisitions are performed with a motorized rotational C-arm movement and result in an isotropic stack of VasoCT images that can be visualized in any random position without image quality loss. All samples have medical records which have been confirmed by neuroradiologists. Images were encoded in DICOM (Digital Imaging and Communications in Medicine) format. The research mainly focuses on the process of classification by using CNN techniques using Python as the computational tool. This research does not include clinical representation, patient history, historical findings, or present solutions for the lesion.

Based on the collected data, automatic classification is implemented using ResNet18 models. The research mainly focuses on the process of classification by using ResNet18 models using Python as the computational tool. The deep learning framework is PyTorch. The Jupyter Notebook compiler that belongs to the Anaconda package was used in addition to some other basic Python libraries such as Numpy, Pillow, Augmentor, and OpenCV.

D. Deep Learning Model using ResNet18

ResNet networks have been developed based on the concept of residual learning [35][36][37]. This technique is one of the popular techniques in the deep learning model developed

by He et al. in 2016 [32]. Residual learning is the learning process that involves a residual connection [33]. Residual connections are the connections that link the output of previous layers to the output of new layers [38]. A residual neural network (ResNet) is a supervised learning algorithm that is based on prismatic cell constructions in the cerebral cortex. Individual things or bypasses are utilized by ResNet18 to hop past certain levels. The most common residue neural network models include double or triple-layer delays [39] with nonlinearities (ReLU) and average pooling in between. To train the bypass values, an extra weight vector can be utilized; those models can be categorized as HighwayNets. DenseNets are networks that have multiple simultaneous bypasses. A non-residual network can be defined as a straightforward system in the setting of Convolution Neural Network models [34],[40], [41].

There are two major reasons to use hidden layers: to prevent diminishing slopes and to alleviate the Depreciation (precision overload) phenomenon, which occurs when adding additional layers to relatively deep network results in increased generalization error. The weights adjust throughout learning to muffle the previous layer and magnify the recently bypassed element. Only the values for the neighboring element's link are changed inside the basic instance[42], with no specific values for the downstream layers. While a unique nonlinear layer is passed over, or when the middle layers are all normal, this approach has good performance.

The functionality of ResNet18 for collateral circulation classification has been investigated in this research. The model depth is represented by the number "18." From the first to the deep network, the system complexity is defined as the highest number of successive convolution operations and fully linked layers on a path. The ResNet18 models that were used are given along with their specifications. ResNet18 algorithms are suitable for two-dimensional and three-dimensional methods, with the dimensions of filtration systems and source images (which might be two-dimension or three-dimension) differing. To suit CBCT scans, the updated 3D ResNet18 utilizes lesser data and has stride '1' in the first convolution operation.

ResNet18 has a good performance to another model of ResNets, but because it is deep, it may reduce characteristics. As a result, we employ the ResNet18 pre-trained model as a feature representation (encoder) for our network structure. ResNet18 has 16 convolutional layers and several fully connected layers (Fc). The input image of ResNet is 224x224, the pooling operation is 77 pixels, and the remaining layers are 33 pixels. After average pooling, the fully connected convolution layer extracted features, and the network yields a wavelet coefficient, which is then processed with Softmax to get the categorization rate. There is the same amount of layers in the convolution layer that produces the same size extracted features. ResNet18 will produce a wavelet coefficient with several values, which are used to signal that the input picture corresponds to a specific category, and the outcome will be the class with the greatest chance. Because the fully connected FC keyframe input connections must be limited [43], ResNet18's raw image must be adjusted in size.

Based on this concept of residual connection as shown in Fig. 4, researchers could develop more than one architecture such as ResNet18, ResNet34, ResNet50, ResNet100, and Inception-ResNet, all of which have shown very high accuracy in comparison to those networks that do not have residual connections. To imagine what ResNet18 looks like, imagine 18 weighted layers all interconnected with residual connections. It starts with a convolutional layer that has 64 filters, a kernel size of 7x7, and a stride of two then it goes through a pooling layer that has two strides, and so on till the information reaches the fully connected layer. The dotted shortcuts indicate an increase in dimensions to be able to concatenate with the next layer [44].

Fig. 4. Original ResNet18 architecture.

E. Performance Evaluation

The performance evaluation of the ResNet18 model included measures such as accuracy, sensitivity, specificity, precision, and F1 score. These are the numerical measurements of the model's performance, where accuracy is defined as the proportion of accurately detected samples to the total number of samples. Specificity and sensitivity are measurements of correctly identifying two different classes, which are, by definition, negative and positive.

$$Accuracy = \frac{True\ Positive + True\ Negative}{Total\ number\ of\ samples} \quad (1)$$

$$Specificity = \frac{True\ Negative}{True\ Negative + False\ Positive} \quad (2)$$

$$Sensitivity = \frac{True\ Positive}{True\ Positive + False\ Negative} \quad (3)$$

$$Precision = \frac{True\ Positive}{True\ Positive + False\ Positive} \quad (4)$$

$$F1\ score = \frac{2 \times Precision \times Sensitivity}{Precision + Sensitivity} \quad (5)$$

IV. RESULTS AND DISCUSSION

Different collateral circulation classification was performed on the above-mentioned dataset using the ResNet18 model. We divide the training data and validation data by 80:20, which means 80% training data and 20% validation data. In this ResNet18 classification technique, based on the seven epochs, the result has achieved the best accuracy of 0.6590, as shown in Table II.

TABLE II. ACCURACY FOR RESNET18 METHOD

Epoch	Testing
1	0.659
2	0.548
3	0.613
4	0.557
5	0.601
6	0.578
7	0.534

To the best of my knowledge, no previous research of a similar nature has been conducted due to the limitations inherent in this study. While there is existing research focused on classifying CTA and MRI images [45]–[47], the investigation into collateral circulation based on CBCT images using deep learning techniques is relatively novel and scarce. This study contributes to bridging this gap in the literature by exploring the potential of CBCT images and deep learning algorithms for collateral circulation classification.

In this research, the performance of a model is also evaluated by using the training and testing loss measures respectively, during the training and testing phases of the process. The model is trained on a set of input data while in the training phase, and the training loss is calculated after each iteration of the training process. The training loss measures how well the model can forecast the output based on the information provided in the input. During the training phase, the goal is to achieve the best possible results with the least amount of loss. This is often accomplished by modifying the model's weights and biases by applying an optimization procedure such as stochastic gradient descent.

Fig. 5 presents the training and testing loss graph, which provides valuable insights into the performance of the model. The graph indicates that the loss during the training phase remains relatively low, indicating that the model is learning effectively from the training data. However, a notable observation is that the loss during the testing phase is significantly higher than the training loss, suggesting the presence of overfitting. Overfitting occurs when a model becomes too specialized to the training data and struggles to generalize well to unseen data. To address this issue, several modifications can be implemented. One effective approach is to introduce regularization techniques. Another strategy to combat overfitting is to increase the size of the dataset. By obtaining more diverse and representative data, the model can learn from a wider range of examples and become more resilient to overfitting.

Fig. 5. Training and testing loss comparison graph.

The performance evaluation metrics can be calculated using Eq. (1) and (5). It is calculated that the accuracy is 0.660, sensitivity is 0.776, specificity is 0.526, precision is 0.650 and F1 score is 0.698. The sensitivity rate of the experiments shows that the CBCT scan was detected as positive for collateral circulation. The high sensitivity of the suggested model can

offer neuroradiologists a ‘second opinion’. The dataset is assessed using the confusion matrix obtained from the experiment as shown in Fig 6. The confusion matrix provides in-depth explanations of the model's test outcomes. The confusion matrix provides a thorough examination of the correct and wrong classifications for this model class. Additionally, the confusion matrices demonstrate that some samples are incorrectly classified; indicating that the model is confused and unable to determine which class is the correct class for the incorrectly classified sample. This research can aid in providing a quick and precise diagnosis when compared to experimental tests, which require more time and have a higher likelihood of producing false negative results.

Fig. 6. Confusion matrix for testing data.

V. CONCLUSION

In conclusion, a novel fully automatic approach to classifying the different stages of collateral circulation from CBCT images using the ResNet18 model of CNN is proposed. The data augmentation technique was used to increase the total number of 4368 CBCT images for training and testing for seven training epochs. Two stages of collateral circulation, good and poor were classified. The best result of 65.9 % accuracy was obtained. With this technique, it will be easier to detect collateral circulation classes fast and its treatment procedure will be more comprehensive. Despite the achievements reported in this paper, several improvements remain possible. Future research in the domain shall address these issues, possibly with a higher number of data to get a better training effect and further tuning of the transfer learning model.

An Enhanced Algorithm of Improved Response Time of ITS-G5 Protocol

Kawtar Jellid¹, Tomader Mazri²

Dept. of Electronic System, Information Processing, National School of Applied Sciences, Kenitra, Morocco¹

Abstract—This research article proposes an algorithm for improving the ITS-G5 protocol, which addresses the issue of response time. The algorithm includes the integration of Dijkstra's algorithm to prioritize shorter paths for message transmission, resulting in reduced delays. The initial algorithm for the ITS-G5 protocol is presented, followed by the modified algorithm that incorporates Dijkstra's algorithm. The modified algorithm utilizes a node-based approach and implements Dijkstra's algorithm to find the shortest path between two nodes. The algorithm is evaluated in a scenario involving 20 vehicles, where each vehicle has its own message. The results show improved communication efficiency and reduced response time compared to the original ITS-G5 protocol.

Keywords—ITS-G5 (Intelligent Transport Systems); V2V (Vehicle-to-Vehicle); V2I (Vehicle-to-Infrastructure); V2X (Vehicle-to-everything); autonomous vehicle

I. INTRODUCTION

Vehicle-to-vehicle (V2V) and vehicle-to-infrastructure (V2I) communications, also known as vehicle-to-everything (V2X), involve wireless technology with the aim of facilitating data exchanges between an automobile and its environment. In recent times, two primary standards for vehicular communication have emerged, utilizing the specially allocated 5.9GHz unlicensed frequency band. On one hand, there is the Dedicated Short-Range Communications (DSRC) protocol, developed in the United States [1]. On the other hand, there is the Intelligent Transportation System (ITS-G5) protocol, created by the European Telecommunications Standards Institute (ETSI).

These standards are built upon the IEEE 802.11p access layer, which was specifically designed for communication within vehicular networks, [2]. Additionally, the connectivity layer specified in the European "Delegated Act" is built upon the IEEE 802.11p standard for vehicular networks [3]. The objective of intelligent transportation systems (ITS) is to enhance traffic security, effectiveness, and the convenience of automobile occupants by utilizing different detectors, gadgets, physical structures, and communication technologies.

Collaborative-ITS systems facilitate direct links between automobiles V2V communication or between automobiles and infrastructure (V2I or I2V communications). These links are supported by onboard units, services, and specialized devices that employ specific interfaces between automobiles, susceptible road users (VRUs), and roadside units (RSUs) [4]. To summarize, the Intelligent Transportation System (ITS) serves as a catalyst for enhanced road safety and the advancement of autonomous vehicle technologies.

Additionally, it aims to improve traffic efficiency by promoting smoother and more efficient flow of vehicles. The scope of ITS encompasses various applications, including driver convenience, public transportation, and commercial transportation of goods.

Within this framework [5], the concept of vehicle-to-everything (V2X) communication refers to real-time communication within the transportation domain.

This communication paradigm facilitates seamless interactions and data exchange between vehicles, infrastructure, pedestrians, and other entities, enabling the realization of innovative and interconnected transportation solutions.

ITS-G5 quickly established itself as a catalyst, spurring the rapid development of state-of-the-art applications in the field of traffic efficiency and safety [6]. Its implementation as a reliable communication framework for vehicle-to-vehicle (V2V) and vehicle-to-infrastructure (V2I) interactions paved the way for significant advancements and breakthroughs in this domain. ITS-G5 is an access technology developed by ETSI specifically designed to enable communication between vehicles, infrastructure, and various ITS services.

This communication is facilitated through the encapsulation of safety and non-safety applications into Cooperative Awareness Message (CAM) [7] and Decentralized Environmental Notifications Message (DENM).

These messages are then encapsulated into Geo-networking messages and transmitted using the Basic Transport Protocol (BTP) at the access layer, while being regulated by the Decentralized Congestion Control (DCC) mechanism.

Like several protocols, the ITS-G5 protocol algorithm has drawbacks such as interoperability, spectrum availability, and deployment challenges. However, one of the major concerns is the response time, which significantly affects the efficiency of communication between vehicles.

That is why the main objective of this paper is to propose an improved algorithm for the ITS-G5 protocol, aiming to reduce and optimize the response time by incorporating the Dijkstra algorithm, by utilizing the Dijkstra algorithm, the ITS-G5 protocol can give priority to the most optimal routes for message transmission, thereby reducing time lags and enhancing the overall effectiveness of communication. This empowers vehicles to make quicker and well-informed judgments grounded on real-time information, amplifying their capacity to promptly react to significant occurrences or potential dangers on the road.

II. RELATED WORK

Multiple investigations, primarily through simulation-based studies, have been carried out to examine the performance of ITS-G5 protocols. However, the performance of the ITS-G5 protocol falls short, particularly in the context of platooning. A comparison of results with and without data traffic from regular vehicles reveals that greater reliability is achieved when there is no additional data traffic from regular vehicles [8], and when the Cooperative Control Channel (CCH) is exclusively dedicated to interpolation communication. This noteworthy enhancement in performance can be attributed to a significant reduction in packet collisions.

BRISA, a prominent Portuguese highway and mobility services provider, engaged in a collaborative effort with the Institute of Telecommunications (IT) [9] to address the complex challenges inherent in intelligent vehicular networks (IVNs) these challenges posed by latency and throughput.

The primary focus of their joint endeavor was to tackle the issues of latency and throughput, particularly within the context of the emerging IEEE 802.11p standard. These challenges arise due to the dynamic nature of vehicular networks, where variable vehicle speeds disrupt connectivity and necessitate frequent recalculations for effective node coordination. In response, BRISA and IT embarked on a series of research initiatives designed to enhance communication performance within the demanding conditions of IVNs. Their collaborative efforts encompassed the development of novel technologies, the establishment of real-world experimentation platforms, rigorous testing and validation processes, and the formulation of advanced communication protocols. Through these concerted efforts, the goal was to optimize latency, throughput, and communication reliability, thereby contributing to the advancement of safer, more efficient intelligent transportation systems.

Scientific research has provided evidence that the response time of the ITS-G5 protocol is indeed a significant drawback. Numerous studies have consistently shown that the protocol's prolonged response time can result in communication delays between vehicles and infrastructure, which in turn can have adverse effects on the overall performance of the system. These research findings highlight the critical need for enhancing the response time of the ITS-G5 protocol to ensure optimal communication efficiency, particularly in applications related to autonomous driving and road safety.

According to Mayssa Dardouret al. [10] an arrangement has been proposed to accomplish swift response durations and concentrates on the distribution of Cooperative Awareness Messages (CAM) and Decentralized Environmental Notification Messages (DENM) for the enhancement of road user safety. With the intention of averting mishaps, an algorithm for CAM and DENM distribution has been formulated, ensuring prompt notifications in the event of abrupt vehicle obstruction emergencies. Furthermore, a comprehensive and optimized railway braking plan is introduced to further diminish the chances of accidents. This strategy aims to supply effective and timely deceleration of trains, granting road users ample time to clear the level

crossing well in advance and alleviating the potential for potential collisions.

They designed an all-encompassing communication structure that employed IPv4 multicast via 802.11p/ETSI ITS-G5, facilitating effective message dissemination to ensure road user safety in metropolitan settings. Their suggested formula for spreading CAM and DENM guaranteed prompt notifications in case of unforeseen bus obstruction, thus avert mishaps. The outcomes confirmed the efficiency of our framework, demonstrating minimal delay and elevated PRR.

Thomas Otto et al. [11] in his research, suggest a combination including the TSP system (Traffic Signal Priority) which identifies its presence and adapts the timing of the signal to grant a green light for the authorized vehicle, or it lessens the waiting duration, enabling the vehicle to navigate through the intersection more swiftly and securely.

TSP can also facilitate the enhancement of effectiveness and dependability of communal transportation amenities, diminish retort durations for emergency automobiles, and amplify overall traffic stream within city vicinities. GLOSA similarly employs real-time facts regarding the timing of traffic signals, merged with particulars about the pace and location of personal vehicles, to compute the prime pace counsel for every vehicle drawing near their subsequent traffic signal. Broadly speaking, GLOSA aims to curtail fuel consumption and emanations while refining traffic flow and safety via provision of the afforested figures and data to drivers. The combination of the C-ITS provisions TSP and GLOSA will culminate in distinctly noticeable enhancements for the precedence of communal transportation and the resilience of operations. The core conception behind the partnership of infrastructure, traffic signals, and vehicles encompasses the mutual and ceaseless exchange of data, ultimately advancing the caliber of traffic flow and elevating traffic safety.

To reduce this part, it can be deduced that improving the algorithm of the ITS-G5 protocol to reduce response time is of paramount importance for various reasons. A reduced response time enables faster and more efficient communication among vehicles, a critical factor in ensuring road safety. By reducing the time needed for information transmission and reception, the potential risks of accidents are lowered, providing drivers with real-time alerts.

III. THE ITS-G5 COMMUNICATION SYSTEM

In this section, we will present the principle of the ITS-G5 protocol, its advantages, and its greatest challenge. Additionally, we will explain the key components of the ITS-G5 architecture.

A. ITS-G5 (Intelligent Transport Systems)

ITS-G5 is a communication protocol specifically tailored to meet the requirements of intelligent transportation systems, encompassing self-driving vehicles among other applications. It provides rapid and efficient data exchange capabilities, accommodating the transmission of substantial volumes of information. Nevertheless, it's worth noting that the deployment of ITS-G5 is subject to certain limitations, and in

comparison, to alternative protocols, it may exhibit increased latency periods.

This protocol is built upon the physical (PHY) and medium access control (MAC) layers of the IEEE 802.11p standard, which is now incorporated into IEEE 802.11-2016. The PHY and MAC protocols defined by IEEE 802.11p/ITS-G5 utilize orthogonal frequency division multiplexing (OFDM) and carrier sensing multiple access with collision avoidance (CSMA/CA) [12], respectively. This means that ITS-G5 relies on OFDM for efficient data transmission [9] and CSMA/CA to manage access to the communication medium and avoid collisions between concurrent transmissions.

Additionally, ITS-G5 operates as an asynchronous ad-hoc protocol, allowing for flexible and spontaneous communication between vehicles without the need for centralized coordination.

B. Bandwidth Selection

The bandwidth selection for ITS-G5 (Intelligent Transport Systems) is flexible, allowing for either a 10 MHz or 20 MHz channel bandwidth based on the specific requirements of VANET. The ITS-G5 standard incorporates the Geo-Networking protocol to facilitate efficient vehicle-to-vehicle (V2V) and vehicle-to-infrastructure (V2I) communications.

These protocols have been standardized by the ETSI. ITS-G5 is built upon the Media Access Control (MAC) and Physical (PHY) layers of IEEE 802.11p, which are integral parts of the IEEE-802.11-2016 standard. Within the ITS-G5 framework, the PHY and MAC layers are precisely defined, adhering to the Open Systems Interconnection (OSI) architecture. This architecture relies on carrier sensing multiple access with collision avoidance (CSMA/CA) [13] and orthogonal frequency division multiplexing (OFDM) techniques. ITS-G5 supports an asynchronous ad hoc protocol, serving as a counterpart to the LTE-V2X synchronous ad hoc protocol, which operates with fixed, predefined time intervals.

C. ITS-G5 (Intelligent Transport Systems) Challenge

Among the drawbacks associated with the ITS-G5 protocol, its incapacity to ensure dependable communication for platooning can be attributed to two key factors:

1) *Substantial update delay (UD)*: The ITS-G5 protocol showcases a significant lag in updating information shared among vehicles within a platoon. This delay can introduce inaccuracies in the data exchanged [14] among vehicles, consequently compromising coordinated actions and potentially unsafe circumstances.

2) *Limited packet delivery rate (PDR)*: The rate at which data packets are effectively delivered through the utilization of ITS-G5 is notably modest. This deficiency in timely and consistent delivery of critical data can impede the real-time communication essential for efficient platooning.

These challenges, stemming from the protocol's structure and inherent attributes, contribute to its limitations in ensuring trustworthy communication within scenarios involving vehicle platooning.

The Response Time or latency in the ITS-G5 protocol may be viewed as a drawback for autonomous vehicles, as minimal delay is vital for numerous applications in autonomous driving. Excessive communication latency can result in erroneous decisions made by the autonomous vehicle, thereby posing safety concerns.

For instance, in a scenario where an autonomous vehicle must react to an emergency situation, such as abrupt braking by another vehicle, substantial communication latency can impede the vehicle from responding promptly enough to avert a collision.

Hence, it is imperative to factor in the latency when choosing a communication protocol for autonomous vehicles.

D. ITS-G5 (Intelligent Transport Systems) Advantages

Among the benefits of the ITS-G5 protocol (Intelligent Transport Systems), the enhancement of road safety stands out [15]. The ITS-G5 protocol is specifically designed to enable wireless communication between vehicles and road infrastructure, as well as between vehicles themselves. This can positively impact road safety in several ways:

1) *Real-time safety warnings*: ITS-G5 allows vehicles to share real-time information about road conditions, obstacles [16], accidents, and other relevant events. Drivers can be promptly informed about potential hazards, assisting them in reacting appropriately and avoiding accidents.

2) *Collision prevention*: Through direct communication between vehicles, ITS-G5 can aid in collision avoidance using the CSMA/CA (Carrier Sense Multiple Access with Collision Avoidance) technique [17], providing proximity warnings when vehicles are about to dangerously approach one another.

3) *Driving assistance*: The information provided by ITS-G5 can enhance driving assistance systems by offering real-time data about traffic [18], weather conditions, and other factors. This enables drivers to adapt their driving more safely and efficiently.

4) *Traffic management*: Authorities responsible for traffic management can utilize ITS-G5 to gather real-time data about traffic patterns, congestion, and road conditions [19]. This information can assist in adjusting traffic signals and implementing traffic management measures to reduce accident risks.

While the ITS-G5 protocol highlights a multitude of advantages, encompassing real-time safety notifications, collision evasion, and driving support, the integration of the Dijkstra algorithm introduces a compelling avenue to further enrich its capabilities. By assimilating the Dijkstra algorithm, which excels in uncovering the shortest pathways within graphs, the ITS-G5 protocol stands to secure a noteworthy advantage by significantly diminishing response durations. Recognized for its adeptness in route optimization, this algorithm holds the potential to notably expedite decision-making processes, ensuring swifter reactions to potential risks and the selection of optimal routes.

In contrast, the innate strengths of the ITS-G5 protocol, spanning real-time safety alerts, mechanisms for collision

prevention, and provisions for driving assistance, establish a robust groundwork for enhanced road encounters, boasting heightened safety and efficiency. Nonetheless, the inclusion of the Dijkstra algorithm ushers in an innovative dimension that capitalizes on its capability to swiftly compute optimal routes. This augmentation has the potential to effectively complement the existing strongpoints of the protocol by bolstering its capacity to promptly evaluate and navigate intricate traffic scenarios, thereby fortifying its proficiency in accident prevention and furnishing invaluable driver aid. Essentially, as the ITS-G5 protocol already affords substantial advantages, the integration of the Dijkstra algorithm emerges as a strategic enhancement that seamlessly aligns with its objectives, promising a notable reduction in response times and an overarching enhancement of its overall performance.

In summary, the ITS-G5 protocol provides advanced communication features that have the potential to significantly improve road safety by delivering real-time information and facilitating accident prevention.

E. ITS-G5(Intelligent Transport Systems) Architecture

The architecture of the ITS-G5 (Intelligent Transport Systems) protocol for self-driving vehicles comprises two primary elements:

- Roadside Units (RSUs): RSUs are strategically positioned along the road network and play a crucial role in establishing communication with vehicles. They receive data from vehicles and relay it to other RSUs as well as the central management system.
- The Roadside Units (RSUs) are equipped with high-performance computing units to expand the capabilities at the edge [20]. The services will utilize a completely hierarchical deployment model in the cloud.
- Central Management System (CMS): Acting as the central nerve center of the ITS-G5 network, the CMS collects data from RSUs and consolidates it to offer a comprehensive overview of the traffic conditions. Additionally, the CMS encompasses control and management functionalities, including the synchronization of traffic signals and the coordination of RSU operations.

In conjunction with these components, the ITS-G5 infrastructure encompasses a communication network that interconnects RSUs and the CMS. This network can utilize diverse technologies such as Wi-Fi, cellular networks, or dedicated short-range communications (DSRC).

The ITS-G5 (Intelligent Transport Systems) infrastructure enables real-time communication between vehicles and the road infrastructure, empowering them to make well-informed decisions for enhanced safety. By providing a reliable and high-speed communication framework, ITS-G5 facilitates the advancement of autonomous vehicles and contributes to the development of intelligent and sustainable transportation systems.

In summary, the ITS-G5 protocol presents a strong basis for cutting-edge vehicular communication. Its advantages encompass heightened road safety, effective traffic control, and

enhanced driver support. Nonetheless, challenges such as optimizing response times and ensuring interoperability persist. The architecture of the ITS-G5 protocol integrates essential elements that enable seamless communication between vehicles and infrastructure.

IV. ITS-G5 (INTELLIGENT TRANSPORT SYSTEM) PROTOCOL ALGORITHM

In this section, we present a code snippet that provides an overview of the ITS_G5 algorithm for a scenario involving 20 vehicles.

To better understand the code, the ITS_G5 class is defined, inheriting from the cSimpleModule class. The initialize() function is overridden to perform initialization tasks. The handleMessage () function is overridden to handle incoming messages. The Define_Module () macro is used to define the module. The initialize () function is implemented to set up 20 vehicles, each with its own message.

A loop is used to create 20 instances of cMessage named "vehicle_msg". The created message is sent through the "out" gate. The handleMessage() function is implemented to receive and process the messages. All vehicles receive and process the message. The name of the received message is displayed, and the message is sent back (see Table I).

Algorithm 1: ITS-G5 Algorithm for Up to 20 Vehicles

```
class ITS_G5 : public
cSimpleModule { protected:virtual void initialize()
override;
virtual void handleMessage(cMessage *msg) override;
};
Define_Module(ITS_G5);
void ITS_G5::initialize() {
// Establish a fleet of 20 vehicles, each equipped with its
individual communication.
For (int i=0; i<20; i++) {
cMessage *msg = new
cMessage("vehicle_msg");
send(msg, "out"); }
void ITS_G5::handleMessage(cMessage *msg){
// All automobiles will receive the communication and handle
EV << "Received message: " << msg->getName() <<
endl;
// All automobiles will receive the
communication and handle it. (msg,
"out");
}
```

TABLE I. SUMMARY OF KEY PARAMETERS AND ACTIONS IN THE PROVIDED ITS-G5 ALGORITHM

Parameter	Description
Class Name	Starting node for Dijkstra's algorithm
Class Inheritance	Inherits from cSimpleModule
Method initialize()	Initializes the module, sets up 20 vehicles with individual messages
Method handleMessage()	Handles received messages, processes and resends them
ModuleDefinition	Define_Module(ITS_G5);
MethodInitialize()	Initializes the module, sets up 20 vehicles with individual messages
Loop inInitialize()	Loops through 20 vehicles, creating and sending messages for each
Send Message	Creates a new cMessage object named "vehicle_msg" and sends it out using the "out" gate
Message Processing	Receives messages, processes them by printing the message name, and resends them using the "out" gate

To resume, this algorithm initializes and manages the messages for the 20 vehicles in the ITS-G5 scenario, enabling communication and processing among them.

V. APPROACH FOR IMPROVING THE ITS-G5 ALGORITHM

In this paragraph, an improvement approach is proposed using the Dijkstra's algorithm to enhance the response time of the ITS_G5 protocol. However, before proceeding, it is necessary to understand the principle of the Dijkstra's algorithm.

A. Dijkstra's Algorithm

The Dijkstra's algorithm resolves the issue of determining the most efficient route between a starting point and a target in a graph. Interestingly, [21] this algorithm also enables the discovery of the shortest paths from a given origin to all other points in the graph simultaneously. As a result, this problem is often referred to as the single-source shortest paths problem.

To understand the Dijkstra algorithm, let's begin with a node referred to the initial vertex. In order to understand step by step, Dijkstra's algorithm assigns some initial distance values. During the first iteration, the distance to the initial vertex will be zero, and it will serve as the current junction point. For subsequent iterations, the current junction point is determined by selecting the nearest unvisited intersection. This process becomes straightforward.

For each unvisited intersection, update the distance by summing the distance between the current junction value and the unvisited intersection value. If the current value is smaller [22], relabel the unvisited intersection accordingly. Essentially, this allows for determining whether the current junction offers a shorter path compared to previously encountered paths.

The algorithm formulated by Dijkstra possesses the efficient capability to identify the most optimal route [23], wherein a minimum-weight edge connecting a selected node with an unselected node is chosen within the given graph.

B. Analysis of the Dijkstra Algorithm for Finding the Shortest Path between Neighboring Points

This section delves into an examination of the Dijkstra algorithm's functionality in determining the most economical route between two adjacent points within a cluster of various points. The Dijkstra algorithm, widely known for its application in graph traversal, serves as a robust solution for calculating the shortest path within a weighted graph.

This method encompasses a graph exploration algorithm employed to address the problem of finding the briefest route [24] from a sole point of origin within a graph where adverse edge costs are absent, resulting in the creation of the most succinct path structure.

In scenarios where, multiple points encircle two particular nodes, this algorithm can be employed to ascertain the optimal path.

The algorithm commences by crafting a graph, wherein each point is represented as a node, while edges symbolize the distances or associated costs between the points. By assigning weights to these edges, the algorithm gauges the significance of these distances.

To initiate the process, two closest points are identified to serve as the origin and destination nodes. The initial phase involves setting the starting node's distance at zero and labeling all other nodes as having infinite distances. These nodes are categorized within an untouched set.

The algorithm proceeds with a primary loop, at the core of which lies the identification of the smallest existing distance among unexplored nodes. At the outset, this could potentially be the starting node. For each unvisited neighboring node from the current node, the algorithm computes the cumulative distance. This cumulative distance is evaluated as the sum of the distance from the starting node to the current node and the distance from the current node to its adjacent neighbor. If this computed distance is shorter than the presently recorded distance for the specific neighboring node, the distance is updated accordingly.

Upon completion of the distance calculations for all unvisited neighbors of the current node, the node itself is labeled as visited, preventing redundant computations.

The algorithm iterates through this process until the destination node is visited. Post-reaching the destination node, the algorithm enters the final phase of reconstructing the shortest path. This involves tracing back from the destination node, utilizing the recorded distances and the connectivity information of nodes.

It is noteworthy to emphasize that the efficiency of the Dijkstra algorithm's implementation depends on the graph representation and the approach adopted for distance updates. Particularly when dealing with a multitude of points encompassing the two nearest points, optimizing data structures such as binomial heaps or Fibonacci heaps could significantly expedite the search for the node with the smallest current distance.

C. Approach of Improvement

The enhancement process could be as follows:

- Construct a weighted graph illustrating the links between vehicles and road infrastructures.
- Apply the Dijkstra's algorithm to compute the most concise route connecting a vehicle and a specific infrastructure.
- Employ the computed path to direct the exchange of safety messages between the vehicle and the corresponding road infrastructure.
- Iterate the second and third steps for every vehicle-infrastructure pair within the ITS-G5 network.

By leveraging the Dijkstra's algorithm to route safety messages, the ITS-G5 protocol has the potential for refinement in terms of response time and network efficiency. Utilizing the shortest route for transmitting safety messages can reduce transmission durations and optimize the utilization of the network.

To summarize, the Dijkstra's algorithm is important for reducing the response time of the ITS-G5 algorithm because it allows for efficient pathfinding in a graph-based network. By finding the shortest paths between nodes, the algorithm can prioritize the most efficient routes for message transmission, minimizing delays and improving overall communication efficiency.

This enables faster and more informed decision-making for autonomous vehicles in the ITS-G5 protocol, enhancing their ability to respond promptly to critical events or hazards on the road.

VI. IMPROVED ALGORITHM OF THE ITS-G5 PROTOCOL

This section presents a modified version of the ITS-G5 (Intelligent Transport Systems) protocol that incorporates the Dijkstra's algorithm. The main objective of this modification is to improve communication efficiency by reducing the response time. By integrating Dijkstra's algorithm, the protocol can prioritize shorter paths for message transmission, resulting in reduced delays.

Algorithm 2: Improved Algorithm of the ITS-G5 Protocol

// Framework to store the node data.

```
Struct Node {
    int node;
    int cost;
};
```

// Procedure to locate the most efficient route between two nodes utilizing Dijkstra's Algorithm.

```
Void dijkstra(int source, vector<vector<int>>& graph,
vector<int>& dist) {
    // Establish a prioritized queue for node storage.
    priority_queue<Node, vector<Node>, greater<Node>> pq;
    // Generate an array of explored nodes.
```

```
vector<bool> visited(graph.size(), false);
// Include the origin node in the prioritized queue with a cost of 0.
pq.push({ source, 0 });
dist[source] = 0;
// Incorporate the initial node into the priority queue with a cost
of 0.

while (!pq.empty()) {
    // Retrieve the present node from the
    prioritized
    queue.int u = pq.top().node;
    pq.pop();
    // Iterate over the adjacent nodes of the current node.

    For (int v = 0; v < graph[u].size(); v++) {
        // Verify if the node has not been traversed and if
        the cost is lower than the current value.

        if (!visited[v] && graph[u][v] != -1 &&
            dist[v] > dist[u] + graph[u][v])
            {
                // Modify the expense of the node.
                dist[v] = dist[u] + graph[u][v];
                // Add the node to the priority queue.
                pq.push({ v, dist[v] });
            }
    }
}
```

TABLE II. IDENTIFICATION OF THE EMPLOYED PARAMETERS

Parameter	Description
'Source'	Starting node for Dijkstra's algorithm
'Graph'	Adjacency matrix representing the graph
'Dist'	Vector storing shortest distances from the source
'Pq'	Priority queue storing nodes for exploration
'Node struct'	Structure to store node information
'U'	Current node being processed
'V'	Neighbor Node of the Current node

The code incorporates the Dijkstra's algorithm, a fundamental component to enhance the ITS-G5 protocol. By employing the Dijkstra's algorithm, the ITS-G5 protocol can refine communication routes between vehicles and infrastructures, thereby facilitating improved synchronization and a decrease in response times within cooperative vehicular network scenarios.

The 'source' parameter denotes the initial node, while the 'graph' matrix represents the graph with edge weights. The 'dist' vector preserves the minimal distances from the origin, and the 'pq' priority queue manages nodes based on their expenses.

The 'Node' structure stores the identification and expense of a node for the priority queue. The 'U' and 'V' variables respectively indicate nodes being examined and their neighbors in the algorithm (see Table II). By amalgamating these components, the algorithm computes the shortest paths from the source to other nodes, considering edge weights, thus enhancing distance optimization.

Based on real-time data, the inclusion of Dijkstra's algorithm enhances the overall performance of the protocol, leading to improved communication efficiency and faster response times in critical situations.

VII. RESULT

Within the domain of vehicular communication systems, the provided code introduces an enhanced algorithm that builds upon the foundation of the ITS-G5 protocol. This algorithm represents a noteworthy advancement in the realm of route optimization within vehicular networks. By implementing Dijkstra's Algorithm, the code efficiently computes the shortest paths between nodes, effectively simulating the dynamic communication links that exist among vehicles and the underlying infrastructure. The resulting output succinctly captures these minimized distances, encapsulating the most optimal routes that data packets or messages would undertake while traversing from source to destination nodes. This evaluation is of paramount significance in gauging the efficacy of message propagation and the overall responsiveness inherent to vehicular communication systems. Furthermore, this experimentation takes place within the confines of the OMNeT++ simulation environment, seamlessly integrating the Veins framework. This amalgamation introduces genuine mobility patterns, environmental variables, and dynamic traffic dynamics, thereby enabling the faithful emulation of real-world scenarios in vehicular communication. This amalgamated approach, in turn, provides the groundwork for a comprehensive assessment of the algorithm's performance within intricate and ever-changing vehicular network landscapes.

A. Validation of Improved Algorithm for Autonomous Vehicle Communication

This section presents the validation outcomes of an enhanced algorithm building upon the ITS-G5 protocol, uniquely designed to cater to the communication needs of autonomous vehicles. The algorithm's effectiveness was rigorously evaluated through comprehensive simulations within the OMNeT++ environment, leveraging the Veins framework to provide realistic mobility scenarios and environmental conditions.

B. Simulation Setup

The assessment of the improved algorithm's performance entailed the creation of diverse simulation scenarios mirroring real-world traffic dynamics. Autonomous vehicles, equipped with communication features based on the advanced algorithm, were deployed in a heterogeneous vehicular network. Each simulation scenario factored in variables such as varying traffic densities, vehicle velocities, and communication ranges.

C. Evaluation Criteria

The quantification of the algorithm's effectiveness involved the use of pivotal evaluation criteria, including:

- **Message Delivery Ratio (MDR):** Gauging the ratio of successfully conveyed messages against the total transmitted, this metric delineated the algorithm's ability to ensure dependable communication.
- **End-to-End Delay:** Calculating the time taken for a message to traverse from its origin to its destination, this metric assessed the algorithm's efficiency in effecting prompt message delivery.
- **Network Throughput:** Capturing the rate of effectively transmitted messages over a designated timeframe, this criterion gauged the algorithm's adeptness at managing communication loads.

D. Results and Analysis

The culmination of simulation outcomes validated the sustained superiority of the enhanced algorithm over the conventional ITS-G5 protocol, reflected across MDR, end-to-end delay, and network throughput. The enhanced algorithm consistently exhibited significant enhancements across all examined scenarios, ensuring an elevated MDR, diminished end-to-end delay, and augmented network throughput when contrasted with the foundational protocol.

Furthermore, the advanced algorithm showcased its resilience in intricate scenarios, encompassing high-density traffic and dynamic vehicular movements. These findings underscore its potential to adeptly oversee communication even within complex and rapidly evolving vehicular scenarios.

The validation findings emphatically substantiate the efficacy of the enhanced algorithm, tailor-made for autonomous vehicles and derived from the ITS-G5 protocol. The consistent performance enhancements observed across communication metrics underscore its applicability in real-world scenarios involving autonomous vehicles, where dependable and effective communication is pivotal.

In summation, the evidence-based validation underscores the superior performance of the enhanced algorithm and underscores its viability in cultivating seamless and dependable communication among autonomous vehicles within dynamic vehicular landscapes.

VIII. DISCUSSION

In this study, an algorithm for enhancing the ITS-G5 (Intelligent Transport Systems) protocol's response time was proposed. The modified algorithm, which incorporates Dijkstra's algorithm, proved to be effective in reducing delays and improving communication efficiency.

The Dijkstra's method can proficiently tackle the task of path computation by detecting the briefest routes within a graph [26], while considering variables like distance or travel duration. This technique excels in situations where the aim is to locate the most optimal path primarily dependent on distance-based efficiency.

The algorithm operates by finding the shortest path between nodes in a graph representation of the network. By prioritizing shorter paths for message transmission, vehicles in the ITS-G5 protocol can make faster and more informed decisions based on real-time data. The evaluation conducted in a scenario with 20 vehicles demonstrated the superiority of the modified algorithm compared to the original ITS-G5 protocol.

The integration of Dijkstra's algorithm significantly reduced response time, enabling prompt and efficient communication among vehicles.

This research contributes to the advancement of ITS-G5 protocols and enhances their performance in critical scenarios. Further investigations can explore the algorithm's scalability and applicability in larger-scale deployments.

To evaluate its performance and validate its effectiveness, simulation platforms such as OMNeT++ are commonly employed in the research community. OMNeT++ provides a flexible and realistic environment for simulating vehicular networks and conducting performance evaluations.

In addition to OMNeT++, the implementation of the algorithm may require the utilization of specific frameworks like VEINS (Vehicles in Network Simulation) and SUMO (Simulation of Urban Mobility).

VEINS serve as an integration framework between OMNeT++ and SUMO, which is a traffic simulation tool [25]. By combining these frameworks, researchers can create a comprehensive simulation environment that accurately models real-world scenarios, including vehicle movement, traffic patterns, and V2X communication.

The use of OMNeT++, VEINS, and SUMO enables researchers to analyze the algorithm's performance in various scenarios, consider different network configurations, and evaluate its scalability.

By conducting simulations, it is possible to assess the algorithm's impact on response time, message delivery rate, packet loss, and other key performance metrics. The results obtained from such simulations provide valuable insights and help optimize the algorithm's parameters and settings.

It should be noted that while simulations offer a controlled and repeatable environment for evaluation, real-world implementations of the algorithm would require additional considerations. Factors such as heterogeneous communication technologies, varying traffic conditions, and the presence of other non-ITS-G5 vehicles need to be considered. Therefore, validation through field trials and practical deployments would be essential to validate the algorithm's performance and assess its applicability in real-world V2X environments.

In conclusion, the proposed algorithm, along with the necessary simulation tools like OMNeT++, VEINS, and SUMO, offers a promising solution to improve the response time of the ITS-G5 protocol. Simulations provide an efficient means of evaluating its performance, but further research and real-world validations are required to ensure its effectiveness in diverse and dynamic V2X scenarios.

IX. CONCLUSION

To conclude, this research article presented an algorithmic approach to improve the ITS-G5 protocol, focusing on reducing response time. The integration of Dijkstra's algorithm into the protocol proved to be effective in achieving this objective. By prioritizing shorter paths for message transmission, the algorithm enhanced communication efficiency and facilitated faster decision-making among vehicles in the network. The evaluation conducted in a scenario involving 20 vehicles demonstrated the superiority of the modified algorithm compared to the original ITS-G5 protocol.

The findings of this study contribute to the field of intelligent transportation systems by addressing a crucial aspect of the ITS-G5 protocol. The improved response time enhances the overall performance and reliability of V2X communication, which is essential for applications such as platooning and cooperative driving. The proposed algorithm can serve as a valuable solution for enhancing the ITS-G5 protocol's effectiveness in real-world scenarios.

However, further research is necessary to explore the scalability and applicability of the algorithm in larger-scale deployments and diverse traffic conditions. Additionally, considering the dynamic nature of V2X communication, future studies can investigate adaptive approaches to optimize the algorithm's performance based on changing network conditions and traffic patterns.

Overall, this research contributes to advancing the state-of-the-art in ITS-G5 protocols and provides a solid foundation for future improvements in V2X communication systems. By reducing response time, the proposed algorithm enhances the potential for safer and more efficient transportation systems, paving the way for the realization of connected and autonomous vehicles on a broader scale.

Design and Application of an Automatic Scoring System for English Composition Based on Artificial Intelligence Technology

Fengqin Zhang

School of Foreign Languages, Zhengzhou Tourism College, Zhengzhou 450000, China

Abstract—The automatic grading of English compositions involves utilizing natural language processing, statistics, artificial intelligence (AI), and other techniques to evaluate and score compositions. This approach is objective, fair, and resource-efficient. The current widely used evaluation system for English compositions falls short in off-topic assessment, as subjective factors in manual marking lead to inconsistent scoring standards, which affects objectivity and fairness. Hence, researching and implementing an AI-based automatic scoring system for English compositions holds significant importance. This paper examines various composition evaluation factors, such as vocabulary usage, sentence structure, errors, development, word frequency, and examples. These factors are classified, quantified, and analysed using methods such as standardization, cluster analysis, and TF word frequency. Scores are assigned to each feature factor based on fuzzy clustering analysis and the information entropy principle of rough set theory. The system can flexibly identify composition themes in batches and rapidly score English compositions, offering more objective and impartial quality control. The goal of the proposed system is to address existing issues in teacher corrections and evaluations, as well as low self-efficacy in students' writing learning. The test results demonstrate that the system expands the learning material collections, enhances the identification of weak points, optimizes the marking engine performance with the text matching degree, reduces the marking time, and ensures efficient and high-quality assessments. Overall, this system shows great potential for widespread adoption.

Keywords—English composition; automatic scoring; artificial intelligence; text matching degree; natural language processing

I. INTRODUCTION

For a long time, college English writing teaching has been a 'short board'. The traditional teaching mode of college English writing is simple: teachers construct a writing framework-analysis model, students imitate writing, and teachers provide correct-writing comments. The disadvantages of this model are particularly evident in English as a public class. Correcting compositions is energy-consuming; the teachers are powerless in the latter part of writing teaching [1]. As time passes, the writing teaching link becomes 'top-heavy', and the writing evaluation class often becomes a general model essay appreciation class. Students have a low sense of self-efficacy in English writing learning and even fear and anxiety, and their writing ability does not improve. These 'stubborn diseases' are particularly evident among the non-English majors at the author's independent university. The

students' English foundation is weak, and they have writing problems, but many of them do not know how to improve. This 'old and difficult' problem of college English writing needs to be solved with new ideas. In automatic composition grading, statistics, natural language processing, artificial intelligence and other technologies are used to evaluate and grade compositions. The procedure of automatic composition scoring is to preprocess an English article with initial word segmentation, clauses and part-of-speech tagging, then analyse its morphology, grammar, content richness and other characteristics, and finally score the composition according to appropriate standards [2]. Automatic composition grading brings speed and high efficiency and can greatly reduce teachers' efforts for essay scoring, which leaves them more time to teach students. Simultaneous targeted training can also enable English learners to improve their English writing ability and, when applied to large-scale tests, can greatly reduce manpower and material resources, improve efficiency, and guarantee the impartiality scores. Technology in the field of education, particularly artificial intelligence, comprehensively and profoundly influences the education concept, teaching model and exam method. Based on speech technology in English listening, oral tests have a wide range of applications. Handwriting recognition and natural language understanding, such as artificial intelligence technology, are also being explored and applied in education examination evaluations. Therefore, it is of practical significance to explore an automatic scoring system that is suitable for nonnative English speakers and has low cost, automation and high accuracy [3-5].

Automatic composition grading involves the use of statistics, natural language processing, artificial intelligence and other technologies to evaluate and grade essays. Automatic composition grading has been widely applied to various examinations; indeed, teaching in the classroom has obtained a certain effect, but in the process of using an automatic scoring system, it has been found that even if the input of an article has nothing to do with the thesis topic, as long as there are not too many grammar and vocabulary errors and high scores can be obtained, researchers can realize the importance of track detection to the thesis [6]. Since the 1960s, with the rapid development of natural language processing technology, automatic composition scoring systems have made great progress and have gradually been introduced for a variety of teaching and exam uses. The PEG scoring system does not use natural language processing technology, there is

no study of the composition or content of the chapter structure, and the theme of the thesis is not considered [7]. The IEA scoring system effectively grades sample essays on a variety of topics, automatically judges the content and quality of essays and provides quick feedback. The E-rater grading system, with its complex feature engineering, can better reflect the quality of composition, so its scoring results are highly consistent with those of manual grading. IntelliMetric uses standardized scoring rules and follows the human brain's judgment of points to extract relevant characteristics of essays and then grades essays based on a constructed model [8]. The BETSY scoring system can first extract the characteristics of the quality of a composition and then, according to these characteristics, the thesis is divided into several different levels of people. After manual annotation data are used as the training sample set, the classification of the training to obtain the composition model needs to follow the same method to test the composition, and the extracted features of a classification model can be assigned to the corresponding collection. The above systems mainly use regression and classification methods to score compositions. In recent years, with the rapid development of deep learning technology, many scholars have attempted to use neural networks to grade English compositions [9, 10]. At present, the composition of the track detection method has a certain effect but also has obvious problems: based on the supervised method, the accuracy is higher, but in daily teaching use, it is flexible in composition. Once the system does not include the new theme in the corpus proposition, track detection accuracy will be discounted, and this method is only applicable to large tests. Based on the unsupervised method, user operation is relatively simple and can also adapt to a variety of different propositions, but the current accuracy is not high and cannot meet the requirements of use [11]. Feature extraction may affect the selection of the training model in the process of constructing an automatic composition scoring model. Therefore, the interaction between these two aspects should be fully considered in the process model construction to select a more appropriate feature extraction method and training model. Most automatic composition grading models can achieve good results, but in supervised learning, especially when the number of candidates is large, much effort is needed for composition annotations, and at the same time, the training process is often dependent on the composition title information and has widespread migration problems, so automatic composition grading also needs to be further examined [12-15].

At present, although the momentum of the development and application of artificial intelligence auxiliary to English writing is good, there are few studies in this field on how to combine students' autonomous learning and improve the enthusiasm of students practising writing outside the classroom for autonomous learning, lifelong learning, and learning views; therefore, it is necessary to conduct further research on the English composition score method [16]. This paper discusses how to apply the machine automatic scoring scheme to composition scoring more effectively to ensure the objectivity, fairness and accuracy of composition scoring in various English exams. This paper examines an automatic scoring system based on artificial intelligence technology English composition design and application with the goal of

exploring the teaching effect of improving English writing classes, improving students' self-efficacy and innovation and cultivating their autonomous learning and consciousness of lifelong learning. Ensuring that students' English composition examination papers are high quality is a good objective and worth reviewing, which will provide a rigorous basis for teaching improvement and talent selection.

Despite the evolving landscape of English teaching and grading, there remains a critical gap, that of the effective and efficient application of modern day technologies, such as artificial intelligence, in the field of English composition writing. English composition education, especially among non-English majors at independent universities, has long suffered from the problems of traditional rote learning, lack of individualized attention and ineffective qualitative assessment. Moreover, the emphasis on understanding student self-efficacy and motivation for autonomous learning in the context of AI-led teaching has been underexplored. This paper seeks to elucidate this understudied area, with a specific focus on nonnative English speakers.

The above work mainly discusses the application of an automatic English composition scoring system based on artificial intelligence technology in college English writing teaching. There are some defects in the traditional teaching mode; for example, correcting compositions consumes teachers' energy and leads to an imbalance in the writing teaching process. Therefore, the introduction of an automatic grading system can improve the efficiency and quality of writing teaching. In general, this paper first provides a brief overview of the application of artificial intelligence-based automatic scoring systems in college English writing teaching. At the same time, it also highlights some problems that need further research and improvement and emphasizes the importance of improving teaching effects and cultivating students' self-learning consciousness through this technical means.

II. TECHNICAL THEORY OF AUTOMATIC COMPOSITION GRADING

Automatic composition scoring mainly involves using natural language processing technology to process composition text content and employing statistical methods for analysis and prediction. Among the many types of questions on an English test, English composition questions can most comprehensively reflect an examinee's comprehensive ability to use English. Through writing, examinees can express and transmit their thoughts and opinions and teachers can examine students' logical thinking and language expression ability.

A. An Overview of Related Natural Language Processing Techniques

Word segmentation and clause segmentation are the basis of natural language processing. English word segmentation is relatively simple, generally using spaces and punctuation for natural separation but also a small number of abbreviations. Clause segmentation refers to an article being divided into a single sentence, usually according to punctuation. The technology of English word segmentation and clause

segmentation is currently quite perfect, and there are many open technologies that are very effective in use. A part of speech is the basic grammatical attribute of a word and is generally called part of speech. Part of speech tagging refers to considering the grammatical category of the vocabulary in a sentence, noting its parts of speech and marking it. The common parts of speech of words are nouns, adjectives, adverbs, verbs and so on. Part-of-speech tagging is one of the basic problems of NLP because data preprocessing of many tasks in NLP requires part-of-speech tagging. Word form reduction is an important part of text preprocessing. In English, it generally refers to the restoration of words in any form to the general tense [17,18]. To put it simply, word restoration removes the affixes of a word and keeps only the main part of the word. Generally, restored words also exist in the dictionary. Form reduction is similar to stem extraction, but it is possible that the word from stem extraction does not appear in the dictionary [19].

Generally, English composition questions have the following characteristics:

1) *Lexical features*: English has strict requirements on the form of words; for example, there are clear usage scenarios for singular and plural nouns.

2) *Phrasal features*: English phrases have many types, such as noun phrases, verb phrases, and prepositional phrases. The collocations of these phrases generally have fixed forms and become modules that constitute sentences. This modular structure ensures the dominant characteristics of English forms.

3) *Syntactic features*: The basic sentence structure is subject and predicate, but English also has complex clauses to express rich content, and the existence form of clauses is flexible.

4) *Structural features*: Cohesion between sentences and paragraphs is the basis of coherence in English composition, and coherence is an important prerequisite for rigorous structure.

The general block diagram of the model is shown in Fig. 1. Given the characteristics of a composition, we should consider the following:

1) *Vocabulary of the composition*: According to the number of novel words in the composition, the number of backbone words is used to evaluate whether students' vocabulary is qualified, and according to the spelling of words, their memory of the vocabulary is evaluated.

2) *Composition syntax*: The use of complex clauses is an important indicator of an examinee's command of English.

3) *Whether the composition structure is rigorous*: The main test for students before and after the description needs to be logical, and the context needs to be appropriate.

4) *Composition content*: This mainly investigates whether the composition content is rich and closely related to the topic.

Therefore, we can find English essay scoring with a strong subjectivity, while a large current test will be equipped with corresponding criteria for English composition, but the scoring

criteria from the linguistics angle only provide guidance and are not combined with specific question operability, which is given a set of scoring rules specific to the process of evaluation [20,21]. Careful evaluation and discussion by highly specialized experts is often needed to determine operational scoring criteria.

B. Evaluation Methodology

The Pearson correlation coefficient is a common linear correlation coefficient that can be used to measure the degree of linear correlation between two variables. For linear variables M and N , for example, the Pearson correlation coefficient can be used to measure the related degree. For x , the value of x ranges from $-1 \sim 1$, and the absolute value of x tends to be closer to 1, showing that the strength of the correlation of M and N is closer to zero, indicating a weaker correlation. A positive x suggests a positive association between M and N , and a negative x indicates a negative correlation [22]. Pearson's correlation coefficient is equal to the covariance between linear variables M and N divided by the product of their standard deviations, as shown below:

$$\rho_{xy} = \frac{\text{cov}(M, N)}{\sigma_M \sigma_N} = \frac{E(M - \mu_M)(N - \mu_N)}{\sigma_M \sigma_N} \quad (1)$$

First, calculate the standard deviation and covariance of samples, that is, calculate the Pearson correlation coefficient between samples, denoted as r :

$$r = \frac{\sum_{i=1}^n (M_i - \bar{M})(N_i - \bar{N})}{\sqrt{\sum_{i=1}^n (M_i - \bar{M})^2} \sqrt{\sum_{i=1}^n (N_i - \bar{N})^2}} \quad (2)$$

r can also be estimated by means of the average standard score of sample points, and the calculation result is equivalent to Eq.(2):

$$r = \frac{1}{n-1} \sum_{i=1}^n \left(\frac{M_i - \bar{M}}{\sigma_M} \right) \left(\frac{N_i - \bar{N}}{\sigma_N} \right) \quad (3)$$

where, $\frac{M_i - \bar{M}}{\sigma_M}$, \bar{M} and σ_M are the standard score, sample mean, and sample standard deviation for sample M_i , respectively.

In the process of evaluating the automatic scoring system of composition, we mainly compare the scoring of the system with the manual scoring. In this model, the following three indicators are mainly referenced: the average error of scoring, the average accuracy of scoring, and the relevance of scoring [23]. The formulas are as follows:

$$\text{AverageScoreError} = \frac{\sum_{i=1}^N |x_i - y_i|}{N} \quad (4)$$

$$\text{AverageScoreAccuracy} = \left(\frac{\sum_{i=1}^N |x_i - y_i|}{y_i} \right) \frac{1}{N} \quad (5)$$

$$\text{ScoreRelevance} = \frac{N \sum_{i=1}^N x_i y_i - \sum_{i=1}^N x_i \sum_{i=1}^N y_i}{\sqrt{N \sum_{i=1}^N x_i^2 - \left(\sum_{i=1}^N x_i \right)^2} \sqrt{N \sum_{i=1}^N y_i^2 - \left(\sum_{i=1}^N y_i \right)^2}} \quad (6)$$

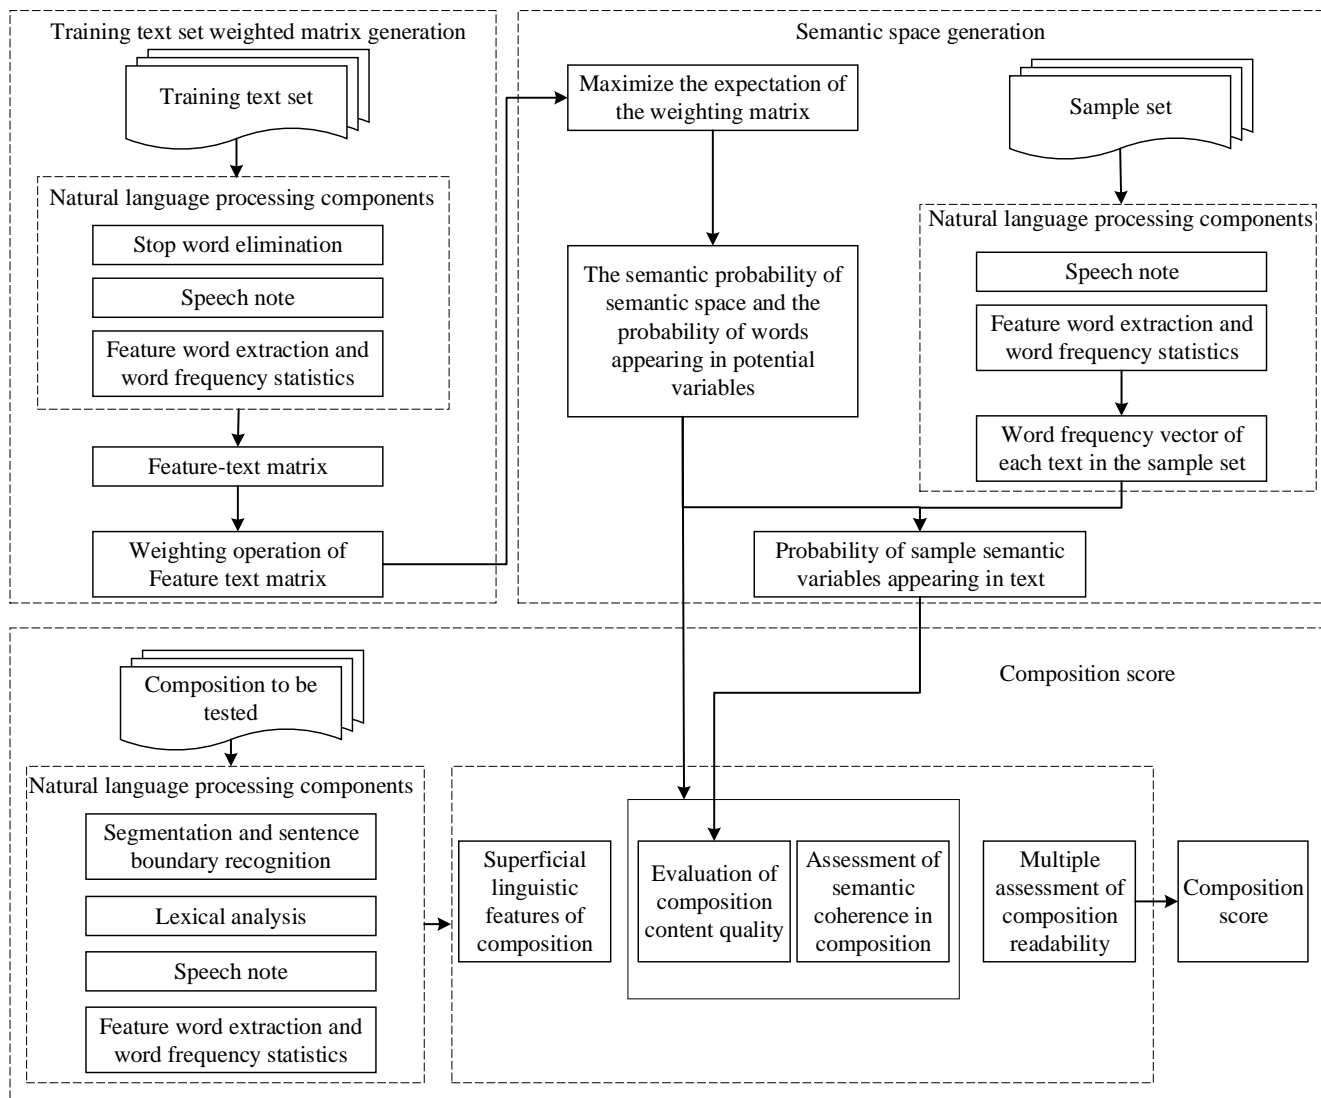

Fig. 1. General block diagram of the model.

C. Neural Network Applications in Natural Language Processing and Composition Grading

Neural networks have always been a research hotspot in artificial intelligence, cognitive science, nonlinear dynamics and other related fields. Neural networks have been used for academic research in recent years. Over the course of these studies, hundreds of neural network models, including pattern recognition, associative memory, signal processing, control engineering, expert systems, combinatorial optimization, image processing and computer graphics, and many other aspects, have been proposed and have made remarkable progress [24]. At present, deep learning has also been introduced in the natural language field, using the concept of word vectors to enable neural networks to complete the work accomplished in the field of statistics. It can be said that neural networks have begun to show advantages in the field of natural language processing. In the process of automatic composition scoring, the biggest problem that puzzles researchers is how to construct a reasonable model for the characteristics obtained from statistical quantification so that it

can evaluate the composition quality well. Because there are many factors that determine the quality of a composition, many different text features can be extracted when the text is processed. These features are complex and changeable, and it is difficult to model them with traditional mathematical theory. Through the understanding of the basic principle of neural networks, combined with the relevant research on automatic scoring technology of composition, the features extracted from composition are processed by artificial neural networks, and the learning, associative memory and distributed parallel information processing functions of neural networks are used to simulate the thinking mode of the human brain [25,26]. Therefore, the constructed neural network model can acquire, learn and reason the expert-rated experience from a large number of expert-rated articles, determine the relationship between the extracted features and the composition score, which is called learning the expert-rated experience, and then grade the text through the learned experience.

After clustering, the word vector has a certain representativeness. Suppose that in the English composition

analysis, after a clustering algorithm has been used to obtain a text clustering, each word in this sentence is in the text clustering, and each different semantic information in the text collection can obtain a word weight value such as frequency and frequency of use [27]. In this paper, by using the automatic grading system of the main statistical, the three characteristics of the term vectors, including word frequency location, size and distribution, the distribution is used to express the sentence, the complexity and diversity of characteristics; for example, in a semantic statement, the author uses more than one word for a description because the authors have a better command of the English language. Based on the above research ideas, this paper extracts and classifies the text features of English compositions.

In the process of grading, teachers can score by item. Usually, there are several indices in grading that are extracted from this model and include the following: score of content quality, semantic coherence, superficial linguistic features of text, and text readability indices. Among them, the semantic score has the largest proportion and indicates whether the central idea of the composition is distinctive and meets the requirements of the topic. If a composition is off topic, then it will have few points. Semantic coherence is also very important; it indicates that the composition of the thought content is consistent, there is a natural smooth transition between statements, text is characterized by shallow linguistics statistics in the text, the word count, the number of sentences, paragraphs and the number of complex words are appropriate, and the main purpose is to evaluate the level of the students to master words, writing skills, etc. The readability index of a text indicates that the text is worth reading. This model uses the features of the existing text to score the text comprehensively.

III. DESIGN AND IMPLEMENTATION OF AN AUTOMATIC SCORING SYSTEM FOR ENGLISH COMPOSITION

A. Requirement Analysis of System

Proposition composition is very common in the daily teaching of a thesis topic. This article designs rating systems, mainly for the proposition composition rate, so the rating system needs to consider not only the composition, such as vocabulary, grammar, and sentences, but also whether the content of the thesis tracks. At the same time, the system's performance and ease of use are also very important [28]. The functional requirements of the system are as follows:

1) The system can easily input composition content and can be repeatedly modified and scored.

2) The system can score multiple compositions at one time, which is convenient for teachers to score the whole class compositions.

3) The interface of the system should be as simple and intuitive as possible so that users can use it quickly and conveniently.

4) The system can efficiently identify the topic of the essay and judge whether the content of the essay to be graded fits the topic.

5) The system can flexibly configure the topic of the thesis composition, which is convenient for users when scoring different thesis compositions.

The automatic scoring system based on the above requirements will be divided into seven modules: login information maintenance, sample volume, candidate set generation, experts, screening and grading, model training and essay scoring, password changes and user information management, including the composition of model training and essay scoring automatic grading and result output two functions.

In summary, an expert-assisted automatic scoring process of English composition can be obtained. Its main workflow includes test paper cutting, image processing, sample paper candidate set generation, sample paper screening and scoring, scoring model training, automatic scoring of composition and result output. The automatic scoring process of English composition is shown in Fig. 2.

1) *Test paper cutting*: The technical staff adopts cutting software to batch cut all candidates' answer sheet images in accordance with the established cutting scheme, forming a separate English composition answer image test paper library.

2) *Image processing*: The English composition answer image examination paper library is processed and the composition content in the picture is obtained and saved as a text form, which is output into a file according to a specific format.

3) *Sample paper candidate set generation*: The machine adopts certain technical means to traverse the whole composition database and screen out the sample paper candidate set that can fully reflect the whole examination paper library of each grade of examination paper level.

4) *Sample volume screening and scoring*: Experts screen relatively uniform sample volume sets from sample volume candidate sets and score them.

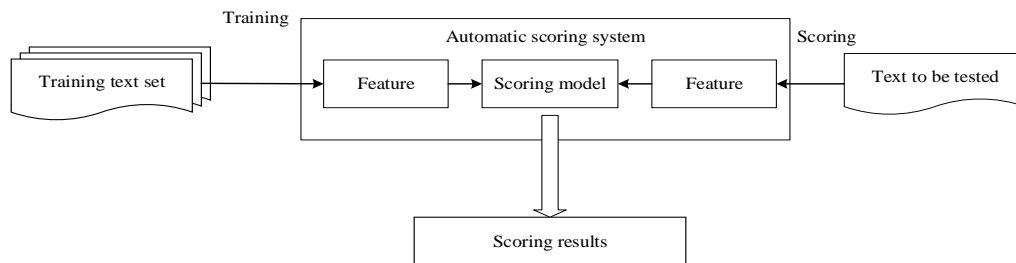

Fig. 2. Automatic scoring process of English compositions.

5) *Training of the scoring model*: The automatic writing scoring model is trained by using the set of selected sample papers and the scores of experts on the set of sample papers as training sets.

6) *Automatic composition scoring*: The automatic composition scoring model obtained by training is applied to paperless marking instead of marking teachers for composition scoring.

7) *Output of scores*: The scores are output.

B. Preprocessing and Feature Extraction for Automatic Grading of English Composition

Before feature extraction of the document, it is necessary to preprocess the composition to some extent to extract feature items. First, it is necessary to divide the composition into paragraphs, sentences, punctuation and words of the text. The obtained paragraphs, sentences, punctuation marks and words are stored separately for the statistical analysis of lexical features and structural features. Natural language processing (NLP) technology is used to tag the parts of speech in the articles to facilitate the statistical analysis of syntactic features and the detection of word errors and grammatical errors. In this paper, the natural language processing tool developed by Stanford University is used for text segmentation and part-of-speech tagging [29].

Composition feature extraction is the core of automatic grading to solve the English composition problem. Because, unlike humans, a computer cannot understand the connotation of a composition or gift and cannot appreciate and evaluate the merits of a composition, it needs to have quantitative data for calculations. Therefore, in the process of implementing automatic grading composition, we need to extract some quantitative data from the text for the computer to calculate and process these data. These data can reflect the real writing level of students. Through these data, we can establish a certain mathematical model, which can be an effective evaluation of students' writing.

The model mainly covers 64 features of composition, such as vocabulary use, phrase collocation, sentence, coherence, organizational structure and fluency, and then divides these features into three types: morphology, syntax and structure. Training sets are used to train the designed neural network [30]. Then, it evaluates the linguistic quality and organizational structure of the composition from the aspects of morphology, syntax and structure. In addition to the evaluation of the above three aspects, this paper also analyses and evaluates the semantic content of the text. Finally, the characteristics of the above aspects are comprehensively scored.

$p(d_i)$ represents the probability of document d_i appearing in the dataset, and $p(z_k|d_i)$ represents the probability distribution of the topic of k document d_i ; $p(w_j|z_k)$ represents the probability distribution of words in topic z_k , each topic

follows a polynomial distribution over all terms, and each document follows a polynomial distribution over all topics. Based on the above probability distribution, a document d_i is randomly selected according to the document probability distribution $p(d_i)$ in the dataset, the topic z_k is selected according to the document topic probability distribution $p(z_k|d_i)$, and then the word of the document d_i is selected according to the keyword probability distribution $p(w_j|z_k)$ of the topic z_k . The data that we can observe are (d_i, w_j) , and z_k represents the implicit variables. The joint distribution of (d_i, w_j) is:

$$p(d_i, w_j) = p(d_i)p(w_j|d_i) \quad (7)$$

$$p(w_j|d_i) = \sum_{k=1}^K p(w_j|z_k)p(z_k|d_i) \quad (8)$$

The $p(z_k|d_i)$ and $p(w_j|z_k)$ distributions correspond to two sets of polynomial distributions. To estimate the parameters of these two sets of distributions, the expectation maximization algorithm should be used. The EM algorithm is divided into E steps and M steps, where the E step is used to solve the post probability distribution of the implicit variable z_k when d_i, w_j is known, and the formula is as follows:

$$p(z_k|d_i, w_j) = \frac{p(w_j|z_k)p(z_k|d_i)}{\sum_{k=1}^K p(w_j|z_k)p(z_k|d_i)} \quad (9)$$

The left side of the formula represents the probability of the occurrence of the k th implied topic under the probability of the occurrence of the i th document and the j th word. Step M is used to solve the posterior probability distribution $p(w_j|d_i)$ of topic words and topic documents when $p(z_k|d_i, w_j)$ are known. The formula is as follows:

$$p(w_j|z_k) \propto \sum_{i=1}^N n(d_i, w_j)p(z_k|d_i, w_j) \quad (10)$$

$$p(z_k|d_i) \propto \sum_{j=1}^M n(d_i, w_j)p(z_k|d_i, w_j) \quad (11)$$

It can be found from the above formula that the E and M steps of the expectation maximization algorithm depend on each other, and the three distributions of , , and can be obtained $p(z_k|d_i, w_j)$ $p(w_j|z_k)$ $p(z_k|d_i)$ after a continuous iterative solution. The scoring process of the composition scoring system is shown in Fig. 3.

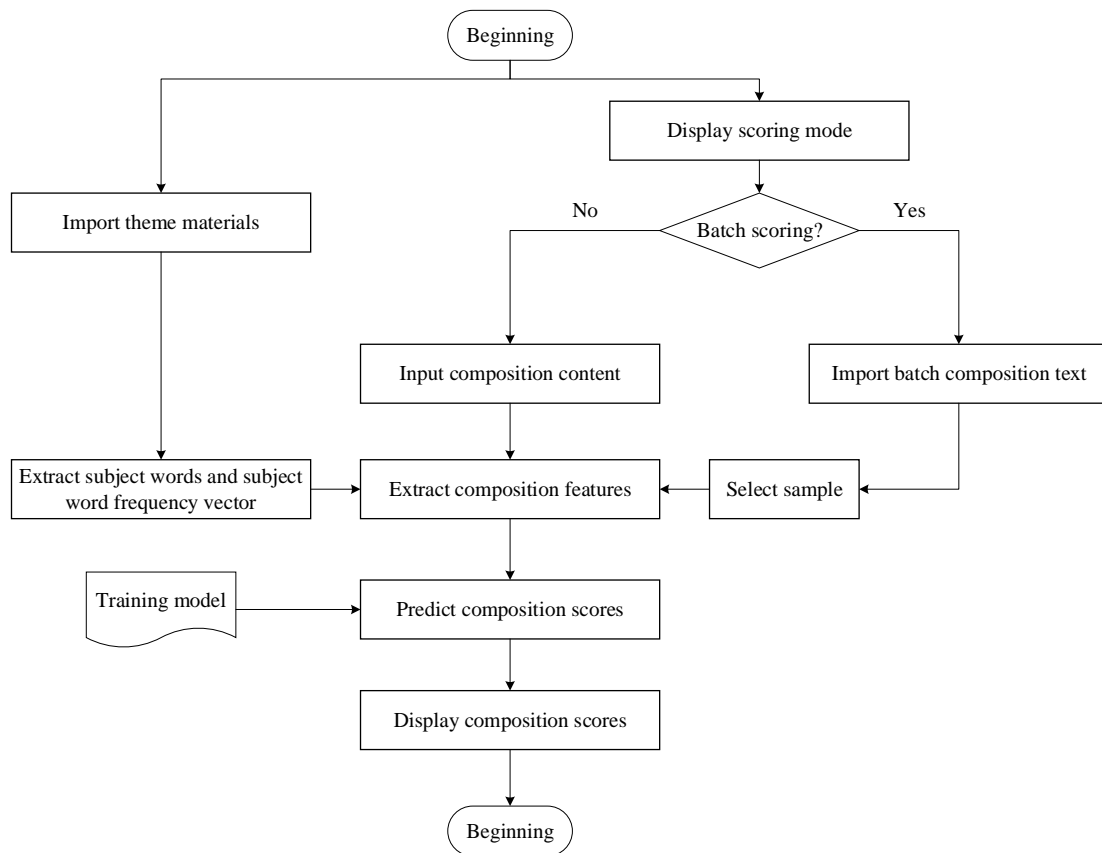

Fig. 3. Scoring process of the composition scoring system.

IV. SYSTEM TEST AND ANALYSIS

A. Evaluation and Verification of an Automatic Scoring System for Composition Based on Word Vector Clustering

To verify the scoring effect of the automatic scoring system based on word vector clustering, this paper takes the standard data provided in a composition scoring competition as the research object, and the total amount of processing of various samples is shown in Fig. 4. In this verification, all the samples except the two parts of the calibration set and the exception answer were scored by a computer. According to the results, the intelligent score of Chinese composition was 420070, accounting for 99.82% of the total sample size, and the intelligent score of English composition was 418820, accounting for 99.53% of the total sample size. The abnormal samples included high similarity with the Chinese text, high similarity with the current test paper (reading comprehension), and high similarity with each other. There were 235 Chinese compositions, accounting for 0.06% of the total test papers. English composition 1469, accounting for 0.35% of the total examination papers. The subject expert group conducts targeted quality inspection re-evaluation on abnormal samples.

In this paper, 235 Chinese compositions and 1469 English compositions were selected and matched with the standard target text. The comparison of the bit error rate of key word recognition is shown in Fig. 5. The statistical results are as follows: the recognition accuracy of Chinese characters is 97.6%, and the recognition accuracy of English words is

97.3%. This high-precision transliteration recognition has three important factors: first, examinees' attention to the composition of the college entrance examination ensures the standardization of writing. Second, the Chinese composition area is designed in square paper format, and the English composition area is designed in a line-by-line underline format to ensure the writing position of characters. Third, there are advanced recognition algorithms. These three factors can ensure the accurate recognition of all the scoring samples, and the overall transliteration recognition rate should be kept at approximately 97%, which can meet the actual requirements of marking papers.

Fig. 4. Total amount of processing of various samples.

Fig. 5. Comparison of the bit error rate of key word recognition.

B. Evaluation and Comparison of Automatic Scoring Algorithms for Composition

The comparison of the training time of different algorithms is shown in Fig. 6. The average score of the machine score and the average score of the manual score were less than 1 point, and the standard deviation was basically the same. The correlation between the machine score and report score is 0.95, and the consistency rate is 95.24%, which is very close to the correlation and consistency rate of Manual 1 and Manual 2 and is at a high level, which proves that the overall effect of the intelligent score is good. At the same time, it also shows from another angle that the intelligent marking system has a very high learning ability for the calibration set and basically reaches the level of mastering the marking standards of the teachers. It can be seen that most students do not resist the use of correcting network writing, and the correcting network has a good impression. The correcting network writing system makes sense and can stimulate students' desire for writing and continuous improvement. This model provides statistics on the content quality, coherence, readability and basic information of the composition and gives students detailed feedback so that students can better understand their own composition.

As seen from the prediction results of automatic scoring based on the random forest model in the figure, in the scoring results of the composition subset based on the random forest algorithm, the quadratic weighted K value is generally above 0.78, the highest value is 0.905, and the average value is 0.862. The lowest value of weighted K obtained by the international scoring algorithm is 0.654, the highest value is 0.755, and the average value is 0.792. In terms of the prediction results, the calculation method in this paper is obviously better than the existing prediction model, 10%~18% higher than the general algorithm, and can basically achieve the matching effect with the artificial score. Further analysis of the composition sample structure shows that the random forest algorithm based on the bagging method can effectively avoid overfitting error in the case of an insufficient sample size after obtaining accurate clustering vector features, thus reducing the variance value. When the number of samples is less than 1400, the quadratic weighted K value of the conventional model prediction algorithm decreases obviously and is basically lower than 0.7. The average score deviation

rate of each formula combination is shown in Fig. 7.

This model not only gives the composition of the overall score as the composition of the machine but also, in this paper, extracts feature feedback to assist students in better understanding their writing level. This process uses internet technology to achieve a short score. With this composition, students can receive reliable information in a timely and effective manner, which is also one of the advantages of intelligent reading systems. As shown in Fig. 8, the score of the essay given by the machine is 8.41; while the score given by the teacher manually is 9.0, indicating that the consistency between the essay and the manual score is very high. The text coherence is 0.25, 0.77, 0.62 and 1.0, indicating that the text coherence is very good. The readability of the text is 11.89, the comprehensibility is 193.98, and the writing level is 10.82. In the linguistic features of the text, the total number of words is 204, word density is the ratio of the number of different words to the total number of words, word density is 0.66, complex word digit number is 36, sentence number is 17, paragraph number is 3, and average sentence length is 12. All these features can effectively give students an intuitive understanding of their own compositions. Therefore, the students know more about their own composition to improve the efficiency of their learning. The impact of different training sets on model performance is shown in Fig. 8.

Fig. 6. Comparison of training time of different algorithms.

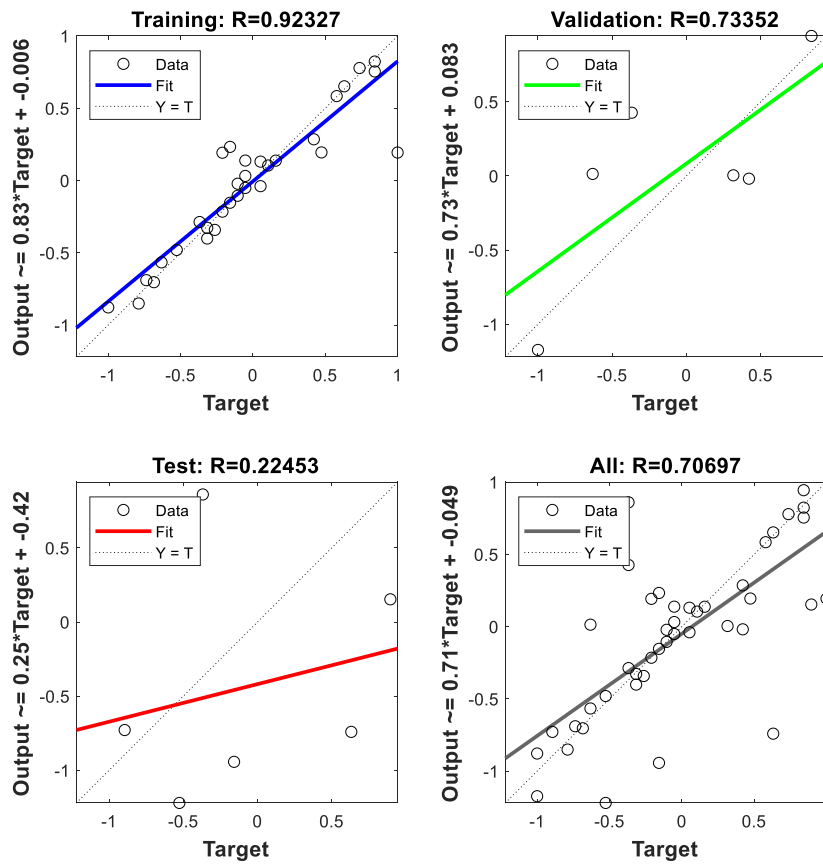

Fig. 7. Average score deviation rate of each formula combination.

Fig. 8. Impact of different training sets on model performance.

V. ANALYSIS

An AI-based English essay grading system utilizes artificial intelligence technology to automatically evaluate and score essays written in the English language. This advanced system has gained popularity due to its potential to efficiently assess a large number of essays with consistent accuracy, saving time for educators and providing immediate feedback to students. The advantages of an AI-based English essay grading system lie in its consistency, time efficiency, scalability, immediate feedback, objective evaluation,

enhanced learning experience, consistent feedback, and analytics capabilities. While it has limitations in contextual understanding and ethical considerations, integrating this technology with human expertise can lead to a balanced approach that leverages the strengths of both artificial intelligence and human judgment to improve the overall quality of writing assessment and instruction.

VI. CONCLUSION

With the further development of global economic integration and internet technology, English has become the mainstream language for people worldwide to communicate. Therefore, an increasing number of governments are paying attention to the learning of English. Early essay scoring was performed manually, that is, when some teachers read the composition of the paper-based test answers directly to score them, the results are affected by the fact that some teachers' subjective factors are quite large, which is almost impossible to achieve in the large exam score standard consistency requirements, and given how much is required by the evaluation objective, impartiality is more difficult to achieve. Over time, the method of writing assessment has reached the stage of combining intelligent correction with teacher correction. To date, the introduction of artificial intelligence into college English writing teaching can effectively assist teachers in completing composition correction and data analysis more efficiently to a certain extent, encourage students to evaluate, learn from each other more conveniently, and cultivate students' awareness of independent English

writing and lifelong learning. Therefore, this paper examines how to apply an automatic scoring scheme to composition scoring more effectively and provides some reference for research on the automatic scoring direction of English composition under the background of artificial intelligence. The main research contents and conclusions are summarized as follows:

1) Natural language processing technology is used to analyse the text features of a composition, including part of speech tagging, syntactic analysis and article organization structure analysis.

2) Through the correlation analysis of the statistical features, the features related to scoring were extracted, and the relevant features were classified according to the different angles of the features reflecting the quality of the composition.

3) Semantic analysis technology was combined to analyse the semantic content of the composition and obtain the content quality characteristics of the composition.

4) The neural network is successfully applied in the automatic composition scoring process, and the mapping relationship between text features and composition scoring is obtained.

5) A comprehensive score for the composition was given based on its morphology, syntax, organizational structure and content quality.

VII. FUTURE WORK

This paper can not only directly evaluate the language quality and organizational structure of a composition but also evaluate the content quality of the composition and conduct statistical analysis of the lexical use, syntactic use, semantic coherence and readability of the composition. Students and teachers can quickly obtain the quantitative indicators of a composition, providing a powerful reference for teachers and students and not only greatly reducing teachers' workload but also increasing the number of English learners' writing. Due to the large number of English learners in China and the shortage of teacher resources, the English composition scoring system has great application value. Although this model has certain functions, it still has certain deficiencies, which are embodied in the following aspects:

1) In this article, the model used in the training process of neural networks included a Chinese English learner corpus, and 1000 compositions were chosen. Among them, 720 were used as the training set, the training set for neural network training was somewhat smaller, and the composition of the training set was not rich. If the training set were larger, the training content would be richer and the performance of the neural network and the accuracy of scoring would be improved.

2) In the semantic analysis module, this model uses more than 20 high-scoring compositions with different topics as sample articles. If more sample compositions with different topics were added, the accuracy of semantic scoring would be greatly improved, and the comprehensive scoring accuracy of compositions would also be greatly improved.

An Efficient Deep Learning with Optimization Algorithm for Emotion Recognition in Social Networks

Ambika G N¹, Dr. Yeresime Suresh²

Assistant Professor, CSE Dept., BMS Institute of Technology and Management, Bangalore-560064, India¹
Associate Professor, CSE Dept., Ballari Institute of Technology & Management, Ballari-583104, India²

Abstract—Emotion recognition, or computers' ability to interpret people's emotional states, is a rapidly expanding topic with many life-improving applications. However, most image-based emotion recognition algorithms have flaws since people can disguise their emotions by changing their facial expressions. As a result, brain signals are being used to detect human emotions with increased precision. However, most proposed systems could do better because electroencephalogram (EEG) signals are challenging to classify using typical machine learning and deep learning methods. Human-computer interaction, recommendation systems, online learning, and data mining all benefit from emotion recognition in photos. However, there are challenges with removing irrelevant text aspects during emotion extraction. As a consequence, emotion prediction is inaccurate. This paper proposes Radial Basis Function Networks (RBFN) with Blue Monkey Optimization to address such challenges in human emotion recognition (BMO). The proposed RBFN-BMO detects faces on large-scale images before analyzing face landmarks to predict facial expressions for emotional acknowledgment. Patch cropping and neural networks comprise the two stages of the RBFN-BMO. Pre-processing, feature extraction, rating, and organizing are the four categories of the proposed model. In the ranking stage, appropriate features are extracted from the pre-processed information, the data are then classed, and accurate output is obtained from the classification phase. This study compares the results of the proposed RBFN-BMO algorithm to the previous state-of-the-art algorithms using publicly available datasets derived from the RBFN-BMO model. Furthermore, we demonstrated the efficacy of our framework in comparison to previous works. The results show that the projected method can progress the rate of emotion recognition on datasets of various sizes.

Keywords—Blue monkey optimization (BMO); deep learning; electroencephalograph (EEG); emotion recognition; human-computer interaction (HCI); radial basis function networks (RBFN)

I. INTRODUCTION

This template, modified in MS Word 2007 and saved as a "Word 97-2003 Document" for the PC, provides authors with most of the formatting specifications needed for preparing electronic versions of their papers. All standard paper components have been specified for three reasons: (1) ease of use when formatting individual papers, (2) automatic compliance to electronic requirements that facilitate the concurrent or later production of electronic products, and (3) conformity of style throughout conference proceedings.

Margins, columns widths, line spacing, and type styles are built-in; examples of the type styles are provided throughout this document and are identified in italic type, within parentheses, following the example. Some components such as multi-leveled equations, graphics, and tables are not prescribed, although the various table text styles are provided. The formatter will need to create these components, incorporating the applicable criteria that follow.

Language, text, action, and other means are all ways that people can express themselves. How to recognize and accurately detect human facial expressions has emerged as a hot research area given the rapidly expanding artificial intelligence field [1]. Numerous businesses including amusement, security, online education, and intelligent medical care, use facial expression detection technologies [2]. Facial expression is a critical factor in human emotion recognition. Since a person's facial expressions convey their emotions, "facial recognition" [3] and "emotion recognition" are often used synonymously. Significant progress has been made in the automotive industry, augmented robotics, reality, neuromarketing, and interactive games. There is growing interests in enhancing all facets of human-computer interaction, particularly in recognizing human emotions.

Facial expression recognition can be used to monitor driver fatigue. An alarm is sent when the driver's face exhibits signs of drowsiness, and a camera records the driver's expression in real time while also analyzing the driver's mental state. This can assist with avoiding traffic accidents induced by fatigued driving. The elderly can benefit from installing a human-computer interaction system with a recognition of facial expressions feature in nursing homes or elderly homes. Facial expression recognition technology can track how each student responds to the lecture and provide the instructor with immediate feedback, which can, to some extent, advance the superiority of education [4]. During the online teaching process, it can be difficult for the instructor to keep track of each student's reaction, but it is still important to make timely adjustments to the course progress.

In the conventional method for recognizing facial expressions, a photograph is taken, its attributes are extracted, and then the image is identified using machine learning [5]. The difficult feature extraction method and the identification performance being easily influenced by the environment and a person's facial activity are some drawbacks of this strategy.

One of today's most vital and challenging techniques is emotional recognition. Applications for emotion recognition include helping to measure stress levels and blood pressure, among other things. When using emotional techniques, one can apply the functions of happy, sad, calm, and neutral facial features. The human body's inner workings can be detected using various methods and algorithms. Real-time emotional recognition can pick up on human thought processes. Identifying diseases early using emotional recognition shields can save humans from severe infections or illnesses. Emotional recognition has the main benefit of assisting in identifying human mentalities without using questions.

Machine learning algorithms accurately predict facial emotions like stress and sadness. The results for emotion recognition, such as sadness and rage, were improved when the ECG and PPG were merged with the 28 features take out from algorithms using machine learning [6]. Without knowledge sharing, facial expressions are essential for determining human mentality. In a few articles, datasets from 2010 to 2021 are combined, along with the majority of the features collected and categorized using deep learning and to support vector machine approach, hence increasing classification accuracy and outcomes.

A subset of machine learning methods called "deep learning" can be used to analyze facial expressions and identify emotions. However, the amount of data will affect how well it works. As data volume rises, performance gets better. Deep learning cannot be applied to facial expression datasets because they are too small. Several studies have found that augmentation techniques like cropping, scaling, translating, or mirroring during the pre-processing stage increase the alteration and, subsequently, the quantity of information.

In various pattern recognition and classification issues, neural networks have been used because they have the best approximation capability. Along with the back-propagation algorithm, face recognition has also used convolution neural networks and multilayer perceptron (MLPs) [7]. Because of its slow convergence rate and uncertainty about whether it will reach global optimums, the back-propagation learning procedure is computationally intensive. Due to their outstanding approximation accuracy and quick processing, radial basis function neural networks (RBFN) with a single hidden layer have been used for facial recognition applications. Radial basis functions in the hidden layer nonlinearly map the contribution face information to linearly divisible information in hidden hyperspace. Some enterprise challenges for hidden layers include defining the RBF unit centers of hidden neurons, their numbers, and the selection and shape of fundamental functions. Second, the success of blue monkey swarms naturally inspired the development of the Blue Monkey (BM) approach, a cutting-edge metaheuristic optimization method. The total number of men in a group is determined via the BM process. Like other forest guenons, blue monkey groups typically only contain one adult male outside the breeding season. With constraints and an unknown search space, this algorithm effectively finds solutions to practical problems. The BM method has some variables and the potential to produce better results [8].

Radial Basis Function Networks (RBFN) with Blue Monkey Optimization is suggested in this paper (BMO). The proposed RBFN-BMO first recognizes faces on large-scale imageries after assessing face landmarks to approximate representations for reaction acknowledgment. The two stages of the RBFN-BMO are convolutional neural networks and patch cropping. The proposed perfect is composed of four categories: feature extraction, ranking, preprocessing and organization. After preprocessing the dataset's collected data for data cleansing, the information is classified, the relevant attributes are extracted from the preprocessed data in the ranking phase, and the correct information is obtained. This study compares the results of the recommended RBFN-BMO method to earlier state-of-the-art methodologies using publicly accessible datasets inferred from the RBFN-BMO model. Furthermore, we have demonstrated that our structure is more efficient than earlier ones.

The projected work is defined in detail below. Section II goes into more excellent aspects of the work associated with the projected outcome. Section III goes over the proposed framework in depth. Section IV goes into great detail about experiment design and performance evaluation. Section V concludes the discussion of future work.

A. Contribution

- Data cleaning and pre-processing are performed on the dataset's collected data.
- The pre-processed data are given the appropriate characteristics during the ranking phase, and the information is then categorized.
- Pre-processing, feature extraction, ranking, and categorization are the four categories that make up the suggested model.
- Before looking at face landmarks to predict facial expressions for emotion detection, the Radial Basis Function Networks (RBFN) - Blue Monkey Optimization (BMO) proposed method first recognizes faces on large-scale images.

II. LITERATURE SURVEY

Chen et al. [9] used a deep sparse auto-encoder network based on Soft-max regression to identify facial expressions of emotion during human-robot interaction. This work minimizes distortion, learning efficiency is determined, and dimensional complexity is measured using the SRDSAN technique. The soft-max simple regression perfect will help categorize the input signal, while the DSAN technique helps with accurate feature extraction.

Babajee et al. [10] suggested using deep learning to recognize human expressions from facial expressions. This paper uses deep knowledge and a convolutional neural network to offer seven methods for identifying facial emotions. This study uses the Facial Action Coding System (FACS) to collect 32,398 facial expressions to identify various types of emotion. The identification approach's failure to be an effective optimization technique is the sole justification for this research.

Satyanarayana et al. [11] used deep learning and cloud access to implement emotional acknowledgment in this study. One of the most effective methods in many presentations is facial emotion recognition. Face recognition makes extensive use of the deep learning algorithm. Her thesis paper examines a variety of emotions, such as sadness, joy, serenity, and rage. The Python code generates a particular IP address for each technique to send this data.

Jayanthi et al. [12] used deep classifiers to develop an organizing strategy for emotional categorizations utilizing speech and static images. One of the most crucial methods for determining someone's stress level is emotion identification. The two traits of emotion perception and speech modulation are essential in determining the stress level in the human body.

Sati et al. [13] used NVIDIA to implement face detection, recognition, and emotion recognition in his paper. In this study by Jetson Nano, face emotion recognition and detection are combined. Facial emotional identifications have historically been among the most challenging techniques to master. This technique's accuracy and classification outcomes can be improved by adding some features. The ANN technique assists in recognizing and classifying facial expressions of emotion.

Wang et al. [14] applied a recently developed deep learning technique in this paper. The four-category deep learning model is used in this paper. Convolutional neural networks and deep architectures fall under the first category. The deep learning model has a significant impact on deep neural networks. This component of the machine learning algorithm is essential. The classification, which includes both linear and nonlinear special functions, is necessary for the accuracy of the data.

The multi-label convolution neural network was implemented by Ekundayo et al. [15] to identify facial expressions and estimate ordinal intensity. This was completed because, while many features, like FER, are consistent with the emotional recognizing method, only one is ideal for the multi-class dynamic classification method. This study utilized a multi-label convolutional neural network.

Using facial expressions, EEG, and machine learning techniques, Hassouneh et al. [16] developed a real-time emotional recognition system. The system could distinguish between smiling, remaining neutral, and losing control. In this study, virtual markers detect facial regression using the optical flow algorithm, since it acknowledges a lower level of computational complexity, the optical flow algorithm system aids in providing people with a physical challenge.

Neuro-sense was used by Tan et al. [17] to implement short-term emotion recognition and comprehension. Spiking neural network simulations of the spatiotemporal EEG patterns served as the foundation for their strategy. The SNN method is used for the first time in this paper. It aids in comprehending how the brain operates. One of the two methods used to analyze the EEG data is arousal-valence space. The various types of segments that make up the arousal-valence space include low arousal, high arousal, high

valence space techniques, and standard valence space methods.

A deep facial expression recognition survey was carried out by Li et al. [18]. One of the system's most significant challenges is recognizing a person's facial expression. The two main challenges to accurate facial expression recognition are a need for training sets and undesirable emotion variations (FER). The data set is first organized using the neural pipeline technique. Consequently, the FER technique's complex problems will be reduced.

Yang et al. [19] used a stacked auto-encoder to implement three-class profound learning-based emotional expressions. This paper demonstrates that discrete entropy calculation can be used to measure the EEG signal. The deep learning algorithm's auto-encoder technique results are more accurate than those from the encoding system's calculation methods. To use the alpha, beta, and gamma values, this method assesses emotions. Classification results are produced more accurately when a deep learning procedure is used. The deep learning procedure typically yields acceptable outcomes for the various classes of emotional recognition.

Yadahalli et al. [20] used a deep learning technique to recognize facial micro expressions. This study uses six different emotional expressions—happy, sad, angry, scared, neutral, and surprised faces—to collect the eight layers of the dataset. Because it has started collecting datasets that contain the FER perfect, the paper assumes that the FER with a CNN improves accuracy and that the removed consequence produces the multimodal facial expression using a single method. Using a single algorithm, the multimodal facial expression is also added to the dataset that has been gathered.

Asaju et al. [21] used a temporal method to recognize facial emotional expressions. This study introduces a CNN-based deep learning procedure that can implement numerous kinds of emotional acknowledgment in the human body. To extract features, VGG-19 methods are used. Both the accurate mapping technique and the recognition of facial emotions method use the BiLSTM architecture.

Yolcu et al. [22] suggested a deep learning-based method for tracking consumer performance patterns that measured head pose assessment and analyzed facial expressions to gauge the level of interest in the product. To follow customer interest, this was done. Deep structured learning was suggested by Walecki et al. [23] as a technique for determining the level of facial expression intensity. Face physics and other pre-processing methods are less critical in deep learning-based face recognition. CNN's convolution layers convolve the input image using various filters. It generates a feature map with fully connected networks to recognize facial expressions.

To identify emotional expressions on faces, Asaju et al. [24] employed the temporal method. This study integrates a CNN with a deep learning technique to create dissimilar kinds of emotional identification in the human body. Use the VGG-19 methods for obtaining features. The title and precise mapping of facial expressions are then carried out using the Bi-LSTM architecture.

Ekundayo et al. [25] implemented a multilabel convolution neural network to recognize facial expressions and estimate ordinal intensities. Although many features can be used with sentimental character segmentation techniques like FER, they are only suitable for some of them for the ideal categorization emotional classification method. Convolutional neural networks with multiple labels are used in this study.

III. PROPOSED SYSTEM

This study suggests combining RBFN and Blue Monkey Optimization (BMO) to acknowledge faces and emotions in high-resolution images. Modules for pre-processing, feature extraction, ranking, and classification can be seen in the block diagram of the proposed system in Fig. 1.

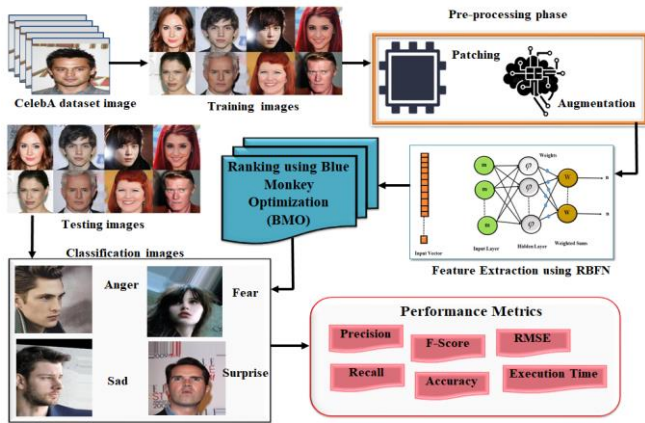

Fig. 1. Proposed method of RBFN-BMO method.

A. Pre-Processing of the Images

Before using the pyramid images approach, the original photographs are downscaled by a feature of 2 until they are 128×128 in dimensions. Additionally, each pyramid image is split into 128×128 pixel-sized patches to simplify processing and reduce memory allocation.

1) *Data augmentation*: Dawn sampling was performed on the input photos using a ratio of 2 up to an image size of 128×128. There was no overlap between the 128×128 patches created from the pyramid photos. If the picture segment is too long for the patches, zeros will be added to make up the difference. Additionally, we employ a data augmentation technique that involves rotating, translating, and flipping the images on their axes at 45-degree perspectives. The data augmentation method increases the number of training examples and progresses the network's ability to simplify under challenging circumstances. The images have been edited to resemble actual facial recognition scenarios. Due to the GPU's memory capacity, we use a batch size of 16 pictures during training. As a result, various combinations of patches for the same image might be created. The initial photo incorporates all sensing forecasts on the same image's patches.

B. Feature Extraction using RBFN

Feed forward neural networks comprise RBFN. The three layers that make up the RBFN's design are the input, hidden, and output layers, as depicted in Fig. 2. Data is sent from the

user's input layer to the concealed layer [26]. Radial basis function (RBF) units, known as hidden neurons, comprise the hidden layer. Each jth RBF unit has a related basis function (φ_j), spread ($\hat{\sigma}_j$), and centre (A_j).

The nonlinear basis functions φ_j are affected by how far the input is from the center of the jth RBF unit. RBFN frequently employs the basic functions Gaussian, multiquadric, inverse multiquadric, and thin spline. The most often used Gaussian basis function was signified in this study as

$$\varphi_j(x) = e^{-\frac{\|m-A_j\|^2}{2\hat{\sigma}_j^2}} \quad (1)$$

The restriction r, which also denotes the function's width, characterizes the spread of the radial basis function, where C_j stands for the jth RBF unit's center. You can think of RBFN as a mapping from (2).

$$R^d \rightarrow R^u \quad (u \gg d) \quad (2)$$

Where u is the amount of RBF units and $P \in R^d$ is the d-dimensional input feature vector. The ith output of the RBFNN, $n_i(m)$, is

$$n_i(m) = \sum_{j=1}^u \varphi_j(x) \times w_{i,j} \quad (3)$$

Where $w_{i,j}$ denotes the degree of connectivity between the ith output neuron and the jth RBF unit.

Fig. 2. Structure of RBFN.

C. Ranking with Blue Monkey Optimization (BMO)

Blue Monkeys are different from the other species. They frequently live in societies where women are the majority, meaning females stay in their natal groups. However, as soon as they reach the mature stage, the males leave their groups [27]. There are usually a lot of females and young in each group of blue monkeys, but only one male. This problem exacerbates the problem of inbreeding. The men leave the group and join another one when they're older. However, finding a new group might take some time, so the males might

initially seem to be by themselves. Regarding social interactions, blue monkeys don't have a perfect sense of intuition [28]. Social interaction only lasts for a short time, typically when playing with and grooming other people.

Babies also connect with the other adults in the group and their mothers. The source of those newborns typically avoids their male counterparts. Baby handlers are the ones who do all the work. The young females tend to the babies and carry and protect them. From this habit, infants pick up how to react like all monkeys.

1) *Group division*: The BMO algorithm imitates the actions of Blue Monkey. Each group of monkeys had to travel through the search area to simulate these interactions. Earlier, it was mentioned that when the monkeys are divided into groups, they start searching for food sources far away in an area where more robust monkeys are out of sight of conventional vision. The young *Cercopithecus mitis* and the male have little to no interaction. Because *Cercopithecus mitis* is a territorial species, young males should venture outside as soon as possible. The dominant male of another family will challenge them. If they succeed in eliminating him, they will assume control of the family and be able to provide young men with food, shelter, and socialization. Blue monkey groups typically consist of a sizable number of females and young, with only one male [29].

2) *Position update*: Each blue monkey in a group updates to the position in the best place within that group. Equations like the ones below describe this behavior:

$$Power_{m+1} = (0.7 * Power_m) + (W_{lea} - W_m) * rand * (Y_{best} - Y_m) \quad (4)$$

$$Y_{m+1} = Y_m + Power_{m+1} * rand \quad (5)$$

W_{lea} stands for the leader weight, W_m for the monkey weight, Y_{best} for the leader location, which can take any value between [0,1], $Power$ for the monkey power rate, and so on.

Using the following equations, the blue monkey's offspring are also updated.

$$Power_{m+1}^C = (0.7 * Power_m^C) + (W_{lea}^C - W_m^C) * rand * (Y_{best}^C - Y_m^C) \quad (6)$$

$$Y_{m+1}^C = Y_m^C + Power_{m+1}^C * rand \quad (7)$$

W_m^C is the child weight at which all weights are random amounts among [4, 6], Y_{best}^C is the child position, Y_{best} is the leader child position, $Rate$ needs to stand for the child power rate, is the leader child weight, and "rand" denotes an arbitrary amount among [0, 1]. Every cycle, the location needs to be reorganized.

Algorithm for Blue Monkey Optimization

```

Initialize the Blue Monkey and their children population
Bm (m=1,...,n)

Initialize power rate and weight of Blue monkey as Power
and W

Where (Power ∈ [0, 1]) (W ∈ [4, 6])

Randomly Distribute Blue Monkey into T groups and
children in one group.

Evaluate the fitness of blue monkey and children in each
group

Select Worstfit and Best fit in  $Y_{lea}^C$  Children group

T=1

While (T ≤ maximum number of group)

    Swap Worstfit =  $Y_{lea}^C$ 

    Update Power and Y position of all blue monkey by
    Eq. (4,5)

    Update Power and Y Position of children by Eq. (6,7)

    Upgrade the fitness of all blue monkeys and kids.

    Most recent Update

    If (New best > Current best) then

        New best = Current best

    End if

T=T+1

End While

The best blue monkey should be returned.
    
```

D. Classification of Emotions Recognition

The centers of hidden neurons or RBFN units can be found using the sub-clusters produced by the proposed RBFN-BMO technique. Since the method evolves the sub-clusters based on the given training statistics, providing the number of sub-clusters for each participant as input for face recognition is unnecessary. Emotion recognition aims to identify a person's emotions. The capacity to perceive emotions varies significantly among people. A significant area of research is emotion recognition with technological assistance. Analyzing facial landmarks, with a focus on the lips, nose, and eyes, is the foundation for identifying emotions. Facial expressions are a huge help in recognizing emotions. The shapes of those sections represent the person's emotions. One can infer a person's emotional state from the points' locations and the distance between them. The main objective was to create the proposed methodology for finding 68 spots; A potential area for emotion detection in each of the locations. The jawline is depicted in points 1 through 17, the left and right brows in points 18 through 22, the left and right eyes in moments 37

through 48, the noise in points 28 through 36, the outer lip area in matters 49 through 60, and the inner lip structure in points 60 through 68. In studies of facial expressions, the location of those points is crucial.

In this study, we suggest using facial features as annotations for emotion recognition. The proposed RBFN-BMO accepts inputs such as high-resolution photos, facial feature annotations, and the face's position. The seven emotions portrayed in this piece are anger, disgust, fear, joy, sadness, surprise, and neutrality. More details about the data set used to train the recommended RBFN-BMO are provided in the following section.

IV. EXPERIMENTAL RESULTS

Details about the experimental setting that was used to develop and evaluate the suggested RBFN-BMO are provided in this section. The experiment was run on a Linux desktop with an Intel i7 processor, 32 GB RAM, and a 4 GB Nvidia GTX960 graphics card. The suggested RBFN was developing using the TensorFlow deep learning framework, cuDNN, and CUDA vibration libraries. For image manipulation, the OpenCV library was used.

A. Dataset Description

We suggest using the celeb datasets [30] to train the suggested RBFN-BMO. There are 202,599 RGB images of well-known people in this dataset. Face, attribute, and landmark acknowledgment was considered when creating the dataset. The CelebA dataset's images are summarised in Fig. 3. This work advocates using facial landmarks and distinctive analysis for face detection and expression acknowledgment.

A training set, a validation set, and a testing set were created from the collected data. The training set consisted of 70% of the data, the validation set of 10% of the training set, and the testing set consisted of 30% of the data.

While pre-processing reduces filter noise, 70% of the data are used as training input. The high dimensionality of the filter is reduced with the help of feature extraction. To decrease the size of the problem space, our work employs various methods for extracting features, such as edge detection. As a result, it generates clear output images with precise dimensional quality. In the data, categorization and part extraction happen simultaneously.

B. Performance Metrics

The effectiveness of the suggested work is assessed using the recognition rate. The classification performance is calculated by dividing the total amount of images into the data sets by the number of facial expressions successfully identified. It is shown as:

The percentage of accurate classifications is measured by precision (Prec). It can be indicated using (8):

$$Precision = \frac{TP}{TP + FP} \quad (8)$$

Fig. 3. Celebrity images data set.

It is also possible to refer to the actual positive rate as the recall rate or recall. It assesses how frequently a classifier gives the right category a favorable result. It is described in (9).

$$Recall = \frac{TP}{TP + FN} \quad (9)$$

The F-Measure represents the harmonic mean of sensitivity and precision (F). It is crucial since higher accuracy typically interprets into lower sensitivity. It can be calculated using (10).

$$F - Score = 2 * \frac{precision * recall}{precision + recall} \quad (10)$$

Accuracy: To calculate the precision of our predicted value, divide all values by the total of true negatives and true positives.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (11)$$

Root Mean Square Error (RMSE)

The only departure from RMSE is the square root sign. The mean absolute error equation is given in (12).

$$RMSE = \sqrt{\sum_{i=1}^n \frac{(y_i - \hat{y}_i)^2}{n}} \quad (12)$$

The messages TP, TN, FP, and FN are confirmed positive, true negative, true positive, and false negative, respectively. The outcome should improve as a component of precision, recall, f-measure, and sensitivity.

1) *Precision analysis*: In Fig. 4 and Table I, the precision of the RBFN-BMO strategy is contrasted with that of other methods currently in use. The graph demonstrates the increased efficiency and precision of the deep learning approach. In comparison to the GRU, LSTM, RNN, DNN, and ANN models, which have precision values of 89.029%, 85.536%, 90.927%, 88.435%, and 93.983% for the 1000 data, the RBFN-BMO model has a precision value of 96.425%. With different data sizes, the RBFN-BMO model has shown its greatest performance. The RBFN-BMO's precision value is 97.927% under 6000 data, compared to the GRU, LSTM, RNN, DNN, and ANN models' precision values of 89.827%, 86.324%, 93.782%, 87.625%, and 95.029%, respectively.

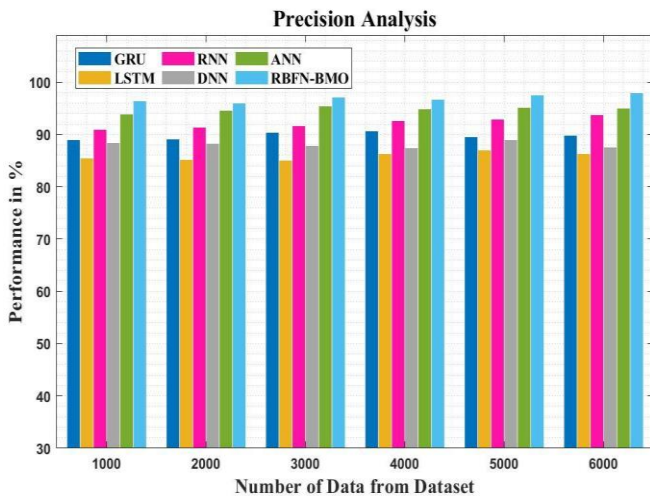

Fig. 4. Precision analysis for RBFN-BMO method with existing systems.

TABLE I. RBFN-BMO METHOD PRECISION ANALYSIS USING EXISTING SYSTEMS

Data from dataset	GRU	LSTM	RNN	DNN	ANN	RBFN-BMO
1000	89.029	85.536	90.927	88.435	93.983	96.425
2000	89.214	85.234	91.425	88.323	94.626	96.029
3000	90.425	85.029	91.728	87.922	95.435	97.182
4000	90.627	86.324	92.637	87.425	94.928	96.728
5000	89.526	86.973	92.938	88.937	95.227	97.632
6000	89.827	86.324	93.782	87.625	95.029	97.927

2) *Recall analysis*: Fig. 5 and Table II illustrate how the RBFN-BMO approach compares to other current methods in terms of recall. The figure demonstrates how the recall performance was enhanced by the deep learning approach. The RBFN-BMO model, for example, has a recall value of 93.827% with 1000 data, while the GRU, LSTM, RNN, DNN, and ANN models have recall values of 79.637%, 80.928%, 84.938%, 86.927%, and 89.627%, respectively.

and ANN models have recall values of 79.637%, 80.928%, 84.938%, 86.927%, and 89.627%, respectively. However, the RBFN-BMO model worked most effectively with various data sizes. For 6000 data points, the recall value of the RBFN-BMO is 95.737% as opposed to the GRU, LSTM, RNN, DNN, and ANN models' respective recall values of 81.924%, 84.536%, 87.736%, 90.326%, and 92.413%.

Fig. 5. Recall analysis for the RBFN-BMO method with existing systems.

TABLE II. RECALL ANALYSIS FOR THE RBFN-BMO METHOD USING EXISTING SYSTEMS

Data from dataset	GRU	LSTM	RNN	DNN	ANN	RBFN-BMO
1000	79.637	80.928	84.938	86.927	89.627	93.827
2000	80.452	82.373	85.324	87.926	90.862	94.435
3000	81.252	82.938	85.738	88.322	91.627	93.324
4000	80.615	83.425	86.029	88.726	92.617	94.928
5000	81.827	83.948	86.435	89.028	91.928	95.324
6000	81.924	84.536	87.736	90.326	92.413	95.737

3) *F-Score analysis*: Fig. 6 and Table III display an f-score contrast of the RBFN-BMO strategy with other existing methods. The graph shows that the deep learning method has produced better performance regarding the f-score. The RBFN-BMO model, for example, has an f-score of 92.536% with 1000 data, while the GRU, LSTM, RNN, DNN, and ANN models have f-scores of 87.928%, 85.435%, 81.526%, 83.425%, and 90.324%, respectively. The RBFN-BMO model, on the other hand, has performed best over a range of data sizes. Similarly, the f-score value of RBFN-BMO under 6000 data is 94.627%, while for GRU, LSTM, RNN, DNN, and ANN models, it is 89.928%, 87.435%, 82.213%, 85.324%, and 91.928%, respectively.

Fig. 6. F-Score analysis for the RBFN-BMO method using existing systems.

TABLE III. F-SCORE ANALYSIS USING TRADITIONAL SYSTEMS USING THE RBFN-BMO METHOD

Data from dataset	GRU	LSTM	RNN	DNN	ANN	RBFN-BMO
1000	87.928	85.435	81.526	83.425	90.324	92.536
2000	87.526	86.928	81.029	83.928	90.928	93.727
3000	89.432	86.425	82.536	83.526	91.243	92.927
4000	88.214	87.928	82.938	84.525	91.627	93.826
5000	88.921	86.029	81.937	84.928	92.173	94.324
6000	89.928	87.435	82.213	85.324	91.928	94.627

4) *Accuracy analysis*: Fig. 7 and Table IV shows the accuracy of the RBFN-BMO approach as compared to that of other currently utilized approaches. The graph shows how deep learning improves performance with accuracy. The RBFN-BMO model, for example, has a 1000-data accuracy of 97.627%, whereas the GRU, LSTM, RNN, DNN, and ANN models have accuracy of 89.536%, 90.917%, 92.524%, 94.526%, and 96.425%, respectively. The RBFN-BMO model, on the other hand, fared well with varying data sizes. Similarly, the accuracy of the RBFN-BMO under 6000 data is 99.546%, while the accuracy of the respective GRU, LSTM, RNN, DNN, and ANN models is 90.716%, 92.817%, 93.926%, 95.736%, and 97.125%.

Fig. 7. Accuracy analysis for RBFN-BMO method with existing systems.

TABLE IV. ANALYSIS OF RBFN-BMO METHOD ACCURACY WITH EXISTING SYSTEMS

Data from dataset	GRU	LSTM	RNN	DNN	ANN	RBFN-BMO
1000	89.536	90.917	92.524	94.526	96.425	97.627
2000	89.029	91.783	92.314	94.213	96.837	97.983
3000	90.314	91.324	93.627	95.063	95.983	98.546
4000	89.213	92.039	94.728	95.213	96.322	98.902
5000	90.516	91.992	93.039	95.536	96.714	98.724
6000	90.716	92.817	93.926	95.736	97.125	99.546

5) *RMSE analysis*: Fig. 8 and Table V display an RMSE similarity between the RBFN-BMO strategy and other earlier techniques. The graph shows that the deep learning strategy has produced better results with a lower RMSE value. For instance, the RMSE value for the RBFN-BMO is 25.637% with 100 data, while the RMSE values for the GRU, LSTM, RNN, DNN, and ANN models are slightly higher at 30.526%, 26.928%, 33.626%, 36.536%, and 43.737%, respectively. The RBFN-BMO model, on the other hand, has demonstrated that it performs best with diverse data sizes while keeping a low RMSE. The RMSE value for the RBFN-BMO model under 6000 data is 26.324%, whereas it is 32.933%, 29.322%, 35.342%, 42.627%, and 47.326% for the GRU, LSTM, RNN, DNN, and ANN models, respectively.

Fig. 8. RMSE analysis of the RBFN-BMO method with existing systems.

TABLE V. RMSE ANALYSIS OF THE RBFN-BMO METHOD USING EXISTING SYSTEMS

Data from dataset	GRU	LSTM	RNN	DNN	ANN	RBFN-BMO
1000	30.526	26.928	33.626	36.536	43.737	25.637
2000	30.425	27.029	33.928	36.928	44.863	26.435
3000	31.252	28.425	34.526	40.425	43.324	25.926
4000	31.627	27.425	35.827	41.627	44.432	25.029

6000	32.933	29.322	35.342	42.627	47.326	26.324

6) *Execution time analysis*: The execution time analysis of the RBFN-BMO technique using existing methods is described in Table VI and Fig. 9. The information clearly shows that the RBFN-BMO method has outperformed the other techniques in every way. The RBFN-BMO process, for example, took only 2.738ms to execute 1000 data, while GRU, LSTM, RNN, DNN, and ANN took 12.837ms, 10.637ms, 8.526ms, 6.938ms, and 4.837ms, respectively. Similarly, the RBFN-BMO method takes 3.624ms to execute 6000 data, whereas the other existing techniques such as GRU, LSTM, RNN, DNN, and ANN have taken 15.526ms, 11.638ms, 9.553ms, 7.425ms, and 5.029ms, respectively.

TABLE VI. ANALYSIS OF RBFN-BMO METHOD EXECUTION TIME WITH EXISTING SYSTEMS

Data from dataset	GRU	LSTM	RNN	DNN	ANN	RBFN-BMO
1000	12.837	10.637	8.526	6.938	4.837	2.738
2000	12.536	10.827	8.928	6.324	4.213	2.324
3000	13.627	10.324	8.435	6.022	4.039	3.029

V. CONCLUSION

Facial expression analysis is one tool used to develop emotional intelligence, which is becoming increasingly important in many fields, including business and education. Numerous factors, such as visual contexts, point-of-view shifts, intra- and inter-class differences and more, impede the development of a reliable emotion recognition system. This paper suggests a convolutional neural network as a potential solution to the emotion recognition problem. To examine facial expressions in images, the proposed RBFN was made face-sensitive. The proposed RBFN-BMO can recognize people in high-resolution photos, evaluate facial expressions using facial features, and predict emotional states. The

recognition during testing validates the proposed efficacy. Regarding output quality, the established RBFN-BMO classification algorithms perform better than those currently used. The RBFN-BMO uses every dataset used for the analysis and achieves the highest level of accuracy possible, which is 99.54%. To evaluate the effectiveness of the proposed classifier, the performance of proposed RBFN-BMO is compared with the existing Gated Recurrent Unit (GRU), Long Short-Term Memory (LSTM), Recurrent Neural Network (RNN), Deep Neural Network (CNN), Artificial Neural Network (ANN). As a result, the RBFN-BMO can produce better results for celebs datasets. Furthermore, it can be inferred that the Blue Monkey Optimization (BMO) meta-heuristic algorithm selects the input data features that are both the most informative and the most pertinent. It helps to achieve better categorization and reduces the error brought on by the Root Mean Square. The future of our research depends on adding new features, classifying facial emotions into their ten subcategories, and researching automatic facial emotion recognition.

Improved Drosophila Visual Neural Network Application in Vehicle Target Tracking and Collision Warning

Jianyi Wu

School of Traffic Management and Engineering, Guangxi Police College, Nanning 530023, China

Abstract—To enable the vehicle tracking and collision warning system to face more complex road information, the Drosophila visual neural network collision warning algorithm has been improved, including image stabilization algorithm, target region synthesis algorithm, and target tracking algorithm. The results showed that the improved image stabilization algorithm had significantly higher image stabilization quality. The peak signal-to-noise ratio of the stabilized image before improvement was the highest at 80dB and the lowest at 54dB. After improvement, the peak signal-to-noise ratio of the stabilized image was the highest at 82dB and the lowest at 60dB. The improved algorithm did not have any false alarms or missed alarms in collision warning. In video 1, there were false alarms in the unimproved algorithm, while in video 2, there were missed alarms. In video 1, all frames were in a safe state, but the original algorithm displayed an alarm in frames 7-12, 13-22, and 23-31. In video 2, there were dangerous situations in frames 8-24 that required an alarm, while the original algorithm displayed an alarm message in frames 8-17, consistent with the actual situation. The improved target tracking algorithm can complete the task of extracting target motion curves. The target tracking algorithm extracted the motion curves of one target in video 1 and two targets in video 2, which were consistent with the video content. The improvement of the Drosophila visual neural network collision warning model through research is effective, which can improve the driving safety of vehicles in complex road conditions.

Keywords—Drosophila visual neural network; collision warning; target calibration; target tracking

I. INTRODUCTION

With the continuous development of the social economy and the continuous improvement of people's travel standards, the number of private cars has reached 402 million. However, with the continuous growth of the number of motor vehicles, the incidence of traffic accidents is also increasing, with traffic accidents accounting for over 80% of all safety accidents [1]. The occurrence of traffic accidents not only causes huge economic losses, but also seriously threatens people's life safety. In large-scale traffic accidents, the survival rate of personnel is basically 0. The lack of concentration among drivers is the main cause of traffic accidents. If a warning system can be designed to provide early warning for drivers, increase their reaction time, and prevent accidents before they occur, it can fundamentally solve traffic safety accidents. This not only protects personal safety, but also avoids economic losses. Therefore, designing an active safety system for

vehicles has become the main research direction of scholars [2]. The driver's information perception mainly relies on visual perception, but human vision has limitations. Some insects, if flies have comprehensive vision, can obtain more driving information. Therefore, we propose to use an improved fruit fly visual neural network for vehicle target tracking and collision warning, providing drivers with more driving information and ensuring safety beside the vehicle.

The study first proposed and applied an improved Drosophila visual neural network for vehicle target tracking and collision warning. This new application fully utilizes the comprehensive view of fruit flies, providing drivers with more driving information, thereby significantly improving the driving safety of the vehicle. And the innovative integrated early warning function can increase the driver's reaction time and even prevent accidents before they occur. This feature will directly reduce the occurrence of large-scale traffic accidents, protect personal safety, and avoid economic losses.

The first part is a review of the current research status of foreign vehicle collision warning and Drosophila visual neural network. The second part is the application research of improved Drosophila visual neural network in vehicle tracking and collision warning. The third part is the analysis of experimental simulation results of model application. The fourth part summarizes the research content and points out the shortcomings, and clarifies the future development direction.

II. RELATED WORKS

Effective vehicle tracking and collision warning system can help drivers avoid many traffic safety accidents. Sanberg et al. believed that the current collision warning system was based on radar system and monocular vision, with more redundancy. To reduce the redundancy of the system, a collision warning system based on stereo vision was proposed, which can detect obstacles on the vehicle path without relying on Semantic information. The final evaluation results indicated that when the obstacle was higher than 0.4m, all obstacles in the dataset can be detected [3]. To solve the anti-collision problem in autonomous vehicle, Hu et al. developed a path planning and tracking framework based on model predictive control. This framework not only considered the friction coefficient between the tire and the road, but also considered the lateral distance control of the vehicle and the adaptive weight of the speed output in various situations. The anti-collision experiment results showed that the framework developed by the author had practical significance. It can cope

with the anti-collision task of the current auto drive system [4]. To reduce the collision probability of autonomous vehicles, Cao and Jiang designed a trajectory planning and tracking control method for formation driving. The trajectory planning of this method was divided into two stages: stable speed tracking and parameter matching. The results showed that this method can effectively avoid static and dynamic obstacles, and compared with traditional controllers, this method had higher stability and more accurate tracking [5]. Zhou et al. designed a trajectory planning and tracking control strategy in order to achieve the safe driving of the driverless vehicle to the destination. This strategy uses the artificial fish school algorithm to plan the optimal path from the starting point to the end point, and uses the forward search algorithm based on Markov chain to plan the path in the local path with obstacles. The simulation results show that, the trajectory planning and control strategy proposed by the author is sufficient to face static obstacles and some dynamic obstacles [6].

Tokuda proposed a visual servo scheme based on convolutional neural networks to make the positioning of the robotic arm more accurate. In this scheme, the eye and hand cameras were used to capture the desired image and the current image to estimate the relative pose between the desired end effector and the current end effector. Simulation results showed the effectiveness of this method [7]. Burguera et al. proposed an architecture based on an automatic encoder for the rapid and stable visual loop detection of underwater robots. The decoder part of this architecture was replaced by a fully connected layer. The results showed that this neural network can improve the visual loop detection efficiency of underwater robots [8]. Gu et al. proposed a novel convolutional neural network architecture for visual availability detection in the fields of robotics and computer vision. The architecture adopted an encoder decoder architecture for acute pixel level availability detection, where the encoder network included residual modules and multi-level dependent attention mechanisms. The experimental results showed that this method improved the performance of the neural network in the attention mechanism and sampling layer networks, laying the foundation for the research on multi task learning of physical robots [9]. To solve the problem of collision perception between robots and autonomous vehicle, Q Fu et al. constructed a visual neural network based on a

lobular giant motion detector. The construction of the network referred to the visual path of locusts. In the simulation experiment, the method passed the system test of real scene stimulation, indicating that the model can effectively detect hidden obstacles under various dynamic and chaotic backgrounds [10].

In summary, the main safety issue faced by autonomous vehicle systems is the collision problem during vehicle operation. Efficient and accurate collision warning can effectively improve the safety of vehicle operation. Collision warning is based on visual detection of obstacles to avoid, and visual neural networks can effectively detect obstacle information in images to achieve vehicle collision warning.

III. VEHICLE TRACKING COLLISION WARNING BASED ON IMPROVED DROSOPHILA VISUAL NEURAL NETWORK

The main content of this chapter is to design and construct a vehicle tracking collision warning model and a target tracking and vehicle collision detection model, which is divided into two sections. The first section is the establishment of a collision detection model based on an improved Drosophila visual neural network, and the second section is the construction of a target tracking and vehicle collision warning model.

A. Collision Detection Model Based on Improved Drosophila Visual Neural Network

During the driving process of vehicles, due to obstacles or unevenness on the road surface, there may be shaking and other phenomena, resulting in missing or unreadable information recorded by the onboard camera. Therefore, the study proposes to divide the image area equally, improve the grayscale projection image stabilization algorithm, and use the improved algorithm to complete the distorted image or video [11-12]. The grayscale projection algorithm can use the grayscale value of the reference frame to complete the motion vector of the current frame, obtain a stable image sequence, study dividing the image into sub grids of equal size, and then use the grayscale algorithm to calculate the motion vector of the target within each sub grid. After integrating the motion vectors within each sub grid, the overall motion vector of the image can be obtained. The overall motion vector estimation algorithm process is shown in Fig. 1.

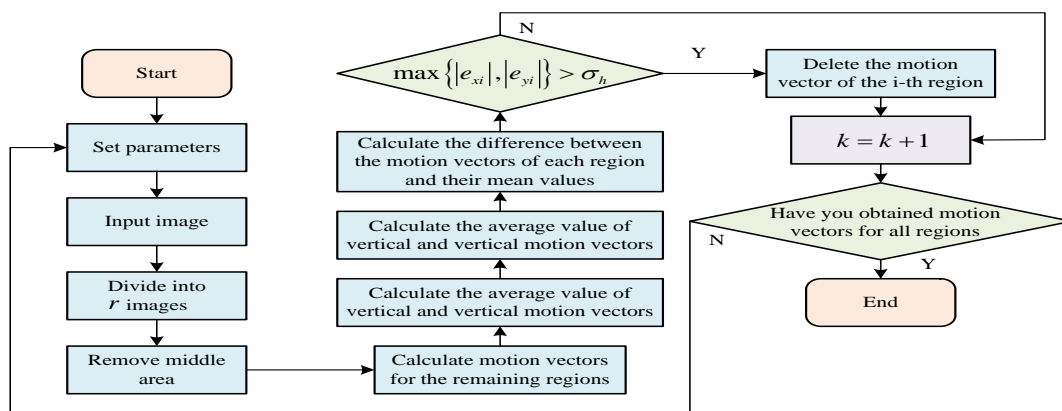

Fig. 1. Global motion vector estimation algorithm.

The threshold of the algorithm is set to σ_h , $k=1$. The image is input into the algorithm. The lower 75% of the image is divided into r small cells of the same size, the motion vectors of the small cells are calculated except for the middle region, and the set of motion vectors is obtained in the horizontal and vertical directions of the region block, as shown in formula (1).

$$\begin{cases} V_x = \{v_{x1}, v_{x1}, \dots, v_{x,r-1}\} \\ V_y = \{v_{y1}, v_{y1}, \dots, v_{y,r-1}\} \end{cases} \quad (1)$$

In formula (1), V_x, V_y represent the sum of motion vectors in the horizontal and vertical directions, and v_{x1}, v_{y1} represent the motion vectors in the horizontal and vertical directions of region 1. After obtaining the motion vectors in the horizontal and vertical directions for all regions except the central region, the average value v_{ax}, v_{ay} of the motion vectors is calculated in the horizontal and vertical directions, and then calculate the deviation value e_{xi} between v_x, v_y and v_{ax}, v_{ay} for each region, to determine whether the deviation value meets formula (2).

$$\max \{|e_{xi}|, |e_{yi}|\} > \sigma_h \quad (2)$$

If satisfied, the motion vectors of each region i in V_x, V_y are deleted, where V_x, V_y is the global motion vector of the image, $k=k+1$. The global motion vector is calculated for the next frame until the global motion vector for each frame is obtained. The above algorithm can obtain the superposition of motion vectors generated by normal shooting or shaking shooting of car mounted cameras [13-14]. The purpose of the image stabilization algorithm is to preserve the motion information obtained by the camera during normal shooting and eliminate information loss caused by shaking shooting. Therefore, a new image stabilization algorithm has been studied and designed, and its process is shown in Fig. 2.

After determining the memory scale U , maximum offset T_1 , cumulative offset $M=0$, and other parameters of the

algorithm, the stable image is output. Then the global motion vector estimation algorithm is used to calculate the global motion vector v_{xi}, v_{yi} of frame i relative to frame $i-1$, $k=k+1$. The grayscale of frame k is input, the global motion vector v_{xk}, v_{yk} of frame k relative to frame $k-1$ is calculated, and then the average motion vector $\bar{v}_{xk}, \bar{v}_{yk}$ in the horizontal and vertical directions of the adjacent L -frame grayscale before frame k is calculated. The cumulative offset M of two frames of images is calculated using formula (3).

$$M = M + \sqrt{\Delta v_{xk}^2 + \Delta v_{yk}^2} \quad (3)$$

In formula (3), $\Delta v_{xk}, \Delta v_{yk}$ represents the difference between the motion vectors of two grayscale images. At this point, if $M < T_1$, the motion vector Δ_{xk}, Δ_{yk} will be compensated for the corresponding distance in the opposite direction, and the image in frame k will be compensated and replaced. Then, $k=k+1$ will start a new round of calculation until $M \geq T_1$, and if $M \geq T_1$, the motion vector $[\Delta_{xk}, \Delta_{yk}]$ will be compensated for the corresponding pixel distance in the opposite direction to compensate for the image in frame k . Let $k=k+1$, $M=0$ start motion compensation for the next grayscale image again until all images have completed stabilization. In addition to the stability of moving images, collision detection algorithms also need to consider the influence of weather factors. Traditional weather recognition algorithms are difficult to meet the needs of weather recognition in complex environments. Therefore, research has proposed adding parameters to improve the weather recognition algorithm. Firstly, the study has added standard deviation parameters, which can reflect the degree of image dispersion. The larger the standard deviation, the smaller the impact on image target extraction, the calculation of standard deviation is shown in formula (4).

$$\sigma = \sqrt{\sum_{i=0}^{L-1} (z_i - m)^2 p(z_i)} \quad (4)$$

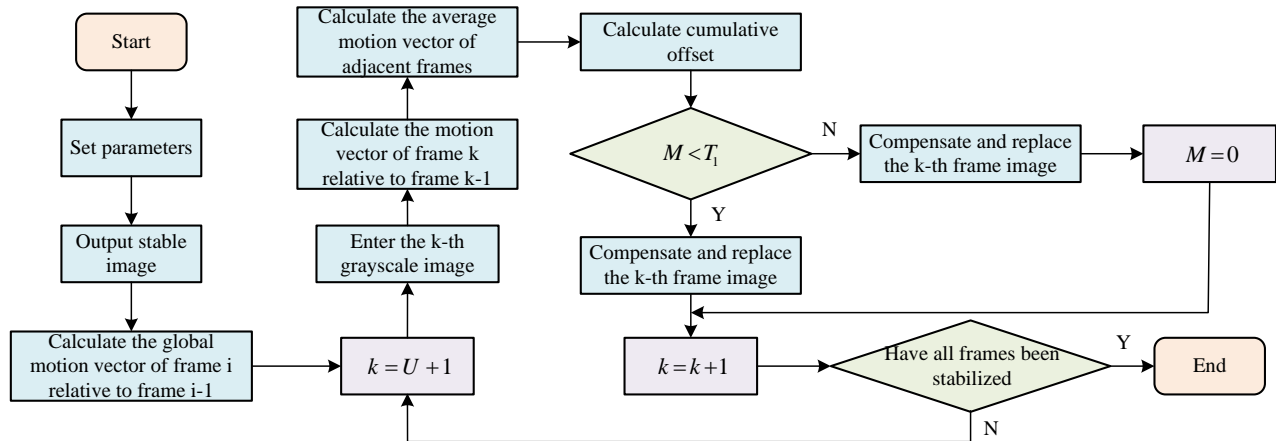

Fig. 2. Image stabilization algorithm flow.

In formula (4), σ represents the standard deviation, L represents the total number of grayscale levels, z_i represents the i -th grayscale level, $p(z_i)$ represents the probability of grayscale being z_i in the grayscale distribution of the histogram, and m is the pixel mean. Secondly, the study adds a smoothness parameter, which is an important characteristic of image texture. The higher the smoothness, the worse is the image smoothness. The calculation of smoothness is shown in formula (5).

$$R = \frac{1}{1 + \sigma^2} \tag{5}$$

In formula (5), R represents smoothness. Finally, the study also adds image entropy, which can reflect the degree of similarity between different images. The calculation of image entropy is shown in formula (6).

$$e = -\sum_{i=0}^{L-1} p(z_i) \log_2 p(z_i) \tag{6}$$

In formula (6), e represents image entropy. After introducing the above three parameters, the indicators for measuring sunny days are shown in formula (7).

$$w_1^i = a_{10}B + a_{11}A + a_{12}C + a_{13}p_r + a_{14}\sigma + a_{15}R + a_{16}e \tag{7}$$

In formula (7), w_1^i represents the sunny day metric, a_{ij} represents the weighting coefficient, A represents the image sharpness, B represents the image brightness, C represents the image contrast, and p_r represents the proportion of image value neighborhoods. The formula for measuring indicators on cloudy days is shown in formula (8).

$$w_2^i = a_{20}(1-B) + a_{21}A + a_{22}C + a_{23}(1-p_r) + a_{24}\sigma + a_{25}R + a_{26}e \tag{8}$$

In formula (8), w_2^i represents that in addition to cloudy and sunny days, the measurement index for cloudy days also needs to consider foggy days. The measurement index formula for foggy days is shown in formula (9).

$$w_3^i = a_{30}(1-B) + a_{31}(1-A) + a_{32}(1-C) + a_{33}p_r + a_{34}(1-\sigma) + a_{35}R + a_{36}e \tag{9}$$

In formula (9), w_3^i represents the measurement indicator for foggy weather. By replacing the indicators in traditional weather recognition algorithms with the above three measurement indicators, an improved weather recognition algorithm can be obtained. The Drosophila visual neural network can detect moving targets, but it is limited to the direction detection of moving targets. After scholars' improvement, the Drosophila visual neural network can perform collision detection of moving targets. The photosensitive cell layer of the visual neural network that can perform collision detection has $I \times J$ photosensitive cells, corresponding to the grayscale value of the grayscale image of size $I \times J$, so that $L_{ij}(t)$ represents (i, j) grayscale value at time t . The output of photosensitive cell (i, j) at time t can be expressed using formula (10).

$$P_{ij}(t) = \frac{1}{2}(L_{ij} + f(L_{ij})), 1 \leq i \leq I, 1 \leq j \leq J \tag{10}$$

In formula (10), $P_{ij}(t)$ represents the output of the photosensitive cell at time t , and $f(\square)$ represents the time delay function. After combining the improved image processing technology with a visual neural network with collision detection function, an improved Drosophila visual neural network algorithm can be obtained. The algorithm process is shown in Fig. 3.

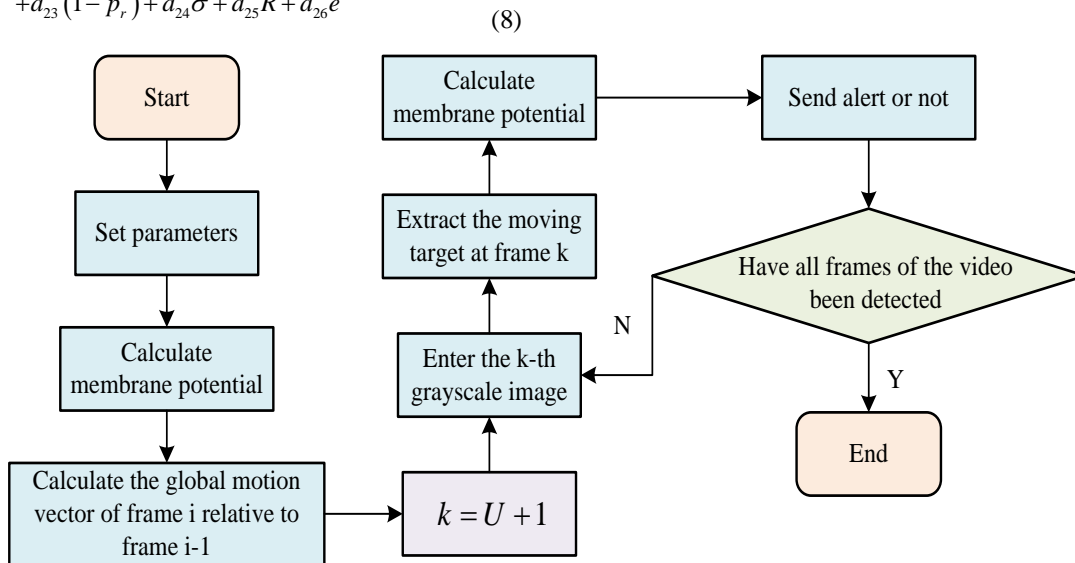

Fig. 3. Improved Drosophila visual neural network collision detection algorithm.

Initial parameters are input, neural network is used to obtain membrane potential $Y_{lob}(0), \dots, Y_{lob}(U)$, and global motion vector is calculated, $k = U + 1$. Grayscale image of frame k is input to extract foreground moving targets and neural network is used to obtain membrane potential $Y_{lob}(k)$.

If $Y_{lob}(k)$ is greater than collision warning threshold, warning signal will be sent, $k \leftarrow k + 1$. Foreground moving targets are extracted in the next frame and membrane potential. Whether warning is needed is determined until each frame of the video completes detection [15-16].

B. Construction of Target Tracking and Vehicle Collision Warning Model

In the binary image of a video, there may be a phenomenon where moving targets are divided into multiple interconnected regions, which affects the recognition of the number of moving targets in the field of view and leads to target tracking failure. Therefore, the study first uses corrosion and dilation algorithms to process the binary image, then calibrates the moving targets in the binary image, records the center point position of the targets, and finally uses region synthesis algorithms to determine the number of moving targets in the image. In a binary graph, different connected regions of the same moving target can be merged using the distance between the bounding rectangles of the moving target area and the distance threshold. The distance between the bounding rectangles is calculated using formula (11).

$$d(L_a, L_b) = \sqrt{d_h^2 + d_v^2} \tag{11}$$

In formula (11), $d(L_a, L_b)$ represents the distance between region a and region b , and d_h, d_v represent the horizontal width distance and vertical height distance of region a, b . The calculation of d_h is shown in formula (12).

$$d_h = \begin{cases} 0, & d_h^{ab} \leq \frac{1}{2}(h_a + h_b) \\ d_h^{ab} - \frac{1}{2}(h_a + h_b), & d_h^{ab} > \frac{1}{2}(h_a + h_b) \end{cases} \tag{12}$$

In formula (12), d_h^{ab} represents the horizontal projection distance between the center points of the bounding rectangle in the target area, and h_a, h_b represent the horizontal height of the target area. The calculation of d_v is shown in formula (13).

$$d_v = \begin{cases} 0, & d_v^{ab} \leq \frac{1}{2}(v_a + v_b) \\ d_v^{ab} - \frac{1}{2}(v_a + v_b), & d_v^{ab} > \frac{1}{2}(v_a + v_b) \end{cases} \tag{13}$$

In formula (13), d_v^{ab} represents the vertical projection distance between the center points of the bounding rectangle in the target area, and v_a, v_b represents the vertical distance of the target area. The target region synthesis algorithm designed for research is shown in Fig. 4.

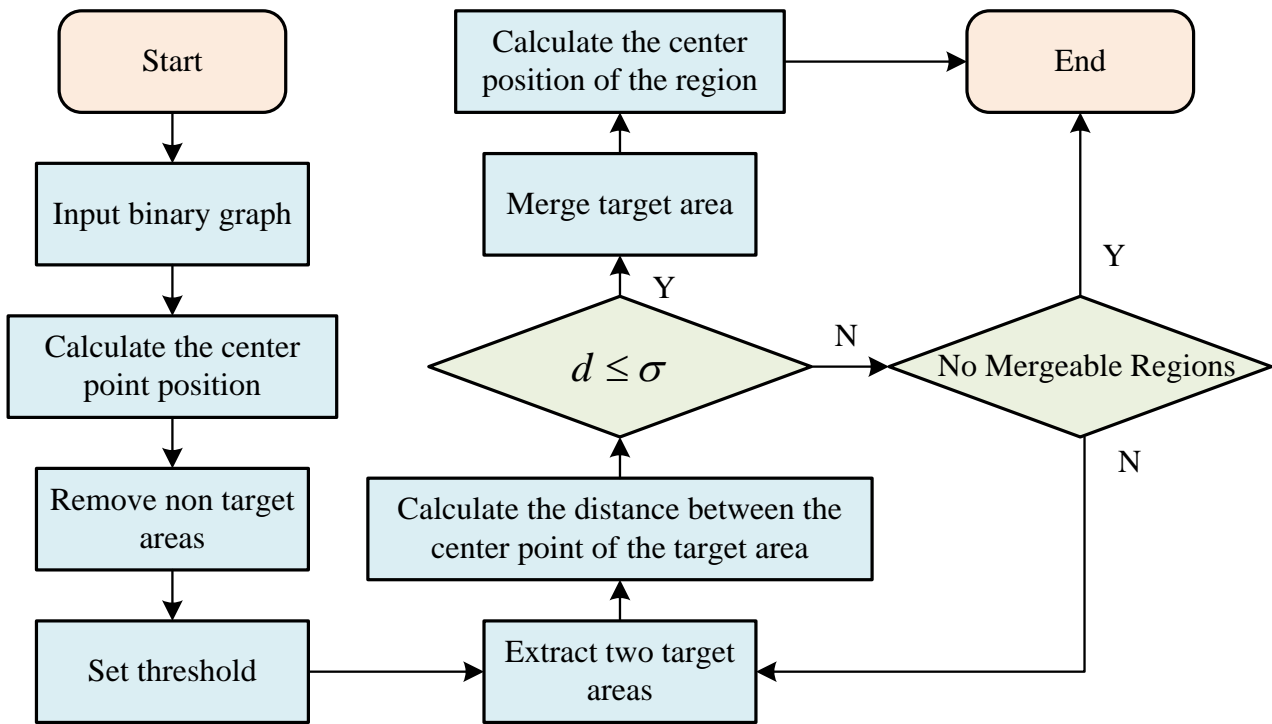

Fig. 4. Target region synthesis algorithm flow.

After inputting the binary image, the synthesized moving target in the target area is output. Through target calibration, the center point positions of the outer rectangles of each connected area are obtained. Then, by eliminating the target area, a binary image containing only the target area is obtained. If n represents the number of target areas, the target area is aggregated as $L = \{l_1, l_2, \dots, l_n\}$, and the distance threshold is set as σ . The distance between adjacent target areas is calculated using formula (11). If the distance between two adjacent target areas is less than or equal to σ , the two target areas will be merged and the center point coordinates of the merged target area will be recalculated. If it is greater than σ , adjacent target areas will be re selected to determine whether to merge until all adjacent target areas have a distance greater than σ . In this algorithm, the center position of the target area can be determined, so the motion speed of the same moving target in adjacent frame images can be calculated using formula (14).

$$v = \sqrt{(x_{1j_ctr} - x_{2j_ctr})^2 + (y_{1j_ctr} - y_{2j_ctr})^2} \quad (14)$$

In formula (14), (x_{1j_ctr}, y_{1j_ctr}) and (x_{2j_ctr}, y_{2j_ctr}) represent the center position of the j -th moving target in adjacent images [17-18]. The target tracking algorithm is not only related to the position and speed of the target, but also to changes in the environment. Therefore, a new target tracking algorithm has been studied and designed, and its process is shown in Fig. 5.

After inputting the initial parameter attribute set $object$, an image sequence of size $I \times J$ is output. The image frame counter is set to 0, various parameters of $object$ are initialized, and then the number of targets is reset. $k = l + 1$, the target region synthesis algorithm and formula (14) are used to calculate the positions and motion velocities of all targets in frame k . If the image frame counter is 0, the position and velocity of targets in frame $object$ are updated. If it is greater than 0, the position of targets in frame $object$ is used to predict the position of targets in frame k . Then, formula (15) is used to calculate the distance d between the target position and the predicted position.

$$d = \sqrt{(x_0 - x_m)^2 + (y_0 - y_m)^2} \quad (15)$$

In formula (15), x_0, y_0 represents the predicted position and x_m, y_m represents the calculated position. At this point, if d is less than the threshold, the target in $object$ matches the target in frame k of the image. The target position in $object$ is updated using the target position in the image until the image target leaves the visual area and all frames of the video image have been detected. This algorithm has improved the input parameter quality of the neural network, but has not improved the neural network and warning scheme. Therefore, the model is only suitable for a single moving target and cannot detect the motion direction of multiple targets. Thus, a new object tracking and collision warning algorithm has been studied and designed, and its process is shown in Fig. 6.

Fig. 5. Target tracking algorithm flow.

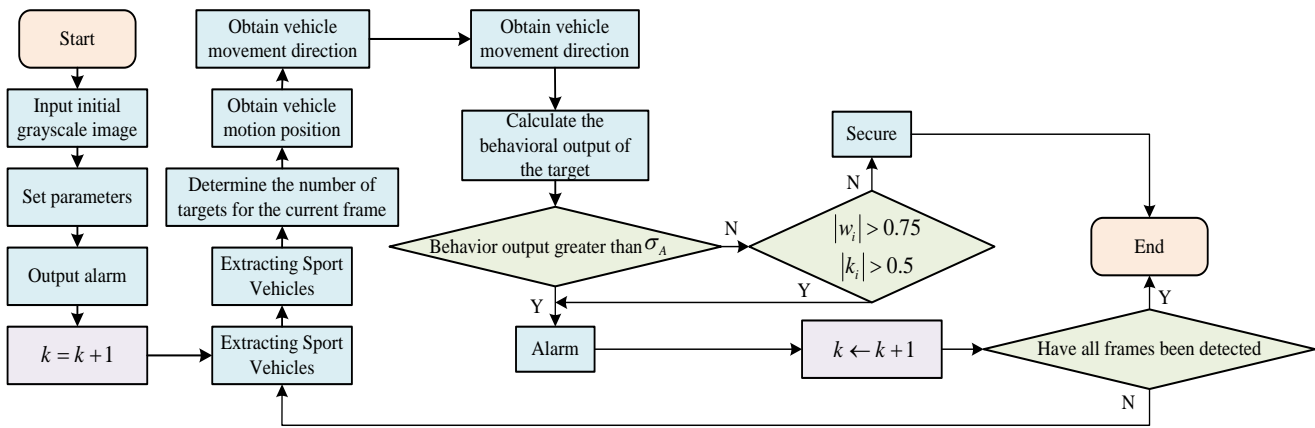

Fig. 6. Target tracking and collision warning algorithm flow.

An initial grayscale image of size $I \times J$ is input, the dynamic threshold σ_A and warning threshold frame number T of the algorithm are set, the warning signal is output. $k = l + 1$, the grayscale image of frame k is input, and the moving target of the image is extracted. The target area synthesis algorithm is used to determine the number of moving targets in the image, and then the target tracking algorithm is used to obtain the vehicle's motion position and direction. After obtaining the motion information of the target in the image, an artificial *Drosophila* visual neural network is used to calculate the behavior output of a vehicle, if the behavior output of the vehicle is greater than σ_A , a warning will be issued. If the behavior output of the vehicle is less than σ_A , the slope of the moving vehicle's motion direction will be calculated. If the absolute value of the moving vehicle's motion direction is greater than 0.75, and the absolute value of the slope is greater than 0.5, a warning signal will be sent. Finally, $k \leftarrow k + 1$, the behavior output of the vehicle can be obtained and compared with σ_A until all image frames are detected.

IV. SIMULATION EXPERIMENTAL RESULTS

This Section is an experimental validation analysis of the content of Section II, divided into two sections. The first section is the experimental validation analysis of improving the *Drosophila* visual neural network collision detection model, and the second section is the experimental validation analysis of target tracking and vehicle collision warning algorithms. The experimental validation analysis of improving the collision detection model of the *Drosophila* visual neural network can verify the recognition accuracy of the proposed algorithm in different situations, and the experimental validation analysis of target tracking and vehicle collision warning algorithms can verify whether the algorithm proposed by the acting team is effective in protecting drivers and personnel.

A. Collision Warning Experiment

To verify the feasibility of improving the *Drosophila* visual neural network collision model through research, experimental research was conducted under the OpenC V2.4.9 configuration in the Visual Studio 2010 software of the Windows 7 system. The study compared the Peak Signal to

Noise Ratio (PSNR) values of the image stabilization images obtained by the improved and original image stabilization algorithms, as shown in Fig. 7.

(a) PSNR value of video screen 1 and stable image

(b) PSNR value of video screen 2 and stable image

Fig. 7. Comparison of image stabilization algorithm results.

Fig. 7(a) shows the comparison of the PSNR values of the stabilized image of Video 1. The PSNR values of the improved stabilized image algorithm intersected with the PSNR values of the other two stabilized images, but overall they were still significantly better than the PSNR values of the other two stabilized images. The PSNR values of the improved stabilized image algorithm were up to 82dB and

down to 60dB, the PSNR values of the original image were up to 77dB and down to 52dB, and the PSNR values of the original stabilized image were up to 80dB and down to 54dB. Fig. 7(b) shows the comparison of the PSNR values of the stabilized image of Video 2. The improved stabilized image algorithm had significantly higher PSNR values than the other two stabilized images. In frame 16, the original stabilized image algorithm had a PSNR value of 71dB, which was higher than the improved stabilized image algorithm's 70dB. In the other frame numbers, the improved stabilized image algorithm had a PSNR value that was significantly higher than the original stabilized image, indicating a significant advantage. After confirming the effectiveness of the research in improving the image stabilization algorithm, the study compared the detection results of the Drosophila visual neural network collision detection algorithm with the improved Drosophila visual neural network algorithm, as shown in Fig. 8.

Fig. 8. Collision warning detection results of video screen 1.

Fig. 8(a) shows the collision warning detection results of the unimproved algorithm. Only at frames 12, 22, 31, and 34, the output value of the algorithm was less than the alarm threshold, and in the remaining frames, the output value of the algorithm was higher than the threshold, requiring an alarm.

Fig. 8(b) shows the collision detection probability results of the improved algorithm. The output value of the algorithm was always below the warning threshold, and there was no need to alarm. Based on the video content, a moving vehicle appears in frame 7 of the video. Afterwards, the moving vehicle began to move away from the camera, and a safe distance was maintained between the moving vehicle and the camera without warning. Therefore, the false alarm situation of the unimproved algorithm was relatively serious, while the improved algorithm did not show any false alarms. The detection results of the two algorithms in video 2 are shown in Fig. 9.

Fig. 9. Collision warning detection results of video screen 2.

Fig. 9(a) shows the collision warning detection results of the unimproved algorithm. Starting from frame 6, the alarm threshold started to rise. At frame 8, when the algorithm output value exceeded the alarm threshold, the algorithm started to alarm. At frames 17 and 20, when the algorithm output value was lower than the alarm threshold, the alarm was canceled. Fig. 9(b) shows the collision warning detection results of the improved algorithm. Starting from frame 5, the alarm threshold rose to around 0.6 and stabilizes. At this point, the algorithm output value was higher than the alarm threshold, and the algorithm remains in an alarm state. Based on the content of video 2, the moving vehicles were gradually approaching the camera, and the predicted results of this settlement method were more in line with the actual results.

B. Collision Warning Effect

Before verifying the collision warning effect, the research first verified the feasibility of target calibration and tracking algorithms to obtain the motion curve of moving targets in the video sequence. The results are shown in Fig. 10.

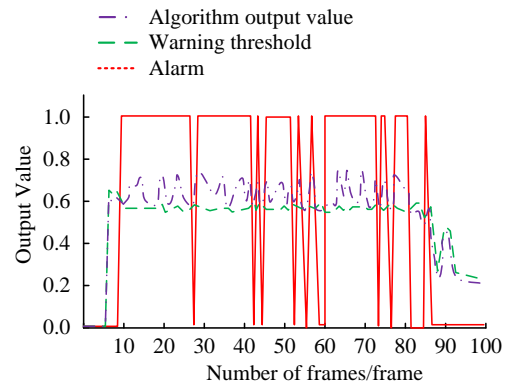

(a) Target motion trajectory of video screen 1

(b) Target motion trajectory of video screen 2

Fig. 10. Motion curves of vehicles with targets in two different types of videos.

Fig. 10(a) shows the tracking curve of the moving target in video 1. In video 1, there was only one target vehicle, and the tracking curve gradually moved from the right side towards the center of the camera's visual area, indicating that the target gradually moved away from the camera from the right side, which was consistent with the actual situation in the video. Fig. 10(b) shows the tracking curve of the moving target in video 2. There were two target vehicles in video 2. The motion curve of the first moving target gradually moved towards the center of the camera's visual area from the left, while the second vehicle hovered on the right side of the camera's visual area, which was consistent with the actual situation in the video. After extracting the target motion curve, the study compared the traditional collision warning model with the collision warning model designed in the study. The warning effect in two video scenarios is shown in Fig. 11 for video 1.

(a) The collision warning detection effect of the original algorithm

(b) Improved Algorithm for Collision Warning Detection

Fig. 11. Comparison of two algorithms for warning effects in video 1.

Fig. 11(a) shows the warning effect of the traditional collision warning algorithm. At frame 6, the moving target began to appear, and the algorithm started to alarm until frame 89. During frames 9 to 89, there were multiple occurrences of non-alarm areas, and the algorithm output values were all above the alarm threshold. Fig. 11(b) shows the collision warning effect of the research and design algorithm. From frame 9 when the moving target appeared to frame 89, the moving target left the visual area, the algorithm was in an alarm state without any missed alarms. The warning effect of Video 2 is shown in Fig. 12.

Fig. 12(a) shows the warning effect of traditional collision warning algorithms. During frames 1 to 18, the moving target appeared, and the algorithm output value and alarm threshold fluctuated. Starting from frame 22, the algorithm started to intermittently alarm, and the overall output value of the algorithm remained above the warning threshold. Fig. 12 (b) shows the collision warning effect of the research and design algorithm. The changes in the algorithm output value and warning threshold from frames 1 to 18 were consistent with traditional algorithms. Since frame 22, the research and design algorithm was always in a warning state. Based on the analysis of video content, traditional algorithms suffered from serious false positives, while research and design algorithms showed no false positives.

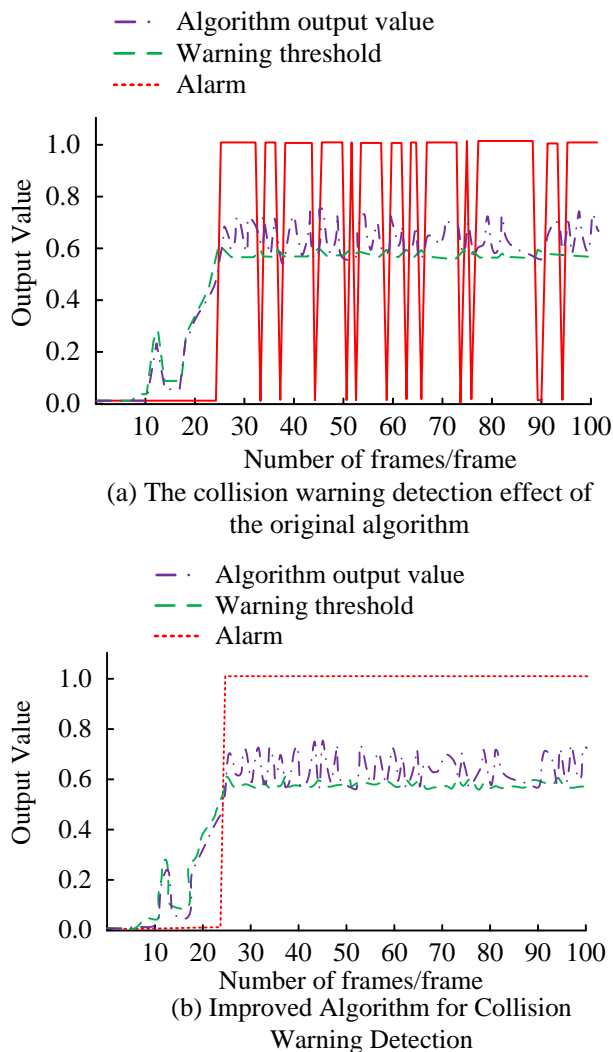

Fig. 12. Comparison of two algorithms for warning effects in video 2.

V. CONCLUSION

To increase the safety of vehicle driving and ensure the safety of drivers' lives and property, a vehicle tracking and collision warning model based on improved Drosophila vision is studied, designed, and constructed. The model adopts motion vector estimation algorithms, image stabilization algorithms, target region synthesis algorithms, target tracking algorithms, and collision warning algorithms that are improved based on traditional algorithms. The results showed that the PSNR value of the improved image stabilization algorithm was always higher than that of the original image and traditional image stabilization algorithms. The PSNR value of the improved image stabilization algorithm was highest at 82dB and lowest at 60dB, while the PSNR value of the traditional image stabilization algorithm was highest at 80dB and lowest at 54dB. The improved Drosophila visual neural network collision warning algorithm had no false positives, and the original algorithm had four false positives in video 1. The research and design of the target region synthesis algorithm can complete the task of extracting motion curves of video moving targets. The algorithm extracted the motion

curves of one target in video 1 and two targets in video 2, which were consistent with the video content. The target tracking and collision warning algorithm designed in the study did not show any false positives. In the collision warning effects of Video 1 and Video 2, the original algorithm showed relatively serious false positives, while the algorithm designed in the study did not, which was consistent with the actual information in the video. The algorithm designed through research has improved the missed and false positives of the original algorithm, but the improved image stabilization algorithm has poor performance when facing multiple objectives. Subsequent research can continue to optimize the application effect of the model in multi-objective situations.

Earth Observation Satellite: Big Data Retrieval Method with Fuzzy Expression of Geophysical Parameters and Spatial Features

Kohei Arai
Information Science Dept.
Saga University
Saga City, Japan

Abstract—A method for fuzzy retrievals of Earth observation satellite image database using geophysical parameters and spatial features is proposed. It is confirmed that the proposed method allows fuzzy expressions of queries with sea surface temperature, chlorophyll-a concentration and cloud coverage as well as circle, line and edge, for instance “rather cold sea surface temperature and a sort of circle feature”. Thus users, in particular, oceanographers may access the most appropriate image data from the database for finding of cold cores (circle features), fronts (arc and line features), etc. in a simple manner. Although this is just an example for oceanographers, it is found that the proposed method allows data mining with fuzzy expressions of geophysical queries from the big data platforms of the earth observation satellite database.

Keywords—Fuzzy retrieval; earth observation satellite; big data; geophysical parameter; oceanographer; circle feature; arc feature; line feature; fuzzy expression

I. INTRODUCTION

These remote sensing satellite data are totally big data. One of the problems on the big data analysis is how to retrieve most appropriate satellite data. In this paper, Earth observation satellite data retrieval method with fuzzy expression of geophysical parameters and spatial features is proposed.

Conventional search engine allows search objects with some multimedia of keywords, images, voices, etc. In terms of Earth observation data retrieval, there is strong demand on satellite imagery data search with geophysical features and spatial features (for instance, “rather cold sea surface temperature and a sort of circle feature”). Such this flexible data search engine is required for the remote sensing imagery data users.

Space development agencies (NASA, NOAA, NASDA, ESA, IRS, CNES, etc.) that are building databases of earth observation satellite data have developed WWW or proprietary search software as a user interface for database search and provide it to users. Search requests from these are translated to be effective in databases based on unique structures and languages (most institutions are Oracle databases (relational databases) [1] and are translated into search requests in SQL language) [1].

The database consists of the earth observation satellite image data to be searched (the unit of search is called a

granule), the inventory data that is its catalog information, and the browse image data with reduced resolution to know the outline of the database (this is called browsing) and their location information and metadata as granule attribute information.

To search for a granule, first, the inventory is searched from the inventory database, and the browse image data that matches the search conditions is searched from the browse image database via the metadata in the meta database. From the database, since location information and the like are linked between these databases, the user only needs to set conditions for retrieving inventory and browse images. In the current space development agency database system, the conditions for inventory search start with the satellite name, sensor name, ground station name, and indicate the observation date and time, location, data quality, cloudiness, etc.

From the inventory data candidates that meet these conditions, the one closest to the desired one is selected, the browse image is displayed and confirmed, and this is repeated until the desired data is reached. However, since neither the inventory data nor the browse image contains information on the physical quantity, which is the evaluation criterion for the user data, the number of repetitions until the desired data is reached is not small.

The retrieval method of the Earth Observation Satellite Image Database: EOSID proposed in this paper aims to reduce the time required for retrieval by adding physical quantities and spatial features of images to inventory data. There are many physical quantities and spatial features of earth observation satellite image data, but here I limited them to those in the marine field as an example. In other words, sea surface temperature and chlorophyll-a concentration are used as physical quantities, and edges, lines, circles, and arcs are selected as spatial features, and based on these quantities, The search conditions were narrowed down.

Furthermore, when specifying these physical quantities and spatial features as search conditions, it is assumed that it is impossible to give them in a limited manner, and a search based on fuzzy theory with a very, slightly, etc., language hedge should be used. This search based on fuzzy theory with language hedging has already been proposed by, for example, Isomoto [2], and is not new at all. And the search method must

be devised. For example, Sobue et al. have proposed a method for searching catalog information of earth observation satellite data using physical quantities as fuzzy search targets [3].

NASA has also applied this to text search for data and information on the global environment. Here, the author proposes a method of further narrowing down the search items by referring to the spatial features by further developing [3]. The author reports the effectiveness of the proposed search method using a virtual Earth observation satellite image database.

In the following section, research background and related research works are described. Then, the proposed method and system is described followed by experimental set-up together with experimental results. After that, concluding remarks and some discussions are described.

II. RESEARCH BACKGROUND

The demand for satellites related to remote sensing has grown significantly, especially in emerging countries where many countries do not have launch vehicles. In emerging countries, there is about four times the demand in the last ten years and the next ten years. It is announced that Metaps, who supports app monetization using artificial intelligence, will start joint research on a big data analysis system using micro satellites in cooperation with space shift. Many new and old players (Google, Facebook, etc.) are promoting market and customer development with various approaches such as resolution, shooting frequency, analysis, cost, etc., the global satellite remote sensing market.

Microsoft and the United States Ocean Atmosphere Agency (NOAA), a joint R & D agreement to develop the best way to extract data from internal systems. This will allow Microsoft to provide weather, water, and oceans provided by NOAA scientists and weather data hosted on Azure cloud platform. This collaboration is an important step in realizing the promise of open data and innovation, which allows governments and businesses to leverage NOAA data aggregated in cloud repositories and then availability of large amounts of computing resources Partners and customers develop new solutions for citizens and customers. Digital Globe, a satellite image provider (34 cm spatial resolution) founded in 1992, signed a long-term contract with the US government in 2002, and merged with GeoEye in 2012, with sales of approximately 60 billion JYen. The company is a major customer of NGA (National Geospatial-Intelligence Agency), and the government business accounts for over 80% of sales. On the other hand, vendors providing mapping services such as Google and Nokia are also customers. Skybox Imaging, which was acquired by Google, will consider releasing satellite data, combining satellite HD video data with map APIs to instantly see the movement of the ground "satellite video". It can be used to monitor the movement of airplanes and ships, and to identify illegal deforestation, etc.

Planet Labs is a company that sells satellite photos collected from a network of 87 small satellites, and with this acquisition, RapidEyes has a six-year archive of six billion square kilometers of global land images, More than 177 Dove satellites are launched on orbit, and a large number of

constellations that shoot the same spot at least once a day (multiple earth observation satellites are thrown in the same orbit, high frequency observation and then provided free of charge by Creative Commons (CC) license Start. The CC license is a new copyright rule for the Internet age, a tool for the author of publishing works to indicate that "you are free to use my work if you comply with these conditions."

Spire, a satellite venture, uses a group of small satellites called satellite constellations to collect various data and analyze geospatial information such as world trade and weather.

Descartes Labs mainly does the analysis of satellite images to understand what is there and to educate the system to extract specific crops from satellite images, extracting significant data from them, Adapt to the yearly satellite imagery. Predict actual yield by applying statistical model to extracted crops. Specifically, take out corn grown on the farm from satellite image and predict the amount of harvest for that year.

Facebook embarks on accurate mapping of the world by using artificially captured images (remote sensing images) and artificial intelligence technology (AI). How many people live in which region of which country know exactly what it is and optimize its global broadband offering, the Connectivity Lab uses AI technology for approximately 14.6 billion satellite images in 20 countries around the world to identify man-made structures etc., how many houses are along the river and along the road, and what communities We analyzed what was formed. Efforts to use "Computer Vision: Business Intelligence" where CIA-affiliated companies can work with Amazon to peek into Earth information at an unprecedented level of detail.

Omni Earth is planning a satellite system consisting of 18 units, and in the future, it will assume an earth observation data volume of 60 petabytes /year. The company is characterized by a partnership, and in 2014, partnered with Dynetics for satellite design and manufacturing, Draper Laboratory for systems engineering, and Spaceflight for launch service. The company emphasizes solution development using satellite image analysis, and acquired the US IRIS maps in August this year, and launched a business solution integrating earth observation images and other data for agriculture, forestry, energy and public sector provide on a cloud basis. The combination of advanced satellite infrastructure and advanced application development can create new innovations.

Services such as Google Maps, Microsoft's Bing, and MapQuest will display various satellite images cut and pasted. On the other hand, in the map box, we use the vast array of satellite image data of NASA and take an approach of stacking innumerable images taken from one area as a layer, to realize a clear image without a seam. A similar framework was born in Europe in February 2016. ESA concludes LOI (Letter of Intent) with SAP for rapid and efficient utilization of huge earth observation data. As satellite observation data by the Earth observation program "Copernicus" advanced by ESA is huge, data processing is difficult with conventional technology. Build an innovative approach to data processing and analysis by leveraging SAP's cloud platform "SAP HANA Cloud". ESA launches TEP and promotes practical use in six fields, Disaster

prevention, Coast, forest, Water resources, Polar region, Cities and infrastructure. One example (coastal): Supporting the Aquaculture Fisheries Industries (SAFI) is a fishery data server for aquaculture companies and fishermen. Such these platforms provide kinds of big data. More importantly, data mining from the big data platform has to be done in efficient and effective manner. The proposed method would like to provide a sophisticated manner of data mining with fuzzy expression of geophysical parameters.

III. RELATED RESEARCH WORKS

Vague search of earth observation image database based on Fuzzy theory using physical quantities and spatial features is proposed [4] together with earth observation satellite image database system allowing ambiguous search requests [5]. On the other hand, user friendly and efficient catalog information management for earth observation data is proposed and well reported [6].

Remote sensing satellite image database system allowing image portion retrievals utilizing principal component which consists spectral and spatial features extracted from imagery data is proposed [7]. Meanwhile, data collection and active database for tsunami warning system is proposed [8].

A review of Chinese Academy of Science (CASIA) gait database as a human gait recognition dataset is conducted [9] together with gait recognition method based on wavelet transformation and its evaluation with CASIA gait database as human gait recognition dataset [10]. Meanwhile, visualization of 3D object shape complexity with wavelet descriptor and its application to image retrievals is proposed and validated [11] together with visualization of 3D object shape complexity with wavelet descriptor and its application to image retrievals [12].

Wavelet based image retrieval method is proposed and evaluated its usefulness [13]. On the other hand, DP matching based image retrieval method with wavelet Multi Resolution Analysis: MRA which is robust against magnification of image size is proposed [14]. Meanwhile, Free Open-Source Software: FOSS based Geographic Information System: GIS for spatial retrievals of appropriate locations for ocean energy utilizing electric power generation plants is proposed [15].

Error analysis of air temperature profile retrievals with microwave sounder data based on minimization of covariance matrix of estimation error is conducted [16]. Meanwhile, visualization of link structure and URL retrievals utilization of interval structure of URLs based on brunch and bound algorithms is well reported [17]. Method for image portion retrieval and display for comparatively large scale of imagery data onto relatively small size of screen which is suitable to block coding of image data compression is also proposed [18].

Content based image retrieval by using multi-layer centroid contour distance is proposed [19]. On the other hand, remote sensing satellite image database system allowing image portion retrievals utilizing principal component which consists spectral and spatial features extracted from imagery data is proposed [20].

Image retrieval and classification method based on Euclidian distance between normalized features including

wavelet descriptor is proposed [21]. Also, numerical representation of web sites of remote sensing satellite data providers and its application to knowledge-based information retrievals with natural language is proposed [22]. Image retrieval based on color, shape and texture for ornamental leaf with medicinal functionality, meanwhile, is proposed [23]. Also, comparison contour extraction based on layered structure and Fourier descriptor on image retrieval is proposed and evaluated its effectiveness [24].

Pursuit Reinforcement Competitive Learning: PRCL-based online clustering with tracking algorithm and its application to image retrieval is proposed [25]. Also, image retrieval method utilizing texture information derived from Discrete Wavelet Transformation: DWT together with color information is proposed [26].

Metadata definition and retrieval of earth observation satellite data is proposed [27]. On the other hand, Open GIS with spatial and temporal retrievals as well as assimilation functionality is proposed [28]. Meanwhile, Geographic Information System: GIS based on neural network for appropriate parameter estimation of geophysical retrieval equations with satellite remote sensing data is proposed [29].

Image retrieval method based on hue information and wavelet description-based shape information as well as texture information of the objects extracted with dyadic wavelet transformation is proposed [30]. Wavelet based image retrievals is attempted [31]. Also, image retrieval method based on back projection is proposed [32].

For the Fuzzy logic related research works, there are the following papers,

Fuzzy Genetic Algorithm (GA) for prioritization determination with techniques for order performance by similarity to ideal solution is proposed [33]. On the other hand, smart grid photovoltaic system pilot scale using sunlight intensity and state of charge (SoC) battery based on Mamdani fuzzy logic control is also proposed [34]. Satellite image database search engine which allows fuzzy expression of geophysical parameters of queries is proposed [35]. Meanwhile, operation of light tracker movement using Fuzzy logic control information and communication technology is proposed [36].

IV. PROPOSED METHOD

A. Search Procedure

The search procedure in the current database system of most space development agencies is as follows:

- 1) As a condition for inventory search, start with satellite name, sensor name, ground station name, and specify observation date and time, location, data quality, cloudiness, etc. The user inputs a standardized search key according to a request from the terminal.
- 2) Search for inventory information based on the input search conditions.
- 3) Search for metadata corresponding to the searched inventory information.

4) Based on the retrieved metadata, a browse image that matches the search condition is retrieved from the database where it is located and presented to the user.

5) If there is no browse image desired by the user, the process returns to step 1. If there is a desired browse image, the original image data corresponding to the selected browse image is further searched.

6) Return the searched image data to the user as a search result.

In contrast, the search procedure proposed here is as follows:

1) *Inventory search conditions include:* satellite name, sensor name, ground station name, observation date and time, location, data quality, cloudiness, sea surface temperature, chlorophyll-a concentration, and other physical quantities and edges, lines, circles, and arcs. And other spatial features. At this time, for the search condition items below the cloud cover, search requests with ambiguous expressions by language hedging are allowed.

2) Search for inventory information based on the input search conditions.

3) Analyze the given ambiguous search condition and find the threshold that matches the condition using fuzzy logic.

4) If there is an image in the database that contains data between the threshold value calculated in 3 and the maximum value of the target membership function, it is assumed that the condition is met and the result is retained. .

5) Process image data with data that meets all the given conditions to create a browse image and display it as a candidate for search results along with attribute data such as sea surface temperature of the image.

6) The original of the browse image data selected by the user display the image data as a result. That is, the points different from the current search method are listed as follows.

a) The physical quantities and spatial features are included in the inventory data, and search conditions can be set based on these.

b) The use of attribute information included in the browse image database to confirm the matching of search conditions for physical quantities and spatial features eliminates the need for a meta database.

c) It is allowed to set ambiguous search conditions for these physical quantities and spatial features.

B. Setting Search Key Items

Since the earth observation field is wide-ranging, the ocean observation data is taken up with particular attention to the ocean field. The concept of the basic search method is common to each field. The search key items used this time are as follows,

1) Sea surface temperature, chlorophyll-a content, cloudiness,

2) Number of edges, number of circles, number of arcs, number of lines from spatial features.

The author chose, in particular, by enabling search using this spatial feature, it is thought that it is useful for search of the earth observation satellite image database by ocean dynamics researchers, topographical geological researchers, etc. For example, those who study ocean dynamics pay attention to the tides and the shape of the current axis when watching the movement of warm and cold currents. This tide is located in the convergence zone of the ocean current, where the temperature difference of seawater is sharp.

The sea conditions in this tidal sea area fluctuate greatly both temporally and spatially, and both hot and cold-water masses are disturbed and local convergence, subsidence areas, divergence, and upwelling areas are complicatedly arranged. In this area, the fishery is generally rich in nutrients and high in productivity and it is easy to gather both cold and warm schools of fish due to the flow, making it a good fishing ground. When this tide is captured as data, there are various shapes such as line, arc, circle, line pair, and the like. For example, looking at a line, there are various factors such as size, angle, and location. There are several of these shapes in one tide. To look at the tide from various angles and know the movements of the warm and cold-water flows, it is necessary to extract the necessary tide locations and images from the database.

In addition, if it becomes possible to search using the spatial characteristics of circles, it can be expected that cold water chunks, etc., which are known for forming good fishing grounds, can be easily searched. As other search key items, the observation place and observation date adopted by the current

Earth observation satellite image database systems were used. These search key items and various quantities of the browse image to be searched are as follows,

- 1) Image number << No. 1 ~ No. 100 >>
- 2) Sea surface temperature << 0-30 degrees >>
- 3) Chlorophyll-a content (0 mg / m³-35mg / m³)
- 4) Number of edges << 0 ~ 14 >>
- 5) Number of circles << 0 ~ 4 >>
- 6) Number of arcs << 0 ~ 5 >>
- 7) Number of lines << 0 ~ 4 >>
- 8) Observation place << random >>
- 9) Observation date << random >>
- 10) Cloud Cover << 1% ~ 100% >>

As described above, one browse image holds ten attribute values.

C. Search Engine Based on Fuzzy Theory

1) *Membership function:* In order to perform a search based on ambiguous search requests from users, a membership function is defined using fuzzy theory that can handle ambiguity. Assemble the search conditions using the defined membership function and perform the search together with observation location, observation date, etc.

It is considered that the analyst to search for is determined by the amount of cloud and is not specified vaguely. Therefore, the author considers a search method that allows ambiguous expressions for the remaining seven items. Therefore, it is

necessary to define a membership function for each physical quantity and space feature that we have taken up this time. However, how people perceive certain terms is different. Therefore, there is a problem that the membership function cannot be determined uniquely. Therefore, here, a questionnaire survey was conducted for members of the Information System Subcommittee of the Forum of the Earth Science and Technology Agency, and the membership function of each search condition item was determined. The exponential function of Eq. (1) was used as the function system.

$$\mu(x) = \int_a^b e^{-c(x-d)^2/x} dx \quad (1)$$

where, x is the value of each search condition item, and a, b, c, d are coefficients of the membership function shown in Table I.

2) *Definition of the language hedge*: The language hedge is a modifier attached to attribute information and is an operator that converts into attribute information (fuzzy set) having a qualifying meaning. The language hedge used this time is as follows:

- a) Pretty
- b) Very (Very)
- c) To some extent (A sort of)
- d) Somewhat (Rather)
- e) Some (More or less)
- f) Slightly

TABLE I. COEFFICIENTS OF THE MEMBERSHIP FUNCTION FOR EACH KEYWORD

Search Keywords	Attributes	a	b	c	d
Sea Surface Temperature	Warm	0	30	0.015	30
	Cool	0	30	0.15	0
Chlorophyll-a Concentration	Concentrated	0	1	0.003	35
	Sparse	0	1	30.0	0
Cloud Coverage	Concentrated	0	100	0.034	17
	Sparse	0	100	3.0	0
No. of Edges	Many	0	14	0.5	5
	Little	0	14	0.32	0
No. of Circles	Many	0	5	0.25	5
	Little	0	5	0.15	0
No. of Arcs	Many	0	6	0.3	6
	Little	0	6	0.2	0
No. of Lines	Many	0	4	0.6	4
	Little	0	4	0.5	0

Membership function: Number of lines "less"

There are six types. In order to calculate the centroid value from the membership function during the search, these were defined as follows respectively,

- a) Pretty A = NORM (INT (A) and not TNT (CON (A)))
- b) Very A = CON (A)
- c) A sort of A = NORM (not CON (A) 2 and DIL (A))
- d) Rather A= NORM (TNT (A))
- e) More or less A = DIL (A)
- f) Slightly A= NORM (A and not (very A))

where, “A” means a fuzzy set, and not means a negation operation and a product operation. Also, CON, DIL, NORM, and INT are called centralization, enlargement, normalization, and contrast enhancement, respectively.

$$CON(A) = A^2, \mu_{con(A)}(x) = \mu^2(x), DIL(A) = \sqrt{A}, \quad (2)$$

$$\mu_{DIL(A)}(x) = \sqrt{\mu(x)}, NORM(A) = \frac{A}{\mu_{max}}, \quad (3)$$

$$\mu_{NORM(A)}(x) = \frac{\mu(x)}{\mu_{max}}, \quad (4)$$

$$\mu_{INT(A)}(x) = 2\mu^2(x), 0 < \mu(x) < 0.5 \\ = 1 - 2(1 - \mu(x))^2, 0.5 < \mu(x) < 1.0 \quad (5)$$

where, x is a search condition item (physical quantity and spatial feature).

3) *AND, OR, NOT in search condition*: In order to allow a combination of multiple different search conditions, a logical operation such as AND, OR, and NOT of search conditions was devised. Center of gravity value. When a search request is issued, the physical quantity and spatial shape data of each image are examined using a membership function corresponding to ambiguous conditions. However, since all data are examined, all data are search results. Therefore, a threshold is set, and if x is included between the threshold and the maximum value of the membership function, it is considered that the condition is met. This time, the threshold value adopted the value using the center of gravity (CG) of the fuzzy set. The center of gravity of the fuzzy set is calculated by the following equation,

$$CG = \int_x x \mu_A(x) dx / \int_x \mu_A(x) dx \quad (6)$$

If there is no data that satisfies the condition input by the user, the data closest to the barycentric value is output as a search result.

4) *Data and browse image search*: In advance, edges, circles, arcs, and lines, which are spatial features, were extracted from the earth observation satellite image, and an index was constructed. For the extraction of the spatial features of these images, we used a combination of simple image classification, edge extraction by the relaxation method, and thinning as a method to extract such spatial features.

For the form on the browser that actually performs input and output, select the form from which the search conditions are actually written from the keyboard, and the conditions that apply to the image you are looking for from the given word group I have prepared two formats that can be searched by pressing the button. In the former, the conditions are entered on the keyboard, and complicated conditions containing AND, OR, and NOT conditions can be entered. Therefore, the operation became a little difficult. On the other hand, the latter makes it possible for anyone to easily search for images and prepares the one that saves the trouble of inputting conditions as much as possible. Therefore, only one mode was selected from the AND, OR, and NOT conditions, and the entered condition was searched according to the mode.

From the homepage (Home Page of the proposed Earth observation satellite image database retrieval system), from which you can select either "text input" or "button input". If "text input" is selected here, it will transition to the input form (the menu for retrieval keyword input in text form) as shown in Fig. 1. Here, the conditions are assembled from the example shown, input from the keyboard, and the search is performed. When "button input" is selected, the screen shifts to the input form (Menu for retrieval keyword input by clicking mouse button) as shown in Fig. 2. In this case, the input method is simpler than "text input", but it is not possible to input complicated conditions with complicated conditions.

V. EXPERIMENT

In this experiment, the browse image size was set to 64 by 64 pixels, and 100 images were prepared. These are a part of the original NOAA-11 / AVHRR¹ image of 3:37 GMT on April 25, 1990. The spatial features are extracted and compiled into a database by the method of reference, and the pixel interval of 1 km is also calculated. An 8 by 8 pixels average filter was used to create a browse image with a pixel interval of 8 km. Here, the condition "A7a and C3a (sea surface temperature is slightly warm, and the number of edges is very large)" is given as a search example.

Fig. 3 shows the example. An example of the retrieval for Sea Surface Temperature is slightly high and the number of edges is very large. The user can select a desired image from a given browse image and data of the image. An example of the retrieved results (Extract image No. 12 from the candidates of the browse images) shows the result of selecting image number 12. Fig. 4 shows an example of the retrieved results (Extract image No. 12 from the candidates of the browse images).

No. of Line: 3

Fig. 4. An example of the retrieved results (Extract image No. 12 from the candidates of the browse images)

Fig. 5 and 6 show examples of browse images and their spatial features extracted as search results. Fig. 6 is obtained from the extracted lines, edges, arcs and circles from the image of Fig. 5 based on the relaxation method² with the thinning algorithm.

Fig. 5. Details of the retrieved browse image (64 by 64 pixels with 8 km of pixel size extracted from the NOAA/AVHRR images).

Furthermore, when 30 subjects who did not have prior knowledge about remote sensing were asked to use the proposed search system, the number of language hedges was too large.

Fig. 6. Extracted spatial features (From the image of Fig.5, lines, edges, arcs and circles are extracted using the relaxation method with the thinning algorithm).

VI. CONCLUSION

A method for fuzzy retrievals of Earth observation satellite image database using geophysical parameters and spatial feature is proposed. It is confirmed that the proposed method allows fuzzy expressions of queries with sea surface temperature, chlorophyll-a concentration and cloud coverage as well as circle, line and edge, for instance “rather cold sea surface temperature and a sort of circle feature”. Thus users, in

particular, oceanographers may access the most appropriate image data from the database for finding of cold cores (circle features), fronts (arc and line features), etc. in a simple manner.

According to the retrieval method proposed in the paper, physical quantities and spatial features extracted from the earth observation satellite image to be retrieved are added to the inventory data, and retrieval can be performed faster and more efficiently using these. In addition, the search condition setting of those physical quantities and spatial features was allowed to be ambiguous, and the user's freedom of search was expanded. It also simplifies the method used by the user to enter conditions and displays browse images and their data as search results so that they can be easily viewed on the WWW, making it easy to visually confirm the results.

FUTURE RESEARCH WORKS

In the future, the proposed search method will be constructed as a database system and made public through WWW (<http://www.kyuic.gr.jp/>), and further improvement proposals from users will be made to be more practical.

ACKNOWLEDGMENT

The authors would like to thank to Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their valuable discussions.

Abstract—Improvements in the quality of tourism services and the number of human resources will affect the quality of social services and information services provided to foreign tourists, thereby enhancing the quality of services offered regarding tourist destination information in the Malang Raya area. Considering the urgency of foreign tourists in obtaining information related to directions, routes, and access roads to their desired tourist destinations, especially in East Java, due to limited data from the government agencies handling the tourism sector, as well as the difficulty in communication with residents who may not understand what is being communicated by foreign tourists. Therefore, the need for an interactive chatbot to assist in obtaining routes and access information to the desired tourist destinations will facilitate foreign tourists. To improve the accuracy of the chatbot's ability to answer sentence selection, the use of artificial intelligence, specifically the Random Forest Classifier, is necessary. This study obtained the highest accuracy value using a tree quantity of 200, a maximum tree depth of 20, and a minimum sample split of 5. Using these quantities resulted in an accuracy of 95.88%, precision of 96.29%, recall of 96.03%, and f-measure of 96.16%.

Keywords—Tourism; chatbot; artificial intelligence; random forest classifier

I. INTRODUCTION

Tourism is a dynamic activity involving many people and stimulating various business sectors. In the current era of globalization, the tourism sector will become the main driver of the world economy and global industry. Tourism will provide significant revenue for regions aware of its potential in the tourism sector [1]. Thus, tourism has become an integral part of human life. The tourism sector has led several regions in Indonesia to develop tourism as their distinctive feature.

One area with great tourism potential is Malang, located in the East Java province of Indonesia. Malang Raya has three administrative areas: Malang Regency, Malang City, and Batu City. Malang Raya is one of the leading tourist destinations in East Java and Indonesia. According to statistical data compiled by the Ministry of Tourism and Creative Economy in 2022, the total number of international tourists visiting Malang Raya reached six million [2].

The Malang Raya region offers many beautiful tourist destinations unique to other areas in Indonesia. Malang Raya offers various tourism categories, from natural to

manufactured attractions. According to data from the Malang Regency's One Data program, there are 16 village tourism objects, 106 natural tourist attractions, 49 cultural tourist attractions, and 24 manufactured tourist attractions in the Malang Regency area [3]. According to data from the Central Statistics Agency (BPS) of Batu City, there are ten manufactured tourist attractions, 12 village tourism objects, five natural tourist attractions, five souvenir tourist attractions, and one religious tourist attraction in the Batu City area [4]. According to data from Malang's One Data program, there are 16 cultural tourist attractions, two historical tourist attractions, four religious tourist attractions, one educational tourist attraction, 2015 culinary tourist attractions, 12 shopping tourist attractions, and 20 manufactured tourist attractions in the Malang City area [5].

The abundance of tourist destinations in the Malang Raya region provides many options for international tourists. However, on the other hand, with the increasing number of tourist destinations, issues arise regarding information about the destinations to be visited. International tourists require comprehensive information about routes, directions, and ways to guide their travel, but not all available information from print media, television, the Internet, and other sources can meet these needs [6]. Another issue in the tourism sector is the low quality of service and quantity of human resources in the tourism industry worldwide. This aspect needs special attention in efforts to improve the tourism sector in the Malang Raya region. The quality of tourism services and the quantity of human resources are among the standards that will be compared to achieve tourist satisfaction [7]. Improvements in the quality of tourism services and the number of human resources will affect the quality of social service and information services provided to international tourists, thereby enhancing the quality of services related to tourist destination information in the Malang Raya region.

Another issue encountered is the current condition of the official websites of the Department of Culture and Tourism of Malang Regency, Malang City, and Batu City, which only provide brief information about tourist attractions and lacks interactive question-and-answer features that can guide foreign tourists in terms of directions, routes, and roads to the destinations. As a result, foreign tourists have to search for routes or access on their own through several stages. The lack of digital information services like this can lead to inefficiency

and ineffectiveness in obtaining access information or routes to selected tourist destinations by foreign tourists [7].

Another issue is the poor communication between residents and foreign tourists. This is due to the lack of knowledge, which prevents residents from understanding what foreign tourists communicate [8]. This has become a significant concern for the government, notably the Tourism Sector Institution in the Malang Raya area. Considering the urgency and the difficulty faced by foreign tourists in obtaining information regarding directions, routes, and access to tourist destinations, especially in East Java, due to limited information from the government agencies handling the tourism sector, as well as the difficulty in communication with residents who do not all understand what foreign tourists are communicating. According to the author, there is a need for an interactive chatbot that can assist in obtaining route information and access to the desired tourist destinations, which will facilitate foreign tourists.

Artificial intelligence must be utilized to improve the chatbot's accuracy in answering sentence selection. Several previous studies have added artificial intelligence to building chatbots. One of which is creating a chatbot related to Covid-19 [9]. Other research is also being carried out in building chatbots with artificial intelligence, namely a classification method to identify intentions rather than user input, it is called purpose classification in the chatbot system [10]. Furthermore, in the field of tourism, another research has been conducted by creating a website along with a chatbot for the city of Kanazawa [11]. The method used in this research is the Random Forest Classifier method. Random Forest Classifier is an algorithm that results from the bootstrapping aggregation of Decision Tree algorithms. This research employs this method due to its advantages over other algorithms, as it falls into Classification and Regression Tree (CART) methods, which utilize historical data to build a decision tree.

Based on the background, the author believes that an interactive chatbot capable of assisting foreign visitors in obtaining information about routes and ways to reach their desired tourist destinations will greatly facilitate them. In this study, it is expected that an interactive chatbot using the Random Forest Classifier method can optimize the accuracy level in sentence prediction performance and utilize the Telegram Messenger to structure the data more effectively while also providing social services.

II. LITERATURE REVIEW

A. Chatbot

Chatbot is a program in artificial intelligence designed to communicate directly with humans as its users. The difference between a chatbot and a natural language processing system is the algorithms' simplicity. Although many bots can interpret and respond to human input, they only interpret keywords in the input and reply with the most suitable keywords or patterns of words from pre-existing data in a database created beforehand [12]. The future of Software Engineering is expected to undergo a significant transformation with the emergence of chatbots. These chatbots will enable software practitioners to communicate and inquire about their projects

using everyday language, revolutionizing how they interact with various services. At the core of every chatbot lies a Natural Language Understanding (NLU) component, which empowers the chatbot to comprehend and interpret human language inputs [13].

Initially, these computer programs (bots) were tested through the Turing test, which involved concealing their identity as machines to deceive the person conversing with them. If a user cannot identify the bot as a computer program, that chatbot is categorized as artificial intelligence.

One famous chatbot is Eliza (Dr. Eliza), developed by Joseph Weizenbaum at the Massachusetts Institute of Technology (MIT). Eliza is a pioneering chatbot known as a chat program that plays the role of a psychiatrist. Eliza simulates conversations between a psychiatrist and their patients in natural English. Eliza was created to study natural language communication between humans and machines. Eliza acts as a psychologist who can answer the patient's questions with reasonable responses or respond with further questions [12].

B. Random Forest Classifier

Random Forest is a method introduced by Breiman, a development and combination of multiple Decision Trees. While a Decision Tree represents a single classification tree, Random Forest creates multiple trees to determine its prediction results. Combining bootstrap aggregating and random feature selection in a Random Forest can reduce the overfitting problem in small training data [14]. Since Random Forest is an ensemble method of CART, it does not assume or work well in non-parametric cases.

The steps involved in the Random Forest as shown in Fig. 1 are explained as follows:

- Determining the parameters of Random Forest. The value of $mtry$, or the number of randomly selected predictor variables, is set to $\frac{p}{3}$ for regression cases, where p is the total number of predictor variables [14].
- Then, determine the recommended number of N_{tree} trees to use, typically 50 trees. According to Breiman [14], 50 trees provide satisfactory results for classification cases. However, $N_{tree} \geq 100$ yields lower misclassification rates [15].
- Specifying the stopping criteria default in scikit-learn Random Forest, where one means that if a subnode/child node contains only 1 sample, it will stop splitting and become a terminal node/leaf node. Therefore, once the branching stops, terminal nodes are generated as the prediction result of a single CART tree [16].
- Splitting the data into training and testing datasets. From the training data, n samples are randomly selected with replacement (bootstrap) to create a new dataset D , where I represents the bootstrap sample division of the i -tree.

- The bootstrap sampling only takes $\frac{1}{3}$ of the entire training data and the remaining $\frac{2}{3}$ is considered out-of-bag (OOB) data, which is useful for measuring the performance of regression trees [17].
- Making predictions based on constructing tree models from the new dataset D, using a combination of randomly selected m predictor variables (random feature selection).

Fig. 1. Flow diagram of random forest.

III. PROPOSED MODEL

The initial stage involves data collection. Data collection for this research uses references from Google, specifically collecting frequently used conversational sentences in English. The data collection for this research is divided into two parts: training data collection and testing data collection. While collecting training data, the author used 100 conversational sentences in English. These sentences were then labeled based on their sentence classes, whether they belonged to the statement (S), question (Q), or chat (C) class. Table I provides

an example of the conversational sentences used as training data, labeled based on their sentence classes.

TABLE I. EXAMPLE DATASET OF SENTENCE FOR MODEL FORMATION AND CLASSIFICATION

No	Sentence	Label
1	Sorry, I don't know about the weather.	S
2	What's the weather like today?	C
3	I am fine	C
4	Where do you live?	Q
5	Are you a chatbot?	Q

After labeling the dataset consisting of 100 conversational sentences, the dataset will be processed by assigning Part-of-Speech (POS) tags to each word in the corpus. Fig. 2 displays the type of Penn treebank tagset. Once POS tags are assigned, the patterns for classifying the training sentence models will be determined. Part-of-Speech (POS) tagging, or simply tagging, is the process of assigning syntactic labels or Part-of-Speech tags to each word in the corpus. Since tags are generally applied to punctuation marks, punctuation marks such as periods, commas, etc., must be separated from the words during the tagging process. The extracted features from the data are used to build the required model by extracting Part-of-Speech (POS) tags, resulting in numerical data features. Fig. 3 provides an example of the POS tagging process in this research.

After that, the tags in each sentence will be calculated according to the predetermined tags, serving as a reference for pattern formation within the sentences. The tags used as markers in this process include a cardinal number (CD), noun singular or mass (NN), proper noun singular (NNP), proper noun plural (NNPS), noun plural (NNS), personal pronoun (PRP), verb gerund or present participle (VBG), and verb 3rd person singular present (VBZ). Table II provides an example dataset table for counting the number of Part-of-Speech (POS) tags.

Tag	Description	Example	Tag	Description	Example
CC	coord. conjunction	and, or	RB	adverb	extremely
CD	cardinal number	one, two	RBR	adverb, comparative	never
DT	determiner	a, the	RBS	adverb, superlative	fastest
EX	existential there	there	RP	particle	up, off
FW	foreign word	noire	SYM	symbol	+, %
IN	preposition or sub-conjunction	of, in	TO	"to"	to
JJ	adjective	small	UH	interjection	oops, oh
JJR	adject., comparative	smaller	VB	verb, base form	fly
JJS	adject., superlative	smallest	VBD	verb, past tense	flew
LS	list item marker	1, one	VBG	verb, gerund	flying
MD	modal	can, could	VBN	verb, past participle	flown
NN	noun, singular or mass	dog	VBP	verb, non-3sg pres	fly
NNS	noun, plural	dogs	VBZ	verb, 3sg pres	flies
NNP	proper noun, sing.	London	WDT	wh-determiner	which, that
NNPS	proper noun, plural	Azores	WP	wh-pronoun	who, what
PDT	predeterminer	both, lot of	WP\$	possessive wh-	whose
POS	possessive ending	's	WRB	wh-adverb	where, how
PRP	personal pronoun	he, she			

Fig. 2. Penn treebank tagset.

Fig. 3. Example of POS tagging.

TABLE II. EXAMPLE DATASET FOR COUNTING THE NUMBER OF PART-OF-SPEECH (POS) TAGS

No	Word Totals	C	N	NNP	NNS	PRP	VBG	VBZ
1	7	0	1	1	0	0	1	0
2	5	0	2	0	0	0	0	1
3	3	0	0	0	0	0	1	0
4	4	0	0	0	0	0	1	0
5	4	0	1	0	0	0	1	0

After collecting the training dataset of conversational sentences and the Part-of-Speech patterns for building the classification model, the next step is to determine the dataset of conversational sentences to be used as the output sentences for the chatbot based on the formed training classification model. The dataset represents the data used in the testing process. There are 4,085 conversational sentences that will be used as the dataset in the testing process. Subsequently, this data will be labeled according to the sentence classes. The labeling is based on the criteria of whether the sentence belongs to the question (Q) or chat (C) class, similar to the labeling in the first dataset. Table III provides an example dataset table of conversational sentences that will be used in the testing process.

TABLE III. EXAMPLES OF OUTPUT SENTENCE DATASETS USED IN THE TESTING PROCESS

No	Sentence	Label
1	Hi there, how are you!?	C
2	My name is Tourist Chatbot, but you can call me Lisa	C
3	ok, thanks!	C
4	Do you like it?	Q
5	What's that?	Q

The next stage is to process the user's input in conversational sentences. The entered conversational sentences by the user will go through the processing stage, which includes preprocessing and training processes. In the preprocessing stage, a Natural Language Processing (NLP) approach is used, which involves case folding to convert all letters in the document to lowercase, tokenization to separate input words into individual tokens, stemming from finding the base form of words and producing the correct language structure, and POS tagging to assign Part-of-Speech tags or syntactic classes to each word in the corpus.

After the preprocessing process, the data will proceed to the training process, which involves training the preprocessed data using the Random Forest Classifier approach (see Fig. 4). In this data training stage, a classification model will be formed through the training using the Random Forest Classifier method. The final stage is testing, which is conducted to obtain accuracy and error values for the chatbot. Once the process is completed, the system will generate an output sentence to be sent as a response to the user's input sentence.

IV. IMPLEMENTATION

The implementation phase is the stage of applying the designed system based on the system design that has been created. The results of this system implementation are used to classify sentences in the virtual route guide chatbot using the random forest classifier method. The implementation phase begins by inputting data into the system that has been created using the Python programming language. The labeled sentence data, stored in .csv format, is inputted into the system, and the column containing the conversational sentences and sentence classes is extracted.

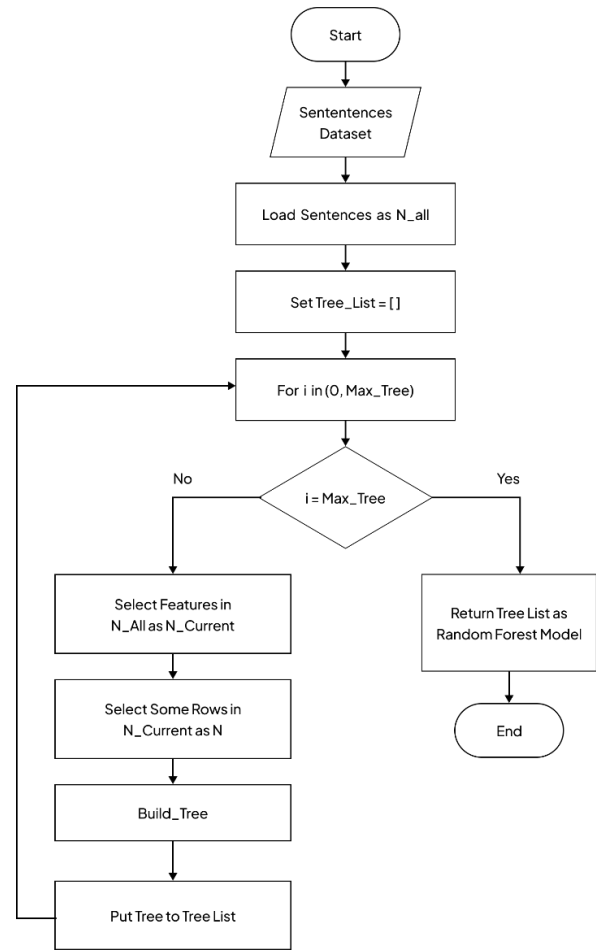

Fig. 4. Random forest classifier algorithm flowchart.

Next, the system proceeds to the initialization stage of part-of-speech patterns for sentence formation, which will be used in feature selection. Several part-of-speech patterns are used in this initialization stage, such as VerbCombos, questionTriples, statementTriples, startTuples, and endTuples. Then, feature_keys are initialized as keywords for the part-of-speech tags used.

After completing the initialization stage, the system moves to the preprocessing stage, including case folding, tokenizing, stemming, and POS tagging. The case folding process utilizes the lower() function to convert the entire sentence to lowercase to avoid case sensitivity. The tokenizing process uses the split() function to separate the sentence into individual words. The stemming process utilizes libraries from

NLTK with the WordNetLemmatizer and SnowBall algorithms. The POS tagging process assigns Part-of-Speech tags to each word in the corpus.

The next step is to create a function to count the frequency of occurrence of part-of-speech tags in each sentence. The processed data, using the function to count the frequency of part-of-speech tags, is then stored in a data frame containing the calculated frequency counts and saved in a new CSV file. This data calculates the number of part-of-speech tags in each sentence. Once the calculated frequency counts of part-of-speech tags are successfully saved, the dataset is imported and loaded into Python. Then, the class variable with the object data type is converted to the int64 data type. This is because the class variable represents a category that indicates it is categorically ordinal.

Next, the feature-selected data stored in a new file will be divided into training and testing data. The training data will be implemented into the system that has been created to build a sentence classification model using the random forest classifier. Based on the rule of thumb, the training and testing data will be split in a 75:25 ratio, with 4,185 pattern data points to be implemented in the system. This data split is done using the model_selection library's train_test_split function.

After dividing the data into training and testing sets, the next step is to train the dataset by creating a classification model using the random forest classifier. The aim is to classify data effectively and efficiently. This model is used to classify data into multiple categories or classes with high accuracy. In creating this classification model, the feature extraction function is used to improve the accuracy of the classification model by eliminating irrelevant features and retaining the most important features in the data. By selecting the most relevant and important features, the classification model can find more accurate patterns and distinguish between different classes better.

Once the training model is created, the next step is to create a Telegram account and access @BotFather. @BotFather is the official Telegram bot that allows users to create their own Telegram bot. After creating the Telegram bot, the next step is to install the python-telegram-bot library. This library is used to connect the bot to the Telegram API and send and receive user messages.

The next step is to write Python code for the bot and add message-handling functions that the bot will process. In creating the Python code, the telegram.ext module from the python-telegram-bot library is required. Then, an Updater object is created with the bot token and the bot is started using the command "updater.start_polling()". The message-handling function will be executed every time the bot receives a new message from the user. Specific logic is added to the message handling function to process user requests and provide appropriate responses based on the received message.

V. EXPERIMENTAL RESULT

In this research, there are two datasets, each consisting of 100 and 4,185 labeled conversational sentences according to the rules of Part-of-Speech (POS) tagging, based on the criteria of whether the sentences belong to the question (Q) or chat (C) class. Table IV shows the number of sentences in each label within the conversational sentence dataset used as training data for the classification model.

TABLE IV. NUMBER OF SENTENCES PER LABEL

Dataset 1		
No.	Label	Number of Sentences
1	S (Statement)	32
2	Q (Question)	43
3	C (Chat)	25
Total Number of Sentences		100
Dataset 2		
No.	Label	Number of Sentences
1	S (Statement)	1473
2	Q (Question)	1.238
3	C (Chat)	3.073
Total Number of Sentences		4.185

The data will be divided into two parts: training and testing data. The training data will be implemented into the system that has been created to build a classification model using the random forest classifier for sentences. Meanwhile, the testing data is used to evaluate the system's performance. The conversational sentence dataset will be divided into testing data and training data with a ratio of 75:25 based on the rule of thumb. In addition, experiments are conducted by varying the number of trees (n_estimators), tree depth (max_depth), and the minimum number of samples required to split a node (min_sample_split). The number of trees tested is 100, 200, and 500, the depth of the trees tested is 5, 10, and 20, and the minimum samples required to split a node tested are 2, 5, and 10.

From Table V, the highest accuracy value is obtained using 200 trees, with a maximum tree depth of 20 and a minimum sample split of 5. Using these parameters yields an accuracy value of 95.88%, precision of 96.29%, recall of 96.03%, and f-measure of 96.16%. On the other hand, the lowest accuracy value is obtained from using 500 trees, with a maximum tree depth of 5 and a minimum sample split of 10. Using these parameters yields an accuracy value of 94.43%, precision of 95.29%, recall of 94.61%, and f-measure of 94.95%. These accuracy results are also depicted in the visualization graph, as shown in Fig. 5.

TABLE V. SHOWS THE TESTING RESULTS USING 100, 200, AND 500 TREES WITH A COMBINATION OF 20 MINIMUM SAMPLES AND 10 MINIMUM SAMPLES REQUIRED TO SPLIT A NODE

Tree	Deep Max. Tree	Min. Sample	Accuracy	Precision	Recall	F-measure
100	5	2	94,58%	95,30%	94,80%	95,05%
		5	94,73%	95,40%	94,95%	95,17%
		10	94,66%	95,35%	94,87%	95,11%
	10	2	95,42%	95,94%	95,61%	95,78%
		5	95,34%	95,89%	95,53%	95,71%
		10	95,11%	95,70%	95,32%	95,51%
	20	2	95,50%	95,83%	95,73%	95,78%
		5	95,73%	96,12%	95,91%	96,02%
		10	95,50%	96,00%	95,65%	95,82%
200	5	2	94,66%	95,45%	94,83%	95,14%
		5	94,73%	95,50%	94,91%	95,21%
		10	94,58%	95,40%	94,76%	95,08%
	10	2	95,57%	96,08%	95,75%	95,92%
		5	95,50%	96,07%	95,65%	95,86%
		10	95,42%	96,01%	95,57%	95,79%
	20	2	95,42%	95,74%	95,71%	95,72%
		5	95,88%	96,29%	96,03%	96,16%
		10	95,57%	96,05%	95,73%	95,89%
500	5	2	94,50%	95,35%	94,69%	95,02%
		5	94,50%	95,35%	94,69%	95,02%
		10	94,43%	95,29%	94,61%	94,95%
	10	2	95,50%	96,00%	95,69%	95,84%
		5	95,42%	95,98%	95,59%	95,78%
		10	95,42%	95,98%	95,59%	95,78%
	20	2	95,50%	95,76%	95,82%	95,79%
		5	95,80%	96,24%	95,95%	96,09%
		10	95,57%	96,05%	95,73%	95,89%

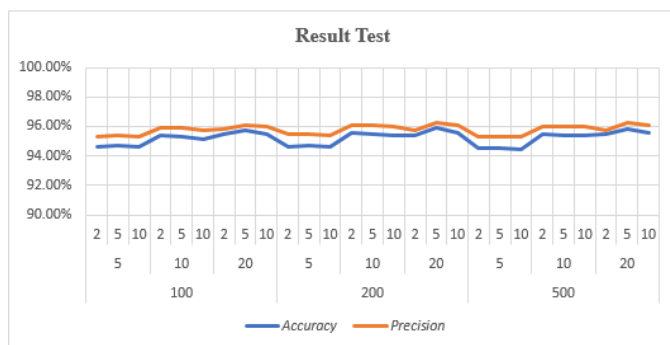

Fig. 5. Visualization of test results in conversational sentences.

VI. CONCLUSION

The result of this research is an interactive chatbot created using the Random Forest Classifier method, which can optimize the level of accuracy in sentence prediction performance and utilizes Telegram Messenger to structure the

data more effectively. According to the test results in the previous section, this study obtained the highest accuracy value using a tree quantity of 200, a maximum tree depth of 20, and a minimum sample split of 5. Using these quantities resulted in an accuracy of 95.88%, precision of 96.29%, recall of 96.03%, and f-measure of 96.16%. This proves that the use of random forest classification affects the sentence classification results. The reason is the existence of feature selection that can reduce the features used.

ACKNOWLEDGMENT

Abstract—In recent years, distance learning has become an increasingly popular mode of education due to its flexibility and accessibility. However, the quality of distance learning programs has been a cause for concern, which has led to the development of various approaches and tools for quality assurance and assessment. This review article aims to provide an in-depth analysis of the current state of play of quality assurance in distance learning. The paper discusses the fundamental requirements to establish quality in distance learning and the challenges associated with ensuring quality in this mode of education. Then it explores the different approaches and tools used for quality assurance and assessment, such as course evaluations, self-assessments, and external reviews. In addition, the paper delves into the development of regulatory documents and manuals for quality assurance, which are essential for ensuring that distance learning programs adhere to established standards. It also discusses in detail the importance of audits and accreditations from assessment organizations in assuring quality in distance learning. As the satisfaction of all stakeholders (including students, faculty, and administrators) is crucial for ensuring the success of distance learning programmes, the paper highlights the various measures HEIs can take to ensure stakeholder satisfaction. Finally, the article discusses the processing of statistical data and performance indicators, which can provide valuable insights into the effectiveness of distance learning programmes.

Keywords—Distance learning; quality assurance; assessment; stakeholder satisfaction; regulatory documents; performance indicators

I. INTRODUCTION

The rapid adoption of distance education in higher education institutions (HEIs) worldwide has brought about demands from scientific and technological developments and some challenges to quality, including technological problems, administration, instructional methods, and student barriers. Quality management in distance learning courses is vital for improving the overall educational experience, yet the indeterminate definitions of quality make it challenging to evaluate effectively [1]. Students and educators face barriers such as low self-organization, lack of effective interaction, and a sense of isolation that can decrease their satisfaction with online learning. While distance learning courses have prevented transfer from theory to design practices, using a quality assurance model for web-based learning and implementing benchmarks[2], e.g. in course development, teaching/learning process, course structure, and faculty support categories, can help. The six dimensions for measuring service

quality in distance education are tangibles, reliability, responsiveness, delivery, assurance, and student participation [3].

The shift towards distance learning has also raised concerns about the impact on crucial social learning aspects, particularly for early elementary children and vulnerable student populations. The move to a distanced setting has reduced opportunities for face-to-face interaction, which is essential for promoting collaboration, teamwork, and socialization. However, the use of innovative technology, such as virtual classrooms, online discussion forums, and social media platforms, can provide alternative ways for students to interact and engage with their peers and instructors [4]. Furthermore, the quality of distance learning depends only on the course design and delivery but also on the level of readiness and support provided by the government and educational institutions. There is a significant association between parents' satisfaction with the quality of education, how they assess teachers' competencies and the level of government readiness to switch to a distance learning format [5]. Therefore, it is essential HEIs to ensure adequate resources and infrastructure and that instructors are adequately trained and equipped to deliver quality distance education.

Another concern is while distance learning cannot replace traditional education to a full degree, it can serve as a valuable complement. HEIs can utilize distance learning to enhance the knowledge and skills of students in various areas [6], such as emerging technologies, digital literacy, and educational technology. Moreover, the relationship between teachers and students has been identified as a significant factor in determining students' satisfaction with distance learning courses. A positive teacher-student relationship plays an intermediary role when linking the attitudes and behaviour of teachers with students' overall satisfaction with learning courses [7].

Additionally, distance learning cannot fully substitute traditional learning forms in HEIs, but distance learning can provide valuable enhancements. It is crucial to acknowledge that transitioning to distance learning may limit certain social learning aspects, particularly among younger students and vulnerable populations. However, HEIs can leverage distance learning to reduce costs and attain sustainable advantages [8]. Furthermore, the relationship between the attitudes and behaviour of teachers and students' overall satisfaction with their courses should be examined through mediation,

underscoring the critical success factors within the quality assurance framework.

Although the topic of quality assurance of distance education has been widely studied by researchers for decades, there is a need to systematize all possible ways to ensure the quality of education.

This paper explores the essential components of quality management in distance education. Section II delves into the specific requirements needed to ensure quality in distance learning. It examines the fundamental aspects that must be considered and implemented to maintain high standards in delivering educational content. Section III focuses on the various definitions of quality in the context of distance learning. As reports of the diverse perspectives and interpretations of quality, this section provides clarity and understanding of the concept, laying the foundation for efficient evaluation. The paper then discusses approaches and tools for assuring and assessing quality in distance education. These include the development of normative documents and manuals that serve as guidelines and benchmarks for quality assurance. In addition, the section emphasizes the importance of conducting audits and accreditation by reputable assessment organizations. The paper further highlights the significance of gathering feedback through periodic surveys among stakeholders, including academic staff, students, and external entities. Finally, it explores the utilization of intelligent data analysis tools, enabling deep insights into the effectiveness and quality of distance learning programs. The Conclusion summarizes the contributions and plans for future work.

II. QUALITY OF DISTANCE LEARNING: DEFINITIONS

Researchers and various stakeholders (students, teachers, HEIs leadership, employers, external evaluators, etc.) widely discuss issues related to the quality of distance learning. All emphasize the need for a better understanding of the aspects that contribute to achieving high quality in distance learning programs [9]. There is no universally accepted definition of quality in distance learning. Quality is a multidimensional concept encompassing a wide range of products, services, supplies and philosophies and attempts to meet the needs and expectations of students and various stakeholder groups with different interests [10].

According to Robinson [11], the quality of distance learning can be the result of various factors, both internal and external to the HEI, for example, the skill levels and experience of the staff, the number of resources available, weak or strong leadership, the effectiveness of administrative systems and the communication infrastructure.

Some researchers emphasize adherence to standards and procedures [10], that apply to each course and influence course design, course layout and the amount of learning content. Burns [12] defines quality as adherence to a set of standards for content, design, and instruction, and Lassoued, Alhendawi, and Bashitialshaer [13] - as a set of procedures and guidelines adopted in the educational institution that supports the management of the organization and provision of services. According to Roe [14], significant components for developing quality distance courses are the assurance of rich multimedia,

asynchronous communication, and faculty mentoring. Achieving quality teaching and learning is a complex endeavour involving multiple dimensions [15], including curriculum design and course content, learning contexts, use of feedback, assessment of learning outcomes, learning environment, and student support services.

Other researchers emphasize the design and delivery of training. To achieve a high quality of training, the academic staff must have experience in developing educational content for distance learning [16], skills in using technology, and applying modern pedagogical approaches to teaching and guiding students in the learning process [17-24]. In addition, educators should implement forms of communication and interaction that are student-centred and encourage their active participation in the learning process [25], provide support to students [26], and use forms of assessment consistent with individual or group distance learning approaches and stimulating critical thinking [16]. Elias [27] presents eight instructional design principles for the quality of distance learning courses - Equitable Use, Flexible Use, Simple and Intuitive, Perceptible Information, Tolerance for Error, Low Physical and Technical Effort, Community of Learners and Support, and Instructional climate. According to McClary [28], high-quality distance courses are those in which the learning content is up-to-date, each module contributes to a specific course objective, the instructor provides the necessary support to students, and there is an effective support system. Lee and Dziuban [29] believe that the success of e-learning largely depends on strategies for evaluating the quality of the distance learning program. Grutzner, Weibelzahl, and Waterson propose four dimensions for assessing the quality of e-courses [30]: the content of learning materials, presentation of learning materials, teaching style, and overall course functioning. According to them, HEIs must consider these dimensions simultaneously and continuously throughout the life cycle of learning e-courses to ensure a high-quality product. Clayton Wright sets out criteria for evaluating the quality of e-courses [31], including general course information, information accessibility, course organization, language, layout, goals and objectives, course content, learning strategies, practice opportunities, learning resources, and assessment.

A third group of researchers emphasize student outcomes [12] and argue that the quality of distance learning can be spoken of when there is evidence that students leave with relevant knowledge and skills for post-graduation employment and employer satisfaction. A significant factor in improving desired learning outcomes and student satisfaction is students' engagement during learning [32-33]. According to Markova, Glazkova, and Zaborova [1], student satisfaction is influenced directly by the skills of teachers to use active learning techniques effectively, integrating high-level interaction and collaboration in instructional design, and ensuring high-quality and timely support and resources for learners.

Another group of researchers defines more components for the quality of the learning process in distance learning. According to Zaman, Ghosh, Datta and Basu [34], the quality of e-learning depends on the quality of the learning content, the quality of the learning management system from a technological point of view (ease of use, reliability, etc.) and

the quality of services (support of e-learning participants). Montedoro and Infante indicate three dimensions of the quality of learning management systems [35]: Technology, Content and Services. Lanzilotti, Ardito and Costabile [36] define the quality of the learning management system as the extent to which the technology, interaction, content, and services offered match the expectations of teachers and learners and enable them to teach/learn with pleasure.

Opponents of distance learning outline issues related to the quality and effectiveness of distance education compared to conventional educational models caused by several reasons. The main one is the ever-increasing demand for informed human resources to participate effectively in the global market [37]. Proponents of distance learning [25], [38-39] argue that distance learning should be as effective as face-to-face learning. HEIs can prove this by demonstrating that the quality of content, delivery, assessment, and outcomes in distance learning is equal to or better than traditional forms of education [9].

E-learning and distance learning are growing in popularity during the COVID-19 pandemic. The imposed restrictions catalyzed the digital transformation and modernization of all educational processes [10], [40-43], including in universities without previous experience in organizing and conducting distance learning. The forced transition to online learning presents HEIs with the challenge of fully transitioning to online learning while maintaining the quality of the education provided [44]. It also increases the interest of researchers in developing tools for assessing the quality of the functioning of educational software in HEIs [10], [43] and identifying elements that influence student satisfaction and allowing HEIs to develop strategies to ensure the quality of digital transformation [42].

According to Robinson [11], an aspect that is receiving increasing attention is how HEIs manage their quality regardless of their structure, context, or circumstances. Quality assurance is an approach to quality management that focuses on process management and aims to demonstrate and improve the quality of educational products and outcomes, to enable systematic management and monitoring of performance against set objectives [11]. Implementing a quality assurance system in higher education requires a share of responsibilities between the managers and all stakeholders [45-49]. It implies solving challenging tasks to address multiple dimensions, aspects, and meanings of quality from different perspectives and interests [10]. The quality assurance system may include a well-defined set of principles and procedures for achieving the overall goals of the institution, standards of achievement, established ways of responding to problems and clear accountability for results, a plan for training and development of staff, monitoring procedures of performance [10-11], [38]. Because HEIs must make continuous efforts to exceed the expectations of students and stakeholders, a good quality assurance system must be focused on student satisfaction [10] and periodically updated. As a result of implementing a systematic and consistent quality assurance system, HEI receives greater public trust, improves its reputation and image, and students are more satisfied and more inclined to recommend the institution.

Whatever approach to quality management is adopted, higher education management needs resources and tools to manage ongoing processes effectively. According to Robinson [11], quality management can be supported by information from core functional areas (finance, student records, etc.) and data from monitoring, evaluation, and satisfaction surveys. Researchers argue that quality can be monitored by looking at the impact of higher education in terms of evidence of high-quality student performance, including wages, employer satisfaction, and success in further study. For monitoring purposes, HEI may also collect personal data.

An effective quality assurance system includes continuous quality assessment [10]. While the internal evaluation is the basis for improvement, external evaluation serves as a benchmark, ensures public trust, and conforms to generally accept good practices for organizing and conducting distance learning.

The hardships in defining the meaning of quality pose challenges in developing quality assessment models and tools [50]. Researchers believe that distance learning programs, in addition to specific criteria [51], should be assessed according to the evaluation criteria of full-time programs [52]. Quality can be measured by student engagement and satisfaction [28], [53-54] and their attitude towards distance learning. In addition to evaluating the quality of the training, HEI can use the student feedback to develop and promote courses and programs for teachers' professional development and take results into account during the attestation of the teachers and when making decisions about their promotion.

III. RESULTS: APPROACHES AND TOOLS FOR QUALITY ASSURANCE AND EVALUATION

The known approaches to ensuring and assessing the quality of distance learning can be divided into five main groups:

- Development of normative documents and manuals for quality assurance.
- Conducting audits and accreditation by evaluation organizations.
- Conducting periodic surveys among stakeholders (academic staff, students, external stakeholders).
- Processing of statistical data and performance indicators, including by using intelligent data analysis tools.

In most cases, these approaches are applied mixed to provide a comprehensive set of data allowing the evaluation of the quality of distance learning and taking measures to improve it.

A. Normative Documents and Manuals

To ensure quality, some universities worldwide develop, adopt and implement internal regulatory documents written following current national and regional regulations and laws. An example of such regulatory documents created for the needs of organizing and conducting distance learning in Bulgaria is presented in the book "Quality and Assessment of

e-learning (with good university practices)” [55]. The proposed package of documents includes a Strategy for the development of distance learning, Regulations for organizing and conducting distance learning, a Student Support System, a Handbook on the rights and obligations of students, Methodology for preparation, organization, and conduct of distance learning, Testing, and evaluation system, Guidelines and standards for development and acceptance of learning documentation, Procedures, and regulations for actions in case of complaints, Procedures for punishing and preventing plagiarism attempts, Directory for organizing access to electronic resources, Regulations for technical and technological provision of training, Document for accounting for the specifics of workload, Measures, and procedures for restoring the infrastructure in case of damage or breakdown.

Many independent organizations worldwide promote and support quality improvement, develop and publish quality assurance guidelines and frameworks, disseminate information on good practices for the organization and delivery of distance learning, and encourage the creation of practitioner networks [56] which can contribute significantly to quality assurance. Examples of such organizations are the European Association of Distance Learning Universities (EADTU), the British Open Learning Association, the Canadian Distance Learning Association, the Norwegian Distance Learning Association, and the International Council for Open and Distance Learning (ICDE). The European Commission for Standardization CEN develops frameworks, specifications, and guidelines to improve the quality and transparency of organizations, products, processes, and services for e-learning. There are currently four published documents: CWA 15555:2006 Guidelines and Support for Building application profiles in E-learning; CWA 15660:2007 Providing good practice for E-Learning Quality Approaches; CWA 15661:2007 Providing E-Learning supplies transparency profiles; CWA 16655-1:2013 In LOC – Part 1: Information Model for Learning Outcomes and Competences.

The Higher Learning Commission [57] developed Assessment Guidelines setting out nine hallmarks of distance learning quality and providing suggestions for sample evidence documents for each. The European Association of Distance Learning (EADL) aims to increase the quality of distance learning and provide student benefits. EADL organizes for its members a forum for open discussions on all matters related to distance learning and for the sharing of ideas and good practices. All association members must meet the quality standards and abide by the code. Minimum quality standards include requirements for pre-enrolment, counseling, examinations, face-to-face training, enrollment and contract, management, instruction, and technology-based learning. Across Europe, EADL membership is seen as a mark of quality. The International Council for Open and Distance Education (ICDE) published a comprehensive global review of quality models in online learning [58], which concluded that a systematic quality assurance process is needed to design distance programs. In the strategic plan for the 2021-2024 period, ICDE sets as its goals the advocacy of distance learning worldwide, the promotion of membership in the organization,

promoting quality in digital, open and flexible learning, and ensuring sustainability.

The Australasian Council on Open, Distance, and e-Learning (ACODE) [59] is developing criteria for using technology in higher education. The ACODE proposes 65 performance indicators covering eight thematic areas (Institution-wide policy and governance for technology-enhanced learning; Planning for institution-wide quality improvement of technology-enhanced learning; Information technology systems, services and support for technology-enhanced learning; The application of technology-enhanced learning services; Staff professional development; Staff support for the use of technology-enhanced learning; Student training for the effective use of technology-enhanced learning; Student support for the use of technology-enhanced learning). Each indicator includes scoping statements, good practice statements, a set of performance indicators, and performance measures for each indicator using a five-point rating scale. Each indicator can be used as an independent indicator, or all indicators to be used together for an overall evaluation.

The Asian Association of Open Universities (AAOU, <https://aaou.ouhk.edu.hk/>) develops Quality Assurance Framework for open and distance learning. It contains 107 statements of good practice for achieving quality, divided into ten categories: Policy and Planning; Internal Management; Learners and Learners ‘profiles; Infrastructure, Media and Learning resources; Learner assessment and evaluation; Research and Community Services; Human Resources; Learners Support; Program Design and Curriculum Development; Course Design and Development.

B. Audits and Accreditation by Evaluation Organizations

Sound quality assurance practices combine self-assessment with external quality assessment by quality assurance and assessment organizations. Accreditation by external accreditation ensures that HEI complies with accepted quality standards and can conduct distance education. Accreditation takes place every few years, depending on the accrediting agency. The accreditation process usually includes the following steps:

- Self-assessment.
- An on-site visit by the expert group, which determines the extent to which the HEI fulfills, the accreditation standards based on a review of supporting documents, conducting interviews with staff and students, and observing distance learning activities.
- Development of a written evaluation report describing strengths and recommendations for improvement in terms of accreditation standards.
- Preparing annual reports on the implementation of the recommendations made.

Kirkpatrick believes that accreditation and assessment are valuable for three reasons [38] - it allows governing bodies to identify challenges and take measures to improve curricula, it catalyzes processes to improve the individual capacity and

qualifications of teachers, it gives a sign of quality and excellence in distance learning programs.

The International Organization for Standardization (ISO) develops the ISO/IEC 1976 series of standards, harmonizing the international concept of e-learning quality by describing the processes influencing the achievement and maintenance of e-learning quality [60]. These processes include content and tool creation, service delivery, training and education, monitoring, evaluation, and all life phases from needs analysis to optimization.

The international organization Quality Matters Program (Quality Matters, <https://www.qualitymatters.org/>) develops a series of rubrics that meet the specific needs of different educational sectors. The quality rubric contains eight core standards (Course Overview and Introduction, Learning Objectives, Assessment and Measurement, Instructional Materials, Learning Activities and Learner Interaction, Course Technology, Learner Support, Accessibility, and Usability) and 41 specific standards for evaluating the quality of online and blended courses, explanations on the application of the standards and the relationship between them, a scoring system and a set of tools that facilitate the assessment process. Three certified reviewers review each course and make specific recommendations for course improvement, the implementation of which will contribute to compliance with quality standards. To be certified learning course must receive at least 85% of the possible points. Certified courses receive a stamp with the year of certification valid for 3-5 years.

The European Foundation for Quality in eLearning (EFQUEL, <http://efquel.org/>) seeks to promote good practice and innovation to achieve high-quality learning worldwide. The primary mission of EFQUEL is to increase the quality of e-learning in European countries by providing services and support to all interested parties. According to EFQUEL, the European Quality Assurance System will strengthen the trust in the quality of e-learning and serve as a reference point worldwide. The Foundation believes that classical approaches to quality assessment (such as defining and documenting minimum requirements for infrastructure, staff competence, administrative services, and technical standards are inadequate if the goal of the quality assurance process is to encourage innovation in e-learning. EFQUEL presents a list of elements divided into five parts (Design principles, Agreement to monitor the quality of teaching practice as a whole, General focus on innovation and transformation of the organization and commitment to the competent customer, Principles for conducting negotiations and when it is possible consensus among partners, Agreement on five steps necessary to obtain accreditation), which can serve as a starting point for creating an alternative approach to quality assurance. EFQUEL develops three quality assessment tools – ECBCheck, UNIQUE and Sevaq+.

ECBCheck (ECBCheck, <http://www.ecb-check.org/>) is a certification framework for e-courses and programs developed by EFQUEL. The quality of e-learning courses and programs is assessed in seven areas (information about the organization of the e-learning program, target group orientation, content quality, program/course design, media design, technology,

evaluation and review) with 51 quality criteria, some of which are mandatory. The educational institution is awarded a quality label after evaluating 51 quality criteria divided into four areas (education and training, organizational strategies and innovations, organizational processes, technologies, equipment and infrastructure), some of which the evaluated institution must fulfill. At the first stage of the assessment, the reviewers check the extent to which the institution met all mandatory criteria. The institution passes to the second stage if it fulfills these mandatory criteria. In the following evaluation stage, reviewers assess the optional quality criteria on a four-point scale (0 – not implemented, one – partially implemented, two – adequately implemented, three – excellently implemented). The final result of the evaluation is the percentage ratio of the sum of the optional criteria and the maximum possible points.

UNIQUE [61] is a quality label awarded to a university for the quality use of information and communication technologies. The evaluation focuses on using information and communication technologies to enhance educational provision and learning support throughout the entire breadth of activity of HEIs. The HEIs who apply must meet the standards for program objectives, program structure, content, resources and learning processes. The assessment process takes place in 6 steps – Application, HEI Eligibility check, HEI Self-Assessment, Peer review by a three-person review team, Decision making for Certification by Awarding Body, and Continuous monitoring of ICT policies in line with the recommendations.

The self-assessment model of e-learning quality SEVAQ [61] was developed based on the Kirkpatrick and EFQM models. The model includes a set of criteria and sub-criteria that cover all aspects of the organization. Internal evaluators assess the quality of training and fill out a questionnaire expressing their agreement level with formulated statements. SEVAQ+ is an extension of SEVAQ [66] developed to allow managers and teachers to participate in the self-assessment process in addition to students. The model covers two main aspects: management of the learning process and resources and management of people. The tool offers both a core of questions and opportunities for a personalized assessment. Assessment results are available in real-time and in different formats, from radial graphs that provide a snapshot to raw data that can be imported into other tools. By identifying areas for improvement, the tool enables institutions to track progress from one semester to the next and compare teaching and learning across institutions. Among the main advantages of Sevaq+ is the combination of a robust assessment framework with the flexibility needed to cover a wide range of institutional and individual contexts.

The Open and Distance Learning Quality Council (ODLQC, <http://odlqc.org.uk/>) contributes to ensuring the quality of education, protecting student interests, and developing standards for quality assurance in education. The proposed standards for quality assurance in open and distance learning are divided into six sections: results, resources, support, sales, suppliers, and collaboration.

After analyzing European policies and projects, the good practices of nine national HE evaluation agencies, and studies

in the field, the Swedish National Agency for Higher Education developed the ELQ model [62-63]. The ELQ model contains ten aspects for evaluating the quality of e-learning in higher education - Material/content; Structure/Virtual Environment; Communication, cooperation, and interactivity; Student assessment; Flexibility and adaptability; Support (students and staff); Vision and institutional leadership; Staff qualification and experience; Resources allocation; Holistic and process aspect. For each of these aspects, the authors develop quality criteria in the form of recommendations for taking specific measures to address problems and issues at the institutional level.

The Distance Education Accrediting Commission (DEAC) produces a handbook detailing accreditation standards, policies and procedures. The accreditation handbook sets out expectations for academic quality, educational services, continuous improvement and ethical business practices for institutions proposing distance learning. This handbook contains 57 main components distributed in twelve quality standards covering all aspects and policies of distance education [64]: Institutional Mission; Institution Effectiveness and Strategic Planning; Program Outcomes, Curricula and Materials; Educational and Student Support Services; Student Achievement and Satisfaction; Academic Leadership and Faculty Qualifications; Advertising, Promotional Literature and Recruitment Personnel; Admission Practice and Enrollment Agreements; Financial Disclosures, Cancellations and Refund Policies; Institution Governance; Financial Responsibility; Facilities, Equipment, Supplies, Record Protection and Retention. The accreditation process assesses an institution's ability to meet all accreditation requirements. DEAC expects institutions to provide evidence of compliance with all specified requirements. Feedback on the institution's performance against these standards can help the institution improve the quality of instruction. DEAC approval is seen as a recognition of quality standards.

The European Association of Distance Learning Universities [65] is developing a Quality assessment for e-learning: a benchmarking approach manual [66]. The organization awards an Excellence award to institutions that ensure the high quality of distance learning. The Quality Assurance Agency for Higher Education (QAA) highlighted the importance of considering student workload carefully in module design and ensuring these expectations are consistent and explicit [67].

Governments refer to published quality assurance frameworks as a reference for establishing their national higher education quality assurance systems [68]. From the beginning of the 1990s, they began to promote the adoption of policies and the creation of national or regional quality assurance agencies and to link public funding of education to quality. The assessment, accreditation, and quality control of distance learning in Bulgarian universities and scientific organizations is carried out by the National Agency for Assessment and Accreditation based on relevant criteria systems and procedures for quality assessment and accreditation. The evaluation is going on in two stages (NAOA, 2017) - I. Evaluation of the organization and environment for conducting and maintaining distance learning, II. Evaluation of a concrete

distance learning program. In the self (assessment) report for the organization and the environment for conducting distance education, HEI must provide evidence of compliance with seven criteria related to educational documentation, internal quality system, procedures for developing and updating documentation, methodological standards for documentation, internal normative documents, policy for the development of the scientific and teaching staff, material-technical and information base. In the report on the (self) assessment of a distance learning program, HEI must provide evidence of compliance with three criteria for implementing the procedures for developing and updating study documentation, rules and activities to stimulate student motivation and financial, material-technical and information base.

C. Periodic Surveys among Stakeholders

Research for ensuring the quality of distance learning dates back to decades ago, resulting in several models and approaches proposed for evaluating and assuring the quality of distance learning by various stakeholders.

The E-Learning Maturity Model (eMM) [69] is a capability assessment model for e-learning processes based on the CMMI and SPICE models. Version 2.3 of the model allows the evaluation of 35 e-learning processes divided into five groups giving an idea of the e-learning maturity degree: Learning, Development, Support, Evaluation and Organization. The authors indicate five e-learning maturity levels: Optimization (continuous improvement of e-learning processes in all aspects); Management (ensuring the quality of resources and student outcomes at the exit); Definition (defining eLearning development and maintenance processes); Planning (clear and measurable goals of eLearning projects), Delivery (creating and delivering process outputs).

Ehlers [70] proposes the requirements for the quality of e-learning from learners' perspective structured into seven groups which include 30 dimensions (a set of criteria from the preferences of learners, grouped based on empirical evidence): Tutor Support; Collaboration; Technology; Cost-Expectations-Benefits; Information Transparency of Provider/Course; Course Structure/Presence Courses, and Didactics.

The SEEQUEL quality framework contains an integrated set of criteria for evaluating the quality of e-learning. The framework proposes three main quality criteria (Learning Processes, Learning Resources, and Learning Context) and 137 sub-criteria [70]. Quality criteria that apply to e-learning can be weighted by different users (people or HEI) using a table with two columns. The first column contains a list of criteria (objective dimensions) for determining quality, and in the second column, stakeholders can put a quantitative assessment of the quality criteria, determining its importance for determining the quality of the object (2 – basic criteria, 1 – important criteria, 0 – minor criteria).

The HELEN model [71] allows the evaluation of the quality of the SE based on 46 criteria divided into six dimensions (Supportive Issues, Learner Perspective, Instructor Attitudes, Technical Quality, Information Quality, and Service Quality). The model allows the learning management system to be evaluated only from the student's point of view. Ozkan and

Koseler emphasize the possibility of its expansion to assess the quality of the learning management system also by other stakeholders - developers, administrators, teachers, designers, external experts, etc.

iQTool [72] is a tool for evaluating the quality of teaching in e-learning curricula and the quality of learning materials. The tool allows creating questionnaires, using the questionnaires for quality assessment and has statistical analysis capabilities to improve the quality of learning materials and teaching. The software tool supports four roles – Assessor, QA Manager, Publisher, and Administrator. The repository for evaluation components offers possibilities for storing and retrieving user profiles and evaluated objects, given within the framework of evaluation procedures answers, definition, and calculation of statistical indicators based on the given answers. The build-on repository is based on IMS Digital Repositories Interoperability. HEIs can integrate the tool with learning management systems. The evaluation module acts as an intermediary between the learning management system and the evaluation component and allows retrieving appropriate questionnaires from the repository according to the object type. The tool records the evaluation result in the repository as a document in IMS QTI Results Reporting format with the user's identification numbers, the resource, and the questionnaire used.

Within the framework of the Excellence project, two tools for assessing the quality of e-learning have been developed - QuickScan (for quick orientation) and FullAssessment (for full assessment) [73] with 33 indicators divided into six areas: Strategic management, Curriculum design, Course design, Course delivery, Staff support, Student support. The QuickScan tool provides a quick insight into the strengths of the eLearning delivered and possible areas for improvement. The questionnaire should be completed by a small team, including representatives of different stakeholders: managers, e-course authors, teachers, and students. The team members can also determine how appropriate the indicators are for evaluating quality in the institution. To prove that the answers are based on facts, it is mandatory to accompany them with supporting documents. FullAssessment makes it possible to determine the effectiveness of e-learning programs and the requirements for improvement by having e-learning experts review the supporting documents and, after a site visit, prepare a report on the overall process and recommendations for improvement. Within the Excellence Next project, some of the indicators for evaluating the quality of e-learning have been updated. The number of indicators for quality assessment is 151.

PDPP is an e-course quality assessment model developed based on the CIPP assessment model [74]. The model allows the evaluation of four phases of the e-learning life cycle: Planning (marketing, applicability, target group, course objectives, funding); Development (design, learning materials design, course web page design, flexibility, student interaction, faculty support, technical support, evaluation); Process (technical support, website usage, interaction, evaluation and support during learning, flexibility); Product (student satisfaction, teaching effectiveness, learning effectiveness, and sustainability).

The e-learning self-assessment tool e-Lsa [75] allows evaluation of the quality of organizations offering e-learning through a set of main criteria and sub-criteria covering aspects related to the organization of learning. For each sub-criterion, the authors define a set of measurable indicators. These indicators are formulated as statements, and the quality is measured through self-assessment by various stakeholders. The self-assessment model is divided into two parts. The first part contains 41 indicators for self-evaluation of the course and the learning process by students at the end of the e-course. The second part includes nine indicators for self-evaluation of learning management (by managers and teachers). A corresponding questionnaire has been developed for each of the two parts. At the end of the assessment, the system analyzes the answers and generates a report that allows the manager to identify the strong and weak criteria and identify the reason for the poor results.

The integrated system for evaluation and improvement of the quality of e-learning [33] allows the assessing the quality of the learning management system in a university consortium based on factors divided into five main groups: Learning objects (quality, validity, media, presentation, copyright), Learning Object Design (concept identification, pedagogical style, media enhancements, interactivity, tests and feedback, interaction, content portability standards, content aggregation), Learner Services (identification, portfolio, records for student activity), Program Presentation (design of graphic elements, colour scheme, font, navigation, interface) and Technology Infrastructure (network frequency, end-user system configuration, server configuration, browser, DB connection, technology, operational compatibility). Based on the above five categories, a questionnaire was developed in which the experts had to rate the characteristics and sub-characteristics. When new course content is added, a message is sent to the experts who must evaluate the content, design, and course presentation and suggest changes. In the proposed evaluation framework, student activity (last login, time, course content read during the session, etc.) is monitored, and feedback and suggestions for improvements are sent based on student performance.

The model proposed by Giorgetti, Romero and Vera [76] for evaluating the quality of distance learning is based on the model for accreditation of distance learning programs of the National Commission of University Evaluation and Accreditation for Evaluation and Accreditation of Universities in Argentina CONEAU and Lorenzo Garcia Aretio's integrated distance university evaluation model. The model assesses three dimensions of the conducted distance learning courses: Professional learning (evaluates students' activity during the training), University Management and Administration (measuring the fit between the university's mission, vision, and goals set for continuous improvement), and Student Support (assessing the ability to allocate material and human resources and their management as part of the learning process). The authors suggest that the quality assessment indicators be divided into six main categories (Functionality, Effectiveness, Efficiency, Availability, Information, and Innovation) and arranged in a table. The frequency with which each indicator must be measured is also defined, and a formula is introduced to calculate the indicator value.

Messo [9] offers an approach for assessing the quality of open and distance learning programs from the students' perspective based on qualitative and quantitative methods. Messo proposes to evaluate indicators in seven areas - registration procedures, access to course instructors, administrative processes, course materials, instructional methods, clarity of syllabus, and exam processes. The collected primary data are analyzed using IBM-Statistical Package for Social Sciences (SPSS version 19) by calculating the mean and distribution frequencies and presenting the results in tables, charts and other statistical presentations. The proposed approach was experimented with evaluate the quality of programs at the Open University of Tanzania by 305 students.

Markova, Glazkova, and Zaborova [1] propose a tool for evaluating the distance learning environment from students' perspective and identifying areas where university administrators, teachers, and technicians can improve their work, to ensure high-quality distance learning. Students rate quality indicators in five domains (interaction and collaboration, instructional design and delivery, assessment, student support services, and e-course design) on a five-point Likert scale. With the proposed tool, quality assessment experiments were conducted among 830 students.

Stracke [77] proposes the Open Ed Quality Framework, which conceptualizes the development of quality at three levels (micro, meso, and macro) and in three dimensions (goals, implementations, and achievements). In this framework, learning designers and learning designs are seen as crucial stakeholders and entities that occupy a meso-level role in the implementation dimension and play a significant role in the quality assurance and evaluation process.

Beskrovnyaya, Freidkina, and Vinogradova [78] propose an approach to design tools for monitoring learning outcomes that allow the assessment of shaping competencies most demanded by the labour market. The empirical basis of the study is the results of the analysis of normative and legal documents on distance learning, information published on the Internet about the educational activity of universities using distance learning technologies in the educational process, scientific research on distance learning, materials of personnel selection agencies, means of learning control (Interactive elements in the lecture, Use of materials created based on the theory of the test to test knowledge, Project implementation).

A team from Plovdiv University is developing a range of tools for evaluating the quality of e-courses and digital resources from the perspective of students and experts in distance learning [79]. The questionnaire for students includes 49 questions divided into 11 areas: learning documentation and educational objectives, distance learning provision team, infrastructure, distance learning preparation and delivery, information support, learning materials and activities, communication, assessment, support, design, and recommendations. The questionnaire developed for experts allows them to evaluate the quality of an e-course regarding content (including basic information), positioning (by composition and type), and design (including model, interactivity, multimedia, communicability, performance, ergonomics and functionality in a hardware and software

environment). Each course and digital resource should be evaluated by at least three experts. The questionnaire for experts contains 50 questions from ten areas: learning documentation and educational objectives, distance learning provision team, distance learning implementation infrastructure, training preparation and delivery, learning information support, learning materials and activities, communication, evaluation, support, and design. The questions require a response on a 5-point Likert scale. With the proposed set of tools, 3350 students evaluated the quality of e-learning in 101 e-courses. By providing automated means for synthesis and analysis of the results for all e-courses, the quality of the e-courses has been assessed by professional directions and areas of higher education. Developed software tools for monitoring student activity in conducted surveys and for subsequent analysis of survey results allowing authorized users to generate summary reports, monitor ongoing surveys, and analyze interim data in real-time.

Firdoussi and colleagues [80] conducted a study to evaluate distance learning in Morocco during the COVID-19 pandemic among 3037 students and 231 teachers. The study explores the limitations of e-learning platforms and how public and private universities conduct these activities. Teachers evaluate distance learning in nine areas - Previous Experience with Distance Learning, Distance Learning Platforms, Use of Platforms, Materials Used, Platforms Assessment, Evaluation during the Confinement Period, Distance Learning in the Future the Workload during the Confinement Period, Expectations of E-learning Platforms. Students rate the quality of distance learning in terms of Previous Experience with Distance Education, Internet Connection Quality, Involvement of Teachers, Use of Materials Produced by Professors, Teaching Methods Preferred by Students, Distance Evaluation, Work Timetable, Preferred Type of Education, Resources Used to Better Understand the Course, Devices Used to Follow the Studies from a Distance, Expectations of Distance Education. The survey results are processed using three methods: descriptive analysis, regression analysis, and qualitative response analysis. Microsoft Power BI is used As a data analysis tool to analyze data, visualize it and draw insights.

Lassoued, Alhendawi, and Bashitialshaer [13] conducted a large-scale study to uncover barriers to achieving quality distance learning during the COVID-19 pandemic among 400 professors and 600 students from universities in the Arab world (Algeria, Egypt, Palestine, and Iraq). For this purpose, a questionnaire was developed, which evaluates 14 obstacles in four categories: Personal obstacles, Pedagogical obstacles, Technical obstacles, and Financial and organizational obstacles. The researchers analyze the results to explore the challenges and opportunities to limit them from the perspectives of faculty and students, classify the barriers and identify differences in identified issues to quality in distance learning during the pandemic by faculty and students, and present suggestions for overcoming these obstacles.

As a result of their studies, Jime'nez-Bucarey and his colleagues [42] proposed a model that measures student satisfaction in three dimensions: teachers, technical service, and service. The impact of each dimension on student satisfaction is assessed using a Partial Least Squares Structural

Equation Model (PLS-SEM). An Importance and Performance Map Analysis (IPMA) is performed to identify improvements that need to be done to increase student satisfaction. The model is tested among 1430 students.

Olney, Li and Luo [81] surveyed 220 employees to identify the necessary skills and staff competencies on which HEIs should focus their professional development activities to improve the quality of distance learning. They use a content analysis methodology to analyze the text responses and compare them to the Competency Framework for Instructional Design proposed by the International Board for Teaching, Performance and Learning Standards (IBSTPI). According to the results of the study, the main competencies identified by the participants were designing training interventions, keeping up with design theories, and communicating to manage stakeholders, teams, and projects.

Toubasi et al. [82] developed a tool to assess the quality of distance learning during the COVID pandemic for the needs of universities in Jordan. The questionnaire consists of 58 questions divided into four sections – student demographic characteristics, student attitudes during the distance learning period, student perceptions of distance learning, and quality evaluation using the DELES tool. DELES include 34 indicators that assess the quality of learning in six areas - instructor support, student interaction and collaboration, personal relevance, authentic learning, active learning, and student autonomy. Each indicator is assessed using a 5-point Likert scale. The questionnaire was presented in Google Forms and shared with students through social networks. Results were analyzed with IBM SPSS.

Sarmiento and Callo [53] surveyed to determine the effect of distance learning factors on the quality of learning during the COVID-19 pandemic among 764 students and 57 faculty members. The questionnaire developed contains questions in three parts - profile of respondents, factors and quality learning. Respondents must rate 18 factors that play a crucial role in quality distance learning, divided into three categories (instructional design, support system, implementation), and define purposeful and meaningful distance learning based on engagement, satisfaction, quality teaching, and quality education. The results show that the factors determining the quality of training during the pandemic are instructional design, support system, and implementation.

D. Processing of Statistical Data and Performance Indicators

When conducting distance learning, a lot of data is accumulated about the training, e.g. logs in the e-learning system, data on learning materials read, data on submitted homework assignments, grades from exams, etc. This fact has stimulated research into using data to gain insights into the quality of distance education delivered and support management decisions to retain students and increase student achievement.

Processing such data for the training can provide valuable insights into key performance indicators (e.g. average weekly usage, modules completed, course completion rate, dropout rate, activity completion rate, average attention rate, etc.), highlighting the effectiveness of courses and curricula. By

analyzing retention rates, pass rates, and student satisfaction, institutions can evaluate which learning courses are performing well and which may require improvement [83]. Utilizing big data analytics allows HEIs leadership to do a more sophisticated analysis than simple summary statistics, enabling the identification of courses with pass rates that exceed expectations based on previous student achievements. Through comparative analysis of course designs, HEIs leadership can identify features that lead to successful learning outcomes [84]. They can utilize this knowledge to stimulate teachers to design more efficient courses. In addition, teachers can monitor their learning courses to identify pinch points, such as areas where student engagement drops sharply. They can then take appropriate action, such as providing additional teaching or rewriting course material for the next cohort. Tutors can also use statistical data and performance indicators to monitor their students and identify those who may benefit from timely interventions. By targeting these students, tutors can increase their chances of passing the course and achieving their learning objectives. Students can also use these data to monitor their performance and learning behaviours' [85]. By comparing their progress over time or against other students in their cohort, they can identify areas where they may need to improve and take action as self-regulated learners. Furthermore, teachers can use automated systems to suggest alternative resources or behaviours' to students who exhibit patterns associated with poor results [86]. These suggestions can help students identify areas for improvement and take action to achieve better learning outcomes.

Design, development, and implementation of intelligent data analysis tools can contribute to distance learning quality assurance [87-89]. Automated evaluation of the quality of distance learning requires the collection, analysis, and interpretation of a huge amount of data reflecting the attitude of students and experts to the training courses, the software tools used, etc.

In connection with the external evaluation by accrediting institutions, several studies have been conducted for the automated extraction and analysis of data for distance learning quality evaluation, including data on the used learning materials, infrastructure, e-learning environment, means of communication and collaboration, student evaluation system, flexibility and adaptability of the learning process, student support, team qualification, etc. Doneva and Gaftandzhieva [90] explore the possibilities for automated data extraction for evaluating the criteria from the criteria system of NAOA for evaluating distance learning programmes were analyzed. This analysis aims to determine which data can be extracted from university systems (e-learning environment, learning process management system, academic staff development system, etc.) to support distance learning quality assessment. Based on the analysis, some experimental web services are developed for extracting data from the Moodle e-learning environment for automated evaluation of the quality of distance learning. The following work [79] proposes the automation of related processes based on an approach for integrating heterogeneous software systems (Service Oriented Integration) and discusses its application to automated data extraction in evaluating the quality of e-learning. Some reports with extracted data from

the learning management system are generated through the developed tools and presented to an expert group during program accreditation of a distance learning program in 2016. Among them are the reports for Activity in communication tools, Study schedule control, Student and teacher workload, Student success, and Educational activities and resources.

As a result of studies in the field and after analysis of the databases of the university information systems, in which data about the training are stored, Gaftandzhieva and Doneva [91] propose a model with a set of indicators, allowing the tracking of training results for the needs of various interested parties (students, teachers, program managers, faculty leadership, university leadership, and quality experts). Based on the indicators from the proposed model, four tools for intelligent data analysis to improve learning outcomes have been designed and developed. The mobile application Mobile LAP [92] allows students to track the values of indicators (for student activity, control of the study schedule, and student success) that can help them achieve their goals in study time and improve their success. As use Mobile LAP, students can track their activity and progress and compare it to the results of other students, as well as monitor whether they are following the study schedule. LATeach application [93] allows teachers to track student activity in learning activities, compare the results of a selected student with those of other students in the course and with the results of students who received excellent grades in previous years, monitor student compliance with the study schedule, track student progress in learning activities and learning outcomes and student success during the learning process, identify at-risk students and self-assess the quality of learning resources based on the students' activity and their results. LATch tool [94] allows the governing bodies in HEIs to generate reports with aggregated data on the students' activity and success rate in selected study programs, which allows them to track the results of students and compare them with those of students from previous years, to identify programs in which students are not performing satisfactorily, to track trends in student success by comparing students' GPA at the end of each academic year, to track student success at graduation, to track student dropout rates, etc. The generated reports for each indicator enable university management at different levels to make informed decisions to improve the quality of education and the results achieved. The LAqe tool [95] allows quality experts to generate dynamic reports for monitoring and evaluating the quality of conducted education for the needs of accreditation procedures. They can use the tool to generate evidence documents and significantly support the preparation of self-assessment reports for internal and external evaluation of the quality of the training provided.

IV. CONCLUSION

This review paper provided a comprehensive analysis of the current state of play of quality assurance in distance learning. The paper has highlighted the challenges associated with ensuring quality in distance learning programs and has discussed various approaches and tools for quality assurance and assessment, including regulatory documents and manuals, audits, and stakeholder satisfaction. Using statistical data and monitoring key performance indicators, HEIs can identify areas for improvement and take appropriate action to enhance

the quality of their distance learning programs. As distance learning continues to grow in popularity, institutions must prioritize quality assurance to ensure that their programs meet established standards and provide students with a high-quality education. Subsequently, this paper serves as a valuable resource for educators, administrators, and policymakers interested in improving the quality of distance learning programs. By implementing the recommendations outlined in this paper, HEIs can enhance the quality of their distance learning programs and provide students with a more rewarding and fulfilling learning experience.

This study was conducted as part of a project to implement software tools to help ensure the quality of educational and administrative services at the university and support management decision-making to ensure high quality of services. In the next part of the research, tools will be designed and developed to track the values of key performance indicators for the needs of different stakeholders (teachers, distance learning centres, dean's and rectors' leaderships).

ACKNOWLEDGMENT

This paper is financed by the European Union-NextGenerationEU, through the National Recovery and Resilience Plan of the Republic of Bulgaria, project № BG-RRP-2.004-0001-C01. The paper reflects only the author's view and the Agency is not responsible for any use that may be made of the information it contains.

Efficient Parameter Estimation in Image Processing using a Multi-Agent Hysteretic Q-Learning Approach

Issam QAFFOU

ISI Laboratory-Department of Computer Science-Faculty of Sciences Semlalia, Cadi Ayyad University
Boulevard Prince My Abdellah B.P. 2390 | 40000 Marrakech. Morocco

Abstract—Optimizing image processing parameters is often a time-consuming and unreliable task that requires manual adjustments. In this paper, we present a novel approach that utilizes a multi-agent system with Hysteretic Q-learning to automatically optimize these parameters, providing a more efficient solution. We conducted an empirical study that focused on extracting objects of interest from textural images to validate our approach. Experimental results demonstrate that our multi-agent approach outperforms the traditional single-agent approach by quickly finding optimal parameter values and producing satisfactory results. Our approach's key innovation is the ability to enable agents to cooperate and optimize their behavior for the given task through the use of a multi-agent system. This feature distinguishes our approach from previous work that only used a single agent. By incorporating reinforcement learning techniques in a multi-agent context, our approach provides a scalable and effective solution to parameter optimization in image processing.

Keywords—Parameter estimation; reinforcement learning; cooperative agents; hysteretic q-learning; optimistic agent; object extraction

I. INTRODUCTION

Image processing tasks often require the application of one or more image processing operators that are parameterized, requiring assignment of values to the parameters. However, changing parameter values can significantly impact the quality of the processing result. Non-expert users may face challenges in manually computing optimal parameter values, particularly when multiple operators are involved. For instance, the Deriche filter [1] is frequently used to detect contours in an image, and its parameter α represents the size of the filter. Non-expert users may need to make several attempts to find satisfactory results, wasting time and computing resources.

To address this issue, we propose a novel approach to automatically estimate parameters in image processing using a multi-agent system and reinforcement learning. Our approach leverages cooperative learning between agents to outperform centralized learning. The main contribution of this paper is the use of a multi-agent system to tackle the challenge of parameter estimation in image processing.

In this paper, we begin by discussing related works in Section II. Section III introduces preliminaries, while Section IV details the proposed approach. In Section V, we present experiments and results to validate our approach's effectiveness. Finally, in Section VI, we conclude the paper and discuss potential future work.

II. RELATED WORKS

The problem of parameter estimation in image processing has garnered interest from various researchers. In their work [2], Elie Zemmour et al. proposed an automatic method for estimating the parameters required for adaptive thresholding to detect peppers and apples in varying lighting conditions. The authors focused on the adjustment of light level threshold, stop splitting conditions, and classification rule direction for detecting the specific objects (apples and peppers) under consideration. However, the proposed algorithm's adaptability to other image processing tasks was not discussed and is likely to depend on the specific object characteristics. Rafael et al. [3] introduced a method that uses a racing algorithm to tune the parameters required for document image binarization. Their approach is based on a statistical method for determining the optimal parameter values for two algorithms used in binarization tasks: the perception of objects by distance and its combination with a Laplacian energy-based method. Meanwhile, in a study aimed at improving image and video codecs that widely employ uniform quantization schemas, Miguel et al. [4] identified the size of the dead zone and the reconstruction point location as the critical parameters affecting the image R/D coding. The authors proposed a parameterized Uniform Variable Dead Zone Quantizer (UVDZQ) for encoding using wavelets, and evaluated its performance against the most popular quantizers used in video and image coding - USQ (Uniform Scalar Quantizer) and USDZQ (Uniform Scalar Dead Zone Quantizer). The optimal display of an image requires an optimal gamma transformation. In [5], Wang et al. proposed a method based on the location of the Zero-Value Histogram Bin (ZVBH) to estimate the gamma transformation parameter. This approach leverages the relationship between the parameter and the number of ZVBHs to approximate the optimal parameter value and its associated interval. When it comes to biological applications, the choice of parameter values can impact the results obtained. Diana B. et al. [6] proposed using Gaussian process learning to estimate the best biological parameters from non-quantitative and noisy image data. They validated their approach on a parametric function and applied it to estimate parameters in a biological setting by adjusting artificial ISH (in-situ hybridization) data of the developing murine limb bud. Machine learning has become a popular solution to optimization problems in image processing, including parameter estimation. In their work [7], Qaffou et al. proposed an automatic solution for adjusting parameters in an object recognition task using the Q-learning algorithm [54]. This algorithm allows the agent to identify the optimal

combination of parameters for two vision operators - GLCM (Gray Level Co-occurrence Matrix) and k-means. In another study [8], the authors proposed a general framework for optimizing the process of operator and parameter estimation independently on a specific image processing task using reinforcement learning. Furthermore, in [9], Qaffou et al. explored a multi-agent architecture for modeling the interaction between the three components of the proposed architecture. Their solution was successfully applied to a segmentation task, and the results demonstrated its ability to adapt to user preferences [10]. However, the multi-agent architecture proposed in [9, 10] only models different types of agents but has only one agent that learns the optimal values. Qingang et al. [11] proposed a decoupled learning methodology that dynamically fits the weights of a deep network as most existing trained models rely on the configuration of a single parameter. Jinming et al. [12] proposed a simple method for learning local parameter tuning in adaptive image processing by extracting local characteristics from an image and learning the relationship between them and the optimal filtering parameters, optimizing any metric that defines the image's quality.

III. PRELIMINARIES

Most image processing tasks involve the use of one or more vision operators, which are typically parameterized. Each parameter has a range of possible values, and in order to execute an operator, the user must assign a value to each parameter. If the resulting output is unsatisfactory, the user may try other parameter values or even switch to a different operator altogether. In this paper, we focus on the parameter estimation process assuming that the operators to be used have already been fixed. The approach proposed in this paper requires the introduction of certain concepts, which are explained in the following subsections.

A. Overview

We assume that image processing tasks require the use of multiple operators, each of which is parameterized with a range of values. The processing is guided by the ground truths provided for the input images. Our proposed approach in this paper is based on the concepts of multi-agent systems, and requires the following components for the agents to function effectively:

- The combination of operators to use.
- The range of possible values for each parameter.
- The input images.
- The image reference which serves as the ground truth for the desired result. For example, in the case of segmentation, the ground truth is a manual segmentation done by an expert, and it is used for evaluation purposes.

Fig. 1 provides a summary of the inputs required for the

multi-agent system used, as well as the output it generates.

B. Multi-agent System

An agent is any autonomous entity that interacts with its environment through sensors and actuators [15]. When such an agent tries to optimize its performance measure, it is called a rational agent. Although intelligent agents are autonomous, they may sometimes need to collaborate and cooperate to complete tasks that require integration or are time-consuming. Agents may or may not cooperate, share knowledge with each other, depending on the task at hand and users' preferences. A system composed of a group of agents capable of interacting with each other is called a multi-agent system (MAS), which constitutes the core of distributed artificial intelligence (DAI) that emerged in the 1980s [13, 14]. Since then, researchers have used MAS to solve problems of distributed or parallel processing in image processing [16-21].

In this study, the multi-agent system used is composed of a team of agents that cooperate using reinforcement learning to speed up the process of finding the optimal values for parameters in image processing tasks. The integration of MAS and reinforcement learning to solve such an optimization problem is an innovative idea.

1) *Reinforcement Learning (RL)*: RL is the technique that forms the basis of the solution proposed in this paper to solve the problem of parameter estimation for a combination of vision operators. We chose this technique because of its adaptability to the dynamicity of environments due to the balance it allows between exploring the environment and exploiting possible solutions [22]. RL was originally developed for Markov Decision Processes (MDPs). RL defines a type of interaction between an agent and its environment, as shown in Fig. 2. In a real state s of the environment, the agent chooses and performs an action a which causes a transition to the state s' . The agent receives a reinforcement signal "r" that is a reward if the action is beneficial or a punishment if not; a null signal means an inability to award a penalty or reward. The agent then uses this signal to improve its strategy, which is the sequence of its actions, in order to maximize the accumulation of future rewards.

To achieve this, the agent must find a balance between exploration and exploitation. Exploration consists of testing new actions that can lead to higher gains, but with the risk that they will be lower, while exploitation consists of applying the best strategy acquired until then (which may not be optimal). Fig. 2 shows the general architecture of an RL agent. There are several methods to find the optimal policy corresponding to the maximum value of the state/action value function. In this paper, the proposed MAS exploits the idea of the Q-learning algorithm, where the agents cooperate and update their Q-values optimistically.

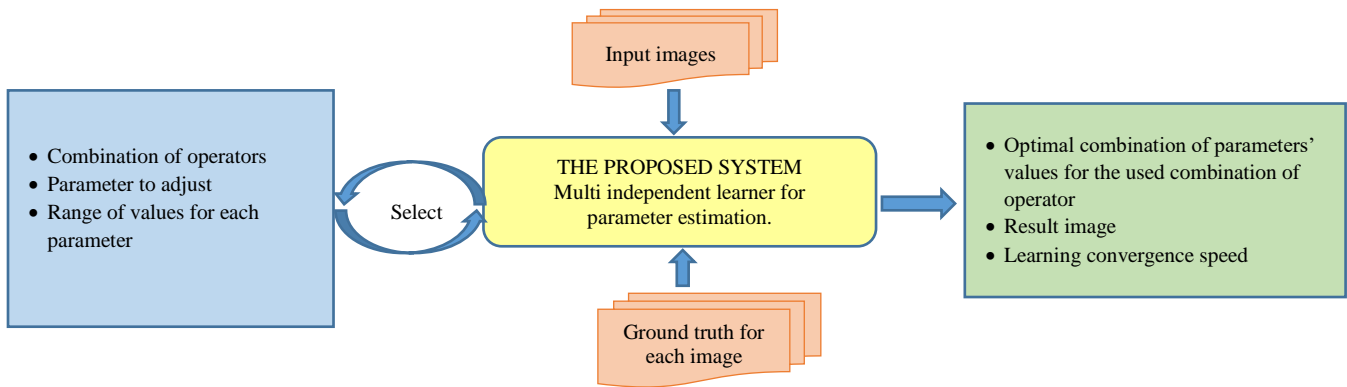

Fig. 1. External architecture of the proposed solution.

Fig. 2. RL agent general architecture.

2) *Q-learning algorithm*: The Q-learning algorithm was proposed by Watkins in 1989 [23]. In this model, the agent learns to act optimally in Markov domains by testing action sequences. It selects an action in a particular state and uses the immediate reward or punishment to estimate the value of that state. By trying different actions in different states, the agent learns which is the best by referring to the long-term update of the rewards [24]. The agent must determine an optimal policy and maximize the total expected rewards. Algorithm 1 gives the procedural form of the Q-learning algorithm [56].

Alg. 1: Q-learning algorithm

1. Initialize $Q(s, a)$ for all $s \in S, a \in A(s)$ randomly
2. Observe the initial state s
3. Repeat until termination:
 4. Select an action a using a policy derived from Q
 5. Take action a , observe reward r and new state s'
 6. Update

$$Q(s, a) \leftarrow Q(s, a) + \alpha[r + \gamma \max_{a'} Q(s', a') - Q(s, a)]$$
 7. $s \leftarrow s'$
8. Until s is a terminal state

In this algorithm, S is the set of possible states, $A(s)$ is the set of possible actions in state s , α is the learning rate, and γ is the discount factor used to balance immediate and future

rewards. The value of $Q(s, a)$ is updated based on the reward received and the estimated value of the next state-action pair. The policy derived from Q is used to select the action in step 4.

3) *Cooperative learning*: G Although reinforcement learning (RL) has promising applications in multi-agent systems (MAS), there are still several challenges to extending RL to a MAS [25]. One major difficulty is the lack of theoretical guarantees, as convergence hypotheses that hold for a single agent may not be valid for a MAS due to the presence of several learners, which makes the environment non-stationary and challenging for multi-agent learning systems [26-29]. Additionally, defining a good learning goal for all RL agents and enabling communication between them pose further challenges for learning in a MAS [30]. Despite these obstacles, researchers have successfully integrated RL into MAS and addressed coordination problems between agents [31-36]. One algorithm that addresses the challenge of cooperation between agents is hysteretic Q-learning, which focuses on optimistic agent behavior and has been shown to perform well in multi-agent environments [29]. We use this algorithm to include RL in our cooperative MAS. The next section provides more details on how we model our cooperative MAS.

IV. THE PROPOSED APPROACH MODELING

To accomplish a task in image processing, such as filtering, image enhancement, segmentation, object recognition, etc., a sequence of operators must be applied. A task could be divided into several sub-tasks that may require a sub-sequence of vision operators to be used. To run an operator, its parameters must be adequately tuned. This problem has been solved using a single agent [7], but it consumes much time to converge. The main contribution of this paper is to propose a quicker and more precise solution to this problem. We model our solution as a multi-agent system using reinforcement learning. Each agent takes one operator and learns to find the optimal values of its parameters depending on the user's preferences. These preferences include the type of process the user wants to perform, the operators they want to use, and the desired result. The agents work together to find the best choice that brings them the highest reward. These agents have a joint action, and each one has its

individual action in the whole process. An agent's individual actions are formed by all possible choices of the values that can be assigned to its parameters. Any value changed is a new action. Formally speaking, if an operator has, for instance, k parameters (p_1, p_2, \dots, p_k) and each parameter p_i has a set of possible values $V_i = \{v_{i_1}, v_{i_2}, \dots, v_{i_p}\}$, an individual action is then:

$$a_j = (u_1, u_2, \dots, u_k) \in V_1 \times V_1 \times \dots \times V_k$$

Each agent chooses its action independently of the choices of the other agents. For the multi-agent system, we talk about a joint action which is a combination of the individual actions. It is the action that the multi-agent system applies on the input image, which represents the environment with which the agents are interacting. A state of the environment is a set of features extracted from the image. For each image, we provide a ground truth to evaluate the result found by the proposed multi-agent system. The reward is calculated by comparing the features of the output image with those of its ground truth. These components, which are the set of actions, states, and the reward function, are the principal elements required to define the reinforcement learning process. Fig. 3 shows the global schema of the proposed multi-agent system. The proposed multi-agent system applies a joint action on the input image, compares the obtained result with the ground truth, and receives a return signal in the form of a reward or punishment. During learning, the system reinforces actions that have been beneficial in the past, and after convergence, it selects the action with the maximum Q-value according to the principle of Q-learning. The definition of actions, states, and reward function in our approach depends on the task to be accomplished and the execution environment. An adaptive definition is provided in Section IV. The use of RL in this system is challenging because the final return concerns all agents, and each agent may question their share of the return. Additionally, since an agent cannot see their teammates' choices, they may be punished for a bad choice made by another agent. To address this issue, we consider all agents to be independent learners. The main challenge for these agents is coordination; how to ensure that all agents choose their individual actions consistently to achieve a Pareto-optimal joint action, where no other strategy benefits any of the agents. This is a complex problem resulting from the combined actions of several factors. Since agents must cooperate, they have no interest in threatening each other, but they must change their policy to improve their rewards and adapt to this change. We can model this setting as a repeated game where the same agents play the same game repeatedly. As the agents share the common goal of achieving the best end result, this game is cooperative and the reward is shared. A simple extension of centralized Q-Learning [56], case of a single learner, to stochastic games takes into account common actions in the calculation of Q-values. Thus, the update equation according to a centralized view of a system of n agents is:

$$Q(s, a_1, \dots, a_n) \leftarrow (1 - \alpha)Q(s, a_1, \dots, a_n) + \alpha^*[r + \gamma^* \max Q(s', a'_1, \dots, a'_1)] \quad (2)$$

Where s' is the new state, α is the learning rate and $\gamma \in [0, 1]$ is the discount factor [23].

In this model, the reinforcement perceived by an agent depends on the actions chosen by the group. Therefore, an agent does not know exactly its share in the total reward, or at least the influence of the received return (positive or negative) on its individual action. Even if an agent executes a good action, it could still be punished because of a bad choice made by the group. It is therefore preferable for an agent to give little importance to a punishment received after choosing an action that has satisfied it in the past. However, the agent must not be completely blind to sanctions, as this could result in a sub-optimal equilibrium or prevent coordination on an optimal joint action [29]. To solve this problem, we use the hysteretic Q-learning algorithm. This algorithm considers that an agent with an optimal individual action should not be punished because of a bad choice made by the group, but it must remain optimistic in order to reduce variations in the learned policy. The equation for updating the hysteretic Q-learning proposed by L. Matignon [29] for an agent i executing the action a_i from state s to transit to state s' is:

$$\delta \leftarrow r + \gamma \max_{a'} Q_i(s', a') - Q_i(s, a_i) \quad (3)$$

$$Q_i(s, a_i) \leftarrow \begin{cases} Q_i(s, a_i) + \alpha\delta & \text{if } \delta \geq 0 \\ Q_i(s, a_i) + \beta\delta & \text{otherwise} \end{cases} \quad (4)$$

Where α and β are two coefficients corresponding respectively to the increase or the decrease of the Q-value of a joint action. To have optimistic learners α must be greater than β . The main goals of using these two coefficients is to minimize the shadowed equilibria's effect and to manage stochasticity of the environment [29]. The Hysteretic Q-Learning algorithm is decentralized; each agent builds his own Q-table whose the size is independent on the number of agents and is linear according to his own actions. Algorithm 2 summarizes the hysteretic Q-learning.

Alg.2: Hysteretic Q-learning algorithm

Begin

Initialize arbitrarily $Q_i(s, a_i)$ for each (s, a_i) from $S \times A_i$

Initialize the initial state s

While s is not an absorbent state do

In the state s , choose the action a_i / phase of decision */*

Apply the action a_i and observe the new state s' and the return r

$q \leftarrow r + \gamma \max_{b \in A_i} Q_i(s', b)$

/ Hysteretic update */*

if $q \geq Q_i(s, a_i)$ then

$Q_i(s, a_i) \leftarrow (1 - \alpha)Q_i(s, a_i) + \alpha q$

else

$Q_i(s, a_i) \leftarrow (1 - \alpha)Q_i(s, a_i) + \beta q$

if $Q_i(s, \arg \max_{u \in A_i} \pi_i(s, u)) \neq$

$\max_{u \in A_i} Q_i(s, u)$ then

choose randomly $a_{max} \in \arg \max_{u \in A_i} Q_i(s, u)$

$\forall b \in A_i \pi_i(s, b) \leftarrow \begin{cases} 1 & \text{if } b = a_{max} \\ 0 & \text{otherwise} \end{cases}$

/ equilibria selection */*

$s \leftarrow s'$

End

Fig. 3. Global schema of the proposed solution.

The proposed multi-agent system consists of two types of agents: learner agents and a supervisor agent. Each learner agent takes one operator and proceeds to estimate its parameters, with each agent representing one of the operators in the combination. The learner agents work together to learn the best values of the parameters for the entire combination of operators. These agents use a hysteretic Q-learning algorithm, which means that they give little importance to the penalties received but are not completely blind to them [37, 38].

The supervisor agent is responsible for distributing the operators to the learner agents and receiving the optimal value of each parameter.

V. EXPERIMENTS AND ANALYSIS

In this section, we evaluate the effectiveness of our approach by applying it to estimate parameters in an object recognition task. Object recognition is a vital area of computer vision with numerous applications such as object tracking, facial recognition, and autonomous driving. The main goal of object recognition is to detect objects in an image by locating, classifying, and framing them with rectangles. Object detection methods can be broadly categorized into two categories: the first approach divides the image into regions and classifies them into object categories, while the second approach treats object detection as a classification or regression problem, producing final results directly. Examples of methods in the first category include R-CNN [39], SPP-net [40], Fast R-CNN [41, 42], Faster R-CNN [43], R-FCN [44], FPN [45] and Mask R-CNN [46]. For the second category we find MultiBox [47], AttentionNet [48], G-CNN [49], YOLO

[50], SSD [51], YOLOv2 [52], DSSD [53] and DSOD [54]. While our work does not aim to propose a new object detection method, we demonstrate how our approach can provide valuable assistance to users seeking to determine the optimal values of each parameter in a combination of operators. We use object detection as a case study to demonstrate the effectiveness of our approach.

A. Experiments' Environment

We conducted an experiment to evaluate our approach using a dataset of 60 mixed textured images, where a disc (also textured) was inserted into 40 images while the remaining 20 did not contain it. The objective was to recognize and extract the disc from these images using a combination of two operators in two phases. In the first phase, a filter operator with two parameters needed to be estimated, and in the second phase, an operator with two parameters was applied to segment textures and classify them into clusters. For each parameter, a set of possible values was proposed, and a system of two agents was assigned to adjust the parameters for each operator. The results obtained using our proposed approach were compared with those found in [7], where the learning was centralized. To facilitate a comprehensive comparison, we implemented our approach using Matlab, which has a rich toolbox of image processing operators and allows for parallel programming using "Workers."

B. Parameter's Value Learning

The operators used in this experiment are "imfilter" and "GLCM_KMeansFct." The "imfilter" operator is an existing operator in the Matlab toolbox and is used for image filtering.

The "GLCM_KMeansFct" operator is a function that we implemented by combining two Matlab operators: "graycomatrix," which computes the gray-level co-occurrence matrix (GLCM) of an image, and "kmeans," which classifies the obtained textures into clusters.

The operator "imfilter" has two parameters:

- the type of filtering with a single value: {'unsharp'}
- alpha (smoothing coefficient) with 2 possible values: {0.2, 0.6}

The operator "GLCM_KMeansFct" has two parameters to adjust:

- the size of the sliding window with 7 possible values: {3, 5, 7, 9, 11, 13, 15}
- the number of clusters with 4 possible values: {2, 3, 4, 5}

The proposed approach in this paper consists of assigning one agent AG1 to "imfilter" and another AG2 to "GLCM_KMeansFct".

C. RL Configuration

The three principal components: actions, states and the return function must be defined adaptively to our approach.

1) *Actions*: An action of the proposed multi-agent system is a joining of individual actions of all the agents. For instance, an individual action for the agent AG1 is {unsharp, 0.2} or {unsharp, 0.6}, and for the agent AG2 is every combination between a size of the sliding window and a number of possible clusters. Thus, a joint action may be, for example, {unsharp, 0.2, 3, 2}.

2) *States*: A state is defined according to the features of the image obtained after the execution of an action. In this paper, we consider four characteristics to define a state.

$$S = [x_1, x_2, x_3, x_4] \quad (6)$$

x_1 : the number of objects in the result image.

x_2 : the ratio between the area of the result object and the area of the entire input image.

x_3 : the ratio between the area of the result object and the area of the reference object.

x_4 : the average of the values of the textural metrics: energy, correlation, entropy and contrast [55].

3) *Return function*: The return can be a punishment or a reward, depending on the quality criterion representing how well the object has been detected. A simple method is to use an objective assessment by comparing the obtained result with the ground truth. This comparison is made between features of the two images to generate a value determining a reward or a punishment. The value calculated from this comparison is a weighted sum of the difference between the features extracted from the two images. The weights reflect the importance of a feature in the final decision.

$$D = \sum_i w_i D_i \quad (7)$$

Where w_i are the weights assigned to each of the following differences:

D1: difference in number of objects;

D2: difference in size of objects;

D3: difference in area of objects;

D4: difference in values of entropy;

If D is greater than a given threshold, the return is a reward. Otherwise it is a punishment.

$$\text{if } (D \leq \varepsilon) r = +10; \\ \text{else } r = -10;$$

Where ε is the threshold. In this experiments, we fix it in 0.15.

D. Results

The experience is based on 40 textured images containing four different textures. In these images we inject an object of interest, which is a disk. Fig. 4 shows some examples of these images.

Fig. 4. Examples of used images.

The process of our approach needs a ground truth. In this experiment, the ground truth is the disc shown in Fig. 5.

Fig. 5. The ground truth in our experiment.

The multi-agent system we propose in this paper, uses some features to compare the obtained result with the ground truth. These features are the same for both images. The reference features are the following data:

NbrTargetArea = 5: represents the number of target zones

TotalSize = 20800: the total size of the image

AreaObjet = 2573: the area of the object of interest.

TextureMesure = 4.550863e+000: the entropy value (GLCM)

The desired state is [1.000 1.000 1.000 1.000] according to the equation (6).

The size and the area are measured in pixels.

For the process of exploration/exploitation, we use the hysteretic Q-learning with the values: Number of episodes and steps (iterations) are respectively 900 and 60, $\alpha = 0.5, \beta = 0.01, \gamma = 0.9, \varepsilon = 0.008$.

After running the proposed multi-agent system, we obtain the extracted object shown in Fig. 6.

The corresponding features of the result disc are:

NbrTargetArea = 6

TotalSize = 23810

AreaObjet = 2371

TextureMesure = 4.3448e+000

Fig. 6. Disc obtained by the proposed MAS.

To compare the two objects, the differences in equation (7) are calculated. Their obtained values are:

$D1 = 2.000000e-001$

$D2 = 1.447115e-001$

$D3 = 7.850758e-002$

$D4 = 2.06063e-001$

The difference between the result disc and the ground truth is given by:

$D = 0.2 * D1 + 0.2 * D2 + 0.3 * D3 + 0.3 * D4 = 9.8672e-002$

The optimal joint action (most rewarding) proposed by our MAS is then {'unsharp', 0.6, 5, 3} and its corresponding state is:

[1.1000 1.1000 0.9000 1.0000]

E. Discussion

The value of D is small; this means that the obtained disc is very closer to the reference. This result demonstrates that the proposed multi-agent system succeeds to extract the object of interest. The main contribution of this paper is not only to propose a method that finds the optimal parameters' values, that is already done in [7], but to propose an approach that outperforms the solution proposed in [7] in terms of speed and accuracy. Fig. 7 shows the curves of learning and the reward gain for the multi-agent system proposed in this paper.

Fig. 7. Results of the proposed approach. Top: Learning curve (steps/episodes). Bottom: Corresponding cumulative reward.

The curve at the top shows the learning process. During the first 10 episodes, the multi-agent system executes several iterations to reach a convergence. A correspondence is clear in the curve below showing the cumulative returns. Indeed, during the first 10 episodes the multi-agent system receives only punishments, then the curve increases to show that the multi-agent system accumulates rewards. This is very logical with the principle of reinforcement learning, and in particular with hysteretic Q-learning.

To show the performance of the proposed multi-agent system as well as its main contribution, we run the one-agent approach [7] in the same environment with the same criteria. Fig. 8 shows the obtained curves.

In the one-agent approach, the top curve shows the execution of many iterations during the first 100 episodes with a high cumulative punishment as the bottom curve shows.

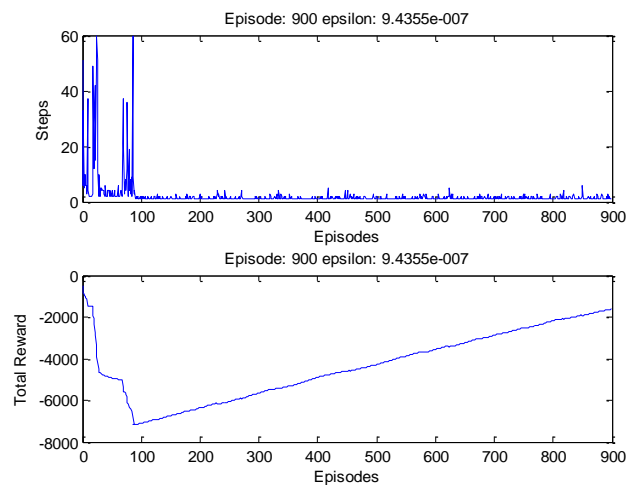

Fig. 8. Results of one-agent approach. Top: Learning curve (steps/episodes). Bottom: Corresponding cumulative reward.

Table I summarizes a comparison between the two approaches, by running them in the same environment and under the same conditions cited above.

TABLE I. COMPARISON BETWEEN MULTI-AGENT AND MONO-AGENT APPROACHES.

	Multi-agent & Hysteretic Q-Learning	One-agent & Q-learning
Quality Result (difference between the result and the ground truth)	10%	12%
Convergence (at which episode)	10	100
Reward (900 episodes)	4200	-
Punishment (900 episodes)	-1200	-7200

The results obtained using the multi-agent approach are significantly better than those obtained by the single-agent approach. The criteria used to evaluate the quality of the

extracted disc include the episode at which convergence starts, the values of punishment (which should be small), and the reward (which should be high). Based on these criteria, we can determine whether one approach is superior to another. In this paper, the multi-agent approach outperforms the single-agent approach. However, it is important to note that the difference between the extracted disc and the reference disc is still relatively high. This is mainly due to the choice of operators and not the proposed approach, which aims to adjust the parameters of the selected operators rather than propose a new method for object extraction.

VI. CONCLUSION

In this paper we have proposed an approach based on multi-agent system and reinforcement learning to automatize the process of parameter selection in image processing. In this work, adjusting parameters is seen as a decision process over time, where experiences gained from past decisions affect future decisions. The solution we have proposed, attributes one agent to an operator to adjust its parameters. We have used hysteretic Q-learning for multi-agent learning to find the best parameters for the given operators and test it to extract an object of interest. The complexity of the images, the speed of convergence and the quality of the results show the potential of the new approach and its adaptability. The results show that the proposed approach outperforms the use of one agent especially in terms of speed. Future works aim to include the operator selection also. In spite of using a predefined operator combination, we can suggest among several possible operators which are the best to use and furthermore what are their optimal parameters' values. Also, we think about using deep reinforcement learning instead of classical reinforcement learning.

Abstract—The shrimp farming industry in Ecuador, renowned for its shrimp breeding and exportation, faces challenges due to diseases related to variations in abiotic factors during the maturation stage. This is partly attributed to the traditional methods employed in shrimp farms. Consequently, a prototype has been developed for monitoring and controlling abiotic factors using IoT technology. The proposed system consists of three nodes communicating through the LoRa interface. For control purposes, a fuzzy logic system has been implemented that evaluates temperature and dissolved oxygen abiotic factors to determine the state of the aerator, updating the information in the ThingSpeak application. A detailed analysis of equipment energy consumption and the maximum communication range for message transmission and reception was conducted. Subsequently, the monitoring and control system underwent comprehensive testing, including communication with the visualization platform. The results demonstrated significant improvements in system performance. By modifying parameters in the microcontroller, a 2.55-fold increase in battery durability was achieved. The implemented fuzzy logic system enabled effective on/off control of the aerators, showing a corrective trend in response to variations in the analyzed abiotic parameters. The robustness of the LoRa communication interface was evident in urban environments, achieving a distance of up to 1 km without line of sight.

I. INTRODUCTION

In recent years, there has been a remarkable growth in the aquaculture industry worldwide. One of the most prominent activities in commercial aquaculture is shrimp production. In this context, Ecuador has been a significant player due to its extensive coastline and longstanding tradition in shrimp farming. According to the 2020 Annual Report of the Instituto Nacional de Pesca (INP) of Ecuador [1], shrimp aquaculture is a strategic industry that contributes significantly to the country's economy.

Despite the favorable conditions for shrimp exports, not all shrimp farming companies have sufficient technology to meet the required care standards. This is because Ecuador faces limitations in technological development. The majority of

patents in the country are focused on preventing viral and bacterial diseases [2].

That is why the use of techniques such as Fuzzy Logic, which allows intelligent and adaptive control in complex systems, using linguistic rules to handle uncertainty and inherent imprecision in aquaculture, is of vital importance. According to [3], the use of Fuzzy Logic has been effective for control and intelligent management of water quality in aquaculture. In this work, they developed a simulation approach in MATLAB for a fuzzy logic-based control system for freshwater aquaculture. On the other hand, in [4], they present a review of works that employ fuzzy logic control in aquaculture systems, and in [5], supported by fuzzy logic and IoT, they develop an intelligent system for monitoring and early warning of water quality for aquaculture.

Additionally, the incorporation of LoRa as a long-range wireless communication technology provides the capacity to transmit data efficiently and reliably, even in remote areas. By combining these technologies with IoT, it is possible to create a real-time monitoring infrastructure and a centralized platform that allows shrimp farmers to supervise and control the shrimp harvest from any location.

Several works have been developed considering the aforementioned approach, such as the study conducted in [6], which highlights the importance of Long Range IoT technologies for remote monitoring and data transmission. On the other hand, in [7], they apply this technology to the monitoring of aquaculture information, and in [8], they explore the same area, developing a control and monitoring system based on IoT using LoRa. In the same vein, in [9], they design a system for monitoring water quality in aquaculture based on LoRa, obtaining encouraging results. On the other hand, the greatest emphasis that needs to be implemented in companies focuses on the shrimp breeding stage, as it is during this phase that the highest number of diseases and deaths in the harvest occur [10]. Shrimp diseases of infectious nature include viruses, bacteria, fungi, and parasites, where water quality directly influences the susceptibility of shrimp to different pathogens. For this reason, one of the most crucial considerations during shrimp breeding is the control of water quality [11].

TABLE I. IMPORTANCE OF ABIOTIC FACTORS

Parameter	Importance
Dissolved Oxygen (DO)	Dissolved oxygen produces crises of hypoxia or anoxia.
pH	When it is out of normal range it can cause stress.
Temperature	This parameter is related to DO in an inversely proportional way. It influences parameters such as solubility, chemical reactions, and toxicity.
Salinity	Affects the behavior of dissolved oxygen.
Turbidity	The cloudier the water, more light is blocked, affecting photosynthesis.
Ammonium	In shrimp farms it can be found as ionized (and non-ionized)

The factors affecting water quality are segmented into three categories: abiotic factors, biological factors, and environmental factors. Among these factors, we will emphasize the abiotic factors for the study, as they have a significant impact on production and harvest. In Table I, the importance of different abiotic factors in aquaculture is evident [12], [13], [14].

As can be seen in the previous table, the different abiotic factors have their influence on other abiotic factors, such as the behavior and growth of the shrimp. Therefore, it is necessary for the abiotic parameters to be within an ideal range.

The ideal range of abiotic parameters is determined based on different criteria presented by various authors. Table II presents the ideal ranges of abiotic parameters according to different authors.

TABLE II. ABIOTIC FACTORS' RANGES

Ref	Temp		Salinity		DO		pH		Nitrite		Ammonium	
	Min	Max	Min	Max	Min	Max	Min	Max	Min	Max	Min	Max
[14]	-	29	-	-	4.0	6.0	6.0	9.0	-	0.09	1.22	2
[15]	29	31	10	13	5.0	-	7.0	8.5	-	0.1	-	0.1
[16]	28	30	15	25	6.0	10.0	8.0	9.0	-	0.1	0.1	1.0
[17]	26	32	-	-	3.7	-	-	-	-	0.1	-	0.12
[18]	26	32	15	25	5.0	-	7.0	9.0	-	0.3	-	0.3
[19]	25	30	15	25	4.0	-	6.0	9.0	-	0.1	-	0.1

Having abiotic parameters within a defined ideal range is considered a controlled environment. There are different consequences when shrimp are not in a controlled environment, meaning when the abiotic parameters are either above or below the range.

To minimize the effect of abiotic factors' variation on aquatic life, monitoring and control of these factors must be carried out [20]. As the demand for shrimp continues to increase and there is a quest to enhance efficiency and sustainability in aquaculture practices, adopting advanced technologies for control and monitoring of shrimp pools becomes crucial. In response to this growing demand, the

present study develops a control and monitoring system based on Fuzzy Logic, LoRa (Long Range), and the Internet of Things (IoT) to address specific challenges faced by Ecuadorian shrimp farms. The approach combines these technologies to achieve intelligent and automated management of environmental conditions, maintaining an optimal environment for shrimp growth and development.

The rest of this manuscript is structured as follows: Section II presents a brief description of work related to the pond shrimp harvesting stage, abiotic factors, IoT architecture features, and the application of fuzzy logic. Section III describes the proposed methodology, the IoT structure, the devices to be used, the survey for the equipment selection and the control system. Section IV presents the experimental results obtained with the designed control and monitoring system. Finally, Section V provides the conclusions of this study and states the future work.

II. RELATED WORKS

The problem encountered during the shrimp pond harvesting stage is not unique to Ecuador; it is also present in various shrimp-producing countries. This section addresses how different authors have dealt with this challenge, and in Table III, a brief description of related works is provided.

TABLE III. RELATED WORKS

Reference	Description	Equipment
[12]	Proposal of a fuzzy model for analyzing the internal parameters of shrimp pools, describing the water status qualitatively.	-
[13]	Proposal for an analysis of water quality to control crises in aquatic systems.	-
[21]	Real-time modeling of a vehicle for shrimp pools, using fuzzy logic algorithms.	pH sensor. DO sensor. Temperature sensor. Turbidity sensor. Arduino Uno. Node MCU.
[22]	Evaluation of feeding strategies for shrimp based on fuzzy logic and mathematical functions.	Applied in a test laboratory. The simulation of the models was done using MATLAB.
[23]	Improving feeding conditions through the use of passive acoustics, computer vision, and telemetry.	Automatic feeder. Hydrophone. Controller. Wireless Communication.

In the work developed in [12], they established different categories for water quality based on abiotic parameters, which were obtained using fuzzy logic. From related literature, they determined that organisms are susceptible to diseases as a consequence of shrimp stress (variations in internal parameters of the pools). Fuzzy logic is considered an effective tool to assist shrimp farmers. In another research [13], it is mentioned that water quality is essential for proper shrimp growth, as they are susceptible to stress due to their ecosystem conditions. Other authors [14] indicate the importance of maintaining the ranges in which the abiotic parameters are found. These parameters are used to produce a quality index. On the other hand, in [21], they achieved a precision of 92% in the applied test to predict the water status. The control algorithm was based on fuzzy logic, and the authors anticipate that

implementing such elements in a shrimp pond will improve conditions. According to [23], having a better understanding of feeding techniques improves the conditions in which shrimp grow. Having a monitoring system in shrimp pools results in an increase in economic returns, as it allows better control of different parameters. The focus of that study was on feeding techniques, with a hydrophone being the selected equipment to analyze the ideal time for shrimp feeding.

A. IoT Architecture

An IoT architecture allows interconnection and communication between different devices by establishing a connection with the cloud. It is not necessary for the devices to be physically located in the same place; instead, the monitoring and visualization of various processes can be done from different platforms [24]. In a shrimp farm where access to technology is challenging, implementing IoT architecture concepts offers many advantages and benefits. Fig. 1 illustrates the characteristics that these services provide.

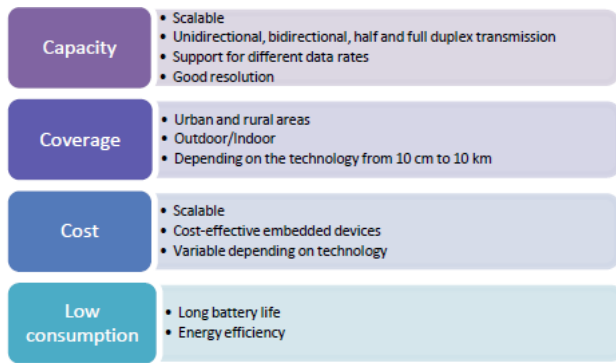

Fig. 1. Characteristics of IoT.

Wireless access networks within the IoT architecture vary and depend on the solution that will be provided to a specific problem, determining which one to use. Fig. 2 illustrates the coverage distance of different networks.

Fig. 2. Wireless access geographic coverage. Proximity networks, Wireless Personal Area Networks (WPAN), Wireless Local Area Networks (WLAN), Wireless Neighborhood Area Networks (WNAN) and Wireless Wide Area Networks (WWAN) [24].

The focus lies in the fact that different communication protocols have their limitations regarding their range. However, when a greater range is required, the use of Low-Power Wide Area Networks (LPWAN) within the can be employed. When considering the range that devices must have to communicate with each other, the modulation and

transmission rate must be carefully analyzed [25]. Table IV presents different communication protocols found in the literature, such as LoRa, Sigfox, and Zigbee [26].

TABLE IV. DIFFERENT COMMUNICATION PROTOCOLS

Characteristics	LoRa	Sigfox	Zigbee
Power	Low [27]	Low [28]	Low [29]
Transmission range	10 km	3 to 50 km	10 to 100 m
Data Rate	0.3 to 50 kbps	100 to 600 bps	20 to 250 kbps
Modulation	Spread spectrum modulation type based on FM pulses.	Ultra narrow band radio modulation	DSSS as a spreading technique
Modulation Technique	Chirp-spread spectrum	BPSK	BPSK
Topology	Star/mesh/point-to-point	Star	Star
Security	Resistance to electromagnetic interference. Robust to multi-path fading.	Low Frequency Accuracy constraint. High resistance to interferences.	Access control list. Frame Counters Encryption of over-the-air communications [30].
Battery	Long battery life	Long battery life	Long battery life
Bandwidth	900 MHz <500 kHz	200 kHz 100 Hz	2.4 GHz 915 MHz 868 MHz

Among the various advantages offered by different physical layer protocols, the LoRa modulation technique stands out for providing enhanced security. The Chirp Spread Spectrum, commonly employed by the military and in communication security applications, is utilized in LoRa [31].

III. MATERIALS AND METHODS

LoRa communications can be modified and depend on different parameters, which can be configured in the application. These parameters include spreading factor, coding rate, transmission power, chirp polarity, and synchronization word. Due to the versatility LoRa offers in device-to-device transmission, it has been selected as the communication method for the study. The LoRa protocol will be used for intercommunication between the different nodes in the pools. Meanwhile, the internet module will be used in the gateway module for communication with the ThingSpeak platform, enabling real-time visualization of the abiotic parameters of the different pools, as shown in Fig. 3.

Fig. 3. Nodes.

In the gateway, the fuzzy logic function is embedded to calculate the next state of the aerator. The sensor nodes are enabled for data transmission, while the actuator nodes are enabled for data reception. The gateway node is configured to receive information from the sensor node and send information to the actuator node.

A. Control

In the process control field, there are different techniques for implementation, and one common type of controller is the PID controller, which provides a fast dynamic response. However, it requires control calibration for events with high precision, and one of its disadvantages is its high sensitivity to noise. An alternative control type is fuzzy logic, which consists of two stages: fuzzification and defuzzification (see Fig. 4).

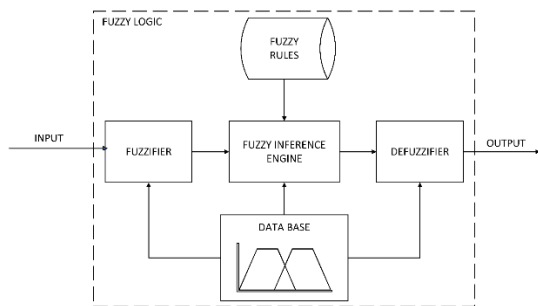

Fig. 4. Fuzzy logic.

The inputs to the controller first go through the fuzzification process to obtain a fuzzy value. This value then goes through an inference mechanism, which is complemented by fuzzy inference rules and fuzzy functions (database). Depending on the fuzzy input values, a fuzzy output value is obtained, which is then transformed into a real value through the defuzzification process.

B. Survey

For the selection of equipment to be implemented and sensors for the prototype, a survey was conducted with 35 shrimp farmers located in the province of El Oro, Ecuador. The most notable data from the survey were as follows:

Fig. 5. Question 1: How many pools do you have?

The first finding pertains to the sizing of the pools and the scalability of the equipment. It is observed that the mode among shrimp farmers is to have four pools (Question 1). However, since there are shrimp farmers with 15 pools, the dimensioning of the devices to be connected in our monitoring network should be able to support and even have a larger capacity (see Fig. 5).

Fig. 6. Question 2: Size in hectares of your smallest pool

Fig. 7. Question 3: Size in hectares of your largest pool

Of the surveyed users, they were asked about the size of the smallest pools they have, and it was observed that they range from 1 to 10 hectares (Question 2) as shown in Fig. 6. Among these, 46% have a standard size of 2 hectares. When analyzing the case of the largest pools, they range from 3 to 19 hectares (Question 3) as depicted in Fig. 7.

Fig. 8. Question 4: How many aerators do you have in your smaller pool?

Fig. 9. Question 5: How many aerators do you have in your largest pool?

By knowing the size of the pools, we can identify how many devices or equipments are installed within each pool. It is observed that the range varies from 1 to 14 aerators (Questions 4 and 5 as shown in Fig. 8 and 9). Both points mentioned not only help determine how many pools are present but also give an idea of the number of devices that need to be installed and controlled in the pools.

Fig. 10. Question 6: Indicate what kind of control mechanism you currently have implemented in your shrimp pool.

From the survey conducted with the shrimp farmers, it was determined that 30 of them perform the process of measuring parameters manually, while only five of them use both manual and automatic measurements (Question 6) as can be determined from Fig. 10.

Fig. 11. Question 7: Measurement Frequency

A key question to determine the water quality among the surveyed shrimp farmers is that the measurement process is mostly done on a weekly basis, with only three shrimp farmers doing it daily. In the most severe cases, the analysis is done bi-weekly or monthly (Question 7) evident from Fig. 11. This information allows us to determine the focus of the final product to be developed.

C. Devices

For the selection of devices to be used, market devices were analyzed, and the summary is presented in Table V.

TABLE V. DEVICES

	Arduino Uno	Arduino Nano	TTGO Lora32 Oled V1	Heltec WiFi LoRa32
Chip	ATmega328P	ATmega328	ESP32	ESP32
Module	-	-	SX1276	SX1276
Processor	-	-	32-bit LX6	32-bit LX6
Transmission power	-	-	+20dB	+20dB
Transfer frequency	-	-	868-915 MHz	868-915 MHz
ROM	-	-	448 kB	448 kB
RAM	-	-	520 kB	520 kB
Flash Memory	16KB/32KB	32KB	4MB	8MB
Operating Voltage	5V	5V	2.7V-3.6V	3.3V-7V
Input Voltage	7V-12V	7V-12V	3.7V-4.2V	3.3V-7V
Input Voltage Limit	6-20V	-	-	-
GPIO	14	14	28	28
Analog Pins	6	8	-	-
PWM Pins	6	6	-	-
Clock Frequency	16 MHz	16 MHz	40MHz	40 MHz

In this way, by comparing the internal features of the devices, the TTGO LoRa32 Oled V1 model was selected, as it has a 32-bit processor and a 4MB flash memory. Although it has a smaller flash memory compared to the Heltec device, it still meets the needs for the sensor and actuator nodes. Having a low input voltage is favorable for achieving longer equipment autonomy.

D. Solution Description

For the monitoring and control of shrimp pools, the solution consists of a stage of measuring the abiotic parameters in the pond using a sensor node. Once the data is obtained, it is sent to a gateway node where it is processed using a fuzzy logic algorithm. This algorithm is designed to determine the next state of the pond's aerator (on or off). This value is then sent to an actuator node, which commands the activation of the aerator using a relay. A brief description of the process is shown in Fig. 12.

Fig. 12. Proposed control system.

The data obtained and used in this work are available at the following link: <https://github.com/josep5097/LoRa-Shrimp-Monitoring-Control>

As mentioned, the concept of the Internet of Things is used for the current model of the control and monitoring system. In Fig. 13, you can observe the structure of the proposed architecture.

Fig. 13. IoT structure.

Within the link layer, there are sensor nodes and actuator nodes, and communication between the devices is through the LoRa protocol. When using the LoRa communication protocol, a topology must be chosen for the communication between devices. For the present system, a star network topology was selected over a mesh network. This decision was made because devices in a full duplex communication (mesh) require being powered on all the time, leading to a higher energy demand. An outline of the established architecture is shown in Fig. 14.

Fig. 14. Topology.

Within the network layer, there is a designated device to serve as our gateway to the Internet, in this case, the gateway node. It communicates with the different nodes in the pools using the LoRa protocol in its physical layer, and with the Internet using the HTTP protocol.

The devices have a synchronization word and ID, as shown in Fig. 13, which means that only devices with this synchronization word in their header can receive the message. Additionally, encryption was implemented to ensure that the messages transmitted by the LoRa devices are understood only by the intended receivers. To avoid signal interference, a gap between message transmissions must be established.

The captured data from the pools is visualized using the ThingSpeak platform, with the information being sent from the gateway device as described in Fig. 15.

Fig. 15. Gateway connection.

In Fig. 15, besides the formation of the JSON object that is sent, you can see the pins used to connect both the OLED and the LoRa module. Similarly, the connection used with the sensor and actuator nodes is described. For the sensor node, GPIO pins are used for the dissolved oxygen and temperature sensors, as shown in Fig. 16.

Fig. 16. Sensor node connection.

Meanwhile, for the actuator nodes, a GPIO pin is used to activate a relay for turning on or off an aerator (see Fig. 17).

Fig. 17. Actuator connection.

E. Pseudocodes

To establish the described behavior of the devices in Fig. 15, 16, and 17, the processes are described using pseudocodes for each of the nodes.

Pseudocode 1: Nodo Gateway

```
# Init variables
DO [ ] = 0;
Temp [ ] = 0;
Aerators = 0;
# Init an array with all ID of nodes
ID_Sensors = {ID_S1, ID_S2};
ID_Actuators = {ID_A1, ID_A2};
# Init all variables in the fuzzy control
Fuzzy_Variables();
# Control Variables
num_Case = 1;
LoRa_Ok = false;

Void Setup {
    Fuzzy_Setup();
    LoRa.Setup();
    LoRa.begin();
    ThingSpeak.begin();
}

Void loop () {
    Switch (num_Case){
        case 1:
            LoRa_Read();
            If ( LoRa_Ok == True)
                num_Case ++;
            } else {
                num_Case = 1;
            }
            break;

        case 2:
            controlDifuso(Do, Temp,Aireadores);
            num_Case++;
            break;

        case 3:
            comunicacionLoRaActuador(destino, origen,
            Aireadores)
            num_Case++;
            break;

        case 4:
            procesoThingSpeak (Do, Temp, Aireadores,
            ID_Piscina);
            num_Case = 1;
            break;
    }
}
```

The monitored variables, such as DO and Temperature, are established along with the controlled variable, which is the Aerator. The Dissolved Oxygen and Temperature values will

be obtained from a sensor node, and the state of the Aerator represents the next state of the corresponding actuator node in the pool from where the sensor node's parameters originated. The value for the Aerator state will be determined using fuzzy logic. To establish a relationship between the sensor nodes and actuator nodes, unique IDs are assigned.

1) *Fuzzy logic configuration subprocess*: The fuzzy control process is described in Fig. 18, the diagram of relationships between entities, in which it can be observed how the variables interact among functions.

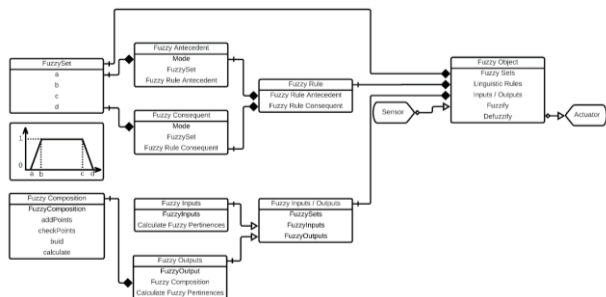

Fig. 18. Diagram of relationships between entities of fuzzy control.

In the fuzzy logic subprocess, the membership functions, as well as the fuzzy rules or linguistic rules, are established. Once these elements are set, the fuzzification process is applied to the inputs, which are values returned by the sensors, and the defuzzification process determines the value for the next state of the actuator.

2) *LoRa configuration subprocess*: The LoRa communication configuration consists of two stages:

- Internal parameter configuration (see Fig. 19).
- Message structure (see Fig. 20).

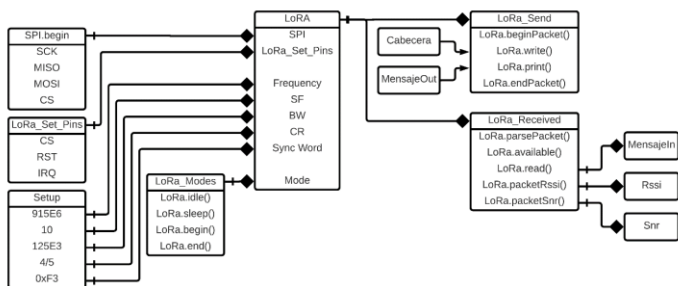

Fig. 19. Entity relationship of LoRa parameters.

For the configuration of internal parameters, the Entity Relationship of Fig. 19 is established, in which the same frequency, Spreading Factor (SF), Bandwidth (BW), Correction Rate (CR), and synchronization word (Init byte) are set for each device. The LoRa message sent has the same structure in different nodes, as shown in Fig. 20.

Fig. 20. LoRa message structure.

3) *Subprocess of thingspeak configuration*: Since the gateway node communicates with the cloud, it is necessary to establish the parameters for communication. This subprocess is described in the entity relationship of Fig. 21.

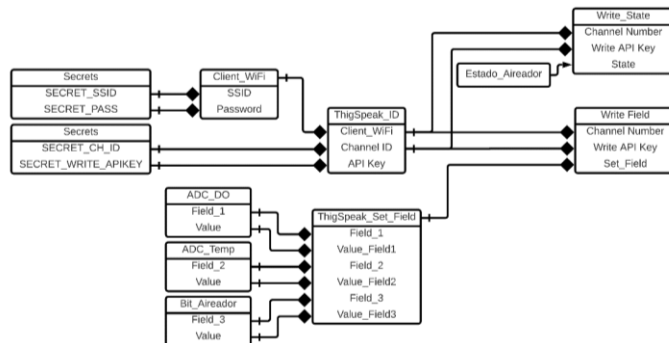

Fig. 21. Entity relationship of the thingspeak configuration subprocess.

The WiFi information, the channel to communicate with in ThingSpeak, and the API Key generated for communication are established. In this same scheme, it can be observed that when all the fields are ready and within the process flow, both a state is updated and fields are written to.

4) *Sensor node*: Since the sensor node is located inside the shrimp pond and operates autonomously, it requires better control over its operation time. Therefore, a reading interval of six hours is established for the process.

Pseudocode 2: Sensor node

```

Init
OD = 0;
Temp = 0;
ID_Coordinador = 0xID;
ID_Local = 0xID;
num_Case = 1;
Tiempo_A_Dormir = 21600; //21600 seconds = 6 hours
Void Setup {
Serial.begin(115200);
Display.begin();
LoRa.setup();
LoRa.begin();
}
Void loop {
Switch (num_Case){
case 1:
DO = lecturaAnalogicaPonderada(pinDO);
Temp = lecturaAnalogicaPonderada(pinTemp);
num_Case ++;
break;
case 2:
comunicacionLoRa(destino, origen, DO, Temp);
num_Case++;
break;
case 3:
num_Case=1;
esp_deep_sleep_start();
break;}}
    
```

5) *Actuator node*: Since the actuator node is directly powered by the control board, the equipment is always active. Its process involves reading the messages transmitted through a coordinator node, and depending on the case, it activates or deactivates the aerator.

Pseudocode 3: Actuator Node

```

Init
Aireador = 0;
ID_Coordinador = 0xID;
ID_Local = 0xID;
num_Case = 1;
Void Setup {
    Serial.begin(115200);
    Display.begin();
    LoRa.begin();
    pinMode(AireadorPin, OUTPUT);
}
Void loop {
    Switch (num_Case){
    case 1:
        LoRa_Read();
        If ( LoRa_Ok == True)
            num_Case ++;
        } else {
            num_Case = 1;
        }
        break;
    case 2:
        if (Aireador == 1){
            digitalWrite(aireadorPin, HIGH);
        } else {
            digitalWrite(aireadorPin, LOW);
        }
        num_Case = 1;
        LoRa_Ok = false;
        break;
    }
}
    
```

IV. RESULTS

In this section, the results obtained with the designed control and monitoring system are described. Fig. 22 illustrates the flow followed for the control of a shrimp pool.

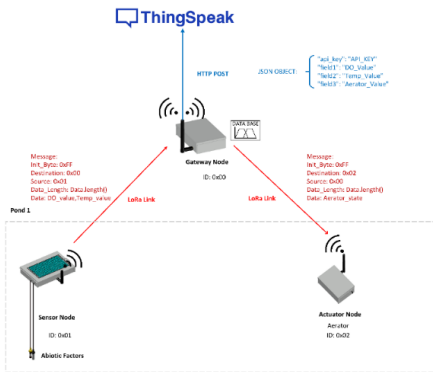

Fig. 22. Process of control in a shrimp pool.

In the embedded system of the coordinator node, linguistic terms, membership functions, antecedents, and consequents for fuzzy rules are established. In this study, three membership functions were applied, as shown in Fig. 23.

Fig. 23. Linguistic terms.

The embedded system uses fuzzy logic to represent the relevant linguistic terms. From these terms, three membership functions are generated: Dissolved Oxygen (see Fig. 24),

Temperature (see Fig. 25), and Aerator (see Fig. 26). These membership functions capture the characteristics and variability of each variable in the system.

Fig. 24. Dissolved oxygen membership function.

Fig. 25. Temperature membership function.

Fig. 26. Aerator membership function.

Since the fuzzy controller was implemented in an embedded system, the membership functions take a trapezoidal form, adapting to the limitations of the system. When establishing the membership functions, the values mentioned in Table II were taken into account. From these membership functions, the corresponding fuzzy rules were generated, which are shown in Fig. 27.

Fig. 27. Fuzzy Rules for the control system

The fuzzy rules used in this study were based on previous research [12], [13], [21]. From these established fuzzy rules, LabVIEW software was used to generate the fuzzy relation function, which reflects the expected behavior of the system. The fuzzy relation function was constructed based on the 12 defined fuzzy rules, and its response is shown in Fig. 28.

Fig. 28. Fuzzy rules.

In the coordinator node, a test was conducted with different values to verify the functionality, from which the results described in Table VI were obtained.

TABLE VI. FUZZY CONTROL RESPONSE

		Dissolved Oxygen (mg/L)												
		3.1	3.5	3.9	4.5	5	6	7	8	8.5	9.5	10	11	15
Temperature (°C)	-5	0.76	0.72	0.72	0.76	0.72	0.72	0.76	0.76	0.76	0.76	0	0	0
	10	0.76	0.72	0.72	0.76	0.72	0.72	0.76	0.76	0.75	0	0	0	0
	15	0.76	0.72	0.72	0.76	0.72	0.72	0.76	0.76	0.75	0	0	0	0
	20	0.76	0.72	0.72	0.76	0.72	0.72	0	0	0	0	0	0	0
	25	0.76	0.72	0.72	0.76	0.72	0.72	0	0	0	0	0	0	0
	30	0.76	0.72	0.72	0.76	0.72	0.72	0.65	0.65	0.65	0	0	0	0
35	0.76	0.72	0.72	0.76	0.72	0.72	0.76	0.76	0.75	0	0	0	0	

For the digital selection of the next state of the aerator, a threshold was established:

$$Aerator [state] > 0.5 \text{ then } Aerator \text{ ON}$$

Considering the threshold described previously, the table of the control response is modified (see Table VII).

The fuzzy system implemented in the embedded system achieves the performance demonstrated in Fig. 29. The interaction of the abiotic parameters with the mechanical movement of the aerator can be observed. The goal is that when the abiotic parameters are within an optimal range, the aerator switches to an off state.

TABLE VII. CONTROLLER RESPONSE - AERATOR STATUS

		Dissolved Oxygen (mg/L)												
		3.1	3.5	3.9	4.5	5	6	7	8	8.5	9.5	10	11	15

V. CONCLUSIONS

The proposed control and monitoring system was established with the input of domain experts and reviewed research. However, it was observed that considering the needs of internal producers is of vital importance in order to encompass the required system activities and to determine the optimal solution based on available market equipment. It was determined that in order to operate within an IoT architecture, various situations and events must be taken into account. One of the key factors is the communication and security aspects that the equipment must possess, as well as the scalability they offer. Therefore, for the monitoring and control system established in this study, a star topology was considered for sensor and actuator nodes. This configuration allows for isolated points of connection, as establishing two-way communication requires higher processing and energy consumption.

Referring to the system's security levels, LoRa technology enabled the allocation of a specific channel, defining bytes for synchronization between devices. Additionally, fields were added to maintain control over transmissions and to determine the source and destination of messages. Identifying and discarding corrupted messages without processing them is crucial. To address this, a validation process was incorporated, which includes a field for assessing this condition.

The communication between the devices was successful in an urban environment of up to 1 km without packet loss, although it was necessary to adjust the LoRa configuration parameters to optimize performance. The use of fuzzy control based on abiotic factors allowed for effective control criteria in the shrimp pool, improving shrimp performance and growth through aerator control.

As future work, it is proposed to expand the number of abiotic factors without affecting performance and improve the range of the devices. An improvement option would be to migrate to a LoRaWAN network to take advantage of its additional benefits in terms of coverage and management capacity.

Abstract—Using image processing technology has become increasingly essential in the education sector, with universities and educational institutions exploring innovative ways to enhance their teaching techniques and provide a better learning experience for their students. Vision transformer-based models have been highly successful in various domains of artificial intelligence, including natural language processing and computer vision, which have generated significant interest from academic and industrial researchers. These models have outperformed other networks like convolutional and recurrent networks in visual benchmarks, making them a promising candidate for image processing applications. This article presents a comprehensive survey of vision transformer models for image processing and computer vision, focusing on their potential applications for student verification in university systems. The models can analyze biometric data like student ID cards and facial recognition to ensure that students are accurately verified in real-time, becoming increasingly vital as online learning continues to gain traction. By accurately verifying the identity of students, universities and educational institutions can guarantee that students have access to relevant learning materials and resources necessary for their academic success.

Keywords—Vision transformers; image processing; natural language processing; image

I. INTRODUCTION

In recent years, deep neural networks such as convolutional neural networks (CNNs) [1], recurrent neural networks (RNNs) [2], graph neural networks (GNNs) [3], and attention neural networks [4] have been widely applied to a variety of artificial intelligence (AI) tasks. In contrast to previous non-neural models, which relied heavily on hand-crafted features and statistical methods, neural models can automatically learn low-dimensional continuous vectors as task-specific features from data, avoiding the need for complex feature engineering. Despite the popularity of deep neural networks, many studies have discovered that one of their fundamental limitations is their data-hungry nature. Due to many parameters in deep neural networks, they are prone to overfitting and have poor generalization capacity without appropriate training data [5].

CNNs are a fundamental component of modern computer vision systems. The advantage of CNNs was that they eliminated the need for manually constructed visual elements instead of learning to execute tasks “end to end” from data. The CNNs minimize manual feature extraction, and the CNN architecture is optimized for images and can be computationally expensive. Recent arguments have claimed that need goes beyond convolutions to represent long-range relationships. These initiatives aim to enhance convolutional models with content-based interactions, such as self-attention and non-local means, to improve performance in various vision tasks [6]. Transformers [7] are models that focus entirely on the self-attention process to establish global dependencies between input and output, and they have dominated natural language modelling in recent years [8-9]. Transformers and their variations have been thoroughly explored and used in natural language processing tasks such as machine translation [10], light-weight transformers [11], dynamic mask attention networks [12], language modelling [13], routing transformers [14], positional encoding schemes [15], and named entity identification [16-17]. The contrasts in size of visual elements and the high quality of pixels in images compared to words in text provide challenges in converting transformer from language to vision. The standard transformer is intended to process sequence data and is expected to receive a 1D series of token embedding. Many applications, including video understanding [18], image recognition [19], image super-resolution [20], object detection [21], segmentation [22], text-image synthesis [23] and visual question-answering [24], have been successfully implemented using transformer models and their variants in a variety of fields.

The survey in [25] explores recent advancements in visual transformers, an architecture originally designed for natural language processing but increasingly applied in computational visual media. The survey categorizes visual transformers based on task scenarios and analyzes their key ideas, with a particular focus on low-level vision and generation. The study reviews in detail backbone design approaches, offers quantitative comparisons, showcases image results, and includes information on computational costs and source code links to facilitate future development. In another recent survey by Jamil

et al. [26], the authors presented the first application of ViTs in computer vision, providing an overview of their usage and performance in various applications such as image classification, object detection, segmentation, compression, super-resolution, denoising, and anomaly detection, along with a comprehensive analysis of existing models, insights, and future research directions. Liu et al. [27] provided a comprehensive review of over one hundred visual transformers, attention-based encoder-decoder models inspired by the Transformer architecture in computer vision. It analyzes their effectiveness in fundamental tasks (classification, detection, segmentation) and different data stream types, presents a taxonomy to organize the methods, evaluates and compares them under various configurations, identifies unexploited aspects for further improvement, and suggests three promising research directions for future development. Subsequently, the survey [28] examines the advancements and trends in utilizing Transformers for video modeling, addressing their limitations with inductive biases and scalability. It analyzes how videos are handled at the input level, architectural modifications to enhance efficiency and capture temporal dynamics, various training regimes, self-supervised learning strategies, and provides a performance comparison against 3D ConvNets, demonstrating the superior performance of Video Transformers in action classification with reduced computational complexity.

Additional work in this approach may aid in a better understanding of Transformer models and detecting any erroneous behaviour or biases in the decision-making process. Since Transformer designs do not incorporate inductive biases (previous knowledge) to deal with visual input, transformers generally require a substantial quantity of training data in pre-training to determine the underlying modality-specific rules [29]. Several neural network architectures are known, including CNN, RNN, and transformer. CNNs were once the standard [30] in the Computer Vision domain, but transformers are gaining popularity [29]. While CNNs may capture inductive biases such as translation equivariance and localization, Vision Transformer overcomes inductive bias through large-scale training. According to the existing research [31], CNNs excel at small datasets, whereas transformers excel at massive datasets. The following fundamental issue is whether to employ in future CNN or a transformer.

Fig. 1 shows the number of publications on different image processing techniques using vision transformers [40].

Fig. 1. The number of publications on different image processing techniques using vision transformers.

TABLE I. SUMMARY OF CONTRIBUTIONS FROM RECENT SURVEYS ON VISION TRANSFORMERS

Reference	Year	Scope	Contributions
Han et al. [32]	2022	General overview	Provides a comprehensive introduction to Vision Transformers
Chen et al. [33]	2021	Image classification	Focuses on the application of Vision Transformers for image classification tasks
Jamilet al. [26]	2023	General overview	Offers an in-depth analysis of Vision Transformers in various domains
Selvaet al. [28]	2023	Recent advancements	Highlights the latest research trends and advancements in Vision Transformers
Gehrig et al. [34]	2023	Object detection	Discusses the utilization of Vision Transformers for object detection tasks
Zhai et al. [35]	2022	NLP to computer vision transition	Explores the adaptation of Vision Transformers from natural language processing to computer vision
Yang et al. [36]	2022	Comprehensive review	Provides an extensive analysis of Vision Transformers and their applications -
Guo et al. [37]	2022	Comparison with CNNs	Compares the performance and characteristics of Vision Transformers with CNNs
He et al. [38]	2022	Medical image analysis	Examines the use of Vision Transformers in the field of medical image analysis
Aleissae et al. [39]	2023	Remote sensing applications	Surveys the application of Vision Transformers in remote sensing tasks

Table I summarizes significant contributions from the existing survey articles on vision transformers.

The contributions of this article are as follows:

- An overview of the background and preliminaries of vision transformers, widely used in natural language processing, and how they can be adapted for image processing.
- Discusses how vision transformers have been used for image classification and enhancement, which involves improving the quality of images by removing noise, enhancing contrast, and increasing resolution.
- Explores how vision transformers can be used for object detection, which is the process of identifying and locating objects within an image, and how they can achieve state-of-the-art performance on this task.
- Highlights the role of vision transformers in education and university systems, specifically in student verification, where they can automate the process of verifying student identities, making it faster and more accurate.
- Discusses how vision transformers can deal with multimodal tasks, where they can process and fuse information from multiple modalities, such as text, image, and audio.

The rest of this article is organized as follows. The second part introduces the background details of the transformer, and the third part explores the usage of the visual transformer variants. The fourth part throws light on multimodal variants of

using vision transformers. It also discusses the future research directions of visual transformers and the fifth part concludes the paper.

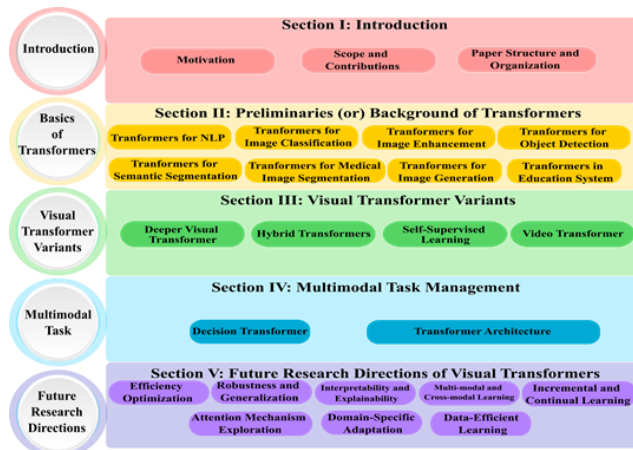

Fig. 2. Overall organization of the article.

Fig. 2 shows the overall organization of the sections presented in this article.

II. PRELIMINARIES (OR) BACKGROUND OF TRANSFORMERS

The transformer is made of L layers, each of which has two major blocks: a Multi-Headed Self Attention (MSA) layer that performs a self-attention operation on various projections of the input tokens and a Multi-Layer Perceptron (MLP). Both the MSA and MLP layers are preceded by layer normalization and followed by a skip connection [41]. The attention mechanism was initially applied for 1-D data processing in natural language processing [42-43]. It has recently expanded to handle two-dimensional images and three-dimensional video data [44].

The fundamental components of a transformer include Multihead Self-Attention (MSA), Multi-Layer Perceptron (MLP), and Layer Normalization (LN) [7]. The authors [45] proposed the Gaussian Error Linear Unit (GELU) used to a great extent as one of the high-performing activation functions for neural networks. The work in [46] discusses the challenges of applying batch normalization to RNNs and introduces a new technique (called layer normalization) which addresses these challenges. Layer normalization computes mean and variance for normalization from all summed inputs to neurons in a layer on a single training case. It is effective in stabilizing hidden state dynamics in recurrent networks. It significantly reduces training time compared to previous techniques.

A. Transformers for NLP

In recent years, the transformer has evolved into a fundamental component of numerous cutting-edge natural language processing (NLP) models. Like RNN, the transformer is a robust performance model helpful for standard NLP applications such as intent identification in a search engine, text creation in a chatbot engine, and classification. The authors proposed a feed-forward network design that relies entirely on attention processes and avoids convolutions and recurrence. It achieved state-of-the-art performance on several tasks significantly and generalized exceptionally well to other

NLP tasks, even with limited data. This design served as the foundation for numerous NLP models. GPT [47-49] and BERT [8] are two pioneering Transformer-based pre-trained models (PTMs) that employ autoregressive and autoencoding language modeling as pre-training objectives, respectively. Different Pre-trained models XLNet [50], RoBERTa [51], ALBERT [52], and T-NLG [53] are used in NLP tasks. Fig. 3 shows the structural difference between Transformer, GPT, and BERT [54].

Devlin et al. utilized the Transformer encoder (and only the encoder) to pre-train deep bidirectional representations from the unlabeled text. This pre-trained BERT model is fine-tuned with just one extra output layer to reach state-of-the-art performance for various NLP tasks without significant task-specific architectural changes. GPT [47] is a framework and training technique for natural language processing problems based on the Transformer architecture. The process for training is twofold. First, unlabeled data was used to learn the initial parameters of a neural network model using a language modeling aim. Then, using the associated supervised goal, these parameters are modified to a target task.

B. Vision Transformers for Image Classification

There have been many efforts to apply Transformers to vision tasks. These works are divided into two categories. The first category comprises models of pure attention. These models frequently use self-attention and strive to create convolution-free vision models. The second category encompasses networks developed using self-attention and convolutions [55]. Self-attention networks have revolutionized NLP and rapidly advanced image analysis tasks such as image classification and object recognition [56-57].

In computer vision, attention is employed in conjunction with or instead of CNN. This reliance on CNN is not required, as a pure transformer applied straight to sequences of image patches can do quite well on image classification tasks. The original text Transformer accepts a series of words as input and then uses them for classification, translation, or other natural language processing tasks. Dosovitskiy et al. [58] made the fewest feasible changes to the Transformer architecture to work directly on images rather than words for the vision transformer. Fig. 4 shows the architecture of the vision transformer.

Vision transformer generates a grid of square patches from an image. Each patch is converted to a single vector by concatenating the channels of all its pixels and then linearly projecting it to the chosen input dimension. Because transformers are structure-independent, they can add learnable position embedding to each patch, allowing the model to learn about the structure of the images. Vision transformer does not know the relative location of patches in the image or even if the image has a two-dimensional structure a priori. It must learn this information from training data and encode it in the position embeddings. Feed the sequence as an input to a state-of-the-art transformer encoder. Pre-train the vision transformer model with image labels, fully supervised then on an extensive dataset. Fine-tune the downstream dataset for image classification.

Fig. 3. Structure of transformer, GPT, and BERT.

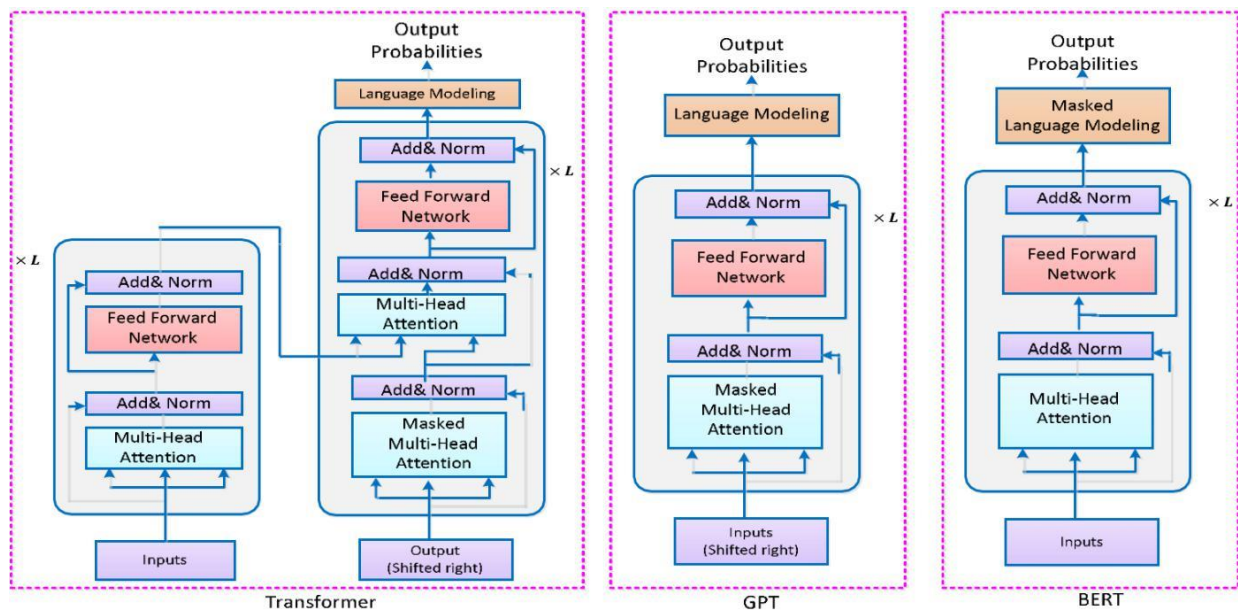

Fig. 4. Vision transformer architecture.

The Image GPT (iGPT) method [59] is an unsupervised generative pre-training technique for developing robust visual representations. By directly applying a GPT-2 [48] model to the image pixels, compelling image completions and samples were obtained, demonstrating that a completely Transformer-based architecture is viable for some visual tasks, regardless of the input image quality.

It does not need to prepare a large dataset to properly train the network in Data-efficient Image Transformers (DeiT) [6]. Instead, student-teacher setup and more intensive data augmentation and regularization are employed, such as stochastic depth [60] or repeated augmentation [61]. The teacher is a neural network designed to guide its student induction bias for convolutions [19].

LeViT is based on the architecture of the vision transformer [58] and the training technique of DeiT [19]. Regarding the speed/accuracy trade-off, LeViT considerably outperforms previous convnets and vision transformers [62]. LeViT is five times faster than EfficientNet on the CPU at 80.

To improve image classification accuracy, Chen et al. [51] describe Cross Vision Transformer (CrossViT) [63], a dual-branch vision transformer learning multi-scale features. The proposed technique analyses separately small-patch and large-patch tokens using two distinct branches with varying computational costs. These tokens are subsequently merged numerous times repeatedly by attention to complement one another. It also created an efficient token fusion module based on cross-attention using a single token for each branch as a query to exchange information with other branches. Cross-attention needs linear time for computational and memory complexity when it usually requires quadratic time.

Transformer-iN-Transformer (TNT) [64] combines both patch-level and pixel-level representation by utilizing an outer Transformer block that processes patch embedding and an inner Transformer block that models the relation between pixel embedding.

C. Transformer for Image Enhancement

Chen et al. developed a pre-trained image processing model based on the transformer design, namely *Image Processing Transformer (IPT)* [65]. The IPT model features multiple heads, multiple tails, and a standard transformer body for performing various image processing tasks such as super-resolution and denoising. The IPT model was trained using supervised and unsupervised methods, demonstrating a significant capacity to capture intrinsic characteristics for low-level image processing. Experiments indicate that IPT can outperform state-of-the-art techniques using a single pre-trained model following a brief fine-tuning phase.

Yang et al. [20] proposed a novel *Texture Transformer Network for Image Super-Resolution (TTSR)* in which the low-resolution (LR) and high-resolution (Ref) images are expressed as queries and keys, respectively, in a transformer. TTSR is a collection of closely linked modules designed for image generation tasks, comprising a learnable texture extractor based on deep neural networks, a relevance embedding module, a hard-attention module for texture transfer, and a soft-attention module texture synthesis.

D. Transformer for Object Detection

Carion et al. [21] introduced *DEtection TRansformer (DETR)* to eliminate the requirement for such hand-crafted components and developed the first fully end-to-end object detector with highly competitive performance. DETR is a basic architecture shown in Fig. 5 that combines CNNs with Transformer encoder-decoders [66]. They use Transformer's versatile and robust relation modelling capabilities to substitute hand-crafted rules when appropriately prepared training signals are used. DETR is a novel approach to object recognition based on transformers and bipartite matching loss for direct set prediction. Applied to the problematic COCO dataset, the method obtains results equivalent to an improved Faster R-CNN baseline. DETR is simple to construct and offers a modular design easily extendable to panoptic segmentation, resulting in competitive performance. Additionally, it outperforms Faster R-CNN on big objects, most likely because of the global information processing produced by self-attention.

However, it has its own range of difficulties. These difficulties are primarily due to the Transformer's attention deficiencies in handling image feature maps as essential elements: (1) DETR's ability to identify small objects is relatively poor. Modern object detectors use high-resolution feature maps to identify small objects more accurately. However, high-resolution feature maps would impose an excessive complexity level on the self-attention module of DETR's Transformer encoder, which scales quadratically with the spatial dimension of the input feature maps. (2) Compared to current object detectors, DETR takes more training epochs to converge. DETR is primarily due to the difficulty of training the attention modules that analyze visual characteristics.

Deformable (DETR) [21] remove the requirement for several handmade components in object detection while exhibiting acceptable performance. However, because of the limitations of Transformer attention modules in processing visual feature maps, it has a sluggish convergence rate and a restricted feature spatial resolution. To address these concerns, authors [67] suggested Deformable DETR, in which the attention modules focus exclusively on a limited number of critical sampling points surrounding a reference. Deformable DETR is a technique for object detection that seeks to address DETR's delayed convergence and high complexity problems. It combines the advantages of deformable convolution sparse spatial sampling with the relation modelling capability of transformers. Deformable DETR introduced a deformable attention module that uses a few sample sites as a pre-filter for conspicuous key components among all feature map pixels. Without relying on FPN, the module may be organically expanded to aggregate multi-scale characteristics. With ten fewer training epochs, deformable DETR can outperform DETR (particularly on tiny objects). Extensive trials on the COCO [68] benchmark validate this method.

Zheng et al. propose a novel transformer variation called the Adaptive Clustering Transformer (ACT) to reduce the computation cost associated with high-resolution input [69]. ACT uses Locality Sensitive Hashing (LSH) to cluster query characteristics adaptively and approximates the query-key interaction using the prototype-key interaction. ACT is capable of reducing the quadratic complexity inherent in self-attention.

Fig. 5. DETR's general architecture. The image is from [21].

Inspired by the tremendous success of pre-training transformers in natural language processing, Dai et al. [70] proposed Unsupervised Pre-train DETR (UP-DETR) for object detection. The proposed UP-DETR model includes pre-training and fine-tuning procedures: (a) the transformers are unsupervised trained on a large-scale dataset without human annotations, and (b) the complete model is fine-tuned using labelled data, similar to the original DETR. Precisely clip random regions from the provided image and send them to the decoder as queries. Pre-trained on these query patches from the original image, the model detects them. The authors solve two critical difficulties during pre-training: multitask learning and multi-query localization. To balance classification and localization preferences in the pretext task, freeze the CNN backbone and propose a patch feature reconstruction branch optimized for conjunction with patch detection. (2) To accomplish multi-query localization, expand UP-DETR from single-query patches to multi-query patches by including object query shuffling and an attention mask. To expedite DETR's training convergence and prediction capability in object detection, Sun et al. [71] conduct extensive experiments and suggest two innovative methods, namely TSP-FCOS (transformer-based Set Prediction with FCOS) and TSP-RCNN (transformer-based Set Prediction with RCNN). These techniques converge considerably quicker than the original DETR and significantly outperform DETR and other baselines regarding detection accuracy

Beal et al. [72] developed ViT-FRCNN, a competitive object detection solution that uses a transformer backbone, implying that sufficiently distinct architectures from the well-studied CNN backbone are viable for advancement on complex vision problems. Transformer-based models have proven capacity to pre-train with large datasets without reaching saturation and fast fine-tune to different tasks, both observed with ViT-FRCNN.

The authors [73] suggested a novel variation of Vision Transformer models based on focal attention, called Focal Transformer that outperforms state-of-the-art (SoTA) vision Transformers on various publicly available image classification and object detection benchmarks.

Extracting strong feature representations is a significant issue in the re-identification of objects (ReID). Although techniques based on CNNs have gained considerable success, they analyze just one local area at a time and suffer from information loss due to convolution and down-sampling operators. To address these constraints, He et al. [74] introduced Transformer for Object re-identification (TransReID), a pure transformer-based object Reid framework. First, encode each image as a sequence of patches and then construct a transformer-based strong baseline with a few essential enhancements that obtain competitive performance on many Reid benchmarks using CNN-based techniques.

E. Transformer for Semantic Segmentation

Lie et al. [75] proposed a novel vision Transformer called Swin Transformer, a hierarchical Transformer with shifted

windows used for general-purpose computer vision. To improve performance, offset windowing restricts self-attention computation to non-overlapping local windows while permitting cross-window connections. This hierarchical architecture can simulate various sizes and has a linear computational cost with image scalability. Swin Transformer used for image classification 86.4 accuracy on ImageNet-1K [76], dense prediction tasks including object identification 58.7 box AP on COCO, and semantic segmentation 53.5 mIoU on ADE20K [77].

Zheng et al. [78] introduced a sequence-to-sequence prediction framework for semantic segmentation. For the first time, authors have eliminated the need for FCN and solved a restricted receptive field problem, unlike current FCN-based techniques that use dilated convolutions and attention modules at the component level. This encoder may be coupled with a primary decoder to build a robust segmentation model called SEgmentation TRansformer (SETR). SETR uses a pure transformer (no convolution or resolution reduction) to encode an image as a patch sequence. MaX-DeepLab [79] is the first end-to-end model for panoptic segmentation that automatically infers masks and classes without the need for hand-coded priors such as object centres or boxes.

The Dense Prediction Transformer (DPT) [80] is a neural network design that successfully uses visual transformers for dense prediction problems. The monocular depth estimation and semantic segmentation tests demonstrate that the given architecture generates more fine-grained and globally coherent predictions than fully convolutional networks. As with previous work on transformers, when trained on large-scale datasets, the DPT reaches its full potential.

F. Transformer for Medical Image Segmentation

Segmentation of medical images is necessary for developing healthcare systems, particularly for disease diagnosis and treatment planning. The U-shaped architecture, commonly known as U-Net [81], achieved remarkable success in various medical image segmentation tasks. However, because convolution processes are intrinsically local, U-Net typically exhibits problems when representing long-range dependence clearly. To fully use the capabilities of Transformers, Chen et al. [82] presented TransUNet, which incorporates a fully global context by considering image features as sequences and effectively uses low-level CNN features via a U-shaped hybrid architectural design. Several experiments were conducted to evaluate the proposed TransUNet system and validate its performance in various scenarios, including 1) model scaling, 2) the number of skip-connections, 3) patch size and sequence length 4) input resolution. TransUNet outperforms many competing methods, including CNN-based self-attention methods, as an alternate framework to the current FCN-based systems for medical image segmentation. Fig. 6 shows the architecture of TransUNet.

Moreover, such a transformer model can also detect fraudulent activity in student identification documents. The model can scrutinize the identification document and highlight any discrepancies or irregularities. For example, the model can identify if the photo on the identification document has been manipulated digitally or if the document has been tampered with in any way. This fact not only streamlines the process of verifying student identities, making it quicker and more precise but also ensures the reliability of the verification process by detecting any fraudulent activity in student identification documents.

III. VISUAL TRANSFORMER VARIANTS

The development of the visual transformer has paved the way for significant advancements in computer vision. Since its inception, researchers have explored several variants of transformer architecture to further improve its performance on visual tasks. In this section, we discuss some of the notable variants of the visual transformer and their applications.

A. Deeper Visual Transformer

Zhou et al. found that in contrast to CNNs, the performance of vision transformers rapidly saturates as the number of convolutional layers increases. As the transformer progresses deeper, the attention maps become increasingly similar after a certain number of layers. The feature maps in the top layers of deep vision transformer models are often similar. It indicates that in the deeper layers of vision transformers, the self-attention mechanism cannot learn appropriate ideas for representation learning, preventing the model from achieving the predicted performance improvement. Zhou et al. [91] identified the problem of the vision transformers' attention collapsing as they progress deeper. They suggest a unique re-attention technique DeepViT to resolve it with the least amount of calculations and memory cost possible. Using Re-attention can sustain an improving performance when the depth of vision transformers increases.

The CaiT [92] network's operation involves two distinct processing phases. The first one, the self-attention stage, is similar to the vision transformer, except there is no class embedding. Second, a series of layers called the class-attention stage (CLS) compile the patch embeddings into a class embedding CLS, given to a linear classifier.

Wang et al. [93] propose a Pyramid vision transformer (PVT), a pure Transformer backbone suitable for dense prediction applications like semantic segmentation and object detection without convolutions. The authors create a progressive pyramid shrinking algorithm and a spatial-reduction attention layer for obtaining multi-scale feature maps

with minimal memory/computation resources. Extensive experimentation on semantic segmentation and object detection benchmarks demonstrates that PVT outperforms well-designed CNN when the parameters are equivalent. Fig. 7 compares the CNN architectures, the vision transformer, and the pyramid transform.

L. Yuan et al. [96] proposed a novel Token-to-Token Vision Transformer (T2T-ViT) model that can be trained entirely on ImageNet and attain performance equivalent to or better than CNN's. Using T2T-ViT, the image structure information is better modelled, and more features are provided. Thus T2T-ViT significantly exceeds the Vision Transformer features. It has a unique tokens-to-tokens (T2T) approach for tokenizing images incrementally and structurally aggregating tokens.

As a result of the improvements in computer vision and the enormous quantity of training data, many people feel Transformers are not appropriate for tiny datasets. The authors of this article [97] debunked the notion that transformers are data-hungry. The authors in [97] demonstrated that proposed Compact Convolution Transformers (CCT) can compete with state-of-the-art CNNs with appropriate data size and tokenization for the first time. Through a unique sequence pooling technique and convolutions, the suggested model eliminates the need for class tokens and positional embeddings.

Heo et al. [98] proposed a novel architecture called Pooling-based Vision Transformer (PiT) to use the pooling layers' advantages. The authors demonstrate that a commonly utilized design concept in CNN spatial dimensional transformation accomplished by pooling or convolution is ignored in transformer-based architectures, negatively affecting the model performance and the transformer architecture benefits from decreasing the spatial dimension. The authors initially examined ResNet and discovered that transforming it in terms of spatial dimension improves computing efficiency and generalization ability. To capitalize on the benefits of Vision Transformer, the authors proposed a PiT that integrates a pooling layer into Vision Transformer, and the PiT demonstrates that pooling layer benefits become effectively matched to Vision Transformer. As a result of considerably increasing the performance of the Vision Transformer architecture, the authors demonstrated that the pooling layer is critical for a self-attention-based design by considering the spatial interaction ratio. Moreover, extensive experiments showed that PiT outperforms the baseline on object detection, image classification, and robustness evaluation. Fig. 8 highlights the difference in dimensions of network architectures ResNet-50, Vision Transformer, and PiT.

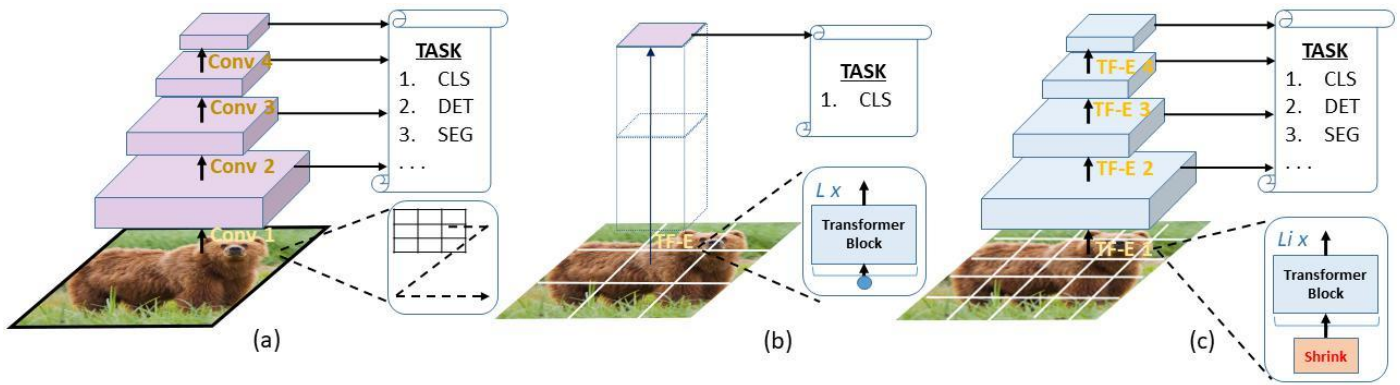

Fig. 7. (a) CNNs: ResNet [94], VGG [95], etc. (b) Vision transformer [58] (c) Pyramid vision transformer [93].

Fig. 8. A schematic diagram illustrates dimension variation in network architectures. (a) ResNet-50, (b) ViT-S/16, (c) PiT-S. image credit [98].

B. Hybrid Transformers

To improve image super-resolution, Z. Lu et al. [99] propose an *Efficient Super-Resolution Transformer (ESRT)*. ESRT is a hybrid Transformer that uses a CNN-based SR network to extract deep features. Backbones for the ESRT include the lightweight CNN (LCB) and lightweight Transformer (LTB). LCB is a low-cost SR network extracting deep SR features by dynamically changing the feature map's size. LTB consists of an efficient Transformer (ET) that consumes less GPU Memory space and benefits from the uniquely efficient multi-head attention (EMHA). The Reformer [100] is a Transformer model capable of processing context windows of up to 1 million words on a single accelerator with only 16GB of memory. Reformer combines two critical approaches for resolving the attention and memory allocation issues that limit the applicability of the transformer to lengthy context windows. The reformer uses locality-sensitive hashing (LSH) to decrease the complexity of attending to long sequences and reversible residual layers to maximize the usage of available memory.

H. Wu et al. [101] introduced a novel architecture, the *Convolutional Vision Transformer (CvT)* that enhances the performance and efficiency of the Vision Transformer by incorporating convolutions into the Vision Transformer. The author's findings indicate that positional encoding, a critical component of existing Vision Transformers, can be safely omitted from the CvT model, simplifying the design for higher-resolution vision applications.

Chu et al. [102] proposed a highly efficient and direct implementation of two architectures - *Twins-PCPVT* and

Twins-SVT vision transformer designs. *Twins-PCPT* is based on PVT [93] and CPVT [103] and utilizes global attention. *Twins-SVT* is based on the proposed SSSA, consisting of two distinct attention operations: locally-grouped self-attention (LSA) and globally subsampled attention (GSA). Both transformer models established new benchmarks for image classification, semantic/instance segmentation, and object detection.

Zhang et al. introduced the *Nested Transformer (NesT)* [104]. The block aggregation function is essential for enabling non-local information transmission across blocks. The accuracy of a NesT trained on ImageNet for 100/300 epochs is 82.3 per cent compared to other techniques [19], [105] that achieved up to 57% parameter reduction. A NesT with 6M parameters trained from scratch on CIFAR10 [106] achieves 96% accuracy using a single GPU.

Visual Transformers (VT) [107] defines the problem in the semantic token space, intending to represent and process high-level concepts in images using visual tokens. Moreover, different parts of the image have different meanings due to their different content. Note that this is entirely different from the transformer that processes information in pixel space (such as Vision Transformer, DeiT, IPT, etc.) because the amount of calculation differs by multiple orders of magnitude. The author [107] uses the spatial attention mechanism to convert the feature map into compact semantic tokens. Then input these tokens into a Transformer, and use the unique functions of the transformer to capture the connection between the tokens. In this way, VT can 1) Focus on those relatively important areas instead of treating all pixels equally like CNN. 2) Encode

semantic concepts in visual tokens instead of modelling all concepts in all images. 3) Use the Transformer to model the relationship between tokens. The VT model is used in classification tasks (Model Base: ResNet, Dataset: ImageNet, reduced by 6.9 times, increased by 4.6- 7 Accuracy) and semantic segmentation tasks (Model Base: FPN, Dataset: LIP and COCO-stuff reduced by 6.4 times the amount of calculation, the increase point 0.35 mIoU) has achieved excellent performance.

C. Supervised Learning in Vision Transformer

Supervised learning enables the transformer to learn a bottleneck representation in which the content and context are mixed around the class token. This results in a relatively superficial data model, and its association with labels needs many training examples. On the other hand, unsupervised learning uses the information redundancy and complementarity inherent in image data by learning to rebuild local content through context integration [108].

In self-supervised learning, no concept whatsoever of labelled data for the training. Self-supervised techniques can be classified broadly as generative or discriminative [109]. Generative methods learn to predict the data distribution. However, data modelling is inherently computationally expensive and may not be required in all cases for representation learning. Discriminative methods, generally implemented in a contrastive learning framework [110] or through pretext tasks [111], have the capacity to create more generalized representations with minimal computing needs.

Auto et al. [112] proposed a *Self-supervised vision Transformer (SiT)*, a unique approach for learning visual representations without supervision. Using the autoencoder transformer's inherent capacity to perform multitask learning, it created a robust self-supervised system that optimizes reconstruction, rotation classification, and contrastive losses concurrently. The last utilizes the strength of the transformer to train SiT to perform three distinct tasks: image reconstruction, rotation prediction, and contrastive learning.

Bao et al. [113] introduced a self-supervised vision representation model *BEiT*, which stands for Bidirectional Encoder representation from image Transformers. The authors proposed a masked image modelling task to pre-train vision Transformers in a self-supervised manner. In pre-training, each image contains two perspectives - image patches and visual tokens. First, "tokenize" the original image into visual tokens. Then, using a random masking technique, feed specific image patches into the backbone Transformer. The purpose of the pre-training is to reconstruct the original visual tokens from the damaged image patches. After pre-training BEiT, fine-tune model parameters directly on downstream tasks by superimposing task layers on the pre-trained encoder. Experiments on image classification and semantic segmentation demonstrate that our model outperforms prior pre-training approaches. For example, base-size BEiT achieves 83.2% top-1 accuracy on ImageNet-1K with the same

configuration, considerably surpassing DeiT training from scratch at 81.8% [19].

D. Video Transformer

Following the recent success of vision transformer models in image classification, Arnab et al. [114] presented pure-transformer-based video classification models *Video Vision Transformer (ViViT)*. To efficiently handle a high count of Spatiotemporal tokens, the authors in [114] constructed multiple model variations that factorize the transformer encoder's many components across spatial and temporal dimensions. The authors in [113] demonstrated how to use additional regularisation and pre-trained models to compensate for the fact that video datasets are often smaller than the image datasets on which Vision Transformer was trained.

The *VisTR*, a new video instance segmentation framework based on Transformers, considers the video in-stance segmentation (VIS) problem an end-to-end concurrent sequence decoding/prediction issue [115]. Fig. 9 shows the architecture of VisTR. The paradigm is qualitatively distinct from previous techniques, streamlining the whole process significantly. VisTR approaches the VIS problem from a novel similarity-based perspective. Segmentation was used to determine pixel-level similarity, whereas tracking was used to determine instance-to-instance similarity. Thus, tracking instances occurs naturally and smoothly in the instance segmentation context. VisTR's success is developing a novel technique, such as sequence matching and segmentation, optimized for the framework. This well-designed method enables monitoring and segmenting instances at the sequence level in their entirety. ViSTR is composed of four major components: 1) a CNN backbone that extracts feature representations from multiple images, 2) an encoder-decoder Transformer that models the relationships between pixel-level and instance-level features and decodes them, 3) an instance sequence matching module that supervises the model, and 4) an instance sequence segmentation module that outputs the final mask sequences. VisTR outperforms other techniques that employ a single model on the YouTube-VIS dataset, reaching 40.1% in mask mAP at 57.7 frames per second.

Fan et al. [116] introduce *Multi-scale Vision Transformers (MViT)* for video and image recognition by fusing the foundational concept of multi-scale feature hierarchies with transformer models. Multi-scale Transformers feature many scale stages with varying degrees of channel resolution.

The industry's high demand for autonomous driving has led to a surge of interest in three-dimensional object detection, resulting in several practical three-dimensional object detection algorithms [117]. Yuan et al. [55] proposed a *Temporal-Channel transformer* to represent spatial-temporal and channel domain relationships for video object detection from Lidar data. The transformer's unique architecture encodes temporal-channel information for many frames, whereas the decoder decodes spatial-channel information for the current frame voxel-by-voxel.

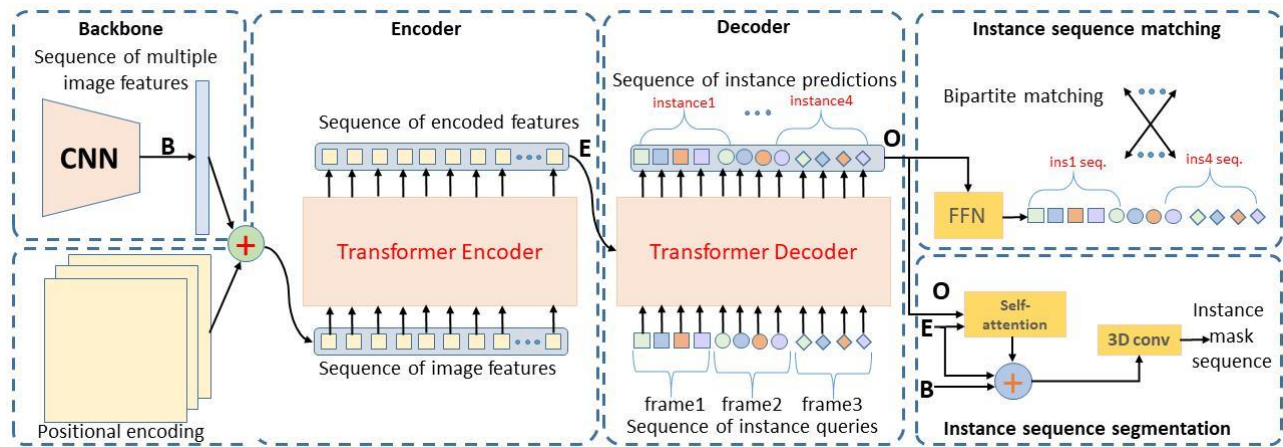

Fig. 9. The architecture of VisTR. image credit ([115]).

IV. MULTIMODAL TASK

With the increasing demand for models that can process both visual and textual inputs, the application of the visual transformer has been extended to multimodal tasks. In this section, we explore the capabilities of the visual transformer in handling multimodal inputs and review some of the recent developments in this area.

Recent breakthroughs in deep learning have resulted in significant advancements in computer vision and natural language processing. These accomplishments enable the integration of vision and language and multimodal learning tasks such as image captioning [118-119], image-text matching, visual grounding [120], and visual question answering [121]. Yu et al. present a novel framework for picture captioning called the Multimodal Transformer (MT) [122]. The MT comprises an image encoder that creates visual representations using deep self-attention learning and a caption decoder that converts the encoder’s visual characteristics to textual captions. Liu et al. [123] explore image captioning as a sequence-to-sequence prediction problem. Li et al. proposed CaPTion Trans- formerR (CPTR), a complete Transformer model, to replace the usual “CNN+Transformer” approach. CPTR is convolution-free and can model global context information at each encoder layer. Evaluation results on the famous MS COCO [68] dataset indicate that the CPTR technique is more successful than “CNN+Transformer” networks. Detailed visualizations illustrate that the CPTR model can use long-range dependencies from the start and that the decoder’s “words-to-patches” attention can pay close attention. The Conditional Position encodings Visual Transformer (CPVT) [103] sub-statutes the predefined positional embeddings used in Vision Transformer with conditional position encodings (CPE), allowing transformers to analyze input images of any size without interpolation.

Hu and Singh [124] developed a *Unified Transformer (UniT)* encoder-decoder model that accepts pictures and(or) text as input and trains on various tasks ranging from visual perception and language comprehension to combined vision-language reasoning. UniT consists of encoding modules that encode each input modality as a sequence of hidden states, a transformer decoder over the encoded input modalities, and

task-specific output heads that apply task-specific output heads to the decoder hidden states to generate the final predictions for each task. Desai and Johnson [125] proposed that visual representations from textual annotations (VirTex) are a pre-training technique for visual representations that use semantically dense captions. First, VirTex jointly trains CNN and Transformer to create natural language captions for images from scratch. Then, apply the newly acquired characteristics to subsequent visual recognition tasks. A Decision Transformer [126] architecture encodes states, actions, and returns using modality-specific linear embeddings and a positional episodic time step encoding. Fig. 10 shows the architecture of the Decision transformer. Tokens are fed into a GPT architecture, which uses a causal self-attention mask to predict behaviors auto-regressively.

The vision transformer architecture is integrated into generative adversarial networks (GANs) for image generation. Regularisation methods for GANs that are now available do not interact well with self-attention, resulting in significant training instability. GANs using Vision Transformers are trained using novel regularization techniques. ViTGAN beats the existing CNN-based StyleGAN2 method on the CIFAR-10, CelebA [127], and LSUN bedroom datasets [128].

V. FUTURE RESEARCH DIRECTIONS OF VISUAL TRANSFORMERS

As the field of Visual Transformers continues to develop, numerous potential avenues for future research exist. This section focuses on the summary of lessons learned from the discussions made throughout the article and future research directions. These directions offer valuable opportunities to enhance the performance and capabilities of Vision Transformers.

A. Lessons Learnt

1) *Adaptation of vision transformers:* The survey highlights the adaptability of Vision Transformers in their use for image processing, which was previously known in natural language processing. This fact demonstrates the chance to use already-developed skills and methods from one field to another, expanding the possible uses of Vision Transformers.

2) *Image enhancement and classification:* The survey shows how well Vision Transformers perform various image enhancement tasks, such as lowering noise, raising contrast, and boosting resolution. Additionally, their efficient use in image classification tasks demonstrates their capacity to extract significant representations from images and achieve competitive performance levels.

3) *State-of-the-Art object detection:* The study demonstrates the remarkable object detection performance of Vision Transformers, which outperforms conventional approaches and produces cutting-edge results. This fact shows the main contribution that Vision Transformers make to the field by enhancing robustness and accuracy in object localization and identification key processes.

4) *Automation in education systems:* The survey looks at how student verification processes used in educational institutions utilize Vision Transformers. Vision Transformers can streamline administrative operations, increasing speed and accuracy by automating the identity of the verification process. This fact demonstrates the crucial role that Vision Transformers have played in changing and strengthening the administrative procedures used in educational institutions.

5) *Multimodal processing:* The survey explores Vision Transformers' ability to handle multimodal tasks that require the processing and fusion of data from many modalities, including text, picture, and audio. This fact demonstrates the potential of Vision Transformers to enable thorough comprehension and analysis of complex data, leading to breakthroughs in areas like cross-modal retrieval, multimodal sentiment analysis, and visual question answering. The review demonstrates the significant contributions and developments made by Vision Transformers for image processing through an in-depth examination. The main findings from this overview highlight the flexibility of Vision Transformers, their effectiveness in image enhancement and classification, their cutting-edge performance in object detection, their potential to automate administrative tasks in educational systems, and their proficiency in handling multimodal data. These priceless insights provide direction for future study and practical use of Vision Transformers across numerous areas, encouraging further development in computer vision.

B. Future Research Directions

1) *Efficiency optimization:* Recent research has focused a lot of attention on finding ways to increase the effectiveness of Visual Transformers. There is a rising need to create methods to increase Visual Transformers' efficiency without sacrificing performance due to the demand for real-time and resource-

constrained applications. Recent studies have looked into several solutions to this problem. For instance, researchers have studied techniques for sparse attention, which concentrate on focusing just on relevant areas of input to lighten the total computing load. Also, low-rank approximations, which approximate the attention matrices with low-rank structures and save a significant amount of computation, have been studied. Additionally, to decrease the memory footprint and inference time of Visual Transformers, researchers have looked into model reduction techniques like pruning or quantization. Recent developments in Visual Transformer efficiency show tremendous promise for enabling implementation in resource-constrained contexts while preserving their efficacy and performance.

2) *Robustness and generalization:* A significant area of research continues to be strengthening the robustness and generalization abilities of Visual Transformers, with current developments tackling the difficulties presented by real-world settings. Researchers have been looking into cutting-edge methods to lessen the effects of occlusions, which frequently impair accurate object detection in complex surroundings, in the pursuit of enhanced resilience. Recent research has looked at techniques to improve performance in obstructed situations, such as partial occlusion handling through attention processes or occlusion-aware training procedures. Additionally, the danger of adversarial attacks has been elevated to a top priority when using computer vision models. By using competitive training techniques or defence mechanisms against such attacks, researchers have made substantial progress toward creating robust Visual Transformers that can tolerate adversarial perturbations. In addition, recent research initiatives have focused on addressing domain transitions. It has been investigated to enhance the generalization abilities of Visual Transformers across various datasets or real-world domains using techniques like domain adaption or domain generalization. Researchers are making progress towards giving Visual Transformers the robustness and generalization skills they need to meet the challenges posed by many complicated real-world circumstances by actively taking into account these recent developments.

3) *Interpretability and explainability:* Various computer vision challenges have revealed impressive performance from Visual Transformers. However, it is difficult to comprehend the logic behind their forecasts because of their lack of interpretability. The recent research aims to overcome this drawback by investigating ways to make Visual Transformers easier to understand. A possible strategy is using attention visualization methods to draw attention to the areas of an image impacting judgment. Researchers and users can learn more about the particular characteristics or regions that the Visual Transformer concentrates on while making predictions by visualizing the attention maps. In addition, techniques like gradient-based attribution approaches and saliency maps have been used to pinpoint the most crucial input features influencing the result. These methods aid in identifying the

primary determinants of the Visual Transformer's choice, enhancing the predictability and interpretability of results. Future research aims to provide users with more transparent and interpretable Visual Transformers, enabling improved understanding and utilization of these potent models in practical applications. The last will be accomplished by continuing to investigate and improve these methodologies.

4) *Multi-modal and cross-modal learning*: A fascinating research area that will help us interpret complicated visual data better is the extension of Visual Transformers to handle multimodal and cross-modal data. Inquiries into integrating Visual Transformers with various modalities, such as text, audio, and depth information, have advanced significantly in recent years. For instance, using the strength of Visual Transformers to interpret visual data alongside textual context, researchers have created unique architectures that integrate vision and language models. Tasks such as image captioning, visual question answering, and cross-modal retrieval have all benefited from this integration. Additionally, research into using audio data in Visual Transformers has produced promising outcomes for tasks like sound event recognition or audio-visual scene analysis. Another fascinating development is integrating depth information with Visual Transformers, which enables comprehensive scene interpretation and 3D perception. Visual Transformers can deliver a thorough and holistic comprehension of complicated visual data by successfully integrating and learning from several modalities, pushing the limits of computer vision research and applications. Continued study in this field can reveal fresh perspectives and enhance Visual Transformers' capacity to handle multimodal and cross-modal input.

5) *Incremental and continual learning*: Recent research has focused heavily on enabling Visual Transformers to continually learn from streaming or updating data since it allows models to adapt to changing contexts and evolving concepts. The flexibility and adaptability of Visual Transformer may be enhanced by recent developments in incremental learning methods. Rehearsal approaches, which save and playback a portion of previously observed data during training to reduce catastrophic forgetting, are one noteworthy strategy. Research has also looked into methods like lifelong learning, where the model gradually picks up new skills while holding on to knowledge from earlier jobs. As a result, Visual Transformers can continuously improve their skills without compromising how well they do previously mastered jobs. Strategies like adaptive learning rates, dynamic network designs, and online learning algorithms have been investigated to address the problem. Visual Transformers can effectively learn from evolving data streams, improve their performance, and keep current knowledge by concentrating on incremental learning and devising ways to adapt to new classes or concepts over time. More research is needed in this field to make Visual Transformers more flexible and adaptable in practical applications and dynamic contexts.

6) *Attention mechanism exploration*: Research on Visual Transformers in recent years has concentrated on understanding and improving attention mechanisms to improve their effectiveness. Different attention types that can improve the modelling skills of Visual Transformers are the subject of one area of research. For instance, non-local attention mechanisms have drawn attention to their ability to identify distant relationships in pictures or movies, facilitating a better comprehension of the whole context. Another interesting approach is sparse attention, which tries to keep good performance while reducing computing complexity by focusing only on pertinent areas or pixels inside an input. Additionally, researchers have looked at the usage of learned attention masks, in which attention weights are dynamically computed based on the input data, enabling the model to assign adaptively attention to the most informative regions. The performance and modelling skills of Visual Transformers could be significantly improved by these latest developments in attention mechanisms. Researchers can open new doors for developing computer vision and expanding the capabilities of Visual Transformers in various applications by exploring these attention variants and continuing to innovate in this area.

7) *Domain-specific adaptation*: Various computer vision challenges have revealed impressive performance from Visual Transformers. However, because of the particular traits and demands of such areas, its application to specific tasks or domains frequently presents difficulties. Future research efforts can concentrate on investigating domain-specific adaptation methods to modify Visual Transformers for specific application domains. Recent studies have begun to explore domain adaptation techniques that use labelled data from the target domain to align the model's representation with the domain-specific features. To adapt Visual Transformers for tasks like disease diagnosis, organ segmentation, or anomaly detection, for instance, researchers in the field of medical imaging have investigated strategies like transfer learning or fine-tuning on medical datasets. Although Visual Transformers have demonstrated potential in satellite image analysis, more study is required to create domain-specific adaptations to deal with issues like size variation, heterogeneous data sources, or a lack of labelled data. In a similar way, in robotics, Visual Transformers can be configured to perform visual perception tasks in specific robotic applications, such as robot localization, object recognition, and scene interpretation. Researchers can bridge the gap between Visual Transformers and certain application areas, enabling higher performance and overcoming the particular difficulties encountered in those domains by concentrating on domain-specific adaption strategies. The investigation of these methods holds promise for releasing Visual Transformers' full potential across many specialized fields and advancing computer vision in particular application areas.

8) *Data-efficient learning*: Visual Transformers have displayed outstanding performance in computer vision

applications, although their training frequently necessitates large amounts of labelled data. Recent research has concentrated on investigating data-efficient learning approaches to lessen the dependence on sizable annotated datasets and enable efficient learning with few labelled examples. In this regard, semi-supervised learning strategies have drawn interest since they use labelled and unlabeled data during training. Visual Transformers can gain from a larger training set and perform better by using the quantity of unlabeled data and incorporating it into the learning process. Another exploratory route, which seeks to learn representations solely from unlabeled data, is unsupervised learning. These techniques allow models to develop helpful presentations from unannotated data that may be applied to subsequent tasks. Unsupervised learning has recently made significant strides in several computer vision areas, including picture categorization, object recognition, and image synthesis. Researchers can harness the potential of Visual Transformers in situations with little labelled data by exploring data-efficient learning techniques, making it possible to deploy these models more frugally and widely in various applications.

V. CONCLUSION

This article discusses critical self-attention architectures and examines in detail transformer models for various image-processing applications. We comprehensively discuss the strengths and weaknesses of existing techniques, particularly the possible future research directions. With a particular emphasis on general image processing problems, this survey offers a unique perspective on recent advances in self-attention and Transformer-based techniques. We discuss state-of-the-art self-attention models for semantic and instance segmentation, image classification, object detection, image captioning, video analysis and classification, multi-model tasks, and three-dimensional data analysis. We hope our work will spark interest among the image-processing community in maximizing the applications of vision-transformed models. Transformer models are pretty complicated from the perspective of parameters, computing time, and resources required. Visualizing and comprehending essential parts in an image for classification purposes is still a problem in transformers, and spatially accurate activation-specific representations are necessary [129]. The use of a vision transformer model in university education systems facilitating the detection of fraudulent activities in student identification documents is also highlighted. The model can thoroughly examine the identification document, detecting inconsistencies or anomalies as highlighting fraudulent activity.

Multimodal Contactless Architecture for Upper Limb Virtual Rehabilitation

Emilio Valdivia-Cisneros, Elizabeth Vidal*, Eveling Castro-Gutierrez
Universidad Nacional de San Agustín de Arequipa, Arequipa, Perú

Abstract—The use of virtual rehabilitation systems for upper limbs has been implemented using different devices, and its efficiency as a complement to traditional therapies has been demonstrated. Multimodal systems are necessary for virtual rehabilitation systems since they allow multiple sources of information for both input and output so that the participant can have a personalized interaction. This work presents a simplified multimodal contactless architecture for virtual reality systems that focuses on upper limb rehabilitation. This research presents the following: 1) the proposed architecture 2) the implementation of a virtual reality system oriented to activities of daily living, and 3) an evaluation of the user experience and the kinematic results of the implementation. The results of the two experiments showed positive results regarding the implementation of a multimodal contactless virtual rehabilitation system based on the architecture. User experience evaluation showed positive values regard to six dimensions: perspicuity=2.068, attractiveness=1.987, stimulation=1.703, dependability=1.649, efficiency=1.517, and novelty=1.401. Kinematic evaluation was consistent with the score of the implemented game.

Keywords—Human computer interaction (HCI); multimodal; feedback; architecture; upper limb; rehabilitation; contactless

I. INTRODUCTION

Limited mobility is a prevalent dysfunction that is observed in patients suffering from neurological diseases such as Stroke, Epileptic Encephalopathy, Cerebral Palsy or Parkinson diseases [1, 2, 3, 4]. The importance of upper limb function rehabilitation is emphasized since upper limbs are used to manipulate objects and to interact physically in Activities of Daily Living (ADL) [5, 6].

Studies present different types of implementations for rehabilitation that respond to different kinds of patients' needs [7, 8, 9] however, sometimes medical conditions do not allow the use of wearable devices [10]. Contactless devices are an alternative for gesture recognition applications in healthcare [11] and permit the tracking of free and natural movements facilitating the user's mobility [12]. Important advances have been made in contactless approaches that grant safety and accuracy [13, 14].

Multimodal systems allow Virtual Reality Systems (VRS) to be implemented with multiple sources of information for both input and output so that the participant can have a personalized interaction with the system [15, 16]. Multimodal systems also consider multimodal feedback that consists of visual, auditory, and tactile feedback that can be combined to increase participant motivation and improve training effectiveness [17].

Literature shows different kinds of focus regarding the use of contactless devices, for example, the analysis of the contactless interactions of new users when they are learning and adapting [18]. Some other research focuses on the impact of a specific device in the rehabilitation process such as Leap Motion Controller [19, 20, 21] or Kinect [22, 23, 24, 25]. Some other studies refer to how virtual rehabilitation using contactless devices reinforce motivation [26, 27, 28, 29].

The main objectives of this work are: 1) to propose a multimodal contactless architecture for a virtual rehabilitation system for upper limbs; 2) implement a virtual rehabilitation system based on the proposed architecture; and 3) evaluate the acceptance of the VRS and the kinematic outcomes.

The rest of the paper is organized as follows: Section II presents the related works; Section III presents the architecture and experiments conducted. Section IV presents results and discussion, and finally Section V gives the conclusions.

II. RELATED WORK

Contactless devices for rehabilitation have been used for many years. Early research makes use of Kinect, and experiences have been carried out for various diseases such as stroke, cerebral palsy or Parkinson disease.

Huang [30] implemented recognition on arm movements. Therapists were able to adjust the rehabilitation movements based on the conditions of the participant. Pastor et al. [31] focused on increasing range of motion to improve functional use of the impaired upper extremity. They developed a game that requires patients to control a cursor on the screen by moving their hand.

Other research has focused on ADL, for example, the work in Adams [32] implemented activities for preparing meals with an avatar for recovery of upper extremities combining a virtual world and a Kinect™ sensor.

There is other research that has focused on active movements of the upper and lower limbs using a Kinect-based game system in addition to conventional therapy. The results showed that Kinect may have supplemental benefits for patients [33] [34].

In recent years, other contactless devices have become relevant in the virtual rehabilitation process due to their small size, accuracy, and low cost. Taraki et al. [35] presented the use of the Leap Motion Controller (LMC) for upper extremity rehabilitation to improve the joint range of motion, muscle strength, coordination, and fine motor functions of the hand and wrist in patients. The results showed quantitatively that

LMC should be used as an effective alternative treatment option in children and adolescents with physical disabilities.

Wang et al. [36] also used six interfaced virtual exercises that are included in the LMC virtual reality system. The games focus on the improvement of dexterity. Their results conclude that LMC facilitates the recovery of the motor function and dexterity of a paretic upper limb. Khademi et al. [37] used LMC to implement the game of Fruit Ninja focusing on finger individuation for stroke patients. The results demonstrated significant correlations between the scores generated from the game and standard clinical outcome measures.

From the review of the literature, it has been observed the importance of the use of contactless systems for certain types of patients who cannot use wearable devices. Likewise, it has been found the effectiveness of therapies that make use of virtual systems as a complement to traditional therapies. Finally, given the different conditions that patients have, it is necessary to adapt the different types of feedback that patients need at the auditory, visual, or tactile level. Even though all of the related works propose different kind of implementations, it had not been found a generic architecture for virtual reality systems oriented to upper limb rehabilitation.

III. METHODS

A. Architecture Proposal Methodology

The software architecture of a system is the structure that considers: 1) software components, 2) the externally visible properties of those components, and 3) the relationships between the components. Software architecture is important because it defines a set of constraints on the subsequent implementation and it focuses on component assembly [38].

For the architecture proposal, this work have adapted the methodology proposed by Parisaca et al. [39] considering only six steps 1) Identification of system quality attribute requirements; 2) Identification of architecturally significant requirements; 3) Design of architecture components; 4) Classification of components; 5) Validation of design decisions; and 6) Analysis and evaluation of software architecture.

The development of each step is described in section B.

B. Multimodal Contactless Architecture for Upper Limb Virtual Rehabilitation

Step 1: Identification of system quality attribute requirements. Upper limbs rehabilitation is important since it allows the use of hands to interact physically in ADL [5]. Sometimes different kinds of medical conditions do not allow the use of wearable devices for virtual rehabilitation. This reason makes it necessary to consider contactless devices for gesture recognition.

Step 2: Identification of architecturally significant requirements. The functional requirements related to the architectural components are shown in Table I.

TABLE I. FUNCTIONAL REQUIREMENTS

Functional Requirements	Architecture Component
Upper Limb interaction	Virtual Reality System: for upper limb rehabilitation
Data capture through hardware	Contactless Tracking Device
Multiple sources of information for feedback to increase participant motivation and improve rehabilitation effectiveness	Visual feedback Auditory feedback Others

Step 3 Design of architecture components.

Based on Dumas, Lalanne and Oviatt [40] work, we propose an architecture for contactless virtual rehabilitation systems that focus on multimodal feedback. The architecture has four components (Fig. 1): i) The Input Modality; ii) The Integration Committee; iii) The Output Modalities; and iv) The Virtual Reality System. The Integration Committee has three elements: i) Dialog Management, ii) Context User Model History, and iii) Output Modalities Fission.

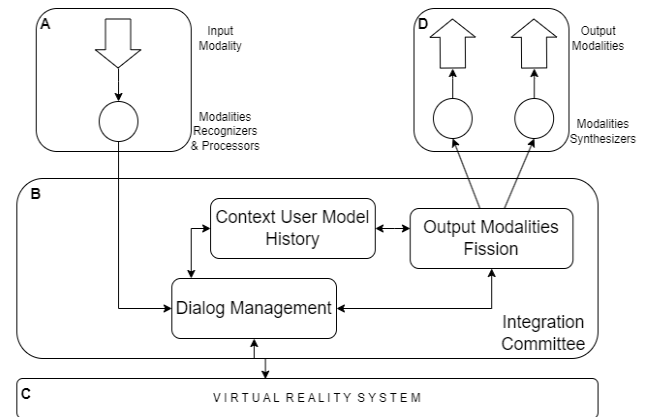

Fig. 1. VRS multimodal contactless architecture.

Input Modality refers to the contactless device that communicates to the Dialog Management. Dialog Management is in charge of identifying the dialog state that takes place in the VRS (the actions to communicate to the VRS and/or the messages to return through the Output Modalities Fission). Output Modalities refers to the auditory or visual feedback that gets the user.

Output Modalities Fission is in charge of returning the feedback to the user through a combination of modalities, depending on the Context User Model History (visual, auditory or other).

Step 4: Classification of components. From the functional requirements described in Table I we have considered: component A (Input Modality) as unimodal and component D (Output Modalities) as multimodal.

Step 5: Validation of the Design Decisions. The validation of the architecture design can be done with different techniques such as scenarios, questionnaires, simulations,

mathematical models, or prototypes [38]. In this work we decided to validate the architecture with a prototype.

For the prototype, the proposed VRS focuses on performing the coordinated actions of handling objects: picking up, manipulating, and releasing them in order to perform exercises to recover hand dexterity [41]. The task of the VRS is to preparing a pizza. The participant must pick up a highlighted ingredient, (one by one) and drop them onto the pizza dough. For each ingredient placed correctly, the participant receives a point (visual feedback). The VRS shows whether it is a hit or a failure (visual feedback). Auditory feedback is also provided, in the case of a hit, a bell rings, and in case of a miss, an error horn sounds (Fig. 2).

Fig. 2. VRS Pizza Game – right hand – 20 elements.

The VRS allows configuring the hand to be used (left or right) and the number of ingredients to be displayed: 5, 10, 15, or 20.

The VRS was developed in Unity with the contactless optical tracking device Leap Motion Controller (LMC). This is a small optical device with sub-millimeter precision oriented to gestural hand movement [13].

The architecture of the VRS is shown in Fig. 3. The Input Modality considers the contactless device LMC. The Output Modalities are implemented with visual and auditory feedback. We also show the interaction of the VRS states. From the user perspective the Decision state represents the person's attention, intention, and emotions. The Action state represents the hand movements. The Perception state is the recognition of the gestures and movements controlled by the LMC. In the Interpretation state, the data captured from the device is processed.

From the perspective of the VRS, the Computation state performs the fission process that allows the VRS to generate the feedback messages based on the context of the user. The Action state refers to the response to the user action in the form of visual and audio cues. The Perception state refers to what the user hears and sees in the VRS. Finally, the Interpretation state refers to new decisions that the participant will make.

Fig. 3. VRS Pizza Game – Architecture.

Step 6 Analysis and evaluation of software architecture. Two experiments have been performed in order to evaluate the acceptance and technical effectivity of the implementation of the proposed VRS.

Experiment 1

The participants were 106 healthy university students. There were sixty-eight males and thirty-eight females. The mean age of the participants was 20 ± 1.4 years old. The instrument was the User Experience Questionnaire (UEQ) [42,43], which measures six dimensions: (a) Attractiveness: attractive, pleasant, friendly, and enjoyable; (b) Efficiency: to perform tasks quickly, efficiently and pragmatically; (c) Perspicuity: easy to understand, clear, simple, and easy to learn; (d) Reliability: interaction should be predictable, safe and meet user expectations; (e) Stimulation: interesting, exciting, and motivating; (f) Novelty: innovative, inventive, and creatively designed. The scale ranges from -3 to +3. Values between -0.8 and 0.8 represent a more or less neutral evaluation of the corresponding scale, values greater than 0.8 represent a positive evaluation, and values lower than -0.8 represent a negative evaluation [43].

With regards to the protocol, first, the researchers explained the instructions for interacting with the VRS. Then each participant interacted with their dominant hand. Each participant interacted with 20 elements without a time limit. Finally, participants filled out the UEQ questionnaire (Fig. 4 shows the interaction of one student).

Fig. 4. VRS Pizza Game – Interaction.

Experiment 2

The participants were four children with moderate hand disabilities. There were two males and two females. The mean age of the children was 12.25 ± 3.4 years old. The study followed the guidelines of the Declaration of Helsinki. It was approved by the Ethical Committee (reference number: 2008-0234).

The second intervention was to evaluate the kinematic outcomes of the study. It focused on the number of hits the participants had when they dropped the ingredients onto the dough. With regards to the protocol, the children interacted with the VRS in ten sessions, first with five elements using their right hand and then with their left hand. Then they interacted with the VRS with ten elements using their right hand and then their left hand. The VRS recorded the number of hits in each interaction.

IV. RESULTS AND DISCUSSION

Experiment 1

Table II shows the values of the 6 UEQ scales, all of which have positive results: < 0.8 .

Fig. 5 shows that the highest value is Perspicuity, with an average of 2.068, which is considered to be Excellent. The perception of clarity is based on the comments obtained from the open-ended questions, which highlight the interactivity and ease of use, the intuitiveness of the game, and the feedback channels (visual and audio cues) that are available to the participants.

TABLE II. RESULTS OF THE UEQ SCALES (MEAN AND VARIANCE)

UEQ SCALES (MEAN AND VARIANCE)		
ATTRACTIVENESS	1.987	0.96
PERSPICUITY	2.068	1.31
EFFICIENCY	1.517	1.15
DEPENDABILITY	1.649	0.95
STIMULATION	1.703	1.16
NOVELTY	1.401	1.33

Fig. 5. Results of the six main areas of user experience according to UEQ, in qualitative intervals.

The second highest value was Attraction, with an average of 1.987, which is considered to be Excellent. According to the opinions of the participants, they found the system to be friendly because, by having both visual and audio feedback, they could achieve the objective of the game. A second aspect mentioned was the use of the LMC for hand recognition, which has no physical contact with the user.

The Stimulation obtained a value of 1.703, which is a value between Excellent and Good. The participants found the interaction with the LMC interesting for moving virtual objects. They also highlighted the importance of sounds for hits and faults. In addition, since it is a scoring game, the users want to improve their performance.

Dependability obtained 1.649, which places it on the borderline between Excellent and Good. A requirement to meet this value is the correct functioning of the input and output modalities, which allows the user's expectations to be met in terms of the virtual hand behaving in the same way as the real hand (no delay in execution time). Safety has been guaranteed since the Leap Motion Controller is certified as being compliant with safety and electrical regulatory standards and has no contact with the user.

Efficiency scored a value of 1.517. The system was considered to be fast and efficient because the user's hand movements are reflected in real-time. However, during the tests, the users identified some occasions in which the hand was not visualized and the pizza topping did not end up falling onto the dough.

Finally, Novelty obtained a value of 1.401 which is considered to be as good. Novelty is given by the creative design of the game that refers to an activity of daily life such as preparing a pizza. The novelty is also given by the fact that the game seeks to be applied as a complement to motor skills rehabilitation therapies. The system captures the history of each participant using the time it takes to move each of the ingredients and the number of success/failures. This information allows performance over time to be evaluated.

Experiment 2

Fig. 6 shows the kinematic outcomes. The study analyzed hand dexterity by counting the number of hits per session.

For the interaction using both the right hand and the left hand with five virtual objects (Fig. 6(a) and Fig. 6(b)), there are different performance measures for each participant. We observed better performance in the interaction with the right hand. This is explained by the fact that, for the four participants, the dominant hand was the right hand.

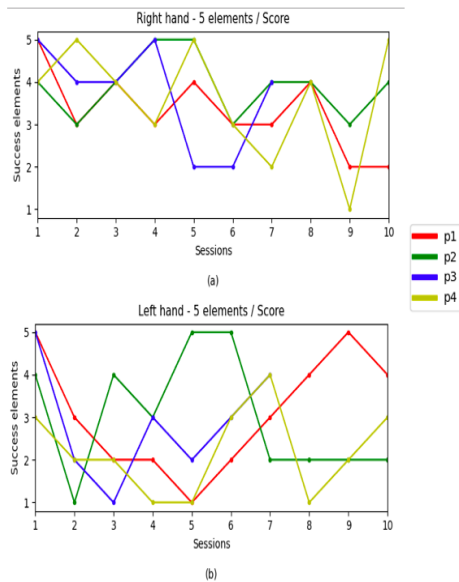

Fig. 6. Results of kinematics: hand dexterity – hits per session.

These results show physical therapist quantitative data in manual dexterity regarding accuracy to capture the dexterity required to complete ADL. This work presents an adapted version of the architecture proposed by Dumas, Lalanne and Oviatt [40] by including only one device for the Input Modality: a contactless device. This decision is proposed based on the context of the type of patients with upper limb disabilities. Likewise, today, contactless devices have shown greater accuracy for data capture. This decision also reduces the complexity described in [40] for the fusion processes in multimodal inputs: data-level fusion and feature-level fusion.

The simplified architecture proposal considered only one input contactless device. This prevents having to deal with problems of noise when dealing with multiple signals. This work considers that upper limb gesture recognitions could be done with only one device since different studies have demonstrated its accuracy [13] [44]. Feature-level fusion handles noise better but needs numerous data training sets before satisfactory performance can be achieved.

V. CONCLUSION

This work has proposed a Multimodal Contactless Architecture for upper limb Virtual Rehabilitation. This work has also implemented a Virtual Reality System based on the architecture for upper limb rehabilitation using the contactless device LMC.

The use of the proposed architecture has allowed the orchestration of four components: 1) the use of a contactless device for gesture recognition; 2) audio and visual cues for multimodal feedback; 3) an integration committee that performs the orchestration between the four components; and 4) the virtual rehabilitation system: Pizza-Game. The architecture focused on multimodal feedback. This study shows that this architecture could be useful for developers for VRS that do not require the use of complex and multiple devices for input modalities. The proposed architecture has considered specific constraints such as the use of contactless

devices for patients that can not use wearable devices due to their medical conditions.

This study had a few limitations. First, the study has only focused on commercial devices that have demonstrated their accuracy such as the Leap Motion Controller device. But the use of custom-made contactless devices whose accuracy has not been proven has not been considered, in that case, an architecture with more input devices is required. Second, since the sample size is small, one must be cautious with respect to the kinematics results obtained at a statistical level. Future studies should be carried out with a representative sample size at a statistical level.

As future work, it is planned to experiment with other contactless devices in order to compare accuracy and user experience. We also plan to incorporate some other devices for multimodal feedback.

ACKNOWLEDGMENT

This contribution was funded by the Universidad Nacional de San Agustín de Arequipa under contract IB-42-2020-UNSA- project "Virtual Rehabilitation System (VR) for motor and cognitive improvement in children with Epileptic Encephalopathy, CEPIVIRT".

Abstract—This paper focuses on two aspects of satellite formation flying (SFF) control: finite-time attitude synchronization and stabilization under undirected time-varying communication topology and synchronization without angular velocity measurements. First, a distributed nonlinear control law ensures rapid convergence and robust disturbance attenuation. To prove stability, a Lyapunov function involving an integrator term is utilized. Specifically, attitude synchronization and stabilization conditions are derived using graph theory, local finite-time convergence for homogeneous systems, and LaSalle's non-smooth invariance principle. Second, the requirements for angular velocity measurements are loosened using a distributed high-order sliding mode estimator. Despite the failure of inter-satellite communication links, the homogeneous sliding mode observer precisely estimates the relative angular velocity and provides smooth control to prevent the actuators of the satellites from chattering. Simulations numerically demonstrate the efficacy of the proposed design scheme.

Keywords—Attitude synchronization; coordinated control; finite-time control; high-order sliding mode observer; inter-satellite communication links; leader-following consensus; switching communication topology

I. INTRODUCTION

Distributed satellite systems (DSS) are an enabling technology for future distributed space missions since they are designed to interact as multi-agent systems for consensus tracking or formation keeping. DSS are deployed at different altitudes and in various configurations (e.g., formations, clusters, swarms, or cancellations) to accomplish distributed space missions like constellation [1], Earth observation [2], remote sensing [3], communication services [4], and meteorology and environmental tasks [5].

Satellite formation flying (SFF) is an attractive concept of DSS flying in prescribed orbits at a fixed separation distance for a given period. This concept enables flexible, reliable, and low-cost space missions [6,7]. However, SFF control requires tight interactions between participating satellites. Relative motion determination is essential for formation keeping and on-orbit reconfiguration. Therefore, SFF systems must meet strict attitude synchronization and tracking requirements before deployment.

The leader-follower-based attitude synchronization has received growing attention in recent years. Several synchronization protocols for SFF systems under fixed and

switching communication topologies have been reported in the literature. Zhou et al. [8] proposed a finite-time control law that guaranteed the coordination of a spacecraft formation under a fixed communication graph. The control law integrated a sliding-mode-based observer, allowing individual satellites to estimate the desired angular velocity. Although the control scheme showed a fast convergence rate, the control torques exhibited chattering effects, which can harm the actuators. Zhao and Jia [9] used a non-singular terminal sliding mode to design a distributed adaptive attitude synchronization algorithm. The chattering of the controllers was avoided using a boundary layer approach. The control algorithm was validated using only a fixed communication graph, which can restrain its ability when switching communication topologies. The attitude synchronization problem for a distributed SFF was investigated by Wang et al. [10]. The authors designed a free-reference attitude control algorithm under communication constraints, demonstrating an asymptotic convergence with an extensive settling time. Zhang et al. [11] discussed the application of integral sliding mode control to the problem of adaptive attitude tracking. The control input was smoothed via the boundary layer method but at the cost of settling time response. Zhang et al. [12] proposed a finite-time attitude synchronization and orbit-tracking control scheme that demonstrated robustness against node failures and torque disturbances. However, the simulations showed a slow convergence rate and high oscillation torques. Combining LQR and robust control approaches, Liu et al. [13] alleviated the effect of nonlinearities and parametric uncertainties on the performance of SFF attitude alignment. The control scheme was validated for a fixed communication topology presenting an asymptotic convergence. Liu et al. [14] designed an adaptive coordinated attitude synchronization control algorithm and a distributed observer for spacecraft formation over a switching network. Although simulations verified the performance of the proposed control scheme, the observer provided an asymptotic convergence to the leader reference attitude, which can degrade formation performance. Lu and Liu [15] further investigated attitude synchronization under switching topologies. The authors proposed a control scheme to guarantee attitude tracking under global and local failures of inter-satellite communication links (ISCLs). However, the consensus protocols showed an asymptotic convergence and required angular speed measurements.

Similarly, Zhang et al. [16] proposed a finite-time distributed attitude synchronization algorithm that requires the availability of the relative angular velocity for all the following satellites, which often leads to a heavy burden of ISCLs and time-consuming control. Zhang et al. [17] used the set theory to develop a new attitude of cooperative control for different SFF structures. Under fixed-time communication topology, the control design worked adequately for the leader-following and leaderless formation structures; however, neither dynamic communication graphs nor external disturbances were considered. Finally, Wei et al. [18] presented a comprehensive overview of the state-of-the-art communication satellite systems in their survey paper. The authors showed that recent publications have focused on designing synchronization techniques for SFF systems with node failures. They concluded that high-accuracy synchronization could be achieved using two-way ISCLs (i.e., undirected communication graphs) and precise observation techniques.

This paper provides solutions to two open problems above finite-time attitude synchronization under ISCLs breaks and robust relative angular velocity estimation. The first problem is solved by designing a distributed attitude synchronization algorithm using a Lyapunov function that involves an integrator term enabling a fast convergence rate. In contrast to the finite-time synchronization schemes available in the literature, the proposed algorithm allows attitude synchronization with time-varying communication graphs. As for the second problem, a high-order sliding mode differentiator estimates the relative angular velocity, guarantees formation robustness, and avoids chattering effects. The distributed observer helps relax the communication topology requirements and reduce the ISCLs burden. Most of the existing velocity-free or observer-based protocols have a slow convergence rate, lack of robustness, or perform only for fixed-time communication topology (e.g., [8,19-23]).

The outline of this paper is given as follows. Section II presents the preliminaries of this work and describes quaternion-based satellite attitude dynamics. A distributed finite-time attitude synchronization controller and relative angular velocity estimator are designed in Section III. Numerical simulations are carried out in Section IV to demonstrate the effectiveness and robustness of the proposed control scheme. Finally, Section V concludes the work.

II. PRELIMINARIES AND DYNAMIC MODELING

A. Graph Theory and Preliminaries

The leader-follower consensus approach is considered in this study to design distributed attitude synchronization and stabilization (ASS) protocols. The satellites are regarded as followers denoted by $'i = 1, 2, \dots, n'$, and the leader (i.e., desired attitude) is represented by $'i = 0'$. The ISCLs topology is modeled by a graph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \mathcal{A})$ where $\mathcal{V} = (v_1, v_2, \dots, v_n)$ denotes the vertices set, $\mathcal{E} \subseteq \mathcal{V} \times \mathcal{V}$ represents the edge set, and $\mathcal{A} = (a_{ij} \geq 0) \in \mathbb{R}^{n \times n}$ is the adjacent matrix corresponding to the graph \mathcal{G} . If a follower-satellite $'i'$ is connected to the leader, then the connection weight is represented by $a_{i0} > 0$; otherwise $a_{i0} = 0$. The

Laplacian matrix $\mathcal{L} = (\ell_{ij}) \in \mathbb{R}^{n \times n}$ associated to the graph \mathcal{G} is defined as

$$\mathcal{L} = \mathcal{D} - \mathcal{A}, \mathcal{D} = \text{diag}(d_{ii}), d_{ii} = \sum_{j \in N_j} a_{ij} \quad (1)$$

where $N_j = \{j | j \in \mathcal{V}, (j, i) \in \mathcal{E}\}$ represents the neighborhood set of a node $'i'$

Lemma 1 [24]: If the matrix \mathcal{L} is associated with a connected undirected graph \mathcal{G} , then its spectrum is given as

- $\lambda_1(\mathcal{L}) = 0$ is a simple eigenvalue of \mathcal{L} with a corresponding eigenvector $\mathbf{1}_n = [1, \dots, 1]_n^T$.
- All nonzero eigenvalues $\lambda_i(\mathcal{L})$ for $1 < i \leq n$ have positive real parts.
- $0 \leq \lambda_2(\mathcal{L}) \leq \dots \leq \lambda_n(\mathcal{L})$.

Lemma 2 [24]: According to the extension theorem, the following condition holds for any integral function f

$$\left\| \int_a^b f(t) dt \right\|_2 \leq (b - a) \|f(t)\|_\infty \quad (2)$$

Definition 1: Let $\mathbf{x} \in \mathbb{R}^n$ be a fixed, measurable function with l_1 -norm $\|\mathbf{x}\|_1 = \max|\mathbf{x}|$ and define an integral operator $L_K \mathbf{x}(t) = \int_X \mathbf{K} \mathbf{x}(t) dt$. Then

$$\|L_K\|_{HS} = \|\mathbf{K}\|_2^2 \quad (3)$$

where X is a compact with kernel \mathbf{K} and HS denotes Hilbert Schmidt norm.

B. Satellite Attitude Kinematics and Dynamics

Let $\bar{\mathbf{q}}_i = [q_{0i} \ \mathbf{q}_i]^T \in \mathbb{R}^4$ and $\boldsymbol{\omega}_i \in \mathbb{R}^3$ denote an i^{th} satellite's orientation and angular velocity within an SFF orbiting in an inertial frame. The nonlinear attitude kinematics and dynamics models are given by

$$\dot{\bar{\mathbf{q}}}_i = -\frac{1}{2} \boldsymbol{\Omega}(\boldsymbol{\omega}) \bar{\mathbf{q}}_i \quad (4)$$

$$\mathbf{J}_i \dot{\boldsymbol{\omega}}_i = -\boldsymbol{\omega}_i \times \mathbf{J}_i \boldsymbol{\omega}_i + \boldsymbol{\tau}_i + \mathbf{d}_i$$

with $\boldsymbol{\Omega}(\boldsymbol{\omega}) \in \mathbb{R}^{4 \times 4}$ is defined as

$$\boldsymbol{\Omega}(\boldsymbol{\omega}) = \begin{bmatrix} 0 & \omega_3 & -\omega_2 & \omega_1 \\ -\omega_3 & 0 & \omega_1 & \omega_2 \\ \omega_2 & -\omega_1 & 0 & \omega_3 \\ -\omega_1 & -\omega_2 & -\omega_3 & 0 \end{bmatrix}$$

\mathbf{J}_i , $\boldsymbol{\tau}_i$, \mathbf{d}_i denote the inertia tensor, torque vector, and external disturbances vector, respectively. Using the matrix $\mathbf{Q}_i(\mathbf{q}_i) = \mathbf{q}_{0i} \mathbf{I}_{3 \times 3} - \mathbf{q}_i^\times$ the model (4) can be rewritten as follows

$$\begin{aligned} \dot{\mathbf{q}}_i &= -\mathbf{Q}(\mathbf{q}_i) \boldsymbol{\omega}_i \\ \dot{q}_{0i} &= -\frac{1}{2} \boldsymbol{\omega}_i^T \mathbf{q}_i \end{aligned} \quad (5)$$

$$\mathbf{J}_i \dot{\boldsymbol{\omega}}_i = -\boldsymbol{\omega}_i^\times \mathbf{J}_i \boldsymbol{\omega}_i + \boldsymbol{\tau}_i + \mathbf{d}_i$$

where \mathbf{q}_i^\times is the skew-symmetric cross-product matrix and $\mathbf{I}_{3 \times 3}$ denotes a three-dimensional identity matrix. The satellites' angular velocities and external disturbances in the model (5) are bounded, as shown in assumptions 1 and 2 [11].

Assumption 1: $\|\boldsymbol{\omega}_i\|_2 \leq \rho$ and $\|\dot{\boldsymbol{\omega}}_i\|_2 \leq \delta$ with $\rho, \delta \in \mathbb{R}^+$.

Assumption 2: There exist $\gamma_0, \gamma_1 \in \mathbb{R}^+$ such that $\|\mathbf{d}_i\|_2 \leq \gamma_1 \|\boldsymbol{\omega}_i\|_2 + \gamma_0$

The control objective here is to design consensus protocols (control torques $\boldsymbol{\tau}_i$) such that the attitude synchronization of SFF orbiting with time-varying interaction topologies is achieved in a finite time. Thus, $\forall \mathbf{x}_i^0 \in D \subset \mathbb{R}^3$ there exists a synchronization time t_s for which

$$\begin{cases} \lim_{t \rightarrow t_s} \|\mathbf{q}_i - \mathbf{q}_d\|_2 = 0 \\ \lim_{t \rightarrow t_s} \|\boldsymbol{\omega}_i - \boldsymbol{\omega}_d\|_2 = 0 \end{cases} \quad (6)$$

where \mathbf{q}_d and $\boldsymbol{\omega}_d$ denote the desired orientations and angular velocities.

III. SYNCHRONIZATION CONTROL LAW DESIGN

A. SFF Attitude Synchronization under Undirected Time-Varying Interaction Topology

Consider the case of a SFF where at least one follower satellite is connected to the virtual leader. The following finite-time distributed torque law is considered for attitude synchronization of the i^{th} satellite I the SFF

$$\begin{aligned} \boldsymbol{\tau}_i = & \boldsymbol{\omega}_i^\times \mathbf{J}_i \boldsymbol{\omega}_i - \mathbf{J}_i \mathbf{Q}_i \boldsymbol{\omega}_i - \\ & k \mathbf{J}_i \{ [\sum_{j \in \mathcal{N}} a_{ij} (\mathbf{q}_i - \mathbf{q}_j) + a_{i0} (\mathbf{q}_i - \mathbf{q}_d)] + \\ & [\sum_{j \in \mathcal{N}} a_{ij} (\boldsymbol{\omega}_i - \boldsymbol{\omega}_j) + a_{i0} (\boldsymbol{\omega}_i - \boldsymbol{\omega}_d)] \} \end{aligned} \quad (7)$$

with $k \in \mathbb{R}^+$ is a control parameter.

Theorem 1: Consider a satellite formation flying under an undirected time-varying communication graph and suppose that the dynamics described in Eq. (5) are undisturbed and satisfy assumption 1. The control law (7) guarantees the finite-time convergence of the formation satellites' states to the desired attitude and achieves the formation consensus (6) if there exists a positive-definite symmetric matrix \mathbf{M} and a control gain k satisfying the following conditions.

$$\begin{cases} \mathbf{M} = \mathbf{L} + \mathbf{diag}(a_{i0}) \\ k > \frac{1}{\lambda_{\min}(\mathbf{M})} \end{cases} \quad (8)$$

Proof - Define the absolute quaternion and angular velocity tracking errors as follows

$$\begin{cases} \mathbf{q}_{ei} = \mathbf{q}_d^\times \mathbf{q}_i \\ \boldsymbol{\omega}_{ei} = \boldsymbol{\omega}_i - \boldsymbol{\omega}_d \end{cases} \quad (9)$$

Let $\mathbf{q}_e = [\mathbf{q}_{e1}^T, \dots, \mathbf{q}_{en}^T]^T$, $\boldsymbol{\omega}_e = [\boldsymbol{\omega}_{e1}^T, \dots, \boldsymbol{\omega}_{en}^T]^T$, $\mathbf{J} = \mathbf{diag}\{\mathbf{J}_1, \dots, \mathbf{J}_n\}$, and $\mathbf{Q}_e = \mathbf{diag}\{\mathbf{Q}_1, \dots, \mathbf{Q}_n\}$. Using the control law (7), the extension, to n satellites, of the undisturbed form of the torque equation in the model (5) gives

$$\mathbf{J} \dot{\boldsymbol{\omega}}_e = -\mathbf{J} \mathbf{Q}_e \boldsymbol{\omega}_e - k \mathbf{J} (\mathbf{M} \otimes \mathbf{I}_3) (\mathbf{q}_e + \boldsymbol{\omega}_e) \quad (10)$$

where \otimes denotes the Kronecker product and \mathbf{I}_3 denotes the (3x3) identity matrix.

To reach the consensus (6) in finite time, consider the following candidate Lyapunov function with an integrator term

$$V = \frac{1}{2} \left[(\boldsymbol{\omega}_e + \mathbf{q}_e) + \int_0^t (\boldsymbol{\omega}_e + \mathbf{q}_e) d\tau \right]^T (\mathbf{M} \otimes \mathbf{I}_N) \left[(\boldsymbol{\omega}_e + \mathbf{q}_e) + \int_0^t (\boldsymbol{\omega}_e + \mathbf{q}_e) d\tau \right] \quad (11)$$

For simplicity, we define a matrix $\bar{\mathbf{M}} = (\mathbf{M} \otimes \mathbf{I}_N)$. Using Eq. (10), the time derivative of the function (11), along with system (5), can be written as

$$\begin{aligned} \dot{V} = & [-k \bar{\mathbf{M}} (\boldsymbol{\omega}_e + \mathbf{q}_e) + (\boldsymbol{\omega}_e + \mathbf{q}_e)]^T \bar{\mathbf{M}} \\ & \left[(\boldsymbol{\omega}_e + \mathbf{q}_e) + \int_0^t (\boldsymbol{\omega}_e + \mathbf{q}_e) d\tau \right] \\ = & -k (\boldsymbol{\omega}_e + \mathbf{q}_e)^T \bar{\mathbf{M}}^T \bar{\mathbf{M}} (\boldsymbol{\omega}_e + \mathbf{q}_e) \\ & + (\boldsymbol{\omega}_e + \mathbf{q}_e)^T \bar{\mathbf{M}} (\boldsymbol{\omega}_e + \mathbf{q}_e) \\ & - k (\boldsymbol{\omega}_e + \mathbf{q}_e)^T \bar{\mathbf{M}}^T \bar{\mathbf{M}} \int_0^t (\boldsymbol{\omega}_e + \mathbf{q}_e) d\tau + \\ & + (\boldsymbol{\omega}_e + \mathbf{q}_e)^T \bar{\mathbf{M}} \int_0^t (\boldsymbol{\omega}_e + \mathbf{q}_e) d\tau \end{aligned} \quad (12)$$

Since \mathbf{M} is symmetric, then $\bar{\mathbf{M}}^T \bar{\mathbf{M}} = \bar{\mathbf{M}}^2$. With $\lambda_{\min}(\bar{\mathbf{M}}^2) = \lambda_{\min}^2(\bar{\mathbf{M}}) = \lambda_{\min}^2(\mathbf{M})$ and $\lambda_{\max}(\bar{\mathbf{M}}^2) = \lambda_{\max}^2(\mathbf{M}) = \lambda_{\max}^2(\mathbf{M})$, expression (12) can be bounded as follows

$$\begin{aligned} \dot{V} \leq & - (k \lambda_{\min}(\mathbf{M}^2) - \lambda_{\min}(\mathbf{M})) \|\boldsymbol{\omega}_e + \mathbf{q}_e\|_2^2 \\ & - (k \lambda_{\max}(\mathbf{M}^2) - \lambda_{\max}(\mathbf{M})) \|(\boldsymbol{\omega}_e + \mathbf{q}_e)^T\|_1 \|(\boldsymbol{\omega}_e + \mathbf{q}_e)^T\|_\infty \\ \leq & -\lambda_{\min}(\mathbf{M}) (k \lambda_{\min}(\mathbf{M}) - 1) \|\boldsymbol{\omega}_e + \mathbf{q}_e\|_2^2 \\ & - \lambda_{\max}(\mathbf{M}) (k \lambda_{\max}(\mathbf{M}) - 1) \|(\boldsymbol{\omega}_e + \mathbf{q}_e)\|_1 \|(\boldsymbol{\omega}_e + \mathbf{q}_e)\|_\infty \end{aligned} \quad (13)$$

Thus if $k > 1/\lambda_{\min}(\mathbf{M})$, then

$$\dot{V} \leq -\lambda_{\min}(\mathbf{M}) (k \lambda_{\min}(\mathbf{M}) - 1) \|\boldsymbol{\omega}_e + \mathbf{q}_e\|_2^2 \quad (14)$$

It follows that $\dot{V} \leq 0$. To prove that V will decrease to zero in finite time, \dot{V} will also satisfy

$$\dot{V} \leq -\lambda_{\max}(\mathbf{M}) (k \lambda_{\max}(\mathbf{M}) - 1) \|(\boldsymbol{\omega}_e + \mathbf{q}_e)\|_1 \|(\boldsymbol{\omega}_e + \mathbf{q}_e)\|_\infty \quad (15)$$

According to lemma 2, with the use of equation (11), the function V satisfies

$$\begin{aligned} V \leq & \frac{\lambda_{\max}(\mathbf{M})}{2} \left\| (\boldsymbol{\omega}_e + \mathbf{q}_e) + \int_0^{t_s} (\boldsymbol{\omega}_e + \mathbf{q}_e) d\tau \right\|_2^2 \\ \leq & \frac{\lambda_{\max}(\mathbf{M})}{2} \left(\|(\boldsymbol{\omega}_e + \mathbf{q}_e)\|_2^2 + \left\| \int_0^{t_s} (\boldsymbol{\omega}_e + \mathbf{q}_e) d\tau \right\|_2^2 \right) \\ \leq & \frac{\lambda_{\max}(\mathbf{M})}{2} \left(\|(\boldsymbol{\omega}_e + \mathbf{q}_e)\|_1^2 + t_s^2 \|(\boldsymbol{\omega}_e + \mathbf{q}_e)\|_\infty^2 \right) \\ \leq & \frac{t_s^2 \lambda_{\max}(\mathbf{M})}{2} \|(\boldsymbol{\omega}_e + \mathbf{q}_e)\|_1^2 \|(\boldsymbol{\omega}_e + \mathbf{q}_e)\|_\infty^2 \end{aligned} \quad (16)$$

where t_s denotes the settling time. It results from Eq. (15) and (16) that

$$\dot{V} \leq -\lambda_{\max}(\mathbf{M}) \left(\frac{\lambda_{\max}(\mathbf{M})}{\lambda_{\min}(\mathbf{M})} - 1 \right) \frac{\sqrt{2}\sqrt{V}}{\sqrt{t_s \lambda_{\max}(\mathbf{M})}} = -\alpha \sqrt{V} \quad (17)$$

which implies that for $\alpha = \frac{\sqrt{2}}{\sqrt{t_s}} \sqrt{\lambda_{\max}(\mathbf{M})} \left(\frac{\lambda_{\max}(\mathbf{M})}{\lambda_{\min}(\mathbf{M})} - 1 \right) > 0$, $V(t) \rightarrow 0$ as $t \rightarrow t_s$.

Finally, the settling time t_s is computed from the integration of Eq. (17) as follows

$$\sqrt{V(t)} \leq \sqrt{V(0)} - \frac{\alpha t_s}{2} \quad (18)$$

Using equation (11) at $t = 0$, the settling time t_s is given as

$$t_s = \frac{\sqrt{2(\boldsymbol{\omega}_e(0) + \mathbf{q}_e(0))^T (\mathbf{M} \otimes \mathbf{I}_N) (\boldsymbol{\omega}_e(0) + \mathbf{q}_e(0))}}{\sqrt{\lambda_{\max}(\mathbf{M})} \left(\frac{\lambda_{\max}(\mathbf{M})}{\lambda_{\min}(\mathbf{M})} - 1 \right)} \quad (19)$$

Thus, $\mathbf{q}_i \rightarrow \mathbf{q}_d$ and $\boldsymbol{\omega}_i \rightarrow \boldsymbol{\omega}_d$ in finite time for $t \geq t_s$.

End of proof.

B. Attitude Synchronization with High-Order Sliding Mode Estimator

In this subsection, a distributed angular velocity observer is introduced to reduce the number of ISCLs and guarantee the robustness of the SFF against loss of communication. First, a finite-time high-order sliding mode differentiator is designed to provide follower satellites with an accurate estimate of the desired angular velocity $\hat{\boldsymbol{\omega}}_i$. To do so, we define the following non-empty sliding mode function.

$$\mathbf{s}(t) = (\mathbf{s}_1^T, \mathbf{s}_2^T, \dots, \mathbf{s}_n^T)^T \quad (20)$$

where $\mathbf{s}_i \in \mathbb{R}^3$ denotes a sliding mode manifold for satellite 'i'. The sliding surface \mathbf{s}_i is defined by an integral sliding mode function as

$$\mathbf{s}_i = \mathbf{e}_{\omega,i} + \int_0^t \mathbf{e}_{\omega,i}(\tau) d\tau \quad (21)$$

with

$$\mathbf{e}_{\omega,i} = \sum_{j \in \mathcal{N}} [a_{ij}(\boldsymbol{\omega}_i - \boldsymbol{\omega}_j) + a_{i0}(\boldsymbol{\omega}_i - \boldsymbol{\omega}_d)] \quad (22)$$

Lemma 1 [25]: Consider a continuous function $f(t)$ with the time-derivative $f^{(r)}(t)$ has a Lipschitz constant $L > 0$ (i.e., $f^{(r)}(t) \leq L$), where r is the relative degree of $\mathbf{s}(t)$. The following high-order sliding mode differentiator produces accurate estimations of $f(t)$ and its successive time derivatives $f^{(k)}(t)$ ($k = 1, \dots, r - 1$) in finite time

$$\begin{cases} \dot{z}_0 = z_1 + \mu_0 |z_0 - f(t)|^{\frac{r-1}{r}} \\ \dot{z}_1 = z_2 + \mu_1 |z_0 - f(t)|^{\frac{r-2}{r-1}} \\ \vdots \\ \dot{z}_{r-2} = z_{r-1} + \mu_{r-2} |z_0 - f(t)|^{\frac{1}{2}} \\ \dot{z}_{r-1} = z_r + \mu_{r-1} \text{sign}(z_0 - f(t)) \end{cases} \quad (23)$$

where z_i ($i = 0, \dots, r$) denote the differentiator states and μ_i define the differentiator parameters. With $z_r = 0$, the differentiator (23) guarantees that $z_0 \rightarrow \hat{f}_i$ and $z_k \rightarrow \hat{f}_i^{(k)}$ ($k = 1, \dots, r - 1$) converge in finite time.

With $f(t) = s_{i,j}(t)$ where 'i' = 1, ..., n' denotes satellite 'i' and 'j' = 1, ..., 3' denotes motion direction, $\hat{\boldsymbol{\omega}}_{i,j} = z_0$ and $\hat{\boldsymbol{\omega}}_{i,j}^{(k)} = z_i^{(k)}$ ($k = 1, \dots, r - 1$) converge in finite time. We note that $\hat{\boldsymbol{\omega}}_{i,j}^{(k)}$ are the successive time-derivatives of the estimate $\hat{\boldsymbol{\omega}}_{i,j}^{(k)}$.

Second, under the results above, the control law (7) is redesigned as follows

$$\begin{aligned} \boldsymbol{\tau}_i = & \boldsymbol{\omega}_i^\times \mathbf{J}_i \boldsymbol{\omega}_i - \mathbf{J}_i \mathbf{Q}_i [\hat{\boldsymbol{\omega}}_i + \sum_{k=1}^{r-2} \mathbf{Q}_i^{(k)} \hat{\boldsymbol{\omega}}_i^{(k)} + \\ & k \{ [\sum_{j \in \mathcal{N}} a_{ij} (\mathbf{q}_i - \mathbf{q}_j) + a_{i0} (\mathbf{q}_i - \mathbf{q}_d)] \\ & + [\sum_{j \in \mathcal{N}} a_{ij} (\hat{\boldsymbol{\omega}}_i - \hat{\boldsymbol{\omega}}_j) + a_{i0} (\hat{\boldsymbol{\omega}}_i - \boldsymbol{\omega}_d)] \}] \end{aligned} \quad (24)$$

where $\mathbf{Q}_i^{(k)}$ denotes the k^{th} time-derivative of the matrix \mathbf{Q}_i used in (5).

Theorem 2: Consider system (5) with $\mathbf{d}_i = 0$ and a sliding function of the form (21). If there exists a constant $k > 0$, then the protocols (24) guarantee that $\lim_{t \rightarrow T} (\mathbf{q}_i - \mathbf{q}_j) = 0$ and $\lim_{t \rightarrow T} (\boldsymbol{\omega}_i - \boldsymbol{\omega}_j) = \lim_{t \rightarrow T} (\boldsymbol{\omega}_i - \boldsymbol{\omega}_d) = 0$, where T is the synchronization time.

Proof: Let $e_0 = z_0 - f(t)$ be the differentiation error, then system (23) can be written as

$$\begin{cases} \dot{e}_0 = e_1 - \mu_0 |e_0|^{-\frac{1}{r}} e_0 \\ \dot{e}_1 = e_2 - \mu_1 |e_0|^{-\frac{1}{r-1}} e_0 \\ \vdots \\ \dot{e}_{r-2} = e_{r-1} - \mu_{r-2} |e_0|^{-\frac{1}{2}} e_0 \\ \dot{e}_{r-1} = -\mu_{r-1} |e_0|^{-1} e_0 - f^{(r)} \end{cases} \quad (25)$$

The error dynamics (25) can be set in the following pseudo linear system form

$$\dot{\mathbf{e}} = \mathbf{A} \mathbf{e} + \mathbf{b} f^{(r)} \quad (26)$$

with

$$\mathbf{e} = [e_0 \ e_1 \ \dots \ e_{r-1}]^T, \quad \mathbf{b} = [0 \ 0 \ \dots \ 1]^T$$

$$\mathbf{A} = \begin{bmatrix} -\mu_0 |e_0|^{-\frac{1}{r}} & 1 & 0 & \dots & 0 \\ -\mu_1 |e_0|^{-\frac{1}{r-1}} & 0 & 1 & \ddots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ -\mu_{r-2} |e_0|^{-\frac{1}{2}} & 0 & 0 & \dots & 1 \\ -\mu_{r-1} |e_0|^{-1} & 0 & 0 & \dots & 0 \end{bmatrix}$$

One can easily find that the determinant of matrix \mathbf{A} is given as

$$\det(\mathbf{A}) = (-1)^r \mu_{r-1} |e_0|^{-1} = \prod_{i=1}^r \bar{\lambda}_i \quad (27)$$

and its characteristic polynomial as

$$p_A(\lambda) = \det(\mathbf{A} - \lambda \mathbf{I}) = \sum_{k=1}^r \lambda^{r-k} (-1)^k \text{tr}(\wedge^k \mathbf{A}) \quad (28)$$

where λ denotes an eigenvalue of \mathbf{A} and $(\wedge^k \mathbf{A})$ denotes the trace of the k^{th} exterior power of \mathbf{A} . Equation (28) gives

$$p_A(\lambda) = \lambda^r + \mu_0 |e_0|^{-\frac{1}{r}} \lambda^{r-1} + \mu_1 |e_0|^{-\frac{1}{r-1}} \lambda^{r-2} + \dots + \mu_{r-1} |e_0|^{-1} \quad (29)$$

The polynomial (29) is stable if its coefficients satisfy the following Schur condition

$$1 > \mu_0 |e_0|^{-\frac{1}{r}} > \mu_1 |e_0|^{-\frac{1}{r-1}} > \dots > \mu_{r-1} |e_0|^{-1} > 0 \quad (30)$$

To fulfill condition (30), the differentiator coefficients μ_i are computed using the following tuning recursive scheme

$$\begin{cases} \mu_0 := \alpha L^{1/r} \\ \mu_i := \mu_{i-1} L^{1/(r-i)} \quad (i = 1, \dots, r - 1) \end{cases} \quad (31)$$

where $\alpha \in \mathbb{R}^+$ is a tuning parameter. According to the scheme (31), for any $r > 1$ and Lipschitz constant $L \in \mathbb{R}^+$, $\exists \alpha$ such that $\mu_0 < 1$. Consequently, condition (30) is guaranteed, and matrix A is stable.

End of proof.

IV. SIMULATION

In this section, numerical simulations are performed to confirm the above theoretical results and prove the performance and effectiveness of the proposed control scheme. The distributed torque laws (7) and (24) and the observer (23) were applied to a four-satellite formation that runs under an undirected switching communication topology shows in Fig. 1. Table I gives the moments of inertia and the initial conditions of the four satellites.

TABLE I. PARAMETERS OF THE SATELLITES

Sat.	Initial attitude/angular velocity (rad/s)	Moment of inertia (kg.m ²)
1	$\mathbf{q}_1 = [0.5916, 0.6, -0.5, -0.2]$ $\boldsymbol{\omega}_1 = [0.02, -0.01, -0.02]$	$\mathbf{J}_1 = \text{diag}[10.15, 10.20, 9.85]$
2	$\mathbf{q}_2 = [0.7874, 0.5, -0.3, -0.2]$ $\boldsymbol{\omega}_2 = [0.03, -0.01, -0.01]$	$\mathbf{J}_2 = \text{diag}[12.1, 10.90, 10.50]$
3	$\mathbf{q}_3 = [0.6245, 0.3, -0.6, -0.4]$ $\boldsymbol{\omega}_3 = [0.02, 0.00, -0.03]$	$\mathbf{J}_3 = \text{diag}[9.55, 12.30, 10.20]$
4	$\mathbf{q}_4 = [0.6403, 0.5, -0.3, -0.5]$ $\boldsymbol{\omega}_4 = [-0.01, 0.02, -0.03]$	$\mathbf{J}_4 = \text{diag}[10.50, 11.20, 10.20]$

First, the satellites are required to align their attitudes to the desired $\bar{\mathbf{q}}_d = (0, 0, 0, 1)^T$ and $\boldsymbol{\omega}_d = (0, 0, 0)^T$. The distributed torque law (7) is applied with $k = 3.7$, and the simulation is run under the communication topology shown in Fig. 1 for a 60 s with a dwell time $\tau = 15$ s. Fig. 2 and 3 depict the quaternions and angular velocities tracking errors, and Fig. 4 shows the required control torques.

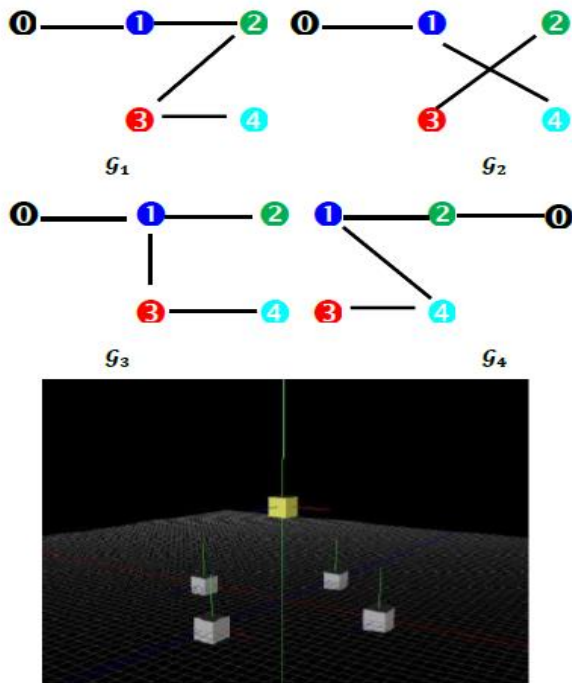

Fig. 1. Switching interaction topology among a four-satellite formation.

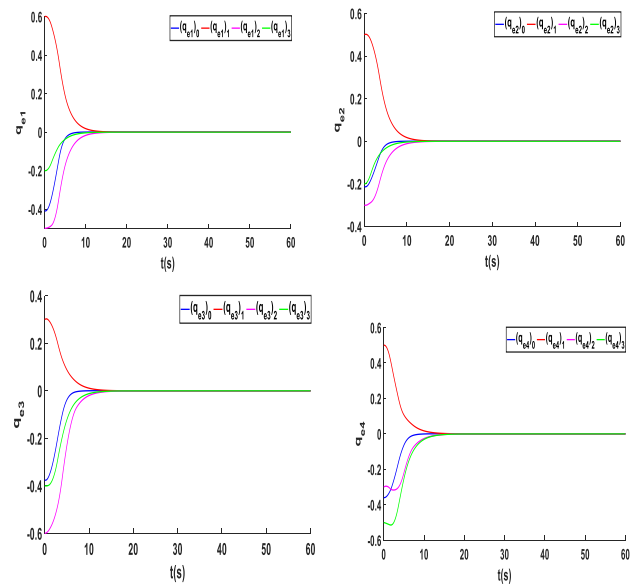

Fig. 2. Quaternions tracking errors.

Fig. 3. Angular velocity tracking errors.

Fig. 4. Control efforts (torques).

The results above indicate that the four satellites can align their attitude to the specified one while effectively maintaining the consensus (6) despite the ISCLS' failures. Next, the case of attitude synchronization without angular velocity measurement is considered. In this scenario, the efficiency of the redesigned torque law (24) with a third-order observer (23) is verified. An external disturbance of $\mathbf{d} = 10^{-4}[\sin(0.12t), \sin(0.5t), \sin(0.18t)]^T$ is introduced to the system (5). The simulation is run with $k = 1.2, \alpha = 0.15$, under the leaderless communication topology shown in Fig. 5. Fig. 6 shows the relative attitude $\mathbf{q}_{ij} = \mathbf{q}_j^* \mathbf{q}_i$ where \mathbf{q}_j^* denotes the cross-product matrix associated with the quaternion vector \mathbf{q}_j . The relative angular velocity errors $\boldsymbol{\omega}_{ei} = \boldsymbol{\omega}_i - \boldsymbol{\omega}_j$ are depicted in Fig. 7.

Fig. 5. Switching interaction topology among a four-satellite formation with loss of the leader.

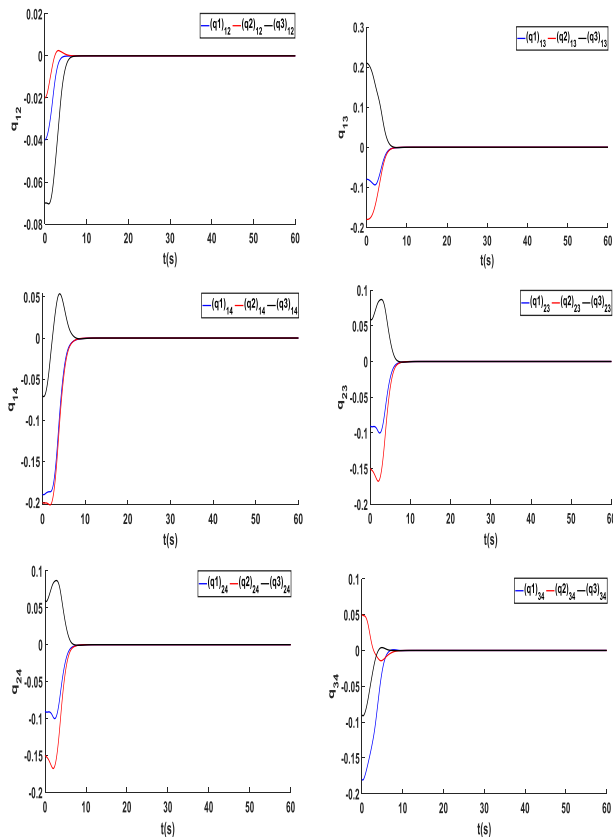

Fig. 6. Relative satellite-to-satellite attitude errors.

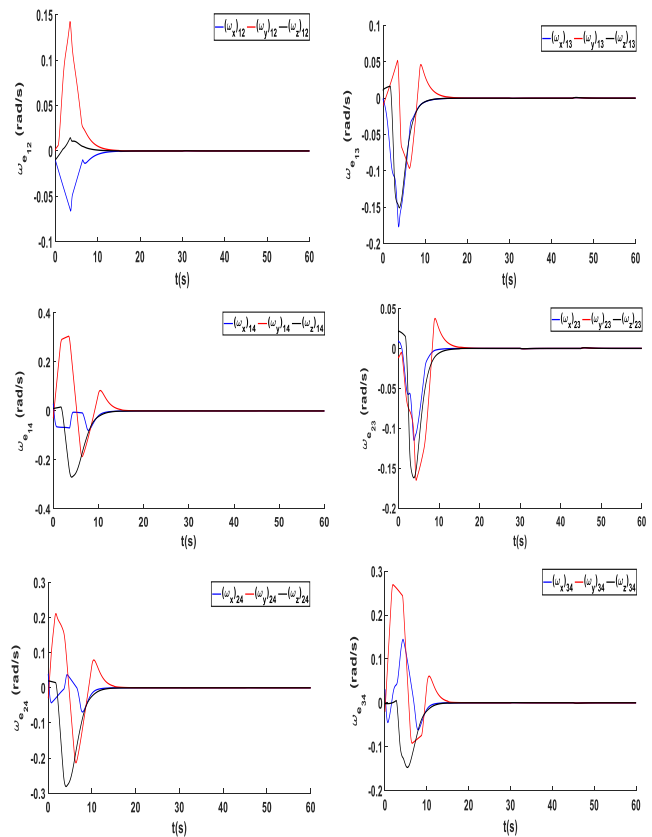

Fig. 7. Relative satellite-to-satellite angular speed errors.

For a fair comparison, attitude synchronization paths for satellites using second and third-order sliding mode observers are shown in Fig. 8.

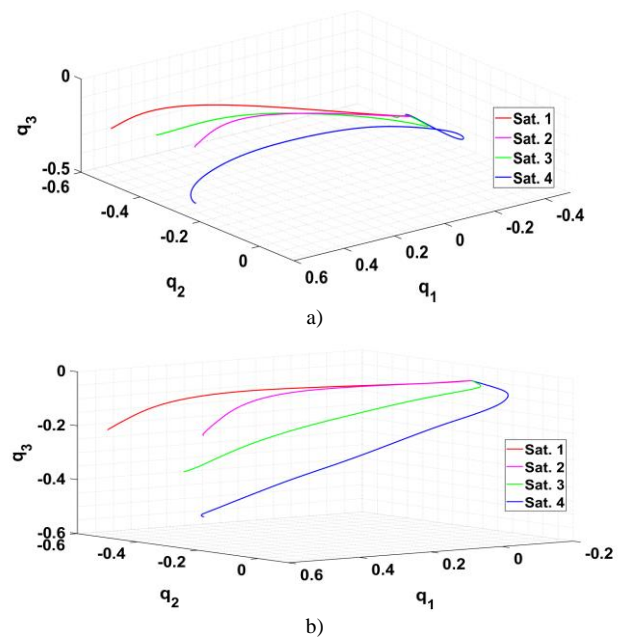

Fig. 8. Attitude synchronization paths with a) second-order observer, b) third-order observer.

Using both static and dynamic communication topologies with and without velocity measurements, the results of the present research demonstrated the feasibility and effectiveness of the proposed finite-time attitude synchronization for satellite formation systems. The results showed that instead of using the actual measured angular velocities, the designed observer with a finite-time high-order sliding-mode generated high-precision estimates. The observer was implemented to lessen the load on the inter-satellite communication lines and guarantee the formation's resilience in the face of link failures. In addition, the performance of the augmented control law (24) is shown to be satisfactory by comparing Fig. 2 and 3 and Fig. 6 and 7. This is the case despite the fact that estimations of relative angular velocities are utilized, as well as the fact that external disturbances are implemented. In addition, it can be shown from Fig. 8 that raising the order of the observer can result in an increase in the precision of the attitude synchronization.

V. CONCLUSION

This paper has investigated the finite-time attitude synchronization for satellite formation systems under switching communication topologies with and without velocity measurements. First, Lyapunov-based distributed torque laws were designed to provide a coordinated synchronization of the states of following satellites with the desired attitudes and angular speeds. The distributed protocols were developed using graph theory, local finite-time convergence for homogeneous systems, and non-smooth LaSalle's invariance principle. Then, a finite-time high-order sliding-mode observer was designed to provide relative angular velocity estimates instead of the measured ones. The distributed observer is introduced to reduce the inter-satellite communication links burden and ensure formation robustness against their breaks. Future works will focus on solving some critical inter-satellite transmission problems such as signal overriding, signal interferences, and communication delays.

ACKNOWLEDGMENT

This project was funded by the Deanship of Scientific Research (DSR) at King Abdulaziz University, Jeddah, under grant no. (G:305-135-1441). The authors, therefore, acknowledge with thanks DSR for technical and financial support.

Abstract—Hussein search algorithm focuses on the fundamental concept of searching in computer science and aims to enhance the retrieval of data from various data warehouses. The efficiency of cloud systems is substantially influenced by the manner in which data is saved and retrieved, given the vast quantity of data being generated and stored in the cloud. The act of searching entails the systematic endeavor of locating a particular item within a substantial volume of data, and searching algorithms offer methodical strategies for accomplishing this task. There exists a wide array of searching algorithms, each exhibiting variations in terms of the search procedure, time complexity, and space complexity. The choice of the suitable algorithm is contingent upon various aspects, including the magnitude of the dataset, the distribution of the data, and the desired temporal and spatial intricacy. This study presents a novel prediction-based searching algorithm named the Hussein search algorithm. The system is designed to operate in a straightforward manner and makes use of a simple data structure. This study relies on fundamental mathematical computations and incorporates the interpolation search algorithm, an algorithm that introduces a search by-prediction method for uniformly distributed lists, it forecasts the precise position of the queried object. The cost of prediction remains consistent and, in numerous instances, falls under the $O(1)$ range. Hussein search algorithm exhibits enhanced efficiency in comparison to the binary search and ternary search algorithms, both of which are widely regarded as the best methods for searching sorted data.

Keywords—Binary search; prediction search procedure; prediction cost; constant time complexity

I. INTRODUCTION

On a daily basis, a substantial volume of data is generated across many formats, including photographs, videos, and text. This material is subsequently stored in cloud-based repositories, serving as a collective resource for retrieval from any given database. The increasing complexity of this matter can be attributed to the substantial volume of data that is generated and stored on a daily basis. The act of searching is of significant importance in various contexts, regardless of whether the item being sought is stored within a cloud-based infrastructure or a localized database. In both scenarios, the use of a search algorithm is essential for the successful retrieval of the desired item. The process of searching is commonly employed as a means of problem-solving, whereby the problem is provided as input and a solution is generated in the form of a sequential set of activities. Numerous instances in practical contexts can be classified as searching problems, such as the task of determining the shortest route between two

nodes. These types of problems can be effectively addressed through the use of graph search algorithms. The act of searching can be categorized into two main types: sequential search and binary search. Various searching algorithms exist, each employing distinct strategies and exhibiting variations in terms of time and space complexity. Certain algorithms employ an informed approach, while others adopt a uniform approach, and a third category utilizes a partial information strategy for the purpose of item retrieval. The uniformity of the sequential search method arises from its lack of concern for any prior knowledge regarding the distribution of items. The binary search algorithm is considered an informed search algorithm due to its reliance on a sorted array. In recent years, there has been limited progress in enhancing the complexity of the search algorithm. This is primarily due to the satisfactory performance of the binary search algorithm in terms of searching complexity. However, it is important to note that the binary search algorithm does encounter challenges related to sorting, as it can only operate on sorted arrays. Additionally, it faces difficulties when dealing with comparison-based input involving searching for candidate items. Hence, the temporal complexity is intricately linked to the duration required for the sorting process, resulting in a trade-off where the time saved when searching is offset by the time invested in sorting. The interpolation search algorithm has a temporal complexity of $O(1)$ when the items in the list are evenly distributed [1]. Therefore, in some scenarios, an interpolation search can provide an accurate estimation of the closest solution to the search problem. The ternary search method is a variant of the binary search algorithm that has a slower temporal complexity [1, 2]. The meta-binary search algorithm is a variant of the binary search method that iteratively creates the index of the desired value within the array. The approach operates in a way akin to the binary search algorithm, exhibiting a time complexity of $O(\log n)$ for locating the desired element. The ternary search technique partitions the array into three segments, utilizing the central point of each segment to locate the desired element. The logarithmic complexity of the search algorithm is determined by the number of steps required to locate the desired element, which is logarithmically proportional to the size of the array, denoted as n . However, the search range, which represents the number of elements that need to be examined during the search, is three times the size of the array ($3n$). Consequently, the worst-case running time of the algorithm can be expressed as the logarithm of three times the size of the array ($\log 3n$), while the best-case running time may be approximated as being linearly proportional to the size of the array ($O(n)$). It is important to note that these

running time estimates are valid only when the array is sorted [3]. The jump search algorithm is a searching technique designed for sorted arrays. It involves performing a fixed number of jumps, denoted by k , on a block of data in order to locate the target element. Within each block, linear search operations are conducted to identify the desired element. The algorithm under consideration is superior to the sequential search method, but it falls short of the binary search technique. Specifically, it requires $m-1$ additional comparisons compared to sequential search, where m represents the size of the block to be traversed [4]. The interpolation search algorithm is a method that generates additional data points within a given range of known data points. Its time complexity is $O(\log \log n)$ for datasets with uniform distributions, and $O(n)$ in the worst-case scenario. The proposed approach represents an advancement over the binary search technique by employing comparison-based approaches that leverage a mathematical formula to approximate the location of the target element based on its value. Subsequently, the search is conducted in the vicinity of this estimated position. This alternative method has the potential to outperform the binary search algorithm under certain circumstances [5]. The exponential search algorithm operates on a sorted array. It begins by selecting a subarray of size 1, then doubles the size of the subarray in each iteration. The algorithm compares the final element of each subarray until the desired element is found. The algorithm in question is commonly referred to as exponential search, which exhibits a temporal complexity of $O(\log n)$ [6]. In the realm of searching for an item within an array of size n , two commonly employed strategies can be identified. The first strategy, known as sequential search, is applicable to unsorted arrays. The second technique, known as binary search, is exclusively applicable to arrays that have been sorted.

The study presented in this paper aims to introduce a novel searching algorithm that operates on a sorted array, relying solely on mathematical operations and a computed prediction approach implemented through a straightforward data structure. The search process in question exhibits a constant time complexity. While the space complexity may exceed that of sequential search, the time complexity can be lowered to $O(1)$ in numerous scenarios and to $O(\text{constant})$ in the worst-case scenario. The algorithm relies on the computation of the array's average, operating under the assumption of a uniform distribution of items within the list. Additionally, it generates supplementary arrays, one of which records the frequency of successful matches, while the other stores the locations where the sought-after items can be located. Part of process is similar to the Knuth-Pratt-Morris algorithm, which is commonly used for pattern matching [7]. The approach under consideration aims to decrease the time complexity by minimizing the number of comparisons and implementing a straightforward prediction system that ensures the absence of collisions through the utilization of error-free lookup tables and basic arithmetic operations.

The primary objectives underlying this research endeavor are to provide a straightforward predictive approach utilizing search techniques and to execute a basic computation with constant time complexity.

The subsequent sections of this study are structured as follows: Section II presents a review of relevant literature pertaining to searching algorithms. It is worth noting that the process of locating sufficient recent works on searching algorithms proved to be challenging. The majority of the literature discovered consisted of dated publications or encompassed broader discussions on binary search algorithms. In Section 3, the proposed algorithm is introduced. In Section IV are shown the results obtained from the proposed study, followed by an examination of the algorithm employed. Finally, the paper concludes with findings and discusses potential avenues for further research in Section V.

II. RELATED WORKS

One of the main benefits of searching operations in computer science is their capability to assist in finding particular data from databases. The effectiveness of the search process directly impacts the overall performance of the system. Searching algorithms are widely employed in several computer applications, such as problem-solving [9], data analysis, and information retrieval, due to their ability to efficiently search through extensive datasets within a limited timeframe. Various searching techniques exist, including sequential, binary, hashing, and graph search. The selection of an appropriate algorithm is contingent upon the particular situation at hand and the attributes of the data being queried [10]. The authors of [5] introduce a hybrid search method known as interpolated binary search (IBS), which integrates the interpolation algorithm and the binary search algorithm to accurately determine the precise position of the desired object. The IBS algorithm commences by employing an interpolation algorithm to estimate the approximate location of the item being searched. It subsequently operates as a binary search algorithm to precisely determine the location of the sought-after item. The Inverse Binary Search (IBS) algorithm exhibits a greater computational cost compared to both the binary search algorithm and the interpolation technique. However, when executed on uniformly distributed data, IBS demonstrates a lower temporal complexity cost than the aforementioned algorithms. Specifically, its time complexity is $O(\log 2 \log 2n)$. On the other hand, when applied to non-uniformly distributed datasets, IBS necessitates $O(\log 2n)$ operations. In [8], a comparison between different search algorithms is presented, the authors analyze the performance of various search algorithms, including uninformed search algorithms (DFS, uniform cost search) and informed search algorithms (A^* and BFS), with a focus on their time complexity and space complexity.

Graph search algorithms typically construct a graph based on the given input data and traverse the nodes of the graph using various strategies in order to locate the desired objects [13]. The algorithms that were examined all exhibited a time complexity of $O(mb)$, where m represents the number of offspring for each node (also known as the branching factor) and b represents the solution depth, which is the length of the path. The binary search algorithm utilizes a value of m equal to 2 and assigns b as the logarithm base 2 of n .

The act of searching is a crucial and widely employed process in several contexts. In order to obtain data of various

types, it is necessary to carry out two fundamental procedures: searching and sorting. In order to address this concern, it is worth noting that the majority of searching algorithms operate on an array that has been sorted. However, it is important to acknowledge that the computational expense of sorting the data can vary significantly, ranging from a best-case scenario of $O(n \log n)$ to a worst-case scenario of $O(n^2)$. This additional cost must be taken into consideration when evaluating the overall efficiency of the search process. The authors of [11] present a novel technique called the bound sequential search (BSS) algorithm, which uses logical gates to simultaneously search for two items. The primary concept is around the utilization of Binary Search with Sorted Subarrays (BSS) to concurrently search for about two items, hence eliminating the need for executing the search process twice, all without the involvement of parallel processors. In the context of Binary Search Systems (BSS), the process of looking for two items, X and Y, involves the utilization of an additional key, Z. This key, denoted as Z, is determined by the logical operation of the inclusive OR between X and Y. Subsequently, Z serves as the key element for conducting a search operation within an unsorted array, denoted as A, which possesses a size of n. The search procedure commences by evaluating each element in the array A against Z, provided that $Z \text{ AND } A[i] \neq A[i]$ indicates that neither of the two elements is present in A[i].

In the event of the most unfavorable scenario, the computational complexity for locating two items in the BSS (Binary Search Structure) is N, as opposed to $2N$ in sequential search or $(n+2 \log n)$ in the binary search algorithm. The Bubble Sort algorithm demonstrates superior performance in terms of comparison count in both the best and worst case scenarios, when compared to the Binary Search algorithm and the Sequential Search method. A limitation of this algorithm is its inability to perform a search for a single item, as it is designed to search for about two objects simultaneously.

Hashing is a technique employed in the search of extensive databases, wherein a distinct key is generated for each record or item. This key serves to designate the specific area within the database where the item is potentially kept. The time complexity for retrieving an item from a big database using hashing can range from constant time ($O(1)$) to linear time ($O(n)$) in the worst-case scenario. The variable n represents the size of the linked list, which is utilized for the purpose of storing colliding data within a single slot, denoted as [12]. The objective is to verify the presence of item X inside a given dataset. As the volume of data expands, the intricacy of the situation escalates. The problem of searching has been introduced and elucidated by Levin and Solomonoff throughout the time span of 1973 to 1984 [14,15, 16, and 17]. In reference [18], a novel quantum technique is presented for the search problem, demonstrating a polynomial time complexity. This algorithm utilizes XOR logical gates to convert the data into a polynomial form, following the amplification process provided in reference [19]. Consequently, the search operation may be executed within a polynomial time frame relative to the input size, denoted as n.

In the cited work [20, 21], the authors introduce a fractional cascade algorithm, which is a method aimed at

enhancing the efficiency of binary search algorithms. This methodology achieves a reduction in the time complexity of binary search algorithms to $O(k + \log n)$ while searching for k elements within a sorted array of size n.

III. HUSSEIN SEARCH ALGORITHM

The Hussein search algorithm is designed to efficiently locate an element in a sorted array. It achieves this by utilizing a prediction table structure and a sequential search algorithm. This approach reduces the time complexity from $O(n)$ in sequential search or $O(\log n)$ in binary search to $O(1)$ [7]. The algorithm achieves this improvement by employing only arithmetic operations and a technique inspired by the interpolation method for searching sorted lists [1]. It is important to note that the algorithm assumes a uniform distribution of elements in the list. The algorithm operates in two distinct phases: the preprocessing phase and the searching phase. During the preparation step, the entirety of the array undergoes arithmetic operations in order to ready the data for the subsequent prediction finding procedure. During the preprocessing phase, an array of integers denoted as A, which has a size of n is examined. The data within this array is created in a random manner. During this phase, the operations conducted involve the calculation of the average value of variable A. The average can be determined by calculating the mean of a set of values. To obtain the mean, each element in array A should be divided by a given value t, and the resulting values should be stored in a new array B. The size of array B is denoted as n. Generate a novel array C, whose size is determined by the floor function applied to the value of t. To iterate through a set of counters starting from 0 to size (c), the ceiling of each element $B[i]$ is compared with the indices of C. The number of matching values is determined, and the resulting matching score is stored in a new list C1 at the corresponding index of the matching item. The elements contained within the array C1 will represent the respective indices of the desired item within the original array. During the searching phase, the following operations are performed to determine whether an item X is present in an array: X is divided by t, and the resulting value is compared with the indices of C1 using the ceiling function. The value found in the corresponding cell of C1 represents the index of the searched item X in the original array. If the corresponding cell is empty, it indicates that the item X is not present in the array.

The following example provides a comprehensive elucidation of the functioning of the Hussein search method. In this scenario, array A of size 16 is randomly produced by [7], and the data within the array is uniformly dispersed. The elements in set A are arranged in ascending order, while the outcomes of dividing each element in set A by the average of the average are recorded in set B (refer to Fig. 1(a)). A new array, denoted as C, is to be created with a size of 30. This array will contain the floor value of the average values obtained from Fig. 1(b). The quantity of corresponding elements in the array is stored in Fig. 1(c). Now, let us explore the scenario where aim to search for item X, which has a value of 310, within the table. Initially, the value of X is divided by 30.89. The resulting quotient is then rounded up to the nearest whole number, denoted as 11. Subsequently, proceed to locate the element within the array by referring to the index position

11. Upon examination, it is determined that the value at this index is 0, indicating that the desired element is not present inside the array. Let X be equal to 275. Next, perform a division operation on X by t, and subsequently apply the ceiling function. The resulting value, 9, is assigned to the index 9 in array C. Upon further examination, we finally, observe that the element at index 9 in array C is 1, indicating that X is located at index 5 in the original array (as depicted in Fig. 2).

Fig. 2. Testing the search operation using Hussein search algorithm.

A. Algorithm Description:

1) *Preprocessing phase:* Consider we have an array of integers A of size n, where the data is randomly generated, in this phase the following operations are performed:

- Calculate the average of A. $average = \frac{sum(A)}{n}$
- Calculate the average of average: $t = \frac{average}{n}$
- Divide all the elements of A by t and store it in a new array B, the size of B is n
- Create a new prediction array C with size floor (t)
- For I counter that start from 0 to size (c), compare the ceiling of B[i] with the indices of C, and count the

matching values and store the matching score in a new list C1 in the corresponding index to the matching item. The values stored in the array C1 will be the corresponding index of the searched item in the original array.

2) *Searching phase:* For searching an item X, if in the array or not is performed the following operations:

- Divide X by t, $S = \frac{X}{t}$
- Compare the ceiling of (S) with the indices of C1; the value found in the corresponding cell will be the index of the searched item (X) in the original array, if the corresponding cell is empty that means the item is not found in the array.

IV. RESULTS AND ANALYSIS

The proposed algorithm is simple and easy to understand and implement. It is implemented and tested in MacBook air i5 processor 1.3 GHz speed, 8 GB ram, using visual studio, C# and in Python, and is tested for large input size list up to 16 mg . Furthermore, we have successfully implemented both the binary search method and the ternary algorithm using the C# programming language. These implementations were carried out in an identical setting, with the input size being consistent with that of the Hussein search algorithm. The objective of the experiment was to conduct N iterations in order to seek a randomly produced list with a size of N. The findings indicate that the speed of the prediction searching method in all evaluated algorithms exhibits a linear relationship with the amount of input. However, it is noteworthy that as the input size increases, the performance of the Hussein search surpasses that of the other algorithms. The Hussein search method exhibits a constant time complexity of O(1) for finding an individual item.

Consequently, the search operation for n items may be accomplished in linear time complexity of O(n). This stands in contrast to the binary search strategy, which necessitates a time complexity of O(n log n) for searching n items. Fig. 3 presents the outcomes achieved by the Hussein search algorithm in contrast to the other algorithms when searching for N items across varying input sizes. while considering input sizes of 8 MB and 16 MB, it has been observed that the Hussein search method exhibits a time requirement that is 20% lower than that of the binary search strategy, and 17.3% lower than that of the ternary algorithm, while searching for all items. Hussein's search method demonstrates a search speed that is approximately 494% greater than that of binary search when applied to a dataset of 16 MB. Table 1 illustrates the speedup, which quantifies the extent to which the Hussein search algorithm outperforms the binary search algorithm across various input sizes. Table I illustrates the observed increase in search speed across various input sizes.

In the Hussein search algorithm the searching process about an item requires O (1), which means searching n items requires only O(n) in comparison with the binary search algorithm that requires O(n log n). Fig. 3, show the results obtained by the Hussein search algorithm in comparison to the other algorithms for different input size. For input size (8 M,

16 M) searching all the items using the Hussein search algorithm requires time that is 20% smaller than the binary search algorithm and 17.3 % smaller than the Ternary algorithm. The search speed in the Hussein search algorithm is increased by about 494% than the binary search for 16 M of data. Table I, and Fig. 3 show the speed up that represents how much Hussein's search is faster than the binary search algorithm in searching about all the input sizes.

TABLE I. THE SPEED UP IN SEARCHING DIFFERENT INPUT SIZE

	Binary	Trenary	Hussein	Speedup
4 k	2	2	4	50%
8k	5	6	2	250%
16 k	4	6	2	200%
32 k	12	13	3	400%
64 k	27	24	5	540%
128 k	43	22	10	430%
256 k	89	109	20	445%
512 k	189	222	39	485%
1 MB	349	419	69	506%
2MB	703	825	140	502%
4MB	1398	1606	259	540%
8MB	3343	3568	629	531%
16MB	5813	6784	1176	494%

Fig. 3. Hussein search algorithm speed up.

```

static float prehusn1(int[] arr)
{
    float avg;
    avg = (arr[0]/2) + (arr[1]/2);
    for(uint i=2;i<arr.Length;i++)
    {
        avg = (avg * i / (i + 1)) + (arr[i] / (i + 1));
    }
    return avg/arr.Length;
}

static int prehsn2(float avg, int[] arra, uint[] arrb, uint[] arcc)
{
    for(uint i = 0; i<arra.Length;i++)
    {
        uint l = (uint)(arra[i] / avg);
        arrb[l]++;
        if (arrb[l] == 1)
            arcc[l] = i;
    }
    return 0;
}

```

Fig. 4. The implementation of mathematical operations in Hussein search algorithm.

Implementation of Hussein Search Algorithm: as mentioned previously Hussein Search algorithm is implemented in C#, with binary search algorithm and ternary algorithm on the same environment and the same data. Fig. 4 and 5 represent the implementation of the main functions of the Hussein search algorithm.

```

static int HusnSearch(int x, float avg, int[] arra, uint[] arrb, uint[] arcc)
{
    uint l = (uint)(x / avg);
    if (l<arrb.Length)
    if (arrb[l]>0)
    {
        uint m = arcc[l];
        for(uint i =m; i<m+arrb[l];i++)
        {
            if (arra[m] == x)
                return (int)m;
        }
        return -1;
    }
    return -1;
}

```

Fig. 5. The implementation of the Hussein search algorithm.

V. CONCLUSION AND FUTURE WORKS

In this study, we introduce the Hussein search algorithm, a novel informed search approach that leverages a straightforward prediction method, basic arithmetic operations, and a simple data structure. The findings demonstrate that the Hussein search algorithm outperforms previous search algorithms in terms of time complexity, particularly when dealing with substantial data sets. Moving forward, there are several avenues for future research. Firstly, it would be valuable to explore the algorithm's performance under different search scenarios and input distributions. Additionally, investigating potential optimizations and further enhancements to the algorithm could yield even more efficient search capabilities. Finally, conducting comparative studies with other state-of-the-art search algorithms would provide a comprehensive evaluation of the Hussein search algorithm's effectiveness. The procedure operates on an array that has been sorted, with the underlying assumption that the data is spread equally. The Hussein search algorithm has a time complexity of $O(n)$ for finding n items. In contrast, the binary search algorithm has a time complexity of $O(n \log n)$, while the sequential search technique requires $O(n^2)$ in the worst case. Given the assumption of a sorted array, the proposed technique offers a notable advantage in terms of computational simplicity and a reduction in the number of comparisons required for item search. Specifically, the algorithm achieves a time complexity of $O(1)$ when searching for an item by index rather than by value. Fig. 6 presents a comparison of the running times for various input sizes. The future objective is to enhance the algorithm based on simple prediction methods to operate with the same time complexity for an unsorted array. Additionally, we aim to offer a sorting algorithm that utilizes the same mathematical processes and achieves linear time complexity in the worst-case scenario.

Testing the Usability of Serious Game for Low Vision Children

Nurul Izzah Othman, Hazura Mohamed, Nor Azan Mat Zin

Faculty of Information Science and Technology, The National University of Malaysia, 43600 Bangi, Malaysia

Abstract—Serious games are prodigious tools for building language, science and math knowledge and skills. Despite a growing number of studies on using serious games for learning, children with visual impairment have obstacles when playing the games. Low vision children have a visual balance that can be assisted with assistive technology. A 2D serious game for learning Mathematics is developed using Unity for low vision children. In order to enhance the game's accessibility for low vision children, accessibility elements have been implemented in the serious game prototype. Those elements are screen design (buttons, menus, and navigation), multimedia (text, graphics, audio, and animation), object motion, and language. Upon completion of the serious game, usability testing was done to identify the accessibility of the serious game to low vision children based on the usability level. The observation technique is used for analysing the serious game. The overall usability score is good based on aspects of effectiveness, efficiency and user satisfaction tested.

Keywords—Serious game; learning; low vision; usability; accessibility

I. INTRODUCTION

Nowadays, information and communication technologies (ICT) are used in education. We can find a lot of educational applications that can help young learners learn. Several ICT applications are on the market, such as e-books, multimedia courseware, and games [1] [2]. Gaming is a very popular activity enjoyed by children. Thus, a serious game is the most promising tool for helping children learn. A serious game is used beyond entertainment [3][4]. Serious games are prodigious tools for building language, science, and math knowledge and skills. Despite a growing number of studies on using serious games for learning, children with visual impairments have obstacles when playing the games. There are two categories of visual impairment: blindness and low vision. Low vision children have a visual balance that can be assisted with assistive technology. The World Health Organisation defines low vision as visual acuity between 20/70 and 20/400 with a possible correction of 20 degrees or less [5]. Low vision children have obstacles accessing graphical elements in games. A preliminary study conducted by [6] indicates that low vision has several accessibility issues, such as visual, animation, audio, and navigation. They need to look at the graphical elements from a very close distance because the size of the text and graphics is small. The colour contrast between the graphics and background is low. The choice of dark colour is unsuitable for the children. They also have difficulties navigating the menus and buttons in games. They also focus on one sound at a time. Besides, fast animation movements affect their vision

when playing games. Thus, to ensure they can play the game, a 2D serious game for learning Mathematics is developed using Unity for low vision children. This serious game runs on mobile devices using the Android operating system. This game's storyline is about a rabbit named "Bunny" trying to save his friends who a tiger kidnaped. Bunny needs to complete the Mathematical tasks provided for each game level to obtain the instructions and tools used in the next challenge. Hints and tools will help Bunny save his friends from the tiger. This game consists of three levels of Mathematical tasks, which are based on the Mathematics Syllabus for Year 1. The game's content consists of an introduction to numbers, shapes, addition, and subtraction.

Serious games should be easily accessible to low vision children. The game design should be flexible, with an interface adapted to the accessibility requirements of low vision children. In order to enhance the game's accessibility for low vision children, accessibility elements have been implemented in the serious game prototype. Those elements are screen design (buttons, menus, and navigation), multimedia (text, graphics, audio, and animation), object motion, and language. The children can set the appropriate background colour and contrast level to see menus and buttons more clearly based on their vision level. The game's navigation is designed to be consistent throughout the game. The text size is large and adapted to the children's vision. The background colour has a high colour contrast. The use of bright colours and large graphics are implemented in the game. Children can adjust the background colour. Thus, children can easily identify and move objects in the game. The background audio must be clear and adjustable based on the needs of children with low vision. Important objects in the game include background sounds to help the children identify the position of the object. The game's task instructions are accompanied by background audio so children can easily understand the game's storyline. Besides, the language used in the game should be easy to understand. For the proposed serious game, the Malay Language is used because it is used in learning Mathematics in primary school. The movement of objects in the game can also be adjusted according to the child's vision so that it is not too fast. The movement of objects in the game is also minimal so that children can control the game based on their needs. Upon completion of the serious game, usability testing was done to identify the accessibility of the serious game to low vision children based on the usability level. Usability testing is conducted to ensure the serious game fulfills the children's accessibility requirements. The serious game user interface is depicted in Fig. 1.

Fig. 1. Serious game user interface.

Thus, this paper presents the usability testing of Math Game, a serious game prototype that was developed specifically for low vision children aged seven years old. The serious game is developed based on the accessibility requirements of low vision children. The effectiveness, efficiency, and user satisfaction of the serious game are tested in the usability testing. The observation technique is used for analysing the serious game. The usability testing aims to identify the serious game's usability level for low vision children.

This paper is organised as follows: Section I discusses introduction, while Section II describes the related work. Section III describes the methodology and Section IV and Section V discusses the results and discussion, respectively, while Section VI presents the conclusion and plan for future work.

II. RELATED WORK

The International Organization for Standardization (ISO) 9241-11 (1998) defines usability as the ability of a product to be used by users to accomplish certain goals effectively, efficiently, and with user satisfaction [1]. Usability also refers to whether a product is easy to use. Usability testing allows a product to be usable by target users to meet accessibility requirements. Based on the ISO 9241-11 definition, usability consists of the following components:

Effectiveness: The accuracy and completeness with which a user can achieve a certain goal in a certain environment.

Efficiency: The effort the user gives to complete a task and achieve the objective of using an application or system.

User Satisfaction: User comfort and acceptance of the system.

Usability testing is conducted to identify usability problems before releasing the serious game in its real context. The usability testing ensures the serious game fulfills the children's accessibility requirements. It is because both usability and accessibility should be considered good design practices and involved in system and application development stages. There is some overlap between the concepts of usability and accessibility. Accessibility enables particular users to access ICT applications independently without accounting for their disability. At the same time, usability refers to the ability of the ICT application to carry out the intended function effectively, efficiently, and with satisfaction when used by users. Therefore, accessibility specifically refers to disabled users, while usability refers to the general population. According to [7], usability testing is also suitable for assessing ICT applications for accessibility.

In human-computer interaction (HCI), usability is one of the focus areas where specified users can use a product to achieve goals effectively, efficiently, and satisfactorily [8]. When designing for usability and accessibility, a usability study should be conducted on the ICT application. Usability is defined as how efficiently user requirements are fulfilled [9]. It has developed usability criteria for accessible websites based on their effectiveness, where the user carries out tasks without experiencing barriers such as clear link texts. For efficiency, the user obtains the desired information quickly, and the system is usable. In contrast, for satisfaction, the user feels joy when navigating the website because the screen design facilitates navigation by the disabled user and avoids the accessibility barrier.

Several evaluation factors in usability testing include screen appearance, consistency, accessibility, navigation, interactivity, and content [8]. The literature comprises many usability testing types, methods, measurements, and respondents. Besides, usability research could be done in many forms based on the scope and goal of the ICT application. There are activities for usability research, such as focus groups, task analysis, user observation, interviews, and surveys. The activities provide insights into how users interact with the ICT application [10]. For example, from the observation and interview, the respondent's reaction when using the product will help the researcher understand the user's satisfaction with the ICT

application [11]. A summative usability evaluation has been done using observation and questionnaires to measure the usability of the Mudah.my mobile application's efficiency, effectiveness, and satisfaction [12]. Ten respondents are involved in the study and will perform five application tasks. Based on the study, the results show that the Mudah.my mobile application is easy to use and consistent. A usability study was also done using the Technology Acceptance Model to evaluate the usability of virtual game-based simulation to help nursing students improve their pediatric nursing skills [13]. The methods involved heuristic evaluation with experts, think-aloud activities while playing the game, and interviews. The study shows high user satisfaction, and they learned about pediatrics care easily. Observation has also been conducted to evaluate the usability of the TVET m-learning application for 30 Multimedia Software Technology course students. A questionnaire was used to measure the usability elements such as system usefulness, ease of use, ease of learning, and user satisfaction. A special room and tools, such as a video camera, notebooks, mobile devices and task lists, are prepared for this usability testing. This study's results showed that students accepted the TVET m-learning application, and the usability score value was at a high level [14].

In addition, usability metrics have been implemented to evaluate the quality of the ICT applications. However, the metrics used for usability testing always change due to new inventions in ICT applications [15]. There are numerous usability measurement tools for usability testing. Website Analysis and Measurement Inventory (WAMMI) is a usability measurement tool that assesses website usability. WAMMI is a questionnaire developed by the Human Factors Research Group (HFRG). WAMMI comprises usability factors such as attractiveness, controllability, efficiency, and helpfulness [16]. WAMMI is used to evaluate the usability level of the Ministry of Education Malaysia (MOE) web portal and provide usability enhancement based on the testing results. There are two stages of usability testing, such as pre-usability testing to evaluate the current web portal and post-usability testing for the web portal that has been enhanced. The pre-usability testing result showed that the usability of the current web portal was at a moderate level. In contrast, the post-usability testing result showed that usability improved significantly [16].

Besides, the Software Usability Measurement Inventory (SUMI) was used as a usability measurement tool to measure system usability. SUMI was used to evaluate user experience when it was introduced in the 1990s. SUMI consists of usability criteria such as effectiveness, efficiency, satisfaction, error management, consistency, adaptability, and compatibility. This evaluation tool assesses a semantic image retrieval application, WebSIR. The results showed that 85% of respondents were satisfied with this application, which is easy to use [16]. Another study by [17] evaluated the usability of South Tangerang E-Government using SUMI. Based on the study, the usability scores of the e-government website are taken as a benchmark for the system's usability. The system usability scores are 85 for effectiveness, 81.5 for efficiency, and 72.5 for satisfaction. Thus, the usability of the e-government website is good.

A representative sample of users must conduct usability testing because users are different and have different problems [18]. Suitable usability testing methods and measurement should be considered when planning the testing with users, especially children. Usability testing with children consists of introspection, direct observation, thinking aloud, and interaction. Simple observation is used to observe users as they perform their tasks. Thus, this technique has been recognised as one of the best techniques for usability testing [19]. The usability testing should be planned before it is conducted on a real user.

III. METHODOLOGY

The usability testing method used in this study is direct observation. The observation method is conducted to evaluate the user experience of the product. This method involved evaluating users by observing them carrying out the tasks provided. Observations are conducted based on effectiveness, efficiency, and user satisfaction. User satisfaction is subjective. Thus, interviews were also conducted with low vision children to get feedback regarding their satisfaction level with the tested serious game. During the interview, emoticons (like, normal, dislike) are prepared to observe the user's reaction to the game. Observations will be recorded on the user satisfaction checklist. Users are required to perform tasks using the provided prototypes.

This usability testing used a selected study sample conducted at Sekolah Kebangsaan Pendidikan Khas Jalan Batu, Kuala Lumpur, and Sekolah Kebangsaan Pendidikan Khas Muar. This testing involves fifteen to seven-year-old low vision children (nine boys and six girls). In order to conduct usability testing, there are ethics that the researcher must follow. Since the testing was conducted during the COVID-19 pandemic, it complied with the Standard Operating Procedures (SOP) set by the Ministry of Education. Before conducting the usability test, consent from parents or guardians is required to ensure that the study meets research guidelines and ethics. The purpose of this research is also explained to the teachers involved.

A. Usability Testing Procedures

The activities involved in usability testing include determining the testing objective, preparing the instruments and testing tools, identifying the task scenario, preparing the testing checklist, and measuring usability testing. The testing procedure begins with the preparation of the testing instruments and tools. The testing procedure is further explained in the following sections.

1) *Determination of testing objective:* This usability testing was conducted to verify the accessibility of serious games to low vision children. Evaluation is important to ensure serious games accomplish development objectives. The evaluation is conducted based on the ISO 9241-11 definition, which covers effectiveness, efficiency, and user satisfaction concerning serious games.

2) *Testing instruments and testing tools preparation:* The testing instruments are prepared before the test is conducted. The testing instruments are reviewed by lecturers who are

experts in multimedia and games. The testing instruments consist of a serious game prototype, a usability testing task list, an observation checklist, a video recording, and a screen recording. Testing tools, such as tablets, a video camera, and a screen recorder, are prepared to support the usability test.

3) *Identify task scenarios*: Usability testing is conducted by giving the user a task scenario while the user plays the game. Researchers help users play the game when needed. The task scenario is an action that needs to be performed by the user during interface testing. The task scenario is based on the game task instructions. The task scenario is prepared according to the game screen and the game's design, such as the start screen, the narration screen, and the game task screen. Researchers use these task scenarios to ensure that all testing activities are going as planned.

4) *Testing checklist preparation*: A checklist is prepared based on the usability construct [1], [19], which consists of effectiveness, efficiency, and user satisfaction. The usability checklist consists of sixty-three items. Checklists are provided based on game functions and actions that players need to perform while playing the game. Table I shows the contents of the usability checklist.

TABLE I. THE CONTENTS OF THE USABILITY CHECKLIST

Accessibility Elements	Effectiveness	Efficiency	User Satisfaction
Menu and Button Screen Design) and Navigation	Children can click the menu and button functions.	Children easily click on menus and buttons. Children click on the right menu and button.	Children's reactions when they click the menu and button.
Multimedia (Graphics, Animation, Text, and Audio)	The multimedia on the screen are interesting for children. The audio used appeals to children.	Children click objects in the game easily. Children do not confuse while playing.	Children's reactions to multimedia in the game.
Object Movement	Adjustable speed of objects helps children to play.	Object movement makes it easier for children to click on the correct object in the game.	Children's reactions to the object's movement.
Language	The language used in the game is understandable and suitable for the children's ability.	The language used does not confuse or cause children to make mistakes while playing.	Children's reactions to the language used.

5) *Measurement of usability testing*: The measurement of effectiveness, efficiency, and user satisfaction are measured using the usability score [15], [20]. There are three observation options, effectiveness, efficiency, and user satisfaction, for the checklist, with the score represented for each option. Scores are awarded based on completing each

task. Scores are then accumulated based on the three observation options. The usability measurements are as follows:

a) *Effectiveness Measurement*: Effectiveness measures is the ability of the user to complete a task within the game. If a task is completed successfully, a score of 5.0 will be marked on the effectiveness checklist item. Half of the task is completed or fails to complete; a score of 2.5 and 0 will be marked on the checklist item, respectively. Table II shows the scoring guide for the effectiveness checklist item during the observation.

TABLE II. EFFECTIVENESS SCORING GUIDELINES

Score	5.0	2.5	0
Details	<p>When the children manage to complete the task successfully, the accessibility elements on-screen help children playing the game as below:</p> <ul style="list-style-type: none"> -Children have no problem navigating the button and menu display on the screen. -Children understand the instructions of the game. 	<p>Children completed half of the task but had several issues, as below:</p> <ul style="list-style-type: none"> -Children have difficulty navigating certain buttons and menu displays on the game screen, but they can still proceed with the game. -Multimedia elements do not consistently attract children's attention. 	<p>Children do not complete the task below:</p> <ul style="list-style-type: none"> -Children have a problem finding all the menus and button displays on the game screen. -Children do not understand the game instructions.

Thus, the usability score for the effectiveness, X, is formulated as:

$$X = (\sum \text{Score for each effectiveness checklist item}) / \text{Total effectiveness checklist item} \quad (1)$$

b) *Efficiency measurement*: Efficiency is measured based on the duration of task completion time, which is the average task completion time. The average task completion time is a reference in efficiency testing [21]. The efficiency aspect is better when the user completes the task faster. The efficiency checklist has three observation options, with the score represented for each option. If the time is taken by the child to complete the task is equal to or faster than the average task completion time, then a score of 5.0 will be marked on the efficiency checklist item. Whereas, if the time the child takes to complete the task exceeds the average task completion time, a score of 2.5 will be marked on the efficiency checklist items. However, if the task fails, a score of 0 will be marked on the checklist items. Table III shows the scoring guide for the efficiency checklist item during the observation.

TABLE III. EFFICIENCY SCORING GUIDELINES

Score	5.0	2.5	0
Details	Children choose the right menu and button based on the game function The assistance provided when children play the game is minimal.	Some menus and buttons in the game are not selected correctly. However, they still could proceed to play the game. Some of the tasks require help.	Children are difficult to choose the right menu and button. Children play the entire game with assistance from the researcher

Thus, the usability scores for the efficiency, X, formulated as:

$$X = (\sum \text{Score for each item of efficiency checklist}) / \text{Total Efficiency Checklist item} \quad (2)$$

c) *User satisfaction measurement*: User satisfaction measurement consists of like, neutral, and disliked. A 5.0 score will be marked on the user's satisfaction checklist items if a child likes the serious game. If the child's reaction is neutral, a score of 2.5 will be marked on the checklist items, and if the child does not like the game, a score of 0 will be marked on the checklist items. Table IV shows the scoring guide for the user satisfaction checklist item during the observation.

TABLE IV. USER SATISFACTION SCORING GUIDELINES

Score	5.0	2.5	0
Details	Children show emoticons provided with "happy" signs. Children can focus on playing the game. Children finish the game successfully.	Children show emoticons provided with "neutral" signs. Children can focus on some of the games. Children stop playing in the middle of the game	Children show emoticons provided with signs "dislike". Children are not focused while playing the game. Children are unable to finish the game.

Thus, usability scores for the user satisfaction category, x, can be formulated as:

$$X = (\sum \text{Score for each item of user satisfaction checklist}) / \text{(Total User Satisfaction Checklist item)} \quad (3)$$

The average value of each usability category is considered the use score for that category. The overall usability score is the average value of usability scores for three usability categories. Thus, the overall usability score, X, can be formulated at Table V:

TABLE V. USABILITY SCORE

Weak	Moderately Good	Good
$.0 \leq x \leq 2.49$	$2.5 \leq x \leq 3.49$	$3.5 \leq x \leq 5.0$

6) *Implementation of usability test*: A pilot study is conducted on the instrument to test its reliability before it is

used in the actual testing. The pilot study involved a sample of five to seven-year-old low vision children. The pilot study was conducted to ensure that the assessment faced no problems. Through a pilot study, children's reactions, behaviours, and play tasks can be recorded. During the usability testing, children played the game with minimal assistance. The camera is used to record testing sessions. Screen recorder software records children's activities on the screen when playing the game. During the observation, researchers must observe the child's actions and reactions to the game tested. Children's actions in the game are recorded on the provided task scenario checklist and transferred to the usability checklist. Scores are given on the user's achievement in the task, which is recorded on the usability checklist based on the effectiveness, efficiency, and user satisfaction constructs. The data collected was analyzed with a descriptive analysis method. Fig. 2 shows the usability testing preparation.

Fig. 2. Usability testing preparation.

IV. RESULTS

The usability measurement is done by analysing the user's success in completing tasks. Usability data is collected as a usability score and determines whether the game design goals

are achieved and the need to improve the serious game. A user's success score indicates how successful the user is at completing a task. Scores are then accumulated based on three categories of usability: measurement of effectiveness, efficiency, and user satisfaction.

Based on the analysis, the effectiveness score for the game screen is 4.74. The children complete the tasks successfully on the game screen. Children begin to adapt in the early stages of the game. They make mistakes when selecting objects in the game and choosing the wrong answer. However, they can still reselect the correct button and complete the task. When the children can play at a higher level in the game, the user can adapt to the game interface. Fig. 3 shows the graph of the effectiveness score for each screen.

Fig. 3. The graph of effectiveness score.

Efficiency scores are given based on the time it takes to complete the task and efficiency measurement metrics. For the level 1 task, the average time the children took to complete the task was seven minutes. Children need more time to complete games because they begin to explore the game interface and begin to adapt to the game environment. The average time the children complete the level 2 and level 3 tasks is five minutes. At level 2 and 3 game tasks, children become more efficient at playing games because they can already adapt to the game interface and environment. They already understand how to play the game. The efficiency score is 4.55. Based on the usability score, the efficiency level is good. The game task can be executed smoothly and easily. Serious game efficiency analysis shows children click on the right buttons and menus to play the game. The assistance given to children is minimal, and they easily correct mistakes. Therefore, children can play the game easily and smoothly. Fig. 4 shows the graph of the efficiency score for each screen.

Fig. 4. The graph of efficiency score.

User satisfaction is measured based on the user's feelings when playing serious games, such as their reactions to screen design, buttons, menus, and games. For user satisfaction constructs, the user satisfaction score is 4.92. Based on usability scores, the level of user satisfaction is good. This shows that the children react positively to playing the game. Children react positively to the game interface, such as buttons, menus, graphics, and animations. Multimedia elements such as audio and in-game animations also attract users to play games. Fig. 5 shows the user the graph of the user satisfaction score.

Fig. 5. The graph of user satisfaction score.

Based on aspects of effectiveness, efficiency, and user satisfaction tested, the overall usability score is 4.76, which is good. Based on descriptive usability analysis, elements of accessibility such as screen design (buttons, menus, and navigation), multimedia, language, and object motion are important in increasing the usability of serious games for low vision children.

V. DISCUSSION

In the context of the usability of serious games, accessibility elements such as screen design, multimedia, language, and object motion help children complete the game successfully. The game interface features a simple screen design with larger buttons, menus, and icons to prevent accidental clicks, enabling children to interact with the game easily. This is consistent with a previous study by Allah et al. [22], which found that screen design elements such as menus and buttons were considered for improving the usability of the user interface.

Animations provide visual and auditory feedback when objects are selected or actions are performed, aiding children to choose the correct answers during gameplay. This finding aligns with the results of Ghanouni et al. [23], who emphasized the important role of animations in game design for children. The game also includes audio to assist children with low vision in understanding the content. The option to adjust audio volume ensures that children can set it to a comfortable level or mute it if needed. This outcome demonstrates that background audio associated with objects in the game assists users in selecting the correct object or answer, as reported by Najjar et al. [24].

Brighter colors are used for important in-game objects. A good contrast between text, graphics, and background colors enhances readability, allowing children to easily identify important object. Concise language helps children understand and follow the game's tasks, and these findings are in line with previous research conducted by Benaïda [25]. However, this study goes further by demonstrating that object speed can be adjusted based on children's preferences to help children control the game.

Furthermore, when children navigate the game interface without confusion, they enjoy the gameplay and feel satisfied with the experience [26]. Multimedia elements make the game more enjoyable for children [14]. When children can easily understand the gameplay and objectives, they experience a sense of accomplishment and satisfaction. Positive reinforcement through sounds or animations can keep users engaged and motivated [27]. Therefore, the use of accessibility elements on each screen is important for helping low vision children play games.

VI. CONCLUSION

In this study, usability testing on a serious game was done successfully, involving low-vision children playing the game. The testing has been done through observation. The results of usability testing show that the effectiveness aspect achieved a good average score of 4.74, while the efficiency aspect obtained an average score of 4.55. Moreover, the user satisfaction aspect received a high average score of 4.92. Thus, the overall level of usability is rated as good, with an average usability score of 4.76. Accessibility elements such as multimedia, screen design, language, and object motion enhance the usability of serious games. With this testing, the prototype will be more usable. Therefore, this serious game meets the usability aspects of serious games for low vision children. In conclusion, this study shows that this serious game

is useful for children with low vision. The design of this game helps children play and learn more comfortably and improves their play experience. Future research could be done on designing an accessibility design for serious games for other disabilities, and new technology, such as artificial intelligence, could be implemented into the game design.

ACKNOWLEDGMENT

This research has received funding from the Ministry of Higher Education and the Faculty of Information Science and Technology, National University of Malaysia under FRGS Program (FRGS/1/2020/ICT03/UKM/02/4).

Cybersecurity Advances in SCADA Systems

Machine Learning-based Insider Threat Detection and Future Directions

Abstract—The management of critical infrastructure heavily relies on Supervisory Control and Data Acquisition [SCADA] systems, but as they become more connected, insider attacks become a greater concern. Insider threat detection systems [IDS] powered by machine learning have emerged as a potential answer to this problem. In order to identify and neutralize insider threats, this review paper examines the most recent developments in machine learning algorithms for insider IDS in SCADA security systems. A thorough analysis of research articles published in 2019 and later, focussed on variety of machine learning methods, have been adopted in this review study to better highlight difficulties and challenges being faced by professionals, and how the study will contribute to overcome them. The results show that, in addition to conventional methods, machine-learning based intrusion detection techniques offer important advantages in identifying complex and covert insider attacks. Finding pertinent insider threat data for model training and guaranteeing data privacy and security are still difficult to address. Ensemble techniques and hybrid strategies show potential for improving detection resiliency. In conclusion, machine learning-based insider IDS has the potential to protect critical infrastructures by strengthening SCADA systems against insider attacks. The similarities and differences between cyber physical systems and SCADA systems, emphasizing security challenges and the potential for mutual improvement were also reviewed in this study. In order to be as effective as possible, future research should concentrate on addressing issues with data collecting and privacy, investigating the latest developments in technology, and creating hybrid models. SCADA systems can accomplish proactive and effective defence against insider attacks by integrating machine learning advancements, maintaining their dependability and security in the face of emerging threats.

Keywords—Threat detection; SCADA security; machine learning-based intrusion detection; cyber-physical systems security; insider attack prevention

I. INTRODUCTION

SCADA systems are widely used in areas such as telecommunications, water management, electricity [1], [2]. These systems employ specialized control units like Master Terminal Units (MTUs) and Remote Terminal Units [RTUs] to automate and manage industrial operations [3]. With the advent of Industry 4.0, the integration of Internet of Things [IoT] devices into Cyber-Physical Systems (CPS) has given rise to Industrial IoT. This technology enables real-time monitoring of machine status, providing operators with immediate feedback and facilitating faster operations in industries that heavily rely on electrical machinery, particularly induction motors [1], [4].

Modernized SCADA systems have evolved into highly advanced and intricate technological systems. The adoption of open standard protocols has significantly enhanced their productivity and profitability. SCADA architecture offers numerous benefits, including improved data access, cost-effectiveness, flexibility, configurability, accessibility, and scalability [5], [7]. However, these advancements have also introduced new threats and vulnerabilities [6]. Similar concerns have been raised by other researchers [2], who emphasized the increasing cyber-attacks on SCADA systems due to their rapid evolution, automation, real-time operation, and decentralized, multi-component design. A few researchers [6],[4],[8] highlighted the complexity and severity of the situation, attributing it to the utilization of the Internet for communications within SCADA systems.

Scope of the Review: The study concentrated on investigation and analysis of recent developments in Insider Intrusion Detection Systems (IDS) in SCADA systems. A variety of machine learning methods, deep learning models, advanced algorithms, and other new techniques utilized for insider IDS in SCADA contexts were covered (Tables I to III). The studies have also examined the difficulties encountered when putting these ideas into practice and assess how well they work at identifying insider threats [9]. In this study the developments over the past five years have been discussed.

Research Problem: As the review study focuses on addressing key challenges by exploring the advancements and issues in insider threat detection systems (IDS) for SCADA environments. The research problem lies here is enhancing the detection and prevention of insider threats within SCADA systems using machine learning-based approaches. By examining the latest developments in this field, we aim to provide a comprehensive understanding of how machine learning techniques can be harnessed to fortify SCADA systems against insider attacks.

The significance of this study is twofold: Firstly, it offers insights into the application and efficiency of Insider IDS in SCADA systems, highlighting their capabilities to identify complex and covert insider attacks. Secondly, it delves into the limitations and obstacles faced while implementing these systems, guiding practitioners and researchers towards more effective and secure solutions. By bridging the gap between the evolving threat landscape and SCADA security, this review contributes to the advancement of cyber-physical system protection and ensures the continuous operation of critical infrastructures [8].

A. *Research Objectives: The Key Objectives of this Study are;*

- 1) to give a thorough review of insider IDS's application and efficiency in SCADA systems.
- 2) to recognize the main issues and new developments in insider threat detection and prevention in SCADA environments.
- 3) to assess the effectiveness and constraints of the current insider IDS systems and suggest additional areas for development.

B. *Research Questions: Based on above Objectives the Study Addressed following Questions;*

- 1) What are the prevalent methods and strategies employed in insider IDS for SCADA systems, and how have they evolved to address the growing challenges posed by insider attacks?
- 2) What are the key issues and challenges in insider threat detection and prevention in SCADA environments, and what are the recent advancements in machine learning-based intrusion detection techniques to overcome these challenges effectively?
- 3) How effective are the current insider IDS systems in SCADA environments, and what are their strengths and weaknesses? Additionally, what are the potential areas for further development to enhance the capabilities of insider IDS systems in SCADA?

This paper is structured as follows: In the Review of Literature section, we delve into the comprehensive body of existing research to establish the context and identify the gaps that motivate our study. The Review Methodology section outlines our approach to analyzing recent advancements and challenges in Insider IDS for SCADA systems. We have then presented our findings in the Discussion and Analysis section, where we explored the strengths, limitations, and potential solutions of different techniques. Then, at challenges and recommendations section, we addressed the identified gaps and provide insights into enhancing the effectiveness of Insider IDS. The Comparison of IDS SCADA and Cyber Physical section highlighted the distinctive features of both realms and their interaction [10]. Finally, we concluded by summarizing our key findings, followed by a discussion of limitations and future research directions.

By following this structure, we aim to offer a holistic understanding of the advancements and challenges in Insider IDS for SCADA systems, providing valuable insights to both researchers and practitioners in the field (Table IV).

II. REVIEW OF LITERATURE

A. *Machine Learning Techniques for Insider IDS in SCADA Systems*

SCADA systems are vital in maintaining and controlling different infrastructures, such as power grids, water treatment

facilities, and transportation networks. These systems come with higher risk of insider attacks as they become more networked and accessible [10], [11]. The security and dependability of SCADA systems are seriously threatened by insider assaults carried out by anyone with authorized access to the system.

Traditional security solutions frequently fall short in addressing these internal risks. Machine Learning [ML] based Insider Intrusion Detection Systems [IDS] have become a potential method for improving insider attack detection and prevention in SCADA systems. The machine learning is commonly known as a branch of artificial intelligence [12]. ML has the capacity to examine massive amounts of data, spot trends, and spot unusual behaviour that might be indicative of hostile intent.

For insider IDS in SCADA systems, machine learning techniques comprise on developing models from past data in order to understand typical system behaviour and spot abnormalities that can point to insider assaults. These methods benefit from flexibility and the capacity to learn from fresh facts, enabling them to advance alongside new dangers [13].

The use of machine learning in insider IDS enables the detection of intricate and covert attacks that rule-based or signature-based methods can miss. Machine learning algorithms may recognize small anomalies and identify aberrant actions that depart from established standards by learning patterns and behaviours from data.

It is not without issues, yet, to implement machine learning methods for insider IDS in SCADA systems [1], [14]. As recognized insider threat data is often difficult to come by due to the frequency of such instances, data collection, pre-processing, and classification can be challenging jobs. Furthermore, it is essential to protect the confidentiality and security of critical SCADA system data while developing machine learning models [14].

The goal of the current study is to examine the most recent developments in insider IDS techniques for SCADA systems. It has explored the many methodologies, approaches, and algorithms applied in this field (Tables I to II). The review has also gone through the advantages, difficulties, and potential future research paths of using insider IDS to improve the security and resilience of SCADA systems [15].

Insider IDS in SCADA systems may strengthen the ability to identify and respond against insider attacks by utilizing machine learning techniques. The subsections below will provide in-depth discussion on particular machine learning techniques and methodology used in insider IDS, as well as the difficulties and opportunities presented by their application in SCADA systems [16].

TABLE I. IDS SOLUTIONS COMPARISONS

IDS Solution	Algorithm Description	Scalability	Limitations	Advantages	Conditions for Algorithm Use
Snort	Rule-based Systems	Snort is suitable for small to medium-sized networks, easily scaled up by adding more hardware or utilizing distributed deployments [10].	Limited in detecting novel or zero-day attacks, requires regular updates to stay up-to-date with emerging threats [10].	Easy customization and quick deployment, widely used and well-established in various network environments.	Rule-based systems are the primary approach in Snort. Machine learning and statistical analysis are used to a limited extent for rule generation and identifying abnormal behavior. [10],[14]
Suricata	Rule-based Systems	Suricata is highly scalable and can handle large network traffic volumes, making it suitable for enterprise-level deployments.	Deployment complexity may require more expertise, continuous tuning for minimizing false positives [15].	Accurate detection of known attack patterns, data fusion capability enhances detection of complex attack scenarios.	Rule-based systems are the primary approach in Suricata. Data fusion is used to correlate data from multiple sources and enhance detection capabilities [15]. [16].
Bro/Zeek	Rule-based Systems, Statistical Analysis	Bro/Zeek is highly scalable and can handle large network traffic volumes, making it suitable for enterprise-level deployments.	Requires more computational resources due to the comprehensive analysis it performs, potential performance impact in high traffic scenarios.	Comprehensive network monitoring capabilities, rule-based approach with added statistical analysis for anomaly detection.	Rule-based systems are the primary approach in Bro/Zeek. Statistical analysis is used to identify anomalies and detect patterns within network traffic [19].20].
McAfee	Rule-based Systems, Machine Learning	McAfee IDS solutions are designed for scalability and can be deployed in various network environments, including small to large enterprise networks.	Complexity in managing machine learning models, potential false positives/negatives depending on training data quality.	Combination of rule-based systems with machine learning techniques for enhanced threat detection, suitable for different network environments [23].	Rule-based systems are the primary approach in McAfee IDS solutions. Machine learning is used to detect unknown or evolving threats in some versions of the solution [20],[25].
Cisco Firepower IPS	Rule-based, Statistical Analysis, Graph-based, Machine / Deep Learning, Data Fusion, NLP, Hybrid Approaches	Cisco Firepower IPS is designed to scale for large enterprise networks and can handle high network traffic volumes.	Complex deployment and management, potential resource-intensive processing for advanced techniques, dependence on quality training data.	Comprehensive set of detection techniques, ability to handle high network traffic volumes, advanced approaches like machine learning and graph-based analysis [14], [16].	Multiple algorithms are used based on the specific requirements and features. The solution employs rule-based systems, statistical analysis, machine learning, deep learning, graph-based approaches, and data fusion [23].

In order to solve the particular difficulties, problems, and traits of insider IDS [Intrusion Detection Systems] in SCADA systems, machine learning approaches have been developed and customized [17]. These modifications take into account the unique demands and limitations of SCADA systems, such as the necessity for rapid and precise anomaly detection and real-time monitoring and large-scale data processing. We have gone through some of the most significant modifications made to machine learning methods for insider IDS in SCADA systems in this part.

- **Feature Engineering:** In SCADA systems, feature engineering is key to machine learning for insider IDS. Domain-specific features must be identified and designed due to the nature of SCADA data, which consists of time-series measurements, sensor readings, and control orders [18]. These characteristics record crucial facets of system activity and give machine learning models useful input. Statistical measurements, signal processing methods, and frequency domain

analysis are a few examples of features frequently found in SCADA systems.

- **Imbalanced Data:** Compared to typical system behaviour, insider attacks are frequently infrequent occurrences. As a result, datasets become unbalanced, with a vastly greater number of regular instances than attacks [1]. Machine learning algorithms may have trouble effectively identifying the minority class of attacks. The performance of machine learning algorithms can be strengthened by rebalancing the dataset using a variety of techniques, such as oversampling, under sampling, or the use of ensemble methods like SMOTE (Synthetic Minority Over-Sampling Technique).
- **Real-time Processing:** SCADA systems work in real-time settings where it's crucial to promptly detect and respond to insider threats. For SCADA systems to handle the high-speed data streams they produce, machine learning algorithms must be modified. Models can update and react in real-time thanks to methods like

online learning or streaming algorithms, ensuring the prompt detection of insider threats [19].

- **Model Interpretability:** In the context of SCADA systems, machine learning model interpretability is crucial. The reasoning behind the judgments made by the models must be understood by system administrators and security staff. Rule extraction, feature importance analysis, or the application of explainable AI [XAI] methodologies are a few techniques that can give insights into model behaviour and improve user confidence in and comprehension of the applied machine learning models [9].
- **Resource Constraints:** SCADA systems frequently use constrained computational resources, necessitating the development of effective and portable machine learning models. Reduce the computing requirements of the models without sacrificing performance by using methods like model compression, model pruning, or the usage of simplified architectures [10].
- **Transfer Learning and Domain Adaptation:** Transfer Learning and Domain Adaptation methods are useful because classified insider threat data is hard to get in SCADA systems [10]. Retrained models from related domains can be used as a starting point or to bootstrap the training process, which may then be fine-tuned using the specific data from the SCADA system. By using this strategy, the machine learning models perform better and the problem of data scarcity is lessened.

The improvements and adjustments of machine learning approaches for insider threats in SCADA systems take into account the particular difficulties and traits of these systems. They make it possible to create intrusion detection systems that are effective and efficient, capable of handling unbalanced data, providing interpretability, and operating within the resource limitations of SCADA environments [12]. In order to strengthen the security of SCADA systems against insider assaults, current research in this area intends to further improve and refine these adaptations along with investigating fresh approaches.

Insider IDS [Intrusion Detection Systems] for SCADA [Supervisory Control and Data Acquisition] systems provide compelling potential for fresh methodologies and applications. These methods improve insider threat detection and prevention by utilizing the capabilities of machine learning algorithms. We'll talk about a few cutting-edge methods and uses of machine learning in this part as they relate to insider IDS for SCADA systems [5], [7].

- **Behaviour Analysis:** Using machine learning algorithms for behavioural analysis in SCADA systems is one cutting-edge strategy. Machine learning models can identify variations that can be signs of insider assaults by learning the typical patterns of user behaviour and system operations [10]. To respond to changing system behaviour, these models can be continuously updated and trained using past data.

- **Anomaly Detection:** Machine learning approaches are excellent at recognizing anomalies, which is essential for identifying insider threats in SCADA systems [9]. Models are able to spot alterations from the norm that could be indicative of malicious activity by learning from the typical system behaviour. Auto encoders, Gaussian mixture models, or one-class SVMs are examples of unsupervised learning techniques that can be used to quickly identify anomalies and flag questionable behaviour [10].
- **Ensemble methods:** To increase detection accuracy and robustness, ensemble approaches mix various machine learning models. Ensembles of models can be built using methods like bagging, boosting, or stacking that were trained on various subsets of the data or with various techniques. This ensemble-based strategy reduces false positives and improves insider IDS's overall performance in SCADA systems [12], [16].

B. Deep Learning Models

For insider IDS in SCADA systems, deep learning models like deep neural networks, have demonstrated potential in a number of fields. These models are capable of discovering complex features and patterns from unprocessed data, which makes it possible to identify sophisticated insider attacks [13]. For evaluating network traffic and time-series data, Convolutional Neural Networks [CNNs] and Recurrent Neural Networks [RNNs] are frequently used in deep learning-based IDS.

- **Graph-Based Approaches:** SCADA systems frequently have a complicated network structure, where components and dependencies can be represented as graphs. The relationships between system items can be captured and potential insider threats can be identified using graph-based machine learning techniques (Tables II and III). In SCADA systems, suspicious patterns, attack pathways, and alert priority can all be found using methods like graph neural networks and graph clustering techniques [17].
- **Hybrid Approaches:** To take use of their complimentary qualities, hybrid approaches incorporate various machine learning techniques such as rule-based systems, statistical analysis, and machine learning algorithms. These methods make it possible to combine several detection techniques, and they improve insider IDS in SCADA systems' precision and robustness [12].
- **Natural Language Processing [NLP]:** Textual information from logs, configuration files, and system messages can offer crucial information for spotting insider threats in SCADA systems according to Natural Language Processing [NLP]. The NLP techniques can be used to process and analyse this textual data, extract pertinent data, and spot potential attack indications.

A thorough insider IDS architecture can benefit from the use of machine learning models that can be trained to categorize and analyze text input [18].

These revolutionary methods and insider IDS for SCADA systems uses of machine learning techniques offer enormous potential to improve security and safeguard crucial infrastructures. Continuous research and development in these field aims to improve the effectiveness of these methods, handle the changing problems brought on by insider threats in SCADA systems, and further these approaches [6].

In addition to the machine learning techniques, deep learning models, and advanced algorithms mentioned earlier, there are other tools and approaches that can be explored in the context of insider IDS in SCADA systems (Table IV). Here are a few examples:

- **Statistical Approaches:** Data from SCADA systems can be examined for patterns, trends, and abnormalities using statistical approaches. Techniques like time series analysis, statistical process control, and multivariate analysis can shed light on unusual behaviour or departures from the way a system is supposed to work [7].
- **Rule-based Systems:** To identify potential insider threats, rule-based systems use a set of established rules or criteria. These guidelines may be drawn from professional judgment or widely accepted commercial norms. To improve detection accuracy, rule-based systems are frequently employed in conjunction with other methods [16].
- **Data Fusion:** To increase the precision of insider threat detection, data fusion merges data from many sources, including sensor data, network logs, and user behaviour. Complex patterns and correlations that might not be obvious when evaluating individual data sources might be found by integrating various data streams [20].
- **Evolutionary Algorithms:** To maximize a solution, evolutionary algorithms imitate the processes of natural selection and genetic evolution. They can be used to improve insider IDS parameters, feature choices, or model architectures in SCADA systems. Examples of evolutionary algorithms include differential evolution, genetic algorithms, and particle swarm optimization [4].
- **Reinforcement learning** includes teaching an agent how to make decisions sequentially in a setting to maximize a reward signal. This method can be used to develop IDS systems that are self-adaptive and self-learn in order to dynamically respond to insider threats in SCADA systems [19].
- **Graphical probabilistic models** called Bayesian networks are used to describe ambiguous relationships between variables. They can be used to simulate causal chains and interdependencies within a SCADA system, making it easier to spot irregularities and possible insider threats.
- **Fuzzy Logic** is a mathematical framework for handling deliberation and decision-making in the face of uncertainty. In insider IDS for SCADA systems, it can be used to describe imprecise or uncertain knowledge,

enabling more adaptable and reliable detection procedures [13], [19].

This broadens the selection of tools available for identifying insider threats in SCADA systems by offering alternatives to conventional machine learning and deep learning techniques. When choosing and implementing these approaches, it's crucial to thoroughly evaluate their applicability for the specific SCADA environment and take into account their advantages, disadvantages and performance traits.

C. Cyber Physical Systems

Cyber-Physical Systems (CPS) are networked systems that combine computing and communication skills with physical aspects [10]. CPS denotes to the integration of SCADA systems with the latest information and communication technologies in the context of this review study. CPS is essential for controlling critical infrastructure, but it also creates new security risks, especially with regard to insider attacks [21],[22]. To increase the security of CPS, the study intends to investigate the most recent advancements and breakthroughs in Insider Intrusion Detection Systems (IDS) based on machine learning. The study seeks to pinpoint major issues and offer suggestions for proactive security against insider assaults in CPS contexts by examining the use and efficacy of various machine learning approaches (Table III).

III. IDS SOLUTIONS

Machine learning is a subfield of artificial intelligence (AI) which entails training computers to learn from data and make judgments or predictions without being explicitly programmed. ML approaches can be applied to Intrusion Detection Systems (IDS) to improve the solutions' capacity for identifying potential hacking attempts or anomalies [5].

The major components of the IDS solutions like Snort, Suricata, Bro/Zeek, McAfee IPS, and Cisco Firepower IPS—use established rules or patterns to identify known threats. These IDS systems can, however, be enhanced using ML algorithms to make them more intelligent and flexible [15],[23].

An outline of how ML relates to IDS solutions is provided below: Data is necessary for ML algorithms to learn from and generate predictions with. In the case of IDS, ML models can be trained using historical network traffic data [24].

Learning Patterns: Machine learning algorithms examine the training data and discover patterns or traits that distinguish between legitimate and harmful activity. For instance, they can spot specific network traffic patterns linked to particular kinds of attacks [13].

Making Predictions: Following training, ML models can be used to generate predictions about incoming network traffic that hasn't yet been seen. The models look for any signs of an ongoing assault or unusual activity by comparing the observed traffic patterns with what they have learnt from the training data.

Adaptability and Anomaly Detection: ML algorithms are also capable of identifying anomalies, which are atypical

patterns or behaviours that don't correspond to well-known assault patterns. Due to their versatility, ML-based IDS solutions can recognize new or undiscovered assaults [12], [13].

Continuous Improvement: As they are exposed to more data over time, ML models can continuously train and get better. They can refresh their knowledge to recognize new risks and respond to changing attack methodologies [12].

In summary, ML algorithms are employed in IDS solutions to learn from historical network traffic data, discover patterns linked to legitimate and nefarious conduct, and generate

forecasts about impending attacks or anomalies. This makes IDS solutions more proficient in identifying and stopping network intrusions.

It's important to note that the conditions for algorithm use as displayed in Table II are general guidelines which may vary based on the specific configurations, versions, and deployment environments of each IDS solution. The performance metrics for each technique, such as detection accuracy, false positive rate, and response time, are compared thoroughly in the Table II. These were selected based on studies [26], [27].

TABLE II. PERFORMANCE METRICS REVIEW FOR INSIDER IDS SCADA SYSTEMS TECHNIQUES

Technique	Detection Accuracy	False Positive Rate	Response Time	Applicability / Usage Condition	Limitation	Advantages	Other Information
Behavioural Analysis	High	Low	Fast	Effective for identifying insider threats	May not capture all insider attack patterns	Captures unusual patterns of behavior that may indicate insider attacks [1],[3]	Measures the accuracy of detecting insider threats based on behavior
Anomaly Detection	High	Low	Fast	Effective for identifying unknown threats	May result in false positives for certain data distributions	Can detect previously unseen insider attack patterns	Measures the accuracy of detecting anomalies in network traffic [3]
Ensemble Methods	High	Low	Fast	Effective for improving overall accuracy	Complexity may lead to higher resource requirements [9]	Combines multiple models to reduce false positives and increase accuracy [14]	Measures the overall detection accuracy of the ensemble
Deep Learning Models	High	Low	Fast	Effective for complex pattern recognition	Requires large amounts of labelled data	Can identify intricate patterns and detect novel insider threats	Measures the accuracy of detecting threats based on deep learning models
Graph-Based Approaches	High	Low	Fast	Effective for capturing network relationships	May face challenges in large-scale networks	Can detect insider threats by analyzing complex relationships in SCADA	Measures the accuracy of detecting threats based on graph analysis [15]
Hybrid Approaches	High	Low	Fast	Effective for improving overall accuracy	Requires careful integration of different techniques	Combines multiple methods to enhance detection capabilities	Measures the overall detection accuracy [14],[15]
Natural Language Processing [NLP]	High	Low	Fast	Effective for analysing textual data	Requires pre-processing of unstructured data	Can identify indicators of potential insider attacks from text data [21]	Measures the accuracy of detecting insider threats based on NLP

IV. REVIEW METHODOLOGY

A structured approach has been used in the review study to collect, evaluate, and synthesize relevant research on insider IDS in SCADA systems. The methodology is comprised on following steps:

Literature Search: To find studies, conferences, and journal publications from the previous five years [2019 to the present] that are relevant to the objectives of the research, a thorough search was carried out in research databases including IEEE Xplore, WOS, ScienceDirect, and Google Scholar.

The selection of relevant research is based on previously established inclusion and exclusion criteria. This study has taken into account works that concentrate on machine learning methods, deep learning models, advanced algorithms, and new insider IDS strategies in SCADA systems. Papers that don't fit the criteria for scope or quality were not being considered.

Data Extraction: Important details from the chosen articles, including the title, authors, publication year, methodology, algorithms employed, performance measures, and conclusions were taken out. In order to facilitate comparison and analysis, such information was displayed in a tabular manner.

The search was conducted in June 2023, and the years 2019 through 2023 were taken into consideration. 183 papers were obtained as a result, including: 59 papers from Science Direct, 77 papers from WOS, Google scholar, and 47 papers from IEEE Xplore. The final collection contained 94 papers after manual inspection and the elimination of the replicated publications.

Additionally, we chose potential articles based on the titles and abstracts, paying particular attention to those that offered novel suggestions for NIDS-specific to SCADA [5],[14]. There were 51 papers in the remaining collection.

After reviewing the complete candidate papers, the goal was to collect a set of original and similar solutions. As a

result, we disregarded publications that were similar in content but had different authors or described the outcomes of the same initiatives, as well as papers that lacked IDS evaluation findings. 27 papers were selected in the end.

Data Analysis: To find patterns, trends, and insights regarding the most recent developments in insider IDS for SCADA systems, the retrieved data was evaluated and synthesized. A comparative analysis was done to assess how

well various strategies and algorithms perform [Reference Table IV].

Development of a Conceptual Framework: Based on the research and analysis, conceptual framework was constructed to classify and comprehend the numerous machine learning methods, deep learning models, and advanced algorithms utilized in insider IDS for SCADA systems (Table III).

TABLE III. CPS AND SCADA SECURITY LANDSCAPE AND LEARNINGS REVIEW

Comparison Aspect	Cyber-Physical Systems [CPS]	SCADA Systems	Security Landscape Comparison	Advantages for Learning
Integration of Technologies	CPS integrates cyber and physical components to create interconnected systems [6].	SCADA focuses on integrating sensors, actuators, and control systems in industrial environments.	Both CPS and SCADA require secure integration of diverse technologies to prevent cyber-physical attacks and ensure data integrity.	CPS can learn from SCADA's focus on industrial protocols and network segmentation to enhance security. SCADA can learn from CPS's advanced encryption and authentication techniques for securing data flow in integrated systems [17].
Data Collection and Analysis	CPS relies on data from sensors and other sources for real-time monitoring and control.	SCADA systems gather data from sensors and devices to monitor industrial processes.	Both CPS and SCADA must secure data collection and analysis to prevent unauthorized access or tampering.[20]	CPS can learn from SCADA's data filtering techniques for efficiently handling large data streams. SCADA can learn from CPS's data analytics capabilities to improve predictive maintenance and anomaly detection [21].
Real-time Monitoring and Control	CPS provides real-time feedback and control in various domains.	SCADA allows operators to monitor and control industrial processes in real-time.	Both CPS and SCADA face real-time security challenges, requiring robust authentication and authorization mechanisms.	CPS can learn from SCADA's focus on redundancy and fail-safe mechanisms for continuous real-time control. SCADA can learn from CPS's distributed control architecture for improved system resiliency [22].
Connectivity and Communication	CPS uses communication networks to facilitate data exchange between cyber and physical components.	SCADA relies on communication networks for data transmission between central control and field devices.	Both CPS and SCADA must ensure secure communication channels to prevent unauthorized access and data interception.	CPS can learn from SCADA's strict access control policies and encryption techniques for secure communication. SCADA can learn from CPS's adaptive communication protocols for handling dynamic network conditions [22].
Security Challenges	CPS and SCADA face security challenges due to their interconnected nature.	Ensuring data and communication security is crucial to prevent cyber-attacks and disruptions.	Both CPS and SCADA must address security challenges related to insider threats, remote access, and supply chain vulnerabilities [21].	CPS can learn from SCADA's robust anomaly detection mechanisms for detecting suspicious activities. SCADA can learn from CPS's threat intelligence integration for proactive identification of potential cyber threats.
Industrial Applications	CPS finds applications in manufacturing, energy, healthcare, transportation, etc.	SCADA is commonly used in industrial sectors for process control and automation.	Both CPS and SCADA play critical roles in enhancing efficiency, automation, and optimization of processes in their respective domains [22].	CPS can learn from SCADA's domain-specific protocols and standards for seamless integration into industrial applications. SCADA can learn from CPS's adaptability to diverse industrial settings for improved flexibility and scalability.

TABLE IV. IDS ALGORITHMS REVIEW

Algorithm	Usage Conditions	Core Strengths	Core Weaknesses	Opportunities	Core Threats	Supporting Technologies & Industries
Ensemble Methods	Diverse dataset, multiple models	Improved prediction accuracy, model robustness	Increased complexity and computational resources [4]	Ensemble learning techniques, model combination	Overfitting, model selection, ensemble diversity	Various machine learning frameworks, successful in various industries such as finance, healthcare, and retail
Evolutionary Algorithms	Complex optimization problems	Effective for global optimization, handle constraints	Computationally expensive, slow convergence	Optimization of insider IDS parameters and features [10], [11]	Premature convergence, parameter tuning	Genetic algorithms, particle swarm optimization [7]
Hybrid Models	Diverse techniques, flexible	Combines strengths of different approaches	Complexity in model integration, interpretability trade-off [10],[13]	Improved detection accuracy, adaptable systems	Increased complexity, model integration challenges [20]	Integration of machine learning and rule-based systems
Anomaly Detection	Unusual patterns, outlier detection	Identifies unknown and rare insider threats	Difficulty in defining normal behaviour, high false positives	Uncovering novel insider threats, pattern recognition	Sensitivity to data quality, evolving threats	Statistical analysis, unsupervised learning, successful in various industries such as cybersecurity and fraud detection [12], [13]
Graph-based Methods	Network or relationship data	Captures complex relationships, detects structural anomalies	High computational cost for large graphs, graph construction	Identifying suspicious connections, network analysis	Scalability, graph sparsity, noise in data	Network analysis tools, successful in social networks, cybersecurity, and transportation systems [7],[20]
Reinforcement Learning	Sequential decision-making tasks	Adapts to dynamic environments, learns from interactions	High sample complexity, sensitivity to reward design	Adaptive and self-learning IDS systems	Exploration-exploitation trade-off, reward design	Q-learning, deep reinforcement learning frameworks
Bayesian Networks	Uncertain relationships, probabilistic reasoning	Captures causal dependencies, handles uncertainty	Requires prior knowledge, limited scalability	Modelling complex relationships, uncertainty handling	Learning structure from data, complexity in learning	Probabilistic programming, successful in medical diagnosis, risk assessment, and fault diagnosis [28], [29]
Fuzzy Logic	Handling imprecise knowledge, reasoning under uncertainty	Captures vague and uncertain information	Interpretability, intuitive reasoning	Modelling linguistic variables, fuzzy rule-based systems	Knowledge representation, fuzzy rule tuning	Fuzzy logic controllers, successful in industrial automation, decision support systems, and robotics [23]

V. CHALLENGES AND RECOMMENDATIONS

A. Challenges

Supervisory Control and Data Acquisition [SCADA] systems must be protected from internal threats by insider intrusion detection systems [IDS]. Insider attacks are more likely as SCADA systems grow more digitalized and networked, therefore strong and flexible security measures are required. This article examines the most recent difficulties encountered by Insider IDS in SCADA systems and makes suggestions to improve their efficiency and resiliency.

Data overload: Sensors, control systems, and communication networks all contribute to the massive volumes of data that SCADA systems produce. Insider IDS faces substantial challenges in processing and evaluating this data in real-time because doing so calls for strong computational capabilities and effective data handling techniques [1].

Anomaly Detection in Complex Environments: In the extremely dynamic and complex SCADA environment, insider IDS must be able to differentiate between legal deviations and probable insider assaults. Finding the right balance between detecting real anomalies and setting out false alarms is difficult, and SCADA operations vary widely [30].

Zero-Day assaults: Conventional signature-based detection techniques may have difficulty spotting new and unidentified assaults, such as zero-day threats. Insiders can take advantage of previously unknown flaws, making more sophisticated detection methods that go beyond specified rules necessary [8],[9].

Unbalanced Data Distribution: In SCADA systems, legitimate activity outweighs criminal activity by a large margin. The Insider IDS algorithms may be biased toward usual patterns as a result of this imbalance, which could affect how accurately they detect threats [1].

Limited Access to Training Data: Due to the sensitive nature of SCADA systems, obtaining labeled training data for Insider IDS can be difficult. Accurate machine learning models could be difficult to construct because of data access limits and privacy issues.

Adaptability to Evolving Attacks: Insider IDS must change in order to detect new and sophisticated threats as insider attack strategies change. To keep the system resilient to new attack vectors, regular upgrades and ongoing learning are essential [18].

SCADA systems need real-time monitoring and reaction capabilities in order to quickly minimize insider threats. The

integrity and safety of critical infrastructure can be severely compromised by any lag in detection and reaction.

B. Recommendations to Address Challenges:

Machine Learning-Based Detection: To improve Insider IDS capabilities, use machine learning techniques like deep learning models and anomaly detection algorithms. Even in complicated SCADA setups, these techniques may learn from prior data and spot patterns that can point to insider assaults [30].

Effective data preparation and feature engineering are essential to overcoming the problems brought on by data overload and unbalanced distributions. Insider IDS's accuracy can be improved by selectively choosing and extracting the most pertinent features [7].

Implement mechanisms for machine learning models that allow for continuous training and updating. The system's ability to respond to changing insider threats is enhanced by routinely providing it with fresh data.

Encourage cooperation between SCADA operators, vendors, and cybersecurity professionals so they can share threat intelligence and experiences. Collaboration can result in the discovery of fresh attack pathways and the creation of more potent detection methods.

Adopt hybrid IDS strategies that incorporate rule-based systems, statistical analysis, and machine learning techniques. Utilizing the advantages of several detection techniques can improve detection precision and lower false positives [1],[26].

User Monitoring and Behavioral Profiling: Use behavioral profiling of users and administrators to find alterations in normal patterns of activity. User monitoring can offer insightful information about shady behavior and possible insider threats [17].

Real-Time Incident Response: Create real-time response plans to quickly stop insider attacks. SCADA systems can avoid future harm with automated reactions like isolating hacked devices or halting unauthorized activity.

VI. COMPARISON OF IDS SCADA AND CYBER PHYSICAL SYSTEMS (TABLE III)

Cyber-Physical Systems [CPS] and SCADA systems are similar and dissimilar in many ways such as the integration of technologies, data collecting and analysis, real-time monitoring and control, connectivity and communication, security issues, and industrial applications. Due to their interconnected nature, CPS and SCADA both need to handle security issues such supply chain vulnerabilities and insider threats [22]. Additionally, for these systems to be protected from cyber-physical threats, unauthorized access, safe integration of various technologies and communication networks is essential.

The strengths of CPS and SCADA can be used to improve each other's security and effectiveness. The emphasis on industrial protocols and network segmentation in SCADA can help CPS, and SCADA can gain knowledge from CPS's cutting-edge encryption and authentication methods for securing data flow in integrated systems. Additionally, SCADA can benefit from CPS's distributed control architecture

and adaptive communication protocols for increased resiliency and flexibility in a variety of industrial settings, while CPS can learn from SCADA's data filtering strategies and emphasis on redundancy for improved efficiency and continuous real-time control [20],[21].

CPS and SCADA can improve their capabilities and security by sharing best practices and leveraging one another's strengths, so enhancing the general effectiveness, safety, and dependability of industrial processes and cyber-physical systems [6], [17], [20].

VII. DISCUSSION AND ANALYSIS

The study has conducted a comprehensive analysis of developments, obstacles, and efficiency to strengthen SCADA security against insider attacks. Examining prevalent techniques like behavioral analysis and anomaly detection, the research identifies their advantages over others for identifying insider threats (Table II). It also reveals barriers to insider IDS integration, such as the difficulty of interpreting models and the lack of available data. Encouraging advancements like explainable AI and federated learning are discussed that may open up new possibilities for cooperative threat detection [30].

The part on research objectives offers a thorough analysis of the use of insider IDS, new advancements, and efficacy evaluation. For researchers and professionals looking to strengthen vital infrastructures, it delivers insightful information.

The primary goal of this study was to offer a thorough analysis of the use and efficacy of insider IDS in SCADA systems. The study discovered that machine learning-based IDS systems have developed significantly to meet the expanding problems encountered by insider threats through a thorough analysis of the most recent developments [11], [12], [14]. These machine learning methods are good at interpreting massive volumes of data, recognizing patterns, and identifying unusual behavior that can point to malicious intent.

The review covered a wide range of machine learning techniques, such as natural language processing [NLP], graph-based approaches, ensemble methods, deep learning models, anomaly detection, behavioral analysis, and ensemble methods. The benefits and drawbacks of each method for identifying insider attacks on SCADA systems were examined (Tables II and III).

Important findings from studies revealed that behavioral analysis, applying machine learning algorithms, successfully learned typical patterns of user behavior and system operations, detecting variations suggestive of insider threats [10], [12]. Another machine learning-driven strategy called anomaly detection, which takes its nods from typical system activity and looks for abnormalities from established patterns, proved essential in identifying complex attacks.

The second objective of the study was to determine whether current insider threat detection and mitigation [IDS] techniques were appropriate for SCADA systems. The study indicated that insider attacks present certain complications that conventional security measures often are unable to meet. Machine learning-based systems demonstrated their capability

for learning from new data and adaptability, continuously improving alongside new threats [5], [11], [29] (Tables I and IV).

The ability to integrate different machine learning models using ensemble approaches like bagging, boosting, and stacking has been shown to improve detection accuracy and boost insider IDS in SCADA systems [2],[6],[8]. The accuracy and robustness of IDS solutions were further enhanced by the hybrid techniques that included various detection techniques.

The third objective of the review study was to find the key challenges and constraints encountered while using insider IDS solutions in SCADA systems. Due to the frequency of such incidents, the study noted the challenge in obtaining recognized insider threat data, making data collection, pre-processing, and classification difficult jobs. The review study findings reveal that it may be addressed by integrating Statistical Analysis techniques with rule based methods in IDS solutions (Tables I and III).

It also emphasized that it's very crucial to protect the security and confidentiality of crucial SCADA system data when creating machine learning models. In order to increase the transparency and interpretability of machine learning-driven IDS solutions and make sure that professionals can understand and trust the judgments made by these models, the review emphasized the necessity to integrate explainable AI. For greater transparency and confidence in the detection process, explainable AI needs to be integrated with IDS solutions in SCADA systems. Potential approaches that can accomplish this goal include ensemble methods, graph-based approaches, and rule-based systems. As they provide concrete concepts for decision-making, rule-based systems are simple to understand [27]. By revealing specific model contributions, ensemble approaches, and explicable AI techniques increase transparency. Understanding complicated relationships and attack pathways is made possible by graph-based techniques and explainable AI [30], [31]. By utilizing these methods, IDS systems in SCADA can deliver precise, comprehensible data, improving security analysts' capacity to recognize and efficiently address insider threats.

VIII. CONCLUSION, LIMITATIONS AND FUTURE DIRECTIONS

In conclusion, the discussion and analysis of this study offered valuable insight into the most recent developments, advantages, and difficulties of insider IDS in SCADA systems. The outcomes highlighted the significance of utilizing machine learning techniques as well as their adaptability and potential to change SCADA security. The review not only advanced academic knowledge in this field but also provided practitioners seeking to strengthen the security of vital infrastructures with practical recommendations (Tables II to IV).

IX. LIMITATIONS

Limited Scope: The study excludes other alternative strategies and technologies that can improve insider threat detection in favor of Insider Intrusion Detection Systems [IDS] for SCADA systems.

1) **Data availability:** An important limitation was the lack of pertinent insider threat data available for model training and evaluation. The findings' applicability to other situations may be restricted by the dearth of data from actual insider attacks.

2) **Time restrictions:** The study only included research papers published in 2019 and later, which may have left out some pertinent studies conducted earlier.

3) **Generalization:** Due to differences in system architectures, data formats, and threat settings, the conclusions and suggestions may not be universally applicable to all SCADA environments.

X. FUTURE DIRECTIONS

Enhanced Data acquiring: To improve the training and assessment of machine learning models, future research might concentrate on acquiring more thorough and varied insider threat data.

Explainable AI Integration: To improve the understand ability and transparency of machine learning-driven IDS solutions, more research can study and apply cutting-edge explainable AI methodologies.

Implementation in the real world: It would be helpful to conduct field tests and case studies to evaluate the usefulness and efficacy of machine learning-based IDS in actual SCADA environments.

Hybrid ways: Researching and creating hybrid ways that combine the benefits of various techniques, such as ensemble methods and rule-based systems, may result in the detection of insider threats being more reliable and accurate.

Exploring federated learning strategies, which enable cooperative model training across several SCADA systems without exchanging sensitive data, may be a promising step toward resolving data privacy issues.

Resistance to Adversarial Attacks: It would be beneficial to conduct research to make machine learning models more resistant to adversarial attacks, which might be used by knowledgeable insiders.

Collaboration between industries: Working together with SCADA system manufacturers and industrial groups could make it easier for machine learning-based IDS solutions to be adopted in practical environments.

The field of insider IDS for SCADA systems can go further by resolving these constraints and pursuing the indicated future directions, protecting critical infrastructures from the growing threat of insider threats.

XI. CONFLICT OF INTEREST STATEMENT

The authors affirm that they have no known conflicts of interest that would have appeared to have an impact on the research presented in this study.

Model Classification of Fire Weather Index using the SVM-FF Method on Forest Fire in North Sumatra, Indonesia

Darwis Robinson Manalu, Opim Salim Sitompul, Herman Mawengkang, Muhammad Zarlis

Doctoral Study Program (S3) in Computer Science,
Faculty of Computer Science and Information Technology,
Universitas Sumatera Utara, Medan, North Sumatera, Indonesia

Abstract—As a tropical country, Indonesia is situated in Southeast Asia nation has vast forests. Forest fire occur busy vary due to land conditions and forest conditions in drought season. The indicator used mitigated potential forest fire is to study the indicator behavior of the fire weather index (FWI). The data is gathered from the observation station in north Sumatra province, computation and estimation FWI by Canadian Forest Fire Weather Index based on the data gathered. It is found that there is gathered outlier data. to hope will it, it is necessary to conduct classification and predict this of the dataset by machine learning approach using Support Vector Machine Forest Fire (SVM-FF), which is a further development of the previous models, known as the c-SVM and v-SVM. This method includes a balancing parameter by determining the lower and upper limits of a support vector. Furthermore, it allowed the balancing parameter value to be negative. The results showed that the classification of FWI was at low, medium, high, and extreme levels. The low FWI value has an average of 0.5 which is in the 0 to 1 interval. There was an increase in the model's accuracy and performance from its predecessor, which include the c-SVM and v-SVM with respective values of 0.96 and 0.89. Meanwhile, it was observed that with the SVM-FF model, the accuracy was quite better with a value of 0.99, indicating that it is useful as an alternative to classify and predict forest fires.

Keywords—Fire weather index; forest fire; support vector machine; SVM-FF model

I. INTRODUCTION

Forest fire mitigation has been a priority for everyone in order to avoid increasing damage to nature [1]. Several methods applied by forest managers in this process include creating awareness on the prohibition of forest burning and monitoring of fire-prone areas, both of which are man-made and natural factors [2]. One of the data sources used to determine forest fires was the distribution of hotspots [3][4].

A previous research on machine learning that employed a random forest model [5] includes performance measurement of Forest Fire Prediction [6][7]. Another one was the application of machine learning for classification and prediction using fire weather index data[8]. Classification by using multiple variables is a frequently encountered related to data mining problem[9]. The components of the fire weather index in the meteorological data [10] are temperature, rain, wind, air humidity, and other supporting elements for calculating the

Fire Weather Index (FWI) [11] daily in forest areas having fire outbreak potential.

This data source was processed to determine the distribution of FWI in North Sumatra Province. However, the observation data used still needs to be pre-processed to avoid missing value or outlier data [12]. It is important to note that one of the characteristics of meteorological and weather data is the outlier, which are the emergence of extreme parameter values [13]. This makes it to have an impact on model misclassification, biases in parameter estimations, incorrect results, and imperfect forecasts [12] [14], which are classified as a loss function using the Support Vector Machine (SVM) method in machine learning [15][16][17].

The research objective was to classify and predict forest fires in North Sumatra using the fire weather index behavior[18]. The benefit of this research is to provide information on fire weather index values as a reference in predicting the potential for forest fires in an area [19], especially in North Sumatra, and early information on disaster mitigation in the forest fire sector. Research urgency is that the classification of potential forest fires [20] should not be based on the distribution of hotspots alone but needs to be reviewed from the behavior of the fire weather index with the Support Vector Machine Forest Fire (SVM-FF) model approach in reducing and mitigating forest fire disasters in the province of North Sumatra.

II. RELATED WORKS

This research dealing with forest fire classification covers the way how to optimize parameters at SVM to reduce misclassification [21]. With the Weather Research and Forecasting (WRF) mesoscale model method, FWI classification and mapping were carried out in Greece [22].

Further research uses a multi-factor forest fire prediction model with a machine learning approach using the random forest model method which aims to determine the highest incidence in China [23]. The determination of hotspot points that are also used the classification algorithm are C5.0 and Random Forest producing rules-based model[24][25] namely Forest Fire Detection carried out by using an application to determine hotspots in forested areas using Landsat 8 and Band ten satellite images or thermal bands having information on temperature [26][27], Predicting Rainfall from Weather

Observations using SVM Approach to identify The Parameter of Fuel Moisture as Fire Weather Index [28], Predicting fire-prone areas with machine learning techniques [29], and Researching into forest risk assessment system in China [30]. The study presents the classification and prediction of forest fires.

III. FIRE WEATHER INDEX

Obtaining the value of Fire Weather Index (FWI) requires a process that includes meteorological elements. The data collection process starts from observation to data processing [31]. The steps taken include calculating the value of Fire Weather Observations, Fire Behaviors Indices, Fine Fuel Moisture Code (FFMC) [32], Duff Moisture Code (DMC), Drought code (DC), Initial Spread Index (ISI), Buildup Index (BUI), and Fire Weather Index (FWI) [29].

This becomes the basis for processing observation data to produce a fire weather index value in numerical form, which is based on the ISI and BUI, utilized as a general fire hazard index for forest areas [33]. The following equations are employed in the calculation of the FWI value.

$$f(D) = 0.626U^{0.0809} + 2, \quad U \leq 80 \quad (1)$$

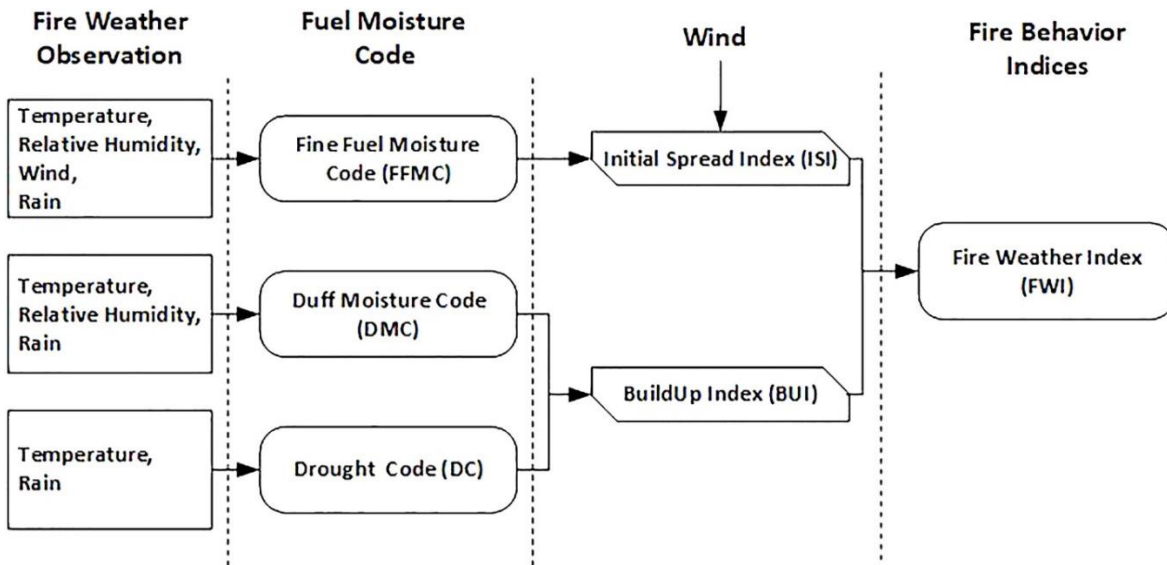

Fig. 1. FWI schematic [34].

One of the classification tasks is building a prediction engine with a good degree of accuracy capable of generalizing [35]. To achieve this purpose, SVM is used to minimize the objective function that contains a loss function [36], with the aim of finding the function $f(x)$ as a hyper-plane and making the error (ϵ) as minor possible [21]. It is important to note that the current studies on SVM generally is focused on improving and formulating loss functions that eventually produce many variants. For example, the C-SVM [37] applied the surrogate function formulation by adding parameters $C \in (0, \infty)$ to the loss function in Eq. (6).

$$\min_{w,b} \frac{C}{2} \|w\|^2 + \sum_{i \in I} [-y_i (w^T x_i + b) + 1]^+ \quad (6)$$

$$f(D) = \frac{1000}{(25+108.64 e^{-0.023U})} + 2, \quad U > 80 \quad (2)$$

$$B = 0.1 R f(D) \quad (3)$$

$$\ln S = 2,72 (0.434 \ln B)^{0.647}, \quad B > 1 \quad (4)$$

$$S = B, Bz \quad (5)$$

Where:

$f(D)$ is the Function of drought (*drought*)

U represents the BUI value

R denotes the ISI value

B the FWI (*intermediate form*)

S represents the FWI (*final form*)

The calculations of these components are based on daily meteorological data observations such as temperature, relative humidity, wind speed, and 24-hour rainfall [32]. The three components of the FWI system provide a numerical rating of the forest's relative fire potential, including Fire Weather Observations, Fuel Moisture Code, and Fire Behaviors Indices. Fig. 1 shows the components of the FWI System.

The v-SVM model in [38] added a parameter to increase the cardinality of the data as expressed in Eq. (7).

$$\min_{w,b,p} v + \frac{1}{|I|} \sum_{i \in I} [-y_i (w^T x_i + b) + 1]^+ \quad (7)$$

In many studies, both C-SVM and v-SVM produced optimal solutions because the parameter v was able to determine the lower and upper bounds of a support vector.

IV. METHODOLOGY

The meteorological data method was used in this research and processing was performed before pre-processing the observation data from all Meteorological, Climatological, and Geophysical Agency (BMKG) stations [39]. The details of the method are shown in Fig. 2.

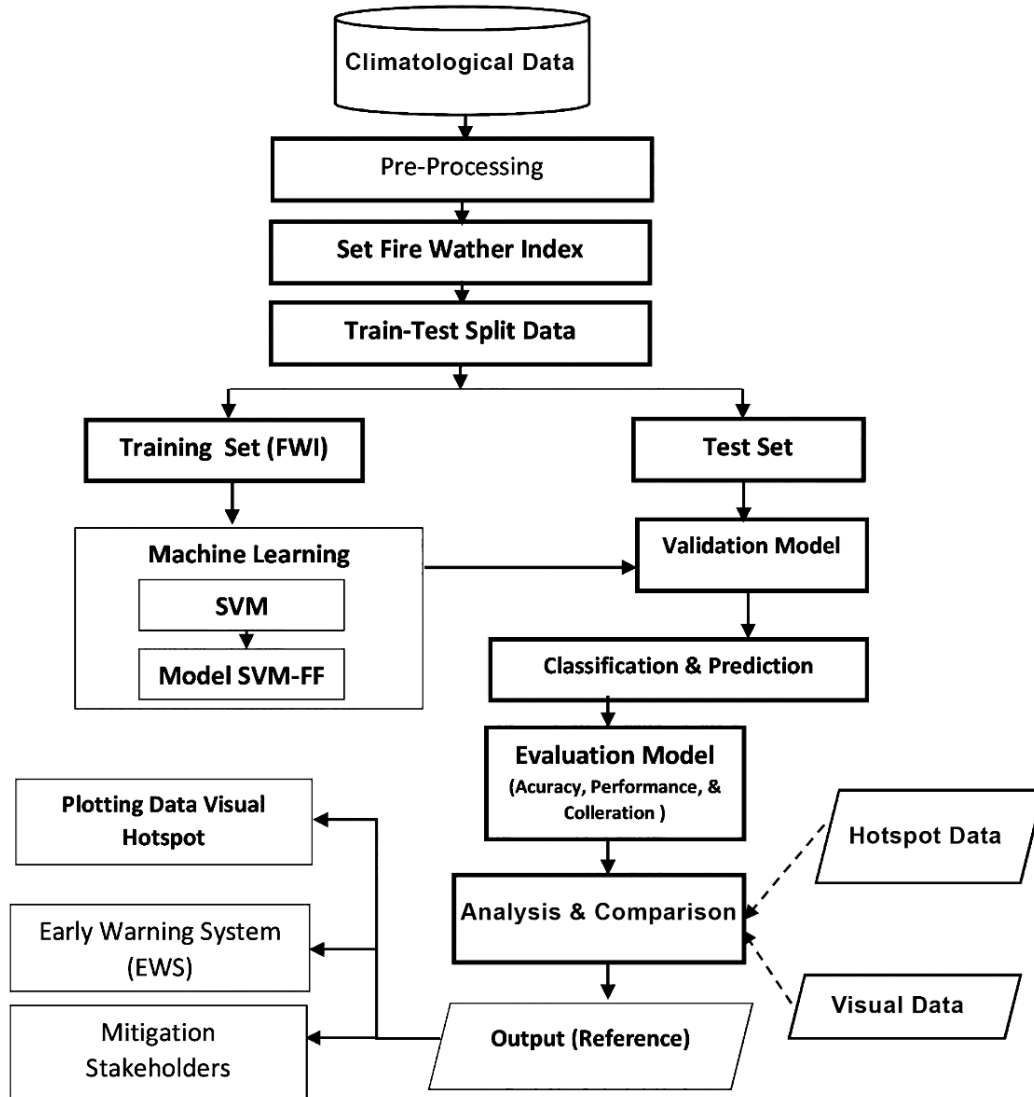

Fig. 2. Research framework.

The SVM-FF focused on increasing negative outlier data in order to get better performance, but when the parameter v in the v -SVM shown in Eq. (7) has an extreme value, the classification model produced poor performance. First, it assigned a large value to the parameter v , which encouraged overfitting [39] and makes the model look too good but not optimal to generalize from the dataset.

Second, it produced a small value of $w=0$ and $b=0$ in Eq. (3) to (5) above, which results in a poor solution. It was observed that the c -SVM and v -SVM models produced optimal solutions because the parameter v was able to determine the lower and upper bounds of a support vector. Based on the above considerations, the proposed solution to force the value of the parameter w in Eq. (7) was to set the value of the parameter p to be negative. This is consistent with [39] that applied optimization to produce negative values as expressed in Eq. (8).

$$C = \min_{w,b,p} \{-vp + \frac{1}{|I|} \sum_{i \in I} [-y_i (w^T x_i + b) + 1]^+\} \quad (8)$$

w : weight

b : biases always positive

p : balancing parameter

y : target/class/category

x : feature data

t : time epoch

i : index

A. SVM-FF Algorithm

The SVM-FF model is based on Eq. (7) with the following steps:

Algorithm 1: SVM-FF model

Initiation value $v \in (0, 1)$, value p, w, b

Minimizing the loss function with equation (8):

$$C = \min_{w,b,p} \left\{ -vp + \frac{1}{|I|} \sum_{i \in I} [-y_i (w^T x_i + b) + 1]^+ \right\}$$

If the value is infinite, the algorithm stops.

Otherwise, the optimal solution is (w_i, b_i)

If value $C_{i+1} = C_i$ the algorithm stops.

Determine as much C_{i+1} sample data from data x_i

Set index to $I_i + 1$

$i = i + 1$

B. Model Validation

The performance test of the SVM-FF model was based on several criteria, such as the average error value using the Receiver Over Characteristic (ROC) curve function [40].

C. Error Plot

An error plot is a graphical representation that shows the range of the actual value to those predicted by the model. When there are many N data observed, then the average of the data is described in Eq. (9) [39].

$$\bar{x} = \frac{1}{N} \sum_{i=1}^N x_i \quad (9)$$

According to Eq. (9), the error value is defined as the square root of the difference between the data x_i and the average data \bar{x} as expressed in Eq. (10).

$$SD = \sqrt{\frac{1}{N-1} \sum_{i=1}^N (x_i - \bar{x})^2} \quad (10)$$

D. Receiver Operating Characteristic

The most recommended test criterion for multi-class classification was Receiver Operating Characteristic (ROC) analysis [41]. The ROC curve is capable of displaying a sensitivity plot in the y-axis, and 1-specificity in the x-axis. Fig. 3 shows a hypothetical ROC curve that represents diagnostic accuracy. In line A, the curve showed 100% accuracy or 1.0, while in line B, it represents 85% accuracy or 0.85, and curve C depicted 50% accuracy or 0.5.

Fig. 3. ROC curve.

V. DISCUSSION

A. BMKG Dataset Exploration

The FWI is a multi-dimensional dataset that consists of 12,897 raw data with ten features and one class. The description of each feature is described in Table I below.

TABLE I. FWI DATASET FEATURES

Feature	Description	Value (max, min, average)
Tn	Real data, minimum temperature	33, 1, 23.25
Tx	Real data, maximum temperature	233, 3, 31.16
Tavg	Real data, mean temperature	31.6, 18.6, 26.9
RH_avg	Real data, average humidity	121, 7, 85.62
RR	Real data, rainfall	8888, 0, 10.23
ss	Real data, duration of sunshine	23, 0, 4.50
ff_x	Real data, maximum wind speed	45, 0, 4.40
ddd_x	Real data, wind direction at maximum speed	2860, 0, 191.62
ff_avg	Real data, average wind speed	15, 0, 1.38
S	Nominal data, dataset class target value	(1,2,3,4)

B. Data Preparation

Climatological dataset contains about 28% of missing value. Data pre-processing involves a series of data preparation process used to handle missing value. Columns in the dataset which are having missing values replaced with the mean of remaining values in the column [42].

C. Condition of Data Outliers

One of the characteristics of disaster, weather, and climate is outlier data. It has been observed that the existence of this data increased as a result of extreme parameters, such as temperature, wind speed, etc. The BMKG data applied in this research was not exempted from the outlier problems. The existence of outliers in data features are shown in Fig. 4 and 5.

Fig. 4. Outliers on the RH_avg feature (Average Humidity).

Fig. 4 shows the condition of the dataset outliers, specifically for the RH_avg feature or mean humidity. It was observed that some values deviate significantly from the median or the middle value of the data (blue). Furthermore, the outlier values move to the right and left of the median.

Fig. 5. Outliers on the ff_avg Feature (Average Wind Speed).

The condition of the outlier dataset in Fig. 5 for other features was ff_avg or average wind speed. Furthermore, the outliers are to the right of the data or values above the median. It is important to note that the first step in the classification process with SVM-FF are parameters initiation that include the conventional SVM, namely the kernel type parameter, w value, gamma value, and r coefficient. Other parameters adapted from the SVM-FF model are the values of v and p which have been described in Eq. (8). The description of each feature is described in Table II below.

TABLE II. INITIALIZATION OF SVM-FF PARAMETERS

No	Parameter	Default value	Model Type
1	Kernel	RBF	SVM
2	w	1	SVM
3	Gamma	1	SVM
4	r Coefficient	0	SVM
5	v	(0,1)	SVM-FF
6	p	(0,1)	SVM-FF

The pre-processed FWI data consists of 12,800 raw data, which consist of low, medium, high, and extreme classes. Furthermore, the number of raw data per class was 6,126, 3,394, 3,150 and 130 data, respectively and the graph of these distributions is shown in Fig. 6.

Fig. 6. FWI dataset class distribution graph.

It is important to note that the data validation scheme is based on the k-Fold cross-validation method with $k=10$. This method randomly divided the dataset into ten sub-datasets. In each fold, the training data was nine sub-datasets, while the testing data was one sub-dataset. The distribution scheme of these datasets is shown in Table III below, is showing that in the first fold, the amount of training data was 11,520 and the testing data was 1,280. The same number of data applies from the Second fold through to the tenth fold.

In the testing phase, the SVM-FF model was applied to classify the dataset based on the attribute values of the FWI dataset. The dataset classification results in the first fold (fold-0) are shown in Table III. A total of 25 raw data are taken in both upper data (1 to 25) and lower data (1,256 to 1,280) out of 1,280 raw data in fold-0, respectively.

The data with serial number 1 has an actual class of "medium", and the classification result is "high", making, the classification status was misclassified. Furthermore, the data with sequence number 2 has a "low" actual class and classification result of "low" respectively, which means a correct classification. It can be concluded that in the fold-0, out of 1,280 raw data, 141 data are misclassified and 1,139 with correct status, indicating that the accuracy of data classification in fold-0 is 0.890 globally.

TABLE III. RESULTS OF DATA CLASSIFICATION USING THE SVM-FF MODEL

No	Actual	Classification	Status
1	medium	high	misclassified
2	low	low	correct
3	high	high	correct
4	medium	medium	correct
5	low	low	correct
6	low	low	correct
7	low	low	misclassified
8	medium	low	correct
9	high	high	correct
10	medium	medium	correct
1,272	low	low	correct
1,273	high	high	correct
1,274	extreme	extreme	correct
1,275	high	high	correct
1,276	extreme	high	misclassified
1,277	high	high	correct
1,278	high	high	correct
1,279	extreme	extreme	correct
1,280	medium	low	correct

Similarly, the accuracy of each fold in both the testing and training stages is described in Table IV. It was observed that in fold-0, the training and testing accuracies were 0.978 and 0.890, respectively. When the overall fold was tested with 10 folds, the average training and testing accuracies were 0.983 and 0.906, respectively.

TABLE IV. AVERAGE ACCURACY OF TRAINING AND TESTING

Fold	Testing	Training
Fold 0	0.890	0.978
Fold 1	0.919	0.978
Fold 2	0.957	0.981
Fold 3	0.906	0.987
Fold 4	0.919	0.982
Fold 5	0.894	0.981
Fold 6	0.904	0.982
Fold 7	0.904	0.988
Fold 8	0.879	0.980
Fold 9	0.879	0.988
Correctly classified	0.906	0.983
Global Classification Error	0.154	0.064
Stddev Global Classification Error	0.020	0.003

In addition to the analysis related to the testing phase, further evaluation was performed to determine the performance of each fold classification per class in the training and testing phases. The results are shown in Table V and Table VI, in which the SVM-FF model has the highest accuracy for the "high" class classification and the lowest results for the "medium".

TABLE V. RESULTS OF PERFORMANCE TEST PER FOLD PER CLASS IN THE TRAINING PHASE

	Low	Medium	High	Extreme
Fold0	1.000	0.887	1.000	0.843
Fold1	1.000	0.867	1.000	0.874
Fold2	0.994	0.908	1.000	0.859
Fold3	1.000	0.887	0.995	0.864
Fold4	0.994	0.882	1.000	0.853
Fold5	0.994	0.892	0.995	0.858
Fold6	0.994	0.893	1.000	0.859
Fold7	1.000	0.908	1.000	0.859
Fold8	1.000	0.872	1.000	0.864
Fold9	1.000	0.897	1.000	0.869
Average	0.998	0.889	0.999	0.860

TABLE VI. RESULTS OF PERFORMANCE TEST PER FOLD PER CLASS IN THE TESTING PHASE

	Low	Medium	High	Extreme
Fold-0	0.880	0.838	0.965	0.692
Fold-1	0.950	0.727	1.000	0.905
Fold-2	0.950	0.818	1.000	0.619
Fold-3	0.950	0.864	0.909	0.714
Fold-4	1.000	0.727	0.952	0.682
Fold-5	0.950	0.636	0.952	0.818
Fold-6	0.950	0.714	1.000	0.714
Fold-7	0.950	0.810	0.955	0.667
Fold-8	0.950	0.714	0.955	0.667
Fold-9	1.000	0.545	0.955	0.810
Average	0.953	0.739	0.964	0.729

D. SVMFF Model Performance

The performance test of the SVM-FF model is based on several criteria, which includes the average value of the error and the Receiver Over Characteristic (ROC) Curve.

E. Error Graph

The error plot of a graph property represents variations in the data, which is due to the errors or uncertainty of a model in the form of visualization of vertical lines in the error point. The benchmark for determining the error plot was Standard Deviation, and the graph for that of SVM-FF model was visualized in Fig. 7 and Fig. 8.

Fig. 7. C-SVM, v-SVM, and SVM-FF model error graphs.

Fig. 8. ROC Comparison graph between SVM-FF, v-SVM, and c-SVM.

It was observed that the error graph or error plot for the SVM-FF model was lower or better compared to the other two models, which include c-SVM and v-SVM.

F. ROC Curve

The ROC curve shows the probability or accuracy of the model in graphical form. According to the test results, the SVMFF model has a better model accuracy in comparison with the other two SVM.

The ROC graph above shows the accuracy and performance of the model, in which the c-SVM and v-SVM models produced accuracies of 0.96 0.89, respectively. When the SVM-FF model was used, the accuracy was improved with a value of 0.99.

G. Decision Region Boundary (DRB)

A two-dimensional graph represents the correspondence of multiple data feature to classes. It is important to note that the SVM-FF method has three types of kernels, which include linear, sigmoid, and Radial Basis Function (RBF). The application of these three kernels affected the shape of the SVM-FF hyperplane. The SVM-FF DRB model is shown in Fig. 9, 10, and 11.

There are four classes of fire weather index datasets, comprising low, medium, high, and extreme respectively indicated with blue, orange, green, and red. The classification was performed in the SVM-FF by placing data features in different regions. It was observed that when the linear kernels were used, there were still deviations in the classification areas,

particularly in the extreme classes, which are marked with red circles.

The data area also appears to have been classified, but some data points still occupied different positions. For example, the maximum margin is still very close to the hyperplane in the form of a straight line. Meanwhile, in the data section with a yellow triangle symbol, some still occupy the blue and green areas. This shows that the accuracy with the kernel liner was not optimal as expected.

Furthermore, with the use of the sigmoid kernel, the position of the hyperplane was observed after the data points. The sigmoid line shape in the green round category is seen in Fig. 11. Based on the three figures and the classification results using the kernel, the RBF type presented a better class distinction when compared to linear or sigmoid kernels.

Fig. 9. DRB with linear kernel.

Fig. 10. DRB with RBF kernel.

Fig. 11. DRB with sigmoid kernel.

H. Model Significance Test

A statistical significance test approach was used to test the significance of the models as shown in Table VII. The Wilcoxon test was applied at a significance level of 95% or an error rate of 5% (0.05), and was declared to be significantly different when the p-value is < 0.05 .

TABLE VII. THE WILCOXON TEST RESULTS OF SVM-FF MODEL

VS	R^+	R^-	Exact P-value	Asymptotic P-value
v-svm	55.0	0.0	0.00195	0.004317
c-svm	55.0	0.0	0.00195	0.004317

According to Table VII, the p-value of SVM-FF VS v-SVM was $0.00195 < 0.05$, indicating that the accuracy of SVM-FF differs significantly from the v-SVM. When the p-value of SVM-FF VS c-SVM was $0.00195 < 0.05$, the SVM-FF accuracy was observed to differ significantly from the c-SVM.

VI. CONCLUSION

In conclusion, the testing results when the SVM-FF model was used for FWI conditions in North Sumatra Province provided four classifications, namely low, medium, high, and extreme, indicated as blue, orange, green, and red zones, respectively. From 2017 to 2020, FWI conditions have been classified as a low-level/blue zone with an average value of 0.5 per day, which is on a scale of 0 and 1.

This classification was conducted using all observational datasets by entering outlier data to determine the performance optimization of the SVM-FF model and was compared to the result of its predecessor. It was observed that the c-SVM and v-SVM models produced accuracies of 0.96 and 0.89, respectively. Meanwhile, the SVM model -FF was able to improve the accuracy with a value of 0.99, indicating that it was able to work more optimally.

The model's performance when several kernel functions were utilized showed that the Radial Basis Function kernel provided classification results with a better hyper-plane

position compared to the maximum position of the data margin.

Abstract—One of the most significant and extensively utilized cryptocurrencies is Bitcoin (BTC). It is used in many different financial and business activities. Forecasting cryptocurrency prices are crucial for investors and academics in this industry because of the frequent volatility in the price of this currency. However, because of the nonlinearity of the cryptocurrency market, it is challenging to evaluate the unique character of time-series data, which makes it impossible to provide accurate price forecasts. Predicting cryptocurrency prices has been the subject of several research studies utilizing machine learning (ML) and deep learning (DL) based methods. This research suggests five different DL approaches. To forecast the price of the bitcoin cryptocurrency, recurrent neural networks (RNN), long short-term memories (LSTM), gated recurrent units (GRU), bidirectional long short-term memories (Bi-LSTM), and 1D convolutional neural networks (CONV1D) were used. The experimental findings demonstrate that the LSTM outperformed RNN, GRU, Bi-LSTM, and CONV1D in terms of prediction accuracy using measures such as Root Mean Squared Error (RMSE), Mean Absolute Error (MAE), Mean Squared Error (MSE), and R-squared score (R^2). With RMSE= 1978.68268, MAE=1537.14424, MSE= 3915185.15068, and R^2 = 0.94383, it may be considered the best method.

Keywords—Cryptocurrency; deep learning; prediction; LSTM

I. INTRODUCTION

The fiat currency used in the present monetary system has various disadvantages, including government control over the money supply; transactions are often carried out via intermediaries like financial institutions, which results in expensive fees and prolonged transfer times, as well as the present ledgers used to record transactions being vulnerable to manipulation [1]. Hence Due to its decentralization, immutability, and security, cryptocurrencies have become a worldwide phenomenon that draws a sizable number of users. They are founded on confidence in technology infrastructure, enabling money transfer from any location with nearly negligible delay [2]. Throughout its limited life, the cryptocurrency market has expanded irrationally and astoundingly [3].

Bitcoin, a kind of electronic money, was originally launched in 2008 and was first used as an open-source in 2009 by a person named Satoshi Nakamoto [4]. As the first currency ever created, it has become the most significant currency [5]. Without a single administrator or central bank, it is decentralized digital money that may be transmitted between

users on a peer-to-peer network without the involvement of mediators like banks [6].

Most cryptocurrencies use blockchain technology and feature attributes like decentralization, transparency, and immutability [7]. Blockchain allows for the permanent recording of network transactions [8], and each record is encrypted and carries the block's [9] cryptographic hash before it. A date, sender and recipient details, and the total amount of money transmitted are all included in each record. An extremely complex technology called a secure shell links transaction blocks [10]. This technology aims to store data that makes it difficult or impossible to alter, hack, or defraud the system [11].

From 2009 to 2017, the price of Bitcoin increased to over USD 20,000. As of December 2019, the daily average market volume was around USD 19.45 billion [12], and as of April 2021, the price of Bitcoin hit an all-time high of around \$65000 [13]. Although investments have yielded rich returns, the constant price swings seen by most cryptocurrencies make them difficult and hazardous [14]. Consequently, it takes work to anticipate the price of cryptocurrencies.

Additionally, the sharp variations in bitcoin prices have emerged as a brand-new worldwide concern. Therefore, it is crucial to foresee changes in the price of Bitcoin [15]. Because of this, investors need a forecasting strategy to efficiently capture swings in the price of cryptocurrencies to reduce risk and boost profits [16].

Cryptocurrency price prediction is a time series prediction problem in its early phases. In contrast, older methods were used to anticipate time series based on linear hypotheses and required information that could be categorized as trend or seasonal [3], such as sales forecasting. Due to the extreme volatility and lack of seasonality in the Bitcoin market, these strategies are unsuccessful. Based on its success in similar domains, deep learning is an attractive technological choice, given the difficulty of the challenge [17]. From this point on, DL methods are considered efficient for time series forecasting since they are noise-resistant, can accommodate data sequences natively, and can recognize non-linear temporal correlations on such sequences [18].

Estimating the price of the Bitcoin cryptocurrency is the aim of this research, and evaluating the forecasting accuracy of five different deep learning models, including LSTM, RNN, GRU, Conv1D, and Bi-LSTM. The research uses the (RMSE),

(MAE), (MSE), and (R^2) as measurement techniques to assess the performance of DL models using the closing price of Bitcoin in USD.

The issue that motivated us to conduct this paper was the lack of a specific model with high accuracy that could be relied upon to predict the price of cryptocurrencies, which may have a significant impact on the increase in financial profits. It was vital to provide a solid approach to address this issue for investors that invest in these encrypted currencies. Deep learning methods were used as a consequence because they produced positive outcomes in various study domains.

This paper contributes to providing knowledge to everyone interested in this field in identifying deep learning techniques and their ability to deal with time series data to predict the prices of cryptocurrencies, where the results of the research proved that the use of deep learning method resulted in better results than the traditional machine learning techniques, and also to assist investors interested in trading cryptocurrencies in selecting the best deep learning model to predict prices, and to make the right decision to decrease their loss exposure and increase profitability during the trading process in this currency.

The paper is divided into seven sections: Section 2 is a literature review, Section 3 provides background knowledge, and Section 4 presents the model to guide our approach. Section 5 tests the suggested model; Section 6 presents the findings of the experiment; Section 7 conclusions and future work.

II. LITERATURE REVIEW

Bitcoin is a cryptocurrency and a kind of electronic money. It is a well-known cryptocurrency with a bright future [19], and it is a web-based trade technique that uses cryptographic tools to carry out financial transactions [20]. It is crucial to forecast the values of this currency because of the considerable price volatility of this encrypted money, which has the potential to impact investors negatively and international and commercial ties [21]. Numerous researches have been carried out to forecast time series and the value of bitcoin [10]. In contrast, deep learning models [13] and machine learning models [4] were employed to forecast the price of Bitcoin.

The prior research on predicting cryptocurrency prices will be examined in the following part, employing various ML and DL models for time series prediction, as shown in Table I.

TABLE I. LITERATURE REVIEW FOR CRYPTOCURRENCY PRICE PREDICTION PRICE USING ML AND DL

Author	Year	Technique	Cryptocurrency	Dataset Source	Data Range	Prediction Methods	Performance Measures and results	Demerit
HASAN et al [7]	2022	DL	Bitcoin Ethereum Monero	Investing.com	between Jan 22, 2015 to Feb 12, 2020	LSTM, RNN and Proposed method	The Proposed method has achieved the best performance when predicting Bitcoin price with MSE= 18.65, MAE= 2.15 and RMSE= 4.21	Not Explored time-series model such as GRU
NEMATALLAH et al [10]	2022	DL	Bitcoin	Kaggle	between 1 Jan 2012 to 31 Mar 2021	RNN LSTM	MAPE and RMSE LSTM performs better than RNN	Not Explored time-series model such as GRU
Bitto et al [22]	2022	ML	Bitcoin, Ethereum, Litecoin and Tether token	Yahoo Finance	between 2015-1-1 to 2021-6-1	AR MA ARMA	MAE and RMSE. AR model giving better performs than others models with 97.21% For bitcoin, 96.04% for Ethereum, 95.8% for Litecoin and 99.91% accuracy for Tether-token	Not considered deep learning models for prediction
Ammer et al [12]	2022	DL	AMP, Ethereum, Electro-Optical System, and XRP	CoinMarketCap	between May 2015 through April 2022	LSTM	MSE, RMSE, NRMSE and R. LSTM achieved R = 96.73% for training And R= 96.09% for testing when predicting XRP price	Not Explored time-series model such as GRU
FAKHARCHIAN et al [15]	2022	DL	Bitcoin	Yahoo Finance	between 05/02/2021 To 10/09/2021	proposed models based on CNN and LSTM	Model-9 achieved the best performance with MSE= 0.00151, RMSE= 0.0388, MAE= 0.02519, MedAE= 0.01747 and R2= 0.98219	Not Explored time-series model such as GRU
ZHANG et al [23]	2022	ML DL	Bitcoin	Data.Bitcoinity. Org, Blockchain.com , and CoinMarketCA P	between 05/02/2021 To 10/09/2021	LSSVM BP SDAE-B	SDAE-B model giving better performs than others models with MAPE= 0.016, RMSE= 131.643 and DA= 0.817	Not Explored time-series model such as LSTM and GRU

GURRIB et al [24]	2022	ML	Bitcoin	CoinMarketCA P	between 17 Jun 2016 to 21 Apr 2021	LDA SVM	LDA model giving better performs than SVM with accuracy of 0.585	Not considered deep learning models for prediction
CAVALLI et al [25]	2021	ML	Bitcoin	CoinMarketCA P	between 28 of Apr 28, 2013 to Feb 15, 2020	1D CNN LSTM	RMSE 1D CNN model giving better performs than LSTM	Not considered deep learning models for prediction
LIU et al [26]	2021	ML DL	Bitcoin	Coindesk.com BTC.com	between Jul 2013 to Dec 2019	BPNN SVR SDAE	SDAE model giving better performs than others models with MAPE= 0.1019, RMSE= 160.63 and DA= 0.5985	Not Explored time-series model such as LSTM and GRU
MARNE et al [27]	2020	ML DL	Bitcoin	Kaggle	between Jan 2014 to Jan 2019	SVM RNN LSTM	LSTM model giving better performs than others models with RMSE = 3.38	Not Explored time-series model such as GRU

III. METHODOLOGY

We will go through several related concepts in this section.

A. Time-Series

It is one of the most effective methods for forecasting situations with some degree of future uncertainty by analyzing past patterns and assuming that future trends will be similar. Time series forecasting is also based on data for efficient and effective planning to solve forecasting problems with a time component [3].

B. Deep Learning Methods used for Bitcoin Price Prediction

The approaches utilized in DL, a subfield of ML, are built on the structure and design of ANNs. Five DL algorithms were used in this study to forecast the price of Bitcoin. LSTM, GRU, BiLSTM, simple RNN, and the 1D CNN algorithm.

1) *Recurrent Neural Network (RNN)*: Artificial neural networks were inspired by how the human brain processes information. The neural network comprises synthetic neurons, and its architecture determines its properties. Traditional neural networks do not have feedback loops, which is how RNNs vary from them. It is thus relevant anytime the input context affects how well a prediction is made. Each neuron's current state depends on its past state due to the recurrent nature of an RNN's layers, which leaves the neural network with a finite amount of memory. Sequential data may be input into a recurrent neural network, and both the networks In and Out may be sequences of variable lengths that pass through each cell consecutively [28]. Suppose there is an input neuron X_t , an invisible output status h_t , and the prior invisible output status h_{t-1} . In that case, the RNN has a single-layer recurrent module with a tanh squashing function. Fig. 1 [29] demonstrates that W represents the weighted matrix and y_t for the result.

Fig. 1. The recurrent neural network simple architecture [29].

2) *Long Short-Term Memory (LSTM)*: Recurrent neural networks with the ability to learn long term dependencies are called LSTMs. The recommended networks by Hochreiter and Schmid Huber [30] because the last state needed to be sufficiently recent and thus influenced the present state, the RNN model may inaccurately predict the current state [31]. From left to right, the LSTM is crafted to keep track of information throughout time and lessen the issue of vanishing gradient descent. Three interconnected layers in the LSTM, the input gate, forget gate, and output gate, control the data flow necessary to forecast the output of the network [32].

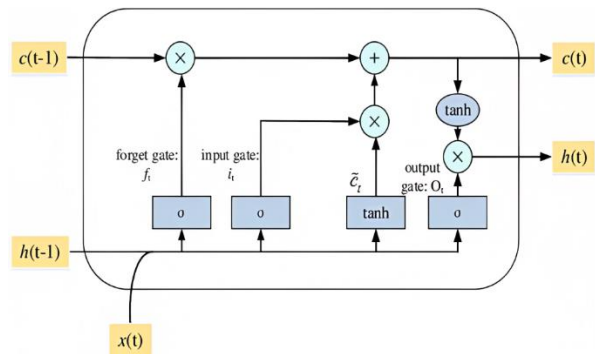

Fig. 2. Schematic diagram of LSTM [33].

Input gate: Information will initially pass through the input gate after importing the data. The switch decides whether or not to store the information based on the state of the cell.

Output gate: The amount of output information is determined by it.

Forget gate: It chooses whether to keep or forget the information obtained. [34, 35], as shown in Fig. 2.

3) *Gate Recurrent Unit (GRU)*: Another RNN version is a GRU, which combines the three gated units into only two gated units: the gate for updating and resetting [36]. GRUs address the vanishing gradient issue of RNNs and the optimization of the structure of the LSTM model. The two gates may store relevant data in the memory cell while transmitting values to the network's later stages. GRU and LSTM are equal when evaluating performance across various test scenarios [37]. Fig. 3 depicts the organization of the GRU units.

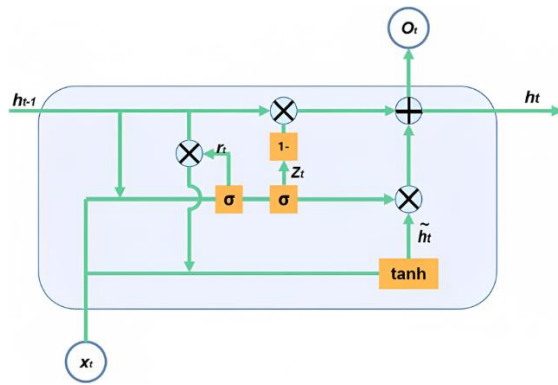

Fig. 3. GRU unit structure [38].

4) *Bidirectional Long Short-Term Memory (BiLSTM)*: The BiLSTM model can extract contextual information from feature sequences by considering both forward and backward dependencies. Using a front LSTM, that processes the sequence in chronological order and a backward LSTM that processes the sequence in reverse order, BiLSTM allows looking ahead. The output is then produced by joining the LSTM's forward and reverse states [39, 40] as seen in Fig. 4.

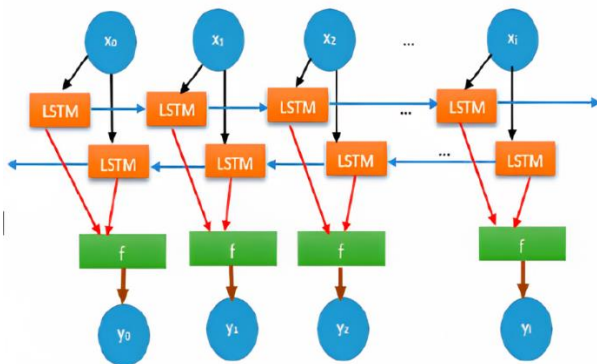

Fig. 4. BiLSTM architecture [11].

5) *1D Convolutional Neural Network (CONVID) model*: It is easy to find basic patterns in data using a convolutional neural network (CNN), which is then used to build more complex patterns in the top layers. A 1D CNN is helpful when

extracting key features from tiny (fixed-length) segments of the whole dataset. The feature's location within the segment is irrelevant; this is correct for analyzing historical data and evaluating sensor data time series. Input, output, and hidden layers comprise a CNN; a feedforward neural network is created using the intermediary layers. Since their inputs and outputs are blind to the activation function and final convolution [31], as illustrated in Fig. 5, these are called hidden layers.

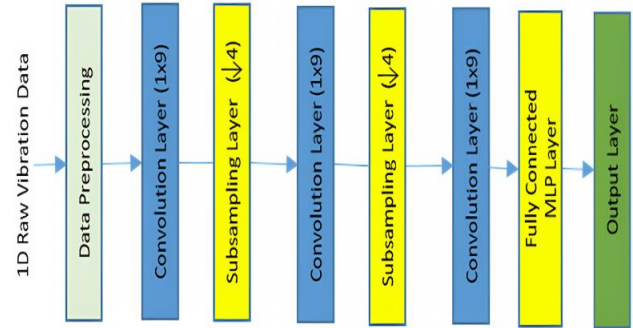

Fig. 5. 1D CNN architecture [41].

IV. THE PROPOSED MODEL FOR PREDICTING CRYPTOCURRENCY PRICE MOVEMENT

This section's suggested model focuses on three key elements. Fig. 6 illustrates the three steps used to anticipate the movement of the cryptocurrency price: (1) Dataset; (2) Data pre-processing; and (3) Deep learning-based algorithms.

Table I displays the literature review, methods used, and limitations of each study, which show the inaccuracy, the use of primitive methods, or a small dataset are all examples of shortcomings. In our research, we used similar and different methods, such as RNNs, LSTMs, GRUs, CONV1D, Bi-LSTM, and different datasets with large sizes from the Kaggle website. Using all these methods helped improve the accuracy.

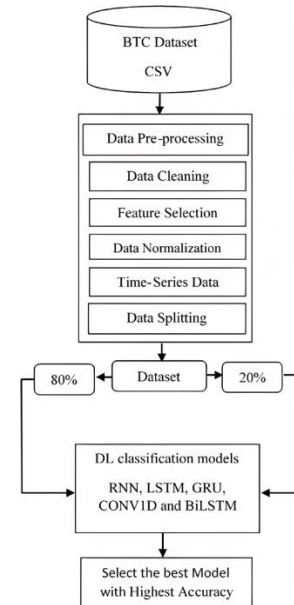

Fig. 6. The proposed model for predicting BTC price.

V. PROPOSED MODEL TESTING

During this research, an experiment was conducted to test five DL models, (RNN), (LSTM), (GRU), (Bi-LSTM), and (CONV1D); the models are designed to predict BTC Price.

A. Dataset

The data used in this study were downloaded from the Kaggle website for Bitcoin Cryptocurrency in CSV format. The dataset contains a variety of columns, including, Open, high, low, close, and Adj close prices and the volume, from the period 2014-09-17 to 2022-02-01, as shown in Fig. 7, the sample data from the datasets of the Cryptocurrency used in the study, and the target variable in this research is only the (Close Prices) Bitcoin.

	Date	Open	High	Low	Close	Adj Close	Volume

B. Data Pre-Processing

Data preparation is the first step of the experiment. Before data is supplied to the DL models, preprocessing is considered a crucial step that must be finished. Many stages were conducted during the processing, including data cleaning, feature selection, data normalization, time-series data, and data splitting.

- **Data Cleaning:** Replacing null or incorrect values with legitimate ones or eliminating the whole data point.
- **Feature Selection:** There are several variables in cryptocurrency data. Since only the Close Prices are the goal variable in our study, only relevant characteristics should be chosen, and extraneous features should be eliminated, as shown in Fig. 8.
- **Data normalization or standardization:** These processes are crucial for ensuring all data is on the same scale. In our models, we employ the MinMaxScaler function to normalize all data to a range of 0 to 1, which is crucial when working with Bitcoin data, which might have a broad range of values.
- **Time-series Data:** Cryptocurrency prices are time series data; as a result, it is crucial to transform the data into a time series format to recognize any patterns, trends, or seasonal impacts.
- **Data Splitting:** Divide the pre-processed data into training and testing sets. The prediction model will be developed using the training dataset, and its effectiveness will be assessed using the testing dataset.

C. Deep Learning Models for Predicting BTC Price Movement

We propose in this section five DL algorithms. (1) RNN (2) LSTM (3) GRU (4) BiLSTM (5) CONV1D. The architecture of these models is shown in Tables II to VI.

1) **Recurrent Neural Network (RNN) model:** Simple RNN is the model's first layer; it has one simple RNN layer consisting of 50 filters that acquire data, process it, and then pass it on to the next layer. The results are in a 7 x 50 matrix using ReLU as an Activation Function. The second layer is another simple RNN, which generates a 1 x 20 matrix using ReLU as an Activation Function. Next, the last stage in the model consists of two fully connected layers, the first one with 50 nodes and the last one with one node, which is the model's output, and we used the Adam optimizer to calculate the learning rate, as shown in Table II.

TABLE II. RECURRENT NEURAL NETWORK (RNN) MODEL

Layer (type)	Output shape	Param #
simple_rnn (SimpleRNN)	(None, 7, 50)	2600
simple_rnn_1 (SimpleRNN)	(None, 20)	1420
dense_4 (Dense)	(None, 50)	1050
dense_5 (Dense)	(None, 1)	51
Total params : 5,121 Trainable params : 5,121 Non-trainable params : 0		

2) **Long Short-Term Memory (LSTM) model:** LSTM is the second DL model; LSTM is the model's first layer consisting of 50 filters that acquire data, process it, and then pass it on to the next layer. The results are in a 7 x 50 matrix using ReLU as an Activation Function. The second layer is another LSTM, which generates a 1 x 25 matrix using ReLU as an Activation Function. Next, the last stage in the model consists of two fully connected layers: the first one with 50 nodes and the last with one node, which is the model's output, and the Adam optimizer method, as shown in Table III.

TABLE III. LONG SHORT-TERM MEMORY (LSTM) MODEL

Layer (type)	Output shape	Param #
lstm_5 (LSTM)	(None, 7, 50)	10400
lstm_6 (LSTM)	(None, 25)	7600
dense_12 (Dense)	(None, 50)	1300
dense_13 (Dense)	(None, 1)	51
Total params : 19,351 Trainable params : 19,351 Non-trainable params : 0		

3) *Gate Recurrent Unit (GRU) model*: GRU is the third DL model, GRU is the model's first layer which generates a 1 x 50 matrix, and the last stage in the model is composed of two fully connected layers, the first one with 50 nodes and the last with one node which is the output of the model, and the Adam optimizer method as shown in Table IV.

TABLE IV. GATE RECURRENT UNIT (GRU) MODEL

Layer (type)	Output shape	Param #
gru (GRU)	(None, 50)	7950
dense_8 (Dense)	(None, 50)	2550
dense_9 (Dense)	(None, 1)	51
Total params : 10,551 Trainable params : 10,551 Non-trainable params : 0		

4) *Bidirectional Long Short-Term Memory (Bi-LSTM) Model*: Bi-LSTM is the fourth DL model. Bi-LSTM is the model's first layer consisting of 200 filters that acquire data, process it, and then pass it on to the next layer. The results are in a 207 x 200 matrix. A dropout layer is a regularization approach that prevents overfitting problems in deep learning by ensuring that no units are codependent with one another. Next, the last stage in the model is composed of two fully connected layers, the first using ReLU as an Activation Function with 20 nodes and the last with one node, which is the model's output, and the Adam optimizer method, as shown in Table V.

TABLE V. BIDIRECTIONAL LONG SHORT-TERM MEMORY (BI-LSTM) MODEL

Layer (type)	Output shape	Param #
bidirectional (Bidirectional)	(207, 200)	81600
dropout (Dropout)	(207, 200)	0
Dense_10 (Dense)	(207, 20)	4020
dense_11 (Dense)	(207, 1)	21
Total params : 85,641 Trainable params : 85,641 Non-trainable params : 0		

5) *1D Convolutional Neural Network (CONVID) model*: 1DCNN is the fifth DL model; 1DCNN is the model's first layer consisting of 64 filters that acquire data, process it, and then pass it on to the next layer. The results are in a 7 x 64 matrix which uses ReLU as an Activation Function. In order to simplify the output and avoid overfitting the data, the maximum pooling layer is used after a CNN layer; This indicates that the output matrix for this layer is 2 x 64 in size. The Max Pooling1D layer shrinks the input representation by taking the maximum value across all time dimensions. Next, the last stage in the model is composed of two fully connected layers, the first with 50 nodes, then using the Flatten layer; the Flatten layer transforms convolutional layer output into a single, one-dimensional vector that may be utilized as the input for a dense layer. The last dense layer has one node, the model's output, and the Adam optimizer method, as shown in Table VI.

TABLE VI. 1D CONVOLUTIONAL NEURAL NETWORK (CONVID) MODEL

Layer (type)	Output shape	Param #
conv1d (Conv1D)	(None, 7, 64)	512
max_pooling1d(Maxpooling1D)	(None, 2, 64)	0
dense_6 (Dense)	(None, 2, 50)	3250
flatten (Flatten)	(None, 100)	0
dense_7 (Dense)	(None, 1)	101
Total params : 3,863 Trainable params : 3,863 Non-trainable params : 0		

VI. EXPERIMENTAL RESULTS AND DISCUSSION

The experiment's results will be discussed in this section.

A. Model Training

To find the best DL model, we trained utilizing DL models on the dataset in the first phase, splitting it into two groups of 80% training and 20% testing. Four assessment measures—RMSE, MSE, MAE, and R^2 —were used to examine and contrast the DL models, as will discuss in Section 6(C).

B. Epochs

The number of training set iterations is called an "epoch." The model's capacity for generalization improves as epochs increase. However, if the number of epochs is excessively high, an overfitting issue is readily created, and the model's capacity for generalization is diminished [42]. Therefore, picking the appropriate number of epochs is crucial. In this research, we used 200 epochs.

Tables VII, to XI show the loss and val_loss for each epoch on the various DL models. As shown in Fig. 9 to 13, the model's loss for the training and validation phases decrease in each epoch, indicating that the model performs optimally. The model predicts the actual and prediction phases shown in Fig. 14 to 18.

TABLE VII. LOSS, VAL LOSS OF RNN MODEL

Epoch	Loss	Val_Loss
1/200	0.0858	0.0042
2/200	0.0039	0.0032
3/200	0.0041	0.0033

C. Evaluation Metrics

R-squared score (R^2), Mean Absolute Error (MAE), Mean Squared Error (MSE), and Root Mean Squared Error (RMSE) were used to assess the performance of the deep learning models.

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (y_{t_i} - \hat{y}_{t_i})^2}{n}} \quad (1)$$

$$MSE = \frac{1}{n} \sum_{i=1}^n (y_{t_i} - \hat{y}_{t_i})^2 \quad (2)$$

$$MAE = \frac{1}{n} \sum_{i=1}^n |y_{t_i} - \hat{y}_{t_i}| \quad (3)$$

$$MAE = \frac{1}{n} \sum_{i=1}^n |y_{t_i} - \hat{y}_{t_i}| \quad (4)$$

D. Deep Learning Prediction Models Outcomes

This section covered the outcomes of the prediction models created utilizing DL models between 22-09-2021 and 01-02-2022. How well prediction models perform Tables XII, to XVI, show the testing and training results regarding RMSE, MAE, MSE, and R^2 . Table XVII displays the outcomes of utilizing various models, with the model with the lowest error values chosen as the best model. The comparison between the actual and expected values for BTC price prediction models is shown in Fig. 19, as well.

TABLE XIII. TESTING AND TRAINING OUTCOMES FOR RNN MODEL

	RMSE	MAE	MSE	R^2
Training	1512.57653	1042.15566	2287887.78387	0.9739
Testing	2312.72885	1855.64295	5348714.75799	0.9232

TABLE XIV. TESTING AND TRAINING OUTCOMES FOR LSTM MODEL

	RMSE	MAE	MSE	R^2
Training	1908.46769	1476.50991	3642248.95956	0.95846
Testing	1978.68268	1537.14424	3915185.15068	0.94383

TABLE XV. TESTING AND TRAINING OUTCOMES FOR GRU MODEL

	RMSE	MAE	MSE	R^2
Training	2091.59478	1631.35273	4374768.76158	0.95011
Testing	2170.99032	1693.30095	4713198.99972	0.93238

TABLE XVI. TESTING AND TRAINING OUTCOMES FOR Bi-LSTM MODEL

	RMSE	MAE	MSE	R^2
Training	1882.75025	1462.76491	3544748.50956	0.95957
Testing	2048.97955	1574.88476	4198317.23545	0.93977

TABLE XVII. TESTING AND TRAINING OUTCOMES FOR CONV1D MODEL

	RMSE	MAE	MSE	R^2
Training	2039.41352	1535.66479	4159207.51736	0.95257
Testing	2418.95978	1949.64524	5851366.42758	0.91606

Table XVII shows that the LSTM model, which has the lowest RMSE, MAE, and MSE values and the greatest R^2 value, performs the best in forecasting BTC prices. Fig. 19, which demonstrate how closely the forecasts of the LSTM model match the actual prices, support this. The findings show that LSTM is a better predictor than RNN, GRU, Bi-LSTM, and CONV1D. The second and third-best models are the Bi-LSTM and GRU, with higher RMSE, MAE, and MSE values.

Fig. 19. Summary of BTC price prediction models between actual and predicting.

TABLE XVIII. SUMMARY OF DIFFERENT DL MODELS PREDICTION IN TERMS OF THE VARIOUS CRITERIA

Model	RMSE	MAE	MSE	R^2
RNN	2312.72885	1855.64295	5348714.75799	0.92327
Conv1D	2418.95978	1949.64524	5851366.42758	0.91606
GRU	2170.99032	1693.30095	4713198.99972	0.93238
Bi-STM	2048.97955	1574.88476	4198317.23545	0.93977
LSTM	1978.68268	1537.14424	3915185.15068	0.94383

These models are reliable and appropriate based models are reliable and appropriate based on the assessment techniques and outcomes. It should be emphasized that these models contain many flaws that may affect how well they can forecast BTC values:

- As cryptocurrency values rely heavily on various factors, LSTMs, RNN, GRU, Bi-LSTM, and CONV1D may only be able to account for some of these

dependencies, producing predictions that could be better.

- These models are vulnerable to overfitting, particularly when trained on small datasets, which can lead to subpar performance when used with new data.

VII. CONCLUSION AND FUTURE WORK

In this research, the market capitalization of the BTC cryptocurrency was utilized to forecast the price using five different deep learning techniques: LSTM, RNN, GRU, Bi-LSTM, and CONV1D. RMSE, MAE, MSE, and R2 values were used to assess the models' performance. The study's findings showed that the LSTM model, followed by the Bi-LSTM and GRU models, offered the best accurate forecasts for the price of the BTC coin. The study's findings show that deep learning algorithms are good at forecasting cryptocurrency values and that the LSTM model outperforms RNN, GRU, Bi-LSTM, and CONV1D.

To increase the precision of BTC predictions, the researcher plans to apply more deep learning algorithms or hybrid DL models in the future. The epoch size might also be increased to get a greater accuracy rate. Deep learning methods will also examine how emotion and tweets affect BTC pricing.

The research limitations can be represented in the following points:

- The prediction process focused on Bitcoin only. It did not apply the prediction to other cryptocurrencies, for example, Ethereum and Litecoin, which can correlate and impact the price of Bitcoin.
- Not considering another factor that can impact the rise and fall of a currency's price, such as comments on social media.

Abstract—Machine learning is a branch of artificial intelligence in which computers use data to teach themselves and improve their problem-solving abilities. In this case, learning is the process by which computers use data and algorithms to build models that improve performance, and it can be divided into supervised learning, unsupervised learning, and reinforcement learning. Among them, reinforcement learning is a learning method in which AI interacts with the environment and finds the optimal strategy through actions, and it means that AI takes certain actions and learns based on the feedback it receives from the environment. In other words, reinforcement learning is a learning algorithm that allows AI to learn by itself and determine the optimal action for the situation by learning to find patterns hidden in a large amount of data collected through trial and error. In this study, we introduce the main reinforcement learning algorithms: value-based algorithms, policy gradient-based reinforcement learning, reinforcement learning with intrinsic rewards, and deep learning-based reinforcement learning. Reinforcement learning is a technology that enables AI to develop its own problem-solving capabilities, and it has recently gained attention among AI learning methods as the usefulness of the algorithms in various industries has become more widely known. In recent years, reinforcement learning has made rapid progress and achieved remarkable results in a variety of fields. Based on these achievements, reinforcement learning has the potential to positively transform human lives. In the future, more advanced forms of reinforcement learning with enhanced interaction with the environment need to be developed.

Keywords—Reinforcement learning; value-based algorithms; policy gradient-based reinforcement learning; reinforcement learning with intrinsic rewards; deep learning-based reinforcement learning

I. INTRODUCTION

Advances in artificial intelligence and machine learning technologies have led to the development and use of AI-based services in many industries. At the same time, models using reinforcement learning, a branch of machine learning, are growing rapidly.

Machine learning is a branch of artificial intelligence in which computers use data to teach themselves and improve their problem-solving abilities. In this case, learning is the process by which computers use data and algorithms to build models that improve performance, and it can be divided into supervised learning, unsupervised learning, and reinforcement learning [1, 2]. Among them, reinforcement learning [3] is a learning method in which AI interacts with the environment and finds the optimal strategy through actions, and it means

that AI takes certain actions and learns based on the feedback it receives from the environment [4]. In other words, reinforcement learning is a learning algorithm that allows AI to learn by itself and determine the optimal action for the situation by learning to find patterns hidden in a large amount of data collected through trial and error. Reinforcement learning is a technology that enables AI to develop its own problem-solving capabilities, and it has recently gained attention among AI learning methods as the usefulness of the algorithms in various industries has become more widely known [5, 6, 7].

This study is structured as follows. Section II presents the history and components of reinforcement learning, and Section III describes the main reinforcement learning algorithms: Value Based Algorithms, Policy Gradient Based Reinforcement Learning, Reinforcement Learning with Intrinsic Reward, and Reinforcement Learning based on Deep Learning. Section IV describes applications of reinforcement learning. Finally, Section V presents trends in the application of Reinforcement Learning in networking and future research directions. Section VI outlines the limitations and Section VII presents the conclusion to the study.

II. HISTORY AND COMPONENTS OF REINFORCEMENT LEARNING

Reinforcement learning can be traced back to an optimisation method for solving sequential decision problems, mathematically modelled by the Markov Decision Process, developed in the 1950s [8]. A Markov decision process is defined as a tuple (S, A, P, R, γ) , where S and A are the agent's state space and action space, respectively. P and R are transition probability and reward functions, respectively, where P is the probability distribution of the next state and R is the reward the agent will receive in the next state if it performs an action $a \in A$ in state $S \in S$. The reward is a metric for judging the goodness or badness of the agent's actions. γ is the discount rate used to write off future rewards when calculating cumulative rewards. This helps the agent reach the goal quickly and prevents the cumulative reward from drifting, so that learning is stable [9]. The optimal policy for the sequential decision problem defined by the Markov Decision Process presented above can be found by reinforcement learning.

A policy is a function that takes a state value as input and determines what action the agent should take. A reinforcement learning agent observes the state of itself and its environment based on its sensors and information from other agents, decides what to do based on the observed state values and policies, and is sometimes rewarded for its actions. At this point, the

reinforcement learning agent learns its policy to maximise its cumulative reward expectation, and the policy that maximises the cumulative reward expectation is the optimal policy. This is based on the Reward Hypothesis. The reward hypothesis states that any goal (e.g., solving a problem) can be described as maximising the agent's cumulative reward.

This implies the importance of designing a reward function. Since reinforcement learning is how an agent learns its policy by interacting with the environment through trial and error, relying on reward cues, a poor reward function will not only make it difficult for the agent to learn, but will also lead to unexpected side effects even if it does learn [10].

In summary, reinforcement learning generally consists of three main elements.

- Agent: An object that performs actions in the environment according to the current policy.
- Environment: The external system with which the agent interacts. The environment provides feedback to the agent in the form of rewards or punishments based on actions taken.
- Reward: Feedback is the positive or negative feedback an agent receives from the environment based on its actions.

The agent's goal is to maximise the total amount of rewards over time, which means that the goal of reinforcement learning is to find a strategy that maximises the cumulative reward in a given environment [11]. In most cases, this means emphasising long-term rewards over short-term rewards. This process of reinforcement learning can be thought of as a trial-and-error process, where the AI learns by taking actions and observing the rewards or punishments that result from those actions. The agent uses this information to update its policies so that it can make better decisions in the future.

III. MAIN REINFORCEMENT LEARNING ALGORITHMS

Reinforcement learning algorithms can be classified into value-based, policy-based, and model-based algorithms.

A. Value-based Algorithms

Value-based algorithms estimate the value of each state or state-action pair and select the optimal action to improve the agent's performance [12]. Typical examples are Q-learning and Deep Q-Network (DQN)(Fig. 1 and Fig. 2).

Q-learning based reinforcement learning approximates the Q-value for a state-action pair each time and then decides which action to take in which state [13]. For exploration, we often use ϵ -greedy policies. An ϵ -greedy policy is a method that chooses a random action in a given state with probability ϵ , and the action with the highest Q-value with probability $(1 - \epsilon)$. Representative examples are DQN and Rainbow [14], which combines DQN with six DQN improvement algorithms.

The technical features of DQN can be summarised as follows: first, the use of convolutional neural networks for image recognition; second, the introduction of empirical replay to eliminate the correlation between samples and increase the efficiency of sampling; and third, the separation of the online

Q-network, which determines the agent's behaviour, and the target Q-network, which is used to calculate the target Q-value, for learning stability [15].

Fig. 1. The concept of deep Q network.

First, Rainbow is a technique that combines DQN with the following six DQN enhancement algorithms. For example, double Q-learning DQN takes the maximum value of the target Q-network in the current state when calculating the target Q-value, resulting in overestimation of the target Q-value and poor learning performance. Double Q-learning prevents the overestimation of the target Q-value by calculating the target Q-value using the behavioural value that maximises the online Q-net as the input of the target Q-net [16].

Fig. 2. Concept of applying gaussian noise to the weights of a neural network.

Second, prioritised experience replay - DQN learns by extracting experiences uniformly from experience replay, i.e. prioritised experience replay is a method of extracting samples that are more likely to be conducive to learning [17].

Third, Dueling Networking-DQN calculates Q-values on the fly. Since the Q-value takes into account both state and behaviour, it can be strongly influenced by behaviour when evaluating the value in a particular state. By decomposing the Q-value into the value of a particular state and the benefit of different actions that can be taken in that state, Dueling Networks can compute the value of a particular state more robustly while taking into account the value of actions [18].

Fourth, multi-step learning DQN uses the reward after the 1-step bootstrap, which is the very next state, to compute the target Q-value. By extending it to learn with the reward information after n-step bootstrapping, it evolves into multi-step learning (ex. with improved learning stability and speed) [19].

Fifth, Distributional RL-DQN, uses the expectation of the Q-value. In this case, the limitation is that it is difficult to

exploit the randomness inherent in the Markov decision process if only the expectation of the Q-value is used. In this case, Distributional RL is a method that uses a distribution of rewards instead of a single average. By using Distributional RL, you can not only improve learning performance, but also design safer agents by allowing agents to avoid risky behaviours [20].

Sixth, Noisy Nets-DQN uses the ϵ -greedy policy. However, the ϵ -greedy policy often leads to inefficient exploration because it outputs random behaviour regardless of the agent's current situation, and there is also the problem of setting the ϵ value. This is where Noisy Nets can be used (Fig. 3). By training a neural network (Noisy Nets) that adds noise to the weights and biases of the policy neural network when training the policy neural network, Noisy Nets has the advantage that the randomness of the agent's behaviour automatically adapts to the state the agent is in and over time (reducing randomness and promoting greedy choices as training progresses) [21].

Fig. 3. The concept of noisy networks.

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \odot \begin{bmatrix} b_{11} & b_{12} & b_{13} \\ b_{21} & b_{22} & b_{23} \\ b_{31} & b_{32} & b_{33} \end{bmatrix} = \begin{bmatrix} a_{11} b_{11} & a_{12} b_{12} & a_{13} b_{13} \\ a_{21} b_{21} & a_{22} b_{22} & a_{23} b_{23} \\ a_{31} b_{31} & a_{32} b_{32} & a_{33} b_{33} \end{bmatrix}$$

Fig. 4. The concept of element-wise multiplication.

B. Policy Gradient-based Reinforcement Learning

A policy-based algorithm directly optimises the policy that determines the agent's behaviour. In other words, policy gradient reinforcement learning directly yields a policy that determines which action to take in which state. A policy can be defined as a parameter vector θ , which is a function that takes observations as input and outputs an action value as output. The use of probabilistic policies in reinforcement learning is efficient for balancing exploration and exploitation. In deep reinforcement learning, this is approximated using a functional rate deep neural network, where the parameter vector θ is the weight and bias of the neural network. Policy gradient based reinforcement learning uses a policy gradient technique to compute this parameter vector, θ . The policy gradient technique is a method that uses gradient multiplication to find θ (Fig. 4). In other words, after finding the gradient of the objective function for a given θ , updating θ by a certain distance in the direction of the increasing gradient is repeated until the gradient converges or for a maximum time step.

The objective function is the expectation of the cumulative reward of acting according to the policy, expressed as in Eq. (1).

$$J(\theta) = E_{\pi_{\theta}}[r(s, a)] \quad (1)$$

The gradient of the objective function is defined by the policy gradient theorem [22], as shown in Eq. (2).

$$\nabla J(\theta) = E_{\pi_{\theta}}[Q_{\pi}(s, a) \nabla_{\theta} \ln \pi_{\theta}(a|s)] \quad (2)$$

The policy gradient updates the policy's parameters in the direction of maximising the objective function, as shown in Eq. (3).

$$\theta \leftarrow \theta + a \nabla J(\theta) \quad (3)$$

A prime example of policy-based reinforcement learning is Proximal Policy Optimisation (PPO) [22]. One of the drawbacks of policy-based reinforcement learning is that the policy of the parameters can change rapidly. This leads to learning instability, which results in slow learning speed and poor performance. To prevent such learning instability, TRPO (Trust region policy optimisation) [23] adds a condition that constrains the Kullback-Leibler (KL) divergence before and after a policy update to be below a certain level. TRPO attracted the attention of researchers due to its success in solving robot control problems with continuous action spaces, which were not solved by DQN. However, TRPO has the disadvantage that it requires a lot of computation to solve the constraints and is incompatible with various neural network structures (e.g., dropout, parameter sharing). To compensate for these disadvantages while maintaining the performance of TRPO, PPO removes the computationally intensive KL divergence constraint and indirectly limits the number of policy renewals by simply clipping the ratio of pre- and post-policy renewals in the TRPO objective function. Although PPO was published in 2017, it is still the state-of-the-art algorithm and has been reported in many studies to be very good in terms of performance, computational efficiency and ease of implementation [24].

C. Reinforcement Learning with Intrinsic Reward

Reinforcement learning is a method of learning by exploring the environment through trial and error. In this case, the agent evaluates its behaviour and updates its policy based on the rewards it receives as a result of its actions. This can work well in environments where every action is rewarded, but policy learning is less successful in environments where rewards are infrequent and darkness is delayed. For example, suppose a game has a single reward for avoiding all obstacles, skeletons, etc. to get the key. In this case, it is difficult to determine whether an action taken in a particular state to get the key was beneficial, harmful or pointless. Even DQNs that outperform humans in many games are likely to fail in the game described above. One way to deal with this problem is to use intrinsic rewards.

Intrinsic rewards are rewards that are generated by the agent rather than given by the environment. It mimics the way humans learn through intrinsic motivation. A typical intrinsic reward function is prediction error. Prediction error is defined as the difference between the agent's predicted next state and

the actual next state. To predict the next state, an agent typically defines one or more prediction models (e.g., artificial neural networks) and trains them along with a policy. As the agent explores the environment and learns the prediction models, this prediction error will be lower for states that are familiar to the agent and higher for states that are unfamiliar to the agent, which has the effect of encouraging the agent to explore and, in games, discouraging the agent from dying and returning to the initial state. This is because the initial state is familiar to the agent, as it is the state to which the agent returns when it dies. The intrinsic reward function is designed so that the agent receives a reward for every action it performs, so it can learn well even in environments where the environment is sparse and black is a delayed reward. This also helps to broaden the application of reinforcement learning, as it reduces the need for a human to design a precise reward function for each task in the environment. However, there are a number of issues that need to be considered, such as the match between the directionality of the task the agent needs to perform and the directionality of the internal reward, the non-stationarity of the reward for performing the same behaviour in the same state as learning progresses, and the scaling of the reward across different environments.

To illustrate this, we refer the reader to Random Network Distillation [25]. Random Network Distillation consists of three neural networks: goal, prediction, and policy. The policy neural network is the one that determines the agent's behaviour, while the goal and prediction neural networks take the next state value as input and output some feature value. The goal neural network is fixed with randomly set weights, and the prediction neural network is a neural network with the same structure as the goal neural network, and is trained together with the policy neural network to produce the same output as the goal neural network. In other words, it is called Random Network Distillation because it has the effect of distilling a random network into a predictive neural network. In Random Network Distillation, the internal reward value function and the external reward value function are obtained separately and then combined, and PPO is used to optimise the policy neural network.

D. Reinforcement Learning (RL) Based on Deep Learning

Reinforcement learning refers to a group of methods for solving stochastic decision problems. Reinforcement learning can be classified as a model belonging to supervised learning or as an independent field of reinforcement learning. The reason it is classified as supervised learning is that it receives feedback or guidance from the environment, including humans, as it learns. On the other hand, it is classified as an independent model because the optimal decision process of reinforcement learning is a learning model that differs from the label-based discriminative approach typical of supervised learning. Reinforcement learning is very similar to the way humans learn, as it uses a trial and error process. For this reason, the core algorithm of AlphaGo, developed by Google DeepMind, is based on reinforcement learning. This makes reinforcement learning the closest model to artificial intelligence. Unlike supervised learning, reinforcement learning is not given training data. Instead, the reinforcement learning problem is given a reward function. The definition of solving

reinforcement learning is to find a policy function that maximises the average of future reward values. To solve reinforcement learning, researchers have borrowed a mathematical model: the Markov decision process (MDP). Intuitively, the Markov property means that, given the present, the past and the future are independent. For example, the score I get on a test tomorrow depends only on my current state and how much I study today. An MDP has four main parts.

- A set of states
- A set of actions
- A transition function
- A reward function

In this study, we will illustrate the above four points with the example in Fig. 5. The most common example used to describe MDPs is the situation of a robot in a lattice space as shown below.

Fig. 5. A robot in a lattice space.

As shown in Fig. 5, the robot can be in one of twelve grids, which is its state space. In each grid the robot can move up, down, left, right or stay in place, and these five actions correspond to the action space. If the robot's movement through the grid is determined, it will move in the desired direction, but if it is stochastic, even if the robot tries to move up, it will move right or left with some probability. In this way, the transition function describes the probability of reaching the next state when a particular action is performed in a particular state. Finally, and most importantly for reinforcement learning, a reward function is defined for each state: in the above lattice space, reaching a gem is rewarded with a +1 reward, and reaching a fire is rewarded with a -1 reward. Given an MDP, solving reinforcement learning means finding a policy function that maximises the sum of expected future rewards. This has several implications, but the most important is that it involves future rewards. While rewards from current behaviour are important, ultimately we need to consider both current and future rewards. The next thing to remember is that we're dealing with a stochastic system. It is possible that our current behaviour will not lead us to the desired state, which means that if we can get the same reward, it is better to get it 'sooner'. The discount factor takes this into account. It is set to a value less than 1 and the reward earned over time is multiplied by this value.

So, given an MDP, how do we find the optimal policy function? The two most basic ways of solving reinforcement learning are value iteration and policy iteration. To explain this, we first need to define value. If we know not only the immediate reward we can get now, but also the consensus expectation of the rewards we can get when we start from that state, we can choose the action that maximises that function each time, and thus find the optimal policy function. This consensus expectation of future rewards is called the value function, $V(s)$. Similarly, given a current state the expected future reward for taking an action in the current state is called the action value function or Q-function, $Q(s,a)$. Value iteration refers to the method of finding this value function. The value function is difficult to define intuitively because it is not only about the current state, but also about future states and the rewards that can be obtained in those states. In general, reinforcement learning uses the Bellman equation to find this value function, which is defined as follows [26].

$$V(s) = \max_a \sum_{s'} T(s, a, s') [R(s, a, s') + \gamma V(s')] \quad (4)$$

We can see that the above formula is a recursive equation with the value function $V(s)$ we want to find on the left and right sides, and the rest is the same as MDP except for $V(s)$. We can initialise $V(s)$ to any value and run the above recursive equation for all states s until it converges, always finding the optimal $V(s)$. In the previous section we looked at value iteration, but now we want to look at policy iteration, which is different from value iteration. Policy iteration consists of two phases: policy evaluation, which evaluates the performance of the current policy function, and policy improvement, which improves the policy based on the evaluation. These two phases alternate until the policy function converges. It is generally accepted that policy iterations converge to the optimal policy function faster than value iterations.

In this section we will investigate how to find the optimal policy function in an MDP when no model is given. This problem is commonly referred to as model-free reinforcement learning. The main difference from the model-based reinforcement learning described earlier is that we no longer know how the environment behaves. In other words, you do something in one state and get a reward for the next state, which is "passively" informed by the environment. Model-free reinforcement learning has several differences from model-based reinforcement learning, the most important of which is exploration. Since we don't know how the environment will behave, we have to experiment and use the results to gradually learn the policy function. Let's see how we can solve model-free reinforcement learning defined in this way. We can't use the Bellman equation directly because we don't know $T(s, a, s')$, which is the part of the Bellman equation used in model-based reinforcement learning.

Policy evaluation is a methodology for evaluating a given $V(s)$, replacing a with $\pi(s)$ above.

$$V(s) = \max_a \sum_{s'} T(s, \pi(s), s') [R(s, \pi(s), s') + \gamma V(s')] \quad (5)$$

The above formula is the policy evaluation formula used in model-free reinforcement learning. $T(s, \cdot (s), s')$ is an unknown value, but if the next state, s' , comes from a model called T , we can replace the sum of T with the sample mean. One method

that replaces the Bellman equation with sampling in this way is temporal difference (TD) learning. In an MDP, experience means that in a state s , I take an action via a given policy function ($a = \pi(s)$), and as a result I receive the next state s' and a reward r . This reward r is a function of (s, a, s') . As the experiences of (s, a, s', r) accumulate, we learn a value function $V(s)$ and an action value function $Q(s,a)$ based on these data. The expression for the Bellman equation for $Q(s,a)$ is as follows.

$$Q(s, a) \leftarrow \sum_{s'} T(s, a, s') [R(s, a, s') + \gamma \max_{a'} Q(s', a')] \quad (6)$$

The above formula can be used to update the behavioural value function $Q(s,a)$. In this formula, we can replace T with the sample estimate, which gives us the following formula.

$$(1 - \alpha)Q(s, a) + \alpha [R(s, a, s') + \gamma \max_{a'} Q(s', a')] \quad (7)$$

Solving reinforcement learning problems using the above formula is called Q-learning. All that is needed to update the Q-function using this formula is the experience of (s, a, s', r) , i.e. the action taken in one state, the observation of the next state, and the reward received, and the Q-function can be obtained using the above formula. The advantage of Q-learning is that it can find the optimal policy function without knowing the model. However, Q-learning is not a one-size-fits-all method. The main disadvantage of model-less reinforcement learning is exploration. Due to the nature of reinforcement learning, rewards may be given only once or sporadically at the end. The difficulty of this exploration increases as the state space grows.

In deep reinforcement learning (DRL) [27], a method that combines this Q-learning with deep learning techniques, one of the most important things is how well it explores. One such method is called Deep Q Network (DQN), made famous by DeepMind. DQN is the algorithm that enabled DeepMind's AlphaGo to win the 2016 World Championship against Lee Sedol and Kasparov. From the algorithmic point of view of traditional reinforcement learning, DQN doesn't bring much new to the table. However, the main advantage of the QL formula is that it can update the Q function without any information about the environment. This property is more important than you might think, because the difficulty of RL compared to traditional SL is that it considers the sum of expected future rewards, but the above formula allows you to update the Q-function with just one experience. It also has the advantage that when choosing (s, a) from (s, a, s', r) , $Q(s, a)$ always converges to the optimal action value function after infinite time, even if a random action a is chosen each time. The right-hand side of the above formula is easy to find if we know the current $Q(s, a)$ function. To find $\max_{a'} Q(s', a')$, the number of possible actions a must be finite. In other words, we can plug in all the possible actions and pick the one with the largest Q value. And if we think of $Q(s, a)$ on the left side as the output of the Q function for some input (s, a) and the right side as the target for that input, the Bellman equation for the Q function above can be interpreted as giving us the input-output pairs for the regression function that we often use in supervised learning.

IV. APPLICATIONS OF REINFORCEMENT LEARNING

Recently, there has been a lot of research and development on reinforcement learning, one of the artificial intelligence algorithms, to solve network system optimisation problems. Reinforcement learning is a system control method in which a reinforcement learning agent in a network management system uses information derived from the network environment to construct a reward function and achieve an optimal goal through iterative improvement. To do this, reinforcement learning agents go through an organic process of changing the state of the environment, controlling the behaviour of the agent, designing the value function, designing the reward function, improving the policy, and deriving the optimisation model. However, in order to learn a value function for decision making by predicting the expected value of output through predefined states and actions, a large amount of time must be invested in learning, and learning may not be performed well due to excessive environmental state information provided, or learning may be performed with the wrong goal. To overcome these problems, reinforcement learning models that improve learning efficiency and prediction accuracy performance by configuring the system's reward function as an artificial intelligence neural network have been studied. In addition, reinforcement learning models that can perform effective learning not only for discrete and limited number of behaviours, but also for very high degrees of freedom of the behaviours to be controlled are being studied.

V. TRENDS IN THE APPLICATION OF REINFORCEMENT LEARNING IN NETWORKING

As the network structure becomes more complex, various problems in the areas of routing, resource management, security and QoS/QoE arise, and to solve them, reinforcement learning application techniques are being studied, which include adaptive optimisation mechanisms for different environments. In the area of routing, research is being carried out to use reinforcement learning to optimise the routing process as network traffic grows exponentially. In resource management, researchers are applying reinforcement learning for efficient resource management and scheduling in rapidly changing network environments such as smart cities or edge clouds. This enables efficient network management by controlling network congestion or reducing overhead. In the area of network security, reinforcement learning is used to detect and respond to anomalies in the network, such as network congestion. In the area of QoS/QoE, researchers are using reinforcement learning to improve overall QoS/QoE by taking into account dynamically changing network characteristics.

VI. LIMITATIONS OF REINFORCEMENT LEARNING

One of the limitations of reinforcement learning is low data efficiency, especially in tasks where data selection is expensive, time consuming or dangerous. Therefore, one of the ways to deal with this is the off-policy technique, which can overcome the limitations of reinforcement learning to some extent if the behaviour policy and the target policy are different and the behaviour policy is carefully learned. Under this premise, imitation learning can also achieve good performance. However, most imitation learning algorithms have difficulties

in achieving performance in suboptimal trajectory situations, and usually require interaction with the environment to overcome them. Therefore, in the future, it is necessary to develop imitation learning with enhanced interaction with the environment that can overcome suboptimal trajectory situations.

VII. CONCLUSION

In summary, reinforcement learning is a learning method at the heart of the AI revolution, enabling unimagined innovations in fields as diverse as autonomous driving, healthcare and gaming. As with any ML technology, it is important to consider the ethical implications of its use and ensure that it is applied in a responsible and beneficial way. In recent years, reinforcement learning has made rapid progress and achieved remarkable results in a variety of fields. Based on these achievements, reinforcement learning has the potential to positively transform human lives. In the future, more advanced forms of reinforcement learning with enhanced interaction with the environment need to be developed.

Abstract—Blockchain technology has gained widespread recognition and adoption in various domains, but its implementation beyond crypto currencies faces a significant challenge - poor scalability. The serial execution of transactions in existing blockchain systems hampers transaction throughput and increases network latency, limiting overall system performance. In response to this limitation, this paper proposes a static analysis-driven data partitioning approach to enhance blockchain system scalability. By enabling parallel and distributed transaction execution through a simultaneous block-level transaction approach, the proposed technique substantially improves transaction throughput and reduces network latency. The study employs a hybrid shard generation algorithm within the Geth node of the blockchain network to create multiple shards or partitions. Experimental results indicate promising outcomes, with miners experiencing a remarkable speedup of 1.91x and validators achieving 1.90x, along with a substantial 35.34% reduction in network latency. These findings provide valuable insights and offer scalable solutions, empowering researchers and practitioners to address scalability concerns and promoting broader adoption of blockchain technology across various industries.

Keywords—Ethereum; shard generation; data partitioning; proof of work

I. INTRODUCTION

Blockchain technology has emerged as a groundbreaking innovation with transformative potential across various industries, revolutionizing the way we conduct transactions and manage data. The decentralized and tamper-resistant nature of blockchain networks, first introduced with Bit coin in 2008 by the enigmatic Satoshi Nakamoto, has paved the way for new applications beyond crypto currencies, such as supply chain management, healthcare, finance, and more. However, as blockchain networks continue to gain traction and see widespread adoption, a critical challenge looms large: scalability. Scalability is a pivotal concern in the broader implementation of blockchain systems [1]. As the number of participants (network nodes) and the volume of transactions grow exponentially, traditional blockchain architectures face limitations in accommodating the increasing demands on their resources and processing capabilities. This has led to performance bottlenecks, increased network latency, and limited transaction throughput, hindering the seamless scalability of blockchain networks. To address this challenge, this paper presents a novel and comprehensive solution that

leverages a combination of hybrid shard generation and data partitioning techniques. The primary objective of this approach is to enhance the scalability of blockchain architectures while preserving the core principles of decentralization, security, transparency, and immutability [2].

Sharding techniques and data partitioning have emerged as promising solutions to address scalability challenges in blockchain networks. By effectively distributing the workload and data across multiple shards or partitions, these techniques aim to enhance transaction throughput and overall network performance [3]. However, implementing sharding and data partitioning in blockchain networks comes with its own set of challenges. Ensuring consensus across multiple shards, facilitating secure cross-shard communication, and maintaining data synchronization are critical considerations.

The proposed solution begins with the introduction of a groundbreaking hybrid shard generation algorithm, inspired by the concept of sharding in database technology. This algorithm intelligently creates multiple shards within the blockchain network, each functioning as an independent blockchain with its own set of verified users and data. By strategically distributing the transaction load among these shards, we aim to optimize resource utilization and improve overall system performance, facilitating seamless scalability. Moreover, to further enhance the efficiency of the blockchain network, we employ a static analysis-driven data partitioning technique. This innovative approach enables the execution of transactions in parallel and distributed fashion across different shards, reducing contention and enhancing coordination among network nodes. By effectively partitioning data and workloads, we mitigate performance bottlenecks, promoting smoother transaction processing and improved scalability [4].

The combination of hybrid shard generation and data partitioning forms a powerful and synergistic approach to tackle the scalability challenge in blockchain networks. By enhancing transaction throughput, reducing network latency, and efficiently utilizing network resources, our solution aims to pave the way for the broader adoption of blockchain technology across diverse industries. The primary goal of this study is to implement the sharding technique in a blockchain network to improve transaction throughput and reduce network latency. By distributing the workload across multiple shards, the aim is to achieve higher transaction processing capacity and faster transaction confirmation times.

The two significant contributions to enhance the scalability of blockchain networks are:

- A novel hybrid shard generation algorithm is introduced, creating multiple shards within the network, each functioning as an independent blockchain with its set of verified users and data. The algorithm strategically distributes transaction load among these shards, optimizing resource utilization and improving system performance.
- A static analysis-driven data partitioning technique is proposed, enabling parallel transaction execution across shards, reducing contention and enhancing efficiency.

The paper is organized with discussions on related work in Section II, followed by the detailed design of the hybrid shard generation algorithm in Section III, explanation of the static analysis-based data partitioning technique in Section IV, and an experimental evaluation in Section V, showcasing impressive speedups for miners and validators and reduced network latency. A comparison with existing solutions highlights the advantages and effectiveness of the proposed approach. Section VI concludes the study.

II. RELATED WORK

This section provides a comprehensive review of the existing literature and research on blockchain scalability, shedding light on the current state of the field and the various approaches proposed to tackle scalability challenges. The related work encompasses studies on sharding techniques, data partitioning, and other scalability solutions tailored for blockchain networks. Satoshi Nakamoto's introduction of blockchain in 2008 [5] numerous industries such as finance, healthcare, supply chain, and real estate have experienced significant benefits from its innovative capabilities. However, both traditional distributed databases and blockchain systems exhibit distinct failure modes, as highlighted in [6]. To address this, a shard formation mechanism has been developed to facilitate the creation of efficient shards for parallel processing. The process of mining, being laborious and computationally intensive, has led to the emergence of distributed mining pools in well-known blockchain systems like Bitcoin and Ethereum. These pools harness distributed computational power to collectively identify the Proof of Work (PoW) and distribute rewards based on pre-established protocols [7]. Notably, the concept of dynamic blockchain sharding has been proposed, enabling the blockchain to alter its sharding configuration in real-time without requiring hard forks. An exemplary implementation of dynamic blockchain sharding is found in RapidChain.

Yizhong Liu et al. [8] present a thorough investigation of sharding in blockchain systems, with a focus on fundamental concepts, diverse approaches, and the challenges related to blockchain scalability. Their study offers a comprehensive overview of the essential building blocks of sharding solutions, with a particular emphasis on partitioning strategies, consensus mechanisms, and data management. Hung Dang et al. [9] have made significant progress in extending sharding to permissioned blockchain systems, emphasizing its potential as

a solution to address scalability challenges in blockchain networks. Their primary goal is to develop a blockchain system capable of accommodating large network size comparable to major crypto currencies like Bitcoin and Ethereum. By doing so, they aim to overcome the limitations of existing blockchain networks, which are often confined to crypto currency applications and struggle to scale consensus protocols for handling average workloads comparable to centralized processing systems[10].

Mahdi Zamani et al. [11] introduce Rapid Chain as a robust and Byzantine-resilient public blockchain protocol. By employing full sharding, Rapid Chain efficiently partitions network nodes into multiple committees, enabling parallel processing of disjoint blocks of transactions and maintaining separate ledgers. This sharding approach brings significant advancements in scalability for blockchain systems. The authors further conduct a comprehensive performance comparison, pitting Rapid Chain against other state-of-the-art sharding-based protocols like Elastico and Omniledger [12]. The evaluation showcases RapidChain's smooth scalability, effectively supporting network sizes of up to 4000 nodes. Deepal Tennakoon et al. [13] introduce a novel dynamic blockchain sharding protocol, which offers advanced capabilities such as creating new shards, adjusting existing shards, and rotating shard participants. This dynamic approach addresses the limitations of traditional blockchain sharding protocols that lacked the flexibility to modify the number of shards used. The authors also emphasize the importance of security during shard creation to prevent malicious nodes from taking control of shards [14][16]. To counter bribery attempts, the paper proposes a shard committee rotation approach through transaction mapping. The performance evaluation of the solution on the CollaChain blockchain demonstrates quasi-linear scalability, highlighting its effectiveness in handling an increasing number of shards [18][19]. A comprehensive and systematic study of sharding techniques in blockchain systems. They extensively examine the key components of sharding schemes and the major challenges associated with each component. The paper thoroughly discusses various methods to generate epoch randomness and techniques for handling cross-sharding transactions [21]. This study provides valuable insights into the state-of-the-art in sharding on blockchain, contributing to a deeper understanding of this important scalability solution [15][17].

III. DESIGN OF HYBRID SHARD GENERATION ALGORITHM

The design of hybrid shard generation algorithm is a novel approach aimed at creating efficient and scalable blockchain networks through the intelligent generation of multiple shards. Hybrid shard generation algorithm is derived through a combination of concepts from traditional sharding techniques and data partitioning strategies, with the aim of optimizing blockchain network scalability. The algorithm follows a systematic process to intelligently create multiple shards within the network, ensuring efficient transaction processing and resource utilization. It is derived through a combination of concepts from traditional sharding techniques and data partitioning strategies, with the aim of optimizing blockchain network scalability [20]. Here is a detailed description of the key steps involved in the hybrid shard generation algorithm:

A. Shard Size Determination

The first step in the algorithm is to determine the ideal size of each shard. This is based on various factors, such as network capacity, computational power, and desired transaction throughput. The goal is to find a shard size that allows for efficient processing of transactions within each shard without causing performance bottlenecks.

B. High-Volume Transaction Identification

The technique analyzes the transaction data to identify high-volume transactions and frequently accessed smart contracts. These high-volume transactions are crucial for shard creation, as they form the basis for creating initial shards.

C. Shard Creation

Shard creation is formed using the identified high-volume transactions and relevant smart contracts, the technique forms initial shards. Each initial shard is designed to handle specific types of transactions efficiently. The technique assigns a unique identifier to each shard for easy reference.

D. Load Balancing

Once the shards are created the load balancing technique analyzes the transaction load on each shard. The goal is to evenly distribute the workload among the shards to optimize resource usage and avoid overloading any specific shard. If there is an imbalance in the transaction distribution, load balancing mechanisms are employed to address it.

E. Dynamic Sharding

One of the key features of the Hybrid Shard Generation Technique is its dynamic sharding capability. This means that the technique can adjust the number of shards in real-time based on changing network conditions and transaction demands. This adaptability allows the blockchain network to scale efficiently as the transaction load fluctuates.

F. Consensus Mechanism Selection

Once the shards are formed the consensus mechanism is applied on each shard, this mechanism defines an appropriate consensus mechanism that suits the specific requirements and characteristics of the transactions processed within that shard. Different shards may use different consensus protocols, depending on their unique needs.

G. Data Partitioning

Data partitioning strategies are implemented to ensure that relevant data is stored within each shard. The aim is to minimize the need for frequent cross-shard communication, as this can impact the overall performance of the blockchain network. Data is partitioned in a way that reduces data access across different shards.

H. Communication Protocol Establishment

Blockchain transactions may require interactions between different shards, the technique establishes a communication protocol to facilitate cross-shard transactions when necessary. This communication protocol ensures secure and efficient communication between the shards.

I. Security Measures

To protect the security and integrity of the blockchain network, the technique incorporates robust security measures. These measures are designed to prevent shard takeovers by malicious nodes and safeguard the overall security and decentralization of the network.

The hybrid shard generation algorithm continuously optimizes the shard configuration, load balancing, and consensus mechanisms based on the dynamic nature of the network. It adapts to changing transaction demands, ensuring that the blockchain network can efficiently scale while maintaining security and performance [16]. The result of the algorithm is a set of optimized shards that work collaboratively to achieve enhanced scalability, increased transaction throughput, and reduced network latency. Hybrid Shard Generation Algorithm is a technique used to intelligently create multiple shards within a blockchain network, optimizing transaction distribution and load balancing to enhance scalability.

The Parameters considered for the design of hybrid shard generation algorithm are as follows [24]:

- **Total Number of Shards:** This parameter defines how many shards will be created in the blockchain network. The number of shards affects the overall network capacity and scalability.
- **Shard Size:** Each shard's size determines the number of transactions it can accommodate. Smaller shard sizes might lead to more efficient processing, but could also introduce overhead due to the increased number of shards.
- **Hybrid Approach Ratio:** If the algorithm combines different shard generation approaches (e.g., static and dynamic), this parameter might define the proportion of each approach to use.
- **Dynamic Thresholds:** If dynamic shard generation is used, parameters related to the thresholds for triggering the creation or merging of shards might be defined.
- **Data Partitioning Criteria:** Parameters related to how transactions are partitioned into different shards, such as transaction attributes, geographical location, or other relevant factors.
- **Security and Consensus Parameters:** Depending on the consensus mechanism used in the blockchain network (e.g., Proof of Work, Proof of Stake), there might be parameters related to security, validation, and consensus that impact shard generation.
- **Load Balancing Criteria:** Parameters related to load balancing across shards to ensure even distribution of transactions and computational resources.
- **Adaptability Parameters:** Parameters that determine how the system adapts to changing conditions, such as variations in transaction volume or network size.

A high-level description of the Hybrid Shard Generation Algorithm and its pseudocode:

Algorithm: Hybrid shard generation algorithm

Input:

Total number of nodes in the blockchain network (N)
Desired number of shards (S)
Sharding criteria and parameters (e.g., transaction load, user verification)

Output:

List of shards with their assigned nodes

Procedure:

- a. Calculate the number of nodes per shard ($\text{Nodes_Per_Shard} = N / S$).
- b. Initialize an empty list to store shards and their assigned nodes (*Shard_Assignment*).
- c. For each shard ($i = 1$ to S), perform the following steps:
 - i. Create a new shard (*Shard_i*).
 - ii. Select *Nodes_Per_Share* nodes randomly from the blockchain network and assign them to *Shard_i*.
 - iii. Add *Shard_i* with its assigned nodes to the *Shard_Assignment* list.
- d. If there are any remaining nodes after all shards have been created:
 - i. Assign the remaining nodes to existing shards to balance the load (e.g., round-robin fashion).
 - ii. Update the *Shard_Assignment* list accordingly.
- e. Return the *Shard_Assignment* list as the final result.

```
def hybrid_shard_generation(N, S):  
    # Calculate the number of nodes per shard  
    nodes_per_shard = N // S  
    # Initialize an empty list to store shards and their assigned  
    # nodes  
    Shard_Assignment = [ ]  
    # Create shards and assign nodes  
    for i in range(S):  
        shard_i = "Shard_" + str(i+1)  
        assigned_nodes=randomly_select_nodes(N,nodes_per_shard)  
        shard_assignment.append ((shard_i, assigned_nodes))  
    # Handle any remaining nodes  
    remaining_nodes = N % S  
    for i in range(remaining_nodes):  
        Shard_Assignment[i][1].append(Nodes[i])  
    return Shard_Assignment
```

IV. STATIC ANALYSIS-BASED DATA PARTITIONING

Static Analysis-Based Data Partitioning is an innovative technique designed to enhance the efficiency and scalability of blockchain networks by optimizing data distribution and transaction execution across different shards. Unlike traditional data partitioning methods that rely on runtime analysis, this approach utilizes static analysis to pre-determine data partitioning strategies, enabling more effective workload distribution and minimizing contention among network nodes. Here is a detailed description of the Static Analysis-Based Data Partitioning technique

A. Data Analysis

The first step in this technique involves a comprehensive analysis of the blockchain data. The goal is to identify data patterns, dependencies, and access frequency for various transactions and smart contracts. Static analysis tools are employed to analyze the code and data structures within the blockchain network.

B. Dependency Graph Generation

Based on the data analysis, a dependency graph is generated. This graph represents the relationships between different data elements and their dependencies on each other. The dependency graph provides insights into how data should be logically grouped and distributed across different shards.

C. Workload Estimation

This technique estimates the workload for each shard based on the transactions and smart contracts that are likely to be executed within each shard. This workload estimation helps in ensuring that each shard is appropriately sized to handle its share of the transactions.

D. Transaction Grouping

Transaction grouping technique groups related transactions together based on their dependencies and access patterns. Transactions that frequently interact with the same data elements are grouped together to reduce the need for cross-shard communication.

E. Shard Allocation

Once transaction grouping operation is performed, the data is partitioned and allocated to specific shards based on the dependencies and workload estimation. The goal is to minimize data access across different shards, thereby reducing contention and enhancing transaction processing speed.

F. Parallel Transaction Execution

Once the data is partitioned and allocated to the shards, parallel transaction execution process is carried out within each shard. Transactions within the same shard can be executed concurrently, optimizing resource utilization and reducing transaction processing time.

G. Cross-Shard Communication Optimization

Although the focus is on minimizing cross-shard communication, some transactions may still require interactions with data in other shards. To optimize such communication, the technique employs efficient communication protocols and algorithms, reducing latency and ensuring secure and timely cross-shard interactions.

H. Scalability Evaluation

The performance of the blockchain network with Static Analysis-Based Data Partitioning is evaluated through experiments and simulations. The goal is to assess the scalability improvements achieved by this technique and compare it with other data partitioning approaches.

Static Analysis-Based Data Partitioning is a technique that optimizes the distribution of data and workloads across different shards in a blockchain network. The goal is to

improve the efficiency of transaction processing and reduce contention among network nodes. Static Analysis-based Data Partitioning offers a proactive and efficient approach to data distribution and transaction execution in blockchain networks. By leveraging static analysis tools and pre-determined partitioning strategies, it minimizes performance bottlenecks, reduces contention, and enhances overall system performance, contributing to the seamless scalability and improved efficiency of the blockchain network [25].

Here is the Pseudocode and algorithm for Static Analysis-Based Data Partitioning:

Algorithm: Static Analysis-Based Data Partitioning

Input:

Transaction pool: List of pending transactions in the blockchain network.

Shards: List of shards in the blockchain network.

Static analysis data: Information about the workload and data distribution of each shard.

Output:

Partitioned transactions: Transactions distributed across different shards based on static analysis.

Procedure:

- a. Initialize an empty dictionary to store the workload estimation for each shard.
- b. For each shard in the Shards list, perform the following steps:
 - i. Calculate the estimated workload for the shard using static analysis data, such as the number of pending transactions and their complexity.
 - ii. Store the estimated workload in the dictionary.
- c. Sort the shards in ascending order based on their estimated workload.
- d. For each transaction in the Transaction pool, perform the following steps:
 - i. Assign the transaction to the shard with the lowest estimated workload.
 - ii. Update the estimated workload for that shard in the dictionary.
- e. Return the partitioned transactions, which are now distributed across different shards based on static analysis.

```
# Initialize an empty dictionary to store the workload estimation for each shard  
workload_estimation = { }
```

```
# Calculate the estimated workload for each shard using static analysis data for shard in Shards:  
workload = calculate_workload_estimate(shard)  
workload_estimation[shard] = workload
```

```
# Sort the shards in ascending order based on their estimated workload  
sorted_shards=sort_shards_by_workload  
(workload_estimation)
```

```
# Initialize an empty dictionary to store the partitioned transactions  
partitioned_transactions = { }  
# Assign transactions to shards based on workload for transaction in Transaction_pool:  
shard_with_lowest_workload = sorted_shards[ ]  
partitioned_transactions[transaction]=shard_with_lowest_workload  
workload_estimation[shard_with_lowest_workload] += 1  
sorted_shards=sort_shards_by_workload(workload_estimation)  
# Re-sort the shards after workload update  
# Return the partitioned transactions  
return partitioned_transactions
```

V. RESULTS AND ANALYSIS

The experiment is carried out using historical transaction data from the Ethereum blockchain, obtained from Google's Bigquery Engine's public-data archive. It's important to note that the proposed hybrid shard generation algorithm might indeed be better suited to some types of data. Blockchain networks often deal with diverse use cases, such as financial transactions, supply chain data, IoT data, and more. A hybrid approach might be optimized for specific types of transactions or use cases, making it perform better in scenarios that align with its design goals. The dataset comprised approximately 5 million transactions distributed across 80,000 blocks. Within the dataset, two types of transactions were considered: monetary transactions, involving simple and low-latency transfers of value, and contractual transactions, which required the execution of smart contracts and took longer to process. Hyperledger Caliper is a benchmarking tool specifically designed to measure the performance of blockchain systems, including transaction scalability. It supports various blockchain platforms, including Ethereum and Hyperledger Fabric, which makes it suitable for evaluating the proposed technique in different blockchain environments.

To evaluate the proposed scalable blockchain architecture, a workload was created by varying the ratios of smart contract and monetary transactions within each block. Different ratios, such as {1/1, 1/2, 1/4, 1/8, 1/16}, were used to represent different transaction scenarios. Each block in the workload contained 140 to 560 transactions based on the specified ratios. The execution setups involved both serial execution and parallel execution with multiple slave setups.

A. Performance Evaluation Metrics

The key metrics considered for assessing the effectiveness of the proposed Hybrid Shard Generation Algorithm and Static Analysis-Based Data Partitioning technique are:

- **Transaction Throughput:** This metric quantified the number of transactions processed per second by the blockchain network. A higher transaction throughput indicates better efficiency in handling a larger volume of transactions within a given time frame. Improving transaction throughput is a crucial aspect of enhancing the scalability of blockchain networks [22].

- Network Latency: Network latency refers to the time taken for a transaction to be propagated and confirmed across the blockchain network. It was measured as the end-to-end block generation time, which indicates how quickly new blocks are created and validated. Lower network latency signifies faster confirmation and validation of transactions, contributing to a more responsive and efficient blockchain system [23].

These performance metrics are fundamental in evaluating the proposed technique's impact on the scalability of the blockchain network. By analyzing transaction throughput and network latency, The aim is to demonstrate improvements in transaction processing speed and reduced network latency, leading to a more scalable and responsive blockchain architecture.

Fig. 1 show the average transaction execution time by the miner in relation to the number of shards generated, ranging from 1 to 5. As the number of shards increases, the transaction execution time decreases, measured in milliseconds (ms). This reduction in transaction execution time is attributed to the increased transaction processing efficiency within a block, resulting in enhanced transaction throughput. A larger number of shards in a block enable higher levels of parallelism, facilitating faster transaction processing and contributing to improved overall system performance.

Fig. 1. Average transaction execution time by miner.

Fig. 2. Average transaction execution time by validator.

Fig. 2 illustrates the average transaction execution time by the validator as the number of shards generated increases from 1 to 5. The transaction execution time, measured in milliseconds (ms), decreases with a higher number of shards. This decrease in transaction execution time is attributed to the increased transaction processing efficiency within a block, resulting in improved transaction throughput. As the number of shards in a block increases, the transaction processing of the transactions within that block becomes more efficient, enabling greater parallelism. This enhancement in parallel processing contributes to the overall improvement in transaction throughput.

Fig. 3. Average end-to-end block creation time by miner (with mining).

Fig. 3 displays the average end-to-end block creation time by the miner (with mining) as the number of shards increases. As the number of shards rises, the block creation time, which refers to the time taken for a block to be accepted and added to the ledger, decreases. This reduction in block creation time is attributed to the efficient processing of more transactions at a faster rate when more shards are utilized. Consequently, the adoption of multiple shards leads to shorter block creation times, as the transactions are processed more rapidly and added to the blockchain in a more efficient manner.

Fig. 4. Speedup of parallel mining over serial mining for average block creation.

Fig. 4 illustrates the speedup of parallel mining over serial mining for average block creation. Speedup represents the increase in transaction throughput compared to the baseline of serial execution, which is assigned a value of 1x. As the number of shards increase, the speedup observed becomes more significant, indicating a higher enhancement in transaction throughput. This increase in speedup is attributed to the efficient parallel processing of transactions achieved with the greater number of shards. Consequently, the adoption of more shards leads to a substantial boost in transaction throughput, demonstrating the effectiveness of the proposed approach in improving the overall performance of the blockchain system.

Fig. 5. Miner average speed increase (without mining) for transaction execution.

Fig. 5 displays the miner's average speed increase (without mining) for transaction execution. Speedup represents the rise in transaction throughput when compared to the baseline of serial execution, where the serial miner execution is assigned a value of 1x. As the number of shards increases, the observed speedup becomes more significant, indicating a higher enhancement in transaction throughput. Notably, the 5-shard architecture offers the highest speedup over the serial miner, suggesting that the adoption of a 5-shard configuration provides the most substantial improvement in transaction processing efficiency. This finding underscores the effectiveness of the proposed technique in optimizing the performance of the blockchain system and achieving higher transaction throughput.

Fig. 6 illustrates the validator's average speed increase for transaction execution. Speedup represents the rise in transaction throughput when compared to the baseline of serial execution, where the serial validator execution is assigned a value of 1x. As the number of shards increases, the observed speedup becomes more significant, indicating a higher enhancement in transaction throughput. Remarkably, the 5-shard architecture offers the highest speedup over the serial validator, signifying that the adoption of a 5-shard configuration provides the most substantial improvement in transaction processing efficiency for validators. This result further reinforces the efficacy of the proposed technique in optimizing the performance of the blockchain system and achieving higher transaction throughput for validators.

Fig. 6. Validator average speed increase for transaction execution.

B. Performance Analysis and Discussion

Table I presents the estimated workload speedup achieved with validators and miners (without mining) for different numbers of slaves in the system. The speedup values indicate how much faster the workload is executed when both validators and miners work concurrently compared to sequential execution (baseline). The table also provides the total number of transactions executed per block for each workload scenario. In the baseline scenario of serial execution, both miners and validators achieve a speedup of 1.00, which means no improvement in transaction throughput compared to sequential execution.

TABLE I. ESTIMATED WORKLOAD SPEEDUP WITH VALIDATOR AND MINER (WITHOUT MINING)

Workload (Average Speedup)		Total number of transactions executed per block				
		100	200	300	400	500
Serial Execution	Miner	1.00	1.00	1.00	1.00	1.00
	Validator	1.00	1.00	1.00	1.00	1.00
1 Slave	Miner	0.82	0.75	0.76	0.86	0.91
	Validator	0.78	0.71	0.69	0.82	0.89
2 Slaves	Miner	1.12	1.01	1.26	1.28	1.32
	Validator	1.03	1.05	1.22	1.24	1.45
3 Slaves	Miner	1.32	1.38	1.40	1.45	1.54
	Validator	1.05	1.34	1.56	1.65	1.72
4 Slaves	Miner	1.42	1.48	1.51	1.58	1.62
	Validator	1.21	1.28	1.31	1.52	1.72
5 Slaves	Miner	1.47	1.58	1.62	1.70	1.82
	Validator	1.28	1.29	1.36	1.79	1.89

The average speedup of miner and validator nodes for varying number of slave nodes as follows:

- 1 Slave: When using a single slave, both miners and validators experience a speedup of less than 1.00. This indicates that concurrent execution with only one slave is slower than sequential execution. The workload is not efficiently distributed among the participants.

- 2 Slaves: With two slaves, both miners and validators show a speedup greater than 1.00. This demonstrates that concurrent execution with two slaves is more efficient than sequential execution. The workload is better distributed, resulting in improved transaction throughput.
- 3 Slaves: As the number of slave increases to three, the speedup for both miners and validators further improves. This indicates that concurrent execution with three slaves is even more efficient in processing transactions compared to sequential execution.
- 4 Slaves: With four slaves, the speedup values continue to increase for both miners and validators, indicating a higher level of efficiency in parallel processing.
- 5 Slaves: The highest speedup values are observed when using five slaves for both miners and validators. This indicates that concurrent execution with five slaves offers the best transaction throughput improvement compared to sequential execution.

The results of the evaluation showcased the speedups achieved by miners and validators using the proposed scalable blockchain architecture. The architecture demonstrated significant improvements in transaction throughput compared to traditional serial execution. Additionally, network latency was reduced, indicating enhanced efficiency in block generation and transaction processing. To further emphasize the advantages and effectiveness of the proposed approach, a comparison with existing solutions was provided. The evaluation demonstrated that the Hybrid Shard Generation Algorithm and Static Analysis-based Data Partitioning technique outperformed conventional blockchain approaches, highlighting its potential to address scalability challenges effectively.

The results of the evaluation showcased the speedups achieved by miners and validators using the proposed scalable blockchain architecture. The architecture demonstrated significant improvements in transaction throughput compared to traditional serial execution. Additionally, network latency was reduced, indicating enhanced efficiency in block generation and transaction processing. To further emphasize the advantages and effectiveness of the proposed approach, a comparison with existing solutions was provided. The evaluation demonstrated that the Hybrid Shard Generation Algorithm and Static Analysis-Based Data Partitioning technique outperformed conventional blockchain approaches, highlighting its potential to address scalability challenges effectively. Overall, the results suggest that as the number of slaves increases in the system, the workload speedup also improves significantly. This demonstrates the benefits of parallel processing and how it enhances transaction throughput when validators and miners work concurrently in the blockchain network. The use of more slaves allows for better workload distribution and improved performance, contributing to the overall scalability and efficiency of the blockchain system.

VI. CONCLUSION

The proposed scalable blockchain architecture presents a significant step forward in addressing the critical challenge of scalability in blockchain networks. By leveraging the Hybrid Shard Generation Algorithm and Static Analysis-based Data Partitioning technique, the architecture effectively enhances transaction throughput and reduces network latency. The experimental evaluation using a blockchain simulation tool validates the effectiveness of these solutions, demonstrating notable improvements in performance. The results of the evaluation reveal that as the number of shards generated increases, transaction execution times by both miners and validators decrease, leading to improved transaction throughput. The speedup achieved by parallel mining over serial mining also increases with the rise in the number of shards, highlighting the advantages of parallel processing and efficient workload distribution. Moreover, the comparative study analysis emphasizes the significance of concurrent execution with multiple slaves, which substantially improves workload speedup for both miners and validators. This underscores the importance of parallel processing in achieving higher transaction throughput and overall network efficiency. The findings of the paper provide valuable insights into the potential of Hybrid Shard Generation and Static Analysis-Based Data Partitioning techniques in addressing scalability limitations in traditional blockchain platforms. These techniques offer practical solutions that make blockchain networks more efficient and adaptable for diverse applications in various industries. As research in this area continues to evolve, it is expected that these innovative techniques will play a pivotal role in shaping the future of blockchain networks, enabling them to handle increasing transaction volumes and meet the demands of an ever-evolving digital landscape.

Abstract—Fast and accurate detection technology for individual pigs raised in herds is crucial for subsequent research on counting and disease surveillance. In this paper, we propose an improved lightweight object detection method based on YOLOv5s to improve the speed and accuracy of detection of herd-raised pigs in real-world and complex environments. Specifically, we first introduce a lightweight feature extraction module called C3S, then replace the original large object detection layer with a small object detection layer at the output (head) of YOLOv5s. Finally, we propose a dual adaptive weighted PAN structure to compensate for the information loss of feature map at the neck of YOLOv5s caused by down sampling. Experiments show that our method has an accuracy rate of 95.2%, a recall rate of 89.1%, a mean Average Precision (mAP) of 95.3%, a model parameter number of 3.64M, a detection speed of 154 frames per second, and a model layer count of 183 layers. Comparing with the original YOLOv5s model and the current state-of-the-art object detection models, our proposed method achieves the best results in terms of mAP and detection speed.

Keywords—Pig; deep learning; computer vision; object detection

I. INTRODUCTION

According to the data of the National Bureau of Statistics 0, the total meat production in China in 2022 was 92.27 million tons, of which the pork production was 55.41 million tons, accounting for about 60.05%. It can be seen that pig farming has become a pillar industry in China's livestock industry, and with the continuous expansion of pig farming, there is a growing demand for intelligent farming technologies to improve efficiency and productivity. Currently, the daily monitoring of pigs in herds is mainly performed by humans, which is subjective and time-consuming. Computer vision technologies such as object detection can realize automatic monitoring, which is more efficient and timely.

In recent years, many studies have investigated pig object detection. However, to obtain high detection accuracy in complex scenes such as piggery requires the deployment of large models, resulting in low detection speed and an inability to meet the real-time requirements. Furthermore, pigs tend to pile up and gather together, leading to severe occlusion and adhesion in images. In addition, pigs in images often appear as small objects occupying few pixels, which makes it more difficult to extract effective features and recognize. In

summary, the main challenges faced by the current pig detection based on computer vision are:

- Detection speed and accuracy cannot be balanced, that means higher detection accuracy need bigger model size with lower detection speed, and it is difficult to meet the demand of high accuracy and real-time detection simultaneously.
- The heavily occluded nature of pigs in real farming scenarios presents a challenge for increasing detection accuracy.
- Detecting small objects such as pigs that occupy few pixels in the image is difficult and often leads to missed detections.

To address the above problems, we propose an improved object detection algorithm based on YOLOv5s for group-farmed pig. The main contributions of this paper are summarized as follows:

- A lightweight module is introduced for achieving better performance and faster speed simultaneously. The C3 module in YOLOv5s with more branches and deeper model layers has a large number of parameters and computation, which affects the model detection speed. Therefore, a more lightweight C3S module is used instead of C3 module to improve the detection speed without reducing the accuracy.
- A small object detection branch is added to the detection layer. Since small objects account for a substantial part of the dataset, and the characteristics of small objects are difficult to detect. A small object detection branch is added instead of the large object detection layer to improve the detection capability of the model for small objects.
- A dual adaptive weighted PAN structure is proposed to enhance the feature extraction ability of the neck. In view of the complexity of the real farming environment, the dual adaptive weighted PAN structure can extract more feature for object detection and thus improve the detection accuracy of the model.

II. RELATED WORKS

In recent years, a series of achievements have been made in the field of individual pig detection based on deep learning.

The detection algorithms mainly consist of one-stage and two-stage, with the one-stage representative algorithms including the YOLO series [2], SSD [5], FOCs [6], etc., and the two-stage representative algorithms including RCNN [7], Fast-RCNN [8], Faster-RCNN [9], etc.

In terms of one-stage algorithms, Yan et al. [10] improved the detection accuracy without introducing additional computation by combining Tiny-YOLO with feature pyramid attention, achieving an accuracy of 85.85% on detecting pigs in group breeding. Shen et al. [11] used the YOLOv3 and FPN algorithm for detecting piglets, achieving a detection accuracy of 93.84%. Fang et al. [12] improved the CenterNet by using MobileNet as the feature extraction network to reduce the number of parameters and increase the computation speed. By introducing a feature pyramid structure to enhance the feature extraction ability, they achieved an mAP of 94.3%. Seo et al. [13] reduced the computational workload of 3×3 convolutions in YOLOv4 to achieve fast detection of individual pigs and improved accuracy through the generation of a three-channel composite image using simple image preprocessing techniques. Ahn et al. [14] combined the test results of two YOLOv4 models at the bounding-box level to increase the pig detection accuracy from 79.93% to 94.33%. These one-stage object detection algorithms have achieved satisfactory detection accuracy in scenarios with lower pig density and less occlusion and adhesion. However, in practical applications, they may not accurately reflect the desired performance. In real breeding conditions, there is still room for improvement in striking a balance between detection accuracy and speed.

In terms of second-stage algorithms, Riekert et al. [15] combined NAS (Neural Architecture Search) with the Faster-RCNN to detect the posture and position of pigs, achieving an average detection accuracy of 80.2%. Li et al. [16] used ResNet101 combined with the FPN algorithm as the backbone network and trained Mask R-CNN with transfer learning to detect pig crawling behavior, achieving a detection accuracy of 94.5%. However, their detection speed does not satisfy the real-time detection requirements, and their large model size makes them difficult to deploy on embedded devices.

III. DATASETS AND PROPOSED METHOD

A. Datasets

The data in this study were collected from Tianpengxingwang pig breeding farm in Shunyi, Beijing in November 2019. A Hikvision camera was fixed above the pigsty at an oblique angle to cover the entire pig pen. The video was recorded in MP4 format with a resolution of 1920×1080 and a frame rate of 30 frames per second. A frame was extracted from the collected video every two minutes or every 3600 frames, resulting in a total of 500 images.

To enrich the background and shooting angles of the dataset, a publicly available group-feeding pig dataset provided by iFlytek was added. This portion of the dataset contains a total of 920 images with a resolution of 1920 × 1080, a bit depth of 24 bits, and 3-channel RGB color images. The two parts of the dataset contain 1,420 images and 43,592 pigs in total. The shooting angle is from a top-down perspective, and the shooting time includes both day and night scenes. Table I

provides a statistical summary of pig density in the dataset used in this study. We augmented the images in the training set online, including HSV transformation, horizontal flipping, translation, proportional scaling, and Mosaic augmentation.

TABLE I. A STATISTICAL SUMMARY OF PIG DENSITIES

Number of individual pigs in a single image	Number of images
13-23	287
24-34	675
35-45	360
46-62	98

B. Improved YOLOv5s

In order to strike a balance between detection speed and accuracy, in this study, we consider adopting a one-stage approach as the base model. YOLOv5 [17] is a one-stage object detection model and has been improved on the basis of YOLOv4 [18], with the characteristics of small size, fast detection speed, and easy deployment. The improvement points that greatly improve its speed and accuracy mainly include the following four aspects:

- Input: Mosaic data augmentation, adaptive anchor box calculation and adaptive image scaling.
- Backbone: CSP structures, Focus structure.
- Neck: The Path Aggregation Network (PAN) [19] and Feature Pyramid Network (FPN) [20] structures are added between the backbone and head layers as a neck network.
- Head: Loss function CIOU-Loss [21] during train, IOU [22] during prediction and Non-maximum suppression (NMS) for prediction box screening.

There are four versions of YOLOv5, which are YOLOv5s, YOLOv5m, YOLOv5l and YOLOv5x, with the network depth and width increasing progressively. While the larger versions of YOLOv5 have higher detection accuracy, they also have a larger number of parameters and computation, making them less suitable for real-time detection scenarios. As a result, we have chosen to use YOLOv5s as the base network, as it has the smallest number of parameters among the four versions and can provide a reasonable trade-off between detection accuracy and computational efficiency. However, it still cannot fully meet the demands of detection of herd pigs, which require faster and more accurate object detection algorithms.

To address the challenges posed by severe occlusion and aggregation of pigs in group-raised pig farming scenarios and the requirement for real-time detection, we propose an improved version that significantly enhances its performance. Fig. 1 shows the structure details of improved YOLOv5s. By replacing C3 with C3S module, the number of parameters and calculation amount are greatly reduced, and the detection speed is accelerated while the accuracy remains unchanged. We also add a small object layer to improve the ability of the network to detect small objects. Finally, a dual adaptive weighted PAN structure is proposed to enhance the feature extraction ability and further improve its detection accuracy.

Fig. 1. The structure of improved YOLOv5s.

C. C3S Module

C3 module consists of convolutional layers (Conv), batch normalization layers (BN), the SiLU activation function, addition operations (add), and feature map concatenation along the channel dimension (Concat). The depth factor controls the number of BottleNeck modules in the structure and can be adjusted to control the model's depth. While the C3 module improves detection performance, it can also result in a deep model that reduces inference speed and increases computational cost and parameter count.

To improve the efficiency of the model, we introduced a lightweight convolutional module called C3S, which replaced the original C3 module. In Fig. 1, the C3S module is composed of 1x1 convolutions, 3x3 convolution, and residual structure to enhance the model's expressive power and feature extraction ability. Specifically, the 1x1 convolution can not only reduce the channel dimension but also promote inter-channel information exchange. Therefore, we first use 1x1 convolutions to reduce the input feature map's channel number by half, aiming to decrease the parameter count and computation cost. Next, we incorporate 3x3 convolutions to strengthen the feature extraction ability, increasing the feature map's channel number to twice the current number and subsequently using another 1x1 convolution to perform cross-channel information integration. Finally, we introduce residual structure to prevent gradient vanishing or explosion during model training. To further improve efficiency, we also decrease the channel number of the C3S module to 3/4 of the original by controlling the width factor.

D. Small Object Detection Layer

The input image resolution is 640x640, and then the downsampling operation is used by convolution with a stride of two, resulting in output feature maps with half the width and height of the input feature map. P1, P2, P3, P4, and P5 denote feature maps obtained via convolutional layers with

downsampling steps of 1, 2, 3, 4, and 5, respectively, resulting in resolutions of 320x320, 160x160, 80x80, 40x40, and 20x20. As shown in Fig. 2, the head of YOLOv5s model consists of three detection layers, which take input feature maps of different resolutions (P3, P4, and P5). The P3 feature map, with the lowest resolution, is used to detect small objects, while the P4 and P5 feature maps are used to detect medium and large objects, respectively. In our dataset, small objects account for a large proportion of the total. Therefore, we replace the original large object detection layer in the head with a smaller one (as indicated by the red solid line) to enhance the model's ability to detect small objects in the images. The removed module is indicated by the light green dashed line.

Directly upsampling the feature map results in four times computational cost increase, which can negatively impact the inference speed. To address this issue, we first reduce the dimension of the input feature map before upsampling, which can partially alleviate the increase in parameters and computational cost. This approach improves the model's inference speed compared to direct upsampling.

$$\begin{aligned}
 Calculated = & B \times O \times [C \times (\frac{H-K+P_h}{S} + 1) \times (\frac{W-K+P_w}{S} + 1) \times (2 \times K \times K - 1) \\
 & + (C-1) \times (\frac{H-K+P_h}{S} + 1) \times (\frac{W-K+P_w}{S} + 1)]
 \end{aligned} \tag{1}$$

Eq. (1) represents the calculation formula for the convolutional computation. In this equation, *Calculated* represents the convolutional computation, *B* represents the batch size used during training, *O* represents the number of input feature map channels, *C* represents the number of output feature map channels, *H* and *W* represent the height and width of the input feature map, *P_w* and *P_h* represent the number of pixels padded in the height and width directions, respectively, *S* represents the stride of the convolutional kernel and *K* represents the size of the convolutional kernel (*H* and *W* are much larger than *K*, *S*, *P_w* and *P_h*).

Fig. 2. Sketch of the model structure after adding the small object detection layer and dual adaptive weighted PAN structure.

E. Dual Adaptive Weighted PAN Structure

A dual adaptive weighted PAN structure was proposed to enhance the feature extraction ability of the neck. The blue part in Fig. 2 represents the dual adaptive weighted PAN structure, which consists of 1×1 convolutions and adaptive addition (AA) operations. In the YOLOv5s model, the features extracted by the backbone are fed into the neck for feature fusion. The neck performs multiple downsampling and upsampling operations to generate feature maps of different sizes for detecting objects of different sizes. However, some feature information is inevitably lost during the downsampling process. To address this issue, we reuse the original features extracted by the backbone and adjust their channel numbers using 1×1 convolutions to match the channel numbers of the large, medium, and small object feature maps output by the neck. We then perform adaptive addition between the adjusted feature maps and the object feature maps. Since the importance of backbone features and neck features may not be the same, direct addition may assume equal importance. Therefore, we define this addition operation as adaptive weighted addition, where a learnable weight is used to adjust the importance of the two types of features. We train the model using backpropagation and gradient descent to update the weight until convergence is reached.

$$X_{out} = w \times X_{input1} + (1-w) \times X_{input2} \quad (2)$$

Eq. (2) represents the adaptive add operation, where X_{out} represents the output feature map, w represents the weight, X_{input1} represents input feature map A, and X_{input2} represents input feature map B.

IV. EXPERIMENTAL RESULTS AND ANALYSIS

A. Experimental Parameters Setting

The experiments in this study were conducted in Linux Ubuntu 18.0.4 environment (CPU: Inter Core i9 10900K, GPU: Nvidia GeForce RTX3060 \times 2, RAM: 64G), and the deep learning framework was Pytorch 1.9.0. See Table II for other parameter settings. The experiments in this paper were conducted using the same experimental configuration.

TABLE II. PARAMETERS SETTING IN THIS PAPER

Configuration	Value
Optimizer	SGD
Learning Rate	0.01
Momentum	0.937
Weight Decay	0.0005
Batch Size	8
Training Epochs	200

B. Evaluation Metrics

The evaluation metrics used in this paper are precision, recall, mAP, model depth, parameter count, computational complexity, F1 score, and Frames Per Second (FPS). Precision represents the proportion of true positive predictions among all positive predictions made by the model, while recall represents the proportion of true positive predictions among all actual positive instances. The mAP is related to both precision and recall, with a higher mAP indicating a higher average detection accuracy of the model. The model's parameter count, computational complexity, and depth affect the inference speed of the model, while FPS measures the number of images the model can process per second, indicating the computational speed of the model. The F1 score is the harmonic mean of

precision and recall and is used to measure the overall performance of the model. The equations for calculating these evaluation metrics are as follows:

$$Precision = \frac{TP}{TP + FP} \quad (3)$$

$$Recall = \frac{TP}{TP + FN} \quad (4)$$

$$AP = \int_0^1 P dR \quad (5)$$

$$mAP = \frac{1}{N} \sum_{i=1}^N AP_i \quad (6)$$

$$F1 = \frac{2 \times (Precision \times Recall)}{Precision + Recall} \quad (7)$$

In the above equations, N represents the total number of classes and TP , FP and FN represent the number of true positive predictions, false positive predictions and false negative predictions, respectively. P and R are abbreviations for precision and recall, respectively.

C. Impact of Different Detection Layers on Model Performance

To explore the impact of varying numbers of detection layers and input feature map resolutions on model performance, we performed three sets of comparative experiments, and the results are presented in Table III. Experiment 1 used YOLOv5's original detection layers ([P3, P4, P5]). Experiment 2 added a small object detection layer with input resolution P2 ([P2, P3, P4, P5]). Compared to Experiment 1, although the precision decreased by 0.4%, the recall and mAP increased by 1.7% and 0.7%, respectively, in Experiment 2. Therefore, the overall performance of the model with the added small object detection layer was superior to that of the original YOLOv5 model. Experiment 3 removed the large object detection layer with input resolution P5 ([P2, P3, P4]). Compared to Experiment 2, the precision, recall, and mAP of the model further improved in Experiment 3, with precision increasing by 0.4%, recall increasing by 0.7% and mAP increasing by 0.5%.

In summary, the performance of the model was improved by adding a small object detection layer, as the feature map with input resolution P2 contained more information about small objects, making it easier to detect them. Furthermore, removing the large object detection layer with input resolution P5 led to further improvements in the model's performance. We believe this is because the number of large objects in our dataset was relatively small, resulting in fewer positive samples allocated to the large object detection layer during training. As a result, the parameters of the large object detection layer were difficult to optimize, making it challenging to accurately predict the presence of large objects, which ultimately affected the overall detection accuracy.

TABLE III. IMPACT OF DIFFERENT DETECTION LAYERS ON MODEL PERFORMANCE

Experiment Number	Input of detection layer Precision(%)	Precision (%)	Recall (%)	mAP (%)
1	[P3, P4, P5] ^a	94.8	85.3	93.3
2	[P2, P3, P4, P5]	94.4	87	94
3	[P2, P3, P4]	94.8	87.7	94.5

^a The input of the detection layer [P3, P4, P5] indicates that there are 3 detection layers, and the input resolutions are 8, 16, and 32 times downsampled from the input image, respectively.

D. Comparison with Different Object Detection Models

To verify the superiority of the improved YOLOv5s model proposed in this paper for individual pig detection in group feeding, we compared its performance with the other five common object detection models, such as Faster-RCNN [9], CenterNet [23], YOLOv3 [4], YOLOv4 [18], and YOLOX [24]. The experiments were conducted using the same experimental configuration. Fig. 3 shows the training accuracy curves for the six models, with the horizontal axis representing Epoch and the vertical axis representing mAP values. It can be seen that our method achieved the highest accuracy during the training phase.

Fig. 3. Training accuracy curves of different models.

Table IV illustrates the detailed quantitative analysis of the model performance on the test dataset under same experimental configuration. It can be found that our proposed method outperforms other methods in terms of accuracy, speed, and computational efficiency. The mAP of our method achieved the highest value of 95.3%, while the FPS reached 154 frames/second. The computational complexity and number of parameters were also the lowest, with only 16.7 GFLOPs and 3.64M parameters, respectively.

To provide a more intuitive comparison of the performance of different models for individual pig detection in group feeding, Fig. 4 compares the detection results of the improved YOLOv5s model with those of other models. The green arrows in the figure indicate the missed pigs detected by each model. Compared to our model, the other models all showed missed detections, and the missed pigs in these models were all in

heavily occluded, with two of them showing only a small part of their bodies, which is a small object detection problem. These results demonstrate that the improved YOLOv5s model performs better in detecting occluded and sticky pigs, as well as small objects, effectively improving the accuracy of individual pig detection in group feeding.

E. Ablation Study

To explore the effectiveness of the proposed improvements in this paper, we conduct extensive ablation study of C3S module, dual adaptive weighted PAN structure and small object detection layer. Table V shows that the C3S module significantly reduces the number of parameters, computation

cost, and model layers while maintaining almost the same detection accuracy, demonstrating its effectiveness in improving the detection speed. Additionally, the proposed dual adaptive weighted PAN structure improves the precision, recall, and mAP of the model while keeping the computation cost, parameter count, and detection speed almost unchanged. By improving the detection layer, the model's recall and mAP are effectively increased with minimal reduction of detection speed. The improved YOLOv5s model shows a 3.8% increase in recall and a 2% increase in mAP, while reducing the parameter count by 48%, increasing FPS by 12.4%, and reducing model depth by 22%.

Fig. 4. Comparison of the detection effect of different models.

TABLE IV. PERFORMANCE COMPARISON OF DIFFERENT OBJECT DETECTION MODELS

Model	Backbone	mAP (%)	Params (MB)	FLOPs(G)	FPS	Model size (MB)
Faster-RCNN	VGG16	86.28	136.7	369.9	20	521
YOLOv3	DarkNet53	92.19	61.5	65.52	47	235
YOLOv4	CSPDarkNet53	86.55	63.9	60	46	244
YOLOX	CSPDarkNet53	93.06	8.9	26.6	61	34
CenterNet	ResNet50	86.83	32.7	70	53	125
Ours	CSPDarkNet53	95.3	3.64	16.7	154	8

TABLE V. RESULTS OF ABLATION EXPERIMENT

Model	Precision (%)	Recall (%)	mAP (%)	Parameters (MB)	FLOPs (G)	FPS	Layers
YOLOv5s	94.8	85.3	93.3	7	15.8	137	235
YOLOv5s+a	94.7	84.8	93	4.4	9.5	169	150
YOLOv5s+a+b	95.3	87.5	94.1	4.57	9.9	164	168
YOLOv5s+a+b+c ^b	95.2	89.1	95.3	3.64	16.7	154	183

^b: Note: a is the C3S module, b is the dual adaptive weighted PAN structure, and c is the small object detection layer.

F. Compared to Existing One-stage Pig Detection Methods

Table VI shows a comparison of the detection results achieved by our proposed improved YOLOv5s model on the test set, as well as the reported results of existing one-stage herd pig detection methods. Our dataset has a higher average number of pigs per image compared to the data reported in [10], [12] and [14]. Moreover, the pigs in our dataset exhibit higher levels of occlusion and adhesion, which increases the difficulty of object detection. Compared to the methods proposed in [10], [12] and [14], our proposed method achieved improvements of 9.45%, 1% and 0.97%, respectively, in terms of mAP.

TABLE VI. COMPARISON OF IMPROVED YOLOV5S AND EXISTING ONE-STAGE PIG DETECTION METHODS

Method	Average number of pigs per image	Model	mAP (%)
[10]	6	FPA-Tiny-YOLO	85.85
[12]	13	MF-CenterNet	94.30
[14]	9	YOLOv4	94.33
ours	31	Improved YOLOv5s	95.30

V. CONCLUSION

In this paper, an improved lightweight object detection method is proposed based on YOLOv5s, which has achieved higher accuracy and faster detection speed in high pig density scenarios with severe occlusion and adhesion. The lightweight C3S module proposed in this paper reconstructs the backbone and neck, resulting in a significant reduction in model parameters, computational complexity, and model depth. These modifications greatly enhance the detection speed to meet the requirements of real-time detection. The proposed dual adaptive PAN structure enhances the feature fusion capability of the neck, leading to improved detection accuracy. Furthermore, replacing the original large object detection layer with a small object detection layer in the detection stage significantly increases the recall rate and average detection precision.

Compared to existing methods for herd pig detection, our method simultaneously satisfies the requirements of high accuracy and real-time detection, making it deployable in practical group-raised farming scenarios and providing significant technical support for disease monitoring and pig counting. For future work, we expect to further enhance the feature extraction capabilities of the backbone network and streamline the model to construct a faster and more accurate object detection model for group-raised pig monitoring.

The Impact of Cyber Security on Preventing and Mitigating Electronic Crimes in the Jordanian Banking Sector

Tamer Bani Amer¹, Mohammad Ibrahim Ahmed Al-Omar²

Assistant Professor, Department of Computer Science, Jadara University, Irbid, Jordan¹

Assistant Professor, Department of Computer Networks and Cyber Security, Jadara University, Irbid, Jordan²

Abstract—As technology advances and cyber threats continue to evolve, cyber security professionals play a critical role in developing and implementing robust security measures, staying ahead of potential risks, and mitigating the impact of cyber incidents. Many studies have examined the impact of cyber security on banks, without focusing on electronic crimes. Despite its importance, to the best of our knowledge, there are no studies on the impact of cyber security on mitigating electronic crimes in the banking sector. Therefore, the purpose of this study is to ascertain how cyber security affects electronic crimes in the Jordanian banking industry. The study sample consisted of 270 senior Jordanian managers and employees who understand the importance of cyber security in the banking sector in 14 Jordanian commercial banks, listed on the Amman stock exchange. The study used SPSS to evaluate how banks can enhance network security infrastructure to prevent unauthorized access and data breaches and also to find out the role of cybersecurity in granting competitive advantage to banks. A relative importance index (RII) was conducted to rank the importance of variables' statements and test the hypotheses. The results found the most important method through which banks can effectively mitigate the risk of electronic crimes and ensure the security of customers' financial data is that banks utilize robust encryption technologies to ensure the protection of customer financial data while it is being transmitted and when it is stored (RII=0.740). About 81.5 % of the sample agree, also, banks that have a strong cyber security system provide a secure platform for digital financial services which increases the competitive advantage as they were ranked first for their relative importance at both the category level and overall ranking with (RII=0.754). The study recommended that the banking industry, must consistently educate its customers on information security techniques and how to avoid hacking into their accounts, and develop an alert system that can raise awareness for both banks and bank customers if there is any possible entry or access to the customer's account or organization confidential information.

Keywords—Cyber security; electronic crime; Jordanian banks; banking sector

I. INTRODUCTION

As technology advances and cyber threats continue to evolve, cyber security professionals play a critical role in developing and implementing robust security measures, staying ahead of potential risks, and mitigating the impact of cyber incidents. Moreover, cyber security refers to the practice of protecting computer systems, networks, and data from

unauthorized access, use, disclosure, disruption, modification, or destruction [1]. With the increasing reliance on technology and the interconnectedness of digital systems, cyber threats have become a significant concern for individuals, organizations, and governments worldwide [2]. The field of cyber security encompasses various measures, technologies, and practices designed to defend against cyber threats and ensure the confidentiality, integrity, and availability of information [3]. It involves protecting not only computers and servers, but also other devices connected to networks, such as smartphones, tablets, and the Internet.

Electronic crimes refer to illegal activities that are carried out using electronic devices, networks, or the internet [4]. With the rapid advancement of technology and the increasing reliance on digital systems, electronic crimes have become a significant concern for individuals, businesses, and governments worldwide [5]. In addition, to combat electronic crimes, governments, law enforcement agencies, and cyber security professionals work together to develop stringent laws, improve cyber security measures, raise public awareness, and promote digital literacy [6]. It is crucial for individuals and organizations to take necessary precautions, such as using strong passwords, keeping software up to date, and practicing safe online behavior, to protect themselves from falling victim to electronic crimes.

According to Arcuri et al. [7], the median cost of electronic crimes has climbed by approximately 200 percent in the last five years. Electronic crime expenditures quadrupled between 2015 and 2019, and it appears that they will double again between 2019 and 2024 [8]. Nonetheless, a considerable fraction of electronic crimes go unnoticed, such as industrial espionage getting access to confidential information. According to Seete [9], cyber risk is a huge potential threat to public and private institutions because of its effects on organizational information systems, reputation, loss of stakeholders' confidence, and financial losses. According to Bonfanti [10], the daily operations of virtually every person and organization are impacted by cyber security. Therefore, we must try to protect ourselves, our customers, and the supply chain against the loss of personal or sensitive information as technology enhances the flexibility, agility, and global reach of day-to-day operations. Must also be on the lookout for intellectual property theft, brand or reputation damage, and of course, monetary and economic losses.

Accordingly, the current study questions can be represented as follows questions:

- How can banks effectively mitigate the risk of electronic crimes and ensure the security of customers' financial data?
- How banks can enhance network security infrastructure to prevent unauthorized access and data breaches?
- How strong cyber security can give banks a competitive advantage?
- How banks can effectively educate and train employees and customers to be aware of and prevent cyber threats?

Many studies have examined the impact of cyber security on banks, without focusing on electronic crimes. However, the results are mixed [11, 12, 13] with cyber security having both a positive and a negative impact. Despite its importance, to the best of our knowledge, there are no studies on the impact of cyber security on electronic crimes in the banking sector. Therefore, the purpose of this study is to ascertain how cyber security affects electronic crimes in the Jordanian banking industry. In the unique context of the Jordanian banking industry, the study offers actual proof of the link between cyber security measures and the prevention and mitigation of electronic crimes. This empirical finding adds to the body of knowledge already available in digital crime prevention and cyber security. The study may aid in the creation and improvement of theoretical frameworks that clarify the complex link between cyber security measures and the decline in electronic crimes. This could improve the theoretical underpinnings of studies in cyber security. By concentrating on the Jordanian banking sector, the study provides context-specific insights into a particular business. For researchers, policymakers, and practitioners looking to grasp the complexities of cyber security within financial institutions, these sector-specific results can be helpful. The research will be separated into sections. We present a literature review and hypothesis development in Section II. We describe the data and methodology in Section III. We review the findings in Section IV and offer our discussions in Section 5 and conclusions in Section 6.

II. LITERATURE REVIEW AND HYPOTHESES DEVELOPMENT

A large number of studies [14, 15, 16, 17, 18, 19, 20, 21] deal with information security breaches, but there is still a limited amount of literature related to the banking sector. Electronic crimes have an unknown economic impact. A breach in information security has a negative economic impact, including decreased sales revenues, more expenses, a loss in future profits and dividends, a deterioration in reputation, and a decrease in market value [22]. Market value symbolizes investor confidence in a bank, and evaluating it is one way to calculate the damage of electronic crimes. Furthermore, Arcuri et al. [7] claim that investor behavior is influenced by what they have seen in the past, i.e., investors make decisions based on the impact of security breaches on a bank's market value in the past.

In the same context, information security plays a crucial role in combating electronic crimes [23]. Electronic crimes, also known as electronic crimes, encompass a wide range of illegal activities that are carried out using digital technologies and the internet. According to Wang et al. [12], these crimes include hacking, identity theft, phishing, malware attacks, data breaches, online fraud, and more. According to Mughal [24], Information security measures such as strong passwords, encryption, access controls, and multifactor authentication help prevent unauthorized access to sensitive data and systems. In addition, information security ensures the integrity and confidentiality of data [25]. Encryption techniques, secure data transmission protocols, and secure storage mechanisms help safeguard data from unauthorized modification, interception, or disclosure. Maintaining data integrity and confidentiality is vital in protecting sensitive information from cybercriminals who exploit it for financial gain or other malicious purposes [26].

According to Burton-Howard [27], network security plays a crucial role in mitigating electronic crimes in firms. Furthermore, effective network security measures help protect an organization's digital assets, including sensitive data, intellectual property, and financial information, from unauthorized access, data breaches, and cyberattacks [28]. Network security measures, such as firewalls, intrusion detection systems (IDS), and access controls, help prevent unauthorized individuals from gaining access to a firm network and systems [29]. Network security plays a vital role in safeguarding sensitive data from unauthorized disclosure or manipulation [30]. According to Prasad et al. [31], network security tools and technologies, such as intrusion prevention systems (IPS), security information and event management (SIEM) systems, and advanced threat detection solutions, enable firms to detect and respond to electronic crimes more effectively. According to Rafea et al. [32], network security plays a critical role in mitigating electronic crimes in the banking sector. As technology has advanced, so have the methods and sophistication of cybercriminals. By implementing robust access controls and encryption protocols, banks significantly reduce the risk of cybercriminals gaining unauthorized access to sensitive financial information [6]. According to Zainal et al. [33], banks store vast amounts of personal and financial information about customers, including account details, social security numbers, and transaction records.

In the same context, operational security known as OPSEC, plays a crucial role in mitigating electronic crimes [34]. According to Bandari [35], operational security measures, such as strong access controls, authentication protocols, and encryption, help prevent unauthorized individuals from gaining access to critical sensitive customer data. Banks hold vast amounts of personal and financial information about customers, making them attractive targets for cybercriminals [36]. According to Ritchot [37], effective operational security measures safeguard this data, ensuring its confidentiality, integrity, and availability. By implementing robust data encryption, secure storage practices, and regular data backups, banks mitigate the risk of data breaches, identity theft, and financial fraud. Operational security encompasses

advanced monitoring and detection systems that identify suspicious activities or anomalies within banking networks [38]. By deploying intrusion detection and prevention systems, security information and event management (SIEM) tools, and real-time monitoring solutions, banks promptly detect electronic crimes, such as malware infections, phishing attempts, or network intrusions [39]. Rapid detection allows for swift incident response, minimizing the potential damage caused by cybercriminals. According to Rivaldo et al. [40], maintaining a strong reputation and customer trust is vital for banks. Operational security measures, including robust cybersecurity frameworks and transparent communication about security practices, contribute to building customer confidence [41].

End-user education plays a crucial role in mitigating electronic crimes in the banking sector [42]. According to Catota et al. [43], end-user education, such as bank-customers and employees, about the risks, best practices, and preventive measures, the overall security posture of the banking sector be significantly improved. According to Alkhalil et al. [44], phishing attacks are a common method used by cybercriminals to trick users into revealing sensitive information like passwords, credit card numbers, or social security numbers. Through education, end-users learn to identify phishing attempts, recognize suspicious emails or websites, and avoid falling victim to such scams. This knowledge helps protect personal and financial information from being compromised. End-user education about safe online practices, such as keeping software and devices updated, avoiding suspicious downloads or attachments, and using secure networks, helps prevent malware infections and unauthorized access to sensitive information [45]. In the same context, end-user education and report suspicious activities promptly. Prompt reporting of potential electronic crimes to the bank security teams helps prevent further damage and enables the bank to take appropriate measures to investigate and mitigate the threat [46]. Reporting incidents also aids in the identification of emerging trends and the development of proactive security measures. Based on the aforementioned, the study develops the following hypotheses:

H1. Cybersecurity plays a crucial role in preventing and mitigating electronic crimes.

H2. Improving network security infrastructure contributes to preventing unauthorized access and data breaches.

H3. Strong cyber security practices give banks a competitive advantage.

H4. Training and educating employees and customers contribute effectively to preventing electronic crimes.

III. RESEARCH METHODOLOGY

A. Research Population and Sampling

The commercial banks listed on the Amman Stock Exchange will be the subject of the research. As the research sample, all 14 Jordan Commercial banks listed on the ASE were chosen. 270 personnel and managers who worked in various areas of the commercial banks listed on the ASE were the research participants. Due to the challenges in precisely

identifying the research population, convenience sampling, a non-probability sample technique, was used. To ascertain the impact of cyber security on electronic crimes in the Jordanian banking sector, the research looks at a questionnaire.

B. Research Design

Based on feedback from bank managers, literature research, and pre-survey analysis, the questionnaire will be created. To make it simpler for the participants to understand, it will be divided into three sections. Demographic information about the participants, such as age, gender, years of experience, position, and educational background, was requested in the first section of the survey. The second half concentrated on cyber security in commercial banks. The dependent variable (Electronic Crimes) was the subject of the third section measurement. A five-point Likert scale, with a rating of 1 for least important and 5 for most important, was used in the questionnaire. The selected sample consisted of senior Jordanian managers and employees who understood the importance of cyber security in the banking sector.

C. Measurement of Research Variables

The current research included several variables that required careful measurement to test the hypotheses and produce useful results. Cybersecurity was used as an independent variable. The electronic crimes in Jordanian banks served as the dependent variable. A structured online questionnaire and key performance indicators will be used to measure the variables. Accordingly, the data was analyzed, and the mean and standard deviation were determined.

To measure the validity of the study, the questionnaire was presented to a group of experts and specialists in the field of cybercrime and cybersecurity to review the data and receive their comments to ensure the suitability of the items of the questionnaire. The questionnaire was written in both Arabic and English to ensure high participation in this work and to obtain diverse perceptions from the sample. The results were analyzed using the SPSS statistical package for social sciences, descriptive analysis, which mainly used the factors of frequency, percentage of the study, and relative importance. After confirming the validity of the study tool and obtaining permission from the sample. A total of 300 questionnaires were distributed and 270 correct answers were received with a response rate of 90%. Responses with missing data or that did not meet serious data were excluded from the analysis.

The study examined the reliability of significant variables widely used in social studies. The main objective of this test is to verify the reliability of the items measuring variables to measure the target factors, also called internal consistency [47]. Cronbach Alpha is the most commonly used measure to perform a reliability analysis of the validity of measurement items [48], the reliability coefficient is rated between 0 to 1, although different assumptions have discussed this issue and suggest different acceptable values, the higher the value of the coefficient, the higher the degree of reliability of the measurements, the reliability analysis for this study was 0.885 which is high.

The feedback from the respondents has been analyzed and the Relative Importance Index technique was used for ranking.

The five-point Likert scale ranging from 1 (very low important) to 5 (very high important) was transformed into Relative Importance Index (RII) for each variable. The RII value has a range from 0 to 1 (0 not inclusive) and has been categorized into five levels of importance as shown in Table I.

TABLE I. RELATIVE IMPORTANCE INDEX VALUE

RII value	Importance level
From 0.8 to 1	High (H)
From 0.6 to 0.8	High-Medium (H-M)
From 0.4 to 0.6	Medium (M)
From 0.2 to 0.4	Medium-Low (M-L)
From 0 to 0.2	Low (L)

IV. RESULTS

A. Demographics Characteristics of Participant

The study includes 270 senior Jordanian managers and employees who understand the importance of cyber security in the banking sector, for gender distribution, the percentage of males 186 (68.9%) was higher than the percentage of females 84 (31.1%), and most of them were aged (31-40) while 94 (34.8%) of them more than 40 years old and 64 (23.7%) of them between (25 -30) About years of experience, the experience of the majority of the sample ranged from (1-5) years, at a rate of 37.4% and 78 (28.9%) from (6-15) years,61(22.6%) from (16-25) and 30 (11.1%) of them from 26-35 years. The majority of the sample was 57.8% of employees and 42.2% of managers. Table II summaries the demographic characteristics of the participants.

TABLE II. RESPONDENTS' DEMOGRAPHICS

Demographic	Frequency	Percent
Gender		
Male	186	68.9
Female	84	31.1
Age		
25-30	64	23.7
31-40	112	41.5
More than 40	94	34.8
Years of experience		
1-5	101	37.4
6-15	78	28.9
16-25	61	22.6
26-35	30	11.1
Nature of work		
Manager	114	42.2
Employee	156	57.8

The results about the normality distribution of the data showed a normally distributed dataset with a range of ± 1.00 to ± 2.00 of the normality distribution measure of skewness and kurtosis respectively. Related to the first question of the study, which states “How can banks effectively mitigate the risk of electronic crimes and ensure the security of customers’ financial data?” To answer this question, we analyze the results of cyber security in commercial banks as the

independent variable and ensuring network security infrastructure and mitigating risks of electronic crimes in banks, SPSS was used to calculate the mean of distribution and the standard deviation of each statement. Table III summarizes the results.

TABLE III. ARITHMETIC MEANS AND STANDARD DEVIATIONS ARE THE ESTIMATES OF THE STUDY SAMPLE ON ENSURING NETWORK SECURITY INFRASTRUCTURE AND MITIGATING RISKS OF ELECTRONIC CRIMES IN BANKS

No.	Statement	Mean	SD
1	Banks regularly provide comprehensive training programs to their employees on electronic crimes and protocols for cybersecurity.	3.04	1.113
2	Banks educate their customers on the risks of electronic crimes, cybersecurity, and the best practices for safeguarding their financial information.	3.23	0.964
3	Banks employ multi-factor authentication methods, such as hardware tokens and SMS-based verification, for customer logins.	3.23	0.925
4	Banks embrace biometric authentication techniques like fingerprint and facial recognition to verify the identity of customers.	3.32	1.136
5	Banks utilize robust encryption technologies to ensure the protection of customer financial data while it is being transmitted and stored.	3.70	0.806
6	Banks enforce strong password policies for both employees and customers.	3.30	0.647
7	Banks conduct regular security audits and vulnerability assessments of their IT systems.	3.49	0.865
8	Banks employ real-time fraud detection and prevention systems.	3.43	1.028
9	Banks have well-defined incident response plans and robust systems in place to recover from electronic crimes.	3.43	1.195
10	Banks implement systems that continuously monitor network traffic and utilize threat intelligence to identify suspicious activities.	3.67	0.798
11	Banks collaborate with cybersecurity firms and share threat intelligence.	3.42	0.656
12	Banks maintain stringent physical security measures at their data centers and server locations.	3.48	0.683
13	Banks keep their systems up to date with the latest security patches and software updates.	3.31	0.990
14	Banks maintain a strong and properly configured firewall infrastructure to prevent unauthorized access to the network.	3.40	1.043
15	Banks utilize secure protocols, such as HTTPS and SSL/TLS, for online transactions and implement disk encryption.	3.47	0.927
16	Banks segment their network into multiple zones and restrict access between them to minimize the impact of unauthorized access.	3.41	1.044
17	Banks employ Data Loss Prevention (DLP) solutions to monitor and prevent the unauthorized transmission or storage of sensitive data.	3.52	0.817
Ensuring Network Security Infrastructure and Mitigating Risks of Electronic Crimes in Banks		3.40	0.442

It is noted from Table III that the arithmetic mean of the estimates of the sample members for how can banks effectively mitigate the risk of electronic crimes and ensure the security of customers' financial data. The results found about 81.5% of the sample agreed that Banks utilize robust encryption technologies to ensure the protection of customer financial data while it is being transmitted and stored with a mean of 3.70 and standard deviation of 0.806 and 80.7% of them ensure their banks implement systems that continuously monitor network traffic and utilize threat intelligence to identify suspicious activities with mean 3.67 and standard deviation 0.798. The results also showed that 68.1% of participants ensure banks employ Data Loss Prevention (DLP) solutions to monitor and prevent the unauthorized transmission or storage of sensitive data and 64.1% agree that their banks maintain a strong and properly configured firewall infrastructure to prevent unauthorized access to the network with mean 3.52, 3.40 and standard deviation 0.817, 1.043 respectively while 37.4% and 35.6% of respondent agree that Banks employ multi-factor authentication methods, such as hardware tokens and SMS-based verification, for customer logins and enforce strong password policies for both employees and customers.

The findings found a high agreement (agree) in 58.1% of the sample with a mean of 3.32 and standard deviation 1.136 which represent that biometric authentication techniques used in the banks like fingerprint and facial recognition to verify the identity of customers. On the other hand, the samples were asked about to which extent banks keep their systems up to date with the latest security patches and software updates and collaborate with cybersecurity firms and share threat intelligence, the results showed also a high agreement of 44% and 46.7% of the sample with a mean of 3.31 and 3.42 and standard deviation 0.990 and 0.656 accordingly. Regarding the second question of the study, which states "How strong is cyber security that can give banks a competitive advantage?" The arithmetic means and standard deviations of the sample's answers to the statements related to the competitive advantage of strong cybersecurity in banks were analyzed. Table IV summarizes the results.

The results in Table IV indicated the arithmetic mean of the estimates of the sample members for the degree of effects of strong cybersecurity on competitive advantage in banks ranged between (3.08) for paragraph No (6) and (3.77) for paragraph No (10). The results show that 83.3% of participants agree that banks with a strong cybersecurity system provide them with a secure platform for innovative digital banking services with a mean (of 3.77) and standard deviation of 0.752 and 66.3% of them believe banks with a strong cybersecurity system enhance the safeguarding of customer data and minimize the risk of data breaches with a mean (3.51) and standard deviation 0.895. Regarding reputation and loyalty, the results show 46.2% confirmed banks with a strong cybersecurity system can bolster reputation and foster customer loyalty with a mean (3.44) and a standard deviation of 0.791. Meanwhile, when the participants were asked if banks with a strong cybersecurity system are less susceptible to operational disruptions or downtime, the findings revealed a moderate agreement of

40.7% of the sample with a mean of 3.08 and a standard deviation of 0.921. Otherwise, 57.8% of the sample understand that Banks with a strong cybersecurity system mitigate financial losses resulting from cyber-attacks and 35.2% understand that banks with a strong cybersecurity system establish trust and confidence among bank-customers with 3.57 and 3.21 and standard deviation of 0.961 and 0.675. Accordingly, 50.3% of participants consider banks with a strong cybersecurity system to be better equipped to detect and respond to emerging threats with a mean of 3.10 and a standard deviation of 1.178.

TABLE IV. ARITHMETIC MEANS AND STANDARD DEVIATIONS ARE THE ESTIMATES OF THE STUDY SAMPLE ON THE COMPETITIVE ADVANTAGE OF STRONG CYBERSECURITY IN BANKS

No.	Statement	Mean	SD
1	Banks with a strong cybersecurity system establish trust and confidence among bank-customers.	3.21	0.675
2	Banks with a strong cybersecurity system enhance the safeguarding of customer data and minimize the risk of data breaches.	3.51	0.895
3	Banks with a strong cybersecurity system attract and retain customers.	3.63	0.839
4	Banks with a strong cybersecurity system mitigate financial losses resulting from cyberattacks.	3.57	0.961
5	Banks with a strong cybersecurity system comply with regulatory requirements and avoid penalties.	3.47	0.839
6	Banks with a strong cybersecurity system are less susceptible to operational disruptions or downtime.	3.08	0.921
7	Banks with a strong cybersecurity system set them apart from their competitors by fostering trust and dependability.	3.24	0.835
8	Banks with a strong cybersecurity system can bolster their reputation and foster customer loyalty.	3.44	0.791
9	Banks with a strong cybersecurity system are better equipped to detect and respond to emerging threats.	3.10	1.178
10	Banks with a strong cybersecurity system provide them with a secure platform for innovative digital banking services.	3.77	0.752
The Competitive Advantage of Strong Cybersecurity in Banks		3.39	0.446

Related to the third question of the study, which states "How can banks effectively educate and train employees and customers to be aware of and prevent cyber threats?" The arithmetic means and standard deviations of the sample's answers to the statements related to effective strategies for educating and training bank employees and customers were analyzed. Table V summarizes the results.

The results in Table V indicated the arithmetic mean of the estimates of the sample members for the degree of effects strategies for educating and training bank employees and customers ranged between (3.73) for paragraph No (2) and between (3.20) for paragraph No (5). The results show that 78.1% of participants agree that Banks can administer simulated phishing exercises to assess employees' awareness and response with a mean (3.73) and standard deviation of 0.541 and 71.1% of them believe banks can encourage the

reporting of suspicious activities or potential cyber threats with a mean (3.57) and standard deviation 1.010. Regarding regular updates, the results show 63.4% confirmed Banks can provide regular updates and reminders about emerging cyber threats and best practices with a mean (of 3.47) and a standard deviation of 0.923. Meanwhile, when the participants were asked if banks can offer frequent training sessions on cybersecurity to the employee, the findings revealed a moderate agreement of 36.3% of the sample with a mean of 3.24 and a standard deviation of 0.720. Otherwise, 48.9% of the sample understand that banks can collaborate with external cybersecurity experts to organize workshops and seminars for employees and customers and 50.8 % understand that banks can regularly assess the effectiveness of cybersecurity education and training programs with a mean of 3.20, 3.31, and standard deviation 1.078, 0.983. Accordingly, 54.8% of participants consider Banks can provide incentives or rewards for active participation in cybersecurity initiatives by employees and customers with a mean of 3.38 and a standard deviation of 0.920.

TABLE V. ARITHMETIC MEANS AND STANDARD DEVIATIONS ARE THE ESTIMATES OF THE STUDY SAMPLE ON EFFECTIVE STRATEGIES FOR EDUCATING AND TRAINING BANK EMPLOYEES AND CUSTOMERS

No.	Statement	Mean	SD
1	Banks can offer frequent training sessions on cybersecurity to employees.	3.24	0.720
2	Banks can administer simulated phishing exercises to assess employees' awareness and response.	3.73	0.541
3	Banks can provide regular updates and reminders about emerging cyber threats and best practices.	3.47	0.923
4	Banks can conduct cybersecurity awareness campaigns through email newsletters, social media, or other platforms.	3.38	0.817
5	Banks can collaborate with external cybersecurity experts to organize workshops and seminars for employees and customers.	3.20	1.078
6	Banks can encourage the reporting of suspicious activities or potential cyber threats.	3.57	1.010
7	Banks can provide incentives or rewards for active participation in cybersecurity initiatives by employees and customers.	3.38	0.920
8	Banks can regularly assess the effectiveness of cybersecurity education and training programs.	3.31	0.983
Effective Strategies for Educating and Training Bank Employees and Customers		3.41	0.509

To determine the importance of the role that cybersecurity plays in preventing and mitigating cybercrime, the ranking method was used to achieve this goal, and the importance was classified based on the relative importance index (RII). Table VI summaries the results.

TABLE VI. RANKING THE ROLE THAT CYBERSECURITY IN PREVENTING AND MITIGATING CYBERCRIME

Statements	RII	Ranking category	Overall ranking	Importance level
Banks regularly provide comprehensive training	0.608	17	35	M

programs to their employees on electronic crimes and protocols for cybersecurity.				
Banks educate their customers on the risks of electronic crimes, cybersecurity, and the best practices for safeguarding their financial information.	0.646	16	29	H-M
Banks employ multi-factor authentication methods, such as hardware tokens and SMS-based verification, for customer logins.	0.646	15	30	H-M
Banks embrace biometric authentication techniques like fingerprint and facial recognition to verify the identity of customers.	0.664	12	23	H-M
Banks utilize robust encryption technologies to ensure the protection of customer financial data while it is being transmitted and stored.	0.740	1	3	H-M
Banks enforce strong password policies for both employees and customers.	0.660	14	26	H-M
Banks conduct regular security audits and vulnerability assessments of their IT systems.	0.698	4	10	H-M
Banks employ real-time fraud detection and prevention systems.	0.686	7	16	H-M
Banks have well-defined incident response plans and robust systems in place to recover from electronic crimes.	.686	8	17	H-M
Banks implement systems that continuously monitor network traffic and utilize threat intelligence to identify suspicious activities.	.734	2	4	H-M
Banks collaborate with cybersecurity firms and share threat intelligence.	.684	9	18	H-M
Banks maintain stringent physical security measures at their data centers and server locations.	.696	5	11	H-M
Banks keep their systems up to date with the latest security patches and software updates.	.662	13	24	H-M
Banks maintain a strong and properly configured firewall infrastructure to prevent unauthorized access to the network.	.680	11	20	H-M

Banks utilize secure protocols, such as HTTPS and SSL/TLS, for online transactions and implement disk encryption.	0.694	6	12	H-M
Banks segment their network into multiple zones and restrict access between them to minimize the impact of unauthorized access.	.682	10	19	H-M
Banks employ Data Loss Prevention (DLP) solutions to monitor and prevent the unauthorized transmission or storage of sensitive data.	0.704	3	8	H-M

Based on the relative importance index, all methods related to cybersecurity methods in preventing and mitigating cybercrime were of medium to high importance, but the most important methods can banks effectively mitigate the risk of electronic crimes and ensure the security of customers' financial data that banks utilize robust encryption technologies to ensure the protection of customer financial data while it is being transmitted and stored (RII=0.740). Then banks implement systems that continuously monitor network traffic and utilize threat intelligence to identify suspicious activities (RII=0.734), banks employ Data Loss Prevention (DLP) solutions to monitor and prevent the unauthorized transmission or storage of sensitive data with (RII=0.704).

Educating customers about the dangers of cybercrime, cybersecurity, and best practices to protect their financial information was also ranked 16th in importance with (RII=0.646) and Banks regularly provide comprehensive training programs to their employees on electronic crimes and protocols for cybersecurity 17th in importance with (RII=0.608).

Related to how strong cyber security gives banks a competitive advantage, the ranking method was used to achieve this goal, and the importance was classified based on the relative importance index (RII). Table VII shows the results.

TABLE VII. RANKING THE ROLE OF CYBER SECURITY ON BANKS' COMPETITIVE ADVANTAGE

Statements	RII	Ranking by category	Overall ranking	Importance level
Banks with a strong cybersecurity system establish trust and confidence among bank-customers.	.642	8	31	H-M
Banks with a strong cybersecurity system enhance the safeguarding of customer data and minimizes the risk of data breaches.	0.702	4	9	H-M
Banks with a strong cybersecurity system attract and retain customers.	0.726	2	5	H-M

Banks with a strong cybersecurity system mitigate financial losses resulting from cyberattacks.	0.714	3	6	H-M
Banks with a strong cybersecurity system comply with regulatory requirements and avoid penalties.	0.694	5	13	H-M
Banks with a strong cybersecurity system are less susceptible to operational disruptions or downtime.	0.616	10	34	H-M
Banks with a strong cybersecurity system set them apart from their competitors by fostering trust and dependability.	0.648	7	27	H-M
Banks with a strong cybersecurity system can bolster their reputation and foster customer loyalty.	0.688	6	15	H-M
Banks with a strong cybersecurity system are better equipped to detect and respond to emerging threats.	0.620	9	33	H-M
Banks with a strong cybersecurity system provide them with a secure platform for innovative digital banking services.	0.754	1	1	H-M

It is clear from Table VII that banks that have a strong cyber security system provide a secure platform for digital financial services, which increases the competitive advantage as they were ranked first for their relative importance both at the category level and overall ranking with (RII=0.754). The results also showed the high importance of a strong cybersecurity system in attracting and retaining customers and mitigating financial losses resulting from cybercrime. With (RII=0.726) and (RII=0.714) accordingly, the results also showed that there is a high importance of a strong cyber security system in banks to protect customer data, reduce risks and data breaches with (RII=0.702), and enhance the bank's reputation and loyalty with (RII=0.688), detect and respond to emerging threats with (RII=0.620)

Regarding training and educating employees and customers to contribute effectively to preventing electronic crimes, the ranking method was used, and the importance was classified based on the relative importance index (RII). Table VIII shows the results.

TABLE VIII. RANKING THE ROLE OF TRAINING AND EDUCATING EMPLOYEES AND CUSTOMERS TO PREVENT ELECTRONIC CRIMES

Statements	RII	Ranking by category	Overall ranking	Importance level
Banks can offer frequent training sessions on cybersecurity to employees.	0.648	7	28	H-M
Banks can administer simulated phishing exercises to assess employees' awareness and response.	0.746	1	2	H-M
Banks can provide regular updates and reminders about emerging cyber threats and best practices.	0.694	3	14	H-M
Banks can conduct cybersecurity awareness campaigns through email newsletters, social media, or other platforms.	0.676	5	21	H-M
Banks can collaborate with external cybersecurity experts to organize workshops and seminars for employees and customers.	0.640	8	32	H-M
Banks can encourage the reporting of suspicious activities or potential cyber threats.	0.714	2	7	H-M
Banks can provide incentives or rewards for active participation in cybersecurity initiatives by employees and customers.	0.676	4	22	H-M
Banks can regularly assess the effectiveness of cybersecurity education and training programs.	0.662	6	25	H-M

The results showed the importance of training and educating employees and customers to contribute effectively to preventing electronic crimes. The statement that Banks can administer simulated phishing exercises to assess employees' awareness and response came in the highest rank of importance (RII=0.746). The results also showed high importance for banks to encourage the reports of suspicious activities or potential cyber threats with (RII=0.714). The results also showed that there is a high importance on providing regular updates and reminders about emerging

cyber threats and best practices with (RII= 0.694) providing incentives or rewards for active participation in cybersecurity initiatives by employees and customers with (RII=0.676), and conducting cybersecurity awareness campaigns through email newsletters, social media, or other platforms with (RII=0.676). Banks can offer frequent training sessions on cybersecurity to employees and assess the effectiveness of cybersecurity education and training programs also banks can collaborate with external cybersecurity experts to organize workshops and seminars for employees and customers all these methods have a highly important role in preventing electronic crimes.

V. DISCUSSION

The results showed that cybersecurity plays a crucial role in preventing and mitigating electronic crimes. Improving network security infrastructure contributes to preventing unauthorized access and data breaches like encryption technologies; employing data loss prevention (DLP) solutions to monitor and prevent the unauthorized transmission or storage of sensitive data; enforce strong password policies for both employees and customers, define incident response plans and robust systems to recover from electronic crimes; configured firewall infrastructure to prevent unauthorized access to the network; use biometric authentication techniques and employ real-time fraud detection and prevention systems. These results are consistent with study of Ghelani et al. [17], which recommended the establishment of a smart internet banking system and intruder detection through the use of biometric prints, fingerprints, passwords, OTPs, and other methods which reduces the number of threats.

The results also showed the importance of training and educating employees and customers to prevent electronic crimes banks can conduct cybersecurity awareness campaigns and banks can collaborate with external cybersecurity experts to organize workshops and seminars for employees and customers. These results agree with Sharma [49] who recommended the key to cyber security solutions is having well-trained staff and effective awareness campaigns to conduct a thorough analysis of risk management, an internal security task team should collaborate with a reliable security vendor. These study results also agreed with Al-Alawi & Al-Bassam's [50] study which shows mandating security awareness training is one of the most commonly used methods by boards of directors and executive managers to reduce cyber risks.

The finding shows that the knowledge and skills of the team of employees who deal with cyber attempts are important factors in determining the effectiveness of the cyber security method used. These results agreed with the study of Malik & Islam [51], which showed that cybercrime incidents harm organizational performance but awareness of information security reduces the negative impact of cybercrime and the roles of awareness related to information security in reducing cyber fraud and enhancing the security of customer information and the overall performance of financial institutions, also agreed with Khan [52] and Al-Daeef et al. [53] studies which emphasized the need to educate employees through programs aimed at educating employees about safe computing practices and the risks of human error that may

lead to security breaches; for example, phishing simulations that provide in-depth worker training scenarios are a proven method for increasing security awareness.

The results ensure that cybersecurity can boost customer trust by preventing sensitive customer data from being leaked and allowing a company to deliver on its promises, so if a bank had no breaches, it would be highly regarded and retained by its customers. These findings agreed with Kosutic [54] which recommended that companies could achieve strategic value that will be challenging to imitate by developing specific cybersecurity dynamic capabilities, and thereby achieve sustainable competitive advantage. Another study by Vijayalakshmi et al. [55] also confirmed this result.

The study also confirmed that one source of competitive advantage for a bank is to have cybersecurity to evaluate the current security measures and protect crucial data which is consistent with Kosutic [54] which explores the elements needed for cybersecurity implementation and management in an organization, as well as how cybersecurity can contribute to the competitive advantage of a company.

The study confirms that cybercrime is an emerging threat to IT facilities, the ever-changing nature of cybercrime and the associated development makes it increasingly difficult for policymakers and government institutions to implement cybercrime laws and policies, as a result, the banking industry must consistently educate its customers on information security techniques and how to avoid hacking into their accounts.

The study recommends to develop an alert system that can raise awareness for both banks and bank-customers whenever there is any possible entry or access to the customer's account or organization's confidential information. Furthermore, the banking industry must take into account the concept of effectively implementing and integrating big data technology into its system mitigating the negative consequences of cybercrime. This will allow for the storage of large files, and the data would aid in the examination, monitoring, and detection of network irregularities.

VI. CONCLUSION

The study's conclusions may directly affect how the Jordanian banking industry develops its regulatory and policy frameworks for electronic crime prevention and cyber security. The study's findings can help policymakers as they create recommendations and legislation. The report might provide banks in Jordan and possibly elsewhere with useful advice for developing effective risk management plans to protect against cybercrime. Based on the study's recommendations, banks can modify their cyber security procedures. The study's findings may help banks to be better equipped to defend against online attacks. Banks can discover weaknesses and put preventative measures in place to stop electronic crimes using the study's insights.

VII. LIMITATION

This study has several limitations; one of the most important is the amount of survey feedback received such as this study would have benefited from more responses. Despite

the limitation mentioned above the results obtained in this study is significant for Jordan's banking and financial institutions, which can use the findings to improve their employees' skills in detecting various cyber-attacks. Furthermore, these findings are critical in broadening the understanding of cybersecurity and its impact on financial matters for organizations. Also, the study was limited to cybersecurity with no examination of areas closely related to cybersecurity such as privacy, fraud, and physical security; these related areas may influence some cybersecurity models presented in this study.

Abstract—This paper proposes a Pro-Dueling DQN algorithm to solve the problems of slow convergence speed and waste of effective experience of the traditional DQN (Deep Q-Network) algorithm for the local path planning of mobile robot. The new algorithm introduces a priority experience playback mechanism based on SumTree to avoid forgetting the learning effective experiences as the number of samples in the experience pool increases. A more detailed reward and punishment function is designed for the new algorithm to reduce the blindness of extracting experience in the early stages of algorithm training. The feasibility of the algorithm is verified by comparative verification on ROS simulation platform and real scene, respectively. The results show that the designed Pro-Dueling DQN algorithm converges faster and the length of planned path is shorter than that of the original DQN algorithm.

Keywords—Deep Q-Network (DQN) algorithm; local path planning; mobile robot; Pro-Dueling DQN algorithm; SumTree

I. INTRODUCTION

It is crucial for robots to avoid obstacles and plan effective paths in the research of mobile robot navigation. There are many effective path planning methods for obstacle avoidance at present. The traditional methods mainly include A* algorithm [1], Dijkstra algorithm [2], fuzzy control algorithm [3], genetic algorithm [4], artificial potential field method [5] and neural network [6]. Reinforcement learning algorithm [7] has received widespread attention because it can solve the shortcomings of traditional algorithms such as strong dependence on environment in robot path planning. It does not require any prior knowledge, and optimizes the strategy by interacting with the environment and accumulating rewards. The combination of deep learning [8] and reinforcement learning has extended traditional reinforcement learning to multidimensional state space and action space in recent years. Deep reinforcement learning [9] combines the ability of deep learning algorithm to understand perception problems and the ability to fit the learning results of reinforcement learning algorithm [10]. It has been widely used in robot path planning research.

Q-learning algorithm is one of the reinforcement learning algorithms proposed by Watkins, which is independent of environmental prior model in the path planning problem of mobile robot[11]. However, the strategy of storing the state-action value function by a Q-value table will cause the disaster of dimension as the environment states become more and more complex. Mnih et al. proposed Deep Q-Network (DQN),

which combined CNN (Convolutional Neural Networks) with Q-learning algorithm to solve the dimension disaster of Q-learning method, and pushed the research of deep reinforcement learning to a new level [12]. Z. Wang et al. innovated the network structure on the basis of DQN and divided the network into two parts: value function and advantage function to reduce the excessive dependence of states on the environment [13]. J.F. Zheng et al. proposed an improved DQN algorithm based on depth image information. PTZ (Pan/Tilt/Zoom) was used to obtain depth image information of obstacles, which improved the convergence speed of the network, but the stability and computational speed of the algorithm could not be guaranteed [14]. Xiaofei Yang et al. proposed a global path planning algorithm based on DDQN, which integrated an action mask method to deal with the invalid actions generated by the amphibious unmanned vehicle, but the algorithm training speed is not ideal[15]. Meng Guan et al. proposed a DQN path planning method combining heuristic reward and adaptive exploration strategy, designed a heuristic reward function based on artificial potential field method, and self-adaptively adjusted the balance between exploration and utilization in the algorithm, which accelerated the learning efficiency of the algorithm. However, the algorithm verification only stayed in the simulation stage, and the efficiency of the algorithm has not been verified in the real scene [16]. The new method improves the efficiency of the algorithm's exploration, but the length of exploration in the direction of exploration increases, resulting in excessive spatial dimensions.

This paper presents a Pro-Dueling DQN algorithm to solve the problems of poor convergence and waste of effective experience in the local path planning of mobile robot using DQN method. The research modifies the DQN neural network structure to combine the state value and action value to obtain a more accurate Q-value. The priority experience playback strategy [17] based on SumTree is adopted to give priority to the samples in the experience pool, and designs a reward and punishment function to solve the convergence difficulty problem caused by sparse rewards in unknown environments. This improves the utilization rate of effective experience in the algorithm, avoids the problem of local optimal solution, and accelerates the convergence speed of the algorithm. Comparing the convergence speed and planned path length of the two algorithms in simulation and real environments, experimental results show that the Pro-Dueling DQN algorithm performs better in various scenarios.

II. DQN ALGORITHM

DQN algorithm combines Q-learning algorithm with deep learning, uses network structure in deep learning to predict Q-value, and generates Q-table dynamically. It not only avoids the disaster of dimensionality in complex space, but also solves the instability problem of approximate representation of value functions for nonlinear functions to a certain extent [18]. Fig. 1 shows the process of DQN algorithm.

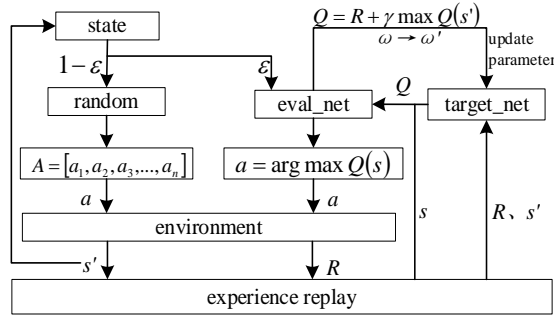

Fig. 1. DQN algorithm process diagram.

The algorithm defines two relatively independent networks with the same structure, namely *eval_net* and *target_net*. The agent interacts with the environment to achieve learning of the training network. All the parameters in the training network are assigned to the target network after the training of a fixed number of steps. The algorithm sets an experience replay unit to reduce the correlation of training samples and improve the instability of the action value function of neural network approximation reinforcement learning [19]. A batch of samples are evenly selected from the experience library and mixed together with the training samples to break the correlation between adjacent training samples and improve the utilization rate of the samples during each training. Where, the LOSS function is:

$$LOSS = \frac{1}{2} (Q_{\omega}(s) - (R + \gamma \max_{\omega'} Q_{\omega'}(s')))^2 \quad (1)$$

In Eq. (1), ω is a parameter in the *eval_net*, ω' is a parameter in the *target_net*. The parameters of *target_net* are synchronized with the training network every N steps to make the updated target more stable, that is, $\omega' \leftarrow \omega$.

III. PRO-DUELING DQN ALGORITHM

This research proposes a Pro-Dueling DQN algorithm to improve the training speed and convergence of DQN algorithm. Two different branches are introduced at the back end of DQN neural network to predict the value of state and action, then the results of these two branches are combined to output the Q-value to reduce the dependence of action on state. In addition, the priority experience playback based on SumTree replaces the uniform sampling playback mechanism of DQN algorithm to increase the sampling rate of important samples. The Pro-Dueling DQN algorithm includes the design of network structure of state space and action space, reward and punishment function and priority experience playback.

A. The Design of State Space and Action Space

The state space is the feedback of the environment information of the mobile robot. The input of the network is the state vector. The robot selects the subsequent action based on the state information, obtains the corresponding reward or punishment, and optimizes the strategy by accumulating the reward value.

The laser radar installed on the robot detects the surrounding environmental information. The detection range of radar sensor is 180°, and a group of data is returned every 15° with a total of 12 groups. Fig. 2 shows the laser radar information.

Fig. 2. Laser radar information.

The position information of the robot consists of the obstacle distance information returned by the radar in 12 directions d_n ($n=0\sim 11$), the distance between the robot and the target point D_g , and the angle between the robot and the target point θ_g . The state space of the robot is defined as:

$$S = (d_n, D_g, \theta_g) \quad (2)$$

The robot's action space includes action information in five directions, defined as:

$$A = \{a_t, t = 0 \sim 4\} \quad (3)$$

The linear speed of the robot is constant, set as 0.15m/s, and the angular velocity is determined by its action. The relationship between the robot angular velocity (Angle_v) corresponding to the five action values of the robot is shown in Table I.

TABLE I. CORRESPONDING RELATIONSHIP BETWEEN ROBOT ACTION AND ROTATION ANGLE

Action	Angle_v (rad/s)
0	-1.5
1	-0.75
2	0
3	0.75
4	1.5

B. Network Structure

The neural network used by Pro-Dueling DQN algorithm contains 14 inputs of the state space and 5 outputs of the action space, as shown in Fig. 3.

Fig. 3. Input and output of Pro-Dueling DQN network.

In the Pro-Dueling DQN algorithm, the output of the network includes a value function and an advantage function. The formula is as follows:

$$Q(s, a; \gamma, \alpha, \beta) = V(s; \gamma, \beta) + A(s, a; \gamma, \alpha) \quad (4)$$

In Eq. (4), $V(s; \gamma, \beta)$ is a value function, $A(s, a; \gamma, \alpha)$ is the advantage function of taking different actions in this state, indicating the difference of taking different actions. γ is a network structure, α is the parameter of value function, β is the parameter of advantage function. It can be seen from the formula that $V(s; \gamma, \beta)$ function is only related to the state, and $A(s, a; \gamma, \alpha)$ depends on both state and action. The neural network outputs the value function and dominance function, respectively, and sums them to obtain the Q value. The robot only pays attention to the value of the state in some cases, and does not care about the difference caused by different actions by modeling $V(s; \gamma, \beta)$ function and $A(s, a; \gamma, \alpha)$ function. The approach works better with states that are less associated with an action.

Fig. 4 shows the network structure of the Pro-Dueling DQN algorithm. L_1 and L_2 are fully connected layers, which contains 128 and 64 hidden neuron nodes, respectively. In the network, input eigenvalues are used to obtain eigenvectors using a convolutional network. When outputting, two fully connected layers are used to correspond to the state value and advantage value, respectively. Finally, the state value and advantage value are added to obtain the action value of each action.

Fig. 4. Pro-Dueling DQN network structure.

C. The Design of Reward and Punishment Function

In the process of reinforcement learning, rewards and punishments obtained by mobile robot in its interactions with the environment are the key to completing tasks. In this research, the reward and punishment function is further refined, which including two parts: R_θ , the reward and punishment function of the angle between the robot and the target point, and R_t , the reward and punishment function of the distance between the robot and the obstacle. The final reward and punishment value R is obtained as follows by adding the two parts:

$$R_\theta = \begin{cases} C, & -\frac{1}{2}\pi < \theta < \frac{1}{2}\pi \\ -C, & \text{else} \end{cases} \quad (5)$$

$$R_t = \begin{cases} r_{goal}, & d_c < c_d \\ r_{collide}, & \min_x < c_o \end{cases}$$

$$R = R_\theta + R_t$$

In Eq. (5), C is a positive integer, θ is the angle of the robot to the target point, r_{goal} is a positive integer which representing a positive reward of the robot reaching the target point, d_c is the actual distance from the robot to the target, c_d is the threshold of reaching the target point. It means that the robot has reached the target point, when d_c is less than c_d . $r_{collide}$ is a negative integer, representing the penalty for the robot to encounter with obstacles, \min_x is the radar minimum, c_o is the safe distance. It is determined that the robot collides with obstacle as the radar value is less than the safe distance.

D. Priority Experience Playback Based on SumTree

The research adopts the priority experience replay strategy to improve this situation. The most valuable experiences are extracted first as training. TD -error determines the priority of the sample. The target function is weighted according to the TD -error of the sample. The greater the deviation, the larger the sample weight, and the higher the priority p is.

A random sampling method combined greedy sampling and uniformly distributed table sampling is used to solve the overfitting problem caused by greedy priority in the process of function approximation. This method ensures that the probability of sampling from the storage container is monotonous, and the lowest priority sample has a non-zero probability of being drawn. The sampling probability is as follows:

$$P(i) = \sum_k^{P_i^\alpha} P_k^\alpha \quad (6)$$

In Eq. (6), P_i is the priority of the i th sample, P_k is the priority of any sample, α is used to adjust the degree of priority. It is reduced to uniform sampling, when $\alpha = 0$. k is the number of batches of samples.

IV. ANALYSIS AND VERIFICATION OF PRO-DUELING DQN ALGORITHM

In this research, the environments of discrete obstacles, U-shaped obstacle and mixed obstacles are set for training to verify the feasibility of the designed Pro-Dueling DQN algorithm. The algorithm is compared in different environments with the traditional DQN algorithm. The environments are built on Gazebo of ROS platform. Their informations are projected into Rviz. The path planned by the mobile robot from the starting point to the target point is displayed on Rviz. In Rviz, the initial position of the robot is the starting point, the gray box represents the target point, the gray cylinder shows the obstacle, and the blue solid line

expresses the trajectory of the robot. A comparison graph of the average return value of each round of the two algorithms is drawn to observe the convergence of the algorithm more clearly and intuitively. The horizontal axis represents the number of training, and the vertical axis expresses the average reward of each training. At the same time, the path lengths of the robot by the two algorithms for path planning are recorded. Table II illustrates the parameter settings in the experiment.

TABLE II. EXPERIMENTAL PARAMETER SETTING

Parameter	Initialization value
learning rate	0.0001
attenuation factor	0.999
experience pool capacity	10000
number of learning experiences per round	128
maximum number of steps per round	400

A. Simulation Verification in Discrete Obstacles Environment

Fig. 5 shows the 7m×7m discrete obstacles environment set in Gazebo. The initial position of the robot is (-2.5, -2.5), and the target point coordinate is (2.2).

Fig. 5. The discrete obstacles simulation environment.

In the discrete obstacles environment, the two algorithms conduct 200 rounds of training, and record the average reward of each round. Fig. 6 shows the recording results. It can be seen from the figure that the average reward of the Pro-Dueling DQN algorithm gradually increases after 25 rounds, indicating that the success rate of the robot in the process of finding the target point is getting higher and higher, and the algorithm tends to converge after the 100th round of training. The convergence speed of it is faster than the traditional DQN algorithm, and the average reward of the convergence algorithm has less fluctuation and is relatively stable.

Fig. 7 shows the paths planned by the model after convergence of the two algorithms. The path planned by the Pro-Dueling DQN algorithm from the starting point to the target point is smoother and has fewer path steps than the traditional one, as can be seen in the figure. The number of steps taken by the designed strategy is 235, while the number is 283 by the traditional one.

B. Simulation Verification in U-shaped Obstacle Environment

Fig. 8 shows a 5m×5m U-shaped obstacle environment set up in Gazebo. The starting point coordinate of the robot is (-2.0, 0.0) and the target point coordinate is (1.5, 1.5).

Fig. 6. The comparison of average reward per round in discrete obstacles environment.

(a) Pro-Dueling DQN (b) DQN

Fig. 7. Path planning in discrete obstacles environment.

Fig. 8. U-shaped obstacle simulation environment.

Fig. 9 shows the record of the average return value of each round after 400 rounds of training by the Pro-Dueling DQN algorithm and the traditional DQN algorithm. Data displayed in the figure show that the average reward of the Pro-Dueling DQN algorithm after the 50th round is significantly higher than that of the traditional DQN algorithm, which indicates that the robot by the Pro-Dueling DQN algorithm can reach the target point more times. The Pro-Dueling DQN algorithm tends to converge after 150 rounds. The convergence speed of the Pro-Dueling DQN algorithm is faster, and the average reward of the convergence algorithm fluctuates less, indicating that the designed algorithm is more stable.

Fig. 10 shows the paths planned by the model after convergence of the two algorithms. The path planned by the Pro-Dueling DQN algorithm from the starting point to the target point is shorter than that by the traditional DQN algorithm. The number of steps is 268, while the number of the traditional one is 298.

Fig. 9. Comparison of average reward per round in U-shaped obstacle environment.

Fig. 10. U-shaped obstacle path planning.

C. Simulation Verification in Mixed Obstacles Environment

Fig. 11 and Fig. 12 show two 6m×6m mixed obstacles environments set up in Gazebo, which include discrete obstacles, 1-shaped obstacles and U-shaped obstacles. In Fig. 11, the starting point coordinate of the robot is (-2.0, 2.0) and the target point coordinate is (2.1,-2.0). In Fig. 12, the starting point coordinate of the robot is (-2.0,-2.0) and the target point coordinate is (2.5, 2.0).
