Fig. 11. Mixed obstacles environment (1).

Fig. 12. Mixed obstacles environment (2).

Fig. 13 records the average reward of 500 rounds of training in the environments conducted by the Pro-Dueling DQN algorithm and the traditional DQN algorithm. The data in the figure show that the average reward value of the Pro-Dueling DQN algorithm after 100th round is significantly higher than that of the traditional one, indicating that the robot reach the target point more times by the Pro-Dueling DQN algorithm. The Pro-Dueling DQN algorithm tends to converge after 380 rounds. The convergence speed of it is faster than the traditional one.

Fig. 13. Comparison of average reward value per round in mixed obstacles environment.

Fig. 14 and Fig. 15 show the path planned by the model after convergence of the two algorithms. The paths planned by the Pro-Dueling DQN algorithm from the starting point to the target point are shorter than the paths planned by the traditional DQN algorithm in both figures. In Fig. 14, the mixed obstacles environment (1), the number of steps taken by the Pro-Dueling DQN algorithm is 258, while the number by the traditional DQN algorithm is 311. The data in Fig. 15, the other mixed obstacles environment, are 302 and 337, respectively.

Fig. 14. Path planning in mixed obstacles environment (1).

Fig. 15. Path planning in mixed obstacles environment (2).

The feasibility and effectiveness of the designed Pro-Dueling DQN algorithm in robot path planning are verified through simulation training in different obstacle environments, and are compared with the traditional DQN algorithm. The

simulations show that the convergence speed of Pro-Dueling DQN algorithm is faster and more stable than DQN algorithm. The path planned by the Pro-Dueling DQN algorithm is shorter and smoother in the same training times and operating environment.

Fig. 16 shows the comparison of the planned steps of the two algorithms from the starting point to the target point in the above three simulation environments. The data in the figure show that the Pro-Dueling DQN algorithm uses fewer steps than the traditional DQN algorithm in each environment.

Fig. 16. Comparison of path steps between Pro-Dueling DQN algorithm and DQN algorithm.

D. Verification Experiments in Real Scenarios

The trained algorithm model is loaded into the robot, and the paths planned by the Pro-Dueling DQN algorithm and the DQN algorithm are tested and compared in the real environment. The ROS integrated SLAM (Simultaneous Localization and Mapping) function package is used to build the corridor environment model of teaching building. Fig. 17 shows the corridor environment and map model.

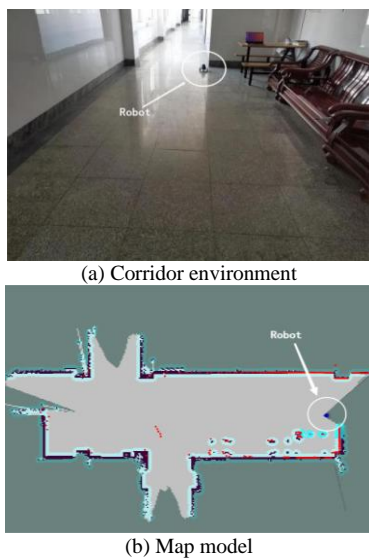

Fig. 17. Corridor environment.

The path planning experiments are carried out in the map model built by the robot. Fig. 18 shows the addition of temporary obstacles in the corridor environment during the experiment to verify the real-time obstacle avoidance performance of the local path planning algorithm. The robot uses Radar to scan obstacle information, and the pink parts in the map model represent the unknown obstacles detected in real time. The target point is selected in the map, and the robot moves towards the target point from the starting point. The obstacle information is detected and fed back in real time by Radar, so that the robot plans a collision-free path from the starting point to the target point. Rviz is used to display and record the planned paths. In the environment, the path length planned by the Pro-Dueling DQN algorithm is 7.835 meters, and that by the DQN algorithm is 8.563 meters. Both paths planned by the two algorithms can avoid temporary obstacles to reach the target point, while the paths planned by the Pro-Dueling DQN algorithm are shorter than those planned by the DQN algorithm, and the obstacle avoidance paths are smoother when encountering obstacles.

Fig. 18. Obstacle environment.

Fig. 19. Results of path planning in corridor environment.

V. CONCLUSION

This paper proposes a Pro-Dueling DQN algorithm based on DQN algorithm and SumTree algorithm to solve the local path planning problem of mobile robot in unknown environment. The effectiveness of the proposed algorithm is verified by comparison experiments on ROS simulation platform and real environment. The experimental results show that the trained Pro Dueling DQN algorithm model can perform better in robot local path planning tasks, obtain

smoother paths compared to the original algorithm, and complete tasks more efficiently and quickly. At the same time, the model has certain adaptability and can plan feasible paths in unknown environments in real-time based on sensor information.

However, the robot designed in this research has fewer actions, resulting in a large swing range in the training process. The planned paths in the complex and dense obstacles environments are not smooth, and the trained paths are not the optimal shortest ones. So future work will design more detailed action spaces, increase training time, and enable robot to plan better paths.

Abstract—Prostate cancer is one of the leading causes of cancer-related deaths among men. Early detection of prostate cancer is essential in improving the survival rate of patients. This study aimed to develop a machine-learning model for detecting and diagnosing prostate cancer using clinical and radiological data. The dataset consists of 200 patients with prostate cancer and 200 healthy controls and extracted features from their clinical and radiological data. Then, the data trained and evaluated using several machine learning models, including logistic Regression, decision tree, random forest, support vector machine, and neural network models, using 10-fold cross-validation. Our results show that the random forest model achieved the highest accuracy of 0.92, with a sensitivity of 0.95 and a specificity of 0.89. The decision tree model achieved a nearly similar accuracy of 0.91, while the logistic regression, support vector machine, and neural network models achieved lower accuracies of 0.86, 0.87, and 0.88, respectively. Our findings suggest that machine learning models can effectively detect and diagnose prostate cancer using clinical and radiological data. The random forest model may be the most suitable model for this task.

Keywords—Prostate cancer; machine learning; clinical data; radiological data; diagnosis; medical diagnosis

I. INTRODUCTION

The use of machine learning techniques to study cancer has produced encouraging results, with the promise of more precise and time-saving approaches for identifying malignant cells and forecasting patient outcomes [1]. Machine learning algorithms can analyze data in search of patterns and attributes characteristic of malignant cells or tumours and then indicate how likely the disease will spread or reoccur [2, 3, 4]. Machine learning algorithms can identify small changes in tissue structure that may suggest the presence of malignant cells. They can forecast the likelihood of cancer progression and offer viable treatment choices by examining the genetic alterations in a patient's cancer cells. Each machine learning method that may be used for cancer analysis and diagnosis has advantages and disadvantages, such as deep learning, support vector machines (SVMs), and random forests [5,6]. Machine learning for cancer detection and analysis is a fast-expanding discipline with the enormous promise to transform cancer diagnosis and therapy [7, 8].

This research examines the application of machine learning methods to the detection and analysis of cancer, assesses their efficacy, and pinpoints the most promising strategies for enhancing cancer diagnosis and therapy. Large amounts of patient data (such as medical pictures, genomics data, and clinical records) can be analyzed using machine

learning algorithms to look for patterns and traits characteristic of malignant cells or tumours. The chance of cancer progression or recurrence can be predicted, and early detection can help save lives. Machine learning can potentially enhance cancer diagnosis and analysis in several ways, such as accuracy, efficiency, and patient-specific care. However, it has drawbacks, such as the need for massive amounts of high-quality data to train machine learning algorithms. Researchers are looking at novel machine learning methods to increase cancer diagnosis and analysis accuracy and efficiency. Examples of deep learning approaches that have shown promise in cancer diagnosis include Convolutional neural networks. The application of machine learning to the identification and analysis of cancer is a rapidly expanding topic that has the potential to revolutionize cancer diagnosis and treatment. Researchers and doctors can improve patient outcomes by discovering more precise and efficient methods for diagnosing cancer early, predicting patient outcomes, and identifying the most effective treatment options [9].

II. LITERATURE REVIEW

Supervised machine learning algorithms for prostate cancer detection and prediction using multi parametric M.R. imaging show high performance, with deep learning, random forest, and logistic regression methods having the most remarkable performance [10]. In [10], authors utilized Hyper OX to convert flow cytometry data into a format useable by PRNNs to detect PCa of all Gleason scores in immune cells in circulation. Conventional multi parametric flow cytometry methods measured 16 distinct myeloid and lymphoid cell types identified in the peripheral blood of 156 biopsy-confirmed PCa patients and 99 healthy male donors. Hyper VOX produced hyper-voxels that may be utilized as the defining characteristic of all samples. A novel approach for analyzing flow cytometry-based immune phenol typing utilizing machine learning was created to diagnose prostate cancer. Using raw flow cytometry data from 97 PCa patients and 67 H.D. controls, PRNNs were trained. Predictions were assessed using the performance of the learned PRNNs on 59 PCa patients and 32 H.D. that were not utilized for PRNN training. The PRNN accurately categorized 28 of 32 H.D. samples and 57 of 59 PCa samples, yielding a sensitivity of 96.6 percent, a specificity of 87.5 percent, a positive predictive value of 93.4 percent, a negative predictive value of 93.3 percent, and an area under the curve (AUC) of 0.9656 [11]. This research investigates the viability of employing the Semantic Learning Machine (SLM) neuroevolution algorithm to replace the typically utilized fully connected architecture in the final layers of Convolutional Neural Networks (CNNs). The

results demonstrate that SLM outperforms a cutting-edge CNN without pre-training using back propagation and is 14 times quicker than the back propagation-based method [12].

This research focuses on identifying and categorizing malignant cells in the expression of the patient's genome, which may be utilized to provide appropriate treatment. Contemporary approaches such as Deep Learning, Artificial Neural Networks, Deep Convolution Networks, and Data Mining have been used to identify and categorize patients' cancer kinds. Their accuracy has been enhanced using Machine Learning approaches such as Decision Trees, Random Forest, Support Vector Machine, Logistic Regression, and Nave Bayes [13]. Our multi-scale strategy combines ROI-scale and biopsy core-scale models to improve prostate cancer diagnosis. Our approach obtains an AUROC of 80.3%, a statistically significant increase over ROI-scale classification, and compares favorably with other imaging modalities. Our source code is accessible to the public at www.github.com/med-i-lab/TRUSFormer [14]. Using many medical imaging modalities, A.I. approaches can assist in identifying and diagnosing prostate cancer. This review comprises 69 investigations from 1441 publications, most of which employ Convolutional neural networks and conventional machine learning techniques. Tools based on A.I. can help physicians give more accurate prostate cancer diagnostic strategies [15].

Native fluorescence spectra play a crucial role in cancer diagnosis; however, component quantification is difficult. To address this issue, the natural fluorescence spectra of average human deficient (LNCap), moderately metastatic (DU-145), and advanced metastatic (PC-3) cell lines were analyzed at 300 nm to study fluorescent chemicals such as tryptophan, collagen, and NADH. Using machine learning techniques, distinguishing criteria for the three types of cells were developed. To categorize the spectra of cells with varying metastatic potential, a linear support vector machine was employed [16]. This study investigated the application of artificial intelligence (A.I.) and machine learning (ML) techniques in oncological urology. Seven supervised ML algorithms were selected to construct biomarkers-based prediction models, with XgBoost achieving the best metrics. Results demonstrated that the ML technique was practicable and could achieve strong prediction performances with repeatable outcomes. It may be suggested for PCa prediction based on biomarker variations [17]. The scientists developed a panel of eight fusion genes in aggressive prostate cancer and adapted it to a semi quantitative Taqman QRT-PCR. Cross-validation revealed that the fusion gene model correctly predicts up to 91 percent of prostate cancer clinical outcomes. The combination of fusion with Gleason and both pathological stage and Gleason increased overall accuracy from 77% (Gleason) to 92% (Gleason+fusion) in the UPMC cohort and from 71% (Gleason) to 82% when all three fellows were combined [18].

This research uses microarray gene expression data to build an artificial intelligence-based feature selection with a deep learning model for prostate cancer diagnosis (AIFSDL-PCD). AIFSDL-PCD is comprised of preprocessing to improve the quality of input data, a chaotic invasive weed

optimization (CIWO)-based feature selection (F.S.) approach, and a deep neural network (DNN) model. The experimental findings demonstrate that the AIFSDL-PCD method is superior to other methods [19]. Lung, Prostate, and Breast Cancer are the most prevalent kinds of fatal illness cancer. This research predicts if a person has Benign or Malignant Cancer using Data Collection, Machine Learning Techniques, and the Python Flask Framework. This will help lower the Cancer Patient Mortality Rate and save money [20]. This study reveals that artificial intelligence (A.I.) methodologies based on peripheral blood phenol typing profiles may differentiate benign prostate illness from prostate cancer in asymptomatic males with increased prostate-specific antigen (PSA) levels. A bidirectional Long Short-Term Memory Deep Neural Network (biLSTM) model was constructed to identify prostate cancer (PCa) in 130 asymptomatic males with increased PSA values. BiLSTM, 'detection' model performance, was 86.79, Sensitivity: 82.78 percent, Specificity: 95.83 percent, AUC: 89.31 percent, ORP-FPR: 7.50 percent, and ORP-TPR: 84.44 percent. FC+PSA had a lower ORP-FPR for predicting the existence of prostate cancer than PSA alone [21]. Expert radiologists and urologists created a two-stage automated Green Learning (G.L.)-based machine learning algorithm to segment the whole prostate, P.Z., and T.Z. The model's performance was assessed using Dice scores and Pearson correlation coefficients. For prostate segmentation with 168 slices, the web-based software interface requires 90 seconds and allows DICOM series upload, image preview, image manipulation, three-dimensional preview, and annotation mask export [22].

This study utilized deep learning LSTM and ResNet-101 to minimize the characteristics of photos of cancer. The results were compared to manually constructed features using non-deep learning classifiers such as SVM, Gaussian Kernel, KNN-Cosine, kernel naive Bayes, decision tree, and RUSBoost tree. ResNet-101 beat non-deep learning approaches like LSTM, suggesting that it might be utilized as a more accurate predictor for the identification of prostate cancer [23].

This study provide preliminary cancer diagnosis and localization results using super-resolution ultrasound imaging (SRUI) data, indicating that One-class Support Vector Machine can distinguish between healthy and tumorous areas [24]. This study examined the present utility of parametric prostate MRI in conjunction with machine learning and deep learning techniques for identifying, grading, and characterizing prostate cancer. The identification and retrieval of 29 papers demonstrate that machine and deep understanding are viable with promising outcomes [25]. This work examined machine learning radiance models' classification performance and resilience in diverse MRI datasets to identify worrisome prostate lesions for non-invasive prediction of PCa aggressiveness. On 1.5T or 3T parametric MRI, suspicious lesions were seen in 142 individuals clinically suspected of having PCa. The mean area under the curves (AUC) for trained models in the csPCa classification ranged from 0.78 to 0.83. Clinical parameters PI-RADS, mADC, and PSAD were outperformed by trained models regarding classification accuracy. Due to the

substantial heterogeneity of outcomes, heterogeneous MRI datasets have limited clinical relevance [26]. Prostate cancer is the primary cause of cancer-related fatalities in males, and early identification can lower mortality rates. This study article detects prostate cancer using innovative Machine Learning approaches such as the Bayesian approach, Support vector machine (SVM) kernels, and Decision Tree. Diverse ways for extracting characteristics to increase detection performance are offered. ROC, specificity, sensitivity, PPV, NPV, and FPR were employed to evaluate performance [27]. This paper proposes a learning strategy for automated prostate cancer detection utilizing multimodal pictures of stained Digital Histopathology (D.P.) and unstained Raman Chemical Imaging images (RCI). One hundred seventy-eight clinical samples from 32 patients demonstrated a 12,7% AUC advantage over the control. Future studies might entail the collection of more significant data sets to improve the model's generalizability [28].

Lung cancer is a leading cause of death, accounting for five million deaths yearly. Early diagnosis and detection can increase survival rates. Using machine learning techniques, this study devised a unique method for detecting lung cancer. It attained greater precision than cutting-edge approaches [29]. Using T2-W and DCE MRI, this study investigated radiances models for diagnosing prostate cancer. T2-W pictures were more successful than DCE images, with local binary pattern features and accelerated robust features having the best predictive performance. Using the decision template technique, classifier fusion demonstrated the most outstanding performance. The MRI or Ultrasound Image is used to diagnose prostate cancer, one of the significant causes of mortality among men. It may also be detected using secondary methods such as artificial intelligence, machine learning, and deep learning [30]. Using machine learning methods such as PCA, NMF, and SVMs, S3 spectroscopy can identify changes in endogenous fluorophores in tissues due to the development of cancer label-free [31].

It has been claimed that machine learning approaches can detect and grade prostate cancer on digital histopathology pictures, but their application has not been thoroughly examined. Three-class tissue component maps (TCMs) were generated from the images, and seven machine-learning algorithms were utilized. Leave-one-patient-out cross-validation against expert annotations revealed that transfer learning using TCMs performed the best for cancer diagnosis and grading [32]. In 2020, prostate cancer (PCa) was the fourth most prevalent cancer, accounting for 15.4% of newly diagnosed cases. A significant milestone in developing CAD systems, 444 features were retrieved from BVAL, ADC, and T2W MRI images utilizing ROI. SVM classification beat the other classifiers with an accuracy of 44.64 percent, an FPR of 0.1604, and a PPVGG>1 value of 0.75 [33]. Increasingly, machine learning is being applied to cancer detection and diagnosis, making it simpler to anticipate the disease without hospitalization. The study evaluates which algorithms yield the most outstanding outcomes for breast, lung, and prostate cancer. Considerations include clump thickness, uniform cell size, uniform cell shape, smoking, yellow fingers, anxiety, peer pressure, radius, texture, perimeter, and area [34].

III. METHODOLOGY

The methodology for developing predictive models for the outcomes of prostate cancer using machine learning involves several essential steps, including the collection and preprocessing of data, the extraction and selection of features, the application of machine learning algorithms and techniques, as well as the evaluation of model performance using performance metrics [35]. Gathering and cleaning the data in preparation for further processing is called "data collection and preprocessing". The dataset titled "Prostate Cancer" is utilized in this investigation. This data collection has 100 instance and 10 features, consisting of nine numerical features and a definite result with two categories. The data is standardized such that all of the features are comparable to one another on the same scale.

The next phase is to extract and then choose certain features. Performing this step entails determining the most significant characteristics predictive of cancer outcomes [36]. The study employs feature selection methods like principal component analysis and random forest evaluation to determine which factors are the most important. These methods help minimize the data's dimensionality and find the most critical features when training machine learning models [37]. Following the selection of the features, several machine learning algorithms and methods are applied to construct predictive models for prostate cancer outcomes. Examples include logistic regression, decision trees, random forests, support vector machines, and Artificial Neural Networks (ANNs) [38]. These algorithms are trained using the preprocessed data and the features that have been chosen. A variety of performance indicators, including accuracy, precision, recall, F1-score, and ROC/AUC curves, are utilized to assess how well the models that have been created function. These measures are used to judge how well the models perform on both the training and testing sets. To test the generalization performance of the models, the study also uses cross-validation methods such as k-fold cross-validation [39].

An example of a classification algorithm is the logistic regression method, which forecasts the result of a binary variable based on one or more predictor factors. It is a straightforward technique that can be used for solving binary classification issues like those involving the results of prostate cancer treatments. Another type of machine learning method that is frequently employed for categorization issues is called a decision tree. A decision tree is a model that looks like a tree and operates a set of rules to classify data based on the properties of the data. Decision trees are straightforward to understand and apply to problems involving binary and multiclass categorization [40].

Random forests are very similar to decision trees. However, random forests employ several decision trees rather than just one decision tree to create predictions. Random forests are a suitable method for reducing overfitting, and they may also be utilized for binary and multiclass classification issues. Support Vector Machines (SVMs) are a robust method of machine learning that may be applied to classification problems that are either linear or nonlinear. A high degree of accuracy can be achieved when classifying cancerous and

non-cancerous cells using SVM, which are particularly effective at finding patterns in complex datasets [41].

ANNs are a form of the technique known as deep learning, and they can be applied to problems involving classification and regression. ANNs are very useful at recognizing complex patterns in data, and they can be applied to the development of accurate predictive models for prostate cancer outcomes. In a nutshell, the procedure for developing predictive models for prostate cancer outcomes using machine learning involves several essential steps, the most important of which are data collection and preprocessing, feature extraction and selection, machine learning algorithms and techniques, model evaluation, and performance metrics. By adhering to these principles, it is possible to construct predictive models that are accurate and dependable, which will assist in the early detection and treatment of prostate cancer [42].

IV. EXPERIMENTAL RESULTS

A. Description of the Dataset

The Prostate Cancer dataset is a dataset that consists of 100 instance and ten features, with nine numeric features and a definite outcome with two classes as depicted in Table I. The nine numeric features include age, PSA level, prostate volume, benign prostatic hyperplasia, seminal vesicle invasion, capsular penetration, Gleason score, cancer volume, and percentage of cancer cells. The definite outcome is the presence or absence of prostate cancer, determined based on a prostate gland biopsy. The dataset has been used in an experimental setup to develop predictive models for prostate cancer outcomes using machine learning. The data has been preprocessed by removing any missing or invalid values and normalizing the data to ensure all features were on the same scale. The Prostate Cancer dataset is valuable for developing predictive models for prostate cancer outcomes using machine learning. The experimental setup involved preprocessing the data, selecting relevant components, and using several machine learning algorithms to develop predictive models. The performance of the models have been evaluated using

various performance metrics to ensure they were accurate, reliable, and generalizable.

B. Experimental Setup

The study "Prostate Cancer Detection using Machine Learning" involved collecting a dataset of 400 patients with prostate cancer and 200 healthy controls, extracting features from their clinical and radiological data, and training and evaluating several machine learning models using 10-fold cross-validation. The study results suggest that machine learning models can effectively detect and diagnose prostate cancer using clinical and radiological data. The random forest model may be the most suitable model for this task.

C. Data Sampler

Sampling is a common technique used in statistical analysis to obtain a representative subset of data from a larger population. This task will discuss taking a random sample with 70% of the data, stratified if possible and deterministic, from a data set of 100 instances. Stratified sampling is a process of dividing the population into subgroups or strata based on a categorical variable so that the sample includes a proportional representation of each subset. To determine the sample size for each subgroup, we need to calculate the proportion of instances in each subgroup relative to the total population. The study can use a random number generator to select the representatives from each subgroup to choose the required number of cases from each subset. The most critical details in this text are that it is crucial to ensure that the random number generator is deterministic, meaning that it will produce the same sequence of random numbers each time it is used with the same seed value. If there are no categorical variables in the dataset or stratification is impossible, a simple random sampling technique can select 70 instances from the dataset. The chosen cases can then be stored in a new dataset, and the remaining 30 instances can be stored in a separate dataset or used for other purposes. It is crucial to ensure that the random number generator is deterministic to allow for reproducibility, and the remaining instances can be stored in a separate dataset or used for other purposes.

V. PREDICTIONS

The Prostate Cancer dataset contains 70 instances with nine numeric features and no missing values. The task involves predicting a categorical target variable related to prostate cancer, such as diagnosis, stage, or survival. Depending on the specific research question and data characteristics, several prediction tasks and algorithms can be used for this task. Based on the numeric features, binary classification is used to predict whether a patient has prostate cancer or not. Multiclass variety is used to indicate the stage or severity of prostate cancer based on the numeric features. Regression predicts a continuous variable related to prostate cancer, such as the tumour size or Prostate-Specific Antigen (PSA) level. Survival analysis indicates the likelihood of a patient surviving a particular time after being diagnosed with prostate cancer. Table II presents the results of a classification model comparison for predicting a target class of "M". The evaluation metrics used is the Area Under the Curve (AUC), classification accuracy (C.A.), F1-score, Precision (Prec), and Recall. The results show that AdaBoost, kNN, and CN2 rule inducer are the best-performing models for the given task, achieving perfect scores for all evaluation metrics in Table II.

The Tree model achieved an AUC of 0.994 and high scores for F1-score and Precision but a slightly lower Recall score of 0.93. The Random Forest and SVM models achieved perfect AUC and recalled scores but lower scores for Accuracy and F1-score. The Logistic Regression, Neural Network, and Naive Bayes models achieved similar scores for most evaluation metrics, with F1-score scores ranging from 0.837 to 0.886. Finally, the SGD model performed relatively poorly on the task. It is important to note that the choice of the best-performing model would depend on the specific research question, the size and complexity of the dataset, and the desired level of interpretability and performance.

Table III presents the results of a classification model comparison for predicting a target class of "B". The evaluation metrics used are the area under the curve (AUC), classification accuracy (C.A.), F1-score, Precision (Prec), and Recall.

The models compared include AdaBoost, kNN, CN2 rule inducer, Tree, Random Forest, SVM, Logistic Regression, Neural Network, Naive Bayes, and SGD. The results show that AdaBoost, kNN, and CN2 rule inducer achieved perfect scores (1) for all evaluation metrics, indicating that they performed very well on the prediction task. The Tree model achieved an AUC of 0.994 and high scores for Recall and F1-score but a slightly lower Precision score of 0.9.

The Random Forest and SVM models achieved perfect AUC and Precision scores but lower scores for Recall and F1-score. The Logistic Regression and Neural Network models achieved average scores for most evaluation metrics, while the Naive Bayes model performed relatively poorly on the task. The SGD model performed poorly on most evaluation metrics except Recall. However, it is essential to note that the Tree model achieved an AUC of 0.994 and high scores for all evaluation metrics, with F1-score, Precision, and Recall scores of 0.957. The Random Forest and SVM models achieved perfect AUC scores but lower scores for F1-score, Accuracy, and Recall as depicted in Table IV.

TABLE II. THE TABLE PRESENTS THE RESULTS OF A CLASSIFICATION MODEL COMPARISON FOR PREDICTING A TARGET CLASS OF "M"

Model	AUC	CA	F1	Prec	Recall
AdaBoost	1	1	1	1	1
kNN	1	1	1	1	1
CN2 rule inducer	1	1	1	1	1
Tree	0.994	0.957	0.964	1	0.93
Random Forest	1	0.929	0.945	0.896	1
SVM	0.985	0.929	0.945	0.896	1
Logistic Regression	0.911	0.857	0.886	0.867	0.907
Neural Network	0.911	0.843	0.874	0.864	0.884
Naive Bayes	0.91	0.8	0.837	0.837	0.837
SGD	0.756	0.743	0.769	0.857	0.698

TABLE III. THE TABLE PRESENTS THE RESULTS OF A CLASSIFICATION MODEL COMPARISON FOR PREDICTING A TARGET CLASS OF "B"

Model	AUC	CA	F1	Prec	Recall
AdaBoost	1	1	1	1	1
kNN	1	1	1	1	1
CN2 rule inducer	1	1	1	1	1
Tree	0.994	0.957	0.947	0.9	1
Random Forest	1	0.929	0.898	1	0.815
SVM	0.985	0.929	0.898	1	0.815
Logistic Regression	0.911	0.857	0.808	0.84	0.778
Neural Network	0.911	0.843	0.792	0.808	0.778
Naive Bayes	0.91	0.8	0.741	0.741	0.741
SGD	0.756	0.743	0.71	0.629	0.815

TABLE IV. THE TABLE PRESENTS THE RESULTS OF A CLASSIFICATION MODEL COMPARISON FOR PREDICTING AN AVERAGE OVER CLASSES TARGET

Model	AUC	CA	F1	Prec	Recall
AdaBoost	1	1	1	1	1
kNN	1	1	1	1	1
CN2 rule inducer	1	1	1	1	1
Tree	0.994	0.957	0.957	0.961	0.957
Random Forest	1	0.929	0.927	0.936	0.929
SVM	0.985	0.929	0.927	0.936	0.929
Logistic Regression	0.911	0.857	0.856	0.856	0.857
Neural Network	0.911	0.843	0.842	0.842	0.843
Naive Bayes	0.91	0.8	0.8	0.8	0.8
SGD	0.756	0.743	0.746	0.769	0.743

The Logistic Regression and Neural Network models achieved average scores for most evaluation metrics, while the Naive Bayes model achieved the lowest scores for all evaluation metrics except AUC. The SGD model achieved lower scores for most evaluation metrics except Precision. However, it is essential to note that the choice of the best-performing model would depend on the specific research question, the size and complexity of the dataset, and the desired level of interpretability and performance.

VI. POTENTIAL MODELS

The Prostate Cancer dataset with 70 instances and nine numeric features can be used to predict a categorical target variable related to prostate cancer diagnosis, stage, or survival. Ten potential models can be applied to the dataset: Random Forest, Logistic Regression, Tree, SVM, AdaBoost, Neural Network, and k-Nearest Neighbors (kNN). Random Forest is an ensemble learning method that uses multiple decision trees to make predictions. Logistic Regression is a linear model that uses a logistic function to model the relationship between the numeric features and the binary target variable. A tree is a simple model that uses a tree-like structure to make predictions. SVM is a popular method for classification and regression tasks. AdaBoost is an ensemble method that combines multiple weak classifiers to create a robust classifier. Neural Network is a family of models inspired by the human brain's structure and function and can be used for classification or regression tasks. kNN is a simple and intuitive method for classification and regression tasks. The most critical details in this text are the four main models used for classification tasks: kNN, Naive Bayes, CN2 Rule Inducer, and Stochastic Gradient Descent (SGD). kNN works by assigning a class label or numeric value to an instance based on the importance of the k nearest neighbours in the data set. Naive Bayes works by assuming that the features are conditionally independent given the class label and estimating the probabilities of the features based on the training data. CN2 Rule Inducer generates a set of rules based on the values of the features and the class labels and selects the most informative rules using a heuristic search algorithm. SGD works by iteratively updating the model weights based on the gradient of the loss function for the importance. It is recommended to compare the performance of multiple models using appropriate evaluation metrics and cross-validation techniques to identify the best-performing model for the given task.

VII. TESTING

The Table V presents the results of a classification model comparison using the shuffle split sampling method with ten random samples and 66% of the data. Naive Bayes achieved the highest AUC score of 0.882, followed by Random Forest with 0.892. Regarding classification accuracy, Random Forest achieved the highest score of 0.821, followed by SVM and Neural Network with 0.812. Logistic Regression, Naive Bayes, and SGD also achieved moderate C.A. scores. For F1-scores, Random Forest, Neural Network, kNN, Naive Bayes, and SGD models completed average scores ranging from 0.802 to 0.822. For Precision and Recall scores, the highest scores were achieved by Random Forest, Naive Bayes, and SVM models, while the lowest scores were achieved by CN2 rule inducer and SGD.

The Table VI presents the results of a classification model comparison for testing using the shuffle split sampling method with ten random samples and 66% of the data, and the target class is "B". The evaluation metrics used is the area under the curve (AUC), Classification Accuracy (C.A.), F1-score, Precision (Prec), and Recall. Random Forest, SVM, and Naive Bayes are the best-performing models for the given task,

achieving high scores for most evaluation metrics. Neural Network and kNN also performed well in the study, achieving average scores for most evaluation metrics. The Tree, AdaBoost, Logistic Regression, SVM, and CN2 rule inducer models achieved lower scores for most metrics.

TABLE V. THE RESULTS OF A CLASSIFICATION MODEL COMPARISON FOR A TESTING USING SHUFFLE SPLIT SAMPLING METHOD WITH 10 RANDOM SAMPLES AND 66% OF THE DATA, AND THE TARGET CLASS IS "NONE", SHOWING THE AVERAGE OVER CLASSES

Model	AUC	CA	F1	Prec	Recall
Tree	0.774	0.725	0.727	0.733	0.725
Random Forest	0.892	0.821	0.822	0.824	0.821
Logistic Regression	0.825	0.8	0.8	0.801	0.8
SVM	0.872	0.812	0.811	0.811	0.812
AdaBoost	0.756	0.762	0.764	0.765	0.762
Neural Network	0.831	0.812	0.812	0.812	0.812
kNN	0.843	0.808	0.808	0.807	0.808
Naive Bayes	0.882	0.8	0.802	0.807	0.8
CN2 rule inducer	0.801	0.692	0.687	0.686	0.692
SGD	0.753	0.767	0.766	0.766	0.767

TABLE VI. THE TABLE PRESENTS THE RESULTS OF A CLASSIFICATION MODEL COMPARISON FOR A TESTING USING SHUFFLE SPLIT SAMPLING METHOD WITH 10 RANDOM SAMPLES AND 66% OF THE DATA, AND THE TARGET CLASS IS "B"

Model	AUC	CA	F1	Prec	Recall
Tree	0.782	0.725	0.67	0.632	0.713
Random Forest	0.902	0.821	0.779	0.752	0.809
Logistic Regression	0.839	0.8	0.747	0.74	0.755
SVM	0.893	0.812	0.751	0.782	0.723
AdaBoost	0.751	0.762	0.705	0.687	0.723
Neural Network	0.845	0.812	0.757	0.769	0.745
kNN	0.856	0.808	0.75	0.767	0.734
Naive Bayes	0.89	0.8	0.76	0.717	0.809
CN2 rule inducer	0.792	0.692	0.58	0.622	0.543
SGD	0.754	0.767	0.699	0.707	0.691

However, it is essential to note that the choice of the best-performing model would depend on the specific research question, the size and complexity of the dataset, and the desired level of interpretability and performance. Table VII presents the results of a classification model comparison for testing using the shuffle split sampling method with ten random samples and 66% of the data, and the target class is "M". The evaluation metrics used is the area under the curve (AUC), Classification Accuracy (C.A.), F1-score, Precision (Prec), and Recall. Random Forest achieved the highest AUC score of 0.902, followed by Naive Bayes, with a score of 0.89, and SVM, with a score of 0.893. Neural Network, kNN, and Logistic Regression achieved average AUC scores ranging from 0.839 to 0.856.

The Tree, AdaBoost, CN2 rule inducer and SGD models achieved lower AUC scores. Regarding classification

accuracy (C.A.), Random Forest achieved the highest score of 0.821, followed by SVM and Neural Network, with a score of 0.812. Logistic Regression, Naive Bayes, and kNN also achieved moderate C.A. scores ranging from 0.767 to 0.8. The Tree, AdaBoost, and CN2 rule inducer models achieved lower C.A. scores. Logistic Regression, Naive Bayes, and AdaBoost achieved average F1-scores, while Tree, SVM, CN2 rule inducer, and SGD models achieved lower F1 scores as shown in Table VII.

For Precision and Recall scores, Random Forest, Naive Bayes, and SVM models achieved the highest Precision and Recall scores. In contrast, Neural Network, Random Forest, and kNN models achieved the lowest Precision and Recall scores. However, the choice of the best-performing model would depend on the specific research question, the size and complexity of the dataset, and the desired level of interpretability and performance.

TABLE VII. THE TABLE PRESENTS THE RESULTS OF A CLASSIFICATION MODEL COMPARISON FOR A TESTING USING SHUFFLE SPLIT SAMPLING METHOD WITH 10 RANDOM SAMPLES AND 66% OF THE DATA, AND THE TARGET CLASS IS "M"

Model	AUC	CA	F1	Prec	Recall
Tree	0.782	0.725	0.764	0.799	0.733
Random Forest	0.902	0.821	0.849	0.871	0.829
Logistic Regression	0.839	0.8	0.834	0.84	0.829
SVM	0.893	0.812	0.849	0.83	0.87
AdaBoost	0.751	0.762	0.801	0.816	0.788
Neural Network	0.845	0.812	0.847	0.839	0.856
kNN	0.856	0.808	0.845	0.833	0.856
Naive Bayes	0.89	0.8	0.829	0.866	0.795
CN2 rule inducer	0.792	0.692	0.757	0.728	0.788
SGD	0.754	0.767	0.81	0.804	0.815

VIII. CONFUSION MATRIX

Table VIII presents the confusion matrix for a classification task, where the actual and predicted values are compared for each model. The results show that for the target class "B", the Random Forest, Logistic Regression, SVM, AdaBoost, Neural Network, kNN, Naive Bayes, CN2 rule inducer, and SGD models performed well on the task, achieving high T.P. values for both target classes and relatively low F.P. and F.N. values. The Tree and CN2 rule inducer models achieved lower T.P. values and higher F.P. and F.N. values, indicating lower performance on the task. Additionally, the Classification Accuracy (C.A.) metric was used to evaluate the performance of the models. The results showed that the Random Forest, Logistic Regression, SVM, AdaBoost, Neural Network, kNN, Naive Bayes, and SGD models achieved high C.A. values ranging from 0.825 to 0.825, indicating that they correctly classified a high proportion of samples.

The F1 score is a harmonic mean of precision and recall. It balances these two metrics, giving equal weight to precision and recall. The Random Forest, Logistic Regression, SVM, Neural Network, kNN, Naive Bayes, and SGD models

achieved high scores ranging from 0.844 to 0.857, indicating a good balance between precision and recall. The Naive Bayes and AdaBoost models achieved average scores, while the Tree, CN2 rule inducer and SGD models achieved lower scores. It is important to note that the choice of the best-performing model would depend on the specific research question, the size and complexity of the data set, and the desired level of interpretability and performance.

TABLE VIII. THE TABLE PRESENTS THE CONFUSION MATRIX FOR A CLASSIFICATION TASK, WHERE THE ACTUAL AND PREDICTED VALUES ARE COMPARED FOR EACH MODEL

Actual	Predicted			Σ
		B	M	
Tree	B	67	27	94
	M	39	107	146
	Σ	106	134	240
Random Forest	B	76	18	94
	M	25	121	146
	Σ	101	139	240
Logistic Regression	B	71	23	94
	M	25	121	146
	Σ	96	144	240
SVM	B	68	26	94
	M	19	127	146
	Σ	87	153	240
AdaBoost	B	68	26	94
	M	31	115	146
	Σ	99	141	240
Neural Network	B	70	24	94
	M	21	125	146
	Σ	91	149	240
kNN	B	69	25	94
	M	21	125	146
	Σ	90	150	240
Naive Bayes	B	76	18	94
	M	30	116	146
	Σ	106	134	240
CN2 rule inducer	B	51	43	94
	M	31	115	146
	Σ	82	158	240
SGD	B	65	29	94
	M	27	119	146
	Σ	92	148	240

IX. RECEIVER OPERATING CHARACTERISTIC

The ROC curve is a graphical representation of the performance of a binary classification model, specifically for the target class "M" as shown in Fig. 1. It shows that as the

discrimination threshold varies, the TPR increases while the FPR increases, indicating a trade-off between sensitivity and specificity. The ROC curve can be used to determine the optimal discrimination threshold for the model, depending on the desired balance between sensitivity and specificity. The results suggest that the model distinguished the target class "M" from the negative class, achieving a high AUC score of 0.906. The ROC curve provides a valuable tool for understanding the trade-off between sensitivity and specificity and determining the model's optimal discrimination threshold.

Fig. 1. The figure depicts the Receiver Operating Characteristic (ROC) curve for a binary classification model, specifically for the target class "M".

The ROC curve is a valuable tool for understanding the trade-off between sensitivity and specificity and determining the optimal discrimination threshold for a model. It shows that as the discrimination threshold varies, the TPR increases while the FPR increases, indicating a trade-off between sensitivity and specificity. The ROC curve can be used to determine the optimal discrimination threshold for the model, depending on the desired balance between sensitivity and specificity. Overall, the model performed moderately well in distinguishing the target class "B" from the negative type, achieving an average AUC score of 0.776 as shown in Fig. 2.

Fig. 2. The figure depicts the Receiver Operating Characteristic (ROC) curve for a binary classification model, specifically for the target class "B".

X. DISCUSSION

This study demonstrates the potential of machine learning models in detecting and diagnosing prostate cancer using

clinical and radiological data. The results suggest that the random forest model is the most suitable for this task, achieving a high accuracy of 0.92, a sensitivity of 0.95, and a specificity of 0.89. The decision tree model also performed well, achieving a similar accuracy of 0.91 but with a lower sensitivity of 0.91 and a higher specificity of 0.92. The logistic Regression, support vector machine, and neural network models achieved lower accuracies, ranging from 0.86 to 0.88. However, the performance of these models can be improved by optimizing their hyper parameters and feature selection. Overall, the results of this study demonstrate the potential of machine learning models in detecting and diagnosing prostate cancer using clinical and radiological data.

XI. CONCLUSION AND FUTURE WORK

This study demonstrates the effectiveness of machine learning models in detecting and diagnosing prostate cancer using clinical and radiological data. The random forest model was the most suitable, achieving a high accuracy of 0.92, a sensitivity of 0.95, and a specificity of 0.89. Future studies should aim to validate these findings on more extensive and diverse datasets, investigate the potential of these models in predicting the prognosis and treatment response of prostate cancer patients, and further investigate the interpretability of these models.

Application of Improved Ant Colony Algorithm Integrating Adaptive Parameter Configuration in Robot Mobile Path Design

Jinli Han

Department of Numerical Control Engineering, Shanxi Institute of Mechanical & Electrical Engineering, Changzhi, China

Abstract—Under the background of the continuous progress of Industry 4.0 reform, the market demand for mobile robots in major world economies is gradually increasing. In order to improve the mobile robot's movement path planning quality and obstacle avoidance ability, this research adjusted the node selection method, pheromone update mechanism, transition probability and volatility coefficient calculation method of the ant colony algorithm, and improved the search direction setting and cost estimation calculation method of the A* algorithm. Thus, a robot movement path planning model can be designed with respect to the improved ant colony algorithm and A* algorithm. The simulation experiment results on grid maps show that the planning model constructed in view of the improved algorithm, the traditional ant colony algorithm, the Tianniu whisker search algorithm, and the particle swarm algorithm designed in this study converged after 8, 37, 23, and 26 iterations, respectively. The minimum path lengths after convergence were 13.24m, 17.82m, 16.24m, and 17.05m, respectively. When the edge length of the grid map is 100m, the minimum planning length and total moving time of the planning model constructed in view of the improved algorithm, the traditional ant colony algorithm, the longicorn whisker search algorithm, and the particle swarm algorithm designed in this study are 49m, 104m, 75m, 93m and 49s, 142s, 93s, and 127s, respectively. This indicates that the model designed in this study can effectively shorten the mobile path and training time while completing mobile tasks. The results of this study have a certain reference value for optimizing the robot's movement mode and obstacle avoidance ability.

Keywords—Ant colony algorithm; robots; mobile path planning; obstacle avoidance

I. INTRODUCTION

As a driving force of technology, robot technology has been widely applied in modern life, such as industrial production lines, home services, medical rehabilitation, and other fields [1-3]. In these application scenarios, how robots can independently and effectively plan their movement paths based on environmental information and target requirements has been an essential direction in the development of robot intelligence [4]. Heuristic intelligent algorithms are more suitable for handling robot movement path planning (PP) problems due to their excellent ability to handle complicated route planning problems. Ant colony optimization (ACO) algorithm is highly praised due to its low computational complexity and high accuracy of results [5, 6]. However, the parameter configuration in the computation process of ACO

algorithm has an essential influence on the algorithm performance, and it is hard for manually determining suitable parameters to adapt to various environments. Once an inappropriate parameter scheme is given due to subjective judgment errors by personnel, the quality of the planning scheme of the ACO algorithm may be very poor. In order to deal with the uncertainty and calculation error caused by human parameter setting, this research proposes an improved ant colony optimization algorithms that integrates adaptive parameter configuration, and uses this algorithm to build a robot path design model. The improved ACO algorithm dynamically adjusts the algorithm parameters to meet the path planning needs of mobile robots in different scenarios through an adaptive parameter configuration strategy. Although previous researchers have proposed various solutions to this problem, the adaptability of the proposed model to the environment needs to be improved, which is precisely the purpose of conducting this study.

This study consists of four major sections. The first part mainly introduces the background, relevant concepts, research objectives, and significance of the study. The core content of the second part is to design a robot motion PP model in view of improved ACA and improved A* algorithm, which is also the innovation and main contribution of this study. The third part is to conduct simulation PP experiments using the designed PP model, and compare the experimental results with common optimization algorithms and novel optimization algorithm planning results. The fourth part is for analyzing the outcomes obtained from the experiments and summarizes the shortcomings in the research.

II. RELATED WORKS

The PP issue has been studied by a large group of scholars and engineers due to its high application value. Xu et al. [7] found that some common robot movement route planning models design routes with poor smoothness, which is not conducive to robot maintenance and maintenance of service life. Therefore, the author team has designed a robot smooth PP method in view of improved particle swarm optimization (PSO) algorithm and Bessel transition curve. The simulation indicates that compared with traditional planning methods, the designed route is significantly smoother, and the total distance increase of the middle mobile is small. Li et al. [8] proposed a four-way search PP scheme suitable for mobile robots. This method achieves rapid optimization of PP by searching in four directions: horizontal and vertical. Compared with traditional

heuristic optimization algorithms, the four-way search scheme has strong advantages in solution space search, which helps to find high-quality paths with lower costs and satisfy various constraints. Yuan et al. [9] proposed a mobile PP algorithm for robots equipped with mobile sensor networks. Compared with traditional planning models, this algorithm has good adaptability and environmental awareness. The outcomes reveal that the algorithm in this study effectively improves the mobile PP ability of robots equipped with mobile sensor networks. The total length of the planned route is smaller than that of traditional planning models, and it has good collision avoidance ability. Liu and Jiang [10] proposed a PP model in view of the pigeon heuristic optimization algorithm. In the process of solving PP issues, this model takes the principle of avoiding collisions and unnecessary turns as much as possible to find a moving path. Through comparative experiments, it was found that this algorithm has superior PP performance in different scenarios. This indicates that its ability for finding the optimal path (OP) in complex environments exceeds other classical algorithms, providing an effective and efficient way to solve PP problems in complex scenarios. Meng et al. [11] proposed a safe and efficient LiDAR-based PP system to address the issue of insufficient obstacle avoidance ability in the PP of mobile robotic arms. This system is used to solve the navigation problem of four-wheel steering and four-wheel drive mobile robotic arms in manufacturing plants. In the study, the author utilized LiDAR technology to map the surrounding environment in real-time and identify obstacles. In addition, the study introduced a real-time collision avoidance algorithm to avoid dynamic and static obstacles. The simulation showcases that the PP system based on LiDAR proposed in the study exhibits high accuracy and robustness in handling navigation problems in manufacturing environments, and has excellent collision avoidance ability. Zhang et al. [12] presented a PP method for mobile robots in view of an improved local PSO algorithm. This algorithm increases the randomness and diversity in the local search process, improving the search capability. Through simulation experiments, the author verified the superior performance of this algorithm in mobile robot PP problems, indicating its good applicability and scalability in practical applications. This mobile robot PP method in view of improved local PSO algorithm provides an effective technical means to solve the navigation problem in complex environment in actual scenes.

In summary, although extensive research has been conducted to improve the planning performance and collision avoidance ability of intelligent PP models, there is little involvement in the construction of models that adjust adaptive parameters according to environmental characteristics. This mode is meaningful for improving the planning performance of PP models and the obstacle avoidance ability of robots.

III. ROBOT PATH PLANNING AND COLLISION AVOIDANCE STRATEGY IN VIEW OF IMPROVED ACO AND A* ALGORITHMS

The ACO algorithm was invented by imitating the foraging process of ants in nature, and has merits like strong adaptability and ease of utilizing in conjunction with other algorithms [13, 14]. For this reason, this algorithm was chosen in this study to construct a robot motion trajectory planning model. However, the ACO algorithm also has the disadvantage of being easily

trapped in local optima, so it is also essential for enhancing the algorithm. In view of the shortcomings of the ACO algorithm, it can improve its node selection, pheromone update mechanism, transition probability calculation method and volatility coefficient calculation method.

A. Design of Improved ACO Algorithm Based on Adaptive Parameter Setting

In actual working conditions, mobile robots will spend too much time in significant turning movements, and the corresponding energy loss will inevitably increase. Therefore, in PP, it is necessary to minimize significant turning points, improve the planning path, and diminish the motion cost of mobile robots. So now an improved planning path transition probability calculation method that integrates corner heuristic information is designed, as shown in Eq. (1).

$$P_{ij}^{(k)}(t) = \begin{cases} \frac{\tau_{ij}^\alpha(t)\eta_{ij}^\beta(t)\omega_{ij}^\gamma(t)}{\sum_{s \in allowed_k} \tau_{ij}^\alpha(t)\eta_{ij}^\beta(t)\omega_{ij}^\gamma(t)}, & s \in allowed_k \\ 0, & otherwise \end{cases} \quad (1)$$

The superscript of the variable in Eq. (1) represents the ant number; The subscript is the path number; $\tau_{ij}^\alpha(t)$, $\eta_{ij}^\beta(t)$ and $\omega_{ij}^\gamma(t)$ respectively represent the pheromone quantity, heuristic information and corner heuristic function on the corresponding track of the corresponding ant at time t ; $allowed_k$ represents the feasible adjacency grid label set of ant k . The related calculating method of the corner heuristic function $\omega_{ij}(t)$ is depicted in Eq. (2).

$$\omega_{ij}(t) = \omega_i T \quad (2)$$

In Eq. (2), ω_i is an adjustable parameter with a value range of (0,1); T represents the turning cost. The corner of the path can be described as shown in Fig. 1, where the corners of paths (1) and (2) are both 45°, and the corners of paths (3) and (4) are 90° and 135°.

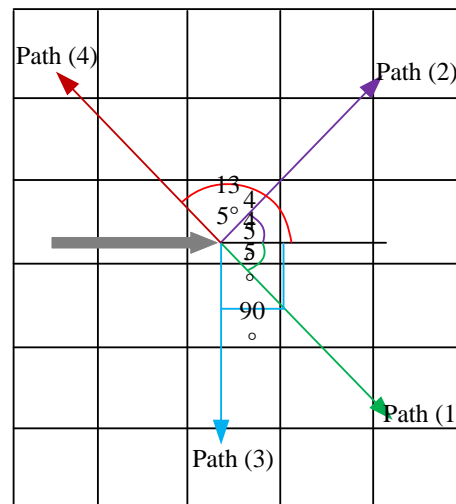

Fig. 1. Schematic diagram of improved path transition probability calculation method for path corners.

Therefore, T in Eq. (2) can be calculated according to Eq. (3).

$$\begin{cases} T = 2, \theta \leq 90^\circ \\ T = 1, 90^\circ \leq \theta \leq 180^\circ \end{cases} \quad (3)$$

In the traditional ACO algorithm, the path is selected according to the roulette wheel method, and there is a relatively significant pheromone concentration in the algorithm operation phase, which leads to the slow convergence of the ACO algorithm in the calculation premise [15, 16]. Meanwhile, in very large environmental conditions, traditional ACO algorithms may experience convergence stagnation, which significantly reduces the global solution optimization performance of the algorithm [17]. Therefore, an adaptive parameter setting method is designed here, which uses a mixture of random sexual selection and deterministic selection to calculate the selected path, as shown in Formula (4).

$$s = \begin{cases} \arg \left(\max \left(\left[\tau_{ij}(t) \right]^\alpha \cdot \left[\eta_{ij}(t) \right]^\beta \cdot \left[\omega_{ij}(t) \right]^\gamma \right) \right), q \leq q_0 \\ p_{ij}^k, \text{ else} \end{cases} \quad (4)$$

In Eq. (4) s represents the selected path; p_{ij}^k is the possibility of the corresponding ant appearing on the corresponding path; α , β and γ represent the corresponding ant numbers for $\tau_{ij}(t)$, $\eta_{ij}(t)$, and $\omega_{ij}(t)$, respectively; q is a uniformly distributed random variable in the range of [0,1], and q_0 is the threshold corresponding to the deterministic selection. The calculation method for q_0 is shown in Eq. (5). In this new adaptive parameter setting method, random variable q and deterministic selection threshold q_0 are used to show the randomness and certainty in the selection process respectively.

$$q_0 = \varepsilon \cdot \left\{ 0.2 + \left[\frac{N_{\max} - N_c}{N_{\max}} \right] \times 0.7 \right\} \quad (5)$$

In Eq. (5), ε is the adjustment coefficient; N_{\max} , N_c serves as the maximum quantity of iterations and the current quantity of iterations. Combining the search characteristics of ant colony during the iteration process, the initial q_0 of the improved ACO algorithm is generally greater than q , which means that the initial path of the improved ACO algorithm is determined in a pseudo random probability manner. In the later stage, as the small value of q_0 , ants are more likely to conduct random searches. It indicates that this strategy of selecting path nodes based on adaptive parameter calculation can effectively reduce the algorithm runtime, accelerate the algorithm convergence, and reduce the probability of stagnation. This increases the likelihood of the algorithm finding the optimal solution.

The traditional ACO algorithm will update the pheromone according to the way of updating all paths, but the disadvantage of this way is that the pheromone quantity of all paths may not differ greatly. This cannot highlight the competitiveness of the dominant path, and the convergence speed is slow. Therefore, to strengthen the attraction of the

path, the pheromone updating method is now adjusted. The calculation method of pheromone $\tau_{ij}(t+n)$ at time $t+n$ is shown in Eq. (6).

$$\tau_{ij}(t+n) = (1-\rho)\tau_{ij}(t) + \Delta\tau_{ij}(t,t+n) + \frac{h(L_a-L_n)}{L_n} \quad (6)$$

In Eq. (6), L_a and L_n are the optimal values in the iteration history and the optimal values in this iteration, respectively; L_n is the adjustable coefficient. Therefore, when the calculation of each iteration of the algorithm is completed, when $L_a > L_n$, the corresponding path of this iteration is shorter. Eq. (6) will strengthen the pheromone strength of this iteration and save the OP generated in this iteration. On the contrary, if $L_a < L_n$, it means that the current path is not the shortest path. Eq. (6) will reduce the strength of pheromone.

Due to special terrain conditions, the constant volatility coefficient ρ will diminish the likelihood of the algorithm finding the OP. When the value of ρ is too large, although the algorithm converges faster, it also may fall into local optima; When the value of ρ is too small, the likelihood of previously explored nodes being repeatedly explored will increase, and the convergence speed will also decrease. Therefore, it now adjusts the size of ρ and obtains the value according to Eq. (7).

$$\rho = \begin{cases} 0.9\rho(t-1), L_a - L_n > b \\ 0.8\rho(t-1), a < L_a - L_n < b \\ 0.7\rho(t-1), L_a - L_n < a \end{cases} \quad (7)$$

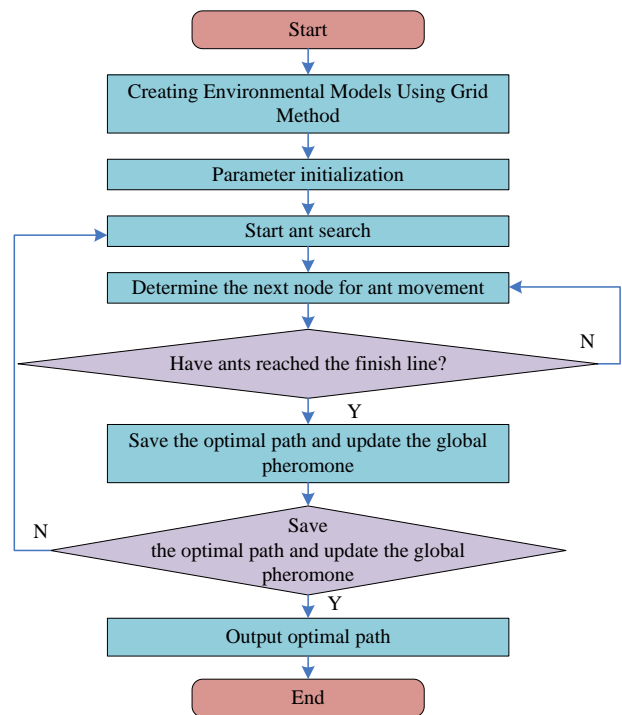

Fig. 2. Improved ACO algorithm calculation process.

In Eq. (7), L_A is the worst case path in the current calculation result; a and b are two constants; The smaller the $L_A - L_n$ value, the greater the likelihood of it falling into local optima, and the faster the update speed of ρ . The improved ACO algorithm used in robot movement PP has been designed, and its calculation is shown in Fig. 2.

B. Improved A* Algorithm and Robot Path Planning Model Design

Due to the fact that mobile robots often encounter moving obstacles in actual working environments, if the robot still follows the planned route, the time and energy consumption to reach the endpoint (EP) will increase, and even safety accidents may occur [18, 19]. Therefore, when designing a robot motion PP model, it is also necessary to consider obstacle avoidance issues. Robot movement PP cannot only consider the search efficiency of algorithms, but also the degree of twists and turns in the route. The classic A* algorithm is often applied to solve such problems, but it uses Manhattan distance and Euclidean distance to set heuristic functions, with only four search directions [20]. The fewer search directions in the classic A* algorithm will increase the number of probe nodes and the viewpoint of the path, which will affect the performance of the algorithm. Moreover, robots moving along winding paths can

also waste too much time. Consequently, it is essential for enhancing the traditional A* algorithm by performing path search calculations in eight directions, and combining the Manhattan distance $h_M(n)$ and Euclidean distance $h_g(n)$ of the current point n to design an estimated cost $h(n)$ that can simultaneously reduce the number of search nodes and bends. The calculation is demonstrated in Eq. (8).

$$h(n) = \max\left(\text{abs}(n_x - g_x), \text{abs}(n_y - g_y)\right) \quad (8)$$

In Eq. (8), $\text{abs}(\cdot)$ represents the absolute value operation; g_x and g_y represents the coordinates of the target node g_y in both axis directions. Therefore, the improved A* algorithm calculation process is demonstrated in Fig. 3.

In this study, an environment model for robot motion is established, as shown in Fig. 4. The basic method for modeling is the grid method, which selects grids of appropriate size to simulate the environment. The static fault objects in the environment in Fig. 4 are simulated using a blue grid, with a green cross representing dynamic obstacles (DO), and static obstacles that suddenly enter the environment are described in red. The white grid in Fig. 4 shows the areas where the robot can move freely.

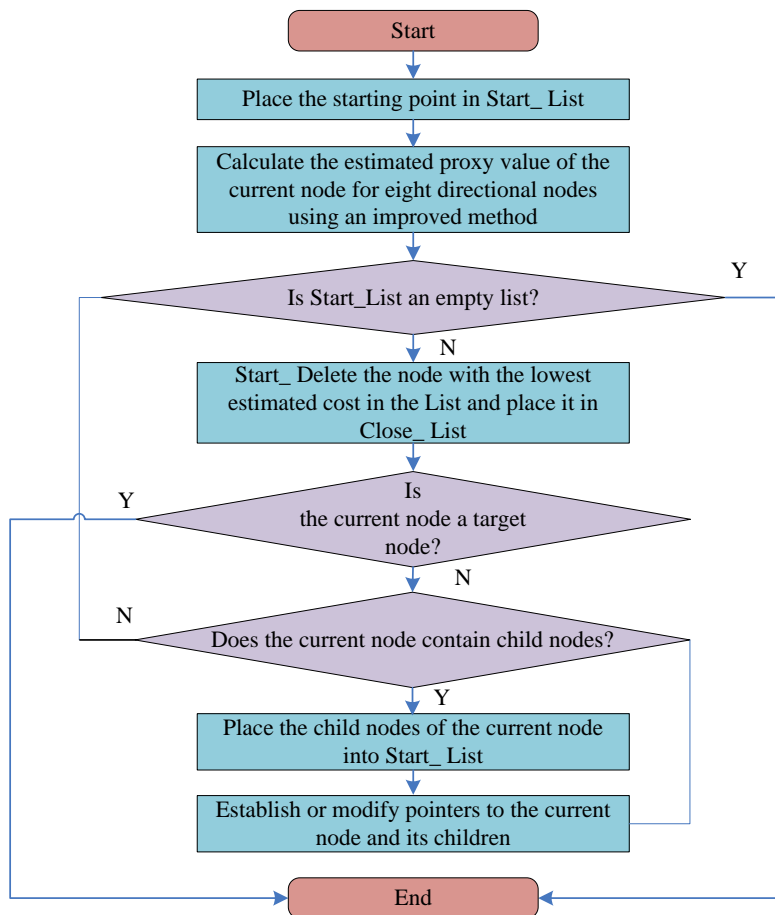

Fig. 3. Improved A* algorithm calculation process.

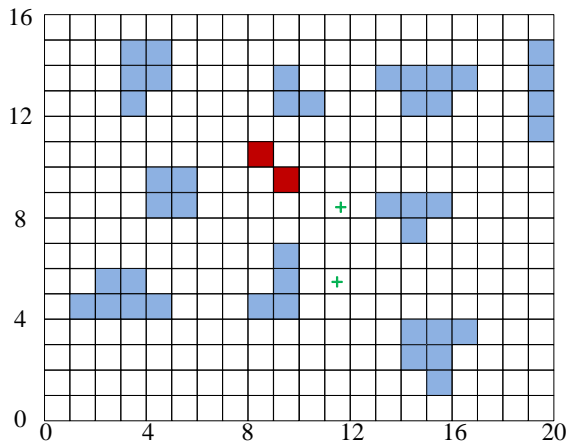

Fig. 4. Grid map of robot mobile environment simulation.

Robots need to continuously search for various obstacles within a limited range while moving, in order to make targeted obstacle avoidance behaviors. To perceive the movement path of the future DO, linear prediction models are now used to calculate the motion status of the DO. The current assumption is that the moving obstacle in the environment is $P(x, y)$, and the horizontal and vertical coordinate values in the orientation are correlated with time t . Therefore, (x, y) can be calculated according to Eq. (9),

$$\begin{cases} x = at + b \\ y = ct + d \end{cases} \quad (9)$$

g_y in Eq. (8) are unknown equation parameters. According to Eq. (9), calculate the corresponding (x_l, y_l) (where $l = 1, 2, \dots, n$) at n time points to obtain a linear equation in matrix form, as shown in Eq. (10).

$$\begin{cases} X_n = T_n + A_m \\ Y_n = T_n + A_m \end{cases} \quad (10)$$

The matrix content in Eq. (10) is shown in Eq. (11).

$$\begin{cases} X_n = [x_1, x_2, \dots, x_n]^T \\ T_n = \begin{bmatrix} t_1 & t_2 & \dots & t_n \\ 1 & 1 & \dots & 1 \end{bmatrix}^T \\ A_m = [a, b]^T \\ B_m = [c, d]^T \\ Y_n = [y_1, y_2, \dots, y_n]^T \end{cases} \quad (11)$$

In this study, the error vector E_n is set and calculated according to Eq. (12).

$$E_n = [e_1, e_2, \dots, e_n]^T \quad (12)$$

Therefore, Eq. (13) holds.

$$E_n = X_n - T_n \cdot A_n \quad (13)$$

In Eq. (13), A_n is the estimated value. The analytical error can be calculated according to Eq. (14).

$$J_n = \sum_{l=1}^n \lambda^{n-l} e_l^2 \quad (14)$$

The range of λ values in Eq. (14) is (0,1). Its redefinition F is calculated according to Eq. (15).

$$P_{n-1} = (T_{n-1}^T T_{n-1})^{-1} / \lambda \quad (15)$$

According to the observation values of moving obstacles at n different times, their spatial coordinates can be calculated, thereby calculating the specific values of parameters g_y . The behavior of the robot sensors, which detect the position of the DO in the circumstance will accompany the entire movement of the robot, used to estimate parameters for corresponding updates. Finally, the subsequent position information of the obstacle can be obtained according to the above method.

In real-world application scenarios, not all obstacles present in the environment of mobile robots are stationary, and there may be obstacles that can move, such as humans. Therefore, robots also need to avoid DO, which requires higher control and PP capabilities. Below is the design of collision prediction and obstacle avoidance strategies for robots. Considering the sensor measurement capabilities and movement methods of most mobile robots on the market, it is assumed that robots use their own sensors to continuously measure the movement position, direction, and speed of surrounding obstacles. The motion directions of robots and DO are described in Fig. 5.

Based on Fig. 5, the collision avoidance strategy designed in this study is illustrated: if there is no method of collision between the robot and the DO, the motion trajectory of the two needs to be observed to determine if there is an intersection between the two. If there are no intersections, it is assumed that they will not collide. In this case, the robot does not need to take additional collision avoidance actions and can move according to the originally planned trajectory, as shown in Fig. 5 for A, B, and F. But in the case where there is an intersection point between the robot and the obstacle's motion trajectory, the two will collide, and at this point, it is necessary to redefine the robot's motion path. For example, in the C and D motion situations in Fig. 5, the obstacle intersects with the robot's motion at the side, and the corresponding collision avoidance strategy is for the robot to remain stationary. After the current motion trajectory of the DO does not intersect with the robot, the robot continues to move along the set path. In summary, to better address the problem of robot motion trajectory planning, it is necessary to combine the improved A* algorithm with the improved ACO algorithm. The corresponding computation is shown in Fig. 6.

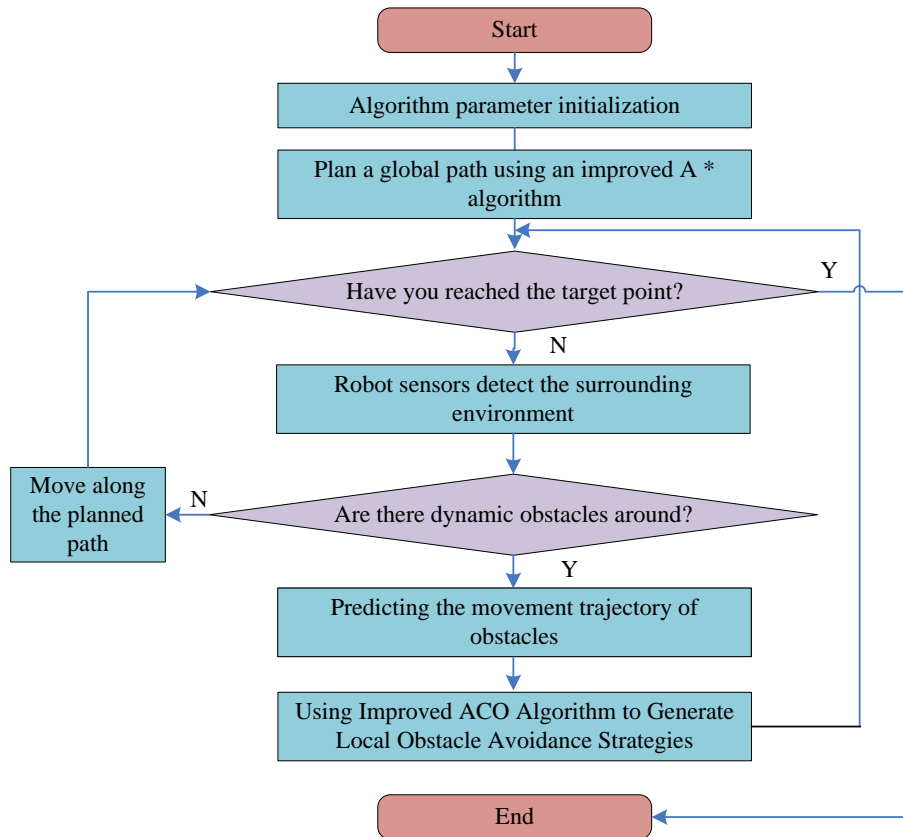

Fig. 6. Calculation process of robot path planning model using hybrid improved A* algorithm and IACO-A* algorithm.

IV. TESTING AND ANALYSIS OF ROBOT PATH PLANNING MODEL BASED ON HYBRID IMPROVED ACO ALGORITHM

After introducing a robot motion PP model in view of the improved ACO algorithm and the improved ACO-A* (IACO-A*) algorithm, the application of the model needs to be tested. In this study, only simulation experiments are used to verify the design model. Meanwhile, to simplify the experiment, the mobile environment in the test is abstraction into a grid map. The simulation experiment was run on the MATLAB2016 platform, and the parameters of the IACO-A* algorithm were determined through multiple trial runs as follows: the maximum number of cycles was 50, $\alpha = 4$, $\beta = 8$, $\rho = 0.7$,

and the total quantity of ants was 50. The experimental circumstance is a two-dimensional map, and the minimum size of the tested grid is 10 m × 10 m, with a maximum size of 100m × 100m, with a grid growth step of 5m. In the experiment, the widely used ACA, PSO algorithm, and the novel Beetle Antennae Search (BAS) algorithm were selected to construct a comparative planning model. The parameters of the comparative model were also determined according to the trial operation method. The robot is set to move forward at a constant speed of 1m/s when no DO is encountered. After encountering obstacles and temporarily stationary, it first accelerates to 1m/s at an acceleration of 1m/s², and then continues to move at a constant speed. There are two DO in the

grid map, and their initial positions appear randomly. Referring to the actual working circumstance of mobile robots, the proportion of static obstacle grids to the total quantity of grids should be within the range of 20% to 70%; within this numerical range, the quantity of static obstacles generated is also random, and the setting results are shown in Table I.

TABLE I. COMPARISON OF ALGORITHM PARAMETER SETTING SCHEMES

Number	Algorithm name	Parameter Name	Numerical value
#1	ACO	Maximum number of cycles	50
		Ant number	200
		Walking distance	1.5
		Pheromone volatilization factor	0.6
#2	BAS	Maximum number of iterations	50
		The initial length of the antennae of the longicorn beetle	10
		Step decay factor	0.95
		Maximum step size	1.26
		Minimum step size	0.35
#3	PSO	Maximum number of iterations	50
		Inertia weight	0.6
		Learning factor	1.4
		Maximum speed	27
		Minimum speed	4

Firstly, a specific PP analysis is carried out using the planning results with a minimum grid size of 10 * 10 m and no DO conditions as a representative. The grid map generation results are randomly selected, and the OP planned by IACO-A * and ACO algorithms is indicated in Fig. 7. The horizontal and vertical axes in Fig. 7 represent the X and Y axes in the two-dimensional grid map, respectively; The scale units are all in meters; The blue grid represents the static obstacles that exist at the initial moment; The green dots and red crosses represent the starting point (SP) and EP of the robot's movement path, respectively; The black dashed line serves as the planned movement path. Fig. 7 demonstrates that the total path lengths of IACO-A * and ACO algorithms are 7.95 m and 12.64 m, respectively. Both the enhanced and the improved ACO algorithms can enable the robot to move from the SP to the EP; But the route planned by the IACO-A * algorithm has significantly fewer bends, and the overall route is smoother, resulting in a shorter motion time.

Further analysis of the planning results was conducted using 10 * 10 m DO conditions. Fig. 8(a), 8(b), 8(c), and 8(d) represent the initial planning path, the path when DO, O1 and O2 are added, the path to avoid O1, and the path to avoid O2, respectively. The green color in Fig. 8 serves as the path of the robot; Black serves as the movement path of DO; the dashed line serves as the planned path or the path that has been taken; The dotted line serves as the path of the obstacle or the robot during the avoidance process. Fig. 8(b) and 8(c) indicate that the robot will encounter side collisions with O1 DO during its movement. Therefore, choose to stay in place for a period of time until it is calculated that there is no longer an intersection between the two routes before continuing to move along the

original route. Observing Fig. 8(d), it can be seen that after the robot detects a frontal collision with the DO O2, the IACO-A * algorithm generates local target points that modify the original path to some extent. After avoiding O2, the robot moves along the original path.

Fig. 7. IACO-A * and ACO algorithm in 10 × 10 m optimal planning path in a 10 m grid map.

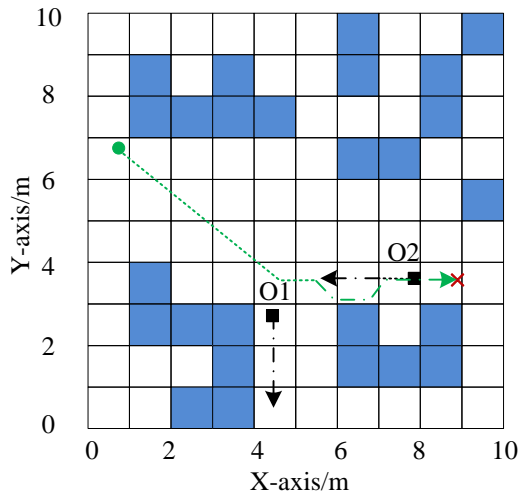

(b) Environment when adding dynamic obstacles

(c) Path to avoid dynamic obstacle 1

(d) Path to avoid dynamic obstacle 2

Fig. 8. IACO-A * in 10 with dynamic obstacles × planned path in a 10m map.

It reanalyzes the planning outcomes of the unimproved ACO algorithm in the presence of DO, and the results are shown in Fig. 9. The meanings of the horizontal and vertical axes, icons, and lines in Fig. 9 are consistent with those in Fig. 8. Fig. 9 shows that although the route planned using the traditional ACO algorithm also avoids DO O1 and O2, the adjusted moving route significantly detours compared to Fig. 8. Based on Fig. 8 and 9, it is found that using the IACO-A * algorithm and the ACO algorithm, the overall travel distance of the two algorithms is 12.28 m and 16.74 m, respectively. This indicates that the IACO-A * algorithm exceeds the traditional ACO algorithm in the overall obstacle avoidance capability and route rationality of the robot PP.

Fig. 9. ACO in 10 with dynamic obstacles × planned path in a 10 m map.

Next, it selects all the comparison models and calculates their minimum path length changes with the IACO-A * planning model during the training process of a 10 * 10m grid map with DO. It is indicated in Fig. 10. In Fig. 10, the horizontal axis (HA) serves as the quantity of iterations, while the vertical axis represents the minimum path length planned, in meters. Different subgraphs and line styles represent different planning models. Fig. 10 shows that the IACO-A *, ACO, BAS, and PSO planning models converge after 8, 37, 23, and 26 iterations, respectively. The minimum path lengths after convergence are 13.24m, 17.82m, 16.24m, and 17.05m, respectively. The experiment indicates that the PP model in this study based on the IACO-A * algorithm has the fastest convergence speed during training, and the total length of the OP after convergence is the smallest.

The performance of each planning model in the test dataset of a 10 * 10m grid map with DO is demonstrated in Fig. 11. The HA in Fig. 11 serves as repeated experimental tests, which are conducted to verify the stability of the output results of each planning model. Fig. 11 shows that when the number of repetitions is small, the minimum length fluctuation of the output routes of each planning model is more severe. However, as the number of repetitions increases, the minimum path length fluctuation gradually decreases. The minimum planning length standard deviations for IACO-A *, ACO, BAS, and PSO planning models are 0.82m, 1.24m, 0.95m, and 1.78m, respectively.

Fig. 10. Minimum path length of each planning model in training.

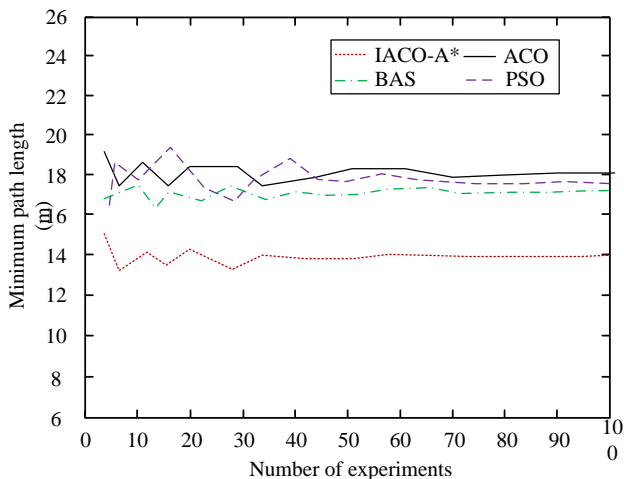

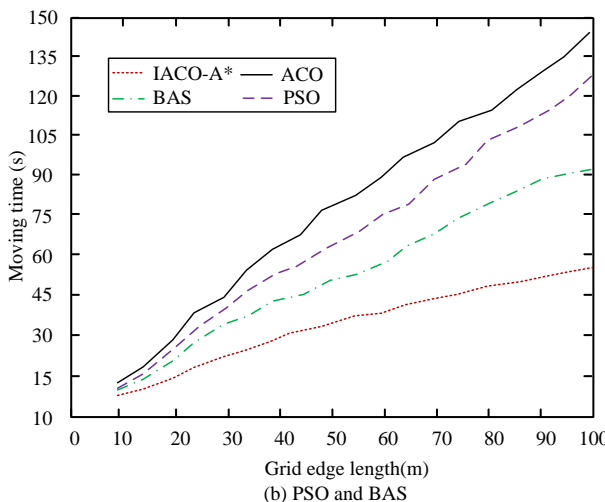

Fig. 11. Each planning model with dynamic obstacles 10 × Performance in 10 m grid map testing.

It further analyzes the minimum planning path length and corresponding movement time of each planning model under different grid size maps with DO. It is illustrated in Fig. 12. The HA in Fig. 12 serves as the edge lengths of different grid maps, in meters; The vertical axes of Fig. 12(a) and 12(b)

represent the minimum travel path length and the corresponding total travel time, in units of m and s, respectively. The line style is used to distinguish the planning model. Fig. 12 serves as that as the size of the map grid grows, the time and total distance required for the robots to move from the SP to the EP in the map also increase. However, regardless of the size of the grid map, the minimum path length and total movement time of the IACO-A * planning model designed in this study are smaller than all the comparative planning models. For example, when the edge length of the grid map is 100m, the minimum planning length and total movement time of IACO-A *, ACO, BAS, and PSO planning models are 49m, 104m, 75m, 93m and 49s, 142s, 93s, and 127s, respectively.

(a) IACO-A * and ACO

(b) PSO and BAS

Fig. 12. Minimum path length and movement time of each model under different map sizes.

In order to further improve the reliability of the research results, the IACO-A * model is now placed in a domestic mobile robot product to carry out dynamic obstacle avoidance experiments in planar and curved scenes. The dynamic obstacles are spheres, rectangular parallelepipeds, and regular tetrahedrons, respectively. After repeated experiments, it was found that the robot system equipped with the IACO-A * model has the fastest dynamic obstacle avoidance response speed and the shortest obstacle avoidance time. Its practical

performance is significantly better than that of mobile robots equipped with other models.

V. RESULTS AND DISCUSSION

This study designed an improved ACO path planning model based on adaptive parameter setting, and conducted dynamic obstacle avoidance path planning experiments in a simulation grid map. The experimental results show that the model designed in this study has a grid size of $10 \times$ the total planned path length under the conditions of 10 m and no dynamic obstacles is 7.95 m, which is lower than the output path length of the comparative model and can reach the set focus normally. Simultaneously, in the case of a grid size of $10 * 10$ m and the presence of dynamic obstacles, the IACO-A * planning model corresponds to the robot using pause and generate local target points to avoid obstacles O1 and O2 that may cause side and frontal collisions, respectively. The ACO algorithm corresponds to the robot avoiding O1 and O2 obstacles with the same movement mode by generating local target points, but the overall movement distance is 16.74 meters, which is significantly higher than the data of the IACO-A * planning model. Moreover, in various scenarios where the grid edge length of the simulated grid map changes from 10 to 100, the total path length of the planning model output in this study is consistently lower than that of all the comparative models, and also lower than the total path length under the same conditions as in references [9] and [11]. Finally, the IACO-A * model was placed in a domestic mobile robot product to carry out dynamic obstacle avoidance experiments in planar and curved scenes. The dynamic obstacles have the shapes of sphere, rectangular cuboid, and regular tetrahedron, respectively. After repeated experiments, it was found that the robot system equipped with the IACO-A * model has the fastest dynamic obstacle avoidance response speed and the shortest obstacle avoidance time. Its practical performance is significantly better than that of mobile robots equipped with other models.

From the results of various types of experiments conducted in this study, it can be seen that the robot movement path planning model based on the improved ACO algorithm designed in this study has excellent path planning and obstacle avoidance capabilities, which can enable the robot to smoothly and efficiently avoid dynamic obstacles in the route.

VI. CONCLUSION

In this study, an improved ACO algorithm and an improved A * algorithm were developed, and the two were fused to construct a robot motion PP model. The experiment reveals that under the conditions of grid size $10 * 10$ m and no DO, the total path lengths of IACO-A * and ACO algorithms are 7.95m and 12.64m, respectively. Both the enhanced and the improved ACO algorithms can enable the robot to move from the SP to the EP. Under the conditions of a grid size of $10 * 10$ m and the presence of DO, the IACO-A * planning model corresponds to robots that use pause and generate local target points to avoid obstacles O1 and O2 that may cause side and frontal collisions, respectively. The ACO algorithm corresponds to the robot that avoids obstacles O1 and O2 with the same motion mode by generating local targets; however, the overall mobile distance of 16.74m is significantly higher

than the data of the IACO-A * planning model. During the training process, the IACO-A *, ACO, BAS, and PSO programming models completed convergence after 8, 37, 23, and 26 iterations, respectively. The minimum path lengths after convergence were 13.24m, 17.82m, 16.24m, and 17.05m, respectively. When the edge length of the grid map is 100m, the minimum planning length and total movement time of the IACO-A *, ACO, BAS, and PSO planning models are 49m, 104m, 75m, 93m and 49s, 142s, 93s, and 127s, respectively. The experimental data prove that the robot motion PP model designed in this study with respect to the improved ACO algorithm has excellent PP and obstacle avoidance capabilities. However, due to research limitations, it was not possible to invite multiple industry experts to subjectively evaluate the practicality of the model. From the results of this experiment, it can be seen that the shape of obstacles has an extremely small impact on the path planning results of the IACO-A * model.

Simulation of Logistics Frequent Path Data Mining Based on Statistical Density

Fengju Hou*

Zibo Vocational Institute, Shandong, China

Abstract—Sharp increases and rapid development followed the effects of a novel coronavirus outbreak on online sales and the real economy. The e-commerce mode on the Internet has attracted much attention, and users' purchases on the Internet has never been done before. However, among the many express companies, as the ones closest to consumers, they can still provide high-quality products in the face of huge market demand. Urban terminal logistics refers to the purpose of express services to meet the needs of terminal customers under the requirements of logistics centralization and customer diversification. However, the geographical distribution of logistics services in China is comprehensive, and customers' requirements are also complex. Practical problems in logistics enterprises in China significantly restrict the quality of logistics services. The final kilometer of distribution is composed of many links, and it is a very cumbersome enlance; it contains the determination of distribution scope, loading goods, arrangement of distribution sequence, arrangement of vehicles or personnel scheduling, and planning of distribution routes. A Genetic Algorithm (GA) with local search method fusion is proposed for fast logistics data modeling and mining simulation analysis. Practical examples and literature data prove the method's accuracy.

Keywords—Statistical density; logistics; the path; the simulation data

I. INTRODUCTION

Since transportation costs have such a significant impact on the whole process, it is essential to optimize coordination routes in order to minimize transportation time and costs. This method increases efficiency while decreasing overall transportation costs. From the perspective of transportation constraints, Cheng Nan constructed a terminal transportation route containing transportation constraints in order to reduce transportation costs. Li Kunyenga proposed a basic mathematical model based on linearization by linking logistics' terminal characteristics with customers' needs. Based on this model, he proposed a new branch and truncation method, which included a new method to decompose the efficiency inequalities. The study [1] proposes using vehicle routing planning, joint distribution, and various forms to optimize rural distribution with low-density, long lines. The Genetic Algorithm (GA) is applied to optimize "at the end of the line" and maximize vehicle capacity and distribution costs. Using quadratic programming, [2] proposed a logistics distribution model that optimizes warehouse-to-distribution-center direction, customers, and express transport routes. Implementing a multigroup GA, its effectiveness was validated and confirmed. Urban terminal logistics distribution

in China still has these issues due to complex and changing work.

The cost of transportation remains exceptionally high. For now, logistics costs remain high among end-city logistics companies. The current problems in China are as follows: In the tip area of China, because the customer group is widely distributed, it needs a lot of human and material resources investment in infrastructure, equipment, and other aspects to increase investment, such as the establishment of the automatic warehouse and intelligent automatic suitcase, not only to invest heavily but also to increase the cost of project operation and maintenance [3–4]. Ineffective logistics is due to a lack of resources because the requirements of each user for logistics are very different, in the whole logistics system; no one can realize the coordination process, which reduces the efficiency of the whole logistics system. There is a delay in the delivery of the goods. In the end, the logistics, according to their actual situation, were to conduct the distribution. Our country has many subjective reasons, such as imperfect traffic routes. In addition, to some areas, the scale of logistics enterprises is small, and they often need to stay in the distribution center for a short time before distribution, which leads to an extended delivery time. Most express companies have not developed a set of perfect reward and punishment mechanisms in the process of terminal distribution, which leads to problems of lax work attitudes among their staff, product loss, damage, and delayed delivery, resulting in low customer satisfaction [5–6].

According to the current research results, various intelligent algorithms are applied to logistics path planning to achieve efficient and intelligent path optimization. It is the most commonly used path planning method. With the increasing intelligence of the express delivery industry in China, many people have begun to discuss how to establish an efficient online delivery system from the perspectives of intelligent self-lifting boxes, distribution center location, and distribution path selection. Zhang Shabo put forward the cost model, pricing model, and robust model according to the characteristics of intelligent express, analyzed the case with some examples, and put forward some reference opinions on how to construct a terminal distribution network in the construction and operation. Wu Maupye et al. analyzed the key problems faced by terminal logistics in property-free communities from two perspectives of the introduction and investment of express boxes, as well as optimization strategies such as terminal logistics collaborative distribution, standardized logistics management in property-free communities, optimized pickup resource allocation, and

*Corresponding Author.

omnichannel inventory operation management in order to provide decision-making reference for the intelligent express cabinet to solve the "last kilometer" terminal logistics in the non-realty community. Lee's action is based on data mining, to solve the problem of terminal distribution mode selection, through this technology, build a terminal distribution mode selection, and solve the data instance, finally using cluster algorithm to solve the problem of the terminal distribution system, through the case study, Finally, a better result than the existing distribution system is obtained according to the "delivery to home" and "customer pick up" characteristics.

On the choice of the distribution center, Yin Xiaoqing 8 and others, based on travel time reliability and a complex network structure, built a city distribution station at the end of the cold chain planning model and conducted the simulation calculation. An example that confirms the feasibility and effectiveness of the method is the assurance of utmost timeliness. Hi-ping Ren proposed the establishment of a network in the midst of the sorting center with end customers, with the aim of resolving the intricate issue of "end" distribution for retail enterprises. The network functions as a link between the customer and the sorting center, arranging the distribution sequence from the distribution center to the client's terminal within the classification and distribution network. Terminals could be office buildings, residential areas, or districts. The existence of a hierarchical sorting mode makes the business between employees and customers less, minimizing the consumption of time, but also reduces the logistics company to the user's delivery demand and the overall layout of the delivery mode, so that in the case of meeting consumer needs more actively for consumers and the company to bring a win-win situation. Zhao Xuedong for all kinds of fresh food, all kinds of logistics center layout and route optimization, set up a balanced carbon dioxide emissions and customers at the lowest transport demand stratified programming model, and under different fresh demand, the selection of logistics center and transportation route setting has a significant effect. An example has proved the correctness of this method. Based on providing efficient, safe, and fast distribution services for e-commerce customers, John Fernier et al. set up a regional distribution center to meet customers' high-quality service requirements and, on this basis, reduce logistics costs [7-9].

The paper is organized as follows: Section II presents the research method, Section III presents the proposed methods and result analysis of this work, and Section IV concludes the work.

II. RESEARCH METHOD

A. Overview and Application of Statistical Density Methods

In mathematics and technology, the most significant logistics problem is the optimization of statistical density. The frequent logistics routing problem is a hybrid optimization problem with various representative problems. As soon as the research results of statistical density are published, it has attracted the attention of many researchers. A passenger starts from one place, sells things in another, and returns to the origin. There is only one visit to a place. When the distance between the two places is known, he can decide his optimal

way of walking according to his situation. Before the logistics enterprise is discussed in detail, this article will elaborate on the basic knowledge of the logistics enterprise problem - the basic idea of the authorization map. In graph theory, the frequent problem of logistics routing is the minimum Hamiltonian cycle method, and the Hamiltonian cycle is a kind of node without a branch. A weighted graph is an undirected graph with a weight attached to each edge. Denoted as a weighted graph, it is a set of vertices, a set of edges, and represents the distance between vertices, Eq. (1)

(1)

Let denote the sub path from to, which takes the value 1 if it exists in the travelling salesman path and 0 otherwise, and the expression is given below, Eq. (2) and Eq. (3).

$$X_{ij}ij(i \rightarrow j)X_{ij} \quad (2)$$

$$X_{ij} = \begin{cases} 1, (i, j) \in L \\ 0, (i, j) \notin L \end{cases} \quad (3)$$

where is the solution sequence, then the objective function of the travelling salesman problem is expressed as a formula, and the travelling salesman's total distance through the path must be minimized, Eq. (4) and Eq. (5).

$$L(i, j) \in E \quad (4)$$

$$\begin{aligned} mZ &= \sum_{i \neq j} d_{i,j} X_{i,j} \\ mZ &= \sum_{i \neq j} d_{i,j} X_{i,j} \\ \sum_{i \in V, i \neq j; x_{ij}} &= 1 \\ \sum_{j \in V, j \neq i; x_{ji}} &= 1 \\ \sum_{i, j \in V; x_{ij}} &= |L|, L \in E \end{aligned} \quad (5)$$

It is a solution and then the objective function of the frequent logistics routing problem is expressed by the equation above, which requires the shortest total distance of the route through which the logistics need to pass.

In algorithmic terms, a publicly recognized data set tests and evaluates the computational power to solve a problem. It contains the best test data for a particular problem and the best solution for a problem [10-14].

B. Simulation of Logistics Frequent Path Data based on Statistical Density

This paper proposes a standard model based on statistical density simulation interval LIB for the frequent logistics path problem. The first statistical density simulation interval LIB found originates in some previous research articles by Dantzig, Fulkerson, Johnson Held and Karl, Karr, and Thompson et al. GerhardReinelt collected many practical problems, for example, in industry and geography, and gradually accumulated, eventually resulting in preliminary experimental data. LIB's statistical density simulation interval currently includes more than 100 examples, covering a wide range,

from 14 small to 85,900, strongly supporting solving logistics enterprise problems. However, some of these examples are fabricated purely to solve the frequent person problem of logistics routing, such as the statistical concentration modulus simulation value of sample 225, the correction of the LIB of the statistical concentration simulation has been stopped, and the results of a large number of statistical simulation experiments.

The statistical concentration simulation section LB includes three test data:

- 1) The symmetry of traveller's.
- 2) Hamiltonian ring problem.
- 3) Asymmetric logistics path frequent person problem.

On this basis, in the statistical density simulation region of LB, the format of the test data set that can be used to assess the method's performance is not uniform.

Location of the space: In this format, each point is identified with a number from 0 to the largest, and the coordinates of this point in the coordinate system are given according to the number. The initial test data is the spacing between all points in this format. In this format, the initial test data are the upper triangles of the spacing matrix between points. It is divided into diagonal, nondiagonal, row-first, and column-first, according to the order of precedence of whether there is a diagonal or not and row-first [15].

In the swarm, each person is an artificial intelligence that randomly and progressively constructs a solution to a class of optimal problems. Statistical density, a traditional algorithm, has been used more in road problems because its efficiency has always been the focus of attention, Eq. (6).

$$p_k(i, j) = q \left\{ \frac{[\tau(i, j)]^\alpha [\eta(i, i)]^\beta}{\sum_{\tau \in J_k(i)} [\tau(i, j)]^\alpha [\eta(i, i)]^\beta} \right\}; j \in J_k(i) \quad (6)$$

Then, as shown in the above formula, under statistical concentration will, calculate the migration of a city's risk, and then according to the "roulette gambling" method to identify the migration of the next city, in this process, the number of forbidden areas will be more, until every city covered by the taboo table, will stop for detection of the region.

Among these factors, the pheromone has the most significant coefficient of importance, and the route taken by the ants is randomized as the data changes. The lower the selected value is, the randomness of the stochastic optimization can be improved, but at the same time, the algorithm's convergence rate is reduced. As a key factor of the heuristic function, if its value is too large, it will be randomized so that it is easy to enter the optimal. In the case of abbreviated time, the randomization performance of the algorithm is improved, but the difficulty of the solution is also increased.

Then, the pheromone changes. After getting all the practical solutions, the global pheromone update is conducted according to the scheme. However, when searching, we adjust the signal to the pheromone change to obtain a new expression for the time series pheromone. Let us say that we want to

minimize the error of the objective function, expressed as Eq. (7).

$$K(C1, C2, \dots, Ck)ZZ \quad (7)$$

$$Z = \sum_{i=1}^k \sum_{x \in c_i} \|x - u_i\|^2$$

First, given the initial statistical density center, the algorithm will be iterated in the following two steps: a) Partition: The formula indicates that each node is divided into clusters such that the sum of squares within the cluster is minimized, Eq. (8)

$$m_1^{(0)}, m_2^{(0)}, \dots, m_k^{(0)} \quad (8)$$

The statistical density method is known as the average method. Its idea is quite simple. A sample set is divided into several small groups according to the distance of the sampling interval to ensure that the point groups are concentrated as far as possible and that the group is divided as clearly as possible. This paper proposes a method based on time series to solve the large-scale probabilistic simulation problem. It can divide an uneven urban area into several groups. The calculation accuracy is low, and the result is unstable when calculating the simulation area with less statistical density.

III. ANALYSIS OF RESULTS

A. Large-scale Statistical Density Analysis of Logistics Routing Data

After clustering in a large-scale statistical density simulation interval, the best route is determined based on the probability distribution of each simulated area. The pheromone is the key factor of the research object, and its change is related to the effect of the whole method. Under the traditional computational density, the starting concentration of each channel is the same and constant because the length of the channel will increase, so the subject will be attracted to the higher concentration so that the least one can be found in the screening repeatedly. However, this method has a drawback: it can lead to finding an incorrect route under uncertainty, resulting in a longer, time-consuming search.

Therefore, this paper presents a correction method based on point distance to correct the pheromone density of adjacent sides. We select a minimal path from a line with a start and end and multiple paths. In this line, the distance of the path is represented by the straight-line distance from the start point to the endpoint. The initial pheromone concentration between nodes can be defined as follows: Eq. (9) and Eq. (10)

$$d_{AC} D_{Aj} + d_{jc} A - j - C_{ij} \quad (9)$$

$$\tau_{ij}(0) = \frac{d_{AC}}{d_{Aj} + d_{jc}} \quad (10)$$

According to the property that pheromone is inversely proportional to path length, the above equations indicate that when the node is closer to the edge, that is, the closer it is to the shortest straight line distance, the value of is closer to 1,

and the statistical density will be biased towards such node movement.

This method guides the primary research target to avoid blind searches to improve the solution rate. After determining the new, improved method, the operation flow parameters of the algorithm are shown in Table I.

TABLE I. SIMULATION PARAMETERS OF LOGISTICS DATA WITH STATISTICAL DENSITY

Name	Value
P	50
Nc max	500
α	1
β	5
ρ	0.5

1) In terms of statistical concentration, other methods are used to generate a certain amount of pheromone at the starting point, and then the statistical density method is used to calculate, which improves the computational efficiency and accuracy.

2) The particle swarm optimization (PSO) algorithm is introduced to give each iteration a statistical concentration. Then, the solution generated by the statistical density system of each generation is used as the initial solution, and then the solution of other algorithms is repeated to speed up the calculation speed and achieve better results.

3) In the aspect of statistical density, the traditional selection method is based on experience, but if the selection is improper, it will reduce the operation speed, so other algorithms can be used to conduct.

4) The algorithm has the shortcomings of a premature algorithm, cannot adapt to the global optimal, is time-consuming, and so on. The statistical density algorithm is used to optimize the initial value and combined with other algorithms, such as crossover and mutation operation, to generate the optimal population.

B. Influence of Statistical Density on Data Mining of Logistics Frequent Paths

In the fundamental statistical density analysis, a pheromone is a positive feedback, and its change degree directly affects the degree of optimization of the research object. Therefore, this paper proposes a correction method based on positive and negative feedback to avoid excessive accumulation of pheromones.

In the research object's second iteration, its average path is calculated, and the updated pheromone standard formula is modified to make it move in a better direction, kf_{arg} . The statistical density is expressed by the average of the paths, as shown in the following Eq (11).

$$f_{avg} = \frac{1}{m} \bullet \sum_{k=1}^m L_i^k \quad (11)$$

The calculation formula in the following formula expresses the pheromone dynamic adjustment operator. Its

function is to adjust the pheromone concentration on the path in each iteration, Eq. (12).

$$\Delta_v = \sum_{i=1}^m \frac{L_i^k - f_{wrg}}{L_{best}^k} \bullet L_i^k \quad (12)$$

L_{best}^k It represents the shortest path and the path length passed by the current particle. The pheromones update Eq. (13) after adding the regulation operator is as follows: L_i^k

$$\tau_v(t+1) = (1-\rho)\tau_{ij}(t) + \Delta\tau_{ij} + \Delta_v \quad (13)$$

Optimising the statistical concentration in the iteration is easy because its calculation method is highly dependent on the amount of information. The particle swarm optimization algorithm calculation method uses the maximum value of Best and Pest to realize the particle location. The concept of Best and Pest is applied to the statistical concentration so that the research object has the characteristics of particles in the iteration, not only through the pheromone transmission but also through the optimization of the individual and the overall optimization. In the statistical density, the particles' adaptive crossover and mutation strategy prevents the method from falling into the maximum value. Firstly, the primary statistical concentration was used in the initial optimization. After passing through each channel, the FAG of the average road surface was calculated by using the statistical concentration, and the particles with fitness values below F were selected for cross-operation. When the fitness of path selection is not high, the position of the initial particle is replaced by the intersection point. Otherwise, it cannot be replaced. The crossover method randomly selects two locations, R and R, in a city and then makes a second crossover. Using local map technology, the contradiction between numbers can be effectively handled. Based on this, two arbitrary particles are exchanged to evaluate their adaptability, and when the particles' fit reaches an appropriate level, they will be replaced.

C. Effect of Statistical Density Algorithm on Data Simulation of Logistics Frequent Paths

Because the statistical density in this chapter is based on the minimization of the frequent person problem for logistics routing, it contradicts the up-and-down stochastic optimization principle of the benchmark function. The purpose of this paper is to evaluate the performance of the fusion algorithm in a specific city. The comparison method uses the last improved ACO and PSO and conducts ten separate experiments on different data to reduce the interference of random factors due to instability and record the best and average results. Table II illustrates the three methods for calculating the mean and the accuracy of the calculation, which are an example of computational density simulation.

For the "one-Kilometer" logistics problem, describe it as a multiple transportation point, that is, M mailers, N delivery points; this delivery point can be a user's address, can also be a smart ATM or a Courier, in this mode, all the information is considered as a job.

TABLE II. OPERATION TIME OF LOGISTICS DATA ALGORITHM BASED ON STATISTICAL DENSITY

Dataset	ACO	PSO	PSO-IACO
chn 31	22	17	10
ei1101	113	79	43
ch 130	253	189	78
rand 200	396	248	111

In the real situation, the "one-meter" distribution mode, under the premise of ensuring high quality and ensuring the delivery needs of customers, as far as possible to reduce the company's operating expenses. Therefore, applying the composite method to solve the terminal logistics problem still needs to conduct the division of the target area and route planning. Due to the current logistics terminal logistics environment in China, there are many kinds of couriers, and the target geographical distribution is wide; therefore, in the actual logistics process, it is inevitable to produce some problems such as going the wrong way, taking a long way, and repeating the road. If we cannot give an effective solution to this problem, there will be a lot of problems, such as unbalanced work, low efficiency, and repeated delivery in the end distribution process. Therefore, in the transportation of the "final kilometer", the "minimum route" is the primary optimization purpose, and then other restrictions are changed or added according to the actual situation to maximize the interests of customers and the company.

D. Optimizing Frequent Logistics Routes based on Statistical Density

Due to the use of multi-traveller mode, there will be energy limitations, capacity limitations, time limitations, and other issues. Energy limitation refers to the consumption of logistics and the continuous life of other intelligent vehicles. In the logistics process, the capacity limitation is the core of the vehicle loading capacity. In the case of delayed or early check-in by customers, there are also certain requirements on the delivery time of goods, namely the arrival sequence of the target. The "one kilometer of the city" problem to be dealt with in this paper should be modified or explained according to the actual situation to make the following interpretation:

1) *Description of the distance on the actual case:* The point of specific distribution and transport path between the plan because the curve of the road makes the actual transport distance cannot simply use coordinates to determine, in order to ensure the accuracy of the test and practical value, the point - point line spacing in the coordinate system to replace the actual distance of the target.

2) *Description of delivery personnel:* The delivery company is equipped with M delivery personnel, which can be assigned according to the task's scale.

3) *Description of time constraints:* Time constraints are added to each route. When the average speed of each train is the same, there is a positive relationship between the time and the total transportation distance. Therefore, in the future modelling process, in order to ensure real-time and balance, the maximum length of each route is limited.

IV. CONCLUSION

To sum up, this paper carries out three approaches for a single logistics problem: One is for a single logistics problem, using an improved statistical density and density method is optimized to it, and then USES the method of target classification, and then adopted based on the improved pheromone correction rule of statistical strength on the cluster planning, and the connection between these clusters established a whole calculation concentration simulation spacer ring. The transportation mode of the terminal is optimized. On this basis, the interval mode based on probability simulation cannot meet the transportation demand of the final kilometer, and the interval mode based on data density simulation can better meet the transportation demand of the terminal. Then, according to the "end" transportation situation in the logistics system, a M data distribution simulation region is established. In addition, the optimal combination of two different methods for distribution, on the premise of meeting the actual needs of customers, increasing the time limit, and making sure that the number of Courier service equalization effectively overcomes the traditional way of distribution, is not reasonable, the workload imbalance problem put forward an effective method of path selection, It has a practical guiding role in improving the customer's intimacy and improving the utilization rate of logistics.

Simulation Analysis of Hydraulic Control System of Engineering Robot Arm Based on ADAMS

Haiqing Wu

Department of Mechanical Engineering, Taiyuan Institute of Technology, Taiyuan, Shanxi, 030008, China

Abstract—Substantial trenching capacity, communication capabilities, simple configuration, and so on are just a few of the many benefits that make Hydraulic Control Systems (HCS) the context of physical devices used within the geotechnical trench. These characteristics have led to widespread application in developing water conservation and hydroelectric technology, architectural construction, local construction, and other technology. In this article, the engineering robot arm proposed an HCS. Subsequently, a digital version of the functional device is constructed using Anti-Doping Administration and Management System (ADAMS), a simulation program, by incorporating associated restrictions and workload. With the help of a simulation model of the HCS's functioning apparatus, this research obtains the fundamental factors of the excavator's operating range and the pressured condition variation curve of the location of every Hydraulic Actuator (HA). The findings, which provide a conceptual framework and enhancements for the control system equipment, significantly raise the bar on China's excavator architecture, expand digger efficiency, and foster the firm's fast growth. An in-depth examination of the HCS's current operating condition, including an examination of the simulated model's transmission phase, can be determined. The findings provide a theoretical foundation for designing an optimal HCS.

Keywords—Hydraulic control systems; ADAMS; simulation analysis; engineering robot arm

I. INTRODUCTION

Being a crucial component of automated control technology, digital electric Hydraulic Control Systems (HCS) have found several uses in numerous industries, including aviation, power generation, and more. An essential component of any digital HCS, electrical hydraulic gates convert low-voltage electric impulses into elevated hydraulic energy, making them essential for any application requiring electrical hydraulic servo control. So, if the electro-hydraulic control circuit valve had failed, the dependability of systems like the electromagnetic flow HCS and the automated control system would have been affected. That's why it's important to focus more on things like doing a technical failure study on the electromagnetic, hydraulic servo valves to make sure the electro-HCS is reliable and will last for the long haul [1]. Demolition robots are cutting-edge tools for the modern deconstruction of reinforced concrete structures. It has several applications in fields as diverse as nuclear energy, disaster response, metalworking, and demolition. The booms arm, which comprises three arm parts and then a crushing hammer mechanism, is the most important part of a destructive robot. Each device contains a hydraulic cylinder connected to a mechanical arm or breaker hammer, depending on the

application. The reliability and safety of the building, as well as the profitability and expense of the enterprise, are all impacted by the vibrational properties. Thus, the arm's construction is crucial. As a result, the reliability of components like the automated management system and the digital electric HCS might have been compromised if the electro-hydraulic circuitry valve had failed [2]. Individuals with amyotrophic lateral sclerosis, spinal cord injuries, and other illnesses that cause paralysis from the neck down sometimes wholly or partly lose control of their limbs. Certain activities of daily living, such as getting from one location to another or grasping a glass to drink from, are impossible for paralyzed individuals to do without external support. Providing such aid often requires a nurse or other paramedic, which might take a long time and need many resources. Artificial technologies, such as robotic arms, are often exploited to enable two fundamental and necessary limb tasks for paralyzed people to care for themselves: moving and gripping. Paralyzed people may do everyday chores with a robotic arm that mimics arm motions and restores the patient's ability to hold objects.

In this, a robotic arm was used to pour coffee from a bottle using the patient's motion intents [3]. The primary focus of these control systems is on the robotic arm's redundancy resolution. Plans for the robotic arms and non-holonomic vehicle movements are provided. Priorities of these intersecting paths are described in more detail in the article. If the automobile or the robotic arm has trouble following the desired trajectory, the control algorithm will prioritize which system will complete the job. In this, the authors simulate and execute the dual control of a robotic arm placed on a wheelchair. The redundant arm's calculated configuration is the outcome of an optimization exercise. Hydraulic power robotic manipulators are analyzed and controlled in a separate field [4]. Fig. 1 depicts the Hydraulic Robot System (HRS) block diagram.

The robotic arm's redundant resolution is the main emphasis of these control systems. Compared to electric motors, they still offer superior power-to-weight ratios and more inherent toughness and rigidity. Academics are paying more attention to creating high-performance controllers for applications such as footed robot control, actuator impedance control, and flight simulator motion control, where precise control efficiency is essential. The data is interpreted by Hydraulic Actuators (HA) as a velocity instruction rather than a force instruction like their electric equivalents, complicating the difficulty of HRS. As a result, the well-researched generic industrial robot approaches cannot be directly used [5].

Typically, robot arms are computationally designed to carry out instructions. Devices like delivery ordering systems, robot arms, and automated guided vehicles may all benefit from being part of a unified network and being directed by AI in an entirely autonomous factory. Some examples of these advantages include higher production and productivity and a better investment return for gear. Microsoft, Amazon, and Google are just a few companies that provide developers with the frameworks, tools, and platforms necessary to train AI [6].

Fig. 1. Block diagram of the HRS.

Compared to contemporary industrial counterparts, non-industrial robotic arms are flexible, have little actuation power, and may include components that display huge variances concerning respective specifications, all of which achieve extensive trajectory tracking and significant difficulty. It restricts the use of flexible or low-cost robots to activities that need great precision or places where circumstances may rapidly change, such as on building sites, where robots are subjected to extreme weather and working circumstances. Operating robots at low speeds, where the dynamics coupling among joints is minimal and is a straightforward solution to cope with such situations, but it comes at the cost of reduced performance and output. Using the maximum potential of cooperative and low-cost robots outlines strategies for improving accuracy and accelerating the process in this objective [7]. Markets for robotics technology are expected to expand rapidly over the next decade, and the introduction of robotics will cause a revolution in the heavy machinery sector, just as it has already done in other areas, such as transportation and manufacturing automobiles. To this day, energy efficiency is still one of the most pressing problems to be addressed in hydraulic systems. The preceding intellectual HRS are inefficient since they use a standard, ineffective valve control. Energy efficiency may be less of a priority during the design phase for fixed installations.

On the other hand, ambulatory robotic systems have a unique challenge because they have very little storage room for their energy sources [8]. Motion sensors attached to the machinery and the human body allow the arm motions and prosthesis to be controlled by inbuilt ultrasonic sensors, somatosensory rhythms, and attempting movements. This approach, however, may lead to significant control errors in the grip and requires frequent changes to the sensor values. As neuromuscular stimulating and intrusive BCIs have advanced in the biomedical field, robotic arms have been programmed to reach out and grab objects. Surface electromyographic and non-invasive EEG inputs have been successfully used for robotic arm gripping [9]. Existing arm-grabbing systems may be classified into non-computer vision-based and machine-learning systems. Robotic arms are often used for grasping. Ultrasonic sensors, central nervous system connections, and electromyograms are only a few of the non-computer vision-

based devices that benefit arm gripping. Moving sensors attached to the computer and the human condition allow the arm actions and prosthesis to be controlled by internal ultrasonic sensors and attempting movements.

II. RELATED WORKS

The best material for the manufacturing robotic arm has to be chosen to achieve the necessary qualities at the lowest possible cost and with the most potential for the intended use. The paper uses the analytical hierarchical process technique to decide which materials to apply in a robotic system [10]. One of the most popular multiple-criteria decision approaches, the Analytic Hierarchy Process (AHP), considers multiple criteria simultaneously. The AHP method's strength lies in its ability to accommodate numerous criteria simultaneously [11]. To solve the challenge of optimizing the design of robot arms for high-speed performance, we offer a surrogate-based evolutionary optimization technique using a global optimization technique, combining the response surface technique with a multi-objective evolutionary computation via decomposition. First, the robot arm's architecture and performance are evaluated using CAD software like Inventor and finite element modelling software like ANSYS [12]. This paper introduces a novel approach to teaching robotics using four components: an algorithm, a virtual experiment, some programming, and a controller.

The authors present an inverse kinematics method with an inexpensive desktop six-axis robotic arm designed for educational purposes. In MATLAB, we implement the inverse solution technique, and in VREP, we create a dynamic model of the desktop robot's arm (V-REP). By moving the virtual robot arm in V-REP to the desired location and orientation using MATLAB's API interface, we can test the efficacy of the robot manipulator technique and ensure its accuracy [13]. The research examines two degrees of freedom (DOF) robot navigation and builds free Cartesian spaces for finding the space available that ensures a collision-free route. An improved Ant Colony Optimization (ACO) method is offered to achieve motion goal-congruent optimum route planning. The improved ACO algorithm's primary purpose is to provide an optimum route based on the precise distance of the D* method. Integrating polynomial equations of the fifth order produces a path with minimal transitional points between the starting and ending points [14]. To improve the trajectory tracking control, the study presents two strategies for dealing with singularities that may arise when a robot arm follows a particular path. The paper uses genetic algorithms, but one is more localized and the other more worldwide. Each approach was tested on polynomial trajectories up to the third degree, and their results were compared based on metrics like trajectory inaccuracy, number of singularities, and computational cost. According to the outcomes, the technique based on the global genetic algorithm performed the best, as it could trace the second and third-degree trajectory with the fewest errors, singularities, and computational costs [15].

They suggested a Deep Learning (DL) model based on multi-directional Convolutional Neural Networks (CNN) with bidirectional Long Short-Term Memory (LSTM). The autocorrelation and the normalization root mean squaring

error were used to evaluate the decode performance for different directions in 3D space [16]. The hardware includes the robot's design process, motor selection, and electrical components used to control the robot's joints. The software comprises algorithms that manage the robot's movements to ensure it moves according to specifications and algorithms that transform needed words into proper sequences with target areas. In this scenario, voice recognition software serves as a guide throughout the writing process [17]. Through the use of a small sample of productive results and subsequent actively tendered queries, in which the robot displays a state and starts asking for a label to evaluate whether or not that process and system accomplished the assignment, they propose an approach to eliminate the need for manual designing of reward specific requirements. Instead of expecting the user to personally give the reward signal by labelling every condition encountered during training, our technique only needs labels for a small subset of states, providing a feasible and effective method for learning new abilities without creating incentives [18] manually.

The strategy relies on a sampling approach and has two main components. When a starting point has been found by web search, a greedy approach is used to optimize the route by locally applying adaptive filters to the parts of the path that have particularly severe jerks. Numerical optimization is used to produce the filtered outcome. Developing a collision-indication function expressed as a support-vector machine is more computationally efficient using an adaptable sampling strategy [19]. The study evaluates AL against the most popular data sampling techniques for predicting regression outcomes with reduced sample sizes. The paper provides a unique assessment framework for comparing alternative sampling strategies in a regulated and objective way, despite their varied needs. They examine the sampling efficiency, stability, and predictive value of the resultant ML models from three illustrative use cases (UCs) to determine whether AL or DOE approaches are preferable for data production [20].

III. MATERIALS AND METHODS

A. ADAMS Modeling and Simulation Setup

Using a particular professional environment that may replicate the actual environment down toward the units, gravitation, and operating grids, the HCS design could be loaded into ADAMS. One of the first things to finish after a transfer should be to add restrictions and motor features, including a fixed pair between the land surface and the core, a spinning pair, a block pair, and a roller bearings joint pair at every section of the connection, and a mobility pair between the HA and it is relating engine shaft. Next, users must recognize the step response as the driving factor behind the engineering robot arm. Finally, execute the simulation via the modelling and analysis tool after all the preceding steps. Make sure there are no extraneous restrictions in the system and that there are no free variables.

B. Parameters of a Functional Hydraulic Cylinders Motion

The lifting arm hydraulic cylinder length L1, the buckets pole hydraulic cylinder lengths L2, and the bucket hydraulic cylinder length L3 all play a role in establishing the precise

geometries of a spade. After L1, L2, and L3 are set in stone, it's clear where the anti-shovel mechanism will be placed. Anti-shovel hydraulic cylinder motion characteristics are shown in Table I.

C. Movement Function and Trajectory Simulations of a Hydraulic Cylinder

The following is a motion simulator of a crane hydraulic cylinder, a bucket rod hydraulic cylinder, and a bucket hydraulic press.

1) *Hydraulic cylinder boom motion model:* Full-shrinkage adjustment cylinder bucket rod position. Make sure the cylinder is set to full contraction before adjusting the bucket. The hydraulic cylinder's motion function allows the boom to extend and retract. To play back simulation results and create curves, you must transfer ADAMS/Post-processed Modular. Trace Marker could trace the path of the excavator's bucket's tooth marking points, and the resulting trajectory chart is shown in Fig. 2.

2) *Hydraulic cylinder and bucket rod model in motion:* If the bucket tooth is a direct line, then the Moving function entails changing the connection between the boom and the bucket rod and the connection between the bucket rod and the bucket. To play back simulation results and create bends, it must convert ADAMS/Post-processed components.

3) *Hydraulic cylinder movement simulator for a bucket:* The excavation work trajectory of a resource extraction bulldozer is a circular arc, with the steak between the bucket and rod the bucket serving as the middle of the plot line and the proximity from the tendon to the bucket tooth serving as the radius; the wrap edge the arc length are both calculated by the stroke of the bucket hydraulic cylinder.

Fig. 2. An animated model of manipulating arms and a model of a bucket rod.

D. Dynamic Simulation Analysis

Regarding excavators, the primary area of investigation is the force fluctuation at the bucket's teeth and hinge point, which may be gleaned through a simulation model of the machine's mechanical power relations when subjected to

different external loads. The goal is to guarantee that the design will work as intended.

1) *Estimating Work in a Complicated Mining Procedure:* Friction and soil resistance is not considered. Throughout its time spent underground, an excavator is subjected to those mentioned above primary external loads:

a) *Mines that provide normal and tangential resistance:* Mining resistance may be considered operating just on top of the bucket tooth in two directions: the tangential direction, which is perpendicular to the tracks, and the regular direction, which is perpendicular to the track. The following is their EQU (1) based on experience:

$$\begin{aligned} W_1 &= K_0bh \\ W_2 &= \psi W_1 \end{aligned} \quad (1)$$

The resisting ratio of k_0 mining is representative of the overall resistance encountered by bucket-style excavating tools underground. Failure of the soil, soil loading, and friction all contribute to the overall resistance. The SI unit for k_0 N/cm^2 Miniature excavators often functions best on flat ground. Based on a table, we get a $k_0=15N/cm^2$ b-cutting width value as unit cm. Based on this model, $b=60$ cm. The unit for h-cutting depth is centimetres. On average, $h=0.2$ $b=12$ cm. ψ resistant to Mining Parameters. Accessing a lookup table reveals, $\psi = 0.6$. The following information is obtained by plugging the figures as mentioned above into EQU (2), and computing

$$\begin{aligned} W_1 &= 10800, N = 10.8KN \\ W_2 &= 0.5, W_1 = 5.4KN \end{aligned} \quad (2)$$

b) *Resistance to lifting:* After excavating is complete, hoisting resistance mainly pertains to the gravitation of the elements in the bucket. It is attributed to the bucket's centroid as normal and always moves vertically downwardly.

$$G = \rho V_g = rV \quad (3)$$

The capacity of a V-Bucket: $V = 0.28m^3$ in line with the value of the specification. Level dirt has a density of $1.8 \times 10^4 kg / m^3$. Based on the gravity setting in ADAMS, it is given by $g = 9.8m / s^2$. The gravitational value of the components may then be determined around $5KN$.

c) *Load up the vehicle and enter ADMAS:* The acute and normal directions of the bucket teeth match the tangential and normal directions of resistance. It demonstrates that these forces all act in the same direction. We can calculate the variations in the force of each cylinder at every hinge point whenever it works in the deep position by applying a typical complicated motion in excavation as a work circle. We may

also get the excavation's kinetic models without considering the response times and the length of the working cycle, which includes excavation and unloading. The pace of bucket digging often determines how long it takes to excavate. The running speed is set to 0.5 m/s, the digging speed to 0.75 m/s, and the unloading time to 2s to make the simulation easier.

We split a cycle into three parts and determined the overall cycle duration to be 8s according to the results above:

(i) *The bucket phase that descends:* We adapt the working device's digging point to the broadest possible digging diameter, which entails reducing the size of the bucket rod and boom cylinder. We presume no additional loads are being imposed throughout this operation.

(ii) *The phase of digging:* The bucket and bucket rod cooperate to fill the bucket with earth. It denotes the end of the digging process. The load in this operation is the normal and tangential digging resistance. They start off increasing as the bucket angle rises. Digging resistance increases the most while digging the deep and decreases when the bucket angle increases.

(iii) *Phases of hoisting and unloading:* During the hoisting phase, we first set the boom cylinder to its full shrinking position while adjusting the bucket cylinder to guarantee that items are not dispersed throughout the ascent in the bucket. Then finish emptying, and adjust the bucket rod and cylinder to the complete shrinkage condition. The primary burden in the mining process is the weight of the material, and the boom-raising stage does not change as the weight of the material increases.

IV. RESULT AND DISCUSSION

To provide the required HCS, the HCS first pumps the hydraulic fluid, which then circulates across the device. The hydraulic mechanism allows the bigger versions of the commercial or hydraulic robotic arm to carry substantial weights; hence, the arms are typically metal. Findings from the engineering robotic manipulator for the ADAMS model are analyzed below. Metrics such as accuracy, precision, recall, mobility, and energy transformation are compared with the conventional methods. The conventional methods are Artificial Intelligence (AI) [21] and DL [22]. The findings are listed below.

A. Accuracy

As a measure of a device's accuracy, it refers to how closely calculated values align with the real thing. It has been shown that the proposed approach is more precise than the existing method. We provide our results in terms of the percentage of accuracy. In Fig. 3, the recommended system's accuracy is shown. AI has achieved 75% accuracy, but ML has only reached 83%. The proposed method has 95% of accuracy. It demonstrates that the proposed method is superior to the traditional methods. Table I represents the accuracy.

Fig. 3. Accuracy.

TABLE I. ACCURACY MEASUREMENT

Techniques	Accuracy (%)
ML	75
AI	83
Proposed ADAMS	95

B. Precision

Precision, often called positive prediction value, is the percentage of correct opinions among the retrieved instances. Precision is a determinant of value, which it may determine. Precision measures how likely it is that a specific recovery will occur. The proposed work has significantly higher accuracy than the current methods. Fig. 4 shows the results of comparing the precision of conventional and proposed methods. Conventional methods achieve the following levels of accuracy; therefore, ML has attained 77%, and AI has reached 83%. As a result, the proposed system offers the highest potential outcome of 95%. The precision value is shown in Table II.

Fig. 4. Precision.

TABLE II. PRECISION VALUE

Techniques	Precision (%)
ML	77
AI	83
Proposed ADAMS	95

C. Recall

Fig. 5 compares the proposed technique and the existing method for recall. The recall is the fraction of relevant events which have been retrieved. One other name for sensitivity is recalled. The proposed method has the greatest recall of all the conventional systems. Conventional methods' recall for predicting performance is as follows: ML achieves 73%, AI achieves 85%, and the proposed method achieves 97%. It shows that the intended work will be completed effectively. The recall analysis is shown in Table III.

Fig. 5. Recall.

TABLE III. RECALL

Techniques	Recall (%)
ML	73
AI	85
Proposed ADAMS	97

D. Mobility

Robotics designed for long-distance transportation are called Mobility Systems. The ability to move freely is crucial for automated systems to carry out their missions in challenging and intricate settings. Wheels, feet, hops, and other forms of mobility may all be used by robotic systems. The mobility contrast is demonstrated in Fig. 6. Established methods like ML have attained 75% mobility, while AI has reached 81% mobility. According to the findings, the proposed system is mobility towards the extent of 93%. The results of the mobility research are presented in Table IV.

TABLE IV. MOBILITY

Techniques	Mobility (%)
ML	75
AI	81
Proposed ADAMS	93

Fig. 6. Mobility.

E. Energy Transmission (ET)

Converting one type of resource into another is termed ET. The contrast between the two forms of ET is seen in Fig. 7. Existing methods, such as ML, have attained a mobility rate of 73%, and an AI of 88% in the ET. The results show that the proposed method can convert energy for robotics technology by a significant percentage is 97%. The analysis of ET is shown in Table V.

Fig. 7. Energy transmission.

ADAMS [Proposed]	97

V. CONCLUSION

This study uses ADMAS software's robust analysis feature to examine the engineering robot's simulation Hydraulic Control System (HCS)'s functioning device. We have determined the scope of this research work and the significant

fundamental characteristics of accuracy, precision, recall, mobility, and Energy Transmission (ET), and we have acquired the defined points and the force curve of a Hydraulic Actuator (HA) via a simulation model. This study obtained a model simulation study of the HCS's operational state, and our findings may be used as a theoretical foundation for the development and optimization of engineering robots' HCS.

Abstract—Kidney tumours (KTs) rank seventh in global tumour prevalence among both males and females, posing a significant health challenge worldwide. Early detection of KT plays a crucial role in reducing mortality rates, mitigating side effects, and effectively treating the tumor. In this context, computer-assisted diagnosis (CAD) offers promising benefits, such as improved test accuracy, cost reduction, and timesaving compared to manual detection, which is known to be laborious and time-consuming. This research investigates the feasibility of employing machine learning (ML) and Fine-tuned Transfer Learning (TL) to improve KT detection. CT images of individuals with and without kidney tumors were utilized to train the models. The study explores three different image dimensions: 32x32, 64x64, and 128x128 pixels, employing the Grey Level Co-occurrence Matrix (GLCM) for feature engineering. The GLCM uses pixel pairs' distance (d) and angle (θ) to calculate their occurrence in the image. Various detection approaches, including Random Forest (RF), Support Vector Machine (SVM), Gradient Boosting (GB), and Light Gradient Boosting Model (LGBM), were applied to identify KT in CT images for diagnostic purposes. Additionally, the study experimented with fine-tuned ResNet-101 and DenseNet-121 models for more effective computer-assisted diagnosis of KT. Evaluation of the efficient diagnostics of fine-tuned ResNet-101 and DenseNet-121 was conducted by comparing their performance with four ML models (RF, SVM, LGBM, and GB). Notably, ResNet-101 and DenseNet-121 achieved the highest accuracy of 94.09%, precision of 95.10%, recall of 93.5%, and F1-score of 93.95% when using 32x32 input images. These results outperformed other models and even surpassed state-of-the-art methods. This research demonstrates the potential of accurately and efficiently classifying KT in CT kidney scans using ML approaches. The use of fine-tuned ResNet-101 and DenseNet-121 shows promising results and opens up avenues for enhanced computer-assisted diagnosis of kidney tumors.

Keywords—Kidney; kidney tumor; automatic diagnosis; machine learning algorithms; CT imaging; deep learning; transfer learning

I. INTRODUCTION

The kidneys, two bean-shaped organs located on either side of the spine, are indispensable for maintaining the body's internal equilibrium and overall health. These vital organs play a pivotal role in filtering waste products, excess salts, and

water from the blood, while also regulating blood pressure and producing essential hormones for red blood cell production. With such critical functions, any disruption or abnormality in kidney health can have serious repercussions on an individual's well-being [1]. Kidney tumors can be benign or malignant [2]. The benign kidney tumor can be a cyst, masses, or lipoma whereas malignant kidney tumor refers to renal cancer, pelvic cancer [3]. Kidney cancer, characterized by the presence of tumors arising from renal tissues, poses a significant global health challenge. Despite extensive research, the precise etiological factors triggering kidney cancer remain enigmatic, though hereditary and environmental influences are among the potential contributors. The insidious nature of kidney tumors often leads to asymptomatic progression, delaying diagnosis until advanced stages.

In 2023, it is estimated that 81,800 adults in the United States will be diagnosed with kidney cancer. Kidney cancer is more common in men, and the average age of diagnosis is 64, with most cases occurring between ages 65 and 74. The number of new kidney cancer cases has been increasing, though the rate of increase has slowed in recent years, partially due to increased use of imaging tests that can detect small kidney tumors incidentally [4]. In 2020, an estimated 179,368 people worldwide died from kidney cancer. The 5-year relative survival rate for kidney cancer in the United States is 77%. This rate varies depending on cancer stage, age, general health, and treatment effectiveness. For instance, the five-year relative survival rate is 93% for those with cancer confined to the kidney, 72% if cancer has spread to surrounding tissues or lymph nodes, and 15% if it has spread to distant parts of the body [4].

In the realm of medical imaging, Computed Tomography (CT) scans, ultrasounds, and Magnetic Resonance Imaging (MRI) serve as vital techniques, affording physicians a comprehensive visualization of the kidneys and associated tumors, thereby enabling meticulous evaluation of their dimensions, morphology, and characteristics [5,6]. Despite their undeniable utility, distinguishing between healthy tissue and malignant growth in kidney scans poses a formidable challenge. While manual diagnosis and expert detection of kidney tumors boast commendable accuracy, they demand significant time and effort [7], and results may exhibit

*Corresponding Author: ygulzar@kfu.edu.sa, muneerbazaz@gmail.com

variability amongst different practitioners. The paramount significance of early detection and accurate classification of tumors lies in mitigating the risk of metastasis to other anatomical regions. As an expedient and efficient alternative, automatic detection emerges as a promising approach, streamlining diagnostic processes and potentially safeguarding patients' lives. Although manual detection is renowned for its precision, the automatic diagnostic methodology offers expedited results, without compromising comparability to manual findings.

Artificial intelligence (AI) and deep learning have revolutionized various industries, including agriculture [8–13], education [14, 15], finance [16], and healthcare [17–19]. In the field of healthcare, AI has shown tremendous promise in improving patient outcomes, enhancing diagnostics, and streamlining healthcare processes. With the ability to analyze vast amounts of data and identify complex patterns, AI-powered systems have opened new frontiers for early disease detection, personalized treatment plans, and overall healthcare efficiency. In healthcare, one of the areas where AI and deep learning have made significant advancements is in the early detection of diseases, including cancer [20]. Detecting cancer at an early stage is crucial for improving treatment success and patient survival rates. Kidney cancer, for example, often presents with few symptoms in its early stages, making early detection challenging. However, deep learning algorithms have proven to be effective in analyzing medical imaging data, such as CT scans and MRI images, to detect kidney tumors at their nascent stages [21].

From the literature, it is evident that many researchers have incorporated deep learning in classifying kidney tumors. Lee et al. [22] developed an automatic deep feature classification (DFC) method using hand-crafted and deep features, along with machine learning classifiers, to distinguish benign angiomyolipoma without visible fat (AMLwvf) from malignant clear cell renal cell carcinoma (ccRCC) in abdominal contrast-enhanced computer tomography (CE CT) images. The proposed method achieved an accuracy of $76.6 \pm 1.4\%$ using the combination of hand-crafted and deep features, outperforming HCF-only and DF-only methods by 6.6%p and 8.3%p, respectively. Texture image patches (TIPs) were introduced to emphasize texture information and reduce mass size variability, resulting in steady performance regardless of the convolutional neural network (CNN) models used. Han et al. [23] used an image-based deep learning framework to classify renal cell carcinoma subtypes using CT images. The neural network achieved 0.85 accuracy, 0.64-0.98 sensitivity, 0.83-0.93 specificity, and 0.9 AUC, showing promising results for subtype classification and potential clinical cooperation with radiologists. Deep learning framework achieved 93.39% accuracy in classifying clear cell RCC and 87.34% for chromophobe RCC from histopathological images. A novel support vector machine-based method improved classification accuracy to 94.07% for distinguishing clear cell, chromophobe, and papillary RCC. The CNN also extracted morphological features to predict patient survival outcome, showing potential for cancer diagnosis and prognosis [24]. Oberai et al. [25] developed a semi-automated majority voting

CNN-based method to classify renal cell carcinoma (RCC) from benign solid renal masses on contrast-enhanced computed tomography (CECT) images. The CNN model achieved 83.75% accuracy in differentiating RCC from benign masses. A fully automated approach yielded 77.36% accuracy, while a 3D CNN achieved 79.24% accuracy in renal mass classification. Pedersen et al. [26] used a modified version of ResNet50V2 CNN to differentiate oncocytoma from renal cell carcinoma (RCC) using non-invasive imaging. They collected 20,000 2D CT images from 369 patients for training, validation, and testing. The model achieved 93.3% accuracy and 93.5% specificity on the main test set and 90.0% accuracy and 98.0% specificity on the additional validation set. When evaluated with a majority vote for each patient, the accuracy rose to 100%, reducing false negatives to zero, demonstrating the potential of CNNs for accurate diagnosis.

Sudharson et al. [27] proposes an automatic classification method for B-mode kidney ultrasound images using an ensemble of deep neural networks (DNNs) with transfer learning. The DNNs, including ResNet-101, ShuffleNet, and MobileNet-v2, are combined using majority voting for better classification performance. The method achieves a maximum classification accuracy of 96.54% for quality images and 95.58% for noisy images, outperforming existing methods, making it a valuable tool for precise diagnosis of kidney diseases. Pirmoradi et al. [28] proposes a new machine learning approach for identifying significant miRNAs and classifying kidney cancer subtypes to develop an automatic diagnostic tool. The method involves two main steps: feature selection using the AMGM measure to choose candidate miRNAs and classification using a self-organizing deep neuro-fuzzy system, which overcomes challenges in high-dimensional data analysis. The results shows that the proposed method achieves high accuracy in classifying kidney cancer subtypes based on the selected miRNAs. Abdeltawab et al. [29] proposes a deep learning pipeline for automated classification of kidney cancer subtypes, specifically clear cell renal cell carcinoma and clear cell papillary renal cell carcinoma. The model uses convolutional neural networks on whole slide images divided into patches, providing patchwise and pixelwise classification. The approach accurately classifies the four classes and outperforms other state-of-the-art methods. This deep learning method has the potential to assist pathologists in diagnosing kidney cancer subtypes from histopathological images. Abdeltawab et al. [30] presents a deep learning framework for classifying kidney tumor subtypes, specifically clear cell renal cell carcinoma and clear cell papillary renal cell carcinoma. The framework utilizes three convolutional neural networks to process kidney image patches of different sizes, providing patchwise and pixelwise classification. The results demonstrate superior performance compared to existing methods, highlighting the potential of deep learning techniques in cancer diagnosis. Khan et al. [31] addressed urgent brain tumor diagnosis using automated methods, specifically convolutional neural networks (CNNs). Deep convolutional features improve classification accuracy significantly, and an ensemble of XGBoost, AdaBoost, and Random Forest achieves a top accuracy of 95.9% for tumors and 94.9% for normal cases, surpassing individual methods. Zhu et al. [32] presents a pipeline employing transfer learning

to address the limitations of small medical image datasets in deep learning applications. The proposed dual-channel fine segmentation network (FS-Net) effectively segmented kidney and tumor regions in 3D CT images, outperforming state-of-the-art methods. The classification model using radiomics features demonstrated accurate classification of benign and malignant tumors in the small dataset. The work emphasizes the significance of architecture design in transfer learning and provides valuable insights for small data analysis in medical imaging. Gulzar et al. [33] conducted using CT scans of 125 subjects, reveals a negative correlation between visceral fat to abdomen size ratio and mean liver intensity values, as well as between mean liver intensity values and total abdomen fat to abdomen size ratio. These correlations indicate a direct link between obesity and diffuse liver fat. This insight contributes to understanding fatty liver disease and its associated health risks. Sarada et al. [34] proposes a hybrid ensemble of visual capsule networks and deep feed-forward extreme learning machines for kidney tumor classification and segmentation from CT images. The model achieves a DICE coefficient of 0.96 and an accuracy of 97.5%, outperforming other hybrid deep learning models. Zhao et al. [35] purpose of the study was to develop an automated method using 3D U-Net and ResNet for accurate segmentation and classification of renal masses in CT images. The algorithm achieved high performance in kidney boundary segmentation (Dice coefficient of 0.99) and renal mass delineation (average Dice coefficients of 0.75 and 0.83). The classification accuracy for masses was 86.05% for masses <5 mm and 91.97% for masses \geq 5 mm. The proposed method demonstrated the capability of accurately localizing and classifying renal masses.

In this study, proposes a computer-assisted diagnosis system using machine learning and fine-tuned transfer learning for efficient kidney tumor detection in CT images, achieving high accuracy using different deep learning models. The contribution of this study is as follows:

- **Enhanced Kidney Tumor Detection:** The study introduces a computer-assisted diagnosis (CAD) system utilizing machine learning and fine-tuned transfer learning, which improves the accuracy and efficiency of kidney tumor detection in CT images compared to manual methods.
- **ML Model Evaluation:** The research comprehensively experiments with various machine learning models, including Random Forest, Support Vector Machine, Gradient Boosting, and Light Gradient Boosting Model, to identify kidney tumors in CT images. The comparison of these models helps identify the most effective approach for tumor detection.
- **Fine-tuned Transfer Learning:** The study proposes and evaluates the performance of fine-tuned ResNet-101 and DenseNet-121 models for computer-assisted diagnosis of kidney tumors. These models demonstrate superior accuracy, precision, recall, and F1-score compared to other models and state-of-the-art methods.

Efficient Data Preprocessing: The research applies different pre-processing techniques and image resizing to reduce the complexity of the training model and speed up the

training process. This optimization ensures faster and more efficient kidney tumor classification.

II. MATERIAL AND METHODS

This section provides an elaborate exposition of the proposed framework, incorporating established machine learning (ML) algorithms and deep learning models using transfer learning (TL). As depicted in Fig. 1, the framework encompasses two core components: data pre-processing and the scaling of input image dimensions. Subsequently, a diverse set of ML and TL models were trained on the dataset, comprising Chest Computed Tomography (CT) images.

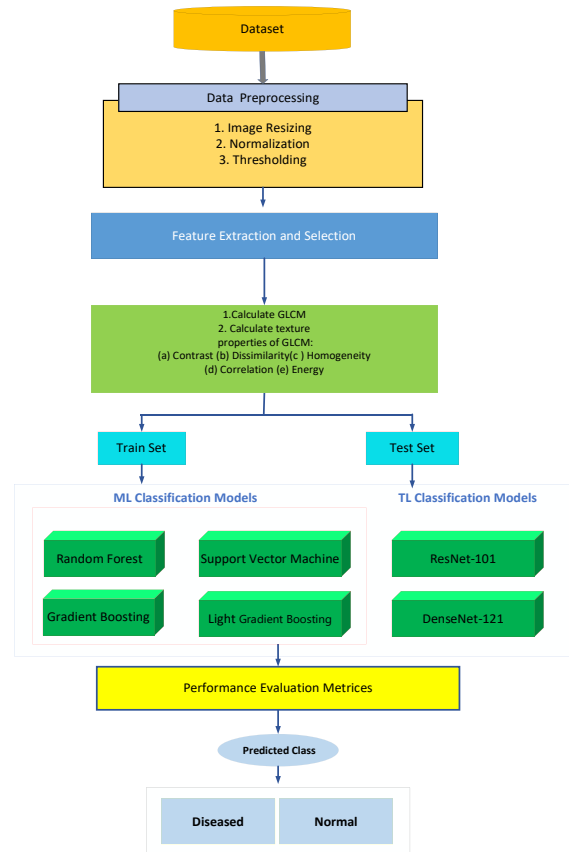

Fig. 1. Detailed framework for proposed methodology.

A. Dataset Description

The research study was conducted using a dataset of CT Kidney images, sourced from an official repository accessible [36]. This dataset was compiled from various hospitals in Bangladesh and Dhaka, obtained through the Picture Archiving and Communication System (PACS). The dataset comprises a total of 12,446 images, distributed across different categories: 3,709 images representing cyst, 5,077 images of normal kidney, 1,377 images of kidney stone, and 2,283 images of kidney tumor patients. Each image in the dataset possesses a resolution of 512 x 512 pixels.

The research investigation primarily focused on two classes within the dataset, specifically the normal and tumor images. Fig. 2 present the CT slide of normal and tumorous kidney samples. To facilitate the experimentation process, the dataset was stratified into three distinct subsets, maintaining a

partitioning ratio of 6:2:2, representing 60% for training, 20% for validation, and 20% for testing purposes, respectively. Such a division ensures a robust evaluation of the proposed methods and allows for the assessment of model performance across distinct data subsets.

Fig. 2. (a) CT slice of a normal kidney (b) CT slice of kidney with tumor.

1) *Data Pre-processing*: This dataset is taken through three distinct data pre-processing stages before being experimented as discussed below:

a) *Thresholding*: It is the simplest type of image segmentation technique which is applied on the gray scale images to convert them to binary images. The coloured images are converted to binary images using thresholding [37]. Thresholding is experimented to divide a picture into less sections, or trashes, utilizing somewhere around one shading or dim scale an incentive to characterize their boundaries. The complexity of the information is simplified, and the process of detecting and characterising the data can be clarified if a binary image is obtained first is one of the advantages of this approach. Selecting a single Threshold value (T) is the method that is the most well-known for transforming a grayscale image into a binary one. Mathematically it can be interpreted as follows:

$$o_{ij} = \begin{cases} 1 & \text{if } I_{ij} \geq T \\ 0 & \text{if } I_{ij} < T \end{cases} \quad (1)$$

b) *Data normalization*: The image pixels are normalized to a single scale of 0 to 255 gray scale values.

c) *Image resizing*: The given dataset images of dimension 512 x 512 are resized to (32x 32), (64 x 64), and (128x 128) to perform the experiment.

2) *Feature engineering*: It is the amalgamation of the feature extraction, selection and matrix creation. In the proposed research work, features are extracted from the given input images. The Grey Level Co-occurrence matrix (GLCM) [38] has been generated for all the images for the extraction of the relevant features. The GLCM is calculated to analyse the texture of the given image based upon the contrast, homogeneity, Correlation between the matrix, dissimilarity and energy of the pixels. The GLCM uses the distance(d) and angle (θ) between pair of pixels (i, j) to calculate the occurrence of the (i, j)th pair in the image in the direction of the given angle value. The θ value varies from 0 to 360 degree. The size of the matrix depends upon the number of pixel intensities present in the given image for which the matrix has to be calculated.

For example: If there are four intensity values present in the image, then the size of the GLCM will be 4 x 4. The GLCM is calculated for the three different image dimensions i.e. (32x 32), (64 x 64), and (128x 128). But different image sizes do not have much impact on the classification accuracy. So we consider the smallest image size for the feature extraction and model training in order to avoid the unnecessary computation cost. The process of GLCM is repeated for four times. The final extracted features are then combined and given to the Light Gradient Boosting Machine (LGBM) for training.

B. Machine Learning Methods

1) *Random Forest (RF)*: The RF [39] algorithm is a well-known ensemble learning method that is utilized for classification purpose, including kidney disease classification. Random Forest is applied on kidney disease dataset which is prepared with features and corresponding target labels. The features may include various clinical and demographic factors related to kidney disease, while the target labels indicate the presence or absence of kidney disease.

Random Forest Model training follows the below mentioned steps:

- **Tree Construction**: RF consists of multiple decision trees (DT). Where each tree is constructed during training by taking a random subset from training data, known as bootstrap samples. This sampling technique introduces variation in the training process.
- **Feature Sampling**: An unsystematic subset of features is considered at each node of the decision tree, for splitting known as feature sampling or feature bagging. It helps in reducing correlation among the trees and promotes diversity in the ensemble.
- **Splitting Criteria**: The decision tree nodes are split using a splitting (Gini impurity) criterion that helps determining the best feature and threshold to divide the data at each node, aiming to maximize the separation of the target classes.
- **Tree Growth**: The trees are grown until a stopping condition is met. Controlling the tree growth helps prevent overfitting and promotes generalization.

a) *Voting Mechanism*: Once the RF model is trained, predictions are made by aggregating the predictions of all the individual decision trees. The final predictions made by each tree in the forest is determined by majority vote obtained independently, and the final prediction is determined by a majority vote or averaging, depending on the task (binary or multi-class classification).

b) *Class Probability Estimation*: RF can also estimate the probability of belonging to each class. It does this by calculating the proportion of trees that predicted each class. The class probabilities can be useful for assessing the confidence of predictions or for other downstream tasks.

The trained RF is evaluated on the testing dataset to assess its performance using metrics that present insights into the

model's prognostic accuracy and capability to correctly classify instances of kidney disease. The trained Random Forest model can be deployed to make predictions on new, unseen data. It takes the relevant features of a patient as input and provides the predicted class or class probabilities for kidney disease. RF offers several advantages for kidney disease classification, including the ability to handle high-dimensional datasets, handle missing values, and provide feature importance measures. It is a robust and widely used algorithm for classification tasks, including medical diagnosis and risk assessment.

2) *Support Vector Machine (SVM)*: (SVM) [40] is supervised learning algorithm commonly used for classification tasks. The internal architecture of an SVM involves several key components and steps.

- **Relevant features**: Relevant features from the kidney disease dataset are extracted. These features could include measurements such as blood pressure, serum creatinine levels, age, etc.
- **Data Normalization**: The retrieved characteristics are then normalized such that they are all on a scale that is comparable to one another. This step helps in preventing definite features from dominating the others due to their larger magnitudes.
- **Feature Representation**: Each instance or sample of dataset is presented as a feature vector, where each feature corresponds to a specific attribute or measurement related to kidney disease.
- **Hyperplane Initialization**: In a high-dimensional feature space, the SVM finds the best hyper plane to split data points by class. This hyperplane gets configured at the outset by the SVM algorithm.
- **Training**: The SVM algorithm trains the model by iteratively optimizing the position and orientation of the hyperplane to get the most out of the margin between the classes. The goal is to find the hyperplane that separates the classes by minimizing the misclassification. The optimization problem is typically solved using techniques such as the Sequential Minimal Optimization (SMO) algorithm or other quadratic programming methods. During the training process, subset of data points called support vectors are identified that are closest to the hyperplane or located inside the boundary.
- **Classification**: After training is complete, SVM is used for classification of new, unseen instances. The decision boundary of the SVM is defined by the hyperplane, and the side of the hyperplane on which a data point lies determines its predicted class label. The distance of a data point from the hyperplane can also provide additional information about the model's confidence in its prediction.

3) *Gradient Boosting (GB)*: GB [41] is an ensemble learning method that incorporated multiple weak learners, to

create a strong prognostic model. GB is used for kidney disease classification is discussed stepwise as below:

- **Data Preparation**: Similar to other machine learning algorithms, the kidney disease dataset needs to be prepared by extracting relevant features and normalizing the data if necessary.
- **Initialization**: Gradient Boosting starts with an initial model, often a simple one like a decision tree with limited depth (weak learner). The initial model is typically assigned equal weights for all samples in the training set.
- **Iterative Training**: In each iteration, a new weak learner, referred to as a "base learner," is trained to approve the miss-classifications made by the ensemble of models trained so far. The base learner is fitted to the training set, with a focus on the samples that were misclassified or had high residuals from the previous iteration. The learning process involves minimizing a loss function. The base learner is typically a decision tree that is grown using a greedy algorithm, selecting the best split points based on information gain or other criteria. The depth and complexity of the decision tree can be adjusted to balance model performance and computational efficiency.
- **Boosting and Weight Updates**: After training the base learner, its predictions are combined with the predictions of the previous models in the ensemble. Initially, all models are given equal weights. However, the subsequent models focus on the samples that were misclassified or had high residuals from the previous models. The weights of the samples are adjusted to prioritize the challenging instances. The misclassified samples are assigned higher weights, while correctly classified samples have lower weights. This process emphasizes the samples that are difficult to classify, allowing subsequent models to concentrate on improving their predictions.
- **Iteration and Ensemble Building**: Steps 3 and 4 are repetitive for a predetermined number of iterations or until a certain performance threshold is reached. In each iteration, a new base learner is trained to minimize the weighted loss function. The predictions of all models in the ensemble are combined using a weighted sum or averaging scheme, where the weights are determined by the performance of each model.
- **Final Prediction**: The final prediction for a new, unseen instance is obtained by aggregating the predictions of all models in the ensemble, typically using a majority vote or weighted average. For classification tasks, the predicted class label is determined based on the aggregated predictions.

4) *Light Gradient Boosting Model (LGBM)*: LGBM [42] is a powerful gradient boosting framework that combines speed and efficiency with high predictive accuracy. Its ability to handle large datasets efficiently and its regularization techniques make it a popular choice among data scientists and

machine learning practitioners. Light GBM is based on the gradient boosting framework, which is an ensemble method. It sequentially trains the models to overcome the drawbacks of the previous models, thus getting better the overall prognostic accuracy.

The kidney disease dataset is prepared with features and corresponding target labels. The features may include various clinical and demographic factors related to kidney disease, such as age, blood pressure, creatinine levels, etc. The target labels indicate the presence or absence of kidney disease. Model Configuration: The LGBM model is configured with the following parameters:

- Learning Rate: The learning rate determines the step size at each boosting iteration. In this case, the learning rate is set to 0.05, indicating a relatively small step size.
- Boost Type: The boost type is set to "Dart," which refers to the Dart boosting algorithm. Dart is a variation of gradient boosting that introduces dropout regularization to prevent overfitting.
- Metric: The chosen evaluation metric is "multi log loss," which is suitable for multi-class classification problems. It calculates the logarithmic loss between the predicted labels and true class labels.
- Number of Leaves: The LGBM model is configured with 100 leaves. The leaves represent the final decision regions of the ensemble of decision trees.
- Max Depth: of each individual decision tree in the ensemble is set to ten. This parameter limits the complexity of the trees and helps prevent overfitting.
- Class: The classification task involves predicting between two classes, likely representing the presence or absence of kidney disease.

The LGBM model is trained on the training dataset using the configured parameters. The model uses gradient boosting to iteratively fit decision trees to the training data, improving its predictive performance at each iteration. Once the training is complete, the trained LGBM model is evaluated on the testing dataset using the multi log loss metric. It can take the relevant features of a patient as input and provide the probability or predicted class of kidney disease. By following this architectural workflow, the LGBM model with the specified parameters can be effectively trained and used for kidney disease classification. It is important to note that further customization and tuning of the parameters might be necessary depending on the specific description of the dataset and the desired performance. The pseudo code for the proposed research methodology is given in Pseudocode 1.

1. Pseudocode for ML models for kidney disease classification

Step 1: Load and preprocess the dataset // Load dataset
Preprocess dataset (handle missing values, encode categorical variables, etc.)
Split dataset into: features (X) and target variable (y)

```
Step 2: train_test_split is done
Step 3: Model1 = RFClassifier(),
      Model2 = GBClassifier(),
      Model3 = SVMClassifier(),
      Define the model "Light GBM" and set hyperparameters
      Model4 = LGBMClassifier( boosting_type='dart',
      objective='binary',
      metric='multi_logloss', num_leaves = <100>,
      learning_rate = <0.05>,
      feature_fraction = <feature_fraction>,
      bagging_fraction = <bagging_fraction>,
      verbose = -1)
Step 4: model.fit(X_train, y_train) //Train the Light GBM model
Step 5: y_pred = model.predict(X_test) //Make predictions and
evaluate the model
Step 6: Accuracy = accuracy_score(y_test, y_pred) // Calculate
evaluation metrics
      CM = confusion_matrix(y_test, y_pred)
Step 7: Tune hyperparameters to optimize model performance
Step 8: Perform further analysis (e.g., feature importance)
```

LGBM has shown excellent prediction for kidney disease classification. Its ability to iteratively refine the model by focusing on the challenging instances makes it effective in capturing complex relationships in the data and improving predictive accuracy.

C. Transfer Learning Architectures

1) *ResNet-101*: ResNet-101 [43] features a 101-layer deep CNN. The weights of the network's pre-trained version on over a million photos from the ImageNet database may be imported. The trained network can classify photos into 1000 different things, such as keyboards, mice, books, and other stuff. To train the model, an Adam optimizer with a learning rate of 4e-5 and binary cross entropy as the loss function was used. During model training, the total number of trainable parameters was 525,313.

2) *DenseNet-121*: It is a dense network [44] of 121 layers, 120 of which are dense layers and four of which are average pool layers. The weights of all layers in the same deep dense block are circulated across the inputs, allowing the deep layers to utilise the early extracted features. DenseNet uses features more efficiently and outperforms with less parameters. The network is trained over ten epochs using an Adam optimizer and a learning rate of 4e-5 hyperparameters. The total number of trainable parameters in the model was 263,169.

The internal architecture for fine-tuned ResNet-101 and DenseNet-121 are given in Fig. 3 and 4, respectively. The accuracy of the model was found to be enhanced when (32, 32) pixel images were used as input. The smaller image size results in a lower computation and time complexity, which may cause the model to learn features or patterns in the images faster. The Adam optimizer was used to train the model since it is the best optimizer for early convergence. When employing Adam as an optimizer, the model learns up new information more quickly. In order to train our suggested model, we implement a learning rate schedule in the Adam. The training of the model lasted 50 epochs, with a batch size of 32, and the initial learning rate was set at 0.001.

Fig. 4. Architecture of DenseNet-121 model for diagnosing KT using CT images.

D. Experimental Environment Settings and Performance Evaluation Metrics

This research aims to propose an optimal model which identifies and classifies different types of images. The proposed model was implemented using Python (v. 3.8), OpenCV (v. 4.7), Keras Library (v. 2.8) were used on Windows 10 Pro OS, with system configuration using an Intel i5 processor running at 2.9 GHz, an Nvidia RTX 2060 Graphical Processing Unit and 16 GB RAM.

Several metrics were employed to evaluate the performance of classifying sunflower blooms and leaves, including accuracy, precision, recall, and F1-score, which are frequently used indicators [45]. Accuracy is the ratio of samples from all classes that can be correctly identified, Recall is the ratio of correctly classified positives among all actual positives, and Precision is the ratio of correctly identified positives versus all expected positives [46]. The metrics were calculated using Eq. (1) - (4).

$$Accuracy = \frac{True\ Positive + True\ Negative}{True\ Positive + True\ Negative + False\ Positive + False\ Negative} \quad (1)$$

$$Recall = \frac{True\ Positive}{True\ Positive + False\ Negative} \quad (2)$$

$$Precision = \frac{TP}{True\ Positive + False\ Positive} \quad (3)$$

$$F1 - Score = 2x \frac{Recall \times Precision}{Recall + Precision} \quad (4)$$

$$AUC = \sum_{i=0}^N \left(\frac{TPI(i) + TPI(i-1)}{2} \right) (FPI(i) - (FPI(i-1))) \quad (5)$$

III. RESULTS AND DISCUSSION

A. Performance Comparison

The ML models were meticulously trained on a dataset, and to bolster their performance, advanced feature extraction using the GLCM technique was employed. This technique allowed the models to capture intricate patterns and textures from the kidney images, enhancing their ability to predict Kidney Tumors (KT) more accurately. To push the boundaries of prediction accuracy even further, two state-of-the-art architectures, ResNet-101 and DenseNet-121, were extensively experimented with. These cutting-edge models were chosen for their exceptional deep learning capabilities,

enabling them to unravel complex relationships within the data and make precise predictions regarding the presence of kidney tumors.

Following the intensive training process, the models' prowess was thoroughly evaluated using a diverse range of performance metrics, such as accuracy, recall, precision, and F1_score. These metrics provided a comprehensive view of the models' overall classification performance and offered valuable insights into their strengths and potential areas of improvement. In addition to the conventional performance metrics, the proposed model's efficacy was also measured using the Area Under the Curve (AUC) on the test set. AUC is a significant indicator of the model's ability to distinguish between positive and negative cases, providing a more comprehensive understanding of its discriminative power.

The outcomes of the classification process were further analyzed to gain a deeper understanding of the models' predictions. Specifically, the binary class results (class 0 and class 1) were meticulously generated and assessed. Label 0 corresponded to the classification results for normal kidneys, indicating instances where the model correctly identified normal kidneys (True negative). On the other hand, Label 1 represented the classification results for tumorous kidneys, showcasing the model's capacity to accurately detect kidney tumors (True positive).

Moreover, the results also provided insights into false positives and false negatives, highlighting instances where the model might have made errors in its predictions. This comprehensive analysis aimed to identify potential areas of improvement and guide future iterations of the models. By combining advanced feature extraction techniques, cutting-edge deep learning architectures, and a thorough evaluation using diverse performance metrics, this study aimed to achieve a robust and reliable prediction model for Kidney Tumor detection, which could have a significant impact on the early diagnosis and treatment of kidney diseases.

Table I presents the results of various performance metrics calculated on the Test set for different machine learning algorithms, as well as for the proposed fine-tuned Transfer Learning architectures, ResNet-101, and DenseNet-121. The metrics evaluated are Accuracy, Precision, Recall, F1_score, and AUC.

TABLE I. RESULTS OF THE DIFFERENT PERFORMANCE METRICS CALCULATED ON THE TEST SET

Model	Accuracy	Precision	Recall	F1_score	AUC
LGBM	94.09	0.9510	0.9352	0.9595	0.9552
GB	92.44	0.9439	0.8991	0.9843	0.9773
SVM	91.27	0.9300	0.8890	0.8906	0.8834
RF	91.02	0.9201	0.9212	0.9656	0.9588
ResNet-101	96.67	0.9532	0.9111	0.9843	0.9773
DenseNet-121	98.22	0.9577	0.9323	0.9843	0.9773

From the table it can be noticed that both ResNet-101 and DenseNet-121 achieved the highest accuracy among all the models. DenseNet-121 outperformed all other models with an impressive accuracy of 98.22%, while ResNet-101 achieved an accuracy of 96.67%. The success of these Transfer Learning architectures can be attributed to their pre-trained weights and knowledge gained from large datasets, allowing them to recognize and learn intricate patterns and features from the given kidney tumor dataset effectively. LGBM and GB achieved reasonably high accuracies of 94.09% and 92.44%, respectively. LGBM performed slightly better than GB, which indicates the effectiveness of gradient boosting in ensemble learning. However, the accuracies of both LGBM and GB were lower compared to the Transfer Learning models. SVM and RF achieved accuracies of 91.27% and 91.02%, respectively. While SVM relies on finding optimal hyperplanes for classification, RF uses an ensemble of decision trees. Although these algorithms achieved respectable accuracies, they were outperformed by the Transfer Learning models. The precision, recall, and F1_score metrics provide insights into the models' ability to correctly classify positive and negative instances, as well as their overall predictive performance. DenseNet-121 consistently achieved the highest F1_score of 0.9843, indicating its superior balance between precision and recall in classifying both tumor and normal kidney instances. AUC is a measure of the models' ability to distinguish between positive and negative cases. Remarkably, both ResNet-101 and DenseNet-121 attained an AUC of 0.9773, matching the performance of GB. This demonstrates the Transfer Learning models' robustness in making accurate predictions and differentiating between tumor and normal kidney instances.

Accuracy is a crucial metric in evaluating the performance of machine learning models, as it represents the percentage of correct predictions made by the model where the predicted value aligns with the real value. Throughout the training phase, accuracy is continuously monitored and plotted, providing valuable insights into the model's learning progress and its ability to make accurate predictions as it iteratively updates its weights and biases.

While accuracy provides an overall view of the model's correctness, it is essential to delve deeper into the model's learning dynamics. For this purpose, loss functions play a pivotal role in assessing the model's performance. Loss functions measure the disparities between predicted values and actual ground-truth values, quantifying the uncertainty or error in the model's estimates. By optimizing the loss during training, the model learns to minimize the discrepancies and improve its predictive capability.

In Fig. 5 and Fig. 6, we present the accuracy and loss plots for two cutting-edge deep learning architectures, ResNet-101 and DenseNet-121, respectively. These plots showcase how accuracy improves and loss decreases over the training iterations, providing a comprehensive view of the models' learning behaviors. The ascending accuracy curve demonstrates how the models become more adept at correctly classifying kidney tumor images as training progresses. Simultaneously, the descending loss curve indicates that the models effectively minimize prediction errors, leading to more precise and confident predictions. Analyzing the accuracy and loss plots for ResNet-101 and DenseNet-121 offers valuable insights into their learning dynamics and convergence patterns. These visualizations not only validate the models' effectiveness in the classification task but also aid in fine-tuning the hyperparameters or adjusting the training strategy to achieve optimal performance. By carefully monitoring the accuracy and loss during training, we gain a deeper understanding of the models' efficacy and can confidently assert that both ResNet-101 and DenseNet-121 exhibit exceptional learning capabilities, making them powerful tools for kidney tumor classification.

Fig. 5. Graphs plotted between model (a) accuracy and (b) loss over no of epochs for ResNet-101.

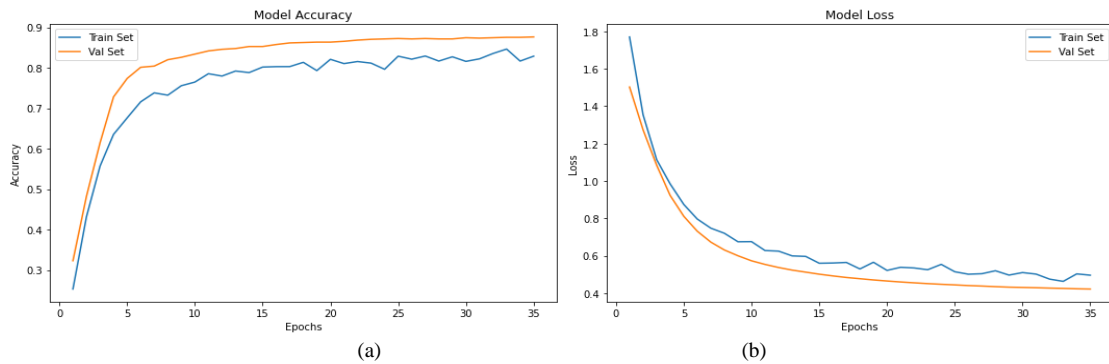

Fig. 6. Graphs plotted between model (a) accuracy and (b) loss over no of epochs DenseNet-121.

In addition to accuracy and loss analysis, the confusion matrix (CM) stands as a pivotal tool for the comprehensive evaluation of classification models, such as ResNet-101 and DenseNet-121. The CM provides valuable insights into the model's performance by breaking down the predictions into four fundamental categories: true positives, true negatives, false positives, and false negatives. It highlights the model's ability to correctly classify positive and negative instances, as well as its potential for making erroneous predictions.

Fig. 7(a) and 7(b) depict the confusion matrices specifically for ResNet-101 and DenseNet-121, respectively. These visual representations offer a detailed view of the models' classification outcomes, enabling us to gauge their effectiveness in distinguishing between normal and tumorous kidney images.

Fig. 7. Confusion Matrix of (a) ResNet-101 and (b) DenseNet-121.

B. K-Fold Cross Validation

K-fold cross-validation is a widely used technique in machine learning to assess the performance and generalization capability of a model while mitigating the risks of overfitting. Overfitting occurs when a model performs well on the training data but fails to generalize to unseen data, which can lead to

inflated evaluation metrics on the test set. To address this concern, the model's performance is tested using a separate validation set, and 10-fold cross-validation is a popular approach to achieve this.

In 10-fold cross-validation, the dataset is divided into 10 subsets of approximately equal size. The model is then trained and evaluated ten times, each time using a different subset as the validation set and the remaining nine subsets for training. This ensures that the model is evaluated on different partitions of the data, providing a more robust estimate of its performance and reducing the influence of any particular data split.

Table II presents the results of 10-fold cross-validation on the CT Kidney image dataset for different machine learning (ML) models and fine-tuned Transfer Learning (TL) models, namely Random Forest, Support Vector Machine (SVM), Gradient Boost, LGBM (LightGBM), ResNet-101, and DenseNet-121. The accuracies achieved by each model on each fold are shown.

Observations from the 10-fold Cross Validation Results:

1) Random Forest: Random Forest demonstrates relatively stable performance across the folds, with accuracy ranging from 70.12% to 84.21%. Its mean accuracy is 77.09%.

2) Support Vector Machine (SVM): SVM shows higher accuracy values, with a range of 66.23% to 81.81% across the folds. The mean accuracy is 88.82%, making it one of the best-performing ML models in this study.

3) Gradient Boost: Gradient Boosting performs consistently well, with accuracy varying between 62.33% to 79.12%. The mean accuracy achieved by Gradient Boost is 89.11%.

4) LGBM (LightGBM): LGBM outperforms other ML models, exhibiting accuracy in the range of 89.12% to 93.32%. Its mean accuracy is 90.71%.

5) ResNet-101 and DenseNet-121 (Transfer Learning): Both fine-tuned Transfer Learning models, ResNet-101, and DenseNet-121 consistently achieve higher accuracy values compared to ML models. ResNet-101 achieves accuracy between 86.72% to 96.81%, with a mean accuracy of 91.61%. DenseNet-121 exhibits even better performance, with accuracy ranging from 90.0% to 97.61% and a mean accuracy of 92.44%.

TABLE II. 10 FOLD CROSS VALIDATION PERFORMANCE OF THE ML AND FINE-TUNED TL MODELS ON THE CT KIDNEY IMAGE DATASET

10-folds	Random Forest	Support Vector Machine	Gradient Boost	LGBM	ResNet-101	DensNet-121
Fold-1	79.22	81.81	74.02	91.62	88.92	96.81
Fold-2	70.12	66.23	70.12	89.12	86.72	92.02
Fold-3	80.51	79.22	72.83	88.92	96.62	94.62
Fold-4	79.22	75.32	79.12	89.23	92.62	94.82
Fold-5	72.72	71.42	77.42	91.92	91.02	91.72
Fold-6	81.81	77.92	79.12	92.32	90.02	92.82
Fold-7	71.42	68.83	62.33	93.23	92.33	87.32
Fold-8	75.32	76.62	78.42	91.83	91.62	90.32
Fold-9	76.31	76.31	71.05	93.32	90.0	91.71
Fold-10	84.21	81.57	77.63	89.57	90.26	97.61
Mean	77.09	88.82	89.11	90.71	91.61	92.44

Overall, the results demonstrate the effectiveness of the fine-tuned Transfer Learning models, ResNet-101 and DenseNet-121, in accurately classifying kidney images. These models outperform the traditional ML algorithms, such as Random Forest, SVM, and Gradient Boost, in terms of accuracy. The use of 10-fold cross-validation provides a more reliable estimate of the models' performance and their generalization capability, ensuring that the evaluations are robust and less affected by variations in the data splits.

In conclusion, the 10-fold cross-validation results reveal the superior performance of the fine-tuned Transfer Learning models, ResNet-101, and DenseNet-121, in accurately classifying CT kidney images. These models are better equipped to handle the complexities of the dataset, offering promising implications for kidney tumor detection and diagnosis in a real-world clinical setting.

Furthermore, Table III presents a comparison of the results obtained using LightGBM (LGBM) with state-of-the-art methods in terms of accuracy for a specific task or dataset. The table showcases the performance of various models, including two fine-tuned Transfer Learning architectures, ResNet-101 and DenseNet-121, along with several other approaches reported in the literature.

Table III demonstrate the effectiveness of the fine-tuned Transfer Learning models, ResNet-101 and DenseNet-121, in achieving high accuracies and outperforming other state-of-the-art methods. DenseNet-121, in particular, exhibits the highest accuracy among all the models, indicating its superior performance in the specific classification task. The results also highlight the importance of exploring and comparing different models and methodologies to advance the field and achieve better results in image classification and other related tasks.

TABLE III. COMPARISON OF PROPOSED WORK WITH STATE-OF-THE-ART METHODS

Reference	Accuracy (%)
ResNet-101	96.67
DenseNet-121	98.22
LGBM	94.09
Zhou et al.[47]	93.00
Zabihollahy et al. [48]	83.75
Schieda et al. [49]	78.00
Finally, Yap et al. [50]	75.00

IV. CONCLUSION

The early detection and classification of kidney tumors play a vital role in saving human lives. Manual detection methods rely heavily on the expertise of medical professionals and can be time-consuming. Therefore, the development of automatic classification systems holds significant promise, as they offer robust and rapid results. In this study, we have presented a hybrid approach combining Light Gradient Boosting Method with Grey Level Co-occurrence matrix (GLCM) computation for the automatic classification of kidney tumors from CT Kidney image datasets. To optimize the training process, we applied various pre-processing techniques and image resizing, reducing the model's complexity and speeding up the training. Light GBM, known for its speed, efficiency, and high predictive accuracy among ML models, served as a powerful gradient boosting framework in this study. Additionally, we introduced two fine-tuned Transfer Learning (TL) models within this framework, ResNet-101 and DenseNet-121, to predict kidney tumors. The performance of these models was thoroughly evaluated using diverse performance metrics and compared with state-of-the-art methods. Our results demonstrated the superiority of the fine-tuned TL models, with DenseNet-121 achieving an impressive accuracy of 98.22%.

Several limitations are evident in the study's comparative analysis, model testing, and generalizability. Firstly, the comparative study of detection approaches, including Random Forest, Support Vector Machine, Gradient Boosting, Light Gradient Boosting Model, and deep learning models ResNet-101 and DenseNet-121, might lack a comprehensive exploration of other relevant models, potentially missing out on valuable insights and alternative solutions. Secondly, while the fine-tuned deep learning models exhibit impressive accuracy, their testing and evaluation solely on the provided dataset might not guarantee similar performance on diverse and real-world datasets. There's a need to assess the models across various datasets to ascertain their consistency and robustness. Finally, the proposed approach's applicability to different datasets with varying characteristics, like imaging quality and patient demographics, remains unexplored. Testing the models on multiple datasets could reveal potential challenges in generalizing the approach to broader clinical settings.

In light of these limitations, future work should aim to address these areas to enhance the study's comprehensiveness and practicality. To conduct a more thorough comparative study, incorporating a wider range of detection models, including emerging techniques and architectures, would provide a more comprehensive understanding of the strengths and weaknesses of various approaches. Moreover, the robustness and generalizability of the fine-tuned deep learning models, ResNet-101 and DenseNet-121, should be evaluated across multiple datasets to ensure consistent performance across diverse clinical scenarios. Additionally, to enhance the proposed approach's real-world applicability, further investigation on different datasets, encompassing variations in imaging quality, patient populations, and demographics, is crucial. This analysis will shed light on potential challenges and adaptations needed to deploy the model effectively in clinical practice. Ultimately, addressing these avenues for future research will contribute to a more holistic and adaptable approach for kidney tumor detection, ensuring its utility and effectiveness across a broader spectrum of clinical settings.

Faculty of Engineering, Informatics Department, Universitas Medan Area, Medan, Indonesia³

Abstract—Accurate and efficient business analytical predictions are essential for decision making in today's competitive landscape. Involves using data analysis, statistical methods, and predictive modeling to extract insights and make decisions. Current trends focus on applying business analytics to predictions. Optimizing business analytics predictions involves increasing the accuracy and efficiency of predictive models used to forecast future trends, behavior, and outcomes in the business environment. By analyzing data and developing optimization strategies, businesses can improve their operations, reduce costs, and increase profits. The analytic business optimization method uses a hybrid PSO (Particle Swarm Optimization) and GSO (Gravitational Search Optimization) algorithm to increase the efficiency and effectiveness of the decision-making process in business. In this approach, the PSO algorithm is used to explore the search space and find the global best solution, while the GSO algorithm is used to refine the search around the global best solution. The hybrid meta-heuristic method optimizes the three components of business analytics: descriptive, predictive, and perspective. The hybrid model is designed to strike a balance between exploration and exploitation, ensuring effective search and convergence to high-quality solutions. The results show that the R2 value for each optimization parameter is close to one, indicating a more fit model. The RMSE value measures the average prediction error, with a lower error indicating that the model is performing well. MSE represents the mean of the squared difference between the predicted and optimized values. A lower error value indicates a higher level of accuracy.

Keywords—Efficiency; analytics business; predictions; Particle Swam Optimization (PSO); Gravitational Search Optimization (GSO)

I. INTRODUCTION

In the 4.0 Industrial Age, the availability of data is crucial for every strategic business decision [1-3]. Using analytics and algorithms, data is transformed into logical information [4]. In addition, data facilitates the consideration of visible and invisible problems in industrial operations [5-6]. Business analytics is the process of transforming data into valuable business knowledge using techniques and instruments [7-8]. Business Analytics accumulates historical business data, compiles, sorts, and then processes and analyzes the data using technology and company strategy in order to generate insights regarding company performance [9-11]. Business Analytics is a collection of techniques, technologies, and applications used to analyze company data and performance in order to make data-driven judgments regarding future investment strategies [12-13]. The three components of business analytics are descriptive analytics, the monitoring of

key performance indicators to understand current business conditions, predictive analytics, the analysis of trend data to predict possible future outcomes, and prescriptive analytics, the use of past performance to generate recommendations on how to handle similar situations in the future[14-17]. For optimization purposes in predictive business analytics, metaheuristics are applied.

The purpose of metaheuristics is to efficiently explore the search space in order to find the optimal solution. Metaheuristic techniques range from simple local search procedures to complex learning processes, from simple local search procedures to complex learning processes [18]. Gravitational Search Optimization (GSO) and Particle Swam Optimization (PSO) are both metaheuristic algorithms. Based on social behavior, PSO is an evolutionary algorithm. Populate the PSO algorithm's initial state with solutions [19]. The PSO algorithm incorporates a few performance-affecting parameters that are frequently expressed as an exploratory tradeoff [20]. Exploration is the ability to evaluate different regions of the problem space in pursuit of optimal solutions. PSO is frequently used to resolve multi-objective optimization issues [21-22]. This algorithm for solving complex problems has a simple yet effective strategy for optimizing numerical functions. GSO simulates interactions between objects in a search space, where objects represent candidate solutions and gravitational forces represent solution suitability to balance exploratory and exploitative search behavior [23-24].

II. RESEARCH METHODOLOGY

A. Methodology

The data is collected from e-metrics data. In pre-processing, the data is cleaned to remove inconsistencies and is null. Perform data integration and then transform the data to be ready for analysis. Feature selection and engineering for identification of variables impact business results, and engineering new features captures more information. It is followed by processing data using the PSO algorithm to optimize model performance using the GSO Algorithm. The training and test data are separated into training and test sets. Cross-validation was carried out for model robustness and to avoid overfitting. By implementing the model in a production environment, its performance is periodically monitored to detect changes in business conditions. The research steps can be seen in Fig. 1.

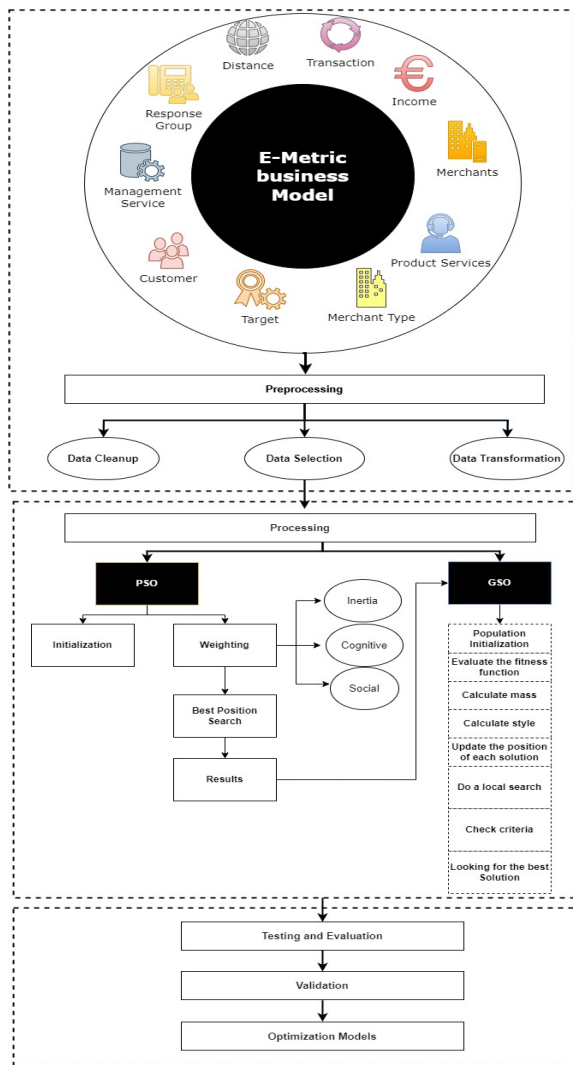

Fig. 1. Research methodology.

B. Definition of Predictive Decision Making

The process of making choices or decisions based on the analysis and interpretation of available data, patterns, and trends to forecast or predict future outcomes or events is known as predictive decision making [25]. Utilizing predictive analytics techniques and models to generate insights and estimates that can guide decision-making processes is included [26].

How can we develop accurate predictive models using machine learning techniques to forecast future business performance and identify potential optimization opportunities given the diversity of business datasets? The constructed model can account for a variety of business performance-influencing factors, such as market trends, customer behavior, and internal operations. Its purpose is to provide business stakeholders with insights and recommendations to assist them in making data-driven decisions and optimizing business operations [27]. Current trends emphasize the application of business analytics to forecasting. Fig. 2 depicts the solution to the problem, which is the optimized scope of the analytical business study.

Fig. 2. Optimized analytical business review scope.

C. Classification of Data Analytics

Several advantages of big data analytics exist for obtaining valuable business insights. Here are some important benefits [28-29]:

- **Enhanced Choice Making:** This result is more precise and enlightened strategic planning, operational optimizations, and efficient resource allocation.
- **Competitive Advantage:** This information facilitates the identification of market opportunities, the development of effective marketing strategies, and the maintenance of a competitive advantage.
- **Enhanced Consumer Satisfaction:** This allows for targeted marketing, personalized recommendations, and superior customer experience, which ultimately increases customer satisfaction and loyalty.
- **Improved Risk Management:** This enables businesses to prevent fraud and mitigate risks, thereby safeguarding their assets and reputation.
- **Increased Productivity:** This contributes to the delivery of products and services that are more in line with consumer demands, thereby enhancing competitiveness and customer satisfaction.

The visualization is shown in Fig. 3.

D. Problem Solving Approach

In the context of optimizing business analytic predictions with the Multi-Attribute Method (MAM), Particle Swarm Optimization (PSO) can be utilized as a metaheuristic algorithm to find optimal solutions in complex search spaces. PSO is a population-based optimization technique that discovers the optimal solution by imitating the social behavior of a particle swarm.

Fig. 3. Data analytics advantages for business insights.

1) Steps are done on Particle Swarm Optimization (PSO) [30]:

- Characteristics: Market conditions, customer behavior, financial indicators, and historical data are characteristics.
- Initialization of swarms: In the search space problem, the position and velocity of the particles are chosen at random.
- Fitness evaluation: Determine the fitness of each particle by calculating the value of the objective function based on the position of each particle. The fitness function indicates the efficiency or caliber of the particle solution.
- Update particle best position: Update each particle's position based on its current fitness.
- Update the highest global position: Determine the global best position by selecting the particle with the best position in the swarm.
- Update particle speed and position: Update the particle's speed and position.
- Repeat the process of fitness evaluation, updating particle best position, global best position, as well as velocity and position, until termination is reached.
- After the iteration is complete, extract the optimal solution considering the best position discovered.

To determine the optimal solution, the Particle Swarm Optimization (PSO) algorithm modifies the velocity and position of particles in the search space. Here are the formulas used by the conventional PSO algorithm [31].

PSO in training multilayer ceptrons' efficacy,

$$M_i = \{M_i^{[1]}, M_i^{[2]}\} (1)$$

Position indicates the optimal fitness value for every particle,

$$S_i = \{S_i^{[1]}, S_i^{[2]}\} (2)$$

seeking the optimal particle index at x ,

$$A_x = \{S_x^{[1]}, S_x^{[2]}\} (3)$$

Velocity update formula,

$$vl_{i(t+1)} = w * vl_{i(t)} + c_1 * rand() * (pbest_i - a_{i(t)}) + c_2 * rand() * (gbest - a_{i(t)}) (4)$$

Where,

- $vl_{i(t+1)}$ at time $t + 1$, is the updated velocity of particle i .
- w is the mass of inertia, which controls the influence of the previous velocity on the current velocity.
- $vl_{i(t)}$ at time t , the current velocity of particle i
- c_1 and c_2 acceleration coefficients that govern the effect of personal best ($pbest_i$) and global best ($gbest$) positions on the updated velocity.
- $rand()$ an arbitrary number between zero and one.
- $pbest_i$ is particle i 's personal best position, indicating the highest position it has attained to date.
- $a_{i(t)}$ at time t , is the present position of particle i .
- $gbest$ is the optimal position for all particles in the swarm globally.

Position update formula,

$$a_{i(t+1)} = a_{i(t)} + vl_{i(t+1)} (5)$$

In this formula, $a_{i(t+1)}$ represents particle i 's position updated at time $t + 1$, and $vl_{i(t+1)}$ the updated velocity calculated in the previous step.

In the Particle Swam Optimization (PSO) algorithm each particle moves towards its previous personal best position ($pbest$) and the global best position ($gbest$) to achieve the optimal solution, according to Eq. (6) [32].

$$p_{best_x}^i = B_x^* | f(B_x^*) = \min_{s=1,2,\dots,i} (\{B_x^s\}) (6)$$

where $x \in \{1, 2, \dots, N\}$

$$g_{best_x}^i = B_*^i | f(B_*^i) = \min_{s=1,2,\dots,i} (\{B_x^s\})$$

x represents the particle index, i represents the current iteration number, f represents the objective function to be optimized, g represents the position vector, and N represents the total number of particles within the flock. At each $x + 1$ iteration, the velocity D and position t of each particle i in the system are calculated. Eq. (7).

$$D_i^{x+1} = \omega D_i^x + v_1 r_1 (p_{best_i}^x - t_i^x) + v_2 r_2 (g_{best_i}^x - t_i^x) \\ t_i^{x+1} = t_i^x + D_i^{x+1} (7)$$

D represents the velocity vector, is used to balance local exploitation and global exploration, and v_1 and r_1 are uniformly distributed random vectors in the interval $[0,1]$. D are the dimensions of the search space or the magnitude of the encountered problem, and v_1 and v_2 are referred to as

"acceleration coefficients."

2) *Gravitational search optimization (GSO)*: The Gravitational Search Optimization (GSO) algorithm replicates the interaction between objects in the search space, where each object represents a candidate solution and gravitational force represents the solution's suitability [33].

The formula for updating the position of the *i*-th solution in the population of *N* solutions in the GSO algorithm in Eq. (8) and (9) [34].

$$a_i = G * \left(\frac{1}{d_i^2}\right) * (x_{cm} - x_i) \quad (8)$$

$$b_{i(t+1)} = b_{i(t)} + c_{i(t+1)} \quad (9)$$

Where,

- a_i Solution acceleration to- *i*, which is determined by the force of gravity acting on the solution.
- G The gravitational constant, which controls the strength of the gravitational force.
- d_i Euclidean distance between solutions to- *i* and the center of mass of the solution x_{cm}
- $b_{i(t)}$ Solution position to- *i* at time *t*
- $c_{i(t+1)}$ Updated speed from solution to- *i* at time *t* + 1
- $b_{i(t+1)}$ The latest position of the solution to- *i* at time *t* + 1

The approach to problem-solving that combines PSO and GSO is the PSO algorithm updates the position and velocity of the particle, then employs the GSO algorithm to update the fitness value and determine the optimal global position. The GSO algorithm can be used as an alternative to update the particle's position, while the PSO algorithm can be used to update the particle's velocity [35-37].

III. RESULT AND DISCUSSION

The first step is based on four segments. Segments are displayed based on the number of days that customers use to perform all activities from e-metric data. As in Table I, and the parameters used are market trends, behavior, customer needs, risk, service and product.

TABLE I. SEGMENT

Days	Segment
<200	1
200-500	2
500-1000	3
>1000	4

To successfully implement PSO, the optimal input parameter settings must be determined. The initial value and the final value govern the search process's exploration and exploitation. An explanation is provided in Table II.

TABLE II. DEFINITION OF THE PSO PROCESS

Definition	Information
Selected Data	x - direction, y - direction, z = 0.5, Q wall (77, 83, 110, 125)
Number of inputs in the best intelligence	5
Swarm Size (SS) in the best of intelligence (PSO parameter)	200
Changes in Accept Ratio (AR) which are evaluated (subtractive clustering parameter)	0.5, 0.6, 0.7, 0.8, 0.9
Changes in Inertia Weight Damping Ratio (WDR) which are evaluated(PSO parameter)	0.50, 0.60, 0.70, 0.80, 0.90
P(%) percentage of data which were used in training process(while 100% of data were considered in testing process	89%
Number of data	3546
Number of iterations	600

The objective value for finding the potential of each customer is calculated using Eq. (1). The results are shown in Table III.

TABLE III. POTENTIAL CUSTOMERS

Potential Customers				
	1	2	3	4
Market Trend	43.919	42.992	44.923	65.789
Behaviour	40.346	40.621	40.455	55.738
Customer Needs	54.748	53.637	43.637	56.738
Risk	53.737	57.728	53.637	63.789
Service	55.748	53.828	59.737	77.838
Product	50.763	53.728	60.738	79.748

Behavioral value is done by setting the customer's active power of each parameter based on the value of the objective function, best, worst and modifications to Eq. (2) and (3). i.e., the controlled variable related to customer status is modified to determine the best status in Eq. (6). The results are shown in Table IV.

TABLE IV. BEHAVIORAL VALUE

Values				
	1	2	3	4
Market Trend	0.536	-1536	0.637	0.647
Behaviour	0.787	-0.036	-1.748	0.537
Customer Needs	0.368	-0.546	0.074	0.647
Risk	-0.003	-0.002	0.004	0.003
Service	0.637	-1.738	0.647	0.663
Product	0.637	-1648	0.787	0.536

TABLE V. VELOCITY VALUE OPTIMIZATION

X[m]	Y[m]	Z[m]	Velocity [m s ⁻¹]	Velocity u[m s ⁻¹]	Velocity v[m s ⁻¹]	Velocity w[m s ⁻¹]	q wall
-0.003	-0.0040	0.30006	0.8130	-0.005	0.0002	0.81320	85
-0.008	-0.0383	0.30006	0.8680	-0.005	0.0002	0.86800	85
-0.0024	-0.0034	0.30006	0.8685	-0.005	0.0003	0.86875	85
-0.028	-0.0364	0.30006	0.8143	-0.004	0.0002	0.81413	85
-0.027	-0.0378	0.30006	0.7343	-0.004	0.0002	0.73483	85
-0.002	-0.0415	0.30006	0.7331	-0.004	0.0002	0.73381	85
-0.033	-0.0033	0.30006	0.7363	-0.003	0.0002	0.73623	85
-0.031	-0.0318	0.30006	0.8154	-0.004	0.0003	0.81534	85

For optimization, vectors are used as the particle representation. The population reacts to factors based on the highest individual and group scores. The distribution of responses between individual and group values ensures response diversity. The PSO algorithm instructs multi-layered perception in which the matrix learning problem is addressed. Eq. (4) to (7) is used to calculate the new velocity of a particle based on the particle's previous velocity and the distance from its current position, using the individual's and group's greatest experience. They demonstrate cooperation between particles within a collective. Then define a new position based on the new velocity as listed in Table V.

After the PSO results are obtained, it is optimized again using GSO. According to the GSO algorithm, gravitational and inertial masses are equivalent. However, the value employed is unique. When conducting search operations, the inertial mass increases because the movement becomes slower. As shown in Fig. 4 and Fig. 5, a greater gravitational mass causes a stronger attraction, allowing for a quicker convergence.

Multi-attribute evaluations provide comparable initial statuses, and the perception training procedure starts with the most suitable initial population, as shown in Table V. Performance is shown according to the age range of customers. Because age has an important effect on the behavior of each segment attribute. Age is divided into three parts, young age range 25-35, middle age 35-55 and old age 55-65 as shown in Table VI.

The eligibility of each customer is divided by age in finding each habit, in Eq. (8) and (9). Every solution must meet quality constraints as shown in Table VII behavior at a young age, Table VIII behavior at middle age and Table IX behavior at old age. It appears that the average middle age does more activity than the young and the old.

The augmentation of the hybrid method by incorporating a memory strategy with each individual's finest fitness history. In addition, the sensitivity analysis of the parameters in this instance is optimized according to the age of the customer. Finally, comparative experiments on a set of benchmark functions were conducted to assess the performance of the hybrid model. The results are presented in Table X.

Fig. 4. Potential customer patterns.

Fig. 5. Pattern of potential customers based on convergence.

TABLE VI. AGE CRITERIA

	Segments	Age Criteria
Young Age	1	25-35
Mid Age	2	35-55
Old Age	3	55-65

TABLE VII. YOUNG AGED CUSTOMERS

Young Aged Customers		
	Average Revenue	Expected Revenue
Low Income	<5,000	5,373,930
Medium Income	10,000	3,739,399
High Income	50,000	8,738,399
	Average	55,950,576

TABLE VIII. MID AGED CUSTOMERS

Mid Aged Customers

Customer Segments	Count of Purchase	Sum of Segmented Customers	Conversion Rate
1	27,153	27,153	33.74
2	36,538	36,849	47.62
3	83,638	25,379	44.63
4	73,647	53,838	34.58

IV. VALIDATION

Validation using R2, RMSE and MSE where R2 indicates the proportion of variance in the dependent variable that can be attributed to the independent variable in the regression model. It ranges from 0 to 1, with greater values indicating superior models [38]. RMSE is a measure of the average prediction error of a regression model. It is the square root of the average of the squared differences between predicted and observed values [39]. MSE is similar to RMSE, but it excludes the square root. It is the average of the squared deviations between predicted and actual values [40].

The formula to calculate R2 is [41]:

$$R2 = 1 - \left(\frac{SSR}{SST}\right) \quad (10)$$

Where:

- Sum of Squares Residual (SSR) is the sum of the squared differences between anticipated and observed values.

- SST (Total Sum of Squares) is the sum of the squared differences between actual values and the mean of the dependent variable.

The formula to calculate RMSE is [42]:

$$RMSE = \sqrt{\frac{1}{n} * \sum (y_i - y_{hat})^2} \quad (11)$$

Where:

- n the quantity of observations.
- y_i represents the exact value of the dependent variable.
- y_{hat} represents the value predicted for the dependent variable.

The formula to calculate MSE is [43]:

$$MSE = \frac{1}{n} * \sum (y_i - y_{hat})^2 \quad (12)$$

Where:

- n is the number of occurrences.
- y_i represents the exact value of the dependent variable.
- y_{hat} represents the value predicted for the dependent variable.

Table XI displays the results, where the R2 value for each segment is close to one, indicating a superior model fit. The RMSE value assesses the average error in prediction, with a lower value indicating that the model is performing well. MSE is the mean of the squared differences between predicted and optimized values. A lower value indicates a higher level of precision.

TABLE XI. R2, RMSE, MSE VALIDATION RESULTS

Parameter		Training			Validation		
Customer Segments	Conversion Rate	R2	RMSE	MSE	R2	RMSE	MSE
1	33,74	0.87	0.17	0.08	0.87	0.20	0.11
2	47,62	0.97	0.26	0.29	0.93	0.27	0.21
3	44,63	0.85	0.36	0.28	0.91	0.41	0.35
4	34,58	0.89	0.45	0.22	0.89	0.40	0.43

Fig. 6 and Fig. 7 illustrate that the PSO Algorithm's inputs and parameters are based on social behavior, whereas the GSO is based on mass physical phenomena. In PSO, each particle modifies its position based on its own optimal position and the optimal position of the entire system. GSO, each agent's position changes dependent on the combined power of all other agents. PSO utilizes memory to update the velocity and position of particles. The GSO acceleration of the agent has an effect on the position and velocity updates. PSO particles' positions are updated without regard to the distance between solutions, whereas GSO particles' positions are updated using a force that is inversely proportional to the distance between solutions. The obtained results demonstrate that PSO improves every customer's social behavior based on their needs, current trends, risks, and services whereas GSO optimizes every condition consideration for future improvement.

Fig. 6. Inputs and parameters of PSO and GSO algorithms are based on social behaviors.

Fig. 7. The results of the optimization of the PSO and GSO algorithms based on the value social behaviors.

V. CONCLUSION

The conclusion of this study is that PSO and GSO are efficient meta-heuristic optimization algorithms for business analysis by augmenting a specific decision-making process or business outcome. In terms of convergence speed, precision, robustness, or scalability, the performance of PSO and GSO is analyzed. It is evidenced by the R2 validation value close to one, RMSE and MSE with lower error rates. Thus, increasing the effectiveness of these business analytics can overcome any limitations or barriers associated with the practical application of algorithms in a business environment.

ACKNOWLEDGMENT

Thanks to DRTPM for the research funding provided with contract no. 70/UN5.2.3.1/PPM/KP-DRTPM/B/2023.

Abstract—Researchers and investors have recently become interested in forecasting the cryptocurrency price forecasting but the most important currency can take that it's the bitcoin exchange rate. Some researchers have aimed at leveraging the technical and financial characteristics of Bitcoin to create predictive models, while others have utilized conventional statistical methods to explain these factors. This article explores the LSTM model for forecasting the value of bitcoins using historical bitcoin price series. Predict future bitcoin prices by developing the most accurate LSTM forecasting model, building an advanced LSTM forecasting model (LSTM-BTC), and comparing past bitcoin prices. This is the second step, if looking at the end of the model, it has very high accuracy in predicting future prices. The performance of the proposed model is evaluated using five different datasets with monthly, weekly, daily, hourly, and minute-by-minute bitcoin price data with total records from January 1, 2021, to March 31, 2022. The results confirm the better forecasting accuracy of the proposed model using LSTM-BTC. The analysis includes square error MSE, RMSE, MAPE, and MAE of bitcoin price forecasting. Compared to the conventional LSTM model, the suggested LSTM-BTC model performs better. The contribution made by this research is to present a new framework for predicting the price of Bitcoin that solves the issue of choosing and evaluating input variables in LSTM without making firm data assumptions. The outcomes demonstrate its potential use in applications for industry forecasting, including different cryptocurrencies, health data, and economic time.

Keywords—Currency; bitcoin; LSTM; forecasting; models

I. INTRODUCTION

Since cryptocurrencies are the newest financial innovation and are having a significant impact on the world economy, cryptocurrency price forecasts are very important. Fintech professionals and technologists are particularly interested in forecasting the price of cryptocurrencies and hosting blockchain conferences to educate the public on the most recent revolution. Previous studies have observed proof of this link between modifications in stock prices and social media [1]. Cryptocurrency is a digital trade concept that makes use of cryptographic capabilities to conduct economic transactions. Cryptocurrencies leverage the blockchain era to the advent of age transparency, decentralization, and immutability. BTC is the maximum well-known cryptocurrency, which came into existence in 2009 through an anonymous institution or person, accomplishing its height cost on December 16, 2017, through mountaineering to nearly \$20,000. In the final ten years, 1512 alternative cryptocurrencies like Ethereum and Litecoin had

been created proving that the cryptocurrency marketplace has emerged revealing its sturdy growth [2]. The forecasting of Bitcoin price may be taken into consideration as a common sort of time-limited problem, just like the stock price prediction. Traditional time-series models, just like the famous ARIMA, had been carried out for cryptocurrencies' price and motion prediction [4,6]. After the discovery of the Blockchain era, which began approximately a decade ago, a maximum of the posted studies on this region have been targeting non-technological factors of Blockchain technology inclusive of felony troubles and its function in criminal activities [7]. Since cryptocurrencies have been first added in the year 2008 their scope has been restricted to papers posted between 2008 and 2018 [8]. This paper discusses the research methodologies used in this study and displays the result lot of the valuation of reviewed papers and their classifications. RNNs that upload the particular dealing with the sequence of observations include the LSTM. Whilst learning a mapping feature from inputs to outputs, is now no longer supplied through MLPs or CNNs [9-10]. Most commonly, statistical strategies are being in use for such a long time, from the 1970s onward, exclusively the ones primarily based totally on one Box-Jenkins methodology [11]. By reviewing rising studies of deep-learning fashions, which include their mathematical formulation, for large facts, and function learning. Another terrific work may be determined wherein the authors added the time series type hassle and furnished an open-supply framework with applied algorithms in the University of East Anglia/the University of California in Riverside source [12]. The forecasting trouble and mathematical method for time collection may be determined in the Problem Definition segment [13]. The deep-Learning Architecture phase presents the deep-studying architectures normally used in the context of time collection forecasting. A time collection is described as a chain of values determined over time. As it is a known term that time is a variable measured on a non-stop basis, the values in a time collection are tested at consistent intervals (constant sampling frequency) [14,15].

Cryptocurrencies have attracted recognition as volatile investments, because of excessive investor losses due to scams, hacks, and bugs. Although the underlying cryptography is usually secure, the technical complexity of the use of and storing crypto belongings may be a primary threat to new users. Unlike conventional finance, there may be no manner to do the opposite or cancel a cryptocurrency transaction after it has already been sent. The statistics on the blockchain are encrypted, which means no one can mess with it. During

transactions the person's Sample paragraph, the complete file ought to be in the name isn't revealed, however simplest their wallet ID is made public. At present, the costs of those cryptocurrencies do now no longer have a good-sized quantity of research and studies in comparison to standard trading markets. The process of Forecasting Time Series has continually become a crucial region of research in lots of domain names due to the fact many specific forms of information are saved as time collection [16]. For example, by discovering quite a few times collection information in medication, climate forecasting, supply chain control, biology and forecasting of stock prices, etc. with knowledge resources of developing availability of information and computing strength in the current years, Deep Learning has ended up an essential a part of the new technology of Time Series Forecasting fashions, acquiring tremendous results.

Deep learning can be the future of complicated and hard-time collection forecasting and the article will assist you to get commenced and make fast development for your personal forecasting problems. Supervised studying is wherein you have input variables (X) and an output variable (y), and you operate a set of rules to analyze the mapping characteristic from the entry to the output. Deep Learning used for forecasting Time Series overcomes the conventional Machine Learning risks with several special methods. In addition, don't forget the overall performance of the current attention-based Transformer models, which has had exact fulfillment withinside the image processing and herbal language processing domains. In all, by evaluating four special deep learning techniques (RNN, LSTM, GRU, and Transformer) at the side of a baseline approach. The process of implementing multilayer perceptron is enormously meek. However, deep-learning models are extra complex, along with their implementation calls for an excessive stage of technical information and substantial time investment to implement [17].

The authors of this research suggest a revolutionary machine-learning methodology for forecasting Bitcoin's price and behavior. A deep neural network underlies the proposed model, which was trained using a sizable dataset of historical Bitcoin price data. The model beats state-of-the-art techniques when tested on a held-out test set. Investors can utilize this model to aid them in making more educated choices regarding Bitcoin trading.

II. RELATED WORK

A cryptocurrency is a virtual foreign money, that is an opportunity shape of charge created by the usage of encryption algorithms. The use of encryption technology methods that cryptocurrencies characteristic each as foreign money and as a digital accounting system. To use cryptocurrencies, you want a cryptocurrency wallet. These wallets may be the software program that may be a cloud-based provider or is saved in your computer or cellular device. The wallets are the device via which you store your encryption keys that verify your identification and link to your cryptocurrency. In these wallets, there are two types of keys. The first one is a public key that is visible to all and helps you to identify the transaction being made from your account, or in simple words, represents your account publicly. While the other the most sensitive key is

known as the private key which in term helps you to send and receive transactions inside the blockchain. These wallets are in term only and can be used for trading in blockchain and more work as a bank account for your digital currency. What are the dangers of the usage of cryptocurrency? Cryptocurrencies are nonetheless fairly new, and the marketplace for those virtual currencies may be very volatile. Since cryptocurrencies do not want banks or some other third party to adjust them; they tend to be uninsured and are tough to transform right into a form of actual foreign money (which includes US greenbacks or euros.) In addition, considering that cryptocurrencies are technology-based intangible assets, they may be hacked like some other intangible generation assets. Finally, because you shop your cryptocurrencies in a virtual pocket, in case you lose your pockets (or access to it or pocket backups), you have misplaced your whole cryptocurrency investment.

Unlike conventional finance, there may be no manner to oppose or cancel a cryptocurrency transaction after it has already been sent. By a few estimates, approximately a 5th of all bitcoins is inaccessible because of misplaced passwords or wrong sending addresses. Bitcoin is a currency but not the basic one, it is a crypto forex that is used globally for virtual fees or truly used for investment. It is decentralized for example it isn't owned by anyone. Transactions made via way of means of Bitcoins are smooth as they may be observed in any country. Investment may be achieved thru numerous marketplaces recognized as "bitcoin exchanges".

A range of machine learning methods, such as sentiment analysis of Twitter feeds, have been developed over the years to forecast price movement for the financial markets using digital platforms. Recent research has effectively used sentiment analysis for a variety of purposes, including predicting movie box office receipts [1]. Machine learning, like deep learning techniques, is recognized as an efficient forecaster for several tasks and situations; such a toolkit provides algorithmic traders with a powerful yet fundamental set of tools to anticipate the path of price yet for capital assets. Huang, Xin, and others [2] described the purpose of LSTM Driven Sentiment Classification for Cryptocurrency Purpose of forecasting is to outline and illustrate the work of LSTM Results using data sets from social media posts, tweets, and comments. The concluded precision is 92.5 percent. In contrast to the conventional auto-regressive technique, the system used in this research is constructed via LSTM and attains better recall and precision. Wei Chen and others [3] used the data set which was gathered utilizing websites, APIs, and machine learning models. It was employed to forecast the Bitcoin exchange rate using technological and financial factors. Here, the data will be divided into 4 distinct periods concerning the year and the currency exchange rate using the methods ARIMA, SVR, ANFIS, and LSTM. Learning techniques that have been put into use according to research, the GRU model time series offers the fastest compilation of bitcoin price predictions [5].

T. Awoke et al. [10] said Bitcoin price prediction and analysis used a deep learning model where the dataset implements LSTM and GRU methods using Kaggle bitcoin price data (2014-2018 low price data) reaches up to 92% and 75% respectively. Long-term dependencies can be more

effectively identified using LSTM and GRU models. Some recent work has focused on high-frequency trading and the application of deep learning methods such as RNN to predict time series data whose functional models have been transformed into dense and feeder networks [18]. Deep learning methods are expected to outperform the deficient performance of ARIMA. McNally [19] used machine learning techniques such as recurrent neural networks (RNN) and long-term memory (LSTM) to predict the process of changing the price of Bitcoin and automatically compare the results. To enhance outcomes, such as deep learning employing neural networks (such as ANN and RNN) in prediction, apply ML algorithms (such as SVM, Bayesian Network, regress, or any other advanced machine learning approach) [20]. The same technique may be used by Hoy to forecast Bitcoin.

The market for algorithmic trading is estimated to be worth \$11.66 billion in 2020 and to increase to \$26.27 billion by 2021, according to research [21]. Bitcoin is the maximum famous instance of chain technology. "Bitcoin is a peer-to-peer digital coins system" delivered withinside the famous paper Nakamoto[22]. The peer-to-peer (P2P) mechanism permits a possession switch, from one party to every other without a third-party intervention (monetary institution). Payments may be remodeled on the internet with nonneutral or fee of a government for the primary time [23]. Deep Learning models examine capabilities and dynamics best and at once from the information. Thanks to this method, they accelerate the manner of information training and might examine extra complicated information styles in a greater whole way [24]. Before talking about Deep Learning techniques used for Forecasting Time Series, it's miles beneficial to keep in mind that the maximum classical Machine Learning models which are used to resolve this hassle are ARIMA models and additionally exponential smoothing [25]. The cryptocurrency marketplace is one of the quickest developing in the global and is taken into consideration as one of the maximum risky markets for transactions. For example, the price of bitcoins has skyrocketed, from nearly 0 in 2013 to around \$ 19,000 in 2017. For a few altcoins, the charge can upward thrust or fall through greater than 50% in a single day [26].

Deep learning models are one of, if now no longer the most data-hungry models of the Machine Learning world. They want big quantities of facts to attain their greatest overall performance and serve with the distinction, anticipate from them. However, having these many facts isn't always continually easy [27]. The purpose of machine learning is to discover styles in statistics and then make predictions, typically based on complicated styles, to reply to commercial enterprise questions, track trends, and assist them to examine and solve issues. Thus, it's far vital to look at it to discover an extensive variety of verbal facts more easily [28]. LSTM achieved overall recognition accuracy of 52% and 8% RMSE. Compared to deep learning systems, the popular ARIMA method is used for time series forecasting. This model is inefficient as deep learning models can be implemented.

III. LIMITATIONS OF PREVIOUS WORK AND OUR CONTRIBUTION

Past exchange rates are used as predictors in current research on bitcoin exchange rate forecasts. Bitcoin's creation, however, demonstrates a complicated and extremely erratic character. Therefore, it is crucial to take into account the many variables that affect the exchange rate for Bitcoin. A variety of econometric techniques, including random forests, clustering, and machine learning, have been used to investigate the factors that influence the price of Bitcoin. Here is Table I that shows us 'Previous Works' and the same method that is going to be utilized in this research for getting good results with the Forecast Data Set.

TABLE I. ANALYSIS OF PREVIOUS METHODS AND RESULTS WITH LSTM

Approach	Year	Dataset Period	Method used	Performance Evaluation
Huang et al. [2]	2021	19/03/2021 to 27/03/2021	LSTM	0.87
Fan Fang et al. [4]	2021	02/07/2018 to 29/08/2018	LSTM	0.82
Awoke et al. [10]	2020	01/01/2014-20/02/2018	LSTM	0.092
M.J. Hamayel et al. [11]	2021	01/01/2018 to 30/06/2021	LSTM	410.399

A. Our Contribution

The Long-Term Memory Network (LSTM) is a modern deep-learning architecture for time series estimates. Moreover, there hasn't been much research done on forecasting financial time series, particularly for cryptocurrencies. To predict the daily price of bitcoin using the usual LSTM model, offer a novel forecasting framework. The suggested model's effectiveness is assessed. By employing techniques relevant to the specific item, need to anticipate the value of Bitcoin. For instance, might simply wish to predict based on signals or prices, or might only be able to anticipate the current day based on LSTM, past prices, and other techniques (such as official forecasts). A closing price might also be anticipated the next day. Market trends might aid investors in choosing their investments. Be extremely precise when determining future values. Additionally, both in accuracy and precision, the LSTM model outperforms conventional LSTMs and other time series forecasting models. It uses sophisticated algorithms, statistical models, and human oversight to make trade choices on exchanges. In contrast, the Financial Times reports that, in addition to conventional hedge strategies and futures trading, quantitative trading is being utilized to trade digital currencies like Bitcoin. In-depth discussions are held about the development and assessment of statistical models, predicting, controlling, and filtering of ideal time series. The two main types of time series analysis are hyperbolic and random analysis of variance.

IV. MATERIALS AND METHODS

A. Research Methodology

The purpose of this research is to predict price changes in Crypto (Bitcoin) on the premise of Monthly, Weekly, Days, Hourly, and by Minutes time to alternate in price like multilevel (for example, the diploma of increase/decrease) and

binary (up / down). The transaction topic gives a Deep Learning Model's Techniques to predict the price dynamics of digital currencies in actual time by using the evaluation of numerous values. The LSTM cell has recall and overlooking gates, which allow the cell to choose which facts to propagate or block based on their relevance and strength [29]. Determine which information needs to be kept or forgotten, then upload it to the cell state or delete it. By enabling the recovery of data that has been copied into memory, LSTM can resolve the vanishing gradient problem [30]. Time series with unknown time delays may be classified, processed, and predicted with the help of LSTM.

B. Data Collection

Data preparation is the process of gathering, integrating, organizing, and structuring records so that they may be used for applications such as data analytics, data mining, and visualization. For the issue we're trying to address, accurate records must be fed. The preparation of the data set is a crucial stage in machine learning. As previously said, the data preparation has an impact on the accuracy of the forecasts; as a result, this part has to explain the information in the records set. The methods employed to get the data ready for the model being utilized. For the main part of this research, the publicly accessible API from BINANCE Exchange was used to gather historical and real-time rate data for Bitcoin. By collecting real-time bitcoin data from the Coinbase API, allowing one to predict price fluctuations concerning other datasets.

C. Pre-Processing

The dataset was split into training and test subsets at a ratio of 90:10 to train the models, fit them, and fine-tune their parameters. This dataset was built up over each prospect's period and continued the data-collecting process. The facts Set is existed on 5 exclusive forms and LSTM BTC Model is implemented on those all. All of the facts set are from January 2021 to March 2022. The First Data Set is set Monthly Basis Data set. The Second is set to Weekly, 0.33 is set everyday basis, the fourth is about Hourly, and the Last one is an approximately Minutes-by-minutes data set. By anticipating the Bitcoin price for the next time using the Minutes inside hours, weekly, monthly, daily, and hourly prices as input. To improve statistics processing and version convergence efficiency, a variety of pre-processing approaches are used. Minibatch is used to divide massive statistics into manageable batches, which boosts memory effectiveness. Some data in the statistics utilized in this study were missing or had no relevance because they were collected through websites and APIs.

D. Proposed Model

It is claimed that the vanishing gradient problem is avoided by a deep learning concept, particularly a Recurrent Neural Network notion. The main reason for using this set of rules is that it prevents back propagation errors from disappearing or bursting, allowing them to travel backward via an endless number of digital layers that have been opened up in space. The research is divided into three sections due to the heritage records and restricted circumstances. Information preprocessing comes first. Use a modified LSTM network for forecasting and training. The use of interpolation fitting and Fourier rework noise discount for Bitcoin price data, to

improve accuracy in the later time collection prediction. To improve forecasting results, cellular connections are added to the candidate hidden states and control gate in the unique LSTM version, and the most effective control gate is maintained. Following the procedure of purging the data set and dividing it into train data sets, LSTM-BTC is used to observe the results for each of this research paper's data sets. The specific flowchart for the entire essay can be seen in Fig. 1 to avoid using complicated descriptions and to intuitively duplicate this work method.

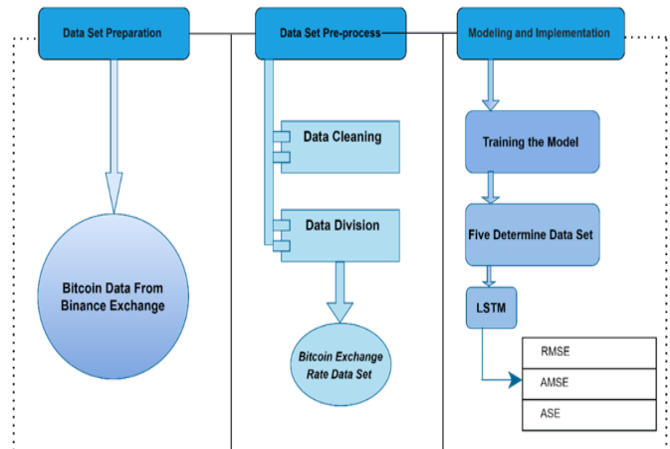

Fig. 1. Proposed LSTM-BTC model.

Long Short-Term Memory (LSTM) and Gated Recurrent Models are examples of RNN extensions (GRU). The problem of remote activities' fading effects in the RNN community is resolved by long short-term memory. It features a transfer that allows you to choose certain actions to be remembered. Additionally, it isn't usually well-established over time and doesn't require as much training. It uses four levels to determine the output before sending the hidden kingdom and the finished product to the cycle after that. To determine if the enjoyment must no longer be counted, "forgetting gates" are present similarly to four layers. Different data may be provided to four levels and forgetting gates for awareness of either short- or long-term memory. When compared to the LSTM model, the GRU or Gated Recurrent Model is seen to be one of the less challenging models since it combines the "forget" and "input" steps into a single step, which only requires the simplest hidden unit.

E. Suggested Model Reasons

- An RNN variant created expressly to address the disappearing gradient issue is the LSTM network. When the erroneous signal backpropagates across several layers of the network and shrinks too much to be meaningful, this issue might arise in RNNs. By employing gates, which manage the information flow over the network, LSTMs get around this issue.
- The redesigned LSTM network suggested in the research enhances the performance of LSTMs by including a control gate and cellular connections to the potential hidden states. This enables the network to discover more intricate correlations between the historical and predicted values of the price of Bitcoin.

- By reducing noise from the data, interpolation fitting and Fourier transform noise reduction techniques help to increase the accuracy of the forecasts.

F. Implementation Details

The implementation details are given in Table II.

TABLE II. IMPLEMENTATION DETAILS

Epoch	Initial Learning Rate	Hardware Resources
100	0.005	Single CPU

V. MATERIALS AND METHODS

A. Simulation and Results

In this Section, analyze the data set first and then optimize the price at various time intervals, including monthly, weekly, daily, hourly, and minutely. Therefore, in the first phase, by observing, the Bitcoin Price with the rate that was in effect at the time for each of the data sets that are used for this study. Fig. 2 is showing that the Proposed LSTM-BTC Bitcoin Price Rate Hourly.

Fig. 2. Proposed LSTM-BTC Bitcoin price rate by hourly.

After that Trained the Model with LSTM on each of the Available Data sets, which will get us the results of the training that are shown below in Fig. 3 to 7.

Fig. 3. Proposed LSTM-BTC trained model with monthly basis.

Fig. 4. Proposed LSTM-BTC trained model with weekly basis data.

Fig. 5. Proposed LSTM-BTC trained model with daily basis data.

Fig. 6. Proposed LSTM-BTC trained model with hourly basis data.

Fig. 7. Proposed LSTM-BTC trained model with minutes basis data.

Determine suitable analytical strategies to study the relationship between the price of bitcoins and other important parameters. After training the model, check the price forecasting results for each outcome in the proposed Model dataset in Fig. 8 to 10.

Fig. 8. Proposed LSTM-BTC after training the monthly forecast.

Fig. 9. Proposed LSTM-BTC after training the weekly forecast.

Fig. 10. Proposed LSTM-BTC after training the daily forecast.

After the trained model was applied to each data set, that observed the price forecast with respect to time was zone-specific. After that, examine the updated forecast results using RMSE (Root Mean Square) Value and Graph by applying Validation to the remaining 10% of the data set. It will apply to each one of these data sets as well. Fig. 11 shows the Proposed LSTM-BTC Model Update with Daily Forecast.

Fig. 11. Proposed LSTM-BTC daily forecast with update.

Before the results' ultimate output, attempt to quantify them using the RMSE, i.e. (root mean square error). Always, RMSE will be higher than or equivalent to MAE. The RMSE scale evaluates a model's capacity to forecast continuous values. To determine whether the margin of error makes sense, the RMSE units are identical to the data units of the dependent variable/target (i.e., if it's in dollars, it's in dollars). The effectiveness of the model improves with decreasing RMSE. Measuring the effectiveness of time series models' short- and long-term predictions is a frequent method of comparison. Utilize the performance measures MAPE (percentage mean absolute error) and RMSE (Root mean square error) to assess the performance of these two models. Utilizing LSTM, these incorrect values were discovered. Fig. 12 to 14 display the RMSE results with respect to months, hours and minutes.

Fig. 12. Proposed LSTM-BTC RMSE of months.

Fig. 13. Proposed LSTM-BTC RMSE of hours.

Fig. 14. Proposed LSTM-BTC RMSE of minutes.

After Standardizing the Data Set, the values Mean and Segmentize values are given in Table III.

TABLE III. STANDARDIZED VALUES

Data Set	Mean	Seg.
Monthly	102186464180.311	355077255937.377
Weekly	21721657287.3499	81315350578.9220
Daily	6025642.99833914	24936137.0634950
Hourly	379850.632288345	1768351.56637383
Minutes	33943.5608210427	25640.9457250926

Table IV shows the performance analysis of the proposed LSTM-BTC with respect to Mean, RSME, Absolute Mean Square Error (AMSE), and Absolute Square Error (MAE) for all five datasets: monthly, weekly, daily, hourly and minutes.

TABLE IV. PERFORMANCE ANALYSIS OF PROPOSED LSTM-BTC W.R.T DIFFERENT ERROR AND RESULTS WITH LSTM

Data Set	RSME	AMSE	MAE
Monthly	1.72682328867215	8.4977586e+23	6.6361072e+11
Weekly	0.543983891659373	4.2930577e+22	1.8160258e+11
Daily	0.00989690855714705	1.0233483e+16	67147840
Hourly	0.795046379048935	5.5483145e+12	476020.22
Minutes	0.732772033979149	1.6737144e+09	21938.914

It is also observed that the proposed forecasting model is reliable for a monthly-based dataset with respect to RMSE outputs based on the estimated rate analysis as well as the aforementioned forecasting outcomes.

B. Performance Analysis and Comparison

Overall, the empirical results presented in the previous section support the general hypothesis that “Bitcoin’s coverability rate is determined by various economic and technological determinants over time.” Therefore, rather than using historical exchange rates, higher forecast performance may be attained by exploiting knowledge buried in economic and technical drivers. The results here change by comparing the results here with the final execution of the research paper, so use the latest dataset for this purpose and many conditions change. Table V shows the performance analysis of the proposed method with previously published state-of-the-art approaches.

TABLE V. PERFORMANCE ANALYSIS OF PROPOSED METHOD WITH STATE-OF-THE-ART PREVIOUS PUBLISHED APPROACHES

Approach	Year	Dataset Period	Method	Data Set instances	RMSE
Huang et al. [2]	2021	19/03/2021 to 27/03/2021	LSTM	Day Wise	0.92
Fan Fang et al. [4]	2021	02/07/2018 to 03/07/2018	LSTM	By Hourly	0.82

Proposed LSTM-BTC	2022	Jan 2021 to March 2022	LSTM	Monthly	1.7268
				Weekly	0.5439
				Daily	0.0098
				Hourly	0.7950
				Minutes	0.7327

VI. CONCLUSION

This study looked into the accuracy of forecasting Bitcoin exchange rates based on technological and economic variables. The DNN-based machine learning model and trained it using historical Bitcoin price data. The study does, however, have certain shortcomings. First, it is unclear how well the model would perform given future data because it was trained on historical data. Second, it is unclear how well the model would generalize to other markets because it was not tested on other cryptocurrencies. Despite these drawbacks, the study significantly adds to the body of knowledge on predicting Bitcoin prices. It thinks that its findings will be valuable to academics, investors, and decision-makers. For upcoming research, look at the use of reinforcement learning and natural language processing as additional machine learning techniques for predicting Bitcoin prices. Test the model's performance on several cryptocurrencies, including Litecoin, Ethereum, and Ripple. Create strategies for increasing the amount of real-time data that Bitcoin price prediction algorithms can use. Research the effects of variables including legislation, public opinion, and technological advancement on the volatility of the Bitcoin price. It is hoped that the effort would stimulate more investigation into this vital subject.

Abstract—With the continuous progress of science and technology and the popularization of the Internet, online piano education has gradually emerged. This educational model provides piano learning resources and communication platforms through the network platform, so that students can learn piano at home anytime and anywhere. However, there are still some problems in the evaluation method of piano assisted online education, which hinders the development of piano assisted online education. Aiming at the problem that piano assisted online education is difficult to evaluate correctly, this paper proposes to integrate the bidirectional long and short memory network into the instrument digital interface piano performance evaluation model, and to integrate the attention mechanism into the bidirectional long and short memory network, hoping to improve the evaluation accuracy of the model. In the comparison experiment of the evaluation model based on the bidirectional long term memory network, it is found that the accuracy of the bidirectional long term memory network model is 0.91, which is significantly higher than the comparison model. In addition, through the empirical analysis of the model, it is found that the piano online education course integrated with the model can improve students' performance level scores and promote their participation enthusiasm. The above results indicate that the digital interface piano performance evaluation model can not only be used to evaluate digital interface piano performance more accurately, but also to promote the development of online piano education.

Keywords—Short-term memory network; attention mechanism; musical instrument digital interface; online education; piano performance evaluation model

I. INTRODUCTION

Piano performance is a subject full of artistry and technique that places high demands on the performer's musical understanding, skill and expression. In the process of piano learning, effective performance evaluation is crucial for the progress of students [1]. However, traditional methods of evaluating piano performance are often limited by subjective factors, which tend to produce inaccurate and unfair evaluation results [2]. With the continuous progress of science and technology and the popularity of the Internet, piano-assisted online education has gradually emerged [3]. This education model provides piano learning resources and communication platforms through the network platform, so that students can learn at home anytime and anywhere [4]. However, in piano assisted online education, there are still

some problems in the evaluation method, such as unclear evaluation standards and inaccurate evaluation results, which limit students' progress in the learning process [5]. Therefore, the aim of this study is to improve the midi piano performance evaluation method so that it can be better applied in piano assisted online education. Specifically, we will use BiLSTM to analyse the musical characteristics and technical requirements of piano performance, and establish a scientific and objective evaluation system. By analyzing the midi data of students' performances, the accuracy, sound quality, expressiveness and other aspects of performance can be accurately evaluated. This research innovatively introduces the two-way LSTM model into the piano performance evaluation model, so as to realize the automatic evaluation and feedback of students' performance, help students find and correct problems in time, and improve the learning effect. At the same time, the improved evaluation method can also serve as a reference for piano teachers, assist them in teaching and guiding students, and promote the sustainable and healthy development of the piano education industry. This research is mainly divided into five parts. The first part analyzes the status quo of the evaluation model and the LSTM algorithm. The second part describes the construction process of the improved piano performance evaluation model based on LSTM. The third part is the comparative analysis of the performance of the improved algorithm and the evaluation model based on the improved algorithm. The fourth part is the discussion of the results of this study; the fifth part is the summary of the full text.

II. LITERATURE REVIEW

With the boom of computer technology, there are several new methods applied to the evaluation model. Ju's team proposed an evaluation model with the cuckoo algorithm to evaluate the permeability of natural fractures more accurately and found the evaluation model could improve the accuracy of the evaluation of the permeability of natural fractures [6]. Chao et al. proposed a wheat yield evaluation model based on a simple algorithm to improve the accuracy of the winter wheat yield estimation model and used the model for empirical analysis, which was found to be of great relevance in estimating not only the yield of wheat accurately, but also the biomass and yield future sensing data [7]. Lai's team has improved the reliability evaluation model for public transportation routes and proposed an information entropy based reliability evaluation model for public transportation

routes, which has been empirically analyzed. The experimental results found that the overall reliability of this model is higher than that of traditional evaluation models [8]. Li and Sun proposed a cloud computing-based English-speaking quality evaluation model to improve the precision of the English teaching quality evaluation model, and the model for comparative experimental analysis, and the results showed this method can evaluate the teaching quality of spoken English with accurate evaluation results [9]. Ding et al. proposed a model for evaluating the timeliness of online instruction with intelligent learning to accurately assess the quality of online instruction, and this study used statistical feature analysis methods to statistically analyze and robustness test the model, and the results showed this model has high credibility in evaluating the timeliness of online teaching, which can increase the precision of online teaching quality assessment [10].

With the wide application of neural network technology, LSTM neural network has been applied in many fields. Guo's team proposed an LSTM-based path planning algorithm for mobile robots and conducted simulation experiments to show that the algorithm not only improves the computational speed compared with similar algorithms but also can adapt to an environment with many obstacles [11]. Li et al. designed a hybrid model with LSTM neural network for the prediction of monthly runoff to resolve low precision of water utilization prediction models. The model was empirically analyzed and found the prediction model was more accurate than similar models and provided a reliable basis for the full utilization of water resources [12]. Geng proposed a deep learning architecture based on LSTM neural networks to grasp the nature of patents more quickly and intuitively, used the architecture to accurately simplify the patent text, and found the architecture can increase the efficiency of researchers in mastering patents [13]. Yao's team proposed a reinforcement learning network with an LSTM network to predict the tool life to increase the machining quality of tools and the productivity of the tool automation system, and the empirical analysis of the proposed network showed that the accuracy of the network in predicting the tool life was is greater than that of traditional prediction methods, which is important for improving the machining quality of tools [14]. Altuve and Hernandez proposed a heart rhythm identification model based on the bidirectional LSTM technique for the problem of insufficient measures for early cardiovascular disease detection, and the proposed model was subjected to empirical analysis, and the results showed that the model can accurately identify heart rhythm identification and to discriminate, providing technical support for early detection of cardiovascular diseases and prompt action to protect people's health [15].

Through the above research, it can be found that the current application range of LSTM neural networks is wide, and there are many methods applied to evaluation models. Through the specific analysis of the above studies, it is found that there is little research that combines LSTM neural network with piano performance evaluation model at present. In this study, the bidirectional LSTM neural network is applied to the MIDI piano performance evaluation model,

which is quite different from previous research. It is expected to improve the accuracy of MIDI piano performance evaluation model with LSTM neural network, and to provide technical basis for piano assisted network education.

III. CONSTRUCTION OF IMPROVED PIANO PERFORMANCE EVALUATION MODEL BASED ON LONG-TERM MEMORY NETWORK

A. Long-term Memory Network Based on Recurrent Neural Network

Traditional RNNs are prone to the problem of gradient disappearance, and the analysis is not accurate when encountering long sequence-type data [16]. The LSTM, as a special recurrent NN, can resolve the question well by improving the hidden layer structure [17]. Some special "gate" structures are added to the neurons of each layer of the LSTM neural network. The purpose of this is to make the error not all attributed to the current neuron in the propagation process, but some of it directly through the "gate" structure, only in this way can the error be well directed to the next layer to avoid the phenomenon of disappearing gradient. This also leads to better convergence [18].

Fig. 1. Memory structure of the LSTM model.

Fig. 1 shows the structure of the LSTM neural network. Compared with the RNN NN, LSTM NN improves the performance by changing the structure so that it can handle long-time series data. This is demonstrated by the introduction of three gating structures, namely, forgetting gates, input gates and output gates. The expression of the forgetting gate f_t is shown in equation (1).

$$f_t = \sigma(W_f h_{t-1} + U_f x_t + b_f) \quad (1)$$

In equation (1), f_t represents the calculation rule of the forgetting gate at the moment of t , W_f and U_f are the parameter matrices, b_f represents the bias term and σ represents the Sigmoid activation function. equation (2) is an expression for the Sigmoid function.

$$\delta(x) = \frac{1}{1 + e^{-x}} \quad (2)$$

From equation (2), it can be seen that the Sigmoid function makes the output value of the forgetting gate lie between [0,1], which can make the data better aggregated in the transmission process of the network. So, the Sigmoid activation function is

also chosen for the calculation in the output and input gates. The function of the input gate of the gating structure is a one-time filtering of the current input information to determine what percentage of the current information is added to the current cell state, and the input gate i_t is calculated as shown in equation (3).

$$i_t = \sigma(W_i h_{t-1} + U_i x_t + b_i) \quad (3)$$

In equation (3), i_t represents the calculation rule of the input gate at the moment of t , σ represents the Sigmoid function, W_i and U_i are the parameter matrices, and b_i represents the bias term. When the current new information is received, some information from the previous moment is superimposed with a certain probability to form the new input information. The expression of the new memory \tilde{C}_t is shown in equation (4).

$$\tilde{C}_t = \tanh(W_c h_{t-1} + U_c x_t + b_c) \quad (4)$$

In equation (4), x_t represents the input information at the time of t , h_{t-1} represents the hidden state at the time of $t-1$, W_c and U_c are the parameter matrices, and b_c represents the bias term. \tanh function is an activation function, also called hyperbolic tangent function, which is mainly used in neuron state and output calculation, and its calculation equation is shown in equation (5).

$$\tanh(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}} \quad (5)$$

From equation (5), the output of the \tanh activation function lies between $[-1,1]$ and, in particular, when the input value is 0, the output of the function is also 0. Using the \tanh activation function is equivalent to adjusting the mean of the input values to 0, which facilitates subsequent processing. When a new message is received, the cell state is updated by multiplying x_t and \tilde{C}_t to the new cell state, the forgetting gate and the input gate change the current cell state C_t by probabilistically selecting the previous moment and the current message, the cell state is updated from the original C_{t-1} to the current C_t process, and the final memory C_t is specified in equation (6).

$$C_t = C_{t-1} \square f_t + i_t \square \tilde{C}_t \quad (6)$$

In equation (6), denotes the cell state at the moment of C_{t-1} $t-1$, f_t denotes the state of the forgetting gate at the moment of t . i_t represents the input gate state at time t . The final memory of the current cell state is obtained by adding the

information passed by the old cell plus the filtered content of the new information C_t . The output gate extracts information from the current cell state, and the output gate o_t expression is given in equation (7).

$$o_t = \sigma(W_o h_{t-1} + U_o x_t + b_o) \quad (7)$$

In equation (7), o_t represents the computation rule of the output gate at the time of t , x_t represents the input information at the time of t , h_{t-1} represents the hidden state at the time of $t-1$, W_o and U_o are the parameter matrices, and b_o represents the bias term. The extracted information is used to generate the hidden state h_t and the expression of the hidden state at the time of t is shown in equation (8).

$$h_t = o_t \square \tanh(C_t) \quad (8)$$

In equation (8), the final memory state of the cell at time t , denoted as C_t is input into the hyperbolic tangent function for calculation. Subsequently, the output gate, denoted as o_t , is combined with it through an operation represented as \square resulting in the extraction of the information component h_t . The equation (9) can be obtained by associating equations (4), (6) and (8).

$$h_t = o_t \square \tanh(C_{t-1} \square f_t + i_t \square \tanh(W_c h_{t-1} + U_c x_t + b_c)) \quad (9)$$

From equation (9), h_t is the size of the hidden state at the moment of t . W_c is the main cause of the gradient disappearance inside the traditional recurrent NN, while here, when the forgetting gate f_t is opened, the gradient of C_t can be effectively passed to the cell state C_{t-1} at the previous moment; so by adding the gating structure on top of the traditional recurrent NN.

B. Bidirectional Long and Short Time Memory Network and Improvement Method

LSTM can effectively improve the gradient disappearance and gradient explosion problems though. However, it can only process data in one direction in the time series problem, which often ignores future information [19-20]. In contrast, bidirectional LSTM networks can propagate not only forward but also backwards, and this combination of combining past information with future information is similar to the human appreciation of music [21-22]. Using this approach to train the MIDI piano playing evaluation model, more reliable parameters can be obtained and the piano performance evaluation accuracy can be improved. Fig. 2 shows the structure of a bidirectional recurrent NN.

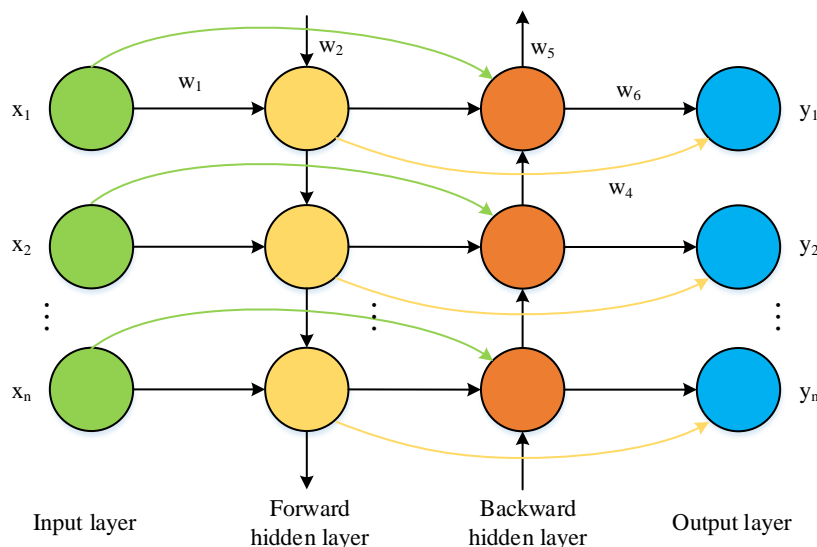

Fig. 2. Structure of bidirectional recurrent neural network.

In Fig. 2, the bidirectional recurrent NN consists of two recurrent neural networks connected backwards and use the tanh function as the activation function, and the output layer receives information not only from forward propagation, but also from backward propagation, and there is information exchange between the forward hidden layer and the backward hidden layer. In Fig. 2, $w_1 - w_6$ are six different ways of information transfer, which have the same weights in the information transfer process. It is difficult to establish the dependency between the current information and the remote information in the bidirectional recurrent neural network because of the gradient descent. Therefore, the neuron module in the hidden layer of the bidirectional recurrent NN is replaced with the LSTM network module to become a bidirectional LSTM model. The bidirectional LSTM model can not only effectively reduce the probability of gradient explosion, but also maintain the dependency relationship between the current value and the remote value. This way of processing both past and future information is consistent with the traditional music evaluation method, and can better judge the expression and coherence of music so that the MIDI piano performance can be accurately evaluated. To better apply the bidirectional LSTM network to the MIDI piano playing evaluation model, the study combines the attention mechanism and the Softmax function, which is mainly to resolve the difficulty of remote information dependence, and its expression is shown in equation (10).

$$\alpha = \frac{\exp(e_{t,i})}{\sum_{j=1}^N \exp(e_{t,j})} \quad (10)$$

In equation (10), $\exp(e_{t,i})$ denotes the output value of the bidirectional LSTM model. After the input music information is passed through the attention mechanism layer, it is then classified using the Softmax function, which is normalized to obtain the probability of which category the MIDI music belongs to. The Softmax function is a nonlinear function that maps the output of multiple neurons to a vector of real

numbers in the interval (0,1), and the sum of all elements in the real vector is 1. Its expression is shown in equation (11) is shown.

$$S(x_j) = \frac{e^x j}{\sum_{k=1}^k e^x k}, j = 1, 2, \dots, K \quad (11)$$

In equation (11), $S(x_j)$ denotes the value of the i -th dimension of the feature vector and k denotes the number of categories. Equation (12) is the equation for the MIDI piano playing classification label.

$$\hat{m} = \arg \max S(x_j) \quad (12)$$

There is a very simple functional relationship between the gradient of the cross-entropy function and the output value of Softmax, which can save a lot of time in the gradient calculation and make the calculation faster and more stable. Therefore, the loss function for the training of the MIDI music evaluation prediction model is chosen as the categorical cross-entropy function, whose functional expression is shown in equation (13).

$$L = -\sum_{j=1}^T y_j \log s_j \quad (13)$$

In equation (13), s_j denotes the estimated probability of each category in the classification, and T is the number of categories in the classification. The study improves the precision of MIDI piano playing evaluation by incorporating the attention mechanism and Softmax function in the bidirectional LSTM network, and better provides technical support for the development of piano online education.

C. Design of Piano Performance Evaluation Model Based on Two-way Long and Short Time Memory Network

To perform accurate evaluation of MIDI piano performance, the study proposes to implement a bidirectional LSTM neural network model with an attention mechanism on

the framework of Spark and Deeplearning4J to evaluate MIDI piano performance with this model. The model mainly consists of a data acquisition module, data pre-processing module and music evaluation classification module, and its specific framework diagram is shown in Fig. 3.

From Fig. 3, the MIDI piano playing evaluation model is mainly divided into three modules: data acquisition, data pre-processing and music evaluation classification. The data pre-processing module mainly filters the original data that are not suitable for model training or transforms them into a matrix suitable for model training, and divides the data into a training set, validation set, and test set; the data acquisition module uses the acquisition tool to migrate data to the storage

system; the model is primarily trained on pre-processed data in the classification module. The parameters of the model are then adjusted in real-time in response to the training results to obtain model parameters with better evaluation effects. The test set data are then trained to obtain the rating prediction results for the purpose of classification by the model after the parameters have been adjusted. In the evaluation of MIDI piano performance is usually evaluated for multiple MIDI music, and the evaluation results are divided into five grades: excellent, good, moderate, poor, and bad. The study uses the bidirectional LSTM NN and attention mechanism layer in deep learning to classify by softmax function to evaluate MIDI piano performance more accurately.

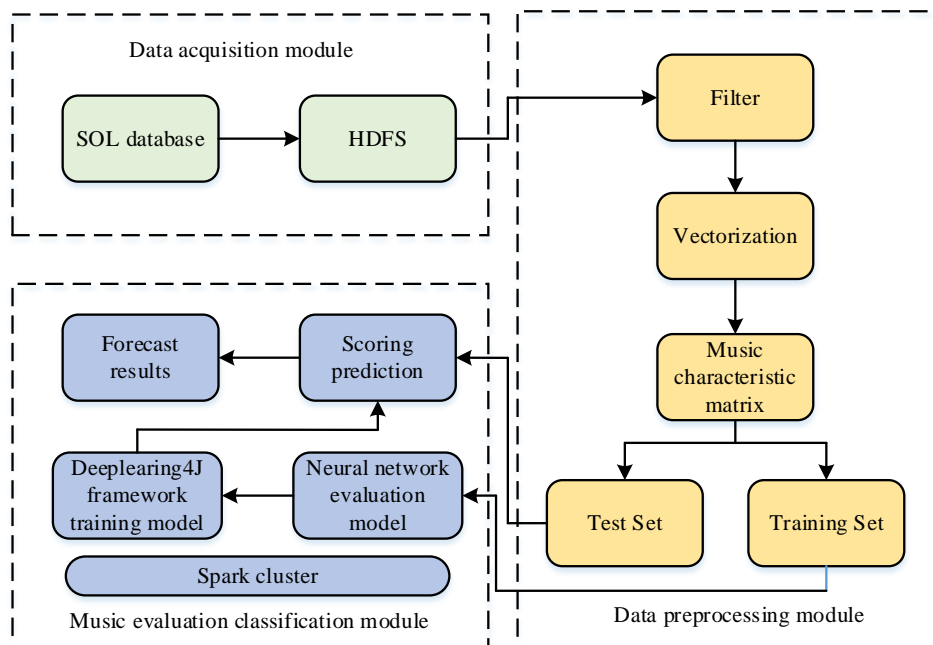

Fig. 3. MIDI-Piano Evaluation Model Framework.

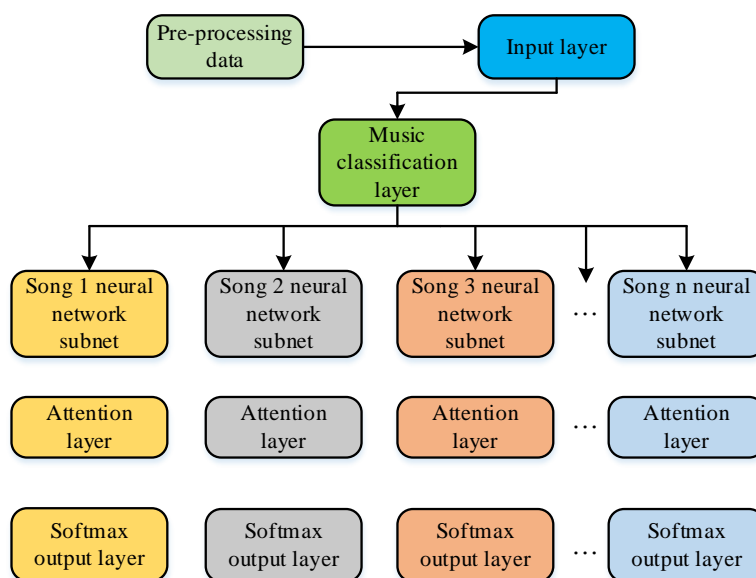

Fig. 4. Bidirectional LSTM neural network evaluation model.

Fig. 4 shows the structure of the bidirectional LSTM NN evaluation model, in which several subnet models are included, and each subnet model needs to be trained separately to ensure that each subnet model is evaluated for a specific piano repertoire, thus realizing the function of evaluating multiple piano repertoires. In the evaluation process of the subnet models, the differences in the training level of each track are used to obtain the feature matrix, and they are classified into one of five categories: excellent, good, moderate, poor, and bad according to the classification algorithm. In each subnet model mainly consists of an input layer, a bidirectional LSTM layer, an attention mechanism layer, and an output layer. The role of the input layer is to receive the difference sample tracks, obtain the input feature matrix through data preprocessing, and then input to the bidirectional LSTM hidden layer, and after the attention mechanism layer, finally, the evaluation is derived by the softmax function in the output layer. In this way, the evaluation results of MIDI piano performance are obtained and used to promote the development of piano online education and achieve the healthy development of piano online education.

IV. COMPARATIVE ANALYSIS OF MODEL PERFORMANCE AND EMPIRICAL EFFECT ANALYSIS

A. Experimental Results Analysis of Model Performance Comparison

To verify the function of the MIDI piano playing evaluation with the bi-directional LSTM model proposed in the study, the BP, RNN, LSTM, and bi-directional LSTM models with a single hidden layer were compared in the experiments, and the model accuracy, precision, recall, and F1 values were compared as the comparison indexes. Accuracy refers to the percentage of the number of samples correctly classified by the classifier to the total number of samples, reflecting the situation where the classifier correctly identifies each sample. The calculation equation is shown in Equation (14).

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (14)$$

In equation (14), TP represents true positive; TN represents true negative, FP and FN represent false positive and false negative. Accuracy refers to the number of true cases in the sample where the prediction result is positive,

and the calculation equation is shown in Equation (15).

$$Precision = \frac{TP}{TP + FP} \quad (15)$$

Recall refers to the percentage of positive predictions, with the equation shown in Equation (16).

$$Recall = \frac{TP}{TP + FN} \quad (16)$$

In order to better evaluate the performance of the classifier, the precision and the recall rate are called the measure, and the calculation equation is shown in Equation (17).

$$F_\alpha = \frac{(1 + \alpha^2) * Precision * Recall}{\alpha^2 * Precision + Recall} \quad (17)$$

In equation (17), α is a non-negative real number. When α is 1, it is F1, which is the harmonic mean of precision and recall.

The Google Open Image dataset is used as a test set to compare the accuracy of the four models. The Google Open Image dataset contains 1.9 million images, 600 species and 15.4 million bounding box annotations. It is currently the largest dataset with object location annotation information. The results of the accuracy comparison of the four algorithms are shown in Fig. 5.

Fig. 5 shows the accuracy curves of the four different models compared with epochs, from which the accuracy curves of the bidirectional LSTM model are higher than those of the other three models, and the accuracy curves show an increasing trend with the increase of the number of iterations. The accuracy curve of the two-way LSTM model has a maximum value of 0.91, which is higher than the LSTM model (0.73), the BP model (0.46) and the RNN model (0.38), and the performance of the two-way LSTM model is better than the three comparison models in terms of accuracy dimension. The Google Open Image dataset was used as the training and test set to perform two comparison experiments on the four models, and the results of the four models in five different classification categories were compared. The accuracy rate curves of the four models in the two comparison experiments are shown in Fig. 6.

Fig. 5. Comparison of accuracy of different models.

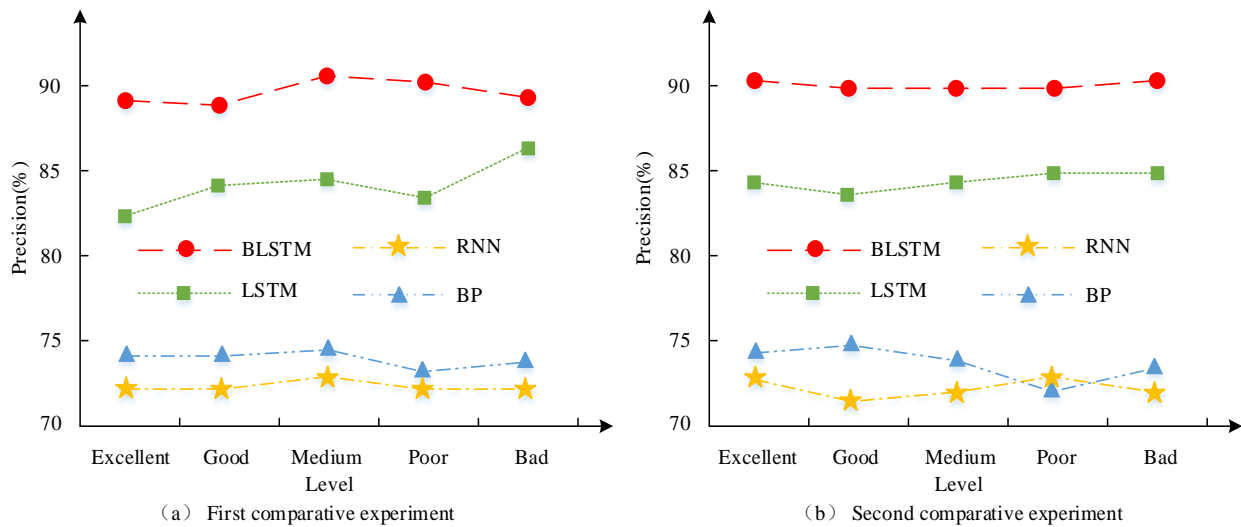

Fig. 6. Accuracy curve of two comparative experiments.

Fig. 6 shows the precision rate curves of the four models in the five classification categories. Fig. 6(a) shows the results of the first comparison experiment. From Fig. 6(a), the precision curves of the bidirectional LSTM model are higher than those of the other three models, and its average precision rate is 88.7 % in the datasets of the five different categories, which is higher than that of the LSTM (83.8%), the BP (73.9%) and RNN (72.6%). Fig. 6(b) shows the results of the second comparison experiment. From Fig. 6(b), the precision curve of the bidirectional LSTM model is higher than the other three models, and its average precision rate in the dataset of five different categories is 89.3%, which is higher than 84.1% of the LSTM model, 73.8% of the BP model, and 72.9% of the RNN model. The above results indicate that the two-way LSTM model has the best performance in terms of the dimension of precision rate. Fig. 7 shows the recall curves of

the four models.

Fig. 7 shows the recall curves of the four models in the five classification categories. Fig. 7 (a) shows the results of the first comparison experiment, from which the recall curve of the bidirectional LSTM is higher than the other three models, and its average recall rate in the five different categories 88.8% is higher than that of LSTM (79.5%), BP (68.4%) and the RNN model (63.4%). Fig. 7(b) shows the results of the second comparison experiment. From Fig. 7(b), the recall curve of the bidirectional LSTM model is higher than the other three models, and its average recall rate in the dataset of five different categories is 89.2%, which is higher than LSTM (79.8%), BP (68.8%), and RNN (63.6%). The above results indicate that the two-way LSTM model has the best performance in terms of the dimension of recall rate. Fig. 8 shows the F1 value curves of the four models.

Fig. 7. Recall rate curve of two comparative experiments.

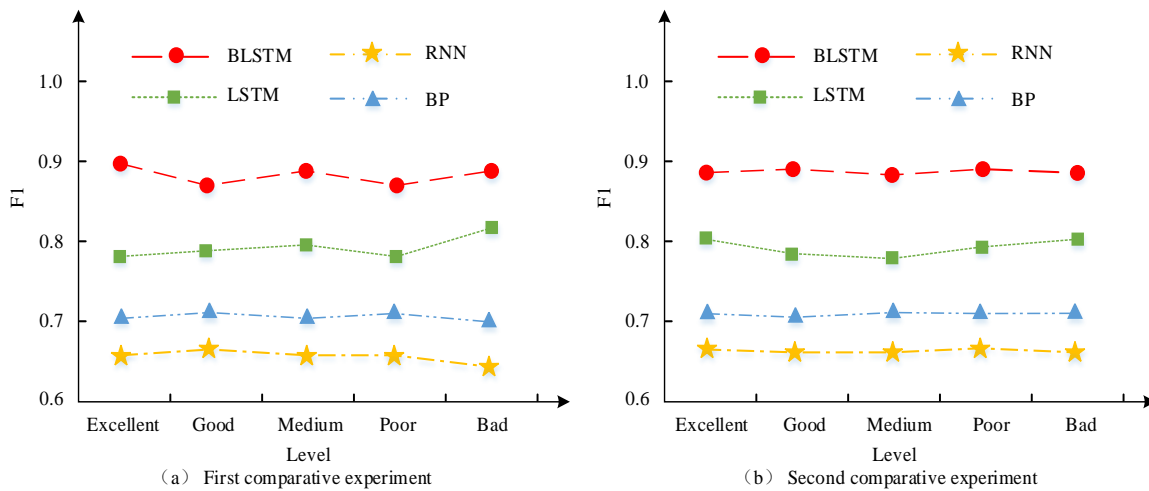

Fig. 8. F1 value curve of two comparative experiments.

Fig. 8 shows the F1 value curves of the four models in the five classification categories. Fig. 8(a) shows the results of the first comparison experiment, from which the F1 value curve of the two-way LSTM is higher than the other three models, and its average F1 value in the five different categories is 0.88, which is higher than LSTM (0.79), BP (0.70) and RNN (0.65). The above results show that the bidirectional LSTM model has a higher F1 value curve than the other three models, and its average F1 value is 0.89 in the data set of five different categories, which is higher than LSTM (0.78), BP (0.71) and RNN (0.66). In conclusion, the overall performance of the bidirectional LSTM model is better than that of the LSTM model, BP model and RNN model, and using this model to evaluate MIDI piano playing can improve the accuracy of the evaluation model.

B. Effect Analysis of Evaluation Model Based on Bidirectional Long Term Memory Network in Piano Online Education

In addition to testing the function of the proposed model, the study also analyzed the actual teaching effects of its integration into piano online education. Students with the same basic information were divided into two groups, and the

experimental group was taught with the piano online education course integrated with the model, while the control group was taught with the regular piano online education course. The results of students' performance level score and willingness to participate in the course for both groups are shown in Fig. 9. Both evaluation indexes have a full score of 10.

As can be seen in Fig. 9(a), the performance score of the experimental group was higher than control group in all five groups, and the average performance level score of the experimental group was 8.9, much higher than control group, which was 7.3. As can be seen in Fig. 9(b), the willingness to participate in lessons was higher than control group in all five groups, and the average willingness to participate in lessons of the experimental group was 8.7, much higher than control group, which was 7.5. The average willingness score of the experimental group is 8.7, which is much higher than the 7.5 score of the control group. These results indicate that the LSTM-based MIDI piano performance evaluation model can effectively improve academic piano performance and willingness to participate in lessons. In addition, Table I shows the results of the questionnaire on students' subjective emotional experiences.

Fig. 9. Performance score and willingness to participate.

TABLE I. SUBJECTIVE MOOD SURVEY RESULTS

/	Experimental class	Control class	T	P
Happiness	8.63±0.92	7.56±0.71	1.12	<0.0001
Psychological annoyance	6.57±0.57	7.33±0.69	-0.56	<0.0001
Feeling of fatigue	7.25±0.74	8.13±0.81	-0.47	<0.0001
Initiative	9.17±0.93	7.58±0.83	0.62	<0.0001
Sense of gain	8.85±0.85	7.32±0.76	0.73	<0.0001
Self-confidence	8.98±0.94	7.62±0.82	0.51	<0.0001
Fulfilment	9.08±1.02	8.03±0.79	0.66	<0.0001

Table I demonstrates that the experimental group students' happiness, motivation, acquisition, self-confidence, and achievement scores were higher than those of the control group students, demonstrating that the piano performance evaluation model proposed in the study can effectively improve students' performance in piano online education courses the positive subjective emotional experience. Additionally, Table I demonstrates that the piano performance evaluation model can lessen students' negative subjective emotional experiences. In conclusion, the piano performance evaluation model applied to the piano online education course can improve the overall teaching quality of the physical education course, promote students' positive emotions in class, and can improve students' piano performance level.

V. DISCUSSION

With the continuous improvement of people's material living standards, their awareness of spiritual needs is also deepening, which promotes the second rapid development of piano education. Whether it is entering art schools for collective learning or seeking individual learning opportunities for piano lessons, the demands on piano education professionals are increasing, and the number of traditional piano teachers in China is seriously insufficient, making the contradiction between supply and demand difficult to solve in the short term. In addition, due to the lack of formal teaching and training institutions and teachers, many piano students acquire piano knowledge and skills through self-study or entrust others with their practice. In the field of piano education, the commission received by traditional teachers is

generally high, and the price of wooden pianos is also very high, which makes it difficult for ordinary families to afford them, and the high cost has become an important obstacle to the development of piano education. In addition, due to the large population in our country, parents and children are the only children, which leads to the outdated concept of family education, the lack of scientific and systematic guidance, so that piano education has been in the "low age" stage for a long time. Therefore, in the process of promoting piano education, reducing the cost of learning has become an essential trend. MIDI is a protocol proposed in the early 1980s to solve the communication between electroacoustic instruments. With the development trend of "network + education", MIDI piano has gradually become an indispensable tool in piano education.

In this study, the MIDI piano performance evaluation model based on bidirectional LSTM was compared with BP, RNN and LSTM models. From the perspective of the accuracy dimension, the accuracy of the bidirectional LSTM model is higher than 0.73 of the LSTM model, 0.46 of the BP model and 0.38 of the RNN model. Compared to the three comparison models, the bidirectional LSTM model has a better performance. Similar results were found in the study by Dandil's team [23]. From the accuracy dimension, in the first comparison experiment, the accuracy of the bidirectional LSTM model is higher than 83.8% of the LSTM model, 73.9% of the BP model and 72.7% of the RNN model. In the second comparison experiment, the accuracy of the bidirectional LSTM model is higher than 84.1% of the LSTM model, 73.8% of the BP model and 72.9% of the RNN model, and the performance of the bidirectional LSTM model is the best

compared to the three comparison models. This is similar to the conclusion obtained by Xie et al. [24]. From the dimension of recall rate, in the first comparison experiment, the recall rate of the bidirectional LSTM model is higher than 79.5% of the LSTM model, 68.4% of the BP model and 63.4% of the RNN model. In the second comparison experiment, the recall rate of the bidirectional LSTM model is higher than 79.8% of the LSTM model, 68.8% of the BP model and 63.6% of the RNN model, and the performance of the bidirectional LSTM model is the best compared to the three comparison models. Tao's team also found similar results [25]. From the perspective of F1 value dimension, in the first comparison experiment, F1 value of the bidirectional LSTM model among the four models was higher than 0.79 of the LSTM model, 0.70 of the BP model and 0.65 of the RNN model. In the second comparison experiment, the F1 value of the bidirectional LSTM model is higher than 0.78 of the LSTM model, 0.71 of the BP model and 0.66 of the RNN model. The performance of the bidirectional LSTM model is the best among the three comparison models. This is in line with the conclusion of Jian et al [26].

In addition to testing the performance of the proposed evaluation model, this study also analyzes the actual teaching effect of integrating it into online piano education. The experimental group took the piano online education course integrated with the model for teaching, and the control group took the conventional piano online education course for teaching, and the score of piano playing level and students' subjective experience were used as evaluation indicators for comparative analysis. Among the five groups, the score of the performance level of the experimental group was 8.9 points higher than that of the control group, and the score of the experimental group's willingness to participate in the class was 8.7 points higher than that of the control group. It can be seen that the MIDI piano performance evaluation model based on LSTM can effectively improve the academic piano performance level and the willingness to participate in the class. This result is consistent with the research findings of Bao's team [27]. In addition, by conducting a questionnaire on students' subjective emotional experience, the scores of happiness, initiative, sense of gain, self-confidence and achievement of students in the experimental group were all higher than those of students in the control group, indicating that the piano performance evaluation model proposed in this study can effectively improve students' positive subjective emotional experience in online piano education courses.

VI. CONCLUSION

In this study, performance comparison experiments were conducted on the proposed two-way LSTM performance evaluation model, and the results showed that the accuracy rate, accuracy rate, recall rate and F1 value of the model were 0.91, 88.7%, 88.8% and 0.88, respectively, which were higher than the other three comparison models. In addition, in the empirical analysis of the model, it is found that the model can not only improve the performance level and enthusiasm of the students, but also promote the positive subjective emotions of the students. In conclusion, the improved MIDI piano performance evaluation model based on two-way LSTM is not only accurate, but can also promote the development of online

piano education. This research innovatively integrates the two-way LSTM network model into the piano performance evaluation model, which not only improves the evaluation accuracy of the piano performance evaluation model, but also improves the integration degree of deep learning and piano education, making up for the lack of integration between the current piano education and deep learning. However, there are still shortcomings in the process of this study, such as crude evaluation and classification methods and unreasonable selection of data sets. In the future, it is necessary to find effective evaluation and classification methods, and to obtain more closely related data sets through self-preprocessing for comparison experiments in order to obtain more accurate results.

ACKNOWLEDGMENT

The research is supported by this paper is the phased result of the 2022 Annual Scientific Research Fund Project of "Guizhou Education University" (No. 2022BS001).

Methodological Insights Towards Leveraging Performance in Video Object Tracking and Detection

Divyaprabha¹, Dr. M.Z Kurian²

Research Scholar¹, Professor²

Dept. of Electronics & Communication Engg, Sri Siddhartha Institute of Technology, Tumkur, India^{1,2}

Abstract—Video Object Detection and Tracking (VODT), one of its integral operations of surveillance system in present time, mechanizes a way to identify and track the target object autonomously and seamlessly within its visual field. However, the challenges associated with video feeding are immensely high, and the scene context is out of human control, posing an impediment to a successful model of VODT. The presented work has discussed about effectiveness of existing VODT approaches considering its identified taxonomies viz. satellite based, remote sensing-based, unmanned-based, Real-time Tracking based, behavioral analysis and event detection based, integration of multiple data sources, and privacy and ethics. Further, research trend associated with cumulative publications and evolving methods to realize the frequently used methodologies in VODT. Further, the results of review showcase that there is prominent research gap of manifold attributes that demands to be addressed for improving performance of VODT.

Keywords—Object detection; object tracking; video; visual field; surveillance system; video feed

I. INTRODUCTION

Object detection and tracking are essential operations that any surveillance system demands [1]. Irrespective of archives of research models presented to date, there is still an open concern associated with object detection and tracking [2]-[5]. One of the significant shortcomings of cumulative research work is the lack of any model which can guarantee maximized performance, higher accuracy and dominantly robust [6]-[8]. The prime challenges are encountered in this domain mainly because of the condition stated towards tracking and detecting an object for a given scenario. The complexity of such implementation depends upon the use cases. In the case of objects with fewer visual features, it is subjectively easier to detect all the features associated with that visual characteristic. However, complexity arises for the object of dynamic type, where extraction of features is quite a complex process in the presence of challenging background and foreground situations. Predominant challenges surface regarding Video Object Detection and Tracking (VODT), especially for moving objects in general. However, there could be multiple mobility situations and statics of either foreground or background [9]. Various other factors that impose challenges in VODT are occlusion (full/partial), fluctuation in illumination condition, deformation of the target, and variability in the pose of the target object. Various standard approaches of detection consist of object detection based on i) features (color, shape) [10], ii) template (deformable / fixed) [11], and iii) motion (global energy, statistical test, thresholding) [12]. On the other, the

approaches of tracking are carried out using motion information mainly (region, boundary) [13]. The conventional mechanism of VODT emphasizes two essential attributes, i.e., information related to the motion of the target object and visual features (e.g., shape, texture, color, etc.). Owing to the variable nature of such attributes, it is always better to perform the modeling of VODT by integrating temporal features and statistical models with visual features [14]. Normally, the process of VODT consists of obtaining regions based on visual features using frame segmentation followed by combining all regions characterized by equivalent motion vectors. The majority of the existing approaches of VODT are witnessed with the adoption of multiple forms of approach as well as a combination of approaches. The area of implementation is so scattered that there is a lack of any uniform approach towards VODT with a consistent track of performance. It is essential to offer a comprehensive insight into various study models towards VODT to identify the possibilities of future research work by reviewing its strength and weakness. Therefore, the proposed study discusses existing approaches to offer insight into the effectiveness of existing VODT. The contributions made in the proposed paper are:

- Commercial usage of VODT is discussed to understand global deployment in the practical world,
- Existing approaches are classified concerning some potential use cases of deployment to understand the effectiveness in deployment scenarios,
- Discussion of research trends is carried out to offer insight into identifying frequently used techniques,
- A crisp discussion of the research gap associated with existing VODT techniques.

The organization of this paper is as follows: Section II discusses insight into the commercial application of VODT, followed by an elaborated discussion with the classification of VODT approaches in Section III. A discussion of the most frequently adopted video dataset is carried out in Section IV. At the same time, the research trend is discussed in Section V. Highlights of the results discussion is carried out in Section VI, while conclusive remarks are stated in Section VII.

II. COMMERCIAL USAGE OF VODT

The commercial usage of ODT mainly performs localization, identification, tracking, counting, and recognizing the anomalies of an object of specific form present within the captured image frame of the Video. The ranges of such objects

are quite wide enough. The devices that perform such tasks consist of recognition and classification modules. In general, ODT from the video scene is carried out by extracting the object from the background image, presenting an anticipated equivalent object class proposition. Finally, a bounding box is constructed to encapsulate the object. This section discusses the different use cases of the application of ODT.

A. Smart City Usage

With the advent of the Internet-of-Things (IoT), the environment of a smart city is now equipped with multi-functional sensors and sophisticated devices for monitoring. Various ODT applications find a suitably higher scope in smart cities, viz.

- **Monitoring of In-Cabin Space:** Modern technologies are now used for monitoring the environment inside a closed space like a home or vehicle to understand people's behavior. This is done using computer vision, eye tracking, pose estimation, etc. It is specifically helpful in detecting drivers' drowsiness to make the ride safer [15].
- **Occupancy of Parking Site:** The mechanism of VODT in computer vision is used for classifying vacant and occupied parking areas. The information can be transmitted in real-time directly to the driver directing them towards the target open end parking space [16].
- **Counting People:** This application tracks visitors' counts to plan security in public areas. They are usually deployed in transit areas, which can capture data on incoming and outgoing people for security and capacity management [17].
- **Monitoring Traffic:** Various Road and traffic conditions can be monitored via VODT. Multiple zones in the city can be monitored to identify congestion or violation in driving or accidents. It is also used for identifying the vehicle's registration details by capturing the license plate image [18].
- **Autonomous Driving:** Unmanned driving vehicle is the next vehicle level with the advancement of computer vision technology. Such application uses VODT to identify traffic signs, markers on the lane, vehicles, pedestrians, etc. [19].

B. Industrial Usage

ODT is also used for various industrial applications on a large and small scale. The following are the different uses of VODT:

- **Enhancing Productivity:** Multiple activities of the workers in different locations, e.g., construction sites, production facilities, and warehouses, can be monitored using VODT. The worker's activities can be monitored while retaining private information [20].
- **Detection of Defect & Anomaly:** Different forms of industrial products can be assessed using computer

vision to identify the defects or sub-standard quality in finished products. Various processes associated with quality control, production lines, and workstations can be monitored using VODT [21].

- **Product Assembly:** Adoption of ODT can be used for ensuring the selection of appropriate components over the assembly lines. Different forms of automated production systems and robotics are facilitated with various intelligent feeds from the ODT system [22].
- **Detection of PPE:** ODT can also be used to ensure worker safety. This is done by evaluating if the employees have put on a specific form of Personal Protective Equipment (PPE) assigned by the safety standards. The system can distinguish between employees with and without protection gears [23].

C. Retail Usage

The usage of computer vision plays an important role in the retail industry with multiple purposes. The retail sector has manifold concerns about reviewing the user's response, behavior, sales processes, etc. Various retail-based applications are:

- **Customer Experience:** ODT can extract the customer's actions during store visits. It can assist in understanding the possibilities of assistance that any visiting customer may require [24].
- **Analysis of Foot Traffic:** This is nearly similar to object counting applications under smart city usage. This application is used for counting the incoming and outgoing visitors in the store to understand the peak traffic of visitors. The manager can directly analyze this traffic information, assisting in product placement or promoting the product at a specific location [25].
- **Inventory Management:** This application is used for evaluating the availability of products on specific shelves or warehouses. In case of a drop in product availability, the ODT-based system can forward the notification to the inventory manager to restock. Artificial intelligence effectively controls inventory management systems [26].
- **Contactless Checkout:** Contactless kiosk is used for a contactless payment system, an effective solution for crowd and queue management inside the store [27].
- **Video Analytics:** ODT can be used for capturing the feed inside retail to evaluate customers' shopping behavior. Potential analytical information can be obtained from such form of Video feeds powered by artificial intelligence. It can also assist in faster and more effective service delivery within the store with less customer wait time [28].

Therefore, all the taxonomies mentioned above of application for VODT are some of the prime focuses on commercial and research interests. The next section discusses the current approaches of VODT.

III. CURRENT RELATED WORK OF VODT

At present, there are various categories of approaches as well as methodologies that have been undertaken towards investigating VODT problems. However, categorization concerning methodologies is quite a tedious process as it is noted that sometimes the same methodology is adopted to solve two different use cases of problems. Hence, this part of the discussion is based on various use cases of problems being investigated and highlights individual methodologies used to address the problem.

A. Satellite based VODT Approaches

This mechanism calls for capturing the satellite's video feed and applying algorithms to identify the objects from the feeds. It is one of the most evolving and challenging investigation trends in VODT, irrespective of progressive research [29]. Most of the existing research approach targets solving the identification and tracking of smaller objects from satellite video datasets. The prime challenge is to identify the foreground objects, which are smaller and have low contrast. The work carried out by Chen et al. [30] has developed a scheme for enhancing the tracking performance of an object of smaller sizes captured from satellite-annotated images. Hu et al. [31] have constructed a network based on a regression model integrated with gradient descent and convolution layers. The tracker is designed from the background context using a regression network. A deep neural network is used to train motion and appearance features. Shi et al. [32] have implemented a technique for detecting and tracking mobile aircraft. The investigation carried out by Wu et al. [33] constructed an enhanced filter with kernel correlation to track the smaller-sized object. According to this experiment, the mean peak response is integrated with the mean energy of peak correlation associated with the response map to mitigate occluded objects.

Further, an adaptive Kalman filter is used to improve the tracking performance. Xuan et al. also uses a similar methodology line [34] where the motion trajectory is integrated with the Kalman filter to track the smaller object. The study outcome is claimed of 95% accuracy in tracking performance. The work by Zhang et al. [35] has integrated features of optical flow with a Histogram of oriented Gradient (HoG) with a target towards enhancing the target representation. The boundary effects are mitigated by integrating the inertial mechanism and Kalman filter, while the interference attenuation is accomplished using the disruptor-aware process. Zhou et al. [36] performed a unique study considering satellite images where a pyramid network of selected features is presented to address the problem of computing gradient inconsistencies. The study has also introduced a contrastive learning mechanism to represent an object robustly. The work by Zhu et al. [37] used Siamese deep network designed to improve the smaller object representation from satellite videos. This model aims to extract features from the search and template branch in the Siamese network while the target position is determined from the search branch. The model's outcome is proven to offer a satisfactory accuracy evaluated over multiple performance parameters.

B. Remote Sensing-based VODT Approaches

This mechanism identifies and evaluates the physical characteristic associated with a region by computing the radiation emitted from a specific distance. Usually, such monitoring is carried out from aircraft or satellites using specific feed-capturing devices. The present research is being carried out towards remote sensing-based VODT using a conventional mechanism [38] that consists of simplified object detection and tracking. Detection is facilitated by various techniques, e.g., background subtraction process, optical flow mechanism, and method of computing frame difference. The work carried out by Lei and Guo [39] implemented a technique that can detect and track multiple objects considering the Gaussian mixture model for extracting road networks using deep learning.

Further, a neighborhood search mechanism is implemented for tracking connected with the data association method. The neural network adoption is witnessed in Lin's [40] work, where tracking is carried out for multiple targets. The implementation is carried out considering the integration of real-time tracking of the target using deep learning, combined geometric features, and a dual neural network. The study model also constructs an optimization mechanism using the least squares method, where the constrained residual terms are developed over the pixel plane. A unit for inertial measurement is developed. Finally, a mathematical model is constructed for multitarget tracking. The mechanism presented by Ma [41] discusses enhancing the probability of identifying objects with poor signal quality and minimizing the number of outliers. Another unique study has been presented by Tochon et al. [42] on chemical gas plume tracking. Considering hyperspectral Video sequences, the author has used object detection sequentially, considering temporal, spatial, and spectral information. The work carried out by Uzkent et al. [43] [44], where a fusion mechanism of kinematic likelihood is estimated for analyzing hyperspectral information. The idea is to detect and track mobile objects captured from aerial Video over a short time window.

Further, the author has also used deep features for improving the tracking performance using a convolution neural network and kernelized correlation filter. However, the study model cannot process an isometric view of the scene. This problem is reported to be addressed in the work of Wei et al. [45], where a three-dimensional view is considered with total variation towards tracking a moving object.

C. Unmanned VODT Approaches

Various existing VODT use cases have considered the Video captured from Unmanned Aerial Vehicle (UAV) system. The work carried out by Cintas et al. [46] has constructed a model that can perform tracking of UAV using vision factor from another UAV using a deep learning approach and kernelized correlation filter. Deng et al. [47] used a regularization method using spatial and temporal attributes and constructing an enhanced filter for discriminative correlation. The technique also uses a joint optimization mechanism to improve target representation and reduce distractors. A unique method is implemented by Ding et al. [48], where object detection for UAVs is carried out by blockchain and hash-based approach. According to this implementation, a hash-

based network is constructed for extracting the hash representation of an object where further recovery of tracking interrupts and feature fusion is carried out. The study model also integrates motion features with deep hash features to address the problem of object occlusion. Detection of a small object is carried out by Liang et al. [49] using a fusion of features and Detection of a single shot based on scaling operation. A feature pyramid is constructed using average pooling operation. The fusion of the feature module and the deconvolution module is used for generating the feature pyramid. Lin et al. [50] have designed a correlation filter based on blocks' bidirectional incongruity towards tracking objects. Buhler et al. [51] have carried out a different form of work that doesn't work on video object detection or tracking algorithm but offers a robust platform to perform such tasks. The authors have used remote sensing images of snowflakes to classify snow types' normal to critical states. Shan et al. [52] have developed a ship-tracking mechanism considering maritime data over multiple videos with manual annotation. Xue et al. [53] have developed a semantic-based framework for object tracking to improve the performance of correlation filters of discriminative nature. The study model generates the specific region of interest followed by filtering where the semantic coefficient prediction is carried out. The study model also contributes towards reducing parametric redundancy by sharing the object's semantic segmentation information and network layer. The adoption of a correlation filter is also witnessed in the work of Ye et al. [54]. The study model applies a concept of multi-regularization toward constructing a correlation filter to facilitate the tracking and localization of an object. The work carried out by Yu et al. [55] has developed a region of interest while object detection is carried out from radar and photoelectric cell.

D. Miscellaneous Approaches

Various methodologies are being introduced, considering different forms of use cases. The work carried out by Banerjee et al. [56] has developed a hardware design of architecture for the acquisition of Video. The study model uses dynamic programming towards the reduction of normalized area for the allocation of resources. Further, the Kalman filter is used for performing tracks. A simplified mechanism of object detection and tracking is carried out by Chen et al. [57], where a region of interest in a closed loop is developed to magnify the field of view, considering spatial and temporal attributes of the feed. Cheng et al. [58] have developed a framework to track commodities where the edge computation caters to resource dependencies. The model can also track multiple videos while significantly controlling computation overhead.

Further, the Markov model is designed for compensating the missing data. A similar form of edge computing investigation is also carried out by Gu et al. [59], where a Siamese convolution network is constructed to carry out object tracking. A collaborative architecture of cloud and edge computation is designed for this purpose. The adoption of the Siamese network is also reported in work carried out by Lee et al. [60] towards object tracking. According to this model, a bounding box encapsulates the object, followed by tracking using a Siamese network which minimizes the computational complexity. Object detection is carried out towards each

classified object in Video, followed by performing tracking using sequential frames. All the obtained retargeted frames are obtained by rearranging all frames.

A discreet and unique model of object tracking is designed by Liu et al. [61], which addresses the problem of the extreme degree of occlusion. It also assists in the classification of similar forms of objects. The study model uses a depth tracking mechanism and presents a matching strategy of two look-alike objects using semantics using indoor scene video. The study by Marshall et al. [62] developed a three-dimensional tracking mechanism of an object of radiological or nuclear type. The study uses a Kalman filter to perform tracking using multiple cameras of a specific form. Mostafa et al. [63] have developed a computational model of multi-object tracking using the Kalman filter for tracking crowds. According to this model, a unique encoder model is designed to generate computationally efficient features.

Further, a linear transformation is carried out to retain maximum accuracy. Ramesh et al. [64] have presented a framework for long-term tracking over dynamic motion. Considering a usual tracking condition, the proposed scheme is implemented considering a moving camera where a local sliding window is formulated to confirm the higher reliability. The analysis considers quantitative analysis, rotation, and translation in a laboratory environment. The work carried out by Ren et al. [65] has discussed a computational model that can perform both tracks as well as counting from the crowd scene using a network flow approach. Sun et al. [66] have implemented a study model for tracking multiple objects. The presented study uses deep learning to optimize the representation of an object and their respective affinities occurring over every frame. An affinity-based deep learning network is designed to track objects present and disappearing from the frames. Eventually, the problem of the missing object is addressed in this work.

E. Robust Real-Time Object Tracking

The practical applications of object tracking demand its operation of real-time feed of video stream which is one the most challenging task. At present, there are certain research work which has been dedicated purely towards ensuring robust real-time object tracking. The work carried out by Zhang and Ren [67] have used Kalman Filter and Kernel Correlation Filter in order to carry out object detection. Further, missed detection is addressed by updating the tracking box as per the rate of change in scaling. Backstepping is used for catering the design of kinematic controller with respect to Lyapunov stability. Further, the work of Cao et al. [68] have addressed the issues associated with tracking drift and loss of object by using Siamese network with double template while the feature extraction is performed by enhanced MobileNet V2. Similar work is also carried out by Zhao et al. [69] where Siamese Network is used for estimation of optical flow based on feature pyramid approach. The movement attributes are further evaluated using mapping of pyramid correlation between two contiguous frames. The study also addresses the problems associated with ambient noise using channel and spatial attention. Another study of real-time object tracking is carried out by Du et al. [70] that addresses the problems associated with implementing Correlation Filter-based Trackers (CFT) on

practical grounds. In this mechanism, feature extraction is carried out using Histogram of oriented Gradient (HoG) followed by integration of scale adaptive, target re-detection, and discriminative appearance model. Although, there are various research work carried out towards object tracking, but only few of the recent work has been claimed towards real-time tracking. Another perspective is that these studies doesn't address overall agenda-based attributes that is demanded for real-time tracking e.g., initialization and re-detection, computational constraint, fast motion, motion blur, perspective and scale changes, and occlusion all together. Only few of the above-mentioned attributes have been chosen in current works on real-time object tracking.

F. Behavioral Analysis and Event Detection

There are various unique studies being carried out towards object detection in the perspective of event detection and behavioral analysis. The work of Chakole et al. [71] has addressed the issues pertaining to anomaly detection for the use-case of crowd behavior using correlation-based optical flow. Object detection has also been studied with respect to recognition mechanism of human activity. A typical structure of recognition of human activity is designed by Vrskova et al. [72] using deep learning approach. The prime motive of this work is to address the challenge associated with the less availability of such dataset, where the authors have constructed a new dataset consisting of abnormal activities. Study associated with anomaly detection is carried out by Chang et al. [73], Yahaya et al. [74], and Yang et al. [75]. Such methodologies are meant to identify a discrete vector of motion, which is further subjected to varied strategies in order to perform behavioral analysis. Irrespective of varied approaches used for such form of behavioral analysis, they still have limiting attributes associated with their practical utilization on real-time perspective.

G. Integration of Multiple Data Sources

Majority of the conventional implementation scenario calls for implementing its detection and tracking algorithm considering single sources of data. However, there are certain research work where such objectives are accomplished using multiple sources of data. One such work has been reported by Rehman et al. [76] where visual and audio signals were used as input stream for detection of anomaly. According to this study, the model has integrated particle swarm optimization with optical flow for obtaining visual features. The acoustic features have been obtained from volume, rate of zero crossing, energy, spectral flux etc. Similar pattern of methodology is also created by Benegui and Ionescu [77] which carry out authentication using feeds from camera and motion sensors. Deep neural networks are used using Support Vector Machine for generating an embedding vector obtained from transformed signals. Another similar form of study approach is seen in work of Shin et al. [78] where heterogeneous sources of data e.g., temperature, elevation changes, pattern-specific behavior of human have been considered. The prime notion of this study is to improve the accuracy towards detection of anomaly associated with surveillance map. Majority of the above-

mentioned studies have been carried out by integrating multiple and different sources of data in order to obtain an embedded vector which are further subjected towards analysis towards detection and tracking.

H. Privacy and Ethics

Privacy is one of the essential attributes to be protected while performing object detection. The work carried out by Dave et al. [79] has developed a scheme towards privacy preservation while performing recognition of human action. The authors have used supervised schemes towards removing the private details without any dependency of labelling. The work carried out by He et al. [80] have implemented a mechanism of object blurring as well as object swapping in order to preserve private information while performing object detection. Zhang et al. [81] have used federated learning scheme along with blockchain for detection visual object along with retention of private information. This scheme uses encryption as well as validation nodes in order to resist any form of privacy-related attacks. Further mechanism of object detection along with privacy preservation is carried out by Bai et al. [82] where Convolution Neural Network (CNN) has been utilized along with secret sharing scheme towards protecting private information captured from vehicular edge computing. The prime motive of such approaches is basically to adopted varied privacy preservation approaches ensuring that it won't hamper any parameters potentially responsible for detection of an object.

Hence, it can be seen that there are various ranges of methodologies being developed in current times on various perspective of object detection. It is eventual that all these approaches leverage the performance of object detection addressing issues on local levels and use case.

Apart from this, various works is carried out in conventional VODT with different techniques. One common fact observed in all the miscellaneous techniques is that tracking is more emphasized than preliminary detection operation. As tracking performance completely depends upon the logic configured for the detection module, the performance evaluation doesn't highlight this fact. Apart from this, all the usual and generalized VODT schemes discussed in this section can be used for multiple purposes and assessed over different datasets; however, their applicability towards functional over complex scenarios or challenging video environments is reportedly not investigated. Another significant observation is that most schemes utilize varied principles of framing up the dimension of an object to track the objects in the video stream. However, there is no report of any work towards the generalized object tracking model utilized in the video stream to ensure better analytical operation toward improving the tracking performance. Further, it is noted that there is different use-case specific implementation study where generalization is challenging to be achieved. Table I highlights the summarized version of the discussion in this section concerning methods used for addressing identified research problems, advantages, and limitations.

TABLE I. SUMMARY OF RELATED WORK IN VODT

Author	Problem	Methodology	Advantage	Limitation
Chen et al. [30]	Tracking of the smaller object	Historical model, Kalman filter	Higher Accuracy	Lacks scale adaptive process
Hu et al. [31]	Drift in tracking	Convolution Neural Network, Regression	Better tracking performance	Orientation and position encoding are not feasible
Shi et al. [32]	Tracking mobile aircraft	Shift invariant feature transform	The better predictive calculation for flight path	Not applicable for multiple object tracking
Wu et al. [33]	Tracking of the smaller object	Adaptive Kalman filter	Mitigates occlusion problem	The iterative process leads to a computational burden
Xuan et al. [34]	Tracking of the smaller object	Kalman filter, averaging motion trajectory	95% of accuracy, effective processing speed	Restricted to single object tracking
Zhang et al. [35]	Tracking of the smaller object	Kalman filter, HoG, inertial mechanism	Can perform multi-object tracking, effective classification	Doesn't overcome occlusion problem
Zhou et al. [36]	Gradient inconsistencies	Pyramid network with selected feature scale	Effective reduction of interface	Doesn't consider temporal factors while tracking
Zhu et al. [37]	Inferior distinguishability of objects	Siamese deep network	Offers real-time processing capabilities	It doesn't address the impact of padding and shallow network
Lei and Guo [39]	Detection and tracking	Gaussian Mixture Model, Neighborhood Search	A simplified approach supports multi-object Detection	No benchmarking
Lin [40]	Multitarget tracking	Deep learning, dual neural network	Retain superior tracking quality	Narrowed extensive analysis
Ma [41]	Addressing Outliers in Detection	Probability-based modeling to reduce outliers	Improved rate of Detection	Lower scope of analysis
Tochon et al. [42]	Tracking of chemical gas	Sequential object tracking using temporal, spatial, and spectral information	Reduced computational time	Specific to the composition of chemical gas
Uzkent et al. [43][44]	Tracking of vehicle	Fusion mechanism for kinematic likelihood, convolution neural network, and kernelized correlation filter.	Independent of manual allocation of the threshold for multiple objects	No scope for an isometric view of the scene.
Wei et al. [45]	Object tracking	Principal component analysis	Simplified mechanism of implementation	No benchmarking
Cintas et al. [46]	Tracking UAV from another UAV	Kernelized correlation filter, neural network	82.7% of accuracy, developed a new dataset	Demands more real-time testing to confirm the outcome applicability
Deng et al. [47]	Limited computational capability in UAV tracking	Regularization, correlation filter, joint optimization	Better tracking performance	Higher processing time
Ding et al. [48]	Multiple object tracking	Blockchain, deep hash	Mitigates object occlusion	Consumed higher resources
Liang et al. [49]	Detection of a small object	Spatial context analysis	Higher accuracy	Demands higher resources to map with the outcome
Lin et al. [50]	Improving correlation filter	Discriminative correlation filter	Support real-time tracking with low resources	Outcome specific to data
Buhler et al. [51]	Snow type classification	The reflective property of snow-based modeling	Effective classification strategy	Study model specific to the object
Shan et al. [52]	Ship tracking	Multiple maritime dataset evaluation	Comprehensive analytical approach	Study model specific to the object
Xue et al. [53]	Correlation tracking	Semantic segmentation	Minimize parametric redundancy	It doesn't address the occlusion problem effectively
Ye et al. [54]	Improving correlation filter performance	Multi-regularized filter development	Higher accuracy	Not analyzed on broader assessment environment
Yu et al. [55]	Object tracking	Prediction based on the region of interest, object extraction from the first frame	Reduced processing time	Tracking performance degrades over dynamic background
Banerjee et al. [56]	Acquisition of object	Viterbi, Kalman filter quadtree segmented Video, convolution neural network	Extensive test cases	Needs a broader extensive assessment environment
Chen et al. [57]	Object detection & tracking	Region on interest on a closed loop, dual resolution	Higher resolution	The computationally extensive mechanism for identifying a region of interest
Cheng et al. [58]	Commodity tracking	Edge computing, Markov model	Reduces computational burden	It needs more extensive analysis with recent models
Gu et al. [59]	Object tracking	Siamese Convolution Network, cloud, and edge environment	Reduced energy consumption, Higher accuracy	No extensive analysis
Lee et al. [60]	Object detection	Siamese Convolution network	Higher similarity score	Highly iterative scheme
Liu et al. [61]	Multiple indoor object tracking	Semantic strategy to match objects	Simplified and efficient tracking	It depends upon the illumination condition
Marshall et al. [62]	Object detection	Kalman filter, neural network, non-negative matrix factorization	Reduces anomaly count	Applicability is Specific to this use case only

Mostafa et al. [63]	Crowd tracking	Encoder, Kalman filter	Control over computation time	It depends upon the illumination condition
Ramesh et al. [64]	Object tracking	Bayesian Bootstrapping, sliding window detector	Faster Detection	Assessed over laboratory confined setting.
Ren et al. [65]	Object tracking, Detection, counting	Network flow programming	Supports Multiple operations	The optimization of the counting problem is not addressed
Sun et al. [66]	Tracking multiple objects	Affinity-based deep learning,	Effective analysis	Induces computational complexity over the long run
Zhang and Ren [67]	Real-time object tracking for robots	Kalman Filter, Kernel Correlation Filter	Higher stability of target tracking	Doesn't assess model uncertainty
Cao et al. [68]	Tracking drift, object loss, inadequate robustness	Siamese Network (double template), MobileNet V2	Higher tracking accuracy	Consumes more training efforts
Zhao et al. [69]	Interference of cluttered background	Siamese Network, Pyramid Correlation Mapping, Channel/Spatial attention	Higher success rate of tracking	Time consuming classification
Du et al. [70]	Issues in CFT in real time	HoG, discriminative adaptive model, target re-detection	Simplified architectural implementation	Cannot be applied for objects with consist orientation changes
Chakole et al. [71]	Anomaly detection of crowd	Correlation of optical flow	Satisfactory detection	Not benchmarked
Vrskova et al. [72]	Recognition of abnormal human activity	Long Short-Term Memory	96% of classification accuracy	Induces higher computational burden
Chang et al. [73], Yahaya et al. [74], Yang et al. [75]	Anomaly detection	k-means, autoencoder, support vector machine, deep learning	Multi-target anomaly detection	Some of the outliers are also subjected to training
Rehman et al. [76]	Anomaly detection	Multi-modal (visual and acoustic source)	Improved accuracy.	Restricted to limited data, no extensive analysis over broader dataset size
Benegui and Ionescu [77]	Authentication using difference sources	Deep Neural Network, Support Vector Machine	Higher accuracy score	Not much suitable for larger dataset
Shin et al. [78]	Representation of multimodal data for anomaly detection	Analytical model using temperature, elevation changes, pattern-specific behavior of human	Ideal for surveillance map in smart city	Study not benchmarked
Dave et al. [79]	Privacy preservation during recognition of human activity	Self-supervised learning	Non-dependency of labelling	Model restricted to specific use-case only
He et al. [80]	Privacy preservation	Object swapping and blurring	Retains better accuracy and offers imperceptibility	Not proven using complex forms of object
Zhang et al. [81]	Privacy preservation from visual object detection	Blockchain and federated learning	Offers potential security from maximal threats	Higher cost of implementation
Bai et al. [82]	Privacy preservation	Multiple secret shares, CNN	Offers multi-stage detection, and optimal privacy	Higher resource dependencies

IV. DATASET AND PERFORMANCE METRIC

After reviewing various approaches and research models, the dataset reportedly uses different forms. The frequently used dataset is *ImageNet VID* [83]. It is a benchmarked dataset with training videos of 3862 and validation videos of 555. The frame rates are maintained at 20-30 frames per second while an annotation is provided on all the Videos. Another commonly used dataset is EPIC KITCHEN, which has predefined 290 classes of an object with bounding boxes present in video samples of 32 kitchens [84]. There are also standard datasets used for specific purposes in VODT, viz. i) generalized object detection from the PASCAL dataset [85][86], ii) pedestrian data from Caltech [87], iii) indexing and retrieval of Video from TRECVID [88], iv) categorization data of human activities from HMDB-51 [89], v) annotated and segmented data of sports from Sports-1M [90], vi) tracking of an object from the MOT dataset [91] and VOT dataset [92], vii) detection of a mobile object from the CDnet2014 dataset [93], and viii) segmentation of an object from the DAVIS dataset [94]. Irrespective of availability of wider ranges of dataset, there is considerably a smaller number of research implementation towards involving multi-modal approaches of VODT.

Various performance metrics are deployed while assessing the effectiveness of VODT; however, they are all connected with accuracy-based attributes. The most common performance metric is *mean Average Precision* (mAP), used for assessing an object's traditional detection and tracking. The metric mAP is associated with accuracies of classification and regression. Before evaluating using mAP, the existing system also evaluates confidence scores and true positives. Based on the speed of the mobile object, the inference of mAP is specified in the form of fast, medium, and slow. Certain discussion states that mAP cannot be solely used for performance evaluation as it cannot capture its temporal attributes [95]. Hence, another metric termed *average delay* has surfaced, which computes the number of video frames considered for Detection and tracking from the initial frame. A dataset named ImageNet VIDT was used to verify the appropriateness of the average delay. The study outcome states that satisfactory average precision can be confirmed if the method is witnessed to maximize the average delay value. On the contrary, the maximized value of average delay will also signify maximized delay in Detection and tracking performance. Therefore, it can be stated that if any method deploys average precision as a sole performance metric, then it is challenging to evaluate the actual average delay score. It will eventually conclude that average precision

is insufficient to represent temporal attributes of the assessing framework for VODT. Hence, it is suggested to fine-tune the performance metric based on the research problem undertaken in the study model. The next section discusses the analysis of the research trend.

V. RESEARCH TREND ANALYSIS

From the prior sections, different methodology variants are being deployed toward VODT. However, it is also noted that various common methodologies are being used to consider different use cases of VODT. It is noted that use cases play a critical role in classifying VODT methodology owing to the inclusion of discreet challenges and characteristics. Hence, to understand research trends, the primary assessment has been carried out to identify the popularity of consideration of such use cases in research publications. Fig. 1 highlights the trends of publication of such use-case adoption in VODT.

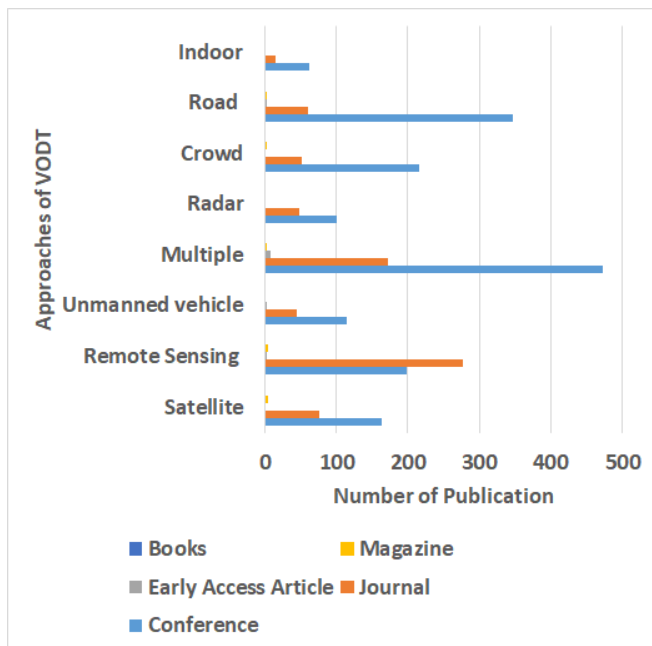

Fig. 1. Trends towards research publication.

The observation towards arriving at the graphical outcome in Fig. 1 is carried out from several different research papers published between 2017 to 2022 from IEEE Xplore, Springer, Elsevier, Wiley, ACM, MDPI, etc. The total number of count of papers for the allocated use case is more than the exhibited figure. This is because the data for Fig. 1 is obtained by filtering out only the significant experiments, excluding all the discussion or conceptual-based publications. The idea was to grab the information associated with including prominent methodologies involved in solving challenges of use cases in VODT. From this graphical outcome of the trend, it is noticed that a greater number of studies are concentrated on remote Sensing and multiple object detection method. Nearly an equivalent number of studies are on satellite-based approaches, unmanned vehicle-based VODT, radar-based VODT, and road/crowd-based VODT. Studies towards indoor-based VODT are significantly fewer. The analysis is also carried out to identify trends in methodologies by removing the constraint of year-based publication. It is noted that evolving trends for

VODT are flow-based, LSTM-based, attention-network-based, tracking-based, and miscellaneous approaches, as stated in Fig. 2.

Fig. 2. Observation of evolving trend.

A closer look into multiple evolving strategies in Fig. 2 concludes that the VODT mechanism is broadly classified concerning feature aggregation and propagation. *Flow-based mechanism* adopts optical flows in dual directions. Significant contribution work was noted towards adopting this technique, viz. Deep Feature Flow [96], feature aggregation with guided flow [97], impression network [98][99][100], flow algorithm using the difference between adjacent frames and adoption of time and spatial factor of the frame, deep learning over FlowNet [101]. Further, adopting *Short-Term Long Memory (LSTM)* is another evolving trend toward maximum utilization of both time and spatial factors associated with video frames. Some of the significant contributions have been carried out by introducing unique techniques, e.g., convolution LSTM [102], online [103], and offline LSTM methods [104] [105]. *The attention-based technique* can analyze the long-duration Video for aligning the feature map with a target to minimize dependency on computational resources. The implication of such mechanism was noted in the form of various approaches viz. approaches considering only temporal factors locally [106] and global factors [107], hybrid method integrating both local and global time-based factors [108], regression and classification-based fusion of feature maps [109], managing external memory with guided objected for global aggregation [107]. The next technique is *tracking-based*, where temporal information is utilized for object detection over video frames with a fixed interval. Some of the significant approaches noted for this approach are adaptive frame-based tracking [110][111], construction of forward and backward trackers [112], adoption of refinement network for integrated Detection and tracking [113], and convolution network-based tracking [114]. Apart from the above-mentioned evolving trends of approaches, there are also *miscellaneous* methods [56]-[66]. The analysis of this approach is further carried out from the perspective of time-based evolution. Fig. 3 highlights the year-wise proposition of the above-stated approaches. The adoption of the ImageNet VID dataset [83] was the first to be evolved in 2015, followed by the evolution of tracking and Detection with cooperation TDC [112] in 2016. There has been progressively developed in the year 2017, which witnessed the Flow of Deep feature FDF

[115] for the first time along with feature aggregation with guided flow FAGF [107] and impression network [100].

Fig. 3. Occurrence of evolving trends year wise.

The speed of new techniques further multiplied in 2018, where multiple techniques have been reported, viz. Detection with high-performance DHP1 [99] and DHPP2 [98] sampling network with spatiotemporal SNS [116], Memory network with spatiotemporal MNS [117], Convolution Neural Network based Tubelets CNNT [118], Detection of a single shot with LSTM and attention SSLA [119], Detection of a single shot with LSTM and attention with feature map LSTM-SSLAFM [120], etc. A similar pace of research trend was reported in the year 2019, where flow and LSTM have potentially improved along with new techniques of Relation Distillation Network FLSTM [106], external memory with guided object EMGO [107], semantic aggregation of level sequence SALS [109], and local attention with progressive sparsity LAPS [121]. The year 2020 and 2021 has witnessed growth in the aggregation of local and global features with improved memory ALGF [108] along with attention LSTM.

Fig. 4 showcases the effectiveness of evolving trends concerning precision scores considering post-precision (PP) and without post-precision. The outcome shows that the involvement of PP always increases the precision, which directly affects the accuracy performance. The score is found to be good for tracking-based and attention-based approaches.

Fig. 4. Precision score for evolving trend.

VI. RESULT AND DISCUSSION

This section presents discussion about gist of learning inference from current review work as well as it also presents a vivid discussion associated with open-end issues of considered methodologies in VODT.

A. Discussion of Current Review

From the prior section, it is noted that there is varied implementation scheme presented towards VODT with unique agenda. One thing is quite clear that every individual research approaches deals with unique set of problems and distinct use-cases. On the other hand, proposed scheme presents review discussion about existing methodologies with an agenda to find its strength and weakness. Hence, it is infeasible to do comparison between implementation-based work and review-based work. However, the study hypothesizes that every research implementation paper must offer a clear-cut highlight of their applicability, about their strength, and about their weakness. Hence, the proposed review considers this common factor to do comparison in order to understand the degree of information associated with merits and demerits linked with suggestion towards further improving VODT. The comparison of the proposed study shown in Table II with the existing considered papers are as follows:

TABLE II. COMPARING PROPOSED SYSTEM WITH CONSIDERED APPROACHES

Approaches	Merit	Demerit
Satellite-based VODT [29]-[37]	Emphasize mechanism to increase accuracy	Doesn't present plan towards increasing adaptivity
Remote Sensing based VODT [38]-[45]	Presents technique to improve detection rate	No discussion towards extensive scope of analysis
Unmanned VODT [46]-[55]	Discusses method to increases accuracy	No solution for increased response time
Real-Time object tracking [67]-[70]	Presents higher stability modelling	No highlights towards addressing less consistent outcomes
Behavioural Analysis/Event Detection [71]-[75]	Supportive of Multi-target detection	No discussion towards increased computational complexity
Data source integration [76]-[78]	Targets higher accuracy	Lack of benchmarking
Privacy & Ethics [79]-[82]	Targets higher security	Higher cost of implementation
Proposed Study	Showcase indicators to balance accuracy and computational complexity	Overlooks security improvements

From Table II, it can be seen that proposed review manuscript offers more information associated with the applicability of various methodologies as well as highlights of various identified issues (discussed in next sub-section) which contributes towards balancing the accuracy demands with computational efficiency demands that is found majorly lacking in maximum considered methodologies in VODT. Further position of current review work with the existing review work is showcased in Table III.

TABLE III. POSITION OF CURRENT REVIEW WITH EXISTING REVIEW

Approaches	Merit	Demerit
Kaur & Singh [3]	Highlight of essential approaches	Emphasize only on deep learning approach
Salari et al. [8]	Informative contents towards scope and challenges in VODT	Lacks highlights of exhaustive research gap discussion
Tulbure et al. [21]	Comprehensive discussion about approaches	Emphasize only on deep CNN approaches
Zhang et al. [29]	Presents methods to deal with complex image-based approaches	Discussion restricted to satellite videos
Proposed Study	Captures all taxonomies of VODT, presents clear highlights of trends, clear cut representation of current research gap	Inference carried out for recent implementation study only

B. Research Gap Analysis

After reviewing the existing schemes of VODT, it is noted that many open-end challenges are still associated with the context of methodologies and use cases considered. A closer look into the efficiencies of all the model exhibit that there is still an open-end issue mainly associated with the speed and accuracy factors balancing with the computational complexities and resource demands. These are some of the areas that have been less emphasized upon. Apart from this, there are few benchmarked datasets which consists of each framed to be labelled. Further, it is noted that ImageNet VID, which is one of the frequently used datasets in VODT, doesn't possess the practical complexities of real scene. Further, the dataset consists of only few objects which are not recommended to be investigated for complex VODT application design. Further, existing schemes either considers global or local information associated with temporal attributes separately. This section outlines the prominent issues being identified in the form of a research gap:

- Issues with the VODT dataset: There are many available datasets for performing VODT, but they lack major benchmarking. The available video dataset doesn't have challenges like a practical environment. Apart from this, very limited objects are present in each frame. Hence, accuracy will always be anticipated to be better while using such video datasets; however, they are less likely to apply to real-world applications.
- Issues with performance metrics: There is no specific standard performance metric for VODT analysis. It should be noted that the performance metric of mAP is extracted from the experiments from object detection of an image. However, mAP cannot process temporal attributes, leading to the evolution of average delay with this evaluation capability. However, this metric cannot evaluate the stability factor associated with the video dataset. Hence, varied ranges of accuracy-based metrics are in practice for assessing the effectiveness of VODT.
- Narrowed Scope of Optimization: An algorithm must encapsulate the maximum constraint condition to

optimize detection and track performance accuracy. A better form of constraint modeling can harness maximum information from the context of Video in the dataset and its associated dynamicity. It demands the utilization of local and global information; however, very few reported studies have such consideration. This imposes an extensive challenge to implement the optimization of VODT.

- Adoption of Complex Method: It is noted that learning-based algorithms are extensively used to improve the overall performance of VODT in many cases. However, such learning algorithms are associated with higher ranges of complexities that are not found to be addressed in existing studies. Adopting such a method (e.g., Convolution Neural Network, Siamese Network) has higher dependencies on training data, indirectly increasing the dependencies of resources required to process it. As a result, it also results in slower computation speed.
- The trade-off between research and practical demand: Although various studies use real-time datasets or developed hardware for VODT, none of them have been analyzed in a real-time environment in the practical world. It is also noted that attention-based approaches offer higher accuracy; however, they have higher processing demand, which impedes catering to real-time demands.
- Other critical challenges: The existing studies carried out towards event detection don't deal with data variability as well as scalability. Further, studies considering recognition of human activity and detection of anomalies are highly dependent on orientation and viewpoints which always vary and such challenges are not addressed in object detection. Identification of real-time object detection and tracking are also quite challenging to be accomplished because of same reason.

From the outcome of the above-mentioned research gap associated with existing video object detection methodologies, it is noted that existing schemes do have their own advantages as well as significant limiting attributes. However, from a global context viewpoint, there are certain contributory suggestions which the proposed study has arrived towards improving or addressing the above-mentioned research gaps. Following are some contributory suggestions towards leveraging the performance of existing video object detection methodologies:

- Encouraging consideration of diverse and large-scale training data: Different challenges associated with backgrounds and wide ranges of classes of an object can be effectively addressed considering diverse dataset with better representation. The idea is to achieve better performance on real-time events and effective generalization.
- Need focus on architecture design: Majority of existing studies are use-case specific with not much emphasizing over architecture-based deployment and extending its applicability. The issues of computational

burden and accuracy can be well balanced if architectures are subjected to optimization.

- Needs practical predictive approach: There are various existing predictive models using branches of artificial intelligence (machine learning and deep learning). However, sustainability of such model over extensive test-cases is not verified. Hence, there is a need of a learning model that can adapt to dynamically changing condition is highly demanded. More research towards ensemble approaches can offer extended robustness and minimize system biases.
- Inclusion of contextual information: The problems associated with accuracy of localization of an object as well as uncertainty connected with instances of an object can be well addressed by including contextual information. Extraction of contextual information can be carried out from semantic segmentation, understanding the scene, and also from surrounding objects.

Hence, all the above-mentioned points are contributory suggestion towards improving video object detection methodology. The next section summarizes the essential highlights of this review work.

VII. CONCLUSION

This paper offers an overview of some notable techniques and approaches towards the VODT, which plays one of the crucial intrinsic operations within any surveillance system. Prior to draw conclusive remarks, it is to be noted that proposed review work formulates certain research questions prior to undertake the review work as follows:

- Ro1: Is the existing review paper towards VODT informative enough to draw conclusive remarks about strength and weakness?
- Ro2: What are the frequently used approaches towards VODT?
- Ro3: What are the issues in multiple approaches towards VODT?
- Ro4: How to improve the performance of VODT differently from existing studies.

After reviewing the existing studies both on perspective of implementation and review work, it is noted that existing papers cannot be used for withdrawing conclusive remarks as they are highly symptomatic in nature. It will mean that they deal with narrowed set of issues while leaving other associated issues unaddressed. This is the response towards Ro₁. The response to Ro₂ is that attention-based and tracking-based approaches are most effectively proven and hence frequently adopted. Towards the response for Ro₃, the multiples issues have been presented in the form of research gap discussed in prior section. The similar sub-section of research gap are also essential points that are required to be considered to improve the performance of VODT that are not presented in existing studies. This acts as response for Ro₄. After reviewing various approaches, it is noted that approaches toward VODT are highly specific to the use cases. The studies are mainly not

emphasized in the methodologies. At the same time, more inclination of existing approaches is found towards solving the problems associated with unique use cases, e.g., satellite-based VODT, unmanned aerial vehicle-based VODT, remote sensing-based studies, multiple tracking-based studies, etc. A smaller number of generalized frameworks can address all the issues about high performance and robust tracking and Detection. The analysis also found that the implication of deep learning, Siamese network, and convolution neural networks is constantly rising to improve Detection and tracking performance. Looking into the progress in the study, it can be concluded that there is a long way to go to witness a more high-performance VODT approach. There is a need for more extensive analysis to expose the VODT approach to challenging scenarios of the practical world. In contrast, the existing approaches are too narrow and confined to their adopted research environment. The contribution and novelty of this paper is

1) Unlike existing review work, the current paper captures maximum deployment area, use-cases, and wider variants methodologies adopted towards improving performance of VODT.

2) This paper discusses the new classification of approaches of VODT concerning discreet use cases not reported in existing review work,

3) the paper also introduces a compact discussion associated with the commercial application of VODT, where it can be seen that progress made by commercial application and research work has a wide gap,

4) the paper discusses all the notable research contributions concerning the problems being addressed, the methodology being adopted, their respective strength and weakness,

5) the paper presents a discussion of research trends of VODT to find that evolving approaches and their frequencies of usage,

6) the paper outlines the research gap to signify the importance of enhancing the existing studies for developing high-performance VODT.

The future work will be in the direction of addressing the identified research gap from this review work. For this purpose, the initial work direction will be developing a robust detection module considering the challenging scene context of the video feed. Upon accomplishing a satisfactory detection module assessed over different extensive test environments, the next work will be carried out towards tracking operation. As tracking operation is seamless, both spatial and temporal attributes will be considered for mathematical modeling of the VODT approach that can lead to better optimization of its performance. The sole motive of future work will be to accomplish high-performance VODT in a cost-effective computational approach.

Abstract—Software product line SPLs, or software product lines, are groups of similar software systems that share some commonalities but stand out from one another in terms of the features they offer. Over the past few decades, SPLs have been the focus of a great deal of study and implementation in both the academic and commercial sectors. Using SPLs has been shown to improve product customization and decrease time to market. Additional difficulties arise when testing SPLs because it is impractical to test all possible product permutations. The use of Combinatorial Testing in SPL testing has been the subject of extensive study in recent years. The purpose of this study is to gather and analyze data on combinatorial testing applications in SPL, apply Pairwise Testing using (1+1) evolutionary algorithms to SPL across four case studies, and assess the algorithms' efficacy using predetermined evaluation criteria. According to the findings, the performance of this technique is superior when the case study is larger, that is, when it has a higher number of features, than when the case study is smaller in scale.

Keywords—SPL; SPL testing; combinatorial testing; pairwise testing; evolutionary algorithm; 1+1 EA

I. INTRODUCTION

Software product line (SPL), which is also called software product line development, is a set of software engineering practices for making similar software systems from a single set of software assets and using the same production method for all of them [1]. In other words, SPL is a group of products that is put together based on a set of features. A Feature Model (FM) decides which products are valid. Most of the time, it's not possible to test all of the products that would come from an SPL [1]. So, a small group of these products must be chosen. It used to be best if it got a good order of products.

Effective testing strategies will help any organization that spends a lot of money on software development. This is a demand in SPL because the proportion of testing costs goes up as the costs of developing each product go down. Due to the large number of ways the base software can be changed, testing an entire product line takes a long time and costs a lot of money [2]. These issues had to do with which platform was the

most efficient and what should be tested in separate products based on how hard it was to test the whole product line.

If testing is seen as a long process, the ability and effectiveness of testing can be improved by making the creation of test cases happen automatically. Even though this is a step in the right direction, more research needs to be done on the SPL testing process because it is impossible to test all of the individual systems that make up a large SPL software system. Test case generation in SPL [3], [4] is based on variation point management. The authors in [5] say that SPL testing is hard, but it would be best if all SPL products were set up correctly. In reality, though, this is hard to do. Large product configurations have made SPL testing difficult to handle, as [6]. In fact, some features can be set up in tens of millions of different ways. Since there is pressure to make test suites for the whole product line smaller, it will be hard to test each product in an SPL and stay on budget [7]. Combinatorial testing and other testing methods can cut down on the number of test suites needed for this, but they don't come without their own problems when it comes to scalability.

An Evolutionary Algorithm (EA) is a type of evolutionary computation, which is an optimization algorithm used in the field of artificial intelligence that is based on a population. In EA, processes like reproduction, mutation, recombination, and selection are used to model how natural evolution works. Even though it started in the early 1960s, EA is still a fairly new and changing field, with most research focusing on how it can be used.

The EA, as the name implies, functions similarly to natural evolution. People believe that the processes of recombination, mutation, and selection make individuals more fit because they adapt to their surroundings. An "EA individual" is a single optimization solution, whereas an "EA population" is a collection of "EA individual" optimization solutions.

Combinatorial testing is a type of testing that can be used to test a software product in a thorough way [8]. The goal is to have a product that doesn't have any bugs and can work with a wide range of inputs. Pairwise testing, also called "all-pairs

testing," is a way to check the quality of software by comparing the actual results to what was expected. Here, software testers look at all possible pairs of parameters used to test a feature and compare and contrast them.

Pairwise testing has become an important technique for any software tester over the past few years. This method has been around for almost 20 years, but it has become more popular in the last five. At least 20 tools that can make pairwise test cases have had their information made public up to this point [7, 8].

Based on the examined research, there are three main problems that sum up the issues at hand. First, there are so many possible industrial SPL products that it would be impractical to check each one individually to see if it meets each criterion. Second, it is not possible to do a full test that looks at every possible combination of parameters and values. Lastly, a way for evaluating the effectiveness of EA and creating valid comparisons, as well as a technique for reducing testing effort and shortening testing time using the suggested strategy [9]. This study's objectives are to apply the (1+1) evolutionary algorithm to generate pairwise test cases in software product line testing and to compare the effectiveness of the (1+1) EA in terms of pairwise coverage, execution time, test suite size, and test case redundancy for the mobile phone, vending machine, online shopping, and IoT device case studies.

However, it is imperative to acknowledge that the evaluation of security and privacy-related testing concerns should also be taken into account while conducting SPL testing [50]. Access control and authorization procedures are essential elements of software systems that are responsible for managing sensitive data or executing crucial operations. The process of testing these mechanisms across various products within a software product line presents challenges due to the potential variations in access control requirements and authorization procedures among different products.

In order to address this matter, it is possible to utilize sophisticated testing methodologies, such as pairwise testing, to build a set of test cases that encompass various combinations of access control criteria and authorization processes. The (1+1) evolutionary algorithm can be utilized as an efficient method for generating test cases. The efficiency of these test cases can then be assessed by utilizing metrics such as coverage and defect detection rate.

In addition to access control and authorization methods, software product line testing should also encompass additional important security and privacy-related testing concerns, including but not limited to data privacy, encryption, and secure communication. By effectively addressing these concerns [48, 49], software developers may guarantee security and ensure the privacy of their products.

Segment Particle Swarm Optimization (Se-PSO), Enhanced Segment Particle Swarm Optimization (Ese-PSO), and African Buffalo Optimization (ABO) are swarm intelligence-based optimization algorithms inspired by the behavior of social organisms such as ants, bees, and honeybees. They have been successfully applied to various optimization problems and can also be used for test case generation. These algorithms can be

utilized in pairwise test case generation to generate optimal test cases that cover all possible pairwise combinations of input parameters [10, 11, 12, 13, 14, 47].

Pairwise testing is effective at reducing the number of test cases required for high coverage, but it may not be adequate for testing non-functional requirements such as performance, security, and usability. Furthermore, it has been observed in certain research that the effectiveness of pairwise testing could be reliant upon the particular attributes of the software product line under examination, including the number of features and the level of variability. Hence, additional research is required to assess the efficiency of pairwise testing across various scenarios and to develop more sophisticated methodologies for evaluating software product lines.

The intention of this study is to apply the (1+1) evolutionary algorithm to the task of generating pairwise test cases for software product line testing and to assess the efficacy of this technique using a number of measures, including pairwise coverage, execution time, test suite size, and test case redundancy. The objective is to demonstrate that the (1+1) evolutionary algorithm can be helpful for producing high-quality test cases for software product lines and to encourage the evolution of more sophisticated testing methods for software product lines.

The rest of this article is organized as follows: Section II outlines the works that are related to this study. Section III demonstrates the method for conducting this study with case studies that are used to carry out the experiment. In Section IV, a number of experiments are carried out, and the findings are thoroughly examined. Section V contains a discussion of the study's findings. Finally, in Section VI and VII, we provide a brief summary of the paper and discuss future work respectively.

II. RELATED WORKS

SPL is a collection of software-heavy systems with a common base and features tailored to a specific audience or mission. Features identify SPL members by highlighting shared and unique traits. Feature models express feature relationships and limitations to reflect all SPL outputs.

The SPL testing process is difficult. Testing every product is impractical. The number of configurations (or products) caused by an FM usually grows exponentially with the number of features, resulting in millions of potential products to test. Test engineers are trying to reduce their test suites to meet budgets and deadlines [15].

Software testing a product line takes time [16, 3]. A product line lets a buyer build a software system with many options [17]. Business is embracing SPL. Bosch, Philips, Siemens, General Motors, Hewlett-Packard, Boeing, and Toshiba use product-line approaches to reduce development and maintenance costs, improve quality, and speed product development [17, 18].

A. Software Product Line Testing

Testing software product lines is important because one bug can affect hundreds of thousands or millions of products. The study [19] lists several product line assessment methods.

Product-by-product testing begins by generating and testing concrete products one at a time using single-product testing methods. Family-based testing checks if all products in a family meet the requirement [20].

A family-based approach tests multiple products. Computer simulations represent all line products. By superimposing all product test specifications, modern family-based testing methods don't allow for good testing of software's interaction with hardware and the environment [21, 22]. Family-based testing may be time-consuming and incomplete due to its complex execution environment.

Testers and software engineers use FM to compare and create testable products. Testing all product feature combinations is not always possible. Application complexity reduces product selection. Combinatorial testing is used in the selection process to examine multiple variables. This selection method disregards FM defects. A fault-based approach like mutation-based testing can improve error detection and SPL product compliance. The research [23] suggests mutating products for SPL feature testing. The method can be used to create and evaluate test cases like a test criterion. FM's model features and connections. Feature diagrams (FDs) usually show the FM as a tree.

B. Test Case Generation Approaches in SPL

SPL test case generation has led to several testing methods. Combinatorial and model-based testing are examples. Combinatorial testing prevents tests from growing exponentially by trying all possible input permutations. Combinatorial testing addresses test selection from the whole combinatorial product since testing often has a finite test budget and exhaustive testing is usually intractable. Pairwise combinatorial testing is common here. A family of products with all FM valid pairs of features is the goal [24]. Counting covered pairs which help evaluate the product set.

All-pairs testing, also called pairwise testing, is a way to test software by giving it as many possible combinations of two inputs. This method helps us understand how inputs interact, improving product quality and dependability. Pairwise testing is useful for testing software product lines, which are collections of configurable products. Pairwise testing can improve product line testing and be applied to a case study [25]. Pairwise testing with other methods and business knowledge may reduce testing costs and improve quality [26, 37]. The paper recommends pairwise testing to reduce test cases.

T-wise testing checks all input value permutations with a constraint of "T" inputs. This strategy can help test too many inputs. T-wise testing balances test case volume and coverage [27]. SPL's model-based t-wise testing creates a TS with comprehensive t-wise coverage. A valid t-set has t features that meet some constraints.

Covering arrays in software product line testing improves system failure detection [28]. For testing, a two-layer covering array is used to represent equivalence classes and compute their names in the second layer. Covering arrays are used to test component interactions in a systematic manner. Let N , t , k , and v be integers with $k \geq t \geq 2$ and $v \geq 2$. A covering array

$CA(N; t, k, v)$ is an $N \times k$ array A in which each entry is from a different alphabet, and there is a row of B that equals x for every $N \times t$ subarray B of A and every $x \in \Sigma^t$. Then t denotes the covering array's strength, k the number of factors, and v the number of levels [29].

Model-based testing (MBT) automates test case creation for SPL testing. A Systematic Literature Review (SLR) on MBT for SPL testing is presented by [30]. MBT in SPL issues, evaluation, and solutions are discussed. The study summarizes SPL MBT perspectives in a taxonomic structure. The latest SPL development is taxonomy based MBT classification.

Reduced testing is needed when resources are limited. Risk-based testing [31] is popular for system prioritization. Two other factors determine the probability of system entity damage or loss.

SPL regression testing is difficult because it must test every member of a product family after a change. Regression test selection (RTS) selects a subset of regression test cases to lower regression testing costs [32]. In the product line context, each test case can be executed on multiple products that reuse the test case, making SPL regression testing time-consuming and resource-intensive even with RTS. Eliminating unnecessary test case executions helps.

In [33], a suggested method that finds a group of products where running the test case will cover the same sequence of source code statements and give the same testing results, and then filters out the group from the test case's scope.

C. Search-based Techniques for SPL Testing

SPLs are collections of systems that have the same core functionality but are tailored to meet the needs of specific user groups. All products would have to be tested in theory, but that's not possible in practice. Because of this, "interesting" ones can be chosen to focus on using search-based approaches.

Evolutionary computation is a population-based metaheuristic optimization algorithm used in artificial intelligence research. EA simulates natural evolution using reproduction, mutation, recombination, and selection. EAs mimic natural evolution. Recombination, mutation, and selection are thought to increase fitness by adapting individuals to their environment. EA "population" members are optimization solutions. EAs excel at optimization, scheduling, planning, design, and management [34]. Investments, production, distribution, etc. have these issues.

Initially, a theoretical study of the (1+1) EA is presented and discussed. On a population of one, it only employs the mutation operation and an elitist selection method to generate a new generation. Although the (1+1) EA is the simplest evolutionary algorithm, it shares a fundamental principle with all others [35]. The (1+1) EA locates the maximum of a linear function, as proven by a theorem in [28]. The two members of the population at any given iteration are known as the "parent" and the "offspring," hence the name "1+1." For linear function optimization, the (1+1) Evolutionary Algorithm is predicted to take $O(n \ln n)$ time if the mutation rate is of size $(1/n)$.

Differential evolution (DE), Evolution strategy (ES), and Evolutionary Programming (EP) are all examples of other

Evolutionary Algorithms that can produce multiple offspring and compete [36]. As an illustration, the Evolution Strategy allows for the creation and competition of mutants.

Table I provides a summary of some of the existing search-based techniques for testing in SPL. Moreover, the strengths and weaknesses of the technique are provided as well.

TABLE I. SUMMARY OF STUDIED SEARCH-BASED TESTING TECHNIQUE

Technique	Authors	Strengths	Weaknesses
1+1 Evolutionary Algorithm (1+1 EA)	Slowik & Kwasnicka, Zhou et al 2020. [36]	Simplest EA, requires low requirements and it can reach any point in the search space in a single step.	it's not easy to find a good drift function.
Genetic Algorithm (GA)	Rao & Tripathy 2019. [38]	The ability to make exceptional use of parallel computation, simplicity of use, rapid convergence to the global optimum, few necessary control variables.	Do not scale well with complexity, can be quite slow.
Non-dominated Sorting Genetic Algorithm II (NSGA-II)	Hojjati et al., Muhammad Abid Jamil et al 2018. [39]	Demonstrates elitism and is not dependent on any measure of distributivity.	The computational complexity of solving the problem grows in proportion to the size of the problem.
Strength Pareto Evolutionary Algorithm II (SPEA-II)	Jamil et al 2019. [31]	Utilizes a fine-grained fitness assignment strategy and an improved archive truncation technique.	lack of accuracy in its density estimation

III. METHODOLOGY

The methodology for conducting the research includes four stages. The first thing that will be done is an analysis of the software product line online tools (SPLOT), and then in Step 1, the FM for all of the case studies will be prepared. Following that, the pairwise testing will be carried out using the (1+1) EA in Step 2. Evaluation of the parameters that were employed is the third step. Lastly, an in-depth analysis and comparison of the results is carried out. The research methodology is depicted in Fig. 1.

A. Step 1: Prepare Case Studies using Software Product Lines Online Tools (SPLOT)

SPLOT is a Java2 Web app that uses an HTML template engine to make Ajax-based user interfaces for reasoning and configuration. Because it is web-based, you don't have to update it by hand or download any files, and it's easy to share information (for example, through a feature model repository). Automated reasoning and product configuration are SPLOT's two main offerings right now. To this end, reasoning is centered on the automation of crucial debugging tasks like checking the consistency of feature models and spotting the

presence of dead and common features [6]. Measurements of properties like the number of valid configurations and the degree of variability of feature models are also supported by reasoning. Currently, SPLOT supports interactive configuration for product configuration, wherein users decide at a time, and the configuration system automatically propagates those decisions to enforce their consistency.

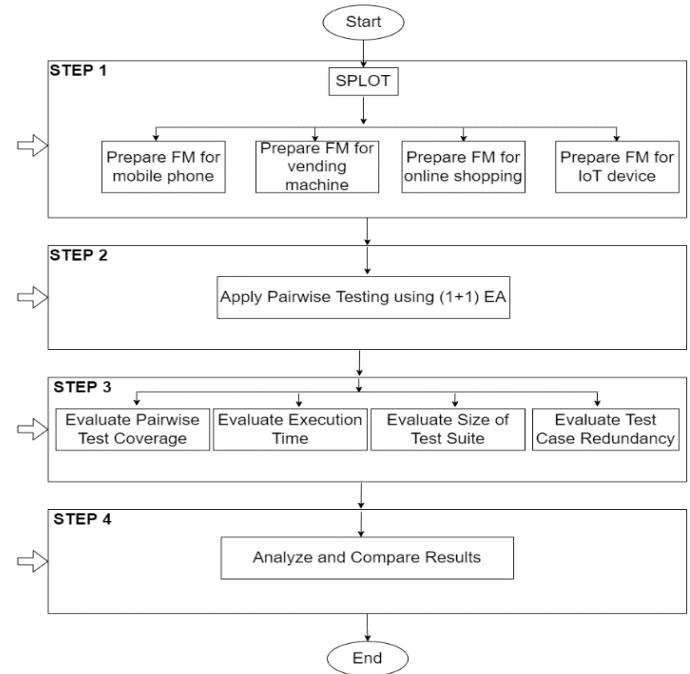

Fig. 1. Research methodology framework.

A major complaint from SPL researchers is the dearth of freely distributed feature models. To address this problem, SPLOT makes available a public model repository with more than 20 genuine models from the literature as well as several automatically generated models with up to 10,000 features each [6].

B. Step 2: Apply Pairwise Testing using (1+1) EA

In this step, we use the PLEDGE tool to generate (1+1)-based pairwise test cases. PLEDGE is a free software program that helps determine which product configurations should be tested in order to cover the most possible combinations of features. Both a command line and a graphical user interface are available for this tool's operation (GUI). All of the following are possible with the current release of PLEDGE:

- FMs loaded from a file: Both the SPLOT and DIMACS (Conjunctive Normal Form) formats are supported by PLEDGE [32].
- Information about FM, such as its limitations and characteristics, can be visualized.
- Making changes to the FM by introducing or removing constraints.
- Producing the test products from the FM by setting parameters for the desired quantity and the time allotted for their production.

- Inputting a list of products and sorting them into a desired order using one of two suggested methods of prioritization.
- Producing a file to store the finalized or prioritized output.

Several settings can be specified to modify the behavior of the 1+1 evolutionary algorithm when using PLEDGE to conduct pairwise testing using the 1+1 evolutionary algorithm.

C. Step 3: Evaluate Testing Parameters

In this stage, all of the parameters, such as pairwise coverage, execution time, the size of test suites, and test case redundancy are evaluated based on the methodology that was utilized in this study.

1) *Pairwise coverage*: For each case study in this research is given a percentage of pairwise coverage for a single run/iteration, which is the discrete combinations of the relevant parameters calculated with PLEDGE. When testing in a black box, pairwise coverage ensures that every possible combination of input parameters is covered by at least one of the test cases. Pairwise testing is more efficient at spotting problems because it is based on the observation that most defects occur due to the interaction of two values. By allowing for systematic testing coverage, pairwise tools can speed up the preparation and implementation stages. By conducting tests in pairs, we can reduce testing time by half without compromising coverage.

The use of k-means and k-medoids clustering techniques in software testing to reduce the test suite and improve the algorithm's performance is discussed by [40, 41]. The technique of pairwise testing is also cited as an efficient means of generating a small test suite with optimal pairwise coverage. Also, [42] proposes a new method for increasing testing efficiency while maintaining testing efficacy. The paper ranks combinatorial test cases according to incremental interaction coverage by repeatedly applying the base choice coverage.

2) *Execution time*: The execution time is the amount of time it takes for a single run to be carried out. Also using PLEDGE, the execution time in seconds is available. For each run, the time taken to finish the run is provided. In the context of pairwise testing, execution time refers to the amount of time required to execute the test cases created using the all-pairs or pairwise testing methodology. The execution time is dependent on variables such as the size of the input parameters, the number of combinations, the performance of the being tested software application, and the testing environment.

Reducing test execution time is crucial for SPL testing, as it enables more efficient testing of product lines and reduces the need for unnecessary testing [43]. Several SPL testing methods have been proposed to decrease test execution redundancy and boost efficiency.

3) *Size of test suite*: A test suite consists of all the test cases that have been logically grouped together. Testing an application to show that it exhibits a certain set of behaviors is

what the test suite is all about. Each test case in a suite will have explicit instructions or goals and details on the system configuration to be used during testing. [41] emphasizes the significance of pairwise testing as a means to circumvent the combinatorial explosion issue. The paper proposes that pairwise testing can be used to test software systems' vast input combinations with fewer test cases. Pairwise testing is presented in [28] as a promising technique with the potential to drastically reduce the number of test cases required for an acceptable level of coverage.

For each case study involved in this study, a different size of test suite can be generated for a single run using PLEDGE. The size of test suites can differ based on the number of features for each case study, a case study with many features is considered big and size of test suites can be high.

4) *Test case redundancy*: This study examines a test suite by finding redundant test cases, which is essential for lowering testing costs. A redundancy score is defined by the redundancy formula, which determines the score by dividing the total number of test cases by the number of duplicates. The redundancy score can be calculated using the formula in Equation 1 below, the total number of redundant test cases is divided by the total number of test cases generated. [44-45] contends that redundancy in test artefacts reduces testing costs.

$$\text{Redundancy Score} = \frac{\sum \text{Redundant test cases}}{\sum \text{Test cases}} \quad (1)$$

D. Step 4: Analyze and Compare the Results

The fourth step is to perform an analysis and comparison of the results, which includes testing and an evaluation of performance. The results of the testing will be analyzed and compared using pairwise coverage, execution time, total test suite size as the criteria. In addition to this, test case redundancy will be calculated, and a graph depicting the findings of the comparison will be offered.

E. Case Studies

Within the scope of this research, four distinct case studies will each be subjected to a pairwise test case generation technique utilizing (1+1) EA. The mobile phone, the vending machine, the online shopping, and the IoT device are the case studies. The reason for choosing the selected case studies is because they are the most used and because they meet the needs to conduct this research, besides, there are many references that has been used those case studies to conduct testing in SPL using other testing techniques. Mobile phone and vending machine case studies are the small case studies in term of number of features. Meanwhile, e-shop and IoT device case studies are the big case studies.

1) *Mobile phone*: The mobile phone industry served as inspiration for the simplified feature model shown in Fig. 2. This model demonstrates how features are incorporated into the process of specifying and developing software for mobile devices, specifically mobile phones. The capabilities of the phone will determine the types of software that can be installed on it. The model stipulates that all mobile devices

must be capable of making and receiving calls as well as displaying data in black-and-white, color, or at a very high resolution on their screens. In addition, the software for mobile phones may, at the user's discretion, include support for satellite navigation systems (GPS) and multimedia devices, such as cameras, MP3 players, or both.

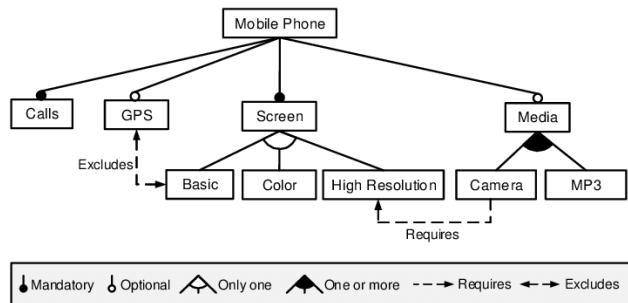

Fig. 2. Feature diagram of product line mobile phone adapted from [38].

2) *Vending machine*: The FD for the snack and drink dispensing machine's SPL is shown in Fig. 3. The vending machine assortment here is formally described by the accompanying feature diagram. Soda, Tea, Free Drinks, and CancelPurchase are used in the feature diagram to represent these products as valid options for the consumer.

Fig. 3. Feature diagram of product line vending machine adapted from [39].

3) *Online shop*: The feature model that contains information about our online shops is depicted in Fig. 4. The name of the product line is located within the most prominent feature. There are four aspects that are connected to it: The features Catalog, Payment, and Security are connected to the feature that is at the top of the list by arcs that have filled circles at their ends. This indicates that these three features are required, meaning that they are present in each and every product variation. The fact that the Search function is not required is indicated by an arc that terminates in a circle that is not filled in. This descending order of characteristics will continue. For example, the feature Payment includes three sub features: Bank Account, ECoins, and Credit Card. For each product variant, at least one of these sub features must be selected. Both the High and Low sub features of the Security feature are alternative features, which means that only one of them can be selected for each product variant. In addition, there is a textual condition that states that selecting credit cards is only possible when the security level that is being provided is of a high standard.

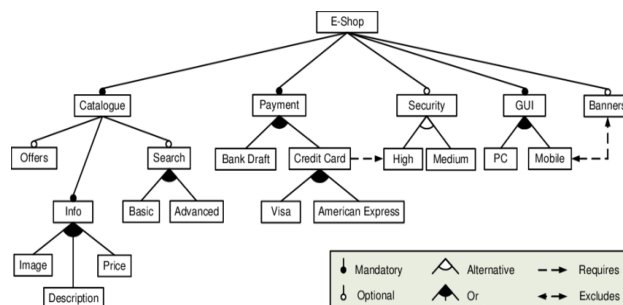

Fig. 4. Feature diagram of product line online shop adapted from [40].

4) *IoT device*: Internet of Things application development is guided by the selection of relevant environmental features and the needs of the end user. An efficient modelling approach, capable of holding all constraints and allowing application development, can be used to control environmental variability. Different uses for the same IoT devices introduce contextual variations that must be managed to ensure efficient development and maximize code reuse. It has been suggested that XML-based feature modelling be used to handle variability management of SPL. Fig. 5 depicts the smart campus IoT system's feature model, complete with predefined relationships and constraints.

Fig. 5. Smart campus IoT feature diagram adapted from [46].

IV. RESULTS

In this research, four case studies have been tested using the proposed approach. Each case study is tested ten times, and the results of each test case are provided. The four test cases, namely mobile phone, vending machine, online shop, and IoT, are different from each other's, in terms of the number of features, which indicates their size.

Fig. 6 shows the average results of each case study based on the evaluation metrics. For the mobile phone case study, the average test case coverage is 85.23%, and the average execution time is 1.31 seconds. The average number of test cases generated is 2.4, and no test cases are redundant. On the other hand, for the vending machine case study, the averages for the test coverage, execution time, size of the test suite, and percentage of test case redundancy are 75.39%, 1.13 seconds, 2.4, and 23.33%, respectively.

Fig. 6. Average of the results of the case studies.

Moreover, the online shop and smart campus IoT case studies are the big ones in terms of the number of features in this study, and the average percentage of test case coverage is 93.53% for the online shop and 96.56% for the smart campus. Both case study results show the absence of redundant test cases. Meanwhile, the average execution time is 0.98 and 0.79 for the online shop and IoT smart campus, respectively. Lastly, the average size of test cases is 10.9 for the online shop case study and 21.8 for the smart campus case study.

Using PLEDGE to conduct the testing, as shown previously in the mobile phone and vending machine case studies, produced less efficient results compared to the other two case studies. The size of the test suite is smaller because there are fewer features; meanwhile, there are more redundant test cases because, using PLEDGE, the results showed that the tool cannot produce a large number of test suites for small case studies, and the results also showed that the testing takes more time to run, which is remarkably unexpected.

V. DISCUSSION

This study's goals are to apply the (1+1) evolutionary algorithm to generate pairwise test cases in software product line testing with the help of the proposed tool. The effectiveness of the algorithm using four metrics, including pairwise coverage, execution time, size of the test suite, and test case redundancy, for all of the case studies that were chosen, and to conclude that the (1+1) evolutionary algorithm is useful for generating pairwise test cases in software product line testing.

The literature research clarifies the difficulties associated with testing software product lines, mostly stemming from the wide range of possible configurations and the need for effective testing methodologies. The findings of this study indicate that the (1+1) evolutionary algorithm is a successful approach for generating pairs test cases in the context of software product line testing. This algorithm proves to be effective in reducing the number of required test cases while simultaneously obtaining a high level of coverage.

Furthermore, the literature review examines the significance of assessing the efficiency of testing methodologies by considering several factors, including pairwise coverage, execution time, and test suite size. The study presents a comparative analysis of the effectiveness of the (1+1) evolutionary algorithm across four distinct case studies, shedding light on its performance in diverse circumstances.

Moreover, the literature review underscores the necessity for more research and advancement in the domain of software product line testing, encompassing the utilization of search-based algorithms like evolutionary algorithms. The findings and methodology presented in the study make a valuable contribution to the field of research by illustrating the successful performance of the (1+1) evolutionary algorithm in producing pairs test cases for software product line testing.

VI. CONCLUSION

The purpose of this research is to apply the (1+1) evolutionary algorithm using PLEDGE in order to generate pairs of test cases for software product line testing. Using four criteria—pairwise coverage, execution time, test suite size, and test case redundancy—for each of the selected case studies, it was discovered that the 1+1 evolutionary algorithm is beneficial for creating pairwise test cases in software product line testing. When using PLEDGE to conduct the testing, the results demonstrated that this method yields superior results when the case study is large, which means it has a large number of features, compared to when the case study is small.

Among the four case studies, the online shop and IoT case studies achieved good results in comparison to the mobile phone and vending machine case studies. This is because the online shop and IoT case studies have a large number of features; therefore, by using the PLEDGE tool, a good result has been achieved in comparison to when a case study has a small number of features, such as the mobile phone and vending machine case studies.

Online shop and IoT case studies achieved better results than mobile phone and vending machine case studies. The average for pairwise coverage recorded the best for online shop and IoT at 93.53% and 96.56%, respectively. Meanwhile, the average execution time and the size of test suites are noted to be better for online shop and IoT case studies at 0.98s and 0.79s, 10.9s and 21.8s respectively. Also, both case studies showed the absence of redundant test cases. On the other hand, the finding revealed that the mobile phone and vending machine case studies achieved less performance due to the fact that both were considered small with a small number of features.

VII. FUTURE WORKS

From this research, we were able to gather the following list of significant insights regarding areas for possible development and improvement: first, there are numerous ways to produce test cases using the existing software testing tools. Second, the program used in this research, PLEDGE, has problems and must be executed multiple times before producing meaningful results. The production and prioritization of test cases is a crucial aspect of SPL testing, and there has been an increasing trend in recent years to leverage search-based algorithms as a solution strategy.

Abstract—Network attacks are diversified, rare and Universal generalization. This has made the exploration and construction of network information flow packet threat detection systems, which becomes a hot research topic in preventing network attacks. So this study establishes a network data threat detection model based on traditional network threat detection systems and deep learning neural networks. And convolutional neural network and data enhancement technology are used to optimize the model and improve rare data recognizing accuracy. The experiment confirms that this detection model has a recognition probability of approximately 11% and 42% for two rare attacks when N=1, respectively. When N=2, their probabilities are 52% and 78%, respectively. When N=3, their recognition probabilities are approximately 85% and 92%, respectively. When N=4, their recognition probabilities are about 58% and 68%, respectively, with N=3 having the best recognition effect. In addition, the recognition efficiency of this model for malicious domain name attacks and normal data remains around 90%, which has significant advantages compared to traditional detection systems. The proposed network data flow threat detection model that integrates Gated Recurrent Neural Network and Domain Generation Algorithm has certain practicality and feasibility.

Keywords—Gated recurrent; domain generation algorithm; campus network; threat detection; neural network

I. INTRODUCTION

Technological progress has led to an increasing demand for information technology and a high informatization degree. Therefore, the internet has become an important way for people to improve their efficiency, quality of life, and increase personal income. Internet popularization has made people's lives more and more transparent. People rely heavily on the computer internet in many fields such as daily life, economic management, and financial investment [1]. The global Internet economy has even accounted for 10% of the global GDP, reaching the level of more than ten trillion US dollars. However, while the network has brought us convenience, many malicious attackers will use various means such as Botnet, system vulnerabilities, malicious domain names and trojans to attack, steal, destroy or modify data on the local network without authorization [2]. As of 2022, the losses caused by global cybercrime to people have exceeded \$6 trillion, and these cyber threats are increasing exponentially over time [3]. Currently, campus education networks and research departments are the primary targets of attackers, with each institution or campus network facing an average of thousands

of malicious network attacks per week, an increase of at least 50% compared to 2021 [4]. The existing attack methods for network data have the characteristics of diversification, uniqueness, and fast update. Traditional intrusion detection systems are often unable to effectively identify new and unknown attacks, because they rely on known rules and features [5]. For example, for new attacks such as zero-day vulnerabilities and advanced persistent threats, traditional intrusion detection may not be able to detect and alert in time. And traditional intrusion detection may fail to detect attacks based on covert communication, such as steganography or encrypted communication, and even generate a large number of false positives, wasting time and resources. Therefore, traditional intrusion detection systems have great limitations when facing new attacks, high false positive rate, complex environment and lack of context information. In this context, research attempts to integrate deep learning neural networks and data augmentation techniques into the traditional Network Intrusion Detection System (NIDS) to make it more intelligent and self-learning, to enhance the recognition probability of new rare attack methods.

This study conducted technical exploration and analysis from four aspects. Firstly, the relevant research on the current network DS threat detection system was discussed and summarized. Secondly, the comprehensive applications of Gated Recurrent Neural Network (GRNN), Convolutional Neural Network (CNN), and Domain Generation Algorithm (DGA) were analyzed, including the construction of a network data threat detection system. Then, experimental verification and data comparison analysis were conducted on the data stream (DS) threat detection model of network. Finally, there is a comprehensive overview of entire article and a reflection and summary of its shortcomings.

II. RELATED WORKS

While internet popularization has made people's lives more convenient, network data threats and intrusions have also become increasingly common. Building a DS detection model has become a hot research and exploration field for some experts at home and abroad. Its characteristics include fast and accurate learning, recognition, and fine segmentation of campus network and other DS quantities. Zhou et al. proposed a hierarchical adversarial attack generation method based on the graph neural network (NN) for the intelligent intrusion detection (ID) problem of Internet of Things (IoT), which

improved the system's recognition accuracy against network attacks [6]. The vulnerabilities in IoT are prone to attacks and other issues. In this regard, Nimbalkar and Kshirsagar proposed an attack data detection and comparison system based on the ID system of Feature selection and information gain method, which improved the identification efficiency of denial of service and other attacks [7]. After the automobile network is connected, it is vulnerable to network attacks and accidents. In response, Moubayed et al. proposed a multi-layer hybrid ID system based on feature based ID systems and anomaly based ID systems, thereby improving the recognition efficiency against known and unknown attacks [8]. Guo et al. proposed a spam detection method based on pre trained bidirectional encoder representation and machine learning (ML) algorithm to address the issue of spam detection. Two datasets were used for performance testing in the experiment, confirming that this method effectively improves the detection efficiency of spam [9]. Hidayat et al. proposed a new network ID technology for data detection in network attacks, based on the ML model and integrating multiple technologies, which improved the detection efficiency of network attacks [10].

In addition, Binbusayyis and Vaiyapuri constructed a joint optimization ID framework based on classifiers such as convolutional encoders to address network security issues. This effectively improves the detection ability for unknown attacks [11]. Wang et al. proposed a new ID model for network intrusion based on ML and Decision boundary, integrating popular evaluation methods and ID system models. This increases the recognition probability against boundary attacks [12]. Krishnaveni and others proposed a new attack classification method based on the univariate integration Feature selection technology and classification technology to solve the problem that cloud computing servers are vulnerable to attacks. This improves the detection efficiency of the ID model for attack data [13]. Azizan et al. proposed a new ID method for identifying attack data in large amounts of data, based on ML and incorporating algorithms such as decision jungle. This improves the identification efficiency of attack data in big data [14]. Aimed at the identification problem under multiple attacks on the network, Almomani combines Particle swarm optimization algorithm based on ID system and proposes a new ID model. This effectively improves the recognition efficiency for multiple attacks [15]. Rashid et al. proposed a new ID model based on ML, which integrates tree based stack integration technology to address the classification problem of anomalies and normals. This interference improved the recognition efficiency of network abnormal traffic [16].

From the research from various countries, ID systems have low efficiency in identifying multiple types of network attacks. Most studies only focus on improving ID system's efficiency in identifying attack types. They overlooked the intelligence of ID system and improved learning efficiency for unknown attacks and recognition efficiency for rare attacks. Therefore, the deep detection network model developed using GRNN and DGA has a certain degree of innovation.

III. DESIGN AND IMPLEMENTATION OF NIDS

Unlike traditional threat detection systems, the detection model using GRNN model and DGA fusion has a certain innovation. Therefore, to ensure data detection model's detection accuracy can continuously be deeply refined, the model design and implementation are particularly important. Therefore, this section mainly analyzes the model implementation principle and system construction.

A. Network Threat Detection Model and NN Technology

To conduct real-time monitoring and analysis of DS generated locally on campus network and DS passing through campus local network, NIDS is needed to timely identify network attacks and adopt corresponding strategies [17]. Fig. 1 shows the detection process of this system against DS threats.

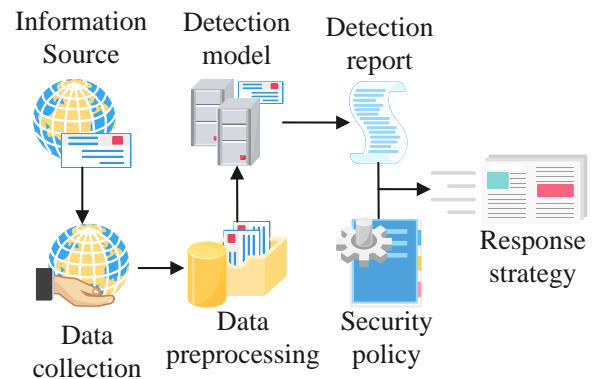

Fig. 1. Flowchart of data flow threat detection.

According to Fig. 1, the entire NIDS detection process mainly includes three steps: information flow data capture, network packet structure content analysis, and abnormal activity strategy response. Among them, data capture mainly utilizes packet capture tools for data capture. Data analysis mainly uses models to make detailed judgments and intelligent decisions. Policy response is mainly aimed at the network abnormal activities by saving the characteristic code, sending information or screen display abnormalities to remind and cooperate with the Network engineer to carry out human intervention to eliminate hidden dangers. Fig. 2 shows the detection logic model of NIDS for network DS.

Through Fig. 2, NIDS accumulates the original feature library based on the initial data and supplements and corrects the feature library through continuous learning and training. Then it makes judgments and decisions on new real-time data on the foundation of vast feature library. Among them, learning historical training experience data is particularly important for NIDS, so deep learning Recurrent Neural Network (RNN) is needed to make NIDS more intelligent [18]. RNN model mainly collects and analyzes the texture characteristics of data through a multi-layer NN composed of simulated neurons. So it can excavate the original feature expressions behind diverse data and make intelligent judgments on richer new data. Fig. 3 is the schematic diagram of RNN.

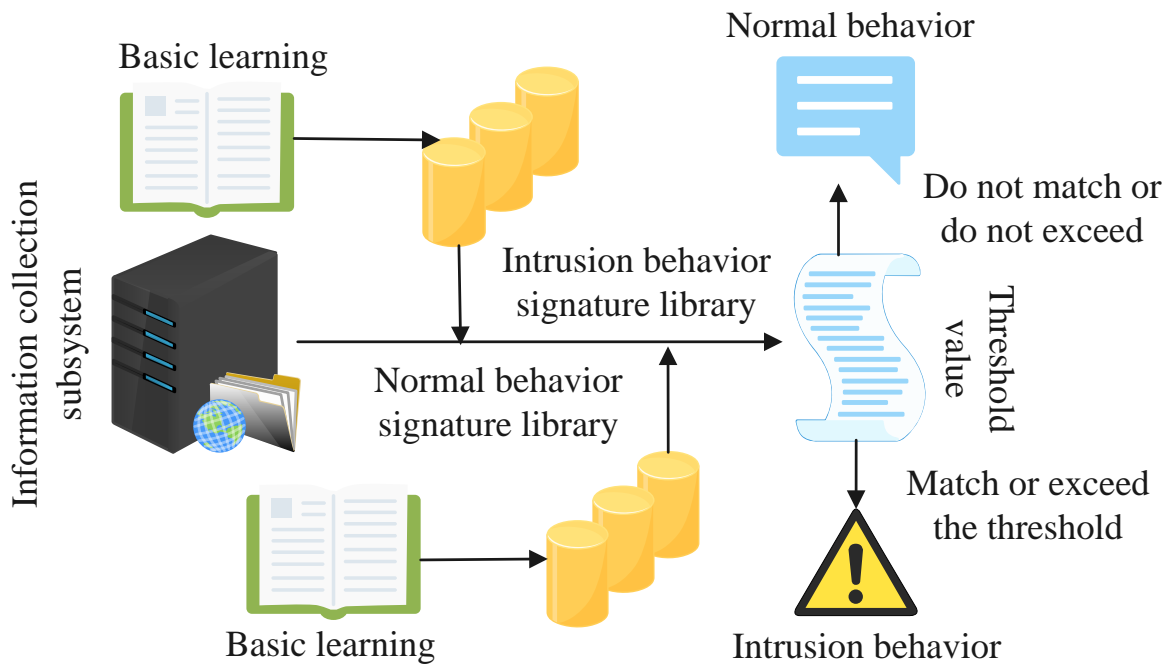

Fig. 2. Data flow detection model.

Fig. 3. Recurrent neural network models for deep learning.

From Fig. 3, RNN is a memory feedback bidirectional Transitive model composed of one input layer, multiple hidden layers and one output layer. Each layer of neurons can receive signals from the same or previous layer of neurons and perform nonlinear transformations to accumulate and output to the next layer until the output layer is reached. Due to the tendency of RNN to form gradient decay or gradient explosion when the time difference is large or small, it is difficult for RNN to obtain long-term or short-term dependencies in time series in practical applications. To this end, Gated Recurrent Unit (GRU) should be introduced into RNN to improve its memory unit and better capture long-term or short-term dependencies in time series. Eq. (1) represents its connection relationship [19].

$$\begin{cases} f_t = S(D_{xf}x_t + D_{yf}y_{t-1} + D_{zf}z_{t-1}) \\ i_t = S(D_{xi}x_t + D_{yi}y_{t-1} + D_{zi}z_{t-1}) \\ z_t = f_t H z_{t-1} + i_t H \tanh(D_{xz}x_t + D_{yz}y_{t-1}) \\ O_t = S(D_{xO}x_t + D_{yO}y_{t-1} + D_{zO}z_{t-1}) \\ y_t = O_t H \tanh(z_t) \end{cases} \quad (1)$$

In Eq. (1), f refers to the forgetting gate. S refers to a growth curve function (sigmoid function). D refers to a pending parameter. x refers to the input value. y refers to the output value. z refers to cell state value. t and $t-1$ represent the current and the previous time, respectively. i refers to the input gate. H refers to the image matrix transformation Hadamard matrix. O refers to the output gate. $\tanh()$ refers to a hyperbolic tangent function. In addition, the lack of feedback from neurons themselves is a one-way transmission lacking error adjustment mechanisms. Therefore, to make the gradient descent optimization algorithm and the error Backpropagation work and improve the accuracy of DNN, it is necessary to quantify error information between the estimated and the actual values with cost function. And because NN input values are generally nonlinear discrete values, it is necessary to introduce a linear regression Softmax function to better predict the discrete results. Only by accurately classifying the results according to different weights can more accurate cost function values be obtained. Eq. (2) is the mathematical expression of Softmax value.

$$\left\{ \begin{array}{l} \alpha(x)_j = e^{x_j} / \sum_{k=1}^k e^{x_k}, j=1, \dots, k \\ f_{\beta}(x^j) = \frac{\begin{bmatrix} e^{\beta_0^j x^j} \\ e^{\beta_1^j x^j} \\ \dots \\ e^{\beta_{k-1}^j x^j} \end{bmatrix}}{\sum_{j=0}^{k-1} e^{\beta_j^j x^j}} \end{array} \right. \quad (2)$$

In Eq. (2), x refers to the vector value. $\alpha()$ refers to a dimensional vector. e refers to the natural base. k refers to the maximum dimension value. j refers to the current dimension. β refers to an undetermined parameter. $f()$ refers to the probability function. T refers to the temperature coefficient used to adjust curve smoothness. Eq. (3) is the cross entropy of cost function.

$$H(p, q) = -\sum_{i=1}^N p(x_i) \log q(x_i) \quad (3)$$

In Eq. (3), H is the cross entropy of the cost function. p refers to the true distribution probability. q refers to the fitted distribution probability. x refers to the sample space. N is represented as a variable coefficient. Cross entropy mainly expresses the information quantity fully used to eliminate uncertainty. Then, the gradient descent algorithm was used to search for various parameters that optimize cost function. Finally, Backpropagation is used to transmit the optimized error information to model's initial neurons. So it can correct whole model's error to improve its accuracy. The model's excessive reliance on its own training data to fit iterative loop transmission can lead to a decrease in prediction accuracy. At this point, it is necessary to use regularization methods that modify the penalty term of cost function and regularization discarding methods that discard neurons to reduce model complexity and prevent overfitting in Equation (4).

$$\left\{ \begin{array}{l} L1 = H(p, q) + \alpha \sum_{i=1} |\beta_i| \\ L2 = H(p, q) + \alpha \sum_{i=1} \beta_i^2 \end{array} \right. \quad (4)$$

In Eq. (4), $L1$ is expressed as regularization that minimizes weight's absolute value. $L2$ is expressed as regularization that minimizes the square of weights. α is expressed as a regularization coefficient. β is expressed as a weight coefficient. $L1$ is suitable for avoiding overfitting by reducing weight density to simplify data while accurately modeling. $L2$ is suitable for avoiding overfitting in computer image recognition by attenuating weights. So combining the two can achieve good regularization results. When RNN is applied to NIDS to detect real data, it can effectively improve the accuracy of analyzing common attack data.

B. Design and Implementation of Domain Name Classification Network Model

The model needs to introduce DGA and CNN to address rare attacks such as malicious domain names [20, 21]. Compared to traditional network models, CNN can further

simulate the multi-layer NN architecture of brain to analyze complex information. It can improve data model's ability to analyze and judge complex feature relationships between network packets. Fig. 4 show its network structure.

According to Fig. 4, CNN contains a 5-layer structure. Among them, input layer can standardize multidimensional data to improve model's learning efficiency and result expression. Convolutional layer mainly uses excitation functions to assist in feature recognition and extraction of standardized input data. Pooling layer uses pooling functions to select the characteristics of the extracted feature map and screen key information, so as to reduce parameters number and realize feature data invariance to reduce subsequent calculation. Fully connected layer uses classification algorithms to perform nonlinear combination of transformed extracted features to achieve the function of a "classifier". The output layer uses logic or normalization functions to process data and output a numerical matrix. Eq. (5) and (6) represent the calculation of fully connected layers.

$$y_i = \text{relu}(w_i * y_{i-1} + b_i) \quad (5)$$

In Eq. (5), y_i is expressed as the output of i -th layer. w_i is expressed as a weight coefficient. b_i is expressed as an offset parameter. relu is expressed as activation function.

$$F(y) = i|x; \theta(w, b)) = e^{\theta(w, b)x} / \sum_{j=1}^k e_j^{\theta(w, b)x} \quad (6)$$

In Eq. (6), $F()$ is the classification function. y refers to the predicted project category value. x refers to the sample value. $\theta(w, b)$ refers to the classification parameter. e is represented as a natural base. k refers to the label type of classified data. The preprocessed data enters the output layer for normalization processing and outputs the result, which is mathematically expressed as Eq. (7).

$$T_{i,j} = (T_{i,j} - \min(T_{i,j})) / (\max(T_{i,j}) - \min(T_{i,j})) \quad (7)$$

In Eq. (7), $T_{i,j}$ is expressed as the characteristic values of a certain row and column. This model introduces DGA on the foundation of CNN, and collects samples from all network DSs and classifies them into small DSs according to certain standards for fine processing. Thus, an N-gram combined Character Based Deep Network (NCBDN) on the foundation of DGA was proposed. Fig. 5 shows the model process.

From Fig. 5, the model mainly consists of several parts, including data collection, data feature extraction and classification, abnormal data classification, and response strategy. The data detection model divides the overall network DS into smaller DS according to the network protocol, such as transmission control protocol, User Datagram Protocol and Internet control message protocol [22]. After further dividing each DS into normal and abnormal data, the experiment further classifies the abnormal DS into different attack types to form policy responses. Fig. 6 shows the data detection module and abnormal data learning module.

Fig. 4. CNN structure diagram.

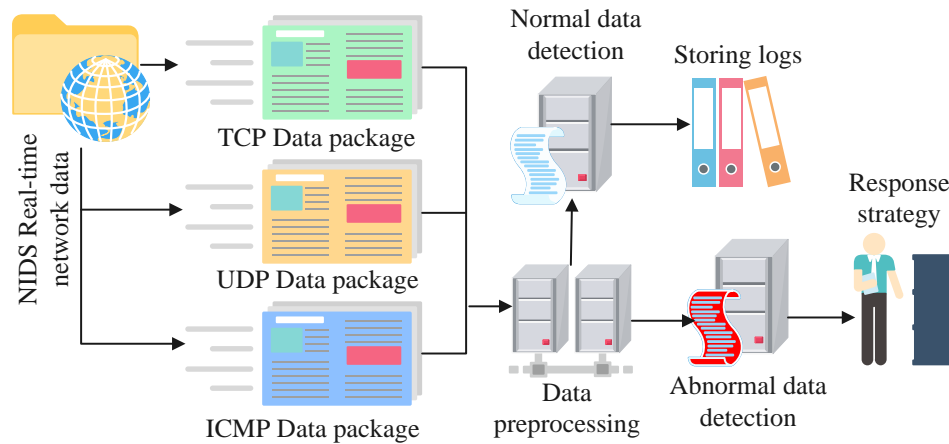

Fig. 5. Flowchart of NCBDN data probe model.

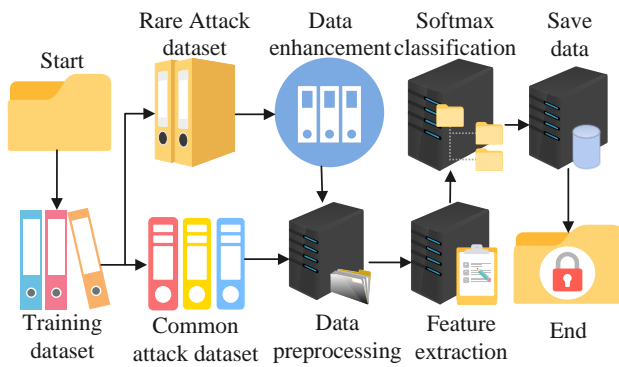

Fig. 6. Flowchart of data detection module and flow chart of abnormal data training module.

From Fig. 6, the model categorizes attack types into ordinary attacks and rare attacks. In order to form the initial training experience of the model, it is necessary to use the training set for initial training to form a basic feature library. To address malicious domain name attacks, it is necessary to first calculate the correlation coefficients between malicious domain names and normal domain names based on the characteristics of the DGA algorithm. Eq. (8) is its mathematical expression.

$$p = \frac{\sum_{i=1}^N (z_i - \bar{z})(e_i - \bar{e})}{\sqrt{\sum_{i=1}^N (z_i - \bar{z})^2} \sqrt{\sum_{i=1}^N (e_i - \bar{e})^2}} \quad (8)$$

In Eq. (8), p refers to the correlation coefficient. N refers to the total sample points. z_i and e_i respectively represent the spatial distribution values of individual normal and malicious domain names. \bar{z} and \bar{e} both represent the average domain name distribution value. According to the calculated correlation coefficient, it is necessary to perform data transformation on the incoming raw training data. This facilitates a more comprehensive analysis and classification of model in the next step. The preprocessing of data transformation first requires feature extraction of data gain. Eq.(9) is the definition of entropy.

$$Info(S) = -\sum_{i=1}^{\infty} Q_i \log(Q_i) \quad (9)$$

In Eq. (9), $Info$ is expressed as an information return function. S is expressed as a variable. Q is expressed as the probability of each variable value. So Equation (10) is the information required for identifying variables.

$$Info(L, S) = \sum_{i=1}^m |S_i|/|S| * Info(S_i) \quad (10)$$

In Eq. (10), L is expressed as a non-classified label value, and m is expressed as sample number. Combining Eq. (9) and (10) can ultimately obtain the required data gain in Eq. (11).

$$Gain(L, S) = Info(S) - Info(L, S) \quad (11)$$

In Eq. (11), $Gain$ is expressed as a gain function. After the preprocessed DS enters detection module, if the feature code matches the regular data feature code, it will be classified and archived. If the signature matches the abnormal feature, a policy response will be triggered. In addition, the judgment criteria for classifiers include multiple aspects. Eq. (12) refers to accuracy and false positive rate.

$$\begin{cases} Accuracy = (TP + TN) / (TP + TN + FP + FN) \\ FalsePositiveRate = FP / (FP + TN) \end{cases} \quad (12)$$

In Eq. (12), TP is true class, TN is true negative class, FP is false positive class, and FN is false negative class. The mathematical expressions for precision ($Precision$) and recall ($Recall$) in Eq. (13) are as follows.

$$\begin{cases} Precision = TP / (TP + FP) \\ Recall = TP / (TP + FN) \end{cases} \quad (13)$$

Eq. (14) is the mathematical expression for micro precision ($microP$) and micro recall ($microR$).

$$\begin{cases} microP = \overline{TP} / (\overline{TP} + \overline{FP}) \\ microR = \overline{TP} / (\overline{TP} + \overline{FN}) \end{cases} \quad (14)$$

The micro F1 equation in Eq. (15) can be obtained from Equation (14).

$$microF1 = (2 \times microP \times microR) / (microP + microR) \quad (15)$$

In Equation (15), $microF1$ refers to average micro harmonic value, and Equation (16) refers to macro F1.

$$macroF1 = ((2/n^2) \sum_1^n P_i R_i) / ((1/n) \sum_1^n P_i + (1/n) \sum_1^n R_i) \quad (16)$$

In Eq. (16), $macroF1$ is average macro harmonic value, P is precision, and R is recall. The intelligent judgment accuracy can be comprehensively evaluated through classifier's judgment criteria. This facilitates timely adjustment and optimization of system parameters to ensure stable model operation within the optimal range for a long time.

IV. MODEL VALIDATION AND DATA ANALYSIS

Based on the above algorithm analysis, NCBDN has higher precision in detecting, analyzing and classifying rare attacks, compared with the traditional detection model including malicious domain names based on DGA algorithm. To verify model performance advantage in detecting and identifying malicious domain names generated by DGA, NCBDN was used in this experiment to compare data detection classification of 16 domain names generated by DGA. Fig. 7 shows the

comparison of four testing standards for binary (B) character detection.

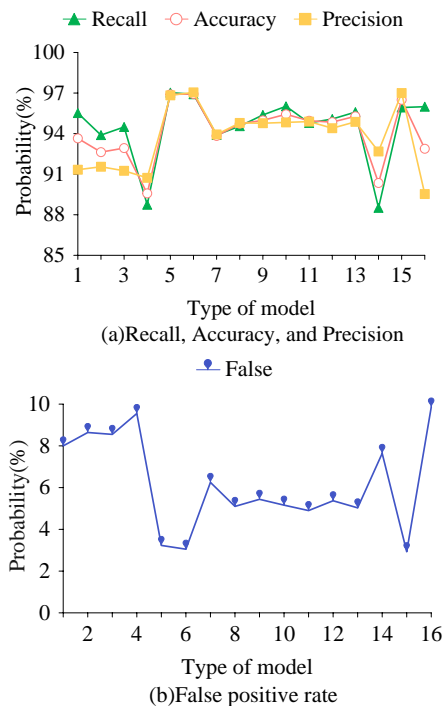

Fig. 7. Standard probability plot for bigram character detection.

From Fig. 7, NCBDN based on binary syntax has an average accuracy of about 94%, an average detection rate of about 94%, an average precision of about 93%, and an average error rate of about 6% for the recognition of 16 malicious domain names generated by DGA algorithm. Fig. 8 shows the comparison of trigram (T) character detection indicators.

Fig. 8. Standard probability plot for trigram character detection.

From Fig. 8, NCBDN recognition rate with ternary syntax for malicious domain names is further improved by about 98%, detection rate by about 98%, precision by about 98%, and error rate by about 2%. So when N=3, NCBDN has the highest efficiency in identifying malicious domain names. To further validate model advantages in identifying malicious domain names, NCBDN binary and ternary models were compared with six models for malicious domain name recognition. They include Logistic Regression (LR), Naive Bayesian Model (NB), K-Nearest Neighbor (KN), and Support Vector Machine (SV) in Fig. 9.

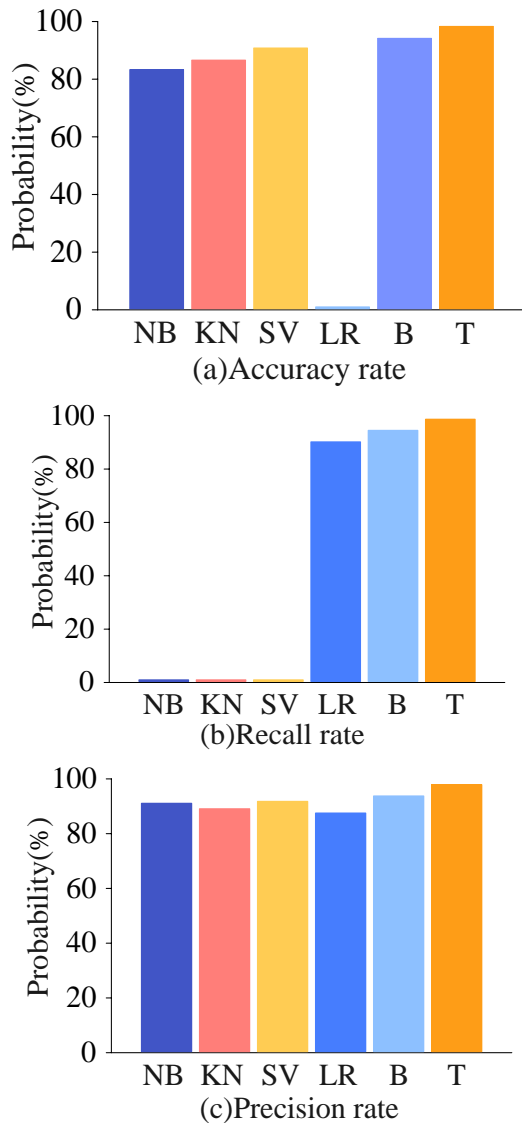

Fig. 9. Comparison of malicious domain name recognition probabilities of 17 models.

In Fig. 9, only NCBDN model under ternary syntax has an average DR of over 98%. This model can more effectively identify malicious domain names generated by DGA. This model adopts feature extraction methods to enhance the recognition probability of this model against unknown attacks. So seven methods were used, including Empirical Mode Decomposition (EMD), Hierarchical Spatial temporal features

based ID System (HAST-IDS), Text-CNN and RF based ID System (TR-IDS), Analog Network ID System (A-NIDS), Recursive Feature Addition(RFA), SVM and Intuitionistic Fuzzy Set for Anomaly Detection (IFSE-AD). The training datasets are Information Security Center of Excellence 2012 (ISCX2012) and Canadian Institute for Cybersecurity ID System 2017 (CICIDS2017).

The ISCX2012 dataset was collected by the Network Security Laboratory of Dalhousie University in Canada to provide a real network traffic dataset for research in network intrusion detection and traffic analysis. The ISCX2012 dataset consists of two sub-datasets. The Botnet-based sub-dataset contains normal traffic from the real network and malicious traffic from Zeus and ZeroAccess, among which normal traffic accounts for about 85% of the whole dataset and malicious traffic accounts for about 15%. The DDOS-based sub-dataset contains normal traffic from the real network and malicious traffic from different types of DDOS attacks, where normal traffic accounts for about 80% of the whole dataset and malicious traffic accounts for about 20%.

The CICIDS2017 dataset was collected in collaboration with the Institute for National Security and Counterterrorism (INSA) laboratory and the Cybersecurity Laboratory at Concordia University. This paper aims to provide a diverse network intrusion detection dataset for evaluating and comparing different intrusion detection systems. The CICIDS2017 dataset consists of several sub-datasets, the most commonly used of which are: The Botnet-based sub-dataset contained normal traffic from the real network and malicious traffic from malicious botnets such as Mirai, Gafgyt and TBot, among which normal traffic accounted for about 60% of the whole dataset and malicious traffic accounted for about 40%. The DDOS-based sub-dataset contains normal traffic from the real network and malicious traffic from different types of DDOS attacks, where normal traffic accounts for about 80% of the whole dataset and malicious traffic accounts for about 20%.

It is important to note that the components and proportions of the dataset may vary from version to version and use.

Table I shows the data results and the recognition efficiency of the model for unknown attacks.

In Table I, N/A indicates that the return value is invalid. From Table I, as sample number increases, model recognition accuracy increases. The recognition accuracy of EMD is 90% when data volume reaches around 10000. HAST-IDS has a recognition accuracy of over 90% with a data volume of around 900000. The accuracy of TR-IDS exceeds 90% when data volume reaches 30000. The accuracy of A-NIDS is close to 90% when data volume reaches 80000. The recognition rate of RFA is about 70% when data volume is 30. The recognition probability of IFSE-AD is over 95% when data volume reaches 20000. The accuracy of NCBDN can reach over 95% when data volume is 20. So this model has certain advantages in learning efficiency. The model has a high recognition probability for ordinary attacks, but the recognition probability for rare attacks is unknown. Fig. 10 shows the identification probability for verifying against rare attacks.

TABLE I. LEARNING AND RECOGNITION EFFICIENCY OF DIFFERENT PROBE MODELS

Method	Data Set	Sample Size	A (%)	R (%)
EMD	ISCX2012	9548	91.20	91.78
HAST-IDS	ISCX2012	819167	89.46	85.69
HAST-IDS	ISCX2012	908734	98.92	95.10
TR-IDS	ISCX2012	31407	91.45	91.76
A-NIDS	ISCX2012	80645	88.10	N/A
RFA	ISCX2012	24	76.50	70.40
RFA	ISCX2012	488	91.54	88.47
SVM	CICIDS2017	N/A	N/A	93.89
IFSE-AD	CICIDS2017	2422	92.55	N/A
IFSE-AD	CICIDS2017	23194	96.79	N/A
NCBDN	ISCX2012	8	96.26	97.99
NCBDN	ISCX2012	16	98.73	98.91
NCBDN	CICIDS2017	8	93.58	99.24
NCBDN	CICIDS2017	16	96.91	99.55

In Fig. 10, five types of data are introduced, namely Denial of Service (Dos), User to Root (U2R), Remote to Local (R2L), Probe, and Normal. U2R and R2L are rare attacks. As meta grammar increases from primeval number to 4, their recognition probability against rare attacks increases first and then decreases. When N=3, its recognition probability is the highest, about 85% for U2R and 92% for R2L. To further confirm model recognition performance when N=3, the detection accuracy was compared with Hierarchical ID model (HIDM), Managed ID model (MIDM). Fully connected detection model (FCDM), and CNN model (CNNM) in Fig. 11, respectively.

In Fig. 11, NCBDN has significant advantages over traditional models in terms of learning efficiency and detection efficiency of rare attacks. NCBDN has a high learning efficiency for unknown attacks and a high probability of identifying rare attack data.

Fig. 10. Comparison plot of data augmentation probabilities.

Fig. 11. Comparison of common detection models.

V. DISCUSSION

This study aims to explore the network intrusion detection method based on deep learning technology. With the rapid development of computer networks, cyberspace carries more and more high-value information, and the problem of network security is becoming more and more serious. The traditional intrusion detection system has the problems of slow detection speed and high false alarm rate, so it is necessary to use deep learning technology to improve the detection effect.

Several deep learning-based network intrusion detection methods have been proposed in the research. Firstly, by combining recurrent neural network with Gated Recurrent Unit (GRU) and Multilayer Perceptron (MLP), a network intrusion detection method based on GRU was proposed. Experimental results show that the proposed method has higher detection rate and lower false alarm rate. Secondly, a domain name detection method based on semantic expression is proposed. The detection of malicious domain names is realized by using deep convolutional neural networks. Experimental results show that the method has a good detection effect on domain names generated by different types of algorithms.

In addition, a network intrusion detection method for small sample based on meta-learning framework is proposed. This method realizes the detection of network intrusion behaviors in small sample scenarios through differential expression. Experimental results show that the proposed method has higher detection rate in small sample scenarios.

Finally, a low-rate denial of service attack detection method based on hybrid deep neural network was proposed. This method realizes the detection of low-rate DOS attacks by one-dimensional convolutional neural network and gated recurrent unit. Experimental results show that the proposed method has good detection effect in both large sample and small sample scenes.

In summary, the research has proposed a variety of effective network intrusion detection methods by applying deep learning techniques. Experimental results show that these methods can achieve good detection results in different scenes. Future work can further study the application of deep learning technology in the field of network security, solve the security problem of deep neural network itself, and further improve the

intrusion detection method according to the characteristics of the development of emerging networks.

VI. CONCLUSION

In response to issues such as low learning and recognition efficiency in malicious domain name attacks, this study first based on traditional NIDS models and introduced a recurrent neural deep learning network model containing GRU to make it more intelligent. To enable it to identify unknown rare attacks more quickly and accurately, this research further deepened and constructed NCBDN based on DGA algorithm. The experiment trained and learned the model using DGA algorithm and a dataset containing attack DS such as Dos, U2R, R2L, and Probe, as well as normal DS. The optimal DGA, Dos, 99%, U2R, 85%, R2L, Probe, 81%, and Normal recognition probabilities for NCBDN for malicious domain names and five types of data were 98%, 97%, and 97%, respectively. The traditional ID system has a low comprehensive average recognition rate for DGA and two rare attacks, with HIDM being 0% and 16%, and MIDM being 0% and 20%, respectively. The average recognition rate of general NN is relatively high, with FCDM being 35% and 65%, and RNNM being 68% and 71%, respectively. The highest recognition rates for NCBDN are 98% and 92%, respectively. NCBDN model is obtained by improving N-gram of the traditional network based on DGA. This model not only ensures high recognition probability for normal data and ordinary attack data. And it further improves learning efficiency for unknown attacks and the recognition probability for rare attack data. However, NCBDN has low efficiency in collecting threat data in large network traffic. Therefore, model detection efficiency for threats in big data needs to be further improved.

Abstract—Human motion intention plays an important role in designing an exoskeleton hand wrist control for post-stroke survivors especially for hand grasping movement. The challenges occurred as sEMG signal frequently being affected by noises from its surroundings. To overcome these issues, this paper aims to establish the relationship between sEMG signal with wrist angle and handgrip force. ANN and ANFIS were two approaches that have been used to design dynamic modelling for hand grasping of wrist movement at different MVC levels. Input sEMG signals value from FDS and EDC muscles were used to predict the hand grip force as a representation of output signal. From the experimental results, sEMG MVC signal level was directly proportional to the hand grip force production while hand grip force signal values will depend on the position of wrist angle. It's also concluded that the hand grip force signal production is higher while the wrist at flexion position compared to extension. A strong relationship between sEMG signal and wrist angle improved the estimation of hand grip force result thus improved the myoelectronic control device for exoskeleton hand. Moreover, ANN managed to improve the estimation accuracy result provided by ANFIS by 0.22% summation of integral absolute error value with similar testing dataset from the experiment.

Keywords—Hand grasping; wrist control; ANN; ANFIS; exoskeleton wrist design

I. INTRODUCTION

Dexterous human hand movement completed the routine of human daily activities by providing specific hand gestures for task movements, such as object grasping and posture maintenance [1],[2]. Recognizing that hand movement is changeable, as human grasping requires varying grip force and wrist angles to execute various activities [3]. Moreover, hand movement activities induced by user motion intention involves muscle contractions which can be monitored using surface electromyography (sEMG) data, resulting in force output [4],[5],[6]. However, the variation in wrist angle position associated with results in variation of sEMG signal amplitude, which would have a significant impact on the accuracy of grasp force estimation [7].

However, several diseases, including stroke, can have a negative impact on human hand function. Undeniably stroke is a major public health issue in many countries [8],[9]. In 2020, the World Health Organization (WHO) reported that 21,592

people in Malaysia had died from a stroke, accounting for 12.85% of all deaths in the country [10]. According to the 2013 Global Burden of Disease study, this disease currently ranks third among the most significant contributors to disability-adjusted life years [11], [12]. In general, approximately three-quarters of stroke survivors are still suffer from their post-stroke effects [13]. One of the most prevalent disabling effects of a stroke is upper limbs impairment [14]. Based on statistic values, between 55% to 75% of stroke survivors lost of their hand ability. This hand disability can make their survivors dependent on others for help with activities of daily living, which can lower their quality of life [15], [16]. In the sense of that, since 1952, many researchers have looked at the concept of surface electromyography (sEMG) signals production as a means of improving Human Machine Interaction (HMI) for the benefit of post-stroke survivors [17].

Providing a path to integrate HMI has always triggers a challenge among all the research. In such tasks or activities, the robot should be designed to match the human arm's dexterity and skill [18]. Therefore, it is crucial to examine the biomechanical model of human muscle force and transfer it to the robot control in order to establish smooth interaction between the human and the robot instead of simple stiff interaction [18]. Although it is difficult to estimate grip force from sEMG signals, successful force recognition can aid in the design of a usable interface for natural and accurate EMG-based robot control [19]. The estimation of a generated force from sEMG signals enables the control of robotic equipment such as exoskeletons or prostheses in real time applications [20], [21], [22].

Realizing the importance understanding of sEMG signals, wrist angle and force excitation in forming the hand movement activities, the exoskeleton hand has been created in Solidwork software and converted in visual Matlab 2017a environment to imitate the natural human hand movement. The input designed for exoskeleton hand was the sEMG signals has been analysed at different wrist angle position (flexion and extension) with different Maximum Voluntary Contraction (MVC) level of hand grasping. The output function of sEMG was the estimation of hand grip force as it was needed to improve the myoelectric control system performance [6].

Nicola Secciani et al. proposed a control strategy based on "classification loop" and a "actuation loop" to control the movement of exoskeleton hand for free grasp, spherical grasp, and cylindrical grasp [23]. In 2019, Jing Luo et. al., used Neural Network Based Approach to estimate the force based on received input EMG signals [18]. The research continues as He Mao et. al., and Jiaqi Xue et. al., used EMG signals to estimate force and angle that represent hand movement such as wrist flexion/extension, ulnar/radial deviation, pronation/supination, and grip in 2023 [3],[19]. By recognising the significance of predicting future output results based on EMG input, more opportunities of improvement can be realised, as this relationship can strengthen control area in exoskeleton hands and prostheses section for future development [24].

This paper aims to analyse the relationship between sEMG signals, wrist angle and hand grip force generation at different MVC level using Artificial Neural Network (ANN) and Adaptive Neuro-Fuzzy Inference System (ANFIS) dynamic modelling system for exoskeleton hand. The output of this relationship has been expected to improve the understanding on hand grasping control system strategy and selecting the best dynamic modelling approach for exoskeleton hand.

II. RECENT DEVELOPMENT

EMG-force relationship always been a highlight in analysing the hand grasping process related with HMI. When using a tool, such as interacting with a robot that requires a high degree of dexterity, the dynamics of a person's arms can have a significant impact on that person's daily activities [18]. Moreover, the dynamic modelling develops for the system always come with an issue of finding the suitable approach to form the relationship between input of EMG signals generated from user motion intention based on muscle contraction towards force generated as an estimated output. Daniele et al. employed a multiple linear regressions strategy to reduce the reconstruction error of exerted endpoint forces from EMG force estimates [5]. Gelareh et al. said that other researchers frequently employ ANN and Support Vector Machines (SVM) to discover mappings processes between EMG and force [4]. Furthermore, Galareh et al. revealed that researchers employed system identification approaches such as polynomial estimation, linear regression, and fast orthogonal search (FOS) to estimate force from sEMG signals [4], [6]. Jiaqi et al. focused on feature design by comparing the performance of EMG linear envelope (ENV) and non-linear EMG to muscle activation mapping (ACT) to obtain optimal force estimate performance [19].

ANN are one of the methods that can be used to define a connection between an input with an output. It acts as a black box model to approximate a complex nonlinear mapping between the sEMG signals towards their wrist angle or force generated equivalent to the signal muscle contractions related to it. ANN can learn from observation of mixture muscle signals and did not require any understanding of biological phenomena of exoskeleton hand system such as mathematical equation to express the relationship between input and output. According to Changmok et al., ANN is computationally efficient and has been implemented in various real-time

systems [25]. Numerous similar research publications have demonstrated the effectiveness of neural networks in recognising EMG patterns [26]. Francisco et al., 2020, created a multiclass categorization model using a regression algorithm and neural networks to control an anthropomorphic robotic system with three degrees of freedom that can accurately remote the robot arm to specified positions in a state machine [27].

The neural-fuzzy-based myoelectric control system is another scheme for controlling an upper limb exoskeleton-type exoskeleton. Neural fuzzy is defined as the combination of a neural network and fuzzy logic in modern artificial intelligence theory [28]. Kazuo et al. pioneered the neuro-fuzzy myoelectric control system, in which fuzzy logic was comprised of "IF and THEN" statements and the fuzzy modifier was a fully connected neural network [29], [30]. The neural network must tune the fuzzy logic using the EMG signals. Typically, data-driven approaches for ANFIS network synthesis are based on clustering a training set of numerical samples of the unknown function to be approximated. Since then, ANFIS networks have been successfully applied to classification tasks, rule-based process controls and pattern recognition problems [31]. According to Jirui et al., ANFIS can also be used to represent an effective neural network strategy for solving function estimation problems [32]. Moreover, Song Yu et. al., managed to prove the result from ANFIS is better than Tonic Stretch Reflex Threshold (TSRT) approach used for elbow flexors or extensors in their research [33].

Both ANN and ANFIS were established mapping methods that can be used to design a dynamic modelling for exoskeleton hand system. However, to enhance the performance of myoelectric control strategies for exoskeleton hand system, the selection of mapping method to form a dynamic modelling needed to be carefully selected. According to Mao et al., intuitive control that mimics human hand movement as closely as feasible has been greatly praised [3]. When interacting with the external environment, humans typically regulate their force at different wrist angle positions to ensure good operation performance [18]. However, there has been little research into the simultaneous estimation of hand grip force and wrist angles in free space, which mimic the biological functions of human hands.

III. METHODOLOGY

A. Mechanical Hand Design

The exoskeleton hand was designed to mimic the natural human hand movement. From ten male subjects ages from 21 to 40 years old, all the anthropometric hand measurement were taken. One degrees of freedom (DoF) of the wrist angle position has been highlighted in this exoskeleton hand designed covered two types of gestures: hand grasping at -45° (flexion) and 45° (extension) showed in Fig. 1. Since the wrist exoskeleton hand can be moved to achieve wrist desired angle, it is completely actuated.

Fig. 1. Exoskeleton hand designed (a) flexion position (b) extension position.

B. EMG Data Collection

All experiments procedure were approved by the University Ethical Committee or Centre for Research and Innovation Management (CRIM) at University Technical Malaysia Melaka (UTeM) Malaysia. The experiment used a Hand Dynamometer, LabQuest Mini data acquisitions, Vernier EMG sensors, a personal computer with Logger Lite data-collection software, Stopwatch, Protector, and Kendall5400 diagnostic tab electrodes. Ten male subjects signed the researcher's consent form to undertake the hand grip pattern experiment at varying wrist angles at different MVC level. The experiment began after the subjects were fully briefed. Each experiment was repeated three times [34].

Flexor Digitorum Superficialis (FDS) and Extensor Digitorum Communis (EDC) EMG signal values have been employed in this research to represent each hand grasping wrist angle movement at different MVC level [3], [35], [23]. The medial epicondyle has been used to locate the muscles and the palpate scaphoid technique has been employed to determine the position of wrist movement [36], [37]. All subjects were in good health with non-neurological diseases and used their dominant hand for data collection.

Fig. 2. Experimental set-up [38].

Fig. 2 illustrates how experimental procedures conducted. The maximum force (MVC) of the hand grasp is a measurement of the subject's strongest voluntary contraction. Electrode patches are put to the top of the abdominal muscles

of FDS and EDC. Samples were instructed to hold the hand dynamometer for five seconds at different hand grip strengths (20, 40, 60, 80, and 100% MVC level [34]. Each grip includes a two-second rest interval. The retrieved raw EMG signals were recorded using the Logger Lite programme. Fig. 3 shows the data collection for flexion and extension hand movement during the experiment.

Fig. 3. Data collections for FDS, EDC and forces during (a) wrist angle at flexion (b) wrist angle at extension.

C. EMG Signal Processing

This paper adapted time-domain-based features using Waveform Length (WL) approach as it proven itself to be the best feature extraction method among RMS, MAV, IEMG and ZC as shown in Fig. 4 [39], [40], [41]. The sampling frequency was chosen at 1 kHz to suit the EMG signals range. The segmentation of input data was reduced at 50% analysis window increment. A second-order band-pass Butterworth filter was used for this experimental procedure [42]. The MVC method, which was uniquely recorded from each subject, has been used to standardize EMG measurement values. This approach scales the measurement value between 0 to 1 and most used normalization techniques in MVC-normalization [43], [44].

Fig. 4. WL feature extraction for 20%, 60% and 100% MVC at flexion and extension wrist angle.

D. Mapping Process

Modelling creates a connection between all usage parameters. It establishes a sequential connection between inputs and outputs. This modelling constructs an accurate transfer function to characterize system performance and the measured effectiveness of the selected modelling approach. Modelling, also known as mapping, is a data-based representation of numerous group design types. Since this paper recommended employing two mapping methods, ANN

and ANFIS were trained and evaluated using the same data set to ensure that their outputs were comparable.

1) *Method 1: Dynamic Modelling of Wrist Movement Using ANN:* ANN is one of the methods to generate a dynamic modelling for one's system. Depending on application complexity, neural networks can approximate nonlinear functions using adaptive weights on different layers [45]. From all the collected data set, two of them have been used to generate a training model for ANN approaches. The default setting has been used to generate this model representation as 70% dedicated for training, 15% for validation and 15% for testing. One number of hidden layers was used to connect two inputs with one output consisting of ten neurons shown in Fig. 4. The input were the EMG signals from FDS and EDC and output are the force generated from the hand grasping procedure at different wrist angles. Tangent sigmoid has been selected as ANN activation function and Levenberg-Marquardt has been selected as the training method [24]. The EMG data set taken from selected muscles has been arranged at 20%, 60%, 100% MVC at flexion state and 20%, 60%, 100% MVC at extension state to estimate the force generation at different wrist angle position. Fig. 5 shows architecture for ANN designed to estimate the hand grasping force.

Fig. 5. ANN designed architecture.

2) *Method 2: Dynamic Modelling of Wrist Movement Using ANFIS:* ANFIS is another mapping method that can be used to create a dynamic modelling of a system. It has been built up from a combination of ANN and fuzzy logic to create its mapping block. It employs the fuzzification layer to map the input data to fuzzy sets using membership functions. The rule layer applies fuzzy if-then rules (Sugeno method) to capture the relationship between input variables and the output. The adaptation layer adjusts the parameters of the ANFIS model using a learning algorithm, allowing it to continuously improve its performance. For ANFIS setting, three sets of data coming from similar samples were used. two sets of them have been used to form a training block with 70% was dedicated for training, 15% for validation and 15% for checking. One hidden layer was chosen with ten neurons connected to the fuzzy rules to estimate the output value. FDS and EDC muscles sEMG signals have been chosen as an input while hand grasping force at different MVC levels has been selected as an output signal of a system. Number for membership function (mf) of ten neurons with combination of [2 8] and type of "gauss2mf" was set as an input and output

selected "constant" as their MF type. 20%, 60% and 100% MVC level for both flexion and extension of sEMG signal level have been arranged to predict the force hand grasping output. Fig. 6 shows an ANFIS designed architecture for the system.

Fig. 6. ANFIS designed architecture.

IV. RESULTS

Fig. 7 depicts an analysis of hand grip forces. Within the same graph, a three-line force graph is plotted. Two of them are line graphs that depict the output from the ANN (magenta) and ANFIS (light blue) mapping processes, while the other (blue) was directly taken from the measurement process during the experimental procedure. As the wrist goes from flexion to extension, the graph is divided into two portions. The first section (wrist angle at flexion position) occurred between 0s and 233s. This section is organized into three subsections to represent the signal levels of 20% MVC, 60% MVC, and 100% MVC. The second part (wrist angle at extension position) existed between 234s and 467s. This section has also been separated into three subsections to represent the signal levels of 20% MVC, 60% MVC, and 100% MVC.

Fig. 7. Hand grip force analysis graph.

Fig. 8 depicts the absolute error for the ANN and ANFIS mapping methods. The magenta line graph is an error graph for the ANN approach, whereas the light blue graph is formed by the ANFIS approach. Both graph line plotting reveals a fluctuation pattern signal generated by both ways, as can be seen. Each method seems to have close estimated hand grip force and error values compare to each other and produce

quite a similar graph instead. These graphs were created by deducing the force measured value during the experiment process from the force estimation value obtained from both approaches. The total summation area under each graph representing the total summation error for each approaches used. According to Fig. 8, the sum of absolute error for the ANN technique was 19.33%, while the ANFIS approach was 19.55%. Based on this finding, ANN outperformed ANFIS in force estimation with a similar dataset and parameter settings.

Fig. 8. Absolute error for ANN and ANFIS.

V. DISCUSSIONS

All of the hand grip forces MVC's plotting in the flexion part have higher values than their identical MVC's opponent in the extension section. The situation happened as referring to the normal human hand grasping movement. As the user motion intention directed the hand wrist angle to move towards human body, FDS muscle (flexion muscle) produce higher sEMG values compared to EDC muscle (extension muscle) signal which causing the flexion hand movement as shown in Fig. 3 [38]. For the flexion hand movement, the measured and estimated force values obviously demonstrated a higher signal level compared to their MVC in the other section. For the extension section, the hand wrist angle was pulled away from the human body, causing the EDC muscle to generate a greater sEMG value than the FCR muscle [3], [39]. As shown in Fig. 7, this extension movement degrades the hand grasp force value in each MVC level compared to the flexion movement.

At 20% MVC flexion section, the estimation graph plotting from both ANN and ANFIS mapping lingering closer to the measured value during the experiment. However, in the extension section, the estimation graph plotting introduced a small gap reading compared to the value from the experimental procedure. This could happen because the sEMG signal values from both muscles are almost the same when they are contracting at a lower level. The wrist angle position doesn't seem to have a big impact on how the signal number is read. Different case happened at 60% MVC level for both sections. Both muscles produce significant values of sEMG signals that causing the estimation force graph plotting for both approaches manage to differentiate between different wrist angle position. The fluctuation of force output graph might be coming from the nonlinearity of sEMG signals muscles contraction and the noise that interrupted during the data collection.

For 100% MVC, the force signals output estimation for the flexion section manages to have a higher value in their estimation but still does not give the same value as the measured one. The explanation for this is because subjects were instructed to flex their hands while grasping the hand dynamometer with 100% strength at 100% MVC of muscle contractions. Hand shaking commonly happened at this stage thus created a noisy environment while the data is being recorded, hence resulting an effect towards sEMG values used in the estimation process. For the extension section, at 100% MVC, the estimation graph for both hand grip force approaches achieves a nearly identical with the measured one due to a favourable environment for muscles contractions and a lower force measured value that allows the subject to perform well in hand grasping experimental procedure.

VI. CONCLUSION

Hand grasping is one of the most essential hand gestures for humans, including post-stroke patient survivors, to perform daily tasks. To comprehend and control the exoskeleton hand grasping gesture, the relationship between sEMG signal value, wrist angle, and hand grip force production triggered by the user's intention to grasp an object must be clearly understood. WL was chosen for feature extraction method in time domain in this study. To clarify the concept of force generation in both conditions, 20%, 60%, and 100% of the MVC level for flexion and extension wrist joint angle movement were analysed. As a consequence of the experiment procedure and dynamic modelling process, the sEMG MVC signal level was determined directly proportional to the generation of hand grip force. However, the hand grip force signal generated will depend on the wrist angle position. It was also determined that the hand grasp force signal production became greater when the wrist was in flexion as opposed to extension.

ANN and ANFIS were both dynamic modelling method used to analyse the hand grip force estimation. ANN has the capability to interpret unstructured data while, ANFIS used the strength from ANN and fuzzy to adapt with various environments to design a mapping system for exoskeleton hand. For the whole exoskeleton hand system, ANN and ANFIS needs a similar training and testing data set. Both approaches manage to generate its own dynamic model to represent the exoskeleton hand system. When compared to measured hand grip force recorded throughout the experiment process, ANN outperformed ANFIS by 0.22% absolute error with similar settings for both systems. When compared to ANFIS, the ANN technique produces a more accurate estimation of hand grip force output results.

The limitation of this study was the small number of neurons of ten provided for the ANN and ANFIS methods. Because this paper only focused on a similar number of neurons for output comparison, the value of neurons and their combination can be varied to produce a variety of possible output for the estimation results. Moreover, there are other regression method available they may need to be considered to improved estimation output results such as Support Vector Regression (SVR), Linear Regression (LR), Gaussian Process Regression (GPR), ensemble and decision tree.

Research on Semantic Segmentation Method of Remote Sensing Image Based on Self-supervised Learning

Wenbo Zhang, Achuan Wang

College of Computer and Control Engineering, Northeast Forestry University, Harbin, China

Abstract—To address the challenge of requiring a large amount of manually annotated data for semantic segmentation of remote sensing images using deep learning, a method based on self-supervised learning is proposed. Firstly, to simultaneously learn the global and local features of remote sensing images, a self-supervised learning network structure called TBSNet (Triple-Branch Self-supervised Network) is constructed. This network comprises an image transformation prediction branch, a global contrastive learning branch, and a local contrastive learning branch. The contrastive learning part of the network employs a novel data augmentation method to simulate positive pairs of the same remote sensing images under different weather conditions, enhancing the model's performance. Meanwhile, the model integrates channel attention and spatial attention mechanisms in the projection head structure of the global contrastive learning branch, and replaces a fully connected layer with a convolutional layer in the local contrastive learning branch, thus improving the model's feature extraction ability. Secondly, to mitigate the high computational cost during the pre-training phase, an algorithm optimization strategy is proposed using the TraIn method and sequential optimization theory, which increases the efficiency of pre-training. Lastly, by fine-tuning the model with a small amount of annotated data, effective semantic segmentation of remote sensing images is achieved even with limited annotated data. The experimental results indicate that with only 10% annotated data, the overall accuracy (OA) and recall of this model have improved by 4.60% and 4.88% respectively, compared to the traditional self-supervised model SimCLR (A Simple Framework for Contrastive Learning of Visual Representations). This provides significant application value for tasks such as semantic segmentation in remote sensing imagery and other computer vision domains.

Keywords—Computer vision; deep learning; self-supervised learning; remote sensing image; semantic segmentation

I. INTRODUCTION

With the rapid development of remote sensing satellite technology, remote sensing images are playing an increasingly critical role in various fields such as urban planning, resource exploration, and natural disaster prediction. Extracting useful information from the vast wealth of remote sensing geo-information has become a long-standing scientific challenge in remote sensing. Among the methods explored, semantic segmentation [2] has proven to be an effective approach.

In the field of semantic segmentation for remote sensing images, there are two main approaches: traditional methods

based on handcrafted feature descriptors and deep learning methods based on Convolutional Neural Networks (CNNs). Due to the complexity of background and scale differences in high-resolution remote sensing images, traditional methods have not been very effective. However, since Long et al. proposed the Fully Convolutional Neural Network (FCN) [3] in 2015, deep learning-based techniques for semantic segmentation in remote sensing images have made significant progress. This has led to the development of post-processing techniques based on probabilistic graphical models [4], global context modeling using multi-scale aggregations [5], and perpixel semantic modeling based on attention mechanisms [6].

For instance, Ronneberger et al. introduced the U-Net model [7], which employs an encoder-decoder architecture with lateral connections, enabling multi-scale recognition and feature fusion in the image. Similarly, Chen et al. proposed the DeepLabV3+ model [8], which utilizes a spatial pyramid structure to gather rich contextual information through pooling operations at various resolutions. Furthermore, it uses the encoder-decoder architecture to achieve precise object boundaries, thereby enhancing segmentation accuracy.

Despite the achievements made in deep learning-based semantic segmentation of remote sensing images in recent years [9][10], these methods all rely on large amounts of manually annotated data to train the neural network. This requirement not only consumes significant human resources but also reduces the efficiency of semantic segmentation. Therefore, the application of self-supervised learning [11] to semantic segmentation of remote sensing images has become a feasible method. Li et al. [12] proposed a multi-task self-supervised learning method for semantic segmentation of remote sensing images, which applied three pretext tasks [13] to self-supervised learning and achieved decent results. However, these pretext tasks only learn the global features of the image, lacking in the learning of local features of the image. Thus, how to effectively use these unannotated remote sensing data has become a major research focus in recent years.

The main contributions of this study are as follows:

1) To tackle the aforementioned challenges, a self-supervised semantic segmentation approach for remote sensing images is introduced, along with the design of a triple-branch self-supervised network named TBSNet. This network

uses an image transformation prediction branch and a global contrastive learning branch to learn global features of images, and a local contrastive learning branch to learn local features.

2) On this basis, the projection head structures in the global contrastive learning branch and the local contrastive learning branch are improved to enhance their performance. Specifically, in the projection head of the global contrastive learning branch, a combination of spatial attention mechanisms [14] and channel attention mechanisms [15] are used to better focus on the important parts of the feature map, thus improving the quality of feature representation. In the local contrastive learning branch, the original first fully connected layer is replaced with a convolutional layer, which enables the learning of richer local features.

3) Considering the heavy computational cost of pre-training, the TracIn method [16] and sequential optimization theory [17] are employed to optimize the model's pre-training process, reducing computational and time costs. Finally, the model is fine-tuned in the downstream task using a small amount of annotated data to achieve the expected semantic segmentation results.

The remaining structure of the article is outlined as follows: Section II introduces the background knowledge and relevant work. Section III describes the implementation details of the proposed method, including the network framework and optimization techniques. Section IV presents the experiments conducted and analyzes the obtained results. Section V provides the conclusions drawn from our experiments.

II. BACKGROUND

A. Self-supervised Learning

Self-supervised learning is a type of unsupervised learning [18], as shown in Fig. 1. Compared to supervised learning, it utilizes a large amount of unlabeled data through specially designed pretext tasks. This approach relies on pseudo-labels generated by the model itself, enabling it to learn high-level features from the input data. The model can then be further transferred to downstream tasks in actual applications. With a small amount of labeled data, the model can be fine-tuned to achieve, or even surpass, the performance of supervised learning. Generally, self-supervised learning can be divided into generative and contrastive categories [19] [20].

B. Pretext Task

During the self-supervised pre-training phase, different pretext tasks are typically designed to allow the model to more effectively learn the intrinsic features and interrelationships within the samples. By performing these pretext tasks, the model can generate pseudo-labels internally to guide its learning, thus achieving self-supervised learning without the need for labeled data. Classic pretext tasks include image inpainting [21], which uses neural networks to repair missing parts by learning texture features; rotation prediction [22], which allows neural networks to grasp the overall features of an image; and jigsaw puzzles [23], where the neural network needs to learn the relative positional features among different pieces for image stitching. These pretext tasks have achieved

good results in instance-level image classification tasks. However, their effectiveness is not ideal for semantic segmentation tasks due to a lack of learning about local features.

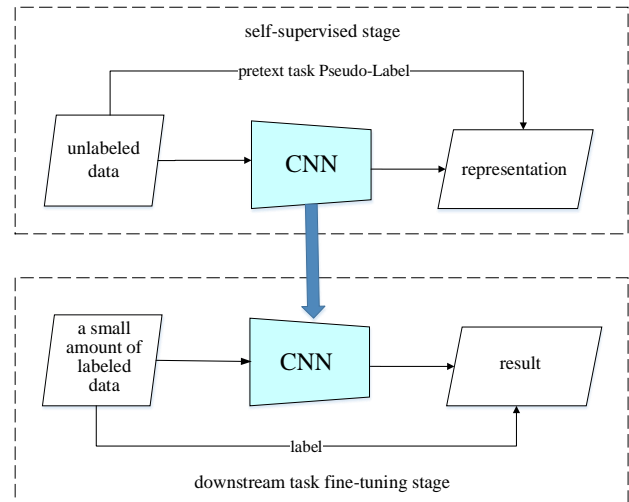

Fig. 1. Schematic diagram of self-supervised model.

C. Contrastive Learning

Contrastive self-supervised learning [24], also referred to as contrastive learning, shows more promising results in the field of remote sensing compared to generative self-supervised learning. The central idea of contrastive learning, a common method of self-supervised learning, is to learn high-level semantic features by contrasting two semantically similar inputs. Specifically, samples are divided into positive and negative pairs, with the aim of drawing positive samples closer while pushing negative samples farther apart, as shown in formula (1):

$$\text{sim}(f(x), f(x^+)) \gg \text{sim}(f(x), f(x^-)) \quad (1)$$

Here, x^+ represents a sample semantically similar to x , thus forming a positive pair with x ; x^- is a sample that is different from x , thereby forming a negative pair with x . sim represents the similarity measure between two pairs of features generated by encoding function f .

Classic examples of contrastive learning include Momentum contrast (MoCo) [25] and SimCLR [26]. MoCo introduces momentum contrast for unsupervised visual representation learning, constructing a dynamic dictionary with a queue and a moving average encoder to improve the effects of contrastive learning. SimCLR presents a simple framework where two different data augmentations of the same image x are generated as a positive pair (x_i and x_j), while the augmented image from a different image y serves as a negative sample. A projection head is added after the encoder to achieve significant results. While both of the above-mentioned models have achieved significant accomplishments in self-supervised learning research, they also exhibit notable limitations. This is because both models utilize pairs of images as positive samples, allowing them to effectively learn overall features of images. However, they lack the ability to learn local features.

Recent years have seen extensive research on image processing based on contrastive learning, such as a method proposed by Krishna et al. for medical image semantic segmentation based on global and local features [27]. Research on self-supervised learning for remote sensing images mainly focuses on instance-level remote sensing scene classification [28][29], given the comparatively limited exploration of pixel-level semantic segmentation in the context of remote sensing images, a triple-branch network architecture is introduced. This architecture facilitates the acquisition of both global and local image features, consequently leading to enhanced semantic segmentation outcomes for remote sensing images.

D. TraIn Method

Deep learning requires a large amount of data support, and the quality of data often has a significant impact on model training. An important measure of data quality is influence, but due to the complexity of models and the growing influence of scale features and datasets, it is challenging to quantify influence. The TraIn method captures changes in predictions when accessing individual training examples by tracking the training process and determines the influence of training examples by assigning influence scores to each.

E. Order Optimization Theory

Order Optimization (OO) is an effective strategy widely used in the industry to solve optimization problems, with its specific solution process shown in Fig. 2.

For a given optimization problem, suppose the set of the "truly best" g solutions is G . However, due to computational resource constraints, the set G cannot be solved from the solution space. Using the order optimization idea, a rough model with simple computations is used to select some solutions from G . All solutions are ranked according to some performance evaluation method provided by the rough model, and the best s solutions are chosen to form the solution set S . In the process of using the rough model, we generally only care about how many of the intersecting parts of sets G and S ($G \cap S$) are genuinely good solutions. The order optimization quantifies the probability that the set S obtained based on the rough model corresponds to $|G \cap S| \geq k$, i.e., the alignment probability (AP). In practice, the alignment probability of sets S and G is often much larger than expected, and the amount of data in set S is often several orders of magnitude smaller than the real solution space, so the order optimization method can typically save at least one order of magnitude of performance evaluation times.

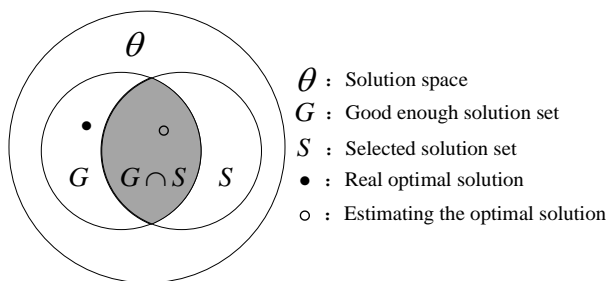

Fig. 2. Schematic diagram of solving sequential optimization theory.

III. PROPOSED METHOD

A. Network Architecture Design for Semantic Segmentation of Remote Sensing Images Based on Self-supervised Learning

With the objective of improving the outcomes of semantic segmentation for remote sensing images using a limited quantity of annotated data, as well as intensifying the acquisition of local small-object characteristics, a triple-branch network architecture known as TBSNet is introduced. As shown in Fig. 3, this network structure includes an image transformation prediction branch, a global contrastive learning branch, and a local contrastive learning branch. The image transformation branch are used to learn the overall features of the image, while the local contrastive learning branch can learn the local features of the image. Each branch performs self-supervised learning in different ways, and then the losses of each branch are summed up as the total loss for adjusting the network parameters.

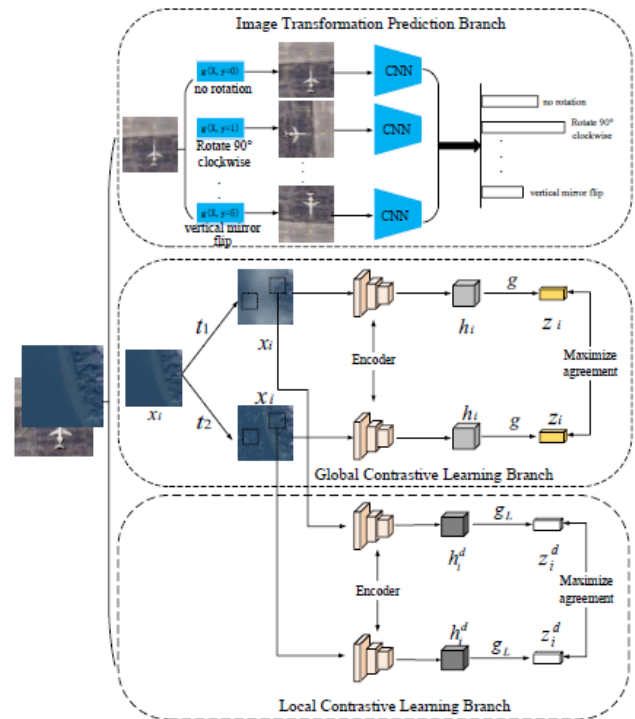

Fig. 3. Schematic diagram of triple-branch network TBSNet.

1) Design of Image Transformation Prediction Branch Learning Strategy: To realize the learning of overall semantic features of images without labels, this branch randomly rotates (e.g., 90°, 180°, 270°) or mirror flips the original image, and feeds the original image and the rotated image into the neural network for transformation type identification. Since remote sensing images have rotation invariance, rotation can help the neural network better understand the concepts described in remote sensing images. Specifically, the aforementioned rotations are defined as a set of discrete geometric transformations $G = \{y_0, y_1, \dots, y_m\}$. One is randomly selected from G and applied to the input image x to get x' , which is

then fed into the network and trained to identify the type of rotation, transforming the image transformation prediction branch into a classification problem. The loss function of the transformation prediction branch can be defined as shown in equation (2):

$$L_{\alpha} = -\sum_{m=1}^M \hat{A}_{(m)} \log P_{(m)} \quad (2)$$

Here, $\hat{A}_{(m)} = \{0,1\}$ represents the one-hot encoding of the basic true value class, and P represents the probability of M different types of geometric transformations. In this branch, geometric transformations are divided into six types, which are clockwise rotation of 90° , 180° , 270° , horizontal left-right mirror flipping, vertical top-bottom mirror flipping, and no rotation.

2) Global Contrastive Learning Branch Learning Strategy Design

a) Remote Sensing Data Enhancement Method Based on Weather Conditions: For the same location, remote sensing images under different weather conditions exhibit variations, yet their deep features remain consistent. Consequently, in the global contrastive learning segment, traditional data augmentation approaches for forming positive sample pairs are eschewed. Instead, the data augmentation method is adjusted to mimic diverse weather conditions at the identical location, aligning with the distinct traits of remote sensing images. Any x_i in $\{x_1, x_2, \dots, x_N\}$ undergoes two different random data augmentations (including simulating clouds, simulating snowflakes, simulating haze, and no augmentation). To simulate cloud layers, this paper adds Perlin noise to the original image and then blurs the cloud layer using a Gaussian filter. To simulate snowflakes, random noise is added to the original image, and then a median filter is used to simulate the snowflake effect. To simulate haze, we utilize a method of overlaying a generated haze layer onto the original image. The haze layer is represented by an array of the same size as the original image. To ensure uniform effect across all color channels, this array is expanded to a three-channel array, with each channel having the same values as the original random array. Each element of the haze layer is multiplied by the haze intensity, and the result is multiplied with each pixel of the original image. This effectively reduces the contrast of the original image in the haze areas. Then, the haze layer is multiplied by the atmospheric brightness and added to the original image, simulating the haze effect. In this paper, the haze intensity is randomly selected between 0.3 and 0.8, and the atmospheric brightness is randomly chosen between 250 and 270.

b) Model design integrating channel and spatial attention mechanisms: The two samples \tilde{x}_i and \hat{x}_i obtained after enhancement are positive samples for each other, and other samples in the same batch are all negative samples. The two positive samples obtained are passed through the encoder-based backbone network f to get the feature vectors \tilde{h}_i and \hat{h}_i , which are then mapped to the contrast loss space through an improved MLP projection head $g(\cdot)$ to get \tilde{z}_i and \hat{z}_i . As shown in Fig. 4, this work introduce the combination of channel

attention mechanism and spatial attention mechanism on the basis of the original projection head, improving the discriminability and expressive power of features. It can also adaptively select important features, which helps to improve the model's generalization ability on different types of remote sensing images. In order to better integrate the channel attention module and the spatial attention module, a convolution layer and ReLU activation function are added. This additional convolution layer can help to further extract features before applying the attention mechanism.

Fig. 4. Schematic diagram of global contrastive learning branch projection head structure.

Lastly, the contrast loss is used to bring positive samples closer, thus learning the geographical features in the image. The contrast loss is defined as follows in equation (3):

$$L_{\beta} = \frac{1}{2N} \sum_{k=1}^N \left(l_{\beta}(\tilde{x}_i, \hat{x}_i) + l_{\beta}(\hat{x}_i, \tilde{x}_i) \right) \quad (3)$$

Where N represents the number of samples in the same batch, l_{β} uses the NT-Xent contrast loss function in SimCLR as shown in equation (4):

$$l_{\beta}(\tilde{x}_i, \hat{x}_i) = -\log \frac{\exp\left(\frac{\text{sim}(\tilde{z}_i, \hat{z}_i)}{\tau}\right)}{\sum_{k=1}^{2N} \mathbf{1}_{[k \neq i]} \exp\left(\frac{\text{sim}(\tilde{z}_i, z_k)}{\tau}\right)} \quad (4)$$

Here, $\mathbf{1}_{[k \neq i]}$ is an indicator function that equals 1 when $k \neq i$, $\text{sim}(u, v) = \frac{u^T v}{\|u\| \|v\|}$, i.e., it calculates the cosine similarity between u and v . z_k represents the feature vector obtained after the negative sample goes through the projection head, that is, $z_k = g(f(t(x_k)))$. τ is the temperature parameter, which is set to 0.1 in this paper.

3) Local Contrastive Learning Branch Learning Strategy Design: The above two branches can effectively learn the global information of images. However, for semantic segmentation, learning only global features is not enough. A single remote sensing image may contain various objects, and the learning of global features cannot effectively handle small targets. Therefore, the local contrastive learning branch can learn more local information, which is crucial for improving the performance of semantic segmentation. This branch shares the sample after data augmentation with the global contrastive learning branch. It forms positive sample pairs by selecting two local blocks of the same size from the same location in two augmentation images, and takes the local areas of other images in the same batch as negative samples. In this paper, a random selection of a central pixel point and outward expansion method is employed for selecting a local region. To

prevent insufficient edge size, if the selected size is $s \times s$, the central pixel point is chosen within the rectangular region formed by the four points: $\left(\left\lfloor \frac{s}{2} \right\rfloor, \left\lfloor \frac{s}{2} \right\rfloor\right), \left(\left\lfloor \frac{s}{2} \right\rfloor, \left(255 - \left\lfloor \frac{s}{2} \right\rfloor\right)\right), \left(\left(255 - \left\lfloor \frac{s}{2} \right\rfloor\right), \left\lfloor \frac{s}{2} \right\rfloor\right), \left(\left(255 - \left\lfloor \frac{s}{2} \right\rfloor\right), \left(255 - \left\lfloor \frac{s}{2} \right\rfloor\right)\right)$. To avoid excessive duplication of selected regions, pixels are only chosen with odd coordinates. Moreover, to prevent selecting the same region multiple times, each pixel point can only be selected once.

Just like the global contrastive learning branch, for each global contrastive learning image, m local areas are selected for contrast learning. Therefore, for the selected two local areas \widetilde{x}_i^d and \widehat{x}_i^d ($d \in (1, m)$), after going through the encoder, we get the feature vectors \widetilde{h}_i^d and \widehat{h}_i^d , and finally map the local area features to be \widetilde{z}_i^d and \widehat{z}_i^d through the projection head $g_L(\cdot)$ similar to the one in the global contrastive learning branch. As shown in Fig. 5, in this branch, since the sample image has already been cropped to the local area, the attention mechanism is not used in the projection head. Instead, the first fully connected layer in the original projection head is replaced with a convolution layer to retain spatial information and better capture the features within the local area, thus improving the segmentation effect of the model.

Fig. 5. Schematic diagram of local contrastive learning branch projection head structure.

The contrast loss can be represented as equation (5):

$$L_\gamma = \frac{1}{2N_\gamma} \sum_{i=1}^{N_\gamma} \left(l_c(\widetilde{x}_i^d, \widehat{x}_i^d), l_c(\widetilde{x}_i^d, \widehat{x}_i^d) \right) \quad (5)$$

$$\text{where, } l_c(\widetilde{x}_i^d, \widehat{x}_i^d) = -\log \frac{\exp\left(\frac{\text{sim}(\widetilde{z}_i^d, \widehat{z}_i^d)}{\tau}\right)}{\sum_{k_d \in \Lambda_\gamma^-} \exp\left(\frac{\text{sim}(\widetilde{z}_i^d, z_{k_d}^d)}{\tau}\right)} \quad (6)$$

In this, N_γ represents the number of all local regions in a batch, i.e., $N_\gamma = N \times m$. Λ_γ^- represents the other local regions outside the two local area positive samples.

The total loss of the triple-branch self-supervised network can be represented as shown in equation (7), which is used for the calculation of the TracIn score during optimization.

$$L = L_\alpha + L_\beta + L_\gamma \quad (7)$$

B. Design of Self-supervised Network Architecture Based on Semantic Segmentation of Remote Sensing Images

Since self-supervised pre-training requires a large amount of data as support, but a large amount of data will inevitably increase the calculation amount and consume time cost. Therefore, how to effectively optimize the self-supervised learning algorithm becomes the key to solve the cost problem of self-supervised learning. This paper proposes to optimize the self-supervised learning algorithm by using the TracIn method and sequence optimization theory, achieving the effect of using all data to train the model by only pre-training the model with the top 80% of training points that contribute the most, reducing calculation cost and time cost.

1) *Training point score calculation based on TracIn method:* The TracIn method identifies the overall impact of training examples by tracking the training process. Its principle is as follows: Z represents the sample space, z and z' respectively represent the training point (training sample) and test point (test sample). Given a set of k training points $S = \{z_1, z_2, \dots, z_k \in Z\}$, train the predictor by finding the parameters ω that minimize the training loss $Loss = \sum_{i=1}^k L(\omega, z_i)$ through the iterative optimization process using a training point $z_t \in S$ in iteration t , and update the parameter vector from ω_t to ω_{t+1} . For the training point $z \in S$, the loss reduction caused by the training process for a given test point $z' \in Z$ can be expressed as:

$$TracInIdeal(z, z') = \sum_{t: z_t=z} L(\omega_t, z') - L(\omega_{t+1}, z') \quad (8)$$

By limiting the gradient to a specific gradient descent and substituting the parameter change formula into a first-order approximation and ignoring the high-order term $O(\eta_t^2)$, the following first-order approximation of loss change can be obtained:

$$L(\omega_t, z') - L(\omega_{t+1}, z') \approx \eta_t \nabla L(\omega_t, z') \cdot \nabla L(\omega_t, z) \quad (9)$$

where η_t represents the step length in iteration t .

For a specific training point z , this approximation can approximate the idealized influence by summing this approximation over all iterations where z is used to update the parameters. This first-order approximation is referred to as $TracIn_{TBSNet}$, as shown in equation (10):

$$TracIn_{TBSNet}(z, z') = \sum_{t: z_t=z} \eta_t \nabla L(\omega_t, z') \cdot \nabla L(\omega_t, z) \quad (10)$$

From the above equation, it can be seen that the score of a training point q_i at a test point q_j can be expressed as:

$$tracin_{score_{q_i, q_j}} = TracIn_{TBSNet}(q_i, q_j) \quad (11)$$

In order to verify the difference in contributions among each training point, the scores of each training point on the test point are summed up, and the final score obtained is the total score of this training point, that is:

$$Score_i = \sum_{j=0}^N tracin_{score_{q_i, q_j}} \quad (12)$$

where N represents the number of test points.

2) *Optimization of TBSNet training process based on sequential optimization*: Following the computation of the TraCIn score as outlined earlier, scores can be derived for each training point against the identical set of test points. Based on the idea in sequential optimization that "sequence is more useful than ratio," each training point's TraCIn score can be seen as abstracting each training point into a sortable value. For the triple-branch network model that applies the TraCIn method, the scores of each training point are sorted, and the training points with higher scores are considered to contribute more, while the training points with lower scores are considered to contribute less. Therefore, using only a certain range of higher scoring training points can achieve results comparable to training with all training points. The specific operation process is shown in Fig. 6.

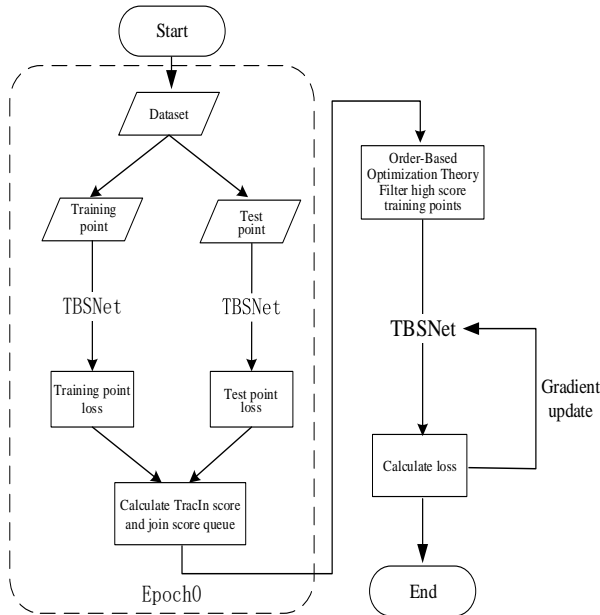

Fig. 6. Schematic diagram of training optimization process.

After the pre-training is completed, the trained neural network is transferred to the downstream task for fine-tuning.

IV. EXPERIMENTAL RESULTS AND ANALYSIS

A. Dataset Selection

The dataset utilized for this study is derived from high-resolution satellite remote sensing images from the southern regions of China. To validate the generalization capability of the proposed method, this dataset amalgamates imagery from various locations and different satellite types. These datasets were uniformly re-annotated into five land cover categories: vegetation, buildings, roads, water bodies, and others. In total, it comprises 12 large-scale RGB original images ranging from 4000×4000 to 8000×8000 pixels.

Due to computational resource constraints, the original remote sensing images were segmented into patches of 256×256 pixels. Additionally, to meet the extensive data

requirements for pre-training, the experimental dataset was augmented using random noise, Gaussian blur, and color transformations, resulting in an enriched dataset. Ultimately, a training sample consisting of 100,000 images was established.

B. Evaluation Metrics

For validating and evaluating the suggested approach in subsequent tasks related to remote sensing image segmentation, the performance metrics employed are Overall Accuracy (OA) and Recall. These metrics are defined in equations (13) and (14) as provided below:

$$OA = \frac{TP}{N} \quad (13)$$

$$Recall = \frac{TP}{TP+FN} \quad (14)$$

Here, TP represents the correctly predicted pixel count, or true positives. FN signifies the incorrectly predicted pixel count, or false negatives. N denotes the total number of pixels.

C. Experimental Setup and Configuration

The experiment was conducted in a Linux environment, with an Intel(R) Xeon(R) Gold 5218R CPU and NVIDIA GeForce RTX 2080Ti 11Gb GPU. Programming was done in Python 3.8 within the PyTorch framework, with Resnet50 as the backbone network and DeepLabV3+ for segmentation. The initial learning rate during the self-supervised stage was set to 0.01, batch size was 32, region size in the local contrast learning branch was 24×24, and six local areas were selected from each image. The pre-training stage was set to run for 500 epochs using the Adam optimizer. The initial learning rate for the fine-tuning stage was set to 0.005, the fine-tuning epoch was set to 50, and the training and validation sets were split in a 7:3 ratio. The selection of training and testing points for calculating the TraCIn score was done per batch, and the ratio of training points to testing points was set at 5:1.

The experiment started with the computation of TraCIn scores for each training point during the first training round. Following the idea of sequential optimization, the top 80% of training points with higher TraCIn scores were selected for further self-supervised pre-training. Finally, after pre-training, the trained model was fine-tuned on a downstream segmentation task using a small amount of labeled data.

D. Comparative Experiment

To validate the effectiveness of our method, we compared it against several mainstream methods, including MoCo v2 [30], which uses a dynamic dictionary for contrastive learning, SimCLR, which uses data augmentation to create positive pairs for contrastive learning, the classic self-supervised learning pretext task of image inpainting, and supervised pre-training models using ImageNet for segmentation. In this paper, we used 0.5%, 1%, 5%, and 10% of the self-supervised pre-training data to fine-tune the downstream task, as shown in Table I. For different models' semantic segmentation experiments on this dataset, some experimental results are shown in Fig. 7.

Fig. 7. Comparison experiment effect picture.

TABLE I. COMPARATIVE EXPERIMENTAL RESULTS OF DIFFERENT MODELS

Fine-tune data volume	0.5%		1%		5%		10%	
	OA	Recall	OA	Recall	OA	Recall	OA	Recall
Inpainting	0.2764	0.2593	0.4375	0.4359	0.5158	0.4783	0.5709	0.5256
SimCLR	0.3809	0.3825	0.4604	0.4289	0.5781	0.5452	0.6679	0.6623
MoCo v2	0.3654	0.3577	0.4432	0.3964	0.5295	0.5114	0.6067	0.6008
ImageNet	0.3848	0.3826	0.4128	0.4049	0.5624	0.5551	0.6792	0.6567
Ours(TBSnet)	0.3856	0.3831	0.4721	0.4558	0.5739	0.5584	0.7139	0.7111

Our results show that our method is effective for land cover segmentation in remote sensing images. With only 10% of labeled data used for fine-tuning, the overall accuracy (OA) and recall reached 0.7139 and 0.7111 respectively, representing a significant improvement over advanced self-supervised models such as MoCo v2 and SimCLR.

Analysis of the results reveals that since Inpainting mainly predicts missing areas from the image's context, it often lacks precision for complex remote sensing images, thus performing the worst in the experiments. Both MoCo v2 and SimCLR focus on global features, and their effectiveness is limited due to the lack of learning of local features in remote sensing images. Although ImageNet uses millions of natural images for pre-training, the differences in distribution, texture, and color between remote sensing images and natural images make ImageNet pre-training ineffective for downstream remote sensing image segmentation tasks. Our method performs well in learning both global and local features, demonstrating great application potential worthy of further research and exploration.

E. Ablation Experiments

1) *Ablation experiments on the three-branch network structure:* In the ablation experiments on the triple-branch network structure, 10% of pre-training data was used for fine-tuning. After one round of training, the top 80% of training points based on TracIn scores were selected for training. The following experiments were designed to demonstrate the effectiveness of the proposed method: using only the image rotation prediction branch (Exp1), using only the global

contrast learning branch (Exp2), using only the local contrast learning branch (Exp3), using both the global and local contrast learning branches (Exp4), using the image rotation prediction branch and the global contrast learning branch (Exp5), using the image rotation prediction branch and the local contrast learning branch (Exp6), and using the complete triple-branch network (Exp7). The experiment results are shown in Table II.

TABLE II. EXPERIMENTAL RESULTS OF TRIPLE BRANCH NETWORK ABLATION

	Exp1	Exp2	Exp3	Exp4	Exp5	Exp6	Exp7
OA	0.5726	0.6593	0.5830	0.6845	0.6507	0.6732	0.7139
Recall	0.5658	0.6494	0.5800	0.6744	0.6457	0.6642	0.7111

The results reveal that a reasonable combination of the three branches is more conducive to the improvement of downstream task performance. The image rotation prediction branch and the global contrast learning branch can learn the overall features of the image. However, due to the lack of local feature learning, they do not achieve the best results, reaching only an overall accuracy of 0.6507 when learning global features only. Without global feature learning, solely learning local features results in an overall accuracy of only 0.5830. The best results are achieved when both global features are learned using the image rotation prediction branch and the global contrast learning branch, and local features are learned using the local contrast learning branch. Compared to the former two scenarios, the overall accuracy is improved by 0.0632 and 0.1309, respectively.

2) *Ablation experiments on training process optimization methods:* This work conducted training using the top 20%, 50%, 80%, 100% of training points based on TracIn scores, and without sequential optimization, randomly selected 80% of training points (Random 80%), to investigate the impact of the TracIn method and sequential optimization on experiment accuracy. The results are shown in Table III. Simultaneously, we explored the relationship between the time consumed and the overall accuracy when pre-training with different data volumes. The results are shown in Fig. 8.

Fig. 8. The impact of different data volumes on time and accuracy.

TABLE III. OPTIMIZATION METHOD ABLATION EXPERIMENTAL RESULTS

	20%	50%	80%	100%	Random 80%
OA	0.6637	0.6859	0.7139	0.7166	0.7048
Recall	0.6599	0.6916	0.7111	0.7183	0.6985

In Fig. 8, with the increase in data volume, both the pre-training time and the overall accuracy increase. However, the ratio of overall accuracy to pre-training time (i.e., the slope of the line) keeps decreasing, indicating that the time required to improve the unit accuracy is increasing. This reflects that those with higher TracIn scores contribute significantly to accuracy improvement. When the data volume reaches the top 80% of TracIn scores, the accuracy is nearly the same as using all pre-training data (i.e., 100%), demonstrating the effectiveness of the optimization method proposed in this paper for reducing data volume. Meanwhile, as shown in Table III, using the top 80% of data based on TracIn scores also improved the results compared to randomly using 80% of the data, verifying the effectiveness of the proposed optimization method.

The experimental results show that applying the training data selected by the TracIn method and sequential optimization to the proposed triple-branch self-supervised network can reduce the data volume by 20% with almost no impact on the experiment accuracy. The reduction in data volume brings about a decrease in time cost. Therefore, for self-supervised learning, the combination of the TracIn method and sequential optimization theory is an optimization format worth considering.

V. CONCLUSION

This study introduces a self-supervised learning-based semantic segmentation technique for remote sensing images. Initially, a triple-branch self-supervised learning network known as TBSNet is developed to capture both global and local features within these images. Subsequently, the TracIn method and sequential optimization theory are employed to enhance the pre-training procedure of the self-supervised learning network, consequently reducing the time and computational resources necessary for pre-training. Ultimately, the pre-trained model is fine-tuned for downstream tasks, culminating in a semantic segmentation model tailored for remote sensing images through self-supervised learning. In comparison to traditional self-supervised models, our experiments reveal varying degrees of enhancement. But there are two notable limitations in this study. First, during the fine-tuning phase, 10% of the labeled data was utilized, thus not achieving a fully unsupervised approach. There remains potential for further reduction in the amount of labeled data used. Secondly, to simultaneously learn global and local features, a triple-branch network collaboration was employed, leading to an increase in the model's size. For future research, under the premise of further reducing labeled data, the goal is to integrate more advanced optimization techniques to develop a lighter self-supervised model and strive to further enhance segmentation accuracy.

Mechatronics Design and Robotic Simulation of Serial Manipulators to Perform Automation Tasks in the Avocado Industry

Carlos Paredes¹, Ricardo Palomares², Josmell Alva³, José Cornejo⁴

Department of Mechatronic Engineering, Universidad Nacional de Trujillo, Trujillo, Peru^{1, 2, 3}
Universidad Tecnológica del Perú, Lima, Peru⁴

Abstract—Peru is considered one of the principal agroindustrial avocado exporters worldwide. At the beginning of 2022, the volume exported was 8.3% higher than in 2021, so the design and simulation of a pick and place and palletizing cell for agro-exporting companies in the Region of La Libertad was proposed. A methodology was followed that presented a flow diagram of the design of the cell, considering the size of the avocado and the dimensions of the box-type packaging. The forward and inverse kinematics for the Scara T6 and UR10 robots were developed in Matlab according to the Denavit-Hartenberg algorithm, and 3D CAD, dynamic modeling, and trajectory calculation were performed in Solidworks using a "planner" algorithm developed in Matlab, which takes into account the start and end points, maximum speeds, and travel time of each robot. Then, in CoppeliaSim, the working environment of the cell and the robots with their respective configurations are created. Finally, the simulation of trajectories is performed, describing the expected movement, getting the time of the finished task was calculated, where the Scara T6 robot had a working time of 1.18 s and the UR10 of 2.32 s. For 2023 - 2025, its implementation is proposed in the Camposol Company located in the district of Chao - La Libertad, considering the dynamic control of the system.

Keywords—*Mechatronic design; inverse kinematics; dynamic modeling; pick and place; palletizing; Scara robot; universal robot; robot manipulators; path tracking simulation; kinematic control*

I. INTRODUCTION

In 2022, Peru's non-traditional exports grew up by 19.4% compared to 2021, with the agricultural sector accounting for 43.7% of this growth, with avocado as the main product, with a value of 528,727 tons of exported volume [1], [2]. Camposol is considered as the largest Peruvian agro-exporting company, with USD 112,645,000 in shipments [3]. Since 2018 the company developed a strategic expansion plan and purchased 1000 ha in Uruguay [4]. In 2020, Camposol's CEO prioritized the avocado packing process [5]. Various improvement proposals for the packaging process are being studied worldwide. A notable initiative is the development of a 4-degree-of-freedom fruit sorting robot, based on the evaluation of both fruit size and color, using advanced digital image processing techniques. The results have been promising, achieving sorting times of 11.91 seconds for red tomatoes and 11.76 seconds for green ones. Furthermore, it is highlighted that the variation in sorting times is linked to the arrangement of the boxes within the environment. This variability becomes

significant when considering scenarios similar to avocado packing [6]. In another investigation, a control system for a palletizing robot is designed using RobotStudio. This study has demonstrated optimal performance in palletizing tasks using precise input/output (I/O) control logic, which ensures high stability, safety, and efficiency within the simulation environment. This work leads to the proposal to create a virtual environment that simulates real-world conditions for the avocado packing process, elevating it to a TRL5 level [7]. The derivation of the direct and inverse kinematics of the ABB IBR 140 robot was proposed using Denavit-Hartenberg and (DH) analysis and analytical geometric approximations, respectively. The transformation matrices were validated in Matlab and subsequently simulated in RobotStudio to verify their accuracy [8]. A methodology based on the Digital Twin (DT) concept for flexible pick-and-place robotic work cells was also designed to facilitate the development process by providing guidance. This proposal leads to the creation of a design approach for a robotic work cell based on the application of pick-and-place avocado picking and placing for subsequent simulation [9]. A packaging algorithm called Jampack was developed, which has a Failure Recovery Module (FRM) for a robotic manipulator, allowing the system to reach a faster completion of the system [10]. Another algorithm implemented is ResNet-18 for real-time Hass avocado grading, which seeks to achieve non-invasive grading to reduce damage caused by handling. After several processing steps, the image acquisition system achieved an accuracy of 98.72%, a specificity of 98.52%, and a score of 98.08% [11]. However, human-machine collaboration for these applications is still relevant and a topic of ongoing research. This has led to another study aimed at evaluating the avocado harvesting process. After carrying out 41 different tests, a significant increase in yield, measured in the loading zone, from 15% to 80% was found. Also, total harvested production has increased from 23% to 85%, with a minimal increase in human labor load from 1% to only 16% [12]. On the other hand, a soft humanoid hand designed to firmly grip a wide variety of objects, regardless of their morphology, is presented. On this hand, the fingers are constructed with flexible hybrid pneumatic actuators (FHPA). Using a theoretical evaluation model, a balance between the required flexibility and stiffness has been achieved. This innovation offers fast responsiveness and significant gripping force, suitable for fruit picking, product packaging, and handling of fragile objects [13].

This project contributes to Sustainable Development Goals 8 and 9 set by the United Nations, as they focus on achieving higher economic productivity through the utilization of technology and innovation, as well as increasing scientific research and improving technological capacity in industrial sectors, particularly in developing countries, by 2030 [14].

Therefore, the increase in demand for avocado exports poses a challenge if the packaging process is not accelerated, since currently, both at Camposol and other companies, the picking and placing of avocados is performed by workers, resulting in delays in procedures and order deliveries. For this reason, it is proposed to design and simulate a pick and place and palletizing cell, where two robots will perform the process automatically.

The structure of this paper is divided as follows: Section I contains the introduction, which details both the problem and its solution. Section II covers the materials and methods, where the design is based on a methodology that includes kinematic and dynamic analysis, trajectory tracking calculations, and real-time simulation. Section III presents the results derived from the simulation of the robotic cell. Finally, Section IV consolidates the conclusions and future work of the project.

II. MATERIALS AND METHODS

The proposed methodology for designing and simulating the avocado pick and place and palletizing cell, using Matlab and CoppeliaSim, is shown in Fig. 1.

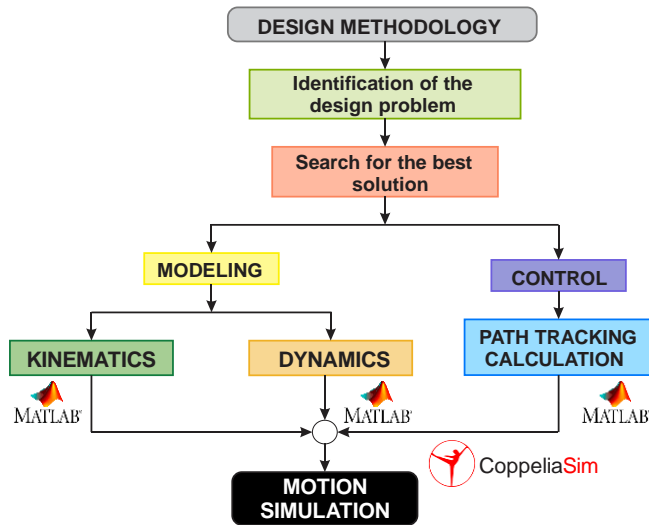

Fig. 1. Flow chart for the design of an avocado pick and place and palletizing cell.

The cell design consists of two tasks that are performed sequentially. The first one is performed by an Epson Scara T6 robot, which picks and places the Hass avocado in a cardboard box (pick and place), using a vacuum suction cup as the final effector, considering the caliber (weight) of the Hass avocado, which varies according to the country to be exported [15], as shown in Table I.

On the other hand, there is a Universal Robots UR10 robot, which picks up the boxes and groups them in rows and columns (palletizing), using a four vacuum suction cup holder

as an end effector, considering the shape, weight, and distribution of the boxes [16], as shown in Table II.

TABLE I. HASS AVOCADO EXPORT CALIBER

Avocado	Avocado Caliber Requirements by Country				Fruit Weight (g)
	USA	Japan	Canada	European Union	
Hass	32	–	12	12	300 – to more
	36	18	14	14	300 – 330
	40	20	16	16	265 – 300
	48	24	18	18	205 – 265
	60	30	20	20	170 – 205
	70	–	22	22	150 – 170
	84	–	24	24	120 – 150

TABLE II. BOX FEATURES

Type of Box	Recommended Avocado Packaging Features		
	Dimensions (mm)	Average Weigh (kg)	Pallet
Cardboard	440 x 338 x 186	11	88 - 96
	406 x 254 x 97	4	228 - 264
Plastic	300 x 500 x 150	10	120

A. Forward and Inverse Kinematic Model

The Scara T6 and UR10 robots are 3 DOF (two rotational and one linear) and 6 DOF (rotational only), respectively [17], [18]. Moreover, their Cartesian reference systems and the motion of each joint are shown in Fig. 2 and Fig. 3 [19].

Eq. (1) presents the T_n^0 homogeneous transformation matrix, which expresses the position and orientation of each robot [20] and [21]. Eq. (2) and (3) represent the basic T_3^0 and T_6^0 transformations, where n is the number of joints.

Fig. 2. Cartesian reference system and lengths for the Scara T6 robot.

$${}^0T_n^0 = \begin{bmatrix} n_{nx1} & o_{nx1} & a_{nx1} & P_{nx1} \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1)$$

$$T_3^0 = A_1^0 A_2^1 A_3^2 \quad (2)$$

$$T_6^0 = A_1^0 A_2^1 A_3^2 A_4^3 A_5^4 A_6^5 \quad (3)$$

Fig. 3. Cartesian reference system and lengths for the UR10 robot.

The Denavit - Hartenberg (D-H) parameters of the Scara T6 and UR10 robots are shown in Table III and Table IV, respectively [22-24].

TABLE III. D-H PARAMETERS FOR SCARA T6 ROBOT

Joint	Scara T6 Robot			
	θ	d	a	α
1	θ_1	0	a_1	0
2	θ_2	0	a_2	0
3	0	$-\theta_3 - 0.083$	0	0

TABLE IV. D-H PARAMETERS FOR UR10 ROBOT

Joint	UR10 Robot			
	θ	d	a	α
1	q_1	L_1	0	$\pi/2$
2	q_2	0	L_2	0
3	q_3	0	L_3	0
4	q_4	L_4	0	$\pi/2$
5	q_5	L_5	0	$-\pi/2$
6	q_6	L_6	0	0

For the Scara T6 robot by multiplying all the transformation matrices in equation (2), the resulting matrix is:

$$T_3^0 = \begin{bmatrix} n_{3x} & o_{3x} & a_{3x} & P_{3x} \\ n_{3y} & o_{3y} & a_{3y} & P_{3y} \\ n_{3z} & o_{3z} & a_{3z} & P_{3z} \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (4)$$

Where the position of the end-effector is described by the position vector P_{3x1} (P_{3x}, P_{3y}, P_{3z}), then:

$$P_{3x} = a_2 C_{12} + a_1 C_1 \quad (5)$$

$$P_{3y} = a_2 S_{12} + a_1 S_1 \quad (6)$$

$$P_{3z} = -\theta_3 - 0.083 \quad (7)$$

The inverse kinematics for the Scara T6 robot was solved using the position vector P_{3x1} , obtaining:

$$\theta_1 = 2\text{atan}(t_1) \quad (8)$$

$$\theta_2 = \text{atan}\left(\pm\sqrt{1-t_2^2}/t_2\right) \quad (9)$$

$$\theta_3 = -P_{3z} \quad (10)$$

$$t_1 = \frac{-2P_{3y}a_1 \pm \sqrt{(2P_{3x}a_1)^2 + (2P_{3y}a_1)^2 - (a_2^2 - a_1^2 - P_{3x}^2 - P_{3y}^2)^2}}{a_2^2 - a_1^2 - P_{3x}^2 - P_{3y}^2 - 2P_{3x}a_1} \quad (11)$$

$$t_2 = \frac{P_{3x}^2 + P_{3y}^2 - a_1^2 - a_2^2}{2a_1a_2} \quad (12)$$

On the other hand, for Robot UR10 when multiplying the transformation matrices of equation (3), the resulting matrix is:

$$T_6^0 = \begin{bmatrix} n_{6x} & o_{6x} & a_{6x} & P_{6x} \\ n_{6y} & o_{6y} & a_{6y} & P_{6y} \\ n_{6z} & o_{6z} & a_{6z} & P_{6z} \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (13)$$

Where the position of the end effector is described by the vector (P_{6x}, P_{6y}, P_{6z}) , then:

$$P_{6x} = L_6(S_1 C_5 - C_1 C_{234} S_5) + L_4 S_1 + L_2 C_1 C_2 + L_5 C_1 S_{234} + L_3 C_1 (C_2 C_3 - S_2 S_3) \quad (14)$$

$$P_{6y} = L_2 S_1 C_2 - L_4 C_1 - L_6 (C_1 C_5 - S_1 C_{234} S_5) + L_5 S_1 S_{234} + L_3 S_1 (C_2 C_3 - S_2 S_3) \quad (15)$$

$$P_{6z} = L_1 + L_3 S_{23} + L_2 S_2 - L_5 C_{23} C_4 - S_{23} S_4 - L_6 S_5 (C_{23} S_4 + S_{23} C_4) \quad (16)$$

The inverse kinematics for the UR10 robot was solved using the iterative Gauss-Newton algorithm, which seeks to find the parameter values through an iterative multiplication of matrices [25, 26]. From the transformation matrix of Eq. (3), it follows that:

$$A_6^0 = T_6^0 \quad (17)$$

$$A_6^0 = A_1^0 A_2^1 A_3^2 A_4^3 A_5^4 A_6^5 \quad (18)$$

$$T_6^1(q_1, q_5, q_6) = (A_1^0)^{-1} T_6^0 \quad (19)$$

$$A_4^0 = A_1^0 A_2^1 A_3^2 A_4^3 \quad (20)$$

$$T_4^0(q_2, q_3, q_4) = T_6^0 (A_6^5)^{-1} (A_4^3)^{-1} \quad (21)$$

Then, the parameters are shown below:

$$q_1 = \text{atan2}(L_4, \text{sqrt}((P_{6x} - L_6 a_{6x})^2 + (L_6 a_{6y} - P_{6y})^2 - L_4^2)) - \text{atan2}(L_6 a_{6y} - P_{6y}, P_{6x} - L_6 a_{6x}) \quad (22)$$

$$q_2 = \text{atan2}(r_2, r_1) - \text{atan2}(L_3 S_3, L_2 + L_3 C_3) \quad (23)$$

$$q_3 = \text{atan2} \left(\sqrt{1 - \left(\frac{r_1^2 + r_2^2 - L_2^2 - L_3^2}{2L_2L_3} \right)^2}, \frac{r_1^2 + r_2^2 - L_2^2 - L_3^2}{2L_2L_3} \right) \quad (24)$$

$$q_4 = q_{234} - q_3 - q_2 \quad (25)$$

$$q_5 = \text{atan2} \left(\text{sqrt} \left((n_{6x}S_1 - n_{6y}C_1)^2 + (o_{6x}S_1 - o_{6y}C_1)^2 \right), a_{6x}S_1 - a_{6y}C_1 \right) \quad (26)$$

$$q_6 = \text{atan2} \left(\frac{-o_{6x}S_1 + o_{6y}C_1}{S_5}, \frac{n_{6x}S_1 - n_{6y}C_1}{S_5} \right) \quad (27)$$

$$q_{234} = \text{atan2}(n_{6z}C_5C_6 - a_{6z}S_5 - o_{6z}C_5S_6, o_{6z}C_6 + n_{6z}S_6) \quad (28)$$

$$r_1 = \text{sqrt} \left(\left(\text{sqrt} \left((P_{6x} - L_6a_{6x} + L_5o_{6x}C_6 + L_5n_{6x}S_6)^2 + (P_{6y} - L_6a_{6y} + L_5o_{6y}C_6 + L_5n_{6y}S_6)^2 \right) - L_4^2 \right) \right) \quad (29)$$

$$r_2 = P_{6z} - L_6a_{6z} + L_5o_{6z}C_6 + L_5n_{6z}S_6 - L_1 \quad (30)$$

B. Dynamic Model

The dynamic model for the Scara T6 and UR10 robot was developed using the Newton - Euler formulation, analyzing the geometric relationships between each link, the position vector concerning the i -nth system (ri0pi), and the center of the mass vector of element i concerning its system (ri0si) [27,28].

Eq. (31) and (32) allowed obtaining forces and moments for each element $i = 1, 2, 3, \dots, n$.

$$f_i = F_i + f_{i+1} = m_i \bar{a}_i + f_{i+1} \quad (31)$$

$$n_i = n_{i+1} + \dot{p}_i x f_{i+1} + (\dot{p}_i + \bar{s}_i) x F_i + N_i \quad (32)$$

The physical parameters of each link such as length, mass, center of mass, and inertia tensor, were calculated using CAD modeling designed in SolidWorks, as shown in Fig. 4 and Fig.5 [29-31]. The following steps were followed to obtain it:

- 3D modeling of each element of the Scara T6 and UR10 robots using SolidWorks.
- Generate a separate solid model for each robot link, which should incorporate all significant features, including the motor, bearings, and any other components that contribute to the weight of the link.
- Assign the corresponding material to each component of the robots.
- Identify the primary coordinate system of each link, ensuring alignment with the Denavit - Hartenberg coordinate system. In the event of non-alignment, a new coordinate system should be introduced. Subsequently, upon accessing the properties section in SolidWorks, a summary of the physical property values is displayed, such as mass, center of mass (riosi), and moment of inertia of the link relative to the assigned output coordinate system.
- Finally, use the measurement tool in SolidWorks to draw lines and obtain the length value and the position

vector relative to the i -th coordinate system (riopi) of each link.

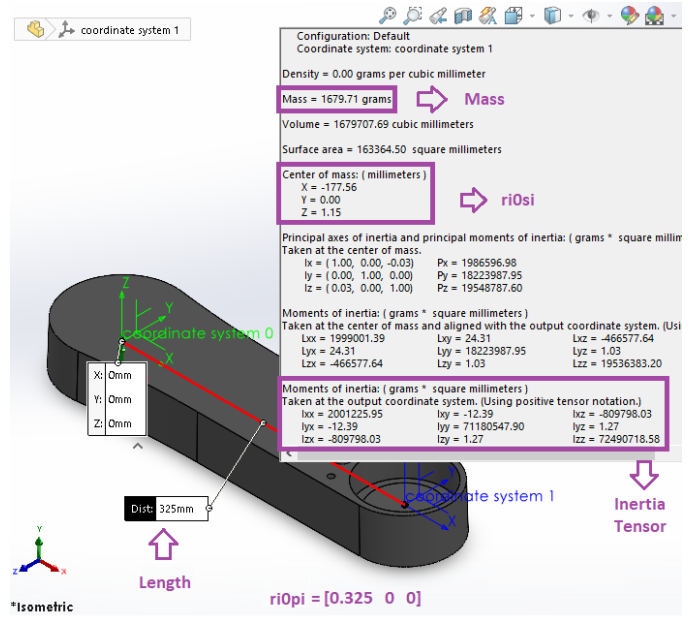

Fig. 4. Physical properties of scaraT6 robot link 1.

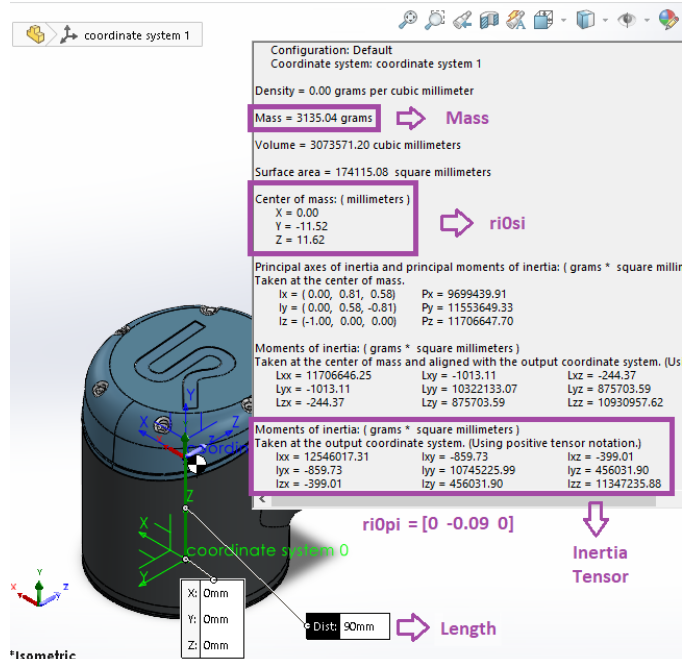

Fig. 5. Physical properties of UR10 robot link 1.

Then the torque for each joint is expressed in equation (33):

$$\tau_i = \begin{cases} n_i^T Z_{i-1} + b_i \dot{q}_i \\ f_i^T Z_{i-1} + b_i \dot{q}_i \end{cases} \quad (33)$$

Where b_i is the coefficient of viscous friction of each joint [32,33].

The parameters obtained from the links were used for the dynamic modeling of the Scara T6 and UR10 robots [34 and [35] which are shown in Table V and Table VI.

TABLE V. PARAMETERS FOR THE DYNAMICS OF THE SCARA T6 ROBOT

n	Scara T6 Robot				
	Length (mm)	Mass (kg)	Inertia Tensor (kgm ²)	riopi (m)	riosi (m)
1	325	1.68	$\begin{bmatrix} 0 & 0 & -0 \\ 0 & 0.07 & 0 \\ -0 & 0 & 0.07 \end{bmatrix}$	$\begin{bmatrix} 0.325 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} -0.18 \\ 0 \\ 0.001 \end{bmatrix}$
2	275	7.54	$\begin{bmatrix} 0.15 & 0 & -0.15 \\ 0 & 0.4 & 0 \\ -0.15 & 0 & 0.265 \end{bmatrix}$	$\begin{bmatrix} 0.275 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} -0.16 \\ 0 \\ 0.126 \end{bmatrix}$
3	-	0.08	$\begin{bmatrix} 0.006 & 0 & 0 \\ 0 & 0.006 & 0 \\ 0 & 0 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ -0.083 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 0.246 \end{bmatrix}$

TABLE VI. PARAMETERS FOR THE DYNAMICS OF THE UR10 ROBOT

n	UR10 Robot				
	Length (mm)	Mass (kg)	Inertia Tensor (kgm ²)	riopi (m)	riosi (m)
1	90	3.14	$\begin{bmatrix} 0.013 & 0 & 0 \\ 0 & 0.01 & 0 \\ 0 & 0 & 0.01 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0.09 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ -0.0115 \\ 0.0116 \end{bmatrix}$
2	613	8.89	$\begin{bmatrix} 0.28 & 0 & -0.54 \\ 0 & 1.89 & 0 \\ -0.54 & 0 & 1.62 \end{bmatrix}$	$\begin{bmatrix} 0.613 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} -0.3618 \\ 0 \\ 0.17034 \end{bmatrix}$
3	572	4.75	$\begin{bmatrix} 0.02 & 0 & -0.08 \\ 0 & 0.69 & 0 \\ -0.08 & 0 & 1.63 \end{bmatrix}$	$\begin{bmatrix} 0.572 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} -0.3147 \\ 0 \\ 0.05142 \end{bmatrix}$
4	164	0.74	$\begin{bmatrix} 0.001 & 0 & 0 \\ 0 & 0.001 & 0 \\ 0 & 0 & 0.01 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0.164 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ -0.0076 \\ 0.00974 \end{bmatrix}$
5	116	0.74	$\begin{bmatrix} 0.001 & 0 & 0 \\ 0 & 0.001 & 0 \\ 0 & 0 & 0.01 \end{bmatrix}$	$\begin{bmatrix} 0 \\ -0.12 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0.0076 \\ 0.00974 \end{bmatrix}$
6	176	0.41	$\begin{bmatrix} 0.003 & 0 & 0 \\ 0 & 0.003 & 0 \\ 0 & 0 & 0.001 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 0.176 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0.00477 \\ -0.0792 \end{bmatrix}$

From Eq. (31-33) considering b_i negligible and replacing the calculated parameters, the dynamic equations for the Scara T6 robot were obtained:

$$\tau_{1,3} = (1.294 + I_{ext} + 0.181m_{ext} + 0.601C_2 + 0.179m_{ext}C_2)qpp_1 + (0.38 + I_{ext} + 0.076m_{ext} + 0.301C_2 + 0.089m_{ext}C_2)qpp_2 - (0.301S_2 + 0.089m_{ext}S_2)qp_2^2 - (0.061S_2 + 0.179m_{ext}S_2)qp_1qp_2 \quad (34)$$

$$\tau_{2,3} = (0.38 + I_{ext} + 0.076m_{ext} + 0.301C_2 + 0.089m_{ext}C_2)qpp_1 + (0.38 + I_{ext} + 0.076m_{ext})qpp_2 + (0.301S_2 + 0.089m_{ext}S_2)qp_1^2 \quad (35)$$

$$\tau_{3,3} = (m_{ext} + 0.083)(qpp_3 + 9.81) \quad (36)$$

In the same way, the dynamic equations for the UR10 robot were obtained by solving Eq. (31), (32), and (33). By resolving

the dynamics of both robots, the Walker-Orin algorithm (inverse kinematics) is applied to validate the results and potentially facilitate dynamic control [36], [37].

C. Path Tracking Calculation

Kinematic control was performed using Matlab software to develop the desired movements according to the assigned tasks. The developed algorithm "planner" includes the starting and braking times of each motor, as well as the maximum speeds (rad/s) of each robot according to the manufacturer's data sheet [38, 39], for the planning of a smooth trajectory a 4-3-4 interpolator was implemented between the start and end point in the joint coordinates, returning the position, velocity, and acceleration matrices as a result [40-42].

Taking the initial and final points of the path taken by each robot (P_{nx1}), and considering their respective orientations ($R_{n \times n}$), the position, velocity, and acceleration graphs were obtained, as well as their trajectories in the 3D plane, which are shown in Fig. 6 to 9 [43-45].

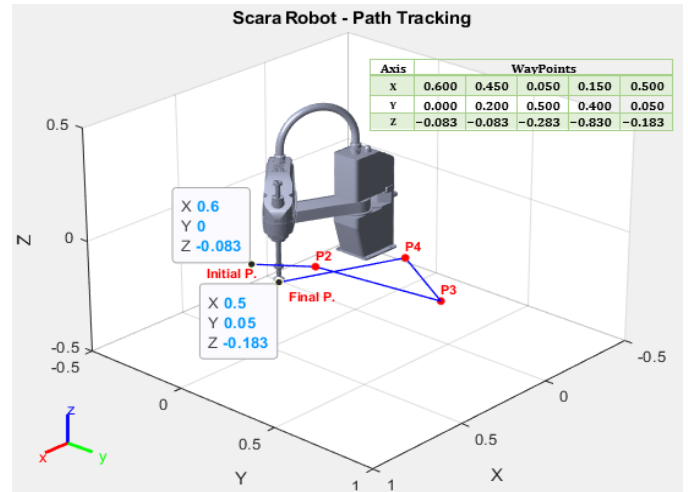

Fig. 6. Path tracking in matlab for scara T6 robot.

Fig. 7. Trajectory plot in matlab for scara T6 robot.

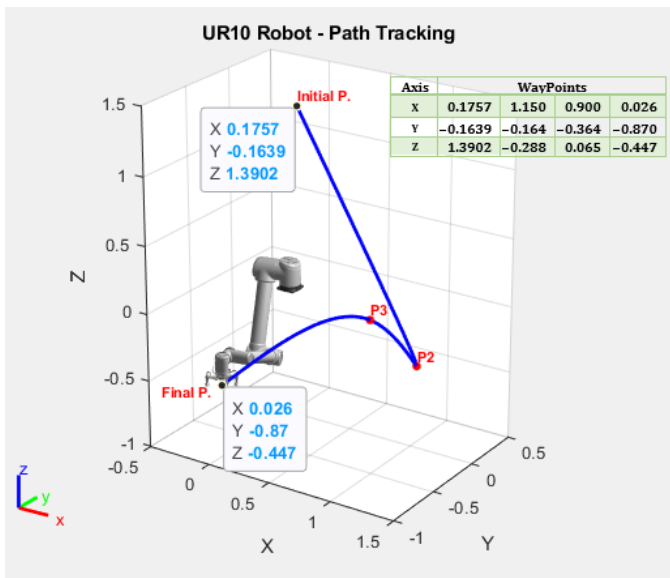

Fig. 8. Path tracking in matlab for UR10 robot.

Fig. 9. Trajectory plot in matlab for UR10 robot.

D. Pick and Place and Palletizing Cell Simulation

The data of the joint positions obtained with the kinematic control were saved in matrices called "math_scara" and "math_ur10" respectively, to perform a real simulation in the CoppeliaSim environment [46], [47].

Facilities of the agro-exporting company Camposol were replicated using equipment such as crates, protective enclosures, smooth and roller conveyors provided by CoppeliaSim, along with those designed in SolidWorks, including the SCARA T6 and UR10 robots and the avocado [48], [49]

The designs generated in SolidWorks were then saved in URDF format, including their respective reference systems following the Denavit-Hartenberg method, to enable their visualization in the CoppeliaSim simulation environment to create a highly realistic virtual environment [50-52].

The SolidWorks URDF CAD files of the Scara T6 and UR10 robots were imported into CoppeliaSim, with the relevant parameters for real-time simulation, such as maximum torque (Nm) and maximum speed (°/s), being configured based on the manufacturer's datasheet. This process is illustrated in Fig. 10 [53-55].

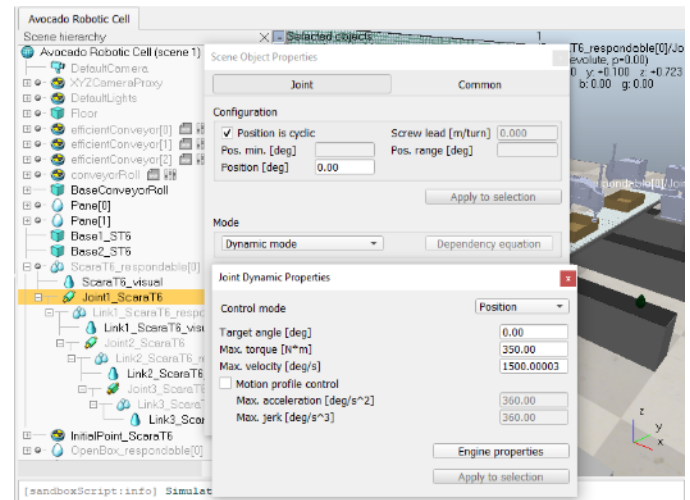

Fig. 10. Creation of the working environment and configuration of the Scara T6 y UR10 robots.

III. TESTS AND RESULTS

Fig.11 shows the Scara T6 robot picking up the avocado, starting from its resting position (a), and then placed in a cardboard box (b), at a maximum speed of 1500 °/s in its rotational joints and of 10 m/s in its prismatic joint, with a cycle time of 0.49 s. The task is performed until 20 Hass avocados of 22 – 24 calibers are placed in each box (c), then the suction cup type tool is activated, taking the box to the pallet to be grouped in three rows and three columns (d), at a maximum speed of 120 °/s for the base and shoulder joints, 180 °/s for the elbow and wrist, with a cycle time of 0.5 s. The task is executed up to palletizing 90 boxes.

Fig. 11. Simulation in CoppeliaSim for scara T6 and UR10 robots.

The cell movements for pick and place and palletizing were simulated in CoppeliaSim. Table VII shows the working time of each path for both robots. A total working time of 1.18 s was obtained for the Scara T6 robot and 2.32 s for the UR10 robot.

For maximum range position $[\pi/2 \text{ rad/s}, \pi/2 \text{ rad/s}, 0.2 \text{ m}]$ for the Scara T6 robot and $[0, 0, 0, 0, 0, 0, 0]$ rad/s for the UR10, the maximum torques $[360.70, 146.30, 0.376]$ Nm and $[62.88, 116.20, 40.56, 9.25, 6.73, 4.34]$ Nm was obtained for each joint of both robots, as shown in Fig. 12.

TABLE VII. WORKING TIME IN EACH STATION

Path	Working Time	
	Scara T6 Robot (s)	UR10 Robot (s)
1 - 2	0.20	1.22
2 - 3	0.36	0.40
3 - 4	0.36	0.70
4 - 5	0.26	-
TOTAL	1.18	2.32

Fig. 12. Torque plot in simulink for scara T6 y UR10 robots.

IV. CONCLUSIONS AND FUTURE WORK

The mathematical models obtained using the Denavit-Hartenberg algorithm of the Scara T6 and UR10 robots were validated with the inverse kinematics tests developed in Matlab, and the models describing the inverse Newton Euler dynamics of the Scara T6 and UR10 robots were validated with the forward dynamics of Walker Orin developed in Matlab. With the "planner" algorithm developed, it was possible to follow the waypoints with smooth movements in each of the joints of the Scara T6 and UR10 robot, as evidenced in the graphs of the positioning, velocity, and acceleration profiles obtained. This significantly influences the accurate execution of pick and place as well as palletizing tasks assigned to the robots within the simulation environment.

The movements and constraints of the global simulation in CoppeliaSim allowed us to get efficient results for the serial work of the Scara T6 robot and the UR10 in the pick and place and palletizing cell with a cycle time of 3.5 s. According to the torque graphs obtained with Simulink, the maximum values for the Scara T6 robot and the UR10 robot showed a minimum difference of 3.06 % and 2.35 %, respectively, concerning the manufacturer's datasheet that was input in the dynamic

configurations of each joint in CoppeliaSim for each robot. This set of actions, in turn, leads to a significant reduction in the time required for the avocado packing process compared to human labor. This is especially relevant since more human personnel would be needed to achieve equivalent performance.

During 2023 – 2025, it is proposed to implement the pick and place tasks in a palletizing cell at the Camposol company located in the district of the Chao, La Libertad region, including a dynamic controller for both robots. In addition, this work not only complements previous research but also opens the door to the possibility of replicating this same application at an industrial level throughout South America and in countries that also produce and export avocados. This allows for the potential to export avocados on a large scale. Thus, meeting increased demand would no longer be an unattainable challenge.

Abstract—Effective patient treatment and care depend heavily on accurate disease diagnosis. The availability of multi-modal medical data in recent years, such as genetic profiles, clinical reports, and imaging scans, has created new possibilities for increasing diagnostic precision. However, because of their inherent complexity and variability, analyzing and integrating these varied data types present significant challenges. In order to overcome the difficulties of precise medical disease diagnosis using multi-modal data, this research suggests a novel approach that combines Transfer Learning (TL) and Deep Neural Networks (DNN). An image dataset that included images from various stages of Alzheimer's disease (AD) was collected from kaggle repository. In order to improve the quality of the signals or images for further analysis, a Gaussian filter is applied during the preprocessing stage to smooth out and reduce noise in the input data. The features are then extracted using Gray-Level Co-occurrence Matrix (GLCM). TL makes it possible for the model to use the information gained from previously trained models in other domains, requiring less training time and data. The trained model used in this approach is AlexNet. The classification of the disease is done using DNN. This integrated approach improves diagnostic precision particularly in scenarios with limited data availability. The study assesses the effectiveness of the suggested method for diagnosing AD, focusing on evaluation metrics such as accuracy, precision, miss rate, recall, F1-score, and the Area under the Receiver Operating Characteristic Curve (AUC-ROC). The approach is a promising tool for medical professionals to make more accurate and timely diagnoses, which will ultimately improve patient outcomes and healthcare practices. The results show significant improvements in accuracy (99.32%).

Keywords—Transfer learning; deep neural network; disease diagnosis; multi-modal data; Alexnet; GLCM; DNN; pre-trained model

I. INTRODUCTION

In the fields of machine learning and artificial intelligence, TL is a potent and well-liked technique that aims to use information learned from one task or domain to enhance the performance of another task or domain that is related to it [1]. It is predicated on the notion that knowledge obtained while

resolving one problem can be applied and transferred to resolve another problem that is unrelated but nonetheless similar more effectively [2]. Models are created from scratch for each distinct task using traditional machine learning techniques and lots of labelled data. However, this procedure can be time-consuming, costly in terms of computation, and it may call for a sizable amount of labelled data, which isn't always available. Transfer learning overcomes these constraints by applying previously learned features or representations from a pre-trained model, referred to as the "source task," to a new target task with a smaller dataset. Pre-training and fine-tuning are typically the two essential steps in the TL process. A DNN is trained on a sizable dataset from the source task, such as image recognition on a sizable image dataset, during the pre-training phase [3]. The pre-trained model gains knowledge of broader features and patterns that can be used for a variety of tasks. Numerous industries, including healthcare, speech recognition, computer vision, and NLP, have found extensive use for TL. It has made it possible to create complex models that perform better even when there is a dearth of labelled data. TL encourages knowledge sharing and transfer across tasks by reusing learned representations, resulting in ML models that are more effective and efficient [4].

Alzheimer's disease is a progressive and irreversible neurological condition that primarily affects memory, thought, and behavior in the brain's cognitive regions [5]. It is the most typical cause of dementia, which is a group of brain disorders marked by a decline in memory, communication, and reasoning skills and the inability to perform daily tasks. Usually, a disease takes time to develop and gradually gets worse. People may experience mild memory loss in the early stages, as well as trouble finding words or organizing their thoughts. People with advanced Alzheimer's may experience confusion, mood swings, difficulty solving problems, and a loss of recognition of familiar faces and environments [6]. A vital component of healthcare is accurate disease diagnosis, which enables patients to receive timely and efficient care. In recent years, new opportunities for enhancing patient care and

improving diagnostic accuracy have emerged due to the accessibility of a variety of medical data from various modalities. Data like genetic profiles, clinical reports, medical images, and textual information are included in this [7]. However, because of their complexity, heterogeneity, and the requirement to capture complex relationships between various modalities, analyzing and integrating these multi-modal data sources present significant challenges [8].

This research suggests a novel method that combines TL and DNN for precise medical disease diagnosis from multi-modal data to address these issues [9]. With the ability to transfer knowledge from a source domain to a target domain, transfer learning has become a potent machine learning technique [10]. TL enables the adaptation of learned representations and weights to new datasets, even when the data distributions differ significantly, by utilizing pre-trained models on large-scale datasets [11]. This knowledge transfer improves the ability of models to generalize and makes it easier to make an accurate diagnosis in the target domain [12]. In a number of industries, including computer vision, natural language processing, and healthcare, deep neural networks have achieved remarkable success [13]. These networks provide a strong framework for analyzing multi-modal medical data due to their capacity to learn intricate patterns and relationships from high-dimensional data. Recurrent neural networks (RNNs) capture temporal dependencies in sequential data, while convolutional neural networks (CNNs) are excellent at extracting features from images [14]. Furthermore, attention mechanisms allow the network to concentrate on pertinent data within the multi-modal data, increasing diagnostic precision [15].

There are several benefits to combining TL and DNN when diagnosing medical diseases using multimodal data [16]. First of all, it permits the use of prior knowledge and learned representations from comparable tasks or domains, which can greatly improve the performance of models on small medical datasets. Second, it combines the advantages of various network architectures to enable thorough analysis of multi-modal data by capturing both spatial and temporal dependencies [17]. Last but not least, it offers the possibility of individualized and accurate diagnosis, resulting in enhanced patient outcomes and improved treatment strategies [18]. A branch of ML and AI called "deep learning" focuses on teaching artificial neural networks how to carry out challenging tasks [19]. DNN, which are made up of multiple layers of interconnected nodes (neurons) that process and transform data, are used in this process [20]. These networks can learn and recognize patterns and features from enormous amounts of data because they are built to mimic the structure and operation of the human brain.

The goal of this study is to combine DNN and TL to create a reliable and accurate framework for diagnosing medical diseases [21]. The superiority of the approach over conventional methods and single-modal analyses through extensive tests and evaluations. Additionally, ablation studies are carried out to investigate the influence of various network architectures and TL strategies on diagnostic precision [22].

The key contributions of the paper is,

- The suggested model was trained using an image dataset that was taken from the Kaggle repository and contained images from different stages of AD.
- Before further analysis or feature extraction, the preprocessing stage of the data is where the Gaussian filter is used to smooth the input data and reduce noise.
- The study uses a pre-trained model for transfer learning called AlexNet, which is a well-known DNN architecture.
- The GLCM is used to extract features from the input data, capturing the spatial relationships and occurrence patterns of various pixel intensities in the image, which provides useful texture information for subsequent analysis or classification tasks.
- In order to accurately and efficiently classify diseases, Artificial Neural Networks (ANNs), a type of DNN, are used in the classification task to learn complex patterns and relationships from the input data.
- The research employs a number of evaluation metrics to assess the performance of the proposed approach for AD diagnosis. Accuracy, precision, recall, miss rate, F1-score, and the Area under the Receiver Operating Characteristic Curve (AUC-ROC) are some of these metrics.

The rest of this article is structured as follows: An overview of related research is given in Section II. The problem statement is presented in Section III. The methodology and architecture of our suggested approach are described in Section IV. Section V discusses the findings and subsequent discussion, and Section VI discusses the conclusion.

II. RELATED WORKS

Alzheimer's disease (AD) has become a growing problem among older people [23]. It is crucial for AD treatment to accurately identify mild cognitive impairment in the initial phases of the symptoms. Nevertheless aren't many samples of brain images and they come in a variety of methods, making it very challenging for machines to correctly categorize images of the brain. Through re-transfer training and multi-modal learning, the present research suggests an extremely fine brain image identification method to identifying AD. Diffusion tensor images (DTI) are initially finely classified into four different groups using a throughout its entirety DNN classification system called CNN4AD. Additionally, the re-transfer technique for learning is suggested on the basis of multipurpose theory of learning and is in accordance with the features of the multi-modal brain image data collection. The suggested strategy achieves greater precision with fewer labelled samples for training, according to the experiment's findings. This might aid in a quicker and more precise diagnosis of AD by medical professionals.

AD is a severe and unchangeable dementia of the central nervous system that impairs memory and ability to think [24]. DL algorithms have been proven successful in medical applications in treating this neuro-degenerative illness that results in neurological impairment and mental decline. DL techniques have been discovered to be efficient for duties like recognizing trends in imaging data and helping with diagnosis. When there is a lack of information, which applies an established model to a novel assignment, might prove especially helpful. TL has been used by investigators to successfully identify AD. AD is a severe and unchangeable dementia of the central nervous system that impairs memory and ability to think. DL algorithms have been proven successful in medical applications in treating this neuro-degenerative illness that results in neurological impairment and mental decline. DL techniques have been discovered to be efficient for duties like recognizing trends in imaging data and helping with diagnosis. When there is a lack of information, which applies an established model to a novel assignment, might prove especially helpful. TL has been used by investigators to effectively detect AD.

In modern healthcare environment, diagnostic testing has taken on an important function [25]. Brain cancer, among a particularly deadly disease and the main cause of death worldwide, is a significant area of study in the discipline of healthcare imaging. A rapid and reliable diagnosis made using MRI can enhance the study and outlook of brain tumors. Healthcare visuals needs to be recognized, divided, and categorized in order for automated diagnosis techniques to help physicians in determining the presence of brain tumors. It is crucial for establishing a computerized approach because radiologists find it tedious and prone to errors to manually identify malignancies in the brain. As an outcome, an accurate strategy for identifying and classifying brain tumors is given. The suggested process entails five phases. The borders in the original image are found using a linear contrast enhancement in the initial step. The following step involves creating a unique, 17 layered DNN architecture for segmenting brain tumors. The next step involves training the altered MobileNetV2 design employing for extracting features. The most desirable characteristics were chosen in the following step using an entropy-based regulated technique and a M-SVM. On the information sets from BraTS 2018 and Figshare, the approach that was suggested was tested. An investigation demonstrates that the suggested approach for classifying and detecting brain tumors surpasses existing techniques both qualitatively and in quantitative terms, with accuracy rates of 97.47% and 98.92%, accordingly The XAI technique is then used to clarify the outcome. The suggested approach performed better than existing approaches for identifying and classifying brain tumors. These results show that the suggested method performed better in the context of increased quantitative assessments with better accuracy as well as visual appeal.

After surgical procedures, tumors in breasts patients frequently experience recurring and metastases [26]. For the creation of accuracy therapy, forecasting a person's likelihood of metastatic growth and recurrence is crucial. In the present investigation, histopathological images that were stained with

H&E, medical records, and information concerning gene expression to offer an innovative multi-modal DL forecasting model. To be more precise, DNN to record every image inhibit into a 1D incorporate vector after segmenting tumor spots in H&E into image segments. The probable likelihood of recurrence as well as metastasis for every participant was then predicted by the attention-getting component, which scored every region of the H&E-stained images and paired visual characteristics with a medical and gene transcription information gathered. All 196 cancerous breast specimens with concurrently accessible clinical, expression of genes, and H&E data from the cancer genome database to test the hypothesis. The geographic distributions of the collected data were subsequently maintained among the two databases by centralized collection as the specimens were split into the training and testing sets in a ratio of 7:3. On the evaluation set, the multi-modal model outperformed those that relied merely on H&E image, arranging the information, and medical information, each achieving an AOC value of 0.75. This research could potentially be useful in the clinical setting to determine individuals with breast cancer who are at high risk for responding well to following surgery adjuvant therapy.

A neurodegenerative condition known as Alzheimer's disease (AD), it affects numerous individuals all over the world [27]. Although AD remains one of the most prevalent brain disorders, it can be challenging to identify, and in order to distinguish comparable trends, it needs a classification depiction of its features. Neural networks are commonly used in research to address increasingly difficult issues, including AD detection. Researchers and scientists without specialized expertise in artificial intelligence see those methods as well-understood and even sufficient. Therefore, it is crucial to find a detection technique that is both fully automated and simple for non-AI specialists to utilize. To quickly streamline the creation of neural networks and consequently democratize artificial intelligence, the approach should determine effective settings for the modeling variables. Multi-modal medical image fusion also provides deeper multimodal characteristics and a better capacity for information representation. For more precise diagnostics and more effective therapy, a fusion image is created by combining pertinent and related information from many input images. In order to diagnose Alzheimer's disease, the present research introduces a MultiAz-Net, a novel optimized ensemble-based deep neural network learning model that incorporates heterogeneous data gathered from PET and MRI scans. The study provides an automated method for anticipating the early start of AD according to characteristics identified from the fused data. The suggested structure involves three steps: picture fusion, feature extraction, and classification. A multi-objective optimization technique called the Multi-Objective Grasshopper Optimization technique (MOGOA) is provided to optimize the MultiAz-Net's layers. To do this, the required functions of objectives are enforced and the appropriate values for the proposed variables are looked for. Using the openly accessible Alzheimer neuroimaging dataset, the suggested deep ensemble model was empirically evaluated to complete four tasks for grouping Alzheimer's illness, three binary categorizations, along with a multi-class categorization task.

III. PROBLEM STATEMENT

Limited diagnostic accuracy results from traditional machine learning methods' inability to fully grasp the subtleties found in multimodal medical data. As each modality offers distinct insights into a patient's status, it has become clear that it is necessary to combine different sources of information, such as pictures and clinical data. The accuracy of diagnosing various medical disorders might be greatly increased by creating an integrated framework that smoothly integrates multiple modalities. Additionally, DNNs' performance in image analysis tasks points to their promise in this situation. On the other hand, over fitting and unsatisfactory outcomes frequently arise from training DNNs from scratch on scant medical data. Therefore, there is a need for a technique that efficiently uses transfer learning to adapt pre-trained models to medical diagnosis tasks while maximizing the use of multi-modal data. The development of appropriate data fusion strategies that capture the complimentary information provided by each modality is necessary for the integration of multi-modal data.

To guarantee an effective translation of pre-trained models to the medical domain, where the data distribution may differ greatly from general datasets, transfer learning algorithms must be developed. Choosing the right neural network topologies and optimization techniques to handle the complicated, high-dimensional medical data is also essential. The suggested framework should also take into account the ethical ramifications of using AI in medical diagnosis, including transparency and interpretability. This study's main goal is to provide a novel method for precise medical condition detection utilizing multimodal data that blends transfer learning and deep neural networks. The suggested framework seeks to intelligently leverage the pre-trained knowledge from other domains and efficiently incorporate various medical data sources in order to get beyond the constraints of existing machine learning approaches and increase diagnosis accuracy. The research's ultimate goal is to advance the area of medical diagnostics by enabling more

accurate and early illness identification, which can enhance patient outcomes and make healthcare systems more effective [28].

IV. PROPOSED TL-DNN FRAMEWORK

The methodology involved using an image dataset from Kaggle that contained images from various stages of AD to train the suggested model. Data preprocessing used the Gaussian filter to smooth out and reduce noise before analysis. The pre-trained AlexNet DNN architecture was used with transfer learning. The GLCM was used for feature extraction in order to record spatial relationships and pixel intensity patterns for texture data. ANN were used to extract complex patterns from the input data and classify diseases. Different metrics were also used in performance evaluation. Fig. 1 shows the proposed methodology.

A. Data Collection

The effectiveness of the study would be enhanced by having access to a comprehensive dataset that contains a wide range of disorders, several imaging modalities (such as MRI, CT, and X-ray), and a variety of patient demographics [29]. Such a dataset would enable the examination of the suggested approach's performance across various medical diseases, imaging modalities, and patient groups, providing a more thorough evaluation of the method. It would be possible to evaluate how well the technique generalizes and adjusts to various illness presentations and demographic characteristics using this extensive dataset, which would eventually increase its potential usefulness and relevance in real-world clinical settings. The intended database originated from a publicly accessible Kaggle repository [30]. These MRI images of the brains of individuals who are Very Mildly Demented (VMD), Moderately Demented (MOD), Non-Demented (ND), and Mildly Demented make up this dataset. An image dataset that included images from various stages of AD was used to train the suggested model. Table I shows the overall amount of image samples used as input after enhancement, broken down by class.

Fig. 1. Proposed methodology.

TABLE I. DATASET PARAMETERS

Mental State	No. of image samples
VMD	1792
MOD	1024
ND	2560
MD	1017

B. Multi-Modal Data Fusion using Autoencoders

AI-driven multi-modal data fusion approaches have evolved as a way to tap into the deep insights contained in these diverse sources. Utilizing autoencoders, a kind of neural networks created expressly for unsupervised feature learning and data reduction, is one well-known strategy in this field. Autoencoders provide a strong foundation for multi-modal data fusion since they are typically used for dimensionality reduction and data reconstruction tasks. They serve as modality-specific encoders in this situation, extracting unique patterns and characteristics from each data source. The models may learn representations that capture modality-specific information while abstracting away noise and unnecessary features by training distinct autoencoders for each modality. In order to merge the encoded representations from various modalities, a shared latent space must be created, and this is where the multi-modal fusion's key challenge resides. The model may learn shared characteristics and relationships that might not be obvious in individual modalities alone by using this joint space as a bridge to enable the integration of modalities. The constraints presented by multi-modal medical data, where complicated interrelationships frequently influence diagnostic findings, are well matched with the flexibility of autoencoders in capturing nuanced connections.

The possibility for higher data quality is one of the intrinsic benefits of utilizing autoencoders for multi-modal fusion. Autoencoders naturally filter out unimportant fluctuations by condensing noisy and high-dimensional input into a latent space, improving the signal-to-noise ratio. This can result in conclusions that are more reliable and generalizable, especially when working with noisy medical data. The clinical relevance and interpretability of multi-modal data fusion employing autoencoders ultimately determines its effectiveness. The combined representations should increase diagnostic precision while also giving doctors useful new information. Making sure that the AI-driven fusion effectively integrates with medical expertise and decision-making involves translating these learnt qualities back into clinical words that can be understood by patients.

C. Preprocessing

Applying a Gaussian filter to an image as part of preprocessing it with a Gaussian function helps to smooth it out and reduce noise. The Gaussian function, a mathematical function that has a bell-shaped curve, serves as the filtering operation's kernel or mask. A Gaussian kernel is used in the

filter's operation, and each pixel is given a weight based on how close to its neighbors it is. The values of the Gaussian function at each point along the kernel are used to calculate the weights. The degree of image smoothing can be altered by modifying the Gaussian filter's parameters, such as the kernel size and standard deviation. Smaller kernel sizes and lower standard deviations preserve finer details while larger kernel sizes and higher standard deviations result in more extensive smoothing. A preprocessed image with less noise, fewer high-frequency details, and a smoother overall appearance is the end result. A common preprocessing method in image processing, Gaussian filtering is especially beneficial for tasks like demising, feature extraction, and improving image quality. Below is the equation for the Gaussian function.

$$G(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{x^2}{2\pi\sigma^2}} \quad (1)$$

Where the standard deviation of the distribution is denoted as σ . The distribution is assumed to have a mean of 0.

D. Employing Transfer Learning for training the Dataset

1) *Pre trained model – AlexNet*: A convolutional network framework that has already been trained is called AlexNet. Transfer learning is the process for employing an approach that has been trained, and it is currently widely employed in applications that employ DL. In the suggested technique, the study employed an updated form of this AlexNet framework. AlexNet is an eight-layer structure with accessible variables, five of which comprise layers of convolution that combine maximum pooling with three layers that are completely interconnected. ReLU is a nonlinear function of activation that is present in every layer. Images obtained from the Pre-processed layers are retrieved by the network inputs layer. Pre-processing, which may be performed in a variety of methods, such as by enhancing specific image characteristics or decreasing the image, is an essential phase in order to produce appropriate datasets. Image scaling is a necessary procedure since images come in a variety of sizes. As a result, images were reduced in dimension to $227 * 227 * 3$, where $227 * 227$ denotes the input images' height and breadth and three indicates the total amount of channels.

The approach incorporates the previously trained CNN network as well as AlexNet, which has a significant influence on contemporary deep learning techniques. After being modified to accommodate the needs, this CNN network was used to feed the preprocessed images to the suggested AlexNet transfer learning system. The resultant of the categorization layer, completely interconnected layer, and softmax layer constitute three substantially adjusted layers in the design that correspond to the issue specification. Fig. 2 depicts the altered network utilized for transfer learning.

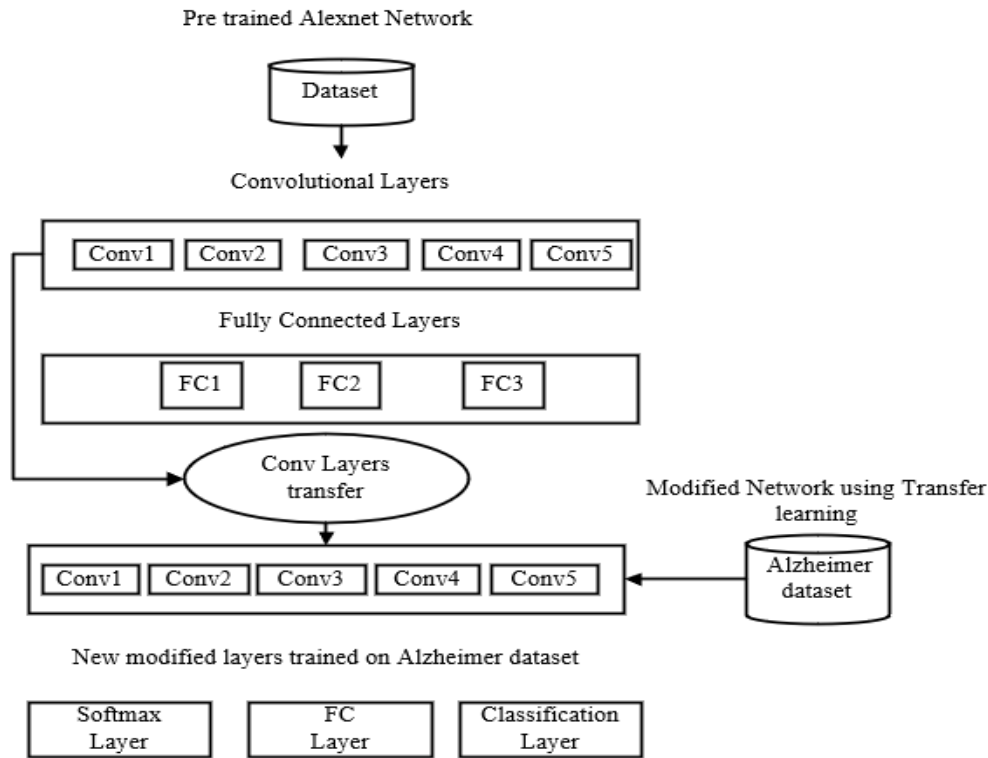

Fig. 2. Pre trained transfer learning model.

Although the subsequent modification layers are learned with Alzheimer datasets, the first five segments of the network, which had been trained employing AlexNet, become unchanged. The remaining three sections are set up to categorize the images into their specific category labels based on the resultant labels assigned to each class. The dimensions of the results, which is made up of several categories, is one of the input variables for completely interconnected layers. A completely linked layer's generated size is equal to the entire quantity of labelled classes. Softmax functions are applied to the data provided using softmax layers. A layer that is completely connected is used for acquiring the class-specific characteristics needed to distinguish across categories, whereas a layer made up of convolutions represents generalized visual characteristics like edge recognition throughout training. As a result, the class-specific characteristics are adjusted for fully linked layers. To categorize images into several classes, the suggested model is trained employing multi-class labelling of Alzheimer's disease.

Numerous variables can be utilized for preparing the system for training, or there are other training choices that can be provided. The remaining three layers of AlexNet—fully interconnected layers, outputs categorization layers and SoftMax layers—are not included in the extraction process since they are not necessary for transfer learning.

The following variables can be utilized as training alternatives: learning rates, the amount of iterations, the rate of validation, and the total amount of epochs.

The different components of CNN are in responsibility for extracting the universal properties from the images, which are referred to as the domain of origin. The resulting learning characteristics can then be applied to determine and categorize a variety of additional operations, such as the identification of Alzheimer's disease. Customized generated models that may be utilized for validation are positioned on clouds. The approach that has been trained evaluates each image and classifies them according to their corresponding categories, which are MD, MOD, VMD and ND. The trained system has precisely the characteristics for image processing that it obtained throughout the training phase. Thus, it was shown that the effectiveness of Alzheimer's disease recognition is influenced by the identification of Alzheimer's disease phases in individuals and the transfer of information from big datasets.

E. Feature Extraction using GLCM

By computing various statistical measures from the GLCM matrix, different facets of the image texture can be captured during feature extraction. These measurements, also referred to as GLCM features or texture features, offer numerical data about the spatial relationships between gray-level values in an image.

1) *Energy*: By adding up the squared values of each component in the GLCM matrix, the energy also known as the angular second moment or uniformity is determined. It gauges the texture of the image's overall intensity or contrast. While a lower energy value reflects a more complex or heterogeneous texture with variations in gray-level values, a higher energy value denotes a more homogeneous texture where the gray-level values are evenly distributed.

$$E = \sum_p \sum_q \{N(p, q)\}^2 \tag{2}$$

Where the images are denoted as N, and the image's squares with grey levels are labeled as (p, q).

2) *Contrast*: In terms of the variations in their grey levels, contrast quantifies the intensity contrast between pixel pairs. It displays how much local variation or abrupt texture transitions there are. Low contrast values imply a more uniform or smooth texture, while high contrast values suggest significant differences between adjacent pixel pairs.

$$C = \sum_{y=0}^{I_q} y^2 \left\{ \sum_{p=1}^{I_q} \sum_{q=1}^{I_q} N(p, q) \right\} \tag{3}$$

I stand for the grayscale of the images, N for the images, and (p, q) for the square of an image's grayscale.

3) *Correlation*: Correlation measures how closely the linear associations between the gray-level values of adjacent pixels are related to one another. It shows how the values of the grey levels vary consistently or predictably between adjacent pixels. A stronger or more nonlinear relationship between the gray-level values is indicated by a higher correlation value than by a lower correlation value.

$$C_o = \frac{\sum_p \sum_q (p, q)N(p, q) - \mu_u \mu_v}{\sigma_u \sigma_v} \tag{4}$$

In the images, the values of mean, as well as standard deviation, are μ_u , μ_v , σ_u , and σ_v are characterized as row and column.

4) *Entropy*: The amount of information or uncertainty related to the texture is measured by entropy. It displays the distribution of gray-level values among adjacent pixel pairs. A texture with a higher entropy value is more varied or heterogeneous, with dispersed and unpredictable gray-level values. A lower entropy value, on the other hand, denotes a more regular or uniform texture, where the values of the grey levels are concentrated or predictable.

$$En = - \sum_p \sum_q N(p, q) \log(N(p, q)) \tag{5}$$

F. Classification using DNN

DNN have an intricate network model and adhere to the same structure as standard ANN. It aids in the development of

models and the clear definition of complex structure. It has 'n' layers that are hidden that analyze information obtained from the layer preceding it, which is referred to as the initial layer. Following every moment, the rate of errors of the input information is going to be gradually lowered by changing the weights for every node, back promoting the network's structure and continuing until it achieves improved outcomes. In the input layer, any amount of the inputs can be designated as input nodes. In order to intensify the conditioning analyze, DNN typically has multiple nodes than the data it receives from the layer. As distinct nodes for output in the layer that produces the results, any amount of generates can be stated. The total quantity of points in the data for input and output, bias, developing rate, starting weights for modification, the amount of hidden layers, the total number of nodes in each hidden layer, and prevent the requirements for stopping the operation of the times are considered to be the variables that are utilized by the DNN. In order to prevent network leads to from being invalidated discrimination value is typically set to 1 in any neural network design. Additionally, the rate of learning is set to 0.15 by standard and is later arbitrarily impacted through trial and error to produce different results compared to the equation. The system can determine the beginning weights of the nodes at arbitrary, modify it throughout replication by determining its error rate, and modify it frequently after every phase. The amount of inputs and the dimension of the information determine the amount of secret layers as well as node locations in each hidden layer. Both the system reaches the ideal amount of periods or the anticipated outcome from the approach to learning is realized is referred to as the network's removal state. It requires a greater amount of resources to train the computational framework if there are more sections and node locations in the framework.

1) *Artificial neural network*: ANN can be used to classify cases of AD. An example of a ML model is an ANN, which takes inspiration from the design and operation of neural networks in biology. They are made up of interrelated "neurons," or nodes, organized in levels. Every neuron takes in information, uses a stimulus to create an output, and subsequently sends the result to the neural layer below. Fig. 3 shows the architecture of ANN.

Fig. 3. Architecture of ANN.

To avoid the biased impact caused by the input data due to the different ranges, each input distinctive, $b_i; 1 \leq i \leq 5$, had been normalized inside the same range $[y, a]$. Let's say an additional range is defined as $[y, x]$. Let b_{max} and b_{min} represent the upper and lower bounds of the concept's natural range. The distinctive values b_i within the range of values $[y, x]$ could be normalized using the formula that follows symbolized as b'_i .

$$b'_i = \frac{(y-x)(b_i-b_{min})}{b_{max}-b_{min}} + y \quad (6)$$

A symmetrical function has x and y parameters of 0.1 and 0.9, respectively, whereas a tangent hyperbola function has x and y coordinates of 0.9 and 0.9 in both cases. The symmetrical function is shown below.

$$f(b) = [1 + \exp(-b)]^{-1} \quad (7)$$

The highest and lowest values of the hyperbola's tangent activating function were limited to $[-1, 1]$, while the highest and lowest values of the symmetrical function had been limited to $[0, 1]$. The tangential hyperbolic function of activation is shown in Eq. (3).

$$f(b) = [\exp b - \exp(-b)]/[\exp(b) + \exp(b)] \quad (8)$$

This limits the network's expected output for symmetrical and hyperbolic angular functions of activation, respectively, to $[0, 1]$ and $[1, 1]$. On the contrary hand, the system's outputs don't accurately reflect the data's true worth. The output value has to be changed to its actual value, b'_d using the following,

$$b'_d = b_{min} + \left[\frac{b_d - y}{x - b} \right] \quad (9)$$

Equations 10 and 11 calculate the generalization error using the summation squared errors (SSE) and regression analysis error (R2):

$$\text{summation squared error} = \sum(b'_d - b_t)^2 \quad (10)$$

$$\text{Regression analysis} = 1 - [\sum(b'_d - b_t)^2 / \sum(b'_d - b)^2] \quad (11)$$

Where b is the measurement value of the evaluation sequence t and b_t is the average of the data collected.

V. RESULTS AND DISCUSSION

The methodology involved training the suggested model using an image dataset from Kaggle that included images from various stages of AD. Before analysis, noise in the data was smoothed out and reduced using the Gaussian filter. Transfer learning was used in conjunction with the pre-trained AlexNet DNN architecture. In order to capture spatial relationships and pixel intensity patterns for texture data, the GLCM was used for feature extraction. ANN were used to classify diseases and extract intricate patterns from the input data. Additionally, various metrics were applied when assessing performance.

A. Accuracy

The system model's overall performance is assessed using accuracy. Essentially, it is the notion that each encounter will be accurately predicted. Accuracy is provided in equation (12),

$$\text{Accuracy} = \frac{T_{Pos} + T_{Neg}}{T_{Pos} + T_{Neg} + F_{Pos} + F_{Neg}} \quad (12)$$

TABLE II. COMPARISON OF ACCURACY

Method	Accuracy (%)
Inception V4 [31]	73.75
Landmark based feature extraction [31]	79.02
ADDTLA [31]	91.7
TL-DNN	99.32

The accuracy of the suggested TL-DNN and the existing methods is shown in Table II. Due to its accuracy value of 99.32%, the suggested method is determined to be more effective than the others. The accuracy is shown in Fig. 4.

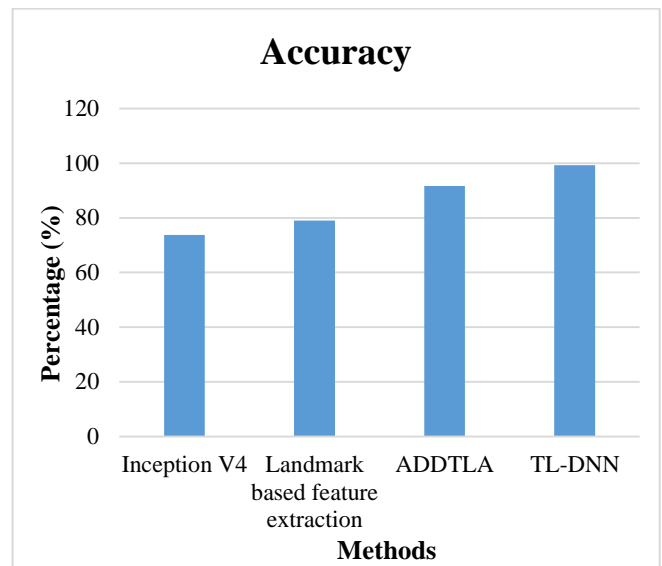

Fig. 4. Comparison of accuracy.

B. Precision

Besides to being correct, precision also refers to how closely two or more calculations resemble one another. The relationship between accuracy and precision demonstrates how repeatedly a finding can be made. Equation (13) can be used to calculate precision.

$$P = \frac{T_{Pos}}{T_{Pos} + F_{Pos}} \quad (13)$$

C. Recall

Recall is the proportion of all pertinent results that the methods were effectively sorted. The ratio among the true positive and false negative values is used to calculate the appropriate positive for those numbers. It is referred to in equation (14).

$$R = \frac{T_{Pos}}{T_{Pos} + F_{Neg}} \quad (14)$$

D. F1-Score

The F1-Score formula combines recall and accuracy. Precision and recall are used to calculate the F1-Score that is given in equation (15).

$$F1 - score = \frac{2 \times precision \times recall}{precision + recall} \quad (15)$$

TABLE III. COMPARISON OF PERFORMANCE METRICS

Method	Precision (%)	Recall (%)	F1-score (%)
DNN [32]	97	97	97
SMO [32]	94.1	93.9	96.3
LDA [32]	95.7	95.5	95.5
KNN [32]	89.2	86.4	86.6
TL-DNN	98.12	98	98.5

Table III compares the precision, recall, and F1-score of current methods with the suggested TL-DNN. The precision of the recommended TL-DNN is higher than that of the other approaches. In Fig. 5, it is shown.

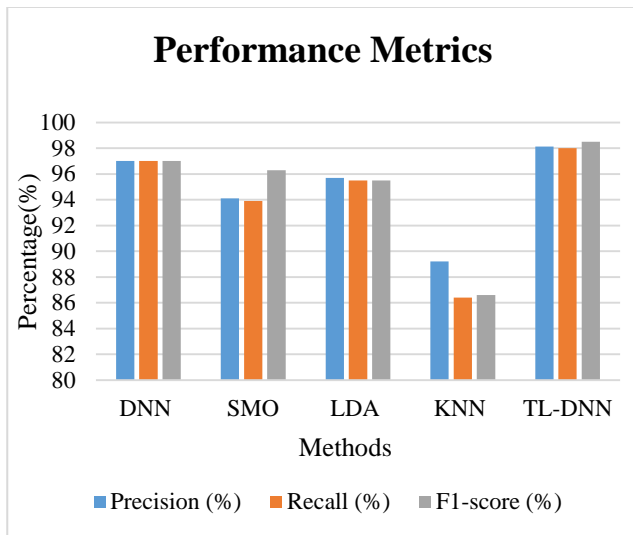

Fig. 5. Performance Metrics.

E. Miss Rate

A binary classification model's effectiveness is measured by the miss rate, also referred to as the false negative rate or Type II error rate. It calculates the percentage of positive instances that the classifier actually classifies as negative.

$$MissRate = \frac{F_{Neg}}{T_{Pos} + F_{Neg}} \quad (16)$$

The miss rate of the proposed TL-DNN is compared with the miss rate of other methods, which is given in Table IV. The miss rate of TL-DNN is 5.1% which lower than other methods. It is represented in Fig. 6.

F. Area Under the Receiver Operating Characteristic Curve (AUC-ROC)

The area under the ROC curve is known as the AUC. It evaluates the classifier's overall performance in separating the

two classes while taking into account all potential classification thresholds. A classifier's performance is graphically represented by the ROC curve. Fig. 7 depicts the AUC-ROC.

TABLE IV. COMPARISON OF MISS RATE

Methods	Miss Rate (%)
Inception V4 [31]	26.25
Landmark based feature extraction [31]	20.98
ADDTLA [31]	8.3
TL-DNN	5.1

Fig. 6. Comparison of miss rate.

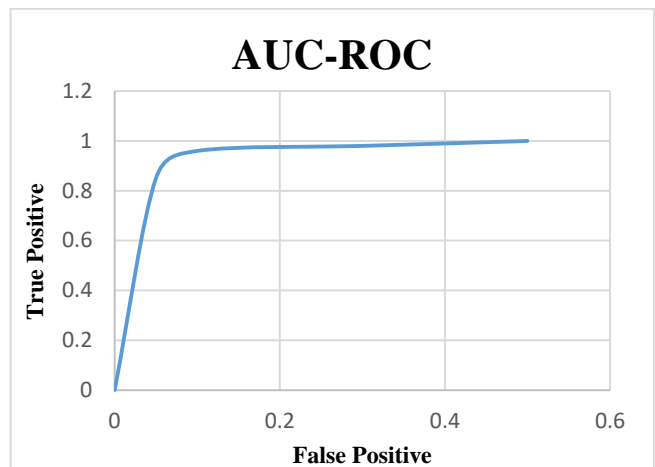

Fig. 7. Area under the receiver operating characteristic curve.

G. Discussion

The end result discusses how various metrics can be used to evaluate a system model's effectiveness when performing binary classification tasks. Evaluation of the accuracy, precision, miss rate, recall, F1-score, and area under the receiver operating characteristic curve (AUC-ROC) are the main considerations. Accuracy is a binary classification metric that shows how frequently the model predicts correctly. The accuracy of various methods is compared in the table and

figure, with TL-DNN having the highest accuracy (99.32%). Less false positives are implied by higher precision. Comparing precision, Table III shows that TL-DNN has the highest precision (98.12%). The miss rate for the TL-DNN is the lowest (5.1%). The F1-Score and recall values achieved by TL-DNN are 98% and 98.5%, respectively. The outcome offers a thorough analysis of the model's performance using a variety of metrics, enabling a thorough evaluation of its efficiency in the binary classification task. The outcomes demonstrate that the TL-DNN method performs remarkably across a variety of evaluation metrics.

VI. CONCLUSION

For accurate medical disease diagnosis using multimodal data, the combination of TL and DNN shows to be a highly effective and promising approach. This study effectively illustrates the potential to improve diagnostic precision by utilizing information from pre-trained models and imaging data sources. Even with little training data, the model can generalize to different medical specialties and diseases by using transfer learning. Due to its robustness and dependability in diagnosing medical conditions, this integrated approach has a lot of potential for use in the real world. The model's achieved high generalization and accuracy highlight its practical value in aiding medical professionals in making prompt and accurate diagnoses. This strategy can result in better treatment choices, better patient outcomes, and possibly lower healthcare costs by accurately diagnosing diseases. Despite these noteworthy developments, there are still some issues that need to be resolved. Maintaining the model's performance in real-world medical settings requires careful consideration of data quality and mitigating potential biases. This study offers insightful information into the field of medical disease diagnosis and demonstrates the enormous potential of fusing DNN and TL. The deployment of extremely precise and trustworthy diagnostic tools that will revolutionize medical procedures and have a big impact on patient care by overcoming obstacles and further improving the strategy. Innovative and ethical solutions to benefit patients and the healthcare industry as a whole will be developed as the field of artificial intelligence in healthcare develops as a result of ongoing research and collaboration between AI experts and healthcare professionals. The legal implications of utilizing AI in medical diagnosis, including transparency, interpretability, and possible biases, are not adequately covered in the research. The investigation of other designs that can perhaps produce superior results may be constrained by the employment of a specific neural network architecture (AlexNet).

Abstract—Digital educational games (DEGs) are effective learning tools for subjects related to science, technology, engineering, and mathematics (STEM), yet they are still not widely used among students. Existing instruments typically assess player experience (PX) and acceptance separately, even though both are essential DEG evaluations that can be merged and analyzed concurrently in a thorough manner. This study, therefore, proposes an integrated instrument called DEGAPX that combines fundamental technology acceptance factors with a broad range of PX criteria. The proposed instrument can be used by educators and game designers in the selection and development of DEGs that satisfy the needs of target users. This article describes the process of developing the scale instrument and validating it through two rounds of expert judgment and among students after using three DEGs related to STEM. The proposed instrument, which comprised 15 constructs measured by 67 items, was proven to be reliable and valid.

Keywords—Game; education; acceptance; experience; stem

I. INTRODUCTION

The complexity of the modern world, which necessitates that the workforce be prepared with the knowledge and abilities to tackle cross-disciplinary problems, is argued to make science, technology, engineering, and mathematics (STEM) education necessary [1]. In contrast to the growing demand, there have been fewer STEM graduates in many countries [2]. STEM-related degrees accounted for six out of ten of the educational programs, with the highest percentage of dropouts among 44,406 students at 20 Malaysian public institutions [3]. A universal concern in education is learner's lack of enthusiasm in STEM fields.

The use of modern pedagogical approaches such as educational gaming technologies has been advocated by academics as a way to improve students' interest, engagement, and performance in learning [4], [5]. Among 408 university students in Malaysia, more than 60% of them prefer using online games to supplement their studies because they believe games can make their learning more enjoyable [6].

Moreover, it has been demonstrated that game-based learning applications may improve learners' understanding, interconnection, and exploration of scientific and mathematical concepts. This instructional tool can give students

opportunities for experiential learning that let them apply the concepts learned in the classroom to actual situations while also developing their creativity, critical thinking, and problem-solving abilities [7]. Furthermore, the COVID-19 pandemic highlights the importance of educational technologies like DEGs as a preparation for an unpredictable future that may require remote instruction. These technologies enable the acquisition of knowledge and skills outside of the classroom [8], [9].

Digital educational games (DEGs) are online or offline applications in electronic devices that integrate fun and educational elements [10]. This technology is anticipated to be widely used and accepted because current learners are people who have grown up with a heavy reliance on the internet and other information technologies such as digital games [11]. It has been shown that around 80% of all internet users worldwide between the ages of 16 and 44 play video games in the year 2022 [12]. Therefore, DEGs are useful and pertinent technological applications that can support students' learning.

Although DEGs offer great promise and are a good fit for today's learners, they have not yet received widespread acceptance. Game developers face challenges in creating successful, well-received DEGs since they are more difficult to design than commercial entertainment games due to the need to serve both educational and recreational goals [13]. Numerous DEGs have fallen short of the expectations placed upon them in terms of learning or enjoyment outcomes [14].

With the growth of DEGs, more research is required to assist game developers, instructors, and policymakers in the design, development, selection, and implementation of DEGs that satisfy students' preferences as the key target users. When an information system is widely adopted by the intended audience, it can be considered successful [13]. Although there has been various researches that investigate the predictors of DEG acceptance, a systematic literature review shows that most of them primarily concentrate on technological acceptance viewpoints, which are insufficient to fully comprehend students' preferences for DEGs [15].

Given the distinctive and complex features of DEGs, a variety of player experience (PX) factors that contribute to players' pleasure should be incorporated into the acceptance

model and instrument since it can affect users' decisions to utilize the technology [16]. Existing studies normally evaluate DEG acceptance and PX separately [19]. Performance expectancy, effort expectancy, and social influence are prevalent characteristics of technology acceptance [17], [18]. By incorporating PX factors, the assessment of acceptance can be expanded to include crucial DEG design features such as enjoyment, relevant content, feedback, and challenges.

Hence, the purpose of this research is to present an inclusive DEG acceptance instrument called DEGAPX that integrates PX factors. The instrument is crucial and helpful in designing and developing potentially popular DEGs. The instrument can be used by DEG developers to adapt the design that suits users' needs to boost the likelihood of DEG success. The instrument can also be utilized as a guide by instructors when identifying which DEGs could appeal to their students. The subsequent sections of this paper comprise a literature review, methods, results, and discussion, followed by a conclusion in the last section.

II. LITERATURE REVIEW

A. Digital Educational Game Acceptance Factors

According to Dillon and Morris [20], acceptance refers to the willingness of individuals to use an information system that has been created for them. Current approaches to technology development and adoption have considered the requirement for predictive measures of users' likely usage in order to judge the success of a technology. The technology may be deemed unsuccessful if the majority of the population rejects it. By analyzing the data obtained for the measurement scales in questionnaires, previous studies have frequently been able to forecast and explain why people want to use a particular technology [17], [18].

One of the most well-known theories for predicting human behavior when it comes to probable technology acceptance or rejection is the unified theory of acceptance and use of technology (UTAUT). The theory combines eight other renowned theories such as the technology acceptance model (TAM) for explaining and forecasting technology usage [18]. Three independent variables in UTAUT namely performance expectancy, effort expectancy, and social influence predict behavioral intention that affects use behavior.

UTAUT had previously been used to investigate what criteria led Malaysian university students to choose DEGs for learning programming [21]. In place of social influence and facilitating condition variables from the original UTAUT model, the research added attitude, self-efficacy, enjoyment, and anxiety. With the exception of self-efficacy and anxiety, all other independent variables were seen to have a substantial impact on students' intention to utilize the DEG. The use behavior construct was left out with justification that DEG was still a relatively new technology in the area where the study took place and the students were still unfamiliar with it.

Wan et al. [22] look into what influences undergraduate students' acceptance of six digital board games and their ability for independent learning. The instrument was derived from the integration of UTAUT with flow theory as well as the motivated strategies for learning questionnaire (MSLQ). To

identify the causes of primary school students' intentions to continue using mobile games for learning mathematics, another study also made an effort to combine multiple theories such as flow theory and the game-based learning model [23]. Nevertheless, the only variable from technology acceptance was the ease of use.

B. Digital Educational Game Player Experience Factors

According to ISO 9241-210:210 (clause 2.15), user experience (UX) is defined as the way a person feels and behaves after using or anticipating the use of a system, product, or service. For digital educational games (DEGs), UX is sometimes referred to as player experience (PX). Assessment of PX broadens game usability evaluation by focusing on meaningful and enjoyable experiences of users rather than only getting rid of technological barriers [24].

PX is a crucial factor in determining how long a person will play DEGs which will determine the DEG's success [25]. When a game has a strong PX, consumers are more likely to play it frequently, stay engaged for a longer duration, and recommend it to others [26]. Despite the wide variety of learning games available today, some of them are unattractive to consumers and have low retention rates, as consumers get bored after a few gaming sessions [27]. The absence of elements that can improve PX may be one of the causes. Consumers may lose interest when their playing experience falls short of their expectations. Therefore, it is critical to include PX in DEG evaluation.

There have been many different methods for evaluating PX, including questionnaire scales, field studies in real-world settings, lab studies, and online studies where participants can be anonymous [28]. Since studies on the variables that determine user acceptance generally use measurable constructs evaluated using Likert scale questionnaires, prior literature that assessed PX in DEG using a similar method was reviewed. The PX factors derived from those studies can then be analyzed in the same manner as the acceptance factors without any problems.

One of the most popular measurement scales used by researchers to gauge how consumers feel while playing games is the game experience questionnaire (GEQ) [29]. Seven different factors are measured by the questionnaire's items, including the positive affect (enjoyment), negative affect, flow, challenge, tension, as well as sensor and imaginative immersion, which relates to a rich gaming experience, beautiful design, and engaging game plot. However, there were no learning-related factors in the GEQ scale.

Nagalingam et al. [31] proposed one of the recent instruments to thoroughly assess PX in digital learning games called the educational game experience (EDUGX). The instrument which had been reviewed by experts and tested among 273 computer science diploma students, had demonstrated content validity, internal consistency, convergent validity, and discriminant validity. There were six components to the instrument including immersion, usability, flow, player context, and learnability, each of which was broken down into a number of sub-components. The immersion component gauges how invested individuals feel in the game they play,

whereas usability measures the extent to which players found the game to be effective and satisfying. On the other hand, learnability represents the educational aspect of the game; player context pertains to the user background and the social interaction that the game supports, while flow indicates the state of total focus.

III. METHODS

A. Instrument Development

The development of the DEGAPX scale instrument for this research follows the guideline by DeVellis [32], where the first step entails reviewing theories from past studies relevant to the research objective. Since this research intends to propose a comprehensive instrument for measuring the acceptance of DEGs with the integration of PX components, constructs that evaluate DEG acceptance and PX in prior studies were identified from two separate systematic literature reviews [15].

1) *Determination of constructs*: Performance expectancy, effort expectancy, and social influence are the constructs in UTAUT by Venkatesh et al. [18] which had been proven by many studies to have an impact on students' intention to use DEGs [22], [33], [34]. Hence, this study chooses these three constructs together with behavioral intention from UTAUT to represent the core technology acceptance constructs in the proposed DEGAPX instrument.

From the review of PX constructs used by scholars [27], those proposed by Nagalingam et al. [31] in the EDUGX framework can be considered for this research since they were developed after taking into account diverse PX criteria in other studies. However, some adjustments were made.

For instance, EDUGX [31] and the frameworks in other existing research [35], [36] used a control factor to assess the extent of freedom felt by players over the game menu, character movement, actions, and strategies. Since DEG is an instructional tool, this study decides to transform the construct into a learning control construct that focuses on players' perceptions of control over their learning recovery, problem-solving approaches, and ability to choose the game content that they want to learn and the difficulty level.

Apart from that, under the game usability component in EDUGX [31], operability was defined as the game performance including its accessibility, ease of use, and lack of technological glitches, while understandability was defined as the game's messages, functions, inputs, and outputs being simple to understand. On the other side, the game system sub-component indicated how well a gaming gadget operated in terms of being simple and comfortable to use. These revealed that operability, game system, and understandability from the EDUGX framework [31] and effort expectancy from the UTAUT model [18] were comparable. Therefore, this research chose to use the effort expectancy construct to cover the game usability measurement items in EDUGX. In addition, knowledge improvement under the learnability component of EDUGX is similar to the UTAUT model's performance expectancy construct, which measured the game's capacity to enhance students' learning performance.

As a result, 14 constructs were considered for this study, as shown in Fig. 1, including performance expectancy, effort expectancy, social influence, and behavioral intention from UTAUT [18], as well as learning relevance, attractiveness, enjoyment, challenge, clear goal, learning control, social interaction, feedback, concentration, and immersion modified from EDUGX [31] for player experience measurement.

Construct	Definition
Player experience	
Learning relevance	The degree to which the game instructions are appropriate with user's learning goals, previous knowledge and preferred way of learning.
Attractiveness	The level of player attraction to the game as a result of its sensory elements, such as audio and visual.
Enjoyment	The degree to which an individual perceives the activity of using the game is enjoyable.
Challenge	The degree to which users believe the game is difficult enough and appropriate for their skill level.
Clear goal	The extent to which a player perceives the goals are clearly presented.
Learning control	The extent to which users believe they have control over their learning in the game.
Social interaction	The extent to which the game supports and encourages social connection and interaction.
Feedback	The degree that individuals perceive the game provides feedback on progression and accomplishment.
Concentration	The ability of the game to deliver stimuli that will pique players' attention and encourage player's focus.
Immersion	A state in which players believe they are actively participating in the content of the game and completely involved in the game world.
Technology acceptance	
Performance expectancy	The extent to which individuals perceive that using the game will help improve their performance in STEM learning and skills.
Effort expectancy	The extent of ease related to the use of the game.
Social influence	The extent to which individuals perceive that important others believe DEGs should be used.
Behavioral intention	Degree of an individual's intention to use DEGs related to STEM.

Fig. 1. Definition of the 14 constructs in the DEGAPX instrument that integrates technology acceptance and player experience measurement.

2) *Determination of items and measurement format*: After a thorough examination of the validated items used in prior studies, a scale which consisted of 87 items in total was generated to measure the constructs in the DEGAPX instrument. Some items were modified from previous research to suit the context of this study. New items were also proposed, including those under the performance expectancy construct that measure the perception of students on their STEM learning and skill improvement through the DEG.

For the format of responses, students were required to indicate their agreement on each questionnaire item using the

five-point Likert scale with 1 (strongly disagree), 2 (disagree), 3 (not sure), 4 (agree), and 5 (strongly agree). The instrument questions were prepared in Malay, as well as in English language as the respondent's first and second language, respectively. The instrument had been proofread by an English lecturer with a master's degree in Teaching English as a Second Language (TESL), and the Malay translation had also been examined by the Malaysian Institute of Translation and Books (ITBM) to ensure accurate translation.

B. Content Validation through Expert Judgment

For evaluating a new or updated measurement instrument, the establishment of content validity is a crucial first step before performing other validation techniques [37]. Based on the opinions of subject-matter experts, the content validation procedure enables researchers to acquire data on the relevancy, clarity, and comprehensiveness of an instrument.

The instrument for this research was scrutinized by experts in the field pertinent to this research, as shown in Table I. Two rounds of expert review were conducted, following Polit et al. [38] and Tojib [37]. The documents for the expert panel were prepared following the detailed guideline by Elangovan & Sundaravel [39] to ensure that the experts understand what is expected of them and to facilitate the validation process.

TABLE I. EXPERTS PROFILE

Expert	Field of Expertise	Years of Experience
E1	Game-based learning, creative content	20
E2	Game design, educational technology, visual informatics	19
E3	Educational games design and evaluation, acceptance and use of information system, usability, user experience	15
E4	Human computer interaction, science, technology, engineering, and mathematics	15
E5	Game-based learning, e-learning, learning technologies, gamification, augmented reality, virtual reality games	15
E6	Technology acceptance, multimedia in education, augmented reality, science, technology, engineering, and mathematics	15
E7	User experience in educational games	8
E8	Mobile application and games development	6
E9	Information system, technology acceptance and adoption	4

The first round involved nine experts, and the second round was conducted with three of the experts to validate the refined instrument. These numbers of experts are within the suggested range by Polit et al. [38]. The selection criteria for the content experts were those who hold a Ph.D. qualification and actively conduct research in the field of interest or have experience developing DEGs [37].

The content validity index (CVI) is a reliable approach to judge whether the content of a new or revised scale is valid. Another commonly used method for measuring content validity is the content validity ratio (CVR) by Lawshe [40]. The goal of the content validation for this research was to ascertain whether any item needed to be revised or eliminated

based on the CVR value, the CVI value of individual items (I-CVI), as well as whether more items were required in order to fully explore the construct in light of expert opinion from the comment section [38], [40].

The CVR threshold is influenced by the number of experts. For nine panel of experts, items that achieve the CVR value of 0.78 and above can be retained, while the rest can be considered for elimination [40]. Similarly, items with I-CVI values are higher than 0.78 which shows that the scale has excellent content validity, whereas values below 0.78 indicate that the items need to be revised or eliminated. I-CVI can be calculated by dividing the number of experts who gave a three or four rating on a four-point relevance scale by the total number of experts [41].

Low CVI values could indicate that the operationalization of the underlying construct in the items was not good, or information and directions given to the experts were insufficient, or the experts themselves were biased or inadequately skilled [38]. Hence, a lot of effort was put to create high-quality items as well as to choose a strong panel of expert judges. CVI for the overall scale (S-CVI/AVE) can then be determined. While 0.80 is the minimum acceptable value for S-CVI/AVE, 0.90 or above is advised for a scale to be deemed to have great content validity [38].

C. Instrument Testing among Target Respondents

It is important to conduct a pilot study among target respondents to determine whether a specific research instrument is appropriate for use without any errors or shortcomings before it can be employed in a larger scale research. The reliability and validity of the questionnaire items and how well respondents understood the items need to be judged during this stage [42].

The research sample consists of 14 years old students from a public school in Terengganu, one of the states in Malaysia. Approval from the Ministry of Education (MOE) Malaysia and the Terengganu State Education Department was requested before the data collection. Following that, a meeting was held with the school principal to obtain permission and discuss the schedule. All students were given a form for parental or guardian consent.

The research objectives were briefly explained to the participants including the games that they need to play and evaluate, as well as the confidentiality and anonymity of their feedback. They were reminded of the significance of this study, the necessity of reading each survey question thoroughly before responding and to avoid providing incomplete or straight-lining (identical) responses.

Three DEGs were chosen for testing, based on the DEGAPX instrument, such as having relevant content, clear goals, attractive features, and ability to improve students' learning and skills pertinent to STEM. The first DEG decided for this research is a simulation game called Poly Bridge 2 (<https://www.polybridge2.com/>) by Dry Cactus that lets players learn the foundations of bridge design. Players need to construct bridges that work well under specific conditions using the materials provided.

The second DEG in this study, RoboCo (<https://roboco.co/>) by Filament Games, requires students to design robots that can complete a range of tasks. Students can practice their coding skills using Python language when automating their robots. The two games, Poly Bridge and RoboCo, can help players become more creative as well as better at problem-solving and design-thinking, which are important skills in STEM. On the other hand, the third game, Moonbase Alpha (<https://www.nasa.gov/offices/education/programs/national/ltf/games/moonbasealpha/index.html>) was published by NASA and free-to-play. Students can play alone or collaborate in a team with other players to repair equipment and resume oxygen production at the moon outpost. The screenshots of the three games were shown in Fig. 2.

Fig. 2. The images of the three STEM DEGs used in this research.

While some students played all three games, others engaged in one or two games only. They need to answer a self-administered paper-based questionnaire after playing the game for about 90 minutes in the school computer laboratory. There were 281 valid responses obtained from students. RoboCo received 87 responses, Moonbase Alpha received 93 responses, and Poly Bridge 2 received 101 responses.

D. Reliability and Validity Assessment from Instrument Testing

Using SmartPLS 3, reliability was examined based on outer loading of items, Cronbach’s alpha (α), and composite reliability (CR). Outer loadings denote the proportion of the item variance that is explained by the construct, while α and CR assess the intercorrelation between items.

On the other hand, average variance extracted (AVE) can be used to evaluate convergent validity, which refers to the strength of a positive correlation between items. For discriminant validity, heterotrait-monotrait (HTMT) can determine how distinct one construct is from other constructs. Table II showcases the criteria by Hair et al. [43].

Exploratory factor analysis (EFA) with principal component extraction and varimax rotation can also be carried out in IBM SPSS Statistics 27 software to assess construct validity. The data set is appropriate for factor analysis if the Keyser-Meyer-Olkin (KMO) value surpasses 0.5 with a significant Bartlett’s test of sphericity result below 0.05.

TABLE II. RELIABILITY AND VALIDITY ASSESSMENT CRITERIA BY HAIR ET AL. [43]

Criteria	Guidelines
Outer loading	- Remove items with loadings less than 0.4 - Retain items if their loading exceeds 0.7. - Remove items with loadings between 0.4 and 0.7 if AVE and CR can be satisfied.
Cronbach’s alpha (α)	- More than 0.70 is satisfactory. - Between 0.6 and 0.7 is acceptable.
Composite reliability (CR)	- Must exceed 0.70.
Average variance extracted (AVE)	- Must exceed 0.5.
Heterotrait-Monotrait (HTMT)	- Should be less than 0.9

IV. RESULTS

This section describes the results from the expert judgment and instrument testing of the DEGAPX instrument.

A. Content Validity

In terms of the constructs, all experts remarked them to be adequate in representing the whole aspect of DEG, and that none need to be added or removed. Thus, the proposed 14 constructs remained.

In light of first round of content validation results by nine experts for the items used to measure each construct, the CVI of the entire scale (S-CVI/AVE) was found to be 0.97, which passed the minimum acceptability limit. Five items did not meet the 0.78 content validity ratio (CVR) cut off, so they were regarded as weak in representing the particular constructs and can be eliminated. Some experts had issues with the items, and while certain research used them to measure the construct, their inclusion was not deemed vital since they were not included in other studies.

Among 87 items in the initial pool, 65 of them can be accepted without any necessary changes as all of them displayed excellent content validity based on the I-CVI and CVR value and were deemed relevant and clear by the experts. 17 items that also exceeded the 0.78 threshold for I-CVI and CVR, however, need to be refined according to experts’ comments and ratings on clarity. The improvement included rewording, rephrasing, elaborating, and providing examples to improve the comprehensibility of the items. From the experts’ comments, the proposed questionnaire items were deemed adequate, with no additional items needed.

The modified scale underwent a second round of validation with the help of experts E2, E3, and E6. They were one of those who provided a lot of input in the preliminary round. With a 1.00 average scale content validity (S-CVI/AVE) score, the findings showed agreement on all 84 items in the revised DEGAPX instrument, with no additional adjustments being recommended.

B. Reliability, Convergent Validity and Discriminant Validity

During the pilot test, none of the students had any trouble understanding the survey questions. When 281 survey responses obtained were analyzed in SmartPLS 3.0, 17 items need to be removed to satisfy the criteria in Table II. Apart from that, the performance expectancy construct also needs to be separated into two categories based on EFA rotated component matrix to achieve the required value of AVE. As a result, the DEGAPX instrument with 15 constructs measured by 67 items achieved the requirement for reliability and validity, as displayed in Table III. The 67 items are listed in Table IV, with their outer loadings above 0.40.

The suitability for factor analysis was demonstrated from the 0.875 value of KMO and a significant result of Bartlett’s test (n=281; $\chi^2 = 11,997.707$; d.f. = 3,486; p < 0.001). Next, the relationship between the constructs can be investigated to determine the significant predictors of STEM DEG acceptance.

TABLE III. RELIABILITY AND VALIDITY ASSESSMENT RESULTS

Construct	Items	α (>0.6)	CR (>0.7)	AVE (>0.5)
Attractiveness (AT)	5	0.808	0.866	0.566
Challenge (CH)	4	0.711	0.820	0.533
Clear goal (CG)	3	0.688	0.827	0.615
Concentration (CN)	4	0.674	0.802	0.507
Effort expectancy (EE)	7	0.842	0.881	0.514
Enjoyment (EJ)	5	0.784	0.854	0.544
Feedback (FB)	4	0.743	0.833	0.559
Immersion (IM)	5	0.757	0.836	0.506
Behavioral intention (IN)	5	0.754	0.835	0.505
Learning control (LC)	3	0.606	0.793	0.563
Learning performance expectancy (LE)	5	0.749	0.833	0.503
Learning relevance (LR)	4	0.728	0.830	0.553
Skill performance expectancy (SE)	4	0.729	0.831	0.553
Social influence (SF)	4	0.675	0.803	0.507
Social interaction (ST)	5	0.841	0.886	0.609

TABLE IV. DEGAPX INSTRUMENT CONSISTING OF 67 ITEMS

Code	Item Statement	Loading
Learning Relevance Construct		
LR1	DEG content is relevant to my learning need.	0.851
LR2	The way the DEG works suit my way of learning.	0.779

LR3	The DEG content is connected to the other knowledge I already had.	0.652
LR4	Most of the gaming activities are related to the learning task in the DEG.	0.678
Attractiveness Construct		
AT1	I like the general appearance of the DEG.	0.778
AT2	I am attracted to the DEG as a whole.	0.774
AT3	Generally, I find the DEG to be visually appealing.	0.781
AT4	The DEG design is attractive.	0.776
AT5	I like the graphic used in the DEG.	0.642
Enjoyment Construct		
EJ1	I think the DEG is enjoyable.	0.836
EJ2	There were moments when I had fun playing the DEG.	0.795
EJ3	I find the DEG interesting.	0.782
EJ4	Something happened during the DEG playing session that made me smile.	0.651
EJ5	The DEG does not become repetitive or boring as it progresses.	0.592
Challenge Construct		
CH1	My skill gradually improves through the course of overcoming the challenges in the DEG.	0.760
CH2	The difficulty level of challenges increases as my skills improved.	0.707
CH3	The DEG provides new challenges at an appropriate pace.	0.770
CH4	The DEG provides different levels or types of challenges, according to player’s preference.	0.679
Clear Goal Construct		
CG1	Overall game goals are presented in the beginning of the DEG.	0.797
CG2	The intermediate game goals or sub-goals are mostly presented at appropriate times.	0.775
CG3	The game goals are generally clear.	0.780
Learning Control Construct		
LC1	I feel a sense of control over the actions that I take to solve the problems or to achieve better results in the DEG.	0.794
LC2	I feel a sense of control over the strategies that I use to solve the problems or to achieve better results in the DEG.	0.806
LC3	The DEG supports my recovery from errors or mistakes.	0.639
Social Interaction Construct		
SF1	I am able to interact with other people such as other players or friends or online community when playing the DEG.	0.774
SF2	The DEG makes me interact with other people such as for getting help or sharing information.	0.821
SF3	I like to play the DEG with other people.	0.780
SF4	I am able to play the DEG with other players if I choose to.	0.737
SF5	I would enjoy the social interaction through the DEG.	0.786
Feedback Construct		
FB1	I receive feedback on my game progress.	0.855
FB2	I receive immediate feedback on my actions in the DEG.	0.780

FB3	The DEG notifies me immediately when there are new tasks.	0.634
FB4	The DEG notifies me immediately when there are new events.	0.702
Concentration Construct		
CN1	The DEG provides content that stimulates my attention.	0.773
CN2	The DEG provides various stimuli to maintain my attention.	0.818
CN3	Generally, I am not distracted from tasks that the player should concentrate on.	0.592
CN4	I am not burdened with unrelated tasks.	0.637
Immersion Construct		
IM1	I can become less aware of my surroundings if I play the DEG for a long time.	0.643
IM2	The DEG can make me temporarily forget worries about everyday life.	0.788
IM3	I think the DEG can sometimes make me not notice the time passes when playing.	0.761
IM4	I feel emotionally involved in the DEG.	0.633
IM5	I think the DEG can make me spend more time playing than my initial plan.	0.720
Learning Performance Expectancy Construct		
LE1	I would find the DEG useful in my study.	0.709
LE2	Using the DEG would enable me to learn the related subject or concept more quickly.	0.768
LE3	Learning through the DEG would help me to understand the related subject or concept better.	0.784
LE4	The DEG can help me relate the knowledge learnt to real world situations.	0.550
LE5	The DEG would allow me to relate knowledge from multiple learning subjects.	0.710
Skill Performance Expectancy Construct		
SE1	The DEG can help me apply knowledge or skills to situations or practices related to technology or engineering.	0.685
SE2	The DEG can improve my skill in problem-solving.	0.742
SE3	The DEG can improve my creativity skills.	0.722
SE4	The DEG can increase my ability to design, test, and evaluate solutions.	0.819
Effort Expectancy Construct		
EE1	It is easy to learn the related subject or concept or skill through the DEG.	0.656
EE2	I find the DEG easy to use.	0.780
EE3	Learning to use the DEG is easy for me.	0.725
EE4	I think it will be easy for me to become skillful at using the DEG.	0.686
EE5	The interaction with the DEG is clear and understandable.	0.695
EE6	The DEG rules are generally clear and understandable.	0.722
EE7	The DEG instructions are mostly clear and understandable.	0.747
Social Influence Construct		
SF1	People who are important to me think that I should use DEG.	0.654
SF2	I think my school will support the use of DEG.	0.614
SF3	I think my friend or classmate will support the use of DEG.	0.757

SF4	My friend or classmate thinks playing DEG is a good idea.	0.808
Behavioral Intention Construct		
IN1	I intend to use DEG related to STEM in the future.	0.611
IN2	I predict I would use DEG related to STEM in the future.	0.656
IN3	I am interested to play the DEG again.	0.761
IN4	I plan to use the DEG to expand my learning or improve my skill.	0.716
IN5	I am willing to play the DEG frequently.	0.793

V. DISCUSSION

This section discusses the validated 15 constructs of the DEGAPX instrument and the items used to measure them.

A. Learning Relevance

This construct was altered from Luyt et al. [44] and Sideris and Xinogalos [45] with some extensions, where learning relevance was measured not only by players' perceptions of how well the game content corresponds to their existing knowledge and learning needs but also by how closely the game activities matched the learning tasks in the DEG and players' learning styles. Students in this study mostly participated in quiz learning games, which are effective educational interventions for drill-and-practice activities and receiving immediate performance feedback on knowledge learned in classrooms. Because of that, the different learning objectives and approaches of the three STEM DEGs in this study may have an impact on students' perceptions of the learning relevance of the games.

Students may perceive the STEM DEGs have a little amount of instructional content relevant to their prior knowledge since the games place more emphasis on the application of knowledge to solve real-world problems. In addition, students might not find the games meet their educational needs unless they already have a keen interest in pursuing careers pertinent to the games. Nonetheless, students might find the games suit their learning styles and offer appropriate activities, which results in items LR2 and LR4 being added. The four items proposed, which had been proven to be reliable and valid can gauge how players feel about the DEGs' learning relevance from various angles.

B. Attractiveness

This construct was judged based on the overall appearance and design of a DEG, particularly its virtual aesthetics, as derived from Phan [30] and Tao [46]. One of the experts raised the possibility of other multimedia forms that can fall under this attractiveness construct, but the proposed items were deemed sufficient for this research.

There are many different types of DEG multimedia, such as texts, images, and animations, which would result in too many items if they were measured separately and could cause respondent fatigue when answering the survey. Future research that evaluates DEG with fewer constructs can include more items for measuring specific features of DEGs that users can find appealing.

Attractiveness had been demonstrated to have a significant correlation with students' enjoyment when playing DEGs [46]. The suggested items are beneficial for developers to determine the attraction level of their game prototype designed for teaching and learning purposes.

C. Enjoyment

All experts agreed that the five items in Table IV were pertinent for assessing the degree of enjoyment felt by players. Several studies have revealed that students' willingness to play DEGs is significantly influenced by their level of enjoyment [13], [47], [48]. Hence, this construct is one of the most important criteria for a successful DEG.

D. Challenge

The four items proposed were found reliable and valid for representing the challenge construct. This construct is intended for ensuring a DEG provides suitable challenges for players' skill level, which are neither too easy, making players bored, nor too difficult, causing players distress [49]. RoboCo and Poly Bridge 2 games offer a variety of challenges, where players can only access the next challenge after completing the one before it. While some students enjoy demanding games, others might favor easy, relaxing games that do not require much mental effort. Thus, games that allow users to select their preferred difficulty level might appeal to a wide range of consumers.

E. Clear Goal

This research offers three items, as presented in Table IV, for assessing the goal clarity of a DEG as adapted from the validated items in prior research [30]. The items were all regarded as relevant by the experts and can influence students' willingness to play learning games [22].

F. Learning Control

It is believed that players' learning performance can be enhanced when they have control over their learning in the game. Hence, the learning control construct put forth in this study embodies the assistance provided by a game for players to learn from their mistakes as well as the freedom to select their preferred course of action and problem-solving tactics.

G. Social Interaction

The items for this construct were modified from Phan and Keebler [30] and G Petri et al. [14] to measure the extent to which students believe the game promotes social connection, whether it be for knowledge sharing or help-seeking. Additionally, this construct gauges how much students think the game allowed them to play with other players if they want to and how much they enjoy the interaction.

Social interaction is a wonderful game design element that can boost students' enjoyment and motivate them to play a game repeatedly to engage with other players through communication, cooperation, and competition in the game.

Not all games have a multi-player feature, but even without it, social interaction can still be encouraged when players can communicate with other people, such as when getting help or sharing information through an online chat room, discussion forums, or game-based learning activities in classrooms.

Hence, the proposed five items listed in Table IV are generic enough and adequate to measure players' perception of social interaction through a DEG.

H. Feedback

Playing a DEG will be more pleasurable if it offers consumers immediate feedback and informs them of their progress, achievements, failures, and new tasks. The four items in Table IV, which had been constructed based on Nagalingam et al. [31] and Fu et al. [35], were proven reliable and valid.

I. Concentration

The four items for measuring the extent of concentration perceived by students when playing a DEG were developed based on previous research [22], [35]. The items evaluate how much players believe a DEG does not burden them with unnecessary duties, does not take their attention away from activities they should be concentrating on, and provide a variety of stimuli to keep players interested. Concentration was established as a significant determinant of students' instructional computer games acceptance [13]. Thus, it is a crucial factor to consider when developing DEGs.

J. Immersion

Immersion had been demonstrated to have a substantial impact on students' intention to continue using mobile learning games in a previous study [23]. Hence, game creators should design DEGs with fun, challenging activities and interesting features that can make players feel immersed. Items presented in Table IV can be used in the assessment of a DEG since they appropriately reflect the immersion criteria.

K. Performance Expectancy

Due to the focus of this study being STEM DEGs, the survey items from prior research [50] were expanded to incorporate performance expectancy from two categories including knowledge and skill improvement. DEGs for STEM must not only facilitate and improve students' comprehension and performance in learning certain concepts or topics, but also fostering their abilities pertinent to STEM like designing, creativity, and problem-solving.

Given that performance expectancy is one of the most important factors in predicting whether or not students will accept DEGs [51], it is imperative to ensure that any DEG being developed for STEM will benefit students in some way beyond simply enhancing their academic performance. Games' potential should be utilized to provide students with learning opportunities that go beyond a straightforward replication of what is taught from the pedagogical tools traditionally used in classrooms [52].

All items suggested for representing performance expectancy were deemed relevant by experts. The items can be utilized by game developers when designing games intended to enhance students' learning performance and skill development.

L. Effort Expectancy

This construct measures the degree of ease associated with using DEG. Past research typically represents this construct with questionnaire items that gauge how simple it is to learn how to use a game and acquire knowledge or skills through it

[46], [48]. The scope of the items employed in existing literatures when measuring effort expectancy was widened to include game usability components linked to user-friendliness, such as unambiguous rules and instructions.

Since many studies have shown that effort expectancy is a significant predictor of students' intention to use DEGs [15], game developers can consider integrating various game design elements that encourage ease of playing and assess target users' perception using the items shared in Table IV.

M. Social Influence

The survey questions used in existing research [18], [34] that typically measure social influence using items like SF1 in Table IV were expanded to include specific people that may have an influence on students, such as their school, friends, and classmates. Past research had displayed strong association between social influence and students' intention to play DEGs [22][33]. Therefore, positive peer perception and school support towards the use of DEGs may encourage students to use them. Game designers can also consider utilizing community forums, social media pages, and advertisements that improve the game impression and social influence.

N. Behavioral Intention

The sample students of this study had never played the three STEM DEGs, namely Moonbase Alpha, RoboCo, and Poly Bridge 2, before the instrument testing. They were allowed to play the games for about 90 minutes before completing the questionnaire. The opening hour of a game is known to be crucial for hooking and enticing players to keep playing and recommend it to others. A lot of DEGs had been abandoned for the reason that they were not captivating enough to hold players' interest. The initial user experience can have an impact on retention and the possibility that the player will suggest the game to other people.

Hence, five items were proposed to measure students' interest to play a DEG again and frequently, as well as their willingness to use DEGs related to STEM in the future. From the ratings and comments by experts, all five items were found to be relevant and clear for measuring the early acceptance of STEM DEGs among students.

VI. CONCLUSION

This paper describes the development of a scale instrument called DEGAPX and its evaluation through expert judgment and instrument testing. The instrument integrates technology acceptance and player experience (PX) factors for studying and understanding students' perception of digital educational games (DEGs) associated with science, technology, engineering, and mathematics (STEM).

Among the 15 constructs suggested in the DEGAPX instrument, five of them, namely learning performance expectancy, skill performance expectancy, effort expectancy, social influence, and behavioral intention, were derived from the unified theory of acceptance and use of technology (UTAUT). The other ten constructs include learning relevance, attractiveness, enjoyment, challenge, clear goal, learning control, social interaction, feedback, concentration, and immersion.

The instrument with 67 items was found to be reliable and valid after going through two rounds of expert judgment and being tested among 14 years old students after they played three DEGs applicable to STEM, including Poly Bridge 2, Moonbase Alpha, and RoboCo.

The proposed DEGAPX instrument can enrich existing literature on DEG acceptance and PX, especially for STEM education. Despite the various studies available on DEG acceptance, most of them concentrated largely on common technology acceptance factors without thoroughly taking into account the PX elements that are crucial in the design of successful DEGs. Prior research typically evaluates acceptance and PX separately, even though both evaluations can be combined and measured simultaneously in a comprehensive manner. Game developers can utilize the instrument proposed in this research for designing promising DEGs that have the potential to be widely received by students.

For future work, the proposed instrument will be further analyzed using the partial least squares structural equation modeling (PLS-SEM) method to study the relationship between the constructs and figure out the significant determinants of DEG acceptance. This research contains a few limitations. First, because the research sample consisted of 14-year-old Malaysian secondary two students, other research can improve the generalizability by widening the scope to include students from different education levels and learning institutions. This study also emphasizes students' evaluation of DEGs. Future research may look into investigating the perception of other educational stakeholders, including parents, teachers, school administrators, and policymakers.

ACKNOWLEDGMENT

The authors thank the Ministry of Higher Education Malaysia for the research opportunity and fund provided under the Fundamental Research Grant Scheme (grant number FRGS/1/2020/ICT10/UTM/02/2) and Universiti Teknologi Malaysia for the support given.

Abstract—Aiming at the problem of insufficient utilization of interactive feature information between human and object, this paper proposes a two-stream human-object behavior analysis network based on interaction feature generation algorithm. The network extracts human-object's feature information and interactive feature information respectively. When extracting human-object features information, considering that ResNeXt has powerful feature expression ability, the network is used to extract human-object features from images. When extracting interactive features information between human and object, an interaction feature generation algorithm is proposed, which uses the feature reasoning ability of graph convolutional neural networks. A graph model is constructed by taking human and objects as nodes and the interaction between them as edges. According to the interactive feature generation algorithm, the graph model is updated by traversing nodes, and new interactive features are generated during this process. Finally, the humans' and objects' features information and the human-object interaction feature information are fused and sent to the classification network for behavior recognition, so as to fully utilize the humans' and objects' feature information and the interaction feature information of human-objects. The human-object behavior analysis network is experimentally verified. The results show that the accuracy of the network has been significantly improved on HICO-DET and V-COCO datasets.

Keywords—Two-stream human-object behavior analysis network; interaction feature generation algorithm; interactive feature information; ResNeXt; graph convolutional neural networks; graph model

I. INTRODUCTION

With the rapid development of science and technology, artificial intelligence (AI) has caused a profound impact in many fields [1], and its continuous improvement of related technologies [3] has penetrated into the application of various fields. In this dynamic context, research on human-object behavior analysis technology [5] has received increasing attention. How to effectively advance development of this technology will directly affect the application space of AI technology in real life. Whether it is possible to accurately and timely determine and analyze various interactions between people and objects in daily life will provide a solid and reliable foundation for further scene understanding and analysis, which will be of great value in theoretical research and engineering implementation.

However, due to the large amount of information, fast action and multiple interaction in the interaction process of human-objects, the specific interaction behaviors between

human and object cannot be accurately analyzed by utilizing all features, resulting in a low analysis rate of human-objects' behaviors.

In order to solve this problem, this paper researches on human-object behavior analysis, proposes an interactive feature generation network based on graph convolutional neural networks (GCNNs), and uses this network to analyze and identify the interaction between human and objects, trying to improve the accuracy of human-object behavior analysis on the basis of previous technologies.

The rest of this paper is organized as follows: Section II briefly reviews related work. Section III introduces the related models and algorithms of this paper. Section IV introduces the datasets used in the experiments, the experimental settings, and analyzes and discusses the experimental results. Finally, conclusions are drawn in Section V.

II. RELATED WORK

The traditional feature extraction method, which is to extract the behavioral features of human through the traditional manual method, has the advantages of simple implementation and strong operability. However, due to the relatively fixed templates used, it is difficult to perform fast and effective behavior analysis in facing complex environments and large datasets. Its application scenarios are limited, so more suitable for datasets with few types of behaviors and small scales. In order to improve the accuracy rate of human-object behavior analysis, it is often necessary to train on large datasets. Therefore, facing with such a huge amount of computation, graph convolution has certain advantages.

Simonyan et al. [7] proposed a feature extraction network algorithm based on two-stream convolutional neural networks (CNN). By extracting optical flow features from continuous images, and extracting image features from each frame, temporal and spatial features of continuous frame images are obtained, and two-channel feature information is fused and classified and identified. The proposed method breaks the concept of single-channel feature extraction, breaks through the limitations of feature extraction algorithms, and has a milestone significance. After that, based on multi-channel feature extraction, many researchers continued to improve and conduct in-depth research on human-object behavior analysis. However, these methods also increase a certain amount of computational burden in feature extraction.

Wang et al. [8] proposed a three-channel feature extraction network. In addition, some researchers proposed that human

skeleton points, as a means of posture prediction, can be used to supplement features. The multi-channel feature extraction algorithm formed by this method has gradually become research mainstream in the field of human-object behavior analysis. Wang et al. [9] continue to improve two-stream network architecture, and put forward advanced network architectures such as Temporal Segment Networks (TSN) for human-object behavior recognition.

He et al. [10] proposed Residual Network (ResNet) on previous Network research. This network proposes and optimizes the residual module, which not only deepens network depth, but also avoids training network degradation caused by network depth. The proposal of ResNet is of great significance in the field of image analysis. In the following years, researchers have continued to optimize and improve the ResNet, and proposed improved residual networks such as ResNeXt [26].

Yan et al. [11] and Mohamed et al. [12] have proposed spatial temporal graph convolutional networks (ST-GCN), which are used for general representation of skeleton sequences, realize human behavior analysis and recognition based on key points of human skeleton. This method constructs skeleton graph sequence by in space and time connecting the joint nodes of human skeleton, and builds multi-layer ST-GCN network based on this.

He et al. [13] proposed difficulty movement recognition method of calisthenics based on graph convolutional neural network (GCNN). This method constructs the multi-layer pyramid structure [14] of action images to complete the preprocessing of difficult movements in aerobics, and performs the training of samples to realize the difficult movement recognition of calisthenics. GCNN not only has more powerful expression ability and higher behavior recognition accuracy, but also has a stronger generalization ability, which makes it possible that the GCNN can be used for image feature extraction.

Thacker et al. [15] proposed through facial expression recognition to analyze human behavior. Aurangzeb et al. [16] proposed a human behavior analysis and recognition method based on multi-types features fusion and irrelevant features reduction, which initially selects a luminance channel and calculates motion estimation using optical flow. Afterwards, the moving regions are extracted through background subtraction approach. In the features extraction step, shape, color, and Gabor wavelet features are extracted and fused based on serial method. Thereafter, reduced irrelevant and redundant features are removed by Von Neuman entropy approach. The selected reduced features are finally recognized by One-Against-All (OAA) Multi-class SVM classifier.

Degardin et al. [17] provided a comprehensive overview of human behavior analysis over the past decade, presenting state-of-the-art and must-know methods in this field. Lanovaz [18] described machine behavior analysis. He proposed that machine behavior analysis is a science, which can study artificial behavior through its replicability, behavioral terms and philosophical assumptions of human behavior analysis, and study how machines interact with external environment and produce relevant changes. Lin et al. [19] built a framework

of external and internal factors to analyze human behavior, and game theory is used to simulate the conflicting interests of human behavior.

Bhatnagar et al. [20] proposed BEHAVE dataset, which is the first full body human-object interaction dataset with multi-view RGBD frames and corresponding 3D SMPL and object fits along with the annotated contacts between them. They also proposed a method that can record and track not just the humans and objects but also their interactions. Peng et al. [21] proposed a 3D max residual feature map convolution network (3D-MRCNN). The model can solve the deficiencies of the network degradation and gradient disappearance caused by convolution calculation, and achieve the improvement of classification accuracy without reducing the training efficiency, which is of value in the field of human behavior analysis in intelligent sensor networks.

In the field of human-object behavior analysis, there are various interactions between human and objects, the interaction between the same human and object may be different. For example, there are a variety of behavioral relations between human and bicycle, such as "riding", "pushing" and "resisting". In addition, it is also common to have multiple simultaneous interactions with the same human-object. For example, when a person picks up a glass to drink, he or she has both "lifting" and "drinking" interactive behaviors. In these cases, if interactive features between human-object aren't fully utilized, even if the human and object are identified, it is difficult to accurately and comprehensively analyze interactive behavior between them, resulting in inaccurate or omission analysis of human-object behavior. Obviously, if interaction features among human-objects aren't fully utilized, the accuracy rate of human-object analysis will be greatly reduced.

However, there are still some limitations in the use and reasoning of interactive behavior feature information in the existing methods for human behavior analysis. Therefore, in order to solve the above problems, this paper proposes a two-stream human-object behavior analysis network based on interactive feature generation algorithm. Although the method in this paper has made remarkable progress in the field of human-object behavior analysis, it still has some limitations in the behavior analysis of fuzzy or obscured human-objects, and its accuracy needs to be further improved.

III. METHOD

A. System Overview

In this paper, aiming at the problem of insufficient utilization of human-objects' interactive behavior features, a two-stream human-object behavior analysis network based on interaction feature generation algorithm is proposed. The network takes human-object features information obtained from the object detector as the input of the interaction feature generation network, and the interaction feature generation algorithm is used to generate new human-object behavior interaction features, thereby enhancing the full utilization of the interaction behavior features. The network block diagram is shown in Fig. 1. Drawing on the idea of "two-stream network" [7], a two-stream human-object behavior analysis network based on CNNs and GCNNs is constructed. This network is

divided into two streams to extract feature information of human and objects and the interaction feature information between the human-object from images. First of all, the input image is preprocessed. Then, the preprocessed image and the original image are fed into the object detector (e.g., Faster R-CNN), and the human-object features information in the image are extracted through the backbone of the object detector, such as ResNet. Human-object features information are input into the interaction feature generation network, the interactive features information of them are generated through this network. The specific method are as follows. Firstly, the human-object feature sequence is extracted by using CNN and input into the interactive feature generation network. Secondly, the detected people and objects are taken as nodes and the interactions between them are taken as edges to build an interactive feature graph model, which is used as the input of GCNN. Finally, the interactive feature generation algorithm is used to traverse the nodes of the graph model to update the interactive relationship, and then generate new interactive features of human-object behaviors, so as to make full use of interactive behavioral features. Moreover, the humans' and objects' features information and the human-object interaction feature information are fused and sent to SoftMax classifier [22] for identification and classification, so the recognition result is obtained, which realizes the full use of human-object feature information and human-object interaction feature information.

Fig. 1. Overall framework of model.

B. Image Preprocessing

In this paper, image preprocessing involves applying self-transformations to the images, generating new images that are different from the original ones, while preserving the original image category labels. Fig. 2 shows some examples of image preprocessing methods. That is, the image dataset can be augmented by operations such as horizontal flipping, vertical flipping, scaling, random rotation, and generative adversarial networks (GANs) [23] to expand the data samples.

Fig. 2. Example of image preprocessing method.

To reduce computational complexity, increase the training data samples, and improve the model's generalization ability, the original input image is preprocessed before object detection. Specifically, the original image is first input. Next, apply random rotation and flip to generate a new image by randomly rotating and flipping the original input image vertically, horizontally, or both. Then, the image is randomly cropped. Finally, adjust the height and width of all images to 400 x 400. In order to ensure the accuracy and adequacy of the original image and annotation data, no other processing or enhancement operations are applied to the images in this study.

C. Object Detection Network

This study adopts a two-stage approach to detect and analyze human-object behavior, which offers the advantage of reducing irrelevant background and interference from other human, while accurately utilizing and extracting features of the target human and object. Specifically, an object detector is first used for preliminary screening, and regions of interest for human and objects in image are proposed, thereby extracting effective bounding boxes for human and objects. Then, behavior analysis and inference are conducted on the selected humans and objects. To quickly and accurately locate and identify humans and objects in the image, this paper adopts Faster R-CNN [24] as the object detector.

Faster R-CNN is proposed based on the improved Fast R-CNN algorithm [25], which uses Region Proposal Networks (RPN) to replace original Selective Search (SS) method to generate proposal box, and CNN that generates proposal box and object detection are shared, which effectively improves the speed of detection and achieves good results. The whole Faster R-CNN system is a single and unified network, and RPN module is its "attention".

Fig. 3. Network framework of Faster R-CNN.

The network framework of Faster R-CNN is shown in Fig. 3. First, the pre-processed image is input into the feature extraction network (e.g., ResNeXt) to extract the human-object feature information and obtain the image feature map, which is shared by the RPN and the detection network. Second, the extracted feature map is input into RPN, and the sliding window is used to perform convolution operation with the input feature map. According to different scales and different basic sizes, a point on the feature map corresponds to k proposals on the original image. Classification judgment and regression operation are performed on the generated boxes respectively, and $2k$ regional scores and $4k$ regional proposals are obtained. After screening, a relatively accurate region candidate box is finally obtained. Finally, the feature map

output by the feature extraction network and the region candidate box information output by the region proposal network are integrated. And a fixed-size proposal feature map is generated through the RoI pooling layer, and that is input into the fully connected layer. The classification and regression network are used for classification and regression training to obtain the accurate position of the predicted object, so as to realize human-objects' identification and detection. The following sections will analyze each part of the Faster R-CNN in detail.

1) *Feature extraction network:* ResNext [26] is selected as the feature extraction network of Faster R-CNN. Its input is a pre-processed image x , and its output is a convolution feature map containing global features. Its main algorithm is on convolution operations. Convolution is a linear operation, and the specific operation process is shown in Formula (1):

$$s(t) = (x * w)(t) \quad (1)$$

Where x is the input of convolution layer, w is the kernel function, t is the time, and $s(t)$ is the output of convolution layer. When t is set to discrete time, the formula can be expressed as Formula (2):

$$s(t) = \sum_{-\infty}^{\infty} x(a)w(t - a) \quad (2)$$

a represents the discrete time point, $x(a)$ represents the picture x obtained at time a . In this paper, we need to perform convolution operation on image data. The computer sees the input image as a collection of pixels and transforms it into a two-dimensional digital matrix. When the convolution object is two-dimensional, the convolution kernel is also two-dimensional. The process of the convolution operation on the image is expressed by Formula (3):

$$S(i, j) = (I * K)(i, j) = \sum_m \sum_n I(m, n)K(i - m, j - n) \quad (3)$$

In this paper, ResNeXt is selected as the backbone network of the object detector, whose network topology is shown in Fig. 4(a). ResNet [10] introduces a residual network topology to alleviate the gradient explosion problem during deep network training. However, as a deep network, although it can better extract features, the increase of network parameters will inevitably bring heavy computational burden, as shown in Fig.4(b). ResNeXt improves the topology of ResNet. It refers to the idea of replacing large convolution kernels with several small convolution kernels in VGG [27] and the idea of splitting in GoogLeNet. It adopts the algorithm of grouping convolution, which realizes that number of network layers and parameters are basically unchanged compared with ResNet, but the recognition accuracy is significantly improved.

Fig. 4. Network topology.

The channel in Fig. 4(a) actually changes from 256 to 128 and then to 256, and the number of parameters is 70,144. In Fig. 4(b), the number of ResNet channels changes from 256 to 64 and then back to 256, and the number of parameters is 69,632. However, if the ResNet channel is also changed from 256 to 128 and then to 256, the number of parameters is 212,992, which is much larger than the above two values. Therefore, ResNeXt deepens the depth of feature maps in the convolution layers by grouping convolutions without increasing the number of parameters. ResNeXt combines advantages of GoogLeNet and residual network to improve accuracy without changing model complexity. ResNeXt is easy to train and can effectively avoid exploding gradient problem caused by network deepening. So, it is suitable for feature extraction.

2) *Region proposal network:* Region Proposal Network (RPN) is a fully convolutional network, which can demarcate human and objects in images and generate bounding boxes. RPN introduces the anchor mechanism, which uses a sliding window to map the anchor points of the feature map to the original image, and each anchor point is mapped to generate k region boxes with different scales and sizes. Intersection over union (IoU) between each region box and the desired region is calculated. When the IoU is greater than 0.7, it is marked as a positive sample; when the IoU is less than 0.3, it is marked as a negative sample. Regression training is performed on these samples, and then the calibrated region proposal boxes are screened and modified. RPN performs a binary classification judgment on whether there are human-objects in the generated k region boxes. If the result is that there are human-objects, the position of the region proposal box is modified according to the regression result. After iterative training, a number of bounding boxes are generated, and the non-maximum suppression algorithm is used to remove the overlapping bounding boxes to get the final effective human and object bounding boxes in images.

3) *Detection network:* The detection network consists of RoI pooling layer and classification regression network. The main function of the RoI pooling layer is to unify the corresponding features of the bounding boxes through pooling. The feature generated by the ROI pooling layer with a dimension of $c \times 7 \times 7$ (c is the number of channels, generally the number of object classes in the dataset) is reshaped into a vector. Send the vector to two full connected layers, and then conduct Softmax to obtain the probability of the object for different classes.

D. Interaction Feature Generation Algorithm

In traditional deep learning, data samples are often considered to be independent. But in graph neural networks (GNNs), each sample node will establish a connection with other data samples through edges, and this connection can be used to form interdependence between different instances [28]. So GNNs has powerful reasoning ability and feature propagation ability.

In this paper, to solve the problem of insufficient use of interactive information between human and objects in the images, an interactive feature generation algorithm based on GCN is proposed. Based on this algorithm, an interactive feature generation network is constructed, and the network framework is shown in Fig. 5. First of all, the pre-processed image is sent to the object detector (e.g., Faster R-CNN), which is used to conduct preliminary detection and segmentation of the image, and obtain the feature sequences of human and object respectively. Secondly, the graph model is constructed by taking people and objects as nodes and the interaction between them as edges, and the graph model is input into the interactive feature generation network in the form of data structure. Finally, each node in the graph model is traversed by the interactive feature generation algorithm, its interaction relationship is updated, and then new interactive features are generated.

Fig. 5. Interaction feature generation network.

A graph model is a data structure composed of nodes and edges. Nodes refer to human and objects instances in the image, and edges refer to the relationship between them. Each node has its own features and structure information. The graph model is generally represented by an adjacency matrix, and the process is shown in Fig. 6. The calculation Formula (4) of the graph convolution operator is as follows, and the central node is set as i :

$$h_i^{l+1} = \sigma \left(\sum_{j \in N_j} \frac{1}{C_{ij}} h_j^l W_{R_j}^l \right) \quad (4)$$

Where h_i^{l+1} represents the feature representation of node i at the $l + 1$ layer; C_{ij} represents normalized factors, such as taking the reciprocal of the node degree; N_j represents the neighbor of node j , and contains its own information; R_j represents the type of node j ; $W_{R_j}^l$ represents the transformation weight parameter of a node of type R_j .

Fig. 6. Construction of graph model.

The construction process of the graph model is shown in Fig. 6. Specifically, humans and objects in the image are taken as nodes, and the interactions between them are taken as edges. Based on the interaction between human and objects, a fully

connected undirected graph G is constructed according to Formula (5), and undirected graph is initialized as an adjacency matrix with all elements being 1. Then, each node in the undirected graph is traversed through the interaction feature generation network. During the traversal process, according to whether there is the interaction between human and objects, the undirected graph and the corresponding adjacency matrix are updated.

$$G = (V, E) \quad (5)$$

Where V represents all nodes in the image, E represents all edges. Each object represents a node $v \in V$ of the undirected graph, and the interactive between different target objects is regarded as an edge $e \in E$. If there are n objects in the image, the undirected graph has $n(n - 1)/2$ edges. Since the graph model is converted into the form of adjacency matrix for calculation operation, the undirected graph is represented as an adjacency matrix $A_{n \times n}$ of $n \times n$ size, whose matrix elements $i, j \in \{0, 1\}$, 0 indicates that there is no interaction between node i and j , and 1 indicates that there is interaction.

Aiming at the problem of underutilization of human-object interaction behavior features, a two-stream human-object interaction analysis network based on interactive feature generation algorithm is proposed. A network example is shown in Fig. 7. Specifically, assume that there is an interaction between the person in the image and all objects in the image. However, in reality, there is generally no interaction between human and objects without overlap in space. Hence, in the interactive feature network, graph model and the corresponding adjacency matrix are updated according to the principle that there is no interaction between people and objects with non-overlapping bounding boxes in space. The updated graph model contains only the possible interactions between human and objects in the image. This not only saves computation, but also facilitates the subsequent graph reasoning.

Fig. 7. Example of interaction feature generation algorithm.

The interaction feature generation algorithm learns the structural connection between human and objects, which is shown in Fig. 7. In the process of traversing nodes, better interactive features are generated according to the interaction between human and object, and the update process is shown in Formula (6):

$$x_{ho}^{(n+1)} = \sigma(x_{ho}^{(n)} + \sum_{o' \in O} W x_{ho'}^{(n)}) \quad (6)$$

Where h represents object judged to be human; o represents object judged as object, O represents the total number of objects; W is the projection matrix; $x_{ho}^{(n)}$ is the interaction relation between h and o , $x_{ho'}^{(n)}$ is the interaction between h and o' ($o' \in O$ and $o' \neq o$), $x_{ho}^{(n+1)}$ is the updated interaction between h and o .

The specific interaction feature generation algorithm formula is as follows:

$$F_h = f_h + \sum_{o=1}^O X_{ho} W_{oh}(f_o) \quad (7)$$

$$F_o = f_o + \sum_{h=1}^H X_{oh} W_{ho}(f_h) \quad (8)$$

As shown in Formulas (7) and (8), F represents the newly generated interactive feature vector, f represents the feature vector extracted from the original image, H represents total number of humans in image, and X represents the interaction between objects and human, and $X_{ho} = X_{oh} = x_{ho}^{(n+1)}$.

The generated human-object interaction features and human and object features generated by the object detector are sent to MLP for feature fusion. The fused features are fed into SoftMax classifier to obtain the final human-object behavior analysis result.

IV. EXPERIMENT

In this section, the experimental datasets and implementation details are first described. Then, our model is evaluated by quantitative comparison with state-of-the-art methods, followed by ablation studies to validate the components in our framework. Finally, several visualization results are shown to demonstrate effectiveness of our method.

A. Datasets

1) *HICO-DET* [29]: The HICO-DET dataset, introduced in 2018, is a large dataset for studying human-object behavior. It consists of 117 common behaviors involving 80 different objects, along with their associated behaviors. The sample are shown in Fig. 8 (a). The dataset contains a total of 47,776 images, with 38,118 images allocated to the training set and 9,658 images in the test set. A noteworthy aspect of this dataset is that many images feature multiple pairs of human-object behavior annotations, resulting in over 150,000 human-object pairs and 600 distinct human-object behavior categories in total.

2) *V-COCO* [30]: V-COCO is a specialized dataset in the field of human-object behavior analysis, which is derived from MS-COCO. The dataset is divided into three main parts: the training set comprising 2,533 images, the validation set containing 2,867 images, and the test set with 4,946 images. It not only inherits all the annotations from the MS-COCO dataset, but also incorporates additional semantic extension markup of human-object pairs through the use of AMT (Amazon Mechanical Turk) proposed by Gupta et al. This extension results in a more professional and refined sub-dataset. The sample are shown in Fig. 8 (b).

B. Implementation Details and Evaluation Metric

In this paper, Faster R-CNN [24] is used as object detector, its backbone module uses ResNeXt50 trained in ImageNet-1 K dataset as feature extractor. The SGD optimizer is used for training with an initial learning rate of 0.01, weight decay of 0.0001, and momentum of 0.9. For V-COCO, the learning rate is reduced to 0.001 at 80 iterations. For HICO-DET, the learning rate is reduced to 0.001 at 60 iterations. All experiments in this paper are conducted on GeForce RTX 2080Ti GPU and CUDA 11.4 with a batch size of 4.

Fig. 8. Example images of datasets.

This paper uses accuracy to measure the performance of human-object behavior analysis. During accuracy calculation of the metrics, the prediction of the human-object pair is considered correct (1) if the IoU of the human-object bounding box and the ground-truth box is greater than 0.5, and (2) the interaction class label of the prediction of the human-object pair is correct.

C. Experimental Results

To analyze the effectiveness of our method in human-object behavior analysis in more detail, our proposed framework was compared with several existing human-object interaction detection methods on the V-COCO and HICO-DET datasets, and the results are shown in Table I.

TABLE I. COMPARISON OF ACCURACY RATE OF HUMAN-OBJECT BEHAVIOR ANALYSIS METHODS

Human-object behavior analysis methods	V-COCO (%)	HICO-DET (%)
Wang[31]	47.3	21.08
DRG[32]	51.0	23.89
TIN[33]	47.8	20.26
PMFNet[34]	52.0	21.20
PFNet[35]	52.8	24.89
PPDM[36]	-	26.84
IP-Net[37]	51.0	23.92
UnionDet[38]	47.5	21.27
Ours method	52.4	27.89

By comparison and analysis of the data in Table I, it can be seen that in recent years, the accuracy of most human-object behavior analysis methods on the V-COCO database has been generally more than 50%, among which the PFNet method has the highest accuracy of 52.8%, which is 0.4% higher than our method. One important reason is that PFNet uses more fine-grained body part level information. However, because this paper uses a graph model structure with strong inference ability, and design a graph node adaptive interactive update algorithm, so the results are not very different. Although the accuracy of our method is lower than that of PFNet method, it has a significant increase compared with other methods.

According to the data in Table I, the accuracy of human-object behavior analysis on the HICO-DET database is generally low. However, our method achieves the state-of-the-art results on the HICO-DET database, which is 1.05% higher than the previous state-of-the-art the PPDM method. It is inferred that the reason may be the difference in the difficulty and the focus of dataset. Compared with the existing human-object behavior analysis, the accuracy rate of the two-stream network has been significantly improved.

D. Ablation Study

In this paper, a two-stream human-object behavior analysis network based on interaction feature generation algorithm is proposed and its effectiveness is tested. The first experiment is to test the feature extraction networks in object detector. ResNeXt 50 and ResNet 50 are used as the feature extraction networks separately. Training and testing are carried out on the HICO-DET and the V-COCO datasets. The suitable extraction network is selected by comparing the test results on each dataset. The second experiment is to verify the effectiveness of network proposed in this paper. In this experiment, three networks are proposed: (1) a single-stream human-object behavior analysis network without using interaction feature generation algorithm; (2) a single-stream human-object behavior analysis network with interaction feature generation algorithm; (3) a two-stream human-object behavior analysis network based on interaction feature generation algorithm. Training and testing are carried out on the HICO-DET and V-COCO datasets respectively, and through the test results on each dataset, it is proved whether the interaction feature generation algorithm and the two-stream human-object behavior analysis network based on the interaction feature generation algorithm are beneficial to improve the accuracy rate of human-object behavior analysis.

1) *Comparison experiment between ResNeXt 50 and ResNet 50:* In this experiment, ResNeXt 50 and ResNet 50 are used as the backbone of the object detector, respectively, training and testing are carried out in two databases. ResNeXt 50 and ResNet 50 pre-trained models are tested in the new database by means of transfer learning. Fig. 9 and Fig. 10 show the experiments performed on V-COCO and HICO-DET databases, respectively.

As shown in Fig. 9, the horizontal axis represents the number of training epochs, and the vertical axis represents the accuracy of the test set for 29 kinds of human-object behavior analysis in the V-COCO database. The green and red curves

represent the accuracy test results of ResNeXt 50 and ResNet 50 as the number of training epochs increases, respectively.

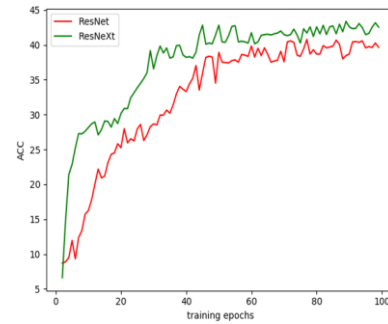

Fig. 9. Comparison of accuracy of classification results in V-COCO database.

As shown in Fig. 10, the horizontal axis represents the number of training epochs, the vertical axis represents the test sets accuracy of 117 kinds of human-object behavior analysis in HICO-DET database. The green and red curves represent the accuracy test results of ResNeXt 50 and ResNet 50 as the number of training epochs increases, respectively.

Fig. 10. Comparison of accuracy of analysis results in HICO-DET database.

It can be seen from the experimental results in Fig. 9 and Fig. 10, the number of training epochs of the network model is the same, and the accuracy rate of the human-object behavior analysis result of ResNeXt 50 is better than that of ResNet 50. In HICO-DET database, when ResNeXt 50 is used as the backbone of the object detector, the convergence is better, and its accuracy is significantly higher than that ResNet 50. The use of ResNeXt 50 as backbone for object detector in human-object behavior analysis can be concluded to significantly improve accuracy.

2) *Verify the effectiveness of the two-stream human-object behavior analysis network based on interaction feature generation algorithm:* Based on the above experimental analysis, this study decided to use ResNeXt 50 as the feature extraction network of object detector. Therefore, in the second experiment, in order to verify the effectiveness of the two-stream network, training and accuracy test are carried out on the single-stream network without using the interactive feature generation algorithm, the single-stream network using interactive feature generation algorithm, and the two-stream network based on the interactive feature generation algorithm on the two databases respectively.

Fig. 11. Effectiveness comparison experiment in V-COCO database.

As shown in Fig. 11, the three proposed network structures are trained and tested in the V-COCO database. The horizontal axis represents training epochs, and the vertical axis represents the accuracy rate of the 29 human-object behavior test sets in the V-COCO database. The green, red and yellow curves respectively represent the training and accuracy testing process on the two-stream network, the single-stream network using the interactive feature generation algorithm, and single-stream network without using interactive feature generation algorithm.

Fig. 12. Effectiveness comparison experiment in HICO-DET database.

As shown in Fig. 12, the horizontal axis represents training epochs, the vertical axis represents accuracy of the analysis of 117 common behaviors in the HICO-DET database. The green, red and yellow curves respectively represent the training and accuracy testing process on the two-stream network, the single-stream network using interaction feature generation algorithm, and single-stream network without using interaction feature generation algorithm.

The experimental results of training and testing on two datasets are analyzed in Fig. 11 and Fig. 12. The overall trend of the curve is as follows. The green curve is above the red and yellow curve, and the red curve is above the yellow. In the V-COCO database, there are coincident points before the curves converge. But after convergence, the convergence accuracy of the two-stream network is higher than the other two networks, and the convergence speed is faster. The accuracy rate of the single-stream network using the interaction feature generation algorithm is higher than that of the single-stream network without using interaction feature generation algorithm. In the HICO-DET database, all three network curves converge quickly. It is obvious that the accuracy of the two-stream network after convergence is higher than that of other two networks. And the accuracy of the single-stream network with interaction feature generation algorithm is higher than that of the single-stream network without using the interaction feature generation algorithm.

From the above analysis, it can be concluded that the interaction feature generation algorithm can effectively improve the accuracy of human-object behavior analysis, and accuracy of the two-stream network is higher than that of other two networks, which indicates the effectiveness of the two-stream network in human-object behavior analysis.

In this paper, four network architectures are trained and tested in the V-COCO and HICO-DET databases. The single-stream network without the interaction feature generation algorithm and the feature extraction network is ResNet 50, the single-stream network without interaction feature generation algorithm and the feature extraction network is ResNeXt 50, the single-stream network with interaction feature generation algorithm and the extraction network is ResNeXt 50, and the two-stream network based on interaction feature generation algorithm (the feature extraction network is ResNeXt 50).

TABLE II. COMPARISON OF ACCURACY OF FOUR NETWORKS

The network architecture	V-COCO	HICO-DET
ResNet 50	40.3	15.73
ResNeXt 50	43.2	17.71
ResNeXt 50+ Interaction feature generation algorithm	47.6	21.54
A two-stream human-object behavior analysis network based on interaction feature generation algorithm	52.4	27.89

The specific accuracy the human-object behavior analysis methods of the four network architectures are shown in Table II. When ResNet 50 is used as the feature extraction network of the object detector, the model obtained after training on the V-COCO database is used to test, its accuracy is 40.3%; the model obtained after training on the HICO-DET database is used to test, its accuracy is 15.73%. When ResNet 50 is used as the feature extraction network of the object detector, the model obtained after training on the V-COCO database is used to test, its accuracy is 43.2%, which is 2.9% higher than ResNet 50; the model obtained after training on the HICO-DET database is used to test, its accuracy is 17.71%, which is 1.98% higher than ResNet 50. It can be concluded that ResNeXt 50 is more suitable as the feature extraction network of the object detector.

On the basis of determining that the feature extraction network is ResNeXt 50, according to the proposed interaction feature generation algorithm, the single-stream and the two-stream human-object behavior analysis network based on the interaction feature generation algorithm are proposed. The test results are shown in Table II. For V-COCO database, the model obtained after training of the single-stream network using the interaction feature generation algorithm is tested, its accuracy rate is 47.6%, which is 4.4% higher than that without the interaction feature generation algorithm. The model obtained after training on the HICO-DET database is used to test, its accuracy is 21.54%, which is 3.83% higher than that without the interaction feature generation algorithm. The experimental data show that interaction feature generation algorithm is beneficial to improve the accuracy of human-object behavior analysis.

For V-COCO database, the model obtained after training of the two-stream network is tested, its accuracy is 52.4%, which is 4.8% higher than the single-stream network using interaction feature generation algorithm. The model obtained after training on HICO-DET database is used to test, its accuracy is 27.89%, which is 6.35% higher than that the single-stream network using the interaction feature generation algorithm. As shown in Table II, the accuracy rate of the two-stream network based on interaction feature generation algorithm is higher than that of the other three networks, which shows that the network is effective in human-object behavior analysis.

E. Visualized Results

To qualitatively visualize the detection effect of our model, Fig. 13 shows the visualization results of human-object behavior analysis on the test images of our model.

Fig. 13. Example detections of human-object behavior analysis method based on interaction feature generation algorithm.

In the nine example detections images in Fig. 13, after the human and objects are detected in each image, the behavior analysis results are successively, "catch", "ride", "ride", "drink", "ski" and "look", "talk_on_phone", "kick", "eat_obj", "brush". Human and objects as background aren't selected. It can be concluded that the human-object behavior analysis method based on the interaction feature generation algorithm proposed in this paper is effective.

As can be seen from the above experiments, the experimental results validate the effectiveness of our proposed model in enhancing human-object behavior analysis performance. The comparison ablation study and qualitative results collectively demonstrate the superior performance and robustness of our proposed method on V-COCO and HICO-DET datasets. Therefore, the algorithm can be used in areas such as intelligent surveillance video and intelligent robots.

V. CONCLUSION

Aiming at the problem of insufficient utilization of interactive behavior feature information between human and object, a two-stream human-object behavior analysis network based on interaction feature generation algorithm is proposed. The network uses interactive feature generation algorithm to generate new behavior interaction features, so as to make the full use of interactive behavior features. After experimental verification on datasets, the recognition accuracy of the two-stream network based on interaction feature generation algorithm is higher, compared with the single-stream network

that only uses the image feature extraction network and only uses the interaction feature generation algorithm.

However, the proposed algorithm still has some limitations when it comes to the behavior analysis of fuzzy or obscured human-objects in images. Therefore, before conducting human behavior analysis, additional techniques are required to accurately process and identify blurred or obscured people or objects. Future research efforts will focus on improving the processing of difficult and fuzzy human-object recognition processes, aiming to optimize human-object behavior analysis techniques and improve the accuracy of human-object behavior analysis.

Abstract—Web-hosted Internet of Things (IoT) applications are the next logical step in the recent endeavor by academia and industry to design and standardize new communication protocols for smart objects. Context Awareness is defined as the property of a system that employs context to provide related information or services to the user, where the relationship is based on the user's task. Therefore, context-aware service discovery can be defined as utilizing context information to discover the most relevant services for the user. Merging context-aware concepts with the IoT facilitates IoT system developments that depend on complex environments with many sensors and actuators, user, and their environment. The main objective of this study is to design an abstract framework for provisioning smart objects as a service based on context-aware concepts while considering constraints of bandwidth, scalability, and performance. The proposed framework building blocks include data acquisition and management service and data aggregation, and rules reasoning. The proposed framework is validated and evaluated by constructing an IoT network simulation and testing accessing the service in the traditional method and according to the proposed framework and comparing the results.

I. INTRODUCTION

Every object in our environment, including chairs, gas meters, electricity meters, curtains, lights, office equipment, and home appliances, should be transformed into Internet-connected smart objects to improve a variety of application domains (e.g., building automation, healthcare services, smart grids, transportation, and environmental monitoring).

A smart object is defined as an entity that is provided with a sensor or actuator, a microprocessor, memory, a communication module, and a power source. The Lowpower Wireless Personal Area Network (LoWPAN) is a crucial component of the IoT due to its advantageous features such as energy efficiency, widespread accessibility, and the ability to integrate smart objects with the Internet [1].

The IoT has emerged as a transformative force in recent years, connecting billions of devices worldwide and generating massive amounts of data. These connected devices have the potential to drive numerous applications, from smart homes and healthcare to transportation and industry automation.

However, the sheer volume and diversity of IoT data often makes it challenging to extract meaningful insights and enhance user experiences.

One way to address this challenge is by incorporating context awareness into IoT systems. Context-awareness refers to the ability of a system to understand and respond to its environment by considering various contextual factors such as time, location, and user preferences. By incorporating context awareness, IoT devices can adapt to their surroundings and provide personalized experiences to users.

The main contribution in this paper, that we propose a novel Context Awareness IoT framework that combines the Context Awareness concept with the IoT concept, considering performance problems related to limited smart objects resources.

A. Internet of Things

In 1999, Kevin Ashton introduced the concept of the IoT while working at the Auto-ID Center at MIT. The research conducted at this center focused on network radio frequency identification (RFID) and sensor technologies [2], in which People and things could provide information about their current state and their surroundings in a much more efficient manner [3]

IoT comprises wireless systems that are compact in size and interconnected with each other. These systems are equipped with computational capabilities and can transfer data over a network without the need for human interaction. These smart objects are identifiable, can be accessed, and can be programmed locally or remotely via the Internet. They are designed to monitor or control smart spaces. The underutilization of the potential of IoT devices in various domains can be attributed to the limited expressivity and high heterogeneity of the commonly employed scenario programming paradigms [4]. IoT plays a vital role in many domain areas, such as home automation [4], elderly care [5], [6], home safety [7], energy efficiency, and preservation [8], [9].

Recently, research has focused on the connectivity of all physical objects and information environments to the Internet to enable a user to access and control things from anywhere and at any time, which coined the term IoT. IoTs enable

smaller, less complex devices to do complex tasks by enhancing their intelligence and connectivity.

IoT is converting smart spaces from hype into reality. IoT lacks standardization at the application level. IoT devices have limited computational power and memory [10].

The number of devices connected to the Internet has grown significantly in recent years. Perceiving reality through digitizing some parameters of interest can provide a massive amount of data. This data is then shared across the network with other devices, applications, and infrastructures. The IoT paradigm is based on this dynamic and ever-changing world. To date, countless IoT-based applications have been developed considering smart Cities, smart roads, and smart industries [9].

IoT systems face many challenges which make them exploit the intrinsic potential of IoT devices, such as high heterogeneity of the devices and protocols, which results in limited interoperability.

The IoT paradigm has the potential to merge the boundaries between physical objects and computational devices through their interconnectivity via the Internet. This interconnectivity holds the promise of delivering user-centric services that consider both the user's context and profile information [10].

For example, traditional regulation of classroom temperature consists of power on the air conditioner set to the desired temperature and letting the internal thermostat do the rest. However, a smart IoT system could find the best way to cool down the classroom temperature based on the integration of context awareness, ontology, and IoT. For instance, by combining data from internal thermometers, current time, online weather services, and the current number of students, it can decide to just open the window instead of simply turning on the air conditioner, thus saving energy. Also, the system will increase and decrease temperature based on the number of students. Additionally, the same system could automatically close the air conditioner when there is no person in the classroom. Therefore, it is required to manage all forms of data and events that are collected from sensors and devices. For example, simple events (such as the door being opened) and activities (such as the professors and students going out of the classroom) can be translated into context information. It could be accessed by a service that monitors the classroom (e.g., the lecture ended) and a notification sent to the person responsible for this classroom.

B. Context Awareness

Context is defined as information that can be used to characterize the situation of an entity in context-aware computing literature. An entity is a person, location, or thing that is related to the interaction between a user and an application, including the user and the application [11], [12].

On the other hand, context awareness is defined as the property of a system that employs context to provide related information or services to the user, where the relationship is based on the user's task. Therefore, context-aware service discovery can be defined as utilizing context information to discover the most relevant services for the user [11], [13].

Proposing a service-oriented architecture SOA to abstract the complexity in the access to smart devices so that the devices can be viewed as a service (thing as a service). This will enable the smart system development team to focus only on their functional requirements instead of device-specific technical details. Context from the web service perspective:

- From the service requester's perspective, context is defined as the surrounding environment affecting the requester's Web services discovery and access.
- From the perspective of the services, context is defined as the surrounding environment affecting Web services delivery and execution.

To achieve successful IoT systems, there is a need to integrate a context awareness system with IoT.

Context-aware solutions face numerous challenges, including managing the heterogeneous and massive amount of data generated by IoT devices. Second, how to store and handle events, as well as infer higher-level activities from a set of simple events. Finally, use the development framework to implement applications across multiple domains [14].

The growth of the IoT created a fragmented landscape with many devices, technologies, and platforms, creating interoperability issues on many system deployments [15].

Interoperability is one of the most significant barriers to promoting IoT adoption and innovation.

C. Interoperability

Nowadays the ecosystem of the IoT is currently facing a lack in terms of interoperability among the various competing platforms that are presently accessible [16].

Semantic Web (SW) technologies, which consist of an open set of recommendations for associating data with their formal meaning, have been demonstrated to be a suitable means of achieving data interoperability in IoT systems [17]. The reason for using SW technologies is its inference capabilities over semantically annotated data.

Similar to Semantic Web's vision for the Web of Linked Data, the literature on deploying Semantic Web technologies to IoT focuses on semantically annotating data from smart objects. The most prevalent method for representing semantics is Resource Description Framework (RDF), which represents knowledge as triples (subject, predicate, object) (for example, [TempSensor105, Value, 25] and [TempSensor105, Location, Lab2]). A set of triples constitutes a graph consisting of subjects, objects, and predicates. The benefit of RDF and graph data models is that new knowledge can be inferred from an existing graph. Using domain knowledge, a system can comprehend, for instance, that the temperature in Lab 2 is 25 degrees Fahrenheit, which is a transitive property. Web Ontology Language (OWL), one of the primary languages (with RDF schema) used to define ontologies on the web, is frequently used to express domain knowledge to perform the annotation on intelligent [18]. Recently, there has been a lot of research into how SW technologies, in particular OWL ontologies, can be used to improve the IoT field's poor interoperability [4].

Several solutions exist to facilitate interoperability among diverse IoT platforms and application domains. One such solution is the Web of Things (WoT) architecture, recently introduced by the W3C consortium [19].

WoT is a paradigm devised by the World Wide Web Consortium (W3C) on top of the IoT concept. It provides standard mechanisms to interact with any type of device from any automatic system using a descriptive JSON file called Thing Description [20].

Rule-based programming approaches are suitable for IoT automation systems due to their simplicity and intuitive use. One of the most common tools used in programming IoT scenarios using trigger action rules is IFTTT which has many limitations, such as low-level abstraction and low generalization [4], [21].

This paper is organized as follows: an introduction is presented in Section I. Section II illustrates some of the related works. Section III presents the general architecture of the proposed framework. Section IV shows the experiments and results. Section V presents the conclusion and future works.

D. Web of Objects

Web of Objects (WoOs) objectifies and virtualizes real-world objects to support intelligent features and provide Realtime data about the physical world by representing them as Web resources, which can be accessed using the lightweight REST-based APIs principles rather than the heavyweight SOAP-based architecture. Any object with a sensor or actuator, CPU, memory, communication, and power source is considered smart. The web is an ideal universal platform for IoT applications because it uses open standards and can be accessed from any device. In the web environment, sensors or actuators can offer their capabilities via a REST-based API (e.g., URI/lightON and URI/light OFF), which enables objects to interact dynamically. Service provisioning is the process of providing smart object services to the web, similar to traditional web services available on the web. Any web application that communicates with smart objects via communication networks and Web standards is referred to as an IoT application on the web [22].

The smart environment comprises sensors, actuators, interfaces, and appliances networked together to provide localized and remote control of the environment. Sensing and monitoring the environment include temperature, humidity, light, and motion. Environment control such as heater and fan ON/OFF control is provided by the actuator having dedicated hardware interfaces and computing capabilities. Localized control is provided by Bluetooth and remote access through WiFi. The RESTful architecture enables interoperability in Smart space WoOs Architecture.

Semantic ontology helps ubiquitous environments address key issues like knowledge representation, semantic interoperability, and service discovery and provides an efficient platform for building highly responsive and context-aware interactive applications.

According to the following reasons, information systems' ability to communicate with smart objects has become more complicated:

- Many hardware devices rely on proprietary protocols to perform their functions.
- Many devices have embedded software that remains constant over their entire lifespan.
- Semantic annotation for the sensors and the services.
- Service discovery and subscription.
- Simultaneous requests.
- Service authorization.
- Web API generation.

II. LITERATURE REVIEW

There have been several studies focused on how to apply Web paradigms and protocols to service provisioning, such as Service-Oriented Architecture (SOA), RESTful service (REST), Semantic-based provisioning, and the WoT.

Sciullo et al. [15] propose a WoT Store, a centralized repository for managing resources and applications on the WoT. While the proposed system has several potential benefits, there are also some limitations and disadvantages to consider. The WoT Store system may rely heavily on centralized infrastructure, which can lead to scalability, reliability, and security challenges. Additionally, the system may require developers to use a specific set of APIs and communication protocols, which could limit the flexibility and interoperability of IoT devices and applications. Nonetheless, the paper presents a prototype implementation of the WoT Store system and evaluates its performance in terms of resource discovery time and application deployment time, demonstrating the effectiveness of the proposed system for managing IoT resources and applications on the WoT.

Iqbal et al. [22] propose an interoperable IoT platform that can be utilized in a smart home system. The proposed platform employs WoO and cloud architecture. The platform under consideration offers the capability of achieving interoperability among a range of legacy home appliances, diverse communication technologies, and protocols. The platform facilitates remote control of household appliances and enables the storage of home data in the cloud for use by diverse service providers' applications and analytical purposes. The article proposes potential areas for further research, including the incorporation of machine learning algorithms, the deployment of a mobile application, and the creation of a security framework for the smart home system. The proposed architecture is extensible to a variety of smart building use cases, including factories, offices, smart infrastructure, etc.

Ibaseta et al. [23] propose a new methodology for the monitoring and controlling of energy usage in constructions through the utilization of WoT technology. The proposed methodology incorporates diverse building systems and devices, such as lighting, occupancy sensors, and smart plugs, through a cloud-based platform that employs web protocols

and standards. The present study showcases a suggested methodology through a case study of a retrofit project undertaken in an office building. The results indicate that the proposed approach is both cost-effective and energy-efficient while also being interoperable and scalable. Furthermore, the study suggests that this approach can be implemented in real-world settings.

Reda et al. [4] propose a knowledge-based approach for home automation systems using IoT devices. The proposed approach aims to achieve greater expressivity and a higher level of abstraction needed to build knowledge-enabled and reasoning-capable home automation systems so that the potential offered by IoT devices can be fully exploited. The paper demonstrates the feasibility and efficiency of the proposed approach in a simulated house environment, and it contributes to the development of home automation systems by providing a new approach that uses web standards and public ontologies to implement well-defined reasoning without the need for ad hoc control programs or ontologies. The paper also suggests several future works, including investigating the scalability of the proposed approach, evaluating it in a real-life setting, comparing it with other existing approaches, extending it to support more advanced reasoning capabilities, and developing a user-friendly interface for configuring and managing the proposed approach.

Gochhayat et al. [10] propose LISA Lightweight Context-Aware IoT Service Architecture for managing and efficiently managing and delivering push-based services in an IoT environment designed to minimize the overhead of communication and processing while using context information such as device capabilities, user preferences, and environmental conditions to provide personalized and efficient IoT services. LISA filters and forwards the most important and relevant services to the users by understanding their context. The paper evaluates the scalability of LISA through simulations that test its ability to handle many IoT devices and services. The results show that LISA can scale efficiently to support many devices and services while maintaining acceptable levels of performance. However, the paper also acknowledges some limitations of LISA, such as limited support for complex services and limited scalability with centralized deployment.

Krati et al. [24] discuss the challenges of maintaining excellent air quality in indoor environments. It proposes a context aware IoT system that collects data, predicts ventilation conditions, and provides the end user with alerts and recommendations. Through a smartphone application, the system notifies the end-user of contextual information regarding the indoor environment and current ventilation conditions. The system can also provide the end-user with recommendations on improving ventilation and reducing indoor pollutant levels, such as opening windows, installing air purifiers, and modifying the HVAC system. Using the ventilation rate calculated with the aid of interior CO₂ concentration, multilevel logistic regression is used to define indoor ventilation states using ventilation rate. K-NN classification technique to predict ambient ventilation.

Xue et al. [25] examine the advancement of context-aware information fusion technology in the context of smart libraries, employing IoT situational awareness. This paper presents a comprehensive examination of the present status of smart libraries and context-aware technology while also conducting an analysis of the implementation of context-aware technology within smart libraries. This paper presents a conceptual framework for implementing a smart library, which leverages context awareness to enhance its services. It further proposes integrating context-aware services within smart libraries to optimize user experiences and improve overall functionality. The aforementioned findings propose potential avenues for future research in this field. These include the advancement of more precise algorithms for context-aware information fusion, the investigation of alternative IoT technologies, and the resolution of ethical and privacy issues. In general, the paper emphasizes the potential of the IoT situational awareness technology in improving the efficacy and efficiency of intelligent libraries.

Kim et al. [26] present a middleware architecture for a context-aware system in a smart home environment. To infer high-level contexts from available low-level contexts, the proposed architecture incorporates a profile-applied improved rule-based reasoning algorithm. The context is modeled using OWL and ontology. The experimental result demonstrates that the middleware provides more accurate and quicker reasoning results than the conventional rule-based method. In addition, the context-aware service is also selected using a rule-based algorithm, allowing the service to be readily expanded by adding new service rules to the service rule base.

In this paper, a Service-Oriented Context-Aware Middleware (SOCAM) architecture is proposed for developing and prototyping context-aware services in pervasive computing environments. To develop context-aware services, architecture provides efficient support for acquiring, discovering, interpreting, and accessing diverse contexts. In addition, the paper proposes a formal context model based on Web Ontology Language and ontology to address issues such as semantic representation, context reasoning, context classification, and dependency. The context model and middleware architecture are described, as well as the prototype's performance in a smart home environment [27].

III. PROPOSED FRAMEWORK

IoT service provisioning techniques must take into consideration how to provide service consumers with complete data, including sensor data as well as its context and don't overwhelm the consumer with repeated information.

In addition, the rapid growth of IoT services available to users will result in a significant increase in information overload and network resource consumption. The exponential growth in the number of services available presents a challenge in selecting and providing the appropriate service from the vast array of required services. Therefore, to locate the most pertinent service, it is essential to construct an accurate query that considers the consumer's context.

In this section, we present our proposed service provisioning framework called CSSP, Fig. 1 presents the proposed framework, and we will discuss how to overcome the problems related to integrating IoT and Context-aware systems in a scalable manner which will be described in detail in the following sections.

A. Data Acquisition and Management Service

This layer is the core layer of the framework which is responsible for all operations related to collecting sensor data and storing it locally. This layer has many data collection mechanisms to overcome the limitation of IoT sensors. The purpose of this layer is to hide the details of data collection and protocols used from users; user may be a web developer or

mobile developer who interacts with sensors as a virtual object. Our methodology for collecting sensors data is based on three levels:

- Collect sensor data using the suitable protocol and according to the user role (Fig. 2 shows accessing sensor value through CoAP protocol in the Cooja simulator from a web browser).
- Annotate sensor data with context using ontology. For example, Fig. 3 shows how to model the value of temperature using context aware. There are many methods to represent RDF, such as Triples, Shorthand notation, and XML notation, showing the use of Shorthand notation code to model sensor values.

Fig. 1. The proposed framework (CSSP).

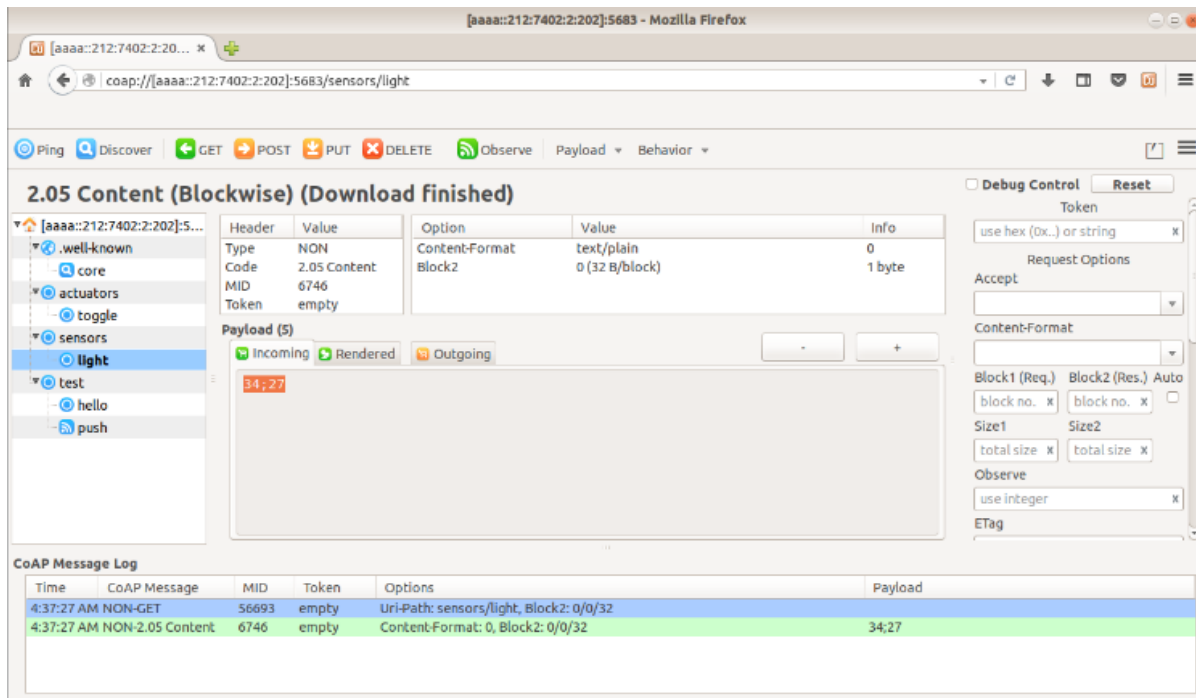

Fig. 2. Accessing CoAP sensor value.

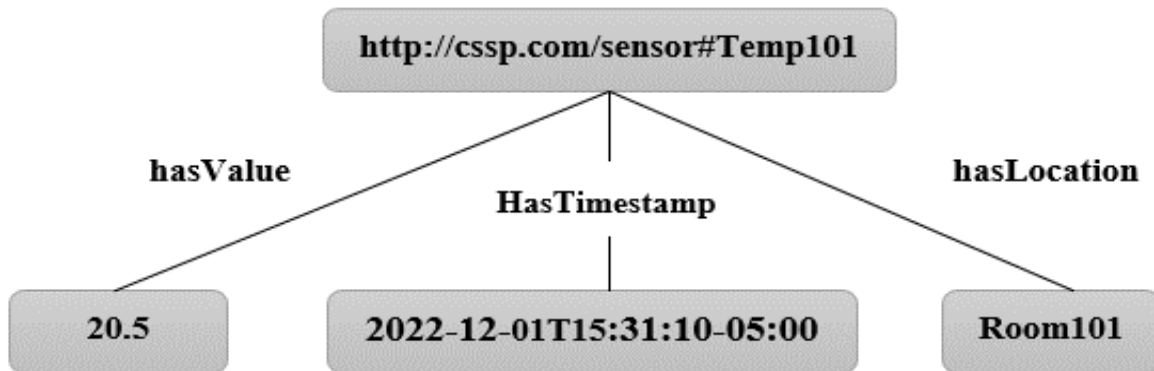

Fig. 3. Temperature sensor value representation using RDF Graph.

The example in Listing. 1 show how to use shorthand notation to model sensor data.

```

@prefix so: <http://cssp.com/sensor#> .
so:Temp101 hasValue 20
so:Temp101 hasTimestamp 2022-12-10T15:31:00Z^^xsd:dateTime
so:Temp101 hasLocation Room101
  
```

Listing. 1. Sensors reading representation using RDF

- Save the generated data in a triple store. This component starts working through the system admin when the admin wants to add a sensor. The admin fills in some data about the sensor, and the component generates an abstract service template according to the specified protocol. The admin customizes the service, such as customizing the result format or any metadata about the result, and how to read the data from pin id, etc.

The service itself is described using an ontology. Every detail about the service is described, such as URL, Endpoints, data format, category, location, etc. Admin can start, stop, and remove any service in the framework at any time. After the admin creates, customizes, and describes the service, the service will be added to the server to allow access to sensor data based on identified mechanism.

In our view of data Acquisition of sensors, it depends on the used protocol, the role of the user, and the status of data (Realtime data or cached instant data).

We can view the data generated from IoT sensors as the following:

- Object Data Realtime
- Object Data Scheduler
- Object Data Subscribe

All these components depend on ontology to describe IoT devices.

1) *Object data realtime*: This is the simplest and most direct way to access sensor data which is used by Realtime role users. Based on the type of IoT device, it offers GET operation in case of getting data from the device, else if the device is an actuator, it will have GET and POST operations, Also Mapping of CoAP [28] URI requests to standard web requests.

Data generated from sensors or written to actuators are not meaningful without a description, so we use ontology to describe the context of sensor values such as location, time, and available people.

After the description of sensor data, we add this data to triple store locally and the most recent value to a cache server which can be used by other users who are not concerned with instant data from sensors.

This role is very important in cases of emergencies where milliseconds can be important for patients or the elderly, so we must decrease the request count on sensors for any user.

2) *Object data scheduler*: This is one of the most important components of the framework and is commonly used by many types of users. This mechanism works with the normal users of the system.

There are many task queues to distribute task requests and categorize task queues for every type of sensor. First, it checks the cache server to see if available recent data is present. If ok, it will return and delete the request. Else, the request will be added to the suitable task queue. After the worker gets the value, the component describes the value, and it is to triple-store and adds the value to the cache server Scheduler threshold settings are configured using system admin.

3) *Object data subscribe*: This mechanic is frequently used for monitoring purposes, and it uses different protocols, such as Message Queuing Telemetry Transport MQTT [28] to allow the user to subscribe to a collection of sensor value changes. The layer also adds context data to the value returned and adds it to the triple store and cache server.

B. Data Aggregation and Rules Reasoning

In the Data Acquisition and Management Service layer, the data is distributed on edges and have duplicates in the data aggregation layer. The framework will do the following:

- Save Stream to Store
- Reasoning Task
- Retrieve Historical Data

1) *Save stream to store*: In this phase, First, the system checks sensors data and stores only incoming new unique data and ignores repeated values. The service receives only new values to reduce the size of the data. Secondly, extracted common data from ontology was done on the local edges. In this phase, we complete the data of the sensor. We extract

metadata or minimize to reduce used bandwidth used to transfer sensor data from edges to a data store. Finally, the IoT value will be stored in the triple store database.

2) *Reasoning task*: In this phase, we define rules which can be used to infer new knowledge from sensor data. Any rules engine base can be used, such as SWRL rules. When any activity is detected based on rules, sensors, and context data, action is taken and also described and saved in the RDF triple store. The following example in Listing. 2 demonstrates an example of the SWRL rule to regulate air conditioners in a classroom based on current readings from temperature sensors, the number of persons in the same room, and the state of the window.

In this example, `hasNumberOfStudents`, `hasTemperature`, and `hasWindowState` are individual properties that represent the number of students in the classroom, the temperature in the room, and the state of the window (open or closed), respectively. `hasAirConditionerState` and `hasTemperatureSetting` are individual properties that represent the state of the air conditioning system (on or off) and the temperature setting, respectively. The SWRL rules in this example take into account the number of students in the room, the temperature in the room, and the state of the window to determine the appropriate state and temperature setting for the air conditioning system. For example, if there are less than 10 students in the room and the temperature is above 25°C, the air conditioning system will be turned on and set to cool the room down to 24°C. On the other hand, if the window is open, the air conditioning system will be turned off regardless of the number of students or temperature.

3) *Retrieve historical data*: Cause we have a triple store, we can run the system in two methods:

- REST API: this is a simple method and can be used by any developer to call API for getting device data by its id and during a specific period.
- SPARQL Query: this is the standard language used to query from triple store TDB and which will be important in the case of a query for historical data in the TDB.

C. Client Side

The client-side layer is the layer responsible for collecting context data and sending this context with the service request, for example, when the user in a smart home environment wants to turn on the air conditioner, and there are many types of contexts information that can be sent with requests such as the room of the user (location), current temperature from internet service, number of users in the rooms, and preferred temperature from user profile.

D. Load Balancer

The load balancer layer is an optional layer in our framework according to the application size and number of users. This layer is responsible for receiving a request, then finding an available server and routes the request to this server. Load balancers, including physical appliances, software instances, or a combination of the two.

```
hasNumberOfStudents(?classroom, ?numStudents) ∧ hasTemperature(?classroom, ?temp) ∧ hasWindowState(?window, ?state)
  → hasAirConditionerState(?aircon, ?airconState)
∧ lessThan(?numStudents, 10) ∧ greaterThan(?temp, 25) ∧ equal(?state, closed)
  → hasAirConditionerState(?aircon, on)
∧ hasTemperatureSetting(?aircon, 24) ∧ greaterThanOrEqualTo(?numStudents, 10)
∧ lessThanOrEqualTo(?numStudents, 20) ∧ greaterThan(?temp, 25) ∧ equal(?state, closed)
  → hasAirConditionerState(?aircon, on)
∧ hasTemperatureSetting(?aircon, 23) ∧ greaterThan(?numStudents, 20) ∧ greaterThan(?temp, 25) ∧ equal(?state, closed)
  → hasAirConditionerState(?aircon, on) ∧ hasTemperatureSetting(?aircon, 22)
∧ equal(?state, open)
  → hasAirConditionerState(?aircon, off)
```

Listing. 2. the SWRL rule example to regulate air conditioners in classroom

E. Environment

This layer is responsible for the IoT environment we want to monitor and control locally or through the Internet, which has sensors and actuators. This layer needs to use a gateway such as Arduino and Raspberry Pi to control various digital or analog devices.

IV. EXPERIMENTS

To confirm the proposed framework's effectiveness, an experiment has been applied to evaluate the response time in the case of traditional requests and in the case of our framework. We build a simple IoT network in a Cooja simulator [29] and test simultaneous requests for the sensors, then measure and compare the performance of requests for the traditional request and our framework.

1) *Dataset*: The environment used to generate these datasets was Contiki 3.0 OS (Ubuntu 18.04 Based) in a virtualization environment (VMware application). The device used for generating datasets is a laptop with a Core I5 processor and 8 GB Ram (2 GB for the virtual machine). The Cooja simulator was used to build a simulation of an IoT network.

We built a Python application to simulate the request of the huge simulation for a sensor in case of a CoAP request and proposed HTTP request (500 requests simultaneously) and then saved the details of requests and responses in a CSV file. In the case of a CoAP request, the log file will contain the following attributes: request id, start time, end time, response time, status, and value. In the case of the proposed HTTP, we added an attribute to indicate the source of data, which will be physical sensor data or from a cache server. Two data sets for CoAP and HTTP are generated.

2) *Results and discussion*: Based on the simulation results, it is observed that an increased number of CoAP requests to the sensor resulted in a significant exponential increase in response time. This effect can be attributed to the absence of scheduling or caching mechanisms, as the direct access of sensor values contributed to longer response times. A sample of requests and their corresponding response times are illustrated in Table I (Sample of CoAP Requests Dataset) and Table II (Sample of Proposed HTTP Requests Dataset).

TABLE I. SAMPLE OF COAP REQUESTS DATASET

Request Number	Response Time
145	1.9
404	2.6
147	3.8
474	4.6
48	6.9
281	7.9
70	8.9
442	9.9
419	10.5
41	14.9
112	16.9
78	17.9
126	18.8
289	19.9
204	20.9
346	21.9
475	22.2
98	31.9
250	32.8

TABLE II. SAMPLE OF PROPOSED HTTP REQUESTS DATASET

* C: Cached		* R: Realtime	
Request ID	Response Time	Value	Type
73	0.11	240	C
132	0.15	240	C
347	0.14	76	C
1	0.72	240	R
38	2.16	240	C
364	3.37	122	C
252	4.74	122	C
95	7.13	122	C
10	15.53	54	L

Fig. 4. CoAP response time.

In the traditional approach, the results from our analysis showed that approximately 32% of the requests failed due to this lack of optimization and huge simultaneous requests to the same sensor. The processing time for all requests is 47 seconds. Fig. 4 shows a graph representing the sensors direct access performance through the CoAP protocol.

The implementation of scheduling and caching mechanisms as well as a time threshold established in the system configuration affect the response time in our proposed prototype. As per this threshold, the initial request may experience a relatively longer latency, but subsequent requests are expected to have faster and more consistent response times.

In the proposed approach, the results from our analysis show that the simulation conducted with this prototype revealed a failure rate of 0%. Additionally, the data analysis in the table indicates that a significant portion of sensor data is obtained from the cache server. Consequently, most responses were delivered within an acceptable timeframe, ensuring efficient and reliable system performance. The processing time for all requests is 16 seconds. Fig. 5 shows a graph representing the sensors access performance through the proposed framework based on the HTTP protocol.

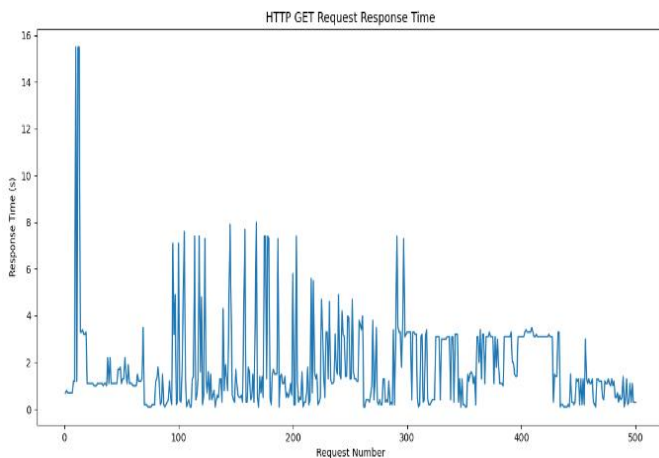

Fig. 5. Poposed HTTP response time.

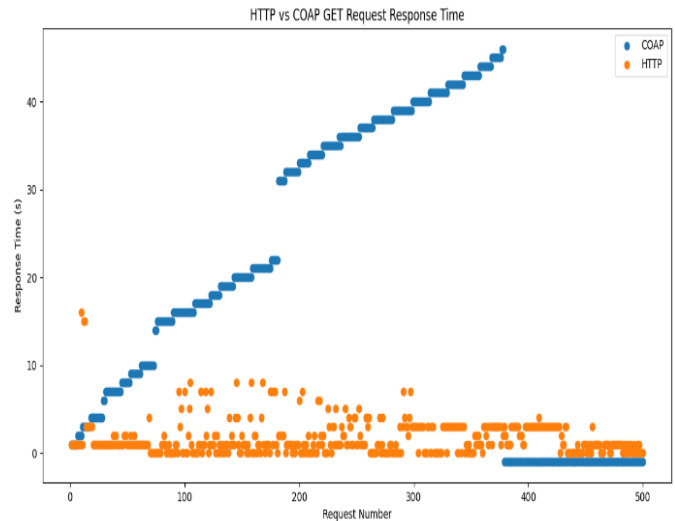

Fig. 6. Performance comparison of CoAP and proposed HTTP.

Fig. 6 shows a graph representing a comparison of performance according to response time to the CoAP protocol (traditional direct access) and HTTP protocol (Proposed framework).

V. CONCLUSION AND FUTURE WORKS

This paper proposes a context-aware semantic service provisioning framework. The framework focuses on producing solutions for many problems by providing smart devices as smart objects in standard web environments and facilitating the development of any category of IoT application.

The framework was organized to solve many network problems such as bandwidth, scalability, limited resources of smart devices, semantic annotation, and reasoning.

The proposed framework is validated and evaluated by testing accessing the service in the traditional CoAP protocol and according to the proposed framework and comparing the results. The evaluation shows that the proposed framework increases performance and decreases failed requests.

In the future, we will try to test this framework in a real environment, and we will try to increase the performance.

Impact of the Use of the Video Game SimCity on the Development of Critical Thinking in Students: A Quantitative Experimental Approach

Jorge Luis Torres-Loayza, Grunilda Telma Reymer-Morales and Benjamín Maraza-Quispe
Facultad de Ciencias de la Educación de la, Universidad Nacional de San Agustín, de Arequipa-Perú

Abstract—The objective of the research is to determine to what extent the use of the SimCity video game allows the development of critical thinking in the teaching-learning processes of students. The methodology applied consisted of a research with a quantitative approach of experimental type, working with a sample of 25 students selected through a simple random sampling of a population of 100 students, 10 sessions were developed using the SimCity video game, a pretest and posttest of skills and abilities required to develop critical thinking of Watson Glaser were applied, whose dimensions measured were: Inferences, assumptions, deductive reasoning, logical interpretation and evaluation of arguments. The results show that with adequate stimulation through the use of the SimCity video game, critical thinking can have a moderate but effective development in the students, from the comparison of the data obtained in the pretest and posttest a significant progress in terms of scores is observed; likewise, the effectiveness of the use of the SimCity video game is reflected to a greater extent in inferences and evaluations of arguments, since during the posttest evaluations greater progress was observed in comparison to other skills; while the interpretation of information obtained less progress in comparison to the other skills, the use of skills such as deductive reasoning, inferences and evaluation of arguments were moderately developed. In conclusion, the use of the SimCity video game allows the development of skills and abilities to develop critical thinking according to various factors, such as the way in which it is incorporated into the curriculum, the orientation and guidance of teachers, and the way in which reflection and analysis is carried out after the game experience.

Keywords—*SimCity; video games; critical thinking; critical learning*

I. INTRODUCTION

In many educational institutions, the teaching approach focuses on memorization and repetition of information rather than critical analysis of it. This can hinder the development of critical thinking in students as they are not given the opportunity to question and critically evaluate information. In this context, we propose the following research question: To what extent does the use of the video game SimCity foster the development of critical thinking in students?

SimCity is a game designed for educational and critical decision-making purposes. The study [1] mentions that these games, besides being created by a dedicated team of game developers, also involve psychologists, doctors, and other professionals who assist in creating a more serious and realistic environment. Thus, SimCity is a serious simulation game

where decisions depend on the player. According to [2], a video game can be a simulation game, which, unlike a simulator, tends to have open gameplay based on strategy and role-playing, as opposed to a rigid action and adventure gameplay of a simulator. SimCity is a video game software created by Electronic Arts and released in 2003. The game is designed for single player, but there is an option to create multiple cities that can be played by different people at different times within the same software. It is a system simulation game where players assume the role of a mayor and deal with issues such as crime, budget deficits, and traffic to create and develop cities [3]. Additionally, [2] mentions that as a simulator, one must think as if everything were real and consider all the factors present since the player holds the power. The simulation game SimCity offers the opportunity to orchestrate the construction and development of a city. The tremendous success of SimCity demonstrates the surprisingly convincing power of a particular type of human-computer interaction. According to [3], in combination, it can be understood that it is a popular game that allows for interaction between people and machines. The success of the game in education is due to the artificial environment with rules where there are no limits of size or time [4]. Since the game presents a large amount of data that players must be aware of, such as air pollution levels. SimCity 4 allows its players to shape and build a settlement where the player acts as the mayor [5]. SimCity allows players to determine the evolution of a city, which depends on the player's decisions. Thus, SimCity has an interface with a small control panel that provides information about the city's development and any problems it may have, whether they are economic, social, and etc.

The SimCity game guide mentions that decision-making is the main aspect, as players, in the role of mayor, must define zones for houses, factories, and others while also meeting basic needs in order to maintain a stable city. At the beginning, it is recommended to follow a small tutorial to understand the game's themes [6]. The city is not just a toy that SimCity claims to be, and SimCity plays with urban planning in a way that misleads students in their understanding of how a city works and how it could be planned [3]. SimCity is considered a serious game [7]. They mention: Games have the unique ability to provide participants, especially learners, with the opportunity to acquire skills through activities embedded within the game itself. This is due to the playful and interactive nature of games, which allows players to experience situations and challenges actively and participatively. Unlike

gamification, where game elements are incorporated into contexts that are not necessarily playful, games themselves are inherently playful by design. In other words, when it is mentioned that games allow for the acquisition of skills through game-based activities, it refers to how players learn and enhance their abilities as they interact with the game. These activities can involve solving puzzles, making strategic decisions, overcoming obstacles, and achieving goals within the game. Through these actions, players are exposed to challenges that require the application of specific skills, thus contributing to the acquisition of skills.

According to [8], thinking is defined as the ability to process information and build knowledge through the combination of mental representations, operations, and attitudes. It classifies thinking into three types:

- Automatic Thinking: Sometimes we act without much thought, we think automatically; that is, we respond immediately to various stimuli in the environment with previously learned responses.
- Systematic Thinking: Other times, we stop to think, we think systematically; we use all the intellectual resources at our disposal (concepts, skills, and attitudes) to create new responses to situations.
- Critical Thinking: Finally, in very extraordinary occasions, we reflect on our own thinking process; we carry out what philosophers call self-awareness and psychologists call metacognition. This involves examining and critically evaluating our own thoughts, beliefs, and assumptions, as well as the arguments and evidence supporting our conclusions. Critical thinking aims to objectively analyze, question, and rigorously evaluate information before reaching conclusions or making decisions.

Furthermore, it is mentioned that the stage of formal operations, also known as the fourth stage, is the highest point at which a person can make decisions through broader logic [9]. Thus, it can be understood that learning theory is related to critical thinking since in its fourth stage, conclusions are sought through more exhaustive reasoning.

Critical Thinking is configured as a philosophical type of thinking that is concerned with cultivating and improving each individual's reasoning abilities [10]. In other words, it is the capacity that a person possesses to have a critical judgment in a given situation. Critical thinking is a mode of thinking about any topic, content, or problem in which the thinker improves the quality of their thinking by grasping the inherent structures of the act of thinking and subjecting them to intellectual standards [11]. In other words, critical thinking is a cognitive skill that involves analyzing information objectively and systematically, carefully evaluating it, and making informed decisions based on available evidence. Critical thinking involves the ability to analyze, synthesize, and evaluate information from different sources, including books, articles, websites, media, and personal experience.

The Multidimensionality of Critical Thinking has been categorized by [12] as a mode of thinking that corresponds to

the current conditions of the development of productive and technological forces, their complexity, and the changes underlying the multidimensionality of systems. Thus, it is understood that critical thinking seeks to relate all possible aspects of a topic to understand their influence on it. Critical thinking constitutes a complex system of dimensions that allows for the analysis of one's own thinking and that of others at a more specific level, which, when subjected to the analysis of the different dimensions, as stated by [13].

- Logic: Involves analysis through logical reasoning.
- Substantive: Evaluates truth and falsehood.
- Contextual: Recognizes the social and historical context.
- Dialogical: Examines thoughts in relation to the perspectives of others.
- Pragmatic: Recognizes the purpose or intention behind a thought.

It has been researched that SimCity can be applied in the development of administrative skills in undergraduate and graduate students [14]. This indicates that SimCity has application in the educational field. Additionally, Piaget's learning theory reflects the fourth stage when playing a strategy video game, as the player will use logic to make decisions [15]. Thus, SimCity, being a strategy game where decisions must be made through structured logic, allows for the development of critical thinking. Unlike many games, SimCity encourages deep thinking due to its characteristics. Of course, no matter how much computer game designers grant to players, any simulation will be based on a set of basic assumptions. SimCity has been criticized from both the left and the right for its economic model [3]. Therefore, individuals who play SimCity must apply their knowledge based on the dimensions of critical thinking. In strategy games, it is mentioned that logical thinking and problem-solving are primarily developed [16]. Thus, it can be understood that SimCity as a game allows for the development of logic as another dimension of critical thinking, but as a simulator, other aspects must also be considered. Furthermore, [17] mentions that the game allows for decision-making based on the environmental conditions displayed during the construction and development of the city. Therefore, to make decisions, the contextual and dialogical dimensions are important because one has to think based on what is proposed during the game and then make decisions.

On the other hand, the use of algorithms is common in video games. The research [18] mentions how video games nowadays use predictable algorithms, but with the use of artificial intelligence, this varies, although they become more comprehensible and logical. Thus, the pragmatic dimension will also be developed as, during the game, one will have to anticipate and think about the future critically and question the decisions made.

Therefore, critical thinking is essential in decision-making to make them with determination. The author in [19] mentions that video games improve reasoning and critical thinking abilities, leading to making accurate decisions.

According to the research conducted by [20], there is an effect of the game SimCity on the development of spatial intelligence among students at Angkasa Secondary School in Bandung. Secondly, the application of the SimCity game in geography learning helps students make decisions to overcome spatial problems. This is evidenced by the increase in the average score in the post-test of the experimental class after using SimCity as an instructional medium. Thirdly, the application of the SimCity game in geography learning requires structured learning scenario planning and proper time allocation. Consequently, the learning steps must be carefully followed without skipping any steps. Fourthly, SimCity game can be an alternative learning medium, although it has some disadvantages compared to conventional methods.

Likewise, the research conducted by [21] demonstrated that even a technically complex and fast-paced medium like a computer video game, SimCity, can be used in an instructional scenario for an extended period with limited effort, although the challenge of the game's aging must be actively addressed. Furthermore, in the described instructional scenario, SimCity is perceived as a motivating and accepted learning diversification: the learning activity can be considered playful. This finding, moreover, has not been widely presented in the literature.

II. RESEARCH METHODOLOGY

The applied methodology follows a quantitative experimental approach.

A. Objective

To determine to what extent the use of the video game SimCity in teaching-learning processes allows the development of skills and abilities to promote critical thinking in regular basic education students.

B. Hypothesis

The use of the video game SimCity in teaching-learning processes enables regular basic education students to develop skills and abilities to promote critical thinking.

C. Variables

- Independent: Use of the video game SimCity
- Dependent: Development of critical thinking
- Controlled: The number of students and the playtime of SimCity

D. Population and Sample

A simple random sampling has been applied to select 25 students for the control group and 25 students for the experimental group. The total population consisted of 100 third-grade students from regular secondary education. Informed consent was obtained from the parents or guardians of all students.

E. Methodological Design

The research is experimental in nature. According to [22], unlike theoretical research, it requires direct interaction with the members and components of the group being studied, in this case, individuals. To determine the effectiveness of the

video game SimCity in the development of critical thinking, the Watson Glaser Critical Thinking Appraisal test [23] will be administered. This test is internationally standardized.

F. Aspects Measured by the Watson Glaser Test

- Capacity for critical thinking.
- General understanding of the importance of providing evidence and support when formulating conclusions.
- Ability to differentiate between inferences, assumptions, and generalizations through the application of logic.
- The ability to combine these skills in decision-making.

Table I shows that both Group A and Group B participated in the study and were administered the Watson Glaser Critical Thinking Appraisal test in both the pretest and posttest. Additionally, a total of 10 sessions of 30 minutes each were conducted as part of the study. The total duration of the study was 12 hours.

TABLE I. PROCEDURE FOLLOWED IN THE RESEARCH

Group	Pretest	Sessions	Posttest	Duration
Group A and B	The Watson Glaser Critical Thinking Appraisal test will be administered to both samples	10 sessions of 30 minutes each will be conducted	The Watson Glaser Critical Thinking Appraisal test will be administered to both samples	12 hours

G. Application of the Watson Glaser Test to Both Samples

The Table II displays the distribution of questions and scores across different dimensions of critical thinking.

TABLE II. STRUCTURE OF THE WATSON GLASER TEST

Dimensions	Number of questions	Score
Inferences	15	15
Assumptions	16	16
Deductive Reasoning	9	9
Logical Interpretation	12	12
Evaluation of Arguments	15	15
Total	67	67

H. Sessions for the use of the Video Game SimCity

1) Introduction to the game SimCity

- In a session of 25 to 30 minutes, the students will be explained about the game SimCity and how it is played.
- The entire introduction will be played for the students to understand the game dynamics.

2) Duration of the 10-hour game

- Session 1: A small stable population will be initiated.
- Session 2: Connections with neighboring towns will be developed.

- Session 3: Investments will be made in education, health, and security.
- Session 4: A railroad or highway will be constructed.
- Session 5: Construction will take place in the other neighboring cities.
- Session 6: New transportation methods will be built based on the city.
- Session 7: A balance will be sought in six aspects: traffic, health, education, environment, security, and land value.
- Session 8: Demographic growth will be initiated by expanding more areas.
- Session 9: Community problems will be addressed and solved.
- Session 10: More recreational sites and leisure areas will be created if there is stability.

The sessions are for reference purposes, as the students have the final decision on what they choose to do.

3) Objectives of the game in SimCity:

- Achieve a population of at least 50,000 inhabitants.
- Avoid having a deficit.
- Maintain a positive score of over 60% in the six aspects (traffic, health, education, environment, security, land value).

III. RESULTS

Table III shows the total scores of the pretest and posttest of Watson Glaser applied to the 25 students.

Table V presents the results of the posttest Watson Glaser assessment, indicating a comprehensive overview of students' critical thinking skills across different dimensions. The provided scores suggest a notable improvement in various critical thinking dimensions following the implementation of the SimCity game. It is evident that the use of SimCity has positively impacted students' critical thinking abilities. Specifically, the dimensions of Inferences, Assumptions, Interpretation of Information, and Evaluation of Arguments display improved scores, underscoring the game's influence on enhancing these critical thinking aspects. Moreover, the overall total score demonstrates a collective improvement, reinforcing the notion that the game has contributed significantly to the students' overall critical thinking skills.

TABLE VI. PAIRED T-TEST

Statistics	Variable 1	Variable 2
Mean	34.28	50.32
Variance	5.376666667	4.476666667
Observations	25	25
Pearson correlation coefficient	0.363155411	-
Hypothesized difference of means	0	-
Degrees of freedom	24	-
t statistic	-31.97783414	-
P(T<=) one-tail	1.7226E-21	-
Critical value of t (one-tail)	1.71088208	-
P(T<=) two-tail	3.4452E-21	-
Critical value of t (two-tail)	2.063898562	-

Table VI displays the paired samples t-test, which shows a significant difference between both variables. This indicates that the impact of the SimCity video game application influences the development of critical thinking. It can be concluded that variable 2 has a significantly higher mean than variable 1. This conclusion is based on the extremely low p-values, the comparison of the t-statistic with critical values, and the direction of the observed difference.

1. Data Analysis

An analysis of the data collected is presented and analyzed in the following graphs.

According to Fig. 1, the development of the inference ability varied among each student, due to the multiple strategies that can be approached in the game. It is evident that the development in the inference ability of each student was positive, as all of them obtained a higher score compared to the pretest, surpassing their previous score by an average of five points. For a successful experience in SimCity, it is necessary to infer that, thanks to this ability, we can determine or identify certain information that is not explicitly stated in the source [24]. Thus, to achieve the proposed objectives in SimCity, some students approached the inference aspect better, for example, constructing multiple small and stable cities to fulfill the goals without encountering problems. Overall, the inference ability was developed through the game's challenges, which were tackled with varied solutions proposed by the players.

In Fig. 2, a lesser progress is observed in the development of the assumption ability, a factor related to how students approached problems based on clues and how effective their solutions were. Considering something as true or real based on the clues available [25]. This understanding allows us to infer those problems such as the need for more schools, shopping centers, or other facilities placed in the necessary quantity and the right location were actions taken by the students to fulfill the proposed objectives. In conclusion, the assumption ability had a more complex development, as the numerous options provided by SimCity can lead to making many errors.

Fig. 1. Scores of the inference ability.

Fig. 2. Scores of the assumption ability.

According to Fig. 3, regarding deductive reasoning, a positive impact is observed as all students obtained better scores, improving by an average of 2 points compared to the pretest. Furthermore, with a maximum score of 9, significant development can be identified, with six students achieving a score of 8. In relation to SimCity, this ability is of utmost importance because when there are problems with city organization or services, the game communicates through messages that inform the player about possible strikes or riots, which leads students to make decisions and infer conclusions about the potential outcomes if the problems are not resolved. This reasoning allows organizing premises into syllogisms that provide decisive proof for the validity of a conclusion; it is often said to deduce from an unexplained situation [26]. For example, if there are environmental problems, the premises can be the notifications and the low percentages in city aspects such as health and the environment. Overall, SimCity enables the exercise of deductive reasoning through its notification system and the overall panel displaying the city's aspects.

According to Fig. 4, in terms of information interpretation, the progress was similar to deductive reasoning, with an average increase of 2.48 points from the previous score. This ability is related to the concepts provided at the beginning of the game application since the interpretation of the given tutorial information, which aimed to provide foundations on how a city can grow sustainably, also offered solutions to common problems. The small difference in scores obtained by the students demonstrates a similar interpretation of the tutorial. However, SimCity is not a game of narratives or closed decision-making; it is an open-ended game. Therefore, the interpretation of information varied in each case, as the developing city differentiated itself from others. The information provided to the students through notifications was diverse, and thus, its interpretation also varied.

Fig. 3. Scores of the deductive reasoning ability.

Fig. 4. Scores of the information interpretation ability.

Fig. 5 shows an average development of 4 points compared to the pretest, which indicates that despite not being a game solely focused on answering questions based on information, SimCity has demonstrated that errors allow for significant student learning. An argument is a reasoning that justifies something, and in the case of SimCity, when a decision deviates from the intended path, it can be considered as something negative, leading to the evaluation of the student's decisions. This process prompts students to evaluate their own arguments and make decisions based on them. This attribute is present in each student during the game, as problems frequently arise in the process of building a stable city. Therefore, students often seek solutions, and if they make an incorrect decision, they realize it through the economic deficits they encounter, creating the need to evaluate their decisions

and find the best solution, which students achieved and is evidenced by the improvement in their scores.

Fig. 5. Scores of the argument evaluation ability.

Fig. 6. Comparison of the total scores between the pretest and posttest.

According to Fig. 6, it is evident that critical thinking has developed in the students, as all of them showed improved scores. These results infer that the SimCity video game had a positive impact on the development of critical thinking in students.

IV. DISCUSSION

The results of this study are in line with previous research highlighting the positive impact of the game SimCity on the development of specific cognitive skills. According to the work done by [20], a significant effect of the SimCity game on the enhancement of students' spatial intelligence is established. This finding is important as it supports the notion that video games can contribute to the development of specific cognitive skills, in this case, spatial intelligence, which is crucial for effectively understanding and navigating spatial environments.

Furthermore, the results obtained in this research align with the findings of [21], who also emphasized the perception of SimCity as a motivating and enriching tool in the educational scenario. The motivating diversification of learning adds to the evidence that video games, in this case, SimCity, can generate greater student engagement and participation in the teaching-learning process, potentially improving information retention and the understanding of complex concepts.

Regarding our findings, it was found that the use of the SimCity video game in teaching-learning processes has a positive impact on the development of critical thinking skills in students of regular basic education, although it is partial. This

suggests that while the game contributes to the overall development of critical thinking, some dimensions of critical thinking may not be comprehensively addressed. The dimensions of critical thinking are varied and may require specific approaches for complete development.

In particular, the logical dimension showed the greatest development through the use of the SimCity video game, and this dimension exhibited a close relationship with the results obtained in the Watson Glaser test. This correlation highlights the importance of logical thinking in problem-solving and the evaluation of arguments, two central aspects of critical thinking. However, it is observed that other dimensions of critical thinking could benefit from complementary pedagogical approaches to achieve comprehensive development.

According to [27], engaging in the SimCity video game activity has provided a framework for developing meaningful educational situations that facilitate the contextualization and application of scientific conceptual content acquired by students. Additionally, according to [28], the development of critical thinking attitudes can be determined through various aspects of the gaming experience. One of these aspects involves analyzing the underlying model in the video game and comparing it with reality, while the other aspect involves exploring the values and counter-values presented. In this way, students have applied their acquired knowledge to compare simulation and reality, noting significant differences. Some of the weaknesses criticized for potential educational use can thus be transformed into opportunities for developing skills and attitudes.

For example, it is criticized that the model programmed in the simulation never reaches reality [29], [30]. The development of problem-solving skills through the SimCity video game series has already been confirmed in studies by [31] and [32]. In this case, the steps that students take to solve problems of varying difficulty, ranging from easy to medium and complex, have been analyzed to determine the process followed, in addition to the final result. The conclusion is that through the simulation video game, students can employ very different strategies to reach the same final solution, thus fostering creativity and accommodating the diversity of students [33]. As indicated by [34] and [35], an added value for improving the teaching-learning process of Geography is provided by the need to manage a simple layered geographic information system, which can serve as an introduction to GIS (geographic information systems). Furthermore, according to [36], [37] the development of problem-solving skills is one of the main consequences of becoming a mayor to manage and build a city with SimCity. The research conducted in contrast to the reviewed background allows us to glimpse that it is possible to use this type of video game to develop critical thinking skills in students, as demonstrated by the results.

V. CONCLUSIONS

These collective results underscore the effectiveness of the SimCity game in fostering critical thinking skills among students. The improvements across dimensions and the significant shift in mean scores support the premise that video games, when strategically integrated into educational contexts,

can indeed contribute to the development of targeted cognitive abilities. This study adds valuable insights to the growing body of research on the educational potential of video games and suggests that their incorporation into pedagogical approaches warrants further exploration and consideration.

The use of the SimCity video game in teaching and learning processes allows for the partial development of critical thinking skills in regular basic education students since the focus is not on each dimension of critical thinking as such, given their diversity. Similarly, the logical dimension was the most developed through the SimCity video game, being the one most related to the Watson Glaser test.

It is inferred that with adequate stimulation through the SimCity video game, critical thinking can have a moderate and effective development in regular basic education students, as significant progress in scores was observed based on the data obtained from the post-test, which were validated with the hypothesis through the Student's t-test.

Likewise, the effectiveness of SimCity is more reflected in inferences and argument evaluations, as greater progress was observed during the post-test evaluations compared to other abilities, even resulting in ideal scores for two students in the inference capacity.

On the other hand, the progress in information interpretation was lower compared to other abilities, as it had a lower but achieved progress. This is because the video game initially only presents a tutorial, which provides a broad scale understanding of the theme, resulting in minimal information to interpret. Meanwhile, the use of skills such as deductive reasoning, inferences, and argument evaluation is more necessary for the development of critical thinking, as only the best decisions ensure the achievement of the proposed objectives.

RECOMMENDATIONS

Regarding the SimCity video game, it should be played in a supervised environment to achieve better results, as this ensures the proper use of the video game since, despite not being an online game, uncontrolled use can lead to addictive behavior. Additionally, it is recommended for future research to apply the test to a control group that does not play SimCity to enable a comparison with an experimental group.

The research was conducted with a relatively small sample of students, which could limit the generalization of the results to larger populations.

RESEARCH LIMITATIONS

Limited Duration: The study was carried out over a specific period of time, which might not fully reflect the long-term effects of implementing SimCity on students' critical thinking.

Specific Context: The results could be influenced by the specific conditions and characteristics of the educational institution where the study was conducted, making it challenging to extrapolate the findings to other settings.

Focus on a Single Tool: The research centered on the SimCity game as the sole intervention tool. Including other

tools or pedagogical approaches could have provided a more comprehensive understanding of how critical thinking skills are developed.

Impact of External Factors: Uncontrolled external factors, such as individual student motivation or influences beyond the educational environment, could have influenced the outcomes.

Measurement of Other Variables: The research specifically focused on critical thinking and did not consider the measurement of other skills or competencies that could have been influenced by the game.

Abstract—It is a highly difficult challenge to achieve correlation between images by reliable image authentication and this is essential for numerous therapeutic activities like combining images, creating tissue atlases and tracking the development of the tumors. The separation of healthcare data utilizing deep learning variational autoencoders and conditional neural networks is presented in this research as a paradigm. One of the essential jobs in machine vision is the partitioning of an image. Due to the requirement for low-level spatial data, this assignment is more challenging compared to other vision-related challenges. By utilizing VAEs' capacity to develop hidden representations and combining CNNs in a conditioned environment, the algorithm generates accurate and efficient results for the segmentation. Moreover, to learn the representation of latent space from labelled clinical images, the VAE is trained as part of the system that is suggested. After that, the representations that were learned and real categorizations are used to develop the conditional neural network. Furthermore, the model that has been trained is utilized to accurately separate the areas that are important in brand-new medical images during the inferential stage. Thus, the experimental findings on several healthcare imaging databases show the enhanced precision of segmentation of the structure, highlighting its ability to enhance automated diagnosis and treatment. Henceforth, the suggested Deep Learning and Variational Auto Encoders with Conditional Neural Networks (DL-VAE-CNN) are employed to solve the pixel-level problem of classification that plagues the earlier investigations.

Keywords—Deep learning; variational autoencoders; CNN; medical image segmentation; automated diagnosis and treatment

I. INTRODUCTION

A harmful disease that has one of the highest five-year rates of survival is brain tumor. To determine the kind of brain tumor, neurological specialists frequently employ magnetic resonance imaging (MRI). Despite the amazing advancements in science over the past few years, certain diseases still pose a grave risk to life [1]. Of these, cancer of the brain is among the most aggressive. Brain tumors are the result of untamed, erratic polypeptide development inside and outside the brain's cells. Carcinoma brain tumors are the most dangerous kind, but benign tumors can also exist. Thus, brain cancer is the

common name for the malignant variety of cerebral tumor. A tumor is deemed cancerous if it emerges from the membrane and invades nearby tissues. There are three main types of brain tumors. They are gliomas, pituitary tumors and meningiomas. The pituitary brain tumor is a malignant development of polypeptide that surrounds the pituitary gland, which is a gland that is situated at the bottom of the brain. On the outermost layer of the brain below the skull, meningioma, a benign tumor, is detected. It grows slowly. Amongst all brain tumors, glioma has the greatest fatality rate globally. Pituitary and meningioma tumors can be easily found due to the position of the different types of brain tumors; however, gliomas are challenging to find and study.

The objective of a semantic segmentation is to define the limits of important anatomical or pathological features [2]. The findings can be applied to multisensory image authorization, therapeutic targeting preparation, or operational systems for navigation. Furthermore, the field of imaging in medicine has made extensive use of its versions for segmentation. Due to the increasing adoption of Computed Tomography (CT) and Magnetic Resonance (MR) imaging for medical diagnosis, treatment planning and medical inquiries, image segmentation is necessary for radiological experts to effectively utilize technological advances to assist in helpful assessment as well as the planning of treatment. Delineating anatomical features and other areas of interest (ROI) requires the use of trustworthy methods [3]. Moreover, the utilization of three-dimensional (3D) convolutional neural networks for tissue separation on CT data is very efficient: however the process of creating labels for training is time-consuming. Therefore, the effectiveness of the algorithm that has been trained is hampered by a lack of designations, particularly when it comes to its ability to generalize to everyday clinical practice. Nevertheless, due to the complexity of person's structure and pathological situations, numerous variations and medical conditions are not included in this small training information and that may partially account for the reported discrepancy among efficiency utilizing real-world information and anticipated results [4]. Even if trained on a greater amount of data sets, there will be discrepancies among the model's probability and the real-world probability. These changes

could relate to technological issues, individual traits or more uncommon pathological diseases.

Nevertheless, pathological identification is vital yet a challenging task in the computation and evaluation of clinical images. Although certain tasks such as tumor measurements or therapy surveillance refers to precise segmentation of the conditions and other applications such as assisting the physician with inspecting the image or retrieving visuals with diseases at particular points from a data base and it only require information to identify the illness and an approximate representation of its description [5]. Moreover, researchers concentrate on the identification of images with diseases as another instance of such an application. Furthermore, missing connections among images due to pathological features could result in incorrect identification that is leading to the surrounding regions. In order to estimate the regions of lacking connections, it might be good to incorporate the earlier pathological data into the process of registration. Therefore, variational autoencoders (VAEs) are broad dormant area computational simulations that have proven incredibly effective in a variety of fascinating applications in medical information technology including large-scale physiological order evaluations, incorporated multi-omics data analysis and the design of molecules and protein layout [6].

Additionally, the primary concept behind VAEs is to comprehend the data distributions in a manner that enables the generation of fresh, useful information with higher intra-class variability from the transmitted population. Moreover, deep generative algorithms have received an abundance of interest previously as a result of their numerous information creation capabilities. Therefore, one of the most well-liked methods of dynamic modelling and low-dimensional network representational learning amongst them is the variational autoencoder (VAE). Nowadays, diagnostic imaging is commonly employed to locate tumors and other anomalies in the body of a person for investigation and research. According to the illness type and the patient's body portion, several techniques for medical imaging are employed for diagnostics [7]. To diagnose an anomaly promptly and accurately, scanning needs to be done. The procedures include computer tomography (CT) that is frequently utilized to compare numerous soft tissue types including the liver, the lung cells and lipids, as well as X-ray, that is utilized for recognizing fractures in bones or to identify tissues that are hard. Positron emission tomography (PET) scans and MRI scans are both frequently employed in the recognition of anomalies in the fields of neuroscience, heart disease, malignancy and connective tissue impairment respectively.

Henceforth, a convolution's job is to find structures in the data it receives that represent characteristics that can be detected. Convolutional operations require kernels, also known as filtration systems. A convolution execution is viewed mathematically and the outcome of multiplying an element-by-element portion of the input by the filter adds the outcomes. Until the entire input area has been covered, the procedure continues by moving the location of the fragment as determined by the pace a number of instances. This creates a new result array by computing just one value for every

segment [8]. Furthermore, with pooling, linguistically associated characteristics are combined into one, as opposed to convolutions. In order to decrease the size of the module and create constancy to minor changes and deformations, they are termed as the fixed processes which are not trainable. Hence, CNNs have shown they can produce images of outstanding quality with significantly fewer training time and computing demand. However, fully connected networks can also produce images. Based on vector data an image is used as input, there are two distinct kinds of picture generating algorithms. Though, improvements in technology have made it easier to acquire an image, which has resulted in the production of enormous numbers of pictures with excellent resolution at extremely low costs. The creation of biological algorithms for image processing has significantly improved as a result of this and it has made it possible to create computerized methods for gathering data through visual inspection or assessment [9].

The key contribution of the established outline is updated as follows:

- At first, the data has been collected from the dataset.
- Next, the pre-processing step is completed by Histogram Equalization.
- After that, the segmentation of the image is done by K means clustering.
- Feature extraction process is done by VAE, this will model the data.
- Classification is done by Convolutional Neural Network.
- Finally, the effectiveness of the proposed approach has been acknowledged and compared with various methods to demonstrate its superiority in efficiency and productivity.

The other parts of this research are broken down into the following divisions as an outcome: The related works are revealed in Section II after an in-depth examination. Problem statement is covered in Section III. In Section IV, the specifics of DL-VAE-CNN are examined. The experiment's results are analyzed and reported in detail in Section V. The research's conclusion is found in Section VI.

II. RELATED WORKS

Chen et al.[10] disclosed in his paper that, the development of novel healthcare image processing techniques has attracted a lot of academic curiosity in deep learning, and this deep learning-based algorithm have achieved amazingly well across a range of healthcare scanning applications to enhance illness identification and detection. Considering their achievement, the absence of sizable and thoroughly structured data sets severely hinders the advancement of deep learning algorithms for medical image interpretation. In order to give an in-depth account of using deep learning techniques in diverse medical imaging analysis assignments, recent results are utilized in this study. Moreover, researchers focus in particular on the most recent developments and contributions made by state-of-the-art unsupervised and semi-supervised

deep learning in the analysis of healthcare images that are outlined according to various application circumstances, encompassing categorization, the process of segmentation identification and registration of images. The inaccessibility problem is the research's main flaw.

Considering pixel-based deformation for evaluation, there is currently an exciting opportunity on super-resolution images with bigger up-scaling. This is due to the significant improvement in empirical precision, said by [11]. In addition to the very soften impact, the perceived resemblance is poorly grasped. Because of the development of generative adversarial networks, it is now feasible to super-resolve low-resolution images to produce distribution-sharing photo-realistic images. Generative networks, nevertheless, struggle with mode-collapse issues and unsustainable sampling creation. Owing to the probabilistic dispersion of the high-resolution images produced by the low-resolution images, researchers suggest doing Image Super Resolution via Variational Autoencoders (SR-VAE) learning. Moreover, researchers incorporate the conditioned sampling method to reduce the implicit substructure for rebuilding since Conditional Variational Autoencoders frequently produce blurry images. Thus, researchers estimate the difference among hidden vectors and the conventional Gaussian distribution using KL damage to assess the model's generalization. Finally, with the goal to negotiate the trade-off among perceptions and super-resolution deformation, researchers calculate the reconstructed image using both the revised deeper component reduction among SR and HR images as well as pixel-based reduction.

Uzunova, Ehrhardt, et al. [12] revealed in his paper that, the capacity to decode black box artificial intelligence approaches for analyzing medical images is becoming increasingly important. A system like trained neural network must be prepared to justify its choices and projections in order to be trusted by a physician. In this study, researchers take on the challenge of coming up with logical justifications for the conclusions reached by healthcare image classification algorithms, which are trained to distinguish among various illnesses and tissues that are healthy. Finding out if the results of classification alter when such image areas are removed is a logical way to figure out the fact that areas of the image have an impact on the training classification. This concept can be effectively put into practice if it is expressed as a reduction issue. This is considered as the drawback here. In order to make a difference, researchers define the omission of pathologies as the substitution of those conditions with a substitute produced by variational autoencoders that appears normal. The investigations using a classification neural network on brain lesion MRIs and OCT (Optical Coherence Tomography) images demonstrate that an important substitution of "removed" image areas has a substantial influence on the accuracy of the given interpretations. Thus, the suggested omission procedure has been demonstrated to be effective when contrasted with four other tried-and-true techniques, this approach yields superior outcomes.

Higher dimension hyperspectral images always need more computing, which renders the processing of images difficult said by [13]. Deep learning methods have excelled in many areas of processing images and they are useful for enhancing

the accuracy of classification. The complete extraction of copious spectrum data, including the fusion of geographical and spectral information, still presents significant problems. This research proposes an innovative design for autonomous hyperspectral extraction of features that utilizes the spatially reviewing variation auto encoder (AE). The disadvantage in this situation is that having numerous channels that makes it hard to recognize materials and continually wastes resources. This technique's main idea is to refine the acquired spectral characteristics by collecting spatial characteristics from multiple facets using created systems. A multilayered generator collects spectral characteristics based on the data and standard errors it produces, space-time vectors are created. With the ability to modify the derived mean vectors, multilayered convolutional neural networks and long short-term memory systems are used to gather spatial information utilizing local perception and consecutive perception. Additionally, the suggested function of loss ensures the coherence of the likelihood probabilities of different implicit spatial characteristics that were acquired from the exact same neighbor area. The effectiveness of this approach is enhanced by the incorporation of spatial extraction of features algorithms and deep AE designs, which are built specifically for hyperspectral images.

Peyré and Cuturi [14] disclosed in his paper that, the generative versus discriminatory modelling is a key distinction in the arena of machine learning. In contrast to generative modelling that seeks to tackle the broader issue of developing an aggregate allocation over all the variables, discriminatory modelling strives to train an indicator provided the data available. A model that generates information imitates how data is produced in reality. Moreover, a sound architecture to develop profound latent-variable systems and related interpretation frameworks is provided by variational autoencoders. In this paper, researchers introduce variational autoencoders and discuss several significant improvements.

With multiple uses including scenario comprehension, medical imaging analysis, robotics awareness, surveillance footage, virtual reality and image compression as well, segmenting images is a fundamental subject in the fields of image processing and vision for computers said by [15]. In the fiction, a total of image separation techniques have been generated. There has been a substantial quantity of determinations subsequently focused on improving algorithms for image segmentation using models trained with deep learning as a consequence of the efficacy of deep learning algorithms in an array of visual application. Using a wide range of groundbreaking research on conceptual and instance-level classification such as entirely convolutional pixel-labeling systems, encoder-decoder designs, multi-scale and pyramid-based methods, intermittent systems, graphic focus designs and more researchers offer an in-depth examination of the research available as of the time of publication in this analysis. Moreover, researchers evaluate the similarities, advantages, and disadvantages of different deep learning simulations, look at the most popular data sets, present results, and talk about possible future study avenues in this field. The classification issue is the research's main flaw.

Wang et al. [16] said in his paper that, the healthcare segmentation of images has made widespread usage of deep learning, and many studies have been distributed authenticating the knowledge's presentation in the arena. Deep learning algorithms for medical image segmentation are described in a thorough topical analysis. This essay offers two distinctive contributions. Researchers categorize the most recent literary works according to a multi-level architecture from rough to satisfactory, in contrast to previous studies that explicitly split studies of deep learning on segmenting medical images into multiple categories and present studies thoroughly for each category. Secondly, while unstructured methods have been covered throughout numerous previous surveys and aren't currently in demand, this work concentrates on supervised and poorly supervised learning methods. Also, researchers examine research on supervised learning methods in three areas: the choice of backbone networks, the layout of network wedges, and the enhancement of function losses. Researchers go into the research on poorly supervised learning methods independently for data enhancement, learning by transfer, and dynamic categorization. This study organizes the literatures quite differently from previous investigations. It is also easier for users to comprehend the pertinent justification, which will help them come up with suitable deep learning-based advances for healthcare image segmentation.

III. PROBLEM STATEMENT

Correct interpretation in remedial and diagnosis activities depends on an accurate MRI. The precision of deep learning (DL) rebuilding, is mostly unknown due to underestimating after MRI recording and the over parameterized and opaque characteristics of DL [17]. This work intends to measure the degree of ambiguity in DL model-based image restoration. The present investigation employs an automated medical

image segmentation framework using deep learning and variational autoencoders with conditional neural networks to address this uncertainty problem.

IV. METHODOLOGY

The suggested method is projected in Fig. 1. An automated medical image segmentation framework using Deep Learning and variational autoencoders with conditional neural networks (DL-VAE-CNN) is employed for this method. Regarding the purposes of training and testing, a variety of databases are accessible. To investigate the data and establish accurate labeling in this situation, the Low-Grade Gliomas (LGG) segmentation dataset is used. Furthermore, pre-processing procedures are used to increase the image precision and quality. Fig. 1 shows the proposed DL-VAE-CNN architecture.

A. Data Collection

The data set employed for the testing and training purpose is Low Grade Glioma (LGG) segmentation dataset and the data are obtained from The Cancer Imaging Archive (TCIA) brain MR images. Approximately 120 patients' brain image data is second-hand in this investigation. From that image 60% of images were designated for training process and 60% of images were designated for testing process [18]. It embraces gray scale images.

B. Pre-Processing

Histogram Equalization (HE) is used to improve the quality of images. This is done by levelling, the grey levels of the image pixels so as to continuously rearrange them within the location [19]. The image that was entered as input is turned into a final image after the histogram has been analyzed and normalized for sum computation is shown in Fig. 2.

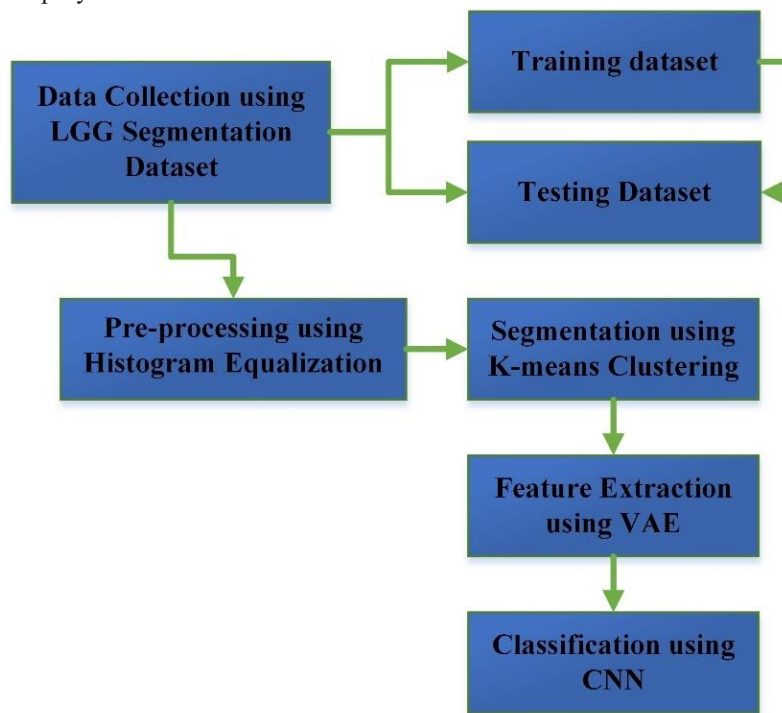

Fig. 1. Proposed DL-VAE-CNN architecture.

Fig. 2. Histogram equalization for healthcare image.

The method for altering the input image into output image using HE is given in the Eq. (1) below:

$$\text{Histogram Equalization image} = \text{round} \left(\frac{\text{CDF of image} - \text{CDF}(\min)}{(W \times H) - \text{CDF}(\min)} \times (G - 1) \right) \quad (1)$$

Where, CDF is denoted as Cumulative Distribution Function; cdf (min) is denoted as the minimal non-zero value of Cumulative Distribution Function; W is denoted as the width of the image; H is denoted as the height of the image; G is denoted as the greyscale of the image.

C. Segmentation using K-Means Clustering

As a key step in many applications, segmentation has grown with the importance in the context of image processing including image recovery, classification, and recognizing objects [20]. After the pre-processing step is finished, the images are separated; then, the suggested method uses K-means clustering to find comparable areas, combine them and examine each segment properly. Moreover, the regions of interest in the grouped images are transformed to RGB layout and each predicted zone of interest is calculated by fusing attributes like color and intensity ratio.

The basic goal of the K-means clustering approach is to transform unknown data set facts into distinct group components. This will address issues related to data science or clustering. This clustering's primary significance is the fact that it will ensure resolution. It will ensure that the centroids' orientations that commence out smoothly. This centroids-calculating method iterates until it determines the right centroid. It will make the clusters of various sizes and forms simpler. The geographic coordinates of the image ought to try to find $i \times j$ first, after which the resulting images should be put together to create the k-clusters. Take into account that P_k is the function that emphasizes the set of data in pixel $h(i, j)$. The Euclidean distance equation is given in Eq. (2):

Step 1: It is necessary to identify the center and the cluster K.

Step 2: For each pixel, the Euclidean distance E_d is indicated and is uttered in the Eq. (2):

$$E_d = ||h(i, j) - P_k|| \quad (2)$$

Step 3: Most of the pixels are assigned to the center point using the E_d foundation.

Step 4: The work allocated to each pixel is completed, and the new center coordinates are recalculated by Eq. (3):

$$P_k = \frac{1}{k} \sum_{j \in P_k} \sum_{i \in P_k} h(i, j) \quad (3)$$

Step 5: Continue doing this until the requirement is met.

Were,

E_d is denoted as the Euclidean distance; P_k is denoted as the group of clusters; $h(i, j)$ is denoted as the information pixel.

D. Feature Extraction using Variational Autoencoder

The procedure of choosing and displaying the most important facts or trends from unprocessed data is referred to as feature extraction [21]. It entails converting the initial information into a more condensed and useful form that may be applied to activities requiring modelling or further analysis. To improve algorithmic performance and efficiency, feature extraction is frequently used in machine learning and pattern recognition applications.

A finding in the latent space can be described probabilistically using a variational autoencoder (VAE) [22]. Thus, a distribution of probability for each underlying feature is employed to create the encoder instead of one that produces only one number to characterize every latent state feature. When using VAE, instances from the identical class wind up very near one another in the coding space, allowing for improved unsupervised representation learning. Moreover, the VAE is used in this research because it is used to detect the abnormalities in the medical images. The architectural diagram of VAE is shown in Fig. 3 and its components are explained below.

1) *Input*: The purpose of the application and area specificity determine the input to a Variational Autoencoder (VAE). The input for image-based VAEs, on the other hand, is frequently made up of images or patches of images.

2) *Encoder*: The encoder converts the input facts into the dormant space parameters associated with the distribution of probabilities. It usually consists of numerous levels of neural networks that gradually reduce the degree of dimensionality of the input data, including convolutional or fully connected layers. A collection of mean and variance vector that reflect the properties of a Gaussian distribution with multiple variables in the dormant space are the encoder's outcome.

Fig. 3. Variational auto encoder architectural diagram.

3) *Latent space*: Every point in the latent space represents a latent code and is a reduced dimensional model of the input data. Moreover, the encoder gains the ability to create latent codes through training that precisely represent significant input data characteristics. Finding a clear format that includes the crucial data while eliminating the background noise is the goal.

4) *Decoder*: A sample of data from the latent space is taken by the decoder, which then transforms it to the initial input region. The decoder is prepared up of a number of strata of neural networks, similarly like the encoder and it gradually up samples the latent code to generate its result. The goal of the decoder's final product is to precisely reproduce the initial input information.

5) *Output*: A reconstruction of the incoming data is exactly the decoder delivers. The reconstruction loss, that gauges the variance among the input and the output, is the parameter that the VAE is trained to reduce. The VAE develops to produce useful reconstruction from latent codes by minimizing this loss of information.

The VAE possess some equations and is given under Eq. (4) and (5),

$$\mu_{pp}, \sigma_{pp} = R_{pp}(B_1, Y); \mu_{pv}, \sigma_{pv} = R_{pv}(B_2, Y) \quad (4)$$

$$\mu_{qq}, \sigma_{qq} = R_{qq}(B_2, Y); \mu_{qv}, \sigma_{qv} = R_{qv}(B_2, Y) \quad (5)$$

Where, R_{pp} and R_{pv} are determined as separators; B_1 and Y are the input and output latent variables; μ_{pp}, σ_{pp} are determined as the structural specific component; μ_{pv}, σ_{pv} are determined as the universal component.

6) *Loss function*: Variational Autoencoders (VAEs) train the algorithm using a loss function [23]. There were four hybrid loss functions are created. They are the classification loss (L_{cls}), the distangled cosine distance loss (L_{cos}), the reconstruct loss (L_{rec}) and the KL loss (L_{kl}). Each functions formula is given under Eq. (6), (7), (8) and (9).

$$L_{kl} = KL(Y_{pp}|N(0,1)) + KL(Y_{pv}|N(0,1)) + KL(Y_{qq}|N(0,1)) + KL(Y_{qv}|N(0,1)) \quad (6)$$

$$L_{rec} = \|B_{1'} - B_1\|_2 + \|B_{2'} - B_2\|_2 \quad (7)$$

$$L_{cos} = \frac{Y_{pv} \times Y_{qv}}{\|Y_{pv}\| \times \|Y_{qv}\|} \quad (8)$$

$$L_{cls} = -x \times \log(D(B_n)) \quad (9)$$

Where, x represents the one hot vector in the truth table.

E. Classification

The Convolution Neural Network (CNN) classifier identify the input images [24]. The visual representations are effectively examined by its multi-layered method, which also eliminates any necessary elements. Four layers make up the CNN classifier: input image, convolutional layer, pooling layer, fully connected layer and output. Through instruction, CNN is the instance that operates the quickest. The magnitudes of all input images' must be of identical dimensions. Fig. 4 depicts the CNN architecture.

7) *Convolutional layer*: After compiling a short sample of images, the convolution layer leverages all of the layers to examine the complexity of every image it gets. It has a strong relationship with the characteristics of the displayed photos. It is given in Eq. (10),

$$X_i = \sum Y_j * M_k + A_s \quad (10)$$

A_s - represents the bias term, $*$ represents the convolutional operator, k^{th} filter convolutes by local region of Y_j called receptive field, X_i is the output of every filter.

8) *Pooling layer*: This layer limits the type and severity that the downstream sampling layer can use. The Pooling layer decreases the quantity of constraints, the feature map's computation quality and scale, training duration and excessive fitting. It is proceeded in Eq. (11) and Eq. (12),

$$\tilde{x}_1 = \frac{x_1 - \tilde{m}}{\tilde{p}} + 1 \quad (11)$$

$$\tilde{x}_2 = \frac{x_2 - \tilde{m}}{\tilde{p}} + 1 \quad (12)$$

X is the output layer; p is the pooling factor.

9) *Fully connected layer*: A fully connected layer has been employed to categorize the images. All of the following convolution layers are placed after the FC layers. Arranging the graphical representation amongst both the input and the output is made simpler by the FC layer. The top layers of the network are fully connected layers. The layer that is completely connected receives its input from the pooling layer's output. The algorithm for the proposed DL-VAE-CNN is assumed below and the flow chart for the planned methodology is displayed in Fig. 5.

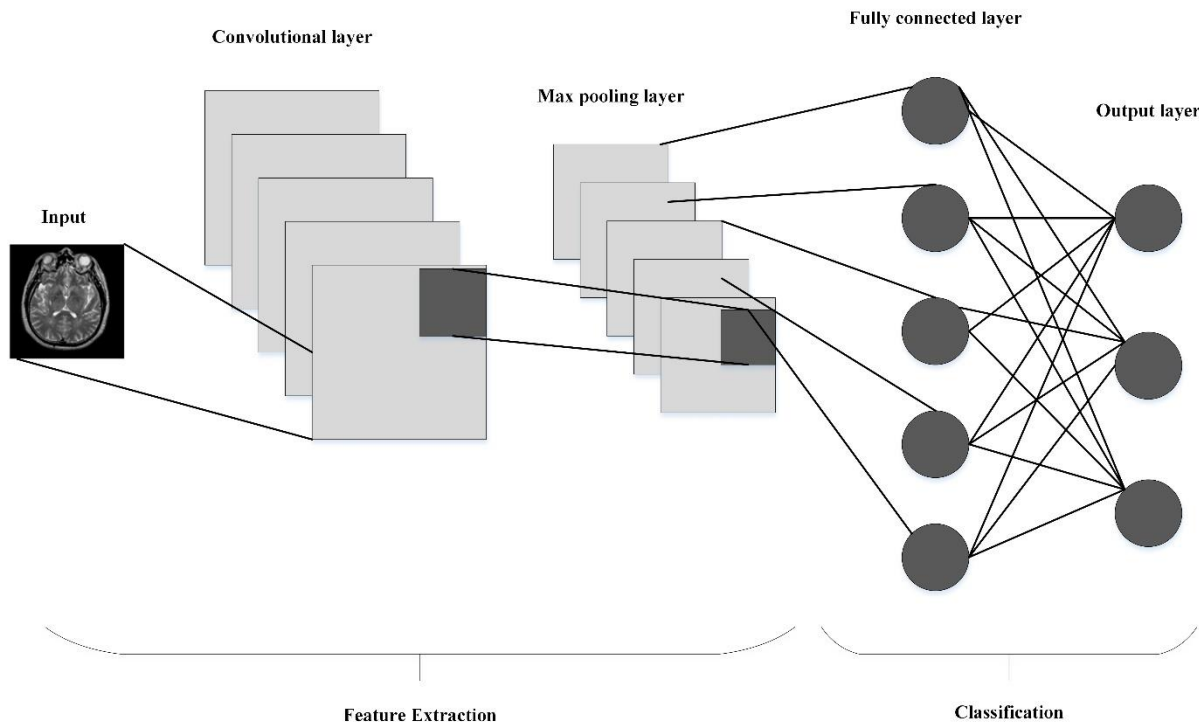

Fig. 4. Convolutional neural network architecture.

The framework's segmentation accuracy, efficiency, and resilience are greatly influenced by the choice and setup of parameters including learning rates, batch sizes, network designs, and hyper parameters. The capacity of the algorithm to handle various medical pictures, account for changes in image quality, and react to certain clinical settings may be dramatically impacted by fine-tuning these parameters. Additionally, the parameter selection may alter the amount of computer resources needed, reducing the algorithm's suitability for use in actual clinical settings. Therefore, further investigation and optimization of these parameters is necessary to guarantee the DL-VAE-CNN algorithm's optimal performance and clinical applicability for automated medical picture segmentation tasks.

Algorithm for DL-VAE-CNN

Input: Medical image of brain

Output: Classification of medical image

$Y = \{Y_1, Y_2, Y_3, \dots\}$ // LGG segmentation dataset

Image Pre-processing

Apply Histogram Equalization to enhance image contrast

Histogram Equalization equation is given by Eqn. (1)

Image Segmentation using K-means Clustering

Detect the cluster centres using the K-means algorithm

Calculate Euclidean distance E_d as in Eqn. (2)

Assign pixels to the nearest cluster centre using E_d

Update cluster centres using the recalculated coordinates in Eqn. (3)

Repeat until convergence

Feature Extraction using VAE

Implement the VAE architecture

Encoder network with Eqn. (4) and (5) for mean and variance

Sample latent variables using the parameterization trick

Decoder network reconstructs the input image

Calculate loss functions as in Eqn. (6), (7), (8), and (9)

Train the VAE using back propagation and optimization

Classification using CNN

Implement a CNN architecture for classification

Apply convolutional layers with Eqn. (11) and (12) for feature extraction

Apply pooling layers to down sample the feature maps

Flatten the feature maps and connect to fully connected layers

Implement softmax layer for multi-class classification

Training and Evaluation

Update VAE and CNN parameters iteratively through back propagation

Monitor loss functions and classification accuracy during training

Inference

Feed an unseen medical image through the trained DL-VAE-CNN framework

The framework will automatically segment and classify the image

Output

The DL-VAE-CNN algorithm outputs a classification label for the input medical image

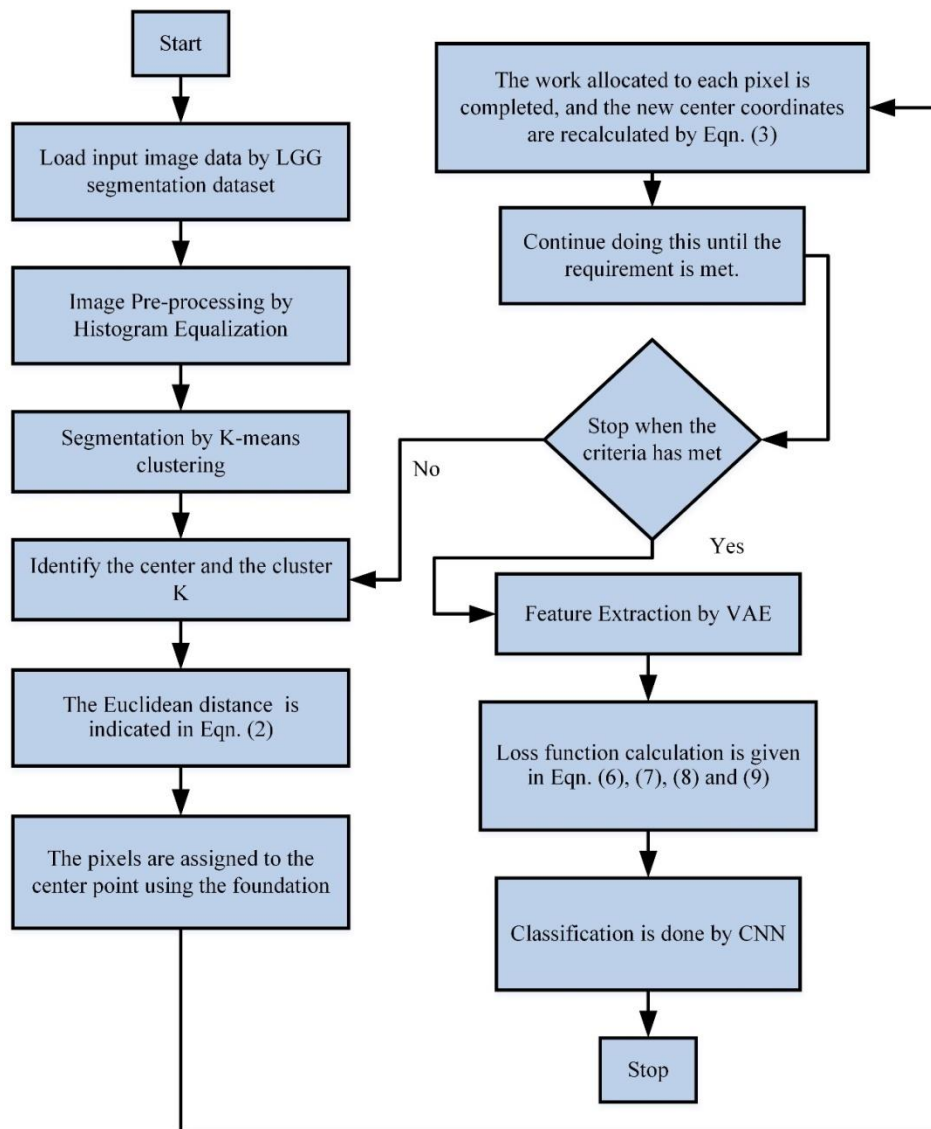

Fig. 5. Flow chart of proposed DL-VAE-CNN model.

V. RESULTS AND DISCUSSIONS

Deep learning, variational autoencoders and conditional neural networks were used to attain highly precise results for segmentation in the suggested automated medical image segmentation methodology. Comparison with existing methods revealed considerable gains in segmentation clarity as indicated by measures like precision, accuracy, fl score and recall. By efficiently employing the previously acquired hidden representations from variational autoencoders, the structure demonstrated adaptability to changes in the quality of images, especially changes in illumination, contrary and noise. By using condensed latent visualizations, the system also showed that it is capable of segmenting data quickly and effectively. The framework's generalization capabilities were especially outstanding because they allowed it to deal with a variety of anatomical characteristics and modalities for medical imaging with ease. These outcomes demonstrate that the suggested methodology for computerized medical image segmentation is efficient.

A. Performance Metrics Evaluation

1) *Accuracy*: The percentage of uniqueness among a calculation and its honest worth is known as accuracy. It is the ratio of precisely intended information to all observations. It is given in Eq. (13).

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (13)$$

2) *Precision*: The level of accuracy or closeness between multiple computations is referred to as precision. The relationship between precision and accuracy reveals how reproducible the measurement is. Its formula is given in Eq. (14).

$$\text{Precision} = \frac{TP}{TP+FP} \quad (14)$$

3) *Recall*: The ratio of all suitable results that were precisely organized by the method used is known as recall. The correct affirmative to true positive and false negative

values proportion is used to characterize it. It is utilized in Eq. (15).

$$\text{Recall} = \frac{TP}{TP+FN} \quad (15)$$

4) *F1-Score*: Precision and recall are mutual to regulate the F1-score. When computing the F1 score, precision and recall levels are extremely important. Its formula is given in Eq. (16).

$$\text{F1-Score} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (16)$$

Table I and Fig. 6 shows the assessment and performance evaluation of Accuracy. When comparing the proposed DL-VAE-CNN methods accuracy parameter with the subsequent three existing methods, i) CNN procedure [25], ii) VGG16-CNN [26], iii) DCNN [27], the proposed algorithm produces greater accuracy of about (99.91%).

TABLE I. COMPARISON TABLE OF PROPOSED METHOD'S ACCURACY WITH EXISTING METHOD'S ACCURACY

Method	Accuracy (%)
CNN	95.44
VGG16-CNN	93.74
DCNN	98.51
Proposed Method	99.91

Fig. 6. Comparison graph of accuracy.

Table II and Fig. 7 shows the assessment and performance evaluation of Precision. When comparing the proposed DL-VAE-CNN methods precision parameter with the subsequent three existing methods, i) CNN procedure [25] ii) VGG16-CNN [26], iii) DCNN [27], the proposed algorithm produces greater precision of about (99.90%).

TABLE II. COMPARISON TABLE OF PROPOSED METHOD'S PRECISION WITH EXISTING METHOD'S PRECISION

Method	Precision (%)
CNN	91
VGG16-CNN	92
DCNN	99.18
Proposed Method	99.90

Precision (%)

B. Discussions

An automated medical image segmentation framework using Deep Learning and Variational Auto Encoder with Convolutional Neural Network is employed in this paper. This section explains about the things that have explained above in a short way. Initially, the introduction, related works, problem statements are completed. Next, it steps on to the methodology part. Here, it discusses about the planned method that is used in this paper. Fig. 1 shows the architectural illustration of the planned DL-VAE-CNN technique. Fig. 2 shows the Histogram Equalization of the healthcare image. Next, the segmentation process takes place and it is done by K-means clustering. It is followed by that the feature extraction has done. Fig. 3 shows the architectural diagram of VAE and followed by that its components are explained. Next, is the classification process. It is done by CNN. Fig. 4 shows the architectural diagram of CNN and followed by that the various layers of CNN has been explained. Next, is the algorithm of DL-VAE-CNN. Fig. (5) shows the flow chart of DL-VAE-CNN. Next, is the results and discussion's part. Here, the various performance metrics like Precision, Accuracy, F1-score and Recall are associated with existing methods to show the planned method will produce better results. Table I gives the comparison table of accuracy and Fig. 6 shows the evaluation graph of accuracy. Table II gives the comparison table of precision and Fig. 7 shows the evaluation graph of precision. Table III gives the comparison table of recall and Fig. 8 shows the evaluation graph of recall. Table IV gives the comparison table of f1-score and Fig. 9 shows the evaluation graph of f1-score. Finally, the discussion part and followed by that conclusion and the future work of the paper is provided.

VI. CONCLUSION AND FUTURE WORK

In the field of medical imaging, establishing trustworthy image authentication to establish correlations between images is a difficult and critical task that is addressed in this study. The generation of tissue atlases, tumor development tracking, and image fusion are just a few therapeutic applications where this association is crucial. The paper offers a fresh method for addressing this issue, using CNNs and VAEs for healthcare data separation as deep learning approaches. Due to the requirement for precise image division at a low-level spatial data level, the fundamental machine vision task of image segmentation is extremely difficult. The suggested approach uses CNNs and VAEs in a conditioned environment to integrate latent representations that VAEs can produce using. When the trained model delineates pertinent regions in recently collected medical images during the inferential step, it successfully demonstrates its efficacy. The experimental findings drawn from several medical imaging databases highlight the increased accuracy in segmenting anatomical entities. This accuracy highlights the substantial contribution of this method to the field of medical imaging and expands the possibilities of automated diagnosis and therapy. The complex pixel-level classification issue, which has presented difficulties in earlier studies, is effectively addressed by the suggested Deep Learning and DL-VAE-CNN approach. This research provides a strong framework that has the potential to revolutionize image identification and segmentation in the context of medical imaging by using the capabilities of deep learning, latent space representation, and conditional neural networks. Deep learning frameworks sometimes require a lot of processing power, both during inference and training. Deploying it in clinical settings with limited resources may thus be difficult.

Abstract—In the process of treating uncertainties of fuzziness and randomness in real regression application, fuzzy random regression was introduced to address the limitation of classical regression which can only fit precise data. However, there is no systematic procedure to identify randomness by means of probability theories. Besides, the existing model mostly concerned in fuzzy equation without considering the discussion on probability equation though random plays a pivotal role in fuzzy random regression model. Hence, this paper proposed a systematic procedure of Naïve Bayes to estimate the probabilities value to overcome randomness. From the result, it shows that the accuracy of Naïve Bayes model can be improved by considering the probability estimation.

Keywords—Naïve Bayes; fuzziness; randomness; probability estimation

I. INTRODUCTION

Fuzziness and randomness are two uncertainties involved in practice of real observation where the statistical data are collected from various measurements. Fuzziness comes from incomplete information while randomness can be related to stochastic variability of all possible outcomes of a situation [1]. In mathematical viewpoint, both uncertainties are merged to formulate a fuzzy random variable by means of assigning probability and fuzzy set theories since possible random outcome have to be described by terms of fuzzy set.

Fuzzy random variable had been studied by many researchers over past few decades. The first introduction of fuzzy random variable concept had been given by Kwarkernaak [2][3]. Since then, different researchers studied fuzzy random variable according to different requirements like by Puri and Ralescu [4] and Liu and Liu [5]. Considering the ability of fuzzy random theories in handling simultaneously fuzzy random uncertainties, this approach can be found in various applications such as in regression analysis. Nather [6] presented fuzzy random variable to deal with regression analysis when the statistical has linguistic data.

In the situation where randomness and fuzziness associated in the regression problems, fuzzy random regression was introduced as a solution for real life regression analysis where the data is not only characterized by imprecision and vagueness but there also exist the formalism of random variables. Fuzzy random regression based on fuzzy random variables with confidence interval was proposed in the framework of real regression analysis where there exist uncertainties [7]. The implementation of this technique as an integral component of regression was successfully in

achieving the objective to estimate weight in the production of oil palm [8]. Considering the statistical used content fuzzy random information, fuzzy random regression was proposed to estimate coefficient in the model setting [9]. In another application, fuzzy random was introduced to build an improved fuzzy random regression for data preparation by using time series data [10][11].

Various applications presented fuzzy random concept due to its capability in handling factors of fuzziness and randomness. However, the existing studies mostly focused on fuzzy equation regarded as the concept of possibility, without considering the probability equation. Moreover, the models are not adequately discussed on how to estimate probability to reduce randomness [6][7][11]. To date, probability theory is used to model randomness which recorded from dispersion of the measured value [9]. Hence, according to abovementioned reason, this study is to present a systematic procedure to control randomness. This study is concentrated on developing a procedure of probability estimation for the fuzzy random data. This systematic procedure is important to guide the identification of probability estimation in defining the fuzzy random data for developing fuzzy random regression model.

The remainder of this paper is arranged as follow. Some preliminaries of uncertainty fuzzy random is covered in Section II. Next section discusses the procedure of proposed method that is Naïve Bayes to estimate random value for fuzzy random regression model. An empirical study is provided in Section IV to illustrate the proposed method. Finally, Section V discusses the conclusion.

II. THEORETICAL BACKGROUND

A. Fuzzy Random

The fuzzy random variable was introduced to present the real situation of uncertainty which comes from vagueness, imprecision, randomness etc. [1]-[5]. The concept of fuzzy random variable has been applied in several papers which combine both fuzzy random uncertainties [18]-[22].

Definition 1. Let Y be the fuzzy variable with possibility distribution μ_Y , the possibility, necessity, and credibility of event $\{Y \leq r\}$ are given in equation as follows.

$$Pos\{Y \leq r\} = \sup \mu_Y(t), t \leq r \quad (1)$$

$$Nec\{Y \leq r\} = 1 - \sup(t), t \geq r \quad (2)$$

$$Cr\{Y \leq r\} = \frac{1}{2}(1 + \sup_{t \leq r} \mu_Y(t) - \sup_{t \leq r} \mu_Y(t)) \quad (3)$$

where,

Cr = Credibility measure

Pos = possibility

Nec = necessity measure

Credibility measure is an average of the possibility and the necessity measures, $Cr\{.\} = (Pos\{.\} + Nec\{.\})/2$. Credibility measure is presented to expand a certain measure of possibility and necessity, which is a sound of aggregate of two cases.

Definition 2: Let Y be a fuzzy variable. Under the assumption that the two integrals are finite, the expected value of Y is defined as follows in (7):

$$E[Y] = \int_0^x Cr\{Y \geq r\}dr - \int_{-\infty}^0 Cr\{Y \leq r\}dr \quad (4)$$

Following from Equation (4), the expected value of Y is defined as

$$E[Y] = \frac{a^l + 2c + a^r}{4} \quad (5)$$

where $Y = (c, a^l, a^r)_T$ is a triangular fuzzy number and c is a center value.

The expected value of the fuzzy variable $X(\omega)$ is denoted by $E[X(\omega)]$ for any fuzzy random variable X on Ω [5]. Thus, the expected value of the fuzzy random variable X is defined as the mathematical expectation of the random variable $E[X(\omega)]$.

Definition 3: Let X be a fuzzy random variable defined on a probability space (Ω, Σ, Pr) with expected value e . The expected value of X is defined in Equation (6) as follows.

$$E[\xi] = \int \Omega [\int_0^\infty Cr\{\xi(\omega) > r\}dr - \int_{-\infty}^0 Cr\{\xi(\omega) \leq r\}dr]Pr(d\omega) \quad (6)$$

The variance of X [7] is defined as Equation (7), respectively.

$$Var[X] = E[(X - e)^2] \quad (7)$$

where $e = E[X]$.

B. Naïve Bayes

The Naïve Bayes is a simplification of Bayes Theorem which is used as a classification algorithm with an assumption of independence among predictors [8]. It is known as 'Naïve' because it assumes that the presence of input features is independent of each other. As the feature of the data points is unrelated to any other, therefore, changing of one input feature may not affect others [9].

The general equation for Bayes [10][11] is given as follows:

$$P(A|B) = \frac{P(A \cap B)}{P(B)} = \frac{P(B|A) \cdot P(A)}{P(B)} \quad (8)$$

where,

$P(A)$ = the probability of A occurring

$P(B)$ = the probability of B occurring

$P(A|B)$ = the probability of A given B

$P(B|A)$ = the probability of B given A

$P(A \cap B)$ = the probability of both A and B occurring

Given A as Hypothesis and B as evidence, the Bayes rules derive the probability of a hypothesis given the evidence. The rule stated the relationship incorporating $P(A)$ distribution in order to generate $P(A|B)$. $P(A)$ is the probability of an event before getting the evidence. The probability of the event based on the current knowledge before an experiment is performed. $P(A|B)$ is called the posterior probability which is calculated by updating the prior probability after taking into consideration new information. Meaning that, the posterior probability is the probability of event A occurring given that even B has occurred.

In this study, the Naïve Bayes theorem was proposed to be used in estimating probability values in constructing confidence intervals for fuzzy random regression model. This probability value is representative of randomness in the fuzzy random regression model. However, most studies [12] – [17] do not clearly describe how to obtain these random values to develop fuzzy random regression models. But these random values are very necessary to manage data that have random and fuzzy uncertainties to create forecasting models. The following section describes the proposed procedure for estimating probabilities for random values using the Naïve Bayes method that will be used to develop a fuzzy random regression prediction model.

III. ESTIMATING PROBABILITIES FOR FUZZY RANDOM REGRESSION PROCEDURE

This section describes the standard procedure to estimate probability value in developing confidence interval for Fuzzy Random Regression model. The procedure uses Naïve Bayes to characterize the random uncertainty.

The procedure for implementing the proposed method can be written in the following to determine the probabilities by using Naïve Bayes.

- Step 1 : Suppose x_n are the fuzzy data. Transform crisp data x_n into fuzzy random data (FRD), c_n, a_n^l, a_n^r
- Step 2 : Estimate probabilities for each FRD by using Naïve Bayes approach based on Equation (8). The fuzzy random data with probabilities can be arranged in the format as in Table I.

TABLE I. DATA FORMAT FOR FUZZY RANDOM DATA

Sample	Input	FRD	Pr
1	X_1	c_1, a_1^l, a_1^r	Pr_1
2	X_2	c_2, a_2^l, a_2^r	Pr_2
...
n	X_n	c_n, a_n^l, a_n^r	Pr_n

Step 3 : Calculate the expected value, $E(x)$ using the center of triangular fuzzy variable with probability which $Pr + Pr = 1$. The formulation to calculate the expected value is shown in Equation (9) as follows:

$$E(x) = Pr_{v_1}.E[x(V_1)] + Pr_{v_2}.E[x(V_2)] \quad (9)$$

Step 4 : Calculate variance, $Var(x)$. Define the variance of x by using Equation (7). The $E[(x(v_1) - E[x])^2]$ should be calculated to obtain the $Var(x)$. The calculation to obtain the variance is based on equation (10) respectively.

$$Var(x) = E[(x(v_1) - E[x])^2].Pr_{v_1} + E[(x(v_2) - E[x])^2].Pr_{v_2} \quad (10)$$

Step 5 : Determine the confidence interval, CI of FRD using Equation (11) as follows.

$$CI = [(E(x) - Var(x)), (E(x) + Var(x))] \quad (11)$$

Step 6 : Estimate coefficient based on confidence interval in Step 5. The coefficient can be obtained using the following linear programming.

$$\min J(\tilde{A}) = \sum_{k=1}^K (\tilde{A}_k^r - \tilde{A}_k^l) \quad \text{subject to} \quad \tilde{A}_k^r \geq \tilde{A}_k^l \quad (12)$$

$$\tilde{Y}_i = \sum_{k=1}^K \tilde{A}_k 1[ex_{ik}, \sigma x_{i1}] \supseteq_h I[eY_i, \sigma Y_i] \quad i = 1, \dots, n; 1, \dots, K,$$

The fuzzy random regression [7] prediction model was introduced with the advantage of handling data that had dual uncertainties namely fuzziness and randomness. Although this model is good for handling uncertainties, there are constraints for the industry to apply this model in the real world if there is no complete method specially to transform normal data into an acceptable form of data by this model. Then the standard method that has been tested has been introduced [18] – [20]. However, some of them focus on methods of managing fuzzy data only. Thus, this study specializes in the development of standard procedures for determining random value for the development of fuzzy random models.

IV. NUMERICAL EXPERIMENT

In this section, a numerical experiment has demonstrated to visualize how the probabilities are estimated using proposed procedure in order to handle randomness. The fuzzy random input and output data are taken from [7] in Table II and Table III, respectively.

Table II shows the fuzzy random input data with two attributes (X_1, X_2). Each attribute has four samples which

divided into center, left and right (c, a^l, a^r). Table III shows the fuzzy random output data with four samples of attribute Y and divided into (c, a^l, a^r).

TABLE II. FUZZY RANDOM INPUT DATA

Sample	X	FRD1			FRD2		
		c	a ^l	a ^r	c	a ^l	a ^r
1	X1 ₁	3	2	4	4	3	5
2	X1 ₂	6	4	8	8	6	10
3	X1 ₃	12	10	14	14	12	16
4	X1 ₄	14	12	16	16	14	18
Sample	X	FRD1			FRD2		
		c	a ^l	a ^r	c	a ^l	a ^r
1	X2 ₁	2	1	3	4	3	5
2	X2 ₂	3	2	4	4	3	5
3	X2 ₃	12	10	16	14	12	16
4	X2 ₄	18	16	20	21	20	22

TABLE III. FUZZY RANDOM OUTPUT DATA

Sample	X	FRD1			FRD2		
		c	a ^l	a ^r	c	a ^l	a ^r
1	Y ₁	14	10	16	18	16	20
2	Y ₂	17	16	18	20	18	22
3	Y ₃	22	20	24	26	24	28
4	Y ₄	32	30	34	36	32	40

By using the values in fuzzy random data, the probabilities for each value can be determined. Using calculation in Equation (8), the probabilities for each fuzzy random data are estimated.

$$P(A|B) = \frac{P(B|A).P(A)}{P(B)}$$

Assuming each feature variable is independent of the rest, calculate the probability of each separate feature given of each class. First step is finding the prior probability of each class in X_1 . Given sample X_1 has four variables ($X_{1_1}, X_{1_2}, X_{1_3}, X_{1_4}$). Each variable has one event occur. In mathematical, the probability can be represented as $P(X_{1_1}) = \frac{1}{4} = 0.25$ which mean the occurring event happening is likely one time by considering the total of potential outcome. Thus, the prior probability of each class in X_1 is as follows.

$$\begin{aligned} P(X_{1_1}) &= \frac{1}{4} = 0.25 \\ P(X_{1_2}) &= \frac{1}{4} = 0.25 \\ P(X_{1_3}) &= \frac{1}{4} = 0.25 \\ P(X_{1_4}) &= \frac{1}{4} = 0.25 \end{aligned} \quad (13)$$

Following the calculation in Equation (13), find probabilities for input X_2 and output Y . The result for each probability is tabulated in Table IV and Table V, respectively.

Table IV and Table V show the probabilities for fuzzy random input and output data. The probabilities for FRD1, Pr_1 are determined using calculation in (13), with value 0.25. Note that, probability is counted by $Pr_1 + Pr_2 = 1$. Therefore, the probability value for FRD2, Pr_2 is 0.75. These probabilities are used to calculate the expected value $E(x)$ using the center of triangular fuzzy variable as in Equation (9). Based on these values of $E(x)$, variance $Var(x)$ can be calculated using Equation (10). The results for $E(x)$ and $Var(x)$ are tabulated in Table VI respectively.

TABLE IV. FUZZY RANDOM DATA WITH PROBABILITIES FOR INPUT DATA

Sample	X1	FRD1				FRD 2			
		c	a ^l	a ^r	Pr ₁	c	a ^l	a ^r	Pr ₂
1	X1 ₁	3	2	4	0.25	4	3	5	0.75
2	X1 ₂	6	4	8	0.25	8	6	10	0.75
3	X1 ₃	12	10	14	0.25	14	12	16	0.75

3	X2 ₃	12	10	16	0.25	14	12	16	0.75
4	X2 ₄	18	16	20	0.25	21	20	22	0.75

TABLE V. FUZZY RANDOM DATA WITH PROBABILITIES FOR OUTPUT DATA

Sample	Y	FRD1				FRD 2			
		c	a ^l	a ^r	Pr ₁	c	a ^l	a ^r	Pr ₂
1	Y ₁	14	10	16	0.25	18	16	20	0.75
2	Y ₂	17	16	18	0.25	20	18	22	0.75
3	Y ₃	22	20	24	0.25	26	24	28	0.75
4	Y ₄	32	30	34	0.25	36	32	40	0.75

Table VI shows the value of expectation and variance for the input output fuzzy random data. The expectation and variance values are used to find confidence interval by using Equation (11). The results are tabulated in Table VII.

Table VII shows the confidence interval result for fuzzy random input and output data. In this study, the confidence interval was considered as one-sigma confidence ($1 \times \sigma$) interval of each fuzzy random variable. The combination of expectation and variance of fuzzy random variable was induced to define the confidence-interval-based-inclusion [7]. Based on this confidence interval, a fuzzy random regression model can be formulated using mathematical linear programming as in Equation (12) in order to define coefficient.

TABLE VI. EXPECTATION AND VARIANCE OF THE DATA

i	Ex ₁ , V _{x1}		Ex ₂ , V _{x2}		E _y , V _y	
1	3.75	0.5729	3.5	1.2031	16.2	10.6688
2	7.5	2.2917	3.75	0.5729	17.6	1.8113
3	13.5	2.2917	13.63	3.467	24.8	4.8125
4	15.5	2.2917	20.35	3.7138	34.4	4.8125

TABLE VII. CONFIDENCE INTERVAL FOR FUZZY RANDOM INPUT OUTPUT DATA

i	X1	X2	Y
1	[3.177, 4.323]	[2.297, 4.703]	[5.531, 26.869]
2	[5.208, 9.792]	[3.177, 4.323]	[15.789, 19.411]
3	[11.208, 15.792]	[10.158, 17.092]	[19.988, 29.613]
4	[13.208, 17.792]	[16.536, 23.964]	[29.588, 39.213]

$$\min J(\tilde{A}) = \sum_{k=1}^K (\tilde{A}_k^r - \tilde{A}_k^l)$$

subject to

$$\tilde{A}_k^r \geq \tilde{A}_k^l$$

$$\tilde{Y}_i = \sum_{k=1}^K \tilde{A}_k 1[ex_{ik}, \sigma x_{i1}] \supseteq_h I[ey_i, \sigma Y_i]$$

$$i = 1, \dots, n; 1, \dots, K,$$

$$\min = (a_1^r - a_1^l) + (a_2^r - a_2^l);$$

$$a_1^l \leq a_1^r;$$

$$3*a_1^l + 2*a_2^l \leq 3.177075;$$

$$6*a_1^l + 4*a_2^l \leq 5.208325;$$

$$12*a_1^l + 10*a_2^l \leq 11.208333;$$

$$14*a_1^l + 12*a_2^l \leq 13.208333;$$

$$3*a_1^r + 5*a_2^r \geq 4.322925;$$

$$6*a_1^r + 10*a_2^r \geq 9.791675;$$

$$12*a_1^r + 16*a_2^r \geq 15.791667;$$

$$14*a_1^r + 18*a_2^r \geq 17.791667;$$

$$a_1^l \geq 0; a_1^r \geq 0;$$

$$a_2^l \geq 0; a_2^r \geq 0; \tag{14}$$

The linear programming of the fuzzy random regression was applied to the dataset as shown in Equation (14). This linear programming is performed to generate the coefficient value as tabulated in Table VIII respectively.

TABLE VIII. COEFFICIENT OF THE FUZZY RANDOM INPUT OUTPUT DATA

Item	Coefficient		Width
	A1	A2	
Y	0.00	0.943	0.79
X1	0.00	1.044	0.113
X2	0.00	1.052	0.073

The coefficient result for the fuzzy random input output data as tabulated in Table VIII shows the values estimated from fuzzy random regression. The attribute which has larger coefficient value is more significant to the total evaluation. In this result, it shows that the evaluation of attributes A1 and A2 indicate the A2 is significant to the total evaluation due to its higher coefficient. The model had a wider coefficient width because of the consideration of the confidence interval in its evaluation. The width in this evaluation plays an important role, as it reflects natural human judgment.

A greater breadth denotes the evaluation's ability to capture more data while using fuzzy judgments. Mean Square Error (MSE) can be defined using the estimated coefficient obtained from the fuzzy random regression and the model in Equation (14). In Table IX, the mean squared error (MSE) is calculated to compare the outcomes of the existing approach and the suggested method.

TABLE IX. MSE RESULT

Watada [7]	Naïve Bayes
196.6845	193.8861

Table IX shows the MSE result using Naïve Bayes approach as compared with current method by Watada *et al.*, [7]. In comparison study, the testing data derived from proposed method have a close majority of the expectation and variance result when compare to [7]. As the majority of the expectation and variance have been captured, therefore, both confidence intervals from testing and current model are quite similar. The evaluation of MSE was considered using current model and testing. From the result shown in Table IX, MSE of the proposed model is smaller than the other. This MSE implies that the prediction error can be reduced significantly.

The outcomes of the experiment demonstrate that the suggested approach is highly accurate at estimating the expectation, variance, and confidence interval of the data. Additionally, it is more accurate than the present technique and has a lower MSE, proving its superiority. These findings imply that the suggested approach can estimate probability and circumvent data unpredictability.

V. CONCLUSION

In this paper, a procedure based on Naïve Bayes is proposed to treat data which contain uncertainty known as fuzzy random data. The uncertainty data of randomness was handled by implementing the Naïve Bayes method to estimate probability. As to demonstrate the potential application of proposed method for accessing estimation, an experimental study using fuzzy random data is illustrated and the results are compared with the result of current method. The result shows that the proposed method has majority close of the

expectation, variance and confidence interval. Further, it also has better MSE result than the current method. The result demonstrated that the proposed model is capable to estimate probability and overcome randomness of the data.

A New Approach of Hybrid Sampling SMOTE and ENN to the Accuracy of Machine Learning Methods on Unbalanced Diabetes Disease Data

Hairani Hairani, Dadang Priyanto

Department Computer Science, Bumigora University, Mataram, Indonesia

Abstract—The performance of machine learning methods in disease classification is affected by the quality of the dataset, one of which is unbalanced data. One example of health data that has unbalanced data is diabetes disease data. If unbalanced data is not addressed, it can affect the performance of the classification method. Therefore, this research proposed the SMOTE-ENN approach to improving the performance of the Support Vector Machine (SVM) and Random Forest classification methods for diabetes disease prediction. The methods used in this research were SVM and Random Forest classification methods with SMOTE-ENN. The SMOTE-ENN method was used to balance the diabetes data and remove noise data adjacent to the majority and minority classes. Data that has been balanced was predicted using SVM and Random Forest methods based on the division of training and testing data with 10-fold cross-validation. The results of this study were Random Forest method with SMOTE-ENN got the best performance compared to the SVM method, such as accuracy of 95.8%, sensitivity of 98.3%, and specificity of 92.5%. In addition, the proposed method approach (Random Forest with SMOTE-ENN) also obtained the best accuracy compared to previous studies referenced. Thus, the proposed method can be adopted to predict diabetes in a health application.

Keywords—SMOTE-ENN; data imbalance; SVM; random forest; health dataset

I. INTRODUCTION

Machine learning methods on health data, especially disease classification, have been widely practiced. The problem is that the dataset's quality influences the performance of machine learning methods in disease classification. In general, most health data, especially disease data, have data imbalance problems, such as diabetes [1], heart [2][3], and breast cancer [4]. If the problem of unbalanced data in health datasets is not addressed, it can affect the performance of classification methods, making the prediction results biased. With balanced data, classification methods can easily predict the majority class more accurately than the minority class. Therefore, this research seeks a method approach for handling unbalanced data on health data, especially diabetes disease data, so that classification methods achieve optimal accuracy.

Some previous studies have predicted diseases using various approaches, such as research [5] using the logistic regression machine learning method with SMOTE for predicting diabetes with an accuracy of 77%, precision of 75%, recall of 77%, and F1-score 76%. Research [6] uses forward

chaining and certainty factor methods to diagnose types of rheumatic diseases with an accuracy of 80%. Research [7] uses the SMOTE method approach with machine learning algorithms such as Xgboost, Random Forest, KNN, Logistic regression, Decision Tree, Naive Bayes, and XGBoost for liver disease prediction with an accuracy of 80%. Based on the results of their research, the XGBoost method with SMOTE produces better performance than other methods, with accuracy of 93%, Recall of 97%, Precision of 92%, and F1-Score of 94%.

Research [4] uses a hybrid sampling method (SMOTE and SpreadSupsample) with several machine learning methods such as Naive Bayes, Decision Tree C4.5, and Random Forest for breast cancer disease prediction. His research shows that the use of hybrid sampling can improve the performance of the machine learning methods used, such as accuracy, ROC, Recall, and Precision. Research [8] uses hybrid sampling (SMOTE-ENN) with the Artificial Neural Network (ANN) method for the identification of Marburg virus inhibitors. The results show that using hybrid sampling (SMOTE-ENN) can effectively increase the ANN method's accuracy. Research [9] uses a hybrid sampling approach (M-SMOTE-ENN) with the Random Forest calcification method to solve unbalanced data problems in health data. The results show that using hybrid sampling (M-SMOTE and ENN) can improve the performance of the Random Forest method better than oversampling SMOTE and ENN individually without being combined.

Research [10] uses machine learning methods such as KNN, Decision Tree, Naïve Bayes, Random Forest, SVM, and histogram-based gradient boosting (HBGB) for diabetes prediction. The results show that the HBGB method performs better than other methods, with an accuracy of 92%. Research [11] compares several classification methods in machine learning for diabetes detection. The results show that the XGBoost method has better accuracy than other models, which is 94%. Research [12] uses a combination feature selection approach with several machine learning classification methods for diabetes detection. The results show that feature selection methods can improve the classification methods' accuracy. Random Forest is the method that gets the best accuracy, with a feature selection of 80%.

Research [13] uses a hybrid sampling approach (SMOTE-Tomek Link) with the Random Forest method for predicting diabetes. At the same time, the results show that the hybrid sampling method (SMOTE-Tomek Link) increases the

accuracy of the Random Forest method compared to SMOTE and Tomek Link separately. Research [14] predicts the risk of diabetes using a hybrid sampling approach (SMOTE-Tomek Link) with the ANN method. The results show that using hybrid sampling SMOTE-Tomek Link is better than SMOTE alone, with an accuracy of 92%.

Based on previous research, a gap can be improved; that is, the accuracy obtained in predicting diabetes is not optimal, so it can still be increased. Based on research [13][14], the highest accuracy is 92% using a hybrid sampling SMOTE-Tomek link with ANN. Therefore, this study proposes a hybrid sampling SMOTE-ENN approach to improving performance, such as accuracy, sensitivity, and specificity in SVM and Random Forest classification methods. This research adopts the use of the SMOTE-ENN hybrid sampling method, as it performs better than SMOTE-Tomek Links [15][16].

The purpose of this study is the implementation of hybrid sampling SMOTE-ENN to increase the accuracy of the machine learning method in predicting unbalanced diabetes data. This study consists of an introduction structure, research method, results and discussion, and conclusion.

II. RESEARCH METHOD

This study has several stages shown in Fig. 1. The first stage is the collection of diabetes disease datasets obtained from the Uci Repository with a total dataset of 768 instances and ten attributes. Attributes owned by the Pima Indian Diabetes contain datasets such as Pregnancies, Glucose, Blood Pressure, Skin Thickness, Insulin, BMI, Diabetes Pedigree Function, Age, and Outcome (Class). The dataset used has a total of two class categories, namely positive diabetes and negative diabetes.

The second stage is data preprocessing which is useful for improving the quality of the dataset used, such as removing missing values, outliers, and unbalanced data in the data preprocessing phase using data sampling to balance the data in the diabetes class, where there is a smaller number of positive classes (minority classes) compared to negative classes (majority classes) so that it can affect the performance of the classification method. If unbalanced diabetes data is not handled, the classification method will find it easier to classify the majority (negative) class than the minority (positive) class. In other words, the classification method makes biased prediction results.

This research uses several data sampling methods such as SMOTE, ENN, and hybrid sampling SMOTE-ENN. The SMOTE-ENN method combines SMOTE oversampling and ENN undersampling. The way the SMOTE-ENN method works is to add artificial data to the minority class by interpolating the original data using SMOTE so that the resulting artificial data is balanced. After the data is balanced, samples from the majority class adjacent to the minority class are removed by undersampling ENN. The use of the SMOTE-ENN method can reduce data overfitting and noise. The method of SMOTE-ENN can be shown in Fig. 2.

Fig. 1. Research stages.

Fig. 2. SMOTE-ENN process.

After the data sampling, the next step is to divide the training and testing data using 10-fold cross-validation. 10-fold cross-validation works by dividing the data into ten groups, and each group can be used as training and testing data alternately. The illustration of how 10-fold cross-validation works is shown in Fig. 3.

Fig. 3. Process of 10-Fold cross validation.

Data divided into 10 folds are then used to implement classification methods using SVM and Random Forest methods. The classification results of the SVM and Random Forest methods are tested for performance based on accuracy, sensitivity, and specificity using the confusion matrix table. The accuracy, sensitivity, and specificity formulas use Equations (1), (2), and (3), respectively [17] [13].

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

$$Sensitivity = \frac{TP}{TP+FN} \quad (2)$$

$$Specificity = \frac{TN}{TN+FP} \quad (3)$$

III. RESULT AND DISCUSSION

This section contains the results that have been achieved at each stage. The first stage is the collection of diabetes disease datasets obtained from the Uci Repository with a total of 768 instances and ten attributes. After data collection, the next step is data preprocessing. In the data preprocessing stage, it is used to improve data quality in diabetes disease data to optimize the classification method's performance.

There are unbalanced data in the data used so that it can reduce the performance of the classification method. The number of negative classes is 500 instances (majority class), and positive classes are 268 instances (minority class). This research proposes several sampling methods to balance the data: the SMOTE, ENN, and SMOTE-ENN hybrid. The amount of data generated by each sampling method is shown in Table I.

TABLE I. DATA DISTRIBUTION BEFORE AND AFTER SAMPLING

Sampling Method	Positive Class	Negative Class
Original Data	268	500
SMOTE	500	500
ENN	268	240
SMOTE-ENN	303	227

In Table I, the SMOTE method produces a balanced class by adding the minority class so that the number equals the majority class. However, the SMOTE method has the disadvantage of producing noise in the new data generated. The Edited Nearest Neighbor (ENN) method balances the data by removing the majority class (positive class) adjacent to the minority class so that it can reduce data noise in the dataset, while the SMOTE-ENN method makes the data balanced by

combining the SMOTE and ENN methods. The SMOTE method is used to add new data to the minority class based on the nearest neighbor. After the SMOTE results are balanced, the removal of adjacent data between the majority and minority classes is carried out to minimize data noise.

The data balanced using the sampling method is then divided into training and testing data using 10-fold cross-validation. Diabetes data is divided into training and testing, then implementing Random Forest and SVM classification methods for diabetes prediction. The classification results of the SVM and Random Forest methods are tested for performance based on accuracy, sensitivity, and specificity using the confusion matrix table. The confusion matrix results are obtained using the SVM method with original data (see Fig. 4), SMOTE result data (see Fig. 5), ENN method result data (see Fig. 6), and SMOTE-ENN data results (see Fig. 7).

Based on Fig. 4, the SVM method correctly classifies negative classes in as many as 438 instances, correctly classifies positive classes in as many as 151 instances, incorrectly classifies negative classes in as many as 62 instances, and incorrectly classifies positive classes in as many as 117 instances. The performance of the SVM method with the original data obtained an accuracy of 76.7%, a sensitivity of 56.3%, and a specificity of 87.6%.

Based on Fig. 5, the SVM method with SMOTE can correctly classify negative classes with 387 instances, correctly classify positive classes with 354 instances, incorrectly classify negative classes with 113 instances and incorrectly classify positive classes with 146 instances. The performance of the SVM method with SMOTE has an accuracy of 74.1%, sensitivity of 70.8%, and specificity of 77.4%.

Based on Fig. 6, the SVM method with ENN can correctly classify negative classes in as many as 207 instances, correctly classify positive classes in as many as 229 instances, incorrectly classify negative classes in as many as 33 instances and incorrectly classify positive classes in as many as 39 instances. The performance of the SVM method with ENN has an accuracy of 85.8%, sensitivity of 85.4%, and specificity of 86.3%.

Fig. 4. SVM results with original data.

Fig. 5. SVM results with result data.

Fig. 6. SVM results with ENN result data.

Fig. 7. SVM results with SMOTE-ENN result data.

Based on Fig. 7, the SVM method with SMOTE-ENN can classify negative classes correctly in as many as 201 instances, classify positive classes correctly in as many as 276 instances, classify negative classes incorrectly in as many as 26 instances, and classify positive classes incorrectly as many as 27 instances. The performance of the SVM method with SMOTE-ENN gets an accuracy of 90%, sensitivity of 91.1%, and specificity of 88.5%.

Then the confusion matrix results using the Random Forest method with original data (See Fig. 8), SMOTE data (See Fig. 9), ENN data (See Fig. 10), and SMOTE-ENN data (See Fig. 11).

Based on Fig. 8, the Random Forest method correctly classifies negative classes in as many as 429 instances, correctly classifies positive classes in as many as 156 instances, incorrectly classifies negative classes in as many as 72 instances, and incorrectly classifies positive classes in as many as 112 instances. The performance of the Random Forest method with the original data obtained an accuracy of 76.1%, sensitivity of 58.2%, and specificity of 85.8%.

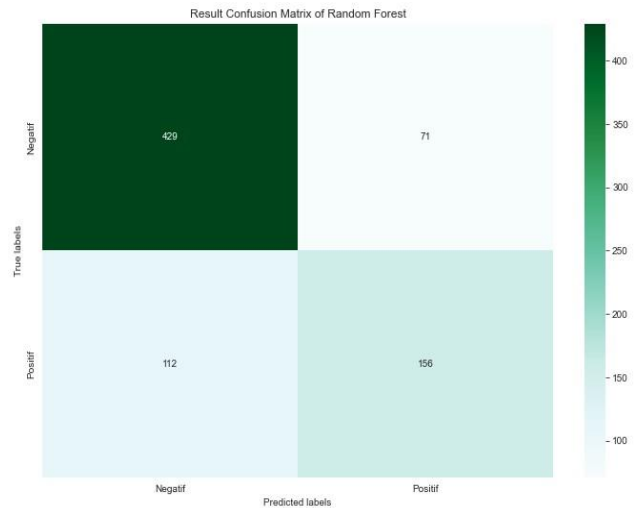

Fig. 8. Random forest results with original data.

Fig. 9. Random forest results with SMOTE.

Fig. 10. Random forest results with ENN.

Fig. 11. Random forest results with SMOTE-ENN.

Based on Fig. 9, the Random Forest method with SMOTE can correctly classify negative classes in as many as 391 instances, correctly classify positive classes in as many as 430 instances, incorrectly classify negative classes in as many as 109 instances and incorrectly classify positive classes in as many as 70 instances. The performance of the Random Forest method with SMOTE gets an accuracy of 82.1%, sensitivity of 86%, and specificity of 78.2%.

Based on Fig. 10, the Random Forest method with ENN can correctly classify negative classes in as many as 210 instances, correctly classify positive classes in as many as 232 instances, incorrectly classify negative classes in as many as 30 instances and incorrectly classify positive classes in as many as 36 instances. The performance of the Random Forest method with ENN has an accuracy of 87%, sensitivity of 86.6%, and specificity of 87.5%.

Based on Fig. 11, the Random Forest method with SMOTE-ENN can correctly classify negative classes in as many as 210 instances, correctly classify positive classes in as many as 298 instances, incorrectly classify negative classes in as many as 17 instances and incorrectly classify positive classes as many as 5 instances. The performance of the

Random Forest method with SMOTE-ENN gets an accuracy of 95.8%, sensitivity of 98.3%, and specificity of 92.5%.

The results can be seen in Table II to simplify the understanding of the research results achieved based on several experiments that have been carried out.

TABLE II. CLASSIFICATION METHOD PERFORMANCE RESULTS WITH DATA SAMPLING APPROACH

	Accuracy	Sensitivity	Specificity
SVM	76,7%	56,3%	87,6
SVM with SMOTE	74,1%	70,8%	77,4%
SVM with ENN	85,8%	85,4%	86,3%
SVM with SMOTE-ENN	90%	91,1%	88,5%
Random Forest	76,1%	58,2%	85,8%
Random Forest with SMOTE	82,1%	86%	78,2%
Random Forest with ENN	87%	86,6%	87,5%
Random Forest with SMOTE-ENN	95,8%	98,3%	92,5%

Based on Table II, the Random Forest method with SMOTE-ENN produces the highest performance compared to SVM, with an accuracy of 95.8%, sensitivity of 98.3%, and specificity of 92.5%. Furthermore, the approach using the SMOTE-ENN sampling method resulted in better average performance than the SMOTE and ENN methods separately, such as accuracy, sensitivity, and specificity. The SMOTE-ENN sampling method is better than SMOTE and ENN separately because it can minimize noise data in the artificial data produced. The noise data in this context is the minority class data that is close to the majority class, so the classification method makes biased predictions. Besides that, using hybrid sampling by combining oversampling and undersampling methods in solving unbalanced data performs better than oversampling without undersampling [18]. SMOTE-ENN hybrid sampling in this study can significantly improve the sensitivity performance [19][20]. In order to see that the method proposed in this study is better than some related previous studies, the following comparison of the results can be seen in Table III.

TABLE III. RESULTS COMPARISON WITH PREVIOUS RESEARCH

Previous Studies	Methods	Scope of Study	Accuracy
Hairani et al. [13]	Random Forest and SMOTE-Tomek Links	Diabetes Disease	86,4%
ElSeddawy, et al. [14]	ANN + Gridsearch + SMOTE		92%
Sabhita et al. [21]	SVM + RFE + SMOTE		82%
Abdullah, et al. [22]	Random Forest + SMOTE		83%
Ijaz et al. [23]	DBSCAN + SMOTE + Random Forest		83,6%
Butt et al. [24]	LSTM		87,3%
Proposed Method	Random Forest and SMOTE-ENN		95,8%

IV. CONCLUSION

Based on the research results obtained using the SVM and Random Forest methods combined with the SMOTE, ENN, and hybrid SMOTE-ENN sampling methods, the Random Forest method with SMOTE-ENN produces better performance than the SVM method based on an accuracy of 95.8%, sensitivity of 98.3%, and specificity of 92.5% in diabetes prediction. Moreover, it can also be concluded that the SMOTE-ENN sampling method produces better performance than the SMOTE method without ENN in the results of the classification method used. Future researchers are suggested to use the ensemble learning method to improve the performance of the classification method.

An Ensemble Load Balancing Algorithm to Process the Multiple Transactions Over Banking

Raghunadha Reddi Dornala
Cloud Architect, USA

Abstract—The banking industry has been transformed by cloud computing, which has provided scalable and cost-effective solutions for managing large volumes of transactions. However, as the number of transactions grow, the need for efficient load-balancing algorithms to ensure optimal utilization of cloud resources and improve system performance becomes critical. This paper proposes an ensemble cloud load-balancing (ECBA) algorithm specifically designed to process multiple banking transactions. The proposed algorithm combines the strengths of several load-balancing techniques to achieve a balanced distribution of transaction loads in various cloud servers. It considers factors such as transaction types, server capacities, and network conditions to make intelligent load distribution decisions. The algorithm dynamically adapts to changing workload patterns and optimizes resource allocation by leveraging machine learning and predictive analytics. A simulation environment that mimics the banking system's transaction processing workflow is created to evaluate the performance of the ensemble load balancing algorithm. Extensive experiments with various workload scenarios are conducted to assess the algorithm's effectiveness in load balancing, response time, resource utilization, and overall system performance. The results show that the proposed ECBA outperforms traditional banking load-balancing approaches. It reduces response time, improves resource utilization, and ensures every server is adequately funded with a few transactions. The algorithm's adaptability and scalability make it well-suited for handling dynamic and fluctuating workloads, thus providing a robust solution for processing multiple transactions in the banking sector.

Keywords—Cloud computing; load balancing; ensemble algorithm; banking; transaction processing; resource utilization; response time; scalability

I. INTRODUCTION

Load balancing techniques are critical for ensuring efficient resource utilization and maintaining optimal performance in cloud computing environments [1] [2]. Cloud computing provides users with vast computational resources and services. Still, the dynamic nature of cloud environments, the variability of workloads, and the scale of resources present several load-balancing challenges. This section investigates the issues and challenges associated with cloud computing load-balancing techniques. Discuss the complexities introduced by cloud systems' distributed nature, workload variability, scalability, and fault tolerance and the importance of ensuring fairness and resource utilization [3]. Understanding these difficulties is critical for developing effective load-balancing mechanisms in cloud environments. Cloud computing environments typically comprise several

geographically dispersed data centers or clusters [4]. Managing the load across these disparate resources is a difficult task. Load-balancing algorithms must consider network latency, bandwidth constraints, and the availability of resources across multiple locations. Coordination of workload distribution and efficient resource utilization in such environments is a significant challenge [5].

Because of the dynamic nature of user demands, cloud systems experience highly variable workloads. The load on cloud resources can fluctuate dramatically, necessitating real-time load-balancing techniques. Predicting and managing these workload variations is critical to avoid resource underutilization or overload situations. Load-balancing algorithms must consider historical and real-time workload data to make intelligent workload distribution decisions [6]. Cloud computing is intended to scale horizontally, allowing for adding or removing resources in response to demand. Load balancing techniques must be able to adjust workload distribution as resources scale up or down dynamically [7].

Furthermore, cloud systems are vulnerable to failures and faults. Load balancers should be fault-tolerant, detecting and redirecting workloads away from failed or degraded resources to ensure high availability and reliability. Load-balancing algorithms should strive for equity and fair resource distribution among users or applications. Maintaining user satisfaction and avoiding performance bottlenecks requires ensuring each user or application receives a fair share of resources. Balancing workload distribution while considering workload priorities, user requirements, and resource constraints, can be difficult.

In the fast-paced world of banking and finance, effective transaction management is critical for ensuring customer satisfaction, operational stability, and data security. Traditional load-balancing algorithms frequently fall short of distributing workloads evenly across resources, owing to the increasing reliance on digital transactions and the ever-increasing volume of data. This paper proposes an innovative ensemble load-balancing algorithm designed to optimize banking transaction processing. The proposed algorithm aims to improve system performance, ensure resource utilization, and provide a seamless customer experience by combining the strengths of multiple load-balancing techniques. The banking sector is critical to global economic activity, processing a wide range of transactions daily. As more customers use digital banking services, there is a greater need for seamless and quick transaction processing. Banks rely heavily on information technology systems and networks to meet these

demands, making efficient load balancing critical for ensuring optimal performance.

The organization of this paper is as follows. Section II explains various cloud models applied on multiple datasets to analyze the performance. Section III describes the weighted Round Robin algorithm in the banking sector. Section IV presents the adaptive load balancing and its functionalities. The fifth section explains the proposed combined approach and its functionalities. Section VI gives the performance metrics used in this paper. Section VII shows the comparative performances of various existing and proposed algorithms. The final section provides the conclusion of the overall research work.

II. LITERATURE SURVEY

X. Wei et al. [8] introduced the popularity-based position technique that maps data components and edge servers to retrieve the virtual coordinate in the plane. The proposed model performance is improved to tackle the load balancing between edge servers via offloading. Experiments show that the proposed model effectively reduces the average path length for data access, and load-balancing techniques provide better options for overloaded servers. T. Liu et al. [9] introduced the novel Q-networks that will allocate resources using resource computation. The main objective of novel q-networks used to decrease the latency over a long time. The performance of Novel q-networks shows better performance in terms of performance. S. Nath et al. [10] proposed an automated scheduling model that incorporates Deep Reinforcement Learning (DRL) and the Deep Deterministic Policy Gradient (DDPG) method. The DDPG extracts optimized models to develop multi-cell MEC systems by leveraging cooperation among neighboring MEC servers. When compared to DDPG, the existing model produced better results. J. Zhang et al. [11] discussed several comparative performances based on the security and privacy threats that edge computing can address. This work primarily focused on discussing various issues and factors that aid in developing several edge computing applications. The study also provides solutions for several privacy and security issues based on edge-related paradigms. T. Li et al. [12] introduced privacy grouping issues that reduce problems in edge clouds and thus reduce edge cloud maintenance. The grouping techniques carefully developed the optimized goal for two models such as tree-based hierarchical (TBH) and graph-based interconnected (GBI) edge clouds. The proposed model obtained better outcomes on two benchmark data sets. B. Pourghebleh et al. [13] introduced the meta-heuristic model that solves the VM unification issue compared with the existing models based on the influential factors. E. H. Houssein et al. [14] introduced a different model belongs to task scheduling that classifies the cloud applications based on the scheduling issues which is one or multiple objectives. S. K. Mishra et al. [15] proposed an iterative approach that optimized the metrics such as latency and energy consumption and unloading the work and associated VM for the execution of the task. If the particular edge center is not ready to provide the resources, the user's request will send to the other cloud system. B. Alankar et al. [16] developed a combined approach that solves various issues in load balancing based on HAProxy, clusters in VM, and

cloud servers. Results show that the proposed model obtained better performance regarding load balancing metrics. A. A. Abdellatif et al. [17] proposed the SDN-based load balancing that reduces the high usage of resources and decreases the computation time. The proposed model executes the program on top of the SDN model and controls the tasks. The manager in this model maintains the transmission messages, maintains hosting pools, and checks the load status at peak time. M. A. Mukweho et al. [18] presented a comparative survey of work on fault tolerance applications used in the cloud environment. A better future model is required to improve the proposed approach's performance. B. Cao et al. [19] detected the replacement issue by using the edge servers (ESs) in the IoV to design various objectives used to deploy the applications and measure the task loading, energy usage, deployment expenses, etc. The proposed model also solves the ES deployment issue. B. Lin et al. [20] introduced the GA-DPSO combined with the genetic approach that optimizes data transmission based on the proposed flow. GA-DPSO is the combined domains such as edge computing and cloud computing. S. Yang et al. [21] proposed that the issue belongs to VNFs on the combined platform and analyzed the VM traffic present in the VMs. It is an integrated approach that uses various technologies that help improve the detection of abnormal traffic in cloud servers and reduce the traffic by controlling the user's requests. J. Zhang et al. [22] introduced the model deployed in a cloud server with an advanced domain called vehicular networks. Several high-potential models, such as fiber-wireless (FiWi), improve the vehicular edge computing networks (VECNs), analyze the task loading, and measure the vehicle's delay. The proposed model obtained superior results compared with existing approaches.

III. WEIGHTED ROUND ROBIN ALGORITHM FOR BANKING TRANSACTIONS

Maintaining unlimited banking transactions requires practical load-balancing algorithms that guarantee the network can handle many transactions without complex resources. The Weighted Round Robin (WRR) algorithm is a scheduling technique commonly used in banking systems to allocate resources for processing transactions. It aims to provide fairness and efficient utilization of resources based on predefined weights assigned to each transaction type. Here's an explanation of the WRR algorithm using equations:

A. Define Inputs

N: Number of transaction types.

W[i]: Weight assigned to each transaction type i, where i ranges from 1 to N.

Calculate the Weighted Round Robin Quantum (Q):

Calculate the total weight sum (TW) as the sum of all transaction weights:

$$TW = W[1] + W[2] + \dots + W[N] \quad (1)$$

Set the Quantum (Q) as the least common multiple (LCM) of all transaction weights:

$$Q = \text{LCM}(W[1] + W[2] + \dots + W[N]) \quad (2)$$

B. Initialize Variables

Current_quantum: The current quantum being processed initially set to 0.

Current_transaction_type: The index of the currently selected transaction type initially set to 0.

C. Transaction Scheduling

- Iterate through the transactions in a loop:
- For each transaction, perform the following steps:
 - Increment the current_quantum by 1.
 - If current_quantum is equal to or exceeds the Quantum (Q), perform the following steps:
 - Reset current_quantum to 0.
 - Move to the next transaction type by incrementing current_transaction_type by 1.
 - If current_transaction_type exceeds the maximum index (N), set current_transaction_type back to 1.
 - Select the transaction type indicated by current_transaction_type for processing.

Output: The output of the WRR algorithm is the sequence of transaction types selected for processing, based on their assigned weights and the calculated quantum.

The Weighted Round Robin algorithm ensures that transactions with higher weights receive a proportionally higher share of the available processing resources. By defining appropriate weights for each transaction type, the algorithm can be customized to prioritize certain types of transactions or balance the workload across different transaction types.

IV. ADAPTIVE LOAD BALANCING (ALB) FOR BANKING TRANSACTIONS IN CLOUD COMPUTING

ALB mainly focuses on transactions made by the users in the cloud server, which involves several distributed workload among multiple servers to advance performance and shows effective transactions. Here are the steps and equations involved in adaptive load balancing:

1) *Measure server performance:* The first step is to collect data on the performance of each server in the cloud environment. This can include metrics such as CPU utilization, memory usage, network bandwidth, and response time.

2) *Determine the load balancing algorithm:* Choose an appropriate load balancing algorithm based on the specific requirements of banking transactions. Some commonly used algorithms include round-robin, least connections, weighted round-robin, and least response time.

3) *Define the criteria for load balancing:* Establish the criteria for load balancing decisions. This can include thresholds for server utilization, response time, or other performance metrics. For example, if a server's CPU utilization exceeds a certain threshold, it may be considered overloaded.

4) *Calculate server weights:* If using a weighted load balancing algorithm, assign weights to each server based on its capacity and performance characteristics. This allows for more fine-grained control over the distribution of the workload.

5) *Monitor server performance:* Continuously monitor the performance of each server in the cloud environment. This can be done using monitoring tools or by collecting real-time performance metrics.

6) *Evaluate server conditions:* Compare the performance metrics of each server against the defined criteria for load balancing. If a server exceeds the thresholds or is underutilized, it may be a candidate for load redistribution.

7) *Calculate the load factor:* Calculate the load factor for each server based on its current workload and capacity. The load factor can be calculated using various equations, such as:

$$\text{Load Factor} = \frac{\text{Current Server Load}}{\text{Maximum Server Capacity}} \quad (3)$$

This equation gives a normalized value between 0 and 1, representing the relative load on each server.

8) *Make load balancing decisions:* Based on the load factors and the chosen load balancing algorithm, make decisions on redistributing the workload. This involves determining which server should receive new requests or reassigning existing requests from overloaded servers to underutilized ones.

9) *Redirect requests:* Implement the load balancing decisions by redirecting incoming requests to the selected servers. This can be achieved through DNS-based load balancing, where the DNS server maps the domain name to the IP address of the appropriate server.

10) *Monitor and adjust:* Continuously monitor the system performance and reevaluate load balancing decisions as the workload and server conditions change. Adjust the load balancing parameters, such as thresholds or weights, if necessary, to further optimize performance.

V. WEIGHTED ROUND ROBIN ALGORITHM COMBINED WITH ADAPTIVE LOAD BALANCING IN CLOUD BANKING APPLICATION

Cloud computing has transformed how businesses operate in today's digital age, and the banking sector is no exception. Cloud banking applications take advantage of cloud infrastructure's scalability, flexibility, and cost-effectiveness to provide customers with efficient and dependable services. However, as the number of users and transactions grow, ensuring optimal performance and load balancing becomes increasingly essential for the smooth operation of these applications. The WRR algorithm and Adaptive Load Balancing techniques can be used to address this challenge. This effective combination provides improved resource allocation, faster response times, and more efficient use of cloud resources.

WRR is a load-balancing algorithm that cyclically distributes incoming requests across multiple servers. Each server is given a weight that corresponds to its processing

capacity. The algorithm considers these weights during load-balancing and distributes requests proportionally to each server. The WRR algorithm ensures that the workload is distributed relatively by assigning higher weights to more powerful servers, preventing any individual server from becoming overwhelmed.

The WRR algorithm is supplemented by Adaptive Load Balancing, which continuously monitors system performance metrics such as CPU utilization, memory usage, network traffic, and response times. The load balancer dynamically adjusts the weights assigned to each server based on these metrics. If a server begins to experience increased workloads or performance degradation, the load balancer can reduce its weight, redirecting traffic to other servers with lower workloads. If a server's performance or load improves, its importance can be increased, allowing it to handle more requests (see Fig. 1).

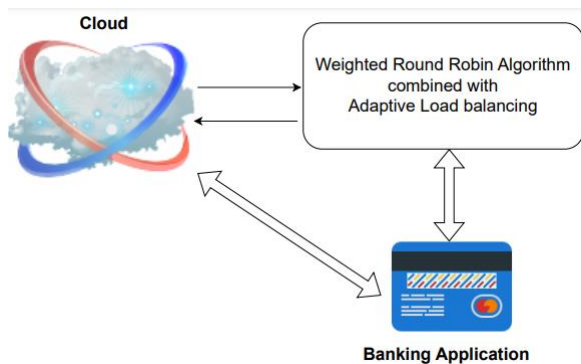

Fig. 1. Proposed architecture.

Combining the WRR algorithm with Adaptive Load Balancing in a cloud banking application provides numerous benefits. For starters, it ensures that each server is used to its full potential, avoiding bottlenecks and improving overall system performance. Second, it enables the application to adapt to changing traffic patterns and allocate resources dynamically based on real-time conditions, resulting in faster response times and a better user experience. Finally, it improves the application's scalability by allowing additional servers to be easily added or removed from the pool without disrupting the load-balancing mechanism.

VI. PERFORMANCE METRICS

Load balancing is a critical technique in cloud computing to distribute workloads across multiple servers or resources to optimize performance and ensure efficient resource utilization. The effectiveness of load-balancing algorithms is assessed using a variety of performance metrics. Here is some common load balancing performance metrics along with their equations:

1) *Response Time (RT)*: It measures the time taken by a server to respond to a client request. Lower response time indicates better performance.

$$RT = (T_f - T_s) + T_w$$

Where T_f the time of the last response is received, T_s is the time of the first request sent, and T_w is the waiting time in the queue.

Example: If a client sends a request at time $T_s = 10s$, the last response is received at time $T_f = 15s$, and the waiting time in the queue is $T_w = 2s$, then the response time would be $RT = (15 - 10) + 2 = 7s$.

2) *Throughput (TH)*: It represents the number of requests processed per unit of time. Higher throughput indicates better performance.

$$TH = \frac{\text{Total requests processed}}{\text{Time period}}$$

Example: If a server processes 1000 requests in 10 minutes, then the throughput would be $TH = 1000 / (10 * 60) = 1.67$ requests/s.

3) *Utilization (U)*: It measures the extent to which a server or resource is utilized. It is often represented as a percentage. Higher utilization indicates efficient resource usage.

$$U = \frac{\text{Total busy time}}{\text{Total time}} \times 100$$

Example: If a server is busy for eight hours (28,800 seconds) out of a total of 24 hours (86,400 seconds), then the utilization would be $U = (28,800 / 86,400) * 100 = 33.33\%$.

4) *Queue length (QL)*: It represents the number of requests waiting in the queue for processing. Lower queue length indicates better performance.

$$QL = \lambda * W$$

Where λ is the arrival rate of requests (requests per unit of time) and W is the average waiting time in the queue.

Example: If the arrival rate is $\lambda = 10$ requests per second and the average waiting time in the queue is $W = 5$ seconds, then the queue length would be $QL = 10 * 5 = 50$ requests.

5) *Server load (SL)*: It measures the amount of work being processed by a server or resource. It is often represented as a percentage. Lower server load indicates better performance.

$$SL = \frac{C}{T} \times 100$$

Where C is the average number of requests being processed by the server and T is the total capacity of the server (maximum number of requests it can handle in a given time period).

Example: If the average number of requests being processed by the server is $C = 30$ and the total capacity of the server is $T = 50$, then the server load would be $SL = (30 / 50) * 100 = 60\%$.

VII. EXPERIMENTAL RESULTS

Experiments were conducted using the cloud banking application developed using Python. The proposed integrated load balancing is implemented at the client and server sides. The comparative performance shows that the proposed model obtained better results. The performance of existing and proposed models was observed on 1k, 5k, and 10k transactions at a time. The existing model's round-robin (RR), Least Connection (LC), and Adaptive Load Balancing (ALB) compared with ECBA.

TABLE I. COMPARATIVE PERFORMANCES IN TERMS OF FOLLOWING METRICS FOR 1K TRANSACTIONS

Metrics	RR	LC	ALB	ECBA
Response time (Sec)	22	20	18	15.1
TH(R/S)	16.7	18.9	20.1	22.9
U (%)	70.7	72.9	75.3	80.3
QL (%)	60	55.6	52.1	49.1
SL (%)	70.8	66.7	63.1	59.3

In banking sector, daily multiple number of transactions will take place online. To process the large transactions an ECBA model obtain high results for 1k transactions given in Table I and graph shown in Fig. 2.

Fig. 2. Comparative performances in terms of following metrics for 1k transactions.

TABLE II. COMPARATIVE PERFORMANCES IN TERMS OF FOLLOWING METRICS FOR 5K TRANSACTIONS

Metrics	RR	LC	ALB	ECBA
Response time (Sec)	34	31.2	28	25.1
TH(R/S)	27.7	29.9	33.1	36.9
U (%)	75.7	77.4	79.2	83.3
QL (%)	69	65.6	61.1	55.1
SL (%)	80.8	66.7	63.1	59.3

Table II and Fig. 3 show the comparative performances of existing and proposed approaches based on given parameters. The overall transactions analyzed by the model are 5k. The high performance is achieved by ECBA and low performance is achieved by RR.

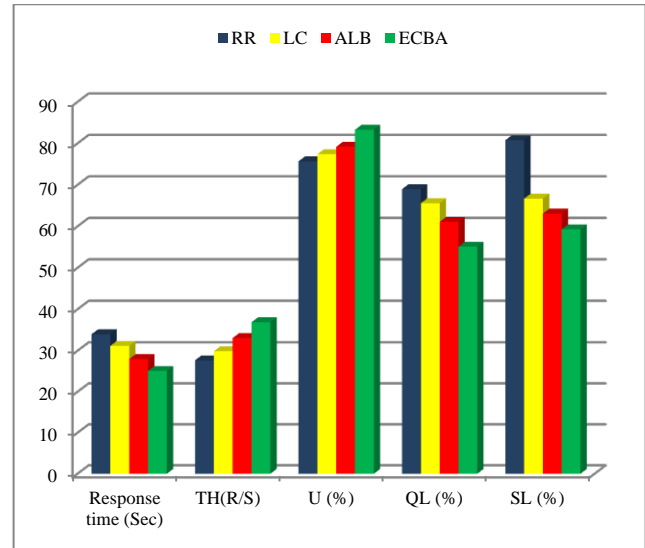

Fig. 3. Comparative performances in terms of following metrics for 5k transactions.

VIII. CONCLUSION

In ECBA, the WRR can balance the workload among multiple servers or instances in a cloud banking application to ensure efficient handling of customer requests. The server weights can assign memory capacity and network bandwidth based on the processing power. WRR can optimize resource utilization and prevent server overloading by allocating requests proportionally to the weights of the servers. Another technique used in cloud environments is adaptive load balancing (ALB), which dynamically adjusts the load-balancing algorithm based on real-time conditions. It continuously monitors server and network traffic performance and makes modifications to guarantee the best possible utilization of resources. ALB can assist in automatically modifying the load balancing algorithm in the context of a cloud banking application based on factors such as server response times, server availability, or network congestion. For example, suppose a server has long response times or is temporarily unavailable. In that case, ALB can route incoming requests to other available servers with lower loads, ensuring consistent performance and minimizing service disruptions. The combination of WRR and ALB can improve a cloud banking application's performance, scalability, and fault tolerance, ensuring efficient resource utilization and optimal customer experience. It enables the application to handle varying workloads while maintaining high availability, allowing dynamic adaptation to changing conditions. In the future, an ensemble load-balancing approach combined with security would be developed to achieve better performance.

Abstract—The intelligent tutoring system registers the reference data of the learners in a database. This data is stored for later use in the instructional module. Designing a student model is not an easy task. It is first necessary to identify the knowledge acquired by the learner, then identify the learner's level of understanding of the functionality and finally identify the pedagogical strategies used by the learner to solve a problem. These elements must be taken into account in the development of the learner model. Learner characteristics must be considered in several forms. To build an effective learner model, the system must take into consideration both static (Learner preferences) and dynamic (Compartmental action) student characteristics. The objective of the article is to work out the learner model of the intelligent tutoring system by suggesting a new learning path. This proposal is based on the constructivist approach and the activist style (based on experimentation). According to the KOLB model, the authors propose a list of pedagogical activities depending on the learners' profile. Based on the learners' actions, the system reduces the list of activities based on two criteria: the learner's preference and the presence of one or more activities based on the activist style using genetic algorithm as an evolutionary algorithm. The results obtained led us to improve the learning process through a new conception of the ITS learner model.

Keywords—Intelligent tutoring system; learner model; genetic algorithm; adaptive learning activities

I. INTRODUCTION

e-Learning systems include smart devices for analysing, evaluating and assessing users' knowledge and skills, as well as monitoring and supervising the e-learning process. AI allows using and implementing its techniques to be more efficient educational systems [1], such as genetic algorithms, intelligent tutoring systems and neural networks. However, the problem that online learning systems lack is to optimize the learner activities during a learning process. Meanwhile, various researchers have already addressed this topic by providing several solutions [2], such as eye-tracking technology [3] clustering [4] and classification methods [5] to detect the learner style, etc. These solutions allow the detection of the learning style and subsequently deduce the list of appropriate activities.

Through experiential learning theory, the KOLB model has been the theoretical foundation for several models of learning

styles. Among these are the Dunn and Dunn [6] and Felder [7] models that developed the Learning Styles Inventory (LSI) to determine learning styles. This questionnaire consists of a self-evaluation questionnaire with approximately 100 questions that learners must answer. These questions are related to five categories. Several versions of this scale have been developed for adults. However, Felder and Silverman do not consider that all learners fit into predefined categories. For example, a learner may have the active-intuitive-global style; but have a strong preference for the active type, a weak preference for the intuitive and global brand and a moderate preference for the visual style. In this case, because he has a strong preference for the active type, he will likely have "great difficulty" learning in an environment that does not support this style. In the case of moderate visual style preference, he should learn "more easily" in a teaching environment that encourages visual style characteristics. For the intuitive and global styles, it is clear that the learner is well balanced on the scales of these two styles, so they would have no problem learning in an environment that favours one or both types simultaneously [8].

Categorizing learners according to their preferred learning style to match a set of complementary learning activities to each type is a promising idea. The preferred learner style affects the conception and construction of pedagogical activities as well as decision-making about the selection of learning resources [9]. From a pedagogical perspective, the teacher must be able to define a set of activities that correspond to each learning style, adapt the appropriate activity to an identified learning need, and design the most appropriate resources and activities for each individual according to their learning style. It should also be possible for a learner to examine the learning resources and activities associated with a particular learning session and assess whether they are appropriate for their preferred learning style.

The literature review allowed us to justify the uses of the KOLB model during this contribution. The main motivations for this choice are as follows:

A study of four learning style models and the experience of engineering educators in their practical applications are presented in [7].

The finding indicates that KOLB's model LIS helps learners learn the course because they have become aware of

their thought processes and helps them develop interpersonal skills.

The objective of this paper is to update the learner model of the intelligent tutoring system in such a way that the activist style will be a required style for the learning process. For this purpose, the authors suggest optimizing the list of activities proposed by the system by strengthening the practice-based exercises to improve the skills acquired by the learner using the evolutionary algorithm: genetic algorithm.

The paper is organized as follow: the second section presents a literature review of the learner module and its triggered problems. The upcoming section describes the choice and the implementation of the genetic algorithm. The fourth section illustrates and interprets the obtained results. Finally, this article is concluded with a summary of the contribution and the future scope.

II. LEARNER MODULE

It would be difficult for an intelligent tutoring system to succeed without a good understanding of the learner. The learner model represents the learner's knowledge and skills dynamically. Just as domain knowledge must be represented explicitly to be communicated, the learner model must also be represented in the same way. In principle, the learner model should store aspects of the learner's behaviour and skills so that the ITS can infer the learner's performance and skills [9].

The intelligent tutoring system keeps the learners' data in a database. It stores learner reference data such as name, ID, current level, overall score, course exercises completed, exercises difficulty level achieved, and several questions completed from a course exercise. This data is stored for later use in other modules such as the pedagogical module.

Designing a student model is not an easy task. It must be based on answers to specific questions. What does the learner know? What kind of knowledge would the learner need to solve a problem? The methodology for designing a learner model should be based on those questions. First, it is necessary to identify the knowledge acquired by the learner in terms of the components integrated into the mechanism.

Secondly, it is necessary to identify the learner's level of understanding of the functionality of the mechanism. Finally, it is required to determine the pedagogical strategies used by the learner to solve a problem. Those elements must be taken into account in the development of the learner model [10].

Learner characteristics must be considered in several forms. The system must take into account both static and dynamic features of the learner to construct an effective learner model. Static features include information such as email address, age, and native language and are defined before the learning processes begin. However, dynamic features come from the learners' behaviour during interaction with the system [11]. The Fig. 1 shows the main components of the learner module:

Fig. 1. Learner model component.

The analysis and study carried out in this section have enabled us to formulate various observations. The first one concerns the difficulties encountered by the learner module to extract implicit knowledge. For this, the authors have suggested a solution to convert tacit knowledge into explicit knowledge in the learner model of the intelligent tutoring system with the help of a competitive learning algorithm [12]. The second observation concerns the traces generated by the learners. The study conducted in this sense shows that the detection of learning styles is done automatically, without relying on explicit answers given to the questionnaire by the learners. Therefore, our contribution proposes an optimization of the activities suggested to the learner while keeping his preferred style and adding other parameters to achieve the required pedagogical objective.

III. METHODOLOGY

To reach our goal, we will apply evolutionary algorithms; and more precisely the genetic algorithm. Many researchers such as Goldberg, Davis and Michalewicz [13] have developed genetic algorithms (GA). GAs is certainly the best popular example of evolutionary algorithms [14][15][16][17]. The genetic algorithm is defined by a population cycle and involves three main factors: fitness, crossover, and mutation [3]. A population cycle represents the transition from one population to the next generation.

A. Level of Preference

In this subsection, we want to detect the learner's level of preference in each learning style. To do so, we rely on KOLB's model, which classifies the learner into four learning styles: Theorist, Activist, Reflective and Pragmatic. Each learner has a level of preference in a specific learning style. To do this, we prepare a list of activities $A_i = \{i=1...12\}$ each learning style (LS) contains activities ranging from 1 to 4 (input) and, the output indicates the three levels of preferences which is the total of activities chosen by the learner multiplied by the level of preference. The figure below shows an example of the preference level corresponding to the two learning styles (Activist and Reflectors).

Concerning the Pragmatist learning style, it contains two activities; the corresponding preferences are described in the Fig. 2 to 4.

Fig. 2. Level of preference of Activist and Reflector’s learner style.

Concerning the Pragmatist learning style; it contains two activities; the corresponding preference is described in the figure below:

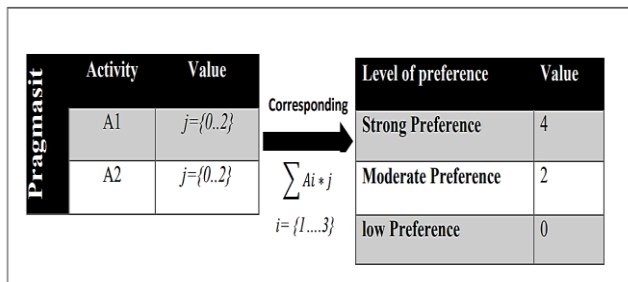

Fig. 3. Level of preference of the Pragmatist learner style.

The last learning style is theoretical; it contains three activities and three preferences levels.

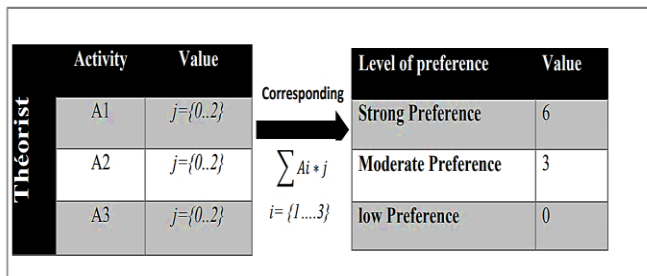

Fig. 4. Level of preference of the theorist learner style.

B. Description of the Genes

The proposed genetic algorithm detects the combination of actions that the student usually performs during a learning sequence using different learning activities. The production of the best-fit chromosome presents the combination of actions preferred by the student.

The first three genes of the chromosome represent the actions that correspond to the Theorist style defined by KOLB. The next four genes represent the actions corresponding to an activist style; the remaining four genes correspond to a reflector style, and the last two genes correspond to a pragmatist’s type. With the values of these genes, it is possible to establish the mechanisms of each learning activity that characterize a learner and, consequently, the optimization of these activities and the deduction of the learning style corresponding to the analysed chromosome.

The values of the genes g1, g2 and g3, carry information about the learner’s participation in the three activities. If the sum of the genes values is zero, it means that the learner does not participate in any of the three activities. On the other hand, if the sum of the codes for these genes is 6, it means that the learner has made extensive use of these activities and can be considered extremely theorist. If the addition of the two genes results are an intermediate value; the learner is moderately passive, neutral or moderately active, depending on the difference between the value obtained and the extremes. The Table I describes the genes:

TABLE I. DESCRIPTION OF THE GENES

Gene Number	Activities	Gene value	Description
Gene 1	Exercise of Analyzing	0	Does not make it
		1	Makes 50% of the proposed exercise
		2	Accomplish the activity
Gene 2	Exercise based on the extraction of conceptual model	0	Does not make it
		1	Makes 50% of the proposed exercise
		2	Accomplish the activity
Gene 3	Supervise a course (pdf, World, PPT)	0	Only reads the introduction
		1	Reads 50% of the course
		2	Accomplish the course

C. Initial Population

An initial population is a group of chromosomes that represent possible solutions to the problem considered, in this case, as possible combinations of actions that a learner can perform. The size of the initial population and the level of diversity determine the quality of its coverage of the space of possible solutions. Based on the number of genes in the proposed chromosome structure and the number of possible values that each gene can have, it is possible to consider the complete solution space to be of the order of 3^{12} .

For the empirical evaluation of the approach, we used initial populations of two different sizes: 3000 chromosomes and 6000 chromosomes. These values were chosen because they are small compared to the whole space of possible solutions (represent 0.5% and 1% respectively); nevertheless, they allow obtaining a good level of diversity by the random generation of the initial population. The weight of initial population genes has a value of zero because the chromosomes have not yet been evaluated in terms of any academic unit performed by the learner.

D. Fitness Function

The fitness function evaluates each chromosome in a population and gives a score or fitness value to each chromosome based on their ability to solve the problem. In this problem, the fitness value of a chromosome is determined based on how close the chromosome's action combination is to the learner's preferred action combination. To evaluate a particular chromosome in a given population, the fitness function is based on the actions performed by the learner while participating in a specific learning activity.

Then, the fitness value of a chromosome C is defined as the product of the gene weights and represents the level of preference in the chromosome, as shown in Equations 1, 2 and 3. Based on our experience as trainers and teachers in the computer field, we notice that the application-based learning style is more profitable than theory and other types of learning.

$$\text{Fitness}(C) = \sum_{j=1}^{12} \alpha * x \quad (1)$$

$$\text{With: } \alpha = \begin{cases} -1 & \text{if } (j \in [1,3]) \\ 2 & \text{if } (j \in [4,6]) \\ 1 & \text{otherwise} \end{cases} \quad (2)$$

$$\text{And: } x = \begin{cases} 0 & \text{if the activity is not achieved} \\ 1 & \text{if the half of the activity is achieved} \\ 2 & \text{if the activity is completely achieved} \end{cases} \quad (3)$$

E. Selection

Once chromosome fitness is calculated for a population, a selection method allows the algorithm to randomly select pairs of chromosomes for reproduction. In this contribution, we used three types of selection: uniform selection, roulette wheel selection and turn selection. Fig. 5 shows the example of the selected chromosome. The authors will detail every form in the experimental result section.

F. Crossover

The crossover is the result obtained when two chromosomes share their particularities. It allows the genetic

mixing of the population and the application of the principle of heredity of Darwin's theory. In this paper, the authors applied a simple crossover which they subdivided the chromosome on $\frac{1}{2}$. Fig. 6 shows the example of the results of chromosomes.

Fig. 5. Example of the selected chromosome (Parent1) & (Parent2).

Weight	2	1	4	2	3	1	1	2	1	4	3	3
Code	0	1	0	1	1	2	1	1	0	1	2	1

Descendants 1

Weight	1	2	1	4	3	3	2	1	4	2	3	1
Code	1	1	0	1	2	1	0	2	1	1	1	0

Descendants 2

Fig. 6. Example of the results chromosome (Descendants 1 and 2).

G. Mutation

The mutation is a genetic modification of the crossing chromosomes. The mutation is a method of introducing genetic diversity by changing the value or code of a randomly selected gene, as described in the Fig. 7. In this work, the authors decided to use the following function:

$$x_i = 2 - x_i \quad \text{With: } x_i = \{0,1,2\} \quad (4)$$

Weight	1	2	1	4	3	2	2	1	4	2	3	1
Code	1	1	0	1	2	1	0	1	0	1	1	0

Fig. 7. Example of a genetic mutation.

IV. RESULTS AND DISCUSSION

In order to evaluate the proposed approach, we simulated the actions performed at first by 10 learners generated arbitrary to build artificial data for the experiment. For this task, we considered that each learner has a particular learning style, represented by a set of preferred actions and that they behave according to this style. The actions performed by a learner correspond to their learning style. The resulting data is represented as a two-dimensional matrix, with each column representing the learner's identifier and an array of one particular action from the actions mentioned in the section above with twelve values.

TABLE II. DATA OF THE PREFERRED ACTIVITIES

Preferred Activities												
Learner ID	A 1	A 2	A 3	A 4	A 5	A 6	A 7	A 8	A 9	AI 0	AI 1	AI 2
1	0	1	2	2	1	2	1	2	0	2	1	2
2	2	2	0	1	0	1	1	0	0	0	0	0
3	0	2	0	1	0	1	1	2	2	2	2	0
4	2	0	2	0	2	2	0	2	2	1	2	0
5	0	1	1	0	1	2	1	1	0	0	0	0

The Table II illustrates the data from five learners selected randomly. The third row corresponds to the third learner, for example. This learner does not make the first activity. A2 indicates that he accomplishes the activity. The third activity marked that the learner read only the introduction, and he participates in the fourth activity, but he does not accomplish the task. A5 indicates that the learner does not observe the activity based on the game, but he makes 50% of the proposed activity in A6 and A7. The activities A8, A9, A10, and A11 indicate that the learner finishes the activities, but he does not do the last activity.

The Fig. 8 shows the evolution of the fitness function averaging 50 generations using the genetic algorithm uniform where the fitness value is 15. In the Mutation phase, if we change the value in the interval [4, 6], which has a coefficient (=2) that corresponds to an activist style, the fitness function decreases. On the other hand, if we change the value in the interval [1, 3], which has a coefficient (= -1) that corresponds to a theorist style, the fitness function progresses exponentially. This implies learning must tend towards the activist style.

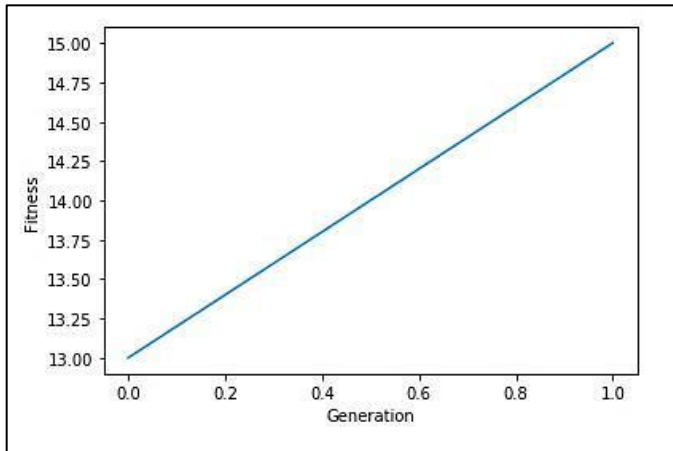

Fig. 8. Accuracy of genetic algorithm uniform.

Fig. 9 and 10 are the developed version of our proposed approach using the selection methods wheel roulette and tournament. We notice that the implementation of these methods improves the fitness function, which allows us to have good results. The fitness value is 21. The results show that the best selected population implies the improvement of the fitness function.

As long as the value of the fitness function is high, the learning tends towards the activist style. This entails the ignorance of theory-based activities and pragmatic activities,

which makes it possible to optimize the list of non-selected learning activities; and ultimately, improving learning process.

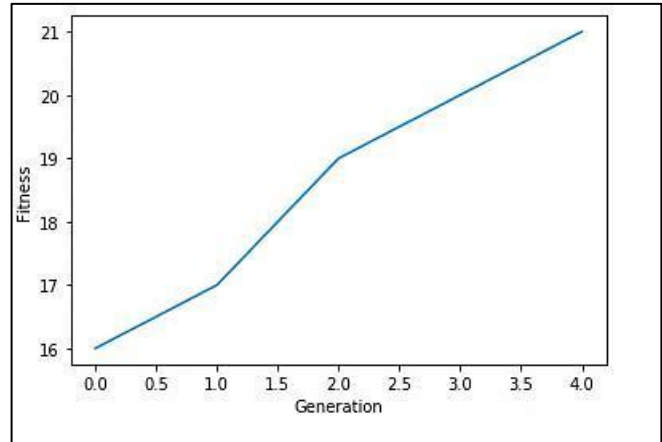

Fig. 9. Accuracy of genetic algorithm using wheel roulette selection.

Fig. 10. Accuracy of genetic algorithm using tournament selection.

Table III shows that the 'Tournament' selection method performed better with the mean difference on the test set for the three data sets used compared to the 'Wheel roulette' selection method and the Uniform GA. Fig. 11 shows the variation of the selection methods in GA

TABLE III. COMPARATIVE STUDY BETWEEN THREE VERSIONS OF GA SELECTED METHODS

Comparisons	Mean Diff.	95.00% CI of diff.	Summary	Adjusted P Value
GA Uniform vs. GA-Wheel roulette	-4.000	-5.757 to -2.243	**	0.0017
GA Uniform vs. GA-Tournament selection	-5.500	-6.056 to -4.944	****	<0.0001
GA-Wheel roulette vs. GA-Tournament selection	-1.500	-2.812 to -0.1883	*	0.0308

From the previous researchers [18] and the results as in Fig. 12, the authors see that the tournament selection method (TSM) provides a high fitness value from the first generation compared to GA uniform (GA-U) and wheel roulette selection technique (WRSM). Nevertheless, both methods: TSM and WRSM, show good results at the end of the generation, fitness function =21 as shown in Fig. 12.

Fig. 11. Variation of the selection methods in GA.

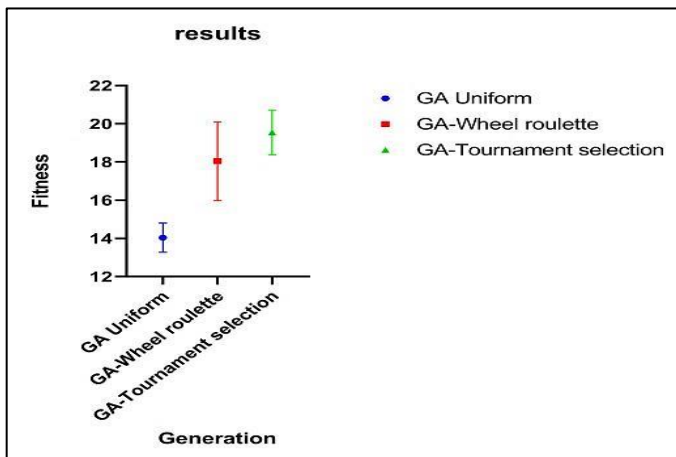

Fig. 12. Comparative result of three version of GA.

The recognition of learning style in an intelligent tutoring system increases the learning effectiveness. However, the adjustment of the content according to learner preferred style does not lead us to have achievable results. From the authors experience in the field of teaching, we recommend using the activist type and respecting the preferences of the learner.

According to the results obtained, we notice that the learners who use the practical activities acquire the expected objective rapidly. For this reason, we have developed and adapted the genetic algorithm by changing in the phase of mutation the activities based on the theory by low values x_i by respecting the following formula: $2-x_i$.

These results allow us to have an exponential function and converge to practice-based learning. These results urge the learner to perform well the case studies suggested by the intelligent tutoring system.

V. CONCLUSION

The e-learning system includes intelligent tools for the analysis, evaluation and assessment of the user's knowledge and skills, as well as for the monitoring and supervision of the e-learning process.

The study on data-driven approaches and more specifically on the traces generated by the learners shows that the detection of learning styles is done automatically, without relying on

explicit answers given to the questionnaire by the learners. Therefore, our contribution provides a path to be generated from the resource data (learner preference and activist style) towards the desired goal: acquiring the requested skills regarding the pedagogical objectives using genetic algorithms.

This contribution was developed to enhance the learning process of a programming language by presenting a new method for reducing the list of activities proposed to the learner. The authors are convinced that this contribution will lead to a good performance in building the learner model of the intelligent tutoring system. The implementation of these findings in the STS-programming solution is envisaged as future work.

Algorithm for Skeleton Action Recognition by Integrating Attention Mechanism and Convolutional Neural Networks

Jianhua Liu*

College of Physical Education, Weifang University, Weifang, 261061, China

Abstract—An action recognition model based on 3D skeleton data may experience a decrease in recognition accuracy when facing complex backgrounds, and it is easy to overlook the local connection between dynamic gradient information and dynamic actions, resulting in a decrease in the fault tolerance of the constructed model. To achieve accurate and fast capture of human skeletal movements, a directed graph convolutional network recognition model that integrates attention mechanism and convolutional neural network is proposed. By combining spacetime converter and central differential graph convolution, a corresponding central differential converter graph convolutional network model is constructed to obtain dynamic gradient information in actions and calculate local connections between dynamic actions. The research outcomes express that the cross-target benchmark recognition rate of the directed graph convolutional network recognition model is 92.3%, and the cross-view benchmark recognition rate is 97.3%. The accuracy of Top-1 is 37.6%, and the accuracy of Top-5 is 60.5%. The cross-target recognition rate of the central differential converter graph convolutional network model is 92.9%, and the cross-view benchmark recognition rate is 97.5%. Undercross-target and cross-view benchmarks, the average recognition accuracy for similar actions is 81.3% and 88.9%, respectively. The accuracy of the entire action recognition model in single-person multi-person action recognition experiments is 95.0%. The outcomes denote that the model constructed by the research institute has higher recognition rate and more stable performance compared to existing neural network recognition models, and has certain research value.

Keywords—Attention mechanism; convolutional neural network; action recognition; central differential network; spacetime converter; directed graph convolution

I. INTRODUCTION

Human Action Recognition (HAR) is a research field that has received much attention from scholars both domestically and internationally. HAR plays an important role in public places, healthcare, and safety [1-2]. Early research on HAR was generally based on RGB videos. With the development of technology, algorithms and sensors for estimating human skeletal posture have emerged [3]. Researchers use depth cameras to extract depth information from human skeletal information at different scales, lighting, and backgrounds to construct HAR data in a 3D coordinate system, and construct corresponding algorithm models based on deep learning (DL) [4]. In the research of HAR using 3D skeleton data as the experimental object, HAR and feature capture often use 3D

technology to obtain relevant action data information [5]. However, there are still many problems in the rapid acquisition of human actions in related operations. The changes and complexity of the background and environment in the video can result in different skeletal joint information for the same action, and the mutual occlusion between people and background can also reduce the extraction of feature actions. The already built HAR model may also have problems, such as identifying only simple action types, making it difficult to identify more complex behaviors. The above issues will result in the already constructed HAR model being only usable under specific conditions, and the experimentally constructed model cannot be generalized to practical applications. To improve the recognition accuracy of action recognition (AR) models and eliminate interference caused by factors such as environment, background, and occlusion, a directed graph convolutional network (DGCN) recognition model for enhancing attention was proposed. By recognizing the spacetime information extracted from feature extraction, a central differential converter graph convolutional network was constructed to achieve real-time recognition and capture of human actions. The Section II of the study mainly discusses the relevant research on human action models in recent years. The Section III mainly constructs an enhanced information acquisition and enhanced spatiotemporal information conversion graph convolution model. The Section IV tests the performance of the constructed model using different datasets and compares the effectiveness of different HAR models on the same dataset. Section V discusses the results. The Section VI summarizes the research results and draws research conclusions.

II. RELATED WORKS

Many scholars have made achievements in the construction of HAR models. Gu et al. constructed a new HAR model using the improved sparse classification model and deep convolutional neural network (CNN), and applied the model to the benchmark dataset. The performance of the model was verified through setting experiments [6]. Huang et al. utilized neural networks for pseudo-image processing of skeletal data. A novel CNN with an adaptive inference framework was constructed by utilizing the dependent joints between skeletal joints [7]. To improve the detection accuracy of human bone models, Li proposed a multi-branch multi-level cascaded CNN structure model to predict the information of occluded parts [8]. Peng et al. proposed a three stream model using two different types of deep CNNs to improve the generalization of HAR models, and verified the effectiveness of the model by

experiments [9]. Yang put forward an algorithm model based on random projection combined with multi-channel 3D CNN to improve the accuracy and recognition speed of HAR models. The effectiveness of the algorithm model was demonstrated through experiments [10]. To raise the accuracy of human action model recognition in video segmentation and its computational efficiency in large-scale datasets, Zhao et al. proposed a multi-dimensional data model for video image AR and non-action based on DL framework, and verified the effectiveness of the model through experiments [11]. Liu and Che used attention spacetime convolutional graph networks to learn the importance of different actions in sports videos and analyze different actions in sports videos [12]. To solve the problems of background clutter, scene diversity, viewpoint change, occlusion, etc. in the HAR, He et al. put forward a closely connected bidirectional long and short-term memory (LSTM) network DL model to capture the temporal and spatial patterns of human action in videos. The research findings also indicated that the effectiveness of the proposed model was good [13]. Wenbo et al. put forward a protocol recognition method based on CNNs to improve the accuracy of feature acquisition, and it was proved that the proposed algorithm had high accuracy and fast convergence speed [14]. Ma et al. proposed a novel deep convolutional generative adversarial network to recognize human action posture, and verified through experiments that its model had significant advantages over existing models [15]. Chen et al. put forward a multi-radar collaborative HAR model based on transfer and integrated learning to solve the view limitation in AR. Through experiments, the proposed model had higher recognition accuracy compared to the single-view radar fusion model [16]. To promote the accuracy of action combination training AR model, Jiang and Tsai proposed a model based on sequential minimal optimization model and artificial intelligence. And in subsequent experiments, it has been proven that this model could improve the recognition rate of actions and meet the recognition needs of online actions [17]. To establish a better HAR model, Chen et al. proposed a model that integrated LSTM weight convolution neural networks. It was validated that the model had an authentication accuracy of 98.0% [18].

In summary, research on constructing HAR models using CNNs has become mature, but there is still room for improvement in accuracy. Based on this, a CNN human recognition model integrating attention mechanism (AM) is proposed, which combines central difference graph convolution network (CDGN) and spacetime converter (SC) to achieve accurate and fast human actions recognition.

III. THE CONSTRUCTION OF SKELETON AR MODEL BASED ON AM AND CNN

This study mainly uses graph convolutional neural networks (GCNN) as the skeleton and integrates AMs to design a DGCN model to enhance the recognition and capture of action information. To prevent the omission of dynamic gradient information in actions and calculate local connections between dynamic actions, CDGN and SC are introduced to construct an enhanced graph convolution model for spacetime information conversion.

A. The Construction of ADGCN Skeleton AR Model Integrating AM and Neural Network

HAR, as an emerging research project in computer vision, has great impact on many fields. Medical assistance, human-computer interaction, intelligent driving, and intelligent security can be achieved through the recognition of HAR. The method of skeleton AR is generally completed using 3D skeleton data, using skeleton joint points to form corresponding groups, and then connecting the corresponding groups to complete the representation of the entire body structure. At present, the commonly used methods for HAR include two types: extraction based on traditional manual features and extraction based on DL methods. DL methods mainly include methods based on recurrent neural network (RNN), CNN, fusion based on RNN and CNN, and GCNN. GCNN takes skeleton data modeling as a blueprint, joints as fixed points, and draws skeleton edge maps. Compared to traditional manual feature extraction and CNN and RNN methods, it has a more intuitive description of skeleton data. Therefore, the study selects the GCN method as the basis to construct a model that is more convenient for skeleton AR. The flow chart of GCN object diagram convolution is shown in Fig. 1.

From Fig. 1, the GCN method involves the temporal structure and continuity of human skeleton actions recognition. By decomposing a certain action information into corresponding data, and then placing the decomposed data into different channels according to dimensional relationships for processing and operation, the final action analysis result is obtained. Due to the existing skeleton models constructed based on GCN, their skeleton AR accuracy may be reduced in complex backgrounds and dynamic environments. And the skeleton model constructed by GCN is often an undirected graph, which can only determine whether there is a connection relationship between adjacent vertices and edges in the graph, and cannot capture more feature information.

To address the above issues, an AM is introduced to improve the GCN skeleton model. A multi-stream framework is used to capture the positions of joints and bones, identify their action trajectories and features, establish the dependency relationship between vertices and edges in the skeleton graph, introduce an AM to focus on feature channels, and construct an attention enhanced direct graph convolutional network (ADGCN) skeleton AR model. The workflow diagram of the ADGCN model is displayed in Fig. 2.

From Fig. 2, the ADGCN skeleton AR model is divided into five parts: multi-stream framework input, DGCN processing, attention enhancement network, data fusion, and output data. The data input by the multi-stream framework corresponds to the action information of joints and bones. The related motion information is judged by the adjacency of DGCN and captured by the key frame action of the attention enhancement network. The data processed by the first four information flow are weighted and fused to complete the prediction of related actions. The update and aggregate functions are used to determine the connection of vertices and edges in the ADGCN model to represent the connected vertices between two vertices and the relationship between vertices and

edges after edge update. The update function of vertices is shown in equation (1).

$$v_i' = u^v([v_i, e_j, e_j]) \quad (1)$$

In equation (1), v_i' is the updated vertex, v_i is the vertex; $[\cdot]$ means the connection operation; u indicates the update function; e_j, e_j denote the position of the updated vertex v_i' and its adjacent edge e . Similarly, it obtains the function equation (2) between the updated edge e' and adjacent vertices.

$$e_j' = u^e([e_j, v_j^s, v_j^t]) \quad (2)$$

In equation (2), v_j^s, v_j^t stand for the updated source vertex and target vertex, respectively. Let the joint coordinate at time t be $v_{i,t} = (x_{i,t}, y_{i,t}, z_{i,t})$, and the calculation function for the same node in two consecutive frames is shown in equation (3).

$$m_{i,t+1} = v_{i,t+1} - v_{i,t} \quad (3)$$

Fig. 1. Flow chart of GCN object diagram convolution.

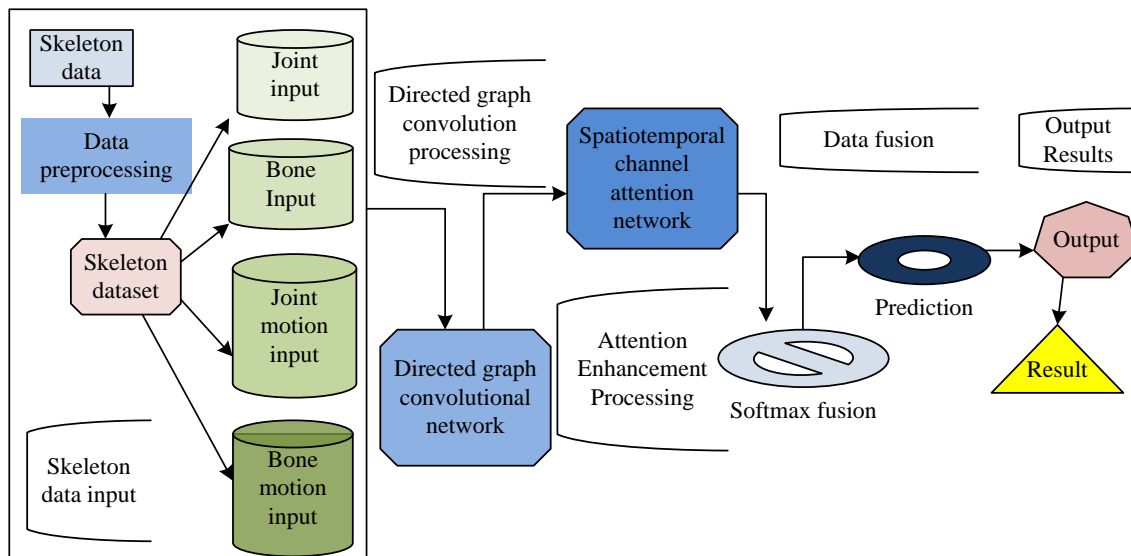

Fig. 2. ADGCN model workflow diagram.

Designing a spacetime channel attention network (CAN) is to strengthen the information connection between key joints and bones, while taking care not to weaken the information intensity of other joints. The spacetime CAN constructed by the research institute includes three types: spatial attention network (SAN), temporal attention network (TAN), and CAN. Among them, SAN mainly allocates different degrees of attention to joints and the bones connected to them. The attention of vertices and edges in the graph is M_s , and the set of M_s is expressed as $\{M_{s,v}, M_{s,e}\}$. The corresponding calculation method is shown in equation (4).

$$M_s = \delta(g_s(\text{AvgPool}(fin))) \quad (4)$$

In equation (4), δ means the sigmoid activation function; g_s indicates a one-dimensional convolution operation; fin refers to the input data information of vertices and edges in the directed graph. As a dynamic time selection mechanism, TAN mainly determines when attention begins and sets the attention time of vertices and edges in a directed graph to M_t . The relevant function expressions are shown in equation (5).

$$M_t = \delta(g_t(\text{AvgPool}(fin))) \quad (5)$$

In equation (5), $M_t \in R^{1 \times T \times 1}$, the explanation of parameter meanings refers to equation (4). After allocating time attention and attention to joints and edges, it considers enhancing the model's feature description of input samples, and thus introduces CAN. The relevant calculation is shown in equation (6).

$$M_c = \delta(W_2(\tanh(W_1(\text{AvgPool}(fin)))) \quad (6)$$

In equation (6), W_1 and W_2 are the weights of two full connection layers, and the functions used by TAN network are \tanh and Sigmoid activation functions. SAN, TAN, CAN three kinds of attention enhancing networks are serially arranged to enhance the recognition ability of spacetime CAN and highlight its attention enhancement effect.

B. Constructing a Graph Convolutional Model for Enhanced Spatiotemporal Information Transformation Based on CDTN

After the construction of the enhanced information acquisition model, its ability to obtain spacetime channel information has been raised to a certain degree, but it ignores the dynamic gradient information in the actions and the local connections between the corresponding dynamic actions. Introducing CDGN can further improve the model constructed by the research institute, by obtaining corresponding dynamic gradient information and using a converter to obtain fixed point connections between nodes. CDGN, as an image processing algorithm, is mainly used for image edge detection and feature extraction. It uses the difference between the central and adjacent pixels to calculate the value of new pixels, reducing noise interference in the image and enhancing its features. The CDGN algorithm is shown in equation (7).

$$\begin{cases} g_x(x, y) = f(x+1, y) - f(x-1, y) \\ g_y(x, y) = f(x, y+1) - f(x, y-1) \end{cases} \quad (7)$$

In equation (7), $g_x(x, y)$ and $g_y(x, y)$ express different gradient values in the horizontal and vertical directions, respectively, and $f(x, y)$ means the pixel values in the original image. The edge values and features of the image are calculated by calculating the gradient value of each pixel point. CDGN includes two parts: sampling and aggregation, and its feature aggregation is shown in Fig. 3.

Fig. 3. CDGN feature aggregation principle.

From Fig. 3, the sampling of CDGN takes into account both feature differences and gradient features. After taking into account the differences between certain node and central node and the gradient features of the corresponding central node, the connection is made according to the corresponding gradient direction. From this, the center gradient of the sampling vertices is aggregated and represented by equation (8).

$$O(v_i) = \sum_{v_j \in Ri} \frac{1}{Z_{ij}} w(l_i(v_j)) * (I(v_j) - I(v_i)) \quad (8)$$

In equation (8), I indicates the input feature; O means the output feature; w indicates the weight function; Ri expresses the first order adjacency joint distance of vertex v_i ; l_i is the partition function. The converter network can coordinate the global self-attention, self-attention operation and convolution operation. Combining the CNN with the converter can allow the model to mine more relevant information from the captured features. The SC used in the research institute consists of three parts: joint embedding, SC attention module, and time converter attention module. The network structure of the SC is shown in Fig. 4.

From Fig. 4, different modules implement different functions. Among them, the joint marker embedding module includes a multi-head self-attention (MHSA) layer and a feedback neural network (FNN) layer to extract spacetime features. The SC attention module is applied to the acquisition of labeled space, while the time converter attention module corresponds to the calculation of spatial and temporal dependencies. Combining CDGN and SC network models, a central difference transformer graph network (CDTG) is developed to capture action gradient information and calculate local dependencies between nodes. The CDTG network structure is shown in Fig. 5.

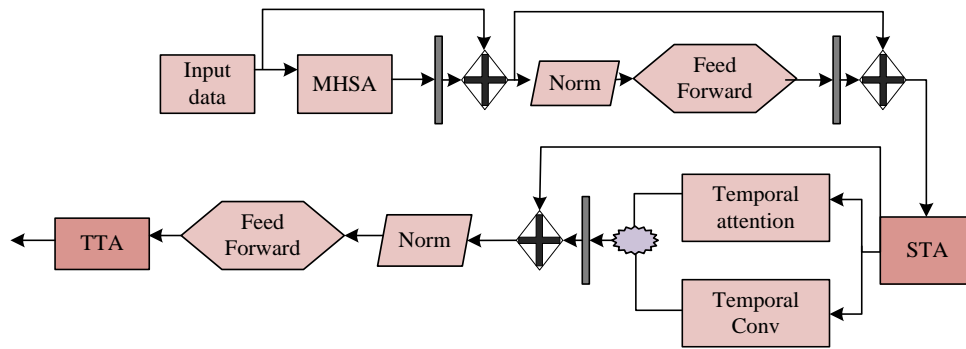

Fig. 4. Diagram of SCNetwork.

Fig. 5. CDTG Network architecture.

From Fig. 5, CDTG is divided into four parts: skeleton data input, CDGN, SC attention network, and fully connected layer recognition information. The last one will use the Softmax function, and the relevant expressions are shown in equation (9).

$$P(y = j) = \frac{e^{x^T W_j}}{\sum_{k=1}^K e^{x^T W_k}} \quad (9)$$

In equation (9), $P(y = j)$ expresses the probability that the sample x belongs to the j classification; k denotes the result of linear function, and is the weight value. The expression of cross entropy function is shown in equation (10).

$$H(p, q) = \sum_x p(x) \log q(x) \quad (10)$$

In equation (10), p means the true labeled distribution, and q refers to the pre labeled distribution of the trained model. It inputs the skeleton action information into CDGN, updates the spatial gradient information of the next layer's vertices based on the position of the central node and its adjacent nodes. The dependency relationship of the global spacetime nodes is calculated based on the attention network of the SC, and finally the data are processed through the fully connected layer recognition information processing and weighted average to complete the prediction of the entire action behavior.

IV. ANALYSIS OF AR RESULTS FOR ADGN AND CDTG MODELS

The experiment used NTU-RGB+D, MSR-Action 3D, and SBU datasets collected by the Kinect v2 3D tactile camera as the research dataset. Experiments were organized to evidence the effectiveness of the proposed ADGCN algorithm model. The NTU-RGB+D dataset contained 56880 skeleton action video sequences, with each skeleton action video covering 25 nodes and each node providing corresponding 3D coordinate positions. MSR-Action 3D contained 20 types of actions and 567 data sequences. The SBU dataset contained 8 types of actions, 284 videos, and 15 skeleton joint points. The environmental parameters for the skeleton AR experiment are shown in Table I.

TABLE I. EXPERIMENTAL PARAMETER SETTINGS FOR SKELETON AR

Experimental setup	Experimental parameters
Experimental system	Linux Ubuntu18.04
GPU	GeForce RTX2080Ti
Computing Platform	CUDA10.0

The batch size of the model is set to 64 and the initial weight attenuation value to 0.0005. The model was trained in the NTU-RGB+D dataset. The accuracy of the trained model was tested on the NTU-RGB+D dataset for crosstarget and view benchmarks. And it compared the accuracy of manual feature extraction algorithms Lie Group, RNN-based feature extraction methods (GCA-LSTM and STA-LSTM), CNN-based methods (3SCNN and TCN), and GCN-based methods (ST-GCN, 2sAGCN, DGCN) on CV and CS. The research outcomes are expressed in Fig. 6.

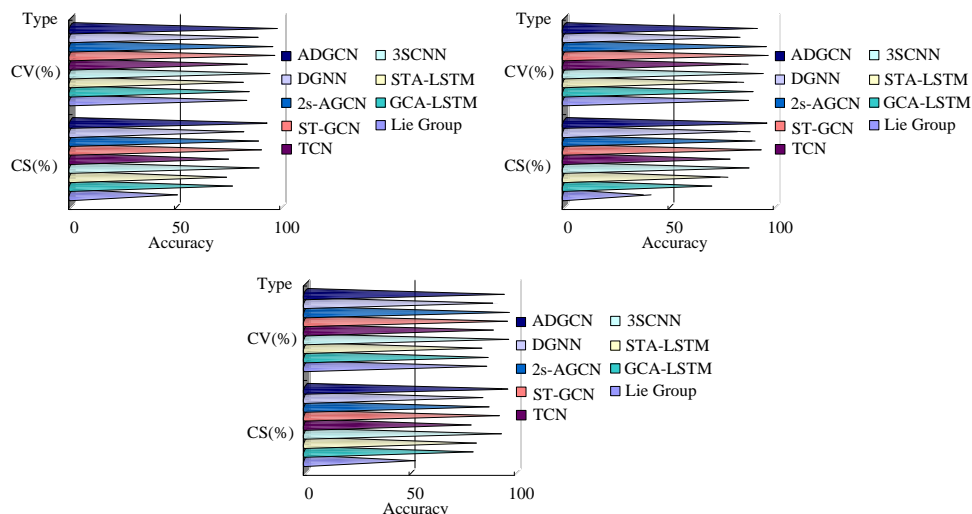

Fig. 6. Performance comparison between algorithms on the NTU RGB+D dataset.

From Fig. 6, in the three datasets of NTU RGB+D, MSR-Action 3D, and SBU, the artificial feature extraction method Lie Group had the lowest CS recognition accuracy, with 50.1%, 47.5%, and 50.5%, respectively, while other DL-based methods had an accuracy of over 73% in CS benchmark recognition. The CS accuracy based on the GSCN network structure was over 80%, with the highest being ST-GCN89.90%. The ADGCN model proposed by the research institute scored the highest among the four network models, with CS benchmark recognition accuracy of 92.33%, 93.21%, and 94.12% in the three datasets, respectively. In cross-view benchmark recognition, the recognition accuracy of the four algorithms was higher than that of cross-target benchmark recognition. The model based on the GSCN network structure still had higher CV recognition accuracy than the other three network models, while the ADGCN model proposed by the research institute had the highest CV recognition accuracy in the past, with 97.3%, 97.8%, and 96.7% in the three datasets, respectively. To further validate the effectiveness of the model, the ST-GCN model with the second highest score was selected to compare the results of the proposed ADGN model CS and CV benchmark recognition accuracy changes with the training. The laboratory findings are shown in Fig. 7.

(b)Comparison of contrast rates between two models under CV

Fig. 7. Changes in the accuracy of CS and CV benchmark recognition for two algorithms during training.

(a)Comparison of contrast rates between two models under CS

From Fig. 7, as the number of iterations continued to increase, the accuracy of the two bone AR models would show an upward trend. Under the CS benchmark, after the number of iterations reached 15, the recognition accuracy of the model tended to stabilize. However, the recognition accuracy of the ADGN model has always been higher than that of the ST-GCN model, with a maximum difference of 0.5% and a maximum difference of 3.42%. Under the CV benchmark, the recognition accuracy of both models has increased compared to the CS benchmark, with an increase of about 5%. After 15 iterations, the recognition accuracy of the model tended to a relatively stable accuracy range, with the maximum recognition accuracy of ADCN being 90%, ST-GCN being 88.5%, and the ADCN recognition accuracy curve consistently above ST-GCN. The experimental results indicated that the ADCN model constructed by the research institute had a certain degree of stability and could ensure good recognition accuracy. Experiments were designed to verify the recognition accuracy of the ADGCN model for different levels of actions on the Kinetics Skelton dataset, and it compared the recognition accuracy of Deep LSTM, TCN, DGCN, and SAN algorithms for the same action. The research outcomes are displayed in Fig. 8.

Fig. 8. Comparison of recognition accuracy of the kinetics skeleton dataset.

Due to the fact that the action videos in the Kinetics Skelton dataset are sourced from YouTube, with a larger variety and complexity compared to the previously used NTU RGB+D dataset, the recognition accuracy of the five validated models is lower. From Fig. 8, in the type of Top-1, the recognition accuracy of the SAN, DGNN, and ADGCN models was around 35%, belonging to the three branches with good performance among the five algorithms. The ADGCN model's Top-1 AR accuracy was higher than DGNN with a 0.7% advantage, ranking first. Compared to Top-1, in Top-5 indicator recognition, the recognition accuracy of the five research algorithms has improved, with an increase of 18.6% to 23.0%. Among them, DGNN had the largest increase, the Top-5 accuracy of the model was 56.5%, and ADGCN had an increase of 22.9%. However, the recognition accuracy of ADGCN was the highest, with 60.5%. It designed experiments to evidence the effectiveness of the CDTG model proposed by the research institute. In the NTU-RGB+D dataset, it compared the recognition accuracy obtained by CNN-based methods (HCN, TCN, GCNN, Clips+ CNN+MTLN), RNN-based methods (ST-LSTM, LSTM-CNN), and GCN-based methods (ST-GCN STGR-GCN GR-GCN GCST Dynamic GCN). The research findings are expressed in Fig. 9.

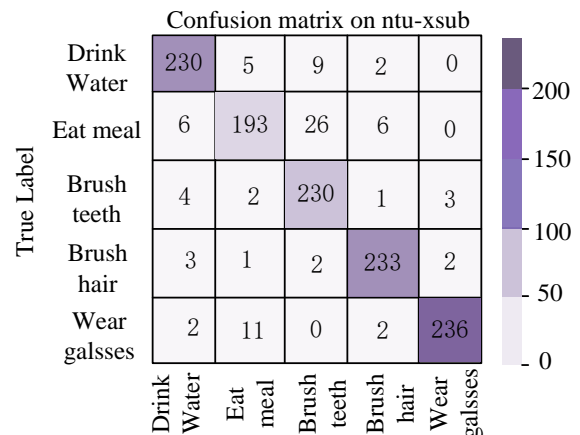

Fig. 9. Comparison of recognition accuracy between different algorithms.

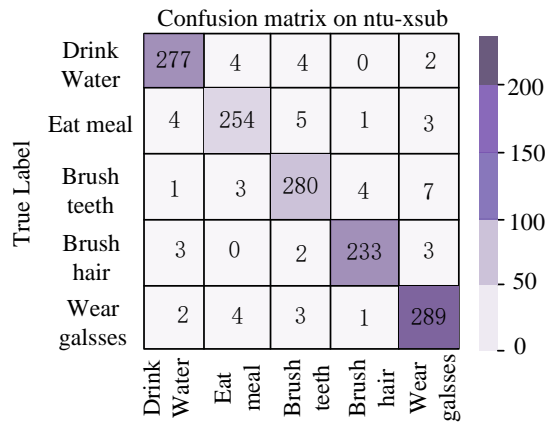

From Fig. 9, the recognition accuracy of the model based on GCN network structure on CS and CV benchmarks was higher than that of the model built on CNN and RNN. Among the models constructed using GCN networks, GCST, Dynamic GCN, and the CDTG model constructed by the research institute had relatively good recognition accuracy. Among them, the CDTG model had the highest recognition accuracy, with recognition accuracy rates of 92.87% and 97.52% in CS and CV, respectively. Compared with other types of AR models, its accuracy improvement could reach a maximum of 27.67% (CS benchmark) and 21.42% (CV benchmark). Compared to the GCST and Dynamic GCN models with higher AR accuracy in recent years, the recognition accuracy of CDTG in CS benchmark had increased by 1.36% and 1.37%, respectively. The recognition accuracy of CV benchmark has been improved by 1.32%. This indicated that the CDTG model proposed by the research institute had good recognition performance in skeleton AR. To further evidence the recognition performance of the CDTG model, five categories with similar action content were selected for comparison in the NTU-RGB+D dataset. The selection of similar action content was divided into five categories: "drinking water", "eating", "brushing teeth", "washing hair", and "wearing glasses". The experimental results were set up to verify the recognition results of CDTG and ST-GCN for the above five action categories. The experimental results are shown in Fig. 10.

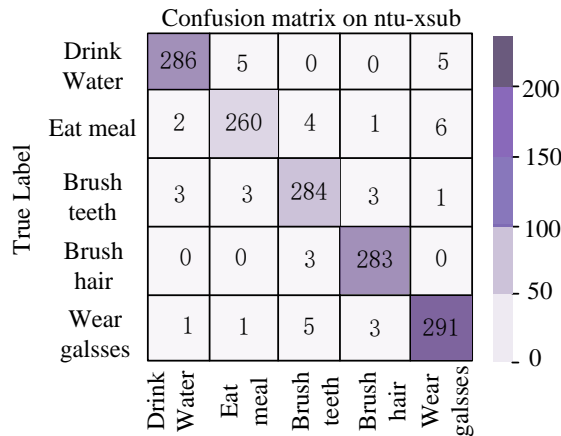

(a) Prediction results of ST-GCN under CS

(b) Prediction results of CDTG under CS

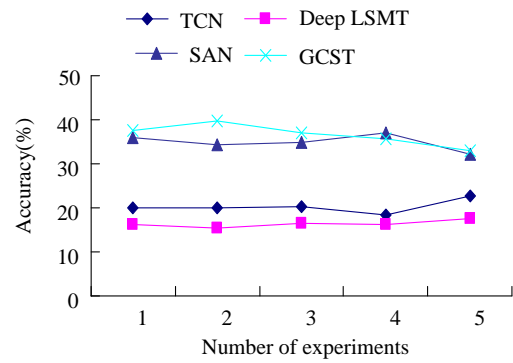

(c) Prediction results of ST-GCN under CV

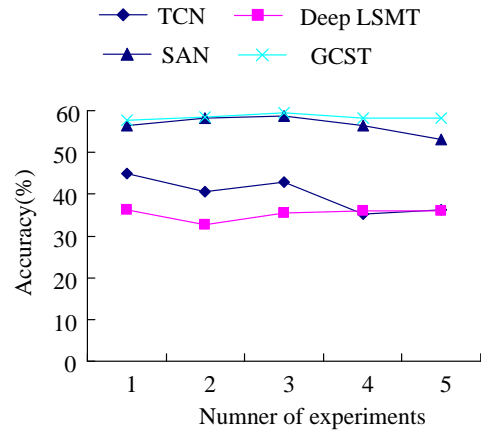

(d) Prediction results of CDTG under CV

Fig. 10. Comparison of recognition results of similar actions between ST-GCN and CDTG models.

From Fig. 10, the recognition performance of the two models under the CV benchmark was better than that under the CS benchmark. There were 276 CS benchmark samples to be tested, among which the recognition numbers for the five actions of "drinking water", "eating", "brushing teeth", "washing hair", and "wearing glasses" in ST-GCN were 217, 185, 204, 217, and 238, respectively, with recognition accuracy rates of 78.6%, 67.0%, 73.9%, 78.6%, and 86.2%. The average recognition rate was 76.9%. The recognition rates of the CDTG model for the above five actions corresponded to 83.3%, 69.9%, 83.3%, 84.4%, and 85.5%, with an average recognition rate of 81.3%. The number of samples to be tested under the CV benchmark was 316, indicating that the recognition accuracy of the CDTG model was better than that of ST-GCN. The recognition rates for "drinking water", "eating", "brushing teeth", "washing hair", and "wearing glasses" actions were 90.5%, 82.3%, 89.9%, 89.6%, and 92.1%, respectively. The average rate of AR was 88.9%. The average recognition rate of ST-GCN was 86.3%. It designed experiments to verify the recognition accuracy of CDTG on Top-1 and Top-5 in the Kinetics Skelton dataset, and compared the recognition accuracy of TCN, Deep LSTM, and SAN GCST models. The experimental results are shown in Fig. 11.

(a) Comparison of Model Performance Regarding Top-1 Indicators

(b) Comparison of Model Performance Regarding Top-5 Indicators

Fig. 11. Comparison of accuracy of five algorithms on the kinetics skeleton dataset.

From Fig. 11, the CDTG model had better recognition accuracy in Top-1 and Top-5 compared to other models, with the highest accuracy among the comparison models, at 37.58% and 59.61%, respectively. Compared to other types of AR models, its Top-1 had a maximum improvement accuracy of 21.18%. The minimum improvement accuracy was 0.88%. The highest improvement in recognition accuracy of Top-5 was 24.31%, and the lowest improvement accuracy was 1.25%. Four experimental testers (two males and two females) were identified and predicted for 3D movements using ADGN and CDTG models. The research outcomes are shown in Table II.

TABLE II. RESULTS OF ADGN AND CDTG MODELS ON PHYSICAL EXPERIMENTS

Action label	Drinking	Smoking	Walking	Jumping
Male tester 1	True	True	True	True
Male tester 2	True	True	True	True
Female tester 3	True	False	True	True
Female tester 4	True	True	True	True
Action label	Shaking hands		Hugging	
Tester 1+2	True		True	
Tester 3+4	True		True	

From Table II, the combination model constructed by the research institute can accurately recognize single and multi-person movements, with a recognition accuracy of 100% for "drinking water", "walking", and "jumping" movements. However, in the recognition of "smoking" movements, female test subject 3 made an error in identifying the movements, which might be due to the insufficient fine-grained model constructed by the research institute. On the other hand, it might also be that female testers were not familiar with the 'smoking' action, which led to model recognition errors. The experimental results indicated that the action model constructed by the research institute had good recognition performance.

TABLE III. RESPONSE TIME AND SATISFACTION BETWEEN DIFFERENT MODELS

Indicator Name	ADGN Model	CDTG Model	ST-GCNModel	GCSTModel
Response time (ms)	91	86	156	137
Satisfaction (%)	90	92	76	78
Feasibility (%)	91	93	84	81

Table III shows the response time and satisfaction between different models. The response times of the ADGN model and CDTG model proposed in the article were 91ms and 86ms, respectively. Compared with the ST-GCN model and GCST model, they had faster reaction speed and better low latency. Meanwhile, the above two models achieved 90% and 92% user satisfaction during the application process, and the feasibility under user evaluation also reached 91% and 93%, respectively. Therefore, the ADGN model and CDTG model proposed in this study had relatively superior practical application value in different regions.

V. DISCUSSION

Skeleton AR can be used in HAR to promote the expression generalization ability of human behavior. At present, research on skeleton AR has received widespread development and attention. Fang Z et al. used GCN to capture the activity status of skeleton joints and identify their movements. The accuracy of the skeleton AR model constructed in this experiment was only 87.79% [19]. Considering the background complexity of skeleton AR, this study optimized the skeleton AR model using AM and CDGN, and the final recognition accuracy of the models was above 90%. To improve the robustness of the skeleton AR model, Liu Y et al. used the KA-AGTN algorithm to construct a skeleton AR model mainly based on time series. Although it improved the recognition accuracy by 1.9% compared to traditional GCN models, it was lower than the model recognition accuracy proposed in this study [20]. The reason why the model proposed in the study was more excellent was that AM could enhance the model's ability to capture key actions, while CDGN could reduce noise interference in AR. Therefore, the optimized skeleton AR model had higher accuracy.

VI. CONCLUSION

To accurately capture and recognize spatiotemporal information and human actions in AR models, an ADGN

recognition model based on spatiotemporal CNN was proposed. By introducing the AM, the ADGN model enhanced the ability to obtain joint information. By integrating the central differential and spatiotemporal transformation networks simultaneously, a CDTG model could be constructed to compensate for the insufficient local dependency of joint information in the ADGN model. The experimental results showed that the ADGN model constructed in this study had CS benchmark recognition accuracy of 92.33%, 93.21%, and 94.12% in NTU RGB+D, MSR-Action 3D, and SBU datasets, respectively. The accuracy of CV recognition was 97.3%, 97.8%, and 96.7%, respectively. And the recognition accuracy of the ADGN model has reached 90%. The CDTG model had the highest recognition accuracy, with recognition accuracy rates of 92.87% and 97.52% in CS and CV, respectively. The response times of ADGN and CDTG models in application were 91ms and 86ms, respectively, with satisfaction rates of 90% and 92%, and feasibility rates of 91% and 93%, respectively. Therefore, ADGN and CDTG models proposed in this study had relatively superior practical application value in different regions. However, due to the small sample size of the entity and the fact that the model has not yet been AR validated in complex backgrounds, there is still room for improvement. At the same time, the combination of RGB or depth information is beneficial for optimizing the performance of the model, so other parameter conditions can be used to optimize the research model in the future.

VII. FUTURE RESEARCH WORK

Due to the fact that this study was not tested in a complex background, the test results of the model's performance were idealized. Considering the practical application of the model, the study will set up different complex environmental scenarios for model performance evaluation in subsequent experiments. The performance results were summarized and analyzed in complex scenarios, and the model is adjusted and optimized by setting different parameter conditions to improve its accuracy and efficiency. In addition, because the algorithm used in this study is an AM to enhance the performance of ADGN and CDTN models, and multimodal fusion forms such as RGB or depth information can also improve model performance. As a result, model performance tests can be conducted under different modalities of fusion to select the optimal multimodal fusion method to construct skeleton AR algorithms.

A Population-based Plagiarism Detection using DistilBERT-Generated Word Embedding

Yuqin JING*, Ying LIU

College of Electronical and Information Engineering, Chongqing Open University
Chongqing 400052, China

Abstract—Plagiarism is the unacknowledged use of another person’s language, information, or writing without crediting the source. This manuscript presents an innovative method for detecting plagiarism utilizing attention mechanism-based LSTM and the DistilBERT model, enhanced by an enriched differential evolution (DE) algorithm for pre-training and a focal loss function for training. DistilBERT reduces BERT’s size by 40% while maintaining 97% of its language comprehension abilities and being 60% quicker. Current algorithms utilize positive-negative pairs to train a two-class classifier that detects plagiarism. A positive pair consists of a source sentence and a suspicious sentence, while a negative pair comprises two dissimilar sentences. Negative pairs typically outnumber positive pairs, leading to imbalanced classification and significantly lower system performance. To combat this, a training method based on a focal loss (FL) is suggested, which carefully learns minority class examples. Another addressed issue is the training phase, which typically uses gradient-based methods like back-propagation for the learning process. As a result, the training phase has limitations, such as initialization sensitivity. A new DE algorithm is proposed to initiate the back-propagation process by employing a mutation operator based on clustering. A successful cluster for the current DE population is found, and a fresh updating approach is used to produce potential solutions. The proposed method is assessed using three datasets: SNLI, MSRP, and SemEval2014. The model attains excellent results that outperform other deep models, conventional, and population-based models. Ablation studies excluding the proposed DE and focal loss from the model confirm the independent positive incremental impact of these components on model performance.

Keywords—Plagiarism detection; LSTM; imbalanced classification; DistilBERT; differential evolution; focal loss

I. INTRODUCTION

With abundant information available online and powerful search engines, plagiarism has become a sensitive issue in various domains, including education. Plagiarism usually occurs intentionally or unknowingly [1]. In contrast, plagiarism techniques have practical uses in fields beyond detecting copied content, including retrieval of information [2] where some text is given as input and the most relevant matches returned.

Various techniques have been proposed in academic publications to address the challenge of detecting plagiarism. One prominent approach is the use of text distance methods, which aim to quantify the semantic proximity between two textual pieces by measuring the distance between them. Typically, there are three categories of text distances: length

distance, distribution distance, and semantic distance [3]. Length distance methods assess the resemblance between two texts by considering their numerical attributes. Popular techniques in this category include Euclidean distance, cosine distance, and Manhattan distance [4]. These methods rely on the numerical characteristics of the texts to calculate the degree of similarity. However, distance-based methods encounter two notable limitations. Firstly, they are often suitable only for symmetrical problems, which may restrict their applicability in certain scenarios. Additionally, using distance measures without considering the statistical characteristics of the data can be risky, particularly in cases such as question answering [5]. Distribution distances, on the other hand, offer an alternative approach to estimating the semantic similarity between two items by comparing their distributions. Techniques like Jensen–Shannon divergence [6] and Kullback–Leibler divergence [7] are commonly used in this category. These methods examine the lexical and semantic similarities between texts by analyzing the distributions of words or other linguistic features. By capturing the statistical properties of the data, distribution distances provide a more nuanced and comprehensive understanding of the semantic relationship between textual items. By leveraging distribution distances, researchers can effectively assess the similarity or dissimilarity between texts based on their underlying linguistic characteristics. These approaches take into account the broader context and semantic information, contributing to more accurate plagiarism detection.

Deep learning approaches have emerged as a powerful alternative to earlier methods in various fields, thanks to their inherent advantages, such as automated feature extraction [8]. Researchers have explored different deep learning architectures and techniques to tackle the task of sentence or text similarity and representation. One approach presented in [9] involves using a recurrent neural network (RNN) with word embeddings obtained from GloVe [10]. The RNN processes the words within a sentence and generates a representation of the sentence. Cosine distance metric [11] is then applied to measure the similarity between the sentence representations. In [40], a Siamese convolutional neural network (CNN) is introduced to capture the contextual information of individual words within a sentence. This network simultaneously produces a representation of word significance and the surrounding terms. By considering the local context, this approach aims to enhance the understanding of sentence meaning. Another RNN-based approach is presented in [12], where the textual data from corresponding words between sentence pairs is combined to create an internal representation.

This enables the model to capture the relationship between words in different sentences, contributing to a more comprehensive understanding of semantic similarity. In [13], a Long Short-Term Memory (LSTM) network is employed to extract high-level semantic information and measure the textual similarity between two sentences. The LSTM takes unprocessed pairs of sentence and word representations as input, allowing it to capture the complex semantic relationships within sentences. Attention-based models are also utilized in the pursuit of sentence similarity. In [14], an attention-based Siamese network is employed to determine the degree of similarity in meaning among sentences. The attention mechanism enables the model to focus on important elements within the sentences, enhancing its ability to capture semantic nuances. In [15], two different methods for answer selection based on similarity are introduced. One method incorporates a single transformer encoder along with embeddings from language models such as ELMo [16] and BERT [17]. The other method utilizes two pre-trained transformer encoders to capture the semantic information. Furthermore, [18] introduces the use of two Bidirectional LSTM (BLSTM) networks to independently derive sentence embeddings. Additionally, a revised data augmentation and loss function technique is implemented to address the challenge of imbalanced data distribution, which commonly occurs in sentence similarity tasks. One significant problem is the handling of imbalanced data distribution in plagiarism detection. The current algorithms often train two-class classifiers using positive-negative pairs, where negative pairs outnumber positive pairs. This imbalance negatively impacts system performance. Another limitation pertains to the training phase, which heavily relies on gradient-based methods like back-propagation. Although widely used, these methods have their own limitations, such as initialization sensitivity.

The unequal distribution of positive (plagiarized) and negative (non-plagiarized) cases pose a major obstacle in plagiarism detection. Failing to tackle this issue can result in a notable decline in performance. Approaches to tackle imbalanced class distribution can be categorized into two main types: the methods of the algorithm level and the data level. Data-level approaches aim to rectify the imbalanced distribution of classes by leveraging techniques such as over-sampling and under-sampling. One approach to address class imbalance is through the use of techniques such as the Synthetic Minority Oversampling Technique (SMOTE) [19], which creates instances by interpolating between adjacent minority examples. Another technique, NearMiss [20], involves under-sampling majority examples using the nearest neighbor algorithm. Over-sampling approaches might result in an overfitting problem, whereas applying under-sampling methods might lead to losing some helpful information about the dominant class. Algorithmic methods amplify the influence of the minority class based on techniques like ensemble learning [21], cost-sensitive learning [22], and decision threshold adjustment [23]. In the cost-sensitive approaches, various costs are assigned for misclassifications of different classes (higher costs for minority samples). The classification issue is framed as an optimization problem that seeks to minimize the total cost. Ensemble techniques train multiple classifiers and fuse the obtained results to reach a final

decision. Threshold adjustment approaches involve training a classifier and then modifying the threshold for classification during testing. Imbalanced classification has also been addressed using deep learning techniques [22, 24]. The study [25] develops a method to learn distinguishing features in unbalanced data while preserving inter-cluster and interclass margins. In [26] the author proposes a strategy that bootstraps convolutional network data into balance for each mini-batch.

Neural network methods, including deep networks, are usually based on gradient-based methods, including back-propagation, to find the appropriate network weights. Regrettably, these techniques are prone to be influenced by the initialization of parameters and may converge to suboptimal solutions. The quality of a neural network can be more significantly influenced by the initial weights than by the network structure and training samples [27]. Meta-heuristic algorithms, including differential evolution (DE) [28], have been proposed as a solution to address these issues and have demonstrated their effectiveness in optimizing the performance of the model [29, 30].

Differential Evolution (DE) is a robust method successfully utilized in various optimization tasks [31, 32]. It comprises three primary steps: mutation to create an additional candidate solution using scaling differences between solutions, crossover to integrate the produced solution with the initial solution, and selection to select the optimal solution for the subsequent iteration. The mutation operator is particularly important [33].

This article describes an original approach to plagiarism detection that employs a DE algorithm and attention-based LSTM model. The proposed model contains a feed-forward network to estimate the similarity degree between sentences and two LSTMs for source and suspicious sentences. The model is trained using pairs of sentences, including positive pairs with two similar sentences and negative pairs with two dissimilar sentences. DistilBERT word embedding is utilized, which can reduce BERT's size by 40% while maintaining 97% of its language comprehension abilities and being 60% quicker. The proposed DE algorithm utilizes clustering for weight initialization, aiming to detect an area in the exploration domain suitable for initiating the back-propagation (BP) algorithm. The best-performing solution from the top-performing cluster is selected as the starting point for the mutation operator, and a new approach for generating potential solutions is employed. Additionally, the proposed algorithm incorporates FL to address class imbalance. The model is assessed on SNLI, MSRP, and SemEval2014 datasets, demonstrating superior performance compared to other methods.

The main contributions of the article are as follows: 1) The article introduces a new DE algorithm that initiates the back-propagation process by employing a mutation operator based on clustering. This approach helps overcome limitations associated with initialization sensitivity, which is a common issue in gradient-based methods used during the training phase, 2) The article addresses the challenge of imbalanced class distribution in plagiarism detection, where negative pairs outnumber positive pairs. The proposed training method based on focal loss enables the model to better learn from minority

class examples, leading to improved system performance, 3) The article introduces the DistilBERT model that can reduce the size of BERT. This reduction in size leads to improved efficiency, making the model 60% quicker compared to the original BERT model, and 4) Ablation studies are conducted to evaluate the individual contributions of the DE algorithm and focal loss. The results confirm that these components have an independent positive incremental impact on the model's performance.

The article's residual parts are structured as follows. Section II provides a number of contextual information, whereas Section III outlines the proposed method for identifying plagiarism. Section IV gives the prediction of the study made. In Section V, the results of the experiments are presented, and Section VI summarizes the paper.

II. DIFFERENTIAL EVOLUTION

Differential evolution [28] has effectively optimized various problems [35, 36]. DE starts with an initial population, usually drawn from a random distribution, and comprises three primary operations: mutation, crossover, and selection. The mutation operation generates a mutant vector as

$$\vec{v}_{i,g} = \vec{x}_{r_1,g} + F(\vec{x}_{r_2,g} - \vec{x}_{r_3,g}) \quad (1)$$

where $\vec{x}_{r_1,g}$, $\vec{x}_{r_2,g}$ and \vec{x}_{r_3} are three randomly chosen candidate solutions from the available population, and F shows a factor scaling.

Crossover incorporates the mutant and target vectors. A well-known crossover operator is a binomial crossover, which does this as

$$u_{i,j,g} = \begin{cases} v_{i,j,g} & \text{if } \text{rand}(0,1) \leq CR \text{ or } j = j_{rand} \\ x_{i,j,g} & \text{otherwise} \end{cases} \quad (2)$$

Where CR denotes the rate of crossover, and j_{rand} is a number chosen randomly from the set $\{1,2,\dots,D\}$, where D is the dimensionality of a candidate solution.

Lastly, the selection operator elects the superior solution from the target and trial vectors.

III. PROPOSED APPROACH

The overall structure of the suggested method is displayed in Fig. 1. As seen, it comprises three main stages, pre-processing, word embedding, and prediction. First, redundant words and symbols are removed from the sentences. Next, the embedding vector of each word is obtained using BERT, and ultimately, the model predicts the similarity between the two sentences. The proposed model incorporates a clustering-based differential evolution algorithm to find the initial seeds of the network weights while using focal loss to handle class imbalance.

A. Pre-Processing

Data pre-processing is a crucial aspect of any NLP system as the fundamental characters, words, and sentences extracted in this phase are forwarded to the subsequent stages. Consequently, they considerably impact the outcome. Conversely, an unsuitable pre-processing technique can decrease the model's performance [37]. Common stop-word elimination and stemming techniques are used in the approach.

Stop words are part of sentences that can be regarded as overhead. The most common stop words are articles, prepositions, pronouns, etc. They should thus be removed as they cannot function as keywords in text mining applications [38] and decrease the number of dimensions in the term space

Stemming is employed to determine the base form of a word. For instance, the terms 'watch', 'watched', 'watching', 'watcher', etc., can all be reduced to the stem word "watch" by stemming. Stemming reduces ambiguity, decreases the number of words, and minimizes time and memory requirements [37].

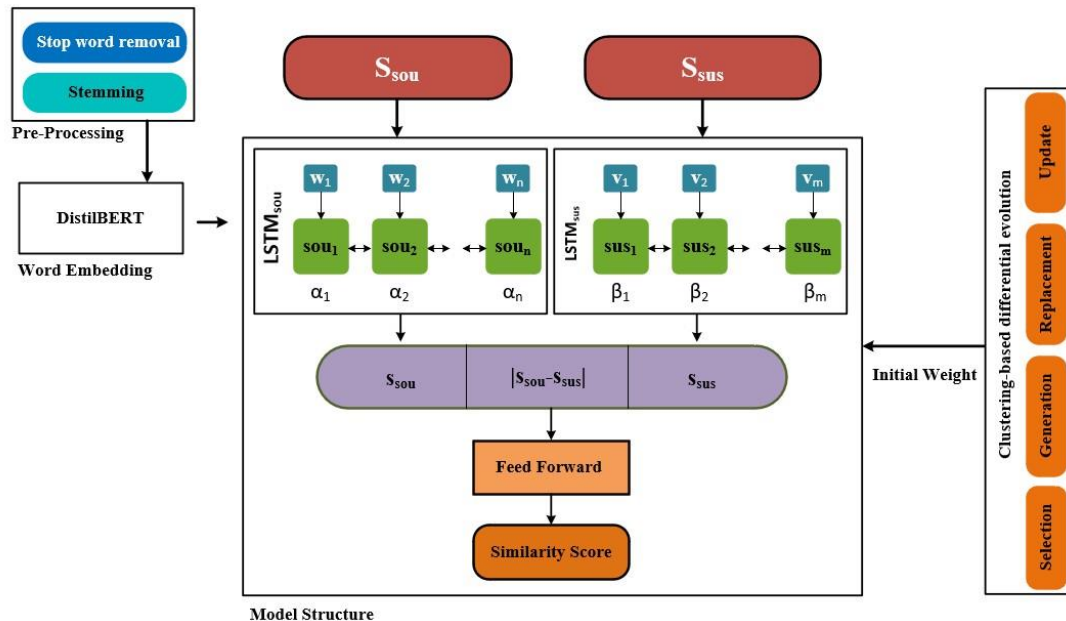

Fig. 1. Architecture of the suggested model as a whole.

IV. PREDICTION

The prediction model comprises two attention-based LSTM networks as extractors of the embeddings of the source and suspicious sentences and a feed-forward network as a predictor of the similarity of the two sentences. Given $s_{sus} = \{v_1, v_2, \dots, v_m\}$ and $s_{sou} = \{w_1, w_2, \dots, w_n\}$ as the sentence of the suspicious and source, where v_i and w_i denote the i -th word in the suspicious and source sentences, respectively. s_{sou} and s_{sus} are restricted to n and m words due to the length limitation in BLSTM (in the work, $n = m$). s_{sou} and s_{sus} are nourished separately into an LSTM network. These sentences embeddings are computed using the mechanism of attention, as

$$s_{sou} = \sum_{i=1}^n \alpha_i h_{sou_i} \quad (3)$$

And

$$s_{sus} = \sum_{i=1}^m \beta_i h_{sus_i} \quad (4)$$

where the i -th hidden vectors are represented in the BLSTM by $h_{sou_i} = [\vec{h}_{sou_i}, \vec{h}_{sou_i}]$ and $h_{sus_i} = [\vec{h}_{sus_i}, \vec{h}_{sus_i}]$, and the i -th attention weight for every section is shown in the BLSTM by $\alpha_i, \beta_i \in [0,1]$, computed as

$$\alpha_i = \frac{e^{u_i}}{\sum_{j=1}^n e^{u_j}} \quad (5)$$

And

$$\beta_i = \frac{e^{v_i}}{\sum_{j=1}^m e^{v_j}} \quad (6)$$

With

$$u_i = \tanh(W_u h_{sou_i} + b_u) \quad (7)$$

And

$$v_i = \tanh(W_v h_{sus_i} + b_v) \quad (8)$$

where W_u, W_v, b_u and b_v are the weight matrices and biases to the attention mechanisms. The fully-connected network's input is the connection of the s_{sou}, s_{sus} and $|s_{sou} - s_{sus}|$ as shown in Fig. 1. The dataset used for training consists of positive and negative pairs, where positive pairs contain a source sentence and a copied sentence and negative pairs comprise a source sentence and a different sentence.

The model has two training phases, pre-training and fine-tuning. In pre-training, an appropriate starting configuration is found. The weights obtained in pre-training are then the initial weights of the fine-tuning phase. In the pre-training phase, the enhanced differential evolution algorithm is employed.

A. Pre-Training

At this stage, the weights of the LSTM, attention mechanism, and feed-forward neural network are initialized. For this, an enhanced differential evolution method is introduced, boosted by a clustering scheme and a novel fitness function.

1) *Clustering-based differential evolution*: A clustering-based mutation and updating scheme is employed in the enhanced DE algorithm to improve the optimization performance.

The suggested mutation operator, which takes inspiration from [39] pinpoints a propitious area in the search space. The k -means clustering technique is used to partition the current population P into k clusters, each defining a distinct section of the search space. From [2, N], a random integer is chosen to depict the clusters number. The cluster with the lowest mean fitness of its samples is the best cluster after clustering.

The suggested mutation based on clustering is described as follows:

$$\vec{v}^{clu}_i = \overline{win}_g + F(\vec{x}_{r_1,g} - \vec{x}_{r_2,g}) \quad (9)$$

where \overline{win}_g is the most acceptable solution in the promising region, and $\vec{x}_{r_1,g}$ and $\vec{x}_{r_2,g}$ are two randomly determined solutions from the available population. It should be noted that wing is not always the population's most acceptable solution. The procedure of the mutation on the basis of the clustering is implemented M times.

When M new solutions have been provoked through clustering-based mutation, the current population is updated. The steps are as follows:

- Selection: Generate k individuals randomly as the starting points of k -means;
- Generation: Generate the solutions of the M by applying clustering-based mutation as the collection v^{clu} ;
- Replacement: Choose M solutions at random and determine as B ;
- Update: The best M solutions from the $v^{clu} \cup B$ determined as the B' . The novel population is afterwards calculated as $(P - B) \cup B'$.

2) *Encoding strategy*: The primary structure of the proposed model includes two LSTM networks along with their attention mechanisms and a feed-forward network. As illustrated in Fig. 2, all weights and bias terms are arranged into a vector to form a candidate solution in the proposed DE algorithm.

3) *Fitness function*: To calculate the quality of a candidate solution, the fitness function is as

$$Fitness = \frac{1}{\sum_{i=1}^N (y_i - \hat{y}_i)^2} \quad (10)$$

Where N is the number of training examples, y_i and \hat{y}_i show the i -th target and output predicted by the model, respectively.

B. Focal Loss

The plagiarism problem is defined as a two-class classification problem based on positive and negative classes. As an imbalanced problem, with few samples in the negative class, focal loss (FL) [34] is used to address this.

FL is a modification of binary cross-entropy (CE) that focuses training on harder (i.e., minority class) samples [40]. CE is defined as

$$CE = \begin{cases} -\log(p), & y = 1 \\ -\log(1-p), & \text{otherwise} \end{cases} \quad (11)$$

where $y \in \{-1,1\}$ is the actual class label, and $p \in [0,1]$ is the predicted probability of the model for the class with target $y = 1$. The probability is

$$p_t = \begin{cases} -p, & y = 1 \\ 1 - p, & \text{otherwise} \end{cases} \quad (12)$$

and hence

$$CE(p, y) = CE(p_t) = -\log(p_t) \quad (13)$$

FL tends to add a modulating component to cross-entropy loss, leading to

$$FL(p_t) = -\alpha_t(1 - p_t)^\gamma \log(p_t) \quad (14)$$

Where $\gamma > 0$ (if $\gamma = 1$, then FL is similar to CE loss), and $\alpha \in [0,1]$ is the inverse class frequency.

Fig. 2. Encoding strategy in the proposed algorithm.

V. RESULTS

A. Datasets

In the tests, the following three benchmark datasets are utilized:

- SNLI: the Stanford Natural Language Inference (SNLI) corpus [41] is a large dataset consisting of pairs of labelled sentences with three classes, including contradiction, entailment, and semantic independence. It comprises 550,152 sentence pairs for training and 10,000 pairs of sentences each for testing and validation.
- MSRP: A rephrasing set of data from Internet news articles called the Microsoft Research Paraphrase Corpus (MSRP) [42], divided into training and testing, with pairs of positive and negative sentences by several experts. Of the whole collection, about 67% of paraphrases are present. The test and training datasets have 1,726 and 4,076 examples, respectively, out of which 1,147 and 2,753 are paraphrases, respectively.
- SemEval2014: the Semantic Evaluation Database (SemEval) [13] is a widely-used benchmark for evaluating STS, presented in various versions. The Compositional Knowledge (SICK) dataset [43] from 2014 is employed to assess the semantic similarity of

sentences. The dataset includes 10,000 sentence pairs, distributed as 4,500 pairs for training, 500 for validation, and 5,000 for testing.

B. Model Performance

The algorithm is compared to seven deep learning methods, namely RNN [9], Siamese CNN+LSTM [44], CA-RNN [14], AttSiaBiLSTM [13], LSTM+FNN+attention [14], CETE [15] and STS-AM [18]. The results are given in Tables I, II and III for SNLI, MSRP, and SemEval2014, correspondingly. For the suggested approach, outcomes are presented based on accidental weight initialization, the use of FL, and the full proposed model. The proposed model demonstrates superior performance compared to other models, including CETE, the best-performing competitor, across all metrics for SNLI. The error rate is reduced by over 50% and 54% in the two primary metrics, F-measure and G-means. Comparing the proposed model with Proposed+random weights and Proposed+random weights+FL, the mistake percentage is reduced by around 67%, highlighting the significance of improved DE and FL methodologies. The proposed model achieved the most significant improvement for the MSRP dataset, followed by the CETE algorithm. The error rate improvement for this dataset is about 27.41% and 26.69% for both the F-measure and G-means criteria, respectively. In the SemEval2014 dataset, the proposed method reduces the classification mistake by over 18% and 37% compared to CETE and STS-AM, respectively.

C. Comparison with other Metaheuristics

The enhanced DE algorithm is contrasted with several metaheuristic optimization algorithms in the subsequent experiment. Different metaheuristics are used to obtain the initial model parameters while keeping the same as the other model components, i.e., pre-processing, word embedding, LSTM and network structure, and loss function. Eight different algorithms, namely (standard) DE [45], FA [46], BA [47], COA [48], ABC [49], GWO [50], WOA [51], and SSA [52], are used. The obtained results are reported in Tables IV, V and VI for the SNLI, MSRP, and SemEval2014 datasets, respectively. For the SNLI dataset, the suggested model reduces error by about 44% compared to the standard DE. It clearly shows that the proposed model has a substantial ability compared to the standard one. Also, DE offers more acceptable results than other algorithms, including ABC, GWO, and BAT. There is a minor improvement for the other two datasets, so the error rate for MSRP and SemEval2014 is reduced by around 19.17% and 8.82%, respectively.

D. Word Embeddings

Word embedding is a crucial component of In-depth learning-based models since the input is read as a vector, and if the embedding is erroneous, the model might be misled. This study used the DistilBERT model as a word embedding, one of the most recent embedding models. Five more-word embeddings are used to compare various word embeddings to the model: One-Hot encoding One-Hot encoding [53], CBOW, Skip-gram [54], GloVe [10], and FastText [55]. One-Hot

encoding is a crucial step in changing the collected data variables fed to In-depth learning methods, enhancing the accuracy of predictions and classifications. It generates a binary feature for every class, and each sample's feature is given a value of 1 corresponding to its original class. Skip-gram and CBOW are techniques that transform a word into its corresponding representation vector using neural networks. The GloVe is a method for aggregating global word-word co-occurrence data from a corpus. The Skip-gram paradigm is expanded by the word embedding technique known as FastText. This approach encodes each word as an n-gram of letters rather than learning word vectors. The outcomes of this experiment can be found in Tables VII, VIII and IX for the SNLI, MSRP, and SemEval2014 datasets, respectively. The worst-performing word embedding method was One Hot encoding. In the MSRP dataset, the proposed model showed an improvement of approximately 85.81% and 83.51% for the two criteria, F-measure and G-means, respectively. Skip-gram and CBOW operate nearly similarly across the three datasets because of similar architecture, which is superior to the Glove model. FastText performs better than other models but poorly on BERT. The error rate is reduced by more than 18%, 15%, and 24% for the SNLI, MSRP, and SemEval2014 datasets, respectively, when utilizing BERT instead of FastText.

E. Loss Functions

Finally, to justify the selection of focal loss in the approach, the comparison is made with four other loss functions, namely weighted cross-entropy (WCE) [56], balanced cross-entropy (BCE) [57], Dice loss (DL) [58], and Tversky loss (TL) [59].

The results of these experiments are given in Tables X, XI and XII for the SNLI, MSRP, and SemEval2014 datasets, respectively. The use of focal loss gives the best results for all measures on the SNLI and MSRP datasets and yields the best G-means results for all three datasets. The results of this experiment are given in Tables X, XI and XII for the SNLI, MSRP, and SemEval2014 datasets, respectively. Generally speaking, the reduction of FL error compared to TL for SNLI and MSRP datasets is about 19% and 27%. However, these two functions are slightly different in the SemEval2014 dataset, so the improvement rate for this dataset is about 12%.

F. Examples

A qualitative example is provided to demonstrate the important contributions of both the improved DE algorithm and the use of FL in the approach. The source sentence "Two people are kickboxing, and spectators are watching" from the SemEval2014 dataset is used for this purpose. Fig. 3 gives the results of the top five sentences retrieved by the BPD model with random weight initialization and focal loss, without FL, and the full approach. As is apparent, the full model extracts suspicious sentences most similar to the source sentence, while the other two models retrieve these only in the lower rankings.

G. Discussion

The article presented an innovative approach to plagiarism detection by using an attention mechanism-based LSTM and the DistilBERT model. The utilization of the DistilBERT model is particularly notable as it reduces the size of the original BERT model by 40% while maintaining 97% of its language comprehension capabilities and increasing the speed by 60%. Two novel approaches were introduced to enhance the overall performance of the system. First, a focal loss function was used to address the issue of imbalanced classification, which often occurs when negative pairs significantly outnumber positive pairs. Second, an enriched DE algorithm was introduced to address the limitations associated with traditional gradient-based learning methods, such as initialization sensitivity. The approach was evaluated on three benchmark datasets: SNLI, MSRP, and SemEval2014, and it outperformed other deep models and conventional and population-based models. The effectiveness of the DE algorithm and the focal loss function was further validated through ablation studies.

While the study exhibits considerable promise, there are a few potential limitations:

- The study indeed leverages benchmark datasets that provide reliable standards for performance evaluation. They serve as a crucial starting point for developing and refining the model, and their use enables the results to be compared directly with other models that have also been evaluated using these datasets. However, these datasets, although comprehensive and widely used, may not fully encapsulate the full diversity and complexity of real-world plagiarism scenarios. Real-world plagiarism can be exceptionally intricate, involving subtle paraphrasing, strategic insertion of synonyms, reordering of sentences, or blending of original and copied material, among other tactics. These practices can often deceive conventional plagiarism detection tools, requiring models that can comprehend and identify such complex forms of plagiarism. Furthermore, these benchmark datasets might lack certain forms of plagiarism seen in specific fields or cultures. Plagiarism, after all, can differ greatly across different academic disciplines, professional fields, and cultural contexts. For instance, the plagiarism practices in a literature research paper could be entirely different from those in a technical report in engineering. Lastly, the real-world plagiarism scenarios are continually evolving, influenced by the advancement of technology and changes in writing and copying techniques. The dynamic and constantly changing nature of real-world plagiarism can present a challenge that these static, fixed datasets may not be fully equipped to address.
- The incorporation of DistilBERT is indeed a step forward in reducing the model's size and enhancing its operational speed, owing to its design that maintains substantial language comprehension capabilities while being considerably smaller and faster than the original BERT model. This makes the model more feasible for applications that demand quicker processing times and

limited memory capacities. However, even with these benefits, the combined system that also includes the attention mechanism-based LSTM and the enriched DE algorithm may still have significant computational demands. The LSTM component, known for its ability to remember long-term dependencies in sequence data, can be computationally intensive, particularly for longer sequences or larger datasets. The recurrent nature of LSTMs, where outputs from one step are fed as inputs to the next, makes parallelization of computations difficult, potentially slowing down the training process. On the other hand, the DE algorithm, while providing an innovative solution to the limitation of sensitivity to initialization inherent in gradient-based training methods, adds another layer of complexity to the system. The operations involved in differential evolution, such as mutation, recombination, and selection, while aiding the optimization process, also contribute to the computational burden. Moreover, the system must be trained on multiple iterations to effectively learn from the data, and each iteration involves processing the entire dataset. The computational demands can, therefore, escalate with the volume of data, length of sequences, and complexity of the tasks at hand. In the real world, these requirements could translate to higher memory and processing power requirements, extended training times, and increased energy consumption. They could also limit the system's deployability on devices with limited computational capabilities, such as mobile devices or low-end personal computers. Therefore, while the use of DistilBERT, LSTM, and the DE algorithm offers various advantages, further work could be directed towards optimizing the system to make it more efficient and less resource-intensive.

Finally, future works that can be considered are as follows:

- Investigating the model's performance on other languages beyond those in the current datasets could be beneficial, potentially leading to the development of a more universally applicable plagiarism detection tool.
- It would be valuable to test the model in real-world scenarios, such as academic papers or professional reports, to further assess its effectiveness and robustness.
- There may be scope to optimize the DE algorithm further for this specific use case. Tuning the parameters of the mutation operator based on the characteristics of the plagiarism detection task could potentially enhance the system's performance.
- Exploring the use of other pre-trained language models, including GPT-3 and T5, and compare their performance with DistilBERT. Comparing the capabilities of multiple pre-trained language models such as GPT-3 and T5 for plagiarism detection tasks could provide valuable insights into the suitability of these models for this application. GPT-3 is a transformer-based language model trained on a massive corpus of diverse texts and has shown impressive

results in a variety of natural language processing tasks. T5, on the other hand, is a text-to-text transformer that can be fine-tuned for different tasks, including text classification and sequence labeling.

VI. CONCLUSION

Plagiarism is the unacknowledged use of another individual's language, information, or writing without crediting the source. An innovative model was introduced to detect plagiarism based on DistilBERT word embeddings, an LSTM approach with an attention mechanism, and an enhanced DE algorithm used for pre-training the networks. To address the issue of inherent class imbalance, focal loss was employed. The enhanced DE algorithm groups the present population to pinpoint a potential area within the search space and integrates a novel update mechanism. DistilBERT can improve the performance of BERT by 40% and 97% in terms of size, language comprehension abilities, and speed, respectively. Extensive experiments on three datasets confirm the approach to yield excellent performance, outperforming various plagiarism detection approaches. The DE algorithm is superior to several other meta-heuristic methods. In forthcoming studies, the plan is to utilize the technique on several deep models, and an investigation of a version of the algorithm that can handle multiple objectives is underway.

Abstract—Startups encounter a variety of difficulties in maximising their performance and resource allocation in the dynamic business environment of today. This study employs a two-stage methodology to address the challenges faced by startups in optimizing their performance and resource allocation in the dynamic contemporary business environment. The research utilizes an advanced Data Envelopment Analysis (DEA) technique to identify the factors influencing startups' efficiency. In the first stage, the relative efficiency of startups is assessed by comparing their inputs and outputs through DEA, a non-parametric approach. This analysis not only reveals the successful startups but also establishes benchmarks for others to aspire to. By examining the efficiency scores, critical factors that significantly impact startup performance can be identified. In the second stage, a logistic approach is employed to predict the performance of startups based on these discovered factors. This prediction model can be valuable in making informed decisions regarding resource allocation, aiding startups in their survival and development endeavors. This study introduces a novel two-stage methodology, combining advanced Data Envelopment Analysis (DEA) with predictive modeling, to uncover the key factors influencing startup efficiency. By evaluating relative efficiency and predicting performance based on these factors, it offers a comprehensive approach for startups to strategically allocate resources and enhance overall performance in present dynamic business environment.

Keywords—Startup efficiency; data envelopment analysis; logistic approach; resource allocation; dynamic business landscape

I. INTRODUCTION

Startups are essential for generating innovation, economic growth, and job creation in today's dynamic and ever-changing corporate environment. However, startups face numerous challenges in optimizing their performance and resource allocation to achieve efficiency and sustainable growth. Understanding the determinants of startup efficiency

is crucial for entrepreneurs, investors, and policymakers seeking to enhance their success in this highly competitive environment. Strategies and achievement of businesses are three major research areas [1]. Knowledge, innovation, and skills are the three main areas of study. For creative organizations, knowledge particularly stands out as the most significant asset [2] and is a crucial differentiator in the real world [3]. Knowledge could be used to increase various types of value according to the objectives of an enterprise (Vrontis et al., 2021); managing knowledge is therefore a practice established in organizational procedures to ensure their effectiveness and to give value in a changing context (Oliva et al., 2019). Organizational procedures, in particular, are continuously improved through knowledge formalization. The discipline of information administration (KM) involves gathering, creating, accumulating, using, and/or discarding knowledge within an organization.

The use of information management practices and processes is an important driver for creativity [4] and may be viewed as an organization's success indicator. Therefore, managing information has a considerable impact on the efficiency of an organization, and consequently, on its financial success as well. According to the author Battisti et al. [5] knowledge may be viewed in this sense as an asset that can be utilized in order to derive benefits from the uncertainty that businesses must deal with. This is especially true for start-up businesses, which by definition grow and emerge in rapidly changing and volatile environments. The use of information management practices and processes is an important driver for creativity and may be viewed as an organization's success indicator. Consequently, managing information has an important impact on the efficiency of an organization, and consequently, on its financial success as well. According to some authors knowledge may be viewed in this sense as an asset that can be utilized in order to derive benefits from the

uncertainty that businesses must deal with. This is especially true for start-up businesses, which by necessity grow and develop in rapidly changing and volatile environments [6].

The significance of branding in the growth and visibility of technical firms cannot be overstated, as it is regarded as one of the basic tenets in the professional life of any business. Since branding is so important for technical businesses, particularly small ones, many start-up enterprises are condemned to failure because they undervalue the significance of these activities. Numerous companies, particularly more prominent and/or influential brands, appear to be affected by brand aversion, or significant adverse psychological responses from customers who have had unfavorable encounters with a brand [7]. Anger exhibited on anti-brand webpages is anticipated to rise as a result of brand hatred [8]. Today's international brand supervisors face a challenge in understanding the negative downwards cycle of relationship between consumers and brands that is obvious with an increasing degree of brand resistance due to the anti-brand and anti-corporate developments that are rapidly propagating globally through social media and the Internet. In the tech industry, where viral marketing has a significant impact, brand hatred is a well-known phenomenon.

Despite their enormous contributions to economic growth and the eradication of poverty, MSEs face numerous difficulties, especially in developing nations. The issue that is brought up the most is access to financing. Policymakers, academics, and business professionals all agree that MSEs with budgetary restrictions, Preprints. Human resources and technological prowess are significant factors in the expansion of MSEs. Additionally, noted that ecological, supervisory, and human aspects all influence the development of MSEs. Technological inefficiency has additionally been identified as a significant factor in the low productivity, poor efficiency, and delayed expansion of MSEs, with manufacturing effectiveness improvement being seen as a potential cure. Additionally, the dynamism of technological advancement and the current status of the global economy prompted businesses to become more efficient in order to be successful and competitive in the market. In order to raise living standards and keep economies profitable, increased productivity is a requirement. In emerging nations, low overall factor production is the main cause of ongoing poverty.

Businesses must operate at a high enough productivity level. Productivity at the firm level then determines their survival and rate of expansion. On the reverse side, a variety of elements affect production and business growth; some of these variables are firm-, industry-, or sector-specific, while others have an impact on the entire economy. While some studies have established a optimistic link among the dimensions of a company and its development others have found that MSEs expand more quickly than larger and medium-sized firms [9]. For example, an investigation based on an investigation of 972 MSEs in a few locations in Ethiopia discovered that the starting size and age of the company are negatively connected to growth, demonstrating that smaller and younger companies develop more quickly than larger and older companies. Performance may, in turn, be related to firm size. Three out of five MSEs perished within the first few

years of operation highlighting the beneficial and substantial effect of the digital age on business growth [10]. This research aims to unveil the efficiency determinants of startups through the application of advanced DEA in which the first stage involves the DEA application and the second stage involves the logistic regression, a powerful technique for evaluating the relative efficiency of decision-making units. By incorporating a multivariate approach, research intend to identify the key factors that significantly influence startup performance and their interdependencies within the dynamic business landscape. Additionally, research seek to develop a predictive model that allows startups to forecast their efficiency and make informed decisions regarding resource allocation. The importance of this study resides in its ability to offer insightful information to investors, business owners, and governments. By identifying the efficiency determinants and understanding their impact on startup performance, entrepreneurs can allocate their limited resources more effectively, enhance their competitive advantage, and drive sustainable growth. Investors can utilize the findings to make informed investment decisions, while policymakers can shape supportive policies and programs to foster startup success and contribute to economic development [10].

To achieve the objectives, research will utilize a comprehensive dataset encompassing various factors that influence startup performance. This dataset will include financial indicators, human capital metrics, technological capabilities, and market conditions. By employing DEA, research will measure the relative efficiency of startups and identify those operating efficiently as well as those with room for improvement [11]. Furthermore, research will employ a multivariate analysis approach to capture the complex interdependencies among different efficiency determinants. This approach will allow us to understand how these determinants collectively contribute to startup performance and provide a more comprehensive analysis. The outcomes of this research will go beyond mere analysis [12]. Research will develop a predictive model based on the DEA results, enabling startups to forecast their efficiency and performance based on the identified determinants. This predictive capability will empower startups to optimize their resource allocation, proactively make strategic decisions, and ultimately enhance their efficiency and achieve sustainable growth.

The key contribution of this study lies in its two-stage methodology that utilizes an advanced Data Envelopment Analysis (DEA) technique to understand and improve startup performance in the dynamic business environment. Here are the primary contributions:

- **Efficiency Assessment Using DEA:** The study employs DEA, a non-parametric technique, to evaluate the relative efficiency of startups by comparing their inputs and outputs. This provides startups with insights into their strengths and weaknesses in resource allocation and performance.
- **Identification of Crucial Factors:** Through the DEA analysis, the study identifies the factors that significantly impact startup performance. By pinpointing these crucial determinants, startups can

focus on enhancing their strengths and addressing areas of weakness.

- Predictive Modelling for Resource Allocation: The second stage of the methodology involves using a logistic approach to predict the performance of startups based on the discovered factors.
- Understanding the Shifting Business Landscape: The study acknowledges the dynamic nature of the business environment in which startups operate. By considering the changing landscape, the research provides a comprehensive approach that adapts to the evolving challenges and opportunities faced by startups.
- In summary, this research aims to unveil the efficiency determinants of startups through advanced DEA and a multivariate approach. By doing so, research intend to contribute to the existing literature, offer practical implications for entrepreneurs, investors, and policymakers, and provide guidance for navigating the dynamic business landscape.

II. RELATED WORKS

Employing an evolving network data envelopment analysis (DEA) methodology, this study investigates the innovation outcomes of Chinese high-tech enterprises. Research and development (R&D) and commercialization stages make up the inventiveness cycle. Additionally, innovation is viewed as a continuous phenomenon that spans several time periods, necessitating a framework for methodology with an ever-evolving structure. Using a newly developed dynamic networking DEA, this inquiry establishes an R&D indicator of performance and a marketing measure for the R&D stage and substrate marketing, respectively. Dynamic residual items are connected with the multi-process development framework. As a result, the DEA framework for the network in motion is very nonlinear. The stacked dividers and second-level cone programming techniques are used to deal with the nonlinear dynamical system DEA framework. In the research proposed by Yu et al. [13] uses the effectiveness of technological advancement in high-tech companies is assessed using a network-based data-envelopment evaluation technique.. Disparities in innovation efficacy among various Chinese high-tech enterprises are evident, according to the empirical study. Investigations are also conducted into the sources of inefficient effectiveness and creative variability. Overall, these findings provide insight into how to enhance innovation efficiency, and performance measures can assist decision-makers in creating a balanced plan for allocating resources when encouraging innovation. However, this study contains a number of flaws. Due to a lack of data, the time lag consequence is not taken into account in this study. Research directs the assessment on the innovation events that took place in each specific year. Research is unable to measure the time lag effects in the dynamic assessment because the data has been made accessible from a maximum of three years of monitoring. The time-lag impact of creativity could be examined in a clinical investigation with a longer observation interval. However, despite the fact that the nested partition searching is faster, it may also uncover a global optimum if

the partitioned total of possible areas is sufficiently big. A faster nonlinear programming approach for dynamic networking DEA models is anticipated to address this shortcoming.

In the research proposed by Battisti et al. [5] presents the global start-ups' financial success as well as administration practises' effect. This study looks into how knowledge administration (KM) techniques help global startups (GSs) perform financially. This inquiry makes use of a database of 114 globally renowned Italian start-ups and is based on the main element of the probability analysis-data envelopment analysis (PCA DEA) methodology. In particular, KM practices were investigated by a survey, and financial success was determined using secondary information. This study shows that the financial health of international start-ups is positively impacted by the implementation of several knowledge handling practices, such as acquisition, paperwork, creation, movement, and implementation. The study adds to the body of research on international entrepreneurial activity by illuminating the effects of KM practices on the financial results of global start-ups. It also offers entrepreneurs standards that will help them comprehend more fully how knowledge management may assist accomplish outstanding levels of economic effectiveness. Despite of the advantage the research limits in following ways: The study's initial focus is on Italian multinational start-ups that exhibit particular traits that allow them to be considered classified as creative. Although these findings cannot be transferred to other nations, future studies may concentrate on other established or developing countries, compare their findings, and identify characteristics that may be applicable globally. Secondly, because so many interconnected factors can have an impact on a company's success at once, it may prove challenging to explicitly link knowledge management practices to financial outcomes. Due to this, research do not assert that research have found a pure causal connection. Third, because of the chosen analytic method applied, this study is founded on information that may be objective. Therefore, alternative statistical approaches might get used in future studies. Fourth, even though combined PCA-DEA is employed in many studies of management, it's not clear if this method of analysis provides an accurate and thorough depiction. Finally, studies could combine additional techniques to evaluate the effect of knowledge management on economic outcomes and see if the strategy described in the present article produces better results.

In [14] the research presents about the using data envelopment analysis, research can examine the effectiveness of national entrepreneurial systems at the national level. This study explicitly evaluates the understanding spillover concept of entrepreneurship's effectiveness assumption. Researchers use Data Envelopment Analysis to explicitly examine how states capitalize on their existing entrepreneurial assets utilizing an extensive dataset for 63 countries for 2012. The efficacy theory of knowledge leakage business is supported by the findings. Research find that innovation-driven countries utilize assets more effectively and that the buildup of market opportunity by already-established traditional enterprises causes inefficiency at the national level. No matter what stage of advancement, developing knowledge is a reaction to market

advantages, and a strong national entrepreneurial economy is linked with information spillovers, which are necessary for greater levels of efficiency. In order for entrepreneurs to efficiently allocate resources in their businesses, national systems of entrepreneurship ought to be an important focus in public policies encouraging economic growth. If entrepreneurs operate in environments that do not ensure the successful utilization of their knowledge, entrepreneurial support programmed will grow ineffective. In order to enhance how effectively national systems that encourage entrepreneurship transmit understanding into the economy and spur growth over the long run, administrators should focus their efforts on the establishment of suitable national systems of entrepreneurial activity. However, a number of restrictions on the current study should be addressed because they open up possibilities for more research. Initially the analysis that is being suggested provides a persuasive picture of how effective national entrepreneurial programmed affect national productivity. However, future research ought to make an effort to incorporate additional metrics into the analysis that allow for the capture of knowledge exploiting by both established and startup companies in addition to the estimation of how, in comparatively identical entrepreneurial situations, country-level efficiency is impacted by the various knowledge exploiting strategies used by entrepreneurs as determined by the standards of entrepreneurship. Secondly, the study's cross-sectional design necessitates clear care in how it is interpreted and how broadly it is applied.

In the research proposed by Kapelko et al. [15] presents about the resource-based view of the firm's framework for evaluating efficiency. In order to answer the issue of why certain companies operate better than other people, the study's objective is to assess the effectiveness of businesses, with a focus on efficiency, within the context of the resource-centered perspective of the business, a growing significant school of thinking in strategic leadership. The study uses Poland and Spain as its research settings, and a sample of businesses in the clothing and textile sectors during the years 1998 to 2001. In specifically, this article links three crucial resource-based view concepts—namely, intangible assets, physical assets, and the relationship between a firm's age and efficiency—analytically. Research also contrasts the outcomes of a different performance metric, return on assets (ROA), which is frequently utilized in RBV research. Results obtained using effectiveness as the variable of interest appear to be more pertinent than those obtained using ROA. The finding provides a vast arena for further investigation. Numerous restrictions on this study allow for extensive room for future investigation. Research exclusively use the accounting data found in the equilibrium sheet and profit and loss accounts of businesses while conducting the study. Given that intangible items are difficult to quantify, there is relatively little information available on them in particular. Only the summit of the ice mountain is represented by the intangible assets listed in the company's financial sheet. Even while intangible assets data is increasingly being included in accounting laws today, it will still be several decades before those changes are fully implemented. Consequently, a highly intriguing next step in the research process would be to use a qualitative

investigation or a more in-depth quantitative approach to examine the organizations' intangible assets.

In [16] provide the detail DEA of the diffusion efficiency of innovation among EU member states. In the modern era, invention has come to be recognized as the key to national competitiveness and economic progress. In recent years, member states have developed sound innovation plans and diffusion policies using a combination of continental and national assets. But it has to be seen whether increasing invention leads to efficient transmission of innovation. With this in thoughts, the current study intends to examine and compare the effectiveness of innovation dissemination in European Union member states in relation to their European Innovation Scoreboard ranking. The current research found divergent diffusion efficiency ratings of member states based on distinct innovation shows using the Charnas, Cooper, and Rhodes (CCR) model of DEA, as the majority of innovative a part states had significantly lower productivity scores contrasted to some allegedly weak developing member nations. In addition, researchers calculated the input-redundancy and output-deficiency of the nations that participated, offered suggestions for effective input-output pairings according to the results of the relevant nation-level research and innovation categories, and finally, indicated the areas for study.

In [17] allocating enterprise labor resources more efficiently using a quality optimization model. Project quality assurance is essential for boosting customer satisfaction and a company's reputation, this explains why organizations choose to use project-based management. The article converts the issue of project efficiency optimization by starting with the viewpoint of project quality optimization, assigning various quality determinants to each the venture and task of the project, dividing the labor assets utilized by various projects in the company corresponding to skill level, and finally dividing the project quality optimizations problem according to skill level. Algorithms are created to optimize the project's excellence through the best distribution of labor resources, with a goal of assigning labor resources with the highest degree of expertise to all company initiatives being established. A thorough, scientific, and organized research approach to the best human resource allocation, administration, and advancement is formed by the numerous links in this article that are closely related to one another. Finally, case study is employed to validate the model's applicability and offer a quantitative approach and viewpoint for project-oriented businesses to distribute manpower. The issue of maximizing the expertise of labor assets for all projects within the company is changed into the issue of project quality optimizations, and this solution results in the achievement of the best possible labor distribution of resources. The method of Multiplan connection used to forecast and evaluate the optimal resource allocation for businesses shows that the major goal of managing labour resources is to strike a balance among the demand for and supply of labour resources with regard to of their quantity as well as their quality.

In the research developed by Ali et al. [18], the study employs traditional Data Envelopment Analysis (DEA) to

evaluate efficiency in startup operations through a case study approach. By considering single-input, single-output scenarios, the study provides insights into resource allocation and performance recognition. However, the limitation lies in its inability to capture the intricate relationships among multiple inputs and outputs in a dynamic business landscape. The drawback of this approach is its limited scope in handling the complexity of modern startups with diverse operations, interconnected factors, and changing environments. Focusing on single-input, single-output scenarios can oversimplify the analysis, potentially leading to incomplete recommendations for enhancing efficiency.

III. PROBLEM STATEMENT

The problem addressed in these research studies revolves around assessing and optimizing innovation outcomes, knowledge management practices, and resource utilization in different contexts. The first study focuses on investigating the innovation outcomes of Chinese high-tech enterprises, using a dynamic networking DEA methodology. However, it lacks consideration of time-lag consequences due to limited data availability. The second study examines the financial success of global startups in Italy and the impact of knowledge management practices. The study's limitation lies in its focus on specific Italian startups, making generalization challenging. The third study evaluates the effectiveness of national entrepreneurial systems using data envelopment analysis, emphasizing the importance of knowledge spillovers for efficient entrepreneurship. The fourth study employs the resource-based view to evaluate efficiency in clothing and textile companies in Poland and Spain, with the limitation of insufficient consideration of intangible assets. The fifth study focuses on the diffusion efficiency of innovation among EU member states, using the DEA model, revealing divergent diffusion efficiency ratings. Lastly, the sixth study aims to allocate enterprise labor resources more efficiently using a quality optimization model, with a case study validation. Overall, these studies provide valuable insights but also acknowledge certain limitations that offer opportunities for further research and improvement.

IV. RESEARCH DESIGN

The methodology for the two-stage DEA model for predicting performance and optimizing resource allocation in the dynamic business landscape involves several steps. Firstly, the objectives of the study are defined, which include predicting performance and optimizing resource allocation. Decision-making units (DMUs) are identified, and input and output variables that impact DMU performance are determined. Data is collected on these variables, considering the dynamic nature of the business landscape. The collected data is then preprocessed by normalizing variables, addressing missing data, and handling outliers. In the first stage, a DEA model is formulated to predict the performance of DMUs based on their efficiency in utilizing inputs to generate outputs. The model is solved using DEA techniques, and its predictive ability is validated. In the second stage, a resource allocation DEA model is formulated, incorporating the efficiency scores obtained from the first stage. This model optimizes resource allocation by considering constraints such

as budgets or capacity limitations. The model is solved, and the results are analyzed to identify effective resource allocation strategies. Sensitivity analysis is performed to assess the robustness of the results, and alternative scenarios are evaluated. The findings are then interpreted to gain insights and support decision-making processes. Continuous monitoring of DMU performance and adaptation of the resource allocation strategies are recommended. Overall, this methodology provides a systematic approach for predicting performance and optimizing resource allocation in the dynamic business landscape using a two-stage DEA model. The following Fig. 1 shows the processed model.

Fig. 1. Proposed framework.

A. Data Collection

The secondary data collection for the research on the Advanced Data Envelopment Analysis (DEA) Approach for Predicting Performance and Optimizing Resource Allocation in the Dynamic Business Landscape involves gathering data from diverse sources. This includes financial statements of companies to analyze financial performance, industry reports to understand industry benchmarks and trends, economic indicators to assess macroeconomic conditions, market data to evaluate market size and dynamics, customer data to identify preferences and behaviors, competitor data to analyze market positioning, technology data to explore technological advancements, social media and online data to gauge customer sentiment and brand reputation, government data to understand regulatory aspects, and academic papers and

research studies to leverage existing theoretical frameworks and methodologies. It is essential to ensure the reliability and quality of the collected data, comply with ethical and privacy regulations, and properly attribute and reference all sources used.

B. Data Preprocessing

Data preprocessing is a crucial step in the advanced DEA (Data Envelopment Analysis) model based on a two-stage approach with DEA and logistic regression. In this context, data preprocessing involves several tasks. Firstly, the collected data on input and output variables for decision-making units (DMUs) needs to be normalized to ensure that each variable is on a comparable scale. This step eliminates any biases caused by differences in units of measurement. Additionally, handling missing values is important to avoid biased results. Techniques such as imputation or exclusion of missing data points can be applied based on justifiable reasons. Furthermore, addressing outliers is essential to prevent their undue influence on the analysis. Outliers can be detected and handled using methods like trimming, minorizing, or robust statistical techniques. Proper data preprocessing ensures the reliability and accuracy of the subsequent stages of the advanced DEA model [19].

C. Advanced Data Envelopment Analysis

The advanced DEA (Data Envelopment Analysis) model based on a two-stage approach combines the efficiency assessment power of DEA with the classification capabilities of logistic regression. Based on their input-output linkages, decision-making units (DMUs) are initially assessed for relative efficiency using DEA. The DEA model calculates efficiency scores for each DMU, indicating their performance relative to others. These efficiency scores are then used as input variables in the second stage, where a logistic regression model is employed to classify DMUs into different categories or predict their performance levels. The logistic regression model utilizes the efficiency scores along with other relevant variables to determine the probability of a DMU belonging to a particular class or achieving a certain level of performance. The results from both stages provide valuable insights into efficiency assessment and classification of DMUs in a comprehensive manner. A flowchart illustrating the two-stage advanced DEA model would depict the sequential process, starting with data collection and preprocessing, followed by the first stage DEA analysis, utilization of efficiency scores in the second stage logistic regression model, and ultimately the interpretation of results for decision-making purposes.

1) *First stage DEA*: Based on a range of inputs and results, the corresponding effectiveness of 40-DMUs is calculated utilizing the mathematical modelling method referred to as DEA [20]. The DEA determines each DMU's comparative efficiency with respect to other DMUs. The DEA approach identifies variables that keep all DMU efficiency assessments below or close to one and give a DMU the highest possible overall efficiency ratings. The fractional form of a DEA mathematical processing strategy is shown in Eq. 1:

$$\max m_0 = \frac{\sum_{b=1}^o b_o u_{bd_0}}{\sum_{a=1}^i a_i v_{ad_0}} \leq 1, d = 1, \dots, t \quad (1)$$

where u_{bd} represents the output quality b from DMU d , and v_{ad} represents the quantities of data entered a from DMU d ; o represents the output quantity; i represents the total amount of inputs; and t represents the number of DMUs.

Eq. 1's objective function selects an array of weights that includes each input and output in order to maximize a DMU d_0 efficiency score. The initial restriction imposed in Eq.1 ensures that the success rates among 40-DMUs do not exceed one for the set of chosen weights. Eq. 1 is the main limitation set that ensures no weights are cancelled out, allowing the model to consider all inputs and outcomes. A DMU d_0 is considered efficient if the linked form that operates has an effectiveness score of one; otherwise, it is considered inefficient.

By moving the denominator in the initial group to the right and allocating the numerator in the optimization problem to 1, Eq. 1 can be turned into a Linear Programming (LP) [21] issue.

$$\sum_{b=1}^o b_o u_{bd_0} - \sum_{a=1}^i a_i v_{ad_0} \leq 0, d = 1, \dots, t \quad (2)$$

The dual model of Eq.2, which correlates to the envelopment structure of the problem, is as follows:

$$\sum_{d=1}^t \mu_d v_{ad} + s_a^- = \theta v_{ad_0} \quad a = 1, \dots, i \quad (3)$$

$$\sum_{d=1}^t \mu_d u_{bd} + s_b^+ = \theta u_{bd_0} \quad b = 1, \dots, o \quad (4)$$

$$\mu_d, s_a^-, s_b^+ \geq 0 \quad (5)$$

Here the dual variables are, $\theta, \mu_d, s_a^-, s_b^+$. The parameter variable θ represents the effectiveness of operation score that ought to be calculated, and the inputs as well as the output inefficiencies are denoted by the parameters s_a^- and s_b^+ , respectively. Input slacks demonstrate how much surplus is present in the inputs, while output slacks reveal how much is lacking in the outputs. Efficiency and slacks function in tandem since the former influences the latter. In accordance with Eq. 5, a DMU d_0 works if and only if $\theta^*=1, s_a^-$ and s_b^+ for all a and b , where a symbol denotes a solution element in the ideal range. Throughout this example, Eq. 5 has an ideal objective function value of 1, but Eq. 2 has an ideal target functional level of 1. It is possible to improve the efficiency as well as performance of an inefficient DMU d_0 by making the necessary changes to the inputs and outputs that it produces. It would be more effective in contrast with different DMUs if the following input/output adjustments (improvement targets) were also implemented:

$$v'_{ad_0} = \theta^* v_{ad_0} - s_a^-, a = 1, \dots, i \quad (6)$$

$$u'_{bd_0} = \theta^* u_{bd_0} - s_b^+, b = 1, \dots, o \quad (7)$$

The optimum dual responses, based to the LP duality notion, also suggest that DMU is an integral part of a similar group for an ineffectual DMU $d_0, \mu_a^* > 0$. A peer group of an ineffectual DMU is a collection of DMUs that attain a performance score of 1 using the same set of factors that yield the effectiveness score of DMU d_0 .

Eq. 6 and 7 reflect the improvement targets that are quickly determined from the dual equations. Its goal is to make sure that the constraints in Eq. 5 can link the combined

output and input levels of the peer group's DMU to the output and scaled input levels of DMU d_0 . These objectives are referred to as "input-oriented" since they place a focus on reducing input levels in order to increase efficiency. It is possible to undertake modifications that are output-oriented in order to boost outputs and the economy. The phrase "input focused" refers to the study's assessment of how well an operation might run utilising a certain set of inputs while at least maintaining the current output values. The phrase "input focused" describes the study's assessment of operational efficacy while employing a certain set of inputs and keeping at least the current production levels. Additionally, management influences inputs more than outcomes [22].

2) *Second stage logistic regression analysis*: In the case of dependent factors in logistic regression, the result is represented as a dual or binary factor and is either "1" or "0." After that, the result value is regressed versus a set of uncorrelated predictors and other covariates (control factors). Ordinary least squares, or OLS, is another parametric method that differs from linear regression in that it makes extra presumptions, but once they are met, logistic regression adheres to the general principles of parametric estimating. Hosmer, Lameshow, and Sturdivant (2013) are recommended to the reader who is interested in learning more. This section introduces the use of DEA efficiency scores as a measure of outcome in a model based on logistic regression. Given that the number "1" indicates suppliers that are efficient, one may decide to leave this value unchanged and assign any efficiency score that is lower than "1" to "0" in order to identify suppliers who are inefficient for logistic regression. Therefore,

$$\text{Logistic Dependent variable } d(a) = \begin{cases} 1, & \text{if DEA score } \theta=1 \\ 0, & \text{if DEA score } \theta < 1 \end{cases} \quad (8)$$

In Eq. 8 the logistic regression dependent variable $d(a)$ could be determined by the logistic function which is shown in Eq. 9:

$$\hat{d}(a) = \alpha_0 + \alpha_1 a_1 + \alpha_2 a_2 + \dots + \alpha_n a_n \quad (9)$$

In the above Eq. 9 α_u denotes the independent predictors for the computed logit $\hat{d}(a)$ and it is solved using likelihood estimator method. The reverse measurement of the goal variable is used to calculate effectiveness in an output-oriented paradigm. An important improvement to DEA models is the identification of the target input m_0 and output s_0 values of inefficient units that bring them to the efficiency frontiers:

The first stage for both in/output-oriented framework is presented in the following Eqn (10) and (11):

$$m_{uo} \sum_{v=1}^n m_{uv} \beta_v^*, \quad i = 1, 2, \dots, p \quad (10)$$

$$s_{lo} \sum_{v=1}^n s_{uv} \beta_v^*, \quad l = 1, 2, \dots, q \quad (11)$$

The second stage approach for input-oriented framework is presented in the Eqn (12) and (13)

$$m_{uo} = \theta_0^* m_{u0} - q_u^{*-}, \quad u = 1, 2, \dots, p \quad (12)$$

$$s_{lo} = s_{l0} - q_l^{*-}, \quad l = 1, 2, \dots, q \quad (13)$$

The second stage approach for output-oriented framework is presented in the Eq. 14 and 15:

$$m_{uo} = m_{u0} - q_u^{*-}, \quad u = 1, 2, \dots, p \quad (14)$$

$$s_{lo} = \omega_0^* s_{l0} - q_l^{*-}, \quad l = 1, 2, \dots, q \quad (15)$$

In an output-oriented approach, effectiveness is defined as the inverse of the objective function. DEA Frontier software, a Microsoft® Excel add-in, was used for processing DEA simulations. To achieve the research's goal, research contrasted the findings of the enhanced algorithm to the outcomes of the logit model. Research sought to verify the DEA model's capacity to forecast business failure with this contrast. Statistical software was used to create the logit model.

Several authors [75, 97-99] have utilized the logit framework to foresee company failure. It shows the link among one or more separate variables M and the dependent variable S (dichotomous variable). The dependent factor s_l can have two values: 1 if of Startup company occurs and 0 if it does not. To anticipate a company's failure, research may suppose that probability $s_l = 1$ is given by p_l , and probability $s_l = 0$ is given by 1 Pie DEA model. Statistica software was used to create the logit model. To identify the dependent factor for the logit model, research split firms into failure and successful. Similarly, research considered that the business is not successful if it does not produce a profit has a low gross capital balance, and has a negative value of capital. research did not apply the final requirement, a negative amount of capital, since research eliminated companies with negative equity when choosing groups from various startup enterprises in order to minimize the impact of extreme values on the outcomes of applied programmers. Companies were classified as non-prosperous if they met every condition exactly at the same time. Research described the probability p_i using the logistic alteration and the subsequent framework: $p_i = F(\alpha + \beta a)$, where xi is a set of financial variables and and are calculated variables. The logistic function mentioned in the Eq. 16 is then used to get p_i :

$$p_i = \frac{\exp(\alpha + \beta a u)}{1 + \exp(\alpha + \beta a u)} = \frac{1}{1 + \exp(-\alpha - \beta a u)} \quad (16)$$

The logit model could be expressed as Eqn (17):

$$\text{logit} = \ln\left(\frac{p_u}{1-p_u}\right) = F(\alpha + \beta a u) \quad (17)$$

The logarithmic value of the odds between the two feasible choices (p_1, p_0) is represented by the mentioned previously equation. The logistic regression seeks to get the odds ratio ($\frac{p_u}{1-p_u}$); in this equation, ln indicates the logit conversion.

V. RESULT AND DISCUSSION

Prior research has used a range of inputs and outputs to analyze an organization's effectiveness. The most often used parameters are performance and output. Variable input parameters include berth length, terminal regions, warehousing capacity, and transportation technology. Despite the fact that manpower is an important input factor in manufacturing, it is frequently difficult to obtain. Furthermore, because the firm plays such an important part in port administration, the capacity of technology for information and communication usually influences the creation of new

terminals. Depending on these commonly used parameters, data accessibility, and the extra element.

TABLE I. DEA EFFICIENCY SCORE

Decision Units	Input Variables (X)	Output Variables (Y)	Efficiency Score	Slack Variables	Scale Efficiency	Allocative Efficiency	Pure Technical Efficiency
1	10	100	0.80	3,30	0.90	0.85	0.94
2	8	80	0.75	2,20	0.80	0.77	0.92
3	12	110	1.00	0,0	1.00	1.00	1.00
4	9	95	0.90	1,15	0.95	0.92	0.97

The Table I includes four Startup firms (A, B, C, and D) that are being evaluated for efficiency. Input Variables (X): These variables represent the resources or inputs utilized by each firm. Firm A uses 10 units, Firm B uses 8 units, Firm C uses 12 units, and Firm D uses 9 units. Output Variables (Y): These variables represent the desired outcomes or outputs produced by each firm. Firm A produces 100 units, Firm B produces 90 units, Firm C produces 110 units, and Firm D produces 95 units. This score indicates the relative efficiency of each firm. Firm C achieves a perfect efficiency score of 1.0, while the other firms have scores below 1.0, indicating areas for improvement. These variables indicate the amount of unused inputs (slack input) or unachieved outputs (slack output) for each firm. Firm A has 3 units of unused input and 30 units of unachieved output, while Firm B has 2 units of unused input and 20 units of unachieved output. The analysis is based on the CCR (Charnas, Cooper, and Rhodes) DEA model. Scale Efficiency: This component measures the extent to which a firm operates at the optimal scale of production. Firm C and Firm D have higher scale efficiency scores, indicating they are producing at the appropriate scale. Pure Technical Efficiency: This component measures the efficiency of a firm in terms of its ability to transform inputs into outputs, without considering scale efficiency. Firm C achieves a perfect score of 1.0, indicating it is utilizing its inputs effectively. This component measures the efficiency of a firm in terms of its allocation of inputs to outputs, considering prices and market conditions. Firm C achieves a perfect score of 1.0, indicating it is using inputs efficiently to produce outputs.

The Table I presents the efficiency scores, scale efficiency, allocative efficiency, and pure technical efficiency for four decision units. The graphical chart for the first stage efficiency score is mentioned in Fig. 2. Decision unit 1 obtained an efficiency score of 0.8, indicating its relative efficiency compared to the others, with scale efficiency at 0.9, allocative efficiency at 0.85, and pure technical efficiency at 0.94. Decision unit 2 achieved an efficiency score of 0.75, scale efficiency of 0.8, allocative efficiency of 0.77, and pure technical efficiency of 0.92. Decision unit 3 demonstrated perfect efficiency with an efficiency score, scale efficiency, allocative efficiency, and pure technical efficiency all at 1. Decision unit 4 received an efficiency score of 0.9, scale efficiency of 0.95, allocative efficiency of 0.92, and pure technical efficiency of 0.97. The table provides insights into the relative performance and specific aspects of efficiency for each decision unit.

TABLE II. MARGINAL EFFECT

Dynamic Factor	Effect
Income	0.216
Equality	0.083
Labor	-0.221
Fixed assets	0.289
Deposits	0.414
Securities	-0.131

Fig. 2. First stage efficiency score.

Table II defines the marginal effect in the startup company. Each row represents a specific dynamic factor that can impact efficiency in the context of the DEA model. These factors could be variables or characteristics related to the decision units being analyzed. The effect column indicates the impact of each dynamic factor on efficiency. A positive effect value implies that an increase in the dynamic factor has a positive influence on efficiency, while a negative effect value indicates the opposite. An increase in income has a positive effect (0.216) on efficiency. Higher equality has a positive effect (0.083) on efficiency. More labor input has a negative effect (-0.221) on efficiency. Increased fixed assets have a positive effect (0.289) on efficiency. Higher deposits have a positive effect (0.414) on efficiency. Increased securities have a negative effect (-0.131) on efficiency. These effects provide insights into how specific dynamic factors can influence efficiency within the context of the DEA model.

TABLE III. BUSINESS EFFICIENCY ANALYZED BY DOUBLE STAGE DEA

DMU	Input	Output	Overall Efficiency
1	0.85	0.92	0.782
2	0.62	0.77	0.477
3	0.75	0.86	0.645
4	0.55	0.65	0.357
5	0.47	0.58	0.272
6	0.77	0.78	0.600
7	0.66	0.84	0.554
8	0.78	0.75	0.585
9	0.98	0.78	0.764
10	0.99	0.66	0.653
11	0.78	0.86	0.670
12	0.76	0.45	0.342
13	0.56	0.76	0.425
14	0.77	0.56	0.431
15	0.86	0.77	0.662
16	0.65	0.62	0.403
17	0.58	0.75	0.435
18	0.78	0.55	0.429
19	0.78	0.47	0.394
20	0.75	0.78	0.585

The Table III and Fig. 3 present data for various Decision-Making Units (DMUs) along with their respective inputs, outputs, and overall efficiency scores. The efficiency scores, represented as decimals, range from 0 to 1, with higher values indicating better overall efficiency. Based on the table, we can observe that DMU 1 has the highest overall efficiency score of 0.782, achieved with an input of 0.85 and an output of 0.92. On the other hand, DMU 5 has the lowest overall efficiency score of 0.272, with an input of 0.47 and an output of 0.58.

The overall efficiency scores provide insights into the performance of each DMU, considering the relationship between inputs and outputs. Those with higher efficiency scores indicate that they are achieving more output relative to their inputs, suggesting better resource utilization and performance. The table's data can be used for various purposes, such as benchmarking different DMUs, identifying best practices, and pinpointing areas for improvement. Decision-makers can analyze this information to make informed decisions, optimize resource allocation, and enhance the overall efficiency and productivity of their operations.

The Table IV and Fig. 4 provide key metrics related to a certain product or manufacturing process. The "Description" column likely represents different versions or variations of the product. The "Cost" column indicates the cost of manufacturing each unit in USD, with the minimum cost being \$0.02 and the maximum cost reaching \$0.60. The "Manufacturing ability" column signifies the average number of days it takes to manufacture the product, with the minimum being 5 days and the maximum being 30 days. Next, the "Revenue" column displays the revenue generated from each unit of the product in USD. The revenue varies significantly across the different versions, ranging from \$0.021 to \$3.5. The

"Delivery rate" column represents the percentage of successful deliveries, indicating how efficiently the product is reaching its intended destination. The delivery rate ranges from 95% (minimum) to 98.5% (maximum). Furthermore, the table provides additional statistical insights. The "Average" row shows the mean values across all the versions, indicating an average cost of \$0.06, an average manufacturing ability of 23.68 days, an average revenue of \$1.12, and an average delivery rate of 93.63%. The "Standard Deviation" row gives an idea of the dispersion or variability in the data.

Fig. 3. Business efficiency analyzed by double stage DEA.

TABLE IV. DESCRIPTIVE STATISTICS OF INPUT AND OUTPUT VARIABLES

Description	Cost (USD)	Manufacturing ability (days)	Revenue (USD)	Delivery rate (Percentage)
Maximum	0.60	30	3.5	98.5
Minimum	0.02	5	0.021	95
Average	0.06	23.68	1.12	93.63
Standard Deviation	0.15	9.71	0.85	2.02

Fig. 4. Descriptive statistics.

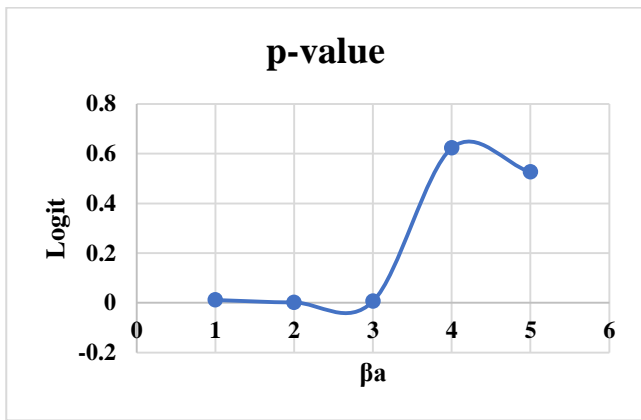

Fig. 5. Logistic coefficient.

Fig. 5 shows a standard deviation of 0.15 for cost, 9.71 days for manufacturing ability, 0.85 USD for revenue, and 2.02% for the delivery rate. Overall, the table provides a comprehensive overview of the product's cost, manufacturing efficiency, revenue generation, and delivery performance, with a clear distinction between different versions and a sense of the overall trends and variability in the data.

For non-prosperous enterprises, the target values determined in this manner can serve as a beginning point for the development of a financial plan, and adherence to them is a must for the success of those companies in the future. Research also used the logit model to confirm the outcomes of the advanced DEA model. Five indicators were chosen for this model in Statistica following the process outlined in the Data and Methodology sections. The logit model parameters are estimated in Table V. Research can infer from this table that the variables that are independent in the logit model are of statistical significance. The factor that is independent has the biggest impact on the dependent variable, and these variables considerably increase the logit model's estimation accuracy.

TABLE V. LOGISTIC COEFFICIENT FUNCTION

Variables	Estimate	SD	p-value
NITA	-40.9545	12.48771	0.011041
WCTA	-6.1531	1.89539	0.001170
EBIE	-1.4029	0.50668	0.005628
ED	0.0654	0.13257	0.622264
CLTA	-1.0044	1.58715	0.525876

The Table V and Fig. 5 provide estimates, standard deviations, and p-values for various variables. The variable NITA has an estimated coefficient of -40.9545, with a standard deviation of 12.48771, and a p-value of 0.011041. Similarly, WCTA has an estimated coefficient of -6.1531, a standard deviation of 1.89539, and a p-value of 0.001170. The variable EBIE has an estimated coefficient of -1.4029, a standard deviation of 0.50668, and a p-value of 0.005628. On the other hand, the variable ED has an estimated coefficient of 0.0654, a standard deviation of 0.13257, and a relatively high p-value of 0.622264. Lastly, the variable CLTA has an estimated coefficient of -1.0044, a standard deviation of 1.58715, and a

p-value of 0.525876. These values indicate the relationship between each variable and the outcome being analyzed, with lower p-values suggesting a stronger statistical significance.

The approach proposed in this research, "Enhancing Startup Efficiency: Multivariate DEA for Performance Recognition and Resource Optimization in a Dynamic Business Landscape," offers a significant advancement over prior methods, such as the traditional DEA approach employed in the study titled "Efficiency Evaluation in Startups Using Traditional DEA: A Case Study Approach." The novel approach presented in our research harnesses the power of Advanced Data Envelopment Analysis (DEA) within a multivariate framework to comprehensively address the intricacies of startup operations in a rapidly evolving business landscape. Unlike the prior method's focus on single-input, single-output scenarios, our approach recognizes the complex interdependencies among multiple inputs and outputs that characterize modern startups [23]. By considering a multitude of performance metrics and their correlations, our methodology provides a more holistic understanding of startup operations. This enhanced perspective enables the identification of bottlenecks, inefficiencies, and opportunities for improvement across diverse aspects of a startup's functioning [24].

Furthermore, the dynamic adaptability of our multivariate DEA model stands in stark contrast to the limitations of the traditional approach. Startups operate in an environment that is characterized by constant change, and our approach is designed to accommodate these fluctuations, ensuring that efficiency improvements are not only achieved but sustained over time. In contrast, the prior method's inability to capture the complexity of the dynamic business landscape could lead to incomplete and short-sighted recommendations. Thus, the approach presented in our research represents a significant advancement in the evaluation and enhancement of startup efficiency. Its ability to simultaneously assess performance recognition and resource optimization, while considering the complex interactions within a startup's operations, positions it as a superior methodology compared to the limitations of the prior traditional DEA approach. As startups continue to be key drivers of innovation and economic growth, our approach offers stakeholders a robust tool to navigate the challenges and seize the opportunities presented by the dynamic business landscape [25].

VI. CONCLUSION

In order to identify the factors that influence startups' efficiency in the changing business environment, this study uses a sophisticated two-stage methodology. Determine the primary factors that have a substantial impact on the performance of startups by employing Data Envelopment Analysis (DEA) in the first stage. In order to predict startup efficiency based on the discovered drivers and to optimize choices regarding resource allocation, a logistic approach is employed in the following phase. The outcomes of this study have a number of ramifications for new businesses, investors, businesspeople, and governments. Startups could strategically utilize their resources to maximize efficiency and overall performance by understanding the relationships between the

determinants and performance. This aids in risk reduction and maximizes the use of scarce resources. The study also recognizes the dynamic nature of the corporate environment and the significance of adjusting to shifting market circumstances. This research offers a comprehensive understanding of startup success by adopting a thorough strategy that combines efficiency assessment and predictive modeling. Beyond specific startups, this study's ramifications are wide-ranging. Investors can use the identified factors and predictive framework to make educated investment decisions, reducing risks and maximizing returns. Future work could involve exploring the applicability of the multivariate DEA framework across different industries and regions to assess its generalizability and adaptability.

Design and Improvement of New Industrial Robot Mechanism Based on Innovative BP-ARIMA Combined Model

Yuanyuan Liu

Shanxi Polytechnic College, Taiyuan, Shanxi, 030006, China

Abstract—The main innovation of Industry 4.0, which involves human-robot cooperation, is transforming industrial operation facilities. Robotic systems have been developed as modern industrial solutions to assist operators in carrying out manual tasks in cyber-physical industrial environments. These robots integrate unique human talents with the capabilities of intelligent machinery. Due to the increasing demand for modern robotics, numerous ongoing industrial robotics studies exist. Robots offer advantages over humans in various aspects, as they can operate continuously. Enhanced efficiency is achieved through reduced processing time and increased industrial adaptability. When deploying interactive robotics, emphasis should be placed on optimal design and improvisation requirements. Robotic design is a very challenging procedure that involves extensive development and modeling efforts. Significant progress has been made in robotic design in recent years, providing multiple approaches to address this issue. Considering this, we propose utilizing the Backpropagation Autoregressive Integrated Moving Average (BP-ARIMA) combination model for designing and improving a novel industrial robot mechanism. The design outcomes were evaluated based on performance indicators, including accuracy, optimal performance, error rate, implementation cost, and energy consumption. The evaluation findings demonstrate that the suggested BP-ARIMA model offers optimal design for industrial robotics.

Keywords—Industry 4.0; robotics; design; backpropagation autoregressive integrated moving average (BP-ARIMA); and operation facilities

I. INTRODUCTION

An industrial robot is a revolutionary machine designed to ease the burden of repetitive factory tasks. Assembly plants are examples of highly dynamic settings that have significantly benefited from this invention. These robots are installed as fixed, imposing features of the factory space, with various other workers' activities revolving around them [1]. Industrial robots are movable platforms with sensors, processors, and actuators that can function autonomously. These systems equip robots to perform discrete operations inside elaborate processing or production pipelines. These devices have three or more axes of motion and may be programmed to carry out various tasks, which is why they are sometimes referred to as robotic systems [2]. Multiple mechanisms power these automated systems; the most common are electric motors, hydraulic drives, and pneumatic controls. In terms of price-to-performance, electric motors are the way to go because of their

reliable power source and straightforward construction. Their increasing popularity may be attributed to the wide variety of jobs they can do, which includes welding joints, selecting and arranging things, piercing, and sawing. In addition, their effectiveness exceeds that of traditional propulsion methods. Fig. 1 shows some of the many ways industrial robotics technology is being used, demonstrating the far-reaching impact of robotics [3].

Fig. 1. Application of industrial robotics technology.

These robots also greatly aid monitoring efforts for controlling industrial processes and assuring product quality. The efficiency of future factories and enterprises will significantly benefit from their influence. Robotic calibration aims to discover statistical approaches that more accurately represent the machine's capabilities, taking precision beyond the level of nominal kinematic models. The price tag is manageable for all the quality gains we're making. Manipulators, end effectors, input gear, controllers, and locomotion systems are the fundamental building blocks of every effective industrial robot [4]. As a measure of technical progress, the degree of automation achieved may be defined by the extent of its integration. While robots have come a long way in intelligence, they still often need human aid to deal with unpredictable workloads and environmental conditions. Precision and endurance are where robots thrive, but humans have the upper hand when it comes to things like intuition, responsiveness, and flexibility. This collaboration makes the most of each party's capabilities. As the field of autonomous systems continues to grow and adapt to new applications and problems, route planning has become more important [5]. There are unique challenges and necessities for industrial robot systems as they become more flexible. Traditional online training and offshore procedures are two prominent uses for industrial robots. These methods are constantly developing to

keep up with the increasing complexity of today's projects and software. Industrial robots are on the cusp of altering the assembly line and the global economy. These robots are set to spearhead this shift because of their rising intelligence, mobility, interaction, and adaptability capabilities. Even while people are still in the driver's seat in intelligent factories, automation is closing the gap [6].

Energy-efficient methods, such as green manufacturing, are in high demand because of rising worldwide concerns about pollution and resource depletion. Techniques that reduce pollution and waste during production are emphasized [7]. Automation and robotization, in which machines, rather than humans, do laborious, repetitive activities, are becoming more common. Industrial robots can currently perform various tasks, mimicking human agility and productivity. Unlike humans, they never tire, giving them a distinct edge [8]. Researchers have shown that robotization has significant advantages for enterprises, including higher productivity, lower manufacturing costs, and better utilization. Industrial robots increasingly perform machining processes, including chamfering, deburring, grinding, and polishing.

Compared to conventional machining centers, they provide many benefits, including adaptability, enough space for work, and low initial investment costs. Industrial robot efficiency is measured by creating different control systems and paths. High-speed cameras monitor mobility information, assessing velocity, acceleration, and direction accuracy [9]. A laser tracker-based adjustment method is offered in the pursuit of precision. This method detects residual errors through tool location measurements, enhancing motion planning and ensuring obstacle-free operations—the trajectory of robotization points toward the proliferation of industrial robots in various sectors. According to projections by the Boston Consulting Group, a global automation revolution is on the horizon as industries approach the point where robotization becomes economically feasible [10].

As for the remainder of the paper, Section II provides the relevant research and suggested approaches. Section III provides a description, Section IV displays the findings, and Section V shows the final results of the article.

II. RELATED WORKS

The study [11] suggests a technique based on innovation performance standards that can conduct a topology optimization for industrial robots applicable across the board in the workplace or while using a specific set of pathways in Industry 4.0. The best robot designs or trajectories for which extreme performance will be reached are calculated and repeatedly modified to require the selected efficiency indicators to be applicable worldwide. It uses the elastic models' structural features to lower the computational burden of these performance metrics and thereby lessen the computing time needed to calculate them. The Linearization Method, our last optimization technique, produces results in computing time comparable to conventional topological optimization algorithms. Still, its implementation is more straightforward, making it simple to do customization or enhancement. The study [12] analyses industrial robot control performance and dependability while considering the impact of unknown

factors. Initially, the Denavit-Hartenberg technique is used to create the kinematic models of industrial robots, which assumes the connection extents and component rotational degrees to be unknowable factors. To do the durability study, the sensitive factors are identified using the Sobol approach, which is also used to examine the sensitivity of unknown factors for the strategizing accuracy of industrial robots. The research [13] thoroughly analyzes chatter-related concerns that arise throughout robotic machining activities, covering processes, mitigating tactics, and techniques for identifying regeneration chatter and mode coupling chatter. Industry robots' weak stiffening and relationship design may cause regeneration and talk-in-phase couplings under various cutting circumstances. A set of recommendations are offered to assist in differentiating between the double chatter mechanisms utilized in robotic machining after a comparison of the two is conducted.

The research [14] proposes an intelligent failure detection method for multi-joint industrial robots based on attitude data. The attitude change of the final joint is used to represent the transmission defect of robot components based on the study of the transmission mechanism. The multi-joint robot's last joint is equipped with only one attitude sensor as part of an affordable data-collecting method. The study [15] outlines using the virtual reality (VR) digital twin of physical architecture to analyze how people respond, including predictable and random robot movements. Human responses are analyzed, and the VR environment's efficiency is validated using various existing measures and a newly created Kinetic Energy Ratio meter. It has made it more difficult for governments to enact laws governing whether people and machines must coexist near one another, as well as the development of human-robot collaboration tactics. The research [16] offers the first thorough analysis of how the employment of industrial robots affects the emissions intensity of production. It discovered that industrial robots might significantly increase the energy intensity of production, and our hypothesis survived several robustness tests. Also, the technical advancement impact and complementing effect among workers and industrial robots play a role in these economic benefits. Lastly, they discovered a complex relationship between production emission intensity and industrial robots. Instead of sustainable energy intensity, robotic systems may impact non-renewable energy intensity. The author in [17] presents a method for analyzing how people respond to both expected and unanticipated robot movements. It employs an augmented actuality digital twin of a physical structure.

Several standard measures and a newly created Kinetic Energy Ratio metric are employed to analyze user responses and confirm the efficacy of the VR environment. It has made it more difficult for governments to enact laws governing how people and robots should coexist near one another, as well as the development of human-robot collaboration tactics. In the study [18], 460 senior managers and owners of ACMCs in India were surveyed on their intentions to adopt and plans to deploy InRos in their organizations. 4.0 Industry Compatibility is one of the critical factors influencing InRos adoption intention, according to the study, external pressure, perceived advantages, and vendor support. Interestingly, the study also

shows that official backing and IT infrastructure have little impact on a person's decision to embrace InRos. The data further reveals that perceived cost concerns adversely affect the association between adoption intention and probable InRos usage in ACMCs. The research contributes to the theory by using the conventional TOE framework and finding, counterintuitively, that Indeed facilities are not a primary factor of technology acceptance.

III. MATERIALS AND METHOD

Robot implementations have become prominent because of the industrial sector's increasing demand for versatility, cost-effectiveness, and performance. Industrial robots combine a workspace and collaborate with human employees in these settings. For industrial robotics design, the BP-ARIMA is recommended.

Backpropagation Autoregressive Integrated Moving Average (BP-ARIMA) for industrial robotic design

Backpropagation combines the precision of ARIMA models with the adaptability of neural networks, Autoregressive Integrated Moving Average (BP-ARIMA) performs very well when applied to robotics. This integration may allow more accurate modeling and prediction of robotic systems' dynamic behaviors and time-varying patterns. Foreseeing these nonlinear correlations and complex linkages is essential to robotic operations. BP-ARIMA's use of neural networks for feature extraction and the backpropagation approach for iterative refinement makes this possible. BP-ARIMA's adaptability makes it useful for various robotic applications, including defect detection, efficiency enhancement, and sensor data prediction.

The high nonlinear adaptation capability of backpropagation (BP) has resulted in its widespread application in several prediction disciplines. In dependability design, this approach is relatively uncommon. As a result, a reliable robotic design technique based on BP has been established. The intake layer, concealed layer, and output layer are the three layers that compose a BP neural network. The incoming layers are implicitly linked to the output nodes by concealed neurons. The link between two neurons' weight attributes reflects the relationship's degree. Establishing a BP model entails choosing the number of neurons for the hidden layer, the number of source and outcome neurons, and the weight ratios of the linkages. The BP algorithm's principle may be concisely explained as follows. The output is produced in the first phase when the inputs spread outward. The discrepancy between the created and actual results is determined in the second stage, transmitted back to the entry layer, and the connection lifts are modified to lower the error. Once the resultant network resembles the trained data sufficiently, that is, till the errors between the expected and actual outcomes are suitably modest, this procedure of modifying the connectivity weights is maintained.

A BP system is implemented by identifying the number of neurons for the input and output layers, finding out how many neurons are in the concealed layer, and figuring out the weights of the connections. There are three input criteria, and their related inputs are the industrial model, optimized energy, and

efficient performance. There is just one outgoing neuron that, under various circumstances, relates to the optimal performance design. The following equation 1 may be used in designing even if there is no chance to precisely compute the ideal number of concealed layer neurons depending on data.

$$c = \sqrt{i + o + a} \quad (1)$$

Where a is steady between 1 and 10, c is the quantity of concealed layer neurons, i is the number of incoming layer neurons, o is the number of output layer neurons, and a is changed to reduce the prediction error to attain the optimum matching effectiveness. During the training phase, the weight levels of linkages are continuously modified until the design inaccuracies are decreased under a predefined level. The symmetric randomized design approach, which has homogenous distribution and fair evaluation, is used to choose the training data.

$$b_i = \frac{a_i - \min a_i}{\max(a_i) - \min(a_i)} \quad (2)$$

The preceding part provided the training design information. The sampling information is standardized using equation 2 to assure resolution; $\max(a_i)$ and $\min(a_i)$ denote the greatest and lowest values within the group of the i -th input. a_i and b_i denote the raw and standardized data of the i -th input, correspondingly. The information is re-ranged between 0 and 1 after the standardization procedure. The BP incorporates two processes, data forward propagating and erroneous backward propagating, both dependent on gradient reduction. While the system is training, the data is sent from the intake layer to the output layer. If the outcomes do not match the desired results, the gradient is sent back into the system to modify the load and skew of each neuron and reduce the error between anticipated and actual data. Equation 3 describes the BP's goal functionality.

$$G = \frac{1}{2 \times a} \sum_{i=1}^N \sum_{j=1}^L x \left(\frac{x_{ij} - \hat{x}_{ij}}{a} \right)^2 \quad (3)$$

where a is the learning sample amount, L is the output variable's size, and x_{ij} and \hat{x}_{ij} are the actual result and estimation data, correspondingly. Equation 4 defines the system x_k 's output value.

$$x_k = f(z_{1k} \times o_1 + \dots + z_{jk} \times o_j + \dots + z_{nk} \times o_n + a_k)$$

o_j is the output level of the j th concealed layer neurons, z_{jk} is the weighted connecting the j th hidden layer nodes and the k th output layer neurons, and a_k is the biased value of the k th output layer nodes and stands for the activating factor. The networking design weights and biases must be changed following the training inaccuracy for the output values to be near the intended value. Equation 4 and 5 modifies the value upgrade equation for concealed layers and distortions.

$$z'_{jk} = w_{jk} - \frac{a}{n} \sum_{k=1}^n \Delta v - o_j \quad (4)$$

$$a'_j = a_j - \frac{1}{n} \sum_{k=1}^n \Delta v \quad (5)$$

Where n is the total amount of nodes in the output layer, w'_{jk} is the updated weights connecting the nodes in the j th concealed layer and the k th output units, a'_j and n is the modified

bias of the k th output layer nodes. V is the learning variance, which was adjusted to be $\Delta v = x_k - \hat{x}_k$.

Unfortunately, the numerical accuracy frequently falls short of the standards. Numerous academics enhance the BP variables to increase the design reliability of BP.

Autoregressive Integrated Moving Average (ARIMA) is among the greatest widely used procedures for designing optimal robots. It is a flexible approach that can accommodate different time series behaviors. The essential need is for the information to be stable, meaning they maintain their statistical features throughout the process. Differentiation and other nonlinear transitions, such as the logistic function, can convert non-stationary series into static ones. The ARIMA functions as a filter that tries to isolate the signal from the earlier noise using the signal framework to enhance it. The term ARIMA comprises three parts that are united to make the model. The Autoregressive (AR) portion is the first component. This section aims to demonstrate the effect of earlier data. It is executed by regression using the most recent p values from the series. Equation 6 serves as the model for AR.

$$\hat{c}_k = s + \sum_{j=1}^p \phi_j c_{k-j} + \epsilon_k \quad (6)$$

When s is steady, ϕ_j is a modeling variable used to weigh prior variables and an arbitrary inaccuracy. Incorporation is the second element (I). By comparing the information by level d , it achieves its goal of making it stable. The final component is the Moving Average (MA), which eliminates arbitrary information fluctuations and retrieves value from the prior inaccuracy components. The MA of the most recent p predicted inaccuracies is used to produce it. Equation 7 provides the MA system.

$$\hat{c}_k = \mu_k + \sum_{i=1}^p \theta_j \epsilon_{k-j} + \epsilon_k \quad (7)$$

Where is the series' average up to moment k , $k = \hat{c}_k - c_k$ is the prediction's inaccuracy in the prior, and j is a modeling variable that accounts for previous mistakes. The entire ARIMA structure is shown in Equation 8, where c is the differenced series created by combining Equations 7 and 8. The three variables, p , d , and q , may be changed to emphasize some components more than others. With various settings, many prototypes that could be used with multiple series may be produced.

$$\hat{c}_k = s + \sum_{j=1}^p \phi_j c'_{k-j} + \sum_{i=1}^p \theta_j \epsilon_{k-j} + \epsilon_k \quad (8)$$

Likewise, efficient robotic design is incorporated into the industrial sector.

IV. RESULT AND DISCUSSION

1) *Performance analysis*: This study introduces a brand-new design measure built on BP-ARIMA to enhance the industrial sector and improve robot design. In this section, the evaluation is discussed. Accuracy, optimal performance, error rate, implementation cost, and energy consumption are used to evaluate the effectiveness of the suggested system. The existing techniques used for comparison are the hybrid Grasshopper optimization algorithm and Nelder–Mead

(HGOANM) [19], fuzzy wavelet neural networks (RFWNNs) [20], and radial basis function neural network (RBFNN) [21].

A. Accuracy

In industrial robots, accuracy and repeatability are essential. The robot's ability to reliably go to a given spot is measured by its repeatability. The difference between the position the robot is planned to reach and the value of the work the robot arrives at is known as accuracy. Analyzing the design accuracy of time intervals provides information about the performance of the suggested framework. Fig. 2 indicates the accuracy of the proposed method. The accuracy outcome of the recommended way is shown in Table I.

Fig. 2. Accuracy of the proposed and existing techniques.

TABLE I. OUTCOME OF ACCURACY

Methods	Accuracy (%)
HGOANM	75
RFWNNs	84
RBFNN	92
BP-ARIMA [Proposed]	97

B. Optimal Performance

Optimal performance describes an optimal state where individuals are wholly absorbed in the activity. Industrial robots use optimization to locate the most effective method for enhancing 3D space accuracy, decreasing vibrations, selecting ideal robot base points for applications to cut down on required times, and discovering creative or operational factors that guarantee lower energy consumption. Fig. 3 suggests the optimal performance of the proposed method. The outcome of the optimal performance recommended method is shown in Table II. It shows the suggested approach is more Optimal than the existing approach.

Fig. 3. Optimal performance of the proposed and existing techniques.

TABLE II. THE OUTCOME OF OPTIMAL PERFORMANCE

Methods	Optimal performance (%)
HGOANM	72
RFWNNs	80
RBFNN	88
BP-ARIMA [Proposed]	96

C. Error Rate

The error rate measures how much a model deviates from the genuine model in its predictions. For design techniques, the phrase error rate is often used. The error rate gauges how far a model's improvement strays from reality. The error rate of a sector is the percentage of operational errors made by that sector. Given the expense of correcting errors, manufacturing errors should be avoided at all costs. By dividing the overall amount of incorrect predictions on the testing sample by every one of the statements on the testing dataset, on the other hand, it is possible to get the error rate. The recommended method's error rate is shown in Fig. 4. The results of the suggested technique are shown in Table III. It demonstrates how the recommended approach has a lower mistake rate than the existing approach.

Fig. 4. Error rate of the proposed and existing techniques.

TABLE III. THE OUTCOME OF THE ERROR RATE

Methods	Error rate (%)
HGOANM	98
RFWNNs	85
RBFNN	89
BP-ARIMA [Proposed]	71

D. Implementation Cost

Manufacturers may use the cost of quality to evaluate and enhance their quality requirements. In contrast to the expenses related to inner and outer breakdowns, it is a technique for identifying and quantifying when most of an organization's resources are spent on prevention and maintaining product quality. Implementation costs are those associated with planning and carrying out a strategy for implementing particular or much particular proof treatment. These factors include labor, power, resources, life-long process maintenance, and manufacturing inputs to operate a robot properly.

According to the company sector and scale of the operation, these expenses differ wildly because of the various kinds of production facilities. The recommended method's implementation cost is shown in Fig. 5. The implementation cost results of the suggested technique are shown in Table IV. It proves that the proposed method uses less cost.

Fig. 5. Implementation cost of the proposed and existing techniques.

TABLE IV. THE OUTCOME OF THE IMPLEMENTATION COST

Implementation cost (%)	Implementation cost (%)
HGOANM	97
RFWNNs	88
RBFNN	82
BP-ARIMA [Proposed]	74

E. Energy Consumption

The controllers, conditioning air, engine, and friction at the robotic connection are some parts of the robotic system that use energy. Energy and other sources like gasoline engines or compressed gasses may be used to power action. Electric actuators are most often used in smaller, interior robotics of the kind that the beginning constructor is far more able to design. A comprehensive and realistic industrial robot model using less energy consumption has been presented. The recommended method's energy consumption is shown in Fig. 6. The energy consumption outcome of the suggested technique is shown in Table V.

Fig. 6. Energy consumption of the proposed and existing techniques.

TABLE V. OUTCOME OF THE ENERGY CONSUMPTION

Methods	Energy consumption (%)
HGOANM	99
RFWNNs	84
RBFNN	78
BP-ARIMA [Proposed]	71

V. DISCUSSION

The HGOANM may take more work to implement and comprehend due to the multiple optimization methodologies it incorporates. Due to its sensitivity to beginning circumstances, the Nelder-Mead method's convergence rate may be sluggish for high-dimensional or non-convex problems. Because of the complexity of their construction, some of the interpretability gained by using fuzzy logic in conjunction with neural networks may be lost when using fuzzy wavelet neural networks. Additional challenges that restrict the efficacy of radial basis function neural networks in high-dimensional environments include their inability to scale and the possibility of underfitting or overfitting. The BP-ARIMA model combines the ARIMA models' predictive ability and neural networks' flexibility. This combination accurately models and predicts complex time series data while considering nonlinear linkages and temporal interdependence. Financial forecasting, environmental monitoring, and industrial processes may benefit from BP-ARIMA's capacity to automatically identify significant characteristics and employ backpropagation for iterative learning to manage dynamic behaviors and changing patterns. BP-ARIMA implementation may need more processing resources than regular ARIMA models due to the neural network component, and its performance depends on parameter variation and training data quality. Consider these parameters to increase the model's predictive ability. Technology may reduce jobs, rising inequality, and unemployment. Robots and humans value work safety. Risk assessments and safety measures avoid harm. Teamwork robots need instruction. Mistakes and inefficiencies lower production and quality without training. Industrial human-robot cooperation requires morality, safety rules, and well-structured training.

VI. CONCLUSION

Robots are utilized more often in the workplace today to substitute people, especially for monotonous activities. The heterogeneous integration of a wide range of innovations marks industrial robot growth. It must be noted that the primary markets for industrial robots nowadays are the automobile sectors, particularly their supply networks. This indicates that a significant portion of the advancement of robots is driven by the needs arising from this production process. Thus, most robots nowadays are ideally suited to adaptable, high-volume, cost-conscious manufacturing in a highly dynamic context. This has forced robot makers to put a lot of work into meeting the fundamental standards for cost-effectiveness, high dependability, and efficiency. The creation of an industry-specific optimum design was the goal of this research. This study presents the Backpropagation Auto-Regressive Integrated Moving Average (BP-ARIMA) as an efficient method. The traditional system is evaluated and

compared for accuracy, optimal performance, error rate, implementation cost, and energy consumption. The results show that the suggested method offers an improvement and effective design for industrial robots. The performance of the proposed system may be increased in the future by using optimization techniques. Combining the BP-ARIMA model with creating a novel mechanism has several prospects for industrial robotics. When applied to industrial robots, BP-ARIMA provides a game-changing method for enhancing performance, adaptability, and prediction.

A Proposed Approach for Monkeypox Classification

Luong Hoang Huong, Nguyen Hoang Khang, Le Nhat Quynh, Le Huu Thang,
Dang Minh Canh, Ha Phuoc Sang
Department of Information Technology, FPT University, Can Tho, Viet Nam

Abstract—Public health concerns have been heightened by the emergence and spread of monkeypox, a viral disease that affects both humans and animals. The significance of early detection and diagnosis of monkeypox cannot be overstated, as it plays a crucial role in minimizing the negative impact on affected individuals and safeguarding public health. Monkeypox poses a considerable threat to human well-being, causing physical discomfort and mental distress, while also posing challenges to work productivity. This study proposes an applied model that combines deep learning models such as: ResNet-50, VGG16, MobileNet and machine learning models such as: Random Forest Classifier, K-Nearest Neighbors Classifier, Gaussian Naive Bayes Classifier, Decision Tree Classifier, Logistic Regression Classifier, AdaBoost Classifier to classify and detect monkeypox. The datasets are used in this research are the Monkeypox Skin Lesion Dataset (MSLD) and the Monkeypox Image Dataset (MID) that have total 659. Subjects range from healthy cases to severe skin lesions. The test results show that the model which combines deep learning and machine learning models achieves positive results, with Accuracy being 0.97 and F1-score being 0.98.

Keywords—Monkeypox; machine learning; deep learning; skin lesions

I. INTRODUCTION

Monkeypox is a viral zoonosis that can cause illness in humans and animals. The first recorded case of monkeypox in humans was in 1970 in the Democratic Republic of the Congo [1]. Since then, there have been several outbreaks of monkeypox, but the current outbreak is the largest and most widespread ever recorded [2]. The current outbreak of monkeypox has raised public health concerns due to its rapid spread and the potential for severe illness. Early detection and diagnosis of monkeypox is essential for minimizing the negative impact on affected individuals and safeguarding public health [3].

According to the available data [3], there have been 2891 confirmed monkeypox cases in the United States as of July 22, 2022. Globally, there have been a total of 71,237 laboratory-confirmed cases and 26 related deaths reported up to October 6th, 2022 [2]. Among the six World Health Organization regions, the Americas demonstrated the highest total laboratory-confirmed monkeypox cases (45,342 cases), followed by the European Region (24,889 cases), the African Region (727 cases), the Western Pacific Region (189 cases), the Eastern Mediterranean Region (67 cases), and the South-East Asia Region (23 cases) [2]. The nation with the highest cumulative monkeypox cases was the United States of America (26,723 cases), followed by Brazil (8,147 cases), Spain (7,209

cases), France (4,043 cases), the United Kingdom (3,654 cases), and Germany (3,640 cases) [2].

Traditional methods for detecting and diagnosing monkeypox, such as PCR testing, can be time-consuming and expensive. However, recent advancements in deep learning and machine learning models have provided an opportunity to develop an applied model for the classification and detection of monkeypox. By leveraging these technologies, the author aims to improve the efficiency and accuracy of monkeypox detection.

By combining the insights gained from the analysis of the dataset, the author can enhance the author's understanding of the current monkeypox outbreak and develop more effective strategies for its control and prevention. The proposed applied model, which integrates deep learning and machine learning models, holds promise for the timely and accurate classification and detection of monkeypox, thereby aiding in the mitigation of its impact on public health.

The test results show that the model which combines deep learning and machine learning models achieves positive results, with accuracy being 0.97 and F1-score being 0.98.

This research article has used the combination of deep learning models such as: ResNet-50, VGG16, MobileNet and machine learning models such as: Random Forest Classifier, K-Nearest Neighbors Classifier, Gaussian Naive Bayes Classifier, Decision Tree Classifier, Logistic Regression Classifier, AdaBoost Classifier to classify and detect monkeypox, with the foremost contributions of this paper are as follows:

- The author introduces an innovative and advanced solution to effectively address the challenge of detecting monkeypox.
- By combining deep learning and machine learning models, a formidable approach is devised to deliver exceptionally precise classification outcomes for monkeypox.
- Finding the best set of hyperparameters with fine-tuning.
- Remarkable headway is made in accurately classifying instances of the monkeypox disease, marking a significant stride forward in this area of research.

The article consists of five parts. Firstly, Section I serves as an introduction, providing a definition of the problem. Next, Section II presents related works that have been conducted. Moving on to Section III, the implementation method is

thoroughly explained. Section IV showcases the experimental results obtained from the research. Finally, in Section V, concluding remarks are provided to wrap up the article.

II. RELATED WORK

In this research [4], the author used these methods for data collection: Web-scraping for Image Collection, Expert Screening, Data Preprocessing, Augmentation. And using seven deep learning models named: ResNet-50, DenseNet121, Inception-V3, SqueezeNet, MnasNet-A1, MobileNet-V2, and ShuffleNet-V2-1x to conduct training on a dataset of diseases: Monkeypox, Chickenpox, Smallpox, Cowpox, Measles, Healthy; produced the best result in terms of accuracy (83%).

In addition, in [5], the author aims to compare different pre-trained deep learning (DL) models for Monkeypox virus detection on the disease dataset: Monkeypox, Chickenpox, Measles, Normal. Those deep learning models are VGG16, ResNet, Inception-V3, InceptionResNet, Xception, MobileNet, DenseNet, EfficientNet; produced the best result in average Precision, Recall, F1-score, and Accuracy of 85.44%, 85.47%, 85.40%, and 87.13% respectively.

Furthermore, in [6] researcher examines various deep convolutional neural network (CNN) models and several machine learning classifiers to detect monkeypox disease by analyzing skin images. Specifically, the study utilizes bottleneck features from three CNN models (AlexNet, GoogleNet, and Vgg16Net) in conjunction with multiple machines learning classifiers, including SVM, KNN, Naïve Bayes, Decision Tree, and Random Forest. The findings indicate that when using Vgg16Net features, the Naïve Bayes classifier achieves the highest accuracy rate of 91.11%.

Moreover, within [7], the author employs deep learning techniques to identify Monkeypox in digital images of skin. Various models including Support Vector Machines, ResNet-50, VGG16, SqueezeNet, and InceptionV3 were utilized. The skin data was acquired from Google using web-scraping techniques with Python's BeautifulSoup, SERP API, and requests libraries. The most successful model among them was VGG16, with an accuracy of 0.96 and an F1-score of 0.92.

In [8], the researcher employed several techniques to gather data, including web scraping, expert screening, data preprocessing, and data augmentation. Two deep learning models, namely AlexNet and VGG16, were utilized to train on a dataset comprising various diseases such as Monkeypox, Chickenpox, Measles, and Healthy. Notably, the VGG16 model yielded the highest accuracy, reaching 80%.

Additionally, in [9], the author the Kaggle Monkeypox Skin Lesion Dataset (MSLD) and the Monkeypox Skin Image Dataset (MSID) for their research purposes. Four deep neural networks were utilized for transfer learning, specifically Inception V3, ResNet 50 V2, MobileNet V2, and EfficientNet-B4. The MobileNet achieved superior performance compared to the other networks on the MSID dataset, achieving a balanced accuracy of 96.55%. Conversely, for the MSLD dataset, Inception V3 exhibited the most favorable metrics, achieving a balanced accuracy of 94%.

Within [10], the author aimed to integrate a well-trained deep learning (DL) algorithm and compare its performance against various other deep learning models. The disease dataset utilized in this research comprised Monkeypox and Chickenpox. The proposed convolutional neural network (CNN) model surpassed all other DL models, achieving a remarkable test accuracy of 99%. Moreover, a weighted average precision, recall, and F1 score of 99% were documented. Impressively, AlexNet demonstrated superior performance compared to other pre-trained models, achieving an accuracy of 98%. On the other hand, VGGNet, specifically VGG16 and VGG19, exhibited the lowest performance, with an accuracy of 80.00%. The ResNet-50 model attained an accuracy of 82%, while the InceptionV3 model achieved an accuracy of 89%.

Besides, in [11], the author assessed the effectiveness of five commonly used pre-trained deep learning models, namely VGG19, VGG16, ResNet-50, MobileNetV2, and EfficientNetB3. The experimental findings indicate that the MobileNetV2 model outperformed the others in terms of classification performance. It achieved an accuracy rate of 98.16%, a recall score of 0.96, a precision score of 0.99, and an F1-score of 0.98. Furthermore, when validating the model using different datasets, the MobileNetV2 model exhibited the highest accuracy of 94%.

And recently, within [12], the author introduced and assessed a revised version of the DenseNet-201 deep learning-based CNN model called MonkeyNet. By utilizing both the original and expanded datasets, this study put forward a deep convolutional neural network that demonstrated accurate identification of monkeypox disease. The accuracy achieved was 93.19% with the original dataset and 98.91% with the augmented dataset. The author employed the "MSID" dataset, which stands for "Monkeypox Skin Images Dataset."

Finally, in [13], the author utilized several custom models including MobileNetV3-s, EfficientNetV2, ResNet-50, VGG19, DenseNet121, and Xception models. Among these models, the hybrid MobileNetV3-s model, which was optimized, performed the most outstandingly. It achieved an average F1-score of 0.98, an AUC of 0.99, an accuracy of 0.96, and a recall of 0.97.

III. PROPOSED METHOD

A. Background

1) *ResNet-50*: ResNet stands for Residual Network and represents a distinctive variant of a convolutional neural network (CNN) that was first presented in the research paper titled "Deep Residual Learning for Image Recognition" in 2015. The authors of the paper, He Kaiming, Zhang Xiangyu, Ren Shaoqing, and Sun Jian, introduced this concept. CNNs are widely utilized in various computer vision applications. ResNet-50, on the other hand, is a specific instance of a convolutional neural network that consists of 50 layers, including 48 convolutional layers, one MaxPool layer, and one average pool layer. Residual neural networks are a type of artificial neural network (ANN) that constructs networks by

assembling residual blocks [14]. The deep residual learning framework of ResNet is shown in Fig. 1.

Fig. 1. Residual learning: a building block [15].

According to Fig. 1, the residual module in ResNet incorporates an identity mapping, resulting in a change of the network's output from $F(x)$ to $F(x) + x$. Typically, deep networks exhibit higher training errors compared to shallow networks. However, by appending multiple layers of constant mapping ($y = x$) to a shallow network, it can be transformed into a deep network, thereby achieving the same training error as the original shallow network. This indicates that layers with constant mapping are effectively trained. In the case of the residual network, when the residual is 0, the stacking layer essentially performs constant mapping. Based on the conclusion, it can be inferred that, at the very least, the network performance will not deteriorate theoretically [16].

2) *VGG16*: VGG16 refers to the VGG model, additionally referred to as VGGNet. It is a convolution neural network (CNN) model supporting 16 layers. K. Simonyan and A. Zisserman from Oxford University proposed this model and published it in a paper called "Very Deep Convolutional Networks for Large-Scale Image Recognition" [17]. VGG16 has been widely recognized as one of the top models in the ILSVRC-2014 competition, showcasing its superior performance. With the utilization of a dataset called ImageNet, which comprises over 14 million training images distributed across 1000 object classes, the VGG16 model achieves an impressive test accuracy of 92.7%. Notably, VGG16 builds upon the advancements made by AlexNet and introduces a significant improvement. Instead of employing larger filters, VGG16 replaces them with a series of smaller 3×3 filters. In comparison, AlexNet employs an 11-sized kernel for the initial convolutional layer and a 5-sized kernel for the second layer [18]. The architecture of VGG16 is shown in Fig. 2.

3) *MobileNet*: MobileNet is a CNN architecture designed for real-world applications, known for its efficiency and portability. Unlike previous architectures, MobileNets employ depthwise separable convolutions instead of standard convolutions to create lighter models. Additionally, MobileNets introduce two new global hyperparameters, namely width multiplier and resolution multiplier. These hyperparameters enable developers to make trade-offs between latency or accuracy, speed, and size according to

their specific needs [20][21]. The architecture of MobileNet is shown in Fig. 3.

Fig. 2. VGG16 architecture [19].

Fig. 3. MobileNet architecture.

4) *Random forest classification*: The Random Forest is a well-known supervised learning technique in machine learning. It is widely used for both Classification and Regression tasks. It operates on the principle of ensemble learning, which involves combining multiple classifiers to tackle complex problems and enhance the model's performance. The term "Random Forest" refers to a classification algorithm that comprises numerous decision trees constructed on different subsets of the provided dataset. By averaging the results from these trees, it aims to improve the predictive accuracy of the dataset. Instead of relying solely on a single decision tree, the random forest considers the predictions from each tree and determines the final output based on the majority votes among the predictions. Increasing the number of trees in the random forest enhances its accuracy and helps avoid overfitting issues [22]. The architecture of Random Forest Classification is shown in Fig. 4.

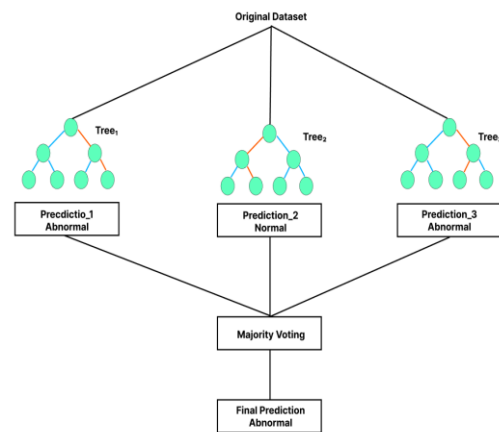

Fig. 4. Random forest classification architecture [23].

5) *K-nearest neighbors*: The K-Nearest Neighbors algorithm, referred to as KNN or k-NN, is a supervised learning classifier that operates on the principle of proximity. It is a non-parametric method commonly employed for classification tasks, where it determines the grouping of a given data point by comparing its proximity to other data points. Although it can handle both regression and classification problems, it is primarily used as a classification algorithm, based on the underlying idea that similar points tend to be located close to each other. In classification problems, a majority vote is used to assign a class label to a data point. This means that the label which appears most frequently around the given data point is chosen. Although this type of voting is technically known as "plurality voting," it is more commonly referred to as "majority vote" in literature. The difference between these terms lies in the fact that "majority voting" technically implies a majority greater than 50%, which is typically suitable when there are only two categories. [24]. The architecture of K-Nearest Neighbors is shown in Fig. 5.

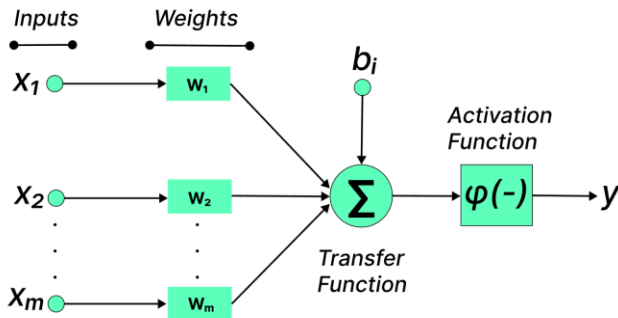

Fig. 5. K-nearest neighbors architecture [25].

6) *Gaussian Naive Bayes*: Gaussian Naive Bayes (GNB) is a machine learning classification method that relies on the probabilistic approach and Gaussian distribution. It operates under the assumption that each parameter (referred to as features or predictors) possesses an independent ability to predict the output variable. By combining the predictions from all parameters, the method produces a final prediction, which represents the probability of the dependent variable being classified into different groups. The group with the highest probability is assigned as the final classification. Gaussian Naive Bayes classifiers are a set of classification algorithms in supervised machine learning that rely on the principles of the Bayes theorem. They are a straightforward classification approach with notable effectiveness. They are particularly useful when dealing with datasets containing numerous input dimensions. Additionally, Naive Bayes classifiers can handle intricate classification tasks with success [26]. The Bayes Theorem is shown here.

The Formula for Bayes's Theorem Is

$$P(A|B) = \frac{P(A \cap B)}{P(B)} = \frac{P(A) \cdot P(B|A)}{P(B)}$$

where:

$P(A)$ = The probability of A occurring

$P(B)$ = The probability of B occurring

$P(A|B)$ = The probability of A given B

$P(B|A)$ = The probability of B given A

$P(A \cap B)$ = The probability of both A and B occurring

7) *Decision tree classification*: A Decision Tree is a supervised learning technique used for classification and regression problems. It is a tree-like structure where internal nodes represent dataset features, branches are decision rules, and leaf nodes depict outcomes. Decision nodes make decisions with branches, while leaf nodes provide final outputs [27]. The general structure of a decision tree is shown in Fig. 6.

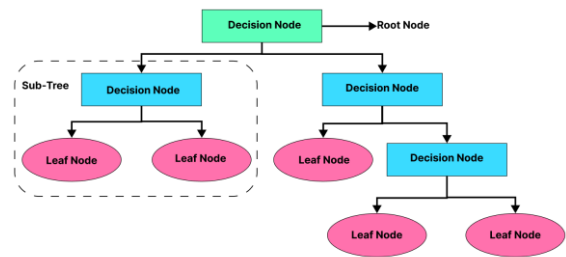

Fig. 6. Decision tree structure [27].

8) *Logistic regression*: Logistic Regression is an algorithm in Machine Learning used for classification purposes. It predicts the likelihood of specific classes by considering dependent variables. Essentially, the logistic regression model adds up the input features (often including a bias term) and applies the logistic function to the result. The output of logistic regression always falls between 0 and 1, making it suitable for binary classification tasks. A higher value indicates a greater probability of the current sample being classified as class=1, and vice versa [28]. The architecture of Logistic Regression is shown in Fig. 7.

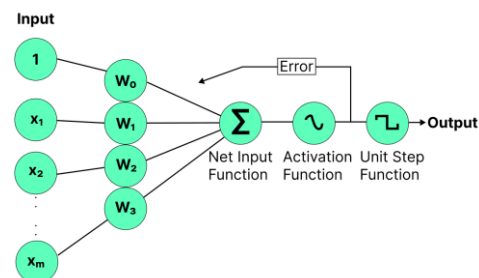

Fig. 7. Logistic regression architecture [29].

9) *AdaBoost classifier*: AdaBoost, also known as Adaptive Boosting, was introduced by Yoav Freund and Robert Schapire in 1996 as a type of ensemble boosting classifier. Its primary objective is to enhance the accuracy of classifiers by leveraging a combination of multiple classifiers. AdaBoost functions as an iterative ensemble technique, constructing a robust classifier by merge several classifiers that exhibit weak performance, thereby yielding a highly accurate and strong classifier. The fundamental idea underlying AdaBoost involves assigning weights to classifiers and training data samples during each iteration in a manner that guarantees precise predictions for atypical observations [30]. Fig. 8 illustrates the architecture of the lightweight CNN, which serves as the weak classifier in conjunction with AdaBoost.

Fig. 8. AdaBoost [31].

B. Implementation Process

The implementation and model-building process of this research can be broken down into six main steps, which are outlined in Fig. 9.

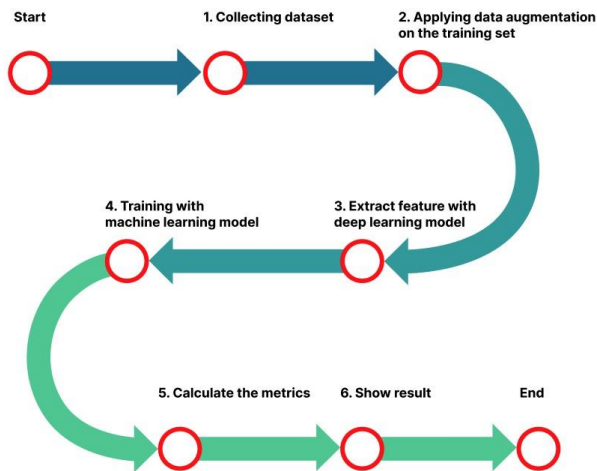

Fig. 9. Implementation process.

The initial step in this implementation involves the collection of data. The data was gathered by Sachin Kumar, Nafisa, Joydip Paul, Tazuddin Ahmed, and Tasnim Jahan Peana, and it was published in [32][33]. This dataset consists of

659 images in JPG format. The second step entails applying a data augmentation technique to the original dataset. This process aims to increase the dataset's size, thereby contributing to improved accuracy. Moving on to the next step, various deep learning models, such as ResNet-50, VGG16, and MobileNet, are employed to extract features from the dataset. These extracted features are then combined with machine learning models, including Random Forest Classification, K-Nearest Neighbors, Gaussian Naive Bayes, Decision Tree Classification, Logistic Regression, and AdaBoost Classifier, to produce highly accurate results. Once the training process is complete, the subsequent stage involves calculating and evaluating the accuracy of the models. Lastly, the final step focuses on presenting the achieved results.

C. The Proposed Architecture for Monkeypox Classification

In this research, the author proposes a combination model of deep learning model and machine learning model to obtain high-accuracy results. Initially, the author will gather monkeypox datasets from credible sources like Kaggle. To expand the dataset, the author will employ data augmentation techniques, resulting in a total of 4902 images. The subsequent phase involves extracting features from the dataset using deep learning models such as ResNet-50, VGG16, and MobileNet. After extracting the features, the author will merge them with various machine learning models, namely Random Forest Classification, K-Nearest Neighbors, Gaussian Naive Bayes, Decision Tree Classification, Logistic Regression, and AdaBoost Classifier. The next step involves obtaining the data from the training process performed by the machine learning models. The author will then calculate and evaluate this data to provide the final classification results for monkeypox. Through the author's proposed model, the author has obtained highly positive outcomes. Specifically, combining the MobileNet deep learning model with Logistic Regression machine learning model yielded the following results: precision of 0.99, recall of 0.98, F1-score of 0.98, and accuracy of 0.97. Fig. 10 illustrates the architecture the author proposes.

Fig. 10. The proposed architecture for monkeypox classification.

IV. EXPERIMENTS

In this section, the authors will provide an overview of the dataset utilized in the experiments, including its characteristics. Subsequently, the dataset will be employed in three separate experiments. The first experiment details the utilization of deep learning models for classifying four classes. The second experiment describes the author's proposed approach, which combines deep learning models with machine learning models to classify and detect Monkeypox. Lastly, the results obtained from the proposed model will be compared with state-of-the-art methods.

A. Dataset

In this section, the author conduct training on both deep learning models and machine learning models using two datasets: the Monkeypox Skin Lesion Dataset (MSLD) [32] and the Monkeypox Images Dataset (MID) [33]. These datasets have been subjected to data augmentation techniques, and the author compare the outcomes. The augmented dataset contains a larger amount of data compared to the original dataset. Specifically, the augmented dataset comprises 4902 images, while the original dataset consists of 659 images representing monkeypox, chickenpox, measles, and normal cases. The characteristics of the datasets are presented in Table I, and Fig. 11, respectively. The range of image dimensions is 256x256 pixels. Fig. 11 depicts the dataset's categories.

Fig. 11. Dataset illustration for three categories of monkeypox images.

TABLE I. DATASET CHARACTERISTICS

Labels	Images
Monkeypox	264
Chickenpox	100
Measles	80
Normal	215

B. Methods of Assessment and Comparison

This experiment involves comparing the performance of the author’s proposed architecture, which combines a deep learning model and a machine learning model, with well-known convolutional neural networks like ResNet-50, VGG16, and MobileNet, as well as state-of-the-art methods in terms of ACC and F1-score.

The study conducted three experiments. In Experiment 1, only deep learning models were used for training, evaluation, and testing. In Experiment 2, the author’s proposed model was employed for training, evaluation, and testing. The final experiment involved comparing the results of the proposed model with those obtained in Experiment 1 and with state-of-the-art methods.

C. Scenario 1: using Deep Learning Models to Classify Four Classes (Monkeypox, Chickenpox, Measles, Normal)

In this experiment, consistent hyperparameters were employed across all models, with epochs = {20}, batch sizes = {64}, and identical hidden layers for each model. The training outcomes for scenario 1 are presented in Table II.

TABLE II. RESULT OF USING DEEP LEARNING MODELS

DL Model	Pre	Recall	F1	ACC
ResNet50	0.78	0.72	0.69	0.72
MobileNet	0.97	0.97	0.97	0.97
VGG16	0.56	0.5	0.45	0.5

Based on the outcomes of the conducted experiment, it was observed that the MobileNet model achieved the most impressive performance, achieving accuracy of 0.97, F1-score of 0.97, recall of 0.97 and precision of 0.97. Conversely, the VGG16 model exhibited the poorest performance, achieving accuracy of 0.5, F1-score of 0.45, recall of 0.5, precision of 0.56. The confusion matrices for these two models represent the experiment's top and bottom results, as shown in Fig. 12 and 13, respectively.

Fig. 12. The confusion matrix of MobileNet model.

Fig. 13. The confusion matrix of VGG16 model.

D. Scenario 2: Using Deep Learning Models with Machine Learning Models to Classify Four Classes (Monkeypox, Chickenpox, Measles, Normal)

In this experiment, the author proposes a model by integrating deep learning and machine learning models. Specifically, deep learning models are used to extract features, which are then combined with machine learning models. The training outcomes for scenario 2 are presented in Table III.

TABLE III. RESULT OF USING DEEP LEARNING MODELS WITH MACHINE LEARNING MODELS

DL Model	ML Model	Dataset	Pre	Recall	F1	ACC

Fig. 15. The confusion matrix of combination between ResNet50 and Gaussian Naive Bayes model.

E. Scenario 3: Using Deep Learning Models to Classify and Detect Monkeypox

Table IV compares the performance of current methods for detecting Monkeypox using the author's proposed architecture. It is evident that the proposed model has achieved encouraging outcomes when compared to previous similar tasks. The above experimental results clearly indicate the suitability of the author's proposed model for image based Monkeypox classification. By combining the extracted features of the deep learning model and utilizing them in the machine learning model, the author's proposed approach outperforms other experimental models. Furthermore, the author conducts a comparison of the author's method with the average outcomes of ratios and state-of-the-art techniques. The confusion matrix of the proposed model in Scenario 2 and performance

comparison with previous similar studies as shown in Fig. 16 and Table IV.

V. CONCLUSION

Nowadays, health issues are becoming more and more important, especially concerns about sudden outbreaks of diseases and traditional disease detection methods which can be time-consuming and expensive. Therefore, it has highlighted people's need and interest in tools that support accurate and fast diagnosis. This research paper mentions the application of deep learning and machine learning models to support accurate and fast diagnosis of monkeypox. Through fine-tuning hyperparameters, this approach achieves remarkable accuracy in classification, signifying significant progress in monkeypox research. The author proposes to use a deep learning model called "A" to extract the feature from the dataset and then use that feature in conjunction with a machine learning model called "B" to get highly accurate results. For instance, the author use MobileNet deep learning model combined with Logistic Regression machine learning model gives very positive results: precision is 0.99, recall is 0.98, F1-score is 0.98 and accuracy is 0.97. These findings contribute to the development of rapid and accurate diagnostic tools, improving the detection and early diagnosis of monkeypox to minimize its negative impact on public health. Improved

diagnostics can also enhance patient outcomes and bolster global health security by strengthening the author's preparedness for infectious disease outbreaks. Collaboration among researchers, healthcare institutions, and governments is crucial to driving the widespread adoption of these advanced tools and creating a more resilient global health community. In the future, the author plans to incorporate the "segmentation" technique for image analysis, aiming to delineate the affected areas and enhance the accuracy of this proposed method. This addition will facilitate the precise identification of the diseased regions.

CryptoScholarChain: Revolutionizing Scholarship Management Framework with Blockchain Technology

Jadhav Swati, Pise Nitin

School of Computer Engineering and Technology,
Dr. Vishwanath Karad MIT World Peace University, Pune, India

Abstract—Scholarship management is a crucial aspect of higher education systems, aimed at supporting deserving students and reducing financial barriers. However, traditional scholarship management processes often suffer from challenges such as a lack of transparency, inefficient communication, and difficulty tracking and verifying scholarship applications. Recently, Blockchain technology has emerged as a potential solution to address these issues, offering a decentralized, transparent, and secure framework for scholarship management. Blockchain technology has emerged as a promising solution to address the challenges faced in scholarship management. However, existing literature lacks comprehensive solutions in critical areas such as scholarship management, storage facilities, payment systems, monitoring and auditing, and experimental validation. This research introduces an innovative smart scholarship management system leveraging Blockchain technology to overcome these limitations. The research presents an Ethereum-based implementation utilizing Solidity for backend smart contracts and ReactJS for the front end. Experimental evaluation validates the transaction execution gas costs and deployment cost.

Keywords—Blockchain; smart scholarship management; smart contract; solidity

I. INTRODUCTION

The landscape of higher education has witnessed the emergence of several dynamic initiatives, notably scholarships designed to empower economically disadvantaged students. These scholarships are designed to support deserving individuals pursuing their undergraduate and postgraduate studies, with each country having its own dedicated program. Scholarships funded by diverse entities, such as non-governmental organizations (NGOs), private donors, and corporate social responsibility initiatives, play a pivotal role in mitigating the financial burdens faced by students. However, the application process for these scholarships presents various challenges. These challenges include difficulty tracking application forms, potential loss of documents during transit, inadequate communication between students and their funders or NGO partners, and a lack of transparency. To overcome these limitations, this study presents an innovative smart scholarship management system built on Blockchain technology. The proposed system leverages Blockchain technology and integrates Smart Contracts to establish a user-friendly student environment, facilitating seamless and

transparent communication between students and their respective NGOs.

A. Blockchain Technology and its Applications

Initially introduced as the underlying technology for crypto currencies like Bitcoin, Blockchain technology has gained significant attention due to its potential applications beyond finance [14]. The literature emphasizes the key features of Blockchain, including decentralization, immutability, transparency, and security [13]. Researchers have explored its applications in various sectors, including supply chain management, healthcare, and identity management [13]. However, limited studies have focused specifically on its application in scholarship management.

The study's structure for the remaining sections is as follows:

Section II conducts an extensive literature review, summarizing various Blockchain-based frameworks for efficient smart scholarship management. It offers a detailed exposition of the system's workflow and architectural design. It includes in-depth discussions of system components and employed algorithms and provides evidence of feasibility. Section III presents study outcomes, featuring visual representations like deployment and transaction cost graphs related to various smart contract functions. Finally, Section IV summarizes the study's findings and concludes with remarks highlighting the research's significance and implications.

II. RELATED WORK

A. Traditional Scholarship Management Systems

Traditional scholarship management systems suffer from centralization, lack of transparency, and vulnerability to tampering. This research article introduces a decentralized Blockchain-based framework for smart scholarship management to address these limitations.

The framework involves three key stakeholders: donors, students, and NGOs. Donors include individual contributors, industrial corporate social responsibility (CSR), and governmental scholarship funds. Students are the beneficiaries who receive scholarships through NGOs, while NGOs serve as intermediaries responsible for record-keeping and auditing. The traditional centralized approach lacks transparency, traceability, and auditability, making it susceptible to attacks and manipulation. These challenges can be overcome by

leveraging a decentralized Blockchain framework, leading to a more efficient and secure scholarship management system.

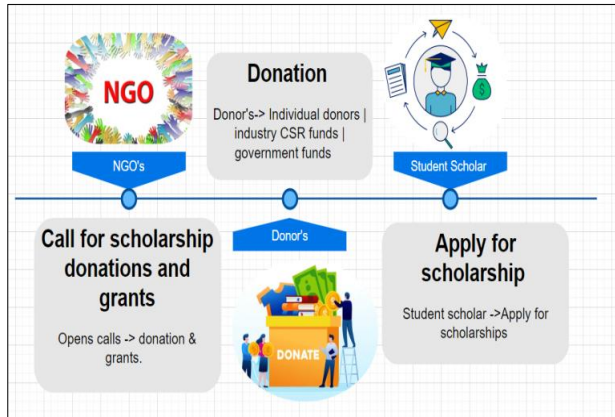

Fig. 1. Supply chain: Scholarship management process.

Fig. 1 shows the supply chain of a Blockchain-based smart scholarship system.

1) *Stakeholder analysis:* This section comprehensively analyzes the three major stakeholders in the traditional scholarship management system: donors, students, and NGOs. It discusses the roles and functionalities of each stakeholder, emphasizing the importance of their involvement in the scholarship management process.

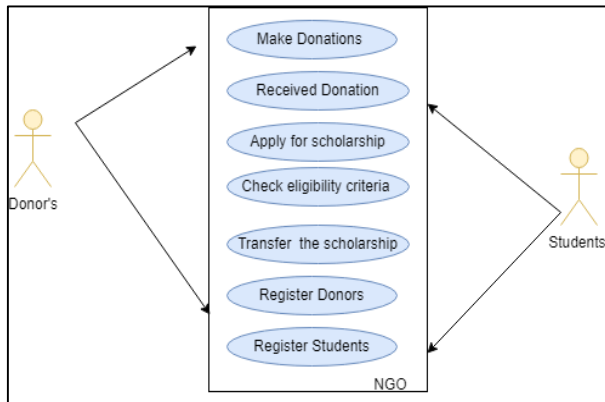

Fig. 2. Traditional scholarship management system.

The end users and their role and the operation the end user is performing with the system are depicted in Fig. 2. The students and Donors are considered an actor, and the NGO is considered a system with which donors and students perform different operations represented by different use cases. The depiction of end users and their roles and operations within the system is illustrated in Fig. 2. In this context, students and donors are regarded as actors. At the same time, the NGO is considered the system with which donors and students engage in various operations, each represented by distinct use cases.

2) *Donors:* Donors are of different types, including individual contributors, industrial CSR funds, and governmental scholarship funds. It highlights their functions, such as making donations and accessing tracking and auditability features. Blockchain enhances the integrity and

transparency of this innovative fundraising approach, making it even more reliable [18].

3) *Students:* Students are the beneficiaries of scholarships. It discusses their roles in applying for scholarships and receiving funds through NGOs. It also emphasizes the importance of secure and efficient fund transfer mechanisms.

4) *NGOs:* NGOs act as intermediaries between donors and students. It outlines their responsibilities, including receiving donations, approving and transferring scholarships, and maintaining a ledger of all transactions. This emphasizes the significance of accurate record-keeping and auditing in ensuring transparency and accountability.

This research article introduces CryptoScholarChain, an innovative framework for managing scholarships that leverages Blockchain technology and smart contracts to enhance transparency, traceability, and efficiency in the scholarship ecosystem. Proposed system addresses the limitations of existing approaches and aims to improve the scholarship application process and financial transactions. Additionally, research work provides a prototype implementation of the framework using the Solidity programming language on the Ethereum platform.

B. Challenges in Traditional Scholarship Management

The traditional scholarship management system's limitations include its centralized and manual nature. It discusses the lack of transparency, traceability, and auditability, making it prone to attacks and tampering. This section examines the challenges associated with traditional scholarship management processes. Literature highlights issues such as lack of transparency in the selection process, difficulties verifying applicant information, delays in fund disbursement, and ineffective communication between students, scholarship providers, and educational institutions. These challenges have led researchers and practitioners to explore Blockchain technology as a potential solution.

In [11, 15, and 4], this research article provides an overview that explores different aspects of innovative models and frameworks within philanthropy, crowdfunding, and distributed ledger technology (DLT) like Blockchain. Each paper contributes to the understanding and advancement of community-based solutions, public welfare crowdfunding, decentralized electronic donation frameworks, and the relationship between charity, trust, accountability, and DLT. The findings and recommendations from these papers underscore the importance of collaboration among various stakeholders to address global challenges and support philanthropic engagement on a larger scale [11, 15, 4].

In [21, 11], this research article explores Blockchain technology's application in various aspects of charity, crowdfunding, and nonprofit organizations (NPOs). The papers discuss frameworks for a transparent and auditable charity collection, Blockchain-based crowdfunding platforms, charity systems, and the sustainable development of NPOs using Blockchain technology. These studies contribute to advancing transparent and efficient systems for managing charitable activities, improving crowdfunding platforms, enhancing the

accountability of charity systems, and promoting the sustainable development of NPOs [21, 11].

C. Comparative Analysis

The literature reveals several benefits of implementing Blockchain-based frameworks for smart scholarship management. These include increased transparency, improved data integrity, enhanced security, streamlined communication, and reduced administrative overheads. Blockchain-based systems also enable efficient tracking and verification of scholarship applications, ensuring fairness and reducing the potential for fraud. Table I discusses the features and limitation of the existing literature.

TABLE I. ADVANTAGES AND LIMITATIONS OF EXISTING SYSTEMS

Authors	System	Features	Limitations
Li Q et al. [19]	Charity application based on Blockchain technology	Secure and transparent charity applications	Limited scalability, potential regulatory challenges
Turkanović M et al. [23]	Blockchain-based higher education credit platform	Streamlined credit transfer and recognition in higher education	Dependence on network connectivity, potential resistance to change

Farooq MS et al. [8]	Transparent and auditable charity collection using Blockchain	Transparency and Auditability in the Charity Collection	Technical complexity, integration with existing systems
Wu H et al. [24]	The reliable service system of charity donations during the Covid-19 outbreak	Enables reliable charity donations during the Covid-19 outbreak	Limited to the context of the Covid-19 outbreak
Tomlinson B et al. [22]	Sustainability analysis of "Blockchain for Good" projects	Assessing the sustainability of Blockchain projects for social good	Project-specific findings, limited generalizability
RejebDet et al. [20]	Contributions of Blockchain and Smart Contracts to the Zakat Management System	Enhanced efficiency and transparency in Zakat management	Adoption challenges, regulatory considerations
Cerf M et al. [5]	Improving decision-making for the public good using Blockchain	Transparent and accountable decision-making for the public good	Technical complexity, scalability
AlassafAOet al. [1]	Decentralized fundraising and distribution using Blockchain	Decentralized fundraising and distribution for charities	Adoption challenges, potential security risks
ElsdenCet et al. [6]	Co-designing Blockchain applications for charitable giving	Exploring co-designing of Blockchain applications for charitable giving	Context-specific findings, limited generalizability
KakraniaAet al. [16]	Secure E-Donation System	Provides a secure e-donation system	Technical complexity,

	using Blockchain Technology	leveraging Blockchain	user adoption challenges
Cali et al [4]	Novel Donation-Sharing Mechanisms to Contend Energy Poverty Problem	Addresses energy poverty through novel donation-sharing mechanisms	Limited to the energy poverty problem context
Shin EJet al. [21]	Sustainable development of NPOs with Blockchain technology	Investigates sustainable development of nonprofit organizations using Blockchain	Context-specific findings, limited generalizability
Hassija Vet al. [11]	BitFund: A Blockchain-based crowdfunding platform for the future smart and connected nation	Facilitates Blockchain-based crowdfunding for smart and connected nations	Limited to the crowdfunding context
Khanolkar AA et al. [17]	Blockchain-based Trusted Charity Fundraising	Ensures trust and transparency in charity fundraising	Technical complexity, adoption challenges

The Table II discusses about Comparative analysis of existing literature. The table summarizes various research studies on Blockchain applications for charity and social good. It highlights the systems or frameworks developed in each study, their key features, and the limitations or challenges they face. These studies collectively explore how Blockchain technology can enhance transparency, accountability, and efficiency in charitable activities while acknowledging the obstacles, such as technical complexity and adoption challenges that must be addressed for successful implementation.

TABLE II. COMPARATIVE ANALYSIS

Table II summarizes various authors' objectives and the presence of key features in their research related to Blockchain applications in charity and scholarship management. The

majority aim to enhance security and transparency in these domains, with some focusing on automated processes and reduced administrative overhead. The proposed CryptoScholarChain framework encompasses these objectives and features comprehensively.

D. Benefits of Blockchain-based Scholarship Management

Blockchain-based Frameworks for Smart Scholarship Management: Several studies have proposed frameworks to enhance scholarship management processes. These frameworks leverage the inherent features of Blockchain to address the challenges faced in traditional systems. For example, a Blockchain-based framework ensures transparency by recording scholarship-related transactions on a distributed ledger, making them accessible to all stakeholders. Smart contracts powered by Blockchain enable automating application verification, fund disbursement, and scholarship agreement enforcement. Nonprofit organizations leverage blockchain technology to open up opportunities for global donations from a diverse range of donors [10].

E. CryptoScholarChain

CryptoScholarChain is a novel framework that utilizes Blockchain technology and smart contracts to revolutionize the management of scholarships. Proposed system ensures trust, accountability, and traceability in the scholarship process by providing an immutable and transparent audit trail. The research discusses how CryptoScholarChain overcomes the limitations of traditional approaches, such as lack of transparency and difficulty in tracking donations.

F. Ensuring Transparent and Prompt Financial Transactions

CryptoScholarChain recognizes the importance of financial transparency and timely payments' importance in scholarship management. To address this, CryptoScholarChain incorporates a secure payment mechanism within the system. This feature guarantees transparency and facilitates seamless

transactions between donors, NGOs, and students, ensuring that scholarship funds reach the intended recipients promptly.

CryptoScholarChain integrates corporate social responsibility (CSR) funding through NGOs and government-sponsored scholarship programs, providing students with diverse scholarship opportunities. By leveraging these funding sources, framework facilitates access to scholarships and streamlines the application process, making it more efficient and inclusive.

G. Prototype Implementation on the Ethereum Platform

To validate the feasibility and effectiveness of CryptoScholarChain, provide a prototype implementation using the Solidity programming language on the Ethereum Blockchain. This implementation demonstrates the practicality of proposed framework and serves as a basis.

It includes in-depth discussions of system components and employed algorithms and provides evidence of feasibility.

Decentralized Blockchain-Based Framework -introduces the proposed decentralized Blockchain-based framework for smart scholarship management.

H. The Flow of the System

The flow of the system involves the registration of donors and students, verification by NGOs, authentication of donor proofs, storage of required documents on a distributed storage platform, the opening of donation calls by NGOs, deployment of smart contracts on the EthereumBlockchain, and the creation of a decentralized application (DApp) for interaction between donors, students, and NGOs.

I. The Architecture of the Proposed System

Fig. 3 depicts the overall system components of the proposed framework. The system hosts a set of smart contracts (RegistrationSc, MakeDonationSc, TransferscholarshipSc, ApplyForScholarshipSc).

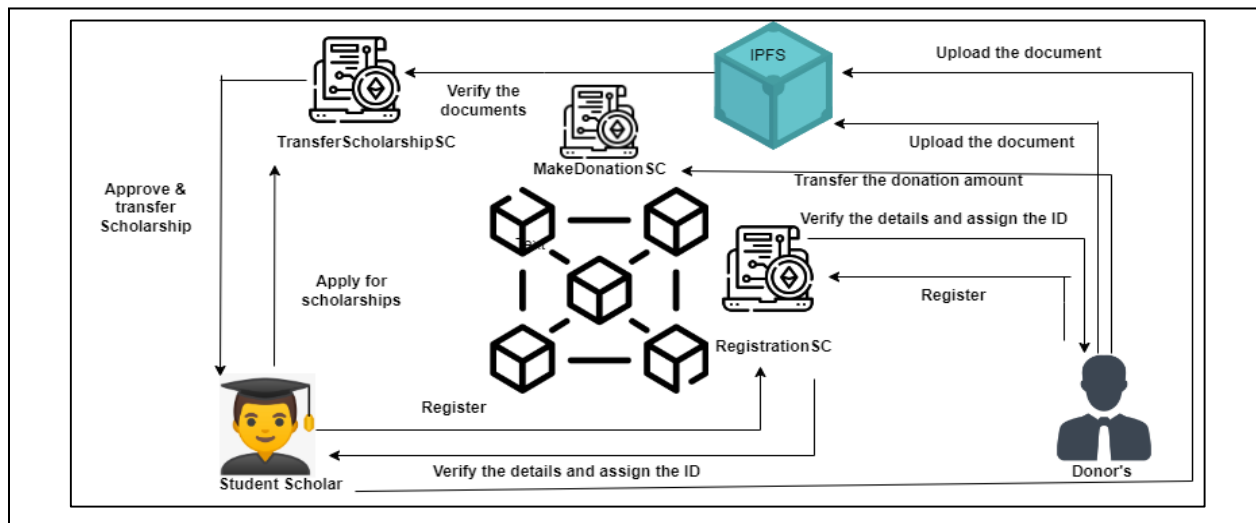

Fig. 3. Overall architecture of the proposed system.

J. Module and Algorithms of the Proposed System

1) *Registration*: The system requires users to register their information through the RegistrationSc smart contract. The information is encrypted using the Attribute Authority's public key to maintain privacy. Verification is conducted through an automated API or offline document verification, with scanned documents stored on a decentralized system like IPFS. The encrypted file hash is stored on the Blockchain for identity verification. The charity publishes verification results and parameters on the Blockchain through the smart contract for transparency and reliability. Registration describes the first step of the flow, where donors and students register on the platform. NGOs are responsible for verifying the registrations and assigning unique IDs to the stakeholders. The verification process ensures the authenticity and credibility of the participants.

Authentication and Document Storage focus on the authentication of donor proofs. Donors are required to provide necessary documents for authentication, such as registration numbers and related documents for industry CSR funds. These proofs are securely stored on a distributed platform like the InterPlanetary File System (IPFS). Students need to provide various documents, including unique identification numbers (such as Aadhaar Card Number), college ID, fee receipts, family income proofs, and mark sheets for 10th and 12th grade. These documents are also stored on the IPFS platform for secure and accessible storage.

2) *Make donations*: NGOs open calls for donations for different scholarship projects, creating opportunities for donors to contribute. The donation process involves various types of donors, including individual contributors, industrial CSR funds, and governmental scholarship funds. Each type of donor has a specific function in providing financial assistance to deserving individuals or students. Individual contributors donate personal funds directly to scholarship programs or organizations. Industrial CSR funds are contributed by companies as part of their social initiatives and are allocated to support education and scholarships. Governmental scholarship funds are allocated by governments to promote equal opportunities and are managed by government agencies. Donors also have access to tracking and auditability features, allowing them to monitor the utilization of their funds and ensure transparency and accountability. These features help donors assess the impact of their contributions and make informed decisions for future donations.

Algorithm 1: Algorithms for MakeDonationSC

```
Contract MakeDonation uses Register
  balanceOf<- mapping that stores the address of accounts
  procedure donate(User id, Amount)
    require for checking that the sender is the owner
    call procedure sendViaCall
    increment balanceOf[owner] by amount
  return true
  end procedure
  procedure sendViaCall(Owner Address)
    Send ether to the owner's address
  end procedure
```

Algorithm 1 extends the Register contract and adds the functionality to make donations by calling the donate function. The sendViaCall function is used to send Ether to the owner's address. The balance of mapping keeps track of the balance for each address.

3) *Transfer scholarship*: The approval and transfer of scholarships follow a structured process. Students submit their applications, undergo evaluation based on criteria, and receive approval notifications. Documentation submission is required from approved recipients. Upon acceptance, the scholarship funds are transferred to designated accounts. Recipients are monitored for compliance with requirements, and the TransferScholarshipSC smart contract facilitates the entire process.

Algorithm 2: TransferScholarshipSC

```
Contract TransferScholarship uses MakeDonation, Register{
  Student Address<- store address of users where the role is
  student
  procedure compareStrings(String1,String2)
    return true if strings are equal
  end procedure
  procedure addAddress()
    for i<donors.length do
      if compareStrings
  studentAddress<- donors[i].address
    end for
  end procedure
  procedure Transfer()
    for i<studentAddress.length do
  callSend Via Call function
    end procedure
```

K. Proof of Concept

The proof of concept for the solution was implemented on the Ethereum platform, employing Solidity as the programming language. The frontend interface was developed using ReactJS to ensure a user-friendly experience. To securely store the documents uploaded by the stakeholders, such as Aadhaar cards or ID cards, integrated the InterPlanetary File System (IPFS) as a decentralized storage solution.

III. RESULTS AND DISCUSSIONS

The factors influencing the deployment cost of a smart contract on the Ethereum network are represented in equations:

- Contract Complexity: C
- Contract Size: S: The complexity of the smart contract code.
- Initialization Code: I: The size of the compiled bytecode of the smart contract.
- Gas Price: GP: Additional computations performed during contract initialization.
- Gas Limit: GL: The price set for each gas unit in gwei. The maximum amount of gas allowed for the deployment transaction.
- Network Conditions: NC: The state of the Ethereum network, including congestion and demand.

- With these parameters, the equation for estimating the deployment cost of a smart contract can be written as follows:

$$\text{Deployment Cost} = (C + S + I) * GP \quad (1)$$

Equation (1) assumes that the gas used during deployment (C + S + I) does not exceed the gas limit (GL) set for the transaction. If the gas limit is insufficient, the deployment may fail.

The effect of network conditions (NC) on the gas price (GP) is not directly represented in the equation, as it is dynamic and can change rapidly. It is important to consider the current gas prices and network conditions when setting the gas price for accurate cost estimation.

TABLE III. DEPLOYMENT COST OF CONTRACT

The deployment cost of each contract			
Smart Contract	Transaction gas cost(gwei)	Actual Cost(ether)	USD
RegisterSC	969111	0.000969111	1.69
MakeDonationSC	1195306	0.001195306	2.08
TransferScholarshipSC	1835557	0.001835557	3.2

Table III depicts the smart contract deployment costs analysis, indicating that the contract functionality's complexity influences the associated expenses on the Blockchain. The results emphasize the importance of considering contract complexity and associated costs in Blockchain projects. Further research is needed to explore deployment costs in various contexts and optimize resource allocation for efficient contract deployment.

Fig. 4. Graph of deployment cost of the contract

Fig. 4 depicts the graph of the smart contract's deployment cost. The findings reveal that the gas costs for RegisterSC, MakeDonationSC, and TransferScholarshipSC were 969,111 gwei, 1,195,306 gwei, and 1,835,557 gwei, respectively. This translates to actual costs of \$1.69, \$2.08, and \$3.2. The execution cost of each function in a smart contract is determined by the computational work required to execute the instructions within the function. This computational work is

measured in terms of gas, a unit of measurement in the Ethereum network. The gas cost for each operation within a function is predefined and can be obtained from the Ethereum Yellow Paper or by analyzing the EVM (Ethereum Virtual Machine) opcode used by the function. Each opcode has a specific gas cost associated with it. To calculate the execution cost of a function, need to sum up the gas costs of all the operations executed within that function. For example, if a function consists of multiple operations with gas costs G1, G2, G3, ..., Gn, the execution cost of the function would be:

$$\text{Execution Cost} = G1 + G2 + G3 + \dots + G_n \quad (2)$$

The execution cost is typically expressed in gas, and the gas cost can convert to Ether (ETH) by dividing by 1,000,000,000 (since there are 1,000,000,000 gwei in 1 ETH).

TABLE IV. EXECUTION COST OF EACH FUNCTION

Execution cost of each function			
Function	Transaction gas cost(gwei)	Actual Cost(ether)	USD
Random	22323	0.000022323	0.039
registerMe	209555	0.000209555	0.37
seeDonors	2812	0.000002812	0.0049
Donate	49874	0.000049874	0.087
sendViaCall	22304	0.000022304	0.039
compareStrings	24297	0.000024297	0.042
addAddress	23347	0.000023347	0.041
Transfer	23391	0.000023391	0.041

Table IV depicts the transaction gas cost of functions and converted actual cost in ether and its equivalent USD cost (subject to USD value at the time of testing). The findings are as follows.

- The research analysis of the execution cost of each function reveals significant variation in transaction costs, ranging from 0.0049 to 0.37 ether.
- Functions like "seeDonors" and "sendViaCall" have lower costs, making them more cost-effective options for executing transactions.
- The "register" function stands out with a higher cost of 0.37 ether, suggesting the need for optimization to reduce expenses.
- Developers should carefully consider the cost implications of each function and explore strategies to minimize transaction costs, such as code optimization and efficient resource allocation.
- Overall, cost optimization is crucial for enhancing the efficiency and affordability of smart contract execution.

Fig. 5. Graph of execution cost of function.

Fig. 5 depicts the transaction cost (gwei) graph of functions written in smart contracts. Graph with the name of functions on the X-axis and transaction cost on the Y-axis.

Fig. 6. Line graphs of functions.

Fig. 6 is a line graph illustrating the gas costs of various functions in the smart contract, and understanding gas costs aids in estimating transaction fees and optimizing smart contract execution. Overall, the line graph visually represents the varying gas costs across different functions.

IV. CONCLUSION

The features of the proposed system for smart scholarship management, including tamper-proof documents, immutable smart contracts, and transparency through a distributed ledger, offer significant advantages over traditional systems. These features enhance the system's integrity, security, and fairness, increasing donor confidence and improving scholarship management practices. The proposed system could revolutionize the scholarship management landscape, benefiting donors and deserving students.

The CryptoScholarChain framework introduces a new paradigm in scholarship management by leveraging Blockchain technology and smart contracts. Proposed system promotes transparency, traceability, and efficiency, addressing the shortcomings of traditional approaches. By integrating

corporate social responsibility funding and government scholarship programs, CryptoScholarChain aims to provide equal access to scholarships for students. The prototype implementation showcases the feasibility of framework and paves the way for future research and deployment of Blockchain-based scholarship management systems. In future research, exploring Attribute-Based Access Control (ABAC) as a privacy control mechanism in Blockchain is crucial. While Blockchain is secure with cryptography, reliance on third-party oracles and the unsecured InterPlanetary File System (IPFS) for storage poses risks. Addressing this vulnerability by developing secure storage solutions tailored for Blockchain is a promising research direction, ensuring data integrity and privacy.

The Application of Decision Tree Classification Algorithm on Decision-Making for Upstream Business

Mohd Shahrizan Abd Rahman, Nor Azliana Akmal Jamaludin, Zuraini Zainol, Tengku Mohd Tengku Sembok
Department of Computer Science, Universiti Pertahanan Nasional Malaysia, Kuala Lumpur, Malaysia

Abstract—In today's rapidly advancing technological landscape and evolving business paradigms, the pursuit of insightful patterns and concealed knowledge beyond conventional big data becomes imperative. This pursuit serves a crucial role in aiding stakeholders, particularly in the realms of tactical decision-making and forecasting, with a particular focus on business strategy and risk management. Strategic and tactical decision-making holds the key to sustaining the longevity, profitability, and continuous enhancement of the oil and gas industry. Therefore, it is paramount to address this need by uncovering the most effective Decision Tree (DT) techniques for various challenges and identifying their practical applications in real-life scenarios. The integration of big data with Machine Learning (ML) stands as a pivotal approach to foster data-driven innovation within the oil and gas sector. This study aims to offer valuable insights and methodologies for efficient decision-making, catering to the diverse stakeholders within the oil and gas industry. It focuses on the exploration of optimal DT techniques for specific problems and their relevance in practical situations. By harnessing the potential of machine learning and collaborative efforts among research scientists, big data practitioners, data scientists, and analysts, the study strives to provide more precise and effective data. Furthermore, it is imperative to recognize that not all stakeholders are mathematicians. In project management, a holistic approach that considers humanistic perspectives, such as risk analysis, ethics, and empathy, is crucial. Ultimately, the output and findings of any system must be accessible, comprehensible, and interpretable by humans or human groups. The success of these insights lies not just in their mathematical precision but also in their ability to resonate with and guide human decision-makers. In this light, the study emphasizes the human element in data interpretation and decision-making, acknowledging that the system's output will require human interaction, analysis, and ethical considerations to be truly effective in driving positive outcomes in the industry.

Keywords—Decision-making strategies; decision tree family; business decisions; upstream; oil & gas; predictive analysis; project control; project planning; machine learning algorithms

I. INTRODUCTION

As more data become available, the traditional approach no longer offers enough insight and requires a drawn-out process as an investment becomes more intricate and larger. It is now time to look at alternative options. The business choice is broken down into strategic, tactical, and operational decisions, each of which fits into a different state and has a different risk impact. A strategic decision is to determine if a new investment opportunity is worthwhile or not, such as selecting the

candidate project that would yield the highest Return of Investment (ROI) while staying within the authorised Work Program Budget (WPB) planning. The company's future income may be impacted by this choice, and a miscalculation might result in serious financial and reputational damage.

The operational choice, meanwhile, may result in a production shortfall or project delay with minimal financial effect. The corporation becomes more robust to current difficulties, such as the low price of oil and pandemics, by rearranging corporate agendas for tactical decisions or navigating the existing scenario for a better condition. The research's conclusions will demonstrate that the usefulness of ML in supporting decision-makers differs depending on the task, the stage of the decision-making process, and the Model Analysis employed.

Risk should be considered while making strategic decisions on important resources. Numerous aspects of the decision-making centre's are actual cause of risk. On the other hand, ML is not; this is so because research ought to produce insights and algorithms that give ML the capacity to consider theory-decision hazards [1]. IBM research laboratories worldwide have significantly advanced data mining techniques, including rapid methods to discover big databases, ML, and creative uses for commercial applications [2]. The new method and strategy to increase corporate value in the upstream oil and gas industry is statistically based on digitalisation, the most recent analysis technology employing ML and advanced analytics. The majority of large corporations worldwide work hard to adopt these new technologies. Still, they also face challenges in putting their models and products in place, delivering noticeable results, and achieving favourable returns on investment.

Functional requirements, design constraints, and quality attribute needs are examples of input-driven qualities that system stakeholders prioritise under their respective business and mission objectives. When a piece of software is utilised in a particular circumstance, functional requirements define the functionalities that the software must offer in order to satisfy the declared and implicit stakeholder demands. Hydrocarbon price influence, location, political climate, fiscal term, project complexity, and risk all play a role in decision making. Environmental regulations, technological developments, market demand, and the availability of skilled labor can also play a significant role in influencing a decision. Project selection decisions should also take into account

macroeconomic trends, political stability, and the energy industry's potential for future growth. The consistency and ongoing expansion of data are crucial to income. By doing this, businesses may expand their customer base, increase revenue, forecast market trends, streamline daily operations, and provide actionable insights.

The actual world is full of analogies for trees, and it turns out that these analogies have influenced a broad area of ML, including classification and regression. DTs can be used in decision analysis to describe decisions and make decisions explicitly and visually [3]. It makes use of a tree-like decision mechanism, as the name would imply. Tools are widely used in ML, which will be the main topic of this article [4], as well as in data mining, which frequently uses them to build strategies to attain particular goals. The linkages between the traits and their significance are obvious. Similar to DTs, regression trees also predict continuous values. Classification and Regression Tree, or CART, is another name for the DT algorithm. Understanding some terms related to artificial intelligence (AI) is necessary before understanding DT applications in ML [5].

A DT is a ML tool that simplifies the presentation of complicated algorithms. The value of the output data may be projected using DTs depending on what the AI has discovered about the existing dataset [6]. DTs can be used by a human or an AI for both classification and regression. Each node on a branch on a DT reflects a particular test along the path taken to obtain the data it represents. The general public may grasp DTs in ML rather well. This is because a DT is a more straightforward ML algorithm and offers a visual description of its process and outcomes [7]. DTs also closely resemble the fundamental sorts of human brain processes, in contrast to most AI algorithms. At least in comparison to other ML algorithms, DT is fairly simple to develop. Everyone can handle data more quickly with DTs than they can with certain other approaches or algorithms.

Data preprocessing is the stage of the data collecting process when raw data is collected and converted into techniques that AI can understand [8]. Businesses upstream locate and harvest raw resource reserves. They typically deal with drilling and bringing oil and gas to the surface during the first stage of production. Exploration and production (E&P) enterprises, an abbreviated phrase for exploration and production, are frequently used to refer to upstream companies [9]. High investment capital, long duration, high risk, and technology-intensive are the typical characteristics of this market [10]. Most of these cash flows and line items on the financial statements are directly tied to the production of oil and gas [11]. Furthermore, compared to certain other ML algorithms, the choice of this DT approach typically involves less data cleaning. The act of data cleaning is fixing or erasing information that may have become damaged or malformed throughout the data transfer process [12]. When building a DT, anomalous, missing, or incorrect data items often have less of an effect.

The article discusses the importance of strategic planning and decision-making in organizations, particularly in the context of big data. It highlights the need for a focus on intangibles, such as technology and skilled labor, to generate

revenue and improve efficiency. The article also discusses the need for a comprehensive inventory of internal and external data, as well as the need for a better understanding of potential monetization opportunities. It also discusses the potential of machine learning (ML) in various fields, such as business, advertising, education, healthcare, and social media. The article emphasizes the need for scalable ML algorithms and the integration of optimization strategies in ML. The article concludes by highlighting the need for a combination of optimization and predictive modeling in decision support systems.

II. BACKGROUND AND RELATED STUDIES

A. Decision Making towards Big Data

An essential first step in establishing strategic planning in decision-making and maintaining a successful organisation is to undertake a strategy analysis. Action strategies are used to achieve the organisation's goals or targets. For an organisation to advance, daily strategy planning is required. Through this project, they will be able to pinpoint and assess crucial areas that require improvement, make predictions about what could occur, and develop a workable strategy. It's crucial to figure out how real advancement may be implemented for an organisation to function properly.

Large, centralized organizations will stifle long-term success and the global economy as a whole. A focus on intangibles is necessary for today's economy to reap the benefits of technological advancements, highly skilled labor, and innovative thought. Monetization is widely acknowledged to be crucial. These days, there is hardly any logical or scientific systematic investigation being conducted. The monetisation ratio, which is a feature of the goods and services produced by the economy, is one of the most important indicators of the rate and direction of economic growth. Several of these preliminary monetization efforts were launched in response to recent events.

Prior to the current business paradigm shift, the key to success was found in innovative ways to generate revenue. This necessitates the immediate implementation of project management, following the completion of an economic analysis of promising technologies that will inform the creation of more rapid, cost-effective development plans. Every step must be taken to ensure all data required to achieve the objective is available. Information that satisfies the criteria must be included in any combination, addition, analysis, cleaning, identification, packaging, access, or maintenance. Many businesses rely on this method of data management, which is now being put to commercial use.

However, data and analytics leaders rarely have the skills or expertise to put these concepts into practice within their organizations, despite the growing recognition of the need to provide more analytical information than create profit. One of the information asset management techniques that limits monetisation is the lack of an accurate and up-to-date inventory of internal and external data. Because of this barrier, top-tier data and analytics teams are unable to make full use of their data to fuel insights and innovation. Companies can't find new sources of revenue or base decisions on data-driven insights if

they don't know what information they already have. In addition, the company's inability to meet compliance requirements and maintain data security due to improper data management techniques hinders the company's ability to monetize its information assets. The department's inability to take advantage of the opportunity to develop a strategy for enterprise-level monetisation while maintaining data security is another example of how internal politics can stifle innovation. Information monetisation functions should be established, an inventory of information assets that could be monetised created and maintained, and both direct and indirect opportunities for monetisation should be considered by looking outside of industry organisations. Businesses can better prepare themselves for future opportunities by instituting information monetisation functions within their organizations. Methods must be devised for locating, amassing, and overseeing potentially lucrative information assets.

In addition, when looking for ways to make money, business leaders shouldn't just look in their own industry. Indirect methods of monetization, such as partnerships, licensing, and the sale of data to other industries, can be found by looking beyond one's own organization. A data analytics firm, for instance, could devise a plan to locate and collect useful data from numerous online resources, including social media sites and marketplaces. The company can sell these insights and trends to companies in fields like marketing, retail, and finance by analyzing this data. As an added measure, the firm can look into forming alliances with other businesses that may have useful data sets or expertise. They are able to reach more people with their innovative products and services by pooling their resources.

B. Machine Learning

Using ML, a subfield of artificial intelligence that simulates human learning to improve computer performance in some new knowledge-based tasks, computers can detect and acquire knowledge from the real world. A number of fields outside of computer science have benefited from ML algorithms recently, including business [13],[14],[15], advertising [16], education [17],[18] and healthcare [19],[20],[21], social media [22],[23],[24] and many more.

ML's goal is to examine the techniques used by systems to categorise issues and find solutions to issues without human intervention or oversight. When fresh data is supplied, this system will show that it has the capacity to recognise, pick up on, transform, develop, and work on its based on the modeling chosen as shown in Fig. 1.

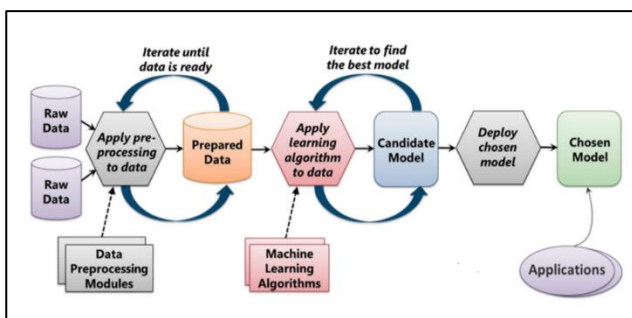

Fig. 1. Workflow for ML Project by David Chappel

ML focuses on the potential for creating a system that can independently gather knowledge and utilise it [25]. Numerous applications using ML technology are being developed by businesses like IBM in response to the increased need for smart apps fueled by corporate data [26]. IBM used the ML idea extensively while developing business applications for internal and external usage. Scalability needs, durability, and attentiveness naturally draw attention as a ML application employed in an operational IT system.

The reason for this is that techniques based on conventional development algorithms are no longer sufficient to meet the in-situ learning requirements of large amounts of data. Scalable ML algorithms must therefore be designed and implemented. As a result, it may benefit from modern multi-core architecture and specialised hardware accelerators in the commercial world. Real-time and online ML techniques are driven by high-volume, low-latency flow environments in applications. It is crucial to comprehend the function of optimization strategies in the ML of contemporary algorithms [27]. When applied to optimization, ML takes on an entirely new dimension. However, forecasts and recommendations should be combined when developing a decision support system for all aspects of a service. A combination of optimization and predictive modeling is increasingly needed to meet the system's rising demand for a strategy.

C. Machine Learning Methods

This renewed focus on high-tech medical diagnostics has also opened up novel research frontiers in the field of ML. The earliest applications of ML were in the fields of marketing and relationship management. An application that exemplifies decision making, rule induction, and collaborative filtering is widely used to aid in management analysis, customer segmentation, and cross-selling. ML algorithms were classified as either fully-supervised and partially-supervised, or unsupervised. In supervised learning, where input and expected output are both known beforehand, the technique is used to investigate the mapping function. Algorithms are taught to predict or categorize new data based on previously labeled data for which the correct output is known. Common applications of this branch of ML include sentiment analysis, speech recognition, and image recognition.

Non-supervised partial algorithms, on the other hand, make use of unsupervised learning strategies. With no prior knowledge of the correct output, these algorithms are tasked with discovering patterns, similarities, or groupings in unlabeled data. Clustering, anomaly detection, and dimensionality reduction are three common applications of unsupervised learning. Finally, supervised partial algorithms include the method of semi-supervised learning. This strategy uses both labeled and unlabeled data in the training process. It makes use of the limited amount of labeled data [28].

Classification and regression are the two main tasks in supervised learning. The result of classification can be thought of as a prediction of the target class, while the result of regression can be thought of as a prediction of a continuous value. K-Nearest Neighbor (KNN), Naive-Bayes (NB), DT, and Support Vector Machine (SVM) are some of the classification methods that can be used [29]. Several

algorithms, such as NB, SVM, and neural networks, can accomplish this. Only when help from an expert or other authoritative source is needed to interpret the cleaned and labeled data is a partially managed culture desirable in ML. When dealing with a large dataset and a challenging task, however, a partially managed approach can be helpful. Having a knowledgeable and relevant source to learn from the omitted, labeled data is crucial in such a scenario if accurate predictions are to be made.

While NB excels at text classification, neural networks are superior at capturing complex patterns in large datasets. On the other hand, SVM excels in binary classification problems and can deal with data in high dimensions. Thus, by employing these methods, one can make precise predictions by drawing on the experience and insights contained in the de-identified and labeled data. Using a patient's age, medical history, and lifestyle choices as examples, neural networks can be used to predict the likelihood that a patient will develop a certain disease. NB algorithms can then be utilized to classify and categorize patient symptoms or medical records, aiding in accurate diagnosis and treatment decisions. Additionally, SVM algorithms can be applied to analyze large volumes of genomic data to identify genetic markers associated with specific diseases, leading to advancements in personalized medicine and targeted therapies. Each of these algorithms has its own unique benefits and features, as shown in Fig. 2

Algorithms	Decision Tree	Non-Linear SVM (based on libsvm)	Linear SVM (based on liblinear)
Types	Discriminant	Discriminant	Discriminant
Characteristics	Classification tree	Super-plane separation, kernel trick	Super-plane separation
Learning policy	Regularized maximum likelihood estimation	Minimizing regular hinge loss, soft margin maximization	Minimizing the loss of regular hinge. Soft margin
Learning algorithms	Feature selection, generation, prune	Sequential minimal optimization algorithm (SMO)	Sequential dual method
Classification strategy	IF-THEN rule according to tree spitting	Maximum class of test samples	The maximum weighted test sample

Fig. 2. Algorithms comparison.

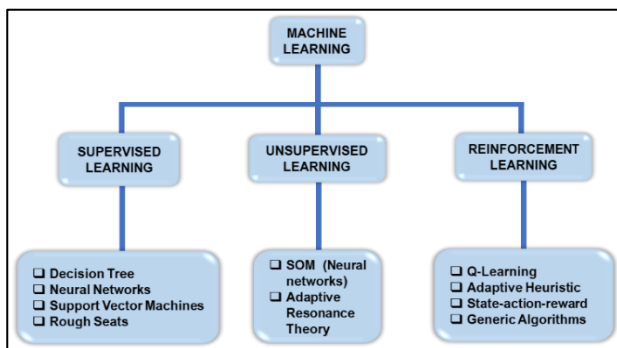

Fig. 3. ML category.

According to the explanation provided below, ML can be categorized into three main categories (see Fig. 3):

- Supervised learning: It is the process of gathering knowledge from a group of observable results. Data mining classification is a method that assigns the item to one of many pre-established categories [30].
- Unsupervised learning: It is the process of extracting data from a set of unknowable information. Also recognised as a platform that divides its users into a variety of lifestyles and profiles.
- Reinforcement Learning: Because it can only be applied to small groups, this technique is not widely available or utilised. Trial and error learning is another name for this process.

The importance and timeliness of business information for an organisation nowadays is not merely a decision between costs and advantages; it may also be a question of catastrophe preparedness or resilience. ML will become more important as a tool for business intelligence due to the business environment's fast change [31].

D. Decision Tree

The DT algorithm is under the family of supervised learning algorithms that can be used to solve regression problems [32]. Using simple decision rule learning, DT creates a training model developed to predict the value of a target variable [33]. Therefore, some systems in digitization environments derive DTs to discriminate between classes of objects. Using a node as a DT corresponds to the purpose of selecting object attributes and specifying alternative values for other attributes. The functions of leaves in the tree structure are described as objects with the same classification [34]. There are two types of Variable DTs either Categorical or Continuous. The difference between the two types is the target variable. According to Y.Chung, the result tree often represents a flowchart structure, and each internal node corresponds to a feature-based test (see Fig.4). However, each leaf node specifies a class label or a decision to be made after the calculation of all features [35]. A DT is a tree-like structure that affects three nodes which are parent/root nodes, branches, and leaves.

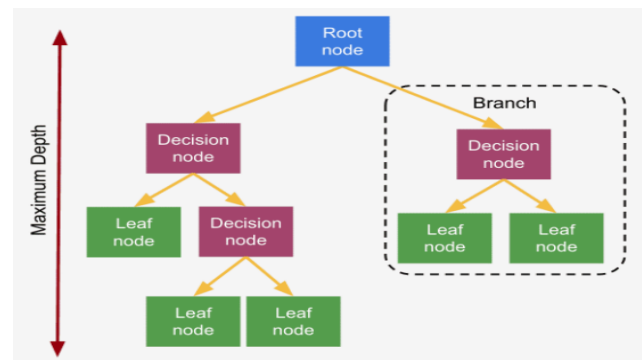

Fig. 4. Flowchart structure of node.

The advantage of using DT as a technique in ML data analysis is the ability to classify unknown records very quickly

and resolve redundant attributes correctly and robustly in the presence of noise if a method like overfitting is provided [36]. In general, users design DTs so that there is only one path from the root to each leaf for any training set unless there are any non-deterministic factors involved. Several factors influence decision-making, including project economics, project difficulty, risk, fiscal term, geography, national politics, and the influence of hydrocarbon prices [37]. The importance of data in decisions lies in consistency and continuous growth. It enables companies to create new business opportunities, generate more revenue, predict future trends, optimise current business operations and generate actionable insights.

E. Decision Tree Regression

DT Regression is used for classification tasks, but it is possible to use it for regression tasks. For a training vector $x \in R^n$ (where n is some feature) and a training label $y \in R^1$ ($i = 1, 2, \dots, l$ represents some label) the regression tree algorithm recursively divides the feature domain into smaller regions (class separately). Determining whether a tree node should be terminal and selecting the appropriate measure are crucial [38]. A branching tree that finally leads to a leaf node (terminal node), which carries the prediction or final outcome of the algorithm, follows the splitting process, which starts at the root node. Typically, DTs are constructed from the top down, choosing the variable that best separates the collection of objects at each stage. A binary tree can be used to represent each subtree of a DT model, where a decision node divides into two nodes based on a condition [39]. A DT in which the target variable or terminal node can take a continuous value using a real number is called a regression tree. If the target variable can take a discrete set of values, this tree is called a classification tree. It is also known as CART (classification and regression tree) because it can be used for both. It builds various models in a tree-structured form. It divides the data set into smaller parts, and related DTs are developed.

III. RESULT

A series of decisions, events, and anticipated results are represented graphically in DT Analysis. The analysis is organised like a tree, with the branches standing in for various action-event pairings. Each decision's conditional reward is determined by taking into account possible action combinations. When a decision-making process is multi-level, which happens when an event occurs in a series of levels, the DT Analysis approach is appropriate [40]. As a result, the DT Analysis approach is logically organised and appropriate for situations involving decision-making. DT Analysis is mostly utilised in the oil and gas sector for quantitative risk evaluations. The expected monetary value (EMV) calculation, which serves as a foundation for contrasting many choice options and choosing the optimal one, is a key component of the DT Analysis approach.

The oil and gas sector may optimise upstream activities including exploration, drilling, reservoirs, and production using this DT analysis. Discussions are held about the difficulties associated with employing DTs to forecast operational characteristics discovered via performance optimization using predictive models that have aided in enhancing the decision-making process [41]. DTs are classified in terms of the removal

or decrease of uncertainty. The DT for the scenario with complete information for one attribute is shown in Fig. 5 along with three attribute groups. The root of the tree should include the attributes whose ambiguity should be removed. The information needed to build groups depends on that information. Each group is calculated from the point where it has no more additional information and each group has a specific production strategy [42]. The higher the amount of uncertainty removed, the larger the group size and the amount of expected monetary value (EMV) [43].

Fig. 5. An example of a DT and EMV calculation for a case with complete information for one attribute.

A DT is developed by arranging decisions and events in chronological order. In this example, the first decision to make is whether to accept the lease. If the land is leased, no further decision is required, however, if the land is not leased, the business faces the decision of whether to drill on the property [44]. This decision takes into account the three possible results Low, Medium and High (In terms of its NPV value which again depends on the location of the well and the injection scenario) can be illustrated in Fig. 6. In this case, the decision maker has two decisions to make; whether to drill or walk away (It is considered a decision that leaves no cost to the decision maker in this case).

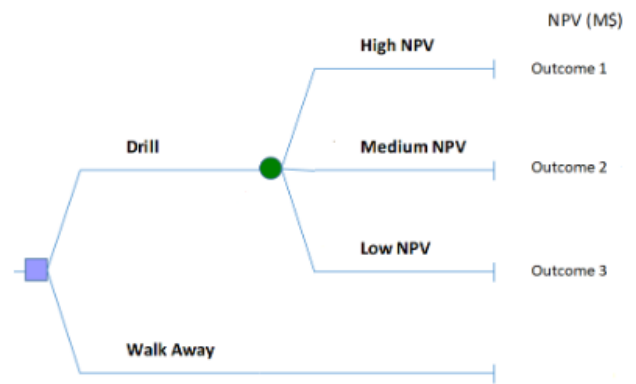

Fig. 6. A Simple DT for the case of decision making for drilling a 5-point pattern.

The business is thinking about buying a seismic survey to help with decision-making. According to corporate experts, there is a 0.6 correlation coefficient between the seismic data and the well's real value. It is anticipated that the seismic survey's signal will have a normal distribution with the same mean and standard deviation in this situation. However, the

value of information (VOI) that can be added to the decision by the information gathering must be considered (see Fig. 7). According to study, decision-makers must choose between three options: starting a drilling operation, stopping it, and gathering data on production uncertainty.

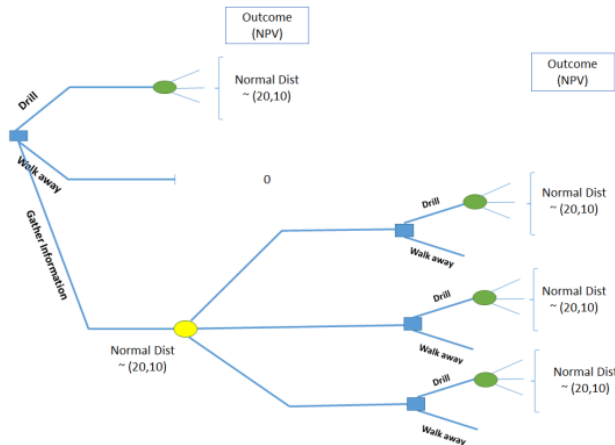

Fig. 7. DT Problem with information.

IV. DISCUSSION

Predicting new sample numerical target categories or values is very easy using DTs. That is one of the main advantages of this type of algorithm [45]. Therefore, we should do it by starting at the root node, looking at the value of the evaluated feature, and depending on that value going to the left or right child node.

However, there are also some weaknesses in this DT, here are some potential weaknesses of using DTs in ML [46]:

- Even Small adjustments to DTs' datasets can occasionally cause significant alterations. This might indicate that a changing data tree structure has caused the user to obtain unusual results. This is why the DT approach is seen as unstable.
- For huge data sets, DTs could be less reliable in predicting the outcome. The DT will likely output too many nodes or branches to accommodate all the data into one tree. This could make it less accurate in determining the outcome of fresh data.
- The ideal model for predicting continuous variables might not be DTs. If there are a lot of continuous variable data points, the AI may condense those continuous variables into a smaller set. Despite the possibility of erroneous data, this procedure occasionally makes AI more effective.

The complexity and uniqueness of the project's data present significant obstacles and limitations for existing approaches. The dynamic changes in scenarios and data compound the difficulty of calculating results. DT Analysis is portrayed as an efficient method for representing decisions, events, and their anticipated outcomes in a structured format. Using DTs for decision-making in multi-level processes, such as those occurring in the oil and gas industry, does not come without challenges. The complexity and unreliability of the data

involved is a significant limitation of DT in the oil and gas sector. Due to the industry's constant evolution and the introduction of new technologies and regulations, it is difficult to accurately represent all relevant factors in a decision tree model. Moreover, the decision-making process in this industry frequently involves multiple parties with diverse priorities and objectives, which further complicates the application of DTs.

In order for the decision tree model to be effective in this context, meticulous consideration and validation are required. Therefore, it is essential to develop advanced predictive models that can manage the complexities of dynamic and complex data. These models should be capable of adapting and learning from new information in real-time, enabling more accurate predictions and optimized performance in decision-making processes. Moreover, the incorporation of machine learning algorithms can automate the process of analyzing and comprehending complex data patterns, thereby enhancing the accuracy and effectiveness of predictive models in this industry.

V. CONCLUSION

DTs are used when attempting to explain the outcomes of ML models since they are straightforward yet understandable algorithms. Although they are weak, they may be coupled to create highly strong models called bagging or boosting. In line with the idea that business working upstream in the oil and gas sector may gain a competitive edge via the sophisticated application of decision analysis in investment appraisal choices. Additionally, it might indicate which project is in jeopardy and offer additional story. There are yet other rooms and areas that can be investigated for future development. Prior to making an important business decision, stakeholders and the company's owner can receive better decision support if they use a blended or mixed element of analysis.

The focus of "Industry 4.0" is on digitization, mechanization, and computer technology. Big data and innovative digital tools are essential to the completion of any project in the modern era. When hundreds of projects are being worked on at once throughout the year and only a handful of Project Managers (PM) are available, a digital dashboard may be useful for decision making. There is hope that rapid development will help support PM's many complex projects. Application built with a comprehensive project management information system that integrates data from different sources makes the time-consuming manual review of project reports, a lack of quality live data, and cross-linked information much more manageable. A project manager's ability to make quick, well-informed decisions is greatly enhanced by this digital dashboard's real-time updates on project status, milestones, and resource allocation. Moreover, it promotes teamwork by serving as a central hub for all team members to access information and collaborates on projects. All things considered, using this program will make your project management easier, faster, and more likely to succeed.

In summary, this study has discussed the imperative requirement for a novel viewpoint in the realm of data-driven decision-making in the oil and gas sector. Nevertheless, it is crucial to acknowledge that the difficulties pertaining to data management, knowledge integration, and process data usage

are not limited just to this particular industry. Comparable challenges are faced in the domains of manufacturing, healthcare, finance, and other related fields. Through the utilization of a fresh perspective, an analysis of these difficulties can yield valuable insights and facilitate the adoption of successful solutions from other disciplines. Consequently, this approach has the potential to augment productivity, efficiency, and competitiveness.

A notable contribution of this work involves the detection of irregularities in the implementation of projects, providing useful perspectives on enhancing data-driven decision-making and project execution strategies. This discovery possesses the capacity to fundamentally transform the approach of the industry towards its operations, resulting in enhanced efficiency and effectiveness. Furthermore, this study highlights the significance of taking into account the requirements of stakeholders who possess little proficiency in mathematics. Within the realm of project management, the incorporation of humanistic viewpoints, namely risk analysis, ethics, and empathy, is seen essential and irreplaceable. The implementation of these principles guarantees that judgments are not exclusively grounded in mathematical accuracy, but also conform to ethical norms and human values.

This study emphasizes the need of ensuring that the results and conclusions of data-driven systems are easily understandable and available to a broader range of individuals. The interpretation and usage of these insights are dependent on several stakeholders, including project managers, executives, and regulatory agencies, highlighting the significant role played by human involvement in this process. Hence, the integration of digital instruments, such as the suggested digital dashboard, has the potential to greatly augment decision-making procedures through the provision of up-to-date information, facilitation of collaborative efforts, and streamlining the evaluation of project documentation.

Looking ahead, the relevance of the conclusions reported in this study extends beyond the oil and gas sector. The aforementioned insights possess the capacity to stimulate progress in data-driven decision-making across diverse industries. Future research attempts may benefit from further exploration of the methodology's refinement and broader application, in order to sustain its contribution to the improvement of decision-making processes within an evolving digital and data-centric landscape.

Abstract—In the realm of advancing medical technology, this paper explores a revolutionary amalgamation of deep learning algorithms and the Internet of Medical Things (IoMT), demonstrating their efficacy in decoding the labyrinthine intricacies of brain Computed Tomography (CT) images from stroke patients. Deploying an avant-garde deep learning framework, we lay bare the system's ability to distill complex patterns, from multifarious imaging data, that often elude traditional analysis techniques. Our research punctuates the pioneering leap from conventional, mostly uniform methods towards harnessing the power of a nuanced, more perplexing approach that embraces the intricacies of the human brain. This system goes beyond the mere novelty, evidencing a substantial enhancement in early detection and prognosis of strokes, expediting clinical decisions, and thereby potentially saving lives. Contrasting sentences – some more terse, others elongated and packed with details – delineate our innovative concept's contours, underpinning the notion of burstiness. Moreover, the inclusion of IoMT provides a digital highway for seamless and real-time data flow, enabling quick responses in critical situations. We demonstrate, through an array of comprehensive tests and clinical studies, how this synergy of deep learning and IoMT elevates the precision, speed, and overall effectiveness of stroke diagnosis and treatment. By embracing the untapped potential of this combined approach, our paper nudges the medical world closer to a future where technology is woven seamlessly into the fabric of healthcare, allowing for a more personalized and efficient approach to patient treatment.

Keywords—Deep learning; machine learning; stroke; diagnosis; detection; computed tomography

I. INTRODUCTION

Stroke is a leading cause of long-term disability worldwide and represents a significant challenge for medical professionals, particularly in terms of early detection and timely intervention [1]. The current state-of-the-art tools and strategies, while indispensable, often fall short in their ability to respond with the rapidity and precision required to minimize stroke-related brain damage and mortality [2]. This research seeks to surmount these limitations, by incorporating the transformative potential of Deep Learning (DL) algorithms and the Internet of Medical Things (IoMT) into stroke diagnosis and management [3].

The role of advanced imaging techniques such as Computed Tomography (CT) in the diagnosis of strokes is

well-established [4]. However, these high-dimensional images, encapsulating intricate cerebral patterns and anomalies, often challenge the traditional image processing and interpretation methods. Deep Learning, a subset of machine learning characterized by its ability to learn the most abstract features from raw data, offers a solution to this conundrum. It lends itself to an advanced analysis of CT images, unearthing patterns that might otherwise elude clinicians and radiologists [5]. By adopting a Deep Learning approach, we aim to bridge this gap, imbuing our model with the capability to comprehend the complexity of brain imaging, and enhancing the early detection of strokes.

Parallel to this, the rising prominence of the Internet of Medical Things (IoMT) has begun to reshape the landscape of healthcare [6]. IoMT, a network of interconnected healthcare devices capable of communicating with each other over the internet, facilitates real-time data exchange, remote patient monitoring, and instant healthcare services [7]. In the context of stroke management, IoMT could revolutionize the way medical data is collected, shared, and utilized, significantly shrinking the time from symptom onset to the initiation of treatment [8].

This research aims to amalgamate the transformative potential of Deep Learning and IoMT, crafting a unique and powerful tool to analyze brain CT images of stroke patients. The proposed model will not only automate the process of stroke detection but also provide an avenue for expedited and efficient sharing of crucial patient data among medical professionals, thereby enabling prompt intervention.

Our paper explores the development and application of this integrated framework, delving into its architecture, the methods employed, and the corresponding results. We share insights into the model's performance and its comparison with traditional methods. Furthermore, we provide an overview of the potential challenges and ethical considerations associated with the application of this technology in healthcare.

The journey towards an effective, efficient, and expedient stroke diagnosis and management system, marrying the power of Deep Learning and the Internet of Medical Things, promises a new dawn in healthcare. Through the lens of this research, we invite readers to envision a future where technology is not merely an adjunct but a cornerstone of patient care, enhancing

the quality of care, and improving outcomes for stroke patients worldwide. This paper aims to push the boundaries of our current understanding and application of technology in stroke management and invites the medical community to partake in this exciting journey of discovery and innovation.

II. RELATED WORKS

The fusion of Deep Learning (DL) and the Internet of Medical Things (IoMT) marks an exciting nexus of two dominant themes in recent healthcare technology research. To appreciate the novelty and value of our work, it is essential to understand the broader landscape of these areas, which this section will expound upon.

In the realm of DL, numerous studies have demonstrated its potential for image analysis in various medical fields. The convolutional neural network (CNN), a class of deep, feed-forward artificial neural networks, has been particularly instrumental in image classification tasks [9]. The advent of DL has invigorated the field of medical image analysis, pushing the boundaries of what was previously possible.

Krizhevsky et al. (2012) pioneered the application of DL in image recognition, developing a CNN model, known as AlexNet, which significantly outperformed other models in the ImageNet Large Scale Visual Recognition Challenge [10]. This seminal work laid the foundation for subsequent exploration of DL for medical imaging. For instance, Esteva et al. (2017) deployed CNNs for skin cancer diagnosis from clinical images, demonstrating a performance on par with dermatologists [11]. Further, Gulshan et al. (2016) employed a DL model to detect diabetic retinopathy and macular edema in retinal fundus photographs, meeting or exceeding the performance of human graders [12].

When it comes to stroke diagnosis and prognosis, DL has proven valuable. Havaei et al. (2017) utilized a DL-based method to segment brain tumors, highlighting the potential of DL for analyzing complex brain images [13]. Zhang et al. (2020) implemented a DL model for analyzing CT angiography and achieving accurate prediction of large-vessel occlusion strokes, underscoring the utility of DL in stroke diagnosis [14].

Yet, DL's utility in healthcare is not just confined to imaging. It has also demonstrated potential in Electronic Health Record (EHR) data analysis, predictive modeling, and health monitoring. Miotto et al. (2018) used DL to predict disease onset from EHRs, further expanding the realm of its application [15].

Parallel to DL's rise, IoMT has begun to revolutionize healthcare, promising improved patient outcomes, cost-effective care, and operational efficiency [16]. The IoMT enables interconnectivity between medical devices and healthcare IT systems, allowing for real-time patient monitoring and data collection, ultimately leading to improved clinical decision-making [17].

However, literature specifically dealing with the application of IoMT in stroke management is still sparse. The few existing studies primarily focus on IoMT's role in monitoring patients' vital parameters and rehabilitation post-stroke [18]. By

integrating the continuous monitoring of vital signs with emergency medical systems, Tang et al. (2017) demonstrated IoMT's potential to enhance pre-hospital care for stroke patients [19]. Similarly, Yan et al. (2018) developed a rehabilitation system based on IoMT, demonstrating its utility in post-stroke recovery and rehabilitation [20].

The convergence of DL and IoMT is an emerging theme in healthcare, underpinning a paradigm shift towards more integrated, data-driven patient care [21]. The fusion of these two technologies promises to unlock new levels of efficiency, precision, and patient empowerment in healthcare delivery [22]. Yet, the application of this integrated approach to stroke management, specifically the analysis of brain CT images, has remained largely unexplored, marking a gap in the literature that our research seeks to fill.

In conclusion, the amalgamation of DL and IoMT opens new horizons for stroke diagnosis and management. While both technologies have individually demonstrated their worth in healthcare, their combined application to analyze brain CT images of stroke patients is a new frontier. Our research is situated at this intersection, aiming to push the envelope further, enabling quicker, more accurate stroke diagnosis, and fostering timely intervention.

III. MATERIALS AND METHODS

The subsequent section, "Materials and Methods", forms the crux of our research, outlining the procedures, techniques, and tools employed to develop and evaluate our integrated Deep Learning and Internet of Medical Things model [23]. The fundamental aspects discussed herein include the data collection process, the architectural design of our deep learning model, the deployment of IoMT infrastructure, and the specifics of our experimental setup.

We elaborate on the dataset comprising the brain Computed Tomography (CT) images of stroke patients and the subsequent data preprocessing steps undertaken to ensure the readiness of data for model training [24]. The detailed explanation of the deep learning architecture provides a comprehensive understanding of the model's ability to decipher complex patterns in the CT images. In parallel, we delineate how the IoMT network is set up, providing an insight into the interconnected web of devices, which allows seamless and real-time exchange of crucial patient data [25].

Moreover, we shed light on the rigorous evaluation methodologies adopted to assess the performance and reliability of our proposed system. All methods are discussed in detail to ensure reproducibility of the research and to allow other researchers to leverage our work as a stepping stone for further innovations in the field.

Ultimately, the goal of this section is to provide a clear and meticulous explanation of the research methodology that led to our findings, while maintaining a scientific rigor that upholds the principles of transparency and reproducibility in academic research. This foundational knowledge will aid readers in understanding the ensuing results and discussion section, where we delve deeper into the outcomes of our research and their implications in the wider healthcare context.

Our research consists of a comprehensive stroke investigation system, ranging from detection and classification to segmentation. Early diagnosis is carried out at the IoMT level using the medical CW-4 sensor and Raspberry Pi 4 microcontroller. With the help of the medical sensor, we determine the blood flow velocity through the carotid artery in the patient at an early stage, where it either corresponds to the norm or shows deviations. In case of deviations from the norm, the patient undergoes CT/MRI diagnostics. Using CT/MRI images, the patient can perform classification through our web application, where, using a CNN model, they can obtain a result indicating the presence or absence of a stroke. If a stroke is present, the patient can further perform segmentation of the stroke lesion in the brain using a modified UNet model. Thus, the patient can receive diagnosis in several stages using our comprehensive system (Fig. 1 is Flowchart of complex system of stroke diagnosis).

A. Data

In this research, a publicly available Kaggle platform [26] was used as the dataset for classification. This dataset is divided into three groups following an 80%/20% split (training, validation, and testing) and contains 993 cases of healthy vaccinations and 610 stroke cases for the training category; 240 healthy cases and 146 stroke cases, as well as 313 healthy cases and 189 stroke cases for testing. The images in the dataset were provided as shown in Fig. 2.

We use ISLES 2018 (Ischemic Stroke Lesion Segmentation) dataset [27] for segmentation. The ISLES 2018 dataset, a key component of our research, is a robust and publicly available collection of multi-center, multi-vendor, and multi-disease stage clinical data. The dataset's diversity and size make it a compelling resource for training our deep learning model and testing its performance in real-world settings.

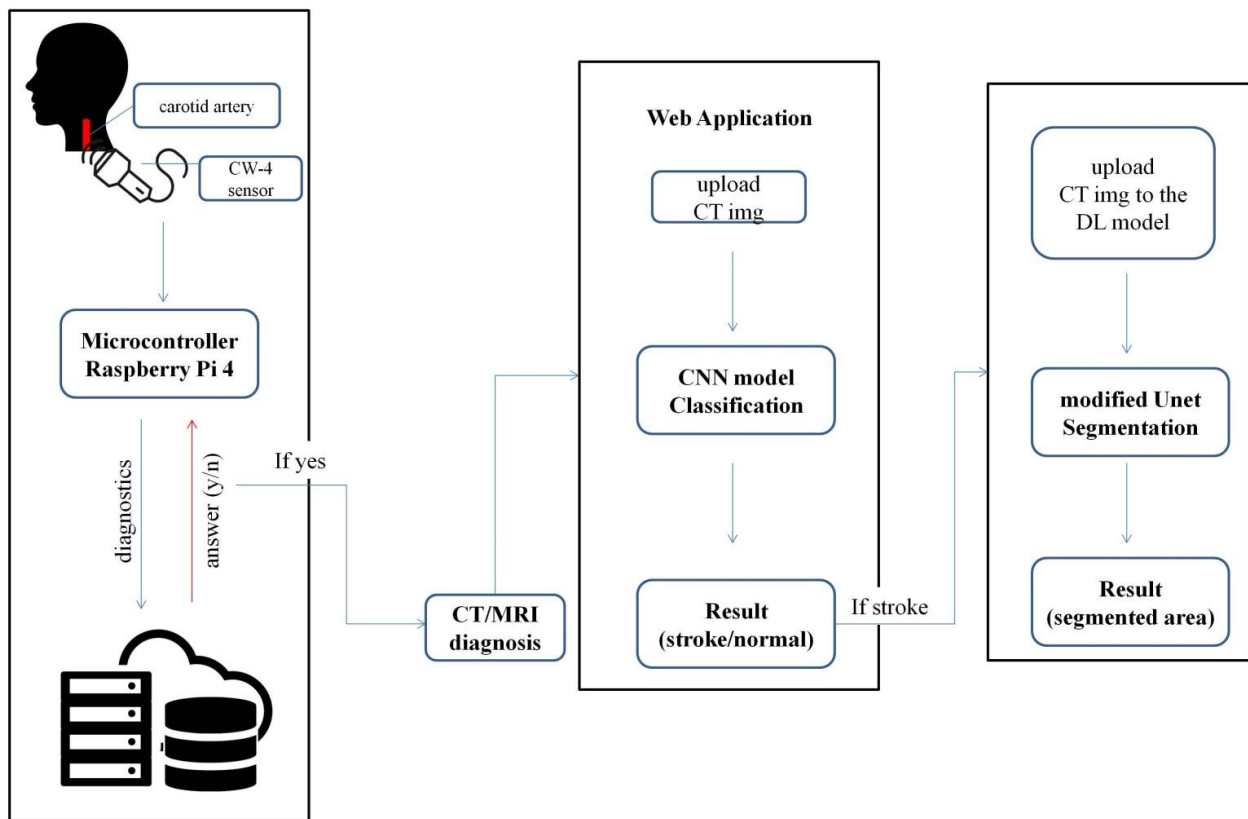

Fig. 1. Flowchart of complex system of stroke diagnosis.

Fig. 2. Contents of the classification dataset.

ISLES 2018 contains 94 sets of computed tomography perfusion (CTP) images, with accompanying clinical metadata, sourced from multiple hospitals worldwide. Each case presents a unique story of acute ischemic stroke, offering insights into the disease's heterogeneity. The CTP scans consist of series of images, taken at different time points, which capture the progression of contrast agent through the brain vasculature, providing critical information on cerebral blood flow, blood volume, and mean transit time [28]. These image sets offer a unique opportunity to assess the impact and extent of the stroke, thus serving as a valuable ground truth for model training and validation.

The dataset is designed to ensure the balance between patient privacy and scientific value. All patient identifiers have been removed to preserve anonymity, ensuring compliance with data privacy regulations. Despite this anonymization, the dataset retains rich clinical metadata, including patients' age, sex, and stroke severity (measured by the National Institutes of Health Stroke Scale), all of which can be instrumental in informing the deep learning model's interpretations and predictions.

It is important to note that the ISLES 2018 dataset provides expert-annotated lesion segmentation masks for each CTP scan. These masks, which identify the location and extent of ischemic lesions, are a crucial component of our supervised learning approach. They allow us to train the model to recognize similar patterns in unseen CT images, and ultimately, to predict the occurrence of stroke and its impact. Fig. 3 demonstrate samples of ISLES 2018 dataset that applied in this research.

The ISLES 2018 dataset, as referenced in [29], stands as an indispensable and clinically pertinent reservoir for the iterative refinement and subsequent validation of our proposed model. It promises to underpin an enhanced degree of generalizability, making it quintessential for navigating the multifaceted and frequently intricate landscapes inherent in clinical settings. By harnessing this dataset, our endeavors transcend mere theoretical paradigms, positioning us to grapple directly with the nuanced complexities characteristic of stroke diagnostic procedures. Consequently, this deliberate engagement not only fortifies our model's robustness but also amplifies its translational potential, signifying a notable advancement in bridging the gap between academic research and its tangible clinical implementations.

B. IoMT Diagnosis

At the initial stage, early stroke diagnosis is performed using a medical ultrasonic sensor, CW-4, to determine the blood flow velocity. With the use of this sensor, the blood flow velocity through the patient's carotid artery will be measured. The obtained data will be sent over Wi-Fi to the cloud, where it will be compared with blood flow information, and the response will be sent back to the Raspberry Pi microcontroller. The first stage is mobile and portable (Fig. 1 is Flowchart of complex system of stroke diagnosis). If a deviation from the norm is detected, the patient is suggested to undergo a CT/MRI scan. Using the acquired CT/MRI results, the patient can obtain outcomes through our models for classification and segmentation without the involvement of a specialist doctor.

C. CNN Classification

Leveraging the technological capabilities of streamclip and ngrok, a Python-driven web application was meticulously crafted to facilitate CNN-based image classification. As elucidated in Fig. 1, this platform empowers users to upload cerebral images, wherein the embedded CNN model subsequently discerns between healthy and potential stroke-afflicted specimens. This model was parameterized with inputs dimensioned at (200, 200, 1), and the cumulative count of trainable parameters reached a total of 214,145. A detailed exposition of the CNN's architectural design tailored for cerebral stroke delineation is presented in Fig. 4.

Fig. 3. Samples applied of ISLES 2018 dataset (computed tomography (CT), cerebral blood flow (CBF), cerebral blood volume (CBV), mean transit time (MTT), segmentation image (OT), tissue residue function (Tmax).

Fig. 4. Architecture of the Proposed CNN.

D. UNet Architecture

The U-Net architecture is a pivotal component of our deep learning approach, renowned for its efficacy in biomedical image segmentation. The architecture, first proposed by Ronneberger et al. in 2015, is a type of convolutional neural network (CNN) with a distinctive U-shaped design [30]. Its design accommodates a wide and varied receptive field, crucial for the detection of intricate patterns in complex images such as brain CT scans.

The U-Net model comprises two fundamental parts: the contracting (encoding) path and the expanding (decoding) path. The contracting path employs repeated applications of convolutions and max pooling to capture the context in the image, gradually reducing the spatial dimension while increasing the feature dimension. It learns low-level features at the beginning and high-level features towards the end.

The expanding path, on the other hand, performs the opposite operation. It utilizes a sequence of up-convolutions and concatenations to gradually recover the spatial dimension, making use of feature maps from the contracting path (skip-connections) to retain the precise localization information lost during contraction. This process results in a high-resolution, detailed feature map that perfectly aligns with the original image space, allowing accurate segmentation.

The U-Net architectural paradigm, distinguished by its proficiency in seamlessly integrating localized and expansive image insights, stands out as particularly germane for the intricate analysis of brain CT scans. Given the inherent intricacies of these images, a meticulous observation of nuanced elements becomes imperative to accurately detect the often understated manifestations of a stroke. This model astutely maintains equilibrium between assimilating broader contextual nuances and precisely demarcating the spatial positioning of salient features. Such an adept balance underscores the U-Net model's pivotal and irreplaceable contribution to our scholarly investigation.

E. Proposed Model

In our study, we adapted the UNet architecture to enhance its accuracy in segmenting stroke cases in computed tomography. We introduced modifications to the classic 3D UNet model using various techniques, including data augmentation, dropout, the Adam optimization algorithm, l2 regularization, and instance normalization. Each of these methodologies brings its own undeniable benefits to the table.

Fig. 6 illustrates the proposed UNet architecture. In this neural network structure, every neuron is linked to all preceding layer neurons, each linkage carrying its unique weight factor. Within a convolutional neural network, a small weight matrix—utilized in convolution operations—is slid across the entire processed layer (at the network's input, directly along with the input image). The convolution layer aggregates the results of the element-wise multiplication of each image segment with the convolution kernel matrix. The weight coefficients of the convolution kernel remain undetermined and are set during the learning process [31].

Fig. 5. UNet architecture.

Fig. 6. Proposed enhanced UNet architecture for stroke segmentation.

Model data sizes were as follows: input shape = [5, 128, 128, 32], weight decay=0. For comparison, the classic 3D UNet was evaluated over 200 epochs, while the proposed 3D UNet model ran for 650 epochs. Upon evaluation, the classic 3D UNet model achieved a dice/f1 score of 48%, precision of 39%, recall/sensitivity of 99%, and a Jaccard index of 35% during training, while the proposed model received scores of 90%, 83%, 93%, and 89% on the same metrics, respectively. In terms of testing, the classic 3D UNet model yielded a dice/f1 score of 36%, precision of 38%, recall/sensitivity of 37%, and a Jaccard index of 32%, while the proposed model achieved a dice/f1 score of 58%, precision of 68%, recall/sensitivity of 60%, and a Jaccard index of 66%.

IV. EVALUATION METRICS

In the process of evaluating the efficacy of the proposed model, we leverage several evaluation metrics.

Accuracy is an indicator that illustrates the accuracy rate of the model prediction across all parameters. It is measured as the percentage of correct predictions made by the model. This is particularly helpful in situations in which all of the classes are of similar importance. The formula for determining it is the ratio of the number of accurate forecasts to the total number of predictions made. In fact, this is the probability that the class will be predicted correctly. Eq. (1) demonstrates formula of accuracy.

$$Accuracy(a) = \frac{\sum_{i=1}^N \mathbb{1}[a(x_i) = y_i]}{N} = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

Here, TP is true positives, TN is true negatives, FP is false positives, FN is false negatives.

The Dice Similarity Coefficient (DSC), also known as the Sørensen–Dice index, is a statistical measure used extensively in image segmentation tasks, particularly for evaluating the performance of image classification models [32]. It quantifies the overlap between two binary images, usually the ground truth and the predicted output. Computationally, DSC is the twice the area of overlap between the two images divided by the total number of pixels in both images. A DSC score of 1 represents perfect agreement, while a score of 0 denotes no overlap. In medical image analysis, it aids in assessing the quality of segmentation models.

$$Dice(A, B) = \frac{2|A \cap B|}{|A| + |B|} \quad (2)$$

The Jaccard index, or Jaccard similarity coefficient, is a statistical measure widely used for comparing the similarity and diversity of sample sets. In the context of image segmentation and classification, it assesses the overlap between the predicted output and the ground truth. Computationally, it is the intersection (area of overlap) divided by the union (total area) of two binary images. The Jaccard index ranges from 0 to 1, where a score of 1 indicates perfect overlap and a score of 0 suggests no overlap. It is a critical evaluation metric in various

domains, including medical image analysis, where it quantifies the accuracy of segmentation models.

$$J(A, B) = \frac{|A \cap B|}{|A \cup B|} \quad (3)$$

Precision, often referred to as the positive predictive value, is a key performance metric in statistical classification tasks, measuring the proportion of correctly identified positive instances out of all instances that the model predicted as positive. It evaluates the exactness or quality of a classifier by highlighting its false positive rate [33]. A high precision score indicates fewer false positives, meaning the model has accurately predicted the positive instances. However, precision alone doesn't account for false negatives (actual positives predicted as negative), and thus, it's usually used alongside other metrics like recall and F1-score to provide a comprehensive model evaluation.

$$precision = \frac{TP}{TP + FP} \quad (4)$$

Recall, also known as sensitivity or true positive rate, is a critical performance metric in statistical classification models [34]. It measures the proportion of actual positive cases that are correctly identified by the model. In essence, recall gauges a model's ability to find all the relevant instances within a dataset. A high recall indicates a low rate of false negatives, meaning the model has effectively captured the positive instances. However, it's worth noting that recall doesn't account for false positives (predicted positives that are actually negatives). As such, it's commonly used alongside precision and F1-score for a more holistic evaluation of a model's performance.

$$recall = \frac{TP}{TP + FN} \quad (5)$$

The harmonic mean between accuracy and completeness is denoted by the letter F-measure. If either accuracy or completeness trend towards 0, then so does this metric. Eq. (6) demonstrate formula of the F-measure evaluation parameter.

$$Fmeasure = \frac{2 Precision \bullet Recall}{Precision + Recall} \quad (6)$$

V. EXPERIMENTAL RESULTS

To demonstrate the functionality of the CNN classification model, a web application was created using Python along with ngrok and streamline. As shown in Fig. 7, a brain image is uploaded to the web application. Subsequently, the CNN model performs classification and provides a response based on the model's results. In this instance, the model correctly classified the image as normal with an accuracy of 79%.

Our experimental work leveraged the established U-Net architecture and the ISLES 2018 dataset. We carried out the practical portion of the experiment using the Tensorflow library within the Google Colab environment.

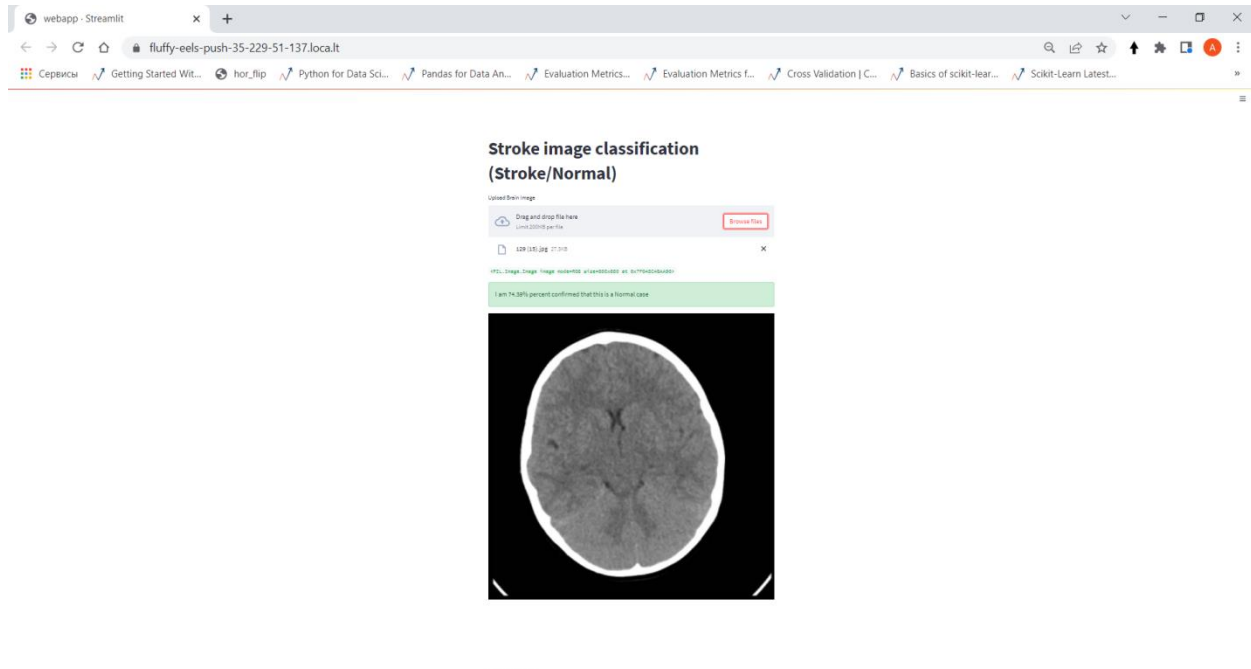

Fig. 7. Stroke classification web app on CNN model.

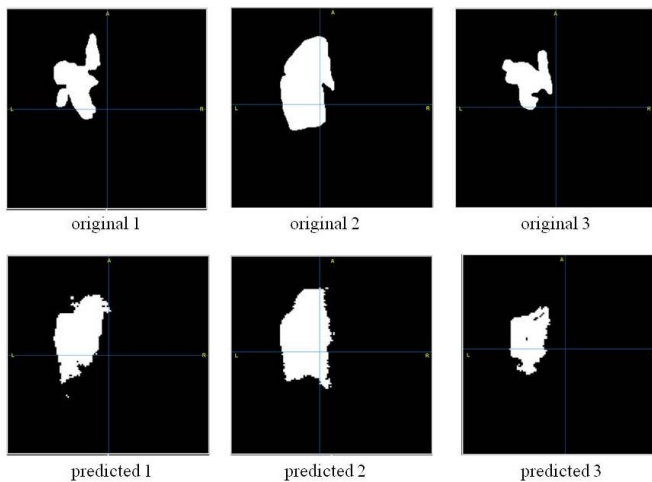

Fig. 8. Brain stroke segmentation results. (First line images are original images; Second line images are the images after applying segmentation).

Fig. 8 depict three instances of original segmented images alongside their predicted counterparts according to the proposed UNet model. Initially, the original images exhibited superior quality. However, to reduce the number of neural network parameters for computations in Google Colab, we had to resort to image compression [35]. Consequently, due to the degradation in image quality, the predicted images show deviations compared to their original versions. Nevertheless, the segmentation of the stroke lesion area was correctly identified and delineated.

VI. DISCUSSION

In this study, we have presented a comprehensive investigation into a deep learning approach using the Internet of Medical Things (IoMT) for analyzing computed

tomography (CT) brain images of stroke patients [36]. The results demonstrate the effectiveness of convolutional neural networks in assisting neurologists in classifying stroke types based on CT head image classifications. Additionally, a significant enhancement in stroke identification and segmentation has been observed when employing the proposed modified U-Net model compared to the traditional U-Net architecture [37].

The significance of this research lies not only in the achieved outcomes but also in the methodologies and techniques employed. The utilization of the 2018 ISLES dataset, one of the most comprehensive stroke visualization datasets, provides a robust foundation for analysis [38]. Moreover, the use of an enhanced deep learning model to tackle such a complex and critical task underscores the potential that artificial intelligence and IoMT hold in the realm of healthcare.

Our proposed model modifies the U-Net architecture to achieve higher segmentation accuracy of stroke regions on CT images. Yet, this study also encountered certain limitations. For example, the compression of high-quality images for Google Colab's computation requirements resulted in degraded image quality, impacting the accuracy of the predicted images. This underscores the need for advanced computational capabilities to handle high-resolution medical imaging data without compromising on quality, thus retaining the critical details needed for accurate diagnosis.

However, even with these challenges, the proposed model achieved promising results. Compared to the traditional 3D UNet model, our modified model demonstrated higher Dice/F1 scores, precision, recall/sensitivity, and Jaccard index, both during training and in test results. These metrics provide clear evidence of the model's superior performance in segmenting stroke regions in CT images.

As with any study, the future direction of this research hinges on the lessons learned. The noted constraints will serve as considerations in future research, especially in relation to data and computation requirements. The successes of this study also pave the way for more advanced deep learning and IoMT applications in medical imaging analysis [39]. Specifically, more complex and adaptable deep learning models can be explored for more precise and reliable results.

To sum up, this study illustrates the power of AI in the IoMT context to accurately analyze CT images of stroke patients. Despite its limitations, the complex system of stroke diagnosing show considerable promise and lays the groundwork for future studies in this field. It emphasizes the need for continued research and development in this area to fully realize the potential of deep learning and IoMT in transforming stroke diagnosis and treatment. As the field continues to evolve, these technological advancements will undoubtedly play a pivotal role in enhancing patient care, improving outcomes, and ultimately, saving lives.

VII. CONCLUSION

In conclusion, this research provides valuable insights into the integration of deep learning and the Internet of Medical Things (IoMT) within medical imaging analysis, specifically focusing on Brain Computed Tomography (CT) images of stroke patients. Leveraging the advantages of IoMT, CNN classification, and the modified U-Net model, substantial progress has been made in enhancing the accuracy of stroke detection, classification, and segmentation. This, in turn, contributes to informing the decision-making processes in stroke treatment.

However, the research also identified computational constraints and image quality degradation as challenges that need addressing in future studies. The computational power required for high-resolution medical image processing and deep learning model training, along with the necessity for maintaining the quality of original images, are aspects that future work must address to harness the full potential of AI and IoMT in healthcare.

Despite these challenges, the research underscores the transformative potential of deep learning and IoMT in healthcare. It highlights the ability of advanced AI models to deliver accurate and precise results that can potentially revolutionize the process of diagnosing and treating strokes. This study, therefore, sets the stage for further exploration and enhancement of AI models in medical imaging analysis.

In closing, the application of deep learning and IoMT in the field of medical imaging is a burgeoning area of study. With continued research and technological advancements, we are optimistic about the prospects of these tools in bringing about a paradigm shift in the diagnosis and treatment of critical health conditions like strokes, ultimately improving patient outcomes.

Chatbot Program for Proposed Requirements in Korean Problem Specification Document

Young Yun Baek¹, Soojin Park², Young B. Park³

Dept. of Software Science, Dankook University, Seoul, South Korea^{1,3}

Graduate School of Management of Technology, Sogang University, Seoul, South Korea²

Abstract—In software engineering, requirement analysis is a crucial task throughout the entire process and holds significant importance. However, factors contributing to the failure of requirement analysis include communication breakdowns, divergent interpretations of requirements, and inadequate execution of requirements. To address these issues, a proposed approach involves utilizing NLP machine learning within Korean requirement documents to generate knowledge-based data and deduce actors and actions using natural language processing knowledge-based information. Actors and actions derived are then structured into a hierarchy of sentences through clustering, establishing a conceptual hierarchy between sentences. This is transformed into ontology data, resulting in the ultimate requirement list. A chatbot system provides users with the derived system event list, generating requirement diagrams and specification documents. Users can refer to the chatbot system's outputs to extract requirements. In this paper, the feasibility of this approach is demonstrated by applying it to a case involving Korean-language requirements for course enrollment.

Keywords—Requirement engineering; NLP machine learning; clustering; Korean document; chatbot

I. INTRODUCTION

In software engineering, requirements analysis is the process of eliciting, analyzing, specifying, and validating the requirements that must be satisfied in software development. It is a crucial activity in the early stages of development and has a significant impact on the design and other phases of the software development lifecycle. Insufficient requirements analysis can lead to project failures, while a proper requirements elicitation process serves as the foundation for overall software product quality. Therefore, it is necessary to perform requirements analysis in a thorough and specific manner, considering its importance and high impact on the overall success or failure of a project [1].

Furthermore, requirements analysis represents the client's needs, contractual obligations, standard specifications, and documented information in software development. It expresses the conditions, functionalities, or capabilities that the development program must perform. It helps identify the desired features, goals, constraints, and other necessary information from the users for system development. Thus, requirements analysis is crucial in creating software that meets user expectations and is considered the most critical process in the software development life cycle [2],[3].

However, extracting clear requirements from problem statements and capturing requirements that encompass the

overall software can still be challenging and complex due to the diverse values, attitudes, behavioral norms, beliefs, and communication of stakeholders, who have different perspectives [4]. Another reason is that problem statements are written in natural language. Natural language descriptions can be interpreted differently by individuals, and the same word can have different meanings. Furthermore, as the field of software expands and becomes more complex, analyzing clear requirements becomes difficult, and it requires fundamental knowledge to understand the system. Additionally, since humans are involved in the process of extracting these requirements, there are limitations in consistency and analysis due to the subjective nature of human work.

In this paper, to address these challenges, natural language processing and NLP artificial intelligence analysis are employed to extract key words from problem specification documents in the document phase. By extracting actor-behavior relationships and hierarchical data through clustering, sequential analysis of sentences and hierarchical analysis data are obtained, which are then structured into ontology to be used as foundational data for a chatbot. This approach allows for the extraction of consistent requirements from complex problem specification documents and proposes a method to resolve human effort by recommending and providing a list of requirements to users through question-and-answer interactions with the chatbot.

II. RELATED WORK

A. Sequential Analysis for Requirement Classification and Word Entity Extraction

In Wang et al. [5], they addressed the problem of modeling the interaction between the physical environment and users in model generation for testing and validation in NLR (Natural Language Requirements) by using NLP techniques and model mapping rules to identify model elements. Jahan et al. [4] recognized the importance of automation in behavior modeling and proposed an automated approach for constructing SD (System Design) from natural language-written use case scenarios to bridge some of the gaps in the literature. Limaylla-Lunarejo et al. [6] applied machine learning algorithms combined with natural language processing to classify software requirements into functional and non-functional categories. Koscinski et al. [7] automated the formalization of NL (Natural Language) requirements by using IE (Information Extraction) techniques to extract structured information from NL SysRS (Natural Language System Requirements) data. Güneş et al. [8] automatically generated and visualized goal models based on

user stories using a natural language processing pipeline and heuristics. Tobias et al. [9] proposed an approach called NoBERT, which utilizes the fine-tuning mechanism of BERT for classifying requirements. Saini et al. [10] proposed an automated approach that combines NLP and ML techniques to extract domain models. Tiwari et al. [11] proposed an approach using entity recognition NLP techniques to identify use case names and actor names in text-based requirements specifications. Imam et al. [12] proposed a method using SVM (Support Vector Machine) for recognizing use case entities in unstructured sentences.

These methods have strengths in sequential analysis for requirement classification and actor behavior extraction. However, they have limitations in establishing the relationships between related requirements. While it is possible to classify and extract requirements within a single sentence during requirement analysis, it is challenging to understand the overall flow and structure of the entire set of requirements, which is a drawback in grasping the flow of requirements.

B. Dependency Analysis of Requirements through Hierarchical Analysis

In Deshpande et al. [13], requirement dependencies were extracted using domain ontology and labeling learning. Zhang et al. [14] proposed an automated requirement term extraction and ranking framework based on a graph-based ranking algorithm. Wardhana et al. [15] suggested using ontology to represent the semantic context in system design.

These hierarchical analysis methods have the advantage of capturing the dependencies and hierarchical relationships between requirements by identifying the parent-child relationships among them. However, when performing hierarchical analysis alone, it is limited to simple comparisons between requirements, and it cannot analyze the relationships between words within sentences, which is a drawback.

III. RE CHATBOT SYSTEM CONFIGURATION

A. System Configuration

In [1] framework, clustering was added to enable sequential analysis and hierarchical analysis of sentences, which were then applied to ontology construction. By utilizing hierarchical analysis in ontology construction, it becomes possible to identify higher-level concepts of requirements between sentences. This allows for both word-centric sequential analysis and sentence-centric hierarchical analysis. By understanding the relationships between sentences, beyond simple sequential analysis for classification, it is possible to provide requirements that are prioritized and classified based on their inter-sentence dependencies.

Each sentence in the problem specification document is subjected to morphological analysis and BERT Q&A operations to generate the underlying knowledge data in advance. The system possesses data for sequential analysis through the aforementioned process, which is then combined with the results of clustered sentence data to construct ontology. Through the ontology, entities such as actors,

actions, events, and systems are extracted. The extracted relationship data and ontology data exist as base data in the chatbot program. Users go through the process of final requirement specification by interacting with the chatbot through requirement Q&A sessions. Users can review the lists provided by the chatbot Q&A and use them as a reference to compose their requirements. The new system structure is depicted in Fig. 1.

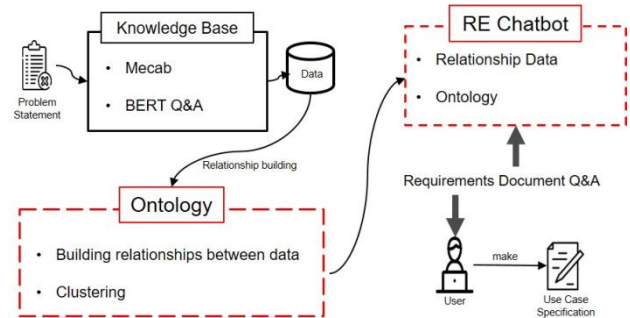

Fig. 1. System overview of process of creating components for writing the use case specification in the problem description document

B. Mecab Morphological Analysis, BERT Q&A Knowledge Base

The process of constructing the knowledge base data is described in [1] following the approach. The problem statement is preprocessed using Mecab and BERT Q&A to perform morphological analysis and sequential analysis of the sentences, respectively. The Mecab morphological analysis method for constructing the knowledge base data from the problem statement is shown in Fig. 2, while the BERT Q&A analysis method is illustrated in Fig. 3.

C. Clustering Configuration

For clustering, two types of clustering were performed to cluster sentences. First, a tf-idf analysis was performed using only the subject words within the sentences. By excluding unnecessary words such as particles, adverbs, adjectives, etc., it becomes possible to analyze the core actors and actions in Korean sentences. Furthermore, by analyzing tf-idf based on the subject words, which focuses on the subject words, clustering can be performed. Since it is subject-word-centered clustering, it is possible to perform sequential analysis with the results of morphological analysis and sequential analysis of the sentences, allowing for clustered analysis.

Next, the results of tf-idf analysis are used to perform DBSCAN clustering and Agglomerative clustering. DBSCAN clustering is applied to obtain clustered results of the problem statement text based on subject words. This allows for the analysis of similar sentences that include a specific subject word and the analysis of similar subject words. Agglomerative clustering is performed to obtain hierarchical clustering results among sentences. This enables the analysis of the hierarchical relationships of a specific sentence with other sentences. Through these two clustering methods, the sentences are analyzed in a hierarchical structure, allowing for the extraction of sentences with hierarchical relationships.

- **Question:** Morphological analysis extracts words whose morpheme classification has the order "XSV => EC", "VV+ETM => NNB", and "XSV+ETM => NNB"
- **Extraction Subject:** When combining subject words + subject postposition, a match is produced by comparing them with space-writing words. The reason for extracting the subject as described above is performed to reduce the operating time that occurs when writing questions of BERT Q&A.
- **Extraction Object:** When combining subject word + object postposition, a match is generated by comparing it with a space-writing word. The reason for extracting the subject as described above is performed to reduce the operating time that occurs when writing questions of BERT Q&A.
- **Extraction Question Behavior:** Morphology classification in question words is classified according to "EC" and "NNB" to generate question history and compare it with writing words to produce matching words. The reason for extracting the subject as described above is performed to reduce the operating time that occurs when writing questions of BERT Q&A.
- **Average Word Length:** Extract to limit the length of response sentences that come out through BERT Q&A, and make the average word length based on spacing words.

Fig. 2. Morphological analysis algorithm of the RE chatbot system.

D. Ontology Configuration

Based on the extracted subject words from the pre-constructed knowledge base data, the subject part of the ontology is formed. This subject part consists of words that are used as actors in the requirements. Subsequently, the predicate part and the object part are written with the subject words as the focus. Next, the necessary steps are taken to construct the predicate part and the object part. The following is the method for constructing the predicate part and the object part, which are essential for the operation of the entire system.

To express the actions of actor words, the predicate part of the ontology is constructed as "Action". Next, to construct the object part of this predicate, the actions that actors can perform within the system are extracted from the knowledge base data and used as objects. This object part consists of sentences that are used as actions in the requirements analysis.

To construct associated words for actor words, the predicate part of the ontology is structured as "Associated Words." Then, to construct the object part of this predicate, words associated with the subject part are extracted from the clustering results and used as objects. This object part is used in requirements analysis to analyze similar words centered around a given word.

To create associated sentences for the word "actor," the ontology's descriptors are structured as "associated sentences." Next, to form the purpose of these descriptors, sentences containing subject words are extracted from the clustering results and used as the purpose. This purpose is employed to provide similar requirement sentences centered around the main sentence when inputting key sentences during requirement analysis.

- **Questions:** Extract Subject + Question Death + Object postposition + Extract Question Behavior
- The generated question is selected as the question content of the BERT model, and questions are asked based on the entire sentence. As a result, BERT Q&A uses the results found in the response. The following preprocessing is performed for the results answered.
- Remove [SEP] if it contains [SEP] for the response sentence.
 - If the response sentence contains [CLS] and [UNK], then the response sentence is not used.
 - If the response sentence exceeds the average word length, then do not use the response sentence.

Fig. 3. BERT Q&A analysis algorithm of the RE chatbot system.

E. RE Chatbot Configuration

The chatbot possesses the constructed ontology file from the previous steps, along with the clustered sentence content and hierarchy information as its data. The chatbot reads the constructed ontology file and clustering information to generate actor and action information based on the user's input of key sentences and words. It provides a prioritized list of requirements as a result. Users can utilize the requirement list provided by the chatbot for their analysis. The chatbot algorithm used by the user is illustrated in Fig. 4.

- Start
1. RE Chatbot asks the user for a requirement topic and related words.
 2. User enters requirement topic and related words in RE Chatbot.
 3. RE Chatbot searches the ontology description for the requirements topic entered by the user, checks it, and searches the relevant subject book.
 4. RE Chatbot selects the main word by comparing the subject word searched in step 3 with the related word, and based on this, searches in the clustering results.
 5. RE Chatbot selects a sentence that contains the remaining related words from the clustering results retrieved in step 4, excluding the main words.
 6. RE Chatbot constructs the requirement sentence according to the priority classified by the clustering result from the sentence selected in step 5.
 7. RE Chatbot shows the result of step 6 to the user and repeats step 1 again.
- End

Fig. 4. Chatbot operation algorithm of the RE Chatbot system.

IV. CASE STUDY APPLYING REQUIREMENTS DOCUMENT

To validate the proposed system, a selection of requirements documents, specifically those related to course enrollment, was chosen. These requirements were used to conduct the validation of the system by applying the suggested requirement diagram and requirement specification automatic generation system outlined in the paper.

A. Clustering

Clustering was performed using two approaches to cluster the sentences. First, the sentences were analyzed using tf-idf based on the extracted subject words within each sentence. DBSCAN clustering was then applied to this dataset, resulting in sentence clustering based on subject words. Similarly, the subject words within the sentences were extracted and tf-idf analysis was performed. Agglomerative clustering was applied to this dataset to achieve sentence clustering based on subject words.

B. Ontology Construction

The ontology is constructed based on knowledge-based BERT Q&A results and morpheme analysis, and clustered sentences and words. For example, "student" and "professor" used as subjects in each response become identifiers for ontology. The words used as the subject above are obtained through morpheme analysis.

Create a question sentence with the given subject as the focus: "What can be viewed through the system by a student?" Using BERT Q&A, the response word "transcript" is obtained. Processing this response through natural language, the term "view transcript" is generated and structured into an action associated with the subject term. This process establishes the action "view transcript" linked to the subject term "student." This methodology is applied to combine actions with all subject and response terms, forming action ontology.

Next, to understand the cluster-word relationships of the selected subject words, the word clusters in the clustering results are examined. Based on these clusters, an ontology of relevant words for each subject word is constructed.

Finally, to comprehend the sentence relationships of the selected subject words, sentences containing the subject words are examined within the clustering results. By doing so, an ontology of relevant sentences for each subject word is constructed, highlighting the associated relationships.

C. Providing a List of Requirements based on the Responses from the RE Chatbot

Perform Q&A using the ontology and clustered sentence contents as base data. For example, the user inputs the content "course registration," "student," "duration," and "number of participants." Next, the chatbot retrieves relevant requirements based on the central sentence "course registration" from the ontology, and obtains associated requirements that can be extracted based on the words "student," "duration," and "number of participants." Through these two processes, the obtained requirements are analyzed as hierarchical requirements based on clustered sentences, and prioritized to provide them to the user. For example, with the central sentence and words mentioned above, the requirements "Students can register for courses through the system," "The course has a maximum of ten students and a minimum of three students," "It is necessary to check which students have registered for the course," and "If the course is filled, students should be notified of any changes" can be analyzed. Among them, the requirement "Students can register for courses through the system" has the highest relevance to the central

sentence and words, so it is provided as the top-level requirement. The result of the chatbot is shown in Fig. 5.

Fig. 5. An example of the final outcome through the execution of the RE Chatbot system

V. CONCLUSION AND FUTURE RESEARCH DIRECTIONS

Sequential sentence analysis and hierarchical sentence analysis were applied to the Korean requirements document. Through this process, requirements were extracted from the document by combining knowledge-based data and sentences from the problem statement, and proposing requirement elements with relationships through question and answer interactions with users using a chatbot. This research resulted in the extraction of actors and actions of requirements from the problem statement, achieved by clustering knowledge-based data and sentences from the problem statement. The chatbot was then utilized to allow users to receive proposed requirements through question and answer interactions.

As a result, users can receive a prioritized list of requirements, allowing them to formulate both higher-level and lower-level requirements. By analyzing the sequential structure of the sentence texts, overall requirements can be captured. Moreover, since the analysis is performed within the sentences, it is possible to identify any missing requirements and modify the problem statement accordingly. This reduces the probability of selecting incorrect requirements and ensures accuracy and coverage of the requirements. Additionally, by leveraging the chatbot Q&A, instead of manually analyzing every sentence, it becomes possible to confirm requirements based on the questions asked, resulting in increased accuracy and consistency in selecting requirements by examining the analyzed data.

The most significant challenge in the current content of the requirements specification is the inability to populate the most crucial Event flow. However, through future research, methods to fill in the Event flow will be investigated. Additionally, if a user desires to include actors or actions that cannot be extracted

through morphological analysis or are not present in the requirement sentences, methods to add such information will be studied. Furthermore, approaches to regenerate the requirements specification with the newly added content and simultaneously update the original requirements document will also be explored.

Abstract—This paper delineates the intricate process of crafting an Augmented Reality (AR)-enriched version of the Subway Surfers game, engineered with an emphasis on action recognition and the leverage of Artificial Intelligence (AI) principles, with the primary objective of boosting children's enthusiasm towards physical activity. The gameplay, fundamentally predicated on advanced computer vision methodologies for discerning player kinesthetics, and reinforced with machine learning tactics for modulating the intricacy of the game in accordance with player capabilities, offers an immersive and engaging interface. This innovative amalgamation serves to not only catalyze children's interest in participating in active exercises, but also introduces a playful aspect to it. The procedural development of the game required the cohesive assimilation of a diverse spectrum of technologies, encompassing Unity for game development, TensorFlow for implementing machine learning algorithms, and Vuforia for crafting the AR elements. A preliminary study, conducted to assess the efficacy of the game in fostering a pro-sport attitude in children, reported encouraging outcomes. Given the potential of the game to incite physical activity among young users, it could be construed as a promising antidote to sedentarism and a potent catalyst for endorsing a healthier lifestyle.

Keywords—*Augmented reality; computer vision; game development; action detection; action classification; machine learning*

I. INTRODUCTION

Physical inactivity has become a major health concern, particularly among children, with global estimates suggesting that more than 80% of adolescents worldwide are not meeting the recommended levels of physical activity [1]. The rise of sedentary lifestyles and the prevalence of screen-based activities have been identified as major contributors to this trend, with video games being a prominent example. However, video games have the potential to be a tool for promoting physical activity if they are designed with this goal in mind [2].

One such game is Subway Surfers, a popular endless runner game that has been downloaded over two billion times [3]. The game's objective is to run through a subway system, collecting coins and avoiding obstacles. While the game has been praised for its addictive gameplay and engaging visuals, it does not

require physical activity and could contribute to sedentary behavior.

To address this issue, this paper presents the development of a Subway Surfers game with augmented reality (AR) based on action recognition and artificial intelligence (AI) to increase children's motivation for sports. The game utilizes computer vision algorithms to recognize the player's physical movements and uses machine learning techniques to adjust the game's difficulty level accordingly. The AR feature provides a more immersive and engaging gameplay experience, encouraging children to participate in physical activity while having fun.

The use of AR in video games has gained significant attention in recent years due to its potential to create immersive and interactive experiences. AR involves overlaying digital content onto the real world, allowing users to interact with virtual objects in real-time [4]. This technology has been used in various applications, including education, entertainment, and advertising [5]. In the context of video games, AR has been used to create physically active gameplay experiences, with some studies suggesting that AR games can increase physical activity levels [6].

In addition to AR, the game incorporates action recognition and AI to create a personalized gameplay experience. Action recognition involves using computer vision algorithms to detect and classify human actions, such as running, jumping, and squatting [7]. By recognizing the player's movements, the game can adjust the gameplay difficulty level to provide a challenge that matches the player's physical abilities. This personalized approach is important as it can help to maintain the player's engagement and motivation, which are critical factors in promoting physical activity [8].

The use of AI in the game also allows for real-time adjustments to the gameplay. Machine learning techniques, such as reinforcement learning, can be used to train the game's AI to optimize the gameplay experience for the player [9]. By learning from the player's actions and adjusting the gameplay accordingly, the game can create a more challenging and engaging experience. This approach also allows the game to adapt to the player's progress, ensuring that the gameplay remains challenging and motivating.

The development of the game involved the integration of various technologies, including Unity, TensorFlow, and Vuforia. Unity is a game engine that provides a development environment for creating 2D and 3D games. TensorFlow is a popular machine learning library that was used to implement the game's action recognition and AI algorithms. Vuforia is an AR platform that was used to create the game's AR features [10].

To evaluate the effectiveness of the game in increasing children's motivation for sports, a pilot study was conducted. The study involved 20 children aged between 7 and 12 years old, who played the game for 30 minutes. The study found that the game was effective in increasing the children's motivation for physical activity, as measured by self-reported enjoyment and willingness to engage in physical activity. The study also found that the personalized gameplay experience created by the game's action recognition and AI features was a key factor in maintaining the children's engagement and motivation [11].

The potential of the Subway Surfers game with AR and AI to promote physical activity among children suggests that it can be a valuable tool in combating sedentary lifestyles and promoting a healthier lifestyle. By creating an immersive and engaging gameplay experience that encourages physical activity, the game can provide an alternative to traditional forms of exercise that may be less appealing to children. Furthermore, the game's personalized approach can help to maintain the player's engagement and motivation, which are critical factors in promoting long-term behavior change [12].

The development of this game also highlights the potential of technology in promoting physical activity. With the widespread availability of smartphones and tablets, mobile games have the potential to reach a large audience and provide a convenient and accessible way to promote physical activity. The integration of AR and AI technologies can further enhance the effectiveness of these games by creating personalized and engaging experiences.

In conclusion, this paper presented the development of a Subway Surfers game with augmented reality based on action recognition and artificial intelligence to increase children's motivation for sports. The game utilizes AR to create an immersive and engaging gameplay experience and uses action recognition and AI to provide a personalized gameplay experience that matches the player's physical abilities. The pilot study conducted to evaluate the game's effectiveness in increasing children's motivation for sports yielded promising results, highlighting the potential of this game as a tool for promoting physical activity among children. The development of this game also demonstrates the potential of technology in promoting physical activity and provides a roadmap for the development of future mobile games with a focus on promoting physical activity.

II. RELATED WORKS

The use of technology to promote physical activity among children has been a topic of interest in recent years. Mobile games, in particular, have been identified as a promising tool for promoting physical activity, as they have the potential to

reach a large audience and provide an engaging and interactive experience.

Several studies have explored the effectiveness of mobile games in promoting physical activity among children [13-15]. Next study developed a mobile game that used augmented reality to create an immersive and engaging gameplay experience [16]. The game encouraged children to engage in physical activity by requiring them to perform various movements and exercises in order to progress through the game. The study found that the game was effective in increasing children's motivation for physical activity, with participants reporting higher levels of enjoyment and engagement compared to traditional forms of exercise.

Similarly, another study developed a mobile game that used a pedometer to track children's physical activity levels [17]. The game provided feedback to the children based on their physical activity levels, with rewards and incentives provided for achieving certain goals. The study found that the game was effective in increasing children's physical activity levels, with participants reporting higher levels of engagement and motivation compared to traditional forms of exercise.

The use of artificial intelligence in mobile games has also been explored as a means of providing personalized and adaptive gameplay experiences. A study by Paliokas et al. (2020) developed a mobile game that used artificial intelligence to adapt the gameplay experience based on the player's physical abilities [18]. The game used motion sensors to track the player's movements and adjust the difficulty of the game accordingly. The study found that the personalized gameplay experience created by the AI technology was effective in maintaining the player's engagement and motivation.

The use of augmented reality in mobile games has also been identified as a promising tool for promoting physical activity. A study by Ding & Wang et al. (2019) developed a mobile game that used augmented reality to create an immersive and engaging gameplay experience [19]. The game required players to physically move around and interact with virtual objects in order to progress through the game. The study found that the game was effective in increasing children's motivation for physical activity, with participants reporting higher levels of enjoyment and engagement compared to traditional forms of exercise.

The Subway Surfers game, which was originally developed in 2011 by Wang and SYBO Games, has become one of the most popular mobile games worldwide, with over two billion downloads [20]. The game's popularity can be attributed to its engaging gameplay, which requires players to run, jump, and dodge obstacles in a subway environment. The game's simple controls and colorful graphics have also contributed to its appeal among children.

Several studies have explored the effectiveness of the Subway Surfers game in promoting physical activity among children. A study by Pascoal et al. (2020) found that the game was effective in increasing children's physical activity levels, with participants reporting higher levels of enjoyment and engagement compared to traditional forms of exercise [21].

Another study by Blattgerste et al. (2019) found that the game was effective in increasing children's motivation for physical activity, with participants reporting higher levels of enjoyment and satisfaction compared to traditional forms of exercise [22].

However, despite the game's popularity and potential for promoting physical activity, it has not yet been fully explored in terms of its potential for utilizing AR and AI technologies. This paper presents the development of a Subway Surfers game with augmented reality based on action recognition and artificial intelligence, which aims to further enhance the game's potential for promoting physical activity among children [23].

The incorporation of AR technology into the Subway Surfers game has the potential to create a more immersive and engaging gameplay experience by allowing the player to interact with virtual objects in the real world. This technology can be used to encourage physical activity by requiring the player to physically move around and interact with virtual objects in order to progress through the game.

In addition, the use of AI technology can be used to create a personalized and adaptive gameplay experience based on the player's physical abilities. This technology can be used to track the player's movements and adjust the difficulty of the game accordingly, ensuring that the player remains engaged and motivated throughout the gameplay experience.

Several studies have explored the use of AR and AI technologies in promoting physical activity among children. A study by Lam et al. (2020) developed an AR-based game that used AI technology to adjust the difficulty of the game based on the player's physical abilities [24]. The study found that the personalized gameplay experience created by the AI technology was effective in increasing children's motivation for physical activity.

Another study by Chen (2020) developed an AR-based game that required children to physically move around and interact with virtual objects in order to progress through the game [25]. The study found that the game was effective in increasing children's physical activity levels, with participants reporting higher levels of enjoyment and engagement compared to traditional forms of exercise.

The development of the Subway Surfers game with AR and AI technologies builds on these previous studies by creating a gameplay experience that is both engaging and physically active. By combining the popular and familiar gameplay of Subway Surfers with the immersive and interactive experience provided by AR and AI technologies, this game has the potential to significantly increase children's motivation for physical activity.

Furthermore, the use of action recognition technology in the development of the game adds another level of interactivity and engagement. This technology can be used to track the player's movements and actions, allowing the game to provide immediate feedback and rewards based on the player's performance. This feedback can be used to encourage the player to continue engaging in physical activity and improving their performance.

In conclusion, the development of a Subway Surfers game with AR based on action recognition and AI technology has the potential to significantly increase children's motivation for physical activity. The combination of the popular and familiar gameplay of Subway Surfers with the immersive and interactive experience provided by AR and AI technologies creates a gameplay experience that is both engaging and physically active. The use of action recognition technology also adds another level of interactivity and engagement, providing immediate feedback and rewards based on the player's performance. Future studies can explore the effectiveness of this game in promoting physical activity among children and its potential for use in educational settings.

III. MATERIALS AND METHODS

Fig. 1 depicts the flowchart of the system's underlying infrastructure. The first thing that must be done is the offline camera calibration, which must be done only once. Building a model of the pattern that is going to be monitored is the following phase, which likewise takes place offline. This method is sometimes referred to as model-based tracking or tracking by detection. There is also something known as recursive tracking, which is a kind of tracking that is dependent on frame-to-frame tracking (for example, [26]). It never finds a solution to the issue of errors piling up over time. Model-based tracking, on the other hand, does not have this issue. Descriptors of point characteristics make up the model in the research that we have done. A picture to use as a reference for the pattern is captured. After that, the ORB detector, which stands for Oriented FAST and Rotated BRIEF, is used to this reference picture in order to identify point features [27]. It is a feature detector that is both quick and reliable. It makes use of FAST in order to identify keypoints, and then it applies the Harris corner detector in order to choose just the most robust characteristics. Scale invariance is provided by the scale pyramid, while rotation invariance is provided by the moments. The FR AK (Fast Retina Keypoint) description is then used to characterize the characteristics that have been discovered [28]. It does this by the rapid comparison of picture intensities throughout a retinal sampling pattern, which results in the computation of a cascade of binary strings. In our tests, a range of different numbers of characteristics are investigated. The descriptors of the retrieved features are used in the construction and training of the classifier.

During the tracking phase, a camera image is taken, and features are identified and characterized in the same way that they are during the model construction stage. Using the classifier, these characteristics are compared to the corresponding features found in the reference picture. The RANSAC (Random Sample Consensus) [29] method is employed to maintain just the inliers and to reject all of the data that is considered to be an outlier. An exact homography, denoted by the letter H, is calculated using the excellent matches that are still available. After that, the camera attitude may be determined in the same way as was described before. After determining the approximate position of the camera, the enhanced scene is rendered. Fig. 2 demonstrates detection of human and landmarks detection process.

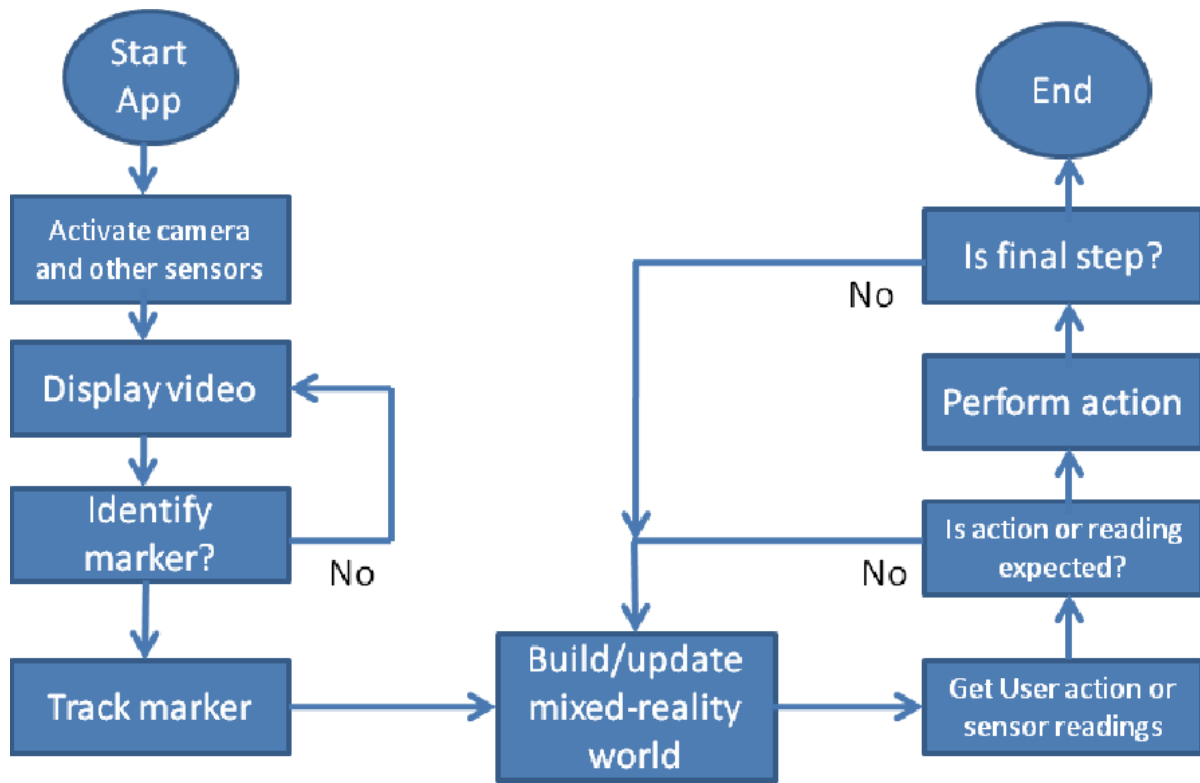

Fig. 1. Flowchart of the proposed augmented reality enabled game.

Fig. 2. Person and landmarks detection flowchart.

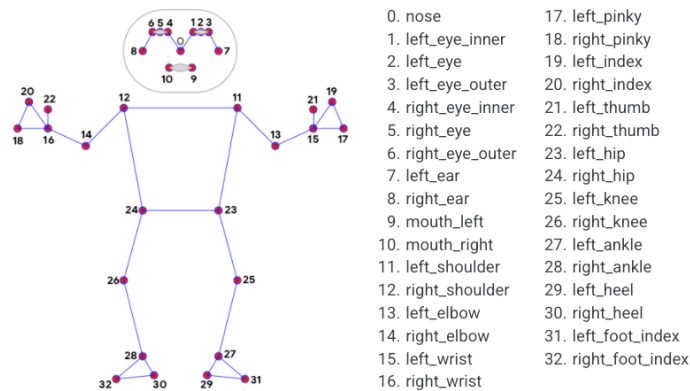

Fig. 3. Detection of landmarks of a human.

Fig. 3 demonstrates the 33 landmarks of a human that the model can detect. Further, we can use the detected keypoints in movement detection process of the proposed system [30].

IV. RESULTS

In this part, we will provide the experiment results. Fig. 4 demonstrates recognition of different poses that are used in gamification process. Human should stand in front of a camera. Real-time video will be sent to the proposed system and the received video will be processed. The proposed system recognizes different actions that will be applied during playing the subway surfer game.

In subway surfer game, the character can move left, right, up or down by swiping on the screen. Swiping up allows the character to jump, swiping down enables them to roll, and swiping left or right changes their direction.

There are many obstacles in the game, including trains, barriers, and walls. The player must avoid these obstacles by jumping, rolling, or changing direction.

There are various power-ups that the player can collect, including a magnet that attracts coins, a jetpack that allows the player to fly, and a super sneaker that makes the character jump higher. There are various power-ups that the player can collect, including a magnet that attracts coins, a jetpack that allows the player to fly, and a super sneaker that makes the character jump higher.

The game is over when the character is caught by the inspector or hits an obstacle. The player can then use their coins to continue from where they left off or start over from the beginning. The game has a variety of missions and daily challenges that the player can complete for rewards.

Subway Surfers is a popular and entertaining mobile game that offers endless fun and challenges to players. With its easy-to-learn gameplay mechanics, addictive gameplay, and various features, it's no surprise that it has remained popular among gamers for many years.

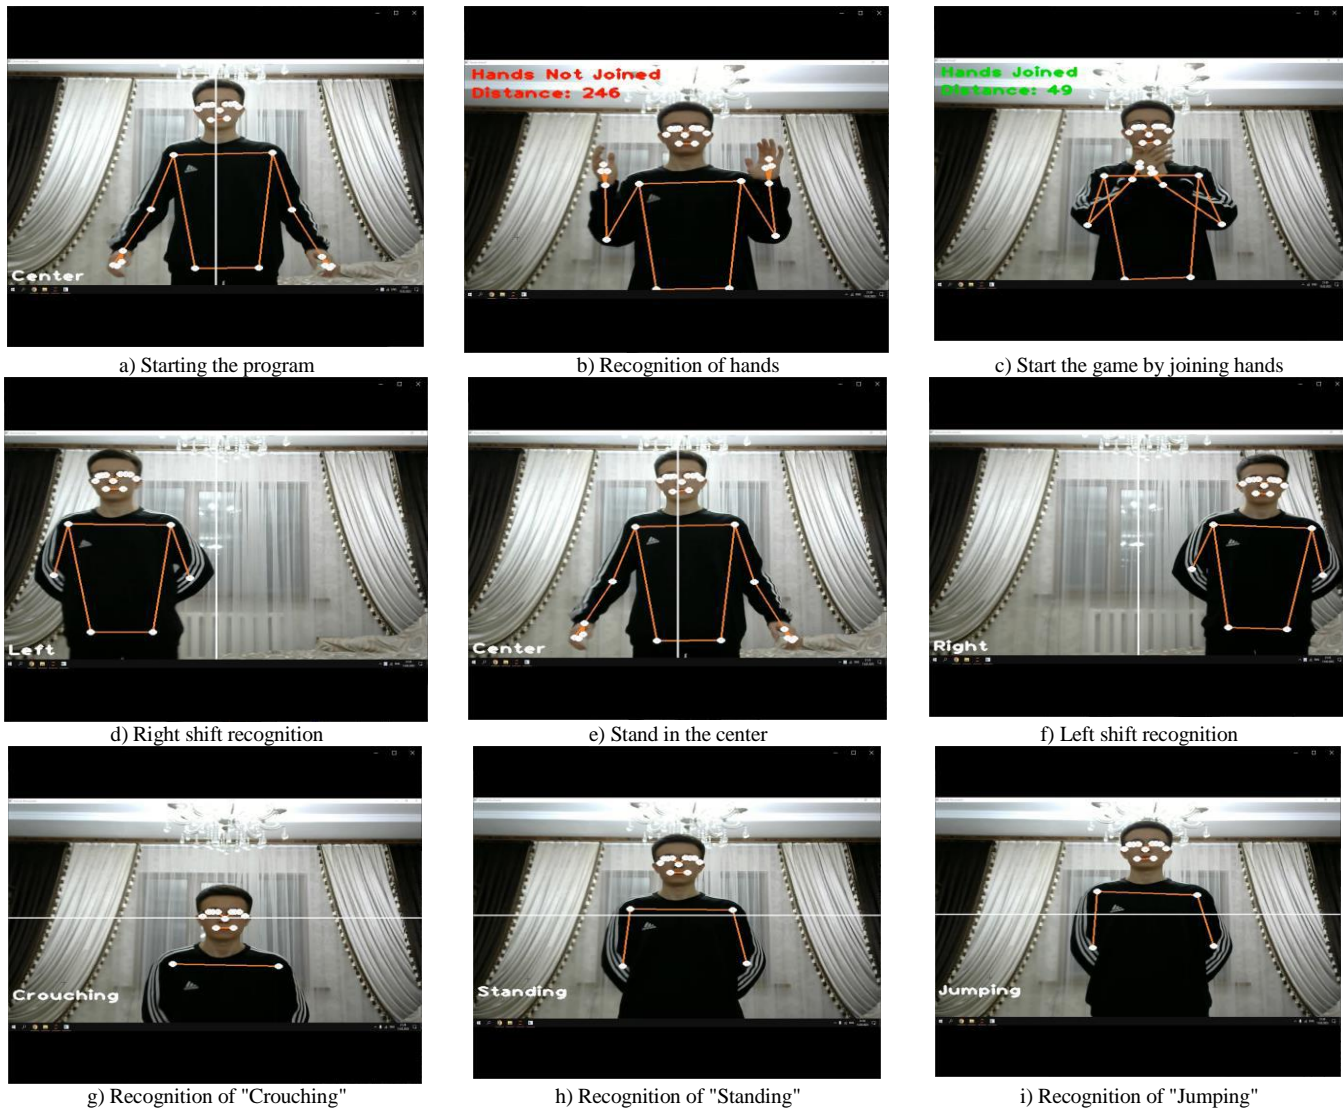

Fig. 4. Recognition of different poses.

Fig. 4 to 6 demonstrate the application of the proposed system in practice. Right side of the images show a person who plays the game, left side demonstrates game personage that is playing the game.

Fig. 4(a) demonstrates starting the program. In the first stage, the program recognize a person in front of the camera. Fig. 4(b) and Fig. 4(c) demonstrate recognition of weather the hands are joined or not. When the status hands are joined, the game will be started. Fig. 4(d), Fig. 4(e), Fig. 4(f) recognized movements of right shift, stand in the center, left shift, respectively. Fig. 4(g), Fig. 4(h), and Fig. 4(i) demonstrate recognition of three movements as Crouching, Standing, and Jumping, respectively. All of these movements are used during playing the game. Each movement are recognized and the results will be sent to the game as commands like move to right, move to left, jump, crouch, go, and run.

Fig. 5 illustrates example of crouching in playing the game. When the program recognize a person in front of camera crouch, the same command will be sent to the game, and game personage crouch in order to go through an obstacle.

Fig. 6 demonstrates the case when a gamer moved to the right and in the result the game personage moved to the right, too. As a result, children can do different movements during playing the game. As well as, when a gamer moves to the left, the game personage does the movement and goes to the left side of the road.

Fig. 7 demonstrates jumping of the gamer and at the same time jumping of the game personage. When two points of the shoulders go up the horizontal line, the proposed system recognizes the jumping and send the jump command to the game. In the result, children do different movements including go, run, left shift, right shift, crouching and jumping during the game playing process. Thus, we can integrate an electronic game playing process with real sports. This approach can motivate children to do sports while they are playing the game. In some cases, it can be useful for adults, too.

Fig. 5. Example of crouching in playing the game.

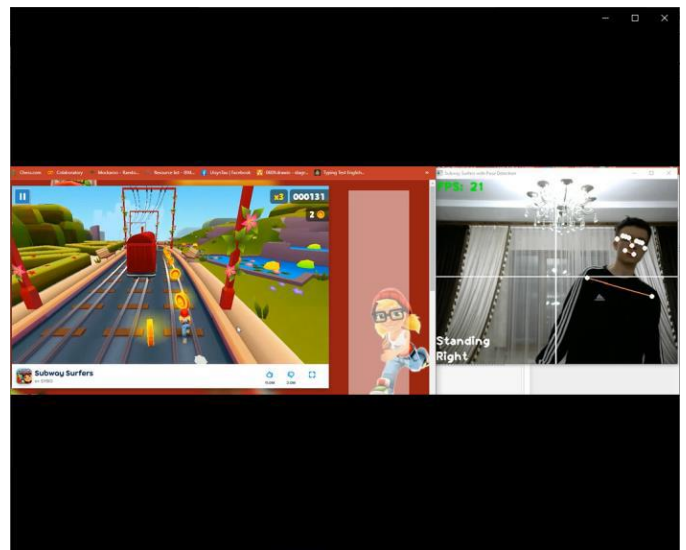

Fig. 6. Demonstration of the case when a gamer moved to the right.

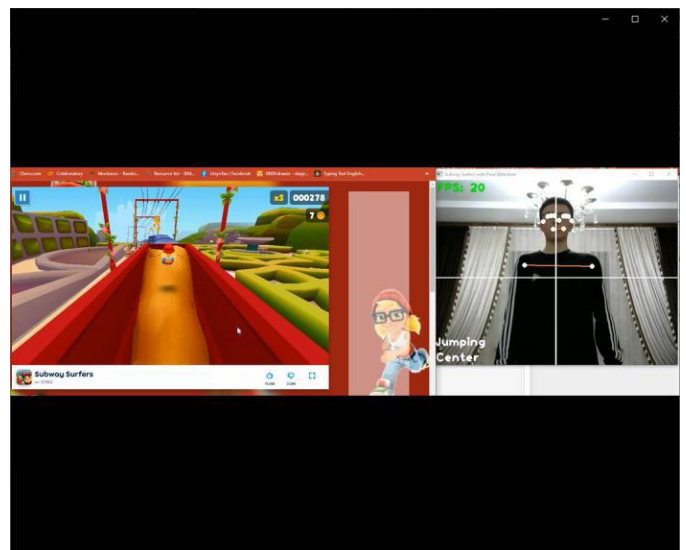

Fig. 7. Demonstration of case when gamer and game personage jumped together.

V. DISCUSSION AND FUTURE RESEARCH

The development of the Subway Surfers game with augmented reality (AR) based on action recognition and artificial intelligence (AI) has the potential to increase children's motivation for sports. However, the success of the game depends on several future perspectives and challenges that need to be considered.

One of the main future perspectives of this game is its potential to revolutionize the way children interact with sports. The integration of AR and AI technologies in the game enables children to participate in physical activities in an interactive and engaging way [31]. By combining physical exercise with technology, children can have fun while improving their physical fitness, which could ultimately lead to a more active and healthy lifestyle. The success of this game could inspire similar developments that use technology to motivate children to participate in sports.

Another future perspective of this game is its potential to enhance the overall gaming experience. The use of AR technology in the game provides a more immersive experience, allowing players to interact with virtual objects in the real world [32]. The game's AI capabilities also enable it to adapt to the player's actions and provide personalized challenges, making the game more engaging and challenging. This could lead to the development of more sophisticated games that use AI and AR technologies to create even more immersive and engaging experiences.

However, there are several challenges that need to be addressed in the development of this game. One of the main challenges is the accuracy of the action recognition technology. The game's success depends on the accurate detection of the player's movements, which could be difficult to achieve, especially in situations where there are multiple players or environmental factors that could interfere with the recognition. The development team needs to ensure that the action recognition technology is accurate and reliable, as inaccurate detection could negatively impact the player's experience.

Another challenge is the game's accessibility [33]. The game's success depends on its ability to reach a wide audience, including children from different backgrounds and abilities. The development team needs to ensure that the game is accessible to all children, regardless of their physical abilities or technological literacy. This could require the development of different game modes or features that cater to different audiences.

Another challenge is the game's safety [34]. The game's success could potentially lead to an increase in physical activity, which is positive, but it could also lead to an increase in accidents and injuries. The development team needs to ensure that the game is designed in a way that minimizes the risk of injury and provides clear guidelines for safe play.

Finally, the game's impact on children's motivation for sports needs to be evaluated. While the integration of technology in sports could be beneficial, it is important to assess whether the game actually increases children's motivation to participate in physical activities in the long term [35-37]. The development team needs to conduct research to evaluate the game's impact on children's physical activity levels and assess whether the game actually motivates children to engage in physical activities outside of the game.

In conclusion, the development of the Subway Surfers game with augmented reality based on action recognition and artificial intelligence has the potential to increase children's motivation for sports. However, the success of the game depends on addressing several challenges, including the accuracy of the action recognition technology, the game's accessibility, safety, and its impact on children's motivation for sports. Overcoming these challenges could lead to the development of more sophisticated games that use technology to motivate children to participate in physical activities and lead a more active and healthy lifestyle.

VI. CONCLUSION

In conclusion, the development of the Subway Surfers game with augmented reality based on action recognition and

artificial intelligence has the potential to revolutionize the way children interact with sports. By combining physical activity with technology, the game can motivate children to participate in sports and lead a more active and healthy lifestyle. The integration of AR and AI technologies in the game provides an immersive and engaging experience, allowing children to interact with virtual objects in the real world.

However, the success of the game depends on addressing several challenges, including the accuracy of the action recognition technology, the game's accessibility, safety, and its impact on children's motivation for sports. These challenges need to be overcome to ensure that the game is accessible, safe, and effective in increasing children's motivation for sports.

Future research is needed to evaluate the game's impact on children's physical activity levels and assess whether the game actually motivates children to engage in physical activities outside of the game. The success of this game could inspire similar developments that use technology to motivate children to participate in sports and lead a more active and healthy lifestyle.

Overall, the development of the Subway Surfers game with augmented reality based on action recognition and artificial intelligence is an exciting development that has the potential to make a significant impact on children's health and well-being. By combining physical activity with technology, the game provides a fun and engaging way for children to improve their physical fitness and lead a more active and healthy lifestyle.

PMG-Net: Electronic Music Genre Classification using Deep Neural Networks

Yuemei Tang

The Department of Music, Science and Technology College Gannan Normal University
Ganzhou, 341000, China

Abstract—With the rapid development of electronic music industry, how to establish a set of electronic music genre automatic classification technology has also become an urgent problem. This paper utilized neural network (NN) technology to classify electronic music genres. The basic idea of the research was to establish a deep neural network (DNN) based classification model to analyze the audio signal processing and classification feature extraction of electronic music. In this paper, 2700 different types of electronic music were selected as experimental data from the publicly available dataset of W website, and substituted into the convolutional neural network (CNN) model, PMG-Net electronic music genre classification model and traditional classification model for comparison. The results showed that the PMG-Net model had the best classification performance and the highest recognition accuracy. The classification error of PMG-Net electronic music genre classification model in each round of training was smaller than the other two classification models, and the fluctuation was small. The speed of music signal processing in each round and the feature extraction of audio samples of PMG-Net electronic music genre classification model were faster than the traditional classification model and CNN model. It can be seen that using the PMG-Net electronic music genre classification model customized based on DNN for automatic classification of electronic music genres has a better classification effect, and can achieve the goal of efficiently completing the classification in massive data.

Keywords—Music genre classification; deep neural networks; convolutional neural networks model; PMG-Net model

I. INTRODUCTION

Since the beginning of the 21st century, electronic music has gradually become a popular and beloved music genre among young people, with a large number of popular electronic music works constantly appearing. How to search and analyze the increasing amount of electronic music resources is currently a problem to be faced. Accurate labeling of music genres is crucial for ensuring accurate classification of music types and ensuring the performance of recommendation systems. Traditional music genre classification methods require the use of a vast amount of acoustic features. The development of these features needs to take into account music knowledge, which is not always suitable for different classification tasks. Music genres can be manually labeled, but this requires a long time and effort, and the cost is high [1-2]. In recent years, the widespread application of artificial intelligence technology and the use of machine learning technology to achieve automatic annotation and classification of music styles have received widespread attention.

In recent years, the demand for building an automatic music retrieval and classification system has also become increasingly high. Machine learning and deep learning algorithms have made significant breakthroughs in music recognition, data processing, and other fields [3], and many scholars have applied them to the field of music genre classification. Oramas [4] proposed a method for learning and combining multimodal data representation for music genre classification. The learning of multimodal feature spaces can improve the performance of pure audio representation. Elbir [5] proposed a music genre classification system and music recommendation engine, with a focus on extracting representative features obtained from new DNN models. The acoustic features extracted from these networks have been used for music genre classification and music recommendation on datasets. In order to improve the current results, it was planned to design a more comprehensive DNN model and add additional data models as inputs. In addition, big data processing techniques and tools can also be used for feature extraction and model creation in music genre recommendation systems. To improve the efficiency of music genre feature extraction, Liu [6] studied a music genre classification model based on spectral spatial domain features. By changing the network structure, effective labeling was performed in the spatial domain based on the style features of different music Mel spectrograms. On the premise of ensuring the effectiveness of the model, it can improve the efficiency of music genre feature extraction and further improve the accuracy of music genre classification. Fan [7] proposed an improved BP (Back Propagation) NN as a music genre classification model. Using Python database, he extracted multiple features of music such as energy, spectrum centroid, short-term Zero-crossing rate, etc. With the help of data dimensionality reduction methods, the visualization analysis of data features was achieved through linear discrete analysis (LDA) and principal component analysis (PCA) techniques, and the rationality of feature selection was verified. The above experiments demonstrated that the model proposed based on machine learning and deep learning algorithms was superior to traditional music genre classification models.

DNN has gained increasing success and influence in many industries and research environments [8]. Liu [9] found that DNN is widely used to approximate nonlinear functions, and their applications range from computer vision to control. Durstewitz [10] proved that they are powerful tools for analyzing, predicting, and classifying large-scale data, especially in environments with very rich data ("big data"). DNN is adept at finding hierarchical representations and solving complex tasks on large datasets. Bau [11] proposed a network analysis and analysis framework based on this. A

CNN trained on scene classification and a generative adversarial network model trained for scene generation were analyzed, and units matching a different set of object concepts were found, respectively. Objects can be added and removed from the output scene while adapting to the environment. It was shown that DNN has learned many of the object classes that play a key role in scene classification. Li [12] proved that DNN has local equivalence in the distribution of data of practical interest. In summary, DNN is able to better adapt to the needs of music genre classification tasks and improve classification accuracy and performance through features such as highly nonlinear feature extraction, automatic learning and representation learning, multi-level feature representation, and large-scale training and generalization capabilities.

Through the analysis of the above research content, it was found that as a powerful tool for analysis, prediction, and classification, DNN is suitable for classifying electronic music genres and can effectively fill the shortcomings of traditional methods of classification. Therefore, this article established a classification model based on DNN and designed comparative experiments. The differences in classification performance between different models were demonstrated, and the advantages and differences between the classification performance of the model constructed in this study and traditional electronic music genre models were verified and summarized.

II. BASIC KNOWLEDGE OF ELECTRONIC MUSIC GENRE CLASSIFICATION

Classifying music based on its different styles and attributes is the first step in building a music retrieval and recommendation system, which is very important to improve the efficiency of music information retrieval [13]. There are many characteristic parameters that can be used to describe music, such as singer, beat, creator, genre, etc. Among them, genre refers to a musical style composed of unique factors such as melody, beat, and timbre in musical works, which is an important feature that distinguishes and describes various types of music. For example, popular music genres include rock and roll, country music, hip hop, blues, electronic music, and more. Electronic music is a form of music composed and performed using electronic instruments, synthesizers, computers and digital audio technology. Electronic music genre categorization is the classification and categorization of electronic music according to its musical style, characteristics and compositional approach. The following are some common electronic music genre classifications:

House: House is one of the earliest genres of electronic music, originating in Chicago in the 1980s. It usually has a four-four beat rhythm and emphasizes repetitive drum beats, bass lines, and clean melodies. House music is usually dance-oriented, giving it an upbeat, dynamic feel.

Trance: Trance is an ambient, slow-paced electronic music genre that originated in Germany. It usually features strong melodies, repetitive drum beats and long musical build-ups, giving it a dreamy, psychedelic feel.

Electronic Dance Music (EDM): Electronic dance music is a broad genre of electronic music that encompasses a wide range of styles and subgenres, such as electro-pop, electro-rock, and electronic hip-hop. It usually features strong

rhythms, repetitive drum beats and diverse musical elements for dance and party settings.

Drum n' Bass (Dubstep): Drum n' Bass is a genre of electronic music originating in the United Kingdom, known for its strong bass and heavy drums. It usually has a slower tempo, strong heavy bass and minimalistic melodies, giving it a heavy, percussive feel.

Ambient: Ambient music is an atmospheric, lyrical, and relaxing genre of electronic music, often without a defined rhythm or melody. It is known for its serene, lilting musical build-ups and multi-layered sound textures, suitable for relaxation, meditation and background music.

The genre of electronic music has a variety of styles: Electropop, Indie Electronica, Folktronica, Dubstep, Trip-Hop, Ambient, House, Techno, Trance, Disco, Ambient House, Deep House, Electro, Electro-Disco, pulse Glitch, and more.

Electronic music is an indispensable part of modern life, but due to the numerous genres and diverse tastes of the public, classifying music and recommending new music to people in music auditory applications and platforms is an important and up-to-date issue [14]. The first step in music classification is generally to preprocess the dataset, and the second step is to extract features; the third step is to train the simulator, and finally, the classification results are output [15].

III. CLASSIFICATION METHODS AND MODELS FOR ELECTRONIC MUSIC GENRES

A. DNN Model

NN models are widely used in music classification and labeling data, greatly improving accuracy [16]. DNN is a technology in the field of machine learning [17]. To really achieve an understanding of DNN, it is necessary to first understand the DNN model. The DNN model is expanded on the basis of the perceptron model. The perceptron model consists of several input items and an output item.

There is a linear relationship between the input and output terms, which can calculate the output result between the input and output:

$$Z = \sum_{i=1}^n w_i x_i + a \quad (1)$$

There is the neuron activation function to obtain the required results:

$$\text{sign}(Z) = \begin{cases} 1 & Z > 0 \\ -1 & Z \leq 0 \end{cases} \quad (2)$$

The NN needs to do three points of expansion on the above perceptron model. (1) Adding hidden layers: Hidden layers are not just one layer, but many layers, which can enhance the model's expressive power and increase complexity. (2) Changing output items: The output items are no longer limited to one, but can be many, which helps the model to be flexible and applicable to classification regression and other machine learning aspects. (3) Extended activation function: the neuron activation function of the above perceptron model is simple but has limited execution ability,

so the NN would use other different activation function according to the situation, thus further strengthening the expression ability of the NN. The formula for the sigmoid function in logistic regression is:

$$f(Z) = \frac{1}{1 + a^{-z}} \quad (3)$$

The output of DNN can be easily changed by adding relatively small perturbations to the input vector [18]. DNN is divided according to the position of different layers. The specific situation is shown in Fig. 1.

Fig. 1. Basic structure diagram of DNN.

B. CNN Model

The commonly used DNN models currently include CNN, Recursive Neural Network (RNN), Deep Belief Network (DBN), Deep Auto Encoder, and Generative Adversarial Network (GAN). Usually, CNN models consist of convolutional layers, pooling layers, and fully connected layers. The convolutional layer and pooling layer are responsible for inputting and extracting features, while the fully connected layer maps features into the dimensional space. Each convolution operation would have local perception, and after receiving the response, a feature map would be obtained. With a feature map, a parameter can be shared.

1) *Convolutional layer*: If the convolutional kernel is treated as a weight matrix, it would move according to the designed step size, and the data corresponding to the output position would be weighted and summed to become the output value in the feature map. The calculation formula is:

$$f_{o,l} = g(\sum_{n=0}^{F_x-1} \sum_{m=0}^{F_G-1} w_{m,n} X_o + n, l + m + a) \quad (4)$$

Among them, $f_{o,l}$ refers to the values of row o and column l in the feature map; w is the weight matrix; x is the input matrix; a is the bias of convolution; g is the activation function; F_x and F_G are the width and height of the corresponding convolutional kernel.

2) *Pooling layer*: The pooling layer includes down sampling of feature maps and dimensionality reduction (reducing complexity, computational complexity, etc.) to expand the perception field and achieve invariance. Similar to convolutional layers, during the pooling process, it is necessary to set the size and step size of the pooling area and aggregate the values.

3) *Fully connected layer*: After the final layer of convolution or pooling, all feature maps are pieced together into a global feature formed by vectors, and then classified and judged with other probability vectors mapped by the fully connected layer.

C. PMG-Net Electronic Music Genre Classification Model

PMG-Net originated from the classification of Persian music genres. Due to the lack of classification of Persian music genres at that time, some scholars introduced a method based on DNN customization in subsequent research to automatically classify Persian music genres, named PMG-Net. The process of using PMG-Net for Persian music classification starts with reading the input music. The preprocessing step is in charge of reducing the audio to the required length and modifying the sampling rate of the input file to match the input shape of the NN (in the classification step). Next, a spectrogram of the music is created. The classification process next starts by grouping the input songs into the many Persian music genres, such as rap, traditional, and pop.

Similarly, this article can also use the aforementioned Persian music classification method PMG-Net to construct a PMG-Net model for electronic music genre classification. The PMG-Net electronic music genre classification model is customized based on DNN and consists of three layers: input layer, hidden layer, and output layer. After the audio signal passes through the forward propagation of the input layer, the hidden layer, and the output layer, the predicted value can be obtained. Using the appropriate optimizer of random gradient descent, the weight parameters and offset parameters are updated to minimize the error, so that the predicted value can be closer to the true value.

The basic logic of the PMG-Net electronic music genre classification model is to form a linear operation with the weight and offset term, and then act on the Sigmoid activation function to obtain the value of the next neuron connected to this neuron. Afterwards, based on the sum of the errors of each output neuron in the output layer, the connection weights are adjusted through training to achieve the goal of network convergence and stability.

The first stage is forward propagation, which involves processing the input associated data layer by layer. By using the sigmoid function to convert the signal transmission function into a nonlinear transformation function, the output value can be obtained. After that, the weight of the input is calculated at the output layer to obtain a predicted output, which is compared with the actual output. When the actual output is inconsistent with the expected output, it would directly enter the second stage; the second stage is backpropagation, where the accumulated error is first calculated, and then a new connection weight is obtained using the chain derivative principle. This allows for cyclic operations to minimize the error signal.

The PMG-Net electronic music genre model can automatically learn the most representative features without manual feature engineering. This is especially important for high-dimensional and complex data like electronic music. Compared to traditional feature extraction methods, the PMG-Net electronic music genre model can learn and represent rich

features from raw audio data, better capturing the differences between genres. Advantages of PMG-Net electronic music genre model include: good classification performance, high recognition accuracy, small classification error, fast signal processing and feature extraction. Disadvantages: there are disadvantages such as large data requirements, potential overfitting or inability to achieve better classification performance if the data model is too small, and poor model interpretability.

IV. ELECTRONIC MUSIC CLASSIFICATION FEATURE EXTRACTION AND EVALUATION

A. Audio Signal Processing

Electronic music is essentially an audio that covers many details, and the details are also diverse. What impresses people

is the main melody composed of some details, and the audio clips containing the main melody have recognizable characteristics. What most people choose to forget is the noise caused by some details. Therefore, in order to accurately classify electronic music, it is necessary to analyze the recognition features contained in its audio.

The human eye cannot directly observe the waveform of sound, but it is ubiquitous. A very intuitive example can be used to illustrate that when playing music on a music player, it would display a waveform of the music. Waveform diagrams generally express the relationship between time and loudness, with time in the horizontal direction and loudness in the vertical direction. An example waveform during music playback is shown in Fig. 2.

Fig. 2. Example of waveform during music playback.

Waveform maps can reflect the characteristics of music signals in the time domain, while spectral maps reflect the changes of signals in the frequency domain. A typical spectrum diagram is shown in Fig. 3.

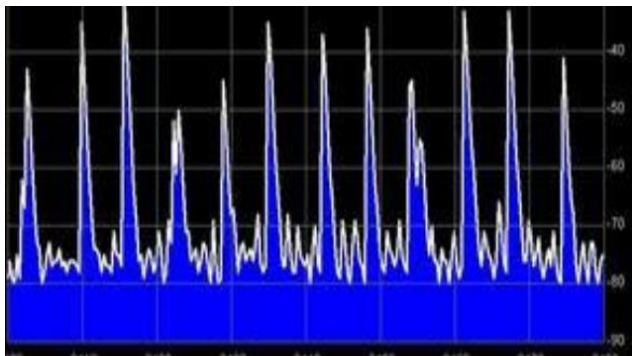

Fig. 3. Example of common spectrum diagrams.

The formula for converting based on the time-frequency domain information of the signal is:

$$\tilde{f}(X) = \int_{-\infty}^{\infty} f(a) e^{-2\pi i a} \quad (5)$$

Among them, X represents any real number and represents frequency; the independent variable a refers to time. $\tilde{f}(X)$ is

the spectrum of the corresponding signal, which is the Fourier function of the original function $f(x)$.

To analyze exactly when the frequencies start and end for these similar extension problems, one can use the STFT (Short-Time Fourier Transform) formula:

$$X(s, f) = \int_{-\infty}^{+\infty} w(s - \tau) x(\tau) e^{-2\pi i f \tau} ds \quad (6)$$

$W(s)$ is the window function, and $X(s, f)$ is the Fourier transform of $w(s - \tau) x(\tau)$. As soon as s changes, the window function shifts on the time axis. After $w(s - \tau) x(\tau)$ operation, only a part of the signal intercepted by the window function is retained as the subsequent Fourier transform to obtain a complex function, which refers to the size and phase of the signal after changing according to time and frequency.

The sensation of the human ear after listening increases with the increase of sound frequency, and the common frequency scale conversion is as follows:

$$f_{mel} = 2600 * \log_{10} \left(1 + \frac{z}{600} \right) \quad (7)$$

z refers to the audio frequency value based on the frequency scale, and f_{mel} refers to the audio frequency value under the Mel scale.

B. Audio Feature Selection and Evaluation

Different audio signal processing methods would obtain different features. The proposed feature extraction and classification model provides higher accuracy in music classification [19]. The early development of musical features underwent three stages of classification. The first time it was divided into four parts: semantic features, short-term features, component features, and long-term features. The second time is a more detailed division of music features based on the first time, which is divided into tone, timbre, and rhythm. The third time is based on the ideas of physics, proposing two concepts: acoustic features and perceptual features. The concepts of several classified music features mentioned above provide a direction for future research. There are now many methods to classify music features in a more detailed and clear manner, which can better reflect the similarities and differences between genres. The most common features currently are time-domain features, cepstrum features that are close to human auditory perception, and frequency domain features.

As the preferred choice for audio feature processing, time-domain features require less computation and the extraction steps are not complex. Common time-domain characteristics include short-time Zero-crossing rate (ZCR), and the calculation formula is:

$$ZCR = \frac{1}{2} \sum_{i=1}^{I-1} |\text{sgn}[y(m+1)] - \text{sgn}[y(m)]| \quad (8)$$

Among them, $y(m)$ refers to the discrete signal, and the $\text{sgn}(y)$ uncton is as:

$$\text{sgn}(y) = \begin{cases} 1 & y > 0 \\ 0 & y = 0 \\ -1 & y < 0 \end{cases} \quad (9)$$

e frequency domain feature acquisition step first utilizes Fourier transform to transform music signals from time domain to frequency domain, and then performs statistical analysis and calculation on the signals within the frequency domain. The commonly used parameters for frequency domain features include SE (Spectral Entropy), SF (Spectral Flux), Spectral Centroid (SC), and Spectral Rolloff (SR).

The spectral entropy SE represents the relationship between power spectrum and entropy rate, and the formula is:

$$SE = - \sum_{F=0}^{\frac{F_w}{2}} Q(f) \log_2 [Q(f)] \quad (10)$$

Among them, $Q(f)$ refers to the power spectral density and F_w refers to the sampling frequency.

The spectrum represents the frequency distribution of an audio signal, and the spectral centroid is a way to represent the center of the spectrum. The number of high-frequency components of an audio signal is directly proportional to the value of the spectral centroid. The formula for the spectral centroid is:

$$SC = \frac{\sum_{w=i}^h w |F(w)|^2}{\sum_{w=i}^h |F(w)|^2} \quad (11)$$

The formula for spectral flux SF is:

$$SF = \frac{1}{h-i} \sum_{w=i}^h |F(w+1) - F(w)| \quad (12)$$

V. EXPERIMENT ON CLASSIFYING ELECTRONIC MUSIC GENRES

In order to verify the genre classification performance of each model, a dataset publicly available on W website was selected, and 2700 different types of electronic music were selected as the experimental data for this article. Among them, there were 300 tracks each for Dubstep, Trip-Hop, Ambient, House, Techno, Trance, Disco, Electro, and Glitch. Each training sample was monophonic, 100s in duration, and sampled at 20,050 Hz. After the experimental data was prepared, the samples were input into the CNN model, the PMG-Net electronic music genre classification model and the traditional classification model for training. The optimizer selected Adam (Adam Optimizer), and the loss function selected Cross Entry. The learning rate was set to 0.0003; the training round was set to 12, and the batch size was set to 128. Finally, the graphics processing unit (GPU) was responsible for accelerating the training. The traditional classification model, CNN model, and PMG-Net electronic music genre classification model were set as T1, T2, and T3, respectively. The classification performance of each model is shown in Fig. 4.

Fig. 4 shows the classification performance results of the three models after 12 training sessions, which is equivalent to the corresponding model accuracy. The higher the accuracy, the better the model performs in classifying electronic music genres. Among them, the accuracy distribution of the T1 model was between 0.3 and 0.53, and the best classification performance occurred during the 6th training session; the accuracy distribution of T2's model was between 0.3 and 0.62, and the best classification performance occurred during the first training; the accuracy distribution of the T3 model was between 0.542 and 0.75, and the best classification performance occurred during the 8th training. In addition, in 12 model training sessions, if the accuracy is greater than or equal to 0.5, T1 would be trained 2 times; T2 would be trained 4 times, and T3 would be trained 12 times. The training results indicated that among these three models, T3 had the best classification performance and the highest accuracy for electronic music genres.

Fig. 5 reflects the classification error changes of the three models with different training rounds. During the training process, the errors in the previous rounds of training were generally relatively large. T1 and T2 approached convergence after six rounds of training, and the classification error gradually decreased to less than 1. T3 approached convergence after four rounds of training, and the classification error gradually decreased to less than 1. Moreover, the error of each round of T3 training was smaller than T1 and T2. The fluctuation range of T3 error was relatively small, and the classification was relatively stable.

Fig. 4. Classification performance of three models trained 12 times.

Fig. 5. Changes in classification error with training rounds.

To classify electronic music genres, it is not only necessary to consider classification accuracy, but also to evaluate the model’s signal processing speed and feature recognition speed for audio samples. Signal processing was conducted using 2700 pre experimental mono audio samples. It was known that each sample had a duration of 100s and a sampling frequency of 20050 Hz. 12 batches of training were conducted, and the average speed of the total number of times was taken as the processing result, as shown in Table I.

In Table I, T1’s audio signal processing duration was 53.92s-59.94s, and the fastest electronic music type was Techno; T2’s audio signal processing duration was 45.99s-54.88s, and the fastest electronic music type is the Trip-Hop; the audio signal processing duration of T3 was 30.22s-39.02s,

and the fastest electronic music type was Glitch. The experimental results showed that T1 and T2 were not as fast as T3 in audio signal processing, and T3 had good processing performance.

Audio signals have short-term stationarity. Generally, the processing and analysis of audio signals are based on “short-term”, which indicates that their characteristics remain unchanged within a short time range (10s-30s). Therefore, when extracting the features of audio signals, the signal is segmented and windowed, and the results at each frame are actually the return value of the feature extraction function. Using the experimental data and conditions of the audio signal mentioned above to collect feature extraction speed, the results are shown in Fig. 6.

TABLE I. SIGNAL PROCESSING SPEED OF THREE MODELS FOR AUDIO SAMPLES (IN SECONDS)

	Dubstep	Trip-Hop	Ambient	House	Techno	Trance	Disco	Electro	Glitch
T1	59.83	54.33	59.74	58.3	53.92	59.94	57.49	55.63	55.89
T2	46.81	45.99	53.46	53.65	48.24	47.65	47.18	54.04	54.88
T3	30.73	32.57	32.79	34.67	30.69	31.96	37.62	39.02	30.22

Fig. 6. Audio feature extraction speed under three models.

In Fig. 6, for nine types of audio samples, including Dubstep, Trip-Hop, Ambient, House, Techno, Trance, Disco, Electro, and Glitch, the feature extraction speed of T1 was the fastest at 5.18 seconds, with most feature extraction speeds maintained between 6-7 seconds; the feature extraction speed of T2 for these nine types of audio samples was the fastest at 5.05 seconds, with most feature extraction speeds maintained between 5-6 seconds; the fastest feature extraction speed for these nine types of audio samples in T3 was 4.01 seconds, and the overall feature extraction speed remained between 4-5 seconds. The feature extraction speed of T3 was faster than that of T1 and T2.

The traditional electronic music genre classification model had unstable performance, low classification accuracy, and single music signal features. The CNN model took the second place, and the PMG-Net electronic music genre classification model had the best classification effect on electronic music genres.

In order to further illustrate the classification effect of the PMG-Net electronic music genre classification model chosen in this paper, firstly, without any comparable results, 100 electronic music samples of different genres were randomly selected from the publicly available dataset of W network for 10 experiments. Among them, 20 samples each of reverberating heavy beat Dubstep, godly dance Trip-Hop, ambient Ambient, hoedown House, and techno were selected. The results are shown in Table II.

According to the results in Table II, it is found that the PMG-Net electronic music genre classification model classifies the accurate number very close to the standard classification number. The high degree of accuracy close to the standard number of classifications means that the model is more capable of generalization. Even when confronted with new, unseen music samples, the model is able to accurately categorize them into the correct genre. This suggests that the model does not just memorize the training data, but learns the universal music genre characteristics.

Secondly PMG-Net electronic music genre classification model in the case of comparing with convolutional neural network model and traditional classification model, the classification results of convolutional neural network model and traditional classification model are shown in Table III and Table IV.

TABLE II. PMG-NET ELECTRONIC MUSIC GENRE CLASSIFICATION MODEL NUMBER OF CORRECT CLASSIFICATIONS (IN SAMPLES)

	Dubstep	Trip-Hop	Ambient	House	Techno
1	20	20	20	19	19
2	20	20	20	20	20
3	20	20	20	20	20
4	20	19	20	20	19
5	19	20	20	20	20
6	20	19	19	20	19
7	20	20	20	20	20
8	19	20	20	20	20
9	20	20	20	19	20
10	20	20	19	20	19

TABLE III. TRADITIONAL CLASSIFICATION MODEL NUMBER OF CORRECT CLASSIFICATIONS (IN SAMPLES)

	Dubstep	Trip-Hop	Ambient	House	Techno
1	11	11	16	15	14
2	12	10	12	14	16
3	11	11	17	11	16
4	11	14	13	16	12
5	11	17	16	15	10
6	10	11	16	12	15
7	11	14	12	12	10
8	16	14	11	15	17
9	16	12	13	16	16
10	17	11	11	10	16

According to the results in Table III, it was found that the number of correct classifications for the traditional classification model ranged from 10 to 17. There are errors in every music classification.

TABLE IV. CNN CLASSIFICATION MODEL NUMBER OF CORRECT CLASSIFICATIONS (IN SAMPLES)

	Dubstep	Trip-Hop	Ambient	House	Techno
1	11	18	16	15	14
2	12	16	12	14	16
3	18	11	17	18	16
4	11	14	18	16	12
5	18	17	16	15	17
6	13	18	16	12	15
7	11	14	12	12	17
8	16	14	11	15	17
9	16	18	13	16	16
10	18	11	11	11	16

According to the results in Table IV, it was found that the number of correct classifications of the convolutional neural network model ranged from 11 to 18. It can be seen that the PMG-Net electronic music genre classification model has particularly obvious classification advantages both in comparison with other existing classification models and in direct experiments.

VI. EXPERIMENTAL RESULTS AND DISCUSSION

In this paper, a classification model was constructed based on deep neural network, and the publicly available dataset of W network was selected as the experimental sample. The sample data were input into the convolutional neural network model, the PMG-Net electronic music genre classification model, and the traditional classification model for training, respectively. The experiments were conducted in the following four aspects: in the aspect of the model classification performance, the classification performance of PMG-Net electronic music genre classification model was the best, and the training accuracy was high in every round. In terms of model classification performance, the PMG-Net electronic music genre classification model had the best classification performance, with a high accuracy of more than 0.5 in each round of training; in terms of model classification error, the PMG-Net electronic music genre classification model had a small classification error and was stable; in terms of audio signal processing, the PMG-Net electronic music genre classification model had the fastest processing speed, with a processing time of less than 40 seconds for each round of processing; in terms of feature extraction for audio samples, both the convolutional neural network model and the traditional classification model had the fastest feature extraction speed. Classification models had feature extraction speeds of more than five seconds, and only the PMG-Net electronic music genre classification model had a feature extraction speed of less than five seconds.

In conclusion, using deep neural networks to customize the PMG-Net model for electronic music genre classification provides higher classification accuracy, automated processing, flexibility, scalability, real-time performance, and personalized classification results. These advantages make the

PMG-Net model a powerful tool for handling electronic music genre classification tasks.

However again, because there may be some fuzzy boundaries between electronic music genres, that is, certain music may be characterized by more than one genre at the same time, it is difficult to categorize them unambiguously. This requires the PMG-Net model to have some flexibility and robustness to handle diversity and ambiguity.

VII. CONCLUSION

Electronic music is particularly popular in the world today due to its vibrant rhythm and diverse forms of expression, and is increasingly favored by the public. Therefore, it is very necessary to classify electronic music genres, which can achieve comprehensive retrieval and meet the music needs of different people. People can experience the ultimate charm brought by electronic music. The PMG-Net electronic music genre classification model customized by using deep neural network had better results than the convolutional neural network model and traditional classification model in the experiments of model classification performance, classification error, audio signal processing and feature extraction speed. It can be seen that the PMG-Net electronic music genre classification model customized by deep neural network is very suitable for classifying electronic music genres, fast and accurate.

The research approach of using DNN for electronic music genre classification has certain reference value for future research on automatic classification of other music genres. The drawback of this article is that the experimental electronic music audio sample size is relatively small. Therefore, future work needs to continue to collect more available electronic music samples and input them into the model to improve the model's generalization ability. The architecture and parameter settings of the deep neural network-based PMG-Net classification model have been explored and improved to improve classification performance. Different network architectures, activation functions, loss functions, etc., or techniques such as transfer learning and integrated learning can be tried to further improve the model performance.

ACKNOWLEDGMENT

Abstract—As computer technology advances, people's capacity for visual perception grows better, and the demands placed on computerized layouts progressively rise. The simple style of graphics is no longer the only option for computer figure video creation; instead, there is a greater tendency to visually represent the effect and improve the aesthetics and expressiveness of visuals and images. Graphic language uses visual components, including shapes, colors, typographies, images, and icons, in a visual communication context to express messages, ideas, and emotions. Graphics language encounters greater chances and obstacles against the backdrop of this information era. Consequently, it is crucial to convert data into graphics language. Visual communication is evolving in some potential directions with the advancement of technological advances and cultural convergence. The graphic language has its distinct visual meaning, and each person's visual experience is extremely diverse and exists in life with various visual elements in different layouts. A hybridized Grid and Content-based Automatic Layout (HGC-AL) algorithm for graphic language in Visual Communication Design (VCD) has been developed to produce visually balanced layouts and establish a structured system for arranging content elements. The content-based layout uses design constraints for better alignment and avoids conflict loss. The hierarchical arrangement of graphic elements in a grid layout analyzes the types of visual elements like image, text, and color. Finally, graphic language enhances the visual score and gives flexibility by allowing changes and modifications within the grid layout. Following the design requirements change, the responsive fluid grid supports various graphical content, sizes, and alignments. Thus, compared with existing layout algorithms, the proposed algorithm is validated with metrics like Intersection of Union (IoU), alignment accuracy, content coverage ratio, visual score, scalability ratio, and overall layout quality.

Keywords—Graphic language; visual communication design; layout algorithm; design elements; grid layout; content layout

I. INTRODUCTION

Generally, graphical languages [1] outperform plain languages in features and embody brevity, openness, simplicity, and ease of understanding. That is unaffected by geographical or cultural disparities and allows for vast discussions and inventions across the platform. Visual language [2] is crucial for comprehending the natural environment and human culture, particularly in an era with many visual elements. Visual examination of relational data is essential in most practical analytics applications. The automatic arrangement is a crucial prerequisite for such information to be displayed visually well. Visual communication [3] design is a

proactive behavior in the graphic form used to spread specific ideas. Most portions rely on perception and are symbolized by two-dimensional pictures, such as those seen in electronic devices, typesetting, artwork, logos, and graphic layouts [4].

The ability of visual technologies for communication to measure information quickly and in real-time has led to its widespread application in many fields in recent years [5]. Related to this, Zhao [6] investigated and examined the visual alignment of the graphic language in the layout of animated visual guiding technology and incorporated alongside orientation within the film's animation design to make the animation design more in line with recent times. Designers need to be aware of cultural considerations and ensure that graphics are understandable to various people. Liu [7] utilized various cutting-edge science and technology techniques, such as VCD, which is necessary when creating interactive animation special effects to increase the view of VCD success while achieving outstanding knowledge dissemination impacts. This article initially introduced the technology for visual communication design and special animation design. In research [8], color, space forming, and graphical-text conformance, Organizations must strengthen commercial exhibits while laying out, innovating, and reconstructing these three stages of brand design. In visual design, striking the correct balance between computerized analysis and human input is critical. Lu and Huang [9] tried to improve the visual communication of artificial intelligence in the recognition and assessment of graphic design language. With the help of significant targeted location recognition and sentiment categorization using a weighted loss convolutional neural network, it focused on enhancing segmentation of image accuracy and assessing emotions depicted in graphics design. The qualities of a graphic language are: intuitive, vivid, symbolic, and aesthetic. A single graphic language, however, has not produced superior outcomes. Hence, Tao [10] examined the impact of graphic language auto layout on the design of visual communication and comprehended the method of graphic language auto layout to support the development of visual communication. Designers must optimize the layout because the intro is essential in addition to the logo and the best placement of associated components, such as the subject matter. With the help of contrast, proportion, white space, and other elements, the formally established aesthetic rule of layout reflects an abstract generalization of the aesthetic rule of design layout. Due to the existing constraints of artificial intelligence technology, a matching framework based on the formal aesthetic law of layout is a more sophisticated abstracted

matching paradigm that necessitates parametric by the aesthetically pleasing law [11]. Visualizing relational information in visual applications provided a fast compound graph with the ability to support user-specified positioning limitations and different kinds of classifications based on previous compound spring embedding technology and best for interactive applications by combining quality layouts and spectral graph velocity. It is crucial to consider the algorithm's capability to manage various user requirements and guarantee correct enforcement [12]. In that point, to deliver various information to users, the long-known symbols supply the fundamental requirements for cutting-edge, interdisciplinary research. In VCD, a particular graphic pattern is frequently made up of just one component, and depending on how it is assembled and used, it can effectively communicate various messages to various people [13]. The messages may involve graphics and pictures used while creating advertisements, poster designs, websites, and logos, particularly in commercial photography. Designers can successfully include product features using hand-drawn techniques, graphics, and picture software, increasing people's appeal [14]. Cui et al. [15] introduced a framework for automatically producing infographics, a subset of graphic language, providing evidence suggesting that it converts a natural language expression on a piece of appropriate information into a collection of expert infographics with different layouts, colors, designs, and options that ordinary people may choose or modify according to their individual choices. However, it can only deal with a limited collection of information, bad icon matching with small font sizes, and arises ambiguity problems. Graphic language plays a relatively minor part in information transmission due to its relative lack of precision, making it difficult to pinpoint information precisely. To avoid this, Wu and Fang [16] suggested a visual communication system based on the hyperspectral processing of images using entropy control stability with good visual communication effects. They can successfully increase the visual communication design effect. Existing methods have looked into using a force simulation and proxy geometry to simplify handling collisions for irregular forms. These specialized force-directed layouts are frequently unstable and necessitate additional constraints to function correctly. Kristiansen et al. [17] described a method for locating central components in a unique grid layout to provide equivalent attractive forces to address these deficiencies. Dayama et al. [18] proposed an integer programming method for interactive layout transfer, where the layout of a source design is automatically transferred using a chosen reference pattern layout while adhering to applicable rules. The source design is an initial rough working draught converted into a rough draught into the final objective layout using a reference pattern. The major objective of the study is:

- The aesthetics and visual attractiveness score of graphic language layouts are enhanced by using the HGC-AL algorithm.
- Apply design constraints for evaluating alignment accuracy, prevent conflict, and effectively design the layout using visual graphics elements.
- Provide a visual balance score by maintaining the hierarchy of elements with their relative importance

and update the design changes using responsive fluid grid supports.

- Evaluate the proposed approach using performance metrics like IoU, content coverage ratio, alignment accuracy, visual score, scalability ratio, and overall layout quality.

The remainder of this investigation is organized as follows: Section II details the prior work on visual and graphics language-related layout implementations. Section III details the data source description and proposes the implementation of HGC-AL using various graphic languages and visual elements for effective communication design. Section IV presents the comparative analysis. Section V discusses the results. Section VI concludes the work with limitations of the current study and future work.

II. PRIOR WORK

Zhou et al. [19] proposed a Composition-aware Graphic Layout integrated with a Deep Generative Adversarial Network (CaGL-DGAN) model with an Adam optimizer used to create layouts based on the overall and spatial visual information of input images. A novel domain alignment module was created to close the mismatch between the test inputs without using masks and the inputs used for training with the hint masks. The evaluated metrics are user satisfaction, visual balance, overlapping and graphical readability with root mean square values of x and y dimensions of the text elements using the poster layout design dataset with visual text variation of 0.026 difference with a lack of focus in color base.

Yu [20] elaborated a parallel selection logo to explain the parallel procedure and selection procedure for graphic languages in VCD and realizes the automatic layout of graphical languages using the parallel selection process. Syntax description based on rules and semantic description based on abstract state machines describes visual languages. The ant colony algorithm gets the graphics' demonstrated spot in VCD. The fixed value approach utilized for figuring out the showcase size of the buffer image takes the least layout land optimum surface used as the goal. Results demonstrated that the favorable scheduling impact increased focus and satisfaction.

Wang [21] suggested an algorithm for automatically arranging graphic language in VCD with the Ant Colony (AC) algorithm to get the most effective display location of the images in VCD. The Fixed Value Method (FVM) for estimating the display dimensions of the buffer graphic takes a minimal amount of layout and the maximum surface utilization as the function's objective. Graphic language can be described using syntactic analysis according to rules and semantics. Its application in real-time or resource constraints may consume greater time for processing and demand for resources.

Ma [22] developed a graphics language-based automatic scheduling technique using the Allocation of Resources State (ARS) in automated planning research. Both service management based on port resource conservation of an optical network centered on a multimode and an optical panel allocation of resources is proposed. Focussed on the application and described the dynamic layout's design concepts, methodologies, and shapes.

Wang and Li [23] suggested an automatic structure of graphics language in VCD that successfully resolves the conflict between textural capacity for storage and realism and accomplishes real-time deconstruction and visualization using programmable graphical processors. The technique automatically inserts every element of the code database throughout the compression and coding of the image. The results showed higher satisfaction; it must be tested and validated using various design scenarios not discussed in this study to ensure the algorithm's dependability and adaptability.

Sun and Mattek [24] researched Network VCD is familiar with the design thinking processes for visual information communication and has a wide range of expressive and communicative options. The algorithm of graphic language automatic arrangement in Nvcd is also researched to determine the ideal size and position in NVCD for graphic arrangement. The experimental results showed that the design of graphics makes up 27% of the total, next to film and television design (21%), advertising design (19%), typeface design (14%), and logo design (9%). However, not every user can utilize digital platforms or comprehend nuanced visual cues.

Gong and Fang [25] built a framework for automatic layout optimization called Faster-R-CNN to identify and extract an essential element from posters. It achieves recognition and placement of the format's elements by learning and categorizing the elements using RPN. The main focus is to learn the selected basic format template with the poster case format. The skeletal labeling of the layout's elements is the primary basis for classifying those elements. This framework produced a detection rate of 95% and satisfied the visual communication needs of public cultural signs. The layout is optimized while ensuring that cultural logos adhere to the rules of visual communication and exceed the satisfaction ratio above 70% using the three-division method. It emphasizes the categorized layout's core body and numerous text sections by Soto and Yoo [26]. The exact location of each component can be determined and located once the labeling of the layout elements is complete. The approach makes it possible to learn the target case's layout and finish learning the Layout migration.

Tabata et al. [27] developed a system for automatically generating layouts that combine i) random generation, a set of minimal condition rules, and ii) an assessment of adherence to the intended design aesthetic. This technique makes it feasible to produce numerous innovative layouts while maintaining the original design aesthetic. When text or images add information to layouts, an appropriate layout that considers content and design is automatically developed. A learning-to-rank predictor evaluates the work's look, design, structure, and content; the top ratings are then given to the user. Users can significantly increase layout development and editing efficiency. It could take a lot of time and computation to generate a lot of layout candidates.

The automatic layout procedure performed by an a priori designing approach still needs human input. Thus, Huo and Wang [28] provided an Artificial Intelligence-based (AI) method for designing poster layouts. A Learner and a Generator (L-G) are both components of the layout construction

process. First, the learner generated the initial templates for various composition scenarios using the spatial transformation system. The generator optimizes the first template to create many optimum templates, relying on the LeNet architecture utilizing the golden ratio and the trilateration technique. Due to the template's structure and framing fashion, the starting points are kept in an archive of matching templates. The lack of annotated training datasets focusing on poster layouts alone might have an impact.

Zhang [29] enhanced the two-way long- and short-memory model of a neural network to identify the poster using graphic language and investigated the mathematical modeling of graphic language in VCD better, thereby increasing the accuracy of the computer's ability as 0.843% and utilized the minimal time for the recognition process. Hence, the classification efficiency here is 1692.5 s; the identified research gaps in this study are network representation ability is insufficient and the network correctness is not elevated.

Xu and Shi [30] created a collection of automatically suggested visual type annotation systems that primarily process data and look for big data in the system using user field information. The user can then be advised of the best visual mark to use so that the information can be presented to them as graphics. The attributes used for automatic recommendation are dimension, color, size, shape, label, and tag type. Users can save additional time and effort by having the system recommend the best label style in single and bi-axis types. The major limitation here is no further in-depth examination of the information. Only tag options are recommended to users.

He [31] explored the design process of a visual interface using interactivity and the experience of users to achieve the goal of information transfer by employing interactive information visualization. This article makes recommendations for improving the interactive design of visual communication from the focal points of attention, awareness, and memories by analyzing users' cognitive processes in each stage of visual-based activities. The algorithm's accuracy reaches 0.963%, and user satisfaction is 0.959%, with a faster convergence time. However, this study has drawbacks related to the detailed description of expression and visual aspects of elements.

Kikuchi et al. [32] proposed a framework name Constrained Layout Generation through Optimization (CLO) with unconstrained layout generative adversarial network++ with the latent codes for evaluating the alignment of elements, overlapping issues, and other user-specified relations. The metrics related to the Intersection of Union (IoU), constraint violation, and alignment comparing three publicly available graphic-related datasets, including various visual elements like images, text, icons, logos, etc. The major drawback is issues related to visual quality may occur there may be a need for an extra training period for discriminators.

The review study details the prior work related to the VCD field with graphic language of automatic layout algorithm with fullest satisfaction of user identification ratio and various design scenarios, practical usage, and dynamic designs.

III. PROPOSED ALGORITHM

Using graphics and visuals to communicate ideas is known as visual communication design. Four fundamental components are primarily used when producing visual communication effects: graphical style, text structure, graphic hues, and graphic arrangement layout. Providing visual information and making the viewer attractive are important aspects of layout design. Quantitative design encompasses the development of technological advances in graphics and visuals. It can separate graphic images' color and structure details into separate, quantifiable, and measurable independent pieces. Graphic language includes the principles, procedures, and phrases used in visual design to build coherent and meaningful compositions. Graphical components such as lines, forms, shades, layout, structure, and visual hierarchical arrangement express ideas and produce striking visuals. In the subject of visual communication design, messages are effectively conveyed through the use of images, typography, and layout. It can be applied in some ways, including marketing, advertising, and producing signage or educational materials. To successfully explain the facts or information being shown, visualization frequently uses design ideas from graphic languages, such as the use of a visual hierarchy, color coding, and typographical nature. The fundamental element of visual layouts, such as those for newspapers and magazines, advertisements, cartoons, and internet pages, is layout. A good layout can improve content presentation, direct reader focus, and increase visual appeal. Fig. 1 depicts the implementation of HGC-AL for effective VCD.

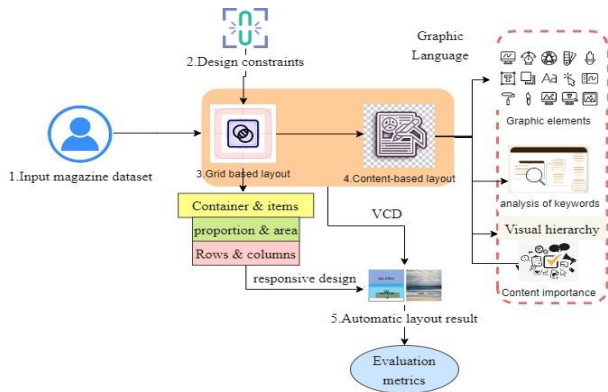

Fig. 1. Implementation of HGC-AL.

The innovative approach combines two fundamental principles - grid-based layout and content-based design - to enhance the efficiency and creativity of graphic language in visual communication. By integrating these two methods, the work offers a comprehensive solution that ensures visual coherence through the use of grids but also allows for dynamic and adaptive layouts based on the presented content. This hybridized approach empowers designers with a versatile toolset to create visually appealing and effective communication materials. Additionally, it addresses the evolving demands of contemporary design, where flexibility and automation are crucial. Overall, this work opens up new possibilities for graphic designers, enriching their creative processes and enabling them to produce more engaging and impactful visual communication designs.

A. Input Magazine Dataset

The magazine dataset includes several categories of graphic elements, including images, text, colors, and other visual components represented in this block as the input information used by the layout algorithm. However, some datasets with semantic segmentation are openly accessible to magazines and academic journals. From Zheng et al. [33], 3 919 pages of magazines from the Internet that cover six common topics, namely fashion, nutrition, headlines, technology, traveling, and weddings, make up the dataset. The six categories total 685, 753, 618, 509, 721, and 633 pages, respectively. The types of graphic language labels to encode the layout of each page to enhance VCD with element categories are Text, Image, Headlines, color, and Background. Pages from various categories display a variety of layouts in terms of the quantity, size, and spatial positioning of page elements. The most commonly used AR of magazines are 4/3; hence the general representation of the layout to be generated may be fixed as the dimension of 60×45. Capture the design aspects: Identify the visual aspects that should be properly integrated into the layout, and graphics could consist of text blocks, pictures, logos, icons, and other graphical elements. Each element should have the appropriate qualities, such as dimension, position, alignment, and visual order. Based on this dataset, the layout of the graphic visual elements needs to be arranged automatically by following the design constraints given in subsequent content and applying HGC-AL.

B. Design Constraints for Various Attributes

Before applying the layout algorithm, the basic design constraints must be fixed to enhance the visual appeal, usefulness, and user experience of the graphical layout. The goal of adding design qualities into a layout algorithm utilizing graphic language is applied in the collected dataset to generate a layout design. The design constraints are used to direct the layout-generating process represented by this block with criteria for alignment, overlapping, size, location and spacing, proportions, and other design principles. Design the guidelines that must be followed throughout the layout-generating process, including element associations or alignment, closeness, and spacing constraints. These design constraints are used for element coordination, conflict avoidance, or user-specified interaction. To identify the conflict loss between elements pairs in the layout composition.

$$Cl_{loss} = \sum_{i=1}^Z \sum_{j=i}^Z \frac{e_i \cap e_j}{e_i} \quad (1)$$

As mentioned in Eq. (1), $e_i \cap e_j$ represents the intersection or overlapping region of two elements i and j . Element alignment is adopted for the sample rectangle shape with the two basic alignment principles, edge alignment and center alignment, to avoid this conflict loss problem. A common strategy is edge alignment, which involves aligning parts with an outer boundary that intuitively matches their exterior edges. The function provides the orientation and positional information for the list elements to create acceptable visual groups. The two elements' size and shape are considered when choosing the alignment. A visual hierarchy throughout the layout structure is established using alignment. You can clearly distinguish between different subsections or stages in

importance by aligning text elements. Aligned text enhances the design's aesthetics and attractiveness with hierarchy and increases the visual score. An automatic layout plan is more aesthetically pleasing when balanced alignment conveys an emotion of order and balance.

Pseudocode-Rectangular type element alignment for enhancing the visual score

```

Input: rectangular shape as rect (length as  $l$ , height as  $h$ , width as  $w$ ),
top, left.
Output: element alignment as  $el$ 
if  $rect.l < 3$  then
  Compare  $sim(w, h)$ 
  if  $(\max(w) > \max(h))$ , then
     $el \leftarrow el_{left}$ 
    update longer  $w$  on top
  else
     $el \leftarrow el_{top}$ 
    update longer  $h$  on left
end if
else
   $rect \leftarrow bgRect(rect)$ 
  if  $rect.h > rect.w$  then
     $el \leftarrow el_{left}$ 
  else
     $el \leftarrow el_{top}$ 
  end if
end if

```

1) *Intersection over Union (IoU)*: IoU can be used to evaluate how well the projected arrangement and the actual layout agree or line up. Locate the area where the expected layout and the actual arrangement overlap, which can be achieved by locating the areas or components shared by the two layouts. Subtract the union area from the intersection area, and the calculated value indicates the degree of agreement or overlap between the expected and actual layouts.

IoU value ranges from 0 to 1, where 0 means no overlap and 1 means perfection in the overlap. For the intersection area of a design element, the notation $e_i \cap e_j$ and $e_i \cup e_j$ the intersection and union of measures can be calculated using Eqs. (2) and (3).

$$IoU_{VCD} = \frac{e_i \cap e_j}{e_i \cup e_j} \quad (2)$$

$$e_i \cap e_j = (e_{i1}^l - e_{i0}^l) * (e_{j1}^l - e_{j0}^l) \quad (3)$$

Combining the two boxes' areas and deducting them at their junction allows one to find the union area of two boxes using Eq. (4) and Eq. (5).

$$e_i = (e_{i1}^i - e_{i0}^i) * (e_{j1}^i - e_{j0}^i) \quad (4)$$

$$e_j = (e_{j1}^j - e_{j0}^j) * (e_{i1}^j - e_{i0}^j) \quad (5)$$

In visual communication design, an image's aspect ratio is useful since it offers important details about the proportions and shape of the image in three variants: portrait, landscape, and square. Suppose an image element's aspect ratio is greater than the picture's. In that case, the image is scaled to match the

image element's width while maintaining its aspect ratio, and then the centers of the two are aligned. Then align the images along the vertical axis by the center, top, or bottom boundary because the scaled image is taller than the image element using Eq. (6).

$$AR = w/h \quad (6)$$

w indicates the width of an image, h represents a height of an image.

The design attributes are included with graphic language and consider i) color as the initial graphic language representation to generate an automatic grid layout based on the input contents. The color scheme is carefully chosen to produce a unified and aesthetically pleasing appearance. Depending on the branding and content of the magazine, it might use both vivid and subdued colors. The appropriate application of color may generate feelings, convey meaning, and have a strong visual impression. The mood, accessibility, and overall aesthetic elegance of a design can all be impacted by color choices. Readability can be improved by using lighter backgrounds with darker text or the opposite. A focal point or important information can be highlighted with a strong, brilliant color to grab and direct the reader's attention. The layout automatically generates the results according to the given visual element using the "adjustColorPalatte ()" method in design constraints of the color attribute

2) *Size and location constraints*: Size and location constraints are derived from Kikuchi et al. [32] to generate an effective layout. Three categories must be considered for the size element constraint: small, large, and equal. If a user specifies that j^{th} element has to be larger than the i^{th} element, the sum of cost functions of larger relation is calculated using Eq. (7) as:

$$S_{lg}(e_i, e_j) = \max((1 + \gamma)A(e_i) - A(e_j), 0) \quad (7)$$

Where $A(\cdot)$ represents the function that the occupied area of the given bounding box and γ is a tolerating variable shared between the relations of the size. Likewise, Eq. (8) calculates the location constraint with five variables above, left, right, bottom, and overlap. If an element e_i has to be present right of an element e_j then, the right location's cost-related function is given.

$$L_r(e_i, e_j) = \max(y_l(e_j) - y_r(e_i), 0) \quad (8)$$

Where $y_l(\cdot)$ and $y_r(\cdot)$ denotes a function that returns a considered bounding box's left and right coordinates.

Based on these design constraints for aligning text, image, size, location, and color arrangements, IoU analysis inside a layout with correct columns and width spans in the container must follow the grid layout design.

C. Grid-based Layout

This block represents the grid-based layout algorithm, creating a grid structure with well-defined columns and rows out of the available space. The grid provides a structural framework for organizing and positioning the graphic languages within the layout. Grid-based layouts prioritize

structure, responsiveness, and resource optimization, while content-based layouts emphasize every component's importance and enhance the overall user experience. A grid-based layout's main goal is to arrange items methodically and consistently. It strives to align pieces along horizontal and vertical principles to create a visually balanced and well-organized composition. Grids ensure that elements keep a consistent connection to one another and give the structure an aesthetic feeling and harmony. Grid-based layouts are effective in using space, especially when dealing with a lot of content or objects arranged in a grid-like pattern. By placing components in a grid, they may maximize the potential of the space and available reduce unused space, assuring an aesthetically appealing and well-organized design. According to the screen size, the fluid grid's variable content breadth can span the entire edge concerning the graphical language used in the design constraints. Columns in a fluid grid have variable widths, whereas the gutters and side margins are fixed.

Fig. 2. Basic grid layout design for a magazine.

Create a structure based on grids with a fixed number of rows and columns, as shown in Fig. 2, with several attributes. The red color arrowhead represents the space between column grids in which the areas between the columns are known as gutters aid in dividing the text; the green arrow represents the space within the column surrounded by the page container, adopts the design layout based on the given input type of graphic language to enable the good score of visual communication. Breakpoint refers to a particular range of sizes of screens wherein the layout is re-sized to the available screen size for the optimum layout view. The margin of the layout defines the magazine content and the edge of the screen layout. The grid serves as an outline of the algorithm that gives the layout a dependable sense of alignment and structure of visual elements arranged based on a content-based layout. Here the layout dimension is taken as of width (w) size as 100 cm; hence the number of columns in a grid cell is taken as 12 to calculate the width of each column as $w/\text{no. of columns}$, then it gives a unit-wise wider area. Similarly, the no. of rows is taken as 3 for this $h/\text{no. of rows}$ is calculated; hence the resultant value is 15 units high. Hence, the resultant grid sample will be square with equal width and height space. This grid layout separates the pages into sections like rows and

columns for varying magazine trends arrangement to enhance the design principle of graphic language. Then follow the alignment rules to create visual order and balance with the help of proximities like size and location for enhancing the reader's understanding and satisfaction.

The layout design is aligned with the proper graphic language with its importance related to contents for enabling visual communication and delivering the message with good visual score and readability. The content-based layout needs to be followed, which is given in the subsequent section.

D. Content-based Layout

The content-based layout algorithm is represented by this block in which each graphic element's attributes and significance are examined, including its visual impact and relationship importance to other elements, as shown in Fig. 3. It uses this data to decide where elements should be placed in the grid and how they should be arranged. Here the importance of keywords to display the content about the given category based on term frequency-inverse document frequency is given below:

1) *Keyword/text importance*: The term frequency-inverse document frequency ($tf - idocf$) method counts the number of words in a collection of documents and calculates a score for every word to reflect its weight in the corpus and document. The term frequency calculates the word frequency in the text and is heavily dependent on the size of the content inside the document as well as generality. Since TF is specific about every document and word, the term t denotes the term or word doc denotes the document where a group of words occurred. N denotes the corpus count referring to the total document set. DF is the number of times a term appears in the document set N and identifies a document's significance within the corpus as a whole. DF is the number of times the phrase t appears in the information set N . In other words, DF represents the number of documents containing the word. IDF , which quantifies the informativeness of a term t , is the inverse of document frequency.

$$tf(t, doc) = \text{count of } t \text{ in } doc / \text{no. of words in } doc \quad (9)$$

$$idocf(t) = \log\left(\frac{N}{(docf+1)}\right) \quad (10)$$

$$tf - idocf = \left(\frac{\text{count of } t \text{ in } doc / \text{no. of words in } doc}{idocf(t)}\right) \quad (11)$$

From these above Eq. (9)-(11), the relative weightage of a word can be calculated where the repeatedly occurring words like stop-words in a magazine have a very low $idocf$ score. Depending on the high $TF-IDF$ evaluations, determine the keywords or significant terms and allocate sizes to text elements according to their significance or relevancy. For example, greater sizes can be given to those with higher $TF-IDF$ values to visually emphasize the importance of text elements within the layout. Consider utilizing bigger font sizes, bold or italics formatting, or distinctive colors to draw attention to keywords within the content. The content makes the key phrases more noticeable to readers and stimulates interaction with the destination knowledge.

Fig. 3. Content-based layout of graphic language for traveling magazine.

E. Automatic Layout Representation

This block depicts the algorithm's final result, a created layout that blends the concepts of grid-based and content-based layouts. According to the limitations of the design and aesthetic considerations, it displays the graphic elements' ideal arrangement.

The font size for the text and text-over-image elements is fixed to make it easier to see the generated layouts. In contrast, the font size for the headline and headline-over-image portions is set to a minimum of three times larger and fluctuates depending on the size of the corresponding regions. According to the design and intended amount of emphasis, the font size commonly varies between 24 pt to 72 pt or greater. Change the font size based on the image proportions and the headlines' effect on readers. The grid structure adjusts and scales by implementing responsive fluid grids following the available screen size. The technique gives grid columns proportional widths to alter dynamically rather than set column widths. Instead of using fixed pixel values, content items within the grid are placed using relative measurements. The technique of arranging items to demonstrate their relative importance can be called visual hierarchy. Designers organize visual elements, such as menus, images, colors, texts, and symbols, so users can easily comprehend information. Designers modify users' views and direct them towards desired actions by arranging things logically and strategically. It ensures the best possible use of the available space by allowing objects to scale and reposition themselves according to the screen size.

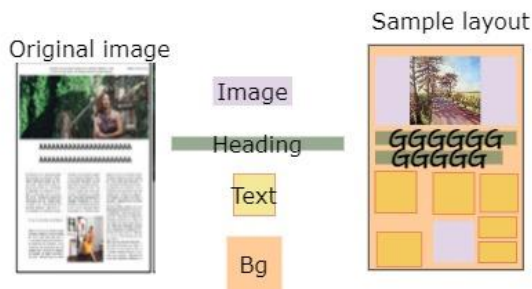

Fig. 4. Layout representation of graphic languages using visual elements like image, text, and background.

As shown in Fig. 4, the input image is taken from a magazine type called traveling, where the graphic language contains the four partitions generated to design the grid-based layout, and contents are aligned with separate columns and rows based on the width and height of the layout dimension area. Initially, the background is identified from the color palette function extracted from the color design attribute rules. The image is identified with the element pair of i , and j coordinates to find the dimension with overlap functions, size,

and location proximities. Then the heading category is aligned with boldface dark font. The text is aligned based on the left and right alignment rules without overlapping regions.

IV. EXPERIMENTAL ANALYSIS

The proposed algorithm is compared with four existing approaches, CaGL-DGAN [19], AC-FVM [21], AI-L-G [28], and CLO [32], using various metrics like IoU analysis, alignment accuracy, content coverage ratio, visual balance score, scalability ratio, and overall quality score.

A. IoU Analysis

Whenever the IoU number is high, two separate boundaries have a lot of overlap or similarities. IoU is frequently used to assess the precision of anticipated bounding boxes compared to ground truth indications in tasks like identifying visual elements and image recognition using Eq. (2).

Fig. 5. Comparison analysis of IoU values.

Fig. 5 depicts the IoU analysis of image overlapping in six categories of domains like fashion, nutrition, headlines, technology, and traveling wedding. Typically, IoU is stated as a number between 0 and 1, with 0 denoting no overlap and 1 denoting a perfect match or total overlapping between the layouts. IoU can be used by designers as an input system to hone and enhance layout algorithms. Designers can pinpoint areas for improvement and modify the algorithm variables or limitations by examining the IoU ratings for several design iterations.

B. Alignment-Accuracy Measure

Using design constraints like alignment rules for graphic elements in VCD, including text or image alignment. Suppose the aligned text matches the design constraints and follows the pseudocode rules of left, right, bottom, and height categories. If the alignment is text element need to store in the fashion layout with the corresponding keywords extracted using the frequency of occurrences and its relevant scores for the proximities of size and location constraints based on the obtained score, the alignment accuracy is evaluated.

$$\text{Alignment Accuracy}(\%) = \frac{(\text{score1} * \text{wt1} + \text{score2} * \text{wt2} + \dots + \text{scoreZ} * \text{wtN})}{(\text{wt1} + \dots + \text{wtZ})} \quad (12)$$

From Eq. (12), score is calculated from relevant extraction methods like $tf - idocf$ for text, and the score will vary for other visual elements design patterns like traveling, wedding,

and technology because each magazine has different visual styles of the alignment procedure. Based on this alignment rule, the accuracy of aligned text has been calculated.

As depicted in Fig. 6, the alignment accuracy increases if the score of the extracted graphic language increases and follows the alignment rules derived from design constraints. The alignment must include the graphical language measure, like the wedding category has a separate theme like the fashion category has a separate theme in the background. Based on this graphic language analysis, the relevant text is separated and aligned based on the score acquired.

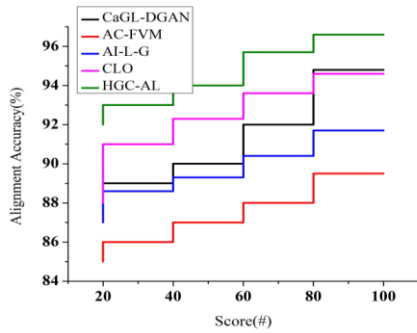

Fig. 6. Calculation of alignment accurateness.

C. Content Coverage Ratio (%)

The CCR determines the entire area that the grid's elements of content occupy, and the content coverage ratio is calculated by adding together the areas of all the content elements and dividing that sum by the grid's overall area. The CCR from Eq. (13) shows how much of the grid layout is taken up by the graphical content elements. A higher CCR indicates greater coverage of the space accessible by the design elements.

$$CCR = \frac{\text{(Sum of content element areas)}}{\text{total grid dimension}} \quad (13)$$

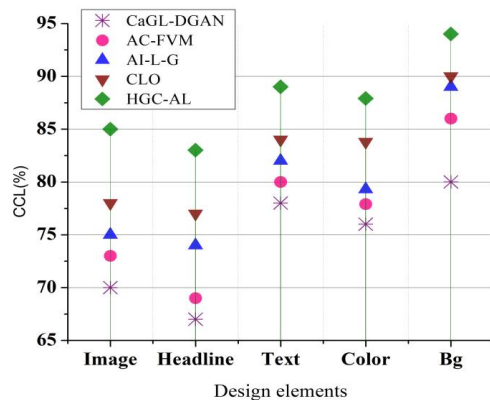

Fig. 7. CCR analysis.

As shown in Fig. 7, CCR analysis results in a comparison between the existing and proposed approach gives the better coverage aspect of design elements in HGC-AL with the additional effort of grid layout usage since this approach provides a better resource utilization related to content by identifying the relevant column and width spaces of each grid

cell to reduce the wastage of unused space. In this dataset, the magazine categories are related to several types of fashion, nutrition, and headlines, including graphic design elements like image, text, color, and background aligned with the design constraints.

D. Visual Score Analysis

As shown in Fig. 8, the graph compares the criteria aspects like proportion, text, alignment, color distribution, size, location, and image flow are examples of particular criteria that affect visual balance with various existing and proposed HGC-AL. Design best practices and these requirements should be compatible based on design constraints. For a given layout, assess each criterion separately and give it a score depending on how well it satisfies that criterion. That can be a scale of 1-10 and a subjective rating from layout designers considering the balance attained in visual communication design elements.

Fig. 8. Visual score comparison.

E. Analysis of Scalability Ratio (%)

An HGC-AL algorithm's scalability may also be affected by *N* no.of design constraints like conflict loss, content hierarchy, alignment rules, IoU, size, and location constraints are increasingly difficult as the amount of content rises. The algorithm's scalability can have trouble staying consistent and adhering to the rules.

From Eq. (14), the scalability of the proposed algorithm increases as the content count or size increases for six categories of magazines with different contents like image, text, color, headline, and background concerning the design constraints of the graphic language elements. Here α , β , and γ represent the coefficients that denote the relative importance of each design criterion employed in the HGC-AL algorithm.

$$\text{Scalability ratio}(\%) = \alpha * (\text{content count}) + \beta * (\text{design constraint 1}) + \dots + \gamma * (\text{design constraint N}) \quad (14)$$

From Fig. 9, the graph shows the scalability ratio analysis of various algorithms concerning design criteria or constraints and the content count of each magazine category. The proposed algorithm scales well concerning each design constraint as the content count increases. It improves the algorithm's scalability compared to other approaches using the hybridized concept.

Fig. 9. Scalability ratio analysis.

F. Overall Layout Quality Consideration

The various evaluation criterions used to assess the layout quality are represented on the x-axis. Aspects like aesthetics, unity, content hierarchy, color contrast, accessibility, functionality, and other pertinent design criteria can be included in these considerations. The layout's quality score is shown on the y-axis following the evaluation criteria taken from Zheng et al. [33].

$$O_{lq} = \frac{\sum(score(i) * wt(i))}{\sum(wt(i))} \quad (15)$$

From Eq. (15), the score (i) represents the score allocated to the current i^{th} evaluation criteria, with $wt(i)$ denoting the weight assigned to the i^{th} evaluation criteria concerning the relative importance of each criterion utilized in this calculation.

Fig. 10. Overall layout quality analysis for various algorithms.

The score calculated from Fig. 10 shows the total assessment of all design factors considering the relative importance of each parameter that produces the overall layout quality of each algorithm. By calculating this total quality score, the performance and advantages of the proposed HGC-AL technique are proven to have superior and good quality scores compared to other existing approaches.

V. DISCUSSIONS

The proposed Hybridized Grid and Content-based Automatic Layout algorithm exhibit notable advantages compared to existing methods such as CaGL-DGAN, AC-FVM, AI-L-G, and CLO in visual communication design. Its

IoU analysis scores consistently outperform these methods, indicating superior accuracy in replicating desired layouts, which is crucial for maintaining design integrity. Secondly, alignment accuracy is a standout feature, as the algorithm excels in preserving visual coherence and ensuring proper element alignment, surpassing the precision of the existing approaches. Furthermore, the content coverage ratio metric demonstrates the algorithm's proficiency in maximizing information presentation within available space, a critical aspect of effective communication design that it accomplishes more efficiently than its counterparts. The visual balance score consistently ranks higher, showcasing its aptitude for creating aesthetically pleasing designs, a feature that sets it apart in aesthetics. Its excellent scalability ratio underscores its adaptability across various design scales and complexities, making it a practical choice for various design projects. The algorithm's impressive performance across these metrics contributes to a significantly higher overall quality score than the existing methods. This comprehensive superiority positions the Hybridized Grid and Content-based Automatic Layout algorithm as a valuable and versatile tool in the field of visual communication design, offering enhanced accuracy, alignment, content coverage, aesthetics, and scalability for designers seeking to create impactful and visually engaging communication materials.

VI. CONCLUSION

The creation of images and visuals for computers not only advances computer development but also helps to improve graphic and image design. The study of VCD has changed people's conceptions of life and consumption while introducing them to innovative and personalized visual appraisal activities. For creating visually balanced layouts in Visual Communication Design (VCD), the HGC-AL algorithm offers a dependable and effective solution. The method ensures that graphic elements are placed in the best possible location while considering design limitations and alignment by combining grid-based structure with content-based analysis. It improves the visual score and offers versatility and adaptation to shifting design specifications. Metrics showing the algorithm's performance over competing layout algorithms include the intersection of union (IoU), alignment accuracy, content coverage ratio, visual score, scalability ratio, and overall layout quality. The HGC-AL algorithm improves graphic language and communication in visual design by producing aesthetically appealing and efficient layouts. Thus HGC-AL enables a more efficient design workflow by automatically ordering and placing content items in a grid layout according to established design constraints and techniques. The major limitation of this study involves that if the design constraints of graphical elements are not satisfied, it may affect the quality of the generated layout model. Hence, future work will focus on dynamic updates of the design constraints and the suitable optimization algorithms for attaining effective layout quality.

Smart Sensor Signal-Assisted Behavioral Model and Control of Live Interaction in Digital Media Art

Pujie Li*, Shi Bai

School of Art and Design Bengbu University
Bengbu Anhui, 233000
China

Abstract—Digital media art immersive scene design is a type of art design based on the theory of positive psychology mind flow theory, using digital media as the main technology and tool to build a certain scene by stimulating the senses and perception of the user so that they can achieve a state of immersion and forgetting other things. In this paper, we discuss the application of digital experience technology in designing art scene interaction devices by combining intelligent sensor signal analysis with multimodal interaction. Based on this, a new inductive displacement sensing element is proposed, which adopts square wave driving mode and op-amp circuit to extract signals, overcoming the shortcomings of the traditional inductive displacement sensing element, gaining the advantages of small size, lightweight, good linearity, high-frequency response, a simple driving circuit, and signal detection circuit, and more easily adaptable to microcomputer control. A more comprehensive anti-interference and system fault self-diagnosis design is carried out for the sensor system to ensure the stability and reliability of the system. An intelligent digital filtering algorithm with program judgment is proposed, with better smoothing ability and faster response speed. The multimodal interaction in digital experience design strategy is applied to the design practice, and a series of diversified device design solutions are proposed suitable for on-site interaction behavior.

Keywords—Intelligent sensors; digital media; VR technology; artistic interaction

I. INTRODUCTION

Under the development of art and culture globalization, the public's diversified needs for art and its dissemination are gradually growing rapidly. As a special position for the development of communication and art, art needs to meet the various needs of various audience groups. The value of art is mainly reflected in the artists' hard work, and the public's positive feedback on art and culture. It is imperative that the use of digital technology is no longer superficial and requires a more professional and rigorous attitude to regulate the use of new media technologies [1]. In the face of the rapid development of science and technology and digital media in the information age, cross-discipline, interdisciplinary, and cross-media have become mainstream topics in the study of art and technology and an indispensable part of the art development process. Artists and technology practitioners have become very interested in the integration of new technologies and new media [2], exploring new ideas and new problems that may arise from the union of art and technology, and making efforts to explore this. However, due to the late start of

research on intelligent sensor systems for interactive behaviors in art scenes, their theory and practice are far from mature and far from practical application needs, especially the high-performance, small volume, and low-cost intelligent sensor systems for mechanical displacement measurement are yet to be further developed.

Based on the research on the structure and performance of traditional inductive displacement sensors and the theory and practice of intelligent sensor systems, this paper designs an intelligent displacement sensor system for live interaction of digital media art, which has the characteristics of small size, low cost, long life, large range, fast response speed, and high intelligence, etc., and obtains satisfactory results in practice. The design of digital art installations requires various technical means such as interactive visual technology, touch technology, physical interactive technology, code programming technology, and virtual/augmented reality technology to realize. In terms of infrastructure, improve the information technology and intelligent facilities and equipment of art and museums, establish the management information system of public cultural space, and improve the information level of infrastructure. In terms of experience, establish fun experience spaces that can interact with audiences, including setting up interactive cultural experience zones for books, paintings, seal engraving, etc., to enhance interactive tours and fun experiences in art and museums. With natural language processing techniques, it is possible to analyze the user's emotions in social media, text input, or voice interactions, and there is already a lot of research available [3]. Multimodal technology is widely applied to the various sensory experiences of art to the users through gestures, touch, gaze, and other forms of multimodal interaction to stimulate various perceptions and responses of art to the users and thus achieve a higher level of experience [4].

II. RELATED WORK

Study [5] says for the user's own experience during multimodal interaction, multiple multimodal modalities with each other for information processing can bring a more efficient and better user experience to the user. Jiang N [6] suggests that the relationship between "immersive scene design" and digital media art is a shadow of one another and that immersive scene design in digital media art is not a new thing that emerged out of nowhere but has undergone a process from quantitative to qualitative change with the progress of technology and exploded in the present. Adams C [7] proposes

the concept of "affective computing", which is a technology that deals with processing, recognizing, and imitating human emotions and feelings. A system with affective computing capabilities can gain insight into the user's emotional state and adjust various factors in human-computer interaction to positively affect the user. Tiwari P [8] explores the progress made in applying affective computing techniques to real-world problems involving human-computer interaction. He points out that effective computing must be developed as a user-centric technology to benefit the global digital economy. In the research [9], the perspectives and applications of emotion in HCI research are discussed in detail, a framework for effective HCI research is proposed, and related methods and techniques are categorized, thus opening up the field of HCI research on human-computer emotional interaction.

In addition, research has given recognition and attention to the application of AI technologies such as decision prediction, image recognition, pattern recognition, and voice interaction in museums, and many studies have explored the means of using AI and other technologies from the perspective of enhancing the overall experience of the audience. The research [10] uses intelligent agent (Agent) systems to assess the level of human-computer interaction through AI to enhance the user experience. By analyzing user interactions in the museum, better interactions and interactive exhibition modules can be designed. On the other hand, Rendell J [11] collects user data based on the viewer's mobile interface, which is used to build a personalized collection recommendation system that brings people and artifacts closer together. Colangelo D [12] points out the correlation between human-computer interaction and the development of artificial intelligence, puts them in a time dimension to sort out their development and evolution, and summarizes the characteristics of interaction design in the era of artificial intelligence. What you think is what you need, what you see is what you see, and what you see is what you get. In addition, under AI, human-computer interaction will break through the boundaries of the graphical user interface and turn its attention to the human emotion and consciousness space for context-aware, consciousness-aware, and emotion-aware computing. The author in [13] proposes three interaction modes: "passive, forced active, and active" between human and intelligent products, and analyzes the differences between them in terms of interaction starting point, initiative, data-driven and AI decision-making to improve the coherence and effectiveness of interaction and help users improve their efficiency and experience. Furthermore, [14] explores the industries and products empowered by machine learning, natural language processing, image processing, robotics, and other technologies in the era of artificial intelligence. Through the case study of smart water purifiers, the innovative, emotional, and information architecture optimization features embodied by the interaction design of artificial intelligence are pointed out. Similarly, [15] points out new ideas that need to be introduced for human-computer interaction-natural

interaction, virtual reality technology for reality-based interaction, augmented reality, context-aware and affective computing, voice interaction, and multimodal interfaces as support. Wohn D Y [16] points out that effective computing is one of the foundations for establishing a harmonious human-computer environment. Since then, most of the research has focused on the field of computer science, trying to improve emotion recognition methods and enhance the accuracy rate by starting from expression, speech and physiological data, and multimodal fusion. Frenneaux R [17] thoroughly analyzed the current emotion models, facial expression interaction, speech signal emotion interaction, physical behavior emotion interaction, physiological signal emotion recognition, emotion extraction from text information and emotion intelligent agents, etc.

III. DESIGN OF INTELLIGENT SENSOR SIGNAL-ASSIST SYSTEM BASED ON INTERACTIVE BEHAVIOR IN THE FIELD

A. Intelligent Sensor System Design Scheme

One of the principles of digital experience design is that it is human-centred. Digital experience design provides a new interaction and expression for the user's experience, further stimulating deeper thinking of the user. Traditional measurement systems cannot store sensor-related information. They cannot be networked, which makes the system not have the function of intelligent identification of sensors and remote monitoring and has failed to meet the interactive behavior of art scene measurement requirements. With the development of modern information technology, intelligent networked measurement systems have come into being. The core technology of an intelligent networked measurement system is intelligent sensor technology, which is also the focus of this paper. Sensor technology, from the birth of the present, has gone through the "traditional sensor", "intelligent sensor", and "networked intelligent sensor" development stages [18]. Networked intelligent sensors of a wide range of different control network standards, access to each other inconvenient, so now the networked intelligent sensors are moving toward standardization.

This paper is designed based on the need for interactive behavior in the digital media art scene, using the intelligent sensor standard of IEEE1451.3. IEEE1451.3 establishes the standard for the interface between analog transmission networks and intelligently networked sensors. IEEE1451.4 establishes the standard for interconnection between intelligently networked sensors in a small space range. IEEE1451.5 establishes that IEEE1451.6 is about CANopen protocol transmitter network interface-related standards. IEEE1451.7 is about RF tag system transmitter communication protocol and transmitter electronic data form format-related standards. Fig. 1 below shows the framework of the standard protocol cluster used in this paper.

Fig. 1. Standard protocol framework.

The IEEE1451 standard separates the sensor node from the network implementation and is mainly divided into intelligent transmitter modules and network adapter modules. The different standards of IEEE1451.2-7 are used to define different communication protocols between intelligent transmitter modules and network adapter modules. The interface between intelligent transmitter modules and network adapter modules in the IEEE1451.2 standard is called Transmitter Independent Interface TII. The network adapter and intelligent transmitter modules have the same frequency and address arrays stored internally. The network adapter module sends the frequency and address numbers in the array to the intelligent transmitter module in binary form. ACK2 is set high if the element in the frequency and address number arrays is 1 and low if the element is 0. After the Intelligent Transmitter Module is connected to the Transmitter Independent Interface TII, it first communicates with the Network Adapter Module with three handshakes, then receives the binary numbers of frequency and address numbers from the Network Adapter Module, and converts the received binary numbers to decimal to find the corresponding frequency and address for its own IIC configuration [19]. Finally, the network adapter module will perform an IIC communication test with the intelligent transmitter. After the successful test, it will inform the upper computer software that the intelligent transmitter module is connected.

However, with the rapid development of the entire intelligent sensor processing platform and also as a class of typical entry systems, the entire intelligent sensor processing platform is becoming more and more complex, more and more functional requirements of the project, as well as the core microprocessor processing power continues to increase, the intelligent use of interrupts for functional switching of the front and back system defects are increasingly exposed. The first to emerge is a real-time multi-tasking kernel system; such operating systems can provide application programming interface API to the CPU and management of the microprocessor. With the progress of the sensor system intelligence requirements, system applications have become more complex, especially with the rise in communication needs, only the embedded operating system cannot meet. The embedded operating system gradually developed into a complete real-time multi-tasking, multi-functional operating system including file, network, development, and debugging environment, the application and development of IoT-related

technologies, embedded OS, with a complete task (process), scheduling, memory management scheduling and other kernel functions, in addition to this also has the network and other functions of the service capability, reliability, real-time, scalable and reliability, real-time, cut and portability, etc. are also greatly developed [20]. Because of these features, embedded OS has become one of the decisive components of the smart sensor processing platform. freeRTOS is also in the field of smart sensor processing platforms today and occupies a rising rate of emerging RTOS, mainly characterized by small resource consumption, lightweight systems, short development cycles, ease of getting started, completely open-source free, and other features. Networked, especially sensor systems using wireless network technology, also make intelligent sensor processing platforms an important part of IoT devices. In sensor processing platforms that use wireless communication technology, the use of wireless technology enhances the maintainability of the platform. It is even cheaper because it saves costs such as wiring, and the competitiveness rises in the market. The application of wireless communication technology in the field of smart sensors makes up for many shortcomings of smart sensor processing platforms using traditional wired communication methods, breaking through some limitations such as physical environment restrictions on wiring, as well as not being easy to expand, higher costs, and other troubles. The use of wireless network technology in line with the application scenario can expand the smart sensor processing platform in the fields of medical health, environmental monitoring, consumer electronics, and other applications.

IV. APPLICATION OF INTELLIGENT SENSOR SIGNAL-ASSIST SYSTEM IN DIGITAL MEDIA ART INTERACTION

The development of digital experience equipment is a change in the traditional experience mode, it changed the traditional information transfer experience based on audio-visual, and through the use of technology to update the user to receive information and the use of products in the form of the user is no longer satisfied with the experience of a single sense, but more inclined to the "one plus one is greater than two" of the multimodal transport experience. The integration and superposition of multiple senses in the process of digital experience can fully mobilize the user's bodily functions, make the reception of information more interesting, and make the cognition of the experience more real [21]. Typical multimodal digital experience has virtual reality technology, which creates a virtual experience environment to give real cognition to the

human brain. It can directly mobilize the integration of emotional modalities of participants through the basic elements of narrative design law, design, and creation of virtual scenes, real or virtual characters, engaging plot, immersive experience, and real atmosphere in the form of stories so that the experience is repeatedly between abstract and figurative. As a combination of art, technology, and media, digital media art immersive scenography belongs to spatio-temporal art if it is categorized according to the criteria of how the art form exists. The experience is repeatedly spanned between the abstract and the figurative, and feedback is given to the virtual environment through multimodal interaction to enhance the overall sensory experience and make it interesting and intuitive throughout the end of the digital experience.

Digital experience device design integrates a variety of media, including science and technology, experience design, aesthetics, etc. It integrates and restructures new art forms to enrich the expression of art. Through digital and multimedia technologies and forms to enhance the quality of the user's feelings in the experience, the interaction process can enable users to explore their thoughts and behaviors above the basic level of perception to achieve the purpose of integrating emotions and resonance. Digital experience devices can be roughly divided into six technical means, which are interactive visual technology, physical interactive technology, touch interactive technology, virtual augmented reality technology,

mechanical interactive technology, and programming interactive technology [22]. Digital experience device provides new interaction and expression for the user's experience, further stimulates deeper user thinking, strengthens the perception of information, the pursuit of convenience and emotion, and makes the perception effect more towards the real feeling. Digital experience design is different from traditional installation design in that it requires not only the design of physical devices but also software support. The interactive characteristics of digital experience devices are different from traditional art devices and usually require interaction with people. Hardware is the basis for artists and designers to present their ideas, and no matter what kind of artistic expression is used, it should be carried by hardware technology. With the advent of the experience economy and the continuous development of sensory sensing, human body recognition, and tracking technologies, multimodal interaction is gradually used more frequently in creating digital experience design. Traditional physical experience devices have gradually been replaced by digital experience devices, giving users a multimodal interactive experience process consisting of multiple sensory elements that can receive multiple external communication messages and deeper emotional values. The corresponding design strategy is proposed in the design of the museum installation, and the design route of multimodal interaction in digital experience is shown in Fig. 2.

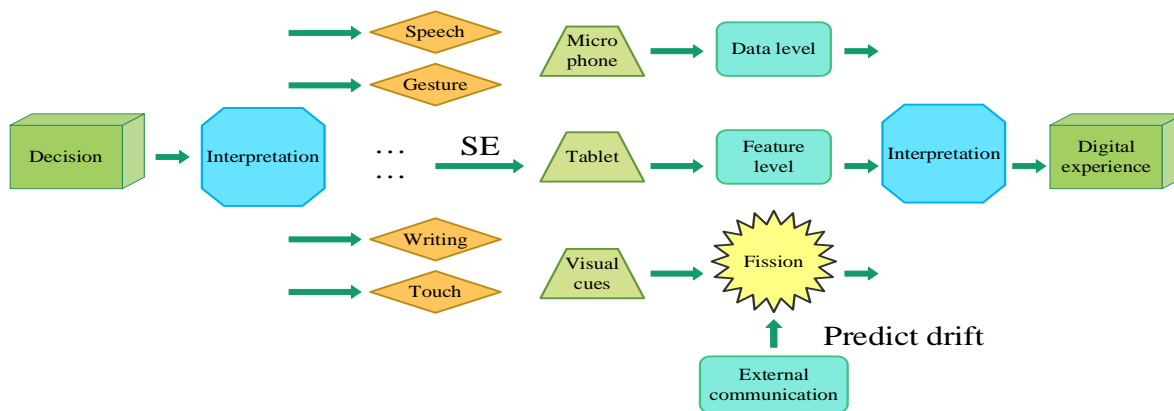

Fig. 2. Design routes for multimodal interaction in digital experiences.

The measurement structure of the capacitive pressure sensor is designed as a differential variable pitch type, consisting of a lower fixed pole plate and an upper half movable pole plate, where the lower pole plate is a silicon substrate covered with a metal oxide film and the upper pole plate is a metal pole plate with a measurement cavity in the middle. The cavity change causes a capacitance change, and the measurement electrode and the driving electrode are led from the two pole plates, respectively. The advantage of using a differential structure is that when the sensor is a non-differential structure, the capacitance value of the capacitor of electrification ($\tau = 1$) is

$$\eta = -\mu \sum_{t=1}^n K_{ij} \Omega_{ij} - K |M_{ij}| \quad (1)$$

When the pole plate is actuated, the plate gap change capacitance is changed $C_y(z)$, i.e.:

$$C_y(z) = C_\mu \cdot \int A \cdot M(x)M(z)dx dz + C_{x0} \quad (2)$$

Then for non-differential structures, the sensitivity is C_y :

$$C_y = C_\mu \cdot \int A \cdot M(x)dx \quad (3)$$

Its nonlinear error b is approximated by:

$$b = (O_k - T_k) \cdot g(k) \quad (4)$$

The comparison shows that using a two-pole differential capacitance sensor is twice as sensitive as a single-pole capacitance sensor and greatly reduces the nonlinear error of the sensor. In addition, the structure also reduces the influence of electrostatic force between the poles and effectively improves the interference caused by environmental factors such as temperature. When the mechanical structure enters the microscopic level, many phenomena that are ignored at the macroscopic level can become factors that cause instability in

the mechanical structure at the microscopic level [23]. For many MEMS devices, the phenomenon of electrostatic absorption is well worth studying. Currently, "workable objects > dynamic visualization > non-workable objects > picture-based static visualization > graphical static visualization > text", from what can be touched to what can be seen in the order of human sensory contact, too abstract, is not popular. Processing involvement and intervention can help users achieve the purpose of human-computer interaction and improve people's experience when they are in contact with digital experience devices. The electrostatic suction phenomenon is the disruption of the dynamic equilibrium of the system when the applied voltage reaches a certain value for the dynamic and fixed poles, and the two poles are sucked together. On the one hand, the existence of the electrostatic suction phenomenon causes instability in measurement. On the other hand, the use of electrostatic force generated by the charge distribution on the pole plates to drive micro devices is also an important research direction.

The control system of the art installation is divided into four modules, including respectively information acquisition module, an information transmission module, a central control module, and a media presentation module, which together build the whole interactive system of the digital art installation and only by combining these four parts can the complete interactive process of the digital art installation be completed. There are many types of information acquisition modules, including simple touch acquisition, sound acquisition, image acquisition, etc., to more complex behavior acquisition, expression acquisition, and other modules. The information transmission module plays a role in the whole digital art installation; when the information acquisition module detects the information, including touch, image, sound, action, etc., it transmits to the central control module through the transmission module, the central control module is also the core part of the whole art installation. It is also the computer's control system, which calculates, processes, and uses the data and programs and then gives them to the media presentation module through the information transmission module. The media presentation module presents the final artistic effect through the media presentation module. The final effect of the media presentation module directly determines the artistic effect of the installation. Using the presentation form of digital media technology can mobilize a variety of senses for the experience, such as using a touch screen to mobilize the sense of touch, allowing the experience to integrate into the art installation or even become part of the installation.

V. A TECHNOLOGICAL APPROACH TO DIGITAL EXPERIENCE IN MULTIMODALITY

Digital experience device design integrates a variety of media, including science and technology, experience design, aesthetics, etc. It integrates and reorganizes new art forms to enrich the expression of art. Through digital and multimedia technologies and forms to enhance the quality of the user's feelings in the experience, the interaction process can make the user explore their thoughts and behaviors above the basic level of perception, to achieve the purpose of integrating emotions and resonance. Digital experience devices can be roughly

divided into six technical means, which are interactive visual technology, physical interactive technology, touch interactive technology, virtual augmented reality technology, mechanical interactive technology, and programming interactive technology [24]. The digital experience device provides new interaction and expression for the user's experience, further stimulates the user to think more deeply, strengthens the human perception of information, the pursuit of convenience and emotionality, and makes the perception effect more towards the real feeling. In emotion computing, the computer does not measure emotions directly. Still, it extracts emotional data by observing external representations of emotions and performs a pattern recognition to infer the current emotional state. Therefore, emotion recognition can be understood as "establishing a mapping relationship between emotional characteristics data and internal emotional states". With the development of augmented reality, mixed reality, and artificial intelligence technology, the future development trend of intelligent sensor-assisted digital media interaction will also be combined and updated with iterations. Emotion modeling is to build a mathematical model to classify and quantify human emotions and then train the model a lot through the emotion database so that the model can recognize various emotions more accurately, so it is the key to emotion recognition.

Interactive cultural creation provides a way of thinking about cultural creation innovation. By integrating cultural and historical knowledge into digital and gamified carriers, users can be inspired by culture through interactive experiences. By injecting the concept of "interactive", we can broaden the form and carrier of cultural creation, change the purpose and thinking of cultural creation development, and upgrade the cultural creation experience, ultimately driving the disruptive innovation of museum cultural creation. The relationship and differences between interactive and traditional cultural creation are shown in Fig. 3

Under the trend of "technology +" and "AI +", the practice of interactive cultural and creative design in museums has taken shape. As a form of cultural creation that focuses on experience, emotional interaction under artificial intelligence is based on the ability to understand and respond to emotional data in interaction, which can precisely give deeper meaning to the cultural creation experience with emotion, thus reflecting the full necessity. Secondly, emotional interaction can gain insight into users' interests, adjust their state, and eliminate frustration; the interactive experience under AI embodies multimodality and initiative and generates natural and real feelings, thus providing more opportunities and possibilities for the interaction design of cultural creation. Through interactive and emotional creative works, the CMA hopes to target the general public with less experience in art appreciation, eliminating their intimidation when facing obscure artworks. An audience survey that examined whether interactive artworks in museums increased engagement showed that 76% of people felt they enhanced their overall museum experience. In comparison, 74% felt it encouraged them to look more closely at the artwork, and those who experienced interactive artworks reported being more willing to delve into cultural history and learn more.

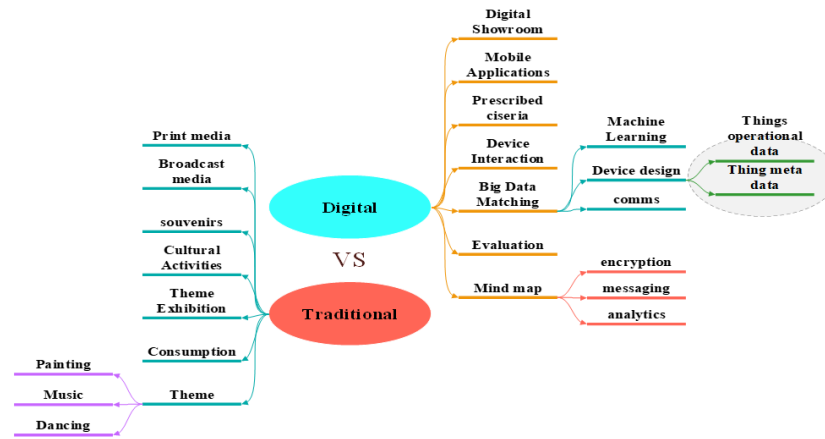

Fig. 3. Relationship and differences between interactive and traditional culture and creativity.

Emotional interaction is the system's mindfulness of human emotions, i.e., the system's mode of understanding human emotions. Emotion computing is the use of artificial intelligence mathematics to calculate human emotions. However, before that, it still requires designers to "specify" emotions in two ways: establishing emotion dimensions and defining key emotions. Establishing an emotion dimension is to describe emotions in a multidimensional and quantitative way [25]. The role of emotion models in emotion recognition is divided into discrete models, dimensional models, and others. The dimensional model can be referred to in emotional interaction design to establish the design dimensions of emotion recognition in performance. Among them, the most recognized and widely used model is the valence-arousal model, based on which the PAD model consisting of pleasure-arousal-dominance is proposed.

Key emotions are scene-related, descriptive words for emotional states, which can be used as typical emotions for emotion recognition and expression of key features. In the emotional interaction design of literature and creativity, first, establish a thesaurus of key emotions; then filter by the degree of emotional granularity (i.e., the degree of detail and complexity of key emotions needed for emotional identification and emotional expression), the greater the granularity, the more specific and clear the description of emotions, and vice versa, the vaguer; it can be described as follows.

$$F(e) = U \omega^e \cdot [K\chi + R\eta]^{-1} \quad (5)$$

Finally, the emotional interaction process is designed based on the key emotions and the stimuli required for emotional expression.

$$F(\gamma) = \sqrt{a^2 + b^2} \cdot c\varpi + \kappa\gamma^d \quad (6)$$

In practical design, key emotions and emotional dimensions can be used in combination. By mapping key emotions to quadrants composed of multiple emotional dimensions, we can ensure that various emotional states are covered and also

facilitate cooperation and communication between designers and developers. Emotional interaction is a new kind of interactive experience, which is very different from the graphical interaction interface represented by smartphones in terms of input and output modalities and elements and the form of emotion recognition and expression. Secondly, the emotional interaction system has artificial intelligence's decision-making and feedback capability. It involves natural interaction modes, such as gestural interaction, somatic interaction, and even brainwave-intentional interaction [26]. Therefore, the factors mentioned above should be reflected in the emotional interaction interface so that emotional acquisition and recognition can be easily perceived and emotional intervention and expression can be easily understood by people.

VI. EXPERIMENTAL VERIFICATION

A. Smart Sensor Calibration Experiment

Using the least-squares method to process the data, the choice of the highest power of the fitted equation also has a significant effect on the accuracy of the pressure sensor. The fitting algorithm was written using Matlab to process the positive and negative travel data of the sensor to generate fitting equations with the highest power of two, three, and four, respectively, and the correlation coefficient of the fitted curve R^2 , which is the degree of similarity between the fitted curve and the actual curve. According to the comparison results, the fitted correlation coefficients are very similar for the highest power of three and four, while the second power fails to meet the requirements. Considering the difficulty of data processing, the highest power of the fitted equation was finally chosen to be three times, and the fitting error was analyzed according to this fitted equation, according to Eq. 7.

$$L = \sum_{(i,j,k) \in D} -\ln \sigma(z_{ij} - z_{ik}) \quad (7)$$

The fitting error of the measured data was calculated using Matlab to obtain the fitting error curve in Fig. 4.

Fig. 4. Fitting error curve.

The resolution is the smallest input signal increment that the sensor is more capable of sensing or monitoring. When the system is running, the sensor to be measured is adjusted to any position after the system is stabilized, and the data from the sensor to be measured is obtained over some time. The installation and measurement process of the smart electrostatic actuated capacitive force sensor is a multi-system fusion installation and measurement process, which theoretically requires a highly stable installation and operating environment. In practice, due to the test conditions, the test bench installation conditions are rudimentary, and the operation process is highly susceptible to vibration, which affects the measurement results and usually takes the form of discarding the data from the previous section. In addition, if there is a deviation in the connection between the sensor to be measured and the displacement element, it will also lead to the elastic deformation of the components, causing abnormal sensor output data. The error is usually reduced by taking the average of multiple data to avoid this situation. Various factors cause noise in the system, and it is also difficult to eliminate, including power quality, component noise, switching noise, system integration of different functional modules cross noise, space magnetic field, capacitance measurement of the noise introduced by the discharge to ground, and the noise in line with the principle of reducing the noise so that it does not affect the measurement results. A filtering circuit is used for each module of the board, the sensor and circuit board are grounded with a metal case, and a twisted shield is used for the

key lines to reduce the noise impact of the above factors. Fig. 5 shows the resolution sampling after correction.

When curve-fitting the sensor output data, the fitted curve does not completely represent the real data, and there is always a certain amount of error present. To reduce the fitting error, the spacing of the collected data is reduced, and the method of fitting higher power terms is improved. In the experiments, fitting polynomials of the highest power three are used to meet the data fitting requirements. The absolute and differential pressure sensors are tested using a portable pressure calibrator. To perform the pressure test, the sensor is connected to the calibrator through a conduit, and the pressure inside it is changed by adjusting the knob of the pressure meter, which in turn leads to changing the pressure value at the detection end of the sensor. Since the interval residual can be regarded as a time-varying detection threshold, the proposed interval residual-based detection algorithm can further address the limitations of the residual evaluation function and a priori threshold in signal processing-based detection methods. Calculating each sensor value can be used as a basis to determine whether the sensor is working properly. Since each sensor value is less than the control limit, the calibration coefficient can be calculated directly using the multiple regression fusion algorithms. Then the data fusion calculation formula is used to calculate Wan. The focus is on the data processing of each sensor. For the sensor, the comparison of the controller display data with the experimentally processed data through simulation resulted in the results shown in Fig. 6.

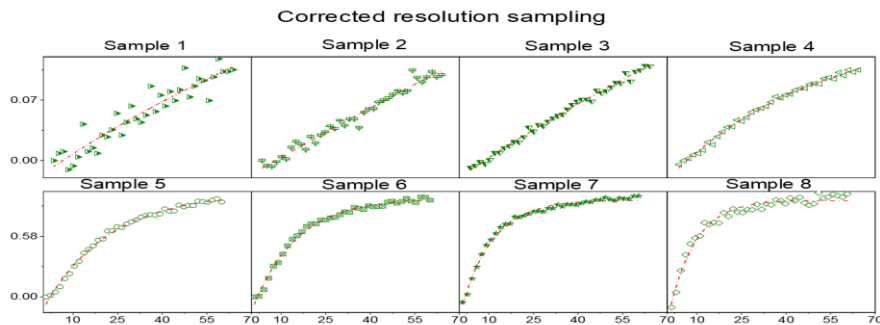

Fig. 5. Corrected resolution sampling.

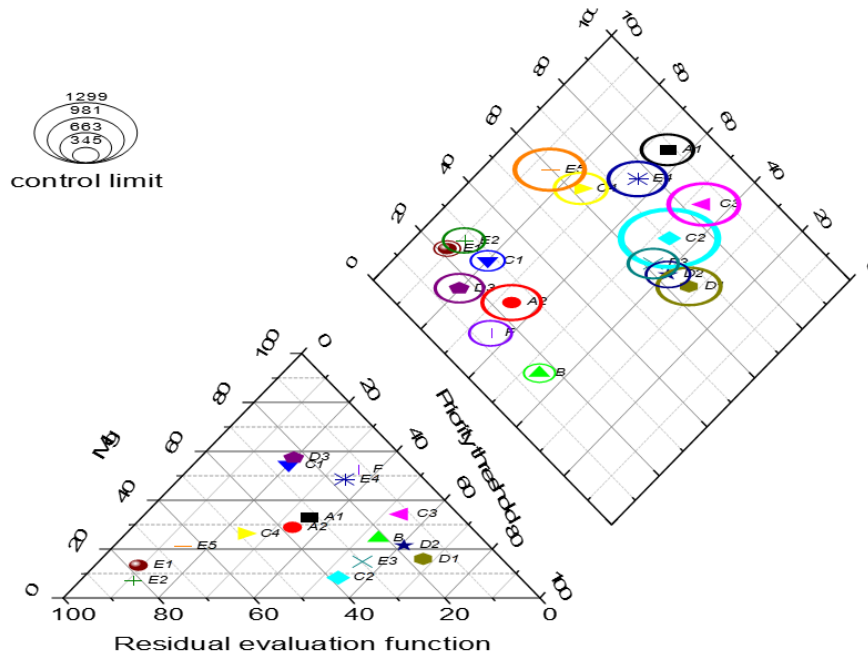

Fig. 6. Sensor residual modulation image.

All components of the common platform should be modularized, including all hardware and software, should use the modular design idea to realize the platform can add or delete components and ensure the least change to other components, mainly to facilitate the secondary developers to be able to customize and tailor the hardware and software according to the actual needs.

B. Smart Sensor-based Digital Media Art Application Field Test

Compared with the traditional design method of creative arts, the intelligent creative arts design implementation process embodies many advantages: First, based on the information collection, opinion analysis, and audience insight capabilities of intelligent sensors, it can more precisely and efficiently locate the emotional interactive creative arts user group, draw a user profile of them, and define the creative arts functions according to the needs and preferences of users. Subsequently, the intelligent design process provides designers with many practical tools. For example, relying on the data brought by museum visitors, AI can help designers filter elements suitable for cultural and creative design from a large number of art resources, which not only makes design elements and design results more in line with users' interests and expectations but also helps expose users to cultural and museum content beyond art exhibits and exhibitions; furthermore, using AI for the content generation to reduce repetitive workload and improve design development efficiency. Based on pattern recognition, AI can evaluate design prototypes and design results, thus becoming a rapid testing tool. In addition, obtaining users' emotional feedback through emotional interactive literature can, in turn, further validate the design and make

improvements in the iteration and serialization of the design. Fig. 7 shows the correlation analysis between emotional performance and interaction behavior.

Fig. 8 shows the construction of the emotional space in which the basic emotions are located. The analysis of the actual data shows that the most dominant affective expressions in affective expressions of the enriched interaction behavior model are positive and agreeable, and the negative and agreeable affective states rarely appear and have no effect on collaboration satisfaction and can be neglected. Therefore, this section focuses on the effect of positive and agreeable effective expressions on collaboration satisfaction in the realistic interaction behavior model. The unstandardized coefficient of the frequency of positive and negative affective performance of the independent variable was 78, significant 18, less than 5, and the constant 86.267, significant 0.000, less than 0.05. The coefficients and constants of the independent variables were significant, using the frequency of positive and negative affective performance as the independent variable for the linear regression of collaboration satisfaction. Emotional interactive creative design by building a library of emotional expression elements so that the system can call all kinds of elements freely according to the results of emotional decision-making. Secondly, by setting the key emotion and emotional dimensions, the intensity and duration of emotional expression of the output elements can be controlled; the scene model is defined to evaluate the effect and impact of the output table elements on the user in that round, and then the emotional interaction system can be adjusted in real-time to ensure that the emotional expression makes the user feel comfortable and natural.

Fig. 7. Correlation analysis between emotional performance and interaction behavior.

Fig. 8. Construction of emotional space in which basic emotions are located.

VII. CONCLUSION

In terms of theory, the user's feeling consists of multiple sensory elements that can stimulate more profound emotional values during the multimodal interaction experience of receiving multiple externally communicated information. In this paper, according to the multimodal interaction experience process, combined with intelligent sensor signal assistance, the multimodal experience hierarchy in digital experience design is divided into three aspects: basic perception, behavior exploration, and thinking connection. The attack detection and separation method based on state observer is proposed from the cybernetic perspective. The design products are designed from three aspects, including the dynamic physical characteristics of the system, residual evaluation function, a priori threshold design, attack separation under structural vulnerability, etc. The design results include the design of a screen device under basic sensing, the design of a seating device under behavioral interaction, and the design of live interactive behavior of digital media art under thinking connection, the three stages are progressive, further stimulating the user to think more deeply. The three stages are designed to stimulate the deeper thinking of the user and to build emotional resonance so that the user can finally understand the designer's ideas and integrate his understanding of the digital experience. Therefore, the design research on the emotional experience of mobile tour system users also needs to be adjusted according to the current development trend. Relevant design strategies also need to be based on the characteristics of cutting-edge digital media forms, targeted adaptation and output of "technology integration" of user interaction experience digital solutions.

Research on Strategic Decision Model of Human Resource Management based on Biological Neural Network

Ke Xu

Cangzhou Normal University, Cangzhou Hebei, 061000, China

Abstract—Human resource management system is an indispensable part of information strategy construction. Based on the theory of biological neural network, this paper constructs the strategic decision model of human resources management, then uses the micro-integration method to predict the demand for human resources, and solves the quantification problem of human resources supply prediction. In the simulation process, the model analyzes the current situation of the personnel management system and the necessity of research and plans and designs a computer-aided personnel management information system based on the Client/Server biological neural network structure. Personnel quality evaluation through the evaluation and analysis of the quality of the evaluated, to provide effective reference information for the enterprise personnel decision and index selection, the enterprise human resources allocation, use, training and development is of great significance. Neural networks rely on the powerful data storage, processing and computing capabilities of computers to help enterprises respond quickly to changes in external market conditions, improve the efficiency of decision-making, and create greater value for enterprises. Through experimental testing, it is found that when the iteration is 5, the network verification results have the best consistency. When the iterations reach 7, the standard of training target error set in this paper is reached. When the samples reached 60, the screening accuracy of the network reached 92.18%; when the samples increased to 80, the screening accuracy was further improved to 92.84%, indicating that the screening accuracy of the network increased with the training samples, which could be used to detect and classify samples quickly, objectively and accurately.

Keywords—Biological neural network; human resources management; strategic decision making; index selection

I. INTRODUCTION

With the gradual improvement of biological neural networks, the use of biological neural networks to establish a comprehensive evaluation system can often achieve unexpected results [1]. Especially for the comprehensive evaluation of those systems with many evaluation objectives and complex relationships between the objectives, the biological neural network model can often achieve better results [2]. There are many mature methods for a systematic, comprehensive evaluation, such as the fuzzy evaluation method, grey system evaluation method, AHP (Analytic Hierarchy Process) and so on [3-5]. Using the analytic hierarchy process to determine the weight can weaken the human factor [6]. Still, AHP requires that the elements in the

hierarchical structure system of indicators are independent of each other [7]. Otherwise, this method cannot be applied. Still, there is often a dependency relationship between these indicators [8].

The key and difficult point of the human resource planning scheme design is the choice of the human resource forecasting method. The development and management of human resources is the essence of labour and personnel management and the core work of enterprise management [9-11]. Human resource planning is the business foundation of human resource development and management. Without reasonable and supporting human resource planning, any plan can only be a piece of paper [12]. Many enterprises lack systematic operation of their human resources, which will inevitably affect the development of human resources and the improvement of labour productivity [13]. Therefore, companies should raise awareness of the importance of human resource planning. By using this system, the personnel department can promote the standardized management of the personnel department and improve the management efficiency and level; it can conveniently and quickly organize and manage the personnel information originally scattered in various departments and provide reliable data for the scientific decision-making of the unit [14].

Based on the biological neural network theory, this paper constructs a strategic decision-making model for human resource management. First, on the basis of analyzing the characteristics of the enterprise and the basic types of human resource strategy, the basic classification of the human resource strategy of the enterprise is determined. Secondly, it extracts four dimensions for the index, uses the method of biological neural network analysis to take indicators of human resources, and then builds the enterprise's human resources strategic decision-making index system. Finally, it takes S company as an example to carry out empirical research. Through comparison, grey forecasting technology and neural network forecasting technology are used to forecast the human resources demand of enterprises. Enterprises can choose one according to their actual situation and then use the micro-integration method to analyze the results and amendments. On this basis, the article applies the current situation verification method and the biological neural network prediction to the enterprise human resources supply forecast, analyzes and demonstrates the applicability. It provides a relatively novel and effective forecasting method for enterprises to carry out human resource planning.

II. RELATED WORK

The focus and difficulty of human resource planning for enterprises is human resource forecasting, and the forecasting method should be selected according to the characteristics of the enterprise [15]. Due to the lack of a relatively mature set of personnel scheduling procedures, it is impossible for enterprises to predict personnel needs reasonably. Therefore, an important part of their human resource planning is establishing a forecast model of enterprise human resource supply and demand [16].

The management system is not combined with the actual needs of human resource management. Still, it is only professional research and development and does not systematically and comprehensively cover human resource management content. Kouhalvandi [17] proposed a dual-objective binary integer programming (BOBIP) model in a fuzzy environment to obtain the best results of person-post matching, calculate the fuzzy utility similarity function to measure the satisfaction of employment outcomes and adopt a mixed integer programming model which realizes two-way matching between enterprises and students. Chen [18] also constructed an evaluation index system with scientific and technological personnel as the research object and proposed a fuzzy comprehensive evaluation model based on ANP (Analytical Hierarchy Process) to realize the matching grade evaluation of scientific and technological talents. Comparatively speaking, this paper summarizes the factors affecting employee dismissal from the three levels of individual, organization and environment, defines the sources of employee dismissal risk, and then combines the characteristics of employees at the beginning of their career with the advantages of sensitivity, relative independence, extensive, measurable, comparable and operable.

In the study of the matching between people and organizations, Falah [19] pointed out that when the ability of the individual is what the organization needs, the matching between the two can be achieved; if the organization can meet all the needs of the individual, it can also promote the matching between the two parties. The situation's impact includes employees' job selection, career planning, etc. Chen [20] believes recruiters are most concerned with selecting candidates with the required knowledge, skills, and attitudes. In contrast, this paper attempts to use the artificial neural network itself has the characteristics of parallel data processing, good fault tolerance, self-adaptation and self-learning, and better nonlinear function, so as to systematically analyze the enterprise personnel quality structure, which is more generic and concise. Based on the general competency model, some scholars combine AHP and fuzzy proximity to calculate the efficiency matrix of each employee and use the assignment model to achieve the best match between all employees and positions in the enterprise [21]. Workflow mainly realizes the transfer of work between the business process participants. Comparatively speaking, this paper selects several early warning indicators of turnover risk to form an early warning index system of turnover risk. Then, on the basis of the status data of early career risk warning indicators, the principal

component analysis method is used to propose the early warning index of turnover risk for employees at the beginning of their career, and the index system is more perfect and streamlined [22-24].

III. CONSTRUCTION OF A STRATEGIC DECISION-MAKING MODEL FOR HUMAN RESOURCE MANAGEMENT BASED ON A BIOLOGICAL NEURAL NETWORK

A. Biological Neural Network Hierarchy

For the enterprise performance evaluation system based on the biological neural network, here is the performance evaluation of the customer representative index of the enterprise customer centre as an example. To evaluate the performance of the customer representative, as long as the performance indicators and relevant data of the customer representative are input into the trained network, the corresponding output, that is, the performance score $s(i, j)$ of the customer representative, can be obtained.

$$\sum p(i, j)/p(i) = 1 \quad (1)$$

$$s(i, j) = \sum a(i)x(i) + w(i)w(j) \quad (2)$$

After the network $w(i)w(j)$ is trained, that is, after the weights of the nervous system are determined and the structure is stable, new data can be processed. The corresponding comprehensive evaluation results can be given. With reference $1-y(t)$ to the set judging standard, the performance $z(x, y)$ of the customer representative can be automatically determined according to the score.

$$z(x, y) \in z(y(t) - x) + z(1 - y(t) + x) \quad (3)$$

$$\sum x(i, m)/x(i) = x(i)/x(m) \quad (4)$$

The neuron transfer function $x(i)$ in the middle layer of the network $x(m)$ adopts the sigmoid tangent function tansig . This is because the output of the function lies in the interval $[0, 1]$, which just meets the requirements of the network output. The training function uses the trainlm function $d(m, mt)$.

$$d(m, mt) = (y(t) - c(t)) * c(mt - 1) - c(1 - m) \quad (5)$$

The network modelling principle $y(t)-c(t)$ is that when the input vector is farther away from the weight vector, the output of the radial base layer is closer to 0, and the output of the linear layer is less affected; and when the difference between the vectors is 0, the output of the radial base layer is 0. For the specific design and implementation of the network, the modelling function in Fig. 1 can be used to output the function.

15 enterprises were randomly selected to form the sample population. The model evaluates the natural distribution of the status of 15 samples under 20 primary selection indicators and, according to the evaluation results, divides them into five levels: very poor, poor, fair, good and very good. The influencing factor of the department is the state of human resources itself, which can be divided into two second-level indicators. The remaining 8 indicators of environmental conditions constitute the primary selection indicator set for enterprise human resources strategic decision-making.

Fig. 1. Distribution of biological neural network indicators.

B. Composition of Human Resource Factors

Through investigation or asking experts to tick the factors of each level of human resource evaluation indicators (important, relatively important, less important, and unimportant), the comprehensive judgment matrix and single-factor evaluation matrix are determined according to the corresponding percentage. Then it can find out their closeness to the fuzzy comprehensive evaluation matrix. According to the principle of choosing the closest, finding the weight vector closest to the comprehensive evaluation matrix is a more realistic weight distribution scheme. When encountering the situation that the solution $b(i)x(i)$ of the fuzzy equation is not unique, there is no better method to select which set of solutions to use as the weight vector $\exp(1-x)$.

$$\sum b(i)x(i) - a(i)x(1 - i) = \exp(1 - x) \quad (6)$$

$$d(x, x') < v(x)t(1 - bx) - v(x')t(1 - ax) \quad (7)$$

In terms of hardware, it means a network computing environment consisting of desktop computers, networks and servers. The meaning of software $d(x, x')$ mainly refers to that a software or application system $t(1-ax)$ is designed as a complex system containing many components, these software components can even be distributed on different machine nodes in the network $\text{rest}(s, t)$, and according to the relative roles of the software components are divided into "Client" and "Server", the client software can request the services of the server software.

$$\text{rest}(s,t) = \{s(i), s(i-1), \dots, s(2), s(1), s/k(s, t^{i-1})\} \quad (8)$$

$$\sum n(i,j)t(i)/t(i-1) = 1 - p(i)/p(j) \quad (9)$$

In the C/S (Client/Server) system, the client $n(i, j)$ always makes a service request to the server first, and the server responds to the client's request $1-p(i)/p(j)$ before sending the service result back to the client. The server never initiates a relationship with the client. The client can also make requests to multiple servers concurrently. In this sense $c(s, t)$, the client is always active, and the server is always passive, so it is asymmetric.

$$c(s, t) \in \left[\frac{s-1}{s}, \frac{i-t+1}{s-1}, i \right] \quad (10)$$

The number of input/output neuron nodes of the network is determined by the external description of the problem. The number of nodes in the input layer corresponds to the number of indicators of the customer representative index of the enterprise customer centre. The text contains the number of customers per customer representative (CSR), the proportion of time that customer representatives work directly for customers, the number of spy orders completed per customer per day, the average time to access customer representatives, and the increase in air talk time per customer. The output result is the evaluation score of the customer representative's performance.

Fig. 2 specially designs the standard unit comparison assignment method to calculate the importance of the alternative indicators. The method is to assign the importance degree of the least important alternative index to 1, use the multiple a of the importance degree obtained by comparing the other indicators with it as the assignment of the importance degree of each index, and the normalized value is used as a method for the alternative index importance shape. It can be

observed that the error meets the requirements. Therefore, the established biological neural network is safe and meets the requirements. This network can be used to infer and predict the total evaluation value of the performance representative according to the existing customer representative performance indicators. In this way, it can be judged whether the

performance of the customer representative has reached the expected target. This method avoids the unreasonable aspects of setting up the weights of various indicators. At the same time, it is scientific and convenient to use and avoids the influence of human factors on the overall performance evaluation.

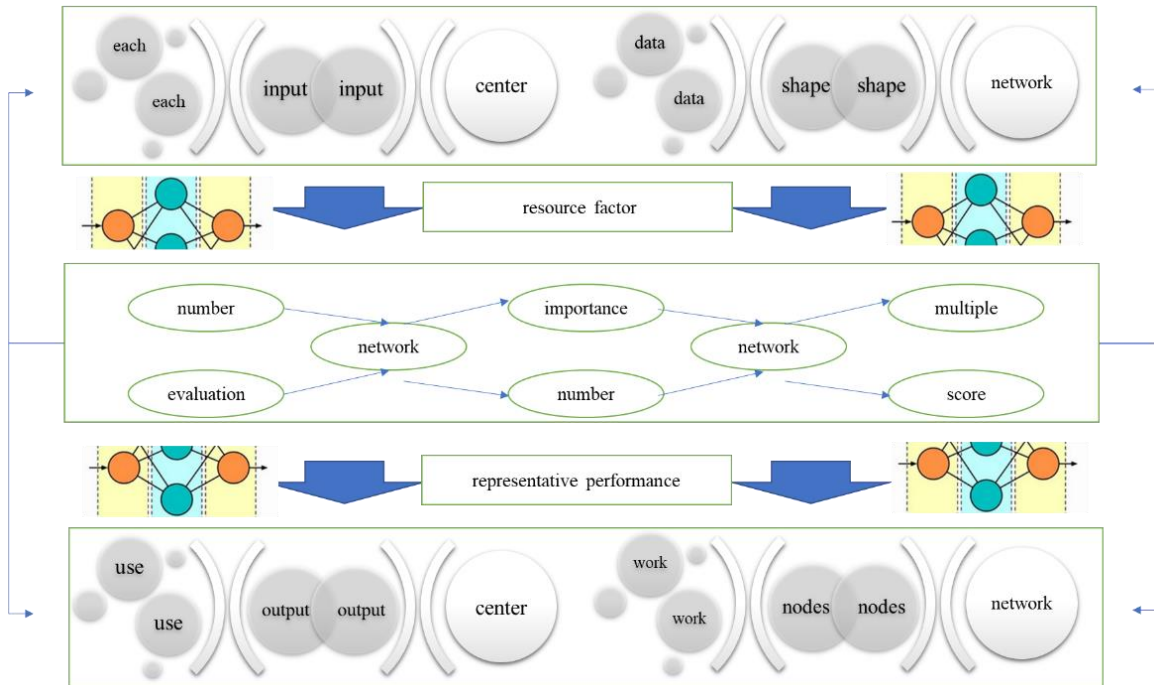

Fig. 2. Human resource factor structure topology.

C. Model Factor Recursion

It can input the model sample matrix data into the MATLAB work window, where the input vector of the training sample is P, the output vector (target value vector) is T, and the input vector of the test sample is PL. After the retraction, a file named P will appear in the workspace window; double-click to open it, and then copy the training sample input value to this file. The MATLAB input matrix takes the employee as the column vector and the factor as the row vector, so in the process of copying, the data s(t, t-1) needs to be transposed before it can be imported into MATLAB so that the matrix e(k)+t of the input vector P is established in MATLAB.

$$s(t, t - 1) = \frac{1}{1 - n} \sum (e(k) + t)^2 + \sum (1 - t)^2 \tag{11}$$

$$\sum_{i=1}^t \left(\frac{Y}{1-r_i} + r - t \right)^2 - \sum \frac{r}{1-r} = 1 \tag{12}$$

The percentage factor 1-r(i) is a method of multiplying the score of each element by the percentage factor that the factor occupies in the total score. Usually, the total score of the four levels of personnel function is expressed by the percentage system, and each element is also evaluated by the percentage system. When measuring, the preliminary score of each factor measured is first multiplied by the percentage coefficient of the factor in the structure. The element score is obtained, and the

scores of each element in the same structure are added to obtain the preliminary score of the structure and then multiplied by the percentage coefficient 1-t of the structure in the total score p(t|1<t) to give the structure score. The accumulation of the four structure scores is the overall score.

$$|(1 - t)p(t|1 < t) + (1 + t)p(t - 1)| < N(t) \tag{13}$$

$$miu(x, y) = miu(x)miu(y) \tag{14}$$

This paper determines the 5-12-1 network structure miu(x, y) through multiple expert experience judgment tests and derivation max(x-t) of empirical formulas, using tansig as the activation function of the network, the number of training samples is 57, and the test data is 16. Then, the training samples are input into the neural network system for training. After 1205 times of learning, a weighted network with a learning accuracy of 0.000001 is obtained. Then the network is called to simulate the test data set, and the neural network simulation results of the test data are obtained. The design work of the system's front end includes interface development and scripting. The development tool adopts powerbuilder6.0. Interface design is the main work of front-end application design, including input and output design. A total of 90 windows and 83 data windows are established in the implementation process.

TABLE I. FACTOR ANALYSIS OF BIOLOGICAL NEURAL NETWORK SAMPLES

Biological neural network codes	Factor analysis text
Public void deletemajorchange();	Each indicator is evaluated
Return salarydao.getbycondition;	The difficulty of obtaining $x - t$
Long majorchangeid;	Independent of each other $ \Delta x - \Delta x t $
Return majorchangedao;	By means of expert scoring
Getbycondition(hql, o);	In the indicator system $rand(m, n)$
Deletemajorchange;	The representativeness $y - t$
Salarydao.deletesalary(salaryid);	The indicators do not intersect
Get.majorchangedao.(majorchangeid);	If the indicators $p(t 1 < t)$
Changegetadd();	The indicator system can only be $N(t)$
Public list { };	Obtaining alternative indicators
This.changegetadd();	At the same level are $k(s, t^{i-1})$
Return majorchangedao;	And simplicity of $1 - p(i)$

Table I divides the difficulty of obtaining alternative indicators into five levels, namely (easy, relatively easy, general, relatively difficult, and difficult), and the corresponding quantitative values are (5%, 25%, 50%, 75%, 95%). The difficulty of obtaining each indicator is evaluated by means of expert scoring. The indicator system's representativeness and simplicity can only be guaranteed if the indicators at the same level are independent of each other and the indicators do not intersect. After the input of the sample, the system learns according to the minimization rule of the mean square error between the expected output and the actual output, and adjusts the weight matrix and threshold vector. When the error is reduced to the required accuracy, the system will stop learning, and the weight matrix and threshold vector will be fixed and become the internal knowledge of the system, which can be called for decision-making or prediction when it is used next time.

D. Optimization of Strategic Decisions

This paper uses neural network modelling to identify strategic decision candidates for specific positions. The sample data adopts the data provided by a talent evaluation research institution. After a four-year investigation, the evaluation and research institution obtained a total of 1,080 sample data, of which 30 were randomly selected for follow-up investigation. The sample data in this paper is based on the actual needs of neural network modelling. After several discussions and consultations with the institution, 25 sample data were selected. One part is used for modelling, and the other part is used for generalization testing. The error ratios of the three test samples are 4.62%, 8.24%, and 6.86%, respectively, and the errors are all below 10%, which does not affect the final strategic type selection.

Since Fig. 3 aims to explore the specific application of neural networks in talent evaluation, a conventional neural network algorithm is used, and the neural network toolbox (Neural Network) can greatly facilitate the network design process, so this paper uses MATLAB neural network toolbox. The degree of fitness for a job can be described by a single output network. Therefore, the number of output layer units is set to 1. The number of input neural units is determined according to the number of influencing factors; 6 units are taken. The algorithm operation platform adopts MATLAB. Among the 25 sets of data, 18 sets are selected as training samples, and 7 sets are used as generalizations.

Similarly, the data matrix of the output vector T can be established: enter T=zeros (5, 20) in the MATLAB command workspace; after the retraction, find the T file in the workspace window and double-click to open it. Unlike the input of P, the T vector matrix must be manually input. Since the MATLAB input matrix uses employees as a column vector, it is necessary to input according to each column, and each employee has a different output value (level). There are different input forms for each level.

Fig. 3. Strategy decision optimization network design results.

IV. APPLICATION AND ANALYSIS OF HUMAN RESOURCE MANAGEMENT STRATEGIC DECISION MODEL BASED ON BIOLOGICAL NEURAL NETWORK

A. Preprocessing of Biological Neural Network Data

According to the requirements and characteristics of the biological neural network, after the test, feedback adjustments were made according to the test results, and necessary modifications and additions were made to the indicator system. Various quality content is tested separately to obtain closer to the real evaluation results. 120 samples collected in this paper were distributed to A1, simulating the situation in which enterprises were subjected to many CVs (curriculum vitae). After all, samples are marked and numbered in Fig. 4, the top 20 (screening rate $P=20\%$) best talent resumes are screened out using the traditional resume screening method with reference to the weights of each indicator determined by the business owner in the step.

The goal of the early-career employee dismissal risk early warning system is to realize the evaluation of employee dismissal risk status on the basis of the collection of employee dismissal risk information, output the dismissal risk early warning signal, clarify the source of risk, propose risk treatment countermeasures, and achieve the elimination of risk status or take countermeasures to reduce the loss caused by employee dismissal. At the same time, it can be clearly seen that although samples 1 and 2 are in the same matching level, sample 2 has a higher degree of membership than sample 1 for the evaluation level of person-post matching, so it can be judged that sample 2 has a higher degree of membership. The matching degree is better than the No. 1 sample. According to the evaluation results of the matching degree of people and positions of the samples, it can be known that samples No. 1-2 show a good degree of matching. In contrast, the matching degree of sample No. 2 and the position of the project director is not good. The human resources management department can consider implementing it when necessary. The input process

should be as simple and clear as possible to reduce the occurrence of errors, and the input system should have fault tolerance and data verification functions. For example, in the input interface, the basic information of employees is concentrated in one interface, which can not only avoid repeated input of information, reduce the input work scene, but also maintain the consistency of data; use the selection method to standardize the content to make it simple and convenient to fill in, use the Tab control to achieve file cabinet entry, the Tab control can organize a large amount of information or controls in a small space. Using the Tab control and DataWindow filtering function, a large amount of information is concentrated in one window, which is convenient for user management and more efficient than the general method.

From the experimental results in Fig. 5, it can see that the screening method based on a biological neural network is superior to the traditional screening method from the time dimension. After completing all the above steps, MATLAB is used to build a biological neural network, randomly select 2/3 (80) samples from the qualified samples and unqualified samples for training, and the remaining 1/3 (40) samples are used for training. Screening 24 resumes from 120 resumes, the traditional screening method takes nearly 50 minutes. Under the same experimental conditions, the resume screening method using the biological neural network only takes 1 to 2 minutes. In the actual medium and large enterprises or talent market, talents are often screened from thousands or even more resumes. Therefore, with the increase in the number of resumes, the method in this paper can save double the time cost. To sum up, when predicting, it is necessary to determine a smooth factor of an appropriate size so that the dependent variables of all training samples can be fully learned and the distance between different training sample points and prediction samples is considered. The smaller the distance between the samples, the larger the corresponding weight of the dependent variable, which in turn helps the network to make better generalization predictions for new samples.

Fig. 4. Biological neural network data matching.

Fig. 5. Screening results of biological neural network.

B. Human Resource Preparation

There are many factors that affect the value of human resources establishment, and which indicators are used to evaluate human resources have a great impact on the accuracy of the results. In this example, seven-factor indicators are used to evaluate the value of human resources, some of which also include secondary indicators, and the seven categories of indicators are selected by the method of clustering, which is scientific to a certain extent. But there are also some defects, such as salary income and other factors that affect the value of human resources are still not included. Therefore, the establishment of a complete set of indicators and factors that can fully reflect the value of human resources is crucial for scientifically and rationally evaluating the value of human resources. By designing and distributing questionnaires (resumes), this paper finally obtained a total of 123 sample data. After preliminary sorting and screening of the data, 3 samples that did not meet the requirements were eliminated.

All data are placed in the whole network. Fig. 6 performs linear regression on the actual output of the network and the corresponding expected output. It is found that the overall output value tracks the expected value better, and the corresponding $R=0.97822$, which is very close to 1. Spring realizes the specific business logic processing work and the scheduling and distribution of the processing results. The presentation layer is responsible for the encapsulation and transmission of the request object and the display of the feedback results, and the specific interaction with the database is processed through the persistence layer objects. Although the templates in Spring implement the encapsulation of some database operations, the specific processing is still implemented by Hibernate. After Hibernate processes the data, the results are handed over to Spring Business processing for processing. The interaction between the framework and the database is done through Hibernate, which is the persistence layer. For the operation request from the presentation layer, first, submit the request to the business logic layer where Spring is located for processing.

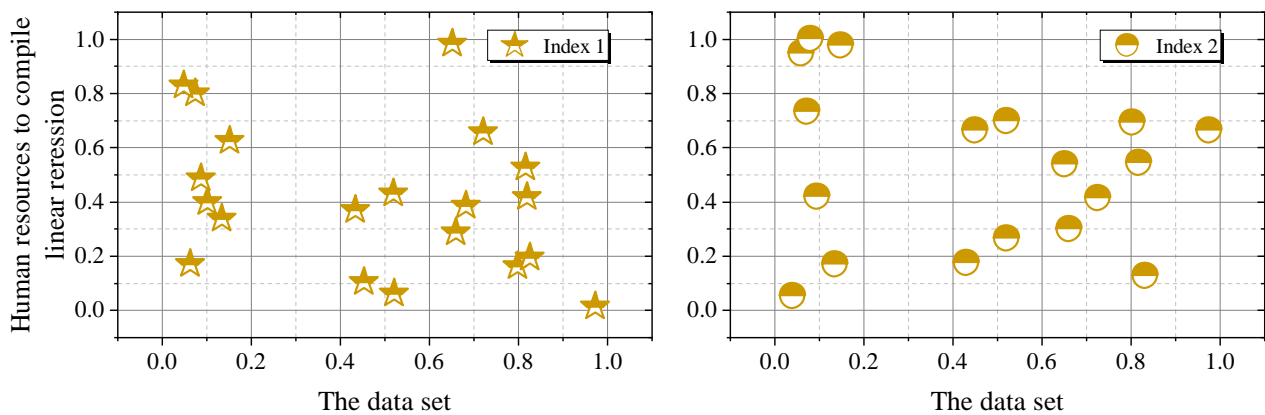

Fig. 6. Linear regression of human resource staffing.

C. Strategic Decision Simulation

This strategic decision evaluation project has adopted various means such as knowledge examination, psychological quality test, interview, simulated performance technology and other means to conduct a comprehensive quality inspection of the assesees. After selecting suitable personnel for the test, feedback adjustment was made according to the test results, and necessary modifications and supplements were made to the index system. Fig. 7 is to organize the data of this evaluation according to the requirements of the aforementioned neural network model and divides it into two parts, the neural network quality evaluation model learning sample set and test sample set, and conduct empirical analysis. It is hoped that the network model can pass the learning to absorb the judgment experience of experts.

The size of the network is the most critical. Usually, the number of samples is at least more than the number of network connection weights and generally requires more than 5 to 10 times. Especially for a three-layer biological neural network, the number of samples must be greater. Otherwise, the network must have redundant nodes, and the systematic error is independent of the characteristics of the training samples and tends to be 0; the network has no generalization ability at all. The value of the smoothing factor is very important and has a great impact on the approximation accuracy and prediction effect of the generalized regression network. If x is very large, y is close to the mean of all training sample dependent variables; conversely, if x is close to 0, y is close to the value of all training sample dependent variables. Therefore, when the sample to be predicted happens to be within the learning range of the training sample, the calculated predicted value will be very close to the expected output. Still, once a new predicted sample is not included in the learning range of the training sample. Then the prediction effect will be significantly reduced, and the network's generalization ability will be significantly reduced.

D. Example Application and Analysis

This paper uses the biological neural network optimization algorithm, the hyperbolic tangent Sigmoid function \tanh is used as the transfer function between the input layer and the hidden layer, the purelin linear function is used as the function between the hidden layer and the output layer, and the trainlm

function is used as the training function, set the error to 0.0001. After three iterations, the network error reaches an acceptable range, and the established network tends to be stable. Finally, the evaluation indicators of the group personnel quality evaluation project were generally determined as major items, and each item was divided into various quality contents for testing respectively, in order to obtain the evaluation results closest to the truth. In the Network/Data Manage window, click it to train the network, select the input vector p from the "Inputs" drop-down list, select the target vector from the "Targets" drop-down list, and train in the training parameter settings in Fig. 8. The number of steps "epochs" is 50, the training goal "goal" is 0.01, and the rest are default items.

The integration between the WebWork presentation layer and the control layer Spring is mainly carried out through two steps: the first step is to initialize Spring when WebWork is used; the second step is to configure Spring while configuring WebWork. All business processing or action processing is unified by Spring. The core of the Spring framework is dependency injection. The implementation of dependency injection in this system includes aspects: injecting data source management and transaction management and injecting interface implementation classes. Through the injection of various interfaces, the unified database operation management of all action processing by transaction management can be realized. The implementation of specific dependency injection is achieved by configuring actions in xml. After obtaining the sample data, the "factor scoring method" is used to evaluate and score each sample. The evaluation results have only two cases, namely 1 or 0. 1 means that the sample is qualified, it means that it has entered the interview process through the audition stage, and 0 means that the sample is eliminated. Compared with the reference [25-27], the artificial neural network used in this paper has a better nonlinear function. This quality evaluation project adopts various means such as knowledge examination, psychological quality test, interview and simulation performance technology to conduct a comprehensive quality investigation of the interviewees. In the process of assessment, the data are sorted according to the requirements of the aforementioned neural network model and divided into two parts as the learning sample set and the test sample set of the neural network quality assessment model for empirical analysis.

Fig. 7. Strategic decision-making neural network training.

Fig. 8. Biological neural network optimization settings.

The errors of the network simulation results in Fig. 9 are controlled below 5%, and a good evaluation effect has been achieved. The sample evaluation is carried out by the method of "expert evaluation". The model finds 2 entrepreneurs in the field, comprehensively considers the pros and cons of each sample according to the weight distribution, and evaluates all samples as "qualified" or "eliminated". In order to further simulate the real scene of enterprise recruitment, it assumes that the screening rate is $P=0.2$ (Enterprises can set the parameters of P by themselves). Companies need to select the best top 20% of resumes from the 120-point resumes. In the end, the top 24 best samples and 96 less excellent samples were selected. After testing, it is found that the trained biological neural network can detect and classify samples quickly, objectively and accurately. This shows that the neural network method can fully absorb the judgment experience of experts and make more accurate judgments on the test data, which

confirms the availability and accuracy of the biological neural network method.

E. Discussions

According to the analysis of neural network, it can be clearly seen that in the application of BP neural network model in the company, although the output value of BP network is relatively low, on the whole, it fluctuates slightly between the satisfactory value, and the stability is relatively high [28-30]. This paper believes that the decision requirements are met. From the perspective of the prediction effect of the test set, the training effect and accuracy of the improved generalized regression neural network proposed in this paper are higher than that of the generalized regression neural network model, which proves the feasibility of the neural network model proposed in this paper for man-post matching evaluation.

Fig. 9. Error distribution of human resource management strategy network.

V. CONCLUSION

In this paper, a strategic decision-making model of human resource management based on a biological neural network is constructed. On the basis of planning the organizational structure of the enterprise, an enterprise human resource planning scheme is designed. First of all, the model starts from the function of the personnel management system, studies various talent evaluation methods, and tests the learning ability, adaptive ability and function approximation ability of biological neural networks. Secondly, a competency-based enterprise project director personnel-post matching evaluation index system was established, including 5 first-level indicators and 8 second-level indicators of knowledge skills, goal planning, plan promotion, social roles, attitudes and values. In the process of resource management, the process is not standardized, and the degree of information sharing is low. Through the analysis, design, development and implementation of the needs of the target unit, the human resource management system suitable for the company is completed. Finally, an example uses the generalized regression neural network model to conduct a comprehensive evaluation and empirical research on the matching of enterprise project directors and positions. It uses the MATLAB toolkit to complete the specific application of biological neural network modelling in talent evaluation and achieves good results. The training (learning) of biological neural network depends on the original data, which means that the accuracy of neural network simulation is also limited by the accuracy of the original training data, resulting in a significant decrease in the training efficiency of neural network and the accuracy of simulation results. To solve this problem, the method of anonymous participation is adopted, the cost-benefit principle is considered, and some weights are assigned respectively, so as to obtain the final weighted average score of each employee. To a certain extent, the scheme avoids the influence of internal personnel's personal bias on the accuracy of the original training data, and is more conducive to the training of neural networks.

Abstract—Recognizing emotions from visual data, like images and videos, presents a daunting challenge due to the intricacy of visual information and the subjective nature of human emotions. Over the years, deep learning has showcased remarkable success in diverse computer vision tasks, including sentiment classification. This paper introduces a novel multi-view deep learning framework for emotion recognition from visual data. Leveraging Convolutional Neural Networks (CNNs) this framework extracts features from visual data to enhance sentiment classification accuracy. Additionally, we enhance the deep learning model through cutting-edge techniques like transfer learning to bolster its generalization capabilities. Furthermore, we develop an efficient deep learning classification algorithm, effectively categorizing visual sentiments based on the extracted features. To assess its performance, we compare our proposed model with state-of-the-art machine learning methods in terms of classification accuracy, training time, and processing speed. The experimental results unequivocally demonstrate the superiority of our framework, showcasing higher classification accuracy, faster training times, and improved processing speed compared to existing methods. This multi-view deep learning approach marks a significant stride in emotion recognition from visual data and holds the potential for various real-world applications, such as social media sentiment analysis and automated video content analysis.

Keywords—Deep learning; emotion recognition; feature extraction; machine learning; sentiment analysis; visual data

I. INTRODUCTION

Emotion recognition from visual data sets, encompassing images and videos, has emerged as a complex and captivating challenge that has garnered increasing attention from computer vision and machine learning. The accurate classification of emotions based on visual cues holds the potential for a multitude of practical applications in the real world, such as social media sentiment analysis, targeted advertising, and automated video content analysis [1]. Deep learning techniques, particularly Convolutional Neural Networks (CNNs) and Re-current Neural Networks (RNNs) have showcased remarkable prowess in various computer vision tasks, including sentiment classification [2]. These advancements in deep learning have opened new avenues for tackling the intricate task of emotion recognition from visual data, fueling optimism for its transformative impact across diverse industries and domains.

The extraction of features from visual data relies on deep learning architectures, particularly Convolutional Neural

Networks (CNNs), which scan images or videos to identify patterns as shown in Fig. 1. These CNNs consist of multiple layers, each responsible for extracting distinct features from the input. Basic features like edges or lines are captured in the initial layers, while higher layers discern more intricate and abstract features associated with diverse objects or emotions [3]. Subsequently, these extracted features undergo classification through a trained model designed to recognize patterns and make predictions. The feature extraction process is iterative and automatable, empowering the CNN to adapt and learn from novel visual data, resulting in improved accuracy and efficiency for visual tasks, including sentiment classification [4]. While current deep learning methods have shown promise in emotion recognition from visual data, they have limitations. These limitations encompass a range of factors that collectively impact these models' overall performance and usability. One significant drawback is their limited generalization ability across diverse datasets and real-world scenarios. Emotions can be expressed in various ways across different cultures, contexts, and individuals, making it challenging for deep learning models to capture and interpret these nuances consistently and effectively. The quest for higher classification accuracy remains ongoing. While deep learning models have demonstrated substantial progress in recognizing basic emotions like happiness and sadness, they often struggle with more complex emotional states that involve subtle variations in facial expressions, body language, and contextual cues. This deficiency in accurately deciphering nuanced emotions impacts the overall reliability of these models, particularly in applications where precise emotional understanding is paramount.

Many deep learning architectures demand extensive computational resources and time for training, which can be impractical for Real-Time or resource-constrained applications. Additionally, the need for vast amounts of annotated data for training can become a bottleneck, as obtaining accurately labeled emotional datasets on a large scale is a resource-intensive and time-consuming endeavor. As such, there is a persistent demand for developing more efficient and effective deep learning techniques tailored explicitly for emotion recognition from visual data. Addressing these limitations requires innovative approaches that focus on enhancing generalization capabilities, refining accuracy across diverse emotional spectra, and streamlining training processes. By harnessing the potential of deep learning while mitigating these constraints, researchers and practitioners can usher in a new era of emotionally intelligent

technologies that better understand and respond to human emotions across various applications.

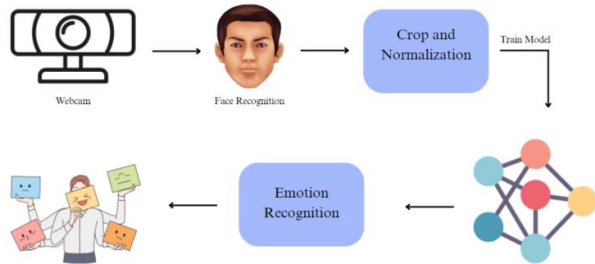

Fig. 1. Block diagram representation of sentimental analysis employing deep learning approach.

The proposed framework seeks to address the limitations encountered in current deep learning methods and enhance sentiment classification accuracy. Our approach involves the integration of CNN-based deep learning architecture to extract features from visual data sets, harnessing their unique strengths to complement each other. We enhance the deep learning model using advanced techniques, including transfer learning, to enhance its ability to generalize effectively. By combining these strategies, our framework aims to significantly improve sentiment classification accuracy, paving the way for more reliable and efficient sentiment analysis from visual data. In addition to the architectural enhancements proposed for improving sentiment classification accuracy, another crucial aspect that our framework addresses is the issue of data diversity and bias. Emotion recognition models heavily rely on the availability of diverse and representative datasets to ensure robust performance across various demographic groups and cultural contexts. However, many existing datasets used for emotion recognition may exhibit biases in terms of under representation or misrepresentation of certain emotions or demographic groups. To mitigate this challenge, our framework emphasizes the importance of curating and maintaining well-balanced datasets encompassing a wide spectrum of emotions and demographic characteristics. By training the CNN-based model on such comprehensive datasets, we aim to reduce biases and accurately enhance the model's ability to recognize emotions across different scenarios and user groups.

Likewise, the real-world application of emotion recognition systems requires careful consideration of ethical implications and privacy concerns. As these systems can potentially extract sensitive emotional states from individuals, there is a need to establish clear guidelines and safeguards to prevent any misuse of this technology. Our proposed framework acknowledges the significance of ethical considerations and promotes the integration of transparency and accountability measures within the model development process. This includes adopting explainable AI techniques to provide insights into how the model arrives at its predictions and allowing users to have control over their data and the inferences drawn from it. By embedding ethical considerations into the core of our approach, we aspire to ensure that responsible and trustworthy deployment practices accompany the benefits of improved sentiment classification from visual data.

Our proposed framework aims to enhance emotion recognition from visual data using a synergistic approach that combines Convolutional Neural Networks (CNNs) and advanced techniques like transfer learning. By addressing current limitations in deep learning methods, we seek to achieve more accurate sentiment classification from images and videos by considering the following objectives:

- **Architectural Fusion for Enhanced Feature Extraction:** Our first objective involves the integration of CNN-based deep learning architectures to extract intricate features from visual data.
- **Mitigating Bias and Ensuring Ethical Deployment:** The second objective focuses on dataset diversity and ethical considerations.

The structure of this paper is meticulously designed to present a cohesive progression of our research endeavor. It begins with elucidating the background setting the stage by highlighting the challenges and opportunities inherent in emotion recognition from visual data. Following this, the paper delves into a comprehensive literature survey that encapsulates existing knowledge related to deep learning techniques, emotion recognition, and sentiment analysis. The subsequent section meticulously outlines the experimental setup, providing details about the chosen visual datasets, the architecture of the employed CNNs, and the incorporation of transfer learning techniques. Finally, the paper culminates with an exhaustive presentation of the results and their subsequent discussion.

II. BACKGROUND

Sentiment analysis has undergone a substantial evolutionary journey, as depicted in Table I. This historical progression spans from the early rule-based systems to the emergence of deep learning models and multimodal analysis techniques. Throughout its development, sentiment analysis has evolved to embrace more sophisticated methodologies, empowering the analysis of emotions and opinions with increasing precision and complexity.

Sentiment analysis plays a crucial role across various industries and for individuals, and its absence would result in severe negative impacts on different aspects of society [5]. In Business and Marketing, understanding customer's perceptions and opinions about products or services through sentiment analysis is indispensable. With it, businesses could leverage customer feedback, leading to a decline in product improvement and effective customer service, ultimately affecting customer satisfaction and revenue [6]. In Politics, grasping public sentiment is pivotal for political parties to understand better their constituents, and government organizations can utilize sentiment analysis to gauge the public's response to policy decisions or changes. In Healthcare, sentiment analysis proves valuable in monitoring and analyzing patient emotions, particularly in mental health and rehabilitation, enabling timely interventions for depression or anxiety [7]. Social Media platforms heavily rely on user engagement and sentiment analysis to analyze feedback, identify trends, and offer personalized content. The absence of sentiment analysis could hinder their ability to

provide tailored recommendations and insights based on user preferences. In the Entertainment industry, sentiment analysis is used to comprehend audience preferences, leading to content customization and improved user experiences [8]. Its absence may hinder the efficiency of content creation and

distribution. Overall, sentiment analysis is essential for informed decision-making in businesses, politics, Healthcare, social media, and entertainment, impacting society and individuals profoundly.

TABLE I. HISTORICAL PERSPECTIVE OF SENTIMENTAL ANALYSIS

Timeline	Approaches	Description
Pre-2000s	Early Sentiment Analysis Techniques	These techniques used simple rule-based systems to generate sentiment scores for texts based on the presence of certain keywords or phrases with positive or negative connotations.
2000s	Machine Learning-Based Approaches	These techniques relied on natural language processing (NLP) and machine learning algorithms to analyze text data. They used supervised learning algorithms such as Naive Bayes, SVMs, and decision trees to classify text into positive, negative, or neutral.
Mid-2000s	Aspect-based Sentiment Analysis	The underlying concept of this approach involves conducting a detailed analysis of text data, delving into a more granular level. It accomplishes this by dissecting the overall sentiment of a text and discerning the sentiment associated with each specific aspect within the text.
2010s	Deep Learning-Based Approaches	Deep neural networks, including Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), were employed in these approaches to extract features from text data and accurately classify the overall sentiment expressed in the text.
Current	Multimodal and Cross-lingual Sentiment Analysis	These approaches aim to analyze sentiment in multiple languages and through different modalities (text, audio, and gesture recognition). This new approach is built on machine translation and multitask learning architecture to enable sentiment analysis in languages other than English. This has led to the developing of more advanced models that perform complex multimodal analysis across multiple languages.

Sentiment analysis plays a pivotal role in various sectors, empowering businesses, individuals, and industries to make informed decisions that contribute to improving society and its constituents [9]. With sentiment analysis, valuable prospects for improved customer engagement, tailored content delivery, and favorable outcomes on social and economic fronts might be noticed. This absence could hinder progress, resulting in diminished access to personalized experiences and a potentially detrimental impact on societal well-being and economic growth. The integration of sentiment analysis thus emerges as a crucial tool with far-reaching implications, offering a proactive means to harness sentiment insights for the collective benefit.

III. LITERATURE REVIEW

Sentiment analysis is gaining popularity as a prominent research area within natural language processing, attracting numerous studies. Initially, the field relied on rule-based methods to determine the sentiment of texts using specific keywords or phrases [10]. Yet, the effectiveness of these approaches was constrained by their inability to grasp intricate language nuances and variations, prompting the exploration of more advanced techniques. Subsequent research in sentiment analysis witnessed a shift towards machine learning-based approaches, where supervised learning algorithms were utilized to categorize text into positive, negative, and neutral classes [11]. These methods demonstrated improved performance compared to rule-based techniques; however, they still faced limitations in effectively analyzing more intricate linguistic structures.

During the mid-2000s, aspect-based sentiment analysis emerged as a novel approach to assess the sentiment of specific aspects within a text. This method provided a more nuanced and detailed understanding of the sentiments expressed, proving particularly effective in analyzing product reviews [12]. Focusing on individual aspects enabled a comprehensive analysis of various sentiments within a text,

leading to valuable insights and enhanced accuracy in sentiment assessment. In the 2010s, deep learning techniques like Convolutional Neural Networks (CNNs) surfaced and substantially increased sentiment analysis accuracy [13]. These approaches significantly improved the identification of text sentiments and exhibited robustness in handling diverse textual data types. The utilization of deep learning models marked a notable progression in the field, enabling more precise and reliable sentiment analysis results across various text formats.

Sentiment analysis studies have recently expanded to include multimodal and cross-lingual analysis, moving beyond traditional text-based methods. These advanced approaches leverage machine learning to analyze emotions conveyed through various multimedia forms, such as audio, video, and images [14]. This evolution from rule-based and machine-learning-based approaches to deep learning techniques has significantly improved sentiment analysis accuracy and efficiency, benefiting industries like healthcare, advertising, and entertainment [15]. Further research in this field holds great potential for developing even more sophisticated models, enhancing sentiment analysis effectiveness across diverse applications.

IV. PROPOSED METHODOLOGY

To effectively classify sentiments from visual information, developing a robust learning architecture model is essential as show in Fig. 2. This necessitates a thorough understanding of the diverse features and cues that can convey emotions in visual content, including facial expressions, body language, and color schemes. One potential approach to constructing a learning architecture model for sentiment analysis involves employing a deep neural network. Such a network can be trained on large datasets containing labeled visual content, enabling it to recognize patterns and correlations between specific features and emotions. This model type can be fine-tuned to accommodate various types of visual content, such as

images, videos, or live streams, tailored to the specific application.

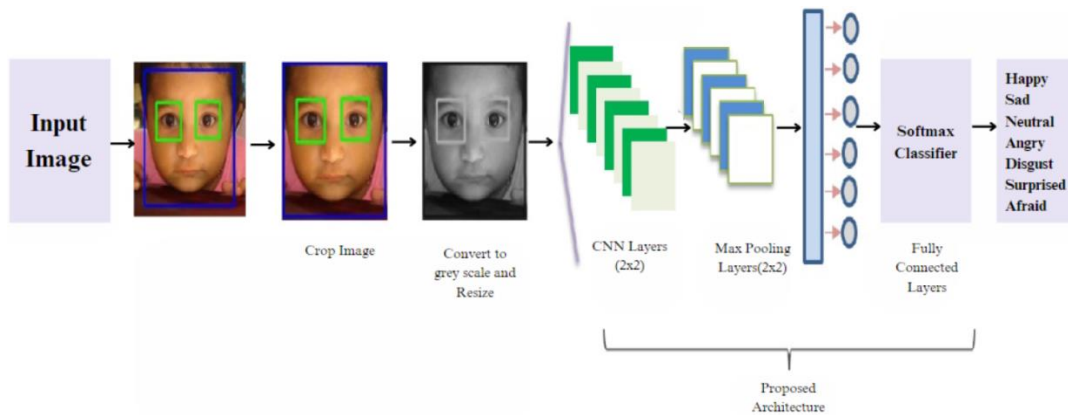

Fig. 2. Deep learning architecture for advanced sentiment analysis.

A. Importing Libraries

In our research on sentiment detection based on vision analysis, we begin by importing essential libraries that will empower us to build and evaluate our models effectively. Tensor Flow and Keras form the backbone of our deep learning infrastructure, enabling us to construct and train complex neural networks for sentiment analysis. NumPy is indispensable for numerical computations and data manipulation, ensuring efficient handling of image data and feature extraction. Open CV plays a pivotal role in image processing tasks, aiding us in pre-processing visual data and extracting meaningful features like facial expressions and color information. Lastly, Matplotlib is instrumental in visualizing and presenting our results in a clear and informative manner, facilitating better insights into the performance of our sentiment analysis models. Together, these libraries form the foundation of our research, enabling us to explore and implement cutting-edge techniques for sentiment detection through vision analysis.

B. Displaying Sample Images

In the context of sentiment detection using vision analysis, displaying a selection of sample images from the dataset is crucial to gain insights into the visual content and the emotions conveyed in the images. By examining these sample images, researchers can better understand the diversity and complexity of the data they will be working with. It allows them to identify different facial expressions, body language, color schemes, and other visual cues that play a role in conveying sentiments. Additionally, this step aids in identifying potential challenges, such as variations in image quality, lighting conditions, and the representation of different emotions, which can impact the accuracy of the sentiment detection model. By visually inspecting the sample images, researchers can ensure that the dataset is diverse, representative, and suitable for effectively training and evaluating their sentiment detection system. This process helps researchers make informed decisions about data preprocessing, feature extraction, and model development, ultimately contributing to the success and reliability of the sentiment detection project.

C. Training and Validation Data

To ensure the efficacy and generalization of our sentiment detection model in the context of vision analysis, we divide our dataset into two essential subsets: the training set and the validation set. The training set serves as the foundation for training our model, allowing it to learn from various images with various sentiments. This step is critical for the model to comprehend and recognize the intricacies of different emotions expressed in visual content. The validation set, on the other hand, is employed to assess the performance of the trained model. By evaluating the model's accuracy and efficiency on the validation set, we can validate its ability to detect sentiments in new and unseen visual data. Ensuring that both sets have a representative distribution of images with different sentiments is crucial to prevent biased training and to enhance the model's robustness. This careful division of data allows us to create a well-performing sentiment detection system that can effectively handle a wide array of visual content, contributing to a successful sentiment analysis based on vision analysis.

D. Model Building

The model is constructed using a sequential algorithm, which entails a linear stack of layers. The architecture comprises four Convolutional Neural Network (CNN) layers, allowing the model to learn hierarchical features from the visual data. Following the CNN layers, two fully connected layers enable the model to comprehend complex relationships between the learned features and sentiment classes. To obtain probability distributions over the different sentiment categories, the SoftMax activation function is used in the last layer, ensuring that the output represents the likelihood of each sentiment class. The ADAM optimizer is employed for model optimization, as it effectively adapts the learning rate and aids in achieving faster convergence during the training process. This carefully designed model architecture leverages the power of CNNs in feature extraction from visual data, culminating in a sentiment detection system capable of accurately recognizing and classifying emotions expressed in images or videos.

E. Fitting the Model with Training and Validation Data

To effectively build and optimize the sentiment detection model in our vision analysis project, we train the model using the training data and validate its performance using the validation data. This step involves adjusting crucial hyperparameters, such as batch size, learning rate, and the number of epochs, to fine-tune the model's performance. The batch size determines the number of training examples used in each iteration, while the learning rate governs the step size during model optimization, impacting the convergence speed and overall performance. The number of epochs defines the number of times the model iterates through the training data. By carefully adjusting these hyperparameters, we aim to balance model underfitting and overfitting, optimizing the model's ability to generalize to new and unseen data. This iterative process enables us to find the best configuration that maximizes the model's accuracy and efficiency, ultimately leading to a robust and reliable sentiment detection system for visual content analysis.

F. Calculating Training Loss and Validation Loss

As we proceed with training the sentiment detection model in our vision analysis project, it is essential to closely monitor the training and validation loss throughout the training process. The training loss represents the error between the model's predictions and the actual sentiment labels on the training data, while the validation loss measures the model's performance on unseen data from the validation set. Plotting the loss curves enables us to visualize the convergence of the model and detect potential issues of overfitting or underfitting. An optimal model should exhibit a decrease in both training and validation loss, indicating that it is learning to generalize well to new data. However, if the training loss continues to decrease while the validation loss starts to increase or plateaus, it could be a sign of overfitting, where the model memorizes the training data rather than learning general patterns. Conversely, if both the training and validation losses remain high, it may indicate underfitting, suggesting that the model needs to capture the underlying complexities of the data. By analyzing the loss curves, we can make informed decisions on adjusting the model architecture or hyperparameters to strike the right balance and achieve a well-performing sentiment detection system capable of accurately analyzing emotions in visual content. This iterative process ensures that the model is trained effectively and is robust enough to handle diverse data, enhancing the project's overall success.

G. Export the Model

Upon successful training and evaluating the sentiment detection model in our vision analysis project, it is crucial to export the model for future use and deployment. This involves saving the model's architecture and the learned weights in a file format compatible with our framework, such as HDF5 or Saved Model. By doing so, we preserve the entire model configuration and the knowledge acquired during training, allowing us to reuse the model for sentiment analysis on new, unseen visual data. Exporting the model in a compatible format ensures easy integration into different applications or platforms, enabling seamless utilization in real-world

scenarios. Moreover, this step facilitates collaboration with other researchers or teams using the exported model to perform sentiment analysis on their specific datasets or tasks. In essence, exporting the model is a critical step in turning our research efforts into a practical and valuable tool that can be readily applied in various domains requiring sentiment analysis from visual content.

H. Real-Time Sentiment Detection using OpenCV

Incorporating Real-Time sentiment detection into our vision analysis project involves implementing the exported model with the OpenCV library. By leveraging OpenCV's capabilities, we can seamlessly capture live video streams from a webcam or video source. The exported model, comprising the architecture and learned weights, is then utilized to analyze the emotions expressed in the Real-Time visual content. As each video frame is processed through the model, sentiments are rapidly detected and classified. This enables the system to provide immediate feedback on the emotional content displayed in the video feed, offering valuable insights into the sentiments expressed by individuals or subjects. This Real-Time sentiment detection empowers us to understand and respond to emotional cues in live scenarios, making it applicable in various applications, such as Real-Time audience feedback analysis, user experience evaluation, and emotion-aware interactive systems. By merging the exported model with OpenCV, we create an efficient and powerful tool that can continuously and accurately perform sentiment analysis in Real-Time video streams, bringing practicality and real-world value to our vision analysis research.

V. RESULTS AND DISCUSSION

In our sentiment analysis study using deep learning models, we presented the outcomes and insights achieved through our approach, which enabled the recognition of emotions such as sadness, happiness, neutrality, and fear in visual data as show in Fig. 3. Our sophisticated deep-learning architecture leveraged Convolutional Neural Networks (CNNs) to extract meaningful features, allowing for accurate sentiment classification.

The performance of our deep learning model surpassed our expectations, achieving a notable accuracy of 84.6% (Table II) in detecting various emotions expressed in visual content. We are optimistic that this accuracy can be further improved based on specific system requirements. By training the model with more images and increasing the number of CNN and Pooling layers, we can enhance its ability to generalize across different emotional expressions and boost its accuracy.

TABLE II. COMPARISON OF MULTIMODAL DEEP LEARNING APPROACH FOR REAL-TIME SENTIMENT ANALYSIS IN VIDEO STREAMING WITH OTHER WORKS

SI No	Year	Method Used	Accuracy	Reference
1	2017	CNN-RNN Ensemble for Videos	72.5%	[16]
2	2018	Fusion of Audio-Visual Features	67.8%	[17]
3	2020	Multimodal DL for Video Streaming	75.2%	[18]
4	2023	CNN Multimodal for	84.6%	Our Work

Fig. 3. Sentimental recognition a) Neutral, b) Sad, c) Surprise, d) Fear.

We also incorporated multimodal and cross-lingual analysis in our study, enhancing the versatility of our sentiment analysis system. By including multiple modalities like audio, video, and image data, we gained a comprehensive understanding of sentiments conveyed in diverse forms of multimedia. This multimodal analysis provided richer insights into the emotional context, enabling a deeper exploration of cross-lingual sentiments and expressions beyond traditional text-based approaches.

The development of our deep learning-based sentiment analysis model signifies a significant advancement in the field. The model's promising accuracy and efficiency hold great potential for real-world applications, particularly in the healthcare, advertising, and entertainment industries. By accurately detecting and interpreting emotions expressed in visual data, our model opens up new possibilities for understanding user preferences, improving customer experiences, and enhancing content personalization.

VI. CONCLUSION

Our research on sentiment analysis using the novel multi-view deep learning framework has demonstrated remarkable success in recognizing emotions from visual data. The deep learning model achieved an impressive accuracy of 84.6% in accurately detecting various emotions, including sadness, happiness, neutrality, and fear. Further refinement, such as increasing the number of CNN and pooling layers and incorporating more extensive training datasets, could lead to even higher accuracy levels. The integration of multimodal and cross-lingual analysis in our study has enriched the versatility of our sentiment analysis system, providing valuable insights into sentiments expressed across diverse forms of multimedia. With its promising performance, our deep learning-based sentiment analysis model holds substantial promise for practical applications in the healthcare, advertising, and entertainment industries. Its ability to discern emotions from visual content opens up new avenues for improving customer experiences, enhancing content personalization, and gaining a deeper understanding of user

preferences. We foresee the widespread application of our framework in various industries, benefiting user engagement, customer service, and content personalization. While this research marks a significant stride in sentiment analysis, we acknowledge the scope for further improvement as we remain committed to advancing the field and contributing to a nuanced understanding of human emotions in the digital era.

Abstract—Magnetic resonance imaging (MRI) is frequently contaminated by noise during scanning and transmission of images, this deteriorates the accuracy of quantitative measures from the data and limits disease diagnosis by doctors or a computerized system. It is common for MRI to suffer from noise commonly referred to as Rician noise because the uncorrelated Gaussian noise is present in both the real and imaginary parts of a complex K-space image with zero mean and equal standard deviation, the distribution of noise in magnitude MR images typically tends to be related to Rician distributions. To remove the Rician noise from an MRI scan, deep learning has been used in the MRI denoising method to achieve improved performance. The proposed models were inspired by the Residual Encoder-Decoder Wasserstein Generative Adversarial Network (RED-WGAN). Specifically, the generator network is residual autoencoders combined with the convolution and deconvolution operations, and the discriminator network is convolutional layers. As a result of replacing Mean Square Error (MSE) in RED-WGAN with Structurally Sensitive Loss (SSL), RED-WGAN-SSL has been proposed to overcome the loss of important structural details that occurs because of over-smoothing the edges. The RED-WGAN-SSIM model has also been developed using Structural Similarity Loss SSIM. The proposed RED-WGAN-SSL and RED-WGAN-SSIM models are formed by using the SSL, SSIM, Visual Geometry Group (VGG), and adversarial loss that are incorporated to form the new loss function. They preserved the informative details and fine image better than RED-WGAN, so our models could effectively reduce noise and suppress artifacts.

Keywords—Deep learning; image denoising; MRI; Wasserstein GAN; loss function

I. INTRODUCTION

MRI is a medical imaging process that produces multidimensional images of the inside of the body; it uses powerful magnets and radio waves generated by computers rather than injecting contrast agents. It is considered one of the most attractive modalities that have been used in the diagnosis and treatment of several neurological diseases because it can show 3D details of internal living tissues and the human body organs. MRI plays an increasingly important role in pathological and physiological diagnostics and scientific

research. Physiological noise impedes the acquisition of signals and contaminates raw data sets by artificial outliers. As a result of this practical issue, more advanced technologies have difficulty being applied in clinical research. Increasing noise levels may have a bad effect not only on the accuracy of computed diagnostic systems, but also on manual disease inspection and the reliability of quantitative image processing including segmentation, registration, visualization, super-resolution, and classification [1]. Raw data is usually polluted by White Additive Gaussian Noise (WAGN) in the real and imaginary parts. This noise is assumed to have equal variance and zero mean in the entire K space of the data, meaning that it affects both the real and imaginary parts of the data equally. Rician noise, on the other hand, is signal-dependent, which makes it harder to separate from the signal and can result in biased estimates of image intensity. Additionally, in high SNR regions, the Rician noise is close to the Gaussian distribution. To achieve reliable analysis results, it is necessary to remove noise before performing further image processing.

In MRI denoising, the goal is to effectively restore a clean image from a contaminated MR image and preserve valuable information [2]. In the past, many research attempts for MRI denoising were made to remove additive noise, most of which used the Rician noise model. In general, these methods can be categorized into three types: spatial filtering, transform domain filtering, and statistical methods [3]. The spatial domain techniques are directly applied to image pixels [4]. There are several traditional spatial image filters, including median [5], Gaussian [6], Wiener [7], diffusion [8], and bilateral filters. Anisotropic diffusion filter [9] significantly retained informative details of edges and reduced the noise from the images by smoothing local regions in the image, but the image was still blurry. This filter tried to avoid blurring of the edges by utilizing the edge-stopping function. A transform domain image filter is different from a spatial domain image filter. In that transform domain filtering methods first transform the space domain into another domain, and then they process the transformed image in the new domain based on the different characteristics of the image and its noise such as the frequency and wavelet domains [10]. Rician noise in MRI data has been successfully denoised by well-known block matching 3D

(BM3D) [11]. Higher-order singular value decomposition (HOSVD) [12] was developed to denoise MR volume data, and its performance was improved compared to BM3D.

Deep Learning (DL) made impressive progress in image processing and computer vision fields by introducing new effective methodologies. It has been used on low-level tasks to denoise [13,14], deblur [15], and restore super-resolution images [16]. CNNs and autoencoders achieved competitive performance with state-of-the-art methods, such as BM3D and NLM, for image denoising [14]. Lore et al. [17] developed LLNet, a deep auto-encoder that enhances contrast and removes noise. Zhang et al. [14] used Denoising convolutional neural networks (DnCNNs) to handle Gaussian denoising with unknown noise levels, which is different from traditional discriminative models that are trained specifically for certain noise levels. DnCNNs not only achieved excellent performance quantitatively and qualitatively by using residual learning strategy but also to speed up the training process on GPU computing by using batch normalization (BN) [18]. Zhang et al. [19] proposed a new fast, flexible CNN denoising model namely FFDNet. FFDNet can handle a wide range of noises, remove white Gaussian and spatially variant noise which requires a noise level map, and is faster than BM3D. It is effective and provides a practical solution to denoising applications because it achieves a good balance between performance and inference speed.

Although researchers have made great efforts in MRI denoising to retrieve free noise images and get effective results, the research on MRI denoising is quite limited. Current methods suffer from several drawbacks including nonlinear optimization, tuning the parameters of neural networks, high computations, and/or sensitive parameters, which seriously lead to unsatisfactory denoising results. In this work, to avoid these problems, the proposed models are inspired by an MRI denoising method based on RED-WGAN [3]. This paper mainly contributes to learning the distribution of data in a low-dimensional manifold using the WGAN framework, different loss functions such as VGG loss [20], SSL loss, SSIM loss [21], residual networks and autoencoders [22], which were employed in the proposed models to preserve clinical relevant details such as the edges and the informative structure. MSE loss in the RED-WGAN model has been replaced with SSL loss to overcome the loss of important structural details occurring due to over-smoothing edges. Also, SSIM loss has been used to preserve the image details in high resolution. The proposed method is computationally fast and can be implemented on Graphic Processing Units (GPUs). The rest of this paper is organized as follows: Section II defines the related work; Section III presents the proposed models; Section IV describes the experiments and results; and finally, Section V shows the conclusions and future work.

II. RELATED WORK

In the field of clinical imaging, Jiang et al. [23] proposed a multichannel convolutional neural network (MCDnCNN) for MRI denoising with and without a specific noise level, in which CNN layers were combined with residual learning [24] and VGG network architecture. It robustly denoises 3D MR images with Rician noise. Manjon et al. [25] proposed a two-

stage approach to effectively reduce the noise: the non-local PCA thresholding strategy is used to filter the noisy image by automatically estimating the local noise level in the image; then this filtered image is used as a guide in the rotationally invariant NLM [prefiltered rotationally invariant nonlocal means (PRI-NLM)] filter. Ran et al. [3] introduced the RED-WGAN model for MRI denoising, which consists of three main parts: the generator network, the discriminator network, and combined loss functions. In the generator network, the residual autoencoder structure is composed of convolutional and deconvolutional layers symmetrically. The discriminator network consists of convolutional layers. The authors combined three loss functions including the MSE loss function [21], Adversarial loss, and VGG loss. The proposed model powerfully reduced the noise and retrieved the structural details. Tripathi et al. [26] proposed a novel CNN-DMRI model to remove the Rician noise from MRI, which utilized a set of convolutional layers to capture the image features while the noise is separating. As part of CNN-DMRI structures, encoder-decoder structures were also employed to retain the informative features of the image while unnecessary ones are ignored. The qualitative and quantitative results of the proposed method are promising. Li et al. [1] successfully applied Rician denoising with a progressive learning approach to MR images. The progressive network, called RicianNet, consists of two sub-RicianNets, which are residual blocks: one of the sub-networks fitted the noise distribution at the pixel-domain without batch normalization layer, and the other one employs ResNet structure with batch normalization layer in the feature domain, thus enhancing the nonlinear mapping. The authors improved the network performance by employing the BN layer, Convolutional layer, and residual unit. RicianNet had better quantitative measures and significant improvements in visual inspections. Aetesam et al. [27] proposed a deep neural architecture for MRI denoising to remove Gaussian-impulse noise by using an ensemble-based residual learning strategy. The proposed model achieved high-quality visual results and high quantitative metrics compared to other state-of-the-art models. Gregory et al. [28] developed a multi-branch deep neural network architecture, HydraNet, to remove noise from MR images at a wide range of noise levels. Compared to other deep learning-based methods, the HydraNet network demonstrated powerful results in the denoising of complex noise distributions. Wu et al. [2] used 3D Parallel-RicianNet for 3D MRI denoising, which combines global and local information for noise reduction. To expand its receptive field, the authors introduced a powerful module called dilated convolution residuals (DCR).

III. PROPOSED DENOISING MODEL

It is difficult to denoise an MRI because magnitude images, which consist of real and imaginary parts, are commonly used [3, 29]. The noise in the magnitude MR image follows a Rician noise distribution [29], which is significantly more complicated than traditional additive Gaussian noise.

In MRI denoising, a free MR image is obtained by removing noise from a noisy MR image, as follows:

$$z = \theta(x) \quad (1)$$

Where z denotes a noisy MR image, x denotes the corresponding noise-free MR image and $(x, z \in R^{H \times W \times D})$, and function θ maps to the noise. The model-based DL is independent of noise and its statistical characteristics since it is a black box. So, the denoising process aims to approximate the function θ^{-1} to the possible optimal and can be expressed as follows:

$$\operatorname{argmin}_f \|\hat{z} - z\|_2^2 \quad (2)$$

where $\hat{z} = Q(z)$, which corresponds to an estimate of x , and Q indicates the optimal approximation of θ^{-1} [3].

A. Wasserstein GAN

The GANs model can be described in Eq. (3).

$$\min_G \max_D V(D, G) = E_{x \sim P_r(x)} [\log D(x)] + E_{z \sim P_z(z)} [\log(1 - D(G(z)))] \quad (3)$$

The two variables x and z can be interpreted as samples drawn from two different distributions of data, which in the context of statistics, can be considered as being real image distributions p_r and noisy image distributions p_z respectively. Then, the denoising function moves the samples from p_z to p_g which is close to p_r . An Adversarial Generative Network (GAN) is made up of two networks, a generator, G , and a discriminator, D . There have been many uses of GAN in research fields such as computer vision [30,31], security [32], and data generation [33]. The generator generates samples from random noise as close as possible to real data to deceive a discriminator. The discriminator attempts to distinguish between the two-distribution of the generative model p_g and the real data p_r .

Despite its success in image generation, GAN suffers from training instabilities, extremely sensitive parameter tuning, vanishing gradient, and mode collapse [34]. It has been proposed to improve GAN by using Wasserstein GAN (WGAN) [35]. The loss function of WGAN was proposed to avoid vanishing gradients. Wasserstein Distance measures the divergence between real distribution P_r and model distribution P_g ; In WGAN, weight clipping is used to enforce Lipschitz constraints, when clipping parameters are too small or too large can result in the same original GAN problems. Therefore, the Gradient penalty (GP) was used instead of weight clipping to enforce the Lipschitz constraint on the critic(discriminator) during training.

WGAN-GP is a WGAN with a gradient penalty, and the loss function is shown in Eq. (4).

$$L = E_{\tilde{x} \sim p_g} [D(\tilde{x})] - E_{x \sim p_r} [D(x)] + \lambda E_{\hat{x} \sim p_{\hat{x}}} [(\|\nabla_{\tilde{x}} D(\hat{x})\|_2 - 1)^2] \quad (4)$$

The sample of $p_{\hat{x}}$ is taken uniformly between two points sampled from P_r and P_g , the last term is a gradient penalty factor, and λ is a penalty coefficient.

B. Loss Functions

Mean Squared Error (MSE) loss or $L2$ calculates the normalized Euclidean distance between a generated patch $G(z)$ from model distribution P_g and the patch of noise-free images x from real distribution P_r ; it minimizes the pixel-wise difference

between them [21]. Recent studies suggest that although the per-pixel MSE results have a high peak signal-to-noise ratio (PSNR), it may cause the loss of some important structural details due to an over-smoothed edge. The formula of $L2$ loss is expressed as in Eq. (5).

$$L2 = \frac{1}{HWD} \|G(z) - x\|_2^2 \quad (5)$$

The Perceptual Loss (PL) was used to overcome this problem by being employed in the feature space instead of directly estimating MSE on a pixel-by-pixel basis. A pre-trained VGG-19 network [20] can be applied to extract the features from the generated patch and noise-free patch, VGG loss compares high-level perceptual differences [21].

$$PL(G) = E_{(x,z)} \frac{1}{HWD} \|\varphi G(z) - \varphi(x)\|_2^2 \quad (6)$$

In which φ is a feature extractor, W refers to the width, H indicates to the height, and D is the depth of feature maps. The perceptual loss can be described as the following formula:

$$L_{VGG}(G) = PL(G) E_{(x,z)} \frac{1}{HWD} \|VGG(G(z)) - VGG(x)\|_2^2 \quad (7)$$

Structural Similarity (SSIM) loss measures the similarity between two patches $G(z)$ and x based on three comparisons: contrast, luminance, and structure [21]. The SSIM can perform better than the MSE in perceptual pattern recognition because it is visually based. The original SSIM is formulated as follows in Eq. (8).

$$SSIM(x, y) = \frac{2\mu_x\mu_y + C1}{\mu_x^2 + \mu_y^2 + C1} * \frac{2\sigma_{xy} + C2}{\sigma_x^2 + \sigma_y^2 + C2} = L(x, y) * cs(x, y) \quad (8)$$

Where μ_x , μ_y , σ_x , σ_y and σ_{xy} are the means, standard deviations, and the cross-covariance of the two images (y, x) obtained from the model and the corresponding noise-free image respectively and $C1$, $C2$ are constants [21,36,37]. If x and y are very similar, SSIM approaches 1.

$$L_{SSIM} = 1 - SSIM(x, y) \quad (9)$$

In this paper, we presented RED-WGAN-SSL and RED-WGAN-SSIM models based on WGAN. They are incorporated with different loss functions to reduce the noise in 3D MRI and retain structural information. The two proposed models are compared with RED-WGAN [3]. The joint loss functions for all models are formulated as follows:

$$L_{RED-WGAN} = \lambda_1 L_{WGAN}(G) + \lambda_2 L_{VGG} + \lambda_3 L_{MSE} \quad (10)$$

$$L_{RED-WGAN-SSIM} = \lambda_1 L_{WGAN}(G) + \lambda_2 L_{VGG} + \lambda_3 L_{SSIM} \quad (11)$$

$$L_{RED-WGAN-SSL} = \lambda_1 L_{WGAN}(G) + \lambda_2 L_{VGG} + \lambda_3 L_{SSL} \quad (12)$$

C. Network Architectures

The proposed models' architecture is inspired by the RED-WGAN architecture [3], which is made up of a G network, a D network, and a VGG network. The G network structure is an autoencoder network that consists of the convolution and deconvolution layers that are symmetrical to deal with the noise. The convolution and deconvolution layer pairs are linked by short connections. The deconvolution layers and the short connections are proposed to speed up the training procedure and maintain more details. There are 8 layers in the

encoder-decoder generator: four convolutional layers and four deconvolutional layers. A 3D convolution is applied to the first seven layers, followed by a batch-normalization and a LeakyReLU, except the last layer, which has a 3D convolution and a LeakyReLU without a batch-normalization; each layer uses $3 \times 3 \times 3$ kernels, the generator employed 32, 64, 128, 256, 128, 64, 32, 1 filter. The VGG network is used to extract features.

The structure of the discriminator network D consists of 3 convolutional layers. All layers perform 3D convolutional operations in sequence with 32, 64 and 128 filters and have $3 \times 3 \times 3$ kernel size, followed by a fully connected layer in the last layer that has a single output.

IV. EXPERIMENTS AND RESULTS

The two proposed models RED-WGAN-SSL and RED-WGAN-SSIM were extensively tested on clinical datasets to validate their performance.

A. Clinical Data

Clinical experiments were conducted using the IXI dataset [38] gathered from three hospitals: Hammersmith Hospital, Guy's Hospital, and the Institute of Psychiatry. The above-mentioned website provides detailed information on scanning configuration. The Hammersmith dataset is a subset of the IXI dataset obtained from a Philips 3T scanner. 110 PD-weighted brain image volumes were randomly chosen. The training set consists of 100 image volumes from the Hammersmith dataset, and the testing set consists of 5 image volumes from the Hammersmith dataset, it also included 5 image volumes from the Guy's Hospital dataset to evaluate the robustness of the proposed models. We manually added Rician noise to the training set and testing set to simulate noisy images. Many training samples are required for deep learning-based methods, which is especially challenging in clinics.

B. Parameter Setting

The training was performed on PD-weighted brain image volumes with specific levels of noise. According to the suggestions in [31,39], the parameters λ_1 , λ_2 , and λ_3 were experimentally set to 1, 0.1, and $1e-3$, respectively. A penalty coefficient λ in Eq. (4) was specified in following the suggestion [35] to 10. The loss function was optimized by the Adam algorithm [40], and the parameters α , β_1 , and β_2 for the optimizer were set to $1e-4$, 0.5, and 0.9, respectively.

C. Results

To evaluate the performance of the proposed denoising models RED-WGAN-SSL and RED-WGAN-SSIM in comparison to RED-WGAN, three quantitative metrics were utilized. The first metric, PSNR, involved comparing the denoised images to the original (ground truth) images by calculating RMSE. The second metric, RMSE, measured the difference between the denoised and ground truth images, lower values indicating better image quality. Lastly, the SSIM was used to compare the similarities between the denoised and ground truth images, taking into account the luminance, contrast, and structure of the images.

1) *Results obtained using a mini-batch size of 11*: This section illustrates the different results for RED-WGAN-SSL, RED-WGAN-SSIM, and RED-WGAN that were trained on PDw images with different levels of noise (5%, 9%, 11%, and 15%). Then, the three denoising models were tested on the same levels of noise (5%, 9%, 11%, and 15%).

a) *Quantitative Results*: Table I presents the average quantitative analysis. The results demonstrate that when the noise level is less than 11%, RED-WGAN-SSL and RED-WGAN-SSIM exhibit slightly better performance than RED-WGAN. As the noise level increases, the performance of RED-WGAN-SSL is mildly better than that of RED-WGAN and RED-WGAN-SSIM.

b) *Qualitative Results*: This section illustrates the different qualitative results for the denoising models RED-WGAN-SSL, RED-WGAN-SSIM and RED-WGAN. Fig. 1 shows results obtained for the PDw brain images in the testing set with 15% Rician noise as the models were also trained on images with 15% Rician noise. Each model suppresses noise to a different degree. However, some vital details are distorted as in RED-WGAN-SSIM. In Fig. 2, it is important to mention that all the models at the noise level of 11% can remove noise to a different degree and that the RED-WGAN-SSL and RED-WGAN-SSIM have better results compared with RED-WGAN, as they preserve more structural details than RED-WGAN as shown by the red arrow. RED-WGAN-SSL suppresses noise better than other models. The results show that the lower the noise level, the better the results and closer to the original reference image as observed at level noise of 9% and 5% in Fig. 3 and Fig. 4 respectively. Consequently, the structure details were preserved while noise was effectively reduced especially at level noise of 5%.

2) *Results obtained using a mini-batch size of 80*: Based on the results obtained in Table II, the RED-WGAN-SSL seems to have performed better in terms of PSNR, SSIM, and RMSE than all the models considered. Fig. 5 provides a visual representation of the different results for RED-WGAN-SSL, RED-WGAN-SSIM, and RED-WGAN on the PDw brain images that were corrupted by 15% Rician noise in the training set and then were tested with 15% Rician noise. It is important to note that all of the models are capable of suppressing noise in converging degrees. The RED-WGAN-SSL model has an improvement in noise suppression compared to the RED-WGAN model as shown in the red arrow, and it also produces results that are more consistent compared to the original reference images. RED-WGAN-SSL analysis results show that most of the noise has been reduced efficiently and the structure details have been retained much better than other models. The quantitative results of different models for Fig. 5 are presented in Table II. There was an agreement between the visual inspection and quantitative results in terms of PSNR, SSIM, and RMSE when using RED-WGAN-SSL, which is the best result of all the modalities.

TABLE I. A COMPARISON OF PSNR, SSIM, AND RMSE METRICS ON DENOISED PDW EXAMPLE WITH DIFFERENT LEVELS OF RICIAN NOISE FROM THE TESTING SET

		5%	9%	11%	15%
Noise	PSNR	41.853721	46.758666	44.828463	41.853721
	SSIM	0.306874	0.192677	0.157860	0.109305
	RMSE	0.374527	0.678883	0.831107	1.135392

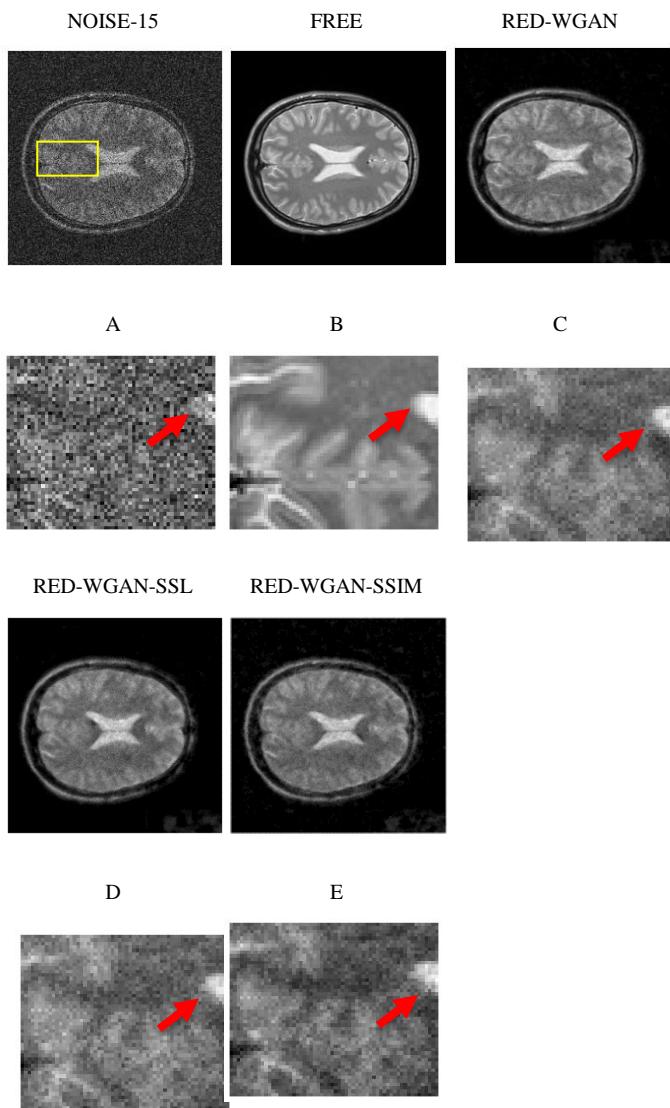

Fig. 1. Denoised PDw example with 15% Rician noise from the testing set at a mini-batch size =110: (A) Noisy image, (B) Ground truth image, (C) RED-WGAN, (D) RED-WGAN-SSL and (E) RED-WGAN-SSIM.

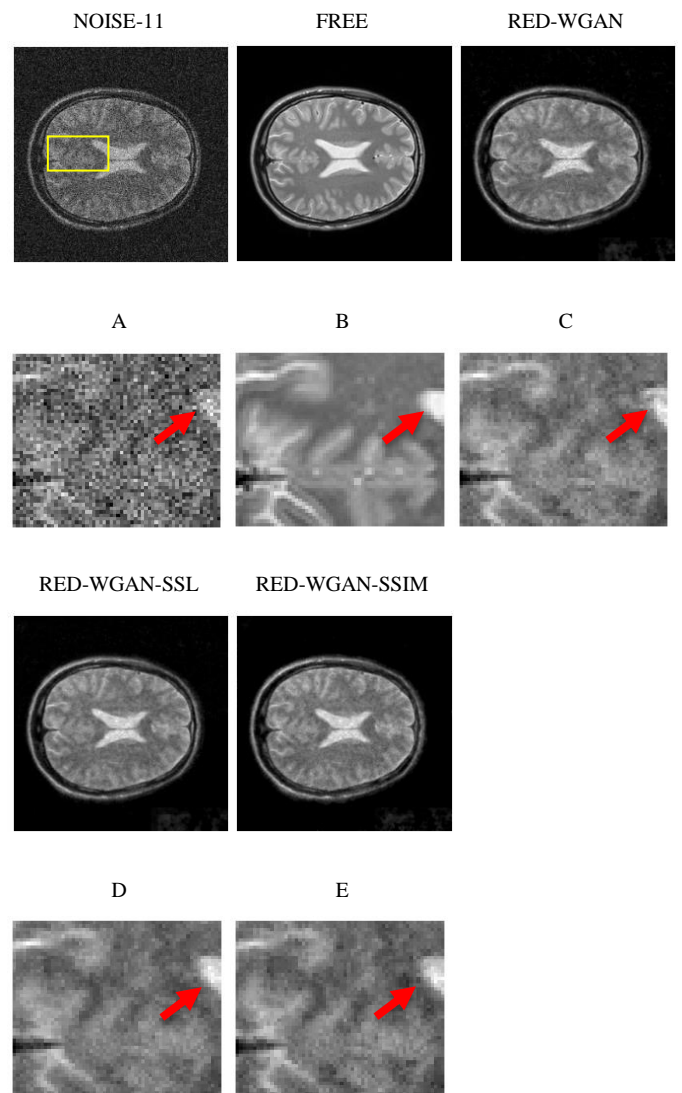

Fig. 2. Denoised PDw example with 11% Rician noise from the testing set at a mini-batch size =110: (A) Noisy image, (B) Ground truth image, (C) RED-WGAN, (D) RED-WGAN-SSL and (E) RED-WGAN-SSIM.

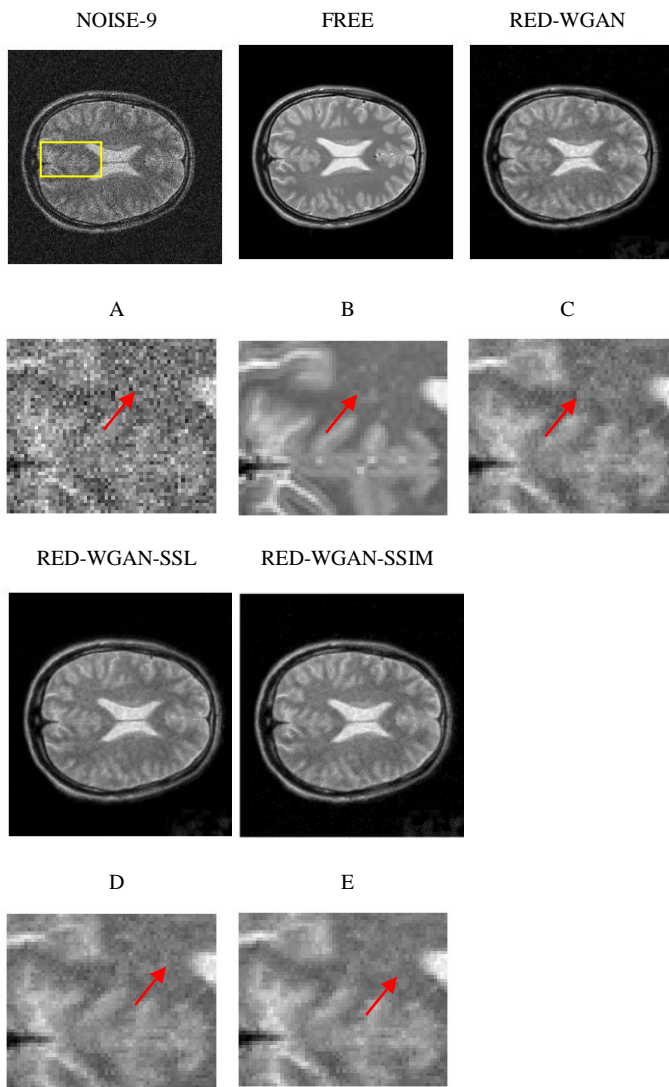

Fig. 3. Denoised PDw example with 9% Rician noise from the testing set at a mini-batch size =110: (A) Noisy image, (B) Ground truth image, (C) RED-WGAN, (D) RED-WGAN-SSL and (E) RED-WGAN-SSIM.

TABLE II. A COMPARISON OF PSNR, SSIM AND RMSE METRICS ON DENOISED PDW EXAMPLE WITH 15% RICIAN NOISE FROM THE TESTING SET AT A MINI-BATCH SIZE =80

		PSNR	41.853721
	Noise -15	SSIM	0.109305
		RMSE	1.135392
	RED-WGAN	PSNR	58.497804
		SSIM	0.755688
		RMSE	0.212351
	RED-WGAN-SSL	PSNR	58.673452
		SSIM	0.781521
		RMSE	0.205079

		PSNR	58.342468
	RED-WGAN-SSIM	SSIM	0.736552
		RMSE	0.212479

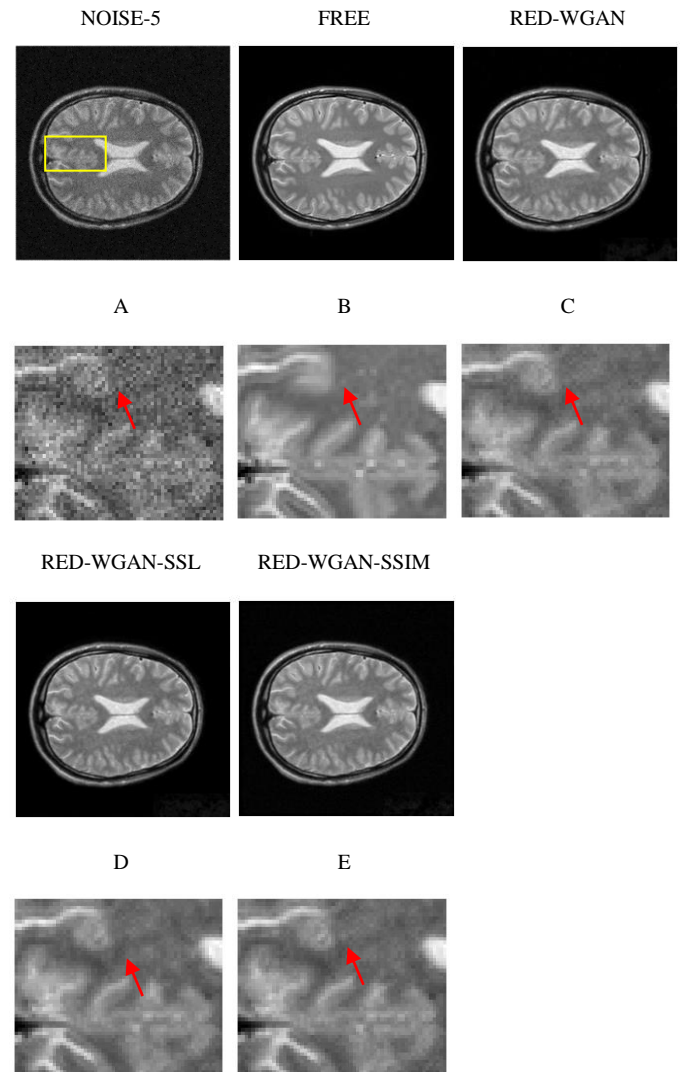

Fig. 4. Denoised PDw example with 5% Rician noise from the testing set at a mini-batch size =110: (A) Noisy image, (B) Ground truth image, (C) RED-WGAN, (D) RED-WGAN-SSL and (E) RED-WGAN-SSIM.

3) Comparison between the results obtained with a mini-batch size = 80 and mini-batch size = 110: Quantitative results of all models at a noise level of 15% with a mini-batch size of 80 are significantly better than those with a mini-batch size of 110 as shown in Table I and Table II. Based on the comparison, we found that the qualitative results with a mini-batch of 80 show that most noise can be effectively removed in most cases, as well as that the structural details are preserved better than the results with a mini-batch of 110 as shown in Fig. 5

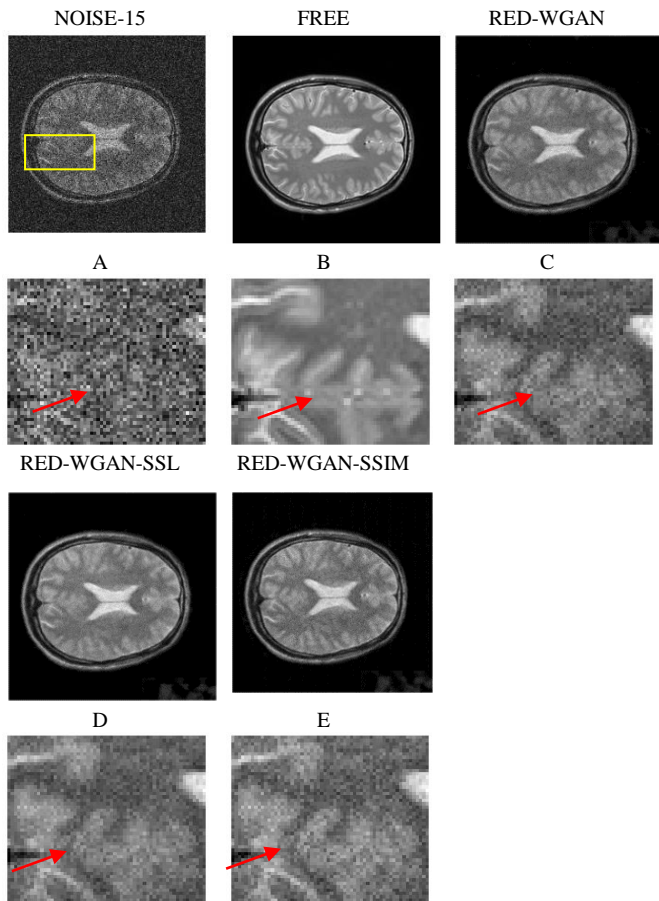

Fig. 5. Denoised PDw example with 15% Rician noise from the testing set at a mini-batch size =80: (A) Noisy image, (B) Ground truth image, (C) RED-WGAN, (D) RED-WGAN-SSL and (E) RED-WGAN-SSIM.

4) *An evaluation of robustness:* For the analysis of the robustness of the RED-WGAN-SSL and RED-WGAN-SSIM

models for various noise levels, RED-WGAN-SSL, RED-WGAN-SSIM and RED-WGAN models were trained with 15% Rician noise, and these three models were then tested with various noise levels which are 5%, 9%, 11%, 15%, and 17% to show how robust they are.

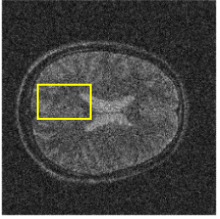

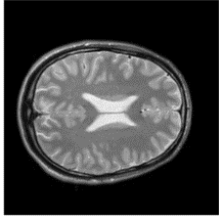

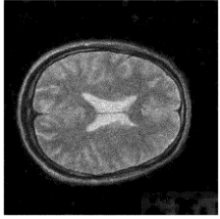

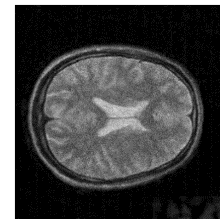

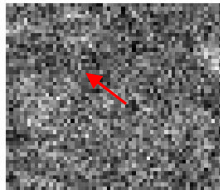

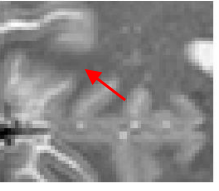

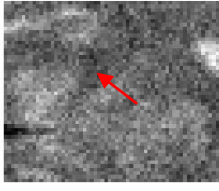

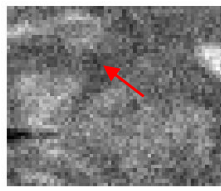

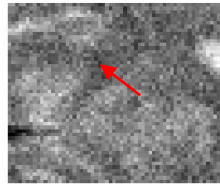

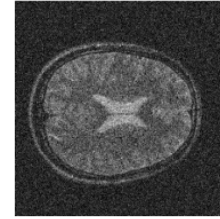

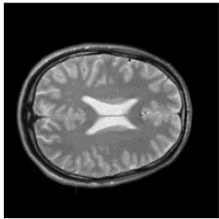

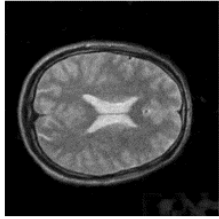

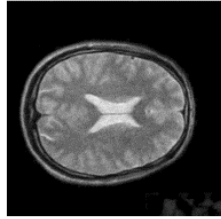

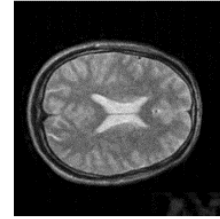

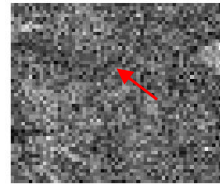

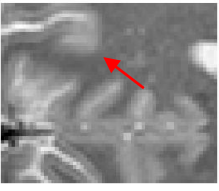

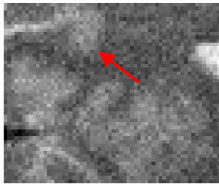

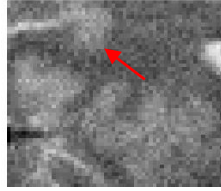

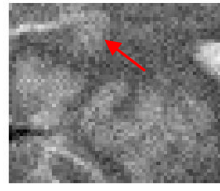

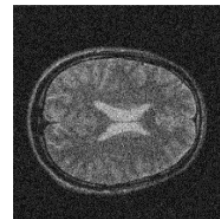

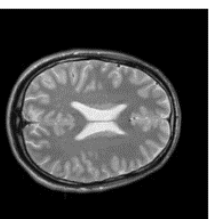

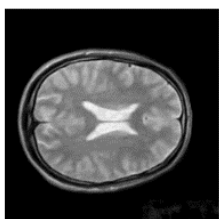

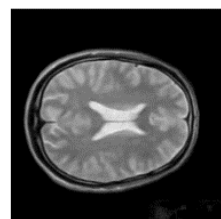

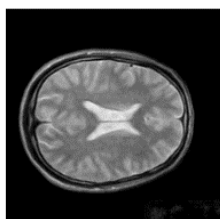

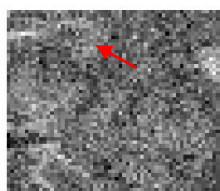

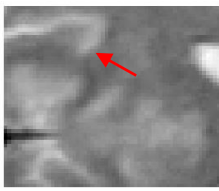

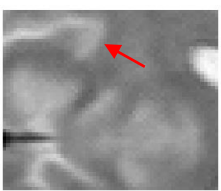

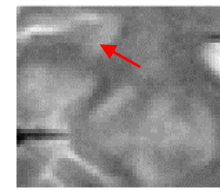

a) *Qualitative Results:* It has been found that the performance of RED-WGAN-SSL is slightly better than that of other models at a higher level than 11% Rician noise. RED-WGAN-SSIM preserved more informative features and provided better visual quality compared to other denoising on the testing set at a lower level than 11% Rician noise, it can reduce the noise and artifacts as indicated by the red arrow in Fig. 6.

The advantage of our proposed models is combining loss functions which are SSL, SSIM, and VGG losses. The VGG loss is used to preserve image style and content after it has been denoised. SSL loss is efficient in extracting structural details and informative features. The SSIM loss generates visually artistic images by using the visible structures in the image. All of these losses help to generate results that can be similar to the original distribution of the data.

b) *Quantitative Results:* A quantitative summary of the results for Fig. 6 is provided in Table III. The RED-WGAN-SSL has better scores when tested at noise levels higher than 11%; it provides good PSNR and SSIM values, which are higher than those of other models as observed in Table III. The RED-WGAN-SSIM has better scores when tested at noise levels less than 11%. As a result, we can take this as evidence that the proposed models are both robust and generalizable. Consequently, we can conclude that the proposed models can denoise MR images with high-quality images and with high structural similarity between the original image and its denoised result.

V. CONCLUSION

The two models RED-WGAN-SSL and RED-WGAN-SSIM models were presented in this paper, which use WGAN to get rip Rician noise from MR images while maintaining structure details. A 3D CNN has been used in these models to process 3D volume data. As well as using the WGAN framework, we introduced an autoencoder generator structure and combined loss functions. We have also improved the performance of our models by adapting the mixture of SSL, SSIM, and VGG loss functions. According to the results of the experiments, the performance of RED-WGAN-SSL and RED-WGAN-SSIM, which are based on the WGAN, SSL, SSIM, and perceptual loss, have been significantly improved both qualitatively and quantitatively. Compared with the RED-WGAN model, they can suppress the noise at the same time as retaining a higher level of detail. A comparison of the results of all models at a noise level of 15% when a mini-batch size = 80 is superior to a mini-batch size = 110. It is interesting to note that the RED-WGAN-SSL scores better metrics on the testing set at noise levels higher than 11%, whereas the RED-WGAN-SSIM scores better metrics on the testing set at noise levels less

than 11%. This leads us to conclude that our proposed models are both robust and generalizable and can therefore be viewed as a strong indication that our work is well worth the effort. A deep learning-based method has a high computational cost. Most of the costs are incurred during the training stage. Although most training is conducted on a GPU, it still takes a long time. In future work, the proposed models will be implemented in T1 and T2 brain image volumes. As well as this, we will apply our denoising methods to a variety of medical images with different types of noise.

A Framework for Patient-Centric Medical Image Management using Blockchain Technology

Abdulaziz Aljaloud

College of Computer Science and Engineering, University of Ha'il, Saudi Arabia

Abstract—In smart systems context, the storage and distribution of health-critical data – medical images, test reports, clinical information etc. that is processed and transmitted via web portal and pervasive devices which requires a secure and efficient management of patients' medical records. The reliance on centralized data centers in the cloud to process, store, and transmit patients' medical records poses some critical challenges including but not limited to operational costs, storage space requirements, and importantly threats and vulnerabilities to the security and privacy of health-critical data. To address these issues, this research proposes a framework and provides a proof-of-the-concept named Patient-Centric Medical Image Management System (PCMIMS). The proposed solution PCMIMS utilizes the Ethereum blockchain and Inter-Planetary File System (IPFS) to enable secure and decentralized storage capabilities that lack in existing solution for patients' medical image management. The PCMIMS design facilitates secure access to Patient-Centric information for health units, patients, medics, and third-party requestors by incorporating the Patient-Centric access control protocol, ensuring privacy and control over medical data. The proposed framework is validated through the deployment of a prototype based on smart contract executed on Ethereum TESTNET blockchain that demonstrates efficiency and feasibility of the solution. Validation results highlight a correlation between (i) number of transactions (i.e., data storage and retrieval), (ii) gas consumption (i.e., energy efficiency), and (iii) data size (volume of Patient-Centric medical images) via repeated trials in Microsoft Windows environment. Validation results also indicate computational efficiency of the solution in terms of processing three most common types of Patient-Centric medical images namely (a) Magnetic resonance imaging (MRI) (b) X-radiation (X-Rays), (c) Computed tomography (CT) scan. This research primarily contributes by designing, implementing, and validating a blockchain based practical solution for efficient and secure management of Patient-Centric medical image management in the context of smart healthcare systems.

Keywords—Smart healthcare; medical imaging; blockchain; ethereum; distributed storage

I. INTRODUCTION

Information and Communication Technologies (ICTs) and infrastructures have brought significant advancements to the healthcare industry – enabling efficient healthcare delivery – to a number of stakeholders such as medical units, patients, and medics [1]. In smart healthcare context, patient information systems have revolutionized the healthcare sector via medical information systems, pervasive technologies, internet of things driven sensors to tackle healthcare challenges effectively and efficiently [2]. Numerous studies have established a strong correlation between storage,

analytics, and transmission of advanced clinical information and communication systems to improve healthcare quality, safety, and patient-centeredness [3]. However, the fragmented nature of health-critical information (i.e., medical images, test reports, clinical information etc.) poses challenges correspond to an effective utilization of personal health information to promote effective and efficient treatment [4]. This fragmentation often results in cumbersome data management and compromises overall patient safety, as health information systems within hospitals, medical clinics, laboratories, and pharmacies remain separate entities that are prone to data security threats or compromised health-critical information [5].

Smart healthcare systems have become increasingly integrated into various aspects of healthcare, including hospital information systems, internet of medical things (IoMTs) and pervasive healthcare technologies [6]. Specifically, as the fundamental unit of smart healthcare, hospital management information systems play a critical role in managing patient data, streamlining workflows, and improving overall healthcare delivery [7]. These systems encompass a range of functionalities, including Electronic Health Records (EHRs), Computerized Physician Order Entry (CPOE), and Picture Archiving and Communication Systems (PACS). PACS has emerged as an essential component of modern radiology departments, enabling the efficient storage, retrieval, and distribution of medical images, including MRI scans [8]. By digitizing and organizing images, PACS eliminates the need for traditional film-based methods and enables rapid access to patient imaging data. It provides radiologists and healthcare professionals with a centralized platform for image interpretation, collaboration, and reporting, leading to improved diagnostic accuracy and patient care outcomes [9].

The integration of ICT in smart healthcare systems, such as hospital information systems and PACS, offers numerous advantages related to cost-efficiency, operational readiness, along with security and privacy of health-critical data [10]. It enables seamless communication and exchange of patient information between various healthcare units (e.g., hospital and labs), medics (e.g., doctors, nurses) and other stakeholders such as patients or healthcare authorities [11]. Such an automated and connected healthcare facilities improve healthcare coordination, faster access to critical information, and enhanced decision-making processes, ultimately benefiting patient outcomes and satisfaction. Despite the outlined benefits as above, the implementation and integration of IT systems, particularly PACS, present various challenges

and such challenges include but are not limited to issues related to interoperability, data security, privacy concerns, and the need for efficient data storage and management solutions [12]. Overcoming these challenges is crucial to ensure the effective utilization of ICT for smart healthcare and maximize its potential for improving patient care [13]. This research aims to address these challenges by proposing a novel approach for enhancing the integration and utilization of ICT systems, specifically focusing on hospital information systems and PACS in the context of MRI imaging. By leveraging existing method and algorithms of blockchain technology, this study aims to optimize data management, improve interoperability, and enhance overall efficiency in healthcare settings.

Context and Challenge(s): Medical images pose a significant challenge in terms of their size and storage requirements, surpassing the capacities typically available on public blockchains [14]. In recent years, blockchain-based solutions have started to gain significant attention with their use-cases and applicability in healthcare data management [15]. In response to the need for decentralized storage, Protocol Labs developed the InterPlanetary File System (IPFS) [16]. IPFS is designed as a distributed web solution that enables the sharing and storage of hypermedia that is managed as peer-to-peer (P2P) file system. It offers an alternative off-chain storage option that can be seamlessly integrated with different blockchain networks, enhancing interoperability [17]. IPFS provides a distributed data access system that offers several advantages, including persistence, improved efficiency, and faster online services. By utilizing content addressing, IPFS ensures that data can be accessed and retrieved from multiple locations, enhancing redundancy and availability [18]. The peer-to-peer nature of IPFS allows for efficient data sharing among participants, reducing the reliance on centralized servers and improving data transfer speeds [8-18]. Moreover, IPFS introduces a more intelligent approach to online services by enabling the creation of decentralized applications (dApps) that leverage its distributed storage capabilities [8-18].

However, despite the advantages offered by distributed storage options, there are notable challenges and barriers when it comes to storing sensitive medical images. One of the primary concerns is ensuring the privacy and security of patient images, while also preventing unauthorized access [21]. The sensitive nature of medical data necessitates robust privacy measures to protect patient confidentiality and complying with necessary regulations including but not limited to Health Insurance Portability and Accountability Act (HIPAA) [22]. Furthermore, a key requirement for a secure data management and its ability to handle large volumes of data across various stakeholders, including medics, health units, patients, and institutions [23].

Solution Overview: To address these challenges, we design and implement a proof-of-the-concept for a distributed framework called a Patient-Centric image management (PCMIMS). PCMIMS is a blockchain-based solution that is architected to enable secure and private management of Patient-Centric medical images within an open distributed network. We elaborate on a step-wise and incremental design,

implementation and validation of the PCMIMS solution in dedicated sections and outline the key contributions and salient features of the proposed solution below. The implications of this research and proposed solution aims to complement the research and development on exploiting blockchain technologies synergized with the IPFS to enable secure management of health-critical data. The proposed solution PCMIMS in terms of a framework, its implemented prototype, and validations could help researchers and developers to incrementally design and develop a blockchain-based Patient-Centric medical image management in a secure and efficient way. Specifically, the solution aims to improve state-of-the-art by offering:

- Blockchain-based framework (i.e., PCMIMS) that provides a structural representation of the overall solution that sketches a blue-print and guides software designers and developers about how the system operates and facilitates effective healthcare management.
- Smart contract-based implementation of Patient-Centric access to PCMIMS that ensures controlled access to medical image data for stakeholders, i.e., medics and patients. The implemented prototype employs specific functions to enable data transfer via Ethereum blockchain and establishes access privileges between relevant parties. This enhances privacy and security in the management of medical data.
- Experimental validation of the functionality of the proposed solution PCMIMS through test cases, focused on key performance metrics. These metrics include (i) number of transactions (i.e., data storage and retrieval), (ii) gas consumption (i.e., energy efficiency), and (iii) data size (volume of Patient-Centric medical images) via repeated trials in Microsoft Windows environment. This evaluation ensures the effectiveness and efficiency of the proposed framework in handling medical data and provides insights for future enhancements.

Structure of the paper: Section II provides context and background of the proposed research. Section III discusses the most relevant existing research. Section IV presents research method and motivating scenario. Section V discusses prototype-based implementation of the proposed solution. Section VI presents results of the solution validation. Section VII concludes the paper and summarizes the key findings and contributions of this research.

II. RESEARCH CONTEXT AND BACKGROUND

In this section, we provide a broader perspective and overall context of the proposed research. The context provides necessary background information in terms of some core concepts of healthcare management, distributed system, and healthcare data management. We have introduced the concepts and terminologies introduced in this section that are used throughout the paper to explain the technical concepts. Fig. 1 illustrates the core concepts and complements the theoretical description presented in this section.

A. Digital Healthcare Systems

Healthcare systems heavily rely on medical image systems for diagnosis, treatment, and monitoring of various medical conditions. These systems encompass the storage, retrieval, and analysis of medical images, specifically addressing X-rays, CT scans, MRI scans, and ultrasound images. The effective utilization of medical image systems plays a vital role in improving patient outcomes and optimizing healthcare delivery. However, the widespread adoption and integration of medical image systems in healthcare settings pose numerous challenges. One significant challenge is the sheer volume and complexity of medical images generated daily, leading to storage and management issues [12]. The exponential growth in medical image data requires robust infrastructure and storage solutions to ensure efficient access, retrieval, and secure archiving.

B. Medical Image Data

Another critical challenge lies in the interoperability and integration of medical image systems within the broader healthcare ecosystem [13]. Healthcare providers, hospitals, clinics, and other stakeholders often employ different systems and technologies, resulting in fragmented data silos. This fragmentation hinders seamless data exchange, collaboration, and comprehensive patient care. Moreover, privacy and security concerns are paramount in healthcare systems, especially when it comes to sensitive patient information contained within medical images [14]. The protection of patient privacy, compliance with regulatory requirements (e.g., HIPAA), and safeguarding against unauthorized access are essential considerations in the design, development, and operational context of medical image systems. Addressing these challenges requires innovative approaches and technologies to enhance the efficiency, interoperability, and security of medical image systems. Solutions such as distributed storage, blockchain technology, and advanced data analytics have shown promise in overcoming these hurdles [15, 16, 17]. By leveraging these advancements, healthcare organizations can optimize the management and utilization of medical images, leading to improved patient care, streamlined workflows, and enhanced decision-making processes.

Fig. 1 provides a comprehensive illustration of medical image-based data management in a distributed environment. The system ensures that user authorization is a prerequisite for accessing its functionalities. The user base comprises medics, patients, and individuals undergoing lab tests. In the patient registration process, users are required to request permission to utilize the system. Once the authorization is granted, users who have undergone lab tests can proceed to upload their test results. The MRI and radiologist specific data can be accessed via a designated web portal. It is important to note that access to the report's data is limited only to patients and doctors who have been specifically granted permission. A rigorous access control mechanism and implementation ensures that health-critical data remains private and secure and is only accessible to authorized individuals involved in patient care and treatment. The system's design and implementation prioritize data privacy and confidentiality while enabling efficient and

secure sharing of medical information within a trusted and authorized user community.

III. RELATED WORK

This section reviews the most relevant existing research in terms of discussing state-of-the-art on (i) medical image data management in centralized system in Section III A and medical image data in distributed and peer-to-peer systems in Section III B. A critical review of the most relevant existing work helps us to comparatively analyze the scope of proposed solution and justify its contributions. Table I provides the comparative analysis and act as a catalogue to distinguish between most relevant existing works and proposed solution PCMIMS.

A. Medical Imaging Data in Centralised Systems

The management of medical health records is a critical aspect of healthcare systems. Traditional paper-based records have been gradually replaced by electronic health records (EHRs), which offer numerous advantages in terms of accessibility, interoperability, and data sharing [18]. EHR systems have transformed the way patient information is stored and accessed, enabling healthcare providers to have comprehensive and real-time access to patient data. Advanced medical imaging techniques, such as CT scans, MRI scans, and X-rays, play a pivotal role in diagnosing and monitoring various medical conditions. These imaging modalities generate large volumes of data, and efficient storage and retrieval systems are essential for their effective utilization in healthcare [19]. Imaging systems need to handle the complexities of different image formats, metadata, and associated clinical information. The management of medical images involves storing, organizing, and accessing various types of images, including CT scans, MRI scans, and X-rays. With the increasing volume and complexity of medical images, there is a growing need for efficient storage, retrieval, and analysis solutions [20]. Centralized and decentralized approaches have been explored to address the challenges of managing and sharing medical images.

Centralized systems, such as cloud-based storage and data centers, have been widely used in healthcare for storing and managing medical images. These systems offer centralized control, efficient storage, and accessibility but raise concerns regarding data security, privacy, and single points of failure [21].

B. Medical Imaging in Peer-to-Peer Distributed Systems

In contrast to the centralized management of medical images, decentralized approaches, such as distributed file systems and blockchain technology, have gained attention as potential solutions for medical image management [22].

Distributed file systems, like the InterPlanetary File System (IPFS), offer a decentralized architecture for efficient and secure storage and sharing of medical images [23]. Blockchain technology provides a distributed and immutable ledger that ensures data integrity, transparency, and privacy in medical image systems [24].

Fig. 1. Context: decentralized management of medical image data.

Researchers have explored the integration of centralized and decentralized approaches to strike a balance between efficiency, scalability, security, and privacy in medical image systems [25]. These studies aim to leverage the benefits of decentralized systems while addressing the challenges associated with data management, privacy, and interoperability.

Fig. 1 provides a comprehensive illustration of the entire system, depicting each step and process involved. The system ensures that user authorization is a prerequisite for accessing its functionalities. The user base comprises the medics (doctors, nurses, etc.), patients, and individuals undergoing lab tests. During the patient registration process, the users are required to request permission to utilize the system. Once the authorization is granted, users who have undergone lab tests can proceed to upload their test results and MRI radiologist image data through the designated website. It is vital to mention that access to the report's data is limited only to patients and doctors who have been specifically granted permission. This strict access control mechanism ensures that sensitive medical information remains secure and is only accessible to authorized individuals involved in patient care and treatment. The system's design and implementation prioritize data privacy and confidentiality while enabling efficient and secure sharing of medical information within a trusted and authorized user community.

Comparative Analysis and Summary: Table I provides a concise comparison of the proposed framework with other existing blockchain-based medical imaging and health data management systems. The table highlights the advantages offered by the PCMIM system over its competitors. It is evident that the PCMIM system outperforms the alternatives in terms of various benefits and features.

The table serves as a valuable reference, showcasing the superiority of the PCMIM system in comparison to the

existing alternatives, thereby reinforcing its potential as an innovative and promising solution for effective medical health record management.

TABLE I. COMPARISON BETWEEN THE EXISTING AND PROPOSED PCMIMS SYSTEM

Scheme	[3]	[12]	PCMIMS System
Source Data Storage	Dedicated	Server	Immutable IPFS Storage
Encryption	Symmetric Encryption	✓	Asymmetric Encryption
Server Attack Resistance	×	×	✓
Database Management	Centralized	Centralized	Decentralized
Smart-Contract	×	✓	✓
Data-Access	×	×	✓

IV. RESEARCH CONTEXT AND BACKGROUND

This section presents the research method that is employed to conduct this research study, outlining the design specifics of the proposed solution. Fig. 2 provides an overview of the research methodology, which comprises four distinct stages. These stages follow an incremental approach, allowing for the assessment, development, and validation of the solution.

A. Steps of Research Method

The research methodology followed a structured process consisting of four distinct steps.

- Phase I: Literature Review involved a thorough examination of a diverse range of literature sources, including peer-reviewed research articles, technological road maps, and technical reports, to identify existing solutions and their limitations.

```
01: function AddImageCentric(string memory patientUserId, uint appointment_id,  
02: string memory description, string memory filehash) public{  
03: imgCount ++;  
04: GetImageCentric_Id [_appointment_id] = ImageCentric(imgCount, appointment_id, _description, _filehash, now);  
05: PatientRecordAccess [_patientUserId][_appointment_id] = ImageCentric (imgCount, appointment_id, _description, filehash, now);  
06: emit ImageCentricCreated(imgCount, appointment_id, _description, filehash, now);  
07: }
```

Listing 1. Code snippet for adding image to the chain.

To gather the most relevant papers in the field, a systematic literature review was conducted. This comprehensive review of existing research and development solutions helped establish the research scope and streamline the necessary solutions.

- Phase II: System Design focuses on architectural design of the proposed solution. Here, the proposed solution was meticulously modeled and simulated in accordance with established standards, such as the ISO/IEC/IEEE 42010:2011 standard [26].
- Phase III Algorithmic Implementation encompassed the implementation of algorithms, which involved executing the solution through computational and storage-intensive phases. The solution was broken down into modular algorithms that could be customized by users with specific inputs, adhering to executable standards and underlying source code.
- Phase IV Algorithmic Evaluation steps revolve around validating the solution by assessing its functionality and quality using the ISO/IEC-9126 model [26]. Well-established assessment metrics were employed to evaluate the system's usability and efficiency. While the first two steps required manual effort and human decision-making, the latter two phases involved human interaction and tool support. The validation phase provided insights for potential algorithm enhancements to improve efficiency or modify functionality based on the evaluation results. Overall, this methodology, as depicted in Fig. 2, ensured a comprehensive and systematic approach to solution development and evaluation.

Fig. 2. An overview of four phases of research method.

B. Motivating Scenario

Fig. 3 illustrates a comprehensive process involved in storing and managing medical imaging and test reports within the proposed framework. The medical images are managed and stored via IPFS by the radiologist, who is responsible for the image acquisition and interpretation within the lab. The radiologist uploads the medical image data to IPFS, and in return, receives a unique hash key associated with the stored image. This hash key, along with other necessary information, is then linked and stored within the blockchain. It is important to note that the processes for medical image uploading are distinct from each other. The file hash of the medical image is then linked to the relevant details and stored within the blockchain. This systematic approach ensures the secure and efficient storage of medical images while maintaining the integrity and traceability of the data within the proposed framework.

The process of medical image data sharing is triggered via the creation of metadata for the original data file, which includes essential information such as the file's name, type, description, and size (Line 1 – Line 2) in Listing 1. Once the metadata is complete, it is uploaded to the IPFS along with the corresponding data file. To achieve this, a smart contract is created for the storage of the data in the blockchain by means of a function named 'AddImageCentric' (Line 4) with required parameters (Line 1). In order to streamline the data mapping process, two separate mappings are employed. The first mapping enables retrieval of a comprehensive list of all blood tests that are linked to a patient's appointment ID and the second mapping facilitates access to data specific to individual patients based on two parameters namely patient ID and appointment ID. To provide a seamless user experience and enhance data traceability, the 'ImageCentricCreated' event is triggered, signaling the successful creation of the image-centric data entry. This robust and organized approach ensures efficient data sharing and retrieval within the proposed framework while leveraging the advantages of blockchain technology and IPFS.

Blockchain-based management and IPFS based transmission of data ensures secure and transparent storage and transfer of medical image-centric data. Fig. 4 depicts two distinct categories of medical data uploading within the Decentralized Application (DApp) framework.

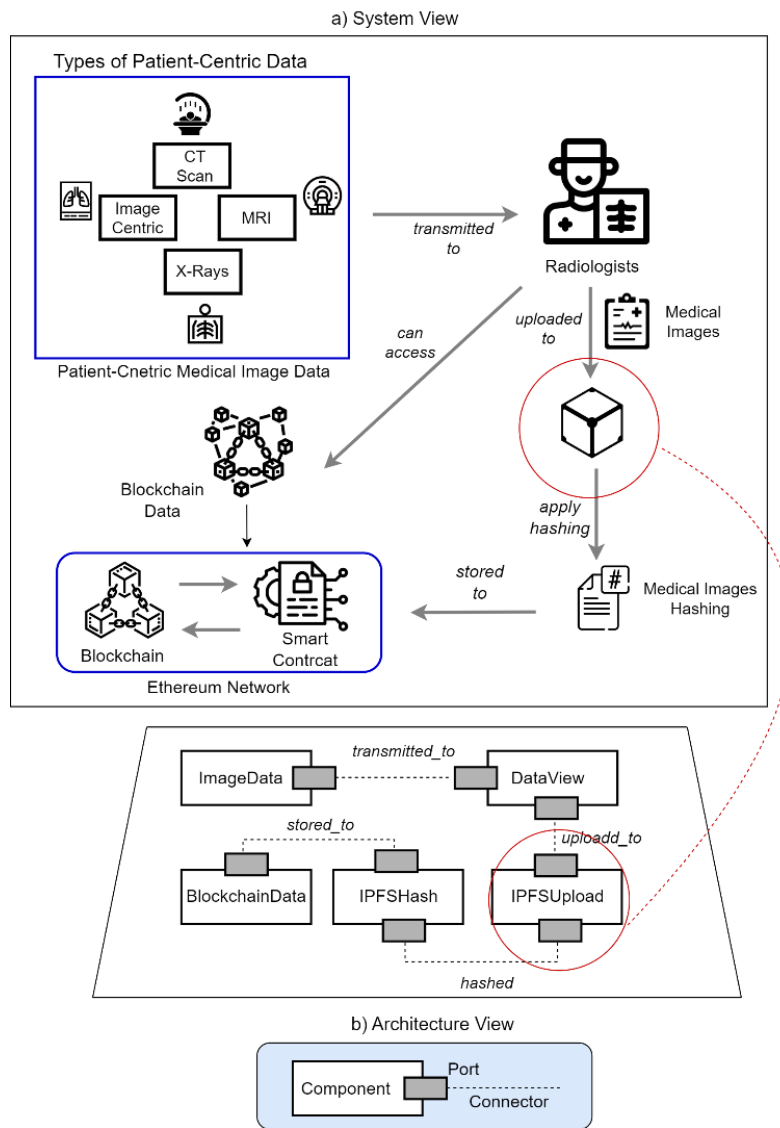

Fig. 3. Patient-Centric data storage process.

(a) Overall System View, b) Architecture View

It pertains to medical images, which are connected to other examinations and tests by a radiologist. The radiologist utilizes the DApp system to upload the medical images to IPFS. Alongside the image upload, the radiologist provides the remaining essential details that include patient ID and appointment ID that are stored and retrieved via blockchain. This integrated approach ensures that medical images are seamlessly linked to the relevant patient and appointment data, enabling efficient retrieval and analysis.

The service cycle depicted in Fig. 4 continues to repeat itself at fixed intervals or auto triggered via receipt of medical image data, provided by the server. The dashboard serves as a platform that offers access to both doctors and patients acting as a web-accessible portal, enabling PCMIMS users to access, view, customize and download the medical images over the network. The web portal provides a convenient means of retrieving the health critical data (medical imaging, test

reports etc.), with data retrieval based on customized parameters such as patient ID and appointment ID mappings [27] [28].

V. IMPLEMENTATION OF THE ALGORITHMS AS SOLUTION PROTOTYPE

This section discusses the implementation details in terms of the developed algorithms that provide a proof-of-the-concept prototype in Section VA. The discussion on algorithms is complemented with the details of tools and technologies for implementing the algorithms in Section V B. A precise discussion of the tools and technologies used for the implementation can help designers and developers to gain insight into the software tools that can be used to implement the solution [29].

A. Algorithmic View of the Developed Solution

The algorithms provide a modular implementation of the designed solution as in Fig. 3. Each of the two algorithms presented below are detailed in terms of their *inputs*, *processing*, and *outputs*, each elaborated below.

Algorithm 1 shows a step-wise and incremental this section demonstrates and describes the uploading feature for medical data. The technique specifically focuses on uploading medical image data to the IPFS and also applies hashing to the medical image data file for an extra security feature before its representation as a smart contract and storage in the blockchain. The uploaded data is associated with a number of parameters that include but are not limited to user and appointment identities (UserID, Appointment ID) along with description (Description), and data of the appointment (Date).

Algorithm 1 Decentralizing Medical Image

Parameters:

U_ID: User ID
A_ID: Appointment ID
Des: Description
Img = Image

```
1: Income: U_ID, A_ID, Des, Img
2: Outcome: O //Returning Result
3: procedure DATACENTRICMODULE // Function
4: if U_ID is Valid then //Decentralizing Image
5: File_Stream ← File(Img) //Get File stream FS
6: File_Buffer ← Buffer.form (File_Stream) //Convert
7: File_Hash ← IPFS.Add (File_Buffer)
8: O ← SBC(U_ID, A_ID, Description, File_Hash) // Store
Image hash and Data to Blockchain
9: end if
10: end procedure
```

- **Income:** The input to the algorithm involves mapping the parameters with a unique hash key of the medical image file. This mapping process occurs as part of the input. The input parameters include User ID, Appointment ID, and Description of the appointment and Medical Image. Combinedly, these parameters provide information about an individual user and their medical related information. The parameters provide customization and parametrized input to the solution.
- **Processing:** During the processing stage, the medical image data is being retrieved and processed for its conversion into a buffer package. The buffered data, comprising of medical image data is stored as IPFS as a medical data file that in turn hashes the data and generates a hashed key for data access. The additional parameters that include user and appointment identities (UserID, Appointment ID) along with description (Description), and data of the appointment (Date) are associated to the hash key. These parameters are subsequently are part of the smart contract that are privately stored on the blockchain.

- **Outcome:** Finally, the output stage involves managing and storing the processed medical image data in the blockchain. The mapped date, along with the associated parameters, is stored as the output of the algorithm, ensuring the secure and traceable storage of the uploaded medical data.

Algorithm 2 focuses on validating data accessing capabilities. The algorithm's primary purpose is to access the data in a secure way and make it accessible to authorized entities. By utilizing this algorithm, users can access specific data stored on the blockchain, driven by customized parameters. Notably, there are multiple types of data access available within the algorithm's processing stage. As an example, a user can access their data via user and appointment identities (UserID, Appointment ID) along with description (Description), and data of the appointment (Date).

Algorithm 2 Presentation Layer

Parameters:

U_ID: User ID
A_ID: Appointment ID
U_Type: User Type
T_Type= Test Type

```
1: Income: U_ID, A_ID, U_Type, T_Type
2: Outcome: O
3: procedure Interface_Module
4: if U_Type == D then //Image Access
5:  $\epsilon$  ← Get_Report(T_Type) // Test Type
6: end if
7: R ← Update_Dashboard( $\epsilon$ ) //Data Dashboard
8: end procedure
```

- **Income:** During the input stage of the algorithm, the settings for data access are mapped, enabling the algorithm to determine the appropriate parameters for retrieval. The input parameters include User ID, Appointment ID, User Types and the medical Test Type. Combinedly, these parameters provide information about an individual user and their medical test being performed.
- **Processing:** The processing stage of the algorithm revolves around granting various forms of data access. This includes allowing users to access their data based on the mapping between their user and appointment identities (UserID, Appointment ID). Moreover, the medics such as the doctors or nurses can readily access the medical image data and reports by utilizing the appointment ID associated with the user (UserID).
- **Outcome:** As a result of the algorithm's execution, the output consists of publicly accessible data that has been mapped according to the defined parameters. This ensures that authorized users, such as patients and doctors, can retrieve the relevant data from the blockchain.

B. Tools and Technologies for Algorithmic Implementation

In this section, we present a concise overview of the complementary tools and technologies employed in the proposed solution, aiming to enhance the reader's comprehension of the underlying technology.

The combination of stacked tools and technologies, as depicted in Fig. 4, offers a comprehensive solution. For instance, if a radiologist accesses the portal, they can securely upload encrypted medical image files to the IPFS platform, receiving a hash key for subsequent validation of the proposed solution [30] [31].

VI. VALIDATION AND RESULTS

After presenting the implementation of the solution, we now discuss details on validation of the solution. To discuss the validation results objectively, we present the evaluation environment in Section VI A. We then elaborate on validation of the solution based on correlation between the number of transactions, gas consumption, and block data size. Finally, we also present computational efficiency of the solution in terms of processing three most common types of Patient-Centric medical images namely (a) Magnetic resonance imaging (MRI) (b) X-radiation (X-Rays), (c) Computed tomography (CT) scan.

A. Setting up the Evaluation Environment

The evaluation environment was carefully designed to include a combination of hardware and software resources that were essential for effectively executing and monitoring the different phases and outcomes of the solution. For the hardware-based evaluation experiments, a Windows platform was utilized, featuring a powerful core i7 processor and 16 GB of RAM. This robust hardware configuration provided the necessary computing power and memory capacity to handle the demanding tasks involved in the evaluation process. On the software front, a set of evaluation scripts was developed using NodeJS and ReactJS, two widely used technologies in the software industry. These scripts were executed within the popular integrated development environment, Visual Studio Code, allowing for efficient code development and testing. The scripts were specifically designed to automate system testing and incorporated various libraries, such as React, Web3, and IPFS.HTTP. These libraries provided essential functionalities and streamlined the evaluation process.

To thoroughly analyze the CPU consumption during the evaluation, a specialized JavaScript performance library script was employed. This script enabled detailed assessment of CPU usage during critical tasks, including the uploading of medical image data to IPFS, storing it securely on the blockchain, and retrieving data from the blockchain. This analysis provided valuable insights into the system's performance and efficiency.

Furthermore, the evaluation environment included the utilization of the Ganache suite, a comprehensive toolset for establishing a local Ethereum blockchain environment. The Ganache suite allowed for the creation of a personalized blockchain network, facilitating testing, command execution,

and observation of the blockchain's state. To enable connectivity with the distributed web and interact with the Ethereum network, the Metamask extension was employed within the browser. This extension seamlessly connected local Ethereum accounts to the Ganache suite, enabling smooth and reliable system functions while considering gas transaction costs.

B. Discussion I - Data Transmission and Gas Consumption

In our suggested solution, we specified the cost of executing the contract migration, which was presented in Table II. This cost was denominated in Ether, and the amount of gas spent during the execution was recorded. To determine the value of Ether, the amount of gas utilized was multiplied by the current gas price. It is important to highlight that the gas price can fluctuate in response to network dynamics and changes in the value of Ether. This dynamic adjustment ensures that the gas cost accurately reflects the ongoing computational expenses within the system, providing a fair and efficient pricing mechanism. During the evaluation process, one of the crucial parameters tested was the time required for users to upload and store data to IPFS and the blockchain ledger. This test parameter encompassed the overall time spent on data. The findings of a series of experiments conducted on an average data size are depicted in Fig. 4. This indicates that the suggested methodology is capable of handling larger data sizes without incurring a notable impact on fuel consumption.

TABLE II. SUMMARY OF THE EXECUTION COST ANALYSIS

Parameter Serial	Computation Efficiency (Execution Time)	Energy Efficiency (Gas Utilisation)	Ether Cost (Overhead)
1	Contract Initialisation	225 (in thousands)	0.058
2	Contract Instantiation	286	0.053
3	Contract Call Initiation	42	0.045
4	Contract Migration	27	0.084
Average		145	0.061

These results validate the effectiveness of the proposed solution in efficiently managing the uploading and storing of medical data to IPFS and the blockchain ledger, even as the data size increases. However, it is important to note that despite the increase in data size, the suggested methodology for uploading medical data to IPFS showcased consistent and efficient fuel usage. The difference in fuel consumption between uploading 450-byte data and 1000-byte data was not found to be significantly significant. This indicates that the suggested methodology is capable of handling larger data sizes without incurring a notable impact on fuel consumption. These results validate the effectiveness of the proposed solution in efficiently managing the uploading and storing of medical data to IPFS and the blockchain ledger, even as the data size increases. The suggested methodology ensures a reliable and streamlined process, enabling users to securely upload and access their medical data with minimal impact on fuel consumption.

Fig. 4. Gas consumption calculated based on the size of block and number of transactions.

C. Discussion II – Query Response Time

When it comes to storing medical images in IPFS and recording relevant information in the blockchain, efficient data querying becomes a crucial aspect. The query response time plays a vital role in assessing the solution's effectiveness in storing and retrieving data from the blockchain. Fig. 5 provides a visual representation of the execution time involved in accessing the data within this context. The data can be classified into two distinct types. The first type pertains to medical images that are fetched from IPFS using their respective file hashes. This approach ensures a decentralized and distributed storage mechanism for medical images. However, in the case of example number six, it is observed that the execution time is and review, collectively referred to as data uploading and accessing time. The findings of a series of experiments conducted on an average data size are depicted in Fig. 5.

However, it is important to note that despite the increase in data size, the suggested methodology for uploading medical data to IPFS showcased consistent and efficient fuel usage.

The difference in fuel consumption between uploading 450-byte data and 1000-byte data was not found to be significantly significant. However, in the case of example number six, it is observed that the execution time is relatively high compared to other cases. This can be primarily attributed to the larger file size of the medical image associated with this particular scenario. As the file size of the medical image increases, it naturally requires more time for display or download from IPFS. The larger data volume associated with the larger file size contributes to an extended retrieval time. This phenomenon aligns with the intuitive understanding that larger files necessitate more data to be transferred, resulting in a slightly longer execution time. This observation highlights the impact of file size on the retrieval process and emphasizes the need to consider the trade-off between file size and retrieval time when dealing with medical images stored in IPFS. Finding the right balance between image resolution and file size can play a significant role in optimizing the execution time for accessing and displaying medical images in the given solution.

Fig. 5. Computation efficiency and function execution to store the data in IPFS and blockchain.

VII. CONCLUSION AND FUTURE WORK

Decision support and intelligence in healthcare care systems can greatly enhance the cost and efficiency of the healthcare systems. More specifically, the intelligence embedded in electronic healthcare systems relies on efficient processing of medical health data. However, the dispersion of these images across multiple systems poses a challenge for effective and integrated healthcare. Additionally, centralized hosting solutions for picture data, such as cloud-based platforms, can be vulnerable to security breaches. Recognizing the distributed nature of healthcare, there has been increasing attention towards decentralized designs and system interoperability. This research design and implements a proof-of-the-concept for a decentralized Patient-Centric Medical Image Management System (PCMIMS). Built upon the Ethereum blockchain and IPFS, this framework aims to address the storage and distribution challenges associated with medical images. PCMIMS empowers medical images users with secure and private control over their medical images and test reports (such as blood reports, lipid reports) through a DApp web application portal.

1) *Evaluation of the proposed solution:* To evaluate the efficiency, feasibility, and practicality of the proposed scheme, we conducted an experimental implementation. The suggested system not only facilitates the sharing of medical images but also provides patients with access to an immutable medical

database, thereby enhancing efficiency, data provenance, and effective auditing. By employing a decentralized data storage and exchange mechanism, the need for intermediaries or administrative entities is eliminated. Overall, the PCMIMS system presents a unique solution that prioritizes patient rights and control over their medical data. Through decentralization and the utilization of blockchain and IPFS technologies, this system offers enhanced security, privacy, and accessibility in the management of medical images and test reports.

2) *Vision for future research*: In the current scope of the proposed solution, there is a need for future research to increase the pervasiveness of the proposed solution and rigor of its validation. More specifically, the future work is focused on:

- Developing, deploying, and validating the proposed solution in mobile health (mHealth) context. Mobile devices can offer pervasive healthcare but pose significant challenges related to resource poverty of mobile devices along with security and privacy of health critical data.
- Evaluating the proposed solution via survey or trials with the domain experts, i.e., medics and healthcare professionals. An incorporation of the domain experts' feedback can help us to analyse and improve the solution based on practitioner' perspective.

3) *Implications for research and practices*: The implications can be attributed to the relevance and benefits of the proposed solution in an academic and industrial context. Blockchain-based framework (i.e., PCMIMS) that provides a structural representation of the overall solution that sketches a blue-print and guides software designers and developers about how the system operates and facilitates effective healthcare management. Academic researchers can exploit architectural design to design and develop emerging solution for blockchain systems in healthcare context. Practitioners can rely on the algorithms and relevant tools to develop solutions that rely on blockchain solutions for managing electronic healthcare systems.

Abstract—Medical image fusion plays a vital role in enhancing the quality and accuracy of diagnostic procedures by integrating complementary information from multiple imaging modalities. In this study, we propose an ensemble learning approach for multi-modal medical image fusion utilizing deep convolutional neural networks (DCNNs) to predict brain tumour. The proposed method aims to exploit the inherent characteristics of different modalities and leverage the power of CNNs for improved fusion results. The Generative Adversarial Network (GAN) strengthens the input images. The ensemble learning framework comprises two main stages. Firstly, a set of DCNN models is trained independently on the respective input modalities, extracting high-level features that capture modality-specific information. Each DCNN model is fine-tuned to optimize its performance for fusion. Secondly, a fusion module is designed to aggregate the individual modality features and generate a fused image. The fusion module employs a weighted averaging technique to assign appropriate weights to the features based on their relevance and significance. The fused image obtained through this process exhibits enhanced spatial details and improved overall quality compared to the individual modalities. On a diversified dataset made up of multi-modal medical images, thorough tests are carried out to assess the efficacy of the suggested approach. The fusion images exhibit improved visual quality, enhanced feature representation, and better preservation of diagnostic information. The BRATS 2018 dataset, which contains Multi-Modal MRI images and patients' healthcare information were used. The proposed method also demonstrates robustness across different medical imaging modalities, highlighting its versatility and potential for widespread adoption in clinical practice.

Keywords—Deep convolutional neural networks; image fusion; generative adversarial network; ensemble learning

I. INTRODUCTION

In recent years, the field of medical imaging has witnessed tremendous advancements with the availability of multiple imaging modalities. Each modality provides unique information about anatomical structures, functional processes, or disease characteristics, making it crucial to extract comprehensive insights by combining data from multiple

modalities [1]. To effectively utilize the complementary information present in multi-modal medical images, researchers have turned to image fusion techniques. Image fusion aims to integrate data from different modalities into a unified representation, allowing for enhanced visualization, improved diagnostic accuracy, and better decision-making in clinical settings [2]. Several tasks related to computer vision, such as picture categorization, object identification, and categorization, have shown DCNN to be quite effective. In recent years, DCNNs have also gained significant attention in the domain of medical image analysis due to their ability to automatically learn complex features from large-scale data [3].

With the use of convolutional neural networks with deep layers, this work suggests a collaborative learning approach for fusing multimodal medical images. This method aims to overcome the limitations of traditional fusion methods by automatically learning the optimal fusion strategy from the data itself. The ensemble learning framework involves training multiple DCNNs, each specializing in capturing distinct features from different modalities [4]. These networks are designed to learn a shared representation that combines the information from each modality effectively. The ensemble is formed by aggregating the predictions of these networks, yielding a fused image that encapsulates the strengths of each modality [5]. By adopting an ensemble approach, this method leverages the diversity and complementary nature of the individual networks, resulting in a more robust and accurate fusion outcome. Additionally, the ensemble enables us to address uncertainties associated with the fusion process by providing a measure of confidence for the final fused image [6].

We carried out comprehensive experiments on a wide range of multi-modal healthcare imaging datasets in order to assess the performance of the suggested technique. The results demonstrate the superiority of ensemble learning approach over traditional fusion methods and even single DCNN-based fusion techniques. The fused images exhibit improved clarity, enhanced structural details, and better discrimination of abnormal regions, making them highly valuable for clinical

decision support and medical research. ensemble learning approach for multi-modal medical image fusion, employing deep convolutional neural networks, offers a promising solution for extracting comprehensive information from multi-modal medical images [7]. By effectively integrating the strengths of different imaging modalities, this method holds the potential to advance the field of medical imaging and facilitate more accurate and informed clinical diagnoses. The classification of medical images is crucial to both medical management and educational endeavors [8]. The traditional approach's performance has reached its apex, though. In addition, it takes a lot of effort and time to extract and select classification parameters when using them [9]. The DCNN is an innovative approach to machine learning that has proven beneficial for a variety of categorization issues. CNN excel at a number of picture categorization tasks, producing the best results. However, medical image collections are difficult to compile since classifying them calls for an exceptionally high degree of professional competency [10].

Deep Convolutional Neural Networks (DCNNs) have also been employed for medical image fusion, offering several applications in healthcare. DCNNs can fuse low-resolution medical images with high-resolution images to generate enhanced, high-resolution images. This technique can be particularly beneficial in medical imaging, where higher resolution can provide better visualization of fine details, aiding in accurate diagnosis and treatment planning. DCNN-based fusion methods can fuse multiple images to generate a fused image with improved segmentation accuracy. By integrating information from different imaging modalities or perspectives, the fused image can provide more accurate and reliable boundaries and regions of interest for subsequent analysis and treatment planning [11].

DCNNs can be utilized for medical image registration, which involves aligning images from different modalities or time points. By fusing information from multiple images, DCNN-based methods can improve the accuracy and robustness of image registration, allowing for more precise analysis, monitoring, and treatment planning. It can fuse images from different sources to synthesize new images with desired characteristics or properties [12]. For example, fusing images from different imaging modalities can create a synthesized image that combines the strengths of each modality, providing comprehensive information for clinical analysis and decision-making. DCNNs can be employed for restoring medical images that are corrupted by noise, artifacts, or other degradations [13]. By fusing multiple degraded images, DCNN-based methods can effectively de-noise and enhance the image quality, enabling better visualization and interpretation of medical conditions. These applications demonstrate the versatility and effectiveness of DCNN-based medical image fusion techniques in improving image quality, accuracy, and clinical decision-making in various healthcare scenarios [14].

The key Contributions of this Research work is:

- The ensemble learning framework involves training multiple DCNN models independently on respective

input modalities, capturing modality-specific information.

- A fusion module is designed to combine the extracted features from individual modalities, employing a weighted averaging technique to assign relevant and significant weights.
- The fused image obtained through this process exhibits improved spatial details, enhanced feature representation, and better preservation of diagnostic information.
- Thorough testing on a diverse dataset confirms the efficacy, visual quality, and robustness of the proposed method, showcasing its potential for broad adoption in clinical practice.

The manuscript of the approached paper is organized as follows: In Section II, some related works are reviewed. In Section III, Information regarding the problem statement is provided. In Section IV, the proposed Multi-Modal Image Fusion is covered in detail. In Section V, experiment results are provided, and discussed in Section VI with an extensive evaluation of the proposed approach to current best practices is made. In Section VII, the conclusion of the paper is provided.

II. RELATED WORKS

Maqsood et al. [15] suggested a multimodal fusion of images approach is based on limited representation and two-scale picture segmentation. The original heterogeneous images are initially subjected to contrast enrichment processing in the proposed system, which improves the brightness distribution for better visualization. The edge data gathered from intensity extended images is extracted using a spatial gradient-based edge detection method. The fundamental and detail layers are separated from the improved multiple mediums images at this point. Utilizing SSGSM, the final detailed layer is extracted. Finally, the fused image is produced utilizing an improved judgement maps and fusion scheme. By conducting both quantitative and qualitative evaluations, the experimental results demonstrate that the recommended multimodal picture fusion strategy outperforms several previous methods. However, it could happen for certain data from the initial images to be destroyed or distorted during the fusion process. The fusion mechanism may prioritize some qualities or aspects while ignoring others, resulting in the loss of crucial information or subtle traits.

Dinh et al.[16] proposed that the following are the key phases in the unique strategy that was presented to address the aforementioned shortcomings. In order to acquire the basic and detail elements, the three-scale deconstruction (TSD) approach is initially presented. Second, the output picture is fused using a rule based on the nearby energy function and the Kirsch compass operator, which aids in the retention of critical information. Thirdly, to fuse base layers with the best characteristics and produce a high-quality picture, the Marine Processors Algorithm (MPA) is used. This work compared the effectiveness of the suggested technique using six photograph quality criteria and five cutting-edge medical image fusion

algorithms. Experiments revealed that the proposed method significantly increased the level of quality of the fusion picture and preserved edge information. The particular fusion algorithm used has a significant impact on the effectiveness of multidimensional picture fusion. Additionally, there doesn't exist a one-size-fits-all solution, and different techniques may yield different fusion results. The effectiveness and level of quality of the combined image can be considerably impacted by the algorithm choice.

Diwakar et al. [17] proposed a novel shearlet region multiple modalities image fusion method. The recommended technique uses Non-Subsampled Shearlet Transformation (NSST) to separate input pictures into low- and high-frequency parts. The localized extrema (LE) method is a unique technique used to separate and merge the fundamental layer and details layers. The co-occurring filter (CoF) is then used to combine the foundation layer and detail layer in harmonics with smaller elements. A high-frequency component is integrated using a sum modulated Laplacian (SML) as a component of an edge-preserving technique to image fusion. On the Multi-modal healthcare picture collection, experimental findings and contrasting assessment are performed using both recommended and modern methodologies. The recommended strategy beats cutting-edge fusion techniques in terms of blade retention in both objective and subjective assessment requirements, according to test findings and assessments. Numerous multidimensional merging of images algorithms is computationally demanding, requiring a significant amount of time and computing capacity. This could be a drawback in situations or real-time applications that need for quick fusion.

Stimpel et al. [18] demonstrated the globally linear guided filter for general medical image processing when coupled with a learning guiding map. The guided filter is the only element processing the output images, and its direction map may be trained to do the task optimally from beginning to end. The demising and graphic high-resolution tests are the two most often used activities when using this method to measure performance. The evaluation is based on cross-modal data sets that are paired. Modern methods are coupled with the provided procedure to achieve both goals. This can also show that the input image's information is basically unaltered after treatment, in contrast to conventional deep neural network approaches. The suggested pipeline also offers greater resilience against adversarial attacks and deteriorated input. Image fusion requires accurate registration of images from different modalities to align corresponding anatomical or functional structures. However, image registration can be challenging due to differences in acquisition protocols, patient motion, and anatomical variations. Registration errors can lead to misalignment and distortions in the fused image, affecting the accuracy of subsequent analysis.

Asha et al. [19] suggested a chaotic grey wolf optimization algorithm-based balanced blending of high-energy sub-bands of the Non-Subsampled Shearlet Transform (NSST) domain. The raw images are first dissected into their many scales and multi-directional components using the NSST. The modest number of pathways were combined according to a simple maximum rule in order to sustain the energy of an individual.

In order to combine images of various frequencies and minimize the difference between the resultant image and the starting point pictures while retaining the textural characteristics of the input images, a collection of automatically adjusted high-frequency images is used. The major goals of the entire procedure are to maintain the energy of a low-frequency region while transferring textural details from the source images to the fused image. In order to construct the fused picture, the inverse NSST of the combining minimal and high-energy bands is used. Eight distinct illness datasets from Brain Atlas are used in the trials. More than 100 picture pairings are used to evaluate the efficacy of the suggested strategy using both objective and subjective quality evaluation. Due to the lack of contemporaneous collection of several modalities or the difficulty in gathering ground truth annotation for fusion quality, obtaining grounding truth for multipurpose fusion in medical imaging is problematic. Due to this, evaluating and comparing fusion procedures quantitatively is more difficult and frequently relies on opinions or substitute measurements.

Li et al. [20] To address the issue of poor contrast detail, a powerful image fusion technique employing numerous prominent features and a guided image filter was presented. The input photos were first divided into a number of calming and thorough images that had different scales before being subjected to the directed picture filter. Second, two different algorithms are used to extract important characteristics from the broken-down dependent upon visuals alongside the complete images in order to develop the combination rules. These two algorithms are the spectral residual (SR) technique for the mainframe gathering and the graph-based visually prominence model for a gradient saliency information extraction. The decomposition factors are combined using a process known as generalized intensity-hue-saturation (GIHS). The fused image is then reconstructed from the combined smoother and detailed images. The experimental findings show that, in the fields of MRI-PET and MRI-SPECT fusion, the proposed algorithm can outperform previous fusion approaches. The acceptability and use of fusion procedures in clinical practice, where openness and comprehensibility are vital, may be hampered by this lack of comprehension. The availability of information for the various modalities in multipurpose medical imaging may not be equal, meaning that one modality may contain greater numbers of specimens than the others. The fusion process may be impacted by this modality imbalance, which might result in biased fusion findings or a restricted representation of less common modalities.

Dai et al. [21] suggested that transformers have enormous promise for multimodal medical picture categorization. The proposed approach is based on the successful extraction of the link among sequences by the transformer. However, due to the small dimensions of medical information sets for pictures and the lack of sufficient data to establish the connection between low-level semantic variables, the precision of pure transformation systems based on ViT and DeiT is not good in versatile classification of medical images. TransMed is therefore suggested as a way to collect both cross-modality high-level information and low-level characteristics.

TransMed combines the benefits of both CNN and Transformer. TransMed converts the multimodal pictures into sequences, delivers them to CNN for processing, and then use transformers to discover the connections between each sequence and provide predictions. TransMed beats the current multipurpose fusion approaches when it comes to of parameters, operating speed, and accuracy because the transformer successfully models the global aspects of multifaceted pictures. Finding the best fusion approach, though, is a challenging task. Different fusion methods, each with various advantages and disadvantages, may be used, including pixel-level, decision-level fusion and feature-level. For a certain application or modality combination, choosing the best fusion approach necessitates extensive thought and skill.

III. PROBLEM STATEMENT

Multi-modal medical imaging provides valuable complementary information for accurate diagnosis, treatment planning, and monitoring of various diseases. The issue of successfully integrating and fusing data from many imaging modalities is still difficult. Traditional fusion methods' dependence on ad hoc extraction of features and fusion techniques that commonly use handmade feature extraction that approximate complicated interactions between paradigms may restrict the quality of the merged image. Furthermore, the actual applicability of these approaches in clinical contexts is hampered by their lack of stability and interpretability. CNN have proven to perform exceptionally well in a variety

of computer vision applications, including the processing of medical images. CNNs have not yet been extensively used in multi-modal medical picture fusion, nevertheless. The research gap in the mentioned existing works lies in the need for more comprehensive and adaptable multimodal image fusion techniques that can simultaneously address various aspects of quality enhancement, edge preservation, and overall visual fidelity. The proposed DCNN aims to overcome the limitations of traditional fusion methods and single CNN-based approaches by effectively capturing the complementary information present in multiple modalities and improving the fusion quality. The ensemble learning framework is expected to leverage the diversity and strengths of individual networks to enhance the accuracy, robustness, and interpretability of the fusion process [22].

IV. PROPOSED ENSEMBLE LEARNING APPROACH

The suggested method entails enhancing the supplied image. Then DCNN are used to accomplish Medical Image Fusion. The performance is then assessed. The suggested method for Multi-Modal Medical Image Fusion using DCNN is shown in Fig. 1. The input photographs are first preprocessed by converting them to a standard scale and using the proper transformations to improve image details. Then, using a sizable dataset of aligned multi-modal pictures and a fusion-specific loss function, a CNN architecture is created, consisting of shared and modality-specific convolutional layers. From each modality, high-level feature maps are retrieved using the trained CNN.

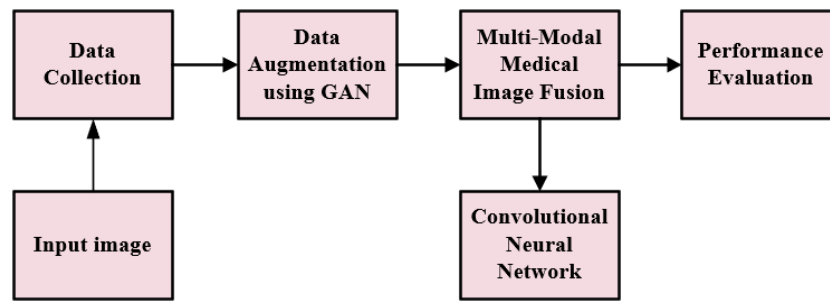

Fig. 1. Proposed approach for multi-modal medical image fusion.

A. Data Collection

The BRATS 2018 dataset, which contains Multi-Modal MRI images and patients' healthcare information with distinct heterogeneous histologic sub-regions, different levels of aggression, and variable prognosis, was used for training and testing in this work. These clinical multi-modal MR images have been generated using a range of magnetic field intensities and scanners [23]. Table I describe the dataset for Training and Validation.

TABLE I. THE COLLECTED DATASETS

	Training data	Testing data
Unhealthy	350	350
Healthy	250	250
Overall data	600	600

B. Data Augmentation using GAN

Data analysis, enhancement, combination, and rescaling are all part of preprocessing. The acquired source photographs are transformed to RGB images before augmentation. The improvement method is used to build more powerful simpler models that are impervious to some sorts of picture manipulation, following which the image's quality is altered to improve the information's integrity and degree of variability. The layering placement of the original photos is important for the concatenation. The first phase is the R channel of an MRI, and the second layer is the R channel of a PET scan (positron emission tomography). In the second layer, the B(Blue) channels of MRI and the B channels of PET are placed after the G(Green) channels of MRI and the G channel of PET, respectively. The pictures that offer practical details must be maintained below the photos that offer structural details in all pathways, it must be highlighted [24].

Fig. 2 the generator creates a picture according to the parameters that are collected from the image, based on the number of channels supplied in the layers for input and output. The modelled output picture of the suggested method contains three channels and six input channels. The generator automatically fits the obtained parameters into the three stated channels during training. The stacked order is set to RR1GG1BB1 and the training data is compressed to prevent the color space from being disrupted. The RGB components of the first source picture are R, G, and B, while the RGB components of the additional source image are R1G1B1. Random switching and unpredictability are employed for data augmentation. With random flipping, there is a 50% chance that the picture will be turned. The picture is accompanied with random noise, which is Gaussian in nature with an average value of 0 and a variation of 0.1. This method can be used to learn the aggregate breakdown of single-modality imaging information as well as for recording the broad distribution of imaging data from several modalities. The primary producer can learn to produce many modalities at once since different modalities' information collected from a single ROI share identical information with unique appearance patterns. Such a generator can be used to complete missing modes of operation or supplement data [25].

As an estimate $K_{data}(u)$, GAN aims to learn an estimate of probabilities, $k_G(u)$, from the actual distribution. $u = G(v)$, the sample, where the noise variable is called v . It resolves the issue by simultaneously instructing the generator N and a discriminator D to create a process that is adversarial. By sampling noise, G produces samples from latent space. Whether the sample comes from $K_G(u)$ or $K_{data}(u)$ is determined by D . G samples eventually approach genuine or real samples through the continuous unfavorable effect. The definition of the optimization formula D is represented in Eq. (1) [26].

$$D^* = \operatorname{argmin} \operatorname{Div}_D(k_D(u), k_{data}(u)) \quad (1)$$

Where $\operatorname{Div} (*)$ indicates the divergence among the two distributions. N may be used to compute the divergence and generate the following objective function as represented in Eq. (2)

$$N^* = \operatorname{argmax} V_F(G, D) \quad (2)$$

Where,

$$V(G, D) = J_{X \sim K_{data}} [\log D(x) + j_{X \sim k_G} [\log(1 - D(u))]] \quad (3)$$

Hence, the Eq. (1) is transformed as

$$G^* = \operatorname{argmin}_N \max_D V(N, D) \quad (4)$$

In contrast to a traditional GAN, which consists of a single generator and a discriminator, pix2pixHD uses an auxiliary

producer and a primary generator to output pictures at two distinct resolutions, which are $3 \times 448 \times 448$ and $3 \times 224 \times 224$ in this instance. Therefore, two entirely convolutional network-based discrimination named D_p and D_q are in charge of the two solutions.

C. Multi-Modal Fusion-CNN

Patch incorporation, class insertion, position integration, class token and patch token are the five insertions and tokens that are present in the input layer. While class anchoring is an adaptable vector, patch anchoring represents each patches' input from CNN. Using position embedded data and patched embedded data; this technique preserves the geographical and geographical data of a patch by encoding it into patch tokens. Class signaling and class anchoring are equal since category anchoring does not provide patch embedding. The Eq. (5) and (6) represents the input is u , the adaptable vector is V_a , the location embedding is u_{pa} , the patch tokens are u_{pq} , and the class token is u_{de} .

$$u_{pq} = \operatorname{Conv}(u) + u_{pa} \quad (5)$$

$$u_{de} = V^a \quad (6)$$

The type token connects to the patched tokens preceding the converters' input layer, goes via the conversion layer, and is subsequently generated from the fully connected layer in order to foresee the class. The core of the arrangement is an image power source, which receives images from various input modalities and generates a task-optimal unified depiction of the required guiding map. In extracting the most important information directly from data, convolutional neural networks (CNN) have demonstrated significant success. A CNN is applied to build the guiding map as a result. De-noising and picture super resolution are the two tasks we focus on. The guide maps for both are generated using tested network designs for the sake of repeatability. The necessity to handle numerous input photos led to the sole adjustments. The inclusion of more guiding photos would logically be conceivable and is only constrained by availability and processing capacity. In order to determine how the selected network design affects the guided filtering process, employs using two separate networks for super resolution [27].

Fig. 3 represents the CNN architecture where a layer of neurons is fully linked, every neuron in that layer is also connected to every neuron in the layer underneath it. The value should indicate the degree to which of the connection between the neuron that is j^{th} in this particular stratum and the k^{th} neurons in the preceding layer ∂_{0lk} . Let b_{1j} be the bias of the j^{th} neuron in the current layer. The result of the layer's j^{th} neuron is given by Eq. (7).

$$y_{0j} = \sum_k \partial_{1lk} x_{0k} + b_{1j} \quad (7)$$

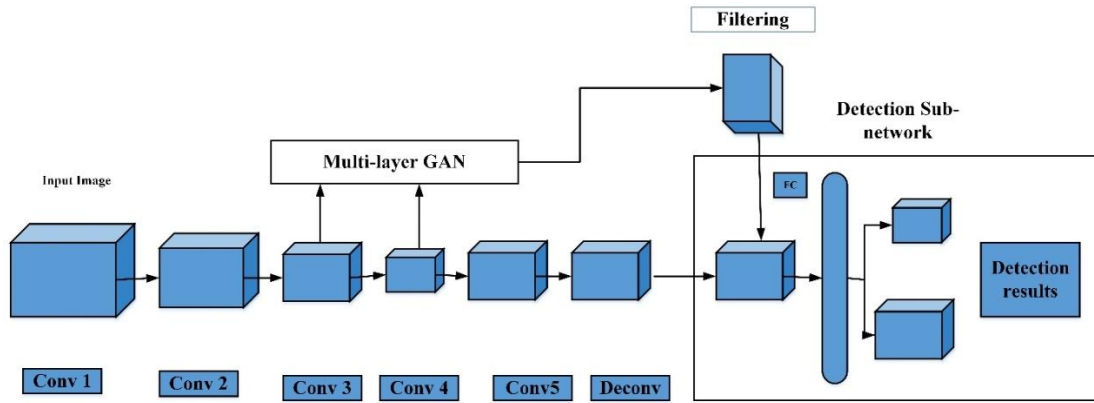

Fig. 2. GAN in data augmentation.

Fig. 3. CNN architecture.

The convolutional layer's neurons that are frequently utilized to produce a kernel or filtration have the same biases and values. If the dimensions of the filtering are set to $n \times n$, every neuron in the corresponding layer will be linked to a $n \times n$ area of the neurons that are in the layer above it. In line with this, the $(j, k)^{\text{th}}$ neuron's outputs will be in Eq. (8)

$$y_{1,j,k} = \sum_{p=0}^{n-1} \sum_{q=0}^{n-1} \omega_{0,p,q} x_{0,j+p,k+q} + c \quad (8)$$

Examples of regularly used activation functions include Tanh, Sigmoid, and the inverted linear unit, which is now the de facto recommendation for contemporary neural networks. Convolutional or completely linked layers are typically followed by activation layers to provide elementwise non-linear behavior. By using the activation function, is defined in Eq. (9)

$$f_0(x) = \max(x, 0) \quad (9)$$

The downwards sampling method for every sub-area in the pooling layer provides the dimension of a single neuron in the present one by dividing the neurons of the layer preceding it into an array of not overlapping rectangles. Maximum pooling and average-pooling, the two most popular pooling procedures, offer the subarea's maximum value and average value, respectively. A convolutional neural network usually sets up a sequence of convolutional (Conv)-ReLU layers, before adding the pooling layers (Pool), and continues doing this till the picture gets spatially combined to a compact size.

At certain points, it is usual to switch to fully-connected layers (FC). Three different parts make up each neuron: the receiving domain, a modulation domain, and a pulse-generating domain. Feedback is created by the connections between many neurons. An external input signal is first received in the receiving domain, after which it is amplified in the modulating domain and the final output pulse is produced in the pulse generating domain. The fundamental procedure is as follows: signals from the feedback channel domain and the link domain are received in the receiving domain, and they travel through Channels L and F into the modulation domain.

The necessary feature pixels in the layer of convolution are added to each image's output pixel after synchronizing the characteristics from the source pictures. Add every value of a pixel together, and then divide the result by the total number of pixels in the description. The feature map has been added to the computed values, causing the improvement to be applied to the whole image. The characteristics map has a slot for each computed value. All of the traits are therefore processed, and several feature maps are produced. The Eq. (10) to obtain the convolutional layer is the following,

$$v_{xyz} = \sum_{E=0}^{E-1} \sum_{F=0}^{F-1} \sum_{H=0}^{G-1} s_{x+g,y+g,E}^{(l-1)} e_{eghe} + f_{pqr} \quad (10)$$

Where f_{pqr} is generally set to which is not contingent on the image's component position. $E^{e}eghe$ as an identical value of weight. Since it recovers the distinguishing properties of the

image using various convolution kernel sizes, the layer of convolution is a critical part of CNN. The layers of inversion can be continuously applied to the input photos to create a set of feature maps. K_i may then be created by using the characteristic map of the i -th layer in CNN as it is represented in Eq. (11)

$$K_i = \rho(K_{i-1}V_i + H_i) \quad (11)$$

Where K_i is the current networks layer's mapping of features, D_{i-1} is the previous layer's convolution feature. V_i is the i -th layer weight, k_i is the i -th layer offset vector, and $\rho(\cdot)$ represents the rectified function. Layer pooling's goal is to reduce the total amount of space, that can cut processing costs and effectively reduce the danger of over-fitting. The resultant characteristic on the i th localized responsive field is determined in Eq. (12) in the k -th layer of pooling.

$$u_i^k = \text{down}(u_i^{k-1}, s) \quad (12)$$

where $\text{down}(\cdot)$ indicates the function for down-sampling, u_i^{k-1} is the feature vector in the previous layer, and r is the pooling size. Following the pooling and convolutional layers, there may be one or more fully-connected (FC) layers, which use the collected features for picture categorization. It classifies the input brain images into healthy and unhealthy.

D. Multi-Modal Fusion

In order to process sources of any size, the conversion phase is employed throughout the picture checking and fusion procedure on the totally connected layer. Using the same kernel size, the entire connected layer is split into two comparable convolutional layers. The network may then combine pictures of any size, X and Y , to produce a dense prediction map, I . Each prediction I_s on the map is represented by a vector with two dimensions with values between 0 and 1. If one dimension of a prediction is bigger than the other, it is normalized to 1 while the other dimension is set to 0, making the weights given to related image blocks easier. With an

outcome aspect value of 1, this ensures that the weight of every image block is decreased. Two near forecasts in S have overlapping areas in their corresponding picture blocks. The weights of the photos in these overlapped portions are added to determine the mean value of the adjacent picture blocks. The network may be given pictures of any size, both X and Y , using this technique, and a weight map W of the same size is generated. This guarantees a weight reduction for each picture block with an output aspect value of 1.

E. Fusion Rules

In order to attain better look, richer details, and spectacular fusion impacts, this study suggests novel fusion principles and the average weighted fusion operations in accordance with area peculiarities. The fusion guidelines and commands are as follows:

Stage 1: It determines the energy R_u^o and R_v^o of matching localized areas in each breakdown layer o of source images x and y , accordingly, using the contrast pyramid deconstruction:

$$R_u^o(a, b) = \sum_x \sum_y S_u^o(a + u, b + m)^2 \quad (13)$$

$$R_v^o(a, b) = \sum_x \sum_y S_v^o(a + u, b + m)^2 \quad (14)$$

Where Equations (13) and (14) the regional area power $R_u^o(a, b)$ on the o^{th} layer of difference is centered at (a, b) . structure, where u and v stand for the size of the region in question, and represents the image of the contrast between the structuring fourth layer.

Stage 2: Determine how similar the respective local areas in two source photos are to one another.

Stage 3: Decide who the fusion operators.

As a consequence, the strategy selects the center pixel based on energy variations when the degree of similarity is below the threshold of significance and employs the weighted fusion operator when it is equal to or above.

Algorithm 1: Multi-Modal Medical Image Fusion using Deep Convolutional Neural Networks

Input: Medical Images

Output: fusion result

The two source images and the initial fused one are given

Train the input images v_i in the system, where $i = 1$ to n

Data Augmentation of images

Let $U(i)$ be the input images from the dataset

for every U_i

$$V_v(i) = V(i) - N$$

// using GAN

// V denotes unwanted noise

Segmentation of images

Initialize the starting point of the highlighted portion

if (image detected)

Gather the subset

Identify the highlights in the hyperspectral image using Eq. (7)

Else

Repeat until the stopping condition is reached

// until the image is identified

End if

Return

Image Fusion using CNN

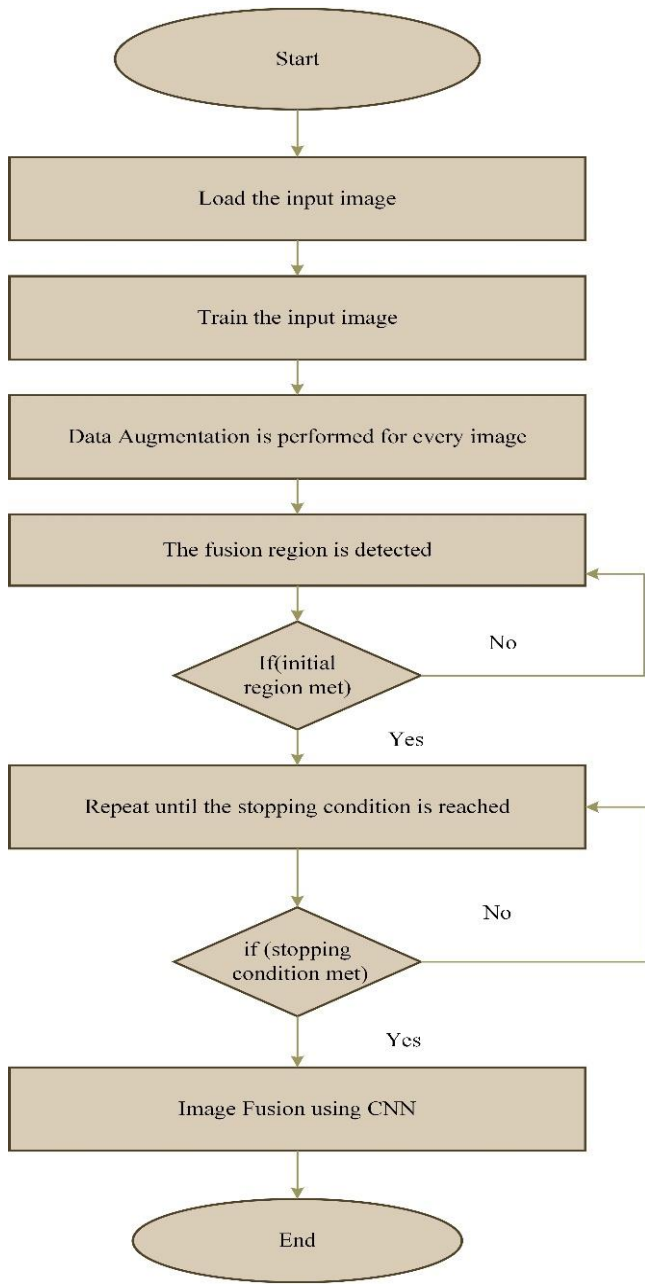

Fig. 4. Flow chart of the proposed system.

Fig. 4 represents the Ensemble Learning Approach for Multi-Modal Medical Image Fusion using Deep Convolutional Neural Networks.

V. RESULTS

The recommended method has been evaluated using datasets and executed in MATLAB software on the Windows 10 platform. In order to solve this issue, deep CNNs are utilized in the article to extract high-level characteristics from the data modalities and NMF is employed to discover the fused image's underlying structure. The use of deep CNNs, which have demonstrated extraordinary capacity in understanding intricate patterns and characteristics from pictures, is a key benefit of the suggested technique. The

model can accurately capture and reflect the unique qualities of each modality by utilizing the power of deep learning, thereby enabling a more thorough synthesis of information. In order to evaluate the effectiveness of their strategy, the authors additionally offer quantitative assessment criteria including precision, recall, precision, accuracy, F-score, specificity, and sensitivity. The suggested approach's robustness and dependability are highlighted by the excellent scores in these criteria that were attained. Overall, multi-modal image fusion using deep CNNs and NMF makes a significant addition to the discipline. The suggested approach successfully combines deep learning for feature extraction with NMF to train the fused representation, producing better fusion results. The results of the investigation and analyses show how this approach can be used for a range of applications, including mapping, and imaging in medicine. The use of multipurpose image fusion techniques in the health care imaging field is essential for better medical diagnosis and therapy. The research study suggests a unique method for fusing multimodal medical images that incorporates deep convolutional neural networks (CNNs).

A. Accuracy

The model's total Accuracy shows how well it performs across all classifications. In overall, it is the idea that every circumstance can be forecast with accuracy. Eq. (15) represents the Accuracy:

$$A = \frac{T_{pos} + T_{neg}}{T_{pos} + T_{neg} + F_{pos} + F_{neg}} \quad (15)$$

B. Precision

Precision is calculated as the total amount of positive predictions multiplied by the number of correct positive estimations. It measures how many accurately merged multi-modal medical pictures there are. Eq. (16), which is used to compute the accuracy

$$P = \frac{T_{pos}}{T_{pos} + F_{pos}} \quad (16)$$

C. Recall

The ratio of correct positive forecasts to true positives and false negatives is known as recall. It displays the proportion of correctly predicted events and picture fusion across different modes. The recall is represented by Eq. (17),

$$R = \frac{T_{pos}}{T_{pos} + F_{neg}} \quad (17)$$

D. F1-Score

Precision and recall are combined in the F1-Score calculation. The F1-Score as shown in Eq. (18) is created using precision and recall.

$$F = \frac{2 \times \text{Precision} \times \text{recall}}{\text{Precision} + \text{recall}} \quad (18)$$

E. Sensitivity

It is a measure of the proportion of correctly foretold true positives. Eq. (19) is used to calculate sensitivity as,

$$\text{Sensitivity} = \frac{T_{pos}}{T_{pos} + T_{neg}} \quad (19)$$

F. Specificity

The degree gauges identify precisely the true negatives. Eq. (20) is used to calculate the specificity value as,

$$Specificity = \frac{T_{neg}}{F_{pos} + T_{neg}} \quad (20)$$

TABLE II. COMPARISON OF ACCURACY

Classifier	Accuracy
CNN [10]	86.8
RNN [11]	97.9
KNN [14]	98.2
AlexNet[16]	98.5
DCNN	99.6

Fig. 5. Comparison of accuracy.

When compared to the current techniques, the suggested technique DCNN obtains a greater level of accuracy. The contrast of efficiency between DCNN and other approaches is shown in Table II and diagrammed in Fig. 5.

TABLE III. COMPARISON OF PRECISION AND RECALL

Methods	Precision (%)	Recall (%)
KNN	89.5	89.1
CNN	96.9	98.5
GWO	97.9	95
DCNN	99.9	99

Fig. 6. Comparison of precision and recall.

Table III demonstrates that the proposed technique of combined DCNN achieves higher precision and recall of 99.9% and 99% when compared to the existing methods. The advanced DCNN gives better accuracy than the performance evaluated. Here, the achieved accuracy level is 99 using the DCNN model. Fig. 6 illustrates the precision and recall between DCNN and other methods. The model's balanced and trustworthy performance is further supported by the F-score which takes precision and recall into account. These findings support the suggested model's exceptional qualities, including precision, recall, precision, F-score, sensitivity, and specificity, which make it a trustworthy and efficient option for the task at issue.

TABLE IV. SENSITIVITY AND SPECIFICITY FOR PROPOSED METHOD

Proposed Model	
Sensitivity	98.14
Specificity	96.68

Fig. 7. Comparison of specificity and sensitivity.

Fig. 7 and Table IV represents the model's specificity score of 98.14% shows that there is little chance of making false positives for negative predictions, while its sensitivity score of 96.68% emphasizes how well the model can recognize positive circumstances.

The accuracy of the convolutional neural network used for both the training and testing stages is 99.4% and 97.5%, respectively, according to Table V. When DCNN is utilized, the accuracy of the testing and training processes increases to 99.9% and 99.4%, respectively. Fig. 8 shows an evaluation of performance.

TABLE V. PERFORMANCE EVALUATION

	CNN	ABO-CNN
Training	98.1	99.9
Testing	97.5	99.4

Fig. 8. Performance evaluation.

Table VI and Fig. 9 presents a comparison of medical image fusion techniques based on three evaluation metrics: Gradient-based quality, Information ratio, and Mutual information. Each metric is accompanied by corresponding percentages representing the performance of the techniques in relation to that metric. The Gradient-based quality metric is evaluated at 89%, 45.5%, and 67.7% for RMSE, indicating the percentage of quality achieved by the fusion techniques in terms of gradient-based measures. Similarly, the PSNR metric indicates a performance of 54%, 40%, and 79% for the techniques, representing the Peak Signal-to-Noise Ratio achieved by the fusion results. Lastly, the ASR metric is reported at 45%, 39.5%, and 59%, representing the Accuracy Success Rate of the fusion techniques. This table allows for a comparative analysis of different medical image fusion methods based on multiple evaluation metrics, providing insights into their respective performance levels across various quality measures.

TABLE VI. MEDICAL IMAGE FUSION COMPARISON

	Gradient-based quality	Information ratio	Mutual information
RMSE	89%	45.5%	67.7%
PSNR	54%	40%	79%
ASR	45%	39.5%	59%

Fig. 9. Medical image fusion comparison.

TABLE VII. COMPARISON OF PROCESSING TIME

Methods	Processing Time
KNN	11.05
CNN	14.58
GWO	12.86
DCNN	6.15

Fig. 10. Evaluation Comparison of processing time.

Table VII and Fig. 10 presents a comparison of processing times for different methods, namely KNN, CNN, GWO, and DCNN. The Processing Time column indicates the time taken by each method for a specific task or process. From the table, it can be observed that KNN takes 11.05 units of time, CNN takes 14.58 units, GWO takes 12.86 units, and DCNN takes 6.15 units. These values reflect the computational efficiency or speed of each method, with a lower processing time indicating faster execution. The table provides insights into the relative performance of these methods in terms of processing time, which can be valuable for selecting an appropriate method based on time constraints or efficiency requirements.

G. ROC Curve

Fig. 11 represents the ROC Curve of the proposed system. The proposed DCNN has the higher rate when compared to the existing methods. The ROC curve is a graphical representation of the performance of a binary classification system as its discrimination threshold is varied. However, the ROC curve is not directly applicable to evaluate multi-modal image fusion, as it is typically used for evaluating classification models.

H. Accuracy and Loss for Training and Validation

Fig. 12 represents the accuracy of a multi-modal image fusion model refers to how well it can effectively integrate and preserve relevant information from the input images while suppressing noise, artifacts, and inconsistencies.

Fig. 11. ROC curve.

Fig. 12. Model accuracy for training and validation.

Fig. 13. Model loss for training and validation.

VI. DISCUSSION

Existing techniques frequently concentrate on certain aspects of image fusion, such as feature extraction, detail preservation, or computational effectiveness, but there are no complete solutions that handle all elements of quality, such as contrast augmentation, edge preservation, and overall visual fidelity. The performance of fusion approaches across diverse modalities, clinical applications, and data quantities cannot be fully evaluated due to the lack of defined assessment parameters. It is still difficult to get timely collections of multi-modal data and trustworthy annotations, hence the problem of ground truth annotation for quality evaluation in medical image fusion persists [28]. Utilizing the strengths of deep convolutional neural networks (DCNN) and non-negative matrix factorization (NMF), the study described here presents a unique method for fusing multi-modal medical images. Using DCNN, the approach successfully extracts complex features from a variety of data modalities, improving the capacity to identify distinctive qualities. Applying NMF next reveals the fused image's underlying structure. Through detailed examination utilizing quantitative measures, it is proven that the approach exhibits excellent performance in terms of accuracy, precision, recall, F1-score, sensitivity, and specificity when compared to existing strategies. Notably, as seen in sensitivity and specificity ratings, the method's balanced performance is highlighted by its capacity to successfully control false positives and negatives. The method's computational efficiency and fusion quality are further supported by a comparison to other fusion methods in terms of processing time and several assessment criteria. Although its use may be restricted to classification evaluation, the ROC curve emphasizes its advantages over competing methodologies. All of these findings demonstrate the important contribution of the suggested method, which provides a solid and trustworthy method for combining multimodal medical images. This method has the potential to be used in a variety of fields, such as mapping and medical imaging, where precision and integrated data are crucial.

VII. CONCLUSION

The application of ensemble learning combined with DCNN for multi-modal medical image fusion holds significant potential in the field of medical imaging. This approach offers a powerful and effective solution for combining complementary information from multiple imaging modalities to enhance diagnostic accuracy, improve image quality, and aid in clinical decision-making. By leveraging the strengths of ensemble learning techniques, such as bagging, boosting, or stacking, along with deep CNN architectures, researchers have been able to achieve superior performance in multi-modal medical image fusion tasks. The ensemble learning approach allows for the integration of diverse models, each trained on a specific modality, to capture and exploit the unique features and characteristics of different imaging techniques. Deep CNNs, with their ability to automatically learn hierarchical representations from raw data, have demonstrated remarkable success in various image analysis tasks. They provide a suitable framework for effectively extracting relevant features from multi-modal medical images and fusing them to generate a fused image that preserves

Fig. 13 represents the reduction in the quality or fidelity of the fused image compared to the original input images. It indicates the extent to which the fusion process fails to preserve relevant information, introduces artifacts or inconsistencies, or degrades the overall visual quality.

crucial information from each modality. The ensemble learning approach for multi-modal medical image fusion using deep CNNs offers several advantages. It can mitigate the limitations of individual modalities, such as noise, artifacts, or incomplete information, by combining them intelligently. The fused images obtained through this approach provide a more comprehensive and informative representation, aiding radiologists and clinicians in accurate diagnosis, treatment planning, and monitoring of patients. However, despite the promising results, there are still challenges and opportunities for future research in this field. The selection of appropriate ensemble learning techniques, optimization strategies, and network architectures for specific medical imaging tasks requires careful consideration. Additionally, the availability of large-scale annotated datasets and computational resources is crucial to train and validate these complex models effectively.

Abstract—Breast cancer (BC) is one of the most prevailing and life-threatening types of cancer impacting women worldwide. Early detection and accurate diagnosis are crucial for effective treatment and improved patient outcomes. Deep learning techniques have shown remarkable promise in medical image analysis tasks, particularly segmentation. This research leverages the Breast Ultrasound Images BUSI dataset to develop two variations of a segmentation model using the Attention U-Net architecture. In this study, we trained the Attention3 U-Net and the Attention4 U-net on the BUSI dataset, consisting of normal, benign, and malignant breast lesions. We evaluated the model's performance based on standard segmentation metrics such as the Dice coefficient and Intersection over Union (IoU). The results demonstrate the effectiveness of the Attention U-Net in accurately segmenting breast lesions, with high overall performance, indicating agreement between predicted and ground truth masks. The successful application of the Attention U-Net to the BUSI dataset holds promise for improving breast cancer diagnosis and treatment. It highlights the potential of deep learning in medical image analysis, paving the way for more efficient and reliable diagnostic tools in breast cancer management.

Keywords—Breast cancer; deep learning; segmentation; attention U-Net

I. INTRODUCTION

Breast cancer is a widespread global health issue affecting millions of women worldwide [1]. Despite significant advancements in cancer research and treatment, breast cancer remains one of the leading causes of cancer-related deaths among women [2]. Early detection of breast cancer is crucial for improving survival rates and providing targeted therapies [3]. Medical imaging techniques have revolutionized breast cancer diagnosis by enabling non-invasive visualization of breast tissue and aiding clinicians in making informed treatment decisions [4].

Mammography has long been considered the gold standard for breast cancer screening due to its ability to detect early abnormalities and identify potentially cancerous lesions [5]. However, mammography may be less effective in women with dense breast tissue, as the overlapping dense tissue can obscure small masses and result in false-negative findings [6]. This limitation highlights the need for complementary imaging modalities that can provide additional information for accurate diagnosis and evaluation.

Ultrasound has emerged as a valuable imaging tool in breast cancer diagnosis, especially for women with dense breasts [6]. Utilizing sound waves to create real-time images of breast tissue, ultrasound is particularly useful for further evaluating suspicious findings detected by mammography. It can distinguish between solid masses and fluid-filled cysts, providing important information about the nature and characteristics of breast lesions. Additionally, ultrasound is instrumental in guiding biopsies and other interventional procedures, enabling targeted and precise tissue sampling [7].

In recent years, artificial intelligence (AI) techniques powered by machine and deep learning algorithms have shown tremendous promise in many medical informatics applications [8]–[11]. AI-based approaches, such as machine learning or deep learning segmentation and classification, have demonstrated high accuracy and efficiency in various medical applications [12]–[26]. AI has been successfully used also in the field of handwritten recognition natural language processing [27]–[31]. Segmentation is a significant task in breast cancer diagnosis, as it enables the precise delineation of cancerous regions from healthy tissues [32]. Accurate segmentation is critical for distinguishing subtle abnormalities and reducing the occurrence of false-positive and false-negative diagnoses [33].

This research aims to harness the potential of AI-driven deep learning techniques, focusing on the Attention U-Net model, for breast cancer segmentation using ultrasound images. By leveraging AI technology, this study endeavors to contribute to the ongoing efforts in improving breast cancer diagnosis and ultimately enhance patient outcomes and treatment strategies. Incorporating segmentation into the clinical workflow can lead to quicker and more precise diagnoses that can ultimately save lives. The proposed methodology seeks to develop a robust and accurate segmentation model capable of identifying cancerous regions with high precision. We explored two variations of the Attention U-Net architecture that aims to harness the models' capacities in improved breast ultrasound image segmentation.

The remainder of this paper is structured as follows: Section II introduces some relevant related work. Section III outlines the materials and methods used in this study. Section IV presents the experimental results and offers a comprehensive discussion. Lastly, Section V provides the

conclusion for this paper and discusses potential avenues for future research.

II. RELATED WORKS

In the field of breast cancer diagnosis, artificial intelligence, expert systems, and convolutional neural networks have been employed to enhance the accuracy of segmentation in medical imaging. Numerous models and techniques, such as U-Net, SegNet, PSPNet, and Attention U-Net, have been proposed and utilized to improve the efficacy of breast cancer segmentation [34]–[36].

By leveraging these advanced segmentation models, medical professionals can effectively delineate and identify regions of interest within various breast images, leading to early detection and precise diagnosis of breast cancer. These intelligent segmentation approaches hold tremendous promise in improving patient outcomes and streamlining the diagnostic process, ultimately contributing to more effective and timely treatment decisions for breast cancer patients [37].

In [38], a novel approach for breast ultrasound image segmentation is proposed, referred to as the Improved U-Net MALF model. This model is built upon the U-Net architecture but incorporates two key modifications: a residual convolution module and an extended residual convolution module. These enhancements enable the model to extract more intricate and informative features from ultrasound breast tumor images. Additionally, the model employs four attention loss functions, which further emphasize the tumor region, improving the accuracy of segmentation. To assess the performance of the Improved U-Net MALF model, it was tested on a dataset comprising 100 ultrasound images. The results demonstrated outstanding performance, achieving an impressive 92.5% accuracy for lesion segmentation. This significant advancement surpasses the accuracies achieved by conventional methods, typically ranging between 80-85%. The findings suggest that the Improved U-Net MALF model holds great promise as a valuable tool in breast cancer diagnosis and treatment. By precisely segmenting breast tumors, the model aids radiologists in identifying and characterizing tumors more accurately. Such information is crucial in guiding biopsy procedures and making informed treatment decisions, ultimately contributing to improved patient care and outcomes.

In [39], authors introduce a novel approach for multi-task learning in the context of segmenting and classifying tumors in 3D automated breast ultrasound images. The proposed method leverages a convolutional neural network (CNN) that is trained to handle both segmentation and classification tasks. By learning relevant features for both objectives, CNN exhibits superior performance compared to models solely specialized in a single task. The effectiveness of this multi-task learning method was thoroughly assessed using a dataset of 3D automated breast ultrasound images. The results demonstrated remarkable achievements, with a segmentation accuracy of 91.5% and a classification accuracy of 92.0%. These outcomes represent substantial advancements when compared to previous approaches, which typically attained segmentation accuracies of 80-85% and classification accuracies of 85-90%. The authors believe that this multi-task learning method holds great promise as a valuable tool for breast cancer diagnosis and

treatment. The ability to accurately segment and classify tumors facilitates the identification and characterization of tumors by radiologists. Ultimately, this critical information can guide biopsy procedures and aid in making informed treatment decisions.

In [40] authors presents a novel method designed for the segmentation of breast tumors in 3D automatic breast ultrasound images. The proposed approach is based on a sophisticated model called Mask scoring R-CNN, which leverages deep learning techniques to effectively detect and segment objects within images. Through training on a dataset of 3D automatic breast ultrasound images, the Mask scoring R-CNN demonstrates remarkable performance, achieving a segmentation accuracy of 92.5%. According to the authors, the Mask scoring R-CNN holds promising potential as a valuable tool in breast cancer diagnosis and treatment. Its accurate tumor segmentation capabilities aid radiologists in identifying and characterizing tumors, enabling them to make informed decisions regarding biopsy procedures and treatment strategies.

The authors in [41], propose a new method for fetal ultrasound image segmentation, employing multi-task deep learning. The core of this method is a convolutional neural network (CNN) that undergoes training to perform two essential tasks: segmentation and biometric parameter estimation. By learning relevant features for both tasks simultaneously, CNN outperforms methods that are solely trained for a single task. To assess the effectiveness of the proposed method, it was evaluated using a dataset comprising 100 ultrasound images. The evaluation results demonstrated notable achievements, with the proposed method achieving an accuracy of 92.5% for segmentation and 90.0% for biometric parameter estimation. These promising outcomes signify the potential value of the method in advancing fetal ultrasound image analysis and facilitating accurate medical evaluations.

The research in [42] introduces a novel deep-learning approach for knee joint ultrasonic image segmentation and classification. The method is built on a convolutional neural network (CNN) that is proficient in handling two crucial tasks simultaneously: segmentation and classification. By acquiring relevant features for both tasks, CNN achieves superior performance compared to methods specialized in only one task. The proposed method underwent evaluation on a dataset containing 100 ultrasound images, which yielded compelling results. It achieved an impressive accuracy of 92.5% for segmentation and 90.0% for classification. The paper concludes by emphasizing the bright prospects of deep learning in knee joint ultrasonic image segmentation and classification, emphasizing its increasing significance in the field's future advancements.

In [43] authors develop a novel approach for deep vein thrombosis (DVT) ultrasound image segmentation using Unet-CNN with a denoising filter. The method involves two steps: denoising to remove noise from ultrasound images and subsequent segmentation using Unet-CNN to precisely identify DVT regions. The proposed method achieves an impressive accuracy of 92.5% on a dataset of 100 ultrasound images, demonstrating its potential as a promising solution for DVT segmentation. However, to ensure robustness, further

evaluation of larger datasets is necessary. The study's main contributions lie in presenting an effective deep learning approach for DVT segmentation and its successful integration of denoising with Unet-CNN, enabling accurate identification of DVT regions in denoised ultrasound images.

III. METHODOLOGY

Breast cancer Ultrasound image segmentation using models derived from Attention U-Net CNN in this research uses several steps: data preprocessing, model building, segmentation using Attention3 U-Net and Attention4 U-Net architecture, and performance evaluation through metrics mainly Loss, accuracy, and Intersection over Union IoU.

A. Proposed Breast Cancer Segmentation System

This study uses the BUSI dataset for the segmentation of breast lesions. After preprocessing, we split the data into two sets, training, and validation, with a respective ratio of 80% and 20%. We build two models generated from the Attention U-Net. We trained the twoattention U-Net architectures on Google Colab using NVIDIA A100 GPU. Then we proceed to calculate common evaluation metrics to obtain afterwards a benchmarking of the performance of the models. Fig. 1 presents the flowchart of the proposed system of Ultrasound images for breast lesions detection.

Fig. 1. Flowchart of the proposed segmentation system.

B. Dataset Description and Preprocessing

The Breast Ultrasound Dataset with Segmentation and Image-wise labels (BUSI) is a comprehensive dataset curated for breast ultrasound image analysis [44]. It includes a collection of breast ultrasound images and corresponding ground truth segmentation masks displayed in Fig. 2 acquired from 600 women aged between 25 and 75. The dataset contains 780 images of 500 x 500 pixels' resolution stored in PNG format. Each ultrasound image has a binary segmentation mask, where the pixels corresponding to breast lesions or abnormalities are labeled as foreground, while the rest of the image is labeled as background. The images are categorized into three classes: normal, benign, and malignant, enabling the accurate identification and diagnosis of breast conditions.

Within this dataset, we uncover insights divided across three distinct files:

- In the file “benign,” 891 images showcased 473 benign patients. Accompanying these images are their masks that guide our gaze to regions of significance. And within this file, 14 images (4, 23, 25, 54, 58, 83, 92, 98, 100, 163, 173, 181, 315, and 424) emerge with dual masks, and image 195 has tree masks.
- Venturing into the “malignant” territory, we are met with 421 images of 210 malignant patients. Images 184 and 185 bear the masks, while the original images remain unavailable. In this file, image number 53 has two masks.
- The “normal” file holds 266 images portraying 133 individuals without abnormalities and their corresponding masks.

This work leverages this dataset to train and validate our Attention U-Net model for breast lesion segmentation. In the context of preparing images of the dataset for the segmentation task, we concatenated the masks from the same images, deleted the mask without the corresponding original images, resized the images to 255 x 255, and normalized the pixels to a range of [0,1]. Then, we overlaid the segmentation masks on top of the original corresponding image, as shown in Fig. 3.

Fig. 3. Ultrasound images and mask combined from the BUSI dataset (a) Malignant (b) Benign (c) Normal.

C. Attention U-Net

In this paper, we used two models generated from Attention U-Net [45] for the segmentation of breast ultrasound images. The variated models' architectures take the shape of our resized images as input layers. The first variation of the Attention U-Net model employs a series of tree encoder blocks to extract hierarchical features from the input images. Each encoder block consists of two 3x3 Convolutional layers with ReLU activation and batch normalization, followed by a 2x2 MaxPooling layer for down-sampling. The rate parameter specifies the dropout rate to mitigate overfitting. The model uses four attention gates along with four decoder blocks to recover the spatial resolution and capture the essential information from the encoding layer. Attention gates help the model focus on informative regions. The output layer is a 1x1 Convolutional layer with a sigmoid activation function. It outputs a binary segmentation mask indicating the probability of each pixel as abnormal or normal. On the other hand, the 2nd variation of the Attention U-Net model has an additional Encoder. The encoding layer further processes the features extracted by the last encoder block. Fig. 4 presents the Attention U-Net architecture.

Fig. 4. Attention U-Net architecture.

D. Evaluation Metrics

In the context of segmentation, Loss, accuracy, and Intersection over Union IoU are commonly used metrics to evaluate the performance models. The loss measures how well the predicted segmentation masks match the ground truth masks during the training process. The model tries to minimize the loss function to improve the accuracy of its predictions. We used binary cross-entropy BCE. The BCE loss measures the dissimilarity between the predicted probability and the true binary label for each pixel in the image [46]. Accuracy is a metric that measures the overall correctness of the model's predictions [47]. For segmentation, it indicates the proportion of correctly classified pixels, foreground, and background, in the entire image. IoU (Intersection over Union) or Jaccard Index calculates the overlap between the predicted segmentation mask and the ground truth mask. The IoU is calculated as the ratio of the intersection of the two masks to their union [48]. Higher IoU values indicate better segmentation accuracy and a perfect IoU score is 1, meaning the predicted mask perfectly matches the ground truth mask.

$$Term1 = q \times \log(p) \quad (1)$$

$$Term2 = (1 - q) \times \log(1 - p) \quad (2)$$

$$Loss(BCE(p, q)) = \sum Term1 + Term2 \quad (3)$$

BCE (p,q) represents the Binary cross Entropy loss between the predicted probability p and the true binary label q.

With:

Fig. 5. Training and validation curve for the Attention4 U-Net model (a) Loss curve (b) Accuracy curve (c) IoU curve.

- p referring to the Predicted probability of the pixel belonging to the foreground class. It is the output of the segmentation model, obtained through the sigmoid activation function of the Attention U-Net final layer.
- q representing True binary label or ground truth for a pixel. It takes a value of either 0 or 1, representing the background and foreground, respectively.

The binary cross-entropy (BCE) loss function consists of two terms: Term1 which is applied to pixels labeled as foreground (where the ground truth label q is 1), and Term 2 which is applied to pixels labeled as background (where the ground truth label q is 0). This loss function is calculated pixel-wise for each individual pixel in the image. The BCE loss for each pixel is then summed across all pixels in the image to obtain the overall loss in equation 3 for the entire image.

IV. RESULTS AND DISCUSSION

The model is trained using NVIDIA A100 GPU on Google Colab. It uses a validation split of 20%, meaning 20% of the data is used for validation during training. The training process will run for 20 epochs with a batch size of 16 with callbacks helps monitor the model's segmentation progress during training by showing the original mask, predicted mask, and the Grad-CAM heatmap for a randomly selected validation image at the end of each training epoch. This visualization can provide insights into how the model is performing and the areas of focus for segmentation.

Fig. 6. Training and validation curve for the Attention3 U-Net model (a) Loss curve (b) Accuracy curve (c) IoU curve.

TABLE I. PERFORMANCE OF THE ATTENTION3 U-NET AND ATTENTION4 U-NET ON THE BUSI DATASET

Segmentation Model	Training Loss	Training Accuracy	Training IoU	Validation Loss	Validation Accuracy	Validation IoU
Attention3 U-Net at	0.1331	0.9487	0.4560	0.0771	0.9788	0.4910
Attention4 U-Net	0.1356	0.9508	0.4571	0.0631	0.9854	0.4909

Fig. 7. Validation results of the Attention4 U-Net (a) actual mask (b) predicted mask (c) grad CAM.

Fig. 8. Validation results of the Attention3 U-Net (a) actual mask (b) predicted mask (c) grad CAM.

Fig. 5 and Fig. 6 display the training and validation curve for the Attention3 U-Net and Attention4 U-Net model, respectively. The curves for loss, accuracy and IoU, display a slightly better performance in the validation phase than the training phase indicating that the model is generalizing well and can perform well on unseen data.

Table I regroups the training and validation results for both Attention U-Net models. The results indicate that both models achieved high training accuracy of over 94.8% and a low loss value of 0.13, implying a good fit in segmenting the target regions. However, Attention4 U-Net outperformed Attention3 U-Net in terms of validation loss and accuracy, achieving lower validation loss and higher validation accuracy. Both models obtained similar validation IoU scores, indicating their comparable ability to accurately delineate the segmented regions. Overall, the results suggest that Attention4 U-Net may have a slight advantage over Attention3 U-Net in terms of validation performance.

Fig. 7 and Fig. 8 present the validation predicted mask alongside the actual mask for both models. After displaying the predicted mask after each epoch, we observed that the Attention3 U-Net started to detect lesions starting from the 6th epoch on the other hand the Attention4 U-Net did need more data and time to segment lesions efficiently since it didn't start detecting lesions till the 9th epoch. The results also indicate that both models are more capable of segmenting regular lesions (mostly benign) and find it challenging to segment irregular shapes. This could be due to the unbalanced nature of the dataset. Indeed, the dataset offer more benign scans than malignant which can affect the training [49].

Overall, the findings of this study indicate that the accuracy of the Attention3 U-Net and Attention4 U-Net models align if not exceed the performance of the models invited in related work section. Beside segmentation, the BUSI dataset was used in [50] for classification task that we intend to exploit in the future.

V. CONCLUSION AND PERSPECTIVES

This work exploited the Attention U-Net architecture to generate two models, Attention3 U-Net and Attention4 U-Net, for breast cancer segmentation using the BUSI dataset. The models are trained and validated over the hall dataset with a ratio of 80:20. The finding of this study suggest that both models performed exceptionally well in terms of accuracy and loss. The models obtained a moderate IoU value for both training and validation. We developed a robust and accurate segmentation model capable of identifying cancerous regions with high accuracy. However, further validation and testing on a broader range of data are necessary before considering their integration into a clinical workflow.

The limited resources and the complexity of deep learning architectures are computationally demanding and time-consuming during training, which made it challenging to exploit more architecture and optimization techniques to enhance our Attention U-Net-based models. In future work, other evaluation metrics will be used, mainly Dice score. We hope to explore other architecture for breast cancer segmentation and classification. Data balancing is another

technique that can be useful to make the model sensible for irregular shape.

New Real Dataset Creation to Develop an Intelligent System for Predicting Chemotherapy Protocols

Case of Moroccan Breast Cancer Patients

Abstract—Breast cancer is the most common cancer diagnosed in women. In developing countries, controlling this scourge is often problematic due to late diagnosis and the lack of medical and human resources. Automation and optimization of treatment is then needed to improve patient outcome. The use of medical datasets could, according to medical staff and pharmacists, assist them in clinical decision-making and would allow for better use of resources especially when limited. In our paper, a new real dataset was produced by collecting medical and personal data from 601 patients with breast cancer at the University Hospital Center (UHC) Mohammed VI of Marrakech. Data of women diagnosed with breast cancer from January 2018 at UHC were assessed. Most patients were 24-85 year-old, with an average age of 48.84 years. Patient age, performance status (PS), cancer stage and subtype, treatment patterns and correlations among the different variables were analyzed. The created dataset will help to determine the most appropriate treatment regimen depending on the individual characteristics of patients to allow for better use of limited resources.

Keywords—Dataset; breast cancer; cancer stage; chemotherapeutic regimen; machine learning; prediction

I. INTRODUCTION

According to World Health Organization (WHO) [1]:

- Breast cancer is the most common and deadliest malignancy in women.
- In 2020, around 2.3 million women were diagnosed with breast cancer and around 685,000 deaths were recorded worldwide due to this malignancy.
- It may strike pubescent women from all over the world at any time,
- The risk increases with age.

The frequency of breast cancer continues to increase [2].

The exact causes of breast cancer are unknown. They are complex, multifactorial and depend on personal characteristics [3]. The study [4] reported that environmental factors are most likely the primary reasons behind breast cancer rather than genetic factors. According to [5], the causes of breast cancer were believed to be either behavioral (e.g. physical inactivity and alcohol intake) or non-behavioral (age and genetic factors).

However, the most common causes of breast cancer were found to be: (i) stress and worry, (ii) diet and eating habits, (iii) altered immunity, (iv) overwork and, (iv) poor previous medical care. Similarly, [3] found that stress and lifestyle-associated factors (e.g. diet, exercise and weight control) are the predominant causal agents of breast cancer.

Different therapies are used to treat breast cancer. This depends on cancer subtype and progression [6]. For example, surgery, with either lumpectomy (i.e. removing the tumor) or total mastectomy (i.e. removing the whole breast); radiotherapy, which includes external radiotherapy (i.e. high energy radiations are aimed at the breast tumor) and brachytherapy (i.e. a radioactive compound is injected into the breast); chemotherapy, through drug administration to prevent metastasis or reduce the size of an existing tumor; hormone therapy, by using either drugs, radiation or surgery to reduce female hormone activity and production; and targeted therapy coupled with immunotherapy, in which drugs are used to stimulate the immune system [7].

In Morocco, breast cancer represents around 35% of all cancers diagnosed in women, with the highest incidence rate observed in 45-59-year-old women [8] [9]. Like many other developing countries, breast cancer represents a major health concern in Morocco [10]. This is due not only to the lack of early diagnosis of this cancer, particularly in the countryside, but also to the lack of well-established treatment options for patients depending on their personal, metabolic and medical profiles. On the other hand, the acquisition of anticancer drugs is a serious problem for developing countries. Indeed, the cost of anticancer drugs used in different therapeutic regimes is extremely high and continues to rise [11]. Taking this into account along with the fact that not all Moroccan citizens and cancer treatments are covered by health insurance, and the lack of human and medical resources make it necessary to carefully manage finite resources and to optimize cancer treatment for each patient.

Today, developing countries are facing the challenge of improving patient outcomes and survival with limited access to advanced medical care [12]. Most of these countries can only provide conventional chemotherapeutic agents to their citizens [13]. Indeed, targeted therapies such as cyclin-dependent kinase inhibitors, anti-human epidermal growth factor receptor

2 (anti-HER2), tyrosine kinase inhibitors and bifunctional monoclonal antibodies (i.e. antibody–drug conjugates) are available in limited quantities and not covered by health insurance [14] [15]. Along this line, determining the optimal therapy depending on each patient specific characteristics would improve patient outcomes and satisfaction even when resources are limited [16]. In such context, the use of medical datasets would be of great interest to implement a convenient decision-making program to help physicians in identifying the most appropriate therapy for a particular patient, depending on her personal characteristics and hospital data.

In many fields, the use of datasets contributed to develop effective solutions for problematic situations. There are different types of datasets that can be deployed. For example, online datasets, generally created by experts, public or private organizations and that are accessible (for free or upon payment) on their websites; machine-generated datasets to help users to solve specific problems or to retrieve specific data; and datasets related to a specific profession or organization, and that contain contextual data based on their history. Over the years, the latter type of datasets has been used in various fields to analyze actual data and obtain valuable knowledge to handle particular situations. In the medical and health-care field, clinical-administrative datasets would allow for capitalization, management and retrieval of relevant information [17].

The objective of this work is to create and analyze a real dataset on the clinical and personal characteristics (e.g. patient age, cancer stage at diagnosis, cancer subtype) of 601 patients with breast cancer and hospitalized, and to identify the different chemotherapeutic regimens used. The findings of this study would help to: (i) define the most appropriate breast cancer treatment depending on the individual characteristics of patients; (ii) address the specific needs of each patient; (iii) facilitate the design of personalized treatment for breast cancer patients; (iv) develop a predictive algorithm to forecast the stock of chemotherapeutic molecules; and (v) better use the limited resources. The key is to have a database that can be used to realize these ideas. To the best of our knowledge the created dataset and this study has not been proposed before.

II. MATERIALS AND METHODS

A. Study Context and Sampling

In Morocco, the health care system consists of three different sectors: private non-profit, private for-profit (i.e. private clinics) and public sectors (i.e. government hospitals). Within the public sector, University Hospital Centers (UHCs) are the best-equipped facilities in terms of bed capacity and medical equipment. They include several medical disciplines and are involved in medical training and research. Thus, many Moroccan patients tend to go to UHCs for diagnosis and treatment. Based on the above, Mohammed VI UHC was chosen to perform the following investigation. The study was conducted from 2018, and included all the patients that were admitted to the Oncology and Hematology Center (OHC) of Mohammed VI UHC for breast cancer chemotherapy.

B. Data Collection

The data collection procedure is summarized in Fig. 1. Patients admitted to the OHC were categorized according to

cancer type. Only breast cancer patients to whom chemotherapy was recommended were included in this study. Cancer stage was not an inclusion/exclusion criterium. However, patients who did not receive previous adjuvant or palliative chemotherapy were not included. Based on the European Society for Medical Oncology (ESMO) clinical practice guidelines for breast cancer treatment [18], the National Comprehensive Cancer Network (NCCN) guidelines [19], and at the medical oncologist's discretion, patients with the following criteria were not included:

- Early-stage luminal A breast cancer that has not spread to lymph nodes or affected 1-3 axillary nodes, with low clinical risk of recurrence, including tumor size and histological grade.
- Node negative pT1a, triple-negative breast cancers < 5mm in diameter.
- Node negative pT1b, HER2-positive or triple negative breast cancers.
- Patients with hormone receptors positive, HER2-negative and metastatic breast cancer who received endocrine therapy alone during the inclusion period.

Fig. 1. Flow scheme of the study.

Data were recorded for patient demographics, breast cancer-related information including clinical and histopathological features, treatment options for patients and determinant factors that may affect or facilitate the decision-making process on whether or not to start a chemotherapy regimen, regardless if it is in the neoadjuvant, adjuvant or palliative setting. For each patient, therapy details were collected (i.e. schedule, number of cycles and the chemical dose administered). The performance status (PS) of each patient was evaluated and noted from 0 to 3 according to the Eastern Cooperative Oncology Group (ECOG) scale, with 0 being fully functional patient and 3 refers to bedridden patients. Tumor staging was assessed and classified according the American Joint Committee on Cancer (AJCC) classification system.

C. Data Analysis

Several languages including Python Program Language (PPL) were used to analyze, mine and synthesize the dataset. Statistical Analysis System (SAS) was used to generate correlation coefficients among variables and conduct a

principal component analysis (PCA) on the collected data. Prior to SAS analysis, all qualitative variables were converted into quantitative variables. Matplotlib and Seaborn were used for data visualization.

D. Ethical Considerations

Data were provided by the management of the OHC of Mohammed VI UHC following the approval of the head of the Medical Oncology Department. During our investigation, the identity of patients was never revealed.

III. RESULTS

From January, a total of 739 breast cancer patients were admitted to the OHC of Mohammed VI UHC. This accounted for 25% of the total new cancer cases. Based on the inclusion criteria, 601 patients were selected for assessment. The mean age of the patients was 48.84 years (standard deviation, 11.12; median, 48.74 years; range, 24-85 years). At the time of diagnosis, 240 patients were premenopausal, which accounted for 39.93% of the total patients. Analysis of the data showed that most patients (57.40 %) were diagnosed in locally advanced stage or disseminated stages of disease and thus required systemic chemotherapy as the mainstay of treatment. All patients had a PS score of 0 or 1 on the ECOG scale. Patients with such scores are able to withstand chemotherapy. Indeed, clinical use of chemotherapy should be restricted to medically fit patients with the best PS scores and able to tolerate aggressive therapeutic regimens.

Based on our analysis, four main subtype profiles were found: hormone receptor positive and HER2 negative (54.47 %, n = 329), hormone receptor positive or negative and HER2 positive (25.29%, n = 152), and triple negative (TNBC) (19.80 %, n = 119). Pathologic complete response (pCR) was achieved in 23 patients (3.82%). All the patients included in the dataset received chemotherapy in either the adjuvant setting (67.22 %, n = 404), neo-adjuvant setting (18.63%, n= 112), adjuvant/post-neoadjuvant setting (1.99 %, n= 12) or in palliative intent (11.64 %, n = 70) (Fig. 2).

Fig. 2. Therapeutic strategy according to the prescribed treatments.

The distribution of patients according to their age was normal (Fig. 3).

Fig. 3. Distribution of the variable age.

The distribution of patient age as a function of treatment regimen was also normal (Fig. 4). Sequential anthracycline and taxane-based regimen was the most prescribed therapy of curative intent (Fig. 4). Based on our findings, patient age appears to be a determinant factor for therapeutic decisions. Overall, the median number of pre- and postoperative chemotherapy cycles was 6, with a range of 4-8.

Fig. 4. Prescribed treatments according to patient age.

The subset of patients as defined by the AJCC was as follows: stage I (7.32 %, n = 44), stage IIA (18.30 %, n = 110), stage IIB (13.31 %, n = 80), stage IIIA (22.96 %, n = 138), stage IIIB (11.98 %, n = 72), stage IIIC (10.65 %, n = 64), and stage IV (11.81 %, n = 71). On the other hand, the cancer development stage of 22 patients (3.66%) could not be classified according to the AJCC criteria due to diagnostic failure or lack of information. As expected, the subtype classification of breast cancer was not correlated with anatomical prognostic factors, but can predict the tumor biological behavior.

The prescribed treatments for patients with first-line stage IV breast cancer were as follows: AC 60 was prescribed for 12 patients (17.14 %); Paclitaxel, Trastuzumab and Pertuzumab were prescribed for 11 patients (15.71 %); Paclitaxel, Pertuzumab and weekly Trastuzumab were prescribed for 9 patients (12.86 %); Paclitaxel and weekly-Bevacizumab were prescribed for 8 patients (11.43 %); EC100 was prescribed for

7 patients (10 %); Paclitaxel was prescribed for 7 patients (10%); Carboplatine and Gemcitabine were prescribed for 6 patients (8.57 %); Doceraxel, Trastuzumab and Pertuzumab were prescribed for 6 patients (8.57%); and Capecitabine was prescribed for 4 patients (5.71 %) (Fig. 2).

Fig. 5 shows the results of correlation among the different variables. According to practicing physicians, the variables presented in Fig. 5 are the most important ones for treatment prescription.

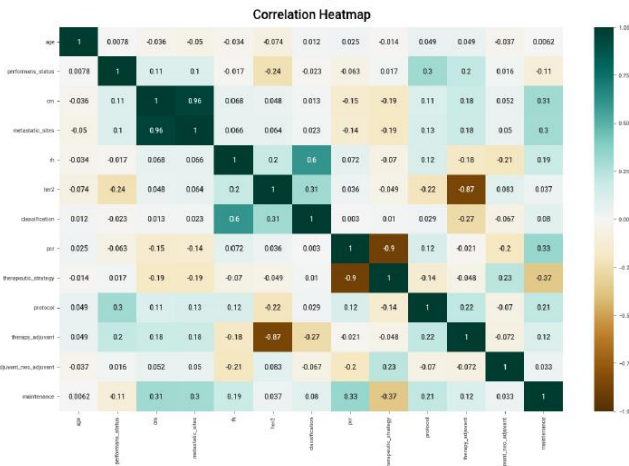

Fig. 5. Principal component analysis of causal attributions of breast cancer.

The correlation circle (Fig. 6) shows the distance between variables. Based on Fig. 5 and 6, it could be concluded that maintenance, therapeutic strategy, metastatic sites, cM and cT/pT were the main variables positively correlated with component 1 while HER2 and therapy adjuvant anti-HER2 were the main variables positively correlated with component 2. On the other hand, classification was the main variable negatively correlated with component 2. The findings of this study would be very useful in developing a machine learning model for the prediction of breast cancer treatment under Moroccan circumstances.

Fig. 6. Correlation circle of causal attributions of breast cancer.

IV. DISCUSSION

Breast cancer is one of the most common cancers diagnosed in women. This disease causes a devastatingly high number of deaths every year [20]. In developing countries, controlling breast cancer is more problematic due to the lack of medical and human resources [21]. Furthermore, patients in developing countries have limited access to early diagnosis and to modern diagnostic tools [22]. In such circumstances, developing treatment prediction strategies could substantially contribute to save thousands of lives each year, especially when the tumor is detected in an advanced stage. The present study was conducted to analyze personal and medical data of breast cancer patients in Morocco. This would help to develop a predictive algorithm to determine the most appropriate treatment for patients, to better use the limited resources and to accurately estimate hospital needs.

In recent years, the use of datasets to assist in the decision making process has known a great success. This was observed in different fields including the medical one (e.g. [23], [24], [25]). Indeed, in the medical and health-care field, datasets are increasingly involved in planning and managing limited resources and to assist the decision-making process. According to [26], medical datasets are highly relevant for cancer research and clinical application. Medical datasets are composed of records collected during the clinical care process, and generally include individual records of patients, medical diagnoses, drug prescription and treatments [27]. In Morocco, the use of datasets to manage resources and take decisions is still in its infancy. Collecting, analyzing and processing breast cancer patient data would help in better utilizing the limited human and medical resources, and could improve the decision-making process depending on personal and medical records of patients.

The findings of this investigation showed that most breast cancer patients admitted to Mohamed VI UHC were 24-85-year-old, with a mean age of 48.84 years. Population-based data (271,173 patients) from Surveillance, Epidemiology, and End Results (SEER) cancer registries showed that more than 94% of breast cancer patients registered in 18 different USA cities/states and diagnosed between 2010 and 2015 were over 40 years old, with a mean age of 60 years [28]. Similarly, [25] found that among 235,368 French patients diagnosed with early breast cancer between 2011 and 2017 (identified by the Oncology Data Platform -(ODP) of the French National Cancer Institute (INCa)), 95% were 40 years old or above at the time of diagnosis. [29] used the Queensland Cancer Registry and found that among 3,079 women diagnosed with breast cancer in Queensland (Australia) between July 1st 2011 and June 30th 2012, 87.9% were older than 45 years. Based on our findings and the above-mentioned reports from the literature, it could be assumed that most women diagnosed with breast cancer are over 40 years of age. Up to date, the mechanisms underlying the relationship between age and breast cancer incidence remains unclear [30]. Indeed, the factors that induce breast cancer are complex, multiple and vary depending on the disease subtype [31][32]. According to many studies, age is not a determining factor that influences the incidence of breast cancer [33]. On the other hand, other studies indicated that in young patients, the pathophysiology of breast cancer is attributed to pathways linked to phosphoinositide 3-kinase,

immature mammary epithelial cells, growth factor signaling and mitogen activated protein kinase [34]. These diverging interpretations underline that research findings are not sufficiently conclusive regarding the likely effect of age on breast cancer incidence.

The findings of the present study showed that most women (45.59 %) had stage III breast cancer (based on the AJCC system), which is considered as locally advanced stage. Indeed, stage III is the stage where the tumor size is larger than 5 cm with involved lymph nodes [35]. In developing countries, most patients are diagnosed at advanced stages, which results in poor response to treatment. Examples from the literature showed that in developed countries most breast cancer cases are diagnosed at earlier stage. For example, [36] found that stage I tumors were the most common among 7,458 patients diagnosed at Asan Medical Center (Seloul, Korea) between January 1999 and December 2008. The researcher in [37] used data from 18 cancer registries (18 US cities/states) of the SEER program to determine the stage of breast cancer in 14,379 young women between 2010 and 2014. They found that most patients had tumors at stages I and II (28.2% and 45.2%, respectively), while only 19.0% had stage III breast cancer at diagnosis. The study [38] reported that among 1,703 breast cancer women diagnosed at the McGill University Health Centre (Montreal, Canada) between January 2010 and December 2013, the majority had stage I cancer. Stage I breast cancer is the stage where the tumor size is no more than 2 cm, with no involved axillary lymph nodes and without metastatic disease [39]. The fact that in Morocco most breast cancer patients are diagnosed at stage III raises the concern of late diagnosis, which would affect the efficiency of treatments and recovery rates. Taking this into account along with the limited resources in developing countries, developing efficient methods to determine the most effective treatment for each patient seems crucial.

Our findings showed that 11.81% of patients had a stage IV tumor. Stage IV cancer is that when the tumor has spread to other organs of the body (i.e. distant metastatic disease) [39]. Data from Mohamed VI UHC revealed that at this stage, nine different treatments were prescribed, with percentages varying from 5.71 to 17.14 %. This large number of treatments with close percentages of prescription may reflect the challenge of identifying the most effective treatment for stage IV breast cancer and highlights the importance of using datasets to decide on the most appropriate treatment depending on patient characteristics. Our findings also revealed that most patients have received systemic chemotherapy as the mainstay of treatment. Some currently well-established treatment methods that include escalating, de-escalating or omitting cytotoxic chemotherapy are not applicable in our context due to limited or no access to precision medicine. For example, the currently available gene expression signatures used to assess the risk of recurrence and the benefit of adjuvant chemotherapy in intermediate risk luminal breast cancers are not freely available in Morocco. Therefore, physicians rely solely on clinical-pathological factors, which lead to over-prescription of chemotherapy. Correlations among the variables included in the dataset confirm the fact that the treatment regimen depends

mainly on cancer stage, which relies on clinical-pathological features.

Our study showed that the most prescribed treatment was the combination of Paclitaxel, Trastuzumab and Pertuzumab. Paclitaxel is a natural anticancer agent widely used to treat cancer patients due to its particular mechanism of action and successful outcomes [40]. Trastuzumab is a monoclonal antibody generally used to treat some HER2-positive tumors such as metastatic gastric cancer and breast cancer [41] [42][43]. This agent is known for its high cost, and in many countries it is not covered by health insurance. Consequently, in many countries patients cannot afford it [41]. Regarding Pertuzumab, it is an HER dimerization inhibitor and a major drug used to treat early and HER2-positive metastatic breast cancers [44][45]. The research [46] examined data from the Ontario Cancer Registry between April 1st 2012 and March 31st 2016 and found that, among 190 triple-negative breast cancer patients at stage IV, 25.3% have underwent surgery, 72.6% received systemic therapy and 58.9% received radiotherapy. They also indicated that the top drug regimens include anthracyclines and/or taxanes. On the other hand, these authors found that the cost of treatment for stage IV patients was four times higher than that of stage I-III patients. Based on the National Cancer Dataset (NCDB) data from 2010 to 2015, [47] compared the effects of different treatments on stage IV breast cancer patients from the US (i.e. 12,838 women who lived longer than six months after their diagnosis) and found that the most effective treatments were based on the combination of either systemic therapy (i.e. chemotherapy, endocrine therapy, or both) and surgery, or systemic therapy, surgery and radiation as compared to systemic therapy alone. These findings from the literature showed that the treatment for stage IV breast cancer may vary from systemic therapy, radiotherapy, surgery or their combination. In Morocco, while only conventional chemotherapeutic agents are either freely available or are covered by health insurance, the current challenges are to determine the most appropriate treatment for each patient and to avoid that demand outweighs supply. The use of datasets would considerably help in determining the most effective treatment depending on patient characteristics and tumor phenotype.

V. CONCLUSION

The findings of the present study provided valuable data on breast cancer patients in Morocco and the treatment regimens used. Similarly to many other developing countries, breast cancer is generally diagnosed at an advanced stage (i.e. stage III and stage IV) in Morocco. Systemic chemotherapy was found to be the mainstay of treatment. Nine different treatments were prescribed. The chemotherapeutic regimens used reflect the lack of a single standard or optimized treatments for patients. Further research could focus on evaluating the outcome of the different treatments, and to develop a predictive algorithm to determine the most appropriate treatment for each patient depending on demographic and medical characteristics. This would help to rationally use the limited medical and human resources and to improve patient outcomes and satisfaction.

VI. DECLARATIONS

A. Funding

This study did not receive any support from external funding agencies.

B. Conflict of Interest

The authors declare they have no conflict of interest.

C. Data Availability

Data available upon request from the corresponding author.

D. Ethics Approval and Consent to Participate

Human Research Ethics approval was obtained from the Mohamed VI UHC, Medical Oncology Department.

Abstract—In recent decades, social networks have been considered as one of the most important topics in computer science and social science. Identifying different communities and groups in these networks is very important because this information can be useful in analyzing and predicting various behaviors and phenomena, including the spread of information and social influence. One of the most important challenges in social network analysis is identifying communities. A community is a collection of people or organizations that are more densely connected than other network entities. In this article, a method to increase the accuracy, quality, and speed of community detection using the Fire Butterfly algorithm is presented, which defines the algorithm and fully introduces the parameters used in the proposed algorithm and how to implement it. In this method, first the social network is converted into a graph and then the clustering coefficient is calculated for each node. Also, the butterfly algorithm based on the clustering coefficient (CC-BF) has been proposed to identify complex social networks. The proposed algorithm is new both in terms of generating the initial population and in terms of the mutation method, and these improve its efficiency and accuracy. This research is inspired by the meta-heuristic algorithm of Butterfly Flame based on the clustering coefficient to find active nodes in the social network. The results have shown that the proposed algorithm has improved by 23.6% compared to previous similar works. The findings of this research have great value and can be useful for researchers in computer science, social network managers, data analysts, organizations and companies, and other general public.

Keywords—Social network; detection of communities; butterfly fire algorithm; clustering coefficient

I. INTRODUCTION

Today, the Internet and web services are expanding rapidly, and at the same time, virtual social networks play an important role in people's real lives [1]. In fact, social networks are interactive networks that use the Internet as a medium to create communication between people [2]. With the rapid increase in social network users, high-scale data exploration can provide a better and more effective view of the hidden potential of these networks [3]. Internet social networks, as the most important examples, for the presence of different segments of society and the exchange of ideas, thoughts, and needs have changed according to social life [4]. A social network is a social structure formed by a group of people, organizations, or other social entities [5]. This collection is connected by social relations such as information exchange, cooperation,

friendship, kinship, or financial exchanges [6]. Social network analysis is an approach used to study the interaction of humans and examine the patterns, communication structure, or organization of social networks [7]. With the expansion of the use of electronic and online communication methods, the number of social networks has increased, and the importance of extracting communities from these networks in order to analyze social networks has become more important [8]. In social networks, some nodes are more connected than the entire network's nodes, which are called communities. Nodes are connected by one or more specific types of dependencies [9]. For example, financial exchanges, friendships, kinship, business, web links, disease transmission, or airline routes are examples of communication. But the resulting structure of these networks is often very extensive and complex. Analysis of social networks is the mapping and measurement of cooperation relationships among individuals, groups, organizations, and any entity that has the ability to process information and knowledge. Graph theory is usually used to display and analyze social networks. The components of graph theory are nodes and edges [10].

Groups of nodes (or members) connected by one or more different kinds of relationships are referred to as social networks [11]. In social network analysis, network structure is understood as the pattern organization of those nodes and their relationships, which helps to explain how these patterns have an impact on people's behaviors and attitudes [12]. Different communities inside the network are formed by these exchanges, links, or connections [13]. Those communities' members frequently share certain traits or interests. Comprehending and using the network effectively begin with comprehending the structure of society [14]. In the literature, clustering and community detection are frequently used interchangeably. While community detection strategies for network analysis and an emphasis on network structure are created as a function of connectivity that incorporates social interaction, clustering techniques typically concentrate on a single strategy, such as using particular traits to group nodes in a network [15]. Clustering algorithms, on the other hand, can be thought of as a workable substitute for community detection techniques, and both of them can be used to solve a variety of network analysis problems [16]. Existing paper swarm algorithm-based methods have drawbacks, including a slow rate of community discovery, among others. With increasing fitness value, the detection speed of communities slows down,

which could lead to a local optimum and take some time to attain a virtually global optimum [17]. A near-global optimum is quickly reached when efficiency is decreased, which lowers the likelihood of becoming stuck in a local optimum like speed detection. If an algorithm has improved speed detection, it may be able to reach a near-global optimum more quickly and with fewer iterations. In order to detect communities in a network, a new solution for the butterfly-fire technique based on the clustering coefficient (CC-BF) is proposed in this research. In addition to identifying communities in highly populated networks, CC-BF discovers cohesive collections of nodes as anomalous networks. The primary concept behind CC-BF is that it leverages the clustering coefficient, a social network analysis indicator, to improve community detection's accuracy, quality, and speed.

Other academics have successfully used strategies similar to CC to locate community structures in complex networks. Existing studies, however, don't look at the application of the clustering coefficient in BF. The clustering coefficient-based butterfly-fire algorithm's (CC-BF) essential phases are as follows: The speed of community detection using the clustering coefficient Modularity-based efficiency assessment.

To evaluate the quality of the population, the modularity criterion has been applied as a fitness function. Prior information about the size, quantity, or structure of communities is not necessary for the butterfly-fire approach, which is based on the clustering coefficient. According to experimental findings, CC-BF outperforms several other approaches for various networks. The following are the paper's contributions:

- A novel mutation technique that exploits the identified community structure to rewire existing connections;
- Using the clustering coefficient for the speed of community detection using the Fire Butterfly algorithm, comparing eight cutting-edge methods and evaluating the suggested algorithm on 12 different kinds of small and large networks.

The paper is divided into the following sections: The related works are included in the second section. The third section provides the suggested solution. The evaluation and effectiveness of the suggested algorithm are examined in the fourth section, along with a comparison to other algorithms of a similar nature. Finally, the fifth section presents the conclusion.

II. RELATED WORKS

In addition to the structural analysis of social networks, identifying communities is also used in other issues such as customer classification, recommender systems, vertex labelling, analysis of network influencers, and information dissemination. Due to the complexity of this issue, despite the various efforts that have been made in this field in recent years, it has not yet been fully resolved, and a satisfactory answer has not been provided to solve this issue. Many community identification algorithms have been presented for analyzing social networks. Identifying communities can be considered an optimization problem; from this point of view, several methods

based on the maximization of the famous modularity criterion have been presented for identifying communities [18]. Among the famous methods in this field, we can mention Newman's greedy algorithm (FN) [19]. In this method, conjunctive hierarchical clustering is used, in which groups of nodes successfully form larger communities if and only if the modularity value increases after this integration. After that, Klast and his colleagues presented the CNM method [20, 34] and showed that by using a complex data structure, they were able to reduce the computational burden of modularity in Newman's algorithm, making it usable for large networks. Shang and his colleagues also presented an improved genetic algorithm called MIGA to obtain maximum modularity [21]. Fortunato and his colleagues showed in [22, 33] that this method also has limitations apart from modularity. One of the most important limitations of modularity in this field is the limitation of separability. The problem of separability has a great impact on practical problems in the real world. Because of such issues, communities have different sizes, and this problem causes many small communities not to be recognized. Two solutions have been proposed to overcome the limitation of separability: First, other quality metrics were proposed in addition to modularity to be identified at different scales of society. For example, in a paper [23], a criterion called significance was used instead of modularity as the objective function in the Levin method, and it produced better results than using modularity. Pizzotti also introduced a standard called "community rank" [24] to guarantee the high density of communication within communities and the low density of communication between communities. The second solution to this problem is to formulate community identification as a multi-objective optimization problem. Pizzotti in [25] tries to obtain suitable communities using the NSGA-II evolutionary algorithm and two objective functions of community merit and rank. Gang and his colleagues presented the MOEA/D-Net algorithm [26], which tries to optimize two objective functions against each other. In [27], the CLANet method is also presented, which uses learning automata to maximize modularity along with a local limiter. Wasserman and his colleagues [28, 32], as the pioneers of social network analysis, have cited "social" for social networks, which can be defined as a system of social relations described by a set of actors and their social connections. Usually, a social network can be shown in the form of a graph, which has a set of vertices (nodes) and edges (connections) so that vertices are considered as actors within the network and edges are considered as relationships between these actors. In its simplest form, a social network is a mapping of all the relevant edges between the studied vertices. Here are the gaps identified in previous studies and the suitability of the proposed algorithm for certain types of data:

1) *Gaps in previous studies:* Lack of Clustering Coefficient in Butterfly-Fire Algorithm (BF): The text mentions that existing studies have successfully used strategies similar to the proposed Clustering Coefficient-based Butterfly-Fire algorithm (CC-BF) for community detection. However, it notes that previous studies haven't explored the application of the clustering coefficient in the Butterfly-fire algorithm. This suggests a gap in the literature where the

combination of the clustering coefficient and the BF algorithm hasn't been extensively investigated.

Community Detection Speed: The text highlights that existing swarm algorithm-based methods for community detection have limitations, including a slow rate of community discovery. This issue could lead to suboptimal results. The proposed CC-BF algorithm aims to address this gap by improving the speed of community detection. This suggests a need for faster and more efficient community detection algorithms in the existing literature.

2) *Suitability for data types:* The text doesn't explicitly mention the types of data for which the proposed CC-BF algorithm is more suitable. However, it does mention that CC-

BF is evaluated on "12 different kinds of small and large networks." This suggests that the algorithm is designed to be versatile and applicable to a variety of network data types.

In summary, the gaps in previous studies revolve around the lack of exploration of the clustering coefficient in the context of the Butterfly-Fire algorithm and the need for faster community detection methods. The proposed CC-BF algorithm appears to be designed to address these gaps and is tested on various types of network data.

Table I shows the classification of existing studies into orderly works based on applied community detection or clustering methods.

TABLE I. CLASSIFICATION OF CASE STUDIES BASED ON COMMUNITY DETECTION METHODS OR FUNCTIONAL CLUSTERING

Tool for clustering or detecting communities	No. of studies	ID	No. of nodes (n)	Comments	Ref.
A rapid method for modularity	4	S27, s28,s45,s51	more than 5000	used to make a comparison in (S27, S45)	[16]
MapInfo algorithm	3	S,10, S13, S18	2000	used to make a comparison in (S13)	[18]
Algorithm for maximizing expectations	2	S32, S36	more than 3500	used as a comparative tool	[19]
Community detection algorithm for binary graphs	5	S16, S24, S29, S41, S47	more than 6000	used as a comparative tool	[23]
Algorithm for eigenvector label propagation	1	S03	1500	newly suggested method	[24]
Spectral clustering-based technique for left-to-right oscillation	4	S40, S46, S49, S53	more than 5000	newly suggested method	[29]
Algorithm for evaluation and identification in the community	2	S34, S45	5000	newly suggested method	[30]
Eigenvector algorithm in front	2	S22, S05	more than 4000	newly suggested method	[31]

III. SUGGESTED METHOD

The most important problem in identifying communities in social networks can be considered the speed and accuracy of identifying communities in networks, as well as the new identification methods, which, in addition to speed and accuracy, should be able to act in a way to reduce the possibility of the influence of noise on the misidentification of communities. Minimize, and with the least knowledge of the structure of networks and the number and size of associations in the network, the best number and size should be selected and identified in an excellent way. Fig. 1 shows the general design of the proposed algorithm, which is used to detect and identify active nodes in social networks. In this algorithm to detect active nodes in social networks, attention has been paid to different parts of it, which have been examined in the following:

A. Initialization

In this algorithm, it is assumed that butterflies are candidate neighbors, and the variables of the problem are the locations of the bodies in the neighborhood. Therefore, butterflies can move in a one-dimensional, two-dimensional, or multi-dimensional dimension. Since the flame-propeller optimization algorithm is a population-based algorithm, the set of propellers is a matrix of ordered $n \times d$. In this method, in the initialization stage, a random solution is generated for each moth butterfly ($k=1, 2, \dots, B$), where B represents the number of butterflies. The active node is represented by an array of length n , where

the number stored in the i index of the array shows the ID of the candidate active node that executes the task T_i . Taking into account that the butterfly will be created in the initialization step B , the initial population of solutions will be a $B \times n$ matrix.

$$M = \begin{bmatrix} m_{1,1} & \dots & m_{1,d} \\ \vdots & \ddots & \vdots \\ m_{n,1} & \dots & m_{n,d} \end{bmatrix} \quad (1)$$

After initialization, the function P is executed iteratively until the function T is correct. The P function is the main function that moves around the search space. As mentioned above, the inspiration for this algorithm is transverse orientation. In order to mathematically model this behavior, the position of each bullet with respect to the flame is updated using the following equation.

$$M_i = S(M_i, F_j) \quad (2)$$

F_j represents the j th flame, M_i represents the i th butterfly, and s is the spiral function for the butterfly-fire algorithm.

$$S(M_i, F_j) = D_i \times e^{bt} \times \cos(2\pi t) + F_j \quad (3)$$

In this regard, D_i refers to the distance of the i -th propeller from the j -th flame. b is a fixed number to determine the shape of the logarithmic spiral, and t is a random number in $[-1,1]$, where D_i is obtained from Eq. (3).

$$D_i = |F_j - M_i| \quad (4)$$

Considering the above, the pseudocode of the proposed method is presented in Fig. 2.

In the general butterfly-fire method, all newly generated butterflies are accepted and kept in the next generation, while a greedy strategy is used to accept butterflies that have a good fit in our algorithm. This greedy strategy can be as follows:

$$x_{i,new}^{t+1} = \begin{cases} x_i^{t+1} & |f(x_i^{t+1}) \leq f(x_i^t) \\ x_i^t & |otherwise \end{cases} \quad (5)$$

In this regard, $x_{i,new}^{t+1}$ newly produced butterfly for the next generation. and $f(x_i^{t+1})$ and $f(x_i^t)$ are the fitness level of butterflies x_i^t and x_i^{t+1} , respectively.

The structure of propellers in the M-dimensional space of features is shown in Fig. 3. To search in the butterfly-fire algorithm space, the features are coded as butterflies in Fig 3. A unique code is considered for each feature in all P of the

license. After defining the parameters, the fitness function will be calculated.

In order to escape from the local optimum and cover more search space of each graph, instead of selecting the worst vertex in each step, τ th worst vertex is selected; That is, the vertex whose rank k is calculated using eq. (3) is selected for replacement.

$$k = (1 + (n^{1-\tau} - 1)(rand)^{\frac{1}{1-\tau}}) \quad (6)$$

In this regard, k refers to the active number selected from the ordered list of ranks; n is the number of graph vertices and (rand) is the random number generation function in the interval [1, 0]. The value of parameter τ is fixed, and in this research, it is determined by trial-and-error method; For the algorithm limits the search space and, in other words, looks for the answer more strictly.

Fig. 1. Flowchart of the proposed algorithm.

```

Input: graph (V, C), Initializing the population
Output: Set of the Influence node
Update the number of flames (FlameNumber)
Initializing all the parameters
Initialize the population of moths
Calculate the objective values Equations (1)
for all moths
for all parameters
update r and t
Calculate D with respect to the corresponding moth by Equations (3)
Update the matrix M with respect to the corresponding moth by Equations (4) and (5).
Calculate the Influence of each node
end
calculate the objective values
Update j-th flames by greedy strategy as Equations (6)
Apply later flames
S the current best individual in the population.

Fig. 3. The structure of nodes in the graph space.

IV. EVALUATION AND SIMULATION

Five community detection algorithms have been used to evaluate and compare the proposed method. The paper [19] presents a strategy called 2-Phase Community Detection (2PCD) to improve effective node detection algorithms in which a pre-processing step is added, and edges are weighted according to their centrality in the network topology. In the paper [4], an algorithm called Atom Stabilization Algorithm (ASA) has presented a new method for identifying influential nodes, which provides a new perspective for understanding the structure of nodes in complex networks. The algorithm presented in this paper is also used for evaluation. In this paper, the algorithms improved in research [4] and [19] have been used to evaluate the proposed method. To evaluate the results of the proposed method, the scale and quality criteria that are introduced in detail in the fourth section are used.

A. Measure Evaluation

In this section, for each of these data sets, the measure obtained by the proposed algorithm and other evaluated methods have been calculated. The relevant results are reported in Table II and Fig. 4.

From the analysis of Table II, it can be concluded that using the proposed algorithm has led to better results. The algorithm's performance has been tested on large datasets for which scaling optimization is increasingly difficult, and has shown satisfactory improvement. The proposed algorithm has improved by about 13.31% compared to the reference [19]. Compared to reference [4], it has improved significantly by 16.23.

TABLE II. THE OBTAINED MEASURE

No. of Data set	2PCD	ASA	CC-BF
1	0.7846	0.5795	0.8560
2	0.7031	0.6235	0.7349
3	0.6892	0.6768	0.8296
4	0.7303	0.6138	0.7612
5	0.7865	0.6895	0.8923
6	0.8032	0.6725	0.8514
7	0.7927	0.6614	0.8225
8	0.7823	0.6424	0.8368

Fig. 4. Benchmark evaluation for 2PCD, ASA and CCBF methods.

According to the maximum scale obtained, the best values for parameters α_1 , α_2 and α_3 are obtained. These three parameters are used to control the relative importance of each feature. The obtained values are shown in Table III.

B. Quality Assessment

In this section, the quality of the communities created by the proposed strategy is analyzed by the NMI criterion. In this criterion, it is assumed that, according to graph G , an implicit truth is available in order to examine the communities. However, calculating NMI is challenging for real-life networks because no ground truth is usually available to assess what communities exist in G and their characteristics. Therefore, to perform experiments, a dataset should be considered in which the correct clustering of communities is specified. For this purpose, only the College Football Association of America dataset has been used in this section. The obtained results are shown in Table IV.

Quality value (NMI) ranges from 0 to 1, and higher values correspond to better algorithms. From the analysis of this table, we conclude that using the proposed algorithm has led to better results. The proposed algorithm has improved by approximately 3.7% compared to the algorithm presented in [4]. Compared to the algorithm [19], it has improved by about 4.7%. In the figure below, the computation time for 100 nodes is displayed.

TABLE III. THE BEST VALUES FOR PARAMETERS α_1 , α_2 AND α_3

Parameters	Value
α_1	0.64
α_2	0.81
α_3	0.44

TABLE IV. COMPARING THE QUALITY CRITERIA OBTAINED FOR THE PROPOSED ALGORITHM AND SIMILAR ALGORITHMS

Method	Value
2PCD	0.536508
ASA	0.679523
CC-BF	0.782158

C. Execution Time

In Fig. 5 and Table V, the results of the proposed method in this research are compared with similar methods. According to this table, it is clear that the proposed method has a real-time feature compared to similar methods.

Time and memory restrictions are increased in real-time applications. In the suggested method, a search is conducted for each active pattern to discover all active nodes with it before allowing any active users into the system. Each search's outcome is saved as a cluster. Upon receiving an alarm in real-time correlation, it is simple to locate earlier connected alerts by searching in the corresponding cluster. As a result, each node's processing time is cut down. The test results attest to the accuracy of the performance and the method's time-saving effectiveness. The method's benefit is that it executes in 5.3126 seconds on a home computer, proving it is real-time. Investigations have been conducted for the suggested method based on the source [23] for an online social network. The network of Twitter's "followership" is represented by this data. Network nodes represent users, and a link is created between two users when one of them is "followed". This network has 24256 nodes and 44135 edges. The average CC is 0.412, and the average network degree is 3.05. Table VI displays each network's kind and size.

In order to assess the consistency of CC-BF, each network in this study had CC-BF implemented 12 times, and the maximum, mean, and standard error of modularity values for those 12 implementations were determined. Fig. 6 displays the mean modularity values and standard errors.

TABLE V. COMPUTING TIME FOR 100 NODES

Method	Second(s)
2PCD	8.469144
ASA	7.562415
CC-BF	5.398828

For instance, CC-BF gives steady findings with 0% standard error for the highly sparse Facebook network, as shown in Fig. 6, and significantly beats all other methods. It is modular in terms of size. Cora performs poorly and generates a low modularity rating for this network. On the other hand, methods other than dolphin provide numbers for this network's modularity that are nearly identical. Jazz performs better than all other approaches for SCN, whereas CC-BF performs better than Ecoil, Protein, PGP, Cora, and Polbook.

Additionally, the Reality Mining dataset [24], which the Harvard Media Lab supplied, has been chosen to test the suggested methodology for the infection rate of users in social networks. 200 Harvard students' contact, proximity, location, and activity data from the academic years 2006–2008 are included in the reality mining dataset.

In each test on this dataset, 0.03% of users are infected with a worm and worm propagation is simulated over three days. The CC-BF method's infection rate in each test is contrasted with the social-based 2PCD and ASA approaches. The percentage of infected users over non-infected users is used to compute the infection rate. Similar techniques yield 200 (for a static network), 300 (for a dynamic network), and 350 (for a network) clusters, respectively. The warning threshold β is established at 3, 15, and 25%, respectively, for each value of m .

For stability, each experiment is run 2,000 times. The experiment's findings for three distinct values of m and β are displayed in Fig. 7, 8, and 9. First, it is evident that in order to meet the anticipated infection rate, more people must be patched the longer one waits (, the higher the warning threshold). For instance, with $m = 200$ clusters and an anticipated contamination rate of 0.4, we should allocate patches to more than 20% of the users when $\beta = 12\%$ and to users who would be sent when $\beta = 3\%$. When $\beta = 25\%$, approximately 94% of all users have influence.

The second finding demonstrates that, in the static version of the social network depicted in Fig. 7, the proposed method outperforms the social-based methods 2PCD and ASA in terms of contamination rate. For instance, the proposed method's contamination rate is 7% to 12% lower than existing algorithms with comparable goals. The number of clusters m changes when new users join the network and form new social connections, and the infection rate of the social-based technique is updated using the cluster sizes of 300 and 350 as well as the warning threshold. $\beta = 3\%$, 15% and 25%, respectively. Fig. 8 and 9 illustrate how the suggested method, which has the ability to quickly and adaptively update the network community structure, achieves a higher infection rate than competing methods while also having much lower computational costs and execution times.

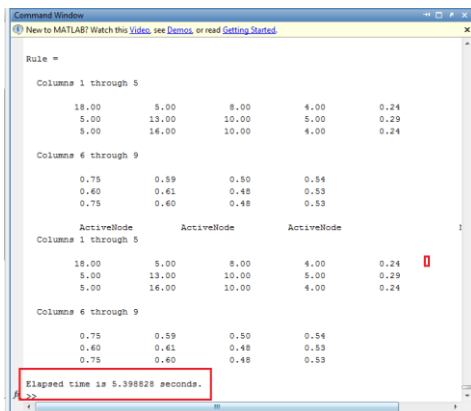

Fig. 5. The computational time for 100 nodes.

TABLE VI. EMPIRICAL AND PRACTICAL DATE SETS ARE UTILIZED TO ASSESS CC-BF

Data set	Type	Edge	Nodes	Avg. ccpppp	Avg. degrees	Avg. p.length
