In (9),  $f_1$  and  $f_2$  are the objective function values for optimizing the efficiency of goods entering and exiting the warehouse and optimizing the stability of the storage space, respectively.  $\omega_1$  and  $\omega_2$  are the corresponding weights for optimizing the efficiency of goods in and out of storage and optimizing the stability of storage locations.  $R_{xyz}$  represents the shipment rate of the goods at location  $(x, y, z)$ .  $t_{xyz}$  represents the time it takes for the goods to move from the storage location to the warehouse.  $m_{xyz}$  and  $n_{xyz}$  correspond to the weight and quantity of the goods. The steps to optimize using the MOG algorithm are as follows: first, use integers for encoding, so that the integers composed of  $(x, y, z)$  correspond to the rows, columns, and layers of the shelves. Secondly, the fitness function is determined. According to the multi-objective mathematical model, the objective function is positive and the minimum demand solution is obtained. The calculation is (10).

$$\begin{cases} Fit(x, y, z) = \sum_{i=1}^n \omega_i \times \frac{1}{f_i - f_{\min} + 1} \\ \begin{cases} 1 \leq x \leq a \\ 1 \leq y \leq b \\ 1 \leq z \leq c \end{cases} \end{cases} \quad (10)$$

Finally, the selection operator and other related parameters are determined, and the selection operator uses the roulette wheel selection method.

#### IV. RESULT ANALYSIS OF VFM FUSED WITH VST

To verify the performance of the VFM system and its effectiveness in practical teaching applications, this chapter first analyzes the performance of the system based on the MOG algorithm and its effectiveness in cargo location optimization, and then analyzes the application of VFM in practical teaching.

##### A. Analysis of Cargo Location Optimization Results based on MOG Algorithm

Firstly, to verify the performance of cargo location optimization based on MOG, MATLAB software is used for simulation experiments. The research will evaluate the optimization results based on the objective function value and cargo distribution. In addition, in order to verify the performance of the algorithm more scientifically, Multi objective optimization algorithm (MOO) commonly used at present is selected for comparative experiments, such as Multi objective Particle Swarm (MOPS), Multi objective Evolutionary algorithm (MOE) and Parallel Single Ended Inheritance (PSEI). Table I shows the cargo attributes and parameter settings of MOG.

From Fig. 7, it can be observed that after 213 iterations of the proposed MOG algorithm, the iteration curve of the total objective function value tends to stabilize, and the effect of cargo location optimization is relatively ideal. At this time, the corresponding total objective function value is 142.5. MOPS

needs to iterate 307 times before the change curve starts to stabilize, with a stable function value of 148.3; MOE stabilized after 256 cycles, with a value of 152.7; PSEI requires 286 iterations to reach a stable state, with a stable value of 150.2. The above results show that the MOG algorithm can obtain lower total objective function values in smaller iterations.

The paper uses MATLAB software for cargo location optimization operations using different multi-objective optimization algorithms.

To further explore the optimization effects of different MOOs in different scale problems, four optimization problems with different scales were set up, as displayed in Table II. From it, the MOG algorithm has the best optimization performance at different scales, followed by MOE and MOPE. And as the target scale problem expands, the optimization performance of each algorithm also shows varying degrees of decline. This is because as the scale expands, the objective function value of the original plan shows an exponential increase, so the decrease in optimization effect is within a reasonable range. From the perspective of convergence, when the scale is small, the iteration times of the four algorithms are not significantly different, because the solution to the optimal solution is relatively simple at small scales. However, the expansion of scale has demonstrated the advantage of MOG in iteration speed. At the maximum scale, the corresponding number of iterations is 411.2, which improves the efficiency of MOPS, MOE, and PSEI by 17.3%, 36.7%, and 40.9%. In summary, the MOG algorithm can effectively improve the probability of local optimization and accelerate convergence, with good cargo location optimization performance.

TABLE I. RELEVANT PARAMETER SETTINGS AND CARGO ATTRIBUTE INFORMATION OF MOG ALGORITHM

Setting of relevant parameters for MOG algorithm	Parameter	Set value	Parameter	Set value
	Number of shelf rows	3	Population size	300
	Number of shelf columns	8	Maximum Number Of Iterations	500
	Number of shelves	6	Crossover probability	0.8
	Location length/m	0.5	Mutation probability	0.08
	Stacker X-axis direction speed/(m/s)	0.6	Shelf spacing/m	0.9
	Stacker Y-axis direction speed/(m/s)	0.5	$\omega_1$	0.5
	Stacker Z-axis direction speed/(m/s)	0.3	$\omega_2$	0.5
Property information of goods	Type of goods	Cargo mass/kg	Delivery rate of goods	
	Column cargo E	0.8		0.5
	Column cargo H	0.6		0.3
	Column cargo I	0.4		0.1

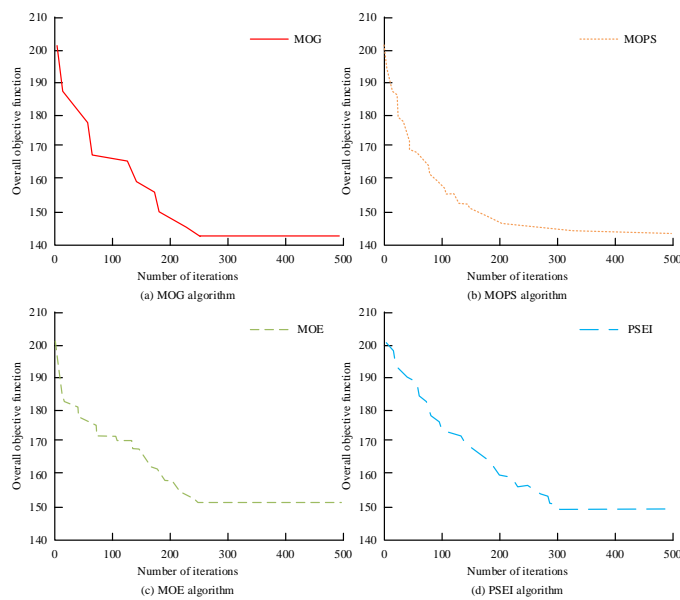

Fig. 7. The variation curve of the total objective function value for cargo location optimization using different MOO.

TABLE II. OPTIMIZATION RESULTS OF VARIOUS MOO IN PROBLEMS OF DIFFERENT SCALES

Number of goods/number of goods		25/120	50/203	75/547	100/810
MOG	$f_1$	99.50	91.34	108.98	132.49
	$f_2$	189.2	193.7	185.3	178.5
	Iterations	194.2	2993.5	336.6	411.2
MOPS	$f_1$	99.59	93.43	112.42	147.43
	$f_2$	189.3	199.0	187.3	234.2
	Iterations	218.8	323.5	419.6	482.3
MOE	$f_1$	102.3	93.6	124.7	139.2
	$f_2$	152.4	198.2	252.8	290.5
	Iterations	276.1	421.5	488.2	562.2
PSEI	$f_1$	112.33	85.43	120.32	141.08
	$f_2$	264.1	223.4	267.8	287.9
	Iterations	284.5	348.3	385.8	579.2

Fig. 8. Effect diagram of the distribution of warehouse locations before and after optimization based on MOG.

To verify the effectiveness of MOG in optimizing warehouse locations, Fig. 8 was developed. Fig. 8(a) and 8(b) represent the distribution of goods before and after the optimization of the cargo location. In Fig. 8(a), the goods were placed in a chaotic and disorderly manner in the warehouse of the VFM system, and there were no goods placed at the bottom of the shelves. This method of placing goods results in poor storage stability and has a negative impact on the efficiency of Tiger House's inbound and outbound operations. In Fig. 8(b), after MOG optimization, some goods are placed in a regular and uniform manner in the warehouse, with heavy items placed at the bottom of the storage space and light items placed at the top of the storage space. The results show that MOG based cargo location optimization can ensure both the efficiency of goods in and out of storage and the stability of shelves.

### B. Application Analysis of VFM

To explore the application of VFM in practical training teaching, the study first prepares three hardware devices: computer, HTC VIVE, and control console. The hardware connection of this system includes the communication connection between the console and the computer, the use of TCP/IP protocol and network cables to complete the communication connection between the computer and PLC, and the connection between the computer and HTC VIVE. Connect the VR helmet to the computer graphics card and

transfer data through HDMI and USB cables. After completing the hardware connection, communication connections between different software on the platform can be made. Simply add PLC geology to complete the communication connection.

During the operation of the VFM system, a schematic diagram of the main virtual flexible equipment can be obtained, as Fig. 9. The main flexible equipment working process includes the three-dimensional warehouse outbound, the gripping operation of the conveying robot, and the machining process of the CNC machine tool. After the construction of HTC VIVE is completed, the VFM system can be visualized in 3D.

To analyze the application of VFM in various universities, a corresponding usability and satisfaction evaluation table was set up, and a survey was conducted on 5000 students using the system in universities across the country. The results are listed in Fig. 10. Most students have a good evaluation of the use of VFM, with scores exceeding 18 for different evaluation questions, and a total score of  $93.34 \pm 3.09$ . This indicates that the user experience of the system is excellent. Students believe that the use of this system can enhance their learning confidence, and most students are willing to continue using the system for learning. The results show that the VFM system is well applied in universities and is widely loved by students.

Fig. 10. Availability and satisfaction analysis of VFM system.

## V. CONCLUSION

Many universities in China lack the application of FMS that is compatible with actual production lines in practical training and teaching, and due to issues such as resource shortages and high documentation costs, actual FMS cannot meet teaching tasks. To address the issue of the inability of university students to translate their knowledge into practical applications, the study first completed the overall design of the VFM system, followed by the design of the VST-VFM system, and finally optimized the efficiency of cargo allocation. Experimental results show that compared with other mainstream algorithms, the proposed MOG algorithm has the least number of iterations of 213. At this time, the iterative change curve of the total objective function value tends to be stable, and the effect of cargo location optimization is ideal. The average value of the corresponding total objective function is 142.5, which shows that the proposed method can not only improve the efficiency of goods in and out of the warehouse, but also enhance the stability of the shelf. With the expansion of the scale, the number of iterations of the proposed MOG algorithm is 411.2 at the maximum scale, which is 17.3%, 36.7% and 40.9% higher than that of mops algorithm, MOE algorithm and PSEI algorithm. The placement of goods in the warehouse optimized by MOG algorithm is regular and uniform, which means that the proposed method can effectively improve the probability of local optimization, accelerate convergence, and have better performance of cargo location optimization. In the evaluation results of the availability and satisfaction of VFM system applied in Colleges and universities, the total score is  $93.34 \pm 3.09$ , which indicates that students are very satisfied with the experience of the system and believe that it can effectively improve their learning confidence. In summary, the VFM system proposed in the study has excellent performance and has good application effects in practical training and teaching in universities. However, there are still shortcomings in the research. The constructed VFM only has basic functions for actual processing and production. In future research, VST can be used to introduce other equipment or models for improvement.

**Abstract**—Effective detection has been extremely difficult due to plagiarism's pervasiveness throughout a variety of fields, including academia and research. Increasingly complex plagiarism detection strategies are being used by people, making traditional approaches ineffective. The assessment of plagiarism involves a comprehensive examination encompassing syntactic, lexical, semantic, and structural facets. In contrast to traditional string-matching techniques, this investigation adopts a sophisticated Natural Language Processing (NLP) framework. The preprocessing phase entails a series of intricate steps ultimately refining the raw text data. The crux of this methodology lies in the integration of two distinct metrics within the Encoder Representation from Transformers (E-BERT) approach, effectively facilitating a granular exploration of textual similarity. Within the realm of NLP, the amalgamation of Deep and Shallow approaches serves as a lens to delve into the intricate nuances of the text, uncovering underlying layers of meaning. The discerning outcomes of this research unveil the remarkable proficiency of Deep NLP in promptly identifying substantial revisions. Integral to this innovation is the novel utilization of the Waterman algorithm and an English-Spanish dictionary, which contribute to the selection of optimal attributes. Comparative evaluations against alternative models employing distinct encoding methodologies, along with logistic regression as a classifier underscore the potency of the proposed implementation. The culmination of extensive experimentation substantiates the system's prowess, boasting an impressive 99.5% accuracy rate in extracting instances of plagiarism. This research serves as a pivotal advancement in the domain of plagiarism detection, ushering in effective and sophisticated methods to combat the growing spectre of unoriginal content.

**Keywords**—Natural language processing; encoder representation from transformers; document to vector + logistic regression

## I. INTRODUCTION

When someone exhibits another individual's software code like their own, whether purposefully or accidentally, while giving them due credit, this is known as plagiarized [1]. Plagiarism is an act of appropriating another individual's original using one's language and thoughts is seen as a breach of morality [2]. "The process or procedure of creating a different person's piece and thought, and presenting as one's

own; artistic thievery" is the meaning of unoriginality in the sense of lexicon. The act of duplicating existing music that is protected by copyright unauthorized authorization is known as music copyright infringement, and it is a hotly contested issue. In certain circumstances, the significant quantity of money at risk elevates the significance of the scenario [3]. Given the speed at which information can be shared via global platforms for collaborative engagement, writers have been motivated to conduct the chosen method of research over the Internet. Plagiarizing ideas from other individuals or research without giving due credit, plagiarism has had a negative impact. With a focus on text mining, NLP, academic literature norms, as well as several unresolved problems with standards and borderline sets, finding plagiarism is currently one of the most crucial occupations [4] [5] [6]. These foundational approaches possess great promise for addressing a variety of NLP issues, such as natural language understanding (NLU) and natural language generation (NLG), as well as potentially creating the foundation for artificial general intelligence (AGI) [7] [8]. Syntax-based and semantic-based plagiarism detection methods are the two categories into which they fall. Exemplary syntax-based methods include string comparison, AST (Abstract Syntax Tree) comparison, and token comparison. Illustrations of semantic-based methods include PDG (Programme Dependence Graph) comparing [9].

Numerous advantages include the large amount of information available on the internet in a variety of languages, as well as the accessibility of tools like engines for searching and knowledge bases, but copying has also grown. Plagiarism is the use of another investigator's ideas, substance, or results without their permission and its attribution to oneself [10]. This denies the initial investigator access to the findings of his study and makes it challenging to hunt down content, concepts, and arguments [11]. Cross-language copying is one kind of plagiarism, and it has become more prevalent as the technology for translation has advanced. To solve this issue, automated cross-language recognition of plagiarism technologies is crucial [12]. The problem of plagiarism in educational environments is not new. Between 50% and 79% of undergraduate pupils will commit plagiarism a minimum of once throughout their time as students, according to studies [13] [14]. Turnitin, which is a service that tracks down

plagiarism online and offers instructional feedback, opened its first office in the Philippines in March 2020. The business has been collaborating with schools and universities to comprehend the pandemic's distant evaluation demands [15].

The Smith-Waterman technique aimed at a regional sequence alignment, which looks for areas where the two sequences are most comparable. Nevertheless, the SW technique's spatial complexity and compute difficulty [16]. Sequencing readings make up the information as it is in its many forms. After read matching and quality-based cutting as part of the second analysis, a complete genomic is produced. Lastly, secondary analytics is defined as the interpretation of findings and the extraction of significant information from the data. Many algorithms and methods can be used in this final phase. These studies also serve as the basis for other applications. The tertiary analysis encompasses a variety of applications, including genomic identification and the development of a vaccine or medication [17]. The NN extracts the feature of the user for generating a rating matrix. In the first block, features are extracted and the probability score is generated for output block representation [18]. The regression problem of a content-based recommendation system makes rating predictions based on the feature of the content. The features are learned to calculate the similarity between the data items based on previously used information [19]. Clustering with one or more attributes is common for identifying different information based on similarity and correlation. The clustering methods which obtain the best grouping are k-Medoids, k-Means, Gaussian Mixtures, Hierarchical clustering, Lloyd's method, CLARA and PAM etc. [20]. The attention-gathering mechanism is a recent breakthrough in DL. The mechanism of attention has shown promising results in computer vision and a variety of NLP uses such as document sentiment classification, content summarization, named entity identification, and automated translation [21]. The key contribution of this paper is the following:

- The paper underscores the limitations of traditional identification techniques in detecting evolving plagiarism strategies, setting the stage for the need for innovative approaches.
- The study introduces a comprehensive assessment framework that considers syntactic, lexical, semantic, and structural elements, emphasizing the need for a holistic perspective.
- In response to the shortcomings of string-matching methods, the research adopts a NLP framework to enhance detection accuracy.
- The preprocessing phase is described in detail, outlining intricate steps like stemming, segmentation, tokenization, case folding, and the removal of redundant elements, which collectively refine raw text data.
- The paper highlights a pivotal aspect of the methodology: the integration of two distinct metrics within the Encoder Representation from Transformers

(E-BERT) approach, enabling a more nuanced exploration of textual similarity.

- Within the NLP realm, the combination of Deep and Shallow approaches is introduced as a lens to delve into the intricate layers of meaning within the text, revealing the potential for swift recognition of substantial revisions by Deep NLP.
- The paper introduces a novel utilization of the Waterman algorithm and an English-Spanish dictionary to enhance the process of attribute selection, improving the system's discernment of plagiarism markers.

This article is arranged in the following manner: Section II examines earlier research on prediction problems using various optimization methodologies. Section III discussed about problem statement. Section IV discusses about proposed method. Section V discusses the performance evaluation. Section VI experimental evaluation comprises mathematically developed system models. The paper is concluded in Section VII.

## II. RELATED WORKS

Patrick NyanumbaMwar et al. [22] proposed the Naive Bayes model for resume selection and classification. Based on the prediction accuracy, a homogeneous Ensemble classifier model was developed for various datasets. When compared with the original Naive Bayes Classifier, the prediction accuracy was improved.

ZhanchengRen et al. [23] developed a multi-label personality detection approach based on a neural network in which the emotional and semantic features were combined. For semantic extraction of text, sentence-level embedding was generated with Bidirectional Encoder Representation from Transformers (BERT). To estimate sentiment information, text corn analysis was invoked with a sentiment dictionary.

Ullah et al. [24] utilize machine learning, to identify software plagiarism in many programming languages. Software copying and the related issue of software plagiarism are becoming increasingly serious problems in today's society. It poses a considerable danger to the computing sector, which annually suffers significant financial losses. A customized version of the initial program may be created by the clients in different kinds of languages for programming. In addition, since every original code format may have unique grammar standards, it might be difficult to identify plagiarism in numerous forms of code sources. The study suggested a technique for multitasking language software plagiarism detection utilizing machine learning methodologies. Despite affecting the real data, characteristics are extracted from the code sources using the Principal Component Analysis. It uses factor evaluation to obtain characteristics from the information set and then transforms the principal elements into adjusted proportional fundamental elements, which are then used for forecasting assessment. Following that, the source code articles are classified by expectations using the multinomial logistic regression model implemented to these elements. It provides the logistic regression's adaptation for several class

issues. Furthermore, a paired z-test is used to assess how well the predictors performed in MLR. The information in the database is gathered in five distinct and well-known languages to conduct the investigation. Every programming language was used in two distinct examinations, Stack and binary searching.

Osman et al. [25] suggested Plagiarism is a high kind of academic rebellion that undermines the entire academic enterprise. In the past few years, several initiatives have been made to detect duplication in text documents. It is necessary to improve the methodologies that scholars have recommended for spotting copied passages, especially when conceptual analysis is required. Plagiarism is on the rise in part due to the ease with which written information may be accessed and copied on the Internet. The topic of this work is text identification of plagiarism in general. It is specifically related to technique and device detecting semantic text copying based on conceptual matching with the aid of semantic role labelling and a fuzzy inference engine. To recognize stolen semantic content, we offer essential arguments nominating strategies based on the fuzzy labelling method. The recommended technique compares text by semantically valuing each term contained in a sentence. Semantic argument construction for each sentence can benefit from semantic role labelling in several ways. To select the most important disagreements, the technique suggests nominating each argument generated by the fuzzy logic.

Hadiat et al. [26] this research aims to determine how Syntax may be used to improve the writing skills of learners in narratives and to ascertain how students perceive its usage in improving descriptive text correctness. Thirty eighth-grade kids are taking part in this particular study. The surveys, the telephone conversations, and the virtual classroom observation were used to collect the data for this study. The probability table, analyzing the content, coding, and triangulation analysis are the four methods used for analyzing data. The research shows that using Grammarly can improve the precision of producing descriptive prose. The research also reveals that the majority of students have favourable opinions of using Grammarly while writing descriptive texts because it can inspire them to improve their writing abilities, make it simple for them to identify textual errors, prevent plagiarism, and help them check their work more carefully when there are errors. To improve this work, future scholars are anticipated to perform quantitative research on related topics.

Kamble et al. [27] Plagiarism may be a situation that is expanding daily since information is developing quickly and the use of computers has grown compared to earlier times. Plagiarism is the improper use of someone else's creative work. Since it might be challenging to manually identify plagiarism, this procedure should be automated. There are several techniques available that may be used to identify plagiarism. Whereas some focus on apparent plagiarism, others focus on internal plagiarism. Processing data is a discipline that may both aid in improving the effectiveness of the procedure and assist in identifying plagiarism.

Cheers et al. [28] proposed Plagiarism within the code itself has long been a problem in postsecondary computing

teaching. Several software identification solutions have been presented to help with source code plagiarism detection. Conventional detection algorithms, nevertheless, are not resistant to ubiquitous plagiarism-hiding changes therefore can be imprecise in detecting plagiarized code from the source. This article introduces BPlag, a behavioural technique for detecting source code plagiarism. BPlag is intended to be both resistant to common plagiarism-hiding modifications and competent in detecting plagiarized code from the source. Monitoring an application's actions provides more robustness and overall accuracy since behaviour is regarded as being the least vulnerable part of a program altered by plagiarism-hiding modifications. BPlag analyzes execution behaviour via the use of symbols and describes an application in a unique graph-based style. After that, plagiarism is discovered by comparing these graphs and calculating similarity scores. BPlag is tested against five regularly used source code plagiarism detection algorithms for durability, accuracy, and efficiency.

### III. PROBLEM STATEMENT

The problem statement of this work is to improve the accuracy of plagiarism detection by implementing the Smith-Waterman algorithm and the English-Spanish dictionary technique. Plagiarism detection is a crucial task in various domains, including academia, journalism, and content creation. However, existing plagiarism detection systems may not always provide accurate results, especially when dealing with text written in different languages or when dealing with paraphrased or reworded content. By incorporating this algorithm into the plagiarism detection system, the aim is to enhance its ability to detect similarities in text, even when significant modifications have been made. Additionally, the English-Spanish dictionary technique involves utilizing a bilingual dictionary to identify similar words or phrases in both English and Spanish. This technique can be particularly useful when dealing with plagiarism across different languages, as it allows for cross-lingual comparisons and can improve the system's ability to identify instances of plagiarism. Therefore, the problem statement revolves around addressing the limitations of existing plagiarism detection systems by implementing the Smith-Waterman algorithm and the English-Spanish dictionary technique, to improve the accuracy and effectiveness of plagiarism detection, particularly when dealing with cross-lingual or rephrased content [29].

### IV. PROPOSED METHOD

This study's primary objective is to investigate the use of NLP techniques for material reprocessed detection. The theory states that a thorough analysis will find a few parallels between the original piece of writing and the modified version. A novel system containing NLP processes, comprising superficial NLP and Deep NLP, as well as more sophisticated techniques, like word2vec, is suggested to check the similarity pattern. Both the initial source material and the revised material are created entirely in English alone. The corpus-based technique is used to evaluate the system by looking at many texts from various perspectives. The use of NLP (Natural Language Processing) when used on translated texts yields more precise outcomes. Although NLP work lacks

an experimental foundation, it is suited for many sets and is motivated by past research in this area. The core components of every PD system are option selection and processing. We may generalize the text during preprocessing, and option separation reduces the overall time required for exploration to expedite the analytical phases. The aforementioned approach is used at various stages of plagiarism detection. Contrarily, certain text preparation stages employ superficial NLP techniques that are extremely straightforward and require the least amount of resources, such as lowercase, stemming lemmatization of stop word removal, and the process of tokenization. The suggested structure is broken down into six separate phases. Fig. 1 shows a flow diagram of plagiarism detection.

Fig. 1. Flow diagram of plagiarism detection.

#### A. Data Collection

The translations were created by qualified technical translators. For the English-Spanish language pair, the parallel corpus includes 18,303 documents, 62,057 phrases, 2,328,713 tokens that are and 14,624,745 symbols.

#### B. Pre-processing

Entering the competition and coming out on top output uses data prepared by pre-processing. Steps in preparation included eliminating stemming, segmentation, tokenization, case folding, stop word removal, null value, and special characters. This entails converting the unprocessed information into an easily readable format, which is a data mining technique by preprocessing. Data importation before using machine learning techniques is a crucial step considered by preprocessing to a textual nature being analyzed the dataset. So many steps are captured during the process. The "reviews" column and the empty rows were eliminated first. The natural language toolkit library (NLTK), a machine learning package for NLP, is also used.

The analysis yields good results, but to be sure, by spelling corrections, the meaning of the sentence has to account for sometimes spelling mistakes. The most appropriate correction is used to determine whether a word is misplaced and recommend a correction by the spellchecker. As you work with text data, the most commonly used methods are tokenization. Creating tokens from private information is the procedure to remove any unnecessary tokens, the tokenization and filtering of text data by way of sentiment analysis. With regard to sentiment analysis, stop words are words that are considered useless. In other words, removing those words won't affect the results of the model nor the precision or recall

of the analysis. They don't contribute to understanding sentences or review real significance. On very large datasets, keeping them would require higher computing power due to their size. Two methods are used to delete any stop words. Using NLTK library, the first method identified symbols with stop words and other stripped such as (e.g., a, it, is, that, and but) taken from reviews. This other method is applied to words that have a frequency greater than 50% and need to be removed from the NLTK stop words collection; use it when the word had a frequency greater than 50% but was removed as a result of low usage. Some examples are unlocked, time, mobile, and phone. Furthermore, discard the rare words that appear less than 6 times. Exclamation marks, full stops, and commas are used to remove punctuation marks. By removing both prefixes and suffixes, lemmatization or stemming returns words to their roots. By lemmas and related terms meanings are linked together. Case-folding involves replacing non-uppercase characters with their uppercase equivalents in a sequence of characters. The term "case-folding" simply refers to uppercasing when it comes to XML. Fig. 2 shows Pre-processing steps.

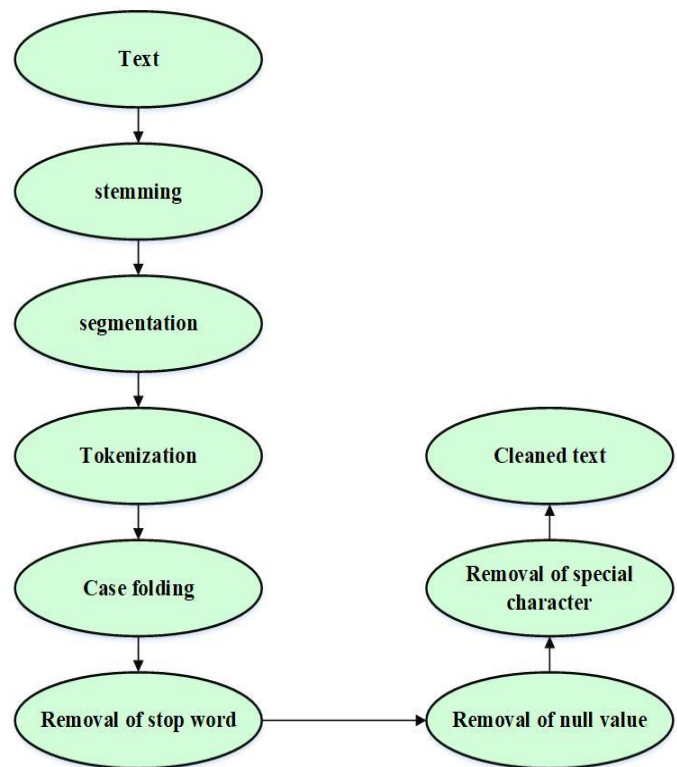

Fig. 2. Pre-processing stages.

#### C. Feature Extraction using Enhanced Bidirectional Encoder Representations from Transformers (E-BERT)

1) *Word vector*: In Chinese text, word separation does not occur and a single word is used as the text's base unit. Vectors contain information about the main features.

2) *Position vector*: Model structure alone cannot determine the placement of the input words by BERT when compared to short- and long-term memory networks and recurrent neural networks. For instance, expressing distinct

emotional dispositions using the phrases "I can't like banana chips" as "I may not like banana chips"

3) *Segment vector*: different tasks by using input and output text to meet the needs of different tasks.

Semantics-containing phrase vector in and vector output of each characters' remaining parts are shown in Fig. 3. In I-BERT, there are seven Transformer layers, of which the Encoder layer is primarily used. As part of the Encoder, attention mechanisms are used to calculate inputs and outputs and to learn features that are not possible to learn through shallow networks. Fig. 3 shows the I-BERT structure.

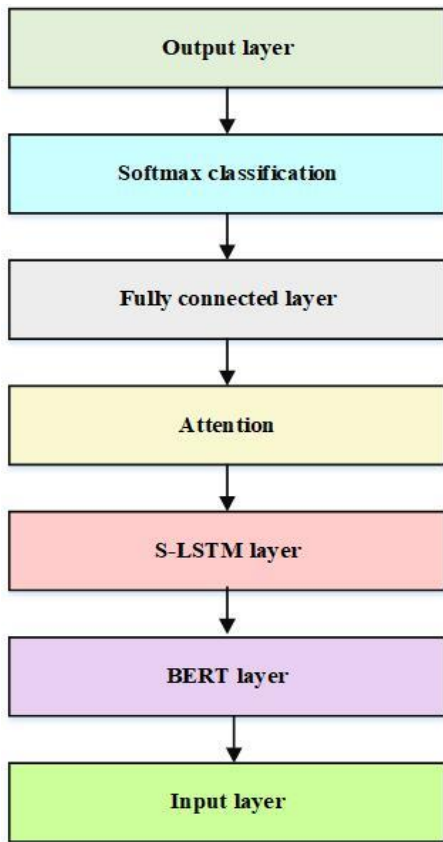

Fig. 3. I-BERT structure.

In addition to looking at the current word and obtaining semantics of the context, the self-attention mechanism does the following: incorporates a residual network and sub-layer normalization. The figure shows the structure of each transform in the I-BERT model.

Each sub-layer output is characterized as follows:

$$sub\_layer\_output = LayerNorm(x + (SubLayer(x))) \quad (1)$$

To enable information transfer between this unit's layers sublayers have been created with remaining connections. An embedded word representation makes up encoder input. An integrated feed-forward neural network is then used to process the normalized vectors. Self-attention is the main module in the Encoder section, and it is based on calculating the relationship between each word in a sentence and all of the

other words in that sentence, and then adjusting the weight of each word based on that relationship. A word vector obtained by this method includes the word's meaning but also how it interacts with other terms which makes it more global than a traditional word vector. An initialized random matrix multiplies the outputs of multiple Self-Attention mechanisms for parallel computations.

*D. Classification using K-Means Clustering (KMC) Algorithm*

Based on distance metrics, the KMC algorithm divides data samples into separate groups. It finds partitions in which the squared error between a cluster's empirical mean and its points is minimised. Let  $O = \{O_1, O_2, \dots, O_n\}$  be a set of  $n$  data samples to be clustered into a set of  $K$  clusters,  $C = C_q, q = 1, \dots, k$ . The purpose of KMC is to minimise the total of squared errors over all  $k$  clusters, which are definite as follows:

$$R(C) = \sum_q^k \sum_{O_l \in C_q} (O_l - Z_q)^2 \quad (2)$$

Where  $C_q, Z_q, O_l$  and  $k$  denote the  $q^{th}$  cluster, its centroid, data samples from the  $q^{th}$  cluster, and the total number of clusters, respectively.

Cluster centroids in KMC are generated at random. The nearest cluster to the data samples is calculated by the separations among each centroid's location and each piece of data. The average value of all the information samples within a cluster is used to modify the centre of each cluster. With the revised cluster centroids, the process of dividing the data sets into suitable clusters is then repeated until the specified termination requirements are met. Data extraction, recognition of patterns, and computer vision are just a few domains where the KMC approach has excelled. It is frequently used to give an initial setup for other sophisticated models as a pre-processing strategy [30].

Despite its benefits and popularity, KMC has some limitations because of restricted norms and effective procedures. One of the major disadvantages of KMC is its sensitivity to initialization. In particular, the method of reducing the sum of intra-cluster distances in KM is essentially a local search centred on original centroids. As a result, the initial arrangement of cluster centroids has a significant impact on KM performance optima traps. One of the primary motives for this research is the disadvantage of KMC. The process of minimizing the sum of intra-cluster distances in KMC optimized with the smith-waterman algorithm and English-Spanish dictionary technique.

$$fit(a) = \min imum(dis_{intra} + \frac{1}{dis_{inter}}) \quad (3)$$

The fitness function evaluation formula reveals that the highest efficiency is gained by lowering intra-cluster distances

and enhancing separation among clusters by maximizing inter-cluster distances [31].

### E. Smith-Waterman Algorithm and English-Spanish Dictionary Technique

In certain instances, the writing in both Spanish and English appeared to be literal translations into another language, as was seen by us. Yet, additional analytic tools have to be added to Spanish. We modified the Spanish components for tokenization when possible and sentence breaking. Use non-breaking prefixes to combine sentence breaking and tokenization, which as a result, we included in the component an inventory of Spanish non-breaking suffixes. Blocks dealing with Spanish-specific aspects were created from scratch. These cover verb tenses, comparatives, and attribute order. The position of adjectives in relation to the unit they modify is known as characteristic order. Words come after the word they modified in English; however, this is not the case in Spanish, except for a few exclusions for metaphorical effect. The element handling comparatives adds new nodes to the Spanish structure, which is particularly important in situations when there is no distinct comparable term in English. At last, a block that addresses the intricate verb tenses in Spanish was produced. This block chooses the right verb form in Spanish based on the English verb's tense, perfectiveness, and progressiveness.

Allow  $G$  as well as  $H$  stand for the patterns that need to be compatible. Let  $n$  and  $m$  stand for the lengths of  $G$  and  $H$ , accordingly. Let  $T_{q,r}$  stand for the maximum alignment score of  $G_0 \dots G_q H_0 \dots H_r$  and. Let  $U, V$  stand for the matrix to track the penalty for increasing the horizontal and vertical gaps. Let  $w(G_q, H_r)$  stand for the score of  $G_q$  aligned to  $H_r$ . The Smith-Waterman method is explained below.

$$U_{q,r} = \max \begin{cases} U_{q,r-1} - S_{ext}, \\ T_{q,r-1} - S_{first} \end{cases} \quad (4)$$

$$V_{q,r} = \max \begin{cases} V_{q-1,r} - S_{ext}, \\ T_{q-1,r} - S_{first} \end{cases} \quad (5)$$

$$T_{q,r} = \max \begin{cases} K, \\ U_{q,r}, \\ V_{q,r}, \\ T_{q-1,r-1} - w(G_q, H_r) \end{cases} \quad (6)$$

Appropriate contexts are inserted at the start and end of a statement to correspond to the words or phrases at the beginning or finish of the phrase in question. These match beacon rows and columns show a match.

## V. RESULT AND DISCUSSION

The novelty of this paper lies in its approach to plagiarism detection, particularly focusing on text and multilingual

plagiarism. The study introduces a framework that utilizes NLP methodology instead of traditional string-matching methods commonly employed for plagiarism detection. This shift in approach allows for a more comprehensive analysis of various aspects of the text, including syntactic, lexical, semantic, and structural elements. The paper also employs several pre-processing techniques, such as stemming, segmentation, tokenization, case folding, and the removal of stop words, nulls, and special characters, to prepare the text data for analysis. These steps help to improve the accuracy and effectiveness of the plagiarism detection system. This research paper introduces a novel approach to plagiarism detection by leveraging advanced NLP techniques, including E-BERT and Deep NLP. Unlike conventional methods, it integrates syntactic, lexical, semantic, and structural elements for more accurate identification. The innovative use of the Waterman algorithm and English-Spanish dictionary enhances attribute selection and captures synonym and phrase changes. This section describes the experimental setup, performance measurements, evaluation datasets, and experimental results. The proposed system will be implemented on the Python platform, and the overall performance of the proposed model will be evaluated in terms of performance metrics such as accuracy, precision, recall, specificity, and so on.

### A. Simulation Setup

An Intel(R) Core(TM) i5 processor running at 3 GHz, with four cores and four logical processors is used for the tests. The computer's name is MT, The System type is a 64-bit operating system, a 64-based processor, Microsoft Corporation is a manufacturer of operating systems, and it has built-in physical memory (RAM) of 8GB (8 GB usable).

### B. Experimental Evaluation

For performance evaluation, accuracy, precision, f-measure, recall, and Area Under the Curve (AUC) are all tested. To demonstrate the efficiency and performance of the feature learned by the suggested technique of plagiarism detection based on clustering. The proposed model is compared to models created utilizing several plagiarism encoding techniques as classifiers: word2vec+CNN, doc2vec+LR, and one-hot +LR. These techniques are supported by a variety of conditions and concepts. This study identifies the best classifier for plagiarism detection extraction.

Fig. 4. Performance metrics of proposed method.

The proposed algorithm achieved a high accuracy of 99.5%, demonstrating its effectiveness. The word2vec+CNN approach achieved an accuracy of 91.18%, indicating its capability to capture semantic information. The doc2vec+LR method achieved an accuracy of 89.27%, while the one-hot encoding + logistic regression approach achieved an accuracy of 88.82%. Fig. 4 shows a comparison graph for accuracy. The proposed algorithm achieved a precision of 77.75%, indicating its ability to accurately classify positive instances. The word2vec+CNN approach achieved a precision of 59.77%, suggesting its moderate success in correctly identifying positive instances. The doc2vec+LR method achieved a precision of 51.06%, while the one-hot encoding + logistic regression approach achieved a precision of 49.19%, both demonstrating lower precision compared to the other algorithms.

Fig. 5. Comparison graph with existing method.

Fig. 5 shows proposed algorithm achieved a high recall of 92.5%, indicating its ability to correctly identify a large proportion of positive instances. The word2vec+CNN approach achieved a recall of 58.51%, suggesting its moderate success in capturing true positive instances. The doc2vec+LR method achieved a recall of 50.67%, while the one-hot encoding + logistic regression approach achieved a recall of 48.46%, both demonstrating lower recall compared to the other algorithms. The proposed algorithm achieved a high F1-score of 98.21%, indicating its overall balance between precision and recall. The word2vec+CNN approach achieved an F1-score of 59.13%, suggesting its moderate performance in achieving a balance between precision and recall. The doc2vec+LR method achieved an F1-score of 50.87%, while the one-hot encoding + logistic regression approach achieved an F1-score of 48.82%, both demonstrating lower F1-scores compared to the other algorithms.

TABLE I. PROPOSED AND EXISTING METHODS COMPARISON

Algorithm	Accuracy	Precision	Recall	F1-score
<b>proposed</b>	95.5	77.75	78.67	78.21
<b>word2vec+CNN</b>	91.18	59.77	58.51	59.13
<b>doc2vec+LR</b>	89.27	51.06	50.67	50.87
<b>One-hot +LR</b>	88.82	49.19	48.46	48.82

Table I shows proposed algorithm achieved an accuracy of 95.5%, indicating its overall effectiveness in correctly classifying instances. It also achieved a precision of 77.75%, a recall of 78.67%, and an F1-score of 78.21%, demonstrating a good balance between precision and recall. The word2vec+CNN approach achieved a slightly lower accuracy of 91.18% with lower precision, recall, and F1-score compared to the proposed algorithm. Similarly, the doc2vec+LR and one-hot encoding + logistic regression approaches achieved lower accuracy and performance metrics compared to the proposed algorithm.

Fig. 6. AUC graph.

The above Fig. 6 shows AUC visualization was used to further analyse the performance of the suggested approach. The AUC curve has the TP rate as the y-axis and the FP rate as the x-axis with the AUC determined to indicate the models' performance. The optimal model is obtained when the AUC value is near to equal to 1.

TABLE II. AUC COMPARISON TABLE.

AUC (true positive rate)					
<b>Proposed</b>	0.1	0.2	0.7	0.8	0.9
<b>Word2vec+CNN</b>	0.1	0.2	0.5	0.6	0.7
<b>Doc2vec+LR</b>	0.1	0.2	0.3	0.4	0.5
<b>One-hot +LR</b>	0.1	0.2	0.25	0.35	0.4

The AUC Table II compares the performance of four different models across five evaluation points. The proposed model consistently achieves the highest AUC values, indicating superior predictive accuracy. The other models, including word2vec+CNN, doc2vec+LR, and One-hot+LR, demonstrate lower AUC scores, suggesting comparatively lower performance.

Fig. 7. Error metrics.

The error metrics consider the FPR and FNR. Fig. 7 shows the error metrics compared with existing methods. Compared with existing methods, the proposed method's error metrics are low.

$$FNR = \frac{FN}{FN + TP} = 1 - TPR \tag{7}$$

$$FPR = \frac{FP}{FP + TN} = -TNR \tag{8}$$

TABLE III. ERROR METRICS TABLE

FPR and FNR					
<b>Proposed</b>	0.03	0.031	0.032	0.033	0.035
<b>Word2vec+CNN</b>	0.1	0.2	0.3	0.39	0.46
<b>Doc2vec+LR</b>	0.15	0.3	0.39	0.5	0.7
<b>One-hot+LR</b>	0.5	0.6	0.65	0.7	0.75

Table III presents error metrics for four different models across five evaluation points. The proposed model consistently exhibits the lowest error values, indicating superior performance. Among the other models, word2vec+CNN and doc2vec+LR show intermediate error rates, while One-hot+LR has the highest error values, suggesting relatively lower accuracy.

TABLE IV. COMPARISON OF PLAGIARISM DETECTION SOFTWARE

Plagiarism Checker	Score
<b>Turnitin</b>	4.1
<b>Viper</b>	2.1
<b>Quetext</b>	2.4
<b>Proposed</b>	4.5

Table IV displays the results of several tools' plagiarism checkers. Higher numbers suggest greater possible plagiarism, with each score representing similarities or plagiarism detection levels. The greatest results go to Turnitin and Proposed, showing that they are better at spotting content similarities, while the lowest values go to Viper and Quetext, suggesting that they may be less sensitive to plagiarism. A technique for plagiarism detection can be chosen by researchers and authors depending on their own requirements.

## VI. CONCLUSION

The study focused on addressing the contemporary challenges of plagiarism detection, particularly in the context of text and multilingual plagiarism. Instead of traditional string-matching methods, an NLP methodology was employed, specifically utilizing the Encoder Representation from Transformers (E-BERT) technique. Various pre-processing techniques, such as stemming, segmentation, tokenization, case folding, and the elimination of stop words, nulls, and special characters, were applied to the text data. By integrating two measures within the E-BERT technique, the system investigated text similarity and employed the k-means clustering algorithm for categorization purposes. The deep feature representation obtained through this approach was compared to models developed using alternative encoding methods and logistic regression as a classifier, including word2vec+CNN, doc2vec+LR, and one-hot+LR. The experimental findings of the research indicated that the implemented system achieved an impressive accuracy level of 99.5% in the extraction. The utilization of the Smith-Waterman algorithm and the English-Spanish dictionary technique helped in selecting the optimal features for plagiarism detection. The future scope of this work involves advancing the plagiarism detection framework by exploring real-time, domain-specific applications and incorporating emerging transformer variants. Additionally, investigating mixed-media plagiarism detection and addressing ethical considerations for fair and transparent usage would further enhance the system's capabilities.

# Comparative Study of Machine Learning Algorithms for Phishing Website Detection

Kamal Omari

Department of Mathematics & Computer Science-Faculty of Sciences Ben M'sik,  
University Hassan II. Casablanca, Morocco

**Abstract**—Phishing, a prevalent online threat where attackers impersonate legitimate organizations to obtain sensitive information from victims, poses a significant cybersecurity challenge. Recent advancements in phishing detection, particularly machine learning-based methods, have shown promising results in countering these malicious attacks. In this study, we developed and compared seven machine learning models, namely Logistic Regression (LR), k-Nearest Neighbors (KNN), Support Vector Machine (SVM), Naive Bayes (NB), Decision Tree (DT), Random Forest (RF), and Gradient Boosting, to assess their efficiency in detecting phishing domains. Employing the UCI phishing domains dataset as a benchmark, we rigorously evaluated the performance of these models. Our findings indicate that the Gradient Boosting-based model, in conjunction with the Random Forest, exhibits superior performance compared to the other techniques and aligns with existing solutions in the literature. Consequently, it emerges as the most accurate and effective approach for detecting phishing domains.

**Keywords**—Phishing detection; cybersecurity; machine learning; Gradient Boosting; Random Forest

## I. INTRODUCTION

Phishing, a widespread and dangerous cyber-attack method, continues to pose significant threats in today's digital world. With the increasing reliance on online platforms, for various activities such as business, transactions and healthcare services, the risk of falling victim to phishing attacks has escalated [1]. Phishing attacks involve the deceptive acquisition of personal and sensitive information through a combination of technical deception and social engineering tactics [2, 3]. These attacks often utilize fraudulent emails or messages that appear to originate from reputable entities, tricking unsuspecting users into sharing their confidential data [2].

Despite advancements in cybersecurity that have greatly improved malware detection and reduced the presence of malware-hosting websites, combating phishing attacks remains challenging due to their social engineering nature [1, 4]. Phishing domains, in particular, exploit users' trust by directing them to counterfeit websites that closely resemble legitimate ones, leading to the compromise of sensitive information [5]. Falling victim to phishing attacks can have severe consequences, including identity theft, financial fraud, and reputational damage [1].

To address the persistent threat of phishing attacks, robust cybersecurity measures are required, and artificial intelligence (AI) has emerged as a promising approach [6]. Machine

learning (ML) algorithms, a subset of AI, offer the potential to detect and classify phishing attacks by analyzing patterns and indicators of fraudulent activity based on historical data [6]. By leveraging ML models, it becomes possible to enhance detection capabilities and accurately predict whether a webpage is a phishing site or legitimate [6].

The objective of this research paper is to compare the effectiveness of ML classification models in detecting phishing domains. By identifying the most accurate ML model among the considered algorithms, the aim is to enhance detection capabilities and mitigate the risks associated with visiting phishing websites, ultimately restoring consumer trust.

The rest of this paper is organized as follows: Section II offers insights into the algorithms used. In Section III, a review of the latest research on phishing attacks is presented. Section IV outlines the methodology employed in this study. The experimental results of our comparative study are presented and discussed in Section V. Finally, Section VI concludes the paper by summarizing the key findings and proposing avenues for future research.

## II. BACKGROUND

Various machine-learning classification methods have demonstrated their effectiveness in detecting phishing domains. Some of the prominent techniques encompass:

### A. Logistic Regression

Logistic regression is a prevalent statistical model utilized for binary classification tasks [7]. As a supervised learning algorithm, it predicts the probability of an instance belonging to a particular class. In logistic regression, the dependent variable is binary or categorical, while the independent variables can be continuous or categorical.

The primary objective of logistic regression is to determine the best-fitting logistic function that establishes the relationship between the independent variables and the probability of the binary outcome. This logistic function, also known as the sigmoid function, maps any real-valued number to a value between 0 and 1 (see Fig. 1) [8]. The resulting probability estimate is then utilized to classify the instances into their respective classes.

The logistic regression model estimates its parameters through maximum likelihood estimation, involving the optimization of the log-likelihood function [7]. Various optimization algorithms, such as gradient descent, are

commonly employed to minimize the cost function and obtain the optimal parameter values.

Fig. 1. Logistic regression algorithm [9].

One of the key advantages of logistic regression is its interpretability. The coefficients of the independent variables offer valuable insights into the influence and direction of each variable on the probability of the outcome [10]. Furthermore, logistic regression can effectively handle both linear and nonlinear relationships between the independent variables and the log-odds of the outcome.

### B. K-Nearest Neighbors (KNN)

K-Nearest Neighbors (KNN) stands as a widely employed non-parametric supervised learning algorithm for classification tasks [11]. Its simplicity, combined with its effectiveness, allows it to predict the class of an instance based on the classes of its nearest neighbors in the feature space.

In the KNN algorithm, the parameter K represents the number of nearest neighbors considered when making a prediction. To classify a new instance, KNN calculates the distances between the instance and all the training instances in the feature space (see Fig. 2). Subsequently, it identifies the K nearest neighbors based on a distance metric, such as Euclidean distance or Manhattan distance [12].

Upon identifying the K nearest neighbors, the majority class among them is assigned to the new instance. In cases of ties, a voting mechanism can resolve the class assignment. One remarkable feature of KNN is that it is a lazy learner, as it performs classification at runtime without requiring an explicit training phase [13].

KNN exhibits versatility, as it adeptly handles both binary and multi-class classification problems. Additionally, it proves to be robust in capturing complex decision boundaries and coping with noisy data [14]. Nonetheless, it is essential to carefully consider the selection of K and the distance metric, as these choices significantly impact the algorithm's performance.

### C. Support Vector Machine

Support Vector Machine (SVM) stands as a potent supervised learning algorithm extensively employed for classification and regression tasks [16]. The fundamental objective of SVM is to identify an optimal hyperplane that effectively segregates data points into distinct classes within the feature space (see Fig. 3).

Fig. 2. K-Nearest neighbors' algorithm [15].

Fig. 3. Support vector machine algorithm [17].

In the SVM approach, the algorithm maps input data into a higher-dimensional feature space using a kernel function, which could be linear, polynomial, or radial basis function (RBF) kernel [18]. By transforming the data in this manner, SVM can discover a hyperplane that maximizes the margin between classes, thereby enhancing its generalization capability.

A key aspect of SVM is to identify the hyperplane that not only separates classes but also maximizes the distance to the nearest data points, known as support vectors. This property renders SVM robust to outliers and allows it to accommodate non-linear decision boundaries through various kernel functions.

SVM is versatile, accommodating both binary and multi-class classification tasks. For binary classification, SVM endeavors to locate a decision boundary that effectively distinguishes between the two classes. In multi-class scenarios, SVM can be extended using approaches such as one-vs-one or one-vs-rest [19].

### D. Naive Bayes

The Naive Bayes classifier stands as a well-known machine learning algorithm based on the application of Bayes' theorem, assuming feature independence [20]. It finds wide application in classification tasks, particularly in natural language processing and text mining.

The Naive Bayes classifier computes the probability of each class given a set of input features and selects the class with the highest probability as the predicted outcome. Its strength lies in its simplicity, efficiency, and ability to handle high-dimensional data effectively (see Fig. 4).

Fig. 4. Naive Bayes algorithm [21].

The algorithm is termed 'naive' due to its assumption of feature conditional independence given the class. This simplifying assumption enables efficient estimation of class probabilities by multiplying individual feature probabilities. While this assumption may not hold true in real-world scenarios, Naive Bayes often performs well and yields reliable results.

Various variations of the Naive Bayes classifier exist, such as Gaussian Naive Bayes, Multinomial Naive Bayes, and Bernoulli Naive Bayes, each suited for different data types and feature distributions [22].

Despite its simplicity, the Naive Bayes classifier has shown competitive performance compared to more complex algorithms. However, it is essential to acknowledge that Naive Bayes assumes feature independence, which may not always hold in practical scenarios.

### E. Decision Trees

Decision Trees are a well-established machine-learning algorithm utilized for classification and regression tasks [23].

These models are renowned for their intuitive and interpretable nature, constructing a tree-like flowchart based on dataset features. The Decision Tree algorithm recursively partitions the dataset, creating a tree-like structure (see Fig. 5), with internal nodes representing features and branches denoting possible feature values, leading to leaf nodes as final predicted outcomes or classes.

Fig. 5. Decision tree algorithm [24].

The construction involves selecting the best feature to split the data at each node based on specific criteria like information gain or Gini impurity, aiming for maximized homogeneity within subsets. Decision Trees handle both categorical and

numerical features, learning complex decision boundaries and effectively managing missing values and outliers [25].

Their applications extend to feature selection and identifying crucial features for decision-making. However, overfitting risks exist, especially with excessively deep or complex trees, mitigated by techniques like pruning and maximum tree depth setting [26].

### F. Random Forest

Random Forest stands as a widely used ensemble learning algorithm renowned for its ability to combine multiple decision trees to make accurate predictions [27]. Its versatility and robustness make it well-suited for a wide range of classification and regression tasks.

The essence of Random Forest lies in building an ensemble of decision trees, each trained on a different subset of the training data through bootstrapping [27]. Moreover, at each node of the tree, only a random subset of features is considered for splitting, introducing an element of randomness that helps mitigate overfitting and enhances the model's generalization ability (see Fig. 6).

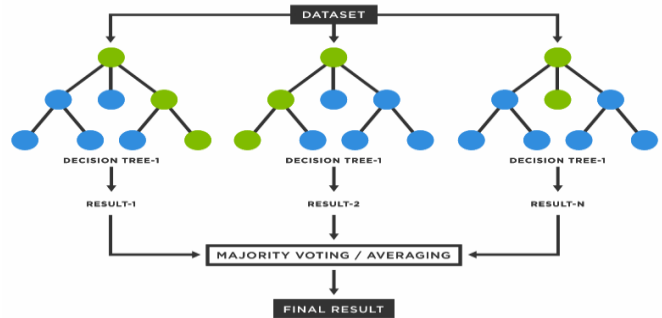

Fig. 6. Random forest algorithm [28].

To produce the final prediction, Random Forest aggregates the predictions of all individual trees either through voting (for classification) or averaging (for regression). This ensemble approach effectively reduces variance and improves the overall performance of the model.

The advantages of Random Forest are numerous, encompassing its capacity to handle high-dimensional data, automatically select important features, and remain robust in the presence of outliers and noisy data [29]. Additionally, it facilitates the estimation of feature importance, offering valuable insights into the underlying data.

However, it is essential to acknowledge that Random Forest may suffer from high computational complexity, and its results may not be as interpretable as those of single decision trees. To optimize its performance, hyperparameter tuning, including adjusting the number of trees and the maximum depth of each tree, becomes necessary [27].

### G. Gradient Boost

Gradient Boost is a highly popular and effective machine-learning algorithm widely employed in various domains due to its ability to combine weak prediction models and create a robust predictive model [30]. It belongs to the category of

boosting algorithms, which iteratively train new models to correct the errors made by previous models.

In Gradient Boost, weak models, typically decision trees, are trained in a stage-wise manner. At each stage, the model is trained on the data with a modified version of the target variable, representing the residuals or errors of the previous models. This process focuses on minimizing the errors made by the ensemble of models (see Fig. 7).

Fig. 7. Gradient boost algorithm [31].

The training process involves optimizing a loss function, such as mean squared error for regression or log loss for classification, to determine the optimal weights and parameters of the weak models. The final model is a combination of these weak models, and their predictions are weighted based on their performance on the training data.

One of the key strengths of Gradient Boost is its ability to handle complex datasets and capture non-linear relationships, leading to accurate predictions [30].

However, it is essential to be cautious about overfitting when using Gradient Boost. Controlling model complexity through regularization techniques, such as shrinkage and subsampling, can help mitigate this issue. Moreover, due to its iterative nature, Gradient Boost can be computationally expensive, necessitating careful tuning of hyperparameters, such as learning rate, tree depth, and number of iterations, to achieve optimal performance [32].

### III. RELATED WORK

URL verification is crucial for protecting users from phishing attacks, an often overlooked vulnerability [33]. However, traditional phishing detection methods exhibit limited accuracy, detecting only around 20% of attempts [33]. To overcome this, machine learning (ML) techniques have shown promise, though challenges arise with large databases and time-consuming processes [34]. Additionally, heuristics-based approaches suffer from significant false-positive rates [34]. Previous research focuses on improving anti-phishing models through feature reduction and ensemble methods [14].

Phishing URL detection is commonly treated as a classification problem using ML algorithms [35]. Constructing an ML-based detection model requires relevant properties to distinguish phishing from legitimate websites [35]. Robust ML approaches have demonstrated high detection accuracy [35], with various feature selection strategies employed to reduce feature numbers [35].

Common classifiers like Decision Trees (DT), C4.5, k-Nearest Neighbors (k-NN), and Support Vector Machines (SVM) are widely used in phishing detection research due to their accuracy and efficiency [36]. However, deep learning models face challenges such as manual parameter adjustment, lengthy training periods, and suboptimal detection accuracy [37]. Researchers emphasize the significance of ensemble learning techniques, feature selection, and reduction to address these issues [38]. Different classifiers, including Naive Bayes (NB) and SVM, have been explored [39]. Random Forest (RF) has also been successful in distinguishing phishing attacks from normal websites, with Subasi et al. [40] achieving an exceptional classification performance of 97.36% using the random forest classifier. Feature selection has been a focus in another study, with characteristics grouped to identify the most effective ones for accurate phishing attack detection [41].

In the field of phishing website detection, Patil et al. [42] proposed three strategies involving URL attribute assessment, validation based on hosting and management, and visual appearance-based analysis. They comprehensively assessed various aspects of URLs and websites using ML methodologies and algorithms.

Joshi et al. [43] conducted research on phishing attack prediction, utilizing a binary classifier based on the RF algorithm and a feature selection algorithm called relief, using data from the Mendeley domain for feature selection and training the RF algorithm.

Ubung et al. [44] explored ensemble learning strategies like bagging, boosting, and stacking to achieve high accuracy in phishing detection by integrating decision tree classifiers.

Similarly, Alsariera et al. [45] investigated phishing website detection using the "Forest by Penalizing Attributes" (FPA) algorithm and its enhanced variations, employing ensemble learning strategies like bagging, boosting, and stacking.

Pandey et al. [46] contributed to the field with a novel hybrid model combining Random Forest and Support Vector Machine (SVM) techniques for detecting phishing on websites. Their experimental results demonstrated an impressive accuracy of 94%, outperforming traditional ML algorithms SVM (90%) and Random Forest (92.96%), highlighting the superior performance of the hybrid model in classifying phishing attacks.

Furthermore, Lakshmi et al. [47] introduced an innovative approach for detecting phishing websites, analyzing hyperlinks in the HTML source code. They constructed a feature vector with 30 parameters to train a supervised DNN model with an Adam optimizer. The model demonstrated exceptional performance, outperforming traditional ML algorithms with a remarkable accuracy rate of 96%.

Table I displays a concise overview of machine learning approaches employed in phishing website detection.

TABLE I. COMPARATIVE ANALYSIS OF RECENT MACHINE LEARNING TECHNIQUES FOR PHISHING DETECTION

Model	Dataset	Algorithm	Accuracy
Subasi et al. [40]	website	RF,	97.36%
		KNN,	97.18%
		SVM,	97.17%
		ANN,	96.91%
		RF,	96.79%

Lakshmi et al. [47]	UCI	DNN +Adam	96.00%

IV. METHODOLOGY

In this research study, our main objective was to identify the most effective machine-learning model for detecting phishing domains. To achieve this, we conducted experiments with seven distinct machine-learning techniques: Logistic Regression (LR), k-Nearest Neighbors (KNN), Support Vector Machine (SVM), Naive Bayes (NB), Decision Tree (DT), Random Forest (RF), and Gradient Boosting.

Our dataset consisted of over 11,055 records, with 31 website parameters and a corresponding class label indicating whether it was a phishing website (1) or not (-1). To improve the models' accuracy, we applied the MinMax normalization feature as a preprocessing strategy.

To ensure robust evaluation, we employed a ten-fold cross-validation method during the classification process. This approach enabled us to obtain a more accurate performance evaluation of the models on the dataset, ensuring reliable results.

After the classification process, we thoroughly assessed the machine learning algorithms' performance using various evaluation metrics commonly used in the field, including accuracy, precision, recall, and F1-score. These metrics allowed us to make meaningful comparisons between the algorithms, ultimately identifying the most suitable approach for effectively detecting phishing websites.

To visually illustrate the concept, (see Fig. 8) presents a graphical representation of the process.

A. The Dataset

The research utilized a dataset obtained from the UCI machine-learning repository, which can be accessed at [48]. The dataset contains 11,055 records, and each sample within the dataset is composed of 31 website parameters. Among these parameters is a class label that indicates whether the website is classified as a phishing website or not, represented by values of 1 or -1 (Table II).

Fig. 8. Model's flowchart.

TABLE II. DESCRIPTION OF STUDIED PHISHING WEBSITE DATASET

<b>Total number of attributes</b>	31	
<b>No. of independent variables</b>	30	
<b>No. of class variables</b>	1	
<b>Details of the class variable</b>	Name: Result	
	Legitimate ==-1	Phishing=1
	4898	6175
<b>Total number of instances</b>	11055	

B. Dataset Representation

The dataset utilized in this research incorporates novel features that have been experimentally introduced [48], including the assignment of new rules to certain well-known parameters. The dataset comprises 30 parameters, which are listed below:

'having\_IP\_Address', 'URL\_Length', 'Shortening\_Service', 'having\_At\_Symbol', 'double\_slash\_redirecting', 'Prefix\_Suffix', 'having\_Sub\_Domain', 'SSLfinal\_State', 'Domain\_registration\_length', 'Favicon', 'port', 'HTTPS\_token', 'Request\_URL', 'URL\_of\_Anchor', 'Links\_in\_tags', 'SFH', 'Submitting\_to\_email', 'Abnormal\_URL', 'Redirect', 'on\_mouseover', 'RightClick', 'popUpWindow', 'Iframe', 'age\_of\_domain', 'DNSRecord', 'web\_traffic', 'Page\_Rank', 'Google\_Index', 'Links\_pointing\_to\_page', 'Statistical\_report'.

C. Visualizing the Dataset: Heatmap of Feature Correlations

To gain further insights into the dataset and understand the relationships between its features, we generated a heatmap to visualize the pairwise correlations among the 30 parameters used in this research (see Fig. 9). The heatmap provides a clear and concise representation of the correlation matrix, allowing us to identify potential associations and patterns that might influence the classification of phishing websites [50].

Fig. 9. The heatmap of dataset features.

Each cell in the heatmap is color-coded based on its correlation value, ranging from highly positive (dark shades) to highly negative (light shades) correlations. A correlation value close to 1 indicates a strong positive relationship, while a value close to -1 denotes a strong negative relationship. Conversely, a correlation value near 0 suggests little to no linear correlation between the respective features.

Upon analyzing the heatmap, several interesting observations emerge. For instance, we observe a strong positive correlation between the 'having\_Sub\_Domain' and 'Links\_pointing\_to\_page' features, indicating that websites with more subdomains tend to have more links pointing to their pages. Conversely, there appears to be a negative correlation between 'URL\_Length' and 'Page\_Rank', suggesting that longer URLs may be associated with lower page ranks.

Additionally, the presence of certain novel features, as experimentally introduced in the dataset, reveals potential correlations with other established parameters. For example, the 'Abnormal\_URL' feature exhibits a moderate negative correlation with 'SSLfinal\_State,' suggesting that websites with abnormal URLs might be less likely to have a valid SSL certificate.

The heatmap not only facilitates the identification of such associations but also aids in assessing potential multicollinearity among the features. Identifying multicollinearity is crucial, as it can impact the performance and interpretability of predictive models.

D. The MinMax Normalization

In our study, our main focus was to boost the precision of our proposed models by introducing MinMax normalization as a critical preprocessing measure. This technique, widely acknowledged in the realm of machine learning, significantly enhances model accuracy, particularly for specific models that rely on it [49]. By employing MinMax normalization in our suggested model, we effectively rescaled the data to a domain of [0, 1], leading to notable improvements in the input quality during model training (see Eq. (1)).

$$X_{normalized} = \frac{X - X_{min}}{X_{max} - X_{min}} \quad (1)$$

Where:

$X_{normalized}$  is the normalized value of the data point X.

X is the original value of the data point.

$X_{min}$  is the minimum value in the dataset.

$X_{max}$  is the maximum value in the dataset.

E. The Ten-fold Cross-validation Method

The ten-fold cross-validation method is a widely used technique in machine learning and statistical analysis to evaluate a model's performance on a dataset [51]. It involves ten iterations with different data splits for training and testing, yielding a robust estimate of the model's abilities. This approach mitigates bias and variance issues, providing a comprehensive evaluation of generalization to unseen data. The final performance metric is obtained by averaging the results from all ten iterations, ensuring an accurate assessment of the model's capabilities.

F. The Evaluation Metrics

The evaluation metrics are essential tools for assessing the performance of machine learning models. They provide quantitative measures of the model's accuracy, precision, recall, and F1-score. By using these metrics, researchers can make meaningful comparisons between different models and identify the most effective approach for their specific task.

1) Accuracy: Accuracy is a fundamental performance metric used to assess the overall correctness of a machine learning model. It represents the ratio of correctly predicted instances to the total number of instances in the dataset. In other words, it measures how often the model makes correct predictions. It is a simple and intuitive metric, but it might not be the best choice when dealing with imbalanced datasets.

$$Accuracy = \frac{\text{Number of correctly predicted instances}}{\text{Total number of instances}} \quad (2)$$

2) F1 Score: The F1 score is a balanced metric that takes into account both precision and recall. It is particularly useful when dealing with imbalanced datasets, where one class might dominate the others. The F1 score computes the harmonic mean of precision and recall, providing a single value that balances the trade-off between false positives (FP) and false negatives (FN).

$$F1\ Score = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (3)$$

3) Recall: Recall, also known as sensitivity or true positive rate, measures the proportion of actual positive instances that are correctly identified by the model. It is essential when the cost of false negatives is high, as it focuses on minimizing the number of missed positive instances.

$$Recall = \frac{\text{True Positives}}{\text{True Positives} + \text{False Negatives}} \quad (4)$$

4) Precision: Precision represents the proportion of true positive predictions among all positive predictions made by the model. It is crucial when the cost of false positives is high,

as it aims to reduce the number of incorrectly classified positive instances.

$$Precision = \frac{True\ Positives}{True\ Positives + False\ Positives} \quad (5)$$

In summary, accuracy measures overall correctness, F1 score balances precision and recall, recall focuses on minimizing false negatives, and precision aims to minimize false positives.

### V. FINDINGS AND ANALYSIS

In this section, we present the experimental results of our comparative study (Table III). We analyze the performance of each machine-learning algorithm using the evaluation metrics defined in the previous section. We provide a comprehensive analysis of the results, highlighting the strengths and weaknesses of each algorithm.

TABLE III. EVALUATION RESULTS IN (%).

Classifier	Accuracy	F1 score	Recall	Precision
Gradient Boost	97.2%	96.9%	97%	96.8%
Random Forest	97.1%	97.3%	97.4%	97.2%
Decision Tree	96.3%	96.7%	96.7%	96.6%
K-Nearest Neighbors	95.6%	96.2%	96.8%	95.7%
Support Vector Machine	93.9%	95%	96.4%	93.7%
Logistic Regression	92.7%	93.8%	95%	92.7%
Naive Bayes Classifier	60.1%	45.3%	29.3%	99.2%

In this analysis, we evaluate the performance of various machine-learning models based on key metrics, including Accuracy, F1-score, Recall, and Precision. The models under consideration are Gradient Boost, Random Forest, Decision Tree, K-Nearest Neighbors, Support Vector Machine, Logistic Regression, and Naive Bayes Classifier.

Starting with Gradient Boost and Random Forest, both models showcase impressive results. Gradient Boost achieves a remarkable Accuracy of 97.2%, indicating its ability to make correct predictions for a majority of instances. The F1-score of 96.9% suggests a well-balanced trade-off between precision and recall. Additionally, with Recall and Precision scores of 97% and 96.8% respectively, it effectively identifies most positive instances while maintaining a high level of accuracy in positive predictions.

Random Forest, another strong performer, demonstrates an Accuracy of 97.1%, marginally trailing behind Gradient Boost. Nevertheless, its F1-score of 97.3% indicates an excellent balance between precision and recall. The model boasts a high Recall score of 97.4%, suggesting its proficiency in correctly identifying positive instances. Furthermore, its Precision score of 97.2% underscores its accuracy in positive predictions.

The Decision Tree model also shows promise with a respectable Accuracy of 96.3%. Its F1-score of 96.7% reflects a good balance between precision and recall. The Recall and Precision scores of 96.7% and 96.6% respectively affirm the model's effectiveness in correctly identifying positive instances and making accurate positive predictions.

K-Nearest Neighbors performs well, attaining an Accuracy of 95.6%. Its F1-score of 96.2% demonstrates a commendable balance between precision and recall. With Recall and Precision scores of 96.8% and 95.7% respectively, the model effectively identifies positive instances and makes accurate positive predictions.

The Support Vector Machine achieves an Accuracy of 93.9%, somewhat lower than the previously mentioned models. Nevertheless, its F1-score of 95% suggests a satisfactory balance between precision and recall. A Recall score of 96.4% indicates its effectiveness in identifying positive instances, and its Precision score of 93.7% underscores its accuracy in positive predictions.

Logistic Regression, with an Accuracy of 92.7%, provides a reasonable performance. Its F1-score of 93.8% signifies a good balance between precision and recall. A Recall score of 95% indicates its ability to effectively identify positive instances, while its Precision score of 92.7% reflects accurate positive predictions.

On the other hand, the Naive Bayes Classifier lags significantly behind the other models with an Accuracy of 60.1% and an F1-score of 45.3%. The low Recall score of 29.3% suggests its struggle to effectively identify positive instances. However, it exhibits an unexpectedly high Precision score of 99.2%, indicating that when it predicts a positive instance, it is usually correct. This discrepancy might imply a bias towards negative instances.

In conclusion, the analysis showcases Gradient Boost and Random Forest as top-performing models, excelling in various metrics. The Decision Tree, K-Nearest Neighbors, and Logistic Regression also demonstrate competitive performances. However, the Naive Bayes Classifier significantly underperforms in comparison to the other models, necessitating further investigation and improvements. By understanding the strengths and weaknesses of each model, we can make informed decisions when selecting the most suitable model.

After a thorough examination of our research findings, we will proceed to conduct a comparative analysis with other relevant studies in the field (Table IV).

TABLE IV. EVALUATION OF CURRENT PHISHING DOMAIN DETECTION MODELS

Authors	Dataset	Algorithm	Accuracy
Ubing et al. [44]	UCI	Ensemble bagging, boosting, stacking	95.4%
Alsariera et al. [45]	UCI	ForestPA-PWDM, Bagged-ForestPA-PWDM, and Adab-ForestPA-PWDM	96.26% 96.5% 97.4%
Lakshmi et al. [47]	UCI	DNN +Adam	96.00%
Alnemari et al. [49]	UCI	Random Forest	97.3%

Ubing et al. [44], in their work, harnessed the power of ensemble learning techniques such as bagging, boosting, and stacking, securing an impressive accuracy of 95.4% on the UCI dataset. This commendable outcome highlights the prowess of ensemble methods in accurately identifying phishing attacks, emphasizing the model's capacity to make precise predictions.

Equally noteworthy, Alsariera et al. [45] proposed multiple meta-learner models rooted in ForestPA-PWDM, Bagged-ForestPA-PWDM, and Adab-ForestPA-PWDM. Their experimental results yielded outstanding accuracies of 96.26%, 96.5%, and a remarkable 97.4%, respectively, on the UCI dataset. This exemplifies the efficacy and versatility of their ensemble-based approaches, which outperformed a majority of existing techniques, underscoring their potential as powerful solutions for phishing detection.

Venturing into the realm of deep learning, Lakshmi et al. [47] introduced the DNN +Adam model, accomplishing an impressive accuracy of 96.00% on the UCI dataset. This result vividly illustrates the effectiveness of deep learning methodologies in tackling phishing attacks, showcasing the model's ability to discern malicious websites with a remarkable degree of accuracy.

Furthermore, Alnemari et al. [49] adopted the Random Forest model, achieving an exceptional accuracy of 97.3% on the UCI dataset. The success of this approach showcases the formidable strength of Random Forest in detecting phishing attacks, operating at a high level of accuracy and outperforming several alternative methods.

Now, shifting our focus to our own research, our results reinforce the notion of competitive performance in the realm of phishing attack detection. With accuracy values ranging from 93.9% to 97.2%, the machine learning models utilized in our study prove their efficacy. Particularly, the Gradient Boost and Random Forest models demonstrated remarkable accuracies of 97.2% and 97.1%, respectively, rivaling or even surpassing the accuracy rates reported in the aforementioned studies.

The alignment of our results with the findings of previous studies accentuates the effectiveness of diverse machine learning techniques in detecting phishing attacks.

Overall, our research findings substantiate commendable performance, with the competitive accuracies achieved by our models showcasing their potential practicality in real-world phishing detection scenarios. The insights gleaned from our study empower us to make informed decisions when selecting the most appropriate machine learning technique to combat phishing threats in diverse applications.

## VI. CONCLUSION

In this research, we have delved into the critical domain of phishing website detection, exploring diverse machine learning techniques and their effectiveness in countering the ever-evolving cybersecurity threat posed by phishing attacks. The rampant increase in such fraudulent activities has presented significant challenges to individuals and organizations worldwide, necessitating the development of robust and efficient methods to detect and thwart these deceitful websites.

Through an extensive analysis of our research results and a thorough comparison with other relevant studies, we have uncovered promising insights into the effectiveness of various machine learning models for detecting phishing attacks. Notably, the Gradient Boost and Random Forest models have demonstrated exceptional performance, showcasing accuracy rates that either align with those reported in the existing

literature. This remarkable potential positions these models as viable candidates for real-world applications in phishing detection scenarios, playing a pivotal role in fortifying cybersecurity measures and shielding users from the dangers posed by phishing attacks.

**Abstract**—The Third-Party Logistics (3PL) industry plays an important role in modern supply chains, facilitating the efficient movement of goods and optimizing logistics operations. With the advent of advanced technologies, such as the Internet of Things (IoT), automation, artificial intelligence, and data analytics, the landscape of the 3PL industry has undergone significant transformation. With their tracking ability and real time data enabling capability, IoT technologies have gained great attention from researchers and practitioners and have been widely used in the supply chain sector. This paper employs the Cournot duopoly model within the framework of game theory to investigate the profound implications of the use of IoT technology on competition and operational strategies within the 3PL sector. In this study, we construct a Cournot duopoly model focusing on the assessment of the service level of third party logistics (3PL) within the market. We consider variables such as service level and the IoT adoption rates as crucial factors influencing the behavior of these firms. Through numerical simulations we quantify the impact of the technology on the overall profitability for both firms. Our findings have demonstrated the positive impact of integrating IoT on enhancing the profits of the 3PL firms. Additionally, the IoT adoption rates and the overall IoT integration costs play a critical role in determining market equilibrium and profit distribution.

**Keywords**—Internet of things; third party logistics; game theory; cournot duopoly

## I. INTRODUCTION

In recent years, the supply chains have faced crucial changes due numerous factors such as the pandemic crisis, increasing customer demands in terms of better quality products, quicker lead times and personalized experiences. Furthermore, in light of the emergence of new international markets, the growth of e-commerce and an increasing awareness of the importance of sustainability, the supply chains operations have become greatly complex. Consequently, there is a pressing need to adopt a fresh perspective on supply chain management by embracing the shift to digitalized sustainable operations. In order to meet the ever-changing demands of customers, the adoption of a sustainable supply chain (SSC) has become imperative for companies. Over the past few decades, there has been a notable increase in the number of studies focusing on sustainable supply chain management (SSCM).

Furthermore, organizations strive to enhance their business processes by implementing technologies aligned with industry 4.0 (I4.0). This latter is revolutionizing the current industrial landscape, bringing about a significant shift in paradigms. I4.0

encompasses various technologies. Internet of Things (IoT), artificial intelligence (AI), blockchain, and the physical internet have become ubiquitous terms in describing the modern world. These digital technologies enable the generation, collection and analysis of vast volumes of data from diverse sources, including ERP systems, mobile devices, customer purchasing behavior, product lifecycle operations, global positioning systems (GPS), radio frequency identification (RFID) tracking, surveillance videos, IoT sensors etc. Incorporating these technologies into the value chain increases flexibility, efficiency, productivity and ensure a better decision-making process [1].

The Internet of Things (IoT) is a global platform that enables the connection of smart devices through the Internet. It facilitates the seamless integration of the supply chain (SC) and communication technology (ICT) infrastructure within an organization, as well as with customers and suppliers externally. Exploring the impact of the internet of things technologies on the supply chain processes have attracted the interest of many researchers [2]–[6]. IoT has proved its impact on promoting sustainability in the supply chains, through its capability to ensure visibility traceability and real time decision making.

On the other hand, the complexity of the supply chain operations, the increased costs and intense competitiveness in the global business world have led manufacturers and businesses to consider outsourcing their logistics activities to experts while focusing on their core competencies. Fast and reliable transportation has become essential, which may lead to higher transportation costs, making 3PL services necessary [7]

Third-Party Logistics (3PL) refers to the practice of engaging external companies to manage some or all of the logistics tasks for a company. 3PL firms primarily offered transportation services. However, due to the increasing competitiveness and continuous demanding customers' needs, 3PL companies have seen the obligation to incorporate a wider range of services and specializations such as now conventional and refrigerated transportation, smart warehousing [8] as well as focusing on developing their IT skills and widen their expertise [7] and providing sustainable activities and strategies [9].

Logistics requirements and expectations have evolved in recent years in view of the continuous developments in advanced technologies and the industry 4.0 revolution. Embracing cutting-edge technologies brings numerous advantages, such as increased operational efficiencies in

transportation and warehousing, as well as effective risk management. Therefore, 3PL companies ought to implement suitable information technology that aligns with their customers' needs [10].

Literature related to the 3PL market is enriched constantly, [11], [12] propose third party logistics selection frameworks using the MCDM approach, [13] explores the challenges and value of adopting the blockchain the 3PL companies. Moreover, various decision-making models for evaluating and selecting 3PL from a sustainability point of view [14]–[18]. Outsourcing logistics activities offers numerous advantages such as better flexibility and overall greater economic benefits [9], which has driven the third-party service providers market to flourish. However, the rise in 3PL companies have resulted in increased competition among them [8].

Game theory approach is one of the preferred mathematical models used in supply chain management. Considering the structure of the supply chain and their many players, game theory offers a thorough mathematical approach helping analyzing and optimizing the decision making and configurations of the supply chains [19]. The author in [20] used game theory approach to study the impact of open innovation for achieving competitive advantage. The author in [9] used game theory to investigate the pricing strategies of 3PL for a sustainable supply chain focusing on decreasing carbon emissions and delivery time. Similarly, [21] focused on pricing decisions in three different strategies considering CSR concerns and introducing a greening degree while [22] focused on investment decisions investigating who will bear the implementation cost of the IoT.

The main objective of the theoretical games in the literature focuses on pricing decision, decision to outsource and decision to investment costs. Although the use of game theory in supply chain is fairly extensive, its use in relation to 3PL, sustainability and IoT impact is under-researched. Strategy making under competitiveness remains challenging [8]. This research will consider a duopoly competition between two 3PL firms in a homogenous environment. The mathematical model will investigate the impact of the integration of the IoT technologies on the performance and quality of service of the 3PL firms.

This research investigates the following questions:

- How sensitive is the 3PL firms profit to changes in the integration rate of the IoT?
- Can IoT be added to a strategy set to enhance the competitiveness in the market of third party logistics?

The paper will be organized as followed: Section II will present a literature review of the streams of research related to our scope, Section III will describe our mathematical model, Section IV presents and discusses a numerical analysis of our model, and lastly a conclusion of our findings will be presented in Section V.

## II. LITERATURE REVIEW

Supply chains remain one of the most challenging to manage considering their complex structure. In view of

increasing customer demands; for better service, better lead times and more sustainable service, more businesses opt for outsourcing their logistics operations in order to focus on their core expertise [18]. Third party logistics providers, also known as 3PL are a well-established logistics business that offer various logistics services. They carry out numerous tasks and activities based on the need of their customer. Their main primary service consists of transportation, however warehousing, inventory management, traceability and many other supply chain activities are carried out. Many studies have pointed out the benefits of outsourcing logistics related activities to third parties. Reducing logistics related costs as well as focusing on the company's core expertise is considered the reasons companies choose to outsource to 3PL providers [17], [18]. Other benefits include better flexibility, higher logistics performance, higher quality better and strategic and operational risk management and sustainability [17]. Research has pointed out that 3PL providers are crucial to attain supply chain sustainability [7].

In these past decades, the business world has seen a drastic change in its operational and strategic levels thanks to the introduction of cutting age technologies in light of the industry 4.0 revolution. Big data analytics, IoT, Artificial intelligence, cloud technology, cybersecurity, and robotics bring important opportunities for the improvement of the supply chain performance and efficiency. The implantation of these technologies throughout the value chain leads to an increased flexibility, efficiency, productivity and better decision-making processes [1]. IoT technologies are one of the main drivers of the shift to a more connected world, enabling traceability and visibility throughout the whole value chain [3], [23].

The application of the internet of things technologies are majorly in the logistics sector [24]. Their use in different stages of the supply chain is not new, however rapid development of technologies brings new opportunities and innovative ways to enhance the logistics operation performance. RFID QR code NFC GPS and other IoT technologies have been adopted extensively achieving a transparent and efficient environment. The shift to a digitalized value chain has brought new value-added services through internet of things, automation big data AI, etc. [25].

As the third-party logistics market has expanded considerably, competition has increased. Shifting to a smart tech driven 3PL provider is a must. Researchers showed their interest in the adoption of the IoT technologies to enhance their performance and decision-making process [26]. Several works have been conducted in relation to the use of IoT in the 3PL market, [27], [28] proposed IoT enabled systems for warehousing management, while [29] proposed an IoT based just in time milk run routing system and [30] proposed an IoT based just in time milk run routing system presented a delivery system architecture for coordinating IoT infrastructure and 3PL service. IoT technologies can be used in different core processes of 3PL services enabling real time logistics, enhanced flexibility and overall improved efficiency of logistics operations. However, this field remains under-researched requiring further developments in order to take advantage of these cutting-edge technologies [31]. On the other

hand, shifting to a smart tech driven logistics remain a challenge, mainly due to cost of investments.

### III. MODEL DESCRIPTION

The SC network comprises two 3PL firms competing in a duopoly environment and multiple suppliers with 3PL as presented in Fig. 1.

We consider a market setting where  $P_1$  and  $P_2$  are two 3PL firms offering their services to  $N$  suppliers. The 3PL firms compete in the market by selecting the quantity of service that will maximize their profit. We consider the game is simultaneous and in a fixed period  $t$ .

In Cournot setting, the two firms offer the same service. The demand function represents the relationship between the total quantity of service demanded by all consumers in the market and the price at which it is offered. The inverse linear demand function is expressed as:

$$P(S) = a - b * S$$

where,  $S$  is the total service in the market,  $P(S)$  is the price of the service,  $a$  and  $b$  are positive constants relative to the market

Within the Cournot model, which examines the actions of firms competing through output quantities rather than prices, the demand function is a critical component. In this framework, each individual firm considers the output of other firms as a constant and subsequently establishes its own output level to maximize their profit.

The firms offer a number of services namely transportation, warehousing inventory management customs and compliances, technology solutions, etc.

Fig. 1. The model chosen market setting comprising 3PL and suppliers.

In order to remain competitive, the firms have invested in the IoT technology to shift to a digitalized supply chain and to foster sustainability.

The use of IoT ensure a transparent and efficient value chain, greener supply chains, reduced emissions, improved lead times, and optimized costs [23], [32].

This paper considers that the firms decide to integrate the technology. We thus consider a parameter  $\beta_i \in [0,1]$  that corresponds to the integration rate of Internet of Things. The marginal cost function of a firm  $i$  is as follows:

$$C(S_i) = c * S_i + C_i^{inv} + C_i^{IoT} S_i \quad (1)$$

where

$$C_i^{inv} = \beta_i C_0 \quad (2)$$

$$C_i^{IoT} = \beta_i C_m \quad (3)$$

The marginal cost of firm  $i$  in terms of  $S_i$  and  $\beta_i$  is as follows:

$$C(S_i, \beta_i) = c * S_i + \beta_i (C_0 + C_m S_i) \quad (4)$$

Eq. (2) represents the investment cost in IoT of firm  $i$  which depends on the degree to which the technology is incorporated  $\beta_i$ , this cost is additionally adjusted by a fixed cost of investment in the IoT technology  $C_0$ . Eq. (3) corresponds to the cost of the use of IoT. It implies that the cost of the IoT use for a firm  $i$  is influenced by how extensively IoT technology is integrated in that firm  $\beta_i$ , and this cost is further scaled by the baseline cost of using IoT technology  $C_m$ .

Eq. (4) represents the marginal cost of the firms  $i$  depending on the service level  $S_i$  and their IoT integration rate  $\beta_i$ . According to the equation, when a firm haven't implemented the IoT technology its cost is equal to  $c$ , which corresponds to the basic cost of service, whereas implementing IoT induces additional charges.

The main challenge of the digitization of the supply chain and the implementation of the industry 4.0 technologies lies in their high investment cost [33]. Hence, we consider two costs related to IoT, the investment cost and the costs engendered by the exploitation of the technology such as maintenance, training, etc.

Considering the expenses associated with planning and implementing IoT initiatives in logistics, the involvement of government regulations becomes pivotal in incentivizing various industries and services [24]. We thus consider in our paper a government incentive function defined as follows:

$$I(\beta_i) = A \ln(1 + \beta_i) \quad (5)$$

where,  $A$  is constant factor that determines the scale of the incentive. In the real world, the government encouragements and incentives have a limit, thus the choice of a logarithmic function. According to (5), as the rate increases, the logarithmic component represents the diminishing returns phenomenon, where the reward gradually becomes less significant.

Based on the aforementioned, the profit function is presented as follows:

$$\Pi(S_i) = TR(S_i) - C(S_i) + I(\beta_i) S_i \quad (6)$$

Where  $TR(S_i)$  is the total revenue function for firm  $i$  defined as:  $TR(S_i) = P(S) \cdot S_i$

$$TR(S_i) = (a - b(\sum_{k \neq i} S_k + S_i)) S_i = -b S_i^2 + a S_i - b S_i \sum_{k \neq i} S_k \quad (7)$$

Substituting (4), (5) and (7) in (6), the profit equation for firm  $i$  is:

$$\Pi_i(S_i, \beta_i) = -b S_i^2 + a S_i - b S_i \sum_{k \neq i} S_k - c * S_i - \beta_i (C_0 + C_m S_i) + A \ln(1 + \beta_i) S_i \quad (8)$$

The marginal profit of the firm is expressed as follows:

$$\frac{\partial \Pi_i(S_i, \beta_i)}{\partial S_i} = -2bS_i + a - b \sum_{k \neq i} S_k - c - \beta_i C_m + A \ln(1 + \beta_i) \quad (9)$$

Since the objective function is concave as  $\frac{\partial^2 \Pi_i(S_i, \beta_i)}{\partial^2 S_i} = -2b < 0$ , the reaction function of firm  $i$  is expressed as follows considering  $\frac{\partial \Pi_i(S_i, \beta_i)}{\partial S_i} = 0$

$$S_i^*(\beta_i) = \frac{a-b \sum_{k \neq i} S_k - c}{2b} + \frac{-\beta_i C_m + A \ln(1 + \beta_i)}{2b} \quad (10)$$

This work focuses in the case of a duopoly market setting, the profit equation for firm 1 and 2 are:

$$\Pi_1(S_1, \beta_1) = -bS_1^2 + S_1[a - c - \beta_1 C_m - bS_2 + A \ln(1 + \beta_1)] - \beta_1 C_0 \quad (11)$$

$$\Pi_2(S_2, \beta_2) = -bS_2^2 + S_2[a - c - \beta_2 C_m - bS_1 + A \ln(1 + \beta_2)] - \beta_2 C_0 \quad (12)$$

And the reaction function for firm 1 and 2 are:

$$R_1(S_1) = \frac{a-bS_2-c}{2b} + \frac{-\beta_1 C_m + A \ln(1 + \beta_1)}{2b} \quad (13)$$

$$R_2(S_2) = \frac{a-bS_1-c}{2b} + \frac{-\beta_2 C_m + A \ln(1 + \beta_2)}{2b} \quad (14)$$

$$\text{Let } \begin{cases} x_1 = -\beta_1 C_m + A \ln(1 + \beta_1) \\ x_2 = -\beta_2 C_m + A \ln(1 + \beta_2) \\ a_0 = a - c \end{cases} \quad (15)$$

$S_1^*$  and  $S_2^*$  at the Cournot equilibrium are thus expressed as:

$$S_1^*(\beta_1, \beta_2) = \frac{1}{3b} (2x_1 - x_2 + a_0) \quad (16)$$

$$S_2^*(\beta_1, \beta_2) = \frac{1}{3b} (2x_2 - x_1 + a_0) \quad (17)$$

Provided that  $2x_1 - x_2 + a_0 > 0$  and  $2x_2 - x_1 + a_0 > 0$

According to this result, in the case where neither firm decides to integrate IoT;  $S_1^*(0,0) = S_2^*(0,0) = \frac{a_0}{3b}$ , both firms reach the same equilibrium output. Furthermore, if firm 1 chooses the strategy to integrate the IoT while the firm 2 chooses not to integrate, their optimal service level is:  $S_1^*(1,0) = \frac{2(-C_m + A \ln 2) + a_0}{3b}$ ,  $S_2^*(1,0) = \frac{-(-C_m + A \ln 2) + a_0}{3b}$  and  $\Delta S = \frac{-C_m + A \ln 2}{b}$ . In this case, the service level that firm 1 has to provide in this case depends on the government incentive and the cost of the use of IoT. If  $\ln 2 > C_m$ , meaning the government incentive is much greater than the IoT exploitation cost, firm 1 has to provide greater service level than firm 2. On the contrary, if the incentive is inferior to the IoT exploitation costs firm 2 should provide greater service level than firm 1.

After finding the Cournot equilibrium, it is observed that the equilibrium points depend on  $\beta_1$  and  $\beta_2$ . It shows that the integration of IoT influences the equilibrium. Therefore, in the second stage, we will analyze the profit with respect to  $\beta_1$  and  $\beta_2$ .

### A. Second Stage Equilibrium Analysis

The profit function in terms of the integration rate  $\beta_i$  by taking (16), (17) in (11), (12):

$$\Pi_1(S_1, \beta_1) = \frac{4x_1(x_1 - x_2 + a_0) + x_2(x_2 - 2a_0) + a_0^2}{9b} - \beta_1 C_0$$

$$\Pi_2(S_2, \beta_2) = \frac{4x_2(x_2 - x_1 + a_0) + x_1(x_1 - 2a_0) + a_0^2}{9b} - \beta_2 C_0$$

Thus, the profit function in terms of  $\beta_1, \beta_2$  is:

$$\begin{cases} \Pi_1(\beta_1, \beta_2) = \frac{4(-\beta_1 C_m + A \ln(1 + \beta_1))^2 + 4(-\beta_1 C_m + A \ln(1 + \beta_1))(\beta_2 C_m - A \ln(1 + \beta_2) + a_0)}{9b} + \frac{(-\beta_2 C_m + A \ln(1 + \beta_2))(-\beta_2 C_m + A \ln(1 + \beta_2) - 2a_0) + a_0^2}{9b} - \beta_1 C_0 \\ \Pi_2(\beta_1, \beta_2) = \frac{4(-\beta_2 C_m + A \ln(1 + \beta_2))^2 + 4(-\beta_2 C_m + A \ln(1 + \beta_2))(\beta_1 C_m - A \ln(1 + \beta_1) + a_0)}{9b} + \frac{(-\beta_1 C_m + A \ln(1 + \beta_1))(-\beta_1 C_m + A \ln(1 + \beta_1) - 2a_0) + a_0^2}{9b} - \beta_2 C_0 \end{cases} \quad (18)$$

The profit equation for both firms enables the calculation of the maximum local profit based on the IoT integration rate. Thus, the derivative of the system is:

$$\begin{cases} \frac{\partial \Pi_1(\beta_1, \beta_2)}{\partial \beta_1} = \frac{4}{9b} \left( \frac{A}{(1 + \beta_1)} - C_m \right) (2x_1 - x_2 + a_0) - C_0 \\ \frac{\partial \Pi_1(\beta_1, \beta_2)}{\partial \beta_2} = \frac{2}{9b} \left( \frac{A}{(1 + \beta_2)} - C_m \right) (x_2 - 2x_1 - a_0) \end{cases} \quad (19)$$

By substituting (15) in (19) our system of derivatives is expressed as:

$$\begin{cases} \frac{\partial \Pi_1(\beta_1, \beta_2)}{\partial \beta_1} = \frac{4}{9b} \left( \frac{A}{(1 + \beta_1)} - C_m \right) (-2\beta_1 C_m + 2A \ln(1 + \beta_1) + \beta_2 C_m - A \ln(1 + \beta_2) + a_0) - C_0 \\ \frac{\partial \Pi_1(\beta_1, \beta_2)}{\partial \beta_2} = \frac{2}{9b} \left( \frac{A}{(1 + \beta_2)} - C_m \right) (-\beta_2 C_m + A \ln(1 + \beta_2) + 2\beta_1 C_m - 2A \ln(1 + \beta_1) - a_0) \end{cases} \quad (20)$$

Solving  $\frac{\partial \Pi_1(\beta_1, \beta_2)}{\partial \beta_1} = \frac{\partial \Pi_1(\beta_1, \beta_2)}{\partial \beta_2} = 0$  simultaneously, the optimal equilibrium solution can be derived:

The solution for  $\frac{\partial \Pi_1(\beta_1, \beta_2)}{\partial \beta_2} = 0$  is either  $\beta_2 = \frac{A}{C_m} - 1$  or  $x_2 - 2x_1 - a_0 = 0$ . However, according to (16)  $x_2 - 2x_1 - a_0 < 0$  thus  $\beta_2 = \frac{A}{C_m} - 1$ . By replacing  $\beta_2 = \frac{A}{C_m} - 1$  in (20) we get:

$$\frac{4}{9b} \left( \frac{A}{(1 + \beta_1)} - C_m \right) \left( -2\beta_1 C_m + 2A \ln(1 + \beta_1) + \left( \frac{A}{C_m} - 1 \right) C_m - A \ln \left( \frac{A}{C_m} \right) + a_0 \right) = C_0 \quad (21)$$

Knowing  $\lim_{x \rightarrow \infty} \frac{\ln(1+x)}{1+x} = \varepsilon$ , we consider  $\ln(1 + \beta_1) = \varepsilon(1 + \beta_1)$ . Considering  $\beta_2 = \frac{A}{C_m} - 1$  and  $\beta_2 \in [0,1]$  we assume  $A \approx C_m$  since  $C_m \leq A \leq 2C_m$ . Taking the latter in consideration in (21) we get,

$$\beta_1^2 2C_m(A\varepsilon - C_m) + \beta_1 \left( \frac{8}{9b} (C_m - A\varepsilon) + C_m(1 + a_0) + C_0 \right) + C_0 - \frac{4}{9b} (2A\varepsilon + a_0) = 0 \quad (22)$$

Finding the solution for (22) we calculate the  $\Delta = \left( \frac{8}{9} (C_m - A\varepsilon) + C_m(1 + a_0) + C_0 \right)^2 + 8C_m(A\varepsilon - C_m) \left( \frac{4}{9b} (2A\varepsilon + a_0) - C_0 \right)$ . To guarantee that our equation accepts real solutions

the following condition must be met  $\Delta > 0 \Rightarrow 9bC_0 < 4(2A\varepsilon + a_0)$ . The solution is thus:

$$\beta_1 = \frac{-\left(\frac{8}{9b}(C_m - A\varepsilon) + C_m(1 + a_0) + C_0\right) \pm \sqrt{\Delta}}{4C_m(A\varepsilon - C_m)}$$

$$\beta_1 = \frac{-\left(\frac{8}{9b}(C_m - A\varepsilon) + C_m(1 + a_0) + C_0\right) \pm \sqrt{\frac{\left(\frac{8}{9b}(C_m - A\varepsilon) + C_m(1 + a_0) + C_0\right)^2 + 8C_m(A\varepsilon - C_m)\left(\frac{4}{9b}(2A\varepsilon + a_0) - C_0\right)}{4C_m(A\varepsilon - C_m)}}}{4C_m(A\varepsilon - C_m)}$$

while  $0 \leq -\left(\frac{8}{9b}(C_m - A\varepsilon) + C_m(1 + a_0) + C_0\right) \pm \sqrt{\Delta} \leq 1$

After finding the optimal equilibrium, we investigate whether the critical points are maximums by calculating the hessian matrix.

$$H(\Pi_1(\beta_1, \beta_2)) = \begin{bmatrix} R_1 & R_2 \\ R_3 & R_4 \end{bmatrix}$$

Where

$$R_1 = \frac{\partial^2 \Pi_1(\beta_1, \beta_2)}{\partial^2 \beta_1}$$

$$R_2 = \frac{\partial^2 \Pi_1(\beta_1, \beta_2)}{\partial \beta_1 \partial \beta_2}$$

$$R_3 = \frac{\partial^2 \Pi_1(\beta_1, \beta_2)}{\partial \beta_2 \partial \beta_1}$$

$$R_4 = \frac{\partial^2 \Pi_1(\beta_1, \beta_2)}{\partial^2 \beta_2}$$

$$R_1 = \frac{4}{9b} \cdot \frac{-2A^2 \ln(1 + \beta_1) + 2A^2 - A(2C_m(\beta_1 + 2) + \alpha_2 + a_0) + 2C_m^2(\beta_1 + 1)^2}{(1 + \beta_1)^2} \quad (23)$$

$$R_4 = \frac{2}{9b} \cdot \frac{A^2(\ln(1 + \beta_2) - 1) + A(C_m(\beta_2 + 2) + 2A \ln(1 + \beta_1) - 2\beta_1 C_m - a_0) + C_m^2(-\beta_2^2 - 2\beta_2 - 1)}{(1 + \beta_2)^2} \quad (24)$$

$$R_2 = \frac{4}{9b} \left(C_m - \frac{A}{\beta_2 + 1}\right) \left(\frac{A}{\beta_1 + 1} - C_m\right) \quad (25)$$

$$R_3 = \frac{4}{9b} \left(C_m - \frac{A}{\beta_1 + 1}\right) \left(\frac{A}{\beta_2 + 1} - C_m\right) \quad (26)$$

The first principal minor is  $|H_1| = \frac{\partial^2 \Pi_1(\beta_1, \beta_2)}{\partial^2 \beta_1}$

$$|H_1| = \frac{4}{9b} \cdot \frac{-2A^2 \ln(1 + \beta_1) - A(2C_m(\beta_1 + 2) - \beta_2 C_m + A \ln(1 + \beta_2) + a_0) + 2A^2 + 2C_m^2(\beta_1 + 1)^2}{(1 + \beta_1)^2} \quad (27)$$

The second principal minor or the hessian determinant  $|H_2| = R_1 R_4 - R_2 R_3$

$$|H_2| = R_1 R_4 + \frac{4}{9b} \left(C_m - \frac{A}{\beta_2 + 1}\right)^2 \left(\frac{A}{\beta_1 + 1} - C_m\right)^2 \quad (28)$$

Following the calculations, the function admits a local maximum when:

$$\begin{cases} R_1 < 0 \\ |H_2| > 0 \end{cases} \text{ therefore, these conditions should be met:}$$

$$-2A^2 \ln(1 + \beta_1) - A(2C_m(\beta_1 + 2) - \beta_2 C_m + A \ln(1 + \beta_2) + a_0) + 2A^2 + 2C_m^2(\beta_1 + 1)^2 < 0$$

$$R_1 R_4 + \frac{4}{9b} \left(C_m - \frac{A}{\beta_2 + 1}\right)^2 \left(\frac{A}{\beta_1 + 1} - C_m\right)^2 \geq 0$$

when these conditions are met, the optimal equilibrium solution for firm 1 is

$$(\beta_1, \beta_2) = \left( \frac{-\left(\frac{8}{9b}(C_m - A\varepsilon) + C_m(1 + a_0) + C_0\right) \pm \sqrt{\frac{\left(\frac{8}{9b}(C_m - A\varepsilon) + C_m(1 + a_0) + C_0\right)^2 + 8C_m(A\varepsilon - C_m)\left(\frac{4}{9b}(2A\varepsilon + a_0) - C_0\right)}{4C_m(A\varepsilon - C_m)}}}{4C_m(A\varepsilon - C_m)}, \frac{A}{C_m} - 1 \right) \quad (29)$$

Following the same approach and calculations, the optimal equilibrium solution for firm 2 is given as:

$$(\beta_1, \beta_2) = \left( \frac{A}{C_m} - 1, \frac{-\left(\frac{8}{9b}(C_m - A\varepsilon) + C_m(1 + a_0) + C_0\right) \pm \sqrt{\frac{\left(\frac{8}{9b}(C_m - A\varepsilon) + C_m(1 + a_0) + C_0\right)^2 + 8C_m(A\varepsilon - C_m)\left(\frac{4}{9b}(2A\varepsilon + a_0) - C_0\right)}{4C_m(A\varepsilon - C_m)}}}{4C_m(A\varepsilon - C_m)} \right) \quad (30)$$

#### IV. NUMERICAL ANALYSIS AND DISCUSSION

This part of the article focuses on performing a numerical analysis to investigate the impact of the parameters and the values of  $\beta_1$  and  $\beta_2$  on the profit of both firms. According to the model, we aim to assess the effects of the IoT integration rate on the profit of 3PL firms in a duopoly market, where we assume they offer identical services, at a fixed period  $t$ .

We first explored the impact of  $\beta$  on the incentives values. Fig. 2 shows the behavior of the incentive function depending on  $\beta$  and  $A$ .

According to the plot, we observe that modifications in integration rates result in proportional alterations in the incentive value. Nevertheless, the parameter  $A$  serves as a scaling factor for the incentive, influencing the magnitude of the incentive's response to changes in beta. A higher value of  $A$  magnifies the influence of beta on the incentive, whereas a smaller  $A$  diminishes this impact.

Fig. 2. Incentive function plot in terms of  $\beta$ .

We then analyzed the impact of  $\beta_1$  and  $\beta_2$  on the profit values. A data set of parameters have been examined in order to analyze the effect of the parameters and the values of  $\beta_1$  and  $\beta_2$  and on the profit values. Adjusting the values of  $C_m, A, a_0, b, C_0$  will help see how different scenarios impact the profit landscape, in different IoT integration strategies. For this purpose, we considered four different cases.

**A. Case 1: Firm 1 and Firm 2 Choose Not to Integrate IoT**

The first case we investigate is when  $\beta_1 = 0$  and  $\beta_2 = 0$ . Table I represents the value of  $\pi_1$  the profit of firm 1 and  $\pi_2$  the profit of firm 2 when both firms chose not to integrate IoT.

TABLE I. PROFIT VALUES OF FIRM 1 AND FIRM 2 AT  $\beta_1 = \beta_2 = 0$

$C_m$	$A$	$a_0$	$b$	$C_0$	$\pi_1 = \pi_2$
15	20	40	1	10	168.888889
32	60	40	1	10	168.888889
45	80	40	1	10	168.888889
15	20	80	1	10	693.333333
32	60	80	1	10	693.333333
45	80	80	1	10	693.333333
15	20	60	1	10	386.666667
32	60	60	1	10	386.666667
45	80	60	1	10	386.666667
15	20	60	1	10	386.666667
32	60	60	1	10	386.666667
45	80	60	1	20	386.666667
45	50	60	1	20	386.666667
30	50	80	1	20	693.333333
0.8	1.2	6	0.5	0.2	5.333333
1	1.5	10	0.7	0.3	12.698413

**B. Case 2 : Firm 1 and Firm 2 Integrate IoT at 100%**

The second case we consider is when both firms integrate fully the IoT. Table II represents the value of  $\pi_1$  the profit of firm 1 and  $\pi_2$  the profit of firm 2 for  $\beta_1=\beta_2=1$

The profits in this case are the same as well since they chose the same strategy of integrating IoT at 100%. In the same setting of the parameters comparing case 1 and case 2, the profits decreases due to additional costs of integrating IoT. However, in case 2 the incentives for integrating IoT impacts majorly on the profits. As the incentives increases the profits of the firms increases as well.

**C. Case 3: Firm 1 Integrate IoT at 100% and Firm 2 does not Integrate IoT**

After exploring the cases where both firms choose the same strategy, we consider the case where one firm integrates IoT fully while the other firm chooses not to integrate it. In Table III, we consider firm 1 integrates IoT at  $\beta_1=1$ , while firm 2 is at  $\beta_2=0$ .

TABLE II. PROFIT VALUES OF FIRM 1 AND FIRM 2 AT  $\beta_1 = \beta_2 = 1$

$C_m$	$A$	$a_0$	$b$	$C_0$	$\pi_1 = \pi_2$
15	20	40	1	10	138.818208
32	60	40	1	10	339.573179
45	80	40	1	10	356.835944
15	20	80	1	10	643.048317
32	60	80	1	10	1034.48573
45	80	80	1	10	1067.08971
15	20	60	1	10	346.488818
32	60	60	1	10	642.585009
45	80	60	1	10	667.58384
15	20	60	1	10	346.488818
32	60	60	1	10	642.585009
45	80	60	1	20	657.518384
45	50	60	1	20	102.748488
30	50	80	1	20	841.338431
0.8	1.2	6	0.5	0.2	5.303033
1	1.5	10	0.7	0.3	12.650859

In this case the profits are differing from firm to another. The firm with higher integration rate has greater profit since the incentives increases the profits.  $C_0$  also impacts the profits as  $C_0$  increase the profits for the firm using IoT decreases.

**D. Case 4: Both Firms Integrate IoT**

The last case we consider is both firms integrate IoT but not at a rate  $\beta=1$ . Table IV presents a number of instances with various values for integration rates for both firms 1 and 2.

TABLE III. PROFIT VALUES OF FIRM 1 AND FIRM 2 AT  $\beta_1=1$  AND  $\beta_2=0$

$C_m$	$A$	$a_0$	$b$	$C_0$	$\pi_1$	$\pi_2$
15	20	40	1	10	139.249174	169.032544
32	60	40	1	10	370.221738	179.105075

0.5	0.5253	1	1.5	10	0.7	0.3	13.2372	13.2282

When both integrate IoT, the rate at which each integrate influences the profits. The higher the rate, the higher is the incentive and the higher is the profits. The firm with higher rate increases their profits considerably as the incentives increases. When the firms integrate IoT at close rates, the difference between the two profits decreases.

Furthermore, in the aim to help further-examine and understand our mathematical model behavior, plotting the function provides us with valuable insights. Essentially, visually clear representation of the function facilitates assessments, insight into parameter effects and supports decision-making. Fig. 1 and Fig. 2 presents the shape of the profit function plot of firm 1 and firm 2 respectively as well as their respective maximum profit related to  $\beta_1$  and  $\beta_2$ .

Fig. 3 and Fig. 4 demonstrate that as the profit fluctuates towards the maximum, it stabilizes. As the integration rate increases, the profit increases up to the maximum point where it stabilizes.

Fig. 3. Firm 1 profit visualisation.

Fig. 4. Firm 2 profit visualization.

### E. Discussion

In the previous section, we explored four different cases depending on the integration rate. Based on the analysis, the four different cases we analyzed can be considered as strategies for the 3PL firms. The first strategy is when no firm integrate IoT, the second strategy is when both firms choose to fully integrate IoT, the third strategy is when one firm integrates fully the IoT while the other firms doesn't integrate it and the last strategy is when both firms integrate IoT at different rates.

Depending on the incentive that the government offers and the costs engendered by the integration of IoT, the firms can choose the strategy where they integrate IoT in order to enhance their profit. In order to be competitive, the firm needs to integrate IoT at a greater rate than its competitive firm.

Parameters such as the incentive, the cost of IoT play an important role in the profit maximization. Maximizing the profits by Integrating IoT at higher rates is contingent upon the correlation between the incentives and the costs of integrating IoT. While the incentives get higher the profits increase. If the government doesn't help considerably with the integration, it is better to choose a strategy with lower IoT rates.

### V. CONCLUSION

Globalization and the growth of e-commerce urged the logistics stakeholders to continuously strive for optimizing their operations. Logistics firms are experiencing significant pressure from customers, stakeholders and competitors to embrace digital transformation. The digitalization of the value chain has been the center of attention of both practitioner and researchers, investigating the ways to seize the opportunities from the I4.0 technologies. However, integrating these technologies is surrounded with several barriers and challenges.

Hence in this paper, we have studied the impact of integrating the IoT technologies in 3PL companies taking into consideration the high investment and maintenance costs that comes with integrating the technology. Using the Cournot duopoly model, we assessed the influence of integrating the IoT technology in the 3PL firm services on establishing competitive advantage. Our model studied the Cournot equilibrium based on the quantities of service offered by the 3PL firms in regards to the IoT integration rate. Our analysis has showed that integrating IoT can be added as a strategy set to enhance the competitiveness in the market of 3PL. Under certain conditions, integrating IoT can lead to higher profits. Both the government incentives and the IoT exploitation costs play a crucial role in determining the best strategy for the 3PL

firms. Integrating IoT at considerably higher rates than the rival firm can bring an important competitive edge, whereas integrating it at closer rates can bring greater profits for both firms.

While this study has provided valuable insights into the understanding of the 3PL industry's response to technological disruptions, it is essential to acknowledge its limitations and the broader implications of our findings. Firstly, our analysis predominantly focused on the duopoly structure, which, although prevalent in many industries, may not fully capture the complexity of the 3PL sector. Future research should explore alternative market structures, such as oligopolies or monopolistic competition, to gain a more comprehensive understanding of the dynamics at play.

Secondly, our investigation primarily focused on economic and competitive factors namely the service level and technology adoption, overlooking the growing significance of sustainability and environmental concerns in modern business environments. The influence of sustainability practices in the supply chain management industry and in the 3PL sector precisely remains a critical avenue for future exploration. Integrating sustainability considerations into our model could provide a more holistic perspective on decision-making processes within the industry.

**Abstract**—Students’ academic success is still a serious problem faced by higher education institutions worldwide. A strategy is needed to increase the students’ academic performance and prevent students from failing. The need to get early accurate information about poor academic performance is a must and could be achieved by constructing a prediction model. Therefore, an effective technique is required to provide the accurate information and improve the accuracy of the prediction model. This study evaluates the filter-based feature selection especially the filter-based feature ranking techniques for predicting academic success. It provides a comparative study of filter-based feature selection techniques for determining the type of features (redundant, irrelevant, relevant) that affect the accuracy of the prediction models. Furthermore, this study proposes a novel feature selection technique based on attribute dependency for improving the performance of the prediction model through a framework. The experimental results show that the proposed technique significantly improved the accuracy of the prediction models from 2-8%, outperforming the existing techniques, and the Decision Tree classifier performs best for predicting with an accuracy score of 92.64%.

**Keywords**—Academic success; framework; filter-based feature selection; classifier; accuracy

## I. INTRODUCTION

Nowadays, students’ academic success is still a severe topic for researchers due to its impact on higher education quality. One of the strategies to keep and enhance it is getting early information about the poor students’ academic performance through constructing a prediction model. The ability to predict students’ academic success accurately will create opportunities to improve educational outcomes, with the result that universities can create academic policies more accurately and effectively [1].

Parallel to this, previous studies have been reported and provided varying results in creating a prediction model [1]–[3]. These reports conclude that there are two main factors in predicting academic success, which are features and prediction methods. The most common prediction method used is the classification [2]. The classification techniques frequently used by researchers to predict student academic success are Decision Tree (44%), Naive Bayes (19%), Artificial Neural Network (10%), K-Nearest Neighbor (5%), and Support Vector Machine (3%) [2]. As shown in this study [2], each technique has given the best result in educational data.

However they still suffer from accuracy because the major issue is not all of the features used in building the model hold predictive information (irrelevant and redundant features). To alleviate this limitation, researchers have applied feature selection techniques to remove the unpredicted information features.

Feature selection plays a vital role in increasing the accuracy of the prediction model. It will remove the redundant and irrelevant features and select the relevant features using a specific method [4]. Inclusion of redundant and irrelevant features will reduce the prediction model’s accuracy [5]. Each feature selection technique, namely filter, wrapper and embedded when compared to each other; filter technique is the fastest in terms of time complexity but low in performance [6]–[12]. Most researchers use filter-based feature selection on the performance of the academic success classification model due to its cheap computational cost since the academic dataset is large (more than 20 features) [13].

Further, filter-based feature selection can be divided into two types: filter-based feature ranking techniques and filter-based feature subset techniques [5], [13]–[16]. Filter-based feature ranking techniques select the features by choosing only top-ranked features using a ranker search method with important scores such as ChiSquared (Statistics-Based Scores), InfoGain and GainRatio (Probability-Based Scores), Symmetrical Uncertainty (Probability-Based Scores) and Relief (Instance-Based Techniques). In contrast, filter-based feature subset techniques can evaluate the feature subset as a whole instead of evaluating individual features using a feature-subset evaluator. Several previous research have compared and proved that filter-based feature selection gives an impact on increasing the performance of academic success classification [17]–[22]. However, the problem arises when using filter-based feature ranking techniques are computationally cheap but do not deal with redundant features [16]. These techniques tend to select redundant and irrelevant features as they do not consider feature interactions [5], [13]–[15], [23]. In contrast, filter-based feature subset techniques are better for deselecting redundant features but are computationally expensive due to repeating steps in a greedy forward fashion to find the best subset based on certain criteria [11], [16] until the desired subset is reached. Even though in these techniques there are efforts to remove redundant features by finding the relevancy between the individual features, but in the fact the techniques only discard a few redundant variables since the measures evaluate features

individually [13], [23]. A brief overview of the filter-based feature selection can be seen in Table I.

Due to these above-said problems, the main contribution of this study is a framework that can act as a guide to build the prediction model by using the classification method through filter-based feature selection that fits into the problem to enhance accuracy. This research focuses on improving filter-based feature ranking techniques by addressing redundant and irrelevant problems with attribute dependency techniques and unique attribute technique. These techniques have ability to find the relationship among features not only individually but also in groups that are related to redundancy and irrelevancy problems [24]–[26]. The evaluation measurement of accuracy is then used to test each prediction model that has been constructed.

Through the proposed framework, higher education can accurately identify failed-risk students who need special attention to prevent them from failing and take appropriate action at right time. This finding can be employed to help poor academic performance students in their next semester examination to get better results. Consequently, it will have an academic impact on higher education to enhance students' academic success.

TABLE I. OVERVIEW OF THE STUDIED FILTER-BASED SELECTION TECHNIQUES ON EDUCATIONAL DATA

Family	Method	References	Merit	Demerit
Filter-based feature ranking techniques	ChiSquared (CHI)	[20]–[22]	Redundant features are selected	Low computational cost
	InfoGain (IG)	[17], [18], [20]–[22]		
	GainRatio (GR)	[17], [18], [20]–[22]		
	Symmetrical Uncertainty (SU)	[17], [18], [22]		
	Relief (RF)	[17], [18], [20]		
Filter-based feature subset techniques	Correlation (CFS)	[17], [18], [20], [21]	Reduce redundant features	High computational cost

The following is how this section of the paper is structured: Section II reviews recent similar works on predicting academic success and limitations of them and presents feature selection methods used in this study. In Section III, the research methodology was described. The research results are given in Section IV, along with the study implications. Finally, Section V presents the conclusion in its entirety.

## II. RELATED WORK

### A. Previous Research

This section discusses the previous works related to the academic success field that have used filter-based feature selection techniques to enhance the performance of the prediction models on education data.

A research by Khasanah [17] discovered that filter-based feature selection may be used to carefully choose high influence features to predict student performance. The filter-based feature selections used are correlation-based attribute

evaluation, gain-ratio attribute evaluation, information-gain attribute evaluation, relief attribute evaluation, and symmetrical uncertainty attribute evaluation. Student attendance and first-semester GPA were shown to be the most important factors. They employed Bayesian Network and Decision Tree algorithms to classify and predict student performance, where the Bayesian Network outperformed the Decision Tree classification in the accuracy case. Hussain [18] conducted a study to find high influence attributes using correlation-based attribute evaluation, gain-ratio attribute evaluation, information-gain attribute evaluation, relief attribute evaluation, and symmetrical uncertainty attribute evaluation. The techniques showed that internal assessment attributes as highly influential attributes, where random forest outperformed the other classifiers in the accuracy case. A study was carried out by Priyasadie (19) to forecast junior high school students' grades using feature selection to enhance classification performance. The outcome demonstrated that Decision Tree outperforms other classification algorithms in general when parameter optimization and feature selection are used and First Semester Natural Science and First Semester Social Science are the most important attribute. Zaffar [20] conducted a study of feature selection techniques to improve the accuracy of academic achievement prediction. The correlation-based feature evaluator (CFS), the chi-squared test, the filtered, gain ratio (GR), the principal component analysis (PC), and the Relief method are the feature selection approaches used in the study. The study used fifteen prediction models and compared them to each other in order to verify the effectiveness of the proposed feature selection techniques. The experiment shows that using feature selection increases accuracy. Sokkhey [22] developed the CHIMI feature selection technique, a combination of the ChiSquare and Mutual Information ranking algorithms to identify the most relevant features affecting classification performance. The results presented that the technique improved the prediction model accuracy.

According to the review previous research above, each filter-based techniques have its advantage, but in general the disadvantages of them are inability or not optimal to remove the redundant and irrelevant features since they choose only top-ranked features without considering feature interactions [5], [8], [15], [23], [27]–[29].

### B. Current Research

This section presents the current work to overcome the limitations in the previous research by proposing a framework through a novel filter-based feature ranking techniques utilizing attribute dependency theory. It presents the central concepts and definitions related to feature selection.

This study presents an analysis of filter-based feature selection techniques on a number of classifiers and then determines each classifier's performance in terms of accuracy. It focuses on the existing filter-based feature ranking techniques compared to this proposed technique to justify its better performance in terms of removal of redundant and irrelevant features and improved classification accuracy, while filter-based feature subset techniques are still used to complete the result of this research.

As known, the existing technique failed to remove the redundant and irrelevant attributes because they are guided by a statistical evaluation metric that ranks the attributes in decreasing order of importance without considering the relationship between the features. Thus, highly relevant features with the class, but redundant with others, will be on the top of the ranking. Meanwhile, the attribute dependency theory has the ability to determine relationship among two or more (group) features based on dependency measures [24]–[26]. Thus, there is a chance and suitable for this theory to address the limitation of removing redundant and irrelevant attributes in the previous technique. For an effective process, the technique requires domain expert/domain knowledge that will be helpful to identify the suspect redundant features for next determining them as redundant features or not using dependency measure.

In general, features in a dataset are classified into redundant, irrelevant and relevant features (strong and or weak features) [30]. Redundant features are those that contain predictive information but it has already been conveyed through any of another features or subset of features. Irrelevant features are those that do not convey any predictive information whereas the relevant features are those that hold predictive information in building learning models. Redundancy among the features or group of features is identified based on the relationship among the features, whereas the relevance is identified by finding the relationship between the feature (or group of features) and the class.

Thus, this study considers attribute dependency to remove redundant features. Using this technique, redundant features are identified and removed by ensuring the strong dependency among the features or group of features. In contrast, the relevant features are identified and selected between the features or group of features and the class. Irrelevant attributes are identified and removed by ensuring the uniqueness values or single value (or dominant only one value).

The proposed feature selection technique is rooted on the concepts of relevance, redundancy and features interaction analysis. In this regard, preliminary concepts related to attribute dependency theory are presented here. Further, the rationale for incorporating these concepts in the proposed framework is explained. Aside from how attributes are evaluated, another important aspect is how the feature selection technique relates to the classification method that will be used to further build the model containing patterns from the selected features. In this sense, five main classifiers may be mentioned. The proposed framework of this research is shown in Fig. 1.

### C. Unique Attribute to Process the Feature Selection as Proposed Method

An attribute that has a different value for each row or record in dataset [24]–[26]. In addition, the attributes (features) that only have one value or one value dominates other values, they also are considered as unique attribute.

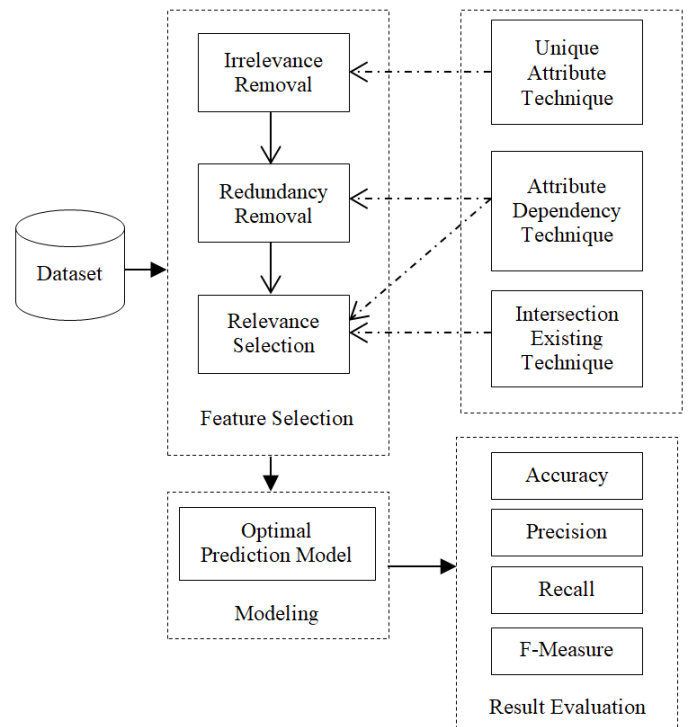

Fig. 1. The proposed framework.

### D. Attribute Dependency to Process the Feature Selection as Proposed Method

Not like the existing technique that selecting features based on statistical measures, attribute dependency selects features based on whether an instance which have the feature value, have the same feature value to others or to the class value. Attribute dependency in the relational model explains the relationship between attributes, or more specifically, the value of an attribute that determines the value of other attributes [24]–[26]. There are several types of dependencies, namely:

1) *Functional Dependency (FD)*: Indicates that if A and B are attributes of relation R, B is functionally dependent on A (denoted  $A \rightarrow B$ ), if each value of A is associated with exactly one value of B.

2) *Full Functional Dependency (FFD)*: Indicates that if A and B are attributes of a relation, B is fully functionally dependent on A if B is functionally dependent on A, but not on any proper subset of A.

3) *Transitive Dependency (TRD)*: A condition where A, B, and C are attributes of a relation such that if  $A \rightarrow B$  and  $B \rightarrow C$ , then C is transitively dependent on A via B (provided that A is not functionally dependent on B or C).

4) *Total Dependency (TD)*: A condition where A and B are attributes of a relation such that if B is functionally dependent on A ( $A \rightarrow B$ ) and A is functionally dependent on B ( $B \rightarrow A$ ).

### E. Proposed Technique

In the proposed work, there are three phases to feature selection. The first phase conducts a preliminary search to remove irrelevant features. In this phase, unique attribute

analysis is employed by identifying features that have a unique value or not, for each row in the dataset. Under this context, features with a unique value means irrelevant and should be removed from the dataset. Another condition is if the features only have one value or if there are more than one value then one value dominates other values, it also means the irrelevant feature, as shown in Algorithm 1 where dataset D as the parameter for configuring the algorithm.

---

Algorithm 1: Irrelevance Removal

---

Input:  
{Dataset} D={F<sub>i</sub>,C}; i=1,2,...,n | F<sub>i</sub> = {f<sub>i1</sub>,f<sub>i2</sub>, .. f<sub>im</sub>} }  
{ where F<sub>i</sub>: features C: class  
n:total number of features  
m:total number of instances  
}  
Result: D<sub>1</sub> {the dataset minus irrelevant features}  
Process:  
i=1;  
D<sub>1</sub> = D  
while i<=n do  
    Get F<sub>i</sub> = {f<sub>i1</sub>,f<sub>i2</sub>, .. f<sub>im</sub>}  
    if (f<sub>i1</sub> ≠ f<sub>i2</sub>...≠ f<sub>im</sub>) or (f<sub>i1</sub> = f<sub>i2</sub>...= f<sub>im</sub>) or  
        (one value dominates other values)  
    then  
        D<sub>1</sub> = D<sub>1</sub> - F<sub>i</sub>;  
    end if  
    i++;  
end  
return D<sub>1</sub>

---

The second phase conducts a search to remove redundant features. Attribute dependency concepts especially total dependency (TD), functional dependency (FD) and full functional dependency (FFD) are employed based on dependency measure in this phase. The first step is applying FFD, the second is applying TD, and the last is applying FD. The advantage of FFD is that it can find not only a relationship between two features but also a group of features (hidden relationship among features).

The hidden relationship among features is the problem that makes the features as redundant features and it cannot be identified by the previous techniques. There is an effort by [31] to address this problem, but only between two features, not for a group of features, and it needs high computational cost. Using FD and FFD, redundant features are identified by measuring the dependency among features or a group of features. The suspected redundant features are easier to find with the help of domain knowledge or domain experts of the dataset. It makes the searching process faster. The more domain knowledge you know the more faster the suspect redundant features you find. By using the FD or FFD evaluation measure, the features or the group of features that are functionally or fully functionally dependent on another feature means that the features or the group of features are redundant and should be eliminated from the dataset. The process of removing the features can be shown in Algorithm 2

below where dataset D<sub>1</sub> as the parameter for configuring the algorithm:

---

Algorithm 2: Redundancy Removal

---

Input :  
{Dataset} D<sub>1</sub>={F<sub>i</sub>,C}; i=1,2,...,n | F<sub>i</sub> = {f<sub>i1</sub>,f<sub>i2</sub>, .. f<sub>im</sub>} }  
{ where F<sub>i</sub>: features C: class  
n:total number of features  
m:total number of instances  
}  
Result: D<sub>2</sub> {the dataset minus redundant features}  
Process:  
D<sub>2</sub> = D<sub>1</sub>  
Repeat  
    { Get the suspected redundant features }  
    { Step 1: utilizing FFD }  
    Get FG = {F<sub>2</sub>, F<sub>3</sub>, ..., F<sub>n</sub>} and F<sub>1</sub> {for example}  
    if FG → F<sub>1</sub> then {F<sub>1</sub> fully FD on FG}  
        D<sub>2</sub> = D<sub>2</sub> - FG  
    end if  
    { Step 2: utilizing TD }  
    Get F<sub>1</sub> and F<sub>2</sub> {for example}  
    if F<sub>1</sub> → F<sub>2</sub> and F<sub>2</sub> → F<sub>1</sub> then {FD each others}  
        D<sub>2</sub> = D<sub>2</sub> - F<sub>1</sub> or D<sub>2</sub> = D<sub>2</sub> - F<sub>2</sub>  
    end if  
    { Step 3: utilizing FD }  
    Get F<sub>1</sub> and F<sub>2</sub> {for example}  
    if F<sub>1</sub> → F<sub>2</sub> then {F<sub>2</sub> FD on F<sub>1</sub>}  
        D<sub>2</sub> = D<sub>2</sub> - F<sub>1</sub>  
    end if  
Until no more suspected redundant features  
return D<sub>2</sub>

---

The third phase conducts a search to select relevant features. The attribute dependency that is used in the second phase is also used in this phase. The difference is only the target that the dependency analysis will be applied between features to the class.

Attribute dependency only yields two values, namely functionally dependent or not, to indicate the dependency between the two or a group of observed features. Related to these, in terms of relevant features, it means there are only two categories, namely relevant features (absolutely strong features) or not relevant features.

Attribute dependency is effective only for absolutely strong features but not for 'not relevant features' (strongly and weakly relevant features). For this reason, in addition to attribute dependency, this study uses a combination of the existing techniques (CHI, IG, GI, Relief, SU) to get the relevant features by applying intersection to the features produced by each technique. The process of selecting the features can be shown in Algorithm 3 below where dataset D<sub>2</sub> as the parameter for configuring the algorithm:

Algorithm 3: Relevance Selection

```

Input :
{Dataset} D2={Fi,C}; i=1,2,...,n | Fi = {fi1,fi2, .. fim} }
{ where Fi: features C: class
  n:total number of features
  m:total number of instances
}
Result: D3 {the selected features}
Process:
D3 = { }
{ Step 1: utilizing FD}
i = 1
while i<=n do
  Get Fi = {fi1,fi2, .. fim}
  if Fi → C then { C FD on Fi }
    D3 = D3 + Fi
  end if
  i++
end
{ Step 2: utilizing the combination of the existing technique}
R, R1 ... R5 = { F1, F2, ..., Fn}
}
D2 = D2 - D3
Get F1 to Fn
R1 = CHI (F,C) {ChiSquared}
R2 = IG (F,C) {Information Gain}
R3 = GR (F,C) {Gain Ratio}
R4 = RF (F,C) {Relief}
R5 = SU (F,C) {Symmetrical Uncertainty}

III. METHODOLOGY

This research methodology consists of four stages. They are data preparation, data processing, modeling and performance analysis.

A. Data Preparation

Related to the goal, this study used the high dimensional public dataset from higher education that consist of irrelevant, redundant and relevant features. The dataset was from the students of Middle East College (MEC), Muscat, Oman, studying in a computing specialization from the sixth semester and above. The dataset was collected from a variety of learning approaches based on Information and Communications Technology (ICT), namely, the Student Information System (SIS), the Learning Management System (LMS) called Moodle, and video interactions from the mobile application called “eDify”. The dataset comprises five modules of data from Spring 2017 to Spring 2021 that consists of 326 student records with 37 features and 1 class in total, including the students’ academic information from SIS (which has 23 features), the students’ activities performed on Moodle within and outside the campus (comprising 10 features), the students’ video interactions collected from eDify (consisting of 4 features) and the outcome of the student either having passed

or failed the module (1 class). The dataset was already clean, so it did not need to clean up the data from the possibility of duplicate data, missing data or other disturbances interfering with the process of classification. It means the data are ready for processing in the next step. An explanation of the data is described in Table II.

TABLE II. DATASET DESCRIPTION

Attribute	Type	Description
	Role	
ModuleCode	nominal	Code of the module in which the student has been registered, such as “Module 1”
	feature	
ModuleTitle	nominal	Title of the module in which the student has been registered, such as “Course 2”
	feature	
SessionName	nominal	Shows the session in which the student has been registered, such as “Session-A”
	feature	
RollNumber	nominal	Identification number of the student, such as “21S1234”
	feature	
ApplicantName	nominal	Name of the student
	feature	
ApplicantMobile	discrete	Mobile number of the student
	feature	
CGPAPoint	discrete	Cumulative grade point average of the student, such as “4.0”
	feature	
CGPADesc	nominal	Category of cumulative grade point average of the student, such as “Very Good”
	feature	
Advisor	nominal	Name of the advisor
	feature	
AttemptCount	discrete	The number of attempts in the module, such as “1”
	feature	
AttemptCountCat	nominal	Category of the number of attempts in the module, such as “Low”
	feature	
RemoteStudent	nominal	Either the student is under remote study mode or not, such as “Yes/No”
	feature	
Probation	nominal	Either the student has a backlog of modules to clear, such as “Yes/No”
	feature	
HighRisk	nominal	The high failure rate in a module, such as “Yes/No”
	feature	
TermExceeded	nominal	Progression rate of the student in the degree plan, such as “Yes/No”
	feature	
AtRisk	nominal	Previously failed two or more modules, such as “Yes/No”
	feature	
AtRiskSSC	nominal	Whether the student been registered by the student success center for any educational deficiencies, such as “Yes/No”
	feature	
SpecialNeed	nominal	Whether the student been registered by the student success center for any special needs, such as “Yes/No”
	feature	
OtherModules	discrete	A student registered in any other modules in the current semester, such as “1”
	feature	
OtherModulesCat	nominal	Category of a student registered in any other modules in the current semester, such as “High”
	feature	
PrerequisiteModules	nominal	Prerequisite module registration, such as “Yes/No”
	feature	

Attribute	Type	Description
	Role	
PlagiarismHistory	discrete	The number of onto which modules the student has been booked for academic integrity violation, such as “1”
	feature	
PlagiarismHistoryCat	nominal	Category of the number of onto which modules the student has been booked for academic integrity violation, such as “Low”
	feature	
CW1	discrete	Marks obtained by the student in their first coursework, such as “86.5”
	feature	
CW1Cat	nominal	Category of marks obtained by the student in their first coursework, such as “Adequate”
	feature	
CW2	discrete	Marks obtained by the student in their second coursework, such as “86.5”
	feature	
CW2Cat	nominal	Category of marks obtained by the student in their second coursework, such as “Excellent”
	feature	
ESE	discrete	Marks obtained in the end semester examination, such as “86.5”
	feature	
ESECat	nominal	Category of marks obtained in the end semester examination, such as “Good”
	feature	
Online C	discrete	User-performed activities within campus (in minutes), such as “25”
	feature	
Online Ccat	nominal	Category of user-performed activities within campus, such as “Poor”
	feature	
Online O	discrete	User-performed activities outside of campus (in minutes), such as “25”
	feature	
Online Ocat	nominal	Category of user-performed activities outside of campus, such as “Poor”
	feature	
Played	discrete	The number of times the video has been played
	feature	
Paused	discrete	The number of times the video has been paused
	feature	
Likes	discrete	The number of times the student has liked the video
	feature	
Segment	discrete	The number of times a student has played a specific portion of the video by using the slider
	feature	
Result	nominal	the outcome of the student either having passed or failed the module
	class	

### B. Data Processing

This phase begins with the identification of the attributes as features and as the class used to build the framework. Based on dataset in the data preparation phase, this study has determined the attribute with label ‘result’ as the class and the rest of attributes as the features as shown in Table II. This process focuses on selecting relevant or strongly features toward the target attribute (class) and removing redundant and irrelevant features or weakly relevant features from the dataset. The prediction model's performance is negatively impacted by redundant and irrelevant features.

Feature selection is one of techniques that greatly impact on enhancing model performance mainly increasing accuracy. In

this research, feature selection is conducted in three stages: (a) irrelevance removal, (b) redundancy removal, and (c) relevance selection.

In the irrelevance removal stage, unique attribute technique is used to test whether the features have (a) a unique value or not, (b) only have one value and (c) one value dominates other values. Features that meet the condition above are removed from the dataset. From this stage, it will get dataset  $D_1$ . The details of the processed are shown in Algorithm 1.

After the irrelevance removal stage, next, it continued to the redundancy removal stage. The total dependency (TD), functional dependency (FD) and full functional dependency (FFD) are used. They are used to test the relationship between two features or features and groups of features. Features or group of features that are functionally (FD) or fully functionally dependent (FFD) on another feature are removed from the dataset. From this stage, it will get dataset  $D_2$ . The details of the processed are shown in Algorithm 2.

After the two stages above, it is followed by relevance selection stage as the last stage. Unlike the two stages before, this stage is employed to select the features used for the construct of the prediction model. There are two concepts used in this stage: (a) attribute dependency, (b) combination of the existing techniques (CHI, IG, GI, Relief, and SU) by applying intersection. Unlike the two stages before, in this stage, the relationship is tested between the features and the class (target attribute). From this stage, it will get the final dataset  $D_3$  as selected features. The details of the processed are shown in Algorithm 3.

### C. Modeling

After obtaining the selected features ( $D_3$ ), the next step is constructing a prediction model. The dataset  $D_3$  is divided into 80% training and 20% testing dataset. Training and testing dataset are used as modeling input. A few of classifiers will be used to process the dataset to classify the student's academic success.

The classifier are Decision Tree (DT), Naive Bayes (NB), Artificial Neural Network (ANN), K-Nearest Neighbor (KNN) and Support Vector Machine (SVM) as the most classifier currently used by researchers to predict student academic success [2]. The process started with training the classifier using the training dataset. The testing dataset tests the classifier in classifying student's academic success. Additionally, depending on measures of classification accuracy and effectiveness, the performance of the classifier model is examined and assessed.

### D. Performance Analysis

This section described how to measure the performance of the prediction model from a number of views since each classifier employed in the modeling process vary. The primary goal of the proposed framework is to achieve the highest accuracy with less number of features. Related to the goal, the confusion matrix is used to determine the accuracy of the prediction model. Comparing the actual value to the predicted value is the approach to assess the model's performance. The confusion matrix is a combination of four different predicted and actual values. In the confusion matrix, the classification

process' outcomes are denoted by four terms: True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN). According to the confusion matrix, the formula for calculating the accuracy are given in (1)(2)(3)(4) [31].

$$\text{Accuracy} = (TP + TN) / (TP + TN + TP + TN) \quad (1)$$

$$\text{Precision} = (TP) / (TP + FP) \quad (2)$$

$$\text{Recall} = (TP) / (TP + FN) \quad (3)$$

$$\text{F-Measure} = (2 * \text{Recall} * \text{Precision}) / (\text{Recall} + \text{Precision}) \quad (4)$$

#### IV. RESULT AND DISCUSSION

The dataset was prepared previously, next used in data processing stage using the proposed feature selection technique.

##### A. Result

Initially, the dataset was processed by applying the Algorithm 1 to remove the irrelevant features and the result is shown in Table III.

TABLE III. IRRELEVANCE REMOVAL

No	Feature	Unique Attribute Measure
1	RollNumber	unique value
2	ApplicantMobile	unique value
3	ApplicantName	unique value
4	RemoteStudent	one value dominated other value (value No : ≥ 99%, value Yes : ≤ 1%)
5	Probation	one value dominated other value (value No : ≥ 96%, value Yes : ≤ 4%)
6	HighRisk	one value dominated other value (value No : ≥ 93%, value Yes : ≤ 7%)
7	TermExceeded	one value dominated other value (value No : ≥ 98%, value Yes : ≤ 2%)
8	AtRiskSSC	one value dominated other value (value No : ≥ 95%, value Yes : ≤ 5%)
9	SpecialNeed	only one value
10	PlagiarismHistory	one value dominated other value (value 0 : ≥ 82%, value 1 : ≤ 17% value 2 : ≤ 1%)
11	PlagiarismHistoryCat	one value dominated other value (value Low : ≥ 99%, value Medium : ≤ 1%)
12	PrerequisiteModules	one value dominated other value (value No : ≤ 8%, value Yes : ≥ 92%)

D<sub>1</sub> = D – Irrelevant Features

D<sub>1</sub> = ModuleCode, ModuleTitle, SessionName, CGPAPoint, CGPADesc, Advisor, AttemptCount, AttemptCountCat, AtRisk, OtherModules, OtherModulesCat, CW1, CW1Cat, CW2, CW2Cat, ESE, ESECat, Online C, Online CCat, Online O, Online OCat, Played, Paused, Likes, Segment

The results in Table III show that there are 12 features that must be removed from the dataset consisting of 1 feature identified as one value (only one value for all instances), 3 features identified as a unique value (different value for each instances), and 8 features identified as one value dominates other value. After removing the irrelevant features, now the rest of the features are: 25 features as a dataset D<sub>1</sub>. The dataset D<sub>1</sub> still have the possibility of redundant features, as a solution, the next step, redundancy removal was carried out. The dataset D<sub>1</sub> was produced by previous stage, then processed by

applying the Algorithm 2 to remove the redundant features and the result is shown in Table IV.

TABLE IV. REDUNDANCY REMOVAL

No	Feature	Attribute Dependency Measure	Type
1	ModuleTitle	ModuleCode ↔ ModuleTitle	TD
2	CGPAPoint	CGPAPoint → CGPADesc	FD
3	AttemptCount	AttemptCount → AttemptCountCat	FD
4	OtherModules	OtherModules → OtherModulesCat	FD
5	CW1	CW1 → CW1Cat	FD
6	CW2	CW2 → CW2Cat	FD
7	ESE	ESE → ESECat	FD
8	Online C	Online C → Online Ccat	FD
9	Online O	Online O → Online Ocat	FD

D<sub>2</sub> = D<sub>1</sub> – Redundant Features

D<sub>2</sub> = ModuleCode, SessionName, CGPADesc, Advisor, AttemptCountCat, AtRisk, OtherModulesCat, CW1Cat, CW2Cat, ESECat, Online CCat, Online OCat, Played, Paused, Likes, Segment

The results (Table IV) show that there are 9 features that must be removed from the dataset consisting of 1 feature identified as Total Dependency (TD), 8 features identified as a Functional Dependency (FD). No one features identified as Full Functional Dependency (FFD). After removing the redundant features, the rest of the features now there are 16 features as a dataset D<sub>2</sub>. The dataset D<sub>2</sub> need further processed to select the relevant or strongly relevant features. It also still have the possibility of weakly or irrelevant features. The last step, relevance selection was carried out by applying the Algorithm 3 based on dataset D<sub>2</sub>. Using the first step in Algorithm 3, no one features functionally dependent on the target attribute (class). It means no feature is selected from this step. Next step, the process continued using the intersection of the combination of the existing technique, and the result is shown in Table V. According to the result as shown in Table V, each technique (CHI, IG, GI, SU) have exactly the same results where the features Paused and Likes are in the lowest rank with the value 0. These two features are irrelevant to the class, so they are removed from D<sub>2</sub>.

While Relief technique have slightly different result where the lowest rank is the feature Paused. Because the value is greater than zero, the feature is still used for processing. After getting the results (R1, R2, R3, R4, R5) of each technique, by applying intersection to the results, the proposed technique got selected features R (Table V) as the final result. The result R consists of 14 features after removing the two lowest ranks. The result R then adds to the result D<sub>3</sub> from the first step. Because in the first step there are no features selected, then D<sub>3</sub> is equal to R that is used for building the model in the step.

TABLE V. RELEVANCE SELECTION

No	Feature Selection Technique	Selected Features	Name of the Result
1	ChiSquared	Advisor, ESECat, Played, ModuleCode, CW1Cat, Segment, CW2Cat, Online Ccat, OtherModulesCat, CGPADesc, Online Ocat, AttemptCountCat, AtRisk, SessionName	R1
2	InfoGain	Advisor, ESECat, ModuleCode, Played, CW1Cat, CW2Cat, Segment, Online Ccat, OtherModulesCat, CGPADesc, Online Ocat, AttemptCountCat, AtRisk, SessionName	R2
3	GainRatio	ESECat, Played, Segment, ModuleCode, Advisor, CW1Cat, CW2Cat, AttemptCountCat, OtherModulesCat, Online Ccat, CGPADesc, AtRisk, SessionName, Online Ocat	R3
4	Symmetrical Uncertainty	ESECat, Played, Segment, Advisor, ModuleCode, CW1Cat, CW2Cat, AttemptCountCat, OtherModulesCat, Online Ccat, CGPADesc, Online Ocat, AtRisk, SessionName	R4
5	Relief	ESECat, ModuleCode, CW1Cat, CW2Cat, Played, Segment, SessionName, Likes, CGPADesc, Online Ccat, Online Ocat, OtherModulesCat, AttemptCountCat, Advisor, AtRisk, Paused	R5
6	Intersection of All	ModuleCode, SessionName, CGPADesc, Advisor, AttemptCountCat, AtRisk, OtherModulesCat, CW1Cat, CW2Cat, ESECat, Online Ccat, Online Ocat, Played, Segment	$R = R_1 \cap R_2 \cap R_3 \cap R_4 \cap R_5$ $D_3 = R$

Evaluation of the prediction model is used to select the best model raised the highest accuracy. Using a dataset split into training and testing data, the value of each model's cross-validation accuracy as an indicator of model performance is evaluated. Table VI shows the evaluation results based on the cross-validation accuracy and F-measure indicators.

TABLE VI. THE PREDICTION MODEL PERFORMANCE FOR CLASSIFICATION OF STUDENT'S ACADEMIC SUCCESS (%)

Classifier	Accuracy	Precision	Recall	F-Measure
DT	92.64	92.6	92.6	92.2
NB	83.13	83.9	83.1	83.5
ANN	84.62	84.1	85.1	82.1
KNN	85.44	85.9	85.4	85.6
SVM	89.57	89.1	89.6	89.1

The result in Table VI shows the proposed framework using the proposed filter selection technique can achieve high accuracy scores for each classifier. The highest accuracy score is 92.64% on the DT classifier, followed by SVM (89.57%), ANN (84.62%), KNN (83.44%) and the last is NB (83.13%).

When compared with the existing technique that is frequently used in predicting academic success, the result is shown in Table VIII. The selected features (dataset) produced by each technique that will be used by classifier is presented in Table VII. The features with the score  $\leq 0$  eliminated from dataset because of the features do not have a relationship to target attribute (class).

TABLE VII. THE NUMBER OF SELECTED FEATURES OF FEATURE SELECTION TECHNIQUE

Feature Selection Technique	Features Category	Sub Total Features	Total Selected Features
CHI, IG, GI, SU	Redundant Features : CW2, CW1, ESE, ModuleTitle, AttemptCountCat, OtherModulesCat, Online Ccat, AtRiskSSC, CGPADesc, Online Ocat, AtRisk, SessionName, RemoteStudent	13	28
	Irrelevant Features : RollNumber, ApplicantMobile, ApplicantName, Probation, HighRisk, TermExceeded, PlagiarismHistoryCat, PrerequisiteModules	8	
	Relevant Features : ESECat, Played, Segment, Advisor, ModuleCode, CW1Cat, CW2Cat	7	
RF	Redundant Features: ModuleTitle, OtherModules, Online O, Online C, CW1, CW2, AttemptCount, CGPAPoint	8	31
	Irrelevant Features: ApplicantMobile, RollNumber, PrerequisiteModules, HighRisk, PlagiarismHistory	5	
	Relevant Features: ESECat, ModuleCode, CW1Cat, CW2Cat, ESE, Played, SessionName, Segment, Likes, Online Ocat, AttemptCountCat, OtherModulesCat, Advisor, AtRisk, CGPADesc, Online Ccat, TermExceeded, Paused	18	
CFS	Redundant Features : CW1, CW2	2	3
	Irrelevant Features: ApplicantName	1	
	Relevant Features: -	0	
Proposed Technique	Redundant Features : -	0	14

Feature Selection Technique	Features Category	Sub Total Features	Total Selected Features
	Irrelevant Features: -	0	
	Relevant Features: ModuleCode, SessionName, CGPADesc, Advisor, AttemptCountCat, AtRisk, OtherModulesCat, CW1Cat1, CW1Cat2, ESECat, Online Ccat, Online Ocat, Played, Segment	14	

The result in Table VII shows the existing techniques successfully reduced the number of features that have not significant affecting to the target attribute. However, the selected features produced by each existing technique still have irrelevant and redundant features, impacting the accuracy of the prediction model is not optimal. The techniques (CHI, IG, GI, SU) have the same result in a number of selected features (28 features) and the features that have been selected. The difference is only the ranking of the selected features. The CFS technique slightly has a different result in producing selected features (only three features). It is an excellent factor in reducing the computational cost. According to these results, it concludes that selected features that still contain redundant and irrelevant features, making the accuracy result is not optimal.

TABLE VIII. THE ACCURACY COMPARISON OF FEATURE SELECTION TECHNIQUE FOR PREDICTING ACADEMIC SUCCESS (%)

Feature Selection Technique	DT	NB	ANN	KNN	SVM
All (No FS Technique used all dataset)	85.88	71.47	81.54	82.21	86.50
CHI	85.89	73.31	82.82	84.96	86.81
IG	85.89	73.31	82.82	84.96	86.81
GI	85.89	73.31	82.82	84.96	86.81
SU	85.89	73.31	82.82	84.96	86.81
RF	85.89	73.31	81.53	82.51	88.03
CFS	84.62	80.98	61.04	81.60	80.98
Proposed Technique	92.64	83.13	84.62	85.44	89.57

The result in Table VIII shows the proposed framework using the proposed filter selection technique compared to existing technique can achieve high accuracy rates for each classifier. According to Table VIII, it can be seen the accuracy of the existing technique is less than the proposed technique due to the existing the irrelevant and redundant features. Based on these results, the proposed technique outperforms the existing technique (CHI, IG, GI, SU, RF), even with the CFS (the filter-based feature subset techniques). The RF technique produced the most selected features, but the accuracy is not quite different from others (CHI, IG, GI, SU as shown in

Table VIII). The RF technique raised the highest accuracy in classifier SVM and the lowest accuracy in ANN and KNN, while in DT or NB have the same result from others (CHI, IG, GI, and SU).

### B. Discussion

According to the results (Table VI), it concludes that the best classifier to classify student's academic success is DT. This statement is supported by the previous studies that appropriate classifier is one of main factor besides feature selection in predicting academic success, and DT leads to the highest accuracy and performs well in a large dataset [1], [2]. This happen because the feature CGPADesc is used as the main feature. The results proved that the proposed framework is feasible to implement. According to Tables VII and VIII, it can be concluded that the criteria of good feature selection are not only determined by the number of selected features but also by the kind of selected features. Even though the result of CFS is the least (Table VII), but the accuracy is the lowest result (as shown in Table VIII). This happen because the result still consist of redundant and irrelevant features and have no relevant features, so it affects to the accuracy of the model [5]. The techniques (CHI, IG, GI, SU) have exactly the same results in each classifier because the dataset (the selected features produced by each technique) is the same. The proposed technique raised the highest accuracy rate even though the number of selected features (14) is greater than CFS (3) due to the nonexistence of the redundant and irrelevant features. It proved that feature selection is another main factor besides the classifier in predicting academic success aligned with the previous studies [1], [2], and the proposed feature selection leads to the highest accuracy and performs well in a large dataset. From the whole result, this research has proven that the framework develop using the proposed feature selection technique reached the highest accuracy score over all the existing technique. This research also proved that the feature selection can increase the prediction model accuracy, and it aligned with the previous studies [17]–[22].

### V. CONCLUSION

Generating graduates with better academic performance through a prediction model is a crucial factor and challenging task in higher education. This study evaluates filter-based feature ranking techniques for predicting academic success and proposes a novel feature selection technique to improve the performance of the prediction model through a framework. The proposed framework will act as a guide that gives suggestions for creating the prediction model. Based on the accuracy rates used to evaluate performance, the best model was chosen. According to the results, it conclude that the best classifier to classify student's academic success is the DT with accuracy = 92.64%. The results show that the proposed framework utilizing the proposed technique significantly improves the accuracy of the proposed prediction models. The proposed technique increase the accuracy compared to existing technique from 2-8%. These results indicate the proposed framework utilizing the proposed technique effectively used to predict student success for the higher education institution making policies or giving intervention to poor academic performance students.

**Abstract**—The extraction of buildings from multispectral Light Detection and Ranging (LiDAR) data holds significance in various domains such as urban planning, disaster response, and environmental monitoring. State-of-the-art deep learning models, including Point Convolutional Neural Network (Point CNN) and Mask Region-based Convolutional Neural Network (Mask R-CNN), have effectively addressed this particular task. Data and application characteristics affect model performance. This research compares multispectral LiDAR building extraction models, Point CNN and Mask R-CNN. Models are tested for accuracy, efficiency, and capacity to handle irregularly spaced point clouds using multispectral LiDAR data. Point CNN extracts buildings from multispectral LiDAR data more accurately and efficiently than Mask R-CNN. CNN-based point cloud feature extraction avoids preprocessing like voxelization, improving accuracy and processing speed over Mask R-CNN. CNNs can handle LiDAR point clouds with variable spacing. Mask R-CNN outperforms Point CNN in some cases. Mask R-CNN uses image-like data instead of point clouds, making it better at detecting and categorizing objects from different angles. The study emphasizes selecting the right deep learning model for building extraction from multispectral LiDAR data. Point CNN or Mask R-CNN for accurate building extraction depends on the application. For building extraction from multispectral LiDAR data, two approaches were compared utilizing precision, recall, and F1 score. The point-CNN model outperformed Mask R-CNN. The point-CNN model had 93.40% precision, 92.34% recall, and 92.72% F1 score. Mask R-CNN has moderate precision, recall, and F1.

**Keywords**—Multispectral LiDAR; Mask R-CNN; Point CNN; deep learning; building extraction

## I. INTRODUCTION

The escalating urbanization of the global population necessitates the development of accurate and efficient techniques for extracting buildings from remote sensing data. The extraction of buildings from remotely sensed data is a crucial procedure with wide-ranging applications, including but not limited to three-dimensional (3D) building modeling, urban planning, disaster assessment, and the maintenance of digital maps and Geographic Information System (GIS) databases [1].

The task of accurately and efficiently identifying buildings from remote sensing data presents several challenges, due to data availability issues, poor data quality, and obstructions caused by nearby objects like trees, automobiles, and

mountains [2]. Despite these difficulties, advancement has been made significant in the recent development of building extraction techniques. Building extraction accuracy and effectiveness are projected to increase over time as deep learning algorithms advance and more high-quality remote sensing data become accessible [3].

The multi-spectral Light Detection and Ranging (LiDAR) provides a field for obtaining different spectral responses from different features and collecting various data about the surface and terrain of the land and water [4]. Due to this rationale, the utilization of multi-spectral LiDAR has significantly advanced the field of remote sensing data due to its vast quantity of high-resolution multispectral and spatial data [5]. However, this abundance of data may present a challenge in terms of the human capacity to accurately extract and classify features from the point cloud. Consequently, the rapid development of computer technology and the emergence of artificial intelligence, including machine learning and deep learning, have made it possible to reduce the time and human effort required for precise feature extraction from LiDAR sensors' point clouds [6, 7]. Automatic extraction of buildings from multispectral LiDAR data is a challenging task, but one that has the potential to be extremely useful for a wide range of applications [7].

The objective of this study is to compare and contrast two distinct methodologies for extracting buildings from multispectral LiDAR data. The first utilizes the deep learning algorithm Mask R-CNN, while the second utilizes Point CNN. Both methods utilize three multispectral LiDAR channels to optimize building extraction.

The paper conforms to this structure. Section II describes the related works. Section III describes the significance of the research. The data and the study area are in Section IV. The Section V describes the methodology. Section VI discusses accuracy assessment mathematically. Section VII provides qualitative and quantitative evaluations of the findings. The discussion and summary concluded in Section VIII.

## II. RELATED WORK

The utilization of LiDAR technology offers a significant advantage in terms of three-dimensional spatial accuracy [8], rendering it an optimal choice for various remote sensing applications, particularly in the mapping of densely populated

urban regions. Multiple scientific studies have provided evidence supporting the utilization of LiDAR data for the extraction of buildings in urban environments [9, 10].

Building extraction from LiDAR data has been extensively researched, resulting in the development of numerous algorithms in recent years. Nevertheless, the majority of these techniques rely on LiDAR data with a single wavelength. There exists a limited body of research pertaining to the utilization of multispectral LiDAR data for the purpose of building extraction. These studies demonstrate that deep learning can be used to accurately extract buildings from single-wavelength LiDAR data. It is essential to note, however, that the efficacy of deep learning models for building extraction can vary depending on the scene's complexity and the quality of the LiDAR data.

One of the earliest studies on building extraction using multispectral LiDAR data was conducted by [11]. They proposed a Graph Geometric Moments Convolutional Neural Network (GGMCNN) model for extracting buildings from airborne multi-spectral LiDAR point clouds. The GGMCNN model is a deep learning model that is specifically designed for processing point cloud data. It takes as input a set of features that are extracted from the point cloud, including the point's elevation, intensity, and spectral information. The GGMCNN model is trained to classify each point cloud as either building or non-building. This study has shown that deep learning can be used to extract buildings from multispectral LiDAR data with high accuracy. However, research is needed to develop and evaluate different deep learning models that deal with point clouds and raster format for this task on more accurate datasets such as multispectral LiDAR data.

Several studies have employed deep learning models to extract buildings from mono-wavelength LiDAR data in a raster format, as evidenced by the works of [3, 12-15]. In contrast, some researchers have studied the extraction of buildings from LiDAR data in the form of point clouds [11]. Nonetheless, a lack of research persists regarding the evaluation of deep learning models that are appropriate for building extraction from multispectral LiDAR data. This is an important area of research, and we hope our study can help fill this gap.

The advent of various deep learning networks specifically designed for processing raw LiDAR data [16-18] has facilitated the direct extraction of buildings from LiDAR point clouds. This is in contrast to previous methods that necessitated data rasterization prior to extracting features from the raster format [19]. Convolutional Neural Networks (CNNs) and their respective lineages are extensively employed and favored networks within the domain of deep learning [20]. One notable advantage of CNNs over previous models is their capacity to autonomously detect significant features without human intervention, rendering them more pragmatic [21]. The deep learning algorithm known as Point Convolutional Neural Network (Point CNN) [19] is distinguished by its capability to directly process raw cloud points, eliminating the requirement for the rasterization process. In a study conducted by [22], a comparative analysis was performed to evaluate the performance of the deep learning algorithm Point CNN in

classifying land points in agricultural areas. The findings of the study demonstrated that Point CNN outperformed traditional methods in terms of accuracy. Furthermore, it has been demonstrated that Mask Region-based Convolutional Neural Network (Mask RCNN), a deep learning algorithm belonging to the same category as CNN, has exhibited notable efficacy in the extraction of buildings from LiDAR data. This is achieved through the conversion of cloud points into raster images [23, 24].

However, to the best of our knowledge, there is a lack of scientific investigations on the automatic extraction of buildings using multispectral LiDAR points based on the Point CNN algorithm, and comparing its results with the Mask RCNN algorithm. Previous studies have not adequately compared these two methodologies. Currently, there exists a significant need for the automated and precise categorization of multispectral LiDAR points across various applications. Also, applying this approach to multispectral LiDAR data is an important step to increase the accuracy of building extraction in complex urban environments and facilitate the emergence of novel applications in subsequent endeavors.

In this study, the main contributions are:

- 1) Compare and contrast two distinct methodologies for extracting buildings from multispectral LiDAR data: Mask RCNN and Point CNN. Both methods utilize three multispectral LiDAR channels to optimize building extraction.
- 2) Investigate the importance of using multispectral LiDAR data for building extraction. Using multispectral LiDAR data can considerably improve the accuracy of building extraction compared to using single-wavelength LiDAR data, according to the study's findings.

Overall, the research on building extraction using deep learning with multispectral LiDAR data is still in its early stages. However, the results from existing studies are promising and suggest that deep learning has the potential to improve the accuracy and efficiency of building extraction in urban environments.

### III. RESEARCH SIGNIFICANCE

This paper presents a significant analysis of two distinct methodologies employed for building extraction from multispectral LiDAR data. The methodologies involve either utilizing point clouds directly or converting them into a raster format. This study demonstrates the effectiveness of deep learning algorithms for building extraction. Furthermore, offers significant insights regarding the utilization of multispectral LiDAR data in the context of building extraction. This study's findings may have a wide variety of practical applications. Urban planners and emergency administrators could use them to automatically generate building footprints, for instance. They could also be used to improve the accuracy of 3D city models.

### IV. STUDY AREA AND DATASET

The study area represents a complimentary dataset provided by the National Center for Airborne Laser Mapping (NCALM), encompassing an urban region located in Houston

in the southeastern sector of Texas, United States of America. The study area, as illustrated in Fig. 1, encompasses the vicinity of the Houston University campus and its immediate surroundings. The study area encompasses an estimated area of 550m<sup>2</sup>. The study area was selected based on its diverse range of building types, encompassing regular residential structures, edifices surrounded by a canopy, and small-scale constructions with haphazard layouts.

Fig. 1. Study area.

The research area was scanned in February 2017 using a Teledyne Optech Titan multi-spectral Airborne Laser Scanning (ALS) system [25]. The ALS dataset included multispectral data from 14 flight lines. All collected points were separately recorded in 42 LAS files, each corresponding to a distinct channel and strip. Every LAS file contained data on the point source ID, scan angle rank, flight line edge, scan direction flag, returns, GPS time, and intensity values. Detailed information about the dataset is shown in Table I; the Titan sensor was put in an Optech aircraft. The flight plan and equipment parameters are shown in the Table II.

TABLE I. SPECIFICATIONS OF OPTECH TITAN MULTI-SPECTRAL ALS LIDAR (TELEDYNE OPTECH TITAN, 2015)

Parameters	Channel 1	Channel2	Channel 3
Wavelength	1550 nm MIR	1064 nm NIR	532 nm Green
Beam divergence	0.35 mrad(1/e)	0.35 mrad(1/e)	0.70 mrad(1/e)
Look angle	3.5 ° forward	nadir	7.0 ° forward
Effective PRF	50–300 kHz	50–300 kHz	50–300 kHz

TABLE II. THE FLIGHT PLAN AND EQUIPMENT PARAMETERS

Flight Parameter	
Sensor ID	The Optech Titan MW (14SEN/CON340) LiDAR sensor
flying height	460 m AGL
swath width	445 m
overlap	50%
line spacing	225 m
Equipment Parameters	
PRF	175 kHz per channel (525 kHz total)
scan frequency	25 Hz
scan angle	±26° and ±2°cut-off at processing

## V. METHODOLOGY

Two strategies for building extraction from multispectral LiDAR data were employed to accomplish the research objective. The first method extracts buildings from the raster data, whereas the second method extracts buildings from the point data.

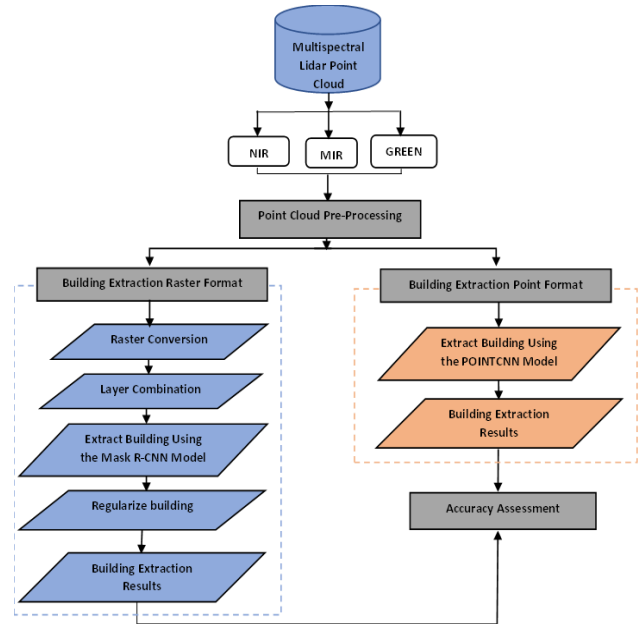

Fig. 2. Pre-processing flow Chart.

The data obtained from Multispectral LiDAR is presented in the LAS format, comprising point cloud values for x, y, z, and intensity. Fig. 2 depicts the flow chart for two distinct approaches to extracting buildings from multispectral LiDAR point cloud data. The building extraction strategy from the raster format is represented in blue, while the building extraction strategy from the point format is represented in orange. The point cloud pre-processing step was executed in two distinct approaches, followed by their respective application to two distinct deep learning algorithms. One algorithm is designed to handle data in raster format, while the other algorithm is specifically designed to process raw data in a point cloud format.

### A. Pre-Processing Point Cloud

The pre-processing of the point cloud is the same for the two methods and it consists of removing the noise points, integrating the point clouds of the three different channels, segmenting the point cloud according to the boundary of the study area, and finally separating the ground and off-ground point clouds. The non-terrain point cloud is of interest in this paper because it contains the features of the buildings. The following will be elaborated upon in a comprehensive manner below:

1) *Data cleaning*: A statistical out-linear removal (SOR) algorithm was utilized to eliminate isolated points or any points that fell outside the intensity range [26]. The logarithmic function operates by computing the spatial separation between a given point and its six adjacent

neighbors. In cases where the mean distance between a given point and its corresponding exceeds the established minimum threshold, the point is eliminated.

2) *Merging and segmenting points*: The absence of control points or reference points in our case has compromised the statistical reporting of geometric quality. In order to evaluate our building extraction methodology, a study area was chosen from a single strip to address the problem at hand. Before performing the step of merging the three different wavelengths into a single LAS file, each channel was cut in three directions based on the borders of the chosen study area. In order to obtain the highest efficiency of the multi-spectral LiDAR points, a merger of the three channels was made, as each channel collects data from a different angle of view and with different intensities, in addition to improving the density of the cloud points. The present study involves the integration of three separate point clouds through the utilization of 3-D spatial join methodology. Each individual point cloud of a specific wavelength serves as the reference point among the three. The reference point cloud employs the closest neighbor searching algorithm to identify neighboring points within the other two wavelengths of point clouds. Subsequently, the segmentation algorithm, which is available via the Cloud Compare software, was employed to clip the multispectral LiDAR points according to the selected boundaries of the chosen study area.

3) *Filtering points*: This research uses deep learning models to extract buildings from multispectral LiDAR data. To simplify this procedure, the Cloth Simulation Filter (CSF) provided by [15] was used to separate ground points and non-ground points as shown in Fig. 3, and concentrate exclusively on the latter because they include buildings. The CSF filter operates through the inversion of the point cloud and drops a simulated cloth model onto the designated points. The cloth undergoes a settling process as it contends with the opposing forces of gravity and internal cloth tension, which occurs over numerous iterations. The filter necessitates the provision of four input parameters, with the first parameter denoting the terrain type. In this case, the area being examined is characterized by flat terrain. Subsequently, a cloth resolution of 2.0, regulates the texture coarseness or smoothness of the cloth's simulation. The terrain simulation's maximum iteration is 500. Ultimately, a classification threshold of 0.5 was established in order to differentiate between terrestrial and non-terrestrial point clouds, utilizing point distances as the determining factor.

### B. Building Extraction of Raster Data

This method utilizes Mask R-CNN and polygon regularization to accomplish its building extraction goals. Mask R-CNN can produce preliminary building polygons from an input image. Then, the basic polygons are transformed into regularized polygons using the polygon regularization technique. The pre-processing stage of the 3D point cloud was conducted to enable the point cloud to be suitable for direct extraction of buildings using the deep learning model Point-

CNN. On the other hand, the deep learning model Mask R-CNN requires several steps to process the multi-spectral LiDAR data, with the most crucial of these steps being the conversion of the three-dimensional point cloud into a horizontal image plane through the process of rasterization.

1) *Raster conversation*: The 3D point cloud was rasterized to a 2D raster with intensity and height information preserved. Cloud intensities at three distinct wavelengths were converted into three distinct intensity images for each channel separately as shown in Fig. 4(a, b, c). The intensity cloud rasterization process was executed by defining a specific set of properties. The cell size parameter was established as 0.1, and the binning interpolation technique was employed to compute the mean intensity value within cells that lack data points. The height raster as shown in Fig. 4(d) was generated from multispectral LiDAR data after merging the three channels and generating a DSM, as opposed to the intensity images for each channel separately. The raster height step was subjected to identical intensity rasterization settings parameters, including interpolation method and cell size, to ensure congruence between the raster resolution and applying the composite process on the four-raster dataset.

Fig. 3. Separation of ground and off-ground multispectral LiDAR points using CSF algorithm, (a) representing ground points and (b) representing above-ground points.

Fig. 4. Rasterization multispectral LiDAR point cloud.

2) *Layer combination*: To streamline the training and validation process of the Mask R-CNN deep learning model, it is necessary to compress the four images within a multi-data image into a new multi-band raster data set. The input dataset comprised a series of four raster images (Raster Intensity Ch-1, Raster Intensity Ch-2, Raster Intensity Ch-3, and Raster height of non-terrain features). All four images possess identical dimensions in terms of length, width, and cell size. The dimensions of the analyzed space were identical to those of the study area, while the depth of the analysis was determined by the quantity of raster images within the input dataset. Specifically, a depth of four was utilized.

3) *Mask R-CNN*: The buildings in this method were extracted using the workflow of the Mask R-CNN deep learning model, as illustrated in Fig. 5. Initially, the multi-spectral LiDAR data underwent a qualification process for its inclusion in the deep learning model, as previously stated [27]. This data is comprised of four images that possess identical length, width, and cell size, and have been compressed accordingly. Subsequently, the training data intended for the deep learning model was exported. To this end, the study area was partitioned into training, validation, and test data sets. Subsequently, the training and validation sets, along with each input image, were utilized to produce the training data set. The input images were partitioned into image tiles of size  $256 \times 256$  pixels, with a 50% overlap step-shift, in order to conform to the input requirements of the Mask R-CNN architecture and to guarantee that all buildings are represented in at least one image tile. The training dataset comprised 184 image slices and 239 features. Following that, the Mask R-CNN model is trained through the utilization of a designated training dataset.

Table III. presents the parameters that were utilized to train the model. The Mask R-CNN architecture comprises several components: including a backbone, a Region Proposal Network (RPN), a Region of an Interest alignment layer (RoI Align), a Bounding box regressor, and a mask generation head [28]. To predict segmentation masks on each Region of Interest (ROI), the Mask R-CNN builds on the Faster R-CNN by adding a network branch to the original (ROI) [24]. To each ROI, the tiny FCN was applied that predicts a pixel-wise segmentation mask for building and nonbuilding regions. The first building polygon is found by following a region's boundary [29]. ArcGIS API for Python, with the Tensorflow and Keras libraries, was used to create and implement the Mask R-CNNs. It's based on a Region Proposal Network (RPN) and ResNet50 backbone.

TABLE III. MASK R-CNN TRAINS THE MODEL PARAMETERS

Parameter	Description
Backbone model	ResNet-50
Training and Test set was split into	70/20%
Validation	10%
Processing type	Nvidia GeForce RTX 2060 GPU
Batch size	4
Learning rate strategy	Stop when the model stop improve
Learning rate	0.0001

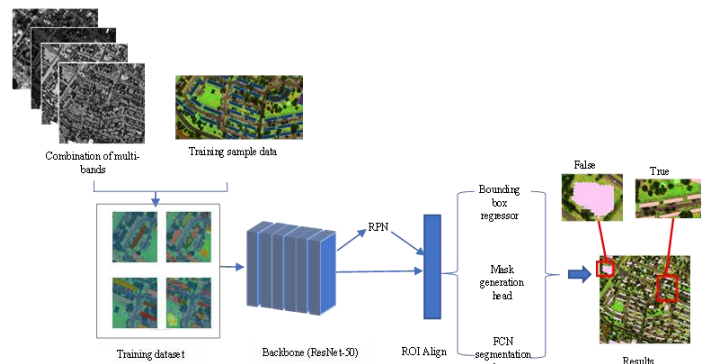

Fig. 5. The Mask R-CNN procedure for building extractions using Multi-Spectral LiDAR Dataset.

4) *Regularize building footprint*: After extracting the buildings with Mask R-CNN, it produces irregular and distorted polygons that don't have straight lines and right angles for edges due to the pixel-labeling location performed by Mask R-CNN [30]. In order to get rid of this randomness in building polygons, the regularized building footprint step was used. A polyline compression algorithm was used to reduce these distortions of building polygons. Table IV shows the parameter used in this algorithm to obtain a much cleaner and closer footprint to buildings than the results that we got from the deep learning algorithm Mask-RCNN.

TABLE IV. REGULARIZE BUILDING FOOTPRINT PARAMETERS

Parameter	Description
Method	Right angle
Tolerance	1
Precision	0.25
Diagonal penalty	1.5
Minimum radius	0.1
Maximum radius	1000000
Processor type	GPU

### C. Building Extraction of Point Cloud Data

The Point Convolutional Neural Network (Point CNN) algorithm is utilized in this research to extract buildings directly from the raw multispectral point cloud without a rasterizing step. The Point CNN architecture consists of an encoder network and a decoder network as shown in Fig. 6, both of which contain X-Conv layers. The cipher network consists of four collective abstraction units to iteratively extract multiscale features of scale (1/256, 1/256, 1/512, 1/1024) concerning the entry point cloud with point number N. Concerning entry points, the entry point merged of intensities of three channels, and adding the elevation point cloud was DSM. K is set from 8 to 16 in this study, where K is the neighboring points around the representative points and N is the number of the point in the previous layer. In this setting, the final point has a 1:0 receptive field since it sees all points from the previous layer, and its features contribute to an accurate semantic interpretation of the shape. In the second X-Conv layer, a dilation rate of  $D = 2$  was used, and then gradually increased in the third and fourth X-Conv layers to ensure that all remaining representative points see the entire figure and are all suitable for making predictions. In this way, the last X-Conv is more thoroughly trained layers, as more connections are involved in the network. The decoder network comprises three feature propagation units, which gradually restore a robust feature mean representation to produce a high-quality classifier point cloud. The output data size of the encoder is  $N/256$ ,  $N/512$ , and  $N/1024$ . Finally, a fully connected layer is added on top of the last output of the X-Conv layer, followed by a loss, to train the network.

Fig. 6. Point CNN architecture for building extraction from multispectral LiDAR where,  $I_1$ : Intensity of channel-1,  $I_2$ : Intensity of channel-2,  $I_3$ : Intensity of channel-3, N: Number of the point in the previous layer.

## VI. ACCURACY ASSESSMENT

The following measures were employed for assessing the effectiveness of the proposed approaches, all of them are

standard for any semantic segmentation and classification work.

$$Precision = \frac{T_p}{T_p + F_p} * 100\% \quad (1)$$

where the term "precision" refers to the proportion of accurately labeled data points relative to the total number of data points that were labeled, the percentage of data points that were successfully classified relative to the total number of data points that were expected to be classified with this value is the recall. F1-score is the arithmetic mean of the precision and recall values are given as follows:

$$Recall = \frac{T_p}{T_p + F_n} * 100\% \quad (2)$$

$$F1 - score = \frac{2 * precision * recall}{precision + recall} \quad (3)$$

Where:  $T_p$  is a number of point clouds that are classified as true positive building extraction,  $T_n$  are truly negative,  $F_p$  is false positive and  $F_n$  is a false negative.

## VII. RESULTS AND DISCUSSION

The study area was subjected to the training of two deep learning models, namely Mask R-CNN and Point-CNN for the purpose of extracting buildings from a Multispectral LiDAR point cloud. The training dataset and validation for both models were selected using the same buildings to facilitate comparison. The evaluation of building extraction results was conducted using a confusion matrix approach. The reference points for ground truth were obtained from orthorectified aerial photographs captured by the same multispectral LiDAR system in the same survey.

### A. Building Extraction Result of Mask R-CNN

As shown in Fig. 7(a), the outcomes of utilizing the mask R-CNN deep learning model on the multi-spectral LiDAR data after converting them into raster format, as this model confirmed its ability to train and extract the footprints of buildings, but in an irregular style. After they were included in the polyline compression algorithm to create the uniformity of the building, the results are shown in Fig. 7(b).

Fig. 7. Building extraction results of mask RCNN: (a) before using regularize, (b) after regularize.

### B. Building Extraction Result of Point CNN

The visual outcomes of building extraction through the utilization of the Point CNN deep learning model are presented in Fig. 8. Specifically, Fig. 8(a) displays the raw multispectral LiDAR points prior to building recognition, with all points

depicted in grey. On the other hand, Fig. 8(b) shows the outcomes attained by the Point CNN model in building recognition, where buildings are highlighted in red and the background is depicted in grey. The employment of Point CNN in contrast to the use of Mask R-CNN is observed to yield superior outcomes. The aforementioned model demonstrated a capacity to discern points of construction with a mean precision of 0.9340 within the given dataset. Furthermore, the algorithm demonstrated a notable proficiency in distinguishing between the points of buildings and those of trees, particularly in cases where buildings were encompassed by thick clusters of trees. This model was also able to extract the points of small and irregular buildings accurately.

Fig. 8. Building extraction results of Point CNN: (a) before building extraction, (b) after building extraction.

The precision achieved through the utilization of the Point format approach surpasses that of the Raster format methodology. It is anticipated that the inclusion of supplementary spectral data, such as indices, may enhance the ultimate outcomes of building extraction. Ongoing investigations are being conducted with the aim of enhancing the precision of the building extraction.

### C. Comparison between Two Methods

The two methods were compared using evaluation scales such as precision, recall, and F1-score to enhance the comparison. Table V displays the obtained results from using the Point CNN model, which indicates a precision of 93.40%, a recall of 92.34%, and an F1-score of 92.72%. While Mask R-CNN gave less accurate results, it demonstrates a precision of 74.66%, a recall of 67.43%, and an F1-score of 71.17%.

According to the findings of our research, Point CNN performs better than Mask R-CNN when it comes to the extraction of buildings from multispectral LiDAR data in terms of both accuracy and efficiency. In comparison to Mask R-CNN, Point CNN is capable of directly extracting features from point clouds without the need for any pre-processing steps such as voxelization. This results in a greater resolution and significantly faster processing times. In addition to this, Point CNN is able to manage irregular point clouds, which are typical in the case of LiDAR data. Nevertheless, Mask R-CNN continues to have advantages compared with Point CNN in a number of contexts, since it operates on raster data like satellite images or aerial photos rather than point clouds. Also, Mask R-CNN is more suited to identifying and categorizing objects seen from a variety of angles. This makes it an ideal candidate for this task: the Precision, Recall, and F1-score obtained from the two different methods.

TABLE V. THE PRECISION, RECALL, AND F1-SCORE OBTAINED FROM THE TWO DIFFERENT METHODS

Method	Mask R-CNN	Point- CNN
Precision%	74.66	93.40
Recall%	64.43	92.34
F1_Score%	69.17	92.72

TABLE VI. THE TRUE-POSITIVE( $T_P$ ), FALSE-POSITIVE( $F_P$ ), AND FALSE-NEGATIVE( $F_N$ ) FROM THE TWO DIFFERENT METHODS

Method	$T_P$	$F_P$	$F_N$
Mask-RCNN (mask)	112	38	85
Point CNN (points)	897392	26528	91137

According to Tables V, and VI, the results suggest that Point CNN is a more effective method for building extraction from multispectral LiDAR data. It has a higher TP, Precision, and F1-Score than Mask R-CNN. However, Mask R-CNN has a higher Recall, indicating that it is less likely to miss buildings.

Comparing our findings to LiDAR building extraction research [13, 30], our study had 93.40% accuracy, 92.34% recall, and 92.72% F1. Point CNN retrieves features from point clouds without rasterization, which may explain this. Accuracy and processing speed improve. Furthermore, the integration of the three distinct spectra of the multi-spectral LiDAR plays a crucial role in accurately discerning and distinguishing buildings and other features.

According to the study's findings, Point CNN outperformed Mask R-CNN in building extraction from multispectral LiDAR data. This is probable because Point CNN processes point cloud data directly, preserving its structure and characteristics. This enables Point CNN to capture fine-grained geometric details and relationships within the point cloud, which is crucial for accurate building extraction and avoids voxelization, which is sometimes required by Mask R-CNN. This improves efficacy because no data is lost in the conversion process. Maintaining the original spatial distribution of points without voxelization is also essential for accuracy in point clouds with irregular spacing. Due to its architecture, it can manage multispectral LiDAR data from a variety of perspectives. The model captures and uses data from diverse perspectives to increase building extraction accuracy. Mask R-CNN, on the other hand, is well-suited for distinguishing and categorizing objects seen from a variety of angles because it operates on raster data such as satellite images or aerial photographs.

In addition, it is recommended that future research endeavors include evaluating the performance of Point CNN and Mask R-CNN on other datasets, including datasets with different types of scenes (e.g., urban, rural, forested) and datasets with different types of multispectral LiDAR data (e.g., different wavelengths, different point densities, and use of spectral indicators).

## VIII. CONCLUSION

A study was conducted to analyze multispectral LiDAR

data to extract buildings from a residential area situated near the University of Houston, situated in the state of Texas, United States of America. The present investigation undertook a comparative analysis of two discrete deep learning models that are categorized under the Convolutional Neural Network (CNN) family. The present investigation aimed to assess the effectiveness of the method employed in extracting buildings in two separate scenarios. The study involved the utilization of a genuine dataset of multispectral LiDAR data for experimentation purposes. Before inputting LiDAR points into the Point CNN deep learning model, processing operations were executed. Similarly, operations were conducted to transform cloud points into pixels for input into the mask R-CNN deep learning model. Furthermore, a classification of architectural structures was conducted after their acquisition via mask R-CNN. The standardization of ground truth reference was implemented to facilitate a comparison between the two methods, as this is orthorectified aerial photographs captured by the same multispectral LiDAR system in the same survey. It can be concluded that the use of the CNN point model with the proposed approach, which combines the advantages of the intensity of the three different wavelengths plus the height component of the DSM gives better results for extracting buildings from multispectral LiDAR point data, where the accuracy of the results improved by about 30%.

#### ACKNOWLEDGMENT

The authors thank the Hyperspectral Image Analysis Lab at the University of Houston for providing the original Optech Titan data.

**Abstract**—The Internet of Things (IoT) has gained significance over the past several years and is currently one of the most important technologies. The capacity to link everyday objects, such as home appliances, medical equipment, autos, and baby monitors, to the internet via embedded devices with a minimum of human interaction has made continuous communication between people, processes, and things feasible. IoT devices have established themselves in many sectors, of which electronic health is considered the most important. The IoT environment deals with many private and sensitive health data that must be kept safe from tampering or theft. If safety precautions are not implemented, these dangers and assaults against IoT devices in the health sector might completely destroy this industry. Detecting security threats to an IoT environment requires sophisticated technology; these attacks can be identified using machine learning (ML) techniques, which can also predict snooping behavior based on unidentified patterns. In this paper, it is proposed to apply five strategies to detect attacks in network traffic based on the NF-ToN-IoT dataset. The classifiers used are Naive Bayes (NB), Random Forest (RF), Decision Tree (DT), Artificial Neural Network (ANN), and Support Vector Machine (SVM) models. These algorithms have been used instead of a centralized method to deliver compact security systems for IoT devices. The dataset was pre-processed to eliminate extraneous or missing data, and then a feature engineering approach was used to extract key features. The results obtained by applying each of the listed classifiers to a maximum classification accuracy of 98% achieved by the RF model showed our comparison to other work.

**Keywords**—IoT; ML; DL; attack classification; e-health

## I. INTRODUCTION

A network of physical items, or "things," that have sensors, software, and other technologies built into them that can connect to and exchange data with other systems and devices through the Internet is referred to as the "Internet of Things" (IoT) [1]. These devices range from basic household goods to cutting-edge industrial equipment. More than 7 billion IoT devices are currently online. IoT Analytics experts predict that by 2023, there will be 14.4 billion linked IoT devices, an increase of 18%, and that by 2025, there may be 27 billion connected IoT devices [2].

The Internet of Things has applications in many different industries. It has proven important in a number of different industries, but the healthcare industry has seen it hard. The medical industry has benefited from modern technology and

digital transformation. As mobile medical devices, mobile health applications, and services have helped improve healthcare services, they are expected to rely more and more on IoT technology in the coming years [3].

The use of the IoT in healthcare is constantly evolving. This fundamental change positively affected patient care because it allowed the clinician to provide a more accurate diagnosis and thus achieve better treatment outcomes [4]. The quality and efficiency of medical services have greatly improved due to the integration of IoT elements into medical devices. Today, IoT technology is widespread in hospitals. It has gotten to the point that many doctors, nurses, and healthcare professionals have abandoned paper in favor of tablets and other Wi-Fi-connected devices [3]. With all these changes and developments, the digital transformation of healthcare has created several difficulties affecting patients, healthcare workers, technology innovators, policymakers, and others. Data interoperability is an ongoing difficulty due to the massive amounts of data generated from various systems that store and encode data differently [5]. These concerns, in turn, raise questions about security and privacy. For example, what if medical devices are hacked? Or what if this sensitive patient data is accessed, leaked, or tampered with?

Data and information are among the most important considerations that must be considered when developing and building IOT to avoid any potential risks related to security. The primary concern of network devices is data protection. Security is paramount in the field of IoT because unauthorized access to or interference with IoT equipment, especially when used for major IoT applications, can endanger human life [6]. The IoT environment deals with a huge amount of private and sensitive health data that must be kept safe from tampering or theft. If safety precautions are not implemented, these dangers and assaults against IoT devices in the health sector might completely destroy this industry. These attacks are often carried out to make money, either by selling the stolen data or by holding the victim's data at ransom to release their data.

The main objective of this research is to build and design a suitable model based on machine learning techniques to increase the accuracy of detecting malicious and benign attacks in an IoT environment using the standard NF-ToN-IoT dataset consisting of network traffic attributes based on different protocols to analyze traffic tracking and behavior of networks and identify malicious attacks. Then, using a

preprocessing and feature selection step, the most important features were extracted, and the dimensionality of the dataset was reduced. Supervised classification algorithms were then applied, which included RF, SVM, DT, ANN, and NB classification algorithms that allow the identification of malicious and benign traffic, which helped in developing an effective intrusion detection system (IDS) that can identify a variety of attacks. The proposed model was then evaluated based on the most appropriate metrics. Finally, compare the proposed model with the latest developments in this field. The contributions of our technology are listed below as detailed previously:

- Proposing an appropriate Machine learning (ML) model for Cyber-attack intrusion detection, by using the NF-ToN-IoT dataset and applying classification techniques that include RF, SVM, DT, ANN, and NB algorithms.
- Evaluation of the proposed model based on the most suitable metrics.
- Comparing the proposed model with state-of-the-art in this field.

The remainder of this research is organized as shown below. The literature review on intrusion detection through the application and use of machine learning and deep learning techniques based on different datasets is summarized in Section II. Section III contains a comprehensive explanation of the methodology proposed for this research. The model implementation and evaluation of the machine learning algorithms implemented in this work and the results of each of them are presented in Section IV, while the obtained result and discussion compared to previous studies are presented in Section V. Finally, the conclusion and future work is presented in Sections VI and VII, respectively.

## II. LITERATURE REVIEW

This section will provide an overview of the available studies and research related to the issue of securing the Internet of Things device in the e-Health system.

Zhu et al. [7] recommend using a nonlinear kernel support vector machine (SVM) to build the e-Diag framework, an efficient and privacy-preserving online medical prediagnosis tool, in an IoT-based e-Health environment. When utilizing e-Diag for online prediagnosis services, sensitive personal health data may be processed without privacy disclosure. On the basis of an improved expression for the nonlinear SVM, a powerful and privacy-preserving classification approach is created, using lightweight multiparty random masking and polynomial aggregation techniques. The SVM classifier and data are hence secure. The approach was tested using the PID database of the UCI machine learning repository.

The focus of the study [8] was on how machine learning affected flow-based anomaly detection in SDN. The authors offered two distinct approaches to intrusion detection systems based on deep neural networks (DNN) and machine learning. The NSL-KDD dataset was employed in the first technique, and feature selection based on the RF classifier led to an

accuracy rate of 82%. However, when paired with DNN-based IDS, the second technique had an accuracy of 88%.

The authors of this study [9] compare the performance of ANN and Random Forest models using a dataset created by combining the benign and malicious datasets for detecting the Mirai virus in relation to seven IoT devices. The NBaloT dataset, which contains information on the features infected with the Mirai virus, is used to propose a novel technique that relies primarily on machine learning technology. In order to avoid over-fitting, the data partitioning approach known as mutual validity was applied, and ANN was used to conduct the experiment. The accuracy attained is 92.8%. The Opcode data collection, which includes 69,860 harmful programs and 70,140 examples of common malware, was employed in this study.

The study [10] is built on a deep learning-based technique for Internet of Things intrusion detection. The researchers discovered that security vulnerabilities rise as the number of Internet of Things devices rises. As a result, a Bot-IoT data set was utilized to compare deep learning techniques like CNN with machine learning techniques like RF and MLP. Through their expertise, CNN attained the maximum accuracy of 91% and the lowest accuracy of 88%.

A novel deep learning-based intrusion detection system for IoT networks and devices is presented by the authors in another paper [11]. A four-layer fully connected (FC) deep network architecture is used by this system to identify malicious traffic that may be used to target linked IoT devices. In order to simplify deployment, the suggested system was created as a communication protocol-independent solution. The ground-breaking IDS powered by deep learning maintain an average detection rate of 93.21%. It made use of the DID dataset.

With the use of outside resources, the authors of this study [12] suggest a comprehensive multi-level, privacy-preserving SVM training and illness diagnosis system. For encrypted data, certain efficient fundamental operational algorithms have been developed. Next, a model training procedure that is effective and protects privacy was created utilizing fundamental operational methods. Then, using the BFV coding system and cryptography method, they created a successful Internet-assisted illness diagnostic scheme. The user only needs to execute a limited number of encryption and decryption operations under their suggested method, which uses cloud servers to accomplish the majority of the illness diagnoses. The efficiency of Internet-assisted illness diagnosis has increased by 85.4% with a total computing cost of 0.175 seconds.

In [13] their study Detecting Cyber Intrusion Using Machine Learning Classification Techniques, the authors demonstrate how artificial intelligence, in particular machine learning techniques, may be utilized to develop a workable data-driven intrusion detection system. Numerous well-known machine learning classification algorithms, such as the Decision Tree, Random Decision Forest, Random Tree, Decision Table, and Artificial Neural Network, have been used to detect intrusions as a result of providing intelligent services in the field of cybersecurity. They conducted studies

to achieve an accuracy of 94% in RF using KDD'99 cup datasets.

The authors of [14] proposed an algorithm to predict patients' current health status in addition to continuing professional monitoring. Additional parameters and methods, such as K-nearest neighbor, logistic regression, support vector machines, random forests, and Adaboost classifiers, are considered using the UCI heart disease dataset. They were successful in providing a tool that would aid patients, medical professionals, and the healthcare system. This way of decision-making is 93% accurate.

IoMT systems are described in [20] as having to manage a sizable amount of data that might be utilized for illness diagnosis, prediction, and monitoring. Medical data about patients should be transferred to cloud storage and external computer devices, respectively, as certain IoMT devices have limited storage and processing capabilities. Security and privacy risks may arise as a result of this approach. A swarm neural network-based approach for identifying intruders in IoMT has been offered as a solution to these problems. The suggested model explores the possibility of properly and effectively evaluating healthcare data as well as identifying intruders during data transfer. An NF-ToN-IoT dataset was used to assess the system's performance, and the findings show that the suggested model achieves 89.0% accuracy.

Based on the above, after examining all the previous studies that were collected and explaining their work and results in detail, it becomes clear that all of them achieved different results through the use of different data sets and algorithms, but the highest accuracy result among them was 94%, while the methodology proposed in our work achieved accuracy higher than all previous studies, reaching 98%.

### III. METHODOLOGY

In this section, the choice of the dataset, as well as the description of its specifics, is discussed. In addition, the dataset pre-processing techniques as well as the feature selection are deliberated. Finally, the model implementation is described.

#### A. Dataset Selection and Description

NF-ToN-IoT was chosen as the data set for this research since it contains a variety of heterogeneous data sources collected from Telemetry datasets of IoT sensors. It contains ten features, and nine types of attacks, namely, (XSS, DDoS, DoS, password cracking attacks, reconnaissance, or verification, MITM, ransomware, backdoors, and injection attacks) [15] [16]. The assaults detected in the dataset used in this study may be classified and defined using the terms below:

1) *XSS attack*: Using XSS technology, malicious code can be injected into trusted Internet applications, such as the web pages of Internet of Things services. In XSS assaults, the attacker transmits malicious code to several end users via an online application, typically a browser-side script.

2) *DDOS attack*: Most of the time, a botnet—a collection of compromised machines—conducts this kind of attack. The

victim's IoT resources are flooded and depleted by this attack's many connections.

3) *DoS attack*: A DoS attack is any attempt to compromise the resources and services of an IoT network. Making IoT services inaccessible is the goal of such an attack.

4) *Password cracking attack*: This hacking approach is used to guess potential password combinations until the precise password is found. Examples include dictionary attacks and brute force assaults. Passwords for IoT services, operating systems, and web apps placed on the test bench can be cracked using this technique.

5) *Scanning attack*: This attack seeks to gather details about test bed network victims' computers, such as active IP addresses and open ports. This assault is the initial phase of a penetration test, often known as an investigation or a cyber-death chain model.

6) *MITM attack*: This kind of attack may happen when hackers place themselves in the middle of users and programs to watch over them or appear to be one of them, creating the false impression that information is flowing normally. Data about networks, online apps, and IoT services might be taken in these hacking scenarios.

7) *Ransomware attack*: It is an advanced form of malware assault that encrypts systems or services and renders them inaccessible to regular users until they pay a ransom. IoT devices and applications might be the target of ransomware attacks since they carry out essential functions.

8) *Backdoors attack*: An attacker can use backdoor malware to obtain unauthorized remote access to infected IoT systems. By controlling infected IoT devices, this threat may launch botnet-based DDoS attacks.

9) *Injection attack*: Attackers use injection techniques to introduce real or fake input data from clients into their targets' systems, such as SQL injection to attack ASP and PHP programs.

Compared to other datasets, the NF-ToN-IoT dataset is appropriate for IoT since it captures the heterogeneous character of contemporary IoT networks. Regarding the statistics of the dataset, the NF-ToN-IoT dataset comprises a total of 1,157,994 rows. The number of rows varies for each attack type, with injection attacks having the highest number of rows (460,812) and ransomware attacks having the lowest number of rows (142). Here is a breakdown of the number of rows for each attack type and benign type in Table I:

TABLE I. STATISTICS OF DATASET

Label	Count
Benign	198450
Backdoor	17243
Ddos	197680
DoS	17056
Injection	460812
Mitm	1288
Password	144792
Ransomware	142
Scanning	20618
Xss	99913

The NF-ToN-IoT includes telemetry data from linked devices, Linux operating system data, Windows operating system logs, and IoT network traffic, among other data sources acquired from the entire IoT system. A medium-scale IoT network provides diverse data. The UNSW Canberra IoT Labs and the Cyber Range designed NF-ToN-IoT. Furthermore, the NF-ToN-IoT is represented in CSV format with a labeled column indicating attack or normal and a sub-category attack type. A CSV is a comma-separated value file, which allows data to be saved in a tabular format. CSV files can be used with most any spreadsheet program, such as Microsoft Excel.

### B. Exploratory Data Analysis

Exploratory Data Analysis (EDA) is one of the essential procedures that can be done on a dataset for several reasons. EDA aims to familiarize the user with the data and provide an understanding of how the data is distributed. Additionally, EDA allows the identification of patterns and relationships between parameters present in the data. EDA is also important because it provides insight into the selection of data and aids in the perfect execution of machine learning tasks [17]. This research used different visualizations as an EDA procedure to understand the NF-ToN-IoT dataset.

The bar graph in Fig. 1 illustrates the different categories of attacks that are present in the selected NF-ToN-IoT dataset, where it contains benign attacks, dos, injection, DDoS, scanning, password, Mitm, XSS, backdoor, and ransomware attacks. The bar graph representation of the dataset shows that the dataset is imbalanced, where different counts of the categories can be seen.

The attack with the most count in the NF-ToN-IoT dataset is the injection, where there are more than 400,000 attacks belonging to it. The second most common attacks are DDoS

and benign attacks, where there are approximately 200,000 of each one of them. The other attacks vary in number, whereas the Mitm and the ransomware attacks are absent in this dataset (zero count).

Furthermore, several features within the dataset can be visualized through histograms to show their form of distribution. For instance, Fig. 2 above represents the distribution of TCP\_FLAGS, FLOW\_DURATION, IN\_PKTS, OUT\_PKTS, PROTOCOL, OUT\_BYTES, L4\_DST\_PORT, and L4\_SRC\_PORT. The representations in Fig. 2 show that all of the features have skewed distributions, whereas only L4\_SRC\_PORT and TCP\_FLAGS have a relatively uniform distribution. The skewness of the features means that they are not well-rounded around the mean value of the feature, which could affect the output results. For this reason, the features with skewness might be subjected to transformation in order to be suitable for use in ML techniques.

### C. Model Architecture

The models were trained using the chosen features representing attack behaviors in this phase. The proposed models were then tested by comparing test data to training data to determine the accuracy of each of the models. The model was only considered ready if the accuracy test was satisfactory; otherwise, the model was retrained until an acceptable accuracy was reached. For performance comparison, algorithms like ANN, RF, SVM, DT, and NB classification techniques were implemented.

These algorithms were chosen because researchers widely use them to detect unusual traffic. Furthermore, they are simple and light, they do not require many operations, they are highly accurate, and they have fewer input features. The architecture of our proposed framework is described in Fig. 3.

Fig. 1. Distribution of attacks in the NF-ToN-IoT dataset.

Fig. 2. Distribution of several features in the NF-ToN-IoT dataset.

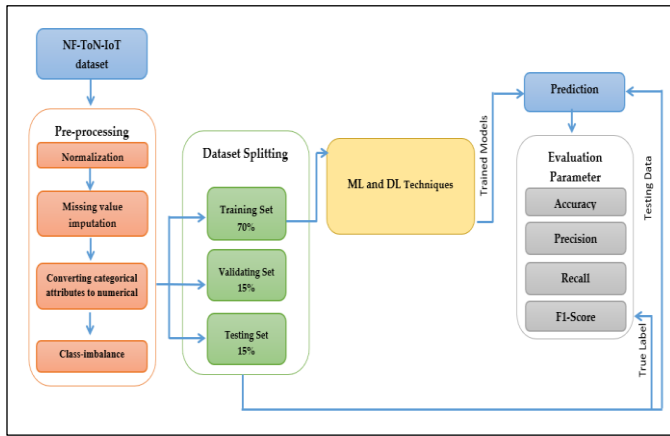

Fig. 3. Architecture of the proposed framework.

As shown in Fig. 3, our framework starts with the acquisition of the NF-ToN-IoT dataset. Then, an essential step is performed, which is the data pre-processing including normalization, imputation of missing values, conversion of categorical attributes to numerical ones, and fixing class imbalance. After the completion of pre-processing, the dataset is subjected to splitting into three different sets: training set (70%), validation set (15%), and testing set (15%). The training set is used for training the ML models (namely, NB, RF, DT, ANN, and SVM). After the training step, the models performed predictions on the testing set in order to find out if the model could accurately generate a result. Different parameters were used for evaluation, such as accuracy, precision, recall, and F1 score.

#### D. Dataset Pre-Processing

Converting unprocessed data into a format that can be read, accessed, and analyzed is known as data pre-processing. Before using ML and DL algorithms, pre-processing is crucial for ensuring or improving any system's overall performance or accuracy. Data is cleaned during the pre-processing phase to

serve a variety of purposes. Some ML algorithms need data in a specific format to ensure the data collection is suitable for many algorithms. The NF-ToN-IoT dataset used in this research presented several challenges, such as missing values, categorical attributes, and class imbalance. To address these issues, the following pre-processing steps were performed:

1) *Missing value imputation*: The NF-ToN-IoT dataset was checked for missing values, but after inspection, it was found that no missing values were found. Therefore, the data set was found to be of high quality and value.

2) *Converting categorical attributes to numerical*: As shown in Table II, the NF-ToN-IoT dataset contains different category features, and the category's attributes must be given numerical values. The conversion process was carried out through LabelEncoder.

TABLE II. CATEGORICAL ATTRIBUTES CONVERTED TO NUMERICAL

Label	Encoded Label	Count
Benign	0	198450
Backdoor	1	17243
Ddos	2	197680
Dos	3	17056
Injection	4	460812
Mitm	5	1288
Password	6	144792
Ransomware	7	142
Scanning	8	20618
Xss	9	99913

3) Class imbalance: Distributions with class imbalances afflict the NF-ToN-IoT dataset. The problem of class imbalance often arises when some classes are far more prevalent than others. Standard classifiers frequently disregard the little classes in these situations because they are too overwhelmed with the large classes.

To address this issue, the SMOTENN (Synthetic Minority Over-sampling Technique and Edited Nearest Neighbors) method was applied to balance the classes in the dataset. The SMOTENN method oversamples the minority class using synthetic data generation (SMOTE) and removes noisy samples using nearest neighbors (ENN) to balance the dataset. Table III shows the number of rows for each attack type before and after applying the SMOTENN method:

TABLE III. DISTRIBUTION OF CLASSES BEFORE AND AFTER SMOTENN

Label	Before	After
Benign	198450	434938
Backdoor	17243	456873

### E. Feature Selection

Giving each potential feature a score before choosing the top features is the feature selection procedure. For intrusion detection, many factors must be examined; certain features will be useful, while others will be useless. Each prospective feature is given a score as part of the selection process, which selects the best (k) attributes [18].

A function of both is obtained by independently calculating the frequency of a feature in training for each positive and negative class occurrence. Removing non-essential features improves performance by reducing overfitting, speeding up the calculation, and enhancing accuracy. We'll utilize the filter method Chi2 for the feature selection technique. A statistical method called the Chi2 technique filters out features that aren't as dependent on the class labels as others, and it calculates a score based on feature dependency [19]. The selected features and their scores obtained from the Chi2 technique are presented in Table IV. The scores are calculated based on the frequency of each feature in the training data for both positive and negative class occurrences. The top (k) attributes with the highest scores are chosen for the final feature set.

The selected features contribute significantly to the intrusion detection task by improving the model's performance. Therefore, the seven features shown in Table IV were chosen and were considered the best in terms of influencing the classification process, while if the number of features were increased, they would not have an impact on the classification process. Removing non-essential features reduces overfitting, speeds up computation, and enhances model accuracy.

TABLE IV. SELECTED FEATURES AND THEIR SCORES

Feature	Score	Selected

## IV. MODEL IMPLEMENTATION AND EVALUATION

In this section, the obtained results of the proposed models are discussed, starting with exploratory data analysis, followed by an evaluation of each of the proposed models. In this study, the proposed models to be evaluated are Random Forest RF, Support Vector Machine SVM, Decision Tree DT, Artificial Neural Network ANN, and Naïve Bayes NB classifier.

### A. Evaluation Metrics

A variety of methodologies for assessing the effectiveness of the ML techniques employed are chosen and specified in order to offer a thorough and accurate description of the findings achieved. In this paper, the used models were trained on an NF-TON-IoT dataset, and then a collection of data isolated from these models was utilized to assess the trained models' accuracy by correctly separating all the data into its various labels. Accuracy, Precision, F1-Score, and Recall are the measures used to evaluate the algorithms' efficacy. Each equation can be defined separately as follows:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN}$$

$$\text{Precision} = \frac{TP}{TP + FP}$$

$$\text{Recall} = \frac{TP}{TP + FN}$$

$$\text{F1 Score} = \frac{2 \times (\text{Precision} \times \text{Recall})}{\text{Precision} + \text{Recall}}$$

1) *Accuracy*: if the classifier can correctly classify the data points, then it is said to have a high accuracy. Accuracy is

represented by the number of correctly predicted instances divided by the total number of predictions.

2) *Precision*: Precision takes into consideration the positive outcomes by the model in comparison to all of the positive outcomes whether they were correctly predicted or not. For this reason, the equation of precision is the ratio of correctly predicted positive outcomes (TP) over all of the positive outcomes (TP and FP).

3) *Recall*: Recall is also known as sensitivity, which represents the fraction of the truly identified positive predictions over the total number of positive instances (represented by TP and FN) because FN should have been predicted as positive results.

4) *F1 Score*: The F1 score combines both precision and recall into a single metric that provides a balanced evaluation of the model's performance. It is a useful metric when there is an uneven class distribution such as in the NF-ToN-IoT dataset.

In all of these equations:

TP stands for True Positive which represents the number of correctly predicted positive instances.

TN stands for True Negative which represents the number of correctly predicted negative instances.

FP stands for False Positive which represents the number of falsely predicted positive instances.

FN stands for False Negative which represents the number of falsely predicted negative instances.

**B. Models' Evaluation**

The evaluation of the different algorithms used is presented separately in this section, which includes RF, SVM, DT, ANN, and NB classifiers. Based on their outcomes on the test dataset, the suggested algorithms' performance is assessed. The performance of models may be assessed using a number of measures, including accuracy, precision, recall, and F1 score. This is how it appears:

- Naïve Bayes:

A supervised machine learning method called the Naive Bayes NB classifier is utilized for classification tasks like text categorization. It also belongs to the family of generative learning algorithms, which implies that it attempts to simulate how an input's distribution varies depending on the class or category.

Upon testing, the Naïve Bayes classifier was able to achieve 72.75% accuracy, which is equivalent to 0.7275. This value indicates that 72.75% of the instances were correctly predicted by the NB classifier. The NB classifier also achieved 0.7567 precision values, which means that out of all of the positively identified instances, 75.67% of them were correctly predicted by the model. A 0.7275 value for recall indicates that the NB model identified 72.75% of the actual positive instances as true positive. Finally, the F1 score achieved by NB was 0.7051 which is a low value, and it means that the overall performance of the model was around 70% well. These

numbers are illustrated in Table V. In addition, a Confusion Matrix Heatmap was generated for the Naive Bayes Classifier in Fig. 4:

TABLE V. NAIVE BAYES CLASSIFIER PERFORMANCE METRICS

Metric	Value
Accuracy	0.7275
Precision	0.7567
Recall	0.7275
F1 Score	0.7051

Fig. 4. Confusion matrix heatmap for the naïve bayes classifier.

- Random Forest:

Classifier with Random Forests This classifier is utilized because of its improved accuracy and because it bases its final prediction on predictions from several decision trees rather than just one. Even if the settings are left alone, this supervised machine-learning method produces great results. In order to establish a final categorization of the attack and normal data, tree prediction was also applied.

The random forest model achieved 98.41% accuracy, a 0.9840 precision value, a 0.9841 recall value, and a 0.9840 F1 score, as shown in Table VI. The values shown in the table indicate that the RF classifier achieves a high accuracy rate, where it correctly classified 98.4% of all of the instances in the data. Similarly, it correctly identified the true positives in 98.4% of the total positive instances and the actual positive instances (precision and recall, respectively). Furthermore, the overall performance of the RF model is represented by the high F1 score, which is 0.9840. Fig. 5 shows the Confusion Matrix Heatmap for the Random Forest classifier.

TABLE VI. RANDOM FOREST CLASSIFIER PERFORMANCE METRICS

Metric	Value
Accuracy	0.9841
Precision	0.9840
Recall	0.9841
F1 Score	0.9840

Fig. 5. Confusion matrix heatmap for the random forest classifier.

- Decision Tree:

DT is a well-known construction method that interpolates leaves and branches to resemble a decision tree, where the inner node stands in for the classification rule and the leaves for the class label. The branch also indicates the outcomes. Using the information gained the best branch and root node properties are chosen during the training phase. A decision node is then constructed using the most information gained. As a result, a new sub tree is established beneath the decision node. As the final value will be determined and utilized as the output value, this method will only end if all items in the chosen subgroups have the same value. If there is just one node in the subgroup and no other options, the cycle may also come to an end.

The evaluation metrics for the DT classifier are shown in Table VII and the confusion matrix heat map is in Fig. 6. The Decision Tree classifier accomplished an accuracy of 97.08%, suggesting that the model accurately classified most of the data instances. With a precision score of 97.06%, it showed a high level of correctness when predicting instances as attacks. The recall score of 97.08% indicates the classifier's ability to identify actual attacks accurately from all the positive instances as well. The F1 Score of 97.07% was high, showing a good performance of the DT model.

TABLE VII. DECISION TREE CLASSIFIER PERFORMANCE METRICS

Metric	Value
Accuracy	0.9708
Precision	0.9706
Recall	0.9708
F1 Score	0.9707

Fig. 6. Confusion matrix heatmap for the decision tree classifier.

- Artificial Neural Network:

An ANN is a collection of linked input-output networks with a weight assigned to each network. As an affiliation, one input layer and one or more intermediary layers make up this structure and only one output layer. The Artificial Neural Network reached an accuracy of 93.20%, demonstrating its ability to classify data instances with a high level of correctness. With a precision score of 93.16%, the classifier presented a strong accuracy when predicting instances as attacks. The recall score which is also the sensitivity value is 93.20%, meaning that the classifier is very effective in identifying actual true attacks in the dataset. The F1 Score of 93.09% shows a good overall performance of the model. The evaluation metrics for the ANN classifier are shown in Table VIII and the confusion matrix heatmap is in Fig. 7.

- Support Vector Machine:

A well-known classification method that can handle both linear and non-linear datasets is Support Vector Machine SVM. It is founded on the idea of separation between hyperplanes, with SVM's main objective being to find the optimal hyperplane that widens the gap between groups. In general, several kernel functions, ranging from linear to nonlinear kernels, may be utilized to describe the hypersurface. It is an approach to supervised machine learning that may be applied to classification or regression issues. It transforms your data using a method known as the kernel trick and then determines the best boundaries between potential outputs based on these alterations.

TABLE VIII. ARTIFICIAL NEURAL NETWORK PERFORMANCE METRICS

Metric	Value
Accuracy	0.9320
Precision	0.9316
Recall	0.9320
F1 Score	0.9309

Fig. 7. Confusion matrix heatmap for artificial neural network.

The Support Vector Machine classifier was able to accurately predict 77.09% of the overall instances in the data. In addition, it accurately predicted 79.2% of the True positive instances compared to all of its predicted positive instances (0.79 precision), and it truly identified 77% of the actual positive instances (0.77 recall). Finally, the overall performance was evaluated by the F1 score, achieving a 75.27% value. Table IX shows the performance of the Support Vector Machine classifier and the confusion matrix heatmap for SVM is shown in Fig. 8.

TABLE IX. SUPPORT VECTOR MACHINE (SVM) PERFORMANCE METRICS

Metric	Value
Accuracy	0.7709
Precision	0.792
Recall	0.7709
F1 Score	0.7527

Fig. 8. Confusion matrix heatmap for SVM classifier.

Finally, from the obtained results, the performance of all five classifiers can be compared to selecting the model that is best suited for the task of identifying attacks in the NF-ToN-IoT dataset. Table X shows that the Random Forest RF classifier was able to score the highest accuracy (0.98), followed by the Decision Tree DT classifier (0.97) and the Artificial Neural Network ANN model (0.93). On the other hand, the Support Vector Machine SVM model scored a low accuracy of 0.77, whereas the lowest accuracy was achieved by the Naïve Bayes NB classifier (0.72). As for the other metrics, such as precision and recall, they can be summed up by the F1 score. The highest F1 score was achieved by the Random Forest RF Model (0.98), followed by the Decision Tree DT and Artificial Neural Network ANN (0.97 and 0.93, respectively). A low F1 score was attained by the Support Vector Machine SVM model (0.75), but the lowest F1 score was for the Naïve Bayes NB classifier, where it scored only 0.7051. A visual representation of the performance of the 5 classifiers in terms of accuracy, precision, recall, and F1 score is shown in Fig. 9.

TABLE X. COMPARISON OF THE PERFORMANCE OF THE 5 DIFFERENT CLASSIFIERS ON THE NF-TO-N-IOT DATASET

## V. RESULT AND DISCUSSION

The inability of standard security systems relying on signatures and rules to identify complex breaches is well recognized. Therefore, utilizing ML and deep learning techniques and various datasets, a number of architectures and algorithms have been created in the prior literature to identify assaults and aberrant behaviors in IoT networks. The studies cited in the literature review were able to achieve relatively good and other not-so-good results. Some studies achieved low accuracy of 85%, 88%, and 89% through RF, DNN, SVM, BFV, and swarm NNs techniques in both [8], [12], and [20]. Other results were able to achieve higher accuracies. For instance, Other studies achieved higher accuracy, ranging from 91% to 92%, by using CNN, RF, and ANN techniques in both [10] and [9], while studies in [11], and [14] achieved an accuracy of 93%. Through IDS and KNN, RF, SVM. On another hand, the studies in both [7] and [13] achieved an accuracy of 94%, which is considered the highest accuracy among the studies through the use of SVM and RF algorithms.

When comparing our methodology, a higher accuracy than all previous studies was achieved by 98% with the RF model.

While it achieved accuracy for both the Decision Tree classifier (0.97) and the artificial neural network model (0.93). On the other hand, the Support Vector Machine model scored a low accuracy of 0.77, while the lowest accuracy was achieved by the Naïve Bayes classified as 0.72. Additionally, the bulk of the researches mentioned in the table used ML and DL systems that were deemed untrustworthy since they were trained mostly on an outdated and unreliable dataset with low accuracy. A more current data set was produced to address this issue and published in [15] [16], which were included in our technique.

The diverse character of the Internet of Things is reflected in this dataset, also known as NF-ToN-IoT. Even though NF-ToN-IoT is better suited for IoT contexts, earlier literature was found to lack data-gathering implementation. Because there aren't many references that utilize the same dataset that we used in our study, a variety of references were employed. A number of references were used that apply to and use different datasets. The following Table XI shows a comparison of our models with other work in the literature review. Also, the visual representation of these results can be seen in Fig. 10.

## VI. CONCLUSION

The internet of things IoT environment deals with a huge amount of private and sensitive health data that must be kept safe from tampering or theft. If safety precautions are not implemented, these dangers and assaults against IoT devices in the health sector might completely destroy this industry. These attacks are often carried out to make money, either by selling the stolen data or by holding the victim's data at ransom to release their data. In the healthcare sector, using technology especially IoT technology can be a big leap forward towards providing a better service for patients and facilitating communications and sharing essential files or tasks. For this reason, implementing IoT in healthcare is essential.

However, several privacy and security concerns arise when using IoT. If safety precautions are not implemented, these dangers and assaults against IoT devices in the health sector might completely destroy this industry. These attacks are often carried out to make money, either by selling the stolen data or by holding the victim's data at ransom to release their data.

Thus, it becomes equally important to implement a system that can provide security while implementing IoT. In this research, five different classifiers were employed to predict the occurrence of attacks while using IoT services. For this purpose, the NF-ToN-IoT dataset was selected, where the data were pre-processed before being split into training and testing data. Upon testing the models, it was evident that the RF model achieved the best results; scoring the highest accuracy (0.98) and highest F1 score (0.98). The second-best model was DT classifier, followed by the ANN model.

## VII. FUTURE WORK

The future works aim to experiment with models with different algorithms and different data sets, as well as to

combine several deep and machine learning algorithms, in order to come up with models that give the highest possible accuracy rates and the lowest possible loss rates to obtain the best optimal results in classifying attacks in IoT devices in the electronic health sector and a comparison between data sets and algorithms.

## ACKNOWLEDGMENT

The Vice Presidency for Graduate Studies and Scientific Research at Jouf University is funding this study as a part of its initiative to encourage scientific publications.

Department of Electronics & Communication Engineering-PES College of Engineering, Mandya, India<sup>2</sup>

**Abstract**—UAV Videos and other remote-sensing innovations have increased the demand for multispectral image stitching methods, which can gather data on a broad area by looking at different aspects of the same scene. For large-scale hyperspectral remote-sensing images, state-of-the-art techniques frequently have accumulating errors and high processing costs. However, this research paper aims to produce high-precision multispectral mapping with minimal spatial and spectral distortion. The stitching framework was created in the following manner: First, UAV collects the raw input data, which is then labeled as a signal using a connected component labeling strategy that correlates to each pixel or label using the EEG (Alpha, Beta, Theta, and Delta) technique. Next, the feature extraction process follows a novel decortification Hydrolysis CNN approach which extracts active and passive characteristics. Then after feature extraction, a novel chromatographic classification approach is employed for separating features without overfitting. Finally, a novel yield mapping georeferencing technique is employed for all images stitched together with proper alignment and segmented overlapping fields of view. The suggested deep learning model is an effective method for real-time mosaic image feature extraction which is faster by an average of 11.5 times compared to existing approaches as noted on the samples for experimental analysis.

**Keywords**—EEG signal extraction; feature extraction; image stitching; multispectral image; UAV video

## I. INTRODUCTION

Unmanned Aerial Vehicles (UAVs) fascinated a whole lot of people in many nations as soon as they were developed and have since been widely used in both the military and civilian sectors (such as for mapping, catastrophe monitoring, and crowd monitoring) as well as for in-flight investigation and border patrol. The photographs captured by UAVs have several undesired qualities, like big numbers, short image vicinity, a partly cover degree, and multiple strips, due to the restrictions of flying height and camera focal length. It is crucial to achieve a complete panoramic perspective using quick image fusion techniques to gain more detailed information and broaden the range of vision in many particular tasks [1]. The usage of image fusion technology, which has become a hot research area, is common in multimedia applications including virtual reality, remote sensing image processing, and video surveillance where the watching component has a tiny field of view but the expected observation is large. Users have access to a variety of software applications, like Autopano and Panorama Photo Stitcher, in the market for creating panoramas.

According to the registration strategy, there are four broad groups for picture mosaic techniques [2]. The first technique relies on the intensity levels or colors of each pixel; while this scheme is straightforward, it performs poorly in terms of noise avoidance and blending effectiveness. The second technique relies on the transform features, which has high noise resistivity, but the stitching requires a lot of calculations and the results are subpar when the image changes in view perspective or zoom. The other technique is based on features, for which the stitching efficiency, resilience, and accuracy of the algorithms are often high and they are typically similar to image size editing, transformation, and rotation. The three conventional feature extraction algorithms are Harris, Scale-Invariant Feature Transform [3], and Oriented Fast and Rotated Brief. On deep learning, the final one is based. Many deep learning methods based on feature extraction and matching have been created to perform picture registration [4]. Despite the recent advancements in image mosaic technology, several techniques still fall short of the instantaneous, reliable, and accuracy demands of UAV image fusions. UAV pictures have a lot of data, tiny phase amplitude, and a higher degree of overlapping [5], among other qualities. Since a UAV video/image contains a lot of data, the mosaic process takes an unacceptably long time [6]. Second, because they are frequently small, UAVs struggle to maintain themselves and are poorly wind-resistant. There will unavoidably be some tilting when taking pictures, even though they have an autopilot and a stabilizing gyroscope. Images captured by UAVs contain significant affine distortion in comparison to the actual scene due to the geometric distortion of the camera caused by the lens [7]. To address this problem, researchers have proposed mounting high-resolution cameras on a UAV. The dimensional fault, which is the difference between the relative offset and the absolute offset, can be thought of as low-frequency noise brought on by the UAV drift, and it can be addressed by using a high-pass filter [8].

The projection matrix-based approach can also be used to extract supreme structural offset from the drone footage, presuming that out-of-plane offsets can be disregarded. The projection matrix was determined using stationary backdrop features, and then it was further honed using the constrained bundle adjustment optimization approach to reduce the re-projection error. Additionally, for this technique to work, the camera must move rather quickly; otherwise, the camera settings in successive frames would be very much close, which will cause a major inaccuracy when applying the bundle

adjustment. However, in-field measurements, the expanse between immobile locale objects and the drone is typically many times greater than the drone motion itself, thus making this approach inapplicable. With the help of homography, also referred to as perspective transformation, it is possible to adjust the camera movement for a planar outlook without the use of camera constraints [9].

Although the homography related methods are numerically effective, there are numerous obstacles in the way of its straight-forward application to the counting of dynamic offsets of massive structures. Because of the limited pixel resolution, it's possible that the camera won't be able to sufficiently capture both the offset measurement points and immobile areas of the organization (i.e., the homography characteristics) in a single image. However, choosing at random from these areas could cause big inaccuracies in the homography computation result. The chosen homography characteristics is expected to be over or near the flat surface in which structural motion occurs since homography requires a planar scene and not all random homographies are realistic picture alterations [10]. And the system's created aerial panorama could have poor aesthetic flaws at pivot points. Then, the stitching is successful for neighboring frames in image sequences where the stitching has been successful in order, but it can be challenging to guarantee the overall stitching effect in multistrip long-distance trips [11]. Additionally, it is challenging to produce useful data from sequences gathered by UAVs during multistrip missions and it is laborious to manually track the chosen homography elements in each frame of a video. The stitching effect, however, can be diminished with a greater volume of images and much identical parts in the prospect [12]. However, it is difficult finding a stationary landmark during an earthquake.

In this work proposed, a novel live drone image mosaic system is proposed. The main contributions are as follows:

- First, proposed a state-of-the-art, real-time framework for drone image mosaicking. The architecture comprises automatic initialization, feature extraction & classification, and live mosaic generation. The setup procedure uses EEG to automatically identify the image clips based on brainwaves (Alpha, Beta, Theta, and Delta).
- After that, all four of these brainwaves are subjected to a feature extraction procedure utilizing deep learning, where a mixture of alpha and beta is used to examine active features while theta and delta are used to consider passive features.
- After feature extraction, the classification process is done then finally real-time mosaic creation makes up the framework's entire structure.
- The primary tasks required in the controlling of large areas, including mosaicking, feature extraction, and classification, are improved in accuracy compared to existing drone-based techniques.

The remaining portion of the paper is structured as follows: Section II explains briefly the existing literature and the research gaps. Section III gives an overview of the proposed

work. Section IV details the proposed system architecture. Section V discusses the results and analysis of implementation. Section VI finally concludes the work.

## II. RELATED STUDY

There has been interesting works available in the literature that paves way for the growth of the techniques and the technology responsible for image applications. Avola et al. [13] proposed the best parameters to automatically predict, specifically, depth and frame rate to recognize the three factors in previous section are suggested and tested. The dimensions of the aimed object to be analyzed, the UAVs' travel speed, and the primary inner dimensions of the video sensor, such as the focal length, field of view, and pixel size, are some of the criteria that are used to estimate the parameters. Both man-made videos produced with the in-flight data and Robotics Simulation (AirSim) and actual film sequences reported in the UAV Mosaicking and Change Detection (UMCD) and NPU Drone-Map datasets served to demonstrate the suggested method's complete effectiveness on the objective. However, ensuring the minimal spatial resolution necessary to complete a given activity is the primary issue to be addressed regarding flying height.

Ranghao et al. [14] proposed a live drone image fusion architecture that solely utilizes the UAV picture frames and does not depend on the global positioning system (GPS), ground control points (CGPs), or any other auxiliary data. Through the use of this framework, it is hoped to produce high-quality panoramas while reducing spatial distortion and speeding up mosaicking operations before choosing key frames to increase efficiency, the framework evaluates the general setting of every new frame to be added. Then, to perform an accurate position computation of the existing scene and lessen the bend brought on by increasing mistakes, a new optimization method based on minimizing weighted reprojection errors is implemented. To produce the best mosaic output, the local picture is fused and updated in real-time using the weighted partition fusion approach based on the Laplacian pyramid. UAVs frequently capture multi-strip and large-scale image sequences, however, it is challenging to create panoramas directly from the stitched photos, and some of the feature points are unstable and challenging to extract.

Srivastva et al. [15] proposed an overview of deep learning methods for on-ground vehicle recognition utilizing aerial data obtained by UAVs (often referred to as drones). To review the works, it is important to consider both the optimization goal and the method used to increase accuracy and decrease computation overhead. To illustrate the parallels and discrepancies between different approaches and to draw attention to the remaining issues in this field, this work is a useful study. Researchers studying AI, traffic surveillance, and UAV applications will find this survey to be useful. However, the processing of a picture takes a long time and results in a lot of false positives.

Woo et al. [16] proposed to drastically lower the error level, identification of fissures was determined using comparative position between components in drone-captured photos rather than using absolute position information. A total of 97 photos were collected using aerial photography. Five

fissures and three reference components were defined using the point-cloud approach, image blending, and homography domain algorithm. Importantly, the comparison of calculated localized values with concrete values obtained from field measurement showed that errors in the range of 24-84 mm and 8-48 mm, respectively, were received based on the coordinates. Additionally, RMSE errors ranging from 37.95 to 91.24 mm were verified. The target concrete construction, however, might not always have enough or the right reference objects accessible.

Rui et al. [17] proposed a Rapid Scale-Invariant Feature Transform (RSIFT) operator to shorten computation time. Then used is the As-Natural-As-Possible (AANAP) technique for picture registration. To remove the motion ghosting, an image segmentation method is used. Finally, a unique collection of aerial photos is created for image mosaics, using which analogous tests using cutting-edge image mosaic techniques are carried out. However, research indicates that SIFT has huge computational complexity.

Zhang et al. [18] proposed an approach based on Oriented Fast and Rotated Brief (ORB) and semantic segmentation. To distinguish between the forefront and surroundings of the image and to get the forefront content, a semantic segmentation network is introduced by the algorithm during image registration. It simultaneously extracts feature points using the quadtree decomposition concept and the conventional ORB approach. The foreground feature points can be removed to achieve feature point matching by comparing the feature point information with the foreground semantic information. The homography domain and the weighted fusion technique will be used to stitch and fuse the images based on precise image registration. However, it is challenging to find trait points in areas with weedy texture, and the major drawback of SIFT is that real-time performance cannot be attained without the aid of hardware or specialized image processors.

In order to locate an intuitively optimal seam in uninterrupted areas of high similarity, Yaun et al. [19] suggested an innovative super pixel-based performance function that incorporates data on material difficulty, color distinction, and gradient difference. Finally, to eliminate seams and provide seamless color transitions, employ an exceptional pixel-based color blending technique. The method is superior to several cutting-edge UAV photo stitching techniques, according to experimental data, and can effectively and rapidly perform seamless stitching. However, owing to the existence of parallax, artifacts always show up in overlapped areas.

Yang et al [20] proposed a straightforward yet effective approach for sewing durable and precise blade images. Introduce the Blade30 dataset, which includes 1,302 real drone-captured photos of 30 entire blades taken in a variety of environments (both on and off-shore) and richly annotated with information on flaws and contaminations, among other things, to encourage further research. By using the recommended patching strategy based on drone-blade lengths and rotor margins at the coarse-grained level, the initial blade portrait is produced. Then, utilizing regression-based roughness and shape losses, fine-grained modifications are optimized. Additionally, this approach makes full use of the drone's

existing knowledge and the characteristics of blade pictures. However, it may be challenging to gather enough labeled data to initiate this, which is primarily due to inefficient inspection techniques.

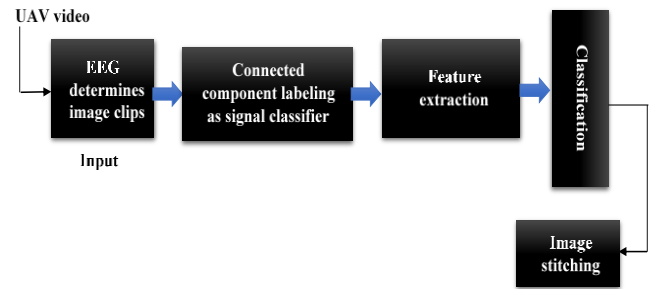

Fig. 1. Block diagram for real-time image stitching of UAV video.

Some of the research gaps identified are: Low-textured picture sewing still presents a number of complicated challenges; since multiple photos were captured from various angles, the patched images also contain projective distortions; Picture stitching combines a number of overlapping images to create a single, larger mosaic with a wider angle of perspective because cameras have a low angle of perspective. Global geometric transformations were typically approximated by older methods for stitching together overlapping pictures; These methods, however, rely on rigid premises that are commonly violated in reality, resulting in defects in the merged images like misalignments or ghosting, such as the camera rotation having a fixed projective center or the scene having a constrained depth variance; Only a small number of points are recognized and matched in some homogeneous regions, making it challenging to predict an exact transformation. The proposed method tries to overcome these challenges and develops an efficient method for image stitching.

### III. OVERVIEW OF THE PROPOSED WORK

The suggested architecture seeks to address the several issues mentioned above for improved target surveillance and real-time image stitching of UAV video. Enhancing real-time target tracks and stitching image serves several purposes, including improved accuracy, easier long-distance stitching, accurate information, and overall performance. It also captures both displacement measurements and homography properties in a single image. UAVs, such as drones or planes, equipped with cameras, sensors, software for control, and interactions, first gather raw data. UAVs can collect visual sensing data via their camera-equipped device. [21]. The pixels or labels in these images are designated as signals, utilizing an analogy to EEG patterns such as alpha, beta, delta, and theta, each linked to distinct frequencies [22]. The process of extracting active and passive features utilizing statistical methodology to ascertain the average weight for all waves and set thresholds is then carried out. If the weighted average value is higher than the threshold, it is considered active else passive. Algorithms based on CNN relate active attributes to alpha and beta, whereas passive attributes are linked to delta and theta. However, this method permits accurate feature extraction,

captures the qualities of both displacement measurement and homography, and has superior accuracy. After this, the classification process follows, effectively segregating these features to prevent overfitting. Finally, using overlapping fields of view, the images are seamlessly combined to provide a segmented, high-resolution image. However, this method makes stitching across large distances simple, provides accurate information, and enhances overall performance. Fig. 1 depicts a block diagram for real-time image stitching of UAV video, which demonstrates raw data. Video is acquired by UAV like a drone or plane, and comprises of a sequence of image clips assessed using EEG. Images are categorized as signals using the connected component labeling technique. Then feature extraction and classification are performed. Finally, the images are seamlessly stitched together to produce a cohesive output.

#### IV. ARCHITECTURE OF THE PROPOSED METHODOLOGY

The proposed design solves low accuracy, overfitting difficulty ensuring stitching effect over long distances, incorrect data, and difficulty capturing both displacement and homography characteristics in a single image. In the beginning, raw data is collected by UAV to capture illustrated sensing information by its camera installed, and the pixels or labels in these images are designated as signals using the connected component labeling technique for using an analogy to EEG patterns such as alpha, beta, delta, and theta, where each linked to distinct frequencies. For removing noise or error in the signal and the signal is then split into two halves using decortification CNN, a proposed feature extraction method that collects both active and passive features. While delta and theta represent passive features, alpha, and beta indicate active features. To identify the alpha, beta, delta, and theta features, use a statistical method. To ensure this, average weights for each wave must be determined, and global thresholds must be set. The characteristic is regarded as active if the estimated weighted average value is higher than the threshold; otherwise, it is regarded as passive.

After feature extraction, classification is carried out by employing the chromatographic approach to separate active and passive features separately without overfitting. However, this approach enables precise feature extraction and categorization and captures both the characteristics of displacement measurement and homography. Finally, a high-resolution image is created by combining all the photographs with their overlapping fields of view, utilizing a yield mapping geo-referenced approach to appropriately align and segment each image. However, this approach makes stitching across vast distances straightforward, high accuracy offers correct data, especially finding stable landmarks after an earthquake is simple and improves overall performance.

The proposed architectural model for the real-time UAV video image stitching process is shown in Fig. 2 which start with the UAV obtaining the raw data and this data comprise a sequence of image clips. Each pixel/label within these images is categorized as a 'signal' using a connected component labeling technique. This idea makes use of the four types of brain waves alpha, beta, theta, and delta to extract active and passive features using CNN, based on their respective

frequencies. The active attributes encompass alpha and beta waves, while the passive attributes encompass theta and delta waves. Subsequently, a classification process utilizing chromatography technique is applied to the extracted features. Finally, the process involves image stitching using a yield mapping geo-referenced technique, seamlessly combining the acquired images.

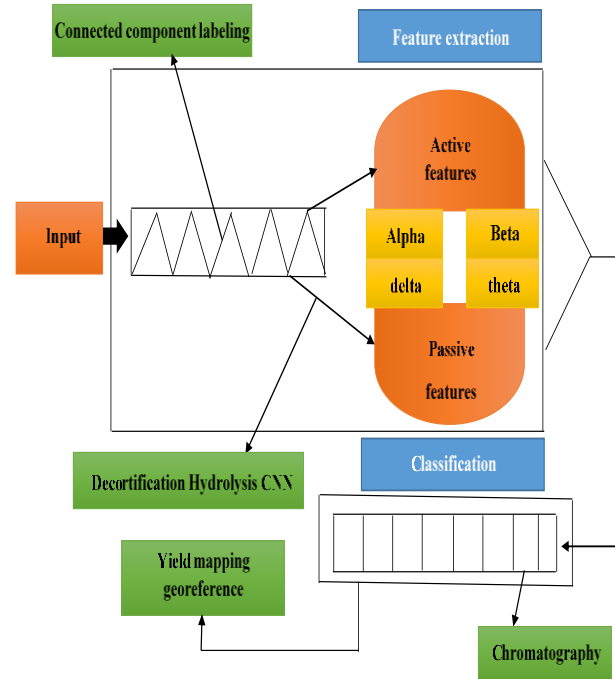

Fig. 2. Proposed architectural model for Real-Time UAV video image stitching.

All of these EEG signal properties (Alpha, Beta, Theta, and Delta) are described below, along with their mathematical expressions:

Average frequency weighting (AFW): The average frequency weighting can be found to estimate the power spectrum of the obtained sequence of signal [22]. Using statistical methods an average value is found for all waves with certain frequency weighting elements. The following mathematical equation can be used to represent the AFW,  $S(k)$  for any N-point signal  $x(n)$ .

$$S(k) = \frac{1}{N} * W \sum_{K=0}^{N-1} |X_p(k)| \quad (1)$$

where  $n$  is a variable that specifies the data points of the time-domain discrete-time input signal  $x(n)$ . For a total number of temporal data points  $N, 0 \leq n \leq N-1$ . Similar to that,  $k$  also refers to a variable that specifies data points in spectral-domain form  $X_p(k)$  of  $x(n)$ . For a total number of spectral data points  $N, 0 \leq k \leq N-1$  [23].

Repeating this calculation across all frequency bands yields the final Power Spectral Density (PSD) values for Delta, Theta, Alpha, and Beta [24].

The PSD according to Welch is expressed by:

$$P_d(f) = \frac{1}{MU} \left| \sum_{k=0}^{N-1} X_p(k)w(k)e^{-j2\pi fk} \right|^2 \quad (2)$$

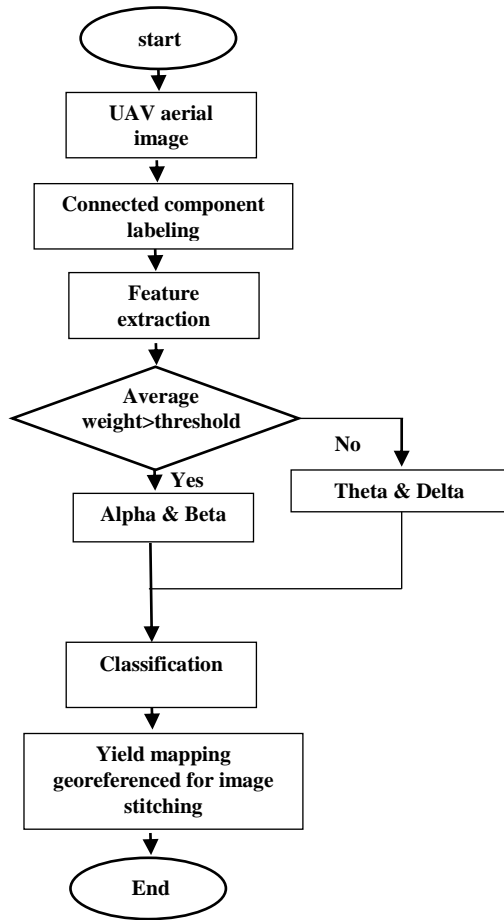

Fig. 3. Flow chart of the proposed architecture.

Let  $x(n)$  be the sequence, with  $N = 1, 2, 3, \dots, N-1$  representing the signal intervals, and  $M$  denoting each interval length.  $U$  is the normalization factor for the power in the window function, and  $w(n)$  is the windowed data, so:

$$U = \frac{1}{M} \sum_{k=0}^{N-1} |w(n)|^2 \quad (3)$$

After extracting all PSD, the alpha, and beta signals are considered active and delta and theta are considered passive features to compare with the overall threshold  $\emptyset$

$$\text{PSD} > \emptyset \text{ or } \text{PSD} < \emptyset \quad (4)$$

The suggested architecture's flowchart is shown in Fig. 3, starting with raw data which is an aerial image that is collected by an UAV as input. A connected component labeling technique is used to classify each pixel or label in these images as a "signal". This concept uses the four different types of brain waves alpha, beta, theta, and delta to extract both active and passive properties. Using a statistical approach, the alpha, beta, delta, and theta features are identified and designated as  $B_1, B_2, B_3, B_4$ , respectively. To do this, average wave weights and global thresholds must be established. The attribute is considered active if the projected weighted average value

exceeds the threshold; otherwise, it is considered passive. The procedure of classification is then performed following feature extraction. Finally segmented using yield mapping georeferenced approach and merged every image with proper alignment.

**Proposed Algorithm:**

Multispectral mapping for image stitching using EEG signal to extract robust feature extraction

**Require:** Multispectral images  $I_p = 1, 2, 3 \dots N$

**Ensure:** Multispectral mapping with high alignment accuracy

**Step 1:** Start  $I_p = 1, 2, 3 \dots N$

**Step 2:** Each pixel in the image is labeled as a signal.

**Step 3:**  $i=1$

**Step 4:** for each sample,  $S_m$  do

**Step 5:** Calculate the average weighted probability for each wave  $B_1, B_2, B_3, B_4$ , and set the threshold  $\emptyset$ .

**Step 6:** Compare weighted probability with threshold

**Step 7:** if  $B > \emptyset$  or  $B < \emptyset$  then

```

{
incorporate  $B_1, B_2$ ;
else {
incorporate  $B_3, B_4$ ;
}
}
i++
end for
    
```

V. RESULT AND DISCUSSION

This section presents the detailed results of the proposed model. To provide a comprehensive performance evaluation, the suggested model was compared to two other models, the SIFT [25] and BRISK [26]. The work was implemented in Python 3.11.4 and the packages used are cv2 and math. Two sample images were used to test the performance of the proposed work.

Fig. 4 shows the input sample 1 image pairs to be stitched. During feature extraction using SIFT algorithm, 4369 features from the first image and 4333 features from the second image are selected as shown in Fig. 5(a) using SIFT. Fig. 5(b) shows the 10038 features and 10774 features selected from images 1 and 2 respectively using BRISK algorithm. Fig 5(c) shows the 500 features from Image 1 and 500 features from image 2 selected using the proposed approach. Fig 6(a), (b) and (c) shows the matching features between the pairs of images using SIFT, BRISK and the proposed algorithm respectively. Fig. 7 shows the sample 1 image pairs fused.

Fig. 8 shows the input sample 2 image pairs to be stitched. During feature extraction using SIFT algorithm, 3532 features from the first image and 2754 features from the second image are selected as shown in Fig. 9(a) using SIFT. Fig. 9(b) shows the 5057 features and 5128 features selected from images 1 and 2, respectively using BRISK algorithm. Fig. 9(c) shows the

475 features from Image 1 and 480 features from image 2 selected using the proposed approach. Fig. 10(a), (b) and (c) shows the matching features between the pairs of images using SIFT, BRISK and the proposed algorithm respectively. Fig. 11 is the stitched image of sample 2 image pairs.

Fig. 12(a) and (b) shows the detection time for feature selection for image mapping for sample 1 image pairs. Fig. 13(a) and (b) shows the detection time for feature selection for image mapping for sample 2 image pairs. The detection time for feature extraction clearly represents that the proposed work is 14 times and ten times faster than the SIFT and BRISK algorithms for the image 1 of sample 1; 17 times and 12 times faster than the SIFT and BRISK algorithms for the image 2 of sample 1; 11 times and nine times faster than the SIFT and BRISK algorithms for the image 1 of sample 2; 9 times and ten times faster than the SIFT and BRISK algorithms for the image 2 of sample 2. Overall, the proposed algorithm on average is 13 times faster than the SIFT algorithm and ten times faster than the BRISK algorithm.

## VI. CONCLUSION

In this work we have proposed a new technique for image fusion using signal extraction technique behind the brain waves using EEG. Decortification technique is used in processing and preparing the images for matching and blending. Live UAV video frames are fused and can be used for various applications like target tracking and distance measurement. The proposed work is able to choose optimal features with good image understanding. The suggested approach outperforms the SIFT and BRISK algorithms on average by a factor of 13 and 10, respectively. In future the proposed work will be implemented in test-bed for live frame sequence transformations to fused images.

# Texton Tri-alley Separable Feature Merging (TTSFM) Capsule Network for Brain Tumor Detection

Vivian Akoto-Adjepong, Obed Appiah, Peter Appiahene, Patrick Kwabena Mensah

Department of Computer Science and Informatics-University of Energy and Natural Resources, Sunyani, Ghana

**Abstract**—Brain tumors represent one of the most perilous and lethal forms of tumors in both children and adults. Early detection and treatment of such malignant disease types may reduce the mortality rate. However, manual procedures can be used to diagnose such disorders, and this process necessitates a careful, in-depth analysis which is prone to errors, tedious for health professionals, and time-consuming. Therefore, this research aims to design a Texton Tri-alley Separable Feature Merging (TTSFM) Capsule Network based on dynamic routing, suitable for the automatic detection of brain tumors. The TTSFM Capsule Network's Texton layer helps to extract important features from the input image, and the separable convolutions coupled with the use of fewer filters and kernel sizes help to reduce the time for training, the size of the model on disk, and the number of trainable parameters generated by the model. The model's evaluation results on the brain tumor dataset consisting of four classes show better performance than the traditional capsule network, and are comparable to the state-of-the-art models, with an overall accuracy of 97.64%, specificity of 99.24%, precision of 97.43%, sensitivity of 97.45%, f1-score of 97.44%, ROC rate of 99.50%, PR rate of 99.00%. The components and properties of the proposed model make the model deployable on devices with low memory like mobile devices. This model with better performance can assist physicians in the diagnosis of brain tumors.

**Keywords**—Texton; separable convolutions; capsule neural network; dynamic routing; brain tumor; brain tumor detection

## I. INTRODUCTION

Brain tumor is among the most fatal and dangerous tumors in both children and adults [1]. Brain and spinal cord tumors are assemblages of abnormal cells that have multiplied uncontrollably inside the brain or spinal cord. There will be 25,050 diagnoses of malignant brain and spinal tumors by 2023 in both men and women[2].

Medical imaging plays a vital role in the diagnosis, monitoring of tumor progression, and treatment of tumors. Magnetic Resonance Imaging (MRI) is the preferred technique for imaging due to its non-ionizing nature. It offers significant insights into the characteristics, dimensions, form, and positioning of brain tumors.

Manually evaluating MRIs is laborious and error-prone, hence an Artificial intelligence (AI)-driven system that operates automatically is required to aid in medical diagnosis. Techniques rooted in machine learning, like support vector machines, have been utilized to aid in accurately detecting

medical conditions [3]. Nevertheless, the outcomes of these approaches fell short of established benchmarks, and the process of extracting features is notably time-intensive. To tackle these challenges, deep learning techniques like convolutional neural networks (CNNs) were embraced to enhance the process of extracting features. Remarkably, CNNs demonstrated a level of performance that is comparable to that of human experts.

Despite CNN's strong achievements, the study found specific constraints including the need for extensive datasets, high computational demands [4], translational invariance [5], and adherence to particular criteria for optimal feature selection [6]. In the field of health, obtaining a voluminous dataset poses a significant hurdle, compounded by a scarcity of skilled annotators and privacy issues [4]. Consequently, to mitigate the overfitting of CNNs on these limited datasets, methods of data augmentation are employed. However, it should be noted that these data augmentation techniques are both time-consuming and labor-intensive [7].

Capsule Network (CapsNet) was introduced to tackle the issues of CNN [8]. In contrast to CNNs, CapsNet does not necessitate extensive datasets, and is resistant to uneven class distributions and spatial orientation changes. These properties of CapsNet render it appropriate for medical image diagnosis. However, CapsNets do have their own set of limitations[9]. They exhibit suboptimal performance on complex images, and those with diverse backgrounds, and try to account for every element in an image. As a result of these properties, the performance of the network may suffer when dealing with detailed malignant images.

In order to further improve CapsNets textural, color, and spatial recognition capabilities, this paper adopts CapsNets dynamic routing algorithm and implements a Texton layer [10], separable convolutions, and a max-pooling layer. This allows CapsNet to decide on which features are essential and the coupling coefficients that need to be decreased in enhancing the hierarchical relationship of closely related capsules. The Texton Tri-alley Separable Feature Merging (TTSFM) Capsule Network model proposed helps to address the crowding problem in CapsNet and performs better than the traditional CapsNet and some other models found in literature on brain tumor detection. The proposed model exhibits better convergence speed and can generalize well on unknown data, hence can serve as an intelligent tool, assisting physicians in diagnosing and administering appropriate

treatments for brain tumors. Fig. 1 depicts the adopted workflow for the proposed work.

Most of the models found in literature performed dataset balancing, data segmentation, data augmentation, and thorough data preparation, before model fitting. This study utilized raw datasets without any data augmentation and data preprocessing to evaluate the proposed model's effectiveness with natural or raw data since data augmentation or segmentation might not be practical in medical emergency situations. Also, this study offers detailed visual representations of image regions that capture the focus of specific parts of our model, evaluation performance on imbalanced datasets using ROC and Precision-Recall (PR) curves, clusters of features at the class capsule layer to assess the model's effectiveness, and the model's transparency and understandability was enhanced by reconstructing input images.

The contributions of this study are:

- 1) A fast, robust, and low-parameterized TTSFM CapsNet, that has efficient feature extraction capabilities is proposed.
- 2) *Separable* convolutions are employed to reduce the size and trainable parameters of the model.
- 3) A comparative analysis was conducted to assess the proposed model with other CapsNet models.
- 4) *The* study presented a comprehensive visual representation of the outputs of layers to help offer notable contributions to the explainable artificial intelligence field.

The study is organized as follows: Related works are presented in Section II. Methodology is presented in Section III. Section IV deals with results and discussion and Section V deals with the conclusion and future works of the study.

## II. RELATED WORKS

Manual diagnosis in the medical field is prone to error, tedious for health professionals, and time-consuming. These limitations led to the employment of algorithms for predicting and detecting radiomic medical conditions. For instance, Gao et al., [11] utilized both 2D and 3D convolutional neural networks (CNNs), the researchers employed these networks to categorize individuals as having tumors, no tumors, or Alzheimer's disease based on CT scans. They were able to attain an accuracy level of 87.6%. A hybrid approach employing CNN and Neutrosophy (NS-CNN), was proposed by Özyurt et al [12]. The approach was used to categorize benign or malignant segmented tumor regions from brain tumor images. The accuracy of the suggested model was 95.62%. Sajjad et al. [13] presented a modified (CNN) based multi-grade system for classifying brain tumor grades. The model's accuracy was 90.67%. In order to solve the classification challenge for brain tumors, Ayadi et al. [14] suggested a new model that makes use of the CNN sequential model. The model has several layers and was designed to categorize MRI brain cancers. The model had a 94.74% accuracy rate. A CNN model was proposed by Badža and Barjaktarovic [15] for classing three distinct forms of brain tumors. The

suggested model, which has a straightforward architecture akin to traditional CNN, accurately classified 96.56% of the brain tumor MRI images in the dataset. Also, Afshar et al. [16], introduced a boosted capsule network (also known as BoostCaps), that makes use of boosting approaches' capacity to accommodate poor learners, by steadily boosting the models. The BootsCaps architecture, according to the results, classified brain tumors with an accuracy of 92.45%. DCNet and DCNet++ were suggested by Phaye et al. [17]. By substituting densely connected convolutions for the typical convolutional layers in the two suggested models, the CapsNet was modified. On Brain Tumor Dataset, the two models were assessed and achieved a validation accuracy of 93.04% and 95.03%, respectively. A capsule network for automatic brain tumor classification that achieves a 92.65% accuracy was proposed by Goceri. This network includes three fully connected layers and utilizes an expectation-maximization (EM)-based dynamic routing algorithm to extract important features from images [18]. In order to increase the focus of CapsNet, Afshar and colleagues suggested an improved CapsNet architecture for classifying brain tumors that incorporates the tumor coarse boundaries as additional inputs. The validation accuracy for the model was 90.89% [19]. According to Adu and friends, an improved CapsNets with several convolutional layers and dilation to preserve image resolution and boost classification accuracy was proposed. The proposed system can guarantee an increase in CapsNets focus by inputting segmented tumor regions within the structure. This model's performance obtained an accuracy of 95.54% [20]. Some researchers presented the BayesCap, a Bayesian CapsNet architecture that can offer both the mean forecasts and entropy as a gauge of uncertainty in forecasting. According to the findings, accuracy can be increased by filtering out uncertain forecasts. The model's maximum accuracy was 73.9% with a CI of: (73.5%, and 74.4%) [21].

All the existing models performed well on the various datasets. But for medical image diagnosis, there is a need for a more robust and efficient model for better diagnosis, hence this study aims to propose an improved, fast, low-parameterized, and robust Capsule Network which incorporates Texton and Separable convolutions for effective feature extraction and better classification of brain tumor diseases. Most of the studies mentioned above performed dataset balancing, data segmentation, data augmentation, and thorough data preparation, before model fitting.

## III. METHODOLOGY

This section presents the methodologies employed to attain our goal of developing a deployable CapsNet that has an effective ability to extract features efficiently with lesser parameters and size on disk. Fig. 1 shows the proposed methods block diagram for the automatic classification of brain tumor types.

### A. Capsule Network

The structure of the baseline CapsNet on which the proposed model is based is found in Fig. 2.

B. Texton Detection

The notion of Texton involves the identification of clusters of shapes within an image that possess a shared characteristic. Julesz further developed this concept [22], placing emphasis on the significance of measuring the distances between texture elements when calculating gradients of Textons. Textures emerge only when neighboring elements are in proximity, and the scale of the elements impacts the surrounding region. Larger elements oriented in a particular direction can slightly impede the initial, instinctive differentiation. Gradients of Texton are only present at the borders of textures, so utilizing a smaller element size, such as 2x2, can enhance the

distinction of textures. The approach of Multi Texton Detection (MTD), utilized to extract information regarding edges and colors, involves the use of six distinct types of Texton ( $T_1, T_2, T_3, T_4, T_5,$  and  $T_6$ ) on a 2x2 grid (shown in Fig. 3) to identify textons. A Texton is generated by the grid when the two shaded pixels share the same value. By systematically shifting the 2x2 block across the image  $C(x, y)$ , textons can be detected in a stepwise manner. If a texton is identified, the original pixel values are preserved; otherwise, the block is disregarded. The resultant image containing textons is represented as  $T(x, y)$  [10], as illustrated in Fig. 4.

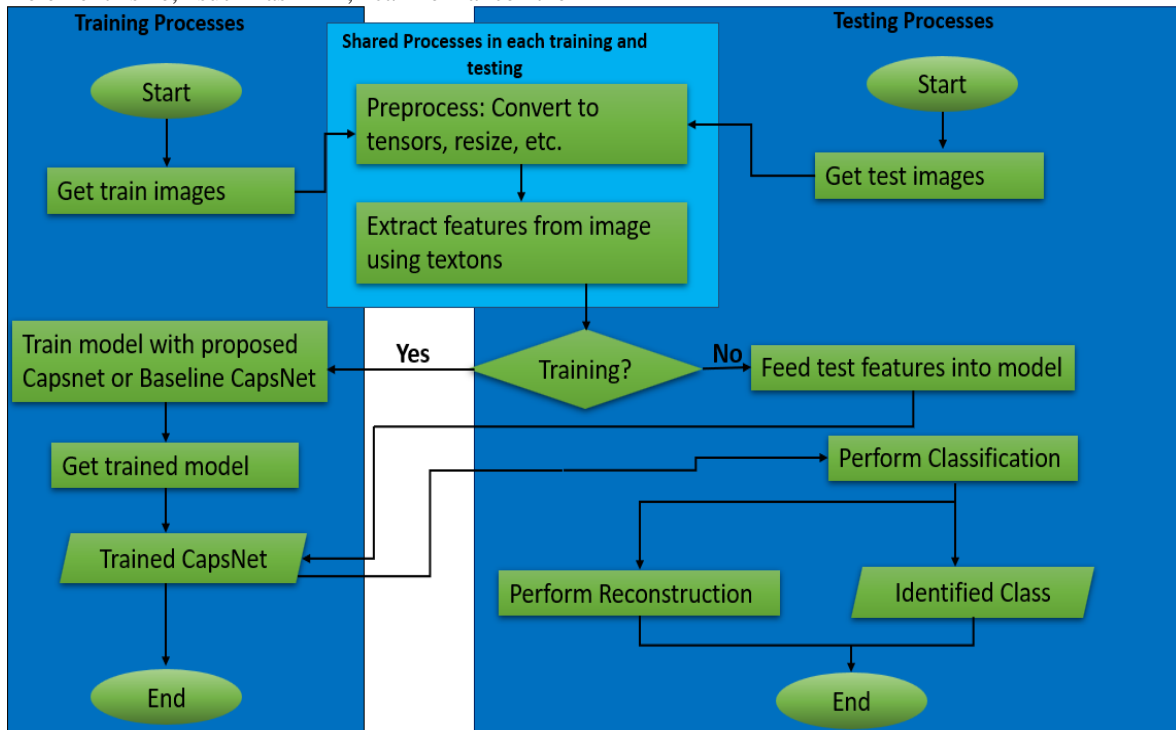

Fig. 1. Workflow diagram of the study.

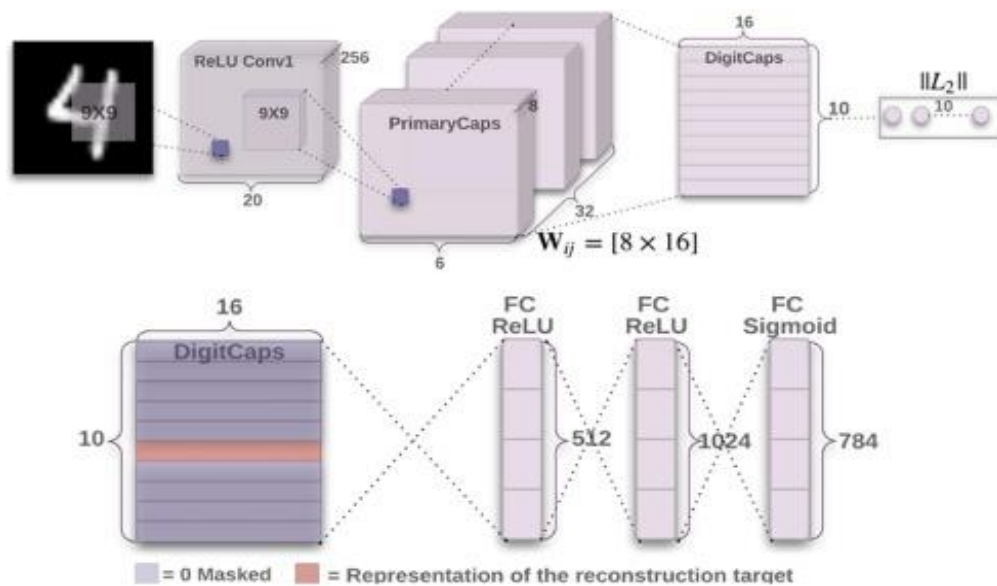

Fig. 2. Architecture of the baseline capsule network model.

Fig. 3. Six Texton types used in Texton detection process: (T) 2x2 grid.

Fig. 4. Illustration of the Texton detection process.

### C. Depthwise Separable Convolution

Two separable convolutions types exist in separable convolutional neural networks. These are depthwise separable convolutions (DSC) and spatial separable convolutions (SSC). DSC is adopted for this study, and can be viewed as grouped convolutions, similar to the concept of 'inception modules' employed in the design of the Xception architecture [23]. It relies on spatial convolution, which operates separately on each input channel. After the spatial convolution, a pointwise convolution (PC) is executed, which involves a standard convolution using  $1 \times 1$  windows. This leads to the creation of a new channel space as a result of projecting the channels calculated during the depthwise convolution (DC). The mathematical expression for depthwise convolution (DC) and pointwise convolution (PC) is presented as follows:

$$PC(W, y)_{(i,j)} = \sum_m W_m \cdot y_{(i,j,m)} \quad (1)$$

$$DC(W, y)_{(i,j)} = \sum_{k,l}^{K,L} W_{(k,l)} \odot y_{(i+k, j+l)} \quad (2)$$

$$DSC(W_p, W_d, y)_{(i,j)} = PC_{(i,j)} \left( W_p, DC_{(i,j)}(W_d, y) \right) \quad (3)$$

$W_p$  and  $W_d$  represent the inputs used for pointwise and depthwise convolutions in the above equations, respectively. The operator  $\odot$  within Eq. (2) pertains to the element-wise multiplication. Consequently, the fundamental idea underpinning depthwise separable convolutions involves splitting the feature extraction process carried out by regular convolutions across a unified "space-cross-channels domain" into two distinct stages: spatial pattern learning and channel fusion. This approach represents a generalization when dealing with convolution operations on 2D or 3D inputs having both relatively independent channels and closely interconnected spatial positions.

### D. Proposed Model

Fig. 5 shows the proposed Texton Tri-alley Separable Feature Merging (TTSFM) CapsNet model that employs Texton, separable convolution, traditional convolutions, max pooling, dropout and reconstruction layers. The Texton layer is used to extract important texture and edge features from the input image. The output features from the Texton layer are processed by three different separable convolutions (each having 32 filters, kernel size of 2x2, depth multiplier of 1, depthwise and pointwise initializers of "ones" and a stride of 1) followed with batch normalization and max pooling, contributing to reduced number of parameters, model size, computational time and complexity of the model, as can be seen at alley\_1\_conv1, alley\_2\_conv1, and alley\_3\_conv1. The feature map from alley\_1\_conv1 serves as input in into alley\_1\_conv2, and the feature maps from alley\_2\_conv1, and alley\_3\_conv1 are merged and serves as input into alley\_2\_conv2, and alley\_3\_conv2. The feature maps from alley\_1\_conv2, alley\_2\_conv2, and alley\_3\_conv2 (all conv2 layers employs 64 filters, kernel size of 3x3, and a stride of 1) are then concatenated and sent as input into a dropout layer, followed with a batch normalization layer. This feature map is sent as input into the primary capsule layer consisting of 32 channels with eight dimensions, a kernel size of 3x3, and a stride of two. Features from this primary capsule are then sent to the TumorCaps layer (by employing dynamic routing algorithm) for classification. This TumorCaps consist of the total classes number in 16D capsules. The output of TumorCaps is directed to the reconstruction layer, which works on rebuilding the characteristics acquired from the TumorCaps. The features are then transferred to the decoder layer within the capsule, which decodes the properties of the entity. This decoder is composed of three layers of fully connected neurons, with counts of 512, 1024, and 3072 respectively. The Texton, max pooling, and convolution layers

help to extract important features from the input images using separable convolutions results in reduced number of parameters, model size, computational time and complexity of the model.

#### E. Dataset Description

Brain Tumor: The dataset comprises 7022 MRI scans of the human brain, which are grouped into four categories: (1) glioma, (2) meningioma, (3) pituitary, and (4) no tumor. To make the dataset more manageable, the images were resized to  $32 \times 32 \times 3$  and redistributed using 70:20:10 leave-out approach. This publicly available dataset can be found at: <https://www.kaggle.com/datasets/masoudnickparvar/brain-tumor-mri-dataset>.

#### F. Experimental Setup

The proposed model was developed and assessed using Keras, Python via Anaconda, and employed the TensorFlow backend on a 64-bit Windows computer. The hardware configuration encompassed an NVIDIA GeForce RTX 2080 SUPER GPU having 8GB of dedicated GPU memory along with 32GB of system RAM. During the training stage, Adam optimizer was employed with a learning rate set to 0.001, and training operations were executed using batches of 100 samples. In order to ensure optimal training progress, the model achieving the highest performance was saved during the training iterations. The evaluation of loss was conducted using the margin loss, represented as  $L_k$  in Eq. (4), with specific details provided below:

$$L_k = T_k \max(0, m^+ - ||v_k||)^2 + \lambda(1 - T_k) \max(0, ||v_k|| - m^-)^2 \quad (4)$$

where,  $T_k$  is 1 when class  $k$  is active and 0 otherwise. Hyper-parameters  $\lambda$ ,  $m$ ,  $m^+$  are set during the learning process.

#### G. Performance Evaluation Measures

The following metrics were employed in this study for the purpose of classification:

Validation Accuracy: Calculates the proportion of accurately classified classes from the total number of classes. The attained overall validation accuracy for the entire set of experiments is reported.

Loss: Evaluates the variance between the model's predictions and the actual labels. This assessment employs the margin loss during testing.

Confusion Matrix: Assist in providing a thorough examination of the tally of correctly and incorrectly categorized images. Factors like True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN) are employed to evaluate diverse measurements such as precision, accuracy, specificity, sensitivity (recall), and additional indicators.

Precision (P): The proportion of accurately detected positive instances compared to the overall number of predicted positive instances.

Recall (R) or Sensitivity: the proportion of accurately detected positive instances in relation to the overall count of positive instances within the dataset.

Specificity: The proportion of negative instances have been accurately recognized in relation to the overall count of negative instances present in the dataset.

F1-Score: The Mean that combines precision and recall in a harmonic manner.

Area under the curve (AUC): The model's performance is assessed on datasets where classes are imbalanced or unevenly distributed by creating Receiver Operating Characteristic (ROC) and precision-recall (PR) curves [24]-[25]. Higher AUC values are favored compared to their smaller equivalents.

Clustering: We utilize t-distributed stochastic neighbor embedding to acquire and examine the clusters within the class capsule layer of the models.

## IV. RESULTS AND DISCUSSIONS

In this section, we present the outcomes of our experiments and demonstrate the favorable performance of the model when tested on the brain tumor dataset in comparison with the baseline Capsule Network [5]. To bolster confidence and ensure the reliability of the model's outcomes, we employed and meticulously executed various evaluation methods. These techniques included evaluating metrics such as classification accuracy and loss, specificity, sensitivity, precision, F1-Score, number of parameters, Area Under the Curve (AUC) for both the Receiver Operating Characteristic Curve (ROC) and Precision-Recall (PR) curves. We also trained a traditional capsule network [5] using the same dataset and compared its results with our model's performance using the aforementioned metrics.

### A. Performance Evaluation

Graphs presented in Fig. 6 illustrate the accuracy and loss trends for both CapsNet models: the proposed and the baseline model. The accuracy and loss graphs during training and validation reveals that the proposed model outperform the baseline CapsNet model, exhibiting superior and consistent accuracy with quicker convergence. It is important to highlight that while accuracy is widely used to assess classification algorithms, it may not be suitable for evaluating medical images due to their small size and significant class imbalance [26]. Despite its limitations, accuracy can offer an overview of overall system.

Fig. 7 displays the ROC and PR curves for both the proposed and baseline models. Analyzing the data from these curves, it becomes evident that the performance of the proposed model surpasses that of the baseline model. This shows that the proposed model performs better on small and imbalanced datasets like medical images [27] than the baseline model.

Fig. 8 depicts confusion matrices illustrating the accurate and erroneous image identifications. The results presented in Table I highlight that the proposed model outperformed the CapsNet baseline by exhibiting fewer misclassifications.

Hence resulted in better per class accuracy, specificity, sensitivity, precision and F1-Score for each class, as compared to the baseline Capsule Network model.

### B. Ablation Study

Conducting ablation experiments involves analyzing the elements of the model that significantly influenced its performance [28][29]. The model's layers are systematically removed in succession to assess their effects on the overall model's performance. As depicted in Table II, the model's performance shows a significant improvement through the integration of the Texton and max-pooling layers.

### C. Number of Parameters and Size on Disk

A number of models found in literature expand their width and depth in order to enhance their performance on complex images. This causes a surge in the number of parameters. For example, ResNet50 [30], AlexNet [31], and VGG16 [32], among others, generate parameter counts of 23 million, 60 million, and 138 million respectively. The intricacy of a model directly correlates with the parameters it generates, resulting

in a substantial computational load that strains the resources of a system. Consequently, this poses a constraint on the feasibility of deploying such models on devices with limited memory, such as mobile phones. The comparison of the parameters of the models as well as size on disk is found in Table III. It can be seen that the size of the model on disk is small and less parameters were generated by the proposed model. This makes the proposed model suitable for deployment on mobile devices.

### D. Model Interpretability

The inner workings of deep learning models are often labeled as black boxes. In order to rely on and employ these models for important functions, such as in the field of healthcare, it is essential that both the operations within the models and the results they produce are explainable. Through the utilization of saliency maps, mathematical models, activation maps, and similar techniques, explainable neural networks [33][34] and model interpretability [29] approaches aid in revealing insights into the operations occurring within the inner layers of deep learning models.

TABLE I. PERFORMANCE METRICS ON THE BRAIN TUMOR DATASET FOR THE PROPOSED AND BASELINE CAPSNET MODELS

Model (Dataset)	Class	TP	FP	TN	FN	Precision	Sensitivity	Specificity	Accuracy	F1-Score	Data Size
Baseline (Brain Tumor)	0	271	16	995	29	0.9443	0.9033	0.9842	96.57%	0.9235	300
	1	283	30	975	23	0.9042	0.9248	0.9702	95.96%	0.9144	306

-alley_1_conv2	97.48
-alley_2_conv1	97.41
-alley_3_conv1	97.41
+ all layers	97.64

TABLE III. COMPARISON OF PARAMETERS OF MODELS AND SIZE ON DISK

Model	Trainable Parameters	Non-Trainable Parameters	Size on disk
Baseline CapsNet model	10,127,104	0	38.6MB
Proposed model	4,834,532	960	18.5MB

### E. Visualization of Activation Maps and Clusters

Here, comparison of activation maps and clusters from the proposed and baseline models are done. This help to know the model that extract more important features from input images. Proposed model features from the Texton layer, extracted by

one of the first separable convolutions is shown in Fig. 9. 1<sup>st</sup> row image 1 and baseline model features extracted by the convolution layer is shown in Fig. 9. In 2<sup>nd</sup> row image 1, insufficient features were extracted. This exhibit that, the baseline convolution layer alone is not enough to extract important features. This inability of the convolution layer of the baseline model affected the primary capsule layer since it did not extract more important necessary to make differentiation between capsules, whereas the proposed model convolution layer extracted better edge and textural features from the Texton layer, hence its primary capsule produced better activation maps as seen in Fig. 9 1<sup>st</sup> row image 2 than the baseline PC activation maps seen in Fig. 9 2<sup>nd</sup> row image 2. These visualizations of layers help to improve the understandability of the inner workings of the black box models and contributes to explainable Artificial Intelligence [35][36][37].

The technique of t-distributed stochastic neighbor embedding (tsne) [38] [39], was employed to visually represent the distinctness of clusters formed within the class capsule layer of the models. The suggested model displays noticeable groupings in contrast to the clusters formed by the baseline model. While a few outliers are evident in both the suggested and baseline model clusters, the outliers in the suggested model remain relatively close to their respective clusters. This highlights the effective discriminatory capability

of the suggested model in comparison to the baseline model as it can be seen in Fig. 10.

F. Prediction and Reconstruction

The process of determining the likely class of an input image and determining if there is a strong likelihood for that categorization is achieved through the application of a

reconstruction method. In light of this, this research showcases reconstructed images of Brain Tumor using the decoder network for both models. The images generated by the proposed model exhibit slightly improved visual quality and demonstrate higher class identification and emphatic probabilities per class compared to the images produced by the baseline model, as observed in Fig. 11.

### G. Comparison of Results

To demonstrate the effectiveness of our novel approach, we conducted a performance comparison between our model and cutting-edge models on brain tumor datasets. Our modifications primarily center around the structure of capsule network, specifically focusing on dynamic routing. Although our main emphasis was on dynamic routing, we extended our

investigation to encompass multiple routing techniques. The outcomes, as detailed in Table IV, indicate that our model's performance matches that of the current state-of-the-art capsule network models. The commendable performance achieved by our proposed model in medical image diagnosis can be attributed to its adeptness in extracting pertinent information from diverse images, which contributes to its capability in achieving accurate results.

Fig. 11. Reconstructed images (top) proposed and (down) baseline model.

TABLE IV. PROPOSED MODEL AND PREVIOUS WORKS COMPARISON ON BRAIN TUMOR DATASET

CapsNet Methods	Validation accuracy (%)
Baseline [5]	95.73
BoostCaps [16]	92.45
DCNet and DCNet++ [17]	93.04 and 95.03
MLAF-CapsNet[40]	93.40 and 96.60
Vimal Kurup et al.[41]	92.60
Afshar et al. [19]	90.89
Dilated CapsNet. [20]	95.54
BayesCaps[21].	73.9
<b>Proposed Model</b>	<b>97.64</b>

## V. CONCLUSION AND FUTURE WORKS

This study introduced a novel architecture that utilizes less time to train with less parameters, small size on disk, and proficient feature extraction capabilities, named Texton Tri-alley Separable Feature Merging (TTSEFM) CapsNet, utilizing a capsule network approach, aimed at the detection of brain tumors. Texton layer helps to extract important features from input image and the separable convolutions coupled with the use of less filters and kernel sizes resulted in using less amount of time for training, small size on disk, and a smaller number of trainable parameters. These components and properties lead to the appreciable performance of the proposed model, making the model deployable on devices with lower memory like mobile devices. We went on to enhance the model's interpretability and practical usability by conducting

thorough analyses, including extensive visualization of layer activation maps, examination of feature clusters, and performing ablation study.

In future, our focus will be on improving the performance of the model, and conducting in-depth experiments using medical datasets to advance the field of explainable artificial intelligence (XAI). Our objective is to remove all uncertainties from the outcomes of the models, ensuring that both professionals and other users can trust the reliable application of these models in disease diagnosis.

# Unraveling Ransomware: Detecting Threats with Advanced Machine Learning Algorithms

Karam Hammadeh, M. Kavitha

Department of Computer Science and Engineering,  
Vel Tech Rangarajan Dr. Sagunthala R&D Institute of Science and Technology, Chennai, India

**Abstract**—In our contemporary world, the pervasive influence of information technology, computer engineering, and the Internet has undeniably catalyzed innovation, fostering unparalleled economic growth and revolutionizing education. This technological juggernaut, however, has unwittingly ushered in a parallel era of new criminal frontiers, a magnet for hackers and cybercriminals. These malevolent actors exploit the vast expanse of electronic devices and interconnected networks to perpetrate an array of cybercrimes, and among these insidious digital threats, ransomware reigns supreme. Ransomware, characterized by its ominous ability to encrypt victims' data and extort payment for its release, stands as a dire menace to individuals and organizations alike. Operating with stealth and propagating with alarming alacrity through digital networks, ransomware has emerged as a formidable adversary in the digital age. This research paper focuses on the evolving stages of ransomware, driven by cutting-edge technologies, and proposes essential methods and ideas to detect and combat this menace. The proposed methodology, anchored in Cuckoo Sandbox, PE file feature extraction, and YARA rules, orchestrates three crucial phases: data collection, feature selection, and data preprocessing, all harmonizing to strengthen our defense against this concealed cyber menace. This paper contributes to the development of effective solutions for detecting and mitigating this hidden and insidious cyber threat. This work involves the application of multiple machine learning algorithms, including LSTM, which achieves an impressive accuracy of 99% in identifying ransomware attacks.

**Keywords**—Ransomware; cuckoo sandbox; PEFile; YARA rules; machine learning; LSTM

## I. INTRODUCTION

Cybersecurity has emerged as a crucial domain within information technology and computer engineering due to the rapid advancement and widespread adoption of technologies in our daily lives. As technology continues to evolve, it brings both positive and negative impacts, making it essential to protect data, preserve individual privacy, and safeguard innovation and intellectual property [1]. The primary objective of cybersecurity is to combat cybercrimes, which have significantly increased since the beginning of the 21st century.

Cybercrime is recognized as one of the most damaging and costly forms of criminal activity. Hackers and criminals exploit the power of networks, programming, and computers to steal valuable data, gain unauthorized access to bank accounts, and mass significant financial gains. Their illegal activities often remain hidden, making it challenging to trace the perpetrators and understand the extent of their actions. There are numerous

methods through which individuals can become involved in cybercrime [2]. One such approach is the development and dissemination of malicious code, such as malware and ransomware, which can wreak havoc on computer systems and networks. Another technique employed by cybercriminals is launching Distributed Denial-of-Service (DDoS) attacks, which dominate servers and disrupt their ability to provide services.

Malware, or malicious software, is a wide-open problem that is difficult to solve in computer science [3]. It is a term used to describe various forms of harmful software designed to compromise computer systems, steal data, or disrupt normal operations. There are different types of malwares, including viruses, worms, Trojan horses, and ransomware [4,5]. Malware aims to change the behavior of either the operating system kernel or some security-sensitive applications without the user's consent, and all services of the system will therefore be undocumented. Some countries are developing this kind of malicious application in central intelligence for spying purposes; individuals or teams are also developing it for hijacking or showing their talent [6, 7].

Ransomware is a serious threat that poses a risk to individuals and organizations. It develops rapidly because it uses newer techniques like RSA and C&C servers. These techniques are difficult to be analyzed and to be detected (binary files, payload) [8, 9]. The first ransomware attack occurred in 1989. It was a trojan called PC Cyborg/AIDS, which was created to hide the folders and encrypt the names of all the files. It targeted the files associated with the ADIS conference, and restoration is achievable provided the filename and extension encryption tables are discovered [10].

At the beginning of this decade, ransomware used new techniques. In 2013, RSA 2048-bit was the main characteristic that was implemented with the public key algorithm for ransomware. After that, it could be used as a command and control (C&C) server to communicate through the Tor network, and it became able to target only specific types of file extensions [9, 11].

Encryption methods in ransomware have been significantly developed. For example, in 2015, most ransomware families were using the default configuration of AES file encryption and getting payment via Bitcoin. Later in 2017, the encryption became hybrid, using the AES algorithm to encrypt the files and RSA to encrypt the AES key [11]. According to [8, 12, 13], ransomware has been separated by researchers into many major types according to how it works methodologically and

what kinds of effects that will cause. First, Crypto-Ransomware, Once the ransomware infects the target's device, the virus stealthily detects and encrypts the victim's important files, and the user will not be able to access, use, or get data until he pays the ransom. Second, Locker-Ransomware, which doesn't encrypt the data, has turned its focus to blocking access to the user's equipment and information by disabling the user interface. Third, MBR-Ransomware works to encrypt the Master Boot Record table on the victim's PC, which means the files will be safe and not affected by encryption, but the system will not recognize the location of files and their mac-Ransomware and Mobile-Ransomware.

Some of the researchers [8, 14, 15] also found that there are three types of ransomware according to the style of encryption algorithm that has been used (see Fig. 1). These types are:

- **Symmetric Ransomware:** It uses symmetrical encryption algorithms like AES and DES to encrypt the victim's data; in this type, the encryption and decryption use the same key.
- **Asymmetric Ransomware:** It uses an asymmetrical encryption algorithm, and ransomware is embedded with a public key to encrypt the victim's data, or it downloads during connection with a command and control (C&C) server, but the private key is saved only with the attacker, which is impossible to get without paying.
- **Hybrid Ransomware:** It uses symmetrical encryption to encrypt the victim's files, but the symmetric key will be encrypted by an asymmetric encryption algorithm. This technique takes advantage of both symmetric and asymmetric encryption.

The 2022 update of the Verizon Data Breach Investigations Report (DBIR), as shown in Fig. 2, reveals a concerning trend in the rise of ransomware attacks. According to the report, the number of ransomware incidents surged by 13% between 2020 and 2021, surpassing the combined increase of the previous five years. This significant escalation in ransomware incidents highlights the growing threat posed by cybercriminals targeting organizations across various sectors [16].

Ransomware detection relies on two core analyses: static and dynamic. Static analysis examines code without execution, offering security but struggling with packed or obfuscated malware. Dynamic analysis executes code in a controlled environment, effectively capturing behavioural patterns but posing security risks. Often, a hybrid approach combines these methods with others to maximize accuracy and minimize associated risks.

This research paper is driven by three core objectives. Firstly, it aims to establish a robust system for the early identification of ransomware threats, prioritizing swift detection to minimize potential damage inflicted upon data and computer systems. Secondly, the paper endeavors to raise awareness among individuals and organizations regarding the substantial risks and dire consequences associated with

ransomware attacks, fostering a proactive and vigilant cybersecurity mindset. Lastly, a central focus of this research is the development and implementation of effective countermeasures and response strategies to mitigate the evolving menace of ransomware. By achieving these objectives, this work not only enhances our ability to combat ransomware but also contributes significantly to the broader realm of cybersecurity, fortifying our digital defences against this persistent and pernicious cyber threat.

## II. RELATED WORK

Palisse et al. [17] recommended using Cryptographic approaches for proactively protecting against Ransomware, where ransomware constructs a dynamic block for calls to cryptographic APIs based on weaknesses and exploits vulnerabilities in cipher modes of operation. A mechanism termed PAYBREAK was suggested by Kolodenkerz et al. [18]. Because the system logs all of the random numbers it generates in a massive log file or database, users may use this information to exhaustively search for encryption keys. That method has proven to be quite effective. Kim et al. [19] used the same methods as the earlier researchers and developed a Deterministic Random Bit Generator (DRBG) to thwart ransomware; the DRBG is used to generate a seed, which is then combined with user DRBG data to produce a decryption key.

Poudyal et al. [20] suggested using reverse engineering to pull elements like assembly instructions and DLLs, which can subsequently be used with machine learning methods like K-fold Cross-Validation to identify ransomware. Ahmadian et al. [14] employed a system that relies on the Connection Monitor & Connection Breaker (CMCB) to identify and detect stealthy ransomware by monitoring and analysing network activity. Tseng et al. [21] and Cabaj et al. [22] conducted researches on the analysis and detection of ransomware attacks from different perspectives. They focused on analysing the HTTP and TCP protocols to identify ransomware attacks. Tseng utilised deep learning techniques for this purpose. On the other hand, Cabaj designed an approach based on Software-Defined Networking (SDN) to both detect and mitigate ransomware attacks. Cusack et al. [23] and Al Mashhadani et al. [8] proposed a framework for monitoring and analyzing data traffic during a ransomware attack. Their approach involved intercepting the communication between an infected machine, unaffected devices, and the command-and-control (C&C) server using a network protocol analyzer like Wireshark. To ensure the security of the monitoring system, they recommended implementing a firewall to shield it from potential threats. Shakir et al. [24] delved into the evolution of ransomware, tracing its development from phone antivirus and deceptive software to the emergence of crypto-ransomware. The study revealed two crucial factors driving the increase in ransomware attacks. Firstly, tracking victim payments to attackers proved to

be challenging due to the use of anonymous channels, making it challenging to trace and apprehend the perpetrators. Secondly, the practicality and effectiveness of employing cryptographic technologies played a significant role in the surge of ransomware attacks. These findings shed light on the key catalysts behind the proliferation and sophistication of ransomware as a malicious threat. The approach of Homayoun et al. [25] relied on the monitoring of activity records to detect and identify ransomware attacks by utilising machine learning methods to identify specific patterns. By analysing and examining activity logs, which capture system and user behaviour, it becomes possible to uncover anomalous patterns that indicate the presence of ransomware whereas Medhat et al. [26] developed a novel framework that relies on a static analysis approach. The framework utilises YARA rules, which are a set of predefined rules for pattern matching, to extract feature rules for each file. By applying these rules and conducting a classification process, the framework can identify files or processes that exhibit ransomware-like behaviour. The details and specific workings of this framework are represented in Fig. 3.

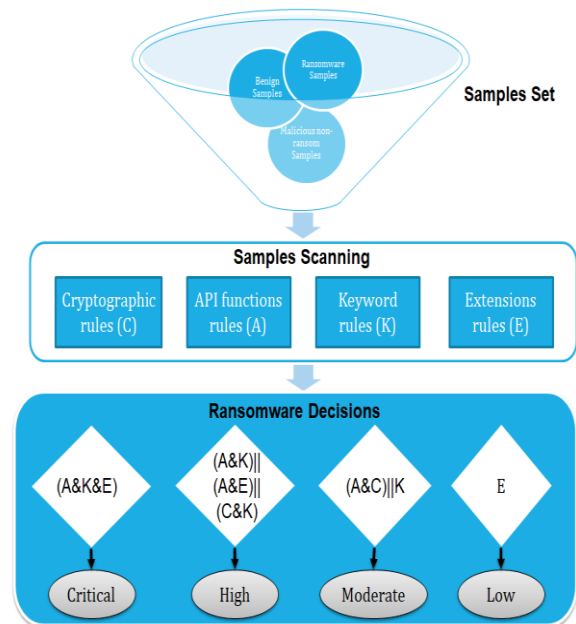

Fig. 3. Static-based framework for ransomware detection [25].

Detecting ransomware is a complex task due to its ever-changing nature, requiring researchers and security professionals to employ diverse strategies. One recommended approach involves monitoring the Master File Table (MFT) for any unusual activity or modifications, as ransomware often targets and encrypts files. Another approach involves leveraging machine learning models to search for specific language patterns associated with ransomware. By analyzing text data using these models, suspicious indicators can be identified. Additionally, examining data flow and network traffic can help detect ransomware [27]. Moore et al. [28] introduced a novel method for detecting ransomware utilising honeypot technology, as depicted in Fig. 4. This approach encompasses several stages to enhance detection capabilities. In the behaviour stage, two tools, namely DatAdvantage and HitmanPro, are utilised. DatAdvantage employs user behaviour analytics to identify abnormal activities, while HitmanPro focuses on detecting unusual system behaviour. The network stage involves monitoring data traffic across the network to detect any exchange of file keys, a common characteristic of ransomware operations. Lastly, in the server stage, changes are monitored using the file server resource manager, and a file screening function is employed to control access and block the writing of unauthorised files. This multi-stage approach aims to provide a comprehensive detection mechanism, combining behavioural analysis, network monitoring, and server-level control to enhance ransomware detection and prevention capabilities.

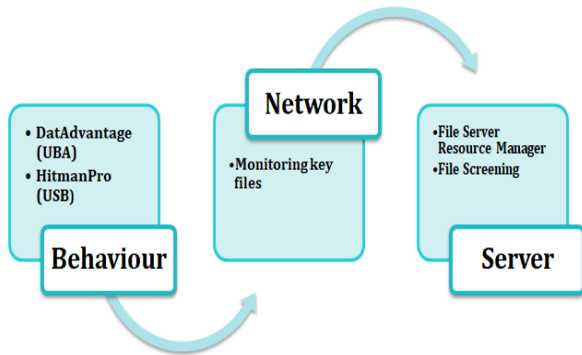

Fig. 4. Honeypot techniques to detect ransomware [28].

Ransomware can be classified into two main types: non-spreading ransomware and ransomware with worm-like characteristics. The primary objective in combating ransomware is to prevent the victim's device from being encrypted and to halt the malware's spread within and beyond the local network. Cabaj et al. [29] utilised SDN to detect non-spreading ransomware variants like CryptoWall and Locky. Their approach involved using the size of the first three HTTP Post packets in sequence as a detection mechanism. Through their implementation, they achieved a high true positive rate of 97-98%. In the case of ransomware that spreads like worms, such as WannaCry and ExPetr, researchers in [30] have suggested utilising two programmes for effective mitigation. The first programme detects and prevents WannaCry from encrypting the victim's device by monitoring and blocking communications between the ransomware and its Command-and-Control (C&C) servers through a dynamic IP blacklist.

The second programme tracks the ports used by WannaCry, enabling the prevention of encryption processes and the identification and containment of the ransomware's spreading behaviour.

### III. METHODOLOGY

The methodology (see Fig. 5) describes a technique for detecting ransomware using Cuckoo Sandbox [31], feature extraction from Portable Executable (PE) files [32], and YARA rules [33]. By analysing the characteristics and patterns of PE files, it is possible to identify potential ransomware threats and lessen their impact. There are three main stages to prepare data to be consumed by the algorithms we test: data collection, feature selection, and data processing. Data Collection is contingent upon collecting a diverse set of PE files, This investigation encompasses both benign components, which include application and system files that form the foundation of our digital activities, as well as malicious ransomware samples obtained from VirusShare, and utilising YARA rules to detect crypto signatures. Feature Selection is applied to analyse extracted characteristics and choose the most useful ones for ransomware detection. We employ Weight of Evidence (WoE) and Information Value (IV). They are used to determine a dataset's predictive potential and select which elements are most significant for a modelling task. Utilising data preprocessing techniques, such as normalisation, dimensionality reduction, data reshaping, and feature scaling is to improve the performance of subsequent machine learning algorithms.

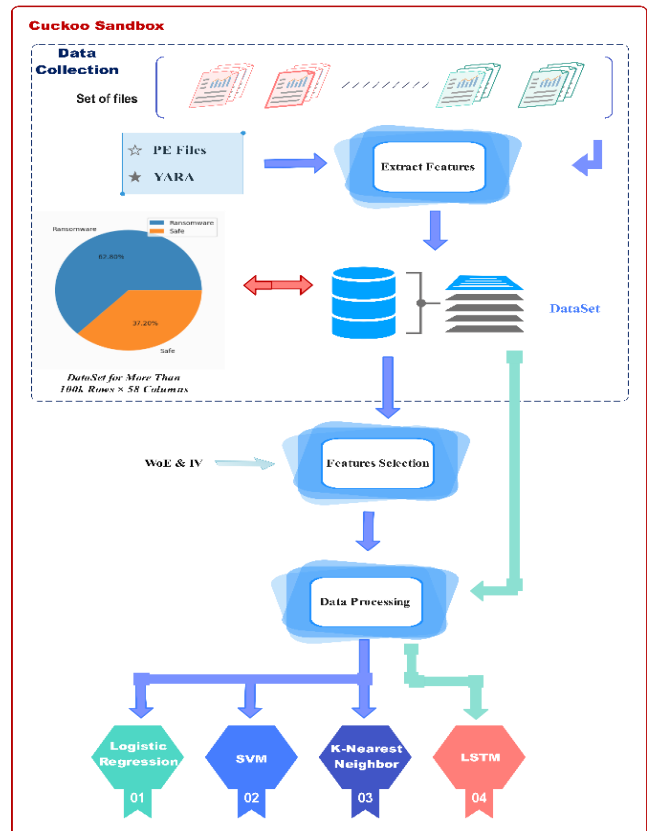

Fig. 5. Proposed methodology for detecting ransomware.

The output of the data processing stage is now suitable to be injected into the algorithms we test. We apply four machine learning algorithms: Logistic Regression, SVM, K-Nearest Neighbor, and LSTM.

Logistic Regression [34] is a type of generalized linear model that is used for classification tasks. The goal of logistic regression is to find the best model that describes the relationship between a set of input features and a binary output variable. The model is represented by a logistic function, which maps the input features to a value between 0 and 1, representing the probability that the output variable is in one of the two classes. In logistic regression, a linear combination of input features is transformed by the logistic function [35], which is also known as the sigmoid function. The coefficients of the linear combination are learned from the training data using a technique called maximum likelihood estimation. Once the model is trained, new data can be input into the model, and the output of the logistic function can be used to predict the probability that the new data belongs to one of the two classes. It is also less prone to overfitting compared to more complex models [36].

Support vector machines (SVMs) can solve classification and regression issues [37]. SVMs find the best boundary for categorising data. This border was chosen to maximise the margin, which is the distance between the boundary and each class's closest data points. After identifying this barrier, additional data may be categorised by its side [38]. SVMs are useful when data is not linearly separable, meaning classes cannot be separated by a straight line. SVMs use the "kernel trick" to shift data into a higher-dimensional space where it may be linearly segregated [39].

The K-Nearest Neighbors (K-NN) is a kind of supervised learning that classifies unknown files in line with previously established categories [40]. Among the many categorization algorithms, K-NN is a useful algorithm for grouping unknown objects into categories with the greatest number of shared attributes [41]. K-NN presupposes that close data points belong to the same class, which may not always be true. The data distribution, characteristics, and distance metric affect K-NN's efficacy [42].

Long-short term memory (LSTM), a standard and enhanced recurrent neural network, is capable of analysing and anticipating time series problems. A memory cell composed of an input gate, a forget gate, and an output gate regulates the transmission of information in the LSTM model. The problem of expanding gradients and vanishing is resolved by LSTM's unique structure [43].

#### IV. EVALUATION AND RESULTS

In order to evaluate the performance of classification models, various evaluation measures are commonly utilized. These measures include accuracy, precision, recall, and the F1 Score. The confusion matrix, represented as Fig. 6, is used to assess the classifier's primary performance indicators.

Accuracy, as expressed by Eq. (1) represents the percentage of correctly classified instances in relation to the entire dataset. Precision, or Detection Rate, as given by Eq. (2), is commonly used when dealing with imbalanced datasets. It measures the proportion of correctly classified instances compared to the total instances that are correctly and incorrectly classified. Recall, described in Eq. (3), is the percentage of accurately classified instances in relation to the total number of actual positive instances. The False Alarm Rate, mentioned in Eq. (4), indicates the frequency with which attacks are misclassified or falsely identified. Finally, the F1 Score or F-measure, described by Eq. (5), provides an overall assessment of the accuracy of a test by combining precision and recall into a single metric. This provides insights into the classifier's primary performance indicators and facilitates further analysis and comparison of different models and techniques.

		Predicted	
		Positive	Negative
Actual	Positive	TP	FN
	Negative	FP	TN

Fig. 6. Confusion matrix.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

$$False\_Alarm\_Rate = \frac{FP}{FP+TN} \quad (4)$$

$$F1\_Score = 2 * \frac{Precision*Recall}{Precision+Recall} \quad (5)$$

In feature selection, we have used WOE and IV as criteria for ranking and selecting variables. Variables with high IV values are considered more predictive and are more likely to be included in the final set of features, as shown in Fig. 7. By focusing on variables with strong predictive power, it can reduce dimensionality and improve the performance and interpretability of the used models.

Table I and Fig. 8 present a comprehensive overview of the performance results of different models utilized for ransomware detection, including LSTM, SVM, LR, and KNN. These findings offer valuable insights into the capabilities and effectiveness of each model in addressing the task at hand. Since the dataset consists of sequences of bits, LSTM's ability to remember and learn from previous information makes it a valuable choice. By utilizing its memory cells and gating mechanisms, the LSTM model can effectively process and interpret the sequential nature of the data, making it well-suited for the task at hand.

Fig. 7. Importance of features based on information value.

TABLE I. EXPERIMENTAL RESULTS

	LSTM	SVM	LR	KNN
TN	28689	28651	28342	28380
FN	235	283	592	494
FP	146	378	640	281
TP	12345	12103	11841	12260
Total	41415	41415	41415	41415
Accuracy	<b>0.9908</b>	<b>0.98404</b>	<b>0.970252</b>	<b>0.981287</b>

Fig. 8. Comprised the results of applied algorithms.

Support Vector Machine (SVM) and logistic regression face challenges when dealing with massive datasets due to their computational complexity, leading to longer training times as the dataset size increases. However, for smaller datasets and lower-dimensional feature spaces, K-Nearest Neighbors (K-NN) remains a valuable and effective classification technique, boasting an impressive accuracy of 98%. K-NN's simplicity and ability to capture patterns make it a practical choice for such scenarios. The LSTM model exhibited the highest accuracy, achieving an impressive score of 0.9908. This indicates that the LSTM model is highly effective in detecting ransomware attacks, showcasing its ability to capture intricate patterns and temporal dependencies within the data. With such a high accuracy, the LSTM model can be considered a robust

choice for ransomware detection. During the training process, the LSTM model continuously updates its internal parameters to minimize the loss, resulting in better predictions and higher accuracy over time. As the model converges, the accuracy typically improves, and the loss decreases as shown in Fig. 9.

Fig. 9. Visualized results of LSTM (a. Accuracy & b. Loss mode).

## V. CONCLUSION AND FUTURE WORKS

In conclusion, the studies on ransomware detection have generally yielded positive results. Researchers have identified distinct static features in ransomware samples, such as cryptographic signatures, API methods, and file extensions, that can aid in their identification. Different approaches, including the use of surveillance and honeypots, have been explored to track down and analyze ransomware. Machine learning and classification techniques have proven to be valuable in enhancing both static and dynamic malware analysis.

Additionally, the application of deep learning, such as the LSTM model, has shown remarkable accuracy, reaching up to 99%, in detecting malware and ransomware. These findings highlight the potential of advanced techniques for improving cybersecurity measures against ransomware threats. Continued research and development in this field can further strengthen the detection and mitigation of ransomware attacks. In future work, we propose extending the dataset used for ransomware detection to include a more comprehensive set of features derived from both dynamic and static analysis. Moreover, we intend to explore the use of a hybrid algorithm combining CNN-LSTM models. This fusion of techniques has the potential to improve the accuracy and robustness of ransomware detection, paving the way for more effective defense mechanisms against evolving ransomware threats.

# K-Means Extensions for Clustering Categorical Data on Concept Lattice

Mohammed Alwersh\*, László Kovács

Department of Information Technology, University of Miskolc, Miskolc, Hungary

**Abstract**—Formal Concept Analysis (FCA) is a key tool in knowledge discovery, representing data relationships through concept lattices. However, the complexity of these lattices often hinders interpretation, prompting the need for innovative solutions. In this context, the study proposes clustering formal concepts within a concept lattice, ultimately aiming to minimize lattice size. To address this, the study introduces two novel extensions of the k-means algorithm to handle categorical data efficiently, a crucial aspect of the FCA framework. These extensions, namely K-means Dijkstra on Lattice (KDL) and K-means Vector on Lattice (KVL), are designed to minimize the concept lattice size. However, the current study focuses on introducing and refining these new methods, laying the groundwork for our future goal of lattice size reduction. The KDL utilizes FCA to build a graph of formal concepts and their relationships, applying a modified Dijkstra algorithm for distance measurement, thus replacing the Euclidean distance in traditional k-means. The defined centroids are formal concepts with minimal intra-cluster distances, enabling effective categorical data clustering. In contrast, the KVL extension transforms formal concepts into numerical vectors to leverage the scalability offered by traditional k-means, potentially at the cost of clustering quality due to oversight of the data's inherent hierarchy. After rigorous testing, KDL and KVL proved robust in managing categorical data. The introduction and demonstration of these novel techniques lay the groundwork for future research, marking a significant stride toward addressing current challenges in categorical data clustering within the FCA framework.

**Keywords**—Clustering algorithms; categorical data; k-means; cluster analysis; formal concept analysis; concept lattice

## I. INTRODUCTION

The technique of data clustering involves an unsupervised classification method that aims to group a set of unlabeled objects into meaningful clusters based on their similarities and differences. This process requires objects within the same cluster to exhibit high similarity, while objects in different clusters should have significant differences. Similarities and dissimilarities between objects are evaluated by considering attribute values that describe the objects, often using distance measures. Typically, objects can be represented as vectors in a multidimensional space, with each dimension representing a feature. When numerical features describe objects, geometric distance measures such as Euclidean or Manhattan distance can be used to define their similarity. However, these distance measures are unsuitable for categorical data, including values like gender or location. In recent years, there has been increasing interest in clustering categorical data [1-3]. For categorical data, a comparison measure, rather than a distance

measure, is commonly used [4]. However, this metric does not differentiate between different attribute values since it only measures equality between pairs of values [5].

The widely acclaimed k-means algorithm [6] excels in simplicity and efficiency, particularly for large numerical datasets. However, it is restricted by its inability to handle categorical data directly. To overcome this limitation, adaptations such as the k-modes [3], k-representative [7], and k-centers algorithms [8] have been introduced. The k-modes algorithm uses simple matching similarity measures and substitutes "means" with "modes" for cluster centers. This modification, however, can result in multiple modes within a cluster, which can influence the algorithm's performance. To navigate this, the k-representative algorithm proposed in [9], presents "cluster centers" uniquely suited to categorical data. In this approach, the defining attribute of a cluster's representative stems from the diversity of categorical values within the cluster itself [9]. Although these adaptations of the k-means algorithm share a similar clustering process, they define "cluster center" and "similarity measure" differently for categorical data, which could potentially result in information loss when categorical data are directly transformed into vector space.

This paper introduces two novel extensions of the k-means algorithm for clustering categorical data: K-means Dijkstra on Lattice (KDL) and K-means Vector on Lattice (KVL). Existing methods such as k-means and its variants are restricted by their inability to adequately handle categorical data, often requiring data transformation techniques that can result in information loss. Additionally, they struggle with representing complex, hierarchical relationships inherent in the data. Our proposed methods, KDL and KVL, aim to overcome these limitations by focusing on learning and integrating the representation of categorical values based on their inherent graph structure. This approach not only preserves the richness of the categorical data but also effectively captures the potential similarity and hierarchical relationships between the values. KDL utilizes Formal Concept Analysis to construct a graph, with nodes symbolizing formal concepts and edges representing hierarchical relationships [10]. A customized Dijkstra algorithm identifies the shortest path between formal concepts, replacing the Euclidean distance from traditional k-means. The centroids are those formal concepts with the least sum of intra-cluster distances. This method accurately identifies data patterns and relationships, providing insights often missed by conventional vector representations. KVL, the second extension, transforms formal concepts into numerical concept description vectors and applies traditional k-means. It evaluates concept similarity, groups related concepts, and positions each

cluster's center as the mean of its concept description vectors. This approach excels in scalability by converting categorical data into numerical formats, enabling efficient analysis of larger datasets. Both KDL and KVL significantly advance our understanding of complex datasets by providing a unique perspective on clustering categorical data. These novel extensions of the k-means algorithm pave the way for further research in this field. The primary contributions of this study are the introduction of KDL and KVL as innovative extensions of the k-means algorithm, the comparative evaluation of these methods against existing algorithms, and the laying of groundwork for future advancements in clustering categorical data within the Formal Concept Analysis frameworks.

The remainder of this paper is structured as follows: Section II provides an overview of Formal Concept Analysis (FCA), elucidating key terminologies and notions. Section III delves into Dijkstra's Algorithm and its variations employed for addressing shortest-path problems. Section IV then explores the k-means algorithm and its extended versions tailored for categorical data. This segues into Section V, where the proposed clustering methodologies are thoroughly discussed. The experimental results and their implications are exhibited in Section VI. The paper concludes in Section VII, summarizing the study's main points and potential future directions.

## II. FCA: KEY TERMINOLOGY AND NOTIONS

Formal Concept Analysis (FCA) emerged as a distinctive mathematical field in the early 1980s. Central to its application are particular diagrams known as line or Hasse diagrams, which are utilized to depict information via concept lattices [10]. To enhance the comprehension of the study, the study provide a succinct overview that delineates the critical concepts and definitions within FCA, supplemented by an easily digestible example. The terms and foundations of FCA discussed in this paper are grounded in the work of [11].

**Definition 1. Formal Context:** A formal context is characterized as a tripartite structure  $(G, M, I)$ , where  $G$  represents a collection of objects,  $M$  stands for a set of attributes, and  $I \subseteq G \times M$ , embodies the incidence relationship between  $G$  and  $M$ . For each object  $g \in G$  and attribute  $m \in M$ , a binary relation  $gIm ((g, m) \in I)$  signifies that object  $g$  possesses attribute  $m$ . Typically, a cross table illustrates a formal context, where rows depict the object names and columns exhibit the attribute names. The presence or absence of a cross demonstrates the existence or non-existence of an incidence relationship between  $G$  and  $M$ , respectively. This context is also referred to as a binary context, as demonstrated in Table I.

Expanding on Table I shows a compact formal context in which the object set  $G$  includes  $\{o_1, o_2, o_3, o_4, o_5\}$ , and the attribute set  $M$  comprises  $\{a_1, a_2, a_3, a_4, a_5, a_6\}$ . The cross (x) at the intersection of the object  $g$  row and the attribute  $m$  column indicates that the object  $g$  possesses the attribute  $m$ , while its absence signifies a lack of relationship between  $g$  and  $m$ . For instance, within this formal context, object  $o_1$  is associated with the attributes  $\{a_2, a_6\}$ .

**Definition 2. Derivation Operators:** In a formal context  $(G, M, I)$ , derivation operators  $\uparrow = 2^G \rightarrow 2^M$ ,  $\downarrow = 2^M \rightarrow 2^G$ , are established for every subset of objects  $A$  within  $G$  and a subset of attributes  $B$  within  $M$ . They are precisely defined as  $A^\uparrow = \{m \in M \mid \forall g \in A: (g, m) \in I\}$ ,  $B^\downarrow = \{g \in G \mid \forall m \in B: (g, m) \in I\}$ . The upward operator  $A^\uparrow$  represents the collective attributes shared by all objects in  $A$ , and the downward operator  $B^\downarrow$  comprises all objects that possess all attributes in  $B$ .

These derivation operators  $A^\uparrow$  and  $B^\downarrow$  are also referred to as  $A'$  and  $B'$ . For example, within the context provided in Table I, it can be easily discerned that:

$$\{o_1\}^\uparrow = \{a_2, a_6\}$$

$$\{o_1, o_3\}^\uparrow = \{a_6\}$$

$$\{a_1\}^\downarrow = \{o_3\}$$

$$\{a_2, a_3\}^\downarrow = \{o_5\}$$

**Definition 3. Formal Concepts:** In a provided context denoted as  $k=(G, M, I)$ , a formal concept is recognized as a pair  $(A, B)$ , where  $A$ , a subset of  $G$ , is referred to as the 'extent' part of the formal concept  $(A, B)$ , while  $B$ , a subset of  $M$ , is known as the 'intent' part of the formal concept  $(A, B)$ , provided that  $A' = B, B' = A$ . For instance, considering the formal context illustrated in Table I, the pair  $(\{o_1, o_3\}, \{a_6\})$  emerges as a formal concept, where  $\{o_1, o_3\}$  represents the extent part and  $\{a_6\}$  embodies the intent part.

**Definition 4. Concept Lattices:** Formal concepts can be arranged based on the subconcept-super concept relation  $\leq$ , expressed as follows:  $(A_1, B_1) \leq (A_2, B_2) \Leftrightarrow A_1 \subseteq A_2$  (or equivalently  $B_1 \subseteq B_2$ ), where  $(A_1, B_1)$  is a subconcept (more specific) and  $(A_2, B_2)$  is a super concept (more general). Within a formal context  $K$ , the assembly of all formal concepts, in conjunction with the partial order  $\leq$ , generally defines a complete lattice, referred to as a concept lattice [10]. The notation  $\mathcal{B}(G, M, I)$  signifies the concept lattice derived from a formal context  $(G, M, I)$ .

Fig. 1. Concept lattice corresponding to the formal context from Table I.

By the initial part of the core theorem on concept lattices [10], a concept lattice  $\mathcal{B}(G, M, I)$  is identified as a complete lattice where the infimum and supremum are present for any arbitrary set. This is represented as  $(A_1, B_1) \wedge (A_2, B_2) = (A_1 \cap B_2, (B_1 \cup B_2)'')$  and  $(A_1, B_1) \vee (A_2, B_2) = ((A_1 \cup A_2)'', B_1 \cap B_2)$ .

TABLE I. FORMAL CONTEXT

Objects/ Attributes	a <sub>1</sub>	a <sub>2</sub>	a <sub>3</sub>	a <sub>4</sub>	a <sub>5</sub>	a <sub>6</sub>
o <sub>1</sub>		x				x
o <sub>2</sub>				x		
o <sub>3</sub>	x				x	x
o <sub>4</sub>				x		
o <sub>5</sub>		x	x			

The concept lattice derived from the formal context showcased in Table I is portrayed in Fig. 1 through a line diagram. The lattice is constituted by formal concepts, which are generated depending on the formal context and their relationship defined by the subconcept-superconcept paradigm [11]. Every node in the line diagram symbolizes a formal concept. These formal concepts in the diagram can be categorized into object concepts, described as  $(\{g\}'', \{g\}')$ , or attribute concepts, defined as  $(\{m\}', \{m\}'')$ , indicating the concepts tied to objects or attributes, respectively. An object concept is represented as  $\gamma(g)$ , while an attribute concept is signified as  $\mu(m)$ . When labeling  $\mathcal{B}(G, M, I)$ , The convention adhered to in this study specifies that each object  $g$  gets its label  $g$  for the corresponding formal concept  $\gamma(g)$ , and each attribute  $m$  is labeled as  $m$  for the formal concept  $\mu(m)$ . Certain concept nodes carry objects below them, while others have attributes above them. More often than not, object labeling is placed underneath a node, while attribute labeling is positioned above it in a line diagram. It's worth highlighting that not every concept within a particular context is necessarily an object or an attribute concept. Any concept has the potential to be an object concept, an attribute concept, a blend of the two, or neither [12,13].

### III. DIJKSTRA'S ALGORITHM AND ITS VARIATIONS FOR SHORTEST PATH PROBLEMS

Dijkstra's algorithm was introduced in 1959 by Dutch computer scientist Edsger W. Dijkstra; Dijkstra's algorithm serves as a leading method for finding optimal paths. This algorithm, notable for its efficiency and effectiveness, has found broad application across various fields. One crucial application is in routing through the Internet's vast interconnected web, determining the shortest paths between network nodes. The algorithm operates on a directed weighted graph denoted as  $G = \{V, E\}$ , where  $V$  is the set of vertices and  $E$  the set of edges. Each edge  $e$  has an associated weight, Edge-Cost ( $e$ ), representing the traversal cost. It's essential for the algorithm's efficiency that all weights are non-negative. By applying Dijkstra's algorithm, one can efficiently ascertain the shortest path from a source vertex to every other vertex in the graph. Such information finds applications in diverse fields, including transportation, logistics, and network communication [14].

The algorithm proceeds by assigning temporary and visited states to vertices and updating their distances from the source. It marks vertices as visited, updating the temporary vertices' distances as it progresses. After visiting all vertices, the algorithm terminates. However, it has limitations: it involves a blind search, leading to inefficient resource use and longer operations. Moreover, it cannot handle negative edges, leading to potential inaccuracies in shortest path calculations [15]. The efficiency of Dijkstra's algorithm can be expressed using Big-O notation. The complexity depends on the number of vertices ( $|V| = n$ ) and the updates for priority queues ( $|E|$ ). Different data structures can be used for the priority queue, resulting in different complexities:

- If Fibonacci heap is used, the complexity is  $O(|E| + |V| \log |V|)$ , with DeleteMin operations taking  $O(\log |V|)$ .
- If a standard binary heap is used, the complexity is  $O(|E| \log |E|)$ , with  $|E|$  updates for the standard heap.
- If a priority queue is used, the complexity is  $O(|E| + |V|^2)$ , where the  $|V|^2$  term arises from  $|V|$  scans of the unordered set New Frontier to find the vertex with the least sDist value.

There are numerous variants of Dijkstra's algorithm, each addressing specific needs and modifications. Among the most well-known is the Bellman-Ford algorithm [16], which caters to negative-weighted graphs. The Floyd-Warshall algorithm [17], employs dynamic programming to find shortest paths, accommodating both positive and negative edge weights. The Johnson algorithm uses the Bellman-Ford algorithm to re-weight the graph, eliminating negative weights, then applies Dijkstra's algorithm, effectively reducing execution time for sparse graphs [18]. Lastly, the A\* algorithm extends Dijkstra's by combining breadth-first search and heuristic methods, potentially increasing speed but failing to ensure absolute accuracy [14]. Depending on the problem's requirements and characteristics, one can choose the most suitable variant to obtain optimal results. Dijkstra's algorithm is utilized to measure distance in the particular use case of clustering categorical data within a concept lattice. This approach allows us to interpret the intricate structures of the lattice effectively, paving the way for efficient clustering and insight generation.

### IV. K-MEANS ALGORITHM AND ITS EXTENSIONS FOR CATEGORICAL DATA

The k-means algorithm [6], is a widely used partitional or non-hierarchical clustering method. Given a set  $D$  of  $N$  numerical data objects, a natural number  $k$  (where  $k$  is less than or equal to  $N$ ), and a distance measure between objects, the algorithm aims to find a partition of  $D$  into  $k$  non-empty and disjoint clusters. The objective is to minimize the sum of squared distances between each data object and its assigned cluster center.

Mathematically, the k-means algorithm can be formulated as an optimization problem. Let  $U = [u_{i,j}]$  be the partition matrix, where  $u_{i,j}$  is a binary indicator variable representing whether object  $X_i$  belongs to cluster  $S_j$ . Let  $Z = \{Z_1, Z_2, \dots, Z_k\}$  be the set of cluster centers. The squared

Euclidean distance  $dis(\cdot, \cdot)$  between two objects  $X_i$  and  $Z_j$  is used as the distance measure [19].

The objective function to be minimized is given by  $P$  problem, as specified in Eq. (1):

$$P(U, Z) = \sum_{j=1}^k \sum_{i=1}^N u_{i,j} dis(X_i, Z_j) \quad (1)$$

The objective function presented in Eq. (1) is to be minimized, and this operation is constrained by specific conditions as outlined in Eq. (2):

$$\begin{aligned} \sum_{j=1}^k u_{i,j} &= 1, \quad 1 \leq i \leq N. \\ u_{i,j} &\in \{0,1\}, \quad 1 \leq i \leq N, 1 \leq j \leq k \end{aligned} \quad (2)$$

where  $U = [u_{i,j}]_{N \times k}$  represent a partition matrix, where each element  $u_{i,j}$  equals 1 if object  $X_i$  belongs to cluster  $S_j$  and 0 otherwise.  $Z = \{Z_1, Z_2, \dots, Z_k\}$  denotes the set of cluster centers. The function  $dis(\cdot, \cdot)$  calculates the squared Euclidean distance between two objects.

The k-means algorithm follows a four-step process until the objective function  $P(U, Z)$  converges to a local minimum:

- Initialize cluster centers as  $Z^0 = Z_1^0, \dots, Z_k^0$ , and set  $t = 0$ .
- With fixed cluster centers  $Z^t$ , solve  $P(U, Z^t)$  to obtain partition matrix  $U^t$ . Each object  $X_i$  is assigned to the cluster with the nearest cluster center.
- With fixed partition matrix  $U^t$ , generate updated cluster centers  $Z^{t+1}$  to minimize  $P(U^t, Z^{t+1})$ . The new cluster centers are computed as the mean of the objects within each cluster.
- If convergence is reached or a stopping criterion is satisfied, output the final result and terminate. Otherwise, increment  $t$  by 1 and go back to step 2.

By iteratively updating the partition matrix and the cluster centers, the k-means algorithm converges to a local minimum, providing an effective approach for clustering numerical data objects. As mentioned above, the K-means algorithm [3] is primarily designed for numerical data. However, the algorithm's direct application to categorical data presents challenges due to the need for a natural numerical representation for categorical variables. Several extensions and adaptations of the K-means algorithm have been proposed to overcome this limitation to enable its use with categorical data. One widely used extension is the K-modes algorithm [3]. Unlike the original K-means algorithm, which relies on the Euclidean distance, the K-modes algorithm utilizes a dissimilarity measure specifically tailored for categorical variables. Instead of computing distances based on coordinates in a multidimensional space, the K-modes algorithm uses a simple matching distance measure and defines "cluster centers" as modes. In the K-modes algorithm, the dissimilarity between two categorical objects,  $X$  and  $Y$  described by  $M$  categorical attributes, is computed by counting the total number of matching attribute values between the two objects. The dissimilarity measure is defined as shown in Eq. (3):

$$dis(X, Y) = \sum_{i=1}^M \delta(X_i, Y_i) \quad (3)$$

where,

$$\delta(X_i, Y_i) = \begin{cases} 0 & \text{if } X_i = Y_i \\ 1 & \text{if } X_i \neq Y_i \end{cases}$$

For a cluster of categorical objects,  $\{X_1, \dots, X_N\}$ , where  $X_i = (x_{i1}, \dots, x_{iM})$  and  $1 \leq i \leq N$ , the K-modes algorithm defines the mode  $Z = (o_1, \dots, o_M)$  of the cluster by assigning  $o_m, 1 \leq m \leq M$ , as the most frequently appearing value within  $\{x_{1m}, \dots, x_{Nm}\}$ . The authors in [3] introduced these modifications to develop the K-modes algorithm, which resembles the K-means method for clustering categorical data. However, it should be noted that the mode of a cluster is not generally unique, which introduces instability into the algorithm depending on the selection of modes during the clustering process.

The k-Representative algorithm [7] is a further extension of the K-means algorithm which incorporates the idea of cluster representatives. Rather than utilizing modes as cluster centers, this concept was brought forward by [7], defining representatives in the following manner. Let's take a cluster  $S$ , comprised of categorical objects, expressed as  $S = \{X_1, \dots, X_p\}$ . Each object  $X_i$  can be represented as  $(x_{i1}, \dots, x_{iM})$  with the condition  $1 \leq i \leq p$ . For each attribute  $m$  ranging from 1 to  $M$ ,  $O_m^S$  symbolizes the set of categorical values derived from  $x_{1m}, \dots, x_{pm}$  within the cluster, that means  $O_m^S$  denotes the set of unique categorical values for attribute  $m$  within a specific cluster  $S$ . This is essentially a collection of all distinct categories for attribute  $m$  across all objects in the cluster  $S$ . For instance, suppose a cluster  $S$  consisting of the following three objects:

- Object 1: (Red, Circle, Large)
- Object 2: (Blue, Circle, Medium)
- Object 3: (Red, Square, Medium)

Upon examining the attribute 1 (color), then  $O_1^S$  would be {Red, Blue}, since these are the unique color values within cluster  $S$ . Similarly,  $O_2^S$  for attribute 2 (shape) would be {Circle, Square}, and  $O_3^S$  for attribute 3 (size) would be {Large, Medium}. The representative of cluster  $S$ , denoted by  $Z_S = (z_1^S, \dots, z_M^S)$ , is characterized as:

$$z_m^S = \{(o_{ml}, fS(o_{ml})) \mid o_{ml} \text{ is an element of } O_m^S\} \quad (4)$$

Here,  $fS(o_{ml})$  signifies the proportional frequency of category  $o_{ml}$  within cluster  $S$ . This is computed by dividing the number of objects in  $S$ , possessing the category  $o_{ml}$  for the  $m^{th}$  attribute, by the total count of objects in  $S$ . This is represented by  $\#S(o_{ml})$  and  $p$ , respectively:

$$fS(o_{ml}) = \#S(o_{ml}) / p \quad (5)$$

In essence, each  $z_m^S$  is a distribution over  $O_m^S$ , defined by the proportional frequencies of categorical values inside the cluster. The k-Representative algorithm employs a simple matching measure,  $\delta$ , to determine the dissimilarity between an object  $X = (x_1, \dots, x_M)$  and the representative  $Z_S$ . The dissimilarity  $dis(X, Z_S)$  is characterized as defined in Eq. (6):

$$dis(X, Z_S) = \sum_{m=1}^M \sum_{o_{ml} \in O_m^S} fS(o_{ml}) \cdot \delta(x_m, o_{ml}) \quad (6)$$

In this context, the dissimilarity  $dis(X, Z_S)$  is predominantly influenced by two key factors: the proportional frequencies of categorical values within the cluster and the basic matching of these categorical values. The proportional frequencies reflect the relative importance and prevalence of different categories within the cluster, while the matching mechanism assesses the similarity between the categorical values of the data object  $X$  and the representative center  $Z_S$ . By considering both the proportional frequencies and the matching aspect, the dissimilarity measure captures the distinctive characteristics and relationships of categorical variables within the cluster. To illustrate this, let's continue with the example above and consider a new object 4: (Blue, Circle, Small). The dissimilarity between object 4 and the representative  $Z_S$  of the cluster  $S$  would be calculated as follows: The representative  $Z_S$  for the previous example cluster would be:

- For attribute 1 (Color): {'Red', 0.67}, ('Blue', 0.33)}
- For attribute 2 (Shape): {'Circle', 0.67}, ('Square', 0.33)}
- For attribute 3 (Size): {'Large', 0.33}, ('Medium', 0.67)}

Let's calculate the dissimilarity between Object 4 and the representative  $Z_S$  using Eq. (6). For each attribute, the contribution to the overall dissimilarity is individually calculated:

For attribute 1 (Color):

$$o_{ml} \text{ in } O_1^S: \{('Red'), ('Blue')\}$$

$$fS(o_{ml}): \{0.67, 0.33\}$$

$$\delta('Blue', 'Red')=1, \quad \delta('Blue', 'Blue')=0$$

Contribution for attribute 1:

$$fS('Red') \cdot \delta('Blue', 'Red') + fS('Blue') \cdot \delta('Blue', 'Blue') \\ = 0.67 \cdot 1 + 0.33 \cdot 0 = 0.67$$

For attribute 2 (Shape):

$$o_{ml} \text{ in } O_2^S: \{('Circle'), ('Square')\}$$

$$fS(o_{ml}): \{0.67, 0.33\}$$

$$\delta('Circle', 'Circle')=0, \quad \delta('Circle', 'Square')=1$$

Contribution for attribute 2:

$$fS('Circle') \cdot \delta('Circle', 'Circle') + fS('Square') \cdot \delta('Circle', 'Square') \\ = 0.67 \cdot 0 + 0.33 \cdot 1 = 0.33$$

For attribute 3 (Size):

$$o_{ml} \text{ in } O_3^S: \{('Large'), ('Medium')\}$$

$$fS(o_{ml}): \{0.33, 0.67\}$$

$$\delta('Small', 'Large')=1, \quad \delta('Small', 'Medium')=1$$

Contribution for attribute 2:

$$fS('Large') \cdot \delta('Small', 'Large') + fS('Medium') \cdot \delta('Small', 'Medium') \\ = 0.33 \cdot 1 + 0.67 \cdot 1 = 1$$

Finally, sum up the contributions from all attributes:

$$dis(Object4, V_S) = 0.67 + 0.33 + 1 = 2$$

Therefore, the dissimilarity between object 4 and the representative  $Z_C$  of cluster  $S$  is 2. Based on this dissimilarity, the cluster assignment of object 4 can be determined by comparing its dissimilarity with other cluster representatives. Object 4 will be assigned to the cluster with the lowest dissimilarity, indicating the cluster it is most similar to.

Several extensions have been proposed to tackle specific issues related to categorical data clustering. The k-Centers algorithm [8] is an extension of the K-means algorithm, defining the cluster center as a set of probability distributions estimated using a kernel density estimation method. Dissimilarities between data objects and cluster centers are calculated using indicator vectors and squared Euclidean distance, providing an effective method for clustering categorical data while preserving the key principles of K-means. Other extensions have been proposed to address specific challenges associated with clustering categorical data. These extensions include fuzzy K-modes [20], scalable K-modes [21], and probabilistic K-modes [22], among others. Fuzzy K-modes permit soft assignments, allowing data points to belong to multiple clusters with various degrees of membership. Scalable K-modes enhance computational efficiency for large-scale categorical datasets, while probabilistic K-modes incorporate probabilistic models for uncertainty in cluster assignments, giving a more refined view of cluster membership.

The development of these extensions demonstrates the ongoing efforts to adapt the K-means algorithm for categorical data clustering. These approaches not only consider the unique characteristics of categorical variables but also address challenges such as missing data, scalability, and uncertainty in cluster assignments. The availability of these extensions expands the applicability of the K-means algorithm, allowing it to be effectively utilized in a wide range of domains where categorical data analysis is prevalent.

## V. PROPOSED CLUSTERING METHODS

### A. K-means Dijkstra on Lattice (KDL)

The K-means Dijkstra on Lattice (KDL) method uniquely merges the structural representation of Formal Concept Analysis (FCA) with the computational efficiency of a customized version of Dijkstra's algorithm. This innovative procedure addresses the distinctive challenges associated with clustering categorical data while duly considering the data's inherent structure. KDL method harmoniously integrates the mathematical rigor of FCA and the algorithmic strength of Dijkstra's approach, crafting a new path in categorical data analysis. The general procedure of KDL as follows:

- **Data Conversion to Formal Context:** In the initial phase, the categorical data is transformed into a formal context. This context is represented by a binary matrix, where rows correspond to distinct objects, and columns represent various attributes. A value of 1 signifies that a given object belongs to a certain attribute category, and a 0 indicates the lack of such a relationship.
- **Formal Concept Derivation:** The FCA is then applied to this formal context. It uses the "NextClosure" algorithm

[23], which ensures that all possible formal concepts in the context are generated. These concepts represent significant associations between objects and attributes and capture the underlying structure and dependencies within the data. The hierarchical relationships among these concepts are represented in a lattice structure or graph, which is constructed using the "Ipred" algorithm, modified to suit the needs of the current study. "Ipred" algorithm is very fast for building the Hasse diagram. For more information about this algorithm, refer to [24]. In the quest for an analytical solution to count concepts, Schüt [25] proposed an upper approximation for the count, expressed as  $|C| \leq 3/2 \cdot 2^{\sqrt{|I|+1}} - 1$ , where  $|C|$  denotes the number of concepts and  $|I|$  represents the number of entries in the formal context. This approximation accommodates not merely the number of objects or attributes but also the overall size of the context, providing a potentially more precise estimate of the concept count [26].

- **Assigning Edge Weights:** This step is critical for defining the cost of moving between concepts within the lattice. Each transition has an associated cost, which can vary depending on the direction of movement. For example, transitioning from a parent concept to a child concept can be assigned a higher cost (let's say a cost of 2), than moving from child to parent (let's say a cost of 1), reflecting the importance of specific transitions in categorical attributes.
- **Using Dijkstra's Algorithm for Distance Measurement:** The method employs the Dijkstra algorithm to measure distance within the concept lattice. It calculates the minimum cost of the shortest path between two formal concepts in a concept lattice using the weights assigned to the edges. This provides an effective measurement for the optimal path within the concept lattice.
- **Calculation and Updating of Cluster Centroids:** The centroids of the clusters, which need to be formal concepts themselves, are calculated and continually updated until the values stabilize. The representative centroid of a cluster is the formal concept with the smallest sum of distances to all other concepts within the cluster, minimizing the overall clustering cost function.

In the context of the proposed clustering method utilizing Formal Concept Analysis (FCA) and Dijkstra's algorithm, an important property arises, for any pair of concepts  $c_1$  and  $c_2$  within the concept lattice, there always exists a path connecting  $c_1$  to  $c_2$ . The concept lattice, constructed through FCA, represents the hierarchy of formal concepts derived from the categorical data. The property asserts that no matter which two concepts are chosen within the lattice, there is always a path connecting them. This means there is a sequence of edges to traverse, moving from one concept to another, ultimately leading from  $c_1$  to  $c_2$ . By relying on the subconcept-super concept relation ( $\leq$ ) transitivity in the lattice prove that a path exists between any two concepts in a lattice as described in Definition 4 in Section II. Let's consider two concepts  $c_1$  and  $c_2$  in the lattice. If  $c_1$  and  $c_2$  are directly connected (i.e.,  $c_1 \leq c_2$  or

$c_2 \leq c_1$ ), then a path exists between them as they are adjacent concepts in the lattice. If  $c_1$  and  $c_2$  are not directly connected, consideration can be given to all concepts that are reachable from  $c_1$  in the lattice. Let's denote this set as  $R(c_1)$ . Similarly, the set of all concepts reachable from  $c_2$  as can be defined  $R(c_2)$ . Since the lattice is a partially ordered set,  $R(c_1)$  and  $R(c_2)$  are subsets of the lattice. Now, let's consider the intersection of  $R(c_1)$  and  $R(c_2)$ , denoted as  $R(c_1) \cap R(c_2)$ . If their intersection is not empty, it means that there exists at least one concept that is reachable from both  $c_1$  and  $c_2$ . Let's denote this concept as  $c$ . Since  $c$  is in  $R(c_1)$ , there is a path from  $c_1$  to  $c$ . Similarly, because  $c$  is within  $R(c_2)$ , a path leads from  $c$  to  $c_2$ . Thus, by connecting these two paths, a continuous path is formed from  $c_1$  to  $c_2$ .

If  $R(c_1) \cap R(c_2)$  is empty, no concepts can be reached from both  $c_1$  and  $c_2$ . Nonetheless, establish a pathway between  $c_1$  and  $c_2$  by considering the concepts that are reachable from each and locating a shared concept that functions as an intermediary. This process can be conducted iteratively, broadening the search for concepts reachable from both  $c_1$  and  $c_2$  until a common concept is discovered. By exploiting the transitivity of the subconcept-super concept relationship and considering the accessibility of concepts within the lattice, a path between any two lattice concepts can always be found.

The concept lattice structure inherently guarantees a path between any pair of concepts, rooted in its construction, which encapsulates all potential combinations of objects and attributes as formal concepts. As a result, the lattice forms a connected structure, allowing for traversal from one concept to another through a series of links. This trait is vital for the suggested clustering method, ensuring the computation of the least costly shortest path between any formal concept pair using the Dijkstra-based distance measure. It confirms that all concepts in the lattice can be accessed, and their dissimilarities compared, facilitating precise cluster assignments based on categorical profiles. The clustering method efficiently leverages this connectivity within the concept lattice, capturing hierarchical relationships, semantic constraints, and directional costs embedded in the data. This inherent lattice connectivity aids in delivering meaningful and accurate cluster assignments, ensuring all concepts within the lattice remain interconnected and accessible.

1) *Dijkstra-based distance measure description:* The Dijkstra-Based Distance Measure is a key component of the K-means Dijkstra on Lattice (KDL) method, serving as a more efficient substitute for the Euclidean distance metric in standard K-means algorithms. The KDL method incorporates Dijkstra's algorithm on a lattice structure generated from categorical data via Formal Concept Analysis (FCA). The algorithm computes the shortest path between two formal concepts in the lattice, considering both cost and path direction. Notably, upward transitions (parent-to-child concept) may incur higher costs than downward transitions (child-to-parent). The algorithm utilizes a min-heap-based priority queue for optimization.

Formally, the Hasse diagram built from a concept lattice  $B(C, <)$ , can be represented as  $\mathcal{H}(C, E)$ , where  $C$  is the set of

formal concepts, and  $E$  denotes the edges representing the hierarchical relationships among them. The start and end formal concepts are denoted as  $C_s$  and  $C_e$ , respectively. The cost to reach a concept  $c$  from the start concept  $C_s$  is represented as  $d(c)$ . The algorithm also defines cost functions "UpCost" and "DownCost," representing the costs of moving upwards and downwards in the lattice. The Dijkstra-based distance measure uses a priority queue  $Q$ , based on a min-heap, where each element is a pair  $(d(c), c)$  sorted by  $d(c)$ . It also maintains a set  $V$  to keep track of the nodes already visited. The cost function  $f: C \times C \rightarrow \mathbb{R} \cup \{\infty\}$  is defined with  $c$  and  $c'$  being two formal concepts in the lattice:

$$f(c, c') = \begin{cases} \text{UpCost}, & \text{if } c \supseteq c' \\ \text{DownCost}, & \text{otherwise} \end{cases} \quad (7)$$

Subsequently, the Dijkstra-based distance measure, represented as  $d: C \times C \rightarrow \mathbb{R} \cup \{\infty\}$ , computes the minimum cost path from the start concept  $C_s$  to the end concept  $C_e$  in the lattice:

$$d(C_s, C_e) = \min\{\sum_{i=1}^{n-1} f(c_i, c_{i+1}) \mid (c_1, c_2, \dots, c_n) \text{ is a path from } C_s \text{ to } C_e\} \quad (8)$$

Here,  $n$  is the number of formal concepts in a specific path from  $C_s$  to  $C_e$ . For each possible path from  $C_s$  to  $C_e$ , sum the costs from each step  $c_i$  to  $c_{i+1}$  in the path, and  $d(C_s, C_e)$  is the minimum of these sums over all possible paths. The algorithm functions as follows:

---

**Algorithm 1:** The Dijkstra-based distance measure algorithm on the concept lattice.

---

**Inputs:**  $C_s, C_e, \mathcal{H}(C, E), \text{UpCost}, \text{DownCost}$ .

**Output:** minimum cost from  $C_s$  to  $C_e$

Initialize:

For each  $c$  in  $\mathcal{H}$ :

$d(c) \leftarrow \infty$

EndFor

$d(C_s) \leftarrow 0$

Initialize  $P$  and  $V \leftarrow \emptyset$

Insert  $(0, C_s)$  into  $Q$

While  $Q \neq \emptyset$  do:

$(d(c), c) \leftarrow \text{Dequeue}(Q)$

If  $c = C_e$  then:

Return  $d(C_e)$ .

EndIf

If  $c$  not in  $V$  then:

Add  $c$  to  $V$

EndIf

For each neighbor  $u$  of  $c$  do:

If neighbor not in  $V$ :

If  $c$  is a superset of  $u$  then:

$cost \leftarrow d(c) + \text{UpCost}$

Else:

$cost \leftarrow d(c) + \text{DownCost}$

EndIf

If  $cost < d(u)$  then:

$d(u) \leftarrow cost$

$P(u) \leftarrow c$

Enqueue  $(d(u), u)$  into  $Q$

EndIf

EndIf

EndFor  
EndWhile

---

In Algorithm 1, several symbols are introduced for clarity. The symbol  $C_s$  denotes the starting concept in the concept lattice, while  $C_e$  represents the ending concept.  $\mathcal{H}(C, E)$  refers to the concept lattice itself, composed of concepts  $C$  and edges  $E$ . The terms 'UpCost' and 'DownCost' specify the costs for upward and downward movements within the lattice, respectively.  $d(c)$  is used to signify the current shortest path distance from  $C$  to any given concept  $c$ . A predecessor map is denoted by  $P$ , where  $P(c)$  reveals the predecessor of a concept  $c$  in the shortest path originating from  $C_s$ . Finally,  $Q$  and  $V$  serve as a priority queue for upcoming nodes to visit and a set for nodes already visited, respectively. The algorithm always returns the minimum cost of the shortest path between  $C_s$  and  $C_e$  due to the property of the lattice structure, which ensures a path exists between any two concepts.

This approach has a time complexity of  $O(E + C \log(C))$ , where  $E$  is the number of edges (relationships between formal concepts), and  $C$  is the total count of formal concepts in the lattice. By leveraging the lattice structure, the cost function, and an efficient min-heap-based priority queue, the Dijkstra-Based Distance Measure provides a more accurate representation of dissimilarities in categorical data. This results in an optimized clustering process and yields more accurate and meaningful cluster assignments.

2) *Cluster centers:* Defining the cluster centers, or centroids, in a concept lattice is vital for effectively implementing the K-means Dijkstra on Lattice (KDL) method. These centroids need to be formal concepts within the lattice. The continual updating and calculation of these representative centroids significantly influence the minimization of the overall clustering cost function. To formally describe this, consider a cluster  $S$  composed of a set of formal concepts  $\{c_i\}$  where  $i = 1, 2, \dots, |S|$ . The representative formal concept, denoted as  $Z$ , is defined as the concept within  $S$  that minimizes the sum of the distances to all other concepts in the same cluster. This can be mathematically expressed as:

$$Z = \operatorname{argmin}_{Z \in S} \left( \sum_{i=1}^{|S|} d(c_i, Z) \right) \quad (9)$$

Here,

$c_i$  represents each concept within the cluster  $S$

In Eq. (9),  $d(c_i, Z)$  is the Dijkstra-based distance from the potential centroid  $Z$  to each concept  $c_i$  within the cluster. The argmin operation is employed to find the formal concept  $Z$  in  $S$  that yields the smallest sum of distances to all other concepts in the cluster  $S$ . It is important to note that  $Z$  inherently belongs to the cluster  $S$ , which allows for a more efficient calculation of the minimal sum of distances to all other concepts within  $S$ . Furthermore, the existence of a center for any set of formal concepts is ensured due to the properties of the Dijkstra-based distance measure. This consistency makes the method universally applicable, regardless of the specific set of formal concepts under consideration. This method of defining cluster centers in the concept lattice adheres to mathematical rigor while being practically feasible, offering a systematic way to

manage and interpret complex categorical datasets. This method enhances the interpretability of clustering results by identifying representative formal concepts for each cluster, fostering more comprehensive and insightful data analysis.

3) *The clustering algorithm:* The K-Means Dijkstra on Lattice (KDL) clustering algorithm, grounded in Formal Concept Analysis (FCA) and the Dijkstra-based distance measure, can be articulated through the following sequential stages:

---

**Algorithm 2:** K-Means Dijkstra on Lattice (KDL) clustering algorithm

---

**Inputs:**  $k$ , the number of clusters;  $\mathcal{B}$ , the lattice of formal concepts.

**Output:** The resulting clusters  $\{S_1, S_2, \dots, S_k\}$ .

**Initialize:**

Select  $k$  formal concepts  $\{c_1, c_2, \dots, c_k\}$  from the lattice  $\mathcal{B}$  randomly as the initial centroids of the  $k$  clusters.

**Assignment:**

For each formal concept  $c \in \mathcal{B}$  do:

Assign  $c$  to the cluster  $S_i$  for which the Dijkstra-based distance measure  $d(c, Z_i)$  is minimized, where  $Z_i$  is the centroid of cluster  $S_i$ .

Using Equations (7, 8)

**Centroid Update:**

For each cluster  $S_i$  do:

Recalculate the centroid  $Z_i$  as the formal concept  $c$  that minimizes the total distance to all other concepts within  $S_i$

Using Equation (9)

**Iteration:**

While centroids change between iterations do:

Repeat steps 2 and 3.

**Finalization:**

Output the resulting clusters  $\{S_1, S_2, \dots, S_k\}$ .

---

4) *Cost analysis of k-means dijkstra on lattice (KDL) method:* This section analyzes the computational complexity of the proposed K-Means Dijkstra on Lattice (KDL) method. The computational cost of each step will be evaluated, from the initialization of clusters to their final assignment. This analysis will provide insights into the efficiency and scalability of the KDL method.

Given the parameters:

- $K$  represents the number of clusters.
- $N$  represents the number of objects.
- $A$  represents the number of attributes.
- $C$  represents the number of concepts.
- $E$  represents the number of edges in the lattice.
- $B$  represents the maximum number of border elements in the lattice construction.

The proposed K-Means Dijkstra on Lattice (KDL) method commences with data preprocessing, wherein the categorical dataset transforms a formal context. This stage involves a binary translation of each dataset entry, leading to a time complexity of  $O(NA)$ . Subsequently, a lattice is generated from the formal concepts obtained in the previous stage. This

phase necessitates looping over all border elements for each concept, inducing a worst-case time complexity of  $O(CB)$ . The final stage of the process encompasses a K-means-like clustering operation. This phase includes iterations over all the concepts to assign clusters and update centroids. The computation of the shortest paths between pairs of concepts within the lattice primarily influences this stage's time complexity. This is achieved using Dijkstra's distance algorithm. Assuming  $I$  iterations are required to reach convergence, the time complexity for computing the shortest paths between all pairs of concepts culminates in  $O(ICK(E + C \log C))$ . To summarize, the KDL method's overall time complexity, significantly influenced by the data preprocessing, lattice construction, and lattice-based clustering stages, can be approximated as  $O(NA + CB + ICK(E + C \log C))$ . It is worth noting that this is a rough estimation, with actual time complexity potentially varying based on the characteristics and data distribution within the formal context. However, focusing on the dominant term for the sake of simplification, the time complexity of the KDL method becomes  $O(ICK(E + C \log C))$ .

**B. K-means Vector on Lattice (KVL)**

The K-means Vector on Lattice (KVL) method is essential for converting categorical data into numerical data. Leveraging the classical k-means algorithm facilitates data grouping, making it instrumental for various data analysis operations, especially when dealing with predominantly categorical or non-numeric data. The essence of this method lies in its capacity to convert formal concepts, regardless of their abstract or categorical nature, into 'concept description vectors'. These vectors exist in a real-valued vector space, which not only makes them easily adaptable to standard mathematical procedures but also optimizes them for computational analysis. Each vector represents the formal concept from which it was derived, encapsulating its fundamental attributes. Every dimension within the vector signifies a different attribute of the concept, with its magnitude corresponding to the prevalence or significance of the attribute within the concept. This forms a compressed yet efficient way to contain the information intrinsic to the formal concept.

With the creation of concept description vectors, these entities can now be subjected to the k-means algorithm. This renowned clustering method partitions the data into a specified number 'k' of distinct clusters. Each cluster is identified by its centroid, which serves as the symbolic or physical center of the cluster. All data points, or concept description vectors in this context, within a specific cluster have a closer similarity to their cluster's centroid than to those of other clusters. This aids in the aggregation of analogous concepts, thereby facilitating insightful analysis of the data.

**Definition 5. Concept Description Vector:** Let  $Y = (A, B)$  be a formal concept, where  $A \subseteq G$ ,  $B \subseteq M$ , and a context  $T = (G, M, I)$  has  $|M| = q$ ,  $|G| = r$ , the incidence relation  $I \subseteq G \times M$  can be represented as a binary matrix, where the rows correspond to the elements of  $G$  (objects), the columns correspond to the elements of  $M$  (attributes), and each entry of the matrix is either 1 or 0, indicating whether the relation  $(g, m)$  exists or not. Let's denote this matrix as  $I$ , with

dimensions  $r \times q$ , where  $r$  is the number of objects in  $G$  and  $q$  is the number of attributes in  $M$ . The rows of the matrix can be labeled by  $g_1, g_2, \dots, g_r$  and the columns by  $m_1, m_2, \dots, m_q$ , the matrix can be defined as shown in Table II:

The concept description vector is defined as  $V_Y = (v_{m_1}, v_{m_2}, \dots, v_{m_q})$ .  $v_{m_h}$  ( $h$  ranging from 1 to  $q$ ) is obtained as follows [5]:

$$v_{m_h} = \begin{cases} 1 & \text{if } m_h \in B \\ \frac{1}{r} \sum_{j=1}^r I(g_j, m_h) & \text{if } m_h \notin B, \forall g_j \in G \end{cases} \quad (10)$$

where  $m_h \in M$ .

The method to calculate each attribute within a concept is different. It depends on whether the attribute is in the intent of each concept or not. The concept vector is the base for getting the similarity between concepts. This vector is obtained from the context based on the intent of each concept. Depending on whether the attribute  $m_h$  is a part of the intent  $B$ . If  $m_h$  is a part of the intent, it is assigned a value of 1, indicating its high importance in defining the concept. If not, it's calculated as the average association of this attribute across all objects, represented as  $\frac{1}{r} \sum_{j=1}^r I(g_j, m_h)$  if  $m_h \notin B$ . This can be perceived as the frequency or relevance of this attribute across the object set  $G$ . The computation of each attribute forms the concept description vector used to ascertain the similarity between concepts.

After defining the concept description vectors, the KVL method introduces the concept similarity measure. This measure, often referred to as Concept Similarity ( $CS$ ), as explicated in Definition 6, is used to ascertain the proximity of these concepts. Concept Similarity is calculated using the Euclidean Distance between any two concept description vectors  $V_{Y_1}$  and  $V_{Y_2}$ . The  $CS$  equation helps us to quantify the closeness between two concepts, taking into account each component of their respective concept description vectors.

**Definition 6. Concept Similarity:** Concept Similarity ( $CS$ ) is calculated based on the concept description vector in Definition 5 using traditional Euclidean distance. For any two concept description vectors

$V_{Y_1} = (V_{Y_1 m_1}, V_{Y_1 m_2}, \dots, V_{Y_1 m_q})$  and  $V_{Y_2} = (V_{Y_2 m_1}, V_{Y_2 m_2}, \dots, V_{Y_2 m_q})$ , the Euclidean distance is defined as per Eq. (5):

$$CS(V_{Y_1}, V_{Y_2}) = \frac{1}{\sqrt{(V_{Y_1 m_1} - V_{Y_2 m_1})^2 + (V_{Y_1 m_2} - V_{Y_2 m_2})^2 + \dots + (V_{Y_1 m_q} - V_{Y_2 m_q})^2}} \quad (11)$$

TABLE II. MATRIX CORRESPONDING TO THE RELATION  $I$

Objects/Attributes	$m_1$	$m_2$	...	$m_q$
$g_1$	$I(g_1, m_1)$	$I(g_1, m_2)$	...	$I(g_1, m_q)$
$g_2$	$I(g_2, m_1)$	$I(g_2, m_2)$	...	$I(g_2, m_q)$
...	...	...	...	...
$g_r$	$I(g_r, m_1)$	$I(g_r, m_2)$	...	$I(g_r, m_q)$

This framework of concept description vectors and concept similarity lays the groundwork for the k-means clustering algorithm. The algorithm takes the concept description vectors as inputs and leverages the concept similarity measure to identify which concepts most resemble each other. Concepts exhibiting high similarity are then grouped into clusters. The center of each cluster, represented by  $Z_i$ , is calculated as the mean of all concept description vectors within that cluster. Let's denote  $S_i$  as the  $i^{th}$  cluster ( $i = 1, 2, \dots, k$ ), where  $k$  is the number of clusters. The centroid of each cluster  $S_i$  can be defined as:

$$Z_i = \frac{1}{|S_i|} \sum_{j=1}^{|S_i|} V_{Y_j}, V_{Y_j} \in S_i \quad (12)$$

The k-means algorithm aims to minimize the within-cluster sum of squares (WCSS) of Euclidean distances. This objective function  $Q$  is as follows:

$$Q = \sum_{i=1}^k \sum_{j=1}^{|S_i|} \|V_{Y_j} - Z_i\|^2, V_{Y_j}, Z_i \in S_i \quad (13)$$

The algorithm alternates between assigning each concept description vector to the nearest centroid and recalculating the centroid of each cluster using Eq. (11) and (12), until the clusters stabilize. The algorithm has converged, and the clusters are optimally partitioned concerning the given concept description vectors.

**1) The clustering algorithm:** The main idea is as follows. Suppose  $T = (G, M, I)$  is a formal context and  $V(T)$  is the set of all concept description vectors and the number of clusters is  $K$ . Firstly, the initial centers,  $Z_t^0 = (A_t, B_t)$  ( $t = 1, 2, \dots, K$ ), of  $K$  clusters are selected randomly, and the corresponding clusters are  $S_t^0 = \{Z_t^0\}$ . Secondly, join a concept description vector  $v \in V(T)$  into one cluster according to the following rule: if the distance between  $v$  and  $Z_t^0$  is lower than that of  $v$  and other centers, then,  $v$  is put into  $S_t^0$ . Each vector in  $V(T)$  can be adjusted according to this rule. Thirdly, the new center of each cluster can be determined by calculating the mean value of vectors within each cluster and set it as a new center. Finally, repeat the above process till the twice computation of each cluster and center are the same. The algorithm steps are as follows:

---

**Algorithm 3.** K-means clustering of concepts.

---

**Input:** All the description vectors of concepts in  $V(T)$ ,  $k$ .

**Output:** The clusters and corresponding centers.

**Initialize:**

Set  $S_1^i \leftarrow \emptyset, S_2^i \leftarrow \emptyset, \dots, S_k^i \leftarrow \emptyset;$

$i \leftarrow 0;$

Select initial center vectors of  $K$  clusters:  $Z_1^i, Z_2^i, \dots, Z_k^i;$

**Assignment:**

For each  $v \in V(T)$  do:

-Find  $t$  such that

$CS(\text{distance})(v, Z_t^i) \leq CS(\text{distance})(v, Z_j^i), (j = 1, 2, \dots, k)$  then,

$v \in S_t^i;$

EndFor

**Centroid Update:**

For each  $S_t^i$  do:

$Z_t^{i+1} = \frac{1}{|S_t^i|} \sum_{s=1}^{|S_t^i|} v_s, v_s \in S_t^i$ , using Equation (12)

---

$$S_t^{i+1} = \{v \in V(T) | CS(v, Z_t^{i+1}) \leq CS(v, Z_j^{i+1})\}$$

using Equation (11)

EndFor

**Convergence Check:**

If  $Z_t^i = Z_t^{i+1}, S_t^i = S_t^{i+1}, t = 1, 2, \dots, K$ , then

Go to step 5.

Else:

$i = i + 1$ ,

Go to Step 2.

**Output:** clusters  $S_1^i, S_2^i, \dots, S_k^i$  and the corresponding centers  $Z_1^i, Z_2^i, \dots, Z_k^i$ .

Algorithm 1 outlines the process for performing K-means clustering on the set of concept description vectors. The input to the algorithm is the set of all concept description vectors, and the output is the resulting clusters and their centers. The algorithm begins by randomly initializing the clusters and selecting the initial centers for the clusters. It then assigns each concept description vector to the cluster whose center it is closest to, based on the concept similarity measure in Eq. (11). It then updates the clusters' centers based on the mean of the concept description vectors within each cluster using Eq. (12) and repeats this process until the clusters stabilize. mapping the vectors back to the original concepts. Once the K-means clustering is done and the clusters are stabilized, the vectors within each cluster can be traced back to their original concepts. The mapping uses the concept description vectors created in the first step.

**Algorithm 4: Mapping vectors to original concepts.**

**Input:** The clusters  $S_1^i, S_2^i, \dots, S_k^i$  and the corresponding centers  $Z_1^i, Z_2^i, \dots, Z_k^i$ .

**Output:** Clusters of original concepts.

**Initialize:**

$NS_1, NS_2, \dots, NS_k \leftarrow \emptyset$ ,

For  $t = 1$  to  $k$  do:

For each description vector in  $S_t^i$  do:

Map back to its original concept and add to  $NS_t$ .

Using the relationship between the concept description vector and the original concept established in Definition 5.

EndFor

**Output:** the new clusters  $NS_1, NS_2, \dots, NS_k$ , each containing the original concepts.

In this way, the numerical data obtained from the K-means clustering is transformed back into categorical data, giving us clusters of similar concepts rather than clusters of similar vectors. This method of approximation and mapping allows for efficient and meaningful clustering of concepts in a context, making it easier to understand and interpret the relationships and similarities between different concepts.

2) *Cost Analysis of the KVL Method:* This section thoroughly reviews the computational complexity of the KVL method to assess its efficiency and scalability. The first stage is data preprocessing, which involves the transformation of a dataset into a formal context. Here, a binary representation of each object with N objects and A attributes is needed, introducing a time complexity of O(NA). After preprocessing, formal concepts are generated and then converted into vectors in an A-dimensional attribute space. For each of the C

concepts, an equivalent vector in the attribute space needs to be calculated, leading to a time complexity of O(AC). The algorithm starts by randomly selecting K centroids from the pool of C concepts, resulting in a time complexity of O(K). Subsequent stages include iterative assignment and update, where each concept is assigned to its nearest centroid, and centroids are updated based on new assignments. This incurs a time complexity of O(CK) per iteration. These processes are performed I times until convergence, resulting in a total time complexity of this stage being O(ICK).

Lastly, the mapped vectors are reconverted to their original formal concepts, which involves a time complexity of O(CK). Summing up the complexities from each phase, the total time complexity of the KVL method is estimated to be O(NA+AC+K+ICK+CK). This is a heuristic estimate, and time complexity could vary based on data distribution and other runtime factors. However, focusing on the dominant term for simplification, the time complexity of the KVL method becomes O(ICK).

## VI. EXPERIMENTAL RESULTS

In this section, the presented experimental results aimed at demonstrating the performance of the Dijkstra-Based Distance Measure, as well as the performance and scalability of the K-means Dijkstra on Lattice (KDL) and K-means Vector on Lattice (KVL) methods. The experiments were conducted on a Mac system equipped with an Apple M1 chip and 8GB of RAM, running Mac OS 13.2.1.

### A. Testing and Evaluation of Dijkstra-based Distance Measure

In the experimental section, the performance of the distance measure based on Dijkstra's algorithm is rigorously evaluated. The testing process involved the following steps:

1) *Random generation of formal contexts:* five formal contexts are randomly generated with varying sizes and densities; the characteristics of these formal contexts are described in Table III. The density parameter in this context refers to the proportion of filled entries (1s) compared to the total number of possible entries in the binary matrix representation of the formal context. It quantifies how much information is present regarding the relationship between objects and attributes. To explain the density parameter, let's consider an example from Table III: Formal Context1 with 600 objects and 125 attributes. The density for Formal Context1 is 0.10, indicating that, on average, each entry in the binary matrix has a 0.10 probability of being filled (assigned a value of 1). A lower density value implies sparser relationships, where fewer objects belong to the given attributes or categories. In contrast, a higher density value indicates denser relationships, where a larger number of objects are associated with the given attributes.

2) In the analysis, four datasets from the UCI Machine Learning repository are meticulously examined. Prior to conducting any experiments, these datasets are transformed into formal contexts, with details outlined in Table III. The

datasets were chosen based on two key criteria: public accessibility and the categorical characteristics of their attributes. The selected datasets include:

- The Balance-Scale dataset is designed to replicate psychological experiment results. Each instance in this dataset can be labeled based on whether the balance scale leans to the left, right, or is balanced.
- The Breast Cancer dataset obtained from the University of Wisconsin hospitals, classifies each instance into one of two potential categories: benign or malignant.
- The Car Evaluation dataset, which results from a simple hierarchical decision model initially designed for DEX's demonstration, classifies each instance into one of four classes: unacc, acc, good, and vgood.
- Tae dataset representing teaching performance assessment over five semesters (three regular and two summers) includes 151 teaching assistant assignments from the University of Wisconsin-Madison's Statistics Department. All instances fall into one of three categories: low, medium, and high.

3) *Extraction of formal concepts:* The NextClosure algorithm was used to extract the set of formal concepts from each formal context. The number of formal concepts generated from each formal context is shown in Table IV.

4) *Hasse diagram construction:* Utilizing the Ipred algorithm, a Hasse diagram was structured optimally for the case study, as elaborated in Section V. The characteristics of the generated Hasse diagrams are shown in Table V, by considering the density parameter in the construction of the Hasse diagram. The density parameter influences the number of edges and nodes in the Hasse diagram. A denser formal context with a higher density value tends to result in a larger number of formal concepts and, consequently, a more extensive concept lattice with a higher number of edges connecting the concepts. On the other hand, a sparser formal context with a lower density value leads to a smaller concept lattice with fewer edges.

TABLE III. CHARACTERISTICS OF RANDOM AND REAL-WORLD FORMAL CONTEXTS

Formal Contexts	#objects	#attributes	density
Formal Context1	600	125	0.10
Formal Context2	11000	30	0.10

Car Evaluation	8001	38928

The analysis involved running a Dijkstra-based distance measure on concept lattices generated from five random formal contexts and four real-world datasets. The formal contexts varied in number of objects, attributes, and density. On the other hand, the real-world datasets were diverse, encompassing balance scale, breast cancer, teaching assistant evaluation, and car evaluation data. After generating the formal contexts and preparing the datasets, Formal Concept Analysis (FCA) using the NextClosure algorithm has been performed to derive formal concepts. The count of these formal concepts varied significantly across the contexts and datasets, ranging from as low as 2989 in Formal Context 4 to as high as 39931 in Formal Context 5. Using these formal concepts, Hasse diagrams (concept lattices) constructed with the help of the Ipred algorithm. The concept lattices illustrated the inclusion relationship between concepts. Again, the number of inclusion relationships was directly related to the complexity and size of the corresponding formal context. Subsequently, the distance measure was evaluated. Concept pairs were randomly chosen from each concept lattice, constituting 25% of the total concepts. The minimum cost of the shortest path between these pairs was calculated using the designated distance measure. This evaluation was performed across ten trials, with both the average runtime and mean distance documented for each.

We're observing a comparison of the average run time of the Dijkstra-based distance measure algorithm and the mean distance between concepts for both randomly generated formal datasets and real-world datasets. As indicated in Fig. 2 and

Fig. 3 for randomly generated datasets, there is a clear correlation between the number of concepts in the lattice and the algorithm's runtime. An increase in the number of concepts leads to a corresponding rise in runtime. This finding aligns with expectations, as a lattice with a greater number of concepts and relationships is likely to be more complex. Consequently, calculating the shortest path between pairs in this intricate structure would naturally demand more computational time and resources. The mean distances were mostly consistent for each context, indicating a relatively stable distance measure despite potential variance in the random generation of the formal contexts. This reinforces the efficacy of the Dijkstra-based distance measure, highlighting its stability across multiple trials of randomly generated data.

Patterns similar to those observed in randomly generated datasets were also evident in real-world datasets, as demonstrated in Fig. 4 and Fig. 5. The runtimes correlate with the number of concepts in the lattice, with larger lattices taking longer to calculate the shortest paths. Interestingly, the Car Evaluation dataset, which had the highest number of concepts (8001), exhibited the shortest mean distance (6.5735) among the real-world datasets. This suggests that although the dataset is complex, the relationships within the data are more straightforward or closer than the other datasets. Meanwhile, the Balance-Scale and Breast Cancer datasets had a more moderate number of concepts (1297 and 2569, respectively) and showed a higher mean distance. This might indicate that, despite having fewer concepts, the relationships in these datasets could be more complex or convoluted.

Fig. 2. Average runtime of distance calculation algorithm on different concept lattice sizes for the random contexts in Table IV.

Fig. 3. Mean distance of distance measure algorithm on different concept lattice sizes for the random contexts in Table IV.

Fig. 4. Average runtime of distance calculation algorithm on different concept lattice sizes of real-world datasets.

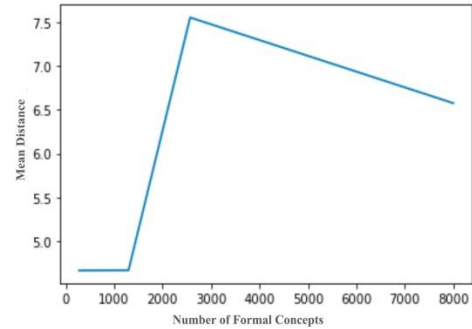

Fig. 5. Mean distance of distance measure algorithm on different concept lattice sizes of real-world datasets.

Overall, the results suggest that the Dijkstra-based distance measure is robust and stable across various randomly generated and real-world contexts. The run time increases as expected with the size and complexity of the dataset, and the measure captures the inherent complexity in the data (as reflected in the mean distances) and provides valuable insights into the structural properties of concept lattices. It allows for identifying concept pairs relatively closer or farther apart within the lattice structure. The results contribute to a better understanding of relationships and structural characteristics within formal contexts and concept lattices. The consistent performance of the measure across different scenarios reinforces its potential utility in handling diverse and complex categorical datasets.

Adapting the FCA, the Dijkstra-based distance measure applies the robust Dijkstra's algorithm to compute the shortest path between two categorical data points. This method, mindful of the hierarchical structure of categorical data, quantifies dissimilarity by evaluating paths within the data space. It provides a viable alternative to Euclidean distance within the clustering context when enhancing the K-means algorithm for categorical data analysis. Replacing Euclidean distance with the Dijkstra-based measure allows the K-means algorithm to cluster categorical datasets better, accurately reflecting the relationships and similarities between categorical variables. Incorporating the Dijkstra-based distance measure in the K-means algorithm aids cluster identification based on categorical patterns, providing meaningful insights and potential applications across numerous domains. It's users in new avenues for examining and interpreting categorical data.

### B. Clustering Performance

In the present section, the performance of two distinct clustering approaches designed for categorical data: K-means Dijkstra on Lattice (KDL) and K-means Vector on Lattice (KVL) is scrutinized. We've chosen the Silhouette Coefficient and the Davies-Bouldin Index (DBI) as the evaluation metrics due to their ability to assess clustering performance without the need for ground truth labels, making them especially useful in real-world applications where such labels might not be available. The Silhouette Coefficient serves as a measure to ascertain the suitability of a data point's allocation to its cluster in comparison to other clusters. The coefficient fluctuates between -1 and 1, with a high positive value implying a well-clustered data point, while a negative one indicates potential misplacement within a cluster. Here's the mathematical expression for the Silhouette Coefficient:

$$\text{Silhouette Score} = (b - a) / \max(a, b) \quad (14)$$

Where 'a' is the mean intra-cluster distance and 'b' is the mean nearest-cluster distance. In contrast, the Davies-Bouldin Index (DBI) is a metric that evaluates the separation and compactness of clusters. A lower DBI value implies an optimal clustering solution. The DBI is calculated as follows:

1) Calculate the average distance between each point in a cluster  $S_i$  and all other points in the same cluster. This is often referred to as the intra-cluster distance. Denote this as  $SC_i$  for cluster  $S_i$ .

$$SC_i = (1 / n_i) \sum ||x - Z_i|| \text{ for } x \in S_i$$

where:

- $n_i$  is the number of points in cluster  $S_i$ ,
- $x$  is a point in cluster  $S_i$ ,
- $Z_i$  is the centroid of cluster  $S_i$ ,
- $||x - Z_i||$  is the distance between point  $x$  and centroid  $Z_i$ .

2) Calculate the distance  $d_{ij}$  between cluster  $S_i$  and  $S_j$ , using a suitable distance measure between the centroids of the clusters.

3) Calculate the ratio  $R_{ij}$  between the sum of the intra-cluster distances of cluster  $S_i$  and  $S_j$ , and the inter-cluster distance between  $S_i$  and  $S_j$ .

$$R_{ij} = (SC_i + SC_j) / d_{ij}$$

4) For each cluster  $S_i$ , find the maximum ratio  $R_i$  which is the maximum  $R_{ij}$  for all  $j \neq i$ .

$$R_i = \max(R_{ij}) \text{ for all } j \neq i$$

5) The Davies-Bouldin Index (DBI) is the average of all  $R_i$ .

$$\Delta \text{BI} = (1 / S) \sum R_i \quad (15)$$

where,  $S$  is the total number of clusters

Again, lower DBI values indicate better clustering because this signifies clusters that are more compact (lower intra-cluster

distances  $SC_i$ ) and better separated (higher inter-cluster distances  $d_{ij}$ ).

The analysis is based on four real-world datasets described in the previous section as shown in Table V and the results in Tables VI and VII. The clustering is performed by setting the number of clusters (k value) equal to the number of classes for each dataset to maintain consistency with the inherent data structure. These results are recorded from the averages of 100 runs for each method. A closer examination of these tables allows for a comparative analysis of the performance of the K-means Dijkstra on Lattice (KDL) and K-means Vector on Lattice (KVL) methods. Regarding the Silhouette Coefficient (Table VI), it is evident that the KDL method, which utilizes the inherent lattice graph structure of categorical data for clustering, consistently outperforms the KVL method, regardless of the dataset used. This outcome is further corroborated by the DBI results (Table VII), where the KDL method again demonstrates superior performance by consistently achieving lower index values across all datasets. This can be attributed to the design of the KDL method. The KDL strategy focuses on integrating the representation of categorical data based on the graph structure, effectively leveraging the potential similarity between these data points. It employs Formal Concept Analysis (FCA), a mathematical framework for generating a concept hierarchy, and Dijkstra's algorithm to calculate the shortest path between formal concepts in the FCA graph. This novel distance measure, which represents the minimal cost of moving from one formal concept to another, facilitates a more accurate clustering process.

On the contrary, the KVL method, while simplifying the clustering process by converting categorical data into numerical vectors and using standard k-means algorithms, risks obscuring the inherent hierarchical relationships between categorical values. This transformation can potentially result in less effective clustering performance.

TABLE VI. SILHOUETTE COEFFICIENT SCORES OF CLUSTERING PERFORMANCE FOR K-MEANS DIJKSTRA ON LATTICE (KDL) AND K-MEANS VECTOR ON LATTICE (KVL) METHODS ACROSS DIVERSE DATASETS

Fig. 6. Silhouette scores by dataset and method.

Fig. 7. DBI scores by dataset and method.

The compelling evidence in Tables VI and VII and their corresponding graphical representations in Fig. 6 and Fig. 7 illuminate the KDL method's superior performance over the KVL method for clustering categorical data. By directly handling categorical data and leveraging its inherent hierarchical structure, the KDL method offers more meaningful and accurate clustering results. This finding corroborates the hypothesis that leveraging the inherent similarities and structure of categorical data can yield improved results. While the KVL method simplifies the process by transforming categorical data into numerical vectors, it potentially obscures the intricate hierarchical relationships between categorical values, thus diminishing the method's effectiveness. This is reflected in the lower Silhouette, and higher DBI scores observed for the KVL method. These findings not only present solid evidence in favor of the KDL method as a more potent tool for clustering categorical data, but they also underscore the importance of utilizing the data's inherent structure where possible. However, these conclusions should uphold the utility of the KVL method. Instead, they serve as a critical reminder of the significance of selecting an appropriate tool for the data at hand, considering each method's potential trade-offs and benefits.

### C. Scalability Test Results Analysis

1) Scalability in relation to the number of clusters: To bolster the robustness of the study concerning the K-means Dijkstra on Lattice (KDL) and K-means Vector on Lattice (KVL) clustering techniques, a meticulous analytical approach was employed. This rigorous methodology underscores the credibility of the performance assessments and findings presented. All results presented in this analysis were derived from the average runtime of five independent runs. This method was utilized to mitigate any outliers' influence and deliver a more precise portrayal of each method's performance.

The investigation was particularly interested in the scalability of these methods in response to an increase in the

number of clusters. The number of clusters was varied from 2 to 18 in the analysis, with the dataset size held constant. This aspect is essential in real-world situations, especially when data is complex and needs to segregate into a limited number of clusters neatly. The performance of both methods in relation to the varying number of clusters was assessed using the 'Car Evaluation' dataset consisting of 8001 formal concepts. From Fig. 8, it is evident that the K-means Vector on Lattice (KVL) method demonstrates scalability. A linear relationship is observed between execution time and the increment in the number of clusters. The execution time varies approximately between 44.48 and 51.56 seconds as the number of clusters changes from 2 to 18. This pattern underscores the efficiency of the KVL method in handling larger and more complex datasets.

This method, thus, shows promise in effectively managing a rise in the number of clusters without causing a substantial increase in execution time. On the other hand, Fig. 9 provides insights into the scalability of the KDL method. This method shows rapid growth in execution time as the number of clusters increases. The time jumps from about 1926.77 seconds for 2 clusters to a massive 49600.10 seconds for 18 clusters. Given the complexity of the lattice graph and the number of formal concepts, the KDL method's computational load increases significantly with the number of clusters, suggesting lower scalability.

The KVL method is better in terms of scalability and efficiency for an increasing number of clusters; the KDL method provides higher-quality clustering, though it demands significantly more computational time and resources. This highlights the importance of finding the right balance between computational efficiency and clustering quality. The preference for one over the other may vary depending on the specific situation and constraints.

Fig. 8. Scalability of KVL Method to the number of clusters when clustering 8001 formal concepts of the 'car evaluation' dataset.

Fig. 9. Scalability of the KDL method to the number of clusters when clustering 8001 formal concepts of the 'car evaluation' dataset.

2) *Scalability in relation to the number of formal concepts*: In examining the scalability of KDL and KVL, performance was assessed with an increasing number of formal concepts, while keeping the cluster count constant at three. This analysis is grounded in multiple iterations of these methods on a selection of real-world datasets, namely Balance-Scale, Breast Cancer, Tae, and Car Evaluation, described in detail in Tables III, IV, and 5. Fig. 10, and Fig. 11, represent the scalability of the KVL and KDL methods, respectively, demonstrating how they fare with a rising count of formal concepts.

Diving into Fig. 10, it's evident that the KVL method shows admirable consistency. The recorded execution times from five separate runs, 43.14, 43.25, 44.15, and 46.35 seconds, corresponding to the datasets featuring 276, 1297, 2569, and 8001 formal concepts. This suggests that as the number of formal concepts increases, the KVL method retains its efficiency, reflecting robust scalability - an attribute crucial for managing large datasets. In comparison, Fig. 11 encapsulates the performance of the KDL method. The execution times here are noticeably higher, registering at 53.67, 301.47, 830.02, and 2026.79 seconds for the same gradual increase in formal concepts. It's clear that as the number of formal concepts expands, the KDL method's execution time climbs drastically, indicating an intensifying computational requirement and limited scalability when tasked with larger datasets.

Fig. 10. Scalability of KVL method with increasing number of formal concepts.

Fig. 11. Scalability of KDL method with increasing number of formal concepts.

This investigation rigorously assesses the K-means Dijkstra on Lattice (KDL) and K-means Vector on Lattice (KVL) algorithms, identifying a trade-off between clustering quality and computational efficiency. KDL excels in quality but is

resource-intensive, making it less scalable. Conversely, KVL is more scalable but may compromise on quality. The choice between the two hinges on task-specific needs: KDL is better for quality-focused tasks with sufficient resources, while KVL is ideal for tasks requiring scalability. Future research could aim to optimize each method's shortcomings, offering a more balanced clustering solution. These refinements would bring us closer to a unified, efficient, and high-quality clustering algorithm for handling categorical data.

## VII. CONCLUSION

In the exploration, the efficacy of a Dijkstra-based distance measure is assessed for conceptual clustering across multiple categorical datasets. This distance measure demonstrated a powerful capability in determining hierarchical relationships among categorical variables, even within complex and dense datasets. The evaluations, conducted across randomly generated formal contexts and real-world datasets, confirmed its robust performance, scalability, and reliability. However, a correlation between the average runtime and the number of concepts suggests potential efficiency enhancements.

The clustering tasks employed two methods: the K-means Dijkstra on Lattice (KDL) method, which uses Formal Concept Analysis (FCA) and the Dijkstra-based distance measure; and the K-means Vector on Lattice (KVL) method, which transforms categorical data into numerical vectors and applies standard k-means algorithms. The KDL method yielded high-quality clusters that accurately mirrored the inherent hierarchical relationships within categorical data. However, when handling larger numbers of clusters or formal concepts, scalability emerged as a challenge for this method. On the other hand, the KVL method demonstrated impressive scalability. Nevertheless, due to its conversion of data into numerical vectors, there's a risk of overlooking the hierarchical structure of the data, which could affect the clustering quality.

Future research has several promising pathways. The lattice structure in the KDL method could be simplified to boost scalability, and the KVL method could be further refined to better capture the structure of categorical data. Additionally, the exploration of alternate or complementary distance measures could be beneficial. A particularly intriguing direction for future research is integrating the Dijkstra-based distance measure into the k-means algorithm, which could significantly advance categorical data analysis. The study of the KDL and KVL methods has under-scored their respective strengths and limitations, illuminating potential areas for future research. These findings are instrumental to the ongoing development of categorical data analysis and refining data clustering methodologies. By investigating the complexities of concept lattices and streamlining the knowledge discovery process of FCA, The study offers a foundational understanding that serves as a basis for the development of more scalable and efficient solutions.

## ACKNOWLEDGMENT

The authors express sincere gratitude to the Department of Information Technology at the József Hatvany Doctoral School, University of Miskolc, Hungary, for the necessary support and resources for this study.

Faculty of Information Technology-Department of CS, Zarqa University, Zarqa-Jordan<sup>3</sup>

**Abstract**—Heart disease is the leading cause of mortality worldwide. Early identification and prediction can play a crucial role in preventing and treating it. Based on patient data, machine learning techniques may be used to construct cardiac disease prediction models. This work aims to investigate the usage of machine learning models for heart disease prediction utilizing a publicly available dataset. The dataset contains patient information on clinical and demographic characteristics and the presence or absence of cardiac disease. Based on classification performance, many machine learning methods were tested and compared. The findings reveal that machine learning models can predict cardiac disease with accuracy and AUC values. Furthermore, the developed system is used to examine some Jordanian patients, and the predictions of the results are satisfactory. The study's findings might have far-reaching consequences for the early identification and prevention of heart disease, as well as for improving patient outcomes and lowering healthcare expenditures.

**Keywords**—Heart disease; machine learning; predictive models; classification; clinical data; predictions

## I. INTRODUCTION

Heart disease is a significant health concern that affects millions of people worldwide. Despite significant advancements in medical science, it remains a leading cause of death globally. Early detection and accurate heart disease prediction are crucial to prevent further complications and improve patient outcomes [1]. Machine learning techniques have shown promising results in several domains such as those in [2-6] and in predicting the occurrence of heart disease and other several diseases allowing for early intervention and better management [7]. Heart disease is a complex condition that involves various risk factors such as age, gender, heredity, smoking, hypertension, obesity, sedentary lifestyle, diabetes mellitus, metabolic syndrome, chronic renal failure, and stress. Identifying these risk factors and their interplay is critical in predicting the onset of heart disease. Traditional methods of heart disease prediction, such as clinical diagnosis, can be time-consuming, labor-intensive, and prone to errors. With the advent of machine learning techniques, accurate and efficient prediction of heart disease is now possible. The motivation behind this study is to develop a machine learning-based system that can effectively predict the occurrence of heart disease [2]. The system should be able to identify the most significant risk factors and their interplay, allowing for early intervention and better management. The study aims to improve upon existing methods of heart disease prediction and provide a reliable and efficient tool for healthcare

professionals. The primary research question of this study is: Can machine learning techniques effectively predict the occurrence of heart disease? Specifically, the study aims to answer the following sub-questions: What are the most significant risk factors for heart disease, and how do they interplay?

To answer this sub-question, the study will comprehensively analyze various risk factors associated with heart disease. For instance, the study may use data from electronic health records (EHRs) containing information on patients' demographics, medical history, lifestyle factors, and laboratory results [8]. The study may use statistical techniques such as logistic regression or correlation analysis to identify the most significant risk factors and their interplay [9]. For example, the study may find that smoking and hypertension are strongly associated with heart disease, and their co-occurrence increases the risk of heart disease even further. Next, which machine learning algorithms are most effective in predicting heart disease occurrence? To answer this sub-question, the study will evaluate the performance of various machine learning algorithms such as decision trees, random forests, support vector machines, and neural networks [10]. The study may use a dataset of patients with and without heart disease and train the models to predict the occurrence of heart disease. The study may use performance metrics such as accuracy, Precision, recall, and AUC to evaluate the models' performance [11].

The rest of the paper is organized as follows. Section II presents the relevant works with the subject under consideration. Additionally, in Section III, dataset description and analysis of the methodology are provided. Then, Section IV discusses the acquired research results. Finally, conclusions and future directions are outlined in Section V.

## II. LITERATURE REVIEW

To increase the accuracy of weak algorithms, an ensemble voting-based model combining many classifiers was presented. The proposed ensemble approach's power is appealing in increasing anemic classifier prognosis accuracy and establishing suitable performance in analyzing the risk of heart disease. An ensemble voting-based approach was used to achieve a remarkable gain in accuracy of 2.1 percent for anemic classifiers [12]. This study aims to create a model that can accurately forecast cardiovascular disorders to lessen the number of people who die from them. The suggested model was applied to a real-world dataset of 70,000 Kaggle instances and achieved the following accuracy: XGBoost: 86.87 percent

(with cross-validation), random forest: 87.05 percent (with cross-validation), multilayer perceptron: 87.28 percent (with cross-validation), and 86.94 percent (with cross-validation) (without cross-validation). AUC values for the suggested models are 0.94 for XGBoost, 0.95 for the random forest, and 0.95 for multilayer perceptron. According to the findings of this study, the multilayer perceptron with cross-validation surpassed all other algorithms in terms of accuracy, with the greatest accuracy of 87.28 percent [13].

Based on Machine Learning methods, this study provides an efficient and accurate solution for diagnosing cardiac disease. Several cutting-edge Machine Learning methods are used to classify a cardiovascular dataset. Machine Learning methods such as Random Forest, Nave Bayes, and SVM are used to introduce the prediction model. The prediction model is intended to provide improved performance with high accuracy [11]. This article examines the numerous machine learning algorithms utilized to accurately predict, diagnose, and treat various cardiac illnesses. The findings revealed that ANN had the highest average prediction accuracy (86.91 percent), whereas the C4.5 decision tree approach had the lowest average (74.0 percent). For automatic prediction, diagnosis, and treatment of heart disease, machine learning algorithms and techniques have been applied to several accessible heart disease datasets. The findings revealed that ANN had the highest average prediction accuracy (86.91 percent), whereas the C4.5 decision tree approach had the lowest average prediction accuracy (74.0 percent) [9]. Cardiovascular disease is a potentially fatal condition that has become more widespread in recent decades. Machine Learning tools and methodologies are employed to treat and diagnose this condition correctly. This study provides a survey of numerous models that accept such approaches and algorithms, as well as an analysis of their performance. Random Forest (RF), Decision Tree (DT), Naive Bayes, ensemble models, K-Nearest Neighbor (kNN), and Support Vector Machine are some common models (SVM) [14]. The heart is the human body's next main organ, and data analytics is utilized to anticipate the incidence of cardiac illnesses. To forecast the development of cardiac disorders, data mining and machine learning techniques such as Artificial Neural Network (ANN), Decision Tree, Fuzzy Logic, K-Nearest Neighbour (kNN), Nave Bayes, and Support Vector Machine (SVM) are utilized. This document includes an overview of known algorithms as well as a summary of previous work [14]. According to the World Health Organization, heart disease kills 33 percent of the world's population. To address this, a UCI Machine Learning Repository dataset was analyzed and predicted heart disease classes. The key characteristics of each assembling technique were retrieved, filtered from the dataset, fitted to a logistic regression classifier, feature scaling, and fitted using logistic regression. Mean Squared Error (MSE), Mean Absolute Error (MAE), R2 Score, Explained Variance Score (EVS), and Mean Squared Log Error (MSLE) were used to analyze performance (MSLE). The feature significance retrieved from the AdaBoost classifier was successful before adding feature scaling, with an MSE of 0.04, MAE of 0.07, R2 Score of 92 percent, EVS of 0.86, and MSLE of 0.16. The feature significance retrieved from the AdaBoost classifier was

successful after feature scaling, with an MSE of 0.09, MAE of 0.13, R2 Score of 91 percent, EVS of 0.93, and MSLE of 0.18 [15].

This research provides a machine learning framework that uses five algorithms to predict the likelihood of developing heart disease: Random Forest, Naive Bayes, Support Vector Machine, Hoeffding Decision Tree, and Logistic Model Tree (LMT). The Cleveland dataset is utilized for training and testing, and the findings demonstrate that Random Forest performs the best [16]. The essential information in this book is that machine learning and deep learning techniques are utilized to predict the range of risks connected with this project. A dataset was constructed by integrating previously accessible datasets and categorizing them into eleven groups. In diagnosing cardiovascular disorders, machine learning techniques outperformed deep learning, and the PCA methodology was used to determine the relative significance of each of the dataset's 11 fields. Random Forest Classifiers, Decision Tree Classifiers, and Naive Bayes algorithms surpassed other MI algorithms regarding accuracy and recalled. In undeveloped, developing, and even industrialized nations, heart disease is the leading cause of mortality. This disease's death rate can be reduced if detected early and accurately predicted. Machine Learning is critical in predicting and preserving key data regarding cardiac illnesses. This paper examines numerous research studies that use datasets to use machine learning in the prediction of cardiac ailments [17]. This will assist medical professionals in taking corrective action.

Cardiovascular diseases (CVDs) are the world's leading cause of sudden mortality today, and valid, accurate, and practical ways to identify them are required. Machine learning algorithms (MLAs) have been created and proven useful and efficient in forecasting CVD issues based on historical data. This thesis proposes a novel methodology that focuses on finding appropriate features by using MLA techniques such as Deep Learning, Random Forest, Generalized Linear Model, Naive Bayes, Logistic Regression, Decision Tree, Gradient Boosted trees, Support Vector Machine, Vote, and HRFLM, with higher accuracy levels of 75.8 percent, 85.1 percent, 82.9 percent, 87.4 percent, 85 percent, 86.1 percent, 78.3 percent, 86.1 percent, [18]. This research investigates the differences in performance of multiple machine learning models on chronic renal disease and cardiovascular disease datasets using Principal Component Analysis dimensionality reduction approaches. Logistic Regression, K Nearest Neighbor, Naive Bayes, Support Vector Machine, and Random Forest Model were utilized to assess the models' performance with and without PCA. The authors discovered that the kNN classifier and logistic regression were the best approaches for predicting renal and heart illness, with 100% accuracy in chronic kidney disease and 85% in heart disease [19]. This research investigates the differences in performance of multiple machine learning models utilizing Principal Component Analysis dimensionality reduction approaches on Chronic Kidney and Cardiovascular Disease datasets. Logistic Regression, K Nearest Neighbor, Nave Bayes, Support Vector Machine, and Random Forest Model were used to examine the performance of the models with and without PCA. The

scientists discovered that the kNN classifier and logistic regression were the best approaches for predicting renal and heart illness, with 100 percent accuracy in chronic kidney disease and 85 percent in heart disease, respectively [11].

Machine Learning is the study of how computers can learn to discover answers without being explicitly programmed. It is a subset of Artificial Intelligence that allows practitioners to identify illnesses more quickly and efficiently. Machine learning enables the creation of models that correlate various characteristics with an illness. However, good analytic tools are scarce for uncovering underlying correlations and patterns in data. Machine learning is becoming more prevalent in the diagnosis field due to the advancement of classification and recognition algorithms in disease categorization [20]. Data analysis is an essential element of healthcare since it allows for extracting hidden information and predicting disease. This research evaluates several machine learning approaches to determine the superiority of the Random forest algorithm in predicting heart disease [21].

### III. METHODOLOGY

The primary objective of this study is to identify an effective and predictive algorithm for the early detection of heart disease. To this end, we applied various machine learning models, including Logistic Regression (LR), Decision Tree, Neural Network, Naive Bayes (NB), the k-nearest neighbors (kNN), Support vector machines (SVM), AdaBoost (AB), Stochastic Gradient Descent (SGD), CN2 rule inducer, Constant and Random Forest (RF), to the Heart Disease Diagnostic dataset and evaluated the results. Fig. 1 outlines the planned architecture in detail.

Fig. 1. Machine learning modeling processes flow diagram.

Our methodology begins with data collection, followed by preprocessing, which consists of four steps: data cleansing, attribute selection, target role setting, and feature extraction. Machine learning algorithms that can predict heart disease for a fresh set of measures are developed using the supplied data. To test the performance of an algorithm, we present the model with labeled new data. This is often accomplished by dividing the obtained labeled data into two sections using the Train test split function. Seventy-five percent of the data is referred to as the training data or training set and is utilized to construct our machine learning model. 25% of the data will be utilized to evaluate the model's performance, referred to as test data or test set. After evaluating the models, we compare the acquired

data to select the algorithm with the highest accuracy and discover the most predictive algorithm for heart disease detection in Fig. 2.

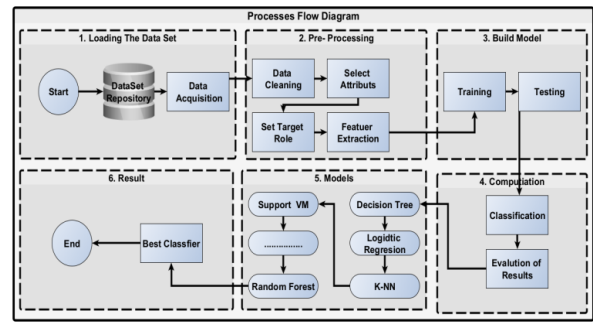

Fig. 2. Processes flow diagram.

#### A. Machine Learning Algorithms

The predictive analysis of machine learning algorithms is accomplished in our study. These are the machine learning algorithms used in our project.

Logistic regression is a statistical model used to estimate the probability of a binary outcome (such as yes/no) based on one or more independent variables. Logistic regression aims to determine the model that best represents the connection between the input features and the dependent variable. Logistic regression uses a logistic function to represent the relationship between the input features and the target variable, allowing for the calculation of the likelihood that the target variable would assume a specific value given the input information [22].

A decision tree model creates a tree-like structure by recursively dividing the data based on the input attributes. Each node in the tree indicates a determination based on a certain characteristic, while the leaves represent the final classification. Decision tree models are simple to read and depict, making them valuable for comprehending the model's decision-making process [23]. However, decision trees might be susceptible to overfitting if the tree is too complicated or if the data contains noise.

Neural Network: Neural networks are simulations of the structure and operation of the human brain. They are composed of layers of interconnected nodes (neurons) that identify data patterns and make predictions based on those patterns. Neural networks can learn intricate correlations between the input data and the target variable [24]. Neural networks can be challenging to comprehend and prone to overfitting if the model is too complicated or if there is insufficient data to train the model.

The Naive Bayes model calculates the probability of a certain class given the input features. It assumes that the characteristics are conditionally independent of one another, which simplifies the probability computation [25]. Naive Bayes is a simple and quick model that works well with tiny datasets, although, in some instances, it may not be as accurate as other models.

kNN is a non-parametric model that classifies new data points according to the class labels of the k nearest neighbours

in the training set. The value of  $k$  controls how many neighbours should be considered [26]. kNN is a simple and intuitive model that can perform well for low-dimensional data. Still, it can be computationally costly for high-dimensional data and may not perform well if the input is noisy or contains irrelevant features.

Support vector machines (SVM) are a model that locates a hyperplane that maximizes the difference between two classes in the data. Translating the input characteristics into a higher-dimensional space can handle both linearly and non-linearly separable data. SVM is a potent model that works well with high-dimensional data, but it is computationally intensive and may not scale well for huge datasets [27]. AdaBoost is a model that combines multiple weak classifiers to produce a powerful classifier. The final classification is based on the weighted combination of all the weak classifiers. AdaBoost is a potent model that can increase the accuracy of poor classifiers, but it is susceptible to noisy data and outliers [28]. SGD: Stochastic gradient descent (SGD) is a model that iteratively updates the model parameters using the gradient of the loss function for the model parameters. It modifies the parameters according to the gradients of the loss function to the parameters determined on a subset of the data (a mini batch). SGD is a quick and effective model that works well with large datasets but may require hyperparameter optimization for optimal performance [29]. CN2 is a model that learns decision rules from the input data. It employs a greedy search technique to determine the optimal collection of rules covering most situations while minimizing the number of rules. CN2 is a basic and interpretable model that works well with small datasets, but in some instances, it may not be as precise as other models [30]. Constant: The constant model is a model that always predicts the same class label for all instances. It is used as a baseline for comparison with other models and can be used to determine if a more complex model is necessary constant: The constant model predicts the same class label for all instances. It is used as a benchmark for comparing other models and to decide whether a more complex model is required [31]. Random Forest is a model that generates several decision trees based on random subsets of data and input attributes. The vote of most of all decision trees determines the highest classification. Random forest is a robust model that can handle high-dimensional data and noisy or irrelevant features. In addition, it is less susceptible to overfitting than decision trees. Random forest models can be challenging to interpret and computationally costly for large datasets [32]. Overall, each model has advantages and disadvantages, and the selection of a model depends on the nature of the problem being addressed and the data features [33]. It is essential to carefully pick and analyze the most suitable model for the work to get the highest potential performance.

### B. Dataset Acquisition

Data Collection and Preprocessing: Data collection entails getting the dataset from a trustworthy source, such as a medical research database or a publicly accessible dataset repository [34]. It is critical to ensure that the dataset is both relevant to the study issue and of acceptable quality. Data preparation is preparing a dataset for analysis by identifying

missing values, outliers, and inconsistencies. Missing values can be managed by imputation or removal, while outliers can be recognized and corrected via winsorization or trimming using statistical approaches or visualization techniques [35]. Inconsistencies can be fixed by looking for data input mistakes or integrating datasets. The models' performance on independent data can be evaluated by dividing the data into training and test sets. The training set trains models, while the test sets assess their performance [36]. It's critical to ensure the split is random and that the test set is representative of the entire dataset.

Extraction and Selection of Features: Categorical characteristics, such as gender or smoking status, have a restricted number of values. One-hot encoding is a method for representing category information as binary variables that may be fed into machine learning models [37]. Numeric characteristics are variables with continuous values, such as blood pressure or age. Scaling is a strategy to guarantee that the numeric characteristics have a consistent scale, preventing greater values from influencing the models [38]. A prominent scaling approach is standard scaling, which changes the data to have a mean of 0 and a standard deviation of 1.

Finding the most relevant characteristics for the classification task is known as feature selection. Correlation analysis may be used to find traits strongly connected to the target variable [39]. The feature importance ranking method may rank characteristics according to their relevance for the classification task.

Algorithms and Techniques for Machine Learning: Decision trees are a common machine-learning approach that builds a tree-like model of decisions and their potential outcomes [40]. Random forests are an ensemble approach that aggregates the forecasts of numerous decision trees.

Logistic regression is a machine learning approach that uses a logistic function to estimate the likelihood of a binary outcome. Support vector machines are machine learning algorithms that create a hyperplane to divide data into two classes. The K-nearest neighbours' method classifies data items based on the class of their  $k$  nearest neighbours [41]. Neural networks are a machine learning approach that uses a network of linked neurons to represent the connection between features and the goal variable.

Hyperparameter tuning entails picking the optimum values for the model parameters to maximise the model's performance on the data. This can be accomplished using grid search, random search, or Bayesian optimization techniques. Ensemble approaches integrate numerous models' predictions to increase their performance [42]. AdaBoost is an ensemble approach combining many weak models to get a stronger one. Bagging is an ensemble approach that uses bootstrap sampling to construct numerous models and then combines their predictions.

Metrics for Model Evaluation and Performance: Accurate is the proportion of correctly identified samples with the total number of samples. Precision is defined as the fraction of genuine positive samples among all positive samples. The

proportion of real positive samples out of the total number of positive samples is referred to as recall [43]. The harmonic mean of accuracy and recall is used to get the F1 score [44]. The area under the receiver operating characteristic curve (AUC-ROC score) evaluates the trade-off between genuine and false positive rates.

Cross-validation is a technique used to assess a model's capacity to generalize to new and previously unknown data [45]. It entails dividing the data into folds and testing the model on each fold while training it on the remaining folds [46]. Statistical tests may be used to assess the performance of several models and see if there are any significant differences [46]. T-tests or ANOVA (analysis of variance) can be employed to compare the means of two or more groups.

To illustrate the performance of the models, ROC curves and confusion matrices can be employed. ROC curves compare the true positive rate against the false positive rate at various threshold levels [47]. Confusion matrices display the model's true positive, true negative, false positive and false negative predictions.

### C. Experimental Environment

All machine learning algorithm tests mentioned in this research were conducted using Orange Data Mining version 3.35.0. The experimental machine was a Lenovo 20FES2FE0E with BIOS version N1GETA9W (1.88), an Intel Core i7-6600U CPU @ 2.60GHz (4 CPUs), and 8192MB of RAM. Windows 11 Pro 64-bit with build number 22621 was the operating system utilized for the experiment. The Heart Disease Diagnostic Datasets were used as the experimental dataset. The information supplied describes a dataset named "Heart Data Set." Here's a quick rundown of the dataset's characteristics:

The dataset has 1025 rows and 14 columns, which contain information about 1025 instances, each with 14 characteristics. The dataset has three categorical variables and ten numerical features, meaning that some features are qualitative (e.g., gender, kind of chest pain) and others are quantitative (e.g., age, resting blood pressure, serum cholesterol). The result variable is a categorical variable with two classes, indicating that the dataset is utilized for binary classification tasks. It isn't easy to interpret the dataset more thoroughly without further information about the target variable. It's worth mentioning that the dataset is popularly known as the Cleveland Heart Disease dataset and is frequently utilized for investigating predictive modeling jobs in the context of heart disease diagnosis.

## IV. RESULTS AND DISCUSSION

The information presented outlines a random sampling procedure used on a dataset of 1025 occurrences. Here's a quick rundown of the data:

The original dataset included 1025 occurrences, implying that it contained information about 1025 people. The random selection technique chose 75% of the data for inclusion, yielding a sample size of 769 occurrences. The sample is a subset of the original dataset that may be utilized for data analysis and modeling.

The remaining cases following the sampling procedure were not chosen for inclusion in the sample and were thus eliminated. In this example, the sample did not comprise 256 occurrences. It's worth noting that the rejected examples may include useful information that might impact the quality of any analysis or modeling conducted on the sample. As a result, it is critical to carefully analyze the sampling method employed and any potential biases imposed by the sampling process.

The material supplied provides a set of ten machine-learning models that may be utilized for various data analysis and modeling applications. Here's a quick rundown of each model:

Each model has advantages and disadvantages and may be better suited to tasks or datasets than others. Before picking the best model, it is critical to evaluate the problem at hand thoroughly, the nature of the data, and the limits of each model. Furthermore, it is critical to assess the model's performance using proper metrics and to interpret the findings with caution, considering any potential biases or restrictions caused by the data or modeling process as shown in Table I, Table II, and Table III.

Fig. 3. Test and score, for the target class show: 0.

Fig. 4. Test and score, for the target class show average over classes.

The performance evaluation criteria for ten distinct machine learning models: interpretation and evaluation: The Random Forest model received excellent scores across all assessment measures, suggesting it did exceptionally well on the classification test. Fig. 4 shows test and score for the Target class Show: 0 whereas Fig. 3 shows the test and score

for the Target class show average over classes. However, it is important to note that the model may have been overfitting the data because it earned excellent scores on the training data. More testing on independent test data is required to demonstrate that the model generalizes successfully to new and previously unknown data. Logistic Regression: The Logistic Regression model performed well in most assessment measures, indicating that it fits the classification problem well. However, several criteria, such as Specificity and LogLoss, fell short, indicating that there may be space for development in these areas. Tree: The Tree model scored poorer than other models across all assessment measures, notably LogLoss. This suggests it may not be the most appropriate model for this classification problem. SVM: The SVM model received excellent scores in all assessment parameters, including AUC, F1, Precision, Recall, MCC, and Specificity. This suggests that it might be a good model for the classification problem. The AdaBoost model received perfect scores across all assessment measures, suggesting it did exceptionally well on the classification test. However, like with the Random Forest model, it must be evaluated on independent test data to ensure it generalizes effectively to new and unknown data. The Neural Network model scored moderate to high in most assessment measures but fell short in others, such as Specificity and LogLoss. This suggests that these areas may have space for improvement. The kNN model received perfect scores on all assessment criteria, suggesting it did exceptionally well on the classification test. However, like with the Random Forest and AdaBoost models, the model must be evaluated on independent test data to ensure it generalizes effectively to new and unknown data. Finally, the SGD model had the lowest scores across all assessment measures, suggesting that it may not be appropriate for this classification job, as shown in Fig. 5.

Fig. 5. Test and score, for the target class show: 1.

The information presented depicts the performance assessment metrics for 10 distinct machine learning models based on five evaluation metrics: AUC, CA, F1, Precision, and Recall. The models are assessed specifically on their ability to categorize data correctly and reliably as shown in Table IV.

According to the evaluation findings, the top-performing models are the Random Forest, AdaBoost, Tree, CN2 rule inducer, and kNN models, which received high scores across all assessment measures. The Random Forest model had the greatest AUC score, suggesting it has the best overall performance in rating the data. The Tree, AdaBoost, and CN2 rule inducer models all received perfect scores across all

assessment measures, suggesting they did exceptionally well on the classification test. The kNN model performed well across all assessment measures, indicating that it is good for the classification job.

TABLE IV. DEMONSTRATES THE ACCURACY SCORES OF VARIOUS MACHINE LEARNING ALGORITHMS APPLIED TO A HEART DISEASE DETECTION DATASET SHOW THE AVERAGE OVER CLASSES

Model	AUC	CA	F1	Prec	Recall
Tree	0.987	0.987	0.987	0.987	0.987
AB	0.986	0.986	0.986	0.986	0.986
RF	0.997	0.984	0.984	0.984	0.984
CN2	0.987	0.979	0.979	0.979	0.979
kNN	0.991	0.969	0.969	0.969	0.969
SVM	0.987	0.953	0.953	0.953	0.953
NN	0.958	0.904	0.904	0.904	0.904
NB	0.931	0.863	0.863	0.863	0.863
LR	0.931	0.857	0.856	0.86	0.857
SGD	0.841	0.843	0.842	0.843	0.843

The SVM model performed well in AUC, F1, Precision, and Recall, indicating that it might be a good model for the classification problem. However, it received a lower CA score, suggesting it may be less accurate in categorizing data than other models.

All assessment criteria gave the Neural Network model good ratings, indicating that it might be upgraded to increase its performance. Similarly, the Naive Bayes and Logistic Regression models performed well in most assessment criteria. Still, they performed poorly in others, such as Precision and Recall, showing space for development in these areas.

Finally, the SGD model had the lowest scores across all assessment measures, suggesting that it may not be appropriate for this classification job. The findings show that the Random Forest, AdaBoost, Tree, CN2 rule inducer, and kNN models are the best at this classification job. However, these models must be evaluated on independent test data to verify that they generalize effectively to new and unknown variables. Furthermore, it is critical to analyze the categorization task's unique goals and restrictions and choose the model that best satisfies those demands.

The information presented depicts the performance assessment metrics for 10 distinct machine learning models based on five evaluation metrics: AUC, CA, F1, Precision, and Recall. The models are assessed based on their ability to identify data appropriately and reliably. According to the assessment findings, the top-performing models are the Tree, Random Forest, AdaBoost, CN2 rule inducer, and kNN models, which received high scores across all evaluation measures. The Tree model had the greatest AUC score, suggesting it has the best overall performance in rating the data. All assessment metrics showed that the Random Forest, AdaBoost, and CN2 rule inducer models performed exceptionally well on the classification test. Except for F1, the kNN model had good scores in all assessment criteria, showing that it is viable for the classification job. The SVM

model scored well in AUC, Recall, and F1, indicating that it might be a good model for the classification problem. It did, however, have a lower Precision score, indicating that it may be less exact in correctly identifying data than some of the other models.

TABLE V. DEMONSTRATES THE ACCURACY SCORES OF VARIOUS MACHINE LEARNING ALGORITHMS APPLIED TO A HEART DISEASE DETECTION DATASET TARGET CLASS: 0

Model	AUC	CA	F1	Prec	Recall
Tree	0.987	0.987	0.986	0.992	0.981
AB	0.985	0.986	0.985	0.984	0.986
RF	0.996	0.984	0.984	0.981	0.986
CN2	0.986	0.979	0.978	0.981	0.975
kNN	0.991	0.969	0.967	0.972	0.962
SVM	0.988	0.953	0.951	0.943	0.959
NN	0.959	0.904	0.897	0.91	0.885
NB	0.933	0.863	0.856	0.859	0.852
LR	0.933	0.857	0.841	0.89	0.797
SGD	0.84	0.843	0.83	0.853	0.808

All assessment measures yielded moderate to low scores for the Neural Network, Naive Bayes, Logistic Regression, and SGD models, indicating that they may not be the optimal models for this classification problem. The assessment findings show that the top-performing models for this classification job are the Tree, Random Forest, AdaBoost, CN2 rule inducer, and kNN models. However, these models must be evaluated on independent test data to verify that they generalize effectively to new and unknown variables. Furthermore, it is critical to analyze the categorization task's unique goals and restrictions and choose the model that best satisfies those demands as shown in Table V.

Looking at the individual assessment measures, the Tree model had the greatest AUC score, suggesting it performs the best overall regarding data ranking. All assessment measures showed that the Random Forest, AdaBoost, CN2 rule inducer, and kNN models performed exceptionally well on the classification test. The CN2 rule inducer model had the greatest Precision score, meaning it is the most accurate at accurately identifying data. The Naive Bayes and Logistic Regression models have the highest Recall ratings, indicating they are the best at detecting true positives. The Neural Network model had the lowest scores across all assessment measures, implying that it is not the best model for this classification job. It's crucial to note that the performance assessment metrics reported here were calculated using a single random sample of the dataset, and the models' performance may change with various samples or on anonymous data. As a result, it is critical to carefully analyze the sampling method employed and any potential biases imposed by the sampling process. Furthermore, the quality of the data used to train and assess the models is important to their performance, and without knowing more about the dataset's origin, collection, and preprocessing, it's difficult to draw definitive conclusions or make suggestions based on this data alone.

The top-performing models for this classification job are the Tree, Random Forest, AdaBoost, CN2 rule inducer, and kNN models, with high scores across all assessment measures. The SVM model is also suitable, with excellent AUC, Recall, and F1 scores. The Naive Bayes and Logistic Regression models are the best at recognizing true positives, while the CN2 rule inducer model is the best at accurately categorizing data. The Neural Network model had the lowest scores across all assessment measures, implying that it is not the best model for this classification job. However, more testing on independent test data is required to demonstrate that these models generalize effectively to new and previously unexplored data. Furthermore, it is critical to analyze the categorization task's unique goals and restrictions and choose the model that best satisfies those demands.

TABLE VI. DEMONSTRATES THE ACCURACY SCORES OF VARIOUS MACHINE LEARNING ALGORITHMS APPLIED TO A HEART DISEASE DETECTION DATASET TARGET CLASS: 1

Model	AUC	CA	F1	Prec	Recall
Tree	0.987	0.987	0.988	0.983	0.993
AB	0.985	0.986	0.986	0.988	0.985
RF	0.996	0.984	0.985	0.988	0.983
CN2	0.986	0.979	0.98	0.978	0.983
kNN	0.991	0.969	0.97	0.966	0.975
SVM	0.988	0.953	0.955	0.962	0.948
NN	0.959	0.904	0.91	0.899	0.921
NB	0.933	0.863	0.871	0.867	0.874
LR	0.933	0.857	0.87	0.833	0.911
SGD	0.84	0.843	0.854	0.835	0.874

The information presented depicts the performance assessment metrics for 10 distinct machine learning models based on five evaluation metrics: AUC, CA, F1, Precision, and Recall. The models are assessed based on their ability to identify data appropriately and reliably. According to the assessment findings, the top-performing models are the Tree, Random Forest, AdaBoost, CN2 rule inducer, and kNN models, which received high scores across all evaluation measures. The Tree model had the greatest AUC score, suggesting it has the best overall performance in rating the data. All assessment metrics showed that the Random Forest, AdaBoost, and CN2 rule inducer models performed exceptionally well on the classification test. Except for Precision, the kNN model received good scores in all assessment criteria, showing that it is viable for the classification job as shown in Table VI.

The SVM model received excellent AUC, Precision, and Recall scores, indicating that it might be a good model for the classification problem. However, it had a lower CA score, indicating that it may be less reliable in accurately categorizing data than other models. All assessment measures yielded moderate to low scores for the Neural Network, Naive Bayes, Logistic Regression, and SGD models, indicating that they may not be the optimal models for this classification problem. The assessment findings show that the top-performing models for this classification job are the Tree,

Random Forest, AdaBoost, CN2 rule inducer, and kNN models. However, these models must be evaluated on independent test data to verify that they generalize effectively to new and unknown variables. Furthermore, it is critical to analyze the categorization task's unique goals and restrictions and choose the model that best satisfies those demands. Looking at the individual assessment measures, the Tree model had the greatest AUC score, suggesting it performs the best overall regarding data ranking. All assessment metrics showed that the Random Forest, AdaBoost, and CN2 rule inducer models performed exceptionally well on the classification test. The CN2 rule inducer model had the greatest Precision score, meaning it is the most accurate in accurately identifying data. The Neural Network model has the greatest Recall score, suggesting it is the best at detecting true positives. The Logistic Regression model has the greatest F1 score, suggesting a good mix of Precision and Recall.

The information supplied displays the classification results of 10 different machine-learning algorithms on a dataset of samples designated as malignant or benign as shown in Table VII. The findings are given as confusion matrices, which indicate the number of samples categorized as malignant or benign by the models and the samples' true labels. According to the assessment findings, the top-performing models include the Tree, Random Forest, AdaBoost, kNN, and CN2 models, which obtained high accuracy in accurately categorizing the data.

TABLE VII. SHOWS THE CONFUSION MATRIX OF SEVERAL MACHINE LEARNING ALGORITHMS APPLIED TO A HEART DISEASE DETECTION DATASET

Algorithms	Malignant	Benign	
Tree	358	7	Malignant
	3	401	Benign
Random Forest	360	5	Malignant
	7	397	Benign
Logistic Regression	291	74	Malignant
	36	368	Benign
SVM	350	15	Malignant
	21	383	Benign
AdaBoost	360	5	Malignant
	6	398	Benign
Neural Network	323	42	Malignant
	32	372	Benign
kNN	351	14	Malignant
	10	394	Benign
Naive Bayes	311	54	Malignant
	51	353	Benign
CN2	356	9	Malignant
	7	397	Benign
SGD	295	70	Malignant
	51	353	Benign

Fig. 6. The ROC curve to the total number of targets 0.

Fig. 6 depicts the ROC (Receiver Operating Characteristic) curve for target 0, a graphical depiction of a binary classification model's performance. The ROC curve is constructed by graphing the true positive rate (TPR) vs. the false positive rate (FPR) at different threshold levels.

The y-axis shows the TPR, also known as sensitivity or recall, which is the fraction of true positive cases accurately detected by the model. The x-axis depicts the FPR, the fraction of true negative cases the model mistakenly classifies as positive.

The ROC curve in the presented Fig. 6 is smooth and steep, indicating a well-performing model. The model's performance improves as the curve approaches the top-left corner of Fig. 6. This figure's curve is in the top-left corner, indicating that the model has a high TPR and a low FPR. In other words, the model can detect real positives while avoiding false positives.

The picture also includes the AUC (Area Under the Curve) score, which is a measure that highlights the overall performance of a binary classification model. The AUC score ranges from 0 to 1, with 1 representing perfect classification accuracy and 0.5 representing random guessing. In this scenario, the AUC value is near one, suggesting that the model performs well in categorizing the data with the goal 0.

Fig. 7. The ROC curve to the total number of targets 1.

Fig. 7 depicts the ROC (Receiver Operating Characteristic) curve for target 1, a graphical depiction of a binary classification model's performance. The ROC curve is constructed by graphing the true positive rate (TPR) vs. the false positive rate (FPR) at different threshold levels.

## V. CONCLUSION AND FUTURE WORK

Finally, this work shows the promise of machine learning approaches for predicting heart disease using clinical and demographic data. The findings indicate that various machine-learning techniques may be utilized to create reliable predictive models for heart disease. The study's findings might have significant implications for the early identification and prevention of heart disease, as well as for improving patient outcomes and lowering healthcare expenditures. According to the findings of this study, machine learning models have the potential to be utilized as a tool for healthcare practitioners in the prediction of cardiac disease and the improvement of patient outcomes. These findings have major consequences for healthcare workers, patients, and healthcare systems. Early identification and prevention of cardiac disease can result in better patient outcomes and quality of life, lower healthcare costs, and more efficient resource allocation. Additional research and development are required to successfully integrate machine learning models in Jordanian hospitals. To ensure the generalizability and dependability of the predictive models, it is vital to evaluate the conclusions using separate datasets. Also required is research on the integration of machine learning models into existing healthcare systems and workflows. This includes addressing data quality, privacy, and interpretability issues, as well as designing user-friendly interfaces for healthcare professionals.

**Abstract**—This paper proposes an innovative ensemble learning framework for classifying medical images using Support Vector Machine (SVM) and Fuzzy Logic classifiers. The proposed approach utilizes logical AND and OR operations to combine the predictions from the two classifiers, aiming to capitalize on the strengths of each. The SVM and Fuzzy Logic classifiers were independently trained on a comprehensive database of medical images comprising various types of X-ray images. The logical OR operation was then used to create an ensemble classifier that outputs a positive classification if either of the individual classifiers does so. On the other hand, the logical AND operation was used to construct an ensemble classifier that outputs a positive classification only if both individual classifiers do so. The proposed method aims to increase sensitivity and precision by capturing as many positive instances as possible, thereby reducing false positives. The scope of the proposed work is validated in terms of overall time complexity and retrieval accuracy. The simulation outcome shows promising result with 98.36 accuracy score and 1.8 seconds to retrieve all the images in query database.

**Keywords**—Medical images; support vector machine; fuzzy logic; X-ray images; time complexity

## I. INTRODUCTION

The digital age has led to an explosion of visual content, from personal photos to professional databases. This has created a challenge for users who want to find specific images based on their content. Content-based image retrieval (CBIR) systems are a valuable tool for addressing this challenge [1]. CBIR systems work by extracting visual features from images, such as color, texture, and shape. These features are then used to compare images and find the best matches [2]. This is in contrast to traditional methods of image retrieval, which rely on textual metadata such as tags and keywords. CBIR is especially useful in domains where manual tagging is impractical or where the sheer volume of images makes keyword-based searching insufficient [3]. For example, CBIR can be used to find images of medical conditions, products, or people, even if they are not tagged with the relevant keywords [4]. The uses of CBIR are manifold. For example, in medical imaging, CBIR can help diagnose disease by comparing patient scans to an annotated image database [5]. In the domain of digital libraries, museums, and archival systems, CBIR facilitates the classification, indexing, and retrieval of visual content. Furthermore, e-commerce platforms have the potential to enable customers to search for products using images [6]. The urgency of efficient CBIR systems stems from our

increasing reliance on digital visuals [7]. As the volume of digital images continues to grow, the need for intelligent, content-based systems becomes even greater. They not only make the retrieval process more efficient but also open up avenues for more nuanced, context-aware searches, which are often lacking in traditional methods [8].

Despite its potential, CBIR systems face several challenges. One of the biggest challenges is the semantic gap. This is the difference between the low-level visual features extracted by CBIR systems and the high-level semantics understood by users [9-10]. For example, a CBIR system might consider two images to be identical based on their visual features, even if they contain different objects or are taken in different conditions. This can lead to mismatches during retrieval, where the system returns images that are not relevant to the user's query. Another challenge for CBIR systems is the heterogeneity of images. This refers to the fact that images can vary in terms of their angle, scale, lighting conditions, and other factors. This can make it difficult for CBIR systems to accurately match images, even if they contain the same objects [11]. Additionally, images often contain multiple objects, and it can be difficult for CBIR systems to identify the subject of interest [12]. This is especially true for images that are cluttered or have a lot of background noise.

However, even with these advances, there are still challenges to overcome. One challenge is ensuring that CBIR systems are both accurate and time-efficient. This is especially important in specialized domains such as medical imaging, where speed is often critical. Additionally, there is still a gap between machine-extracted features and human interpretation. This can lead to mismatches during retrieval, where the system returns images that are not relevant to the user's query. One possible solution to these challenges is to use an efficient set of classifiers. Our work aims to solve the challenges of CBIR in medical imaging by using an innovative combination of SVM and fuzzy logic. The study believes that this approach can bridge the semantic gap and improve the accuracy and efficiency of CBIR systems in this domain.

This paper introduces a novel approach to CBIR by amalgamating SVM and Fuzzy Logic, harnessing their combined strengths for enhanced image retrieval in the medical domain. The ensemble method, pivoting on logical operations, promises to address the challenges outlined above. The following are the key contributions:

- This paper presents a novel approach to CBIR integrating SVM and fuzzy logic.
- The proposed method aims to bridge the semantic gap that exists between the user's low-level visual features and high-level semantic understanding.
- This article introduces logical AND and OR operations as integration methods within a system. This allows switching between sensitivity and precision based on specific requirements, providing flexibility and adaptability for image retrieval tasks.
- Conduct in-depth analysis of time complexity to set benchmarks for real-time image capture. This contribution is significant, especially in critical areas such as medical imaging where time efficiency is critical.

Following this introduction, the remainder of this paper is organized in a structured manner as follows: Section II offers a brief survey of the existing work, presenting an overview of various methodologies and technologies currently in practice; In Section III, architectural design of the proposed system is discussed along with elucidating the processes of feature database creation, query image formulation, feature extraction, and the intricacies of the retrieval system; Section IV, discusses the system implementation, shedding light on the integration of SVM and Fuzzy Logic in CBIR, and the amalgamation of Ensemble SVM and Fuzzy System using Logical Operations; Section V, present a comprehensive evaluation of our system against a medical imaging database, highlighting the improved precision and recall rates. Finally, Section VI concludes the paper, summarizing the key findings, contributions, and implications of our work. It also outlines the potential avenues for future research, discussing the scalability, adaptability, and possible enhancements to our CBIR system.

## II. RELATED WORK

CBIR became known in the early 1990s and gained a lot of attention in research. Over the past decades, different feature extraction techniques have been employed based on appearances such as color, boundary contour, texture, and spatial layout. The work carried out by Younus et al. [13] devised a CBIR system considering color and texture-based feature descriptors and employed a joint approach of k-means and particle swarm optimization (PSO) for image retrieval. The presented scheme is validated on the WANG dataset. Based on the experimental outcome, it is identified that the precision for most classes is improved, but overlooked shape in similarity computations. The study conducted by Sajjad et al. [14] introduced a CBIR system customized to remain invariant to alterations in texture rotation and color features. For color feature extraction, they opted for the HSV color space, and a color histogram was employed for quantization. Notably, to circumvent the effects of illumination changes, only the Hue and Saturation channels were considered. To address rotation variance in textures, they utilized Local Binary Patterns (LBP). The effectiveness of the presented approach is justified based on three datasets namely, Zurich Building, Corel 1 K, and Corel 10 K.

Ashraf et al. [15], combined texture and color in a CBIR approach using HSV color moments, DWT, and Gabor wavelet. Their 1x250 dimensional feature vector improved accuracy but at the cost of slowed searches. The validation of the presented method is done against Corel and GHIM-10 K datasets. Based on the overall outcome analysis it has been identified that the presented method has achieved high precision, but also missing some texture and spatial details. The work presented by Alsmadi et al. [16] addresses the limitations of current CBIR systems by presenting a different scheme that extracts and stores comprehensive color, shape, and texture features as vectors. Techniques include RGB color paired with neutrosophic clustering, YCbCr color with wavelet transform, and gray-level matrices for texture. Utilizing a metaheuristic algorithm for similarity evaluation, the presented model demonstrated superior precision and recall against existing systems. The work of Choe et al. [17] presented an approach leveraging deep learning to retrieve similar chest CT images, aiming to assist examiners in the ILD (interstitial lung disease) diagnosis.

The work carried out by Garg and Dhiman [18] introduces a content-based image retrieval technique that combines discrete wavelet transformation with a rotationally invariant texture descriptor, enhancing feature extraction and reduction. By leveraging magnitude data and GLCM for texture classification, the approach, when tested on the CORAL dataset, demonstrated superior performance across classifiers like SVM, KNN, and decision trees in accuracy and other metrics. It has been observed that the existing CBIR methods falter in multi-class searches due to semantic similarities across image classes. Addressing this, the work of Khan et al. [19] introduces a hybrid CBIR method combining feature descriptors, a genetic algorithm, and an SVM classifier. By integrating color moments, various wavelets, and the L2 Norm for similarity measurement, the method effectively handles class imbalances. Tested on four datasets, it surpassed 25 CBIR techniques in retrieval performance. The authors in the study of Ma et al. [20] introduced a Privacy-preserving CBIR method for cloud-based multimedia, addressing current shortcomings in data encryption and feature extraction. Hybrid encryption is proposed alongside an enhanced DenseNet model for feature extraction from encrypted images. This ensures secure CBIR execution on cloud servers. Tested on two benchmarks, the method outperforms existing solutions by 1.9% and 10% in terms of accuracy, while also reducing computational costs and model parameters significantly.

Monowar et al. [21] introduced, a self-supervised image retrieval system using neural networks (NN), addressing the challenges of expensive or unfeasible data labeling. Trained on pairwise constraints, the model can function in self-supervised environments and with partially labeled datasets. It uses NN to extract and fuse image embeddings for retrieval. Banu et al. [22] explored CBIR using colour and texture features combined with high-level semantics. The proposed system outperforms traditional CBIR systems in speed and efficiency through an ontology model for content analysis when tested on a vast image database. The work of Rani in [23] presented a satellite image retrieval system for forest fire detection using hybrid feature extraction and a unique optimization algorithm

for feature selection; the method shows enhanced precision and recall, surpassing existing fire detection techniques.

Wang et al. [24] introduce a CBIR framework for skin diseases using multi-sourced information. This system fuses dermoscopic, clinical images, and meta-data, and with a graph-based community analysis, boasts a 0.836 precision on the EDRA and ISIC 2019 datasets. Arya and Vimina [25] presented the Local Neighborhood Gradient Pattern (LNGP) for CBIR, capturing local patterns in an 8-bit format. Tests on diverse datasets yield precision ranging from 40.66% to 86.12%, underlining its CBIR efficiency. Madhu and Kumar [26] unveil a hybrid algorithm for medical image feature extraction, merging techniques like DWT, PCA, and GLCM. Using various images, the approach is validated through K-means clustering, with an emphasis on enhancing classification precision via edge detection.

### III. PROPOSED SYSTEM

This section presents the proposed CBIR system and discusses the implementation procedure adopted to retrieve similar images from the image database. The prime aim of the research work reported in this paper is to evolve with an optimal approach of CBIR while achieving optimal decisions regarding content retrieval with higher precision and retrieval accuracy. In this regard, the study presents a unique and different approach from the existing work where the proposed study locally employs two different models to exploit their decision capability to get optimal results. The schematic depiction of the proposed CBIR system is shown in Fig. 1.

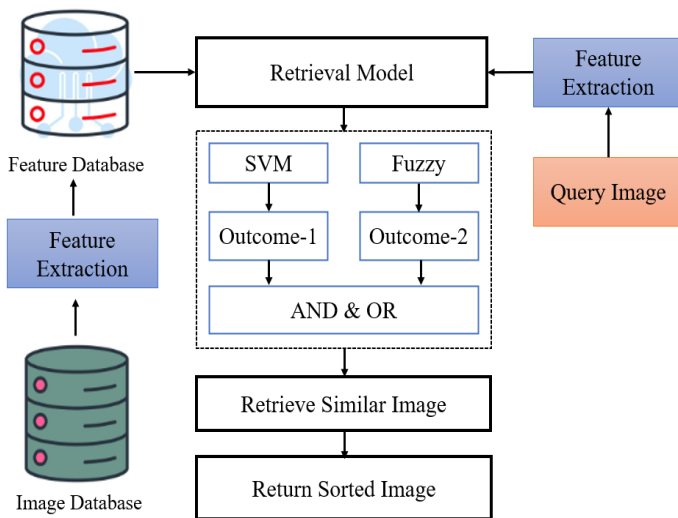

Fig. 1. Schematic architecture of the proposed CBIR system.

As shown in the above Fig. 1, the entire modeling of the proposed system can be divided into three core modules: i) construction of the feature database, ii) query image and its feature extraction, and iii) retrieval system itself. Each of these modules plays a pivotal role in ensuring the efficiency and efficacy of the entire process. Each of these modules plays a pivotal role in ensuring the efficiency and efficacy of the entire process. The system introduced in this paper emphasizes the need to optimize content retrieval, guaranteeing superior precision and accuracy.

#### A. Construction of Feature Database

This initial module plays a pivotal role in our CBIR approach. It involves meticulously processing the image database to extract and essential features. These features, which serve as unique identifiers for each image, form the foundation of our subsequent retrieval procedures. The system creates a feature-rich database that enables effective comparison and matching by capturing intrinsic characteristics like texture, colour, and shape. The database construction phase is twofold, customized to the distinct feature sets extracted for the SVM and Fuzzy Logic-based systems. For the SVM-based system, the feature extraction process revolves around three pivotal aspects:

- **CLD Coefficients:** Extracted to capture the spatial distribution of color in images, CLD coefficients provide insights into color layout variations. This feature is integral for distinguishing diverse medical image content.
- **Block Division:** By dividing images into smaller regions, block division enables localized analysis. This feature facilitates the identification of unique patterns and textures within specific image regions.
- **Edge Histogram:** Capturing the distribution of edges or gradients within images, the edge histogram feature highlights significant structural information. This attribute contributes to classifying images based on prominent edge distributions.

For the Fuzzy Logic-based system, the feature extraction process encompasses different elements:

- **Layer Segmentation:** The segmentation of images into distinct layers aids in identifying intricate structures within the medical images. These layers serve as crucial reference points for subsequent comparisons.
- **Region of Interest (ROI):** Extraction of ROIs isolates specific areas of medical interest. This feature guides the system towards recognizing critical regions with relevance to diagnosis.
- **Harris Corner and Fuzzy Corners:** Corner detection methodologies like Harris Corner and fuzzy corners enable the identification of distinct points in the image. These points, often representing unique features, enrich the feature database.

#### B. Query Image and Feature Extraction

The second module addresses the central challenge of CBIR—processing user queries effectively. Each query image presents a unique challenge and opportunity. This module employs advanced techniques to extract pertinent features from the query image. These extracted features are then organized into a structured representation that is well-suited for comparison with the features in our database.

#### C. Retrieval System

The third module is the heart of our CBIR system. Drawing on the extracted features and processed data from the previous

steps, this module executes the retrieval process. During the retrieval phase, the feature extraction process is applied to the query image. Subsequently, the SVM and Fuzzy Logic models independently process the query image, generating classification outputs based on their respective feature databases. In a harmonious ensemble, the outputs of both SVM and Fuzzy Logic classifiers are combined to derive the final retrieval decision. This amalgamation leverages the unique strengths of both models, enhancing the overall accuracy and robustness of the CBIR system. The diversity of features extracted from the two distinct databases ensures a comprehensive understanding of image content, enabling the system to provide more informed and precise retrieval outcomes.

#### IV. SYSTEM IMPLEMENTATION

This section discusses the implementation procedure adopted in the proposed system development.

##### A. SVM based CBIR

The SVM classifier used in our system is designed for CBIR which operates by extracting significant features from the images, specifically focusing on edge histogram, block division, and color layout descriptor (CLD) features. Block division allows the classifier to consider smaller regions of the image independently, providing local information that can further enhance the classification. CLD encapsulates the spatial distribution of color in the image, another crucial factor in differentiating between various images. It is one of the descriptors defined in the MPEG-7 standard, which is aimed at representing the spatial distribution of color in an image in a very compact form. CLD is highly effective for representing the spatial distribution of colors, even though the descriptor has a very small size. The implementation steps involved in the computation of CLD features are described as follows:

The algorithm begins by reading the input image, which is the target for color distribution analysis. To better represent color information, the image is converted from its original color space to YCbCr. This color space separation allows for a more effective analysis of color distribution. Further, the image is divided into non-overlapping blocks of size 8x8 pixels. If the image's dimensions are not evenly divisible by 8, padding is applied to ensure compatibility. Each block will be processed independently to capture color distribution characteristics. For every 8x8 block, the algorithm calculates the average color value. This is done in the YCbCr color space, where each pixel within the block contributes to the average.

---

##### Algorithm-1: CLD Feature Computation

---

###### Start:

1. Divide the image into non-overlapping 8x8 blocks
2. Get dimensions (h, w)
3. Blocks:  $N_{blocks} = \left\lfloor \frac{h}{8} \right\rfloor \times \left\lfloor \frac{w}{8} \right\rfloor$
4. If  $h \% 8 \neq 0$  or  $w \% 8 \neq 0$
5. do padding to get compatibility with the block size
6.  $\forall$  block  $B = 1:n$
7. compute the average color value
8.  $B_{i,j} \cdot C_{avg}^{i,j} = \frac{1}{8 \times 8} \sum_{y=0}^7 \sum_{x=0}^7 B_{i,j}(x,y)$

9. Apply 2D DCT to the 8x8 average color image

10. DCT coefficient for block  $B_{i,j}: D_{coeff}^{i,j}(u,v) = \alpha(u)\alpha(v) \sum_{y=0}^7 \sum_{x=0}^7 C_{avg}^{i,j}(x,y) \cos\left(\frac{(2x+1)u\pi}{16}\right) \cos\left(\frac{(2y+1)v\pi}{16}\right)$

11. The quantized coefficient for block

$$B_{i,j}: Q_{coeff}^{i,j}(u,v) = \text{round}\left(\frac{D_{coeff}^{i,j}(u,v)}{Q_{table}(u,v)}\right)$$

12. Arrange quantized DCT coefficients in 1D using zigzag scanning.

$$Z = [Q_{coeff}^{0,0}, Q_{coeff}^{0,1}, \dots, Q_{coeff}^{7,7}]$$

---

##### End

---

The computed average color values will represent the color essence of each block. The 2D DCT is employed on the average color values of each block. This mathematical transformation converts the spatial color information into frequency components, essential for capturing color distribution patterns. To reduce the amount of data while retaining crucial information, the DCT coefficients are quantized. Quantization involves dividing the coefficients by predefined quantization tables, which effectively reduces their precision. The quantized DCT coefficients are rearranged into a 1D array through zigzag scanning. This process converts the 2D array of coefficients into a compact, linear form, which is crucial for efficient storage and transmission of the descriptor. The resulting 1D array of zigzag-scanned quantized DCT coefficients forms the Color Layout Descriptor (CLD). This descriptor represents the image's color distribution in a highly compact yet informative manner. The computed CLD coefficients can now be used for various applications, such as image retrieval, content analysis, or classification, where the color distribution plays a pivotal role. The second feature namely edge histogram captures the local edge distribution in the image, which has proven to be a significant feature in distinguishing different types of medical images. The implementation steps involved in the computation of edge histogram features are subjected to multiple computing operations. The algorithm first loads the input image, which is then processed for edge histogram computation. To facilitate the process of edge detection, the algorithm transforms the image into grayscale via a weighted combination of its original color channels. This operation yields a single-channel representation where pixel values correspond to intensity levels. To identify edges within the grayscale image, an edge detection algorithm is engaged. This step may encompass techniques such as employing the Sobel or Canny algorithms, adept at highlighting zones of swift intensity fluctuations, often indicative of edges.

The outcome manifests as an edge map, delineating potential edge locations throughout the image. This edge map is then partitioned into discrete, non-overlapping blocks of a predefined magnitude, like 8x8 pixels. The division into smaller blocks fosters simplified analysis and a contextually confined comprehension of edge distribution within the image. For each of these blocks, the algorithm calculates an edge histogram, which quantifies the dispersion of edge orientations within the respective block. This procedure encompasses evaluating the intensity of each pixel's edge and allocating it into predefined bins associated with distinct edge orientations. The individual edge histograms derived from each block are

eventually amalgamated into a singular histogram, encompassing the collective distribution of edge orientations spanning the entire image. This unified histogram forms a succinct representation of how the edges are positioned within the image. The resulting composite histogram, the edge histogram, becomes a versatile asset applicable in diverse contexts. It effectively encapsulates the prevailing edge orientations present in the image and can be harnessed for tasks like image retrieval, object detection, or other undertakings that draw value from insights into the distribution patterns of edges.

---

**Algorithm-2:** Edge Histogram Computation

---

**Start:**

1. Convert the image to grayscale using a suitable color conversion formula
2. Grayscale intensity at pixel  $(x, y)$
3.  $I(x, y) = 0.29 \times R(x, y) + 0.58 \times G(x, y) + 0.11 \times B(x, y)$
4. Apply an edge detection algorithm (e.g., Sobel, Canny) to the grayscale image.
5.  $E(x, y)$  represents the edge map resulting from the algorithm
6. Divide the edge map into non-overlapping 8x8 blocks
7. Blocks:  $N_{blocks} = \left\lfloor \frac{h}{8} \right\rfloor \times \left\lfloor \frac{w}{8} \right\rfloor$
8. Edge histogram

$$H_{edge}^{i,j}(k): H_{edge}^{i,j}(k) = \sum_{y=0}^7 \sum_{x=0}^7 \delta(E_{i,j}(x, y), k)$$

9. Combine edge histograms of all blocks into a single

$$H_{combined}(k): H_{combined}(k) = \sum_{i=0}^{N_{blocks}} \sum_{j=0}^{N_{blocks}} H_{edge}^{i,j}(k)$$

---

**End**

---

Once the features are extracted, they are organized into a feature vector for each image. This vector becomes the input for the SVM that captures the image's unique characteristics. The extracted features are organized into a feature vector for each image. For example, consider there is  $m$  different features extracted for an image, then feature vector can be represented as follows:

$$x = x_1, x_2, x_3 \dots x_n \quad (1)$$

The combination of the extracted features into a single vector allows the SVM to effectively analyze the image data and make predictions based on these features. The SVM requires training to learn how to distinguish between different classes or categories. SVM learns to find a hyperplane that maximizes the margin between classes. The optimization problem involves finding the optimal  $\bar{w}$  and  $\bar{b}$  that define the hyperplane while considering misclassified points. SVM is a supervised learning model used for classification and regression tasks. The fundamental idea behind SVM is to find a hyperplane that best separates data points of different classes while maximizing the margin between these classes. This hyperplane serves as the decision boundary for classification, and the data points closest to the hyperplane are known as support vectors. Given a set of training data  $X = (x_1, y_1), (x_2, y_2) \dots (x_n, y_n)$ , where  $x_i$  represents the feature vector and  $y_i$  is the corresponding class label (either +1 or -1), the SVM aims to find a hyperplane  $w \cdot x + b =$ , that separates the two classes. The distance between the hyperplane

and the support vectors is given by the margin, which is proportional to  $1/||w||$ . The optimization problem for SVM can be formulated as follows:

$$\min: ||w||^2 + C \sum_{i=1}^n \xi_i \quad (2)$$

$$\text{subjected to: } y_i(w \cdot x + b) \geq 1 - \xi_i, s. t \xi_i \geq 0$$

where,  $C$  denotes a regularization parameter that balances the trade-off between maximizing the margin and minimizing the classification error, and  $\xi_i$  slack variables that allow for misclassified points or points within the margin. The goal is to minimize the value of  $||w||$ , while satisfying the classification constraints.

For image retrieval, a user provides a query image. The same feature extraction and vectorization process is applied to the query image. The SVM requires training to learn how to distinguish between different classes or categories. In the context of image retrieval, each image is assigned a label indicating its category. During training, the SVM constructs a decision boundary, known as a hyperplane that optimally separates the feature vectors of different classes. This hyperplane maximizes the margin between classes, effectively determining the most discriminative features for classification. Once the SVM is trained, it can be used for classification. For image retrieval, a user provides a query image that needs to be classified and compared against the images in the database. The query image undergoes the same feature extraction and vectorization process as the training images. The trained SVM then assesses the query image's feature vector and places it on the appropriate side of the decision boundary, classifying it into one of the predefined categories.

The SVM-based image retrieval process doesn't end with classification. Instead, it ranks the retrieved images based on their proximity to the decision boundary. Images that are closer to the decision boundary are considered more similar to the query image in terms of their feature characteristics. As a result, these images are ranked higher in the retrieval process. Finally, the retrieved images are presented to the user in the order of their ranking. Images that closely match the query image's features are displayed at the top of the list, providing the user with the most relevant results first.

**B. Fuzzy System-based CBIR**

The Fuzzy Logic-based classifier in our system focuses on edge detection for image retrieval. Edge detection is a fundamental tool in image processing and is critical in segmenting regions of interest in medical images. By employing Fuzzy Logic, the classifier can handle the inherent uncertainty and imprecision in edge detection, leading to a more robust image retrieval. The initial step involves extracting relevant features from the images. This could include processes such as median filtering, ROI extraction, and Harris corner detection. The outcome of this step is a collection of extracted features that serve as inputs to the subsequent fuzzy logic framework. Next, layer segmentation involves partitioning images into discrete layers. This process aids in the identification and isolation of intricate structures within medical images. Mathematically, the layer segmentation can be represented as dividing the image  $I$  into  $n$  distinct layers such

that:  $L_1, L_2, L_3, \dots, L_n$  where  $n$  denotes the number of layers; further, extracting Regions of Interest (ROIs) involves isolating specific areas within the images that hold medical relevance. Mathematically, an ROI can be defined as a subset of pixels within an image  $I$  defined by a set of coordinates  $(x, y)$  that denote the spatial bounds of the ROI. Corner detection techniques like Harris corners and fuzzy corners identify distinct points in the image. These points often correspond to unique features that contribute to the overall understanding of the image. Mathematically, Harris corner detection involves evaluating the corner response function  $R$  for each pixel in the image and identifying points with high corner responses. The implementation steps for computing Harris corner and fuzzy corners features are discussed in Algorithm 3.

The algorithm presented is a comprehensive approach for detecting both Harris corners and Fuzzy Corners within grayscale images. Starting with the Harris Corner Detection, the algorithm initially computes the gradients of the image using derivative filters, followed by the calculation of products of gradients and their smoothing through a Gaussian filter. The Harris response function is then computed for each pixel, reflecting the intensity of corner features. Non-maximum suppression is applied to identify potential corner locations, and a threshold is set to retain corners with significant Harris responses. However, what sets this algorithm apart is the incorporation of Fuzzy Corners. For each detected Harris corner, a degree of "cornerness" is calculated using a sigmoidal membership function (step-9). This degree of cornerness adds a layer of nuance to the corner detection, capturing the intensity of corners in a fuzzy manner. Linguistic variables are introduced to categorize corners based on their degree of cornerness, offering a more comprehensive understanding of corner characteristics. By combining traditional corner detection with fuzzy logic, the algorithm enhances the corner detection process. The inclusion of fuzzy degrees of corners brings a new dimension to corner characterization, allowing for a more nuanced representation of corner features within images. This approach is particularly valuable in scenarios where corners exhibit varying degrees of intensity, contributing to a richer understanding of image content. In essence, this algorithm presents a holistic framework for corner detection that embraces both crisp corner points and the fuzzy characterization of corner intensity, broadening the scope of corner analysis in image processing. The image retrieval process based on the provided steps involves a unique approach that combines fuzzy logic with the concepts of similarity measurement and defuzzification.

**Algorithm-3:** Harris Corner and Fuzzy Corners Detection

**Input:** Grayscale image  $I$  of size  $M \times N$ , Threshold  $T$  for corner intensity

**Output:** Sets of detected Harris corners and Fuzzy Corners

**Start:**

1. Convert the image  $I$  into gradients  $I_x$  and  $I_y$
2. Compute the products of gradients  $\forall$  pixel:  
 $I_x^2, I_y^2$  and  $I_{xy} = I_x \cdot I_y$
3. Apply a Gaussian filter to smooth the computed products:  
 $S_{I_x^2}, S_{I_y^2}$  and  $S_{I_{xy}}$
4. Compute the Harris response function for each pixel

$$R = \det(M) - k \times \text{trace}(M)^2$$

Where  $M$  is the matrix of second-order derivatives,  $k$  is an empirical constant (between 0.04 and 0.06),

$$\det(M) = S_{I_x^2} \cdot S_{I_y^2} - S_{I_{xy}}^2 \text{ and}$$

$$\text{trace}(M) = S_{I_x^2} + S_{I_y^2}$$

5. Apply non-maximum suppression to identify potential corner locations.
6. Set a threshold  $T$ , on  $R$  and retain corners with  $R$  above the threshold
7. Process: Fuzzy Corners
8.  $\forall C$
9. compute the degree of corners using a membership function:

$$\text{degreeofcornerness}(C) = \frac{1}{1 + e^{-\alpha \cdot R(C)}}$$

Where  $R(C)$  is the Harris response at corner  $C$ , and  $\alpha$  is a tuning parameter that controls the steepness of the membership curve.

10. Define linguistic variables low cornerness, moderate cornerness, and high cornerness using appropriate fuzzy sets.
11. Categorize each detected corner into one of the fuzzy sets based on its degree of corners
12. Return:  
Sets of detected Harris corners and their corresponding degrees of corners (fuzzy membership values)  
Categorized Fuzzy Corners based on their degree of corners

**End**

The adopted computing process offers a unique perspective on image similarity, enhancing the traditional methods used for content-based image retrieval. In the image retrieval, the degree of similarity between a query image and a database image is computed using fuzzy logic. This step capitalizes on the capability of fuzzy rule-based systems to handle imprecision and variability in data. Fuzzy rules are defined to establish relationships between the features of the query image and the database image, leading to the determination of similarity. The membership functions used in the proposed algorithm are defined based on the three factors viz. (i)  $\mu_Q(Q)$  Is the membership function for the query image's high corner intensity (HCI), (ii)  $\mu_D(D)$  is the membership function for the database image's HCI, and (iii)  $\mu_S(S)$  is the membership function for the degree of Similarity. Here, the variable  $Q$  represents the degree of HCI in the query image, similarly variable  $D$  represents the degree of HCI in the database image and variable  $S$  represents the degree of similarity between the query and database images. Using these variables and membership functions, the fuzzy rules are defined as follows:

$$\text{IF } Q = \text{High AND } D = \text{High, THEN } S = \text{HIGH} \quad (3)$$

$$\text{IF } Q = \text{Low AND } D = \text{Low, THEN } S = \text{Low} \quad (4)$$

These rules allow for a flexible interpretation of image similarity. If both the query image and the database image possess high corner intensities, their similarity is rated as high.

Conversely, if either the query or database image has low corner intensities, the similarity is considered low. However, the algorithm does not consider the logic for MEDIUM as it can lead to introduce redundancy, increase complexity, and may not add substantial value to the ranking and retrieval process. While the concept of a "Medium" category could theoretically represent a middle ground in corner intensities and hence, medium similarity, its practical implementation may not be as meaningful or effective given that the inherent numerical nature of intensities already provides a continuous scale of similarity. Therefore, the presented approach provides a nuanced way of assessing similarity based on multiple factors, leading to more contextually relevant image retrieval.

### C. Ensemble SVM and Fuzzy System using Logical Operation

The proposed ensemble learning approach ingeniously integrates the SVM and Fuzzy Logic classifiers by employing logical AND and OR operations. Given an input  $x$ , the outputs of the OR operation-based ensemble  $Y_{OR}(x)$  and the AND operation-based ensemble  $Y_{AND}(x)$  can be expressed as follows:

$$Y_{OR}(x) = SVM(x) \vee Fuzzy(x) \quad (5)$$

$$Y_{AND}(x) = SVM(x) \wedge Fuzzy(x) \quad (6)$$

where,  $SVM(x)$  represents the binary outputs of the SVM classifier and  $Fuzzy(x)$  refers to Fuzzy Logic classifiers, respectively. The symbols  $\vee$  and  $\wedge$  represent the logical OR and AND operations, respectively. In this new ensemble learning system, the OR-based ensemble predicts an instance to be positive if either the SVM or the Fuzzy Logic classifier predicts it to be positive. This arrangement increases the system's sensitivity by capturing more positive instances but also slightly increases the risk of false positives. Conversely, the AND-based ensemble predicts an instance to be positive only if both classifiers predict it to be positive. This increases the system's precision by reducing the risk of false positives but also slightly increases the risk of missing some true positives. This ensemble learning system aims to provide a more adaptable and robust solution for the challenging task of medical image classification by strategically leveraging the complementary strengths of both classifiers. In the OR operation, the ensemble essentially combines the outputs of both classifiers using majority voting. If the SVM or Fuzzy Logic classifier predicts a positive class, the ensemble also predicts a positive one. On the other hand, the AND operation involves constructing a meta-model that integrates the predictions of both classifiers. The ensemble only predicts a positive class if the SVM and Fuzzy Logic classifiers agree on the classification outcome. By intelligently fusing their decision-making capabilities through logical operations, the system ensures a more adaptable and resilient solution for the intricate task of medical image classification, addressing the need for sensitivity and precision in different clinical contexts. Algorithm 4 outlines a systematic process for combining SVM and Fuzzy Logic classifiers through ensemble learning. It involves training both classifiers using distinct features and then classifying test instances using both classifiers. The results from SVM and Fuzzy Logic classifiers are combined using logical operations to create two ensemble results. Depending on the outcomes of these ensemble results, instances are

classified as positive. This approach allows for harnessing the strengths of both classifiers, contributing to a more robust and flexible image classification system.

---

#### Algorithm-4: Ensemble Learning Using AND and OR

---

##### Inputs:

$D_{image}$  (Train Data attributed to Image Database)

$D_{query}$  (Test Data attributed to Query Database)

##### Outputs:

$\mathcal{R}_{OR}$  (results from the OR operation-based ensemble)

$\mathcal{R}_{AND}$  (results from the AND operation-based ensemble)

##### Start

1. Initialize Classifiers  
SVM classifiers:  $\mathcal{C}_{SVM}$   
Fuzzy logic classifier:  $\mathcal{C}_{FL}$
2. Classifier:  $\mathcal{C}_{SVM}$   
Extract feature  $\mathcal{F}_{SVM}$  including edge histogram, block division, and color layout  
Train  $\mathcal{C}_{SVM}$  using  $D_{image}$  and  $\mathcal{F}_{SVM}$
3. Classifier:  $\mathcal{C}_{FL}$   
Apply Fuzzy Logic-based edge detection on to obtain edge features  $\mathcal{F}_{Fuzzy}$   
Train Classifiers  $\mathcal{C}_{FL}$  using  $D_{image}$  and  $\mathcal{F}_{Fuzzy}$
4. Classify test instances  
For each instance  $x_i$  in  $D_{query}$ :  
Extract relevant features  $\mathcal{F}_i$  from instance  
Obtain SVM classification result:  
 $y_{SVM}(x_i) = \mathcal{C}_{SVM}(\mathcal{F}_i)$   
Perform Fuzzy Logic-based edge detection to extract edge features  $\mathcal{F}_{Fuzzy}^i$  from instance  
Obtain Fuzzy Logic classification result:  
 $y_{FL}(x_i) = \mathcal{C}_{FL}(\mathcal{F}_{Fuzzy}^i)$
5. Ensemble Classifications  
For each instance  $x_i$  in  $D_{query}$ :  
Compute AND ensemble:  
 $y_{AND}(x_i) = y_{SVM}(x_i) \wedge y_{FL}(x_i)$   
Compute OR ensemble:  
 $y_{OR}(x_i) = y_{SVM}(x_i) \vee y_{FL}(x_i)$
6. Return  
 $\mathcal{R}_{OR}$  consisting of all  $y_{OR}(x_i)$   
 $\mathcal{R}_{AND}$  consisting of all  $y_{AND}(x_i)$

##### End

---

## V. RESULT ANALYSIS

The proposed CBIR system was designed and developed using the Matlab and Python computing environments. The system was implemented on a Windows 10, core i7, system type 64-bit with 16GB RAM. The performance analysis of the proposed system is primarily carried out concerning retrieval accuracy and processing time with support of extensive discussion.

### A. Image Database Adopted

In this study a custom dataset comprising multi-modal images were created to evaluate the proposed CBIR system. The custom dataset was primarily based on the UNIFESP dataset, which contains 2,481 medical images. However, the study did not use all the images from this dataset. Instead, it used 1,500 images from UNIFESP and 858 images from other

sources. The experimental analysis was performed on a custom dataset of 1,920 images, which was divided into a training set (database) of 1,482 images and a test set (query database) of 438 images. The rationale behind this choice lies in the limited availability of comprehensive multi-modality datasets and as intended application of the proposed CBIR system is to facilitate analysis which should imitates real-world scenarios where users frequently search for diverse images. The database comprises a wide range of medical images, encompassing chest, hand, and ankle X-rays.

Fig. 2. Sample visualization of images in the database.

As shown in Fig. 2 above, the images are sourced from authoritative medical repositories and are characterized by their clinical relevance. Including medical images caters to the system's applicability in healthcare, enabling accurate retrieval of specific anatomical regions for diagnosis and reference.

### B. Visual Analysis of SVM Feature Descriptor

This section presents a visual analysis of the features descriptor obtained for the SVM-based CBIR system. The analysis provided for testing Ankle X-ray images from the query database.

Fig. 3. Visual analysis of feature descriptor for SVM.

Fig. 3(a) shows that the initial image chosen for analysis is an Ankle X-ray image from the dataset. In Fig. 3(b) here, the same input Ankle X-ray image is displayed to provide a precise

reference for subsequent feature analyses. In Fig. 3(c), the Color Layout Descriptor (CLD) coefficients is exhibited, illustrating the spatial distribution of colours in the input Ankle X-ray image.

Fig. 4. Edge histogram descriptor

Fig. 4 present the edge histogram descriptor, which encapsulates the distribution of local edges in the image. This descriptor contributes to the system's ability to differentiate various image regions based on edge patterns. This visual analysis succinctly showcases the various feature descriptors generated by the SVM-based CBIR system. These descriptors are instrumental in enabling the system to capture distinct characteristics of the input image, facilitating effective content-based retrieval. This section gives readers insight into the transformative impact of feature extraction on the CBIR process.

### C. Visual Analysis of Fuzzy Feature Descriptor

This section presents a visual analysis of the features descriptor obtained for a fuzzy-based CBIR system. The analysis provided for testing Ankle X-ray images from the query database.

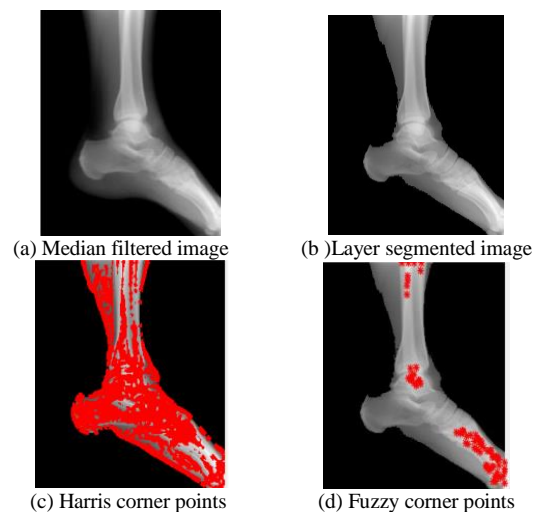

Fig. 5. Visual analysis of fuzzy feature descriptor.

In Fig. 5, a comprehensive visual analysis of the feature descriptors derived from the Fuzzy-based CBIR system, is

meticulously presented. Fig. 5(a) unveils the image after undergoing median filtering. This procedure smoothens the image, reducing noise while retaining essential structural information, rendering it an ideal input for subsequent analyses. Fig. 5(b) showcases the outcome of the layer segmentation process applied to the Ankle X-ray image. This segmentation facilitates the identification of distinct anatomical layers, facilitating precise feature extraction. The image depicted in Fig. 5(c) illustrates the Harris corner points, which are crucial for pinpointing distinctive features within the image. These points serve as significant landmarks in the feature extraction process. Fig. 5(d) brings forth the Fuzzy corner points, representing unique features identified within the image. These points contribute to the descriptor generation process, encapsulating salient attributes for retrieval. This visual analysis provides a profound understanding of the diverse feature descriptors synthesized by the Fuzzy-based CBIR system. These descriptors contribute to capturing intricate characteristics embedded within the input image. By navigating this section, readers better understand how feature extraction through Fuzzy Logic contributes to the CBIR process, enhancing the system's aptitude for content-based image retrieval.

#### D. Performance Analysis Concerning Retrieval Accuracy

The cornerstone of any CBIR system lies in its ability to retrieve relevant images based on user queries accurately. In the context of our proposed system, retrieval accuracy serves as a critical indicator of success. The assessment measures the proportion of retrieved images genuinely relevant to the query, thus quantifying the system's ability to discern and match image features. A high retrieval accuracy validates the efficacy of our approach in effectively capturing and exploiting distinctive features for content-based retrieval. The retrieval accuracy is calculated as a percentage, reflecting the proportion of correctly retrieved relevant images out of the total number of relevant images. This metric quantitatively assesses the CBIR system's ability to accurately identify and retrieve images that match the user's intent.

$$\text{Retrieval Accuracy} = \frac{\text{Number of Relevant Images Retrieved}}{\text{Total Number of Relevant Images}} \times 100$$

Fig. 6. Analysis of retrieval accuracy.

The results demonstrated in Fig. 6 clearly showcase the performance outcomes of each retrieval model, SVM, Fuzzy System, and Ensemble Learning. The SVM-based CBIR model demonstrates a retrieval accuracy of 93.44%. However, despite its high accuracy, SVM might encounter challenges in handling the intricacies of image data due to its linear nature. This limitation can lead to a slightly lower accuracy when compared to more adaptable models. The Fuzzy-based CBIR model exhibits an impressive retrieval accuracy of 95.35%. This higher accuracy can be attributed to the nature of Fuzzy Logic, which accommodates uncertainty and imprecision in image data. Fuzzy Logic is particularly well-suited for image segmentation and feature extraction, as it can handle varying degrees of membership. The Ensemble Learning-based CBIR model outshines the others with a remarkable retrieval accuracy of 98.36%. This higher accuracy can be attributed to the model's ability to harness the strengths of both SVM and Fuzzy Logic. The ensemble approach intelligently combines the decisions of these models using logical operations, striking a balance between precision and sensitivity. By doing so, it minimizes the weaknesses of individual models and leverages their combined potential. The SVM model provides a strong baseline, while the Fuzzy Logic model's adaptability enhances accuracy. The Ensemble Learning approach capitalizes on the synergies between SVM and Fuzzy Logic, leading to the highest accuracy due to its ability to adapt to different images and decision scenarios.

#### E. Performance Analysis Concerning Processing Time

While retrieval accuracy is paramount, it must be complemented by efficient processing time. The CBIR system's speed is integral, particularly in real-world scenarios where rapid responses are vital. The proposed system's processing time is evaluated as a measure of its computational efficiency. Lower processing times enhance user experience and render the system suitable for time-critical applications.

Fig. 7. Analysis of processing time.

The above Fig. 7 presents the performance analysis of the proposed system in terms of system response time for the different CBIR models, namely, SVM-CBIR, Fuzzy-CBIR, and Ensemble-CBIR. SVM-CBIR exhibits a longer processing time of 4.50 seconds on average. This can be due to the inherent complexity of the SVM's training process. Training of

SVMs involves iteratively optimizing the decision boundary that effectively separates the different classes. This process can lead to longer processing times in medical imaging scenarios, where datasets can be extensive and feature spaces complex. Fuzzy-CBIR, in contrast, exhibits a lower average processing time of 2.10 seconds. This efficiency is mapped to the nature of fuzzy logic operations, which handle membership degrees and linguistic variables. These operations enable quick calculations and quick decision-making. The processing efficiency of fuzzy-CBIR makes it particularly suitable for applications where quick retrieval with approximate similarity estimation is sufficient. The Ensemble-CBIR model balances accuracy and efficiency with an average processing time of 1.80 seconds. By combining the strengths of both SVMs and fuzzy logic classifiers through logical operations, the group adapts to the accuracy and sensitivity requirements. Although slightly higher than Fuzzy-CBIR due to Ensemble operation calculations, Ensemble-CBIR is more efficient than SVM-CBIR. This balance makes it an attractive solution for various medical image retrieval scenarios.

It is to be noted that the analysis of system processing time is also directly related to the time complexity analysis, which can be described as follows: The time complexity of the SVM-based CBIR model primarily revolves around two main phases: training and testing. The training phase involves extracting features from the training images and training the SVM model. If we denote the number of training images as 'n' and the number of features as m, the time complexity of feature extraction is typically  $O(n \times m)$ . The training of the SVM model will be  $O(n \times m^2)$ . Similar to the training phase, feature extractions and classification have a time complexity of  $O(m)$ . Several factors influence the time complexity of the Fuzzy Logic-based CBIR model. Edge detection and feature extraction involve processing each pixel of an image. If 'n' represents the number of pixels in an image, the time complexity for these steps is generally  $O(n)$ . Fuzzy Logic classification evaluates the fuzzy rules for each feature. The number of fuzzy rules and their complexity affect the time complexity, but it's typically  $O(1)$  for each feature. The time complexity for testing the Ensemble model depends on the testing time of both SVM and Fuzzy Logic classifiers and the time complexity of the ensemble operation (*OR* or *AND*). If we denote the time complexities of SVM and Fuzzy Logic testing as  $T_{svm}$  and  $T_{fuzzy}$ , respectively, and the time complexity of ensemble operation as  $T_{ensemble}$ , the overall time complexity can be approximated as  $O(T_{svm} + T_{fuzzy} + T_{ensemble})$ .

Hence, the time complexity analysis highlights that Fuzzy-CBIR generally has a lower time complexity due to its more effective feature extraction process. At the same time, SVM-CBIR and Ensemble-CBIR involve more complex feature extraction and classification steps.

## VI. CONCLUSION

This paper significantly contributes to content-based image retrieval (CBIR) systems. The authors explore a variety of methodologies, including support vector machines (SVMs), fuzzy logic, and ensemble learning, to develop an advanced CBIR system with potential applications beyond medical imaging. The proposed system's retrieval accuracy and

processing efficiency have been empirically validated, demonstrating its effectiveness in providing precise results promptly. The adaptable ensemble learning approach, which combines the strengths of established techniques, provides a balanced solution for diverse image retrieval scenarios. While this paper has made significant strides in the development of an effective and lightweight CBIR system, there remain several promising scopes for future research and improvement. In the future, the proposed work will be extended towards automated feature extraction process leveraging potential of the deep learning-based approaches to capture new and latent image characteristics, leading to even more precise retrieval results in dynamic and complex scenarios. In future, the study will evolve to incorporate multi-modal data combining medical images with textual patient records to offer a more comprehensive and context-aware CBIR system, especially in healthcare settings.

**Abstract**—Digital twin implementation enables more effective terms of evaluation and planning, and also effective utilization of resources with a flood of knowledge to improve the real-time services. The hospitality industry settings utilize digital twin technologies to introduce new ideas with sensor, actuators, AR/VR improve production, and improve customer services. Currently, the hospitality industry is focused to create a fast, virtual world space where customers can get a real world of hospitality. The technologically digital twin of a vast inn office can be implemented to create both discrete and continuous event recreations in order to precisely conceptualize the events that occur in distinct frameworks. Based on the above facts, the adoption of the digital twin in the hospitality industry has gained significant attention. With this motivation, the study aims to investigate the significance and application of the digital twins in the hospitality industry for establishing innovative and digital infrastructure. In addition to this, the study discusses different elements that are significant for the digital twin. Finally, the article summarizes and recommends vital recommendation in the adoption of digital twin in hospitality industry.

**Keywords**—Hospitality industry; digital twin; sensor and actuator; IoT; augment and virtual reality

## I. INTRODUCTION

The Sustainable Development Goals act as a road map for building a better and more sustainable future for all while also addressing urgent, serious global issues [1]. This article will examine some of the challenges that the hotel industry may encounter to assist it to contribute to the Sustainable Development Goals (SDGs) [2]. It will also provide some deeper, more thorough viewpoints on industrial sustainability. One of the primary hospitality-related SDGs of the 2030 Agenda of the United Nations is "sustainable tourism"[3]. Three SDGs specifically mention the hospitality industry: life below water (SDG 12), sustainable consumption and production (SDG 12), and sustainable economic growth (SDG 8) [4]. For many years, hospitality industry facing challenges in the consumer perception of the way to facilitate the services to improve the quality and reliability [5]. The hotel industry's assertiveness is influencing numerous substantial and small collaborators to leverage technologies to alleviate limitations [6]. The hospitality industry is undergoing a digital transformation that will result in a far more personalized,

customer-focused experience. Digital twin technologies are an indication of this development because they offer guests more flexibility over even the most modest components of their stays [7].

With the use of digital twins, restaurants, hotels and other hospitality businesses can get an advantage over rival businesses [8]. The majority of hotels employ connected devices nowadays to streamline customer requests and identify their unique characteristics in order to provide customized services. Examples of this include Marriot and other stakeholders' design of smart hotels and the use of concierge digital twins by various groups [9]. When used correctly, digital twin arrangements are capable of accurately recreating various resources, cycles, and frameworks in a virtual environment. This effectively makes the digital twin an option for huge accommodations were monitoring multiple cycles within a framework while executing innovative concepts is a frequent occurrence [10]. This diagram illustrates how the hospitality sector uses digital twins to portray digital pictures of all management.

This paper makes up a commitment to the top-of-the-line digital twins for putting together and coordinating operational frameworks for the hospitality industry. The primary goal of this study is to draw attention to the divergence between the theoretical and imaginary network of digital twins for assembly and storage and their practical application in considerations of theatrical illustration. The main contributions of the study are presented in the following:

- The most recent advancements in reenactment techniques that might establish the foundation for digital twins with advanced levels of information reconciliation, mechanization, and smart skills.
- This study uses a similar approach to analyze fictitious and specialized preparation for building highly devoted and powerful digital twins for the hospitality industry.
- Although digital twin technologies have shown significant advantages, their implementation still faces difficulties.

- In this paper, we are representing the future benefits of digital twins in this sector because new research opportunities have been made possible by the introduction of digital twin technology.

The study organized as follows: The background of the hospitality sector and digital twin covered in Section II, along with an overview of the technology in Section III, sensor and actuator presentations in Section IV, the Internet of Things in Section V, AR and VR in Section VI, and digital twin in the hospitality sector in Section VII.

#### A. Methodology

This section includes the methods used to complete the review on the digital twin in the hospitality industry. All the sections contain the analysis, data collection, criteria, and the searched strategy over the digitalization with digital twins. The concern of the review is to connect the digital twins and related technologies with the hospitality industry for future automation. The research question is: How digital twin technology can automate the hospitality industry? Based on this research question, we have collected research and review papers. The research paper was collected from various databases such as Scopus and web of science. The following parameters have been followed for the inclusion and exclusion of articles for analysis and they are: abstract of the paper but the full text of the study is not examined in the review. Algorithms and methodologies were used in the review but results are not used in this review. Research articles without peer review are not taken into consideration for review. There is no review of book chapters, patent applications, or communications for this review.

In this review, we are representing the statistics of the reviewed paper for different technologies. Fig. 1 represents the percentage of technology used in this literature survey: 48% digital twin's technology, 24 % & AR/VR, 14 % sensor & actuator, and 14 % IoT technology review for this review paper.

Fig. 1. Overview of the review paper of technologies.

## II. BACKGROUND OF THE HOSPITALITY INDUSTRY AND DIGITAL TWIN

Technologies used in the hospitality industry 4.0 present fresh possibilities for advancing sustainable growth [11]. Innovation has increased over the past few years in the hospitality business; self-registrations, contactless assistance, web-based seeking, and payment through applications have become the new norm [12]. While many businesses specifically target socioeconomics, the hospitality industry is more distinctive. Even inside the same place, Industry 4.0 offers diverse experiences to distinct groups [13]. Technologies used in the hospitality industry 4.0 present fresh possibilities for advancing sustainable growth. It can assist hospitality firms in streamlining operations; better marketing themselves, and meeting visitor needs [14] [15]. Organizations need to have fallback plans in place so they may be prepared for any challenges the world of innovation may throw at them [16]. If the innovation framework isn't set up at all or goes down, it can stop the entire presentation structure.

Customers give businesses online reviews via comments, ratings, and photos on internet platforms, which are growing in popularity daily. In order to improve its standing, the neighborhood company has been working hard to establish points of strength for interaction with customers [17]. Organizations can be destroyed or glorified by audits and comments; therefore, the business must take advantage of certain opportunities and manage its reputation. The hospitality industry is noted for having a high employee turnover rate, with about 33% of workers quitting after only six months on the job and about 45% remaining for an average of two years [18]. The industry is expected to continue to grow, which means that businesses must ensure that their representatives have strong personal qualities, professional skills, and knowledge in order to remain competitive [19]. Associations must be informed of the most recent trends for attracting and retaining employees because representative assumptions are constantly changing and evolving. This is becoming a constant challenge within the hospitality industry. Technology-based comparison is shown in Table I which shows the need for technology in the hospitality industry to improve the feature, quality, and services.

Online registration and looking voluntarily become more important to the business with visitors not coming to the front work area to receive a key due to new pleasant separation measures and a concentration on neatness [20]. As more people use their smartphones to request room management, computerized advancements made possible by mobile applications will become the norm for many businesses. The implementation of these innovations will require a significant initial investment but will ultimately result in efficiency and cheaper prices [21]. Rapid invention development has simultaneously created a variety of previously distinct arrangements that are now coming together.

TABLE I. OVERVIEW OF THE DIGITAL TWIN APPLICATION SCOPE AND FINDINGS

Ref.	Objective	Digital Twins (Sensor/Actuator/IoT)	Key Findings	Advantages	Future Scope
[7]	Hospitality Industry “Accommodation and services”	NA	Hospitality industry, Tourism, Services, Hospitality units, Tourists	Accommodation and service management are easy to improve for the customer	Technologies are required for customer satisfaction and service improvement
[8]	Identifying determinants of success in the development of new high-contact services: Insights from the hospitality industry	General Technologies such as mail and simple data collection methods are used only.	Service operations, Design and development, Hospitality services, Employee involvement	Services improvement, Market improvement, Process improvement and Hospitality improvement	Technologies are required to digitalize the hospitality industry for better customer satisfaction
[9]	Analyzing service quality in the hospitality industry	The general method used to make the hospitality industry reliable	Hospitality industry, Measurement, Service quality	Reliability, Responsiveness, Assurance, Empathy, Tangibles and Combined scale	Technologies are required to digitalize the hospitality industry for better customer satisfaction
[10]	Why do employees stay? a qualitative exploration of employee tenure	Quantitative and qualitative analysis of data without technology	Retention, Interviews, Turnover, Employee and Restaurant	Employee stability in hotels and restaurants, Hospitality Improvement	Technologies are required to digitalize the hospitality industry for a better customer Retention rate
[12]	Technology in Hospitality Industry	IoT, AR, Energy management, Beacon, and Automation	Interoperability, Data management, security, and Privacy	Modern Service platform for customer	Need to be overcome to institute a lasting, future proof solution for the hospitality industry.
[14]	The Digital Future of the Tourism & Hospitality Industry	AI, AR, VR and Blockchain	Customer Service, Customer Travelling, Technology used	Effectiveness, Improvement in Customer Services	Need to use the latest technologies to develop a sustainable and effective system for the hospitality industry
[40]	Research progress on virtual reality (VR) and augmented reality (AR) in tourism and hospitality	AI, AR	Augmented reality; Hospitality; Review; Technology; Tourism; Virtual reality	Virtually concept makes the easy to use for the customer in the hospitality industry	Need to use the latest technologies to develop a sustainable and effective system for the hospitality industry

This can create a challenging environment, especially for larger accommodation networks, which usually deal with a unique set of technological challenges [22]. However, integrating technologies and data across entire corporate ecosystems may be necessary to fully realize their potential [23]. Companies today use digital twin capabilities in several different ways. They are increasingly important mechanisms for modernizing entire manufacturing value chains and developing new goods in the hotel and aviation industries [24]. Operators in the hotel business collect and analyze massive amounts of in-hole data, which they then use to construct digital models that control drilling operations in real-time. With the use of digital twins, hotels, resorts, and other hospitality businesses can get an advantage over rival businesses, and then it is shown in Fig. 2. There are different elements, in which the digital twin can be beneficial in the hospitality industry such as interior direction; online concierge; personalized marketing; operation effectiveness.

Fig. 2. Overview of the Digital Twins in the hospitality industry.

#### A. Interior Direction

The immediate benefit of employing digital twin technology in the hospitality sector is probably indoor navigation. Virtual representations of resorts, which are typically accessed through a mobile app, allow visitors to navigate to different on-site amenities like the pool or bar with turn-by-turn directions. Visitors can visually visit a hotel room or even the entire resort thanks to indoor navigation. Even when booking a suite, guests can specify a certain view or location. These amenities are a great way for prospective customers to choose whether they want to stay at a specific hotel.

#### B. Online Concierge

The level of customization and virtual concierge service that digital twins can provide are challenging to match. With a digital twin, visitors can remotely control anything from lighting and temperature to choosing a room from digital floor plans, having a drink delivered just to their location within the resort, and even submitting maintenance issues.

#### C. Personalized Marketing

Both guests and management benefit from this technology's targeted marketing advantages. Based on consumer behavior, management might promote certain room or service improvements to customers, encouraging guest spending. In turn, offerings that are pertinent, timely, and customized make guests happier.

#### D. Operation Effectiveness

The operational advantages that digital twins offer significantly enhance the guest experience. In order to save expenses (by optimizing staffing, lighting, and temperature during specific hours), comprehend how facilities are actually used, and meet operational performance goals, management might leverage data from consumer behavior. Finding possibilities to boost revenue, raise customer satisfaction, and maximize employee efficiency all depend on this data. Digital twins are advantageous to property managers as well as visitors. Through way finding, 3D visual experiences, virtual concierge services, and other means, they provide visitors with tailored experiences. They also give management analytical insight into how to improve staff productivity, increase operational efficiency, and deliver individualized guest marketing.

### III. OVERVIEW OF DIGITAL TWIN TECHNOLOGY

A digital twin is a representation of a physical product, procedure, or service in the digital world. A digital twin is a digital representation of a real-world object, such as a jet engine, wind farm, or even larger objects like a building or even an entire city [25]. The digital twin technology can be used to duplicate processes in order to gather data and forecast their performance, in addition to physical assets [26]. In essence, a digital twin is computer software that simulates how a process or product would work using data from the real world. To improve the output, these systems can use artificial intelligence, software analytics, and the internet of things [27]. Additionally, before any physical deployment is started, digital twin environments establish an environment that is conducive to testing new business operations, regulations, and assets to determine their performance levels [28].

The simple state to understand the digital twin is shown in Fig. 3. A virtual model can help identify surrenders and predict when an item's life will expire. Digital Twins can speed up creation, shorten the time it takes to market new products, and help reduce support expenses [29]. IoT, sensor, and actuator technologies are employed to convert physical systems into virtual concepts for novel setups and phenomena. This facilitates forecasting, adjusting, and decision-making on the real-time monitoring of performance and ease of future work [30].

Digital twin starts the work with sensor, actuator and IoT together to collect the information and to create the information to further digital work environment. There are two components of the digital twin to the work first is hardware component and other is software component [31]. Hardware components consist of IoT, sensor and actuator that assist the information for the whole process in the digital twins. In the software component the research engine, which turns naive observations into crucial business knowledge, is a key component of digital twinning. It is frequently governed by AI models [32]. In digital twin there are digital threat may be creating the complication in the data collection from the physical components of the system shown in Fig. 4. You can connect actual structures and their virtual representations into a closed circle known as a computerized string if all the necessary components are nearby.

Fig. 3. Simple state and representation of digital twin concept.

Fig. 4. Digital threat in the software and hardware component of the digital twin.

Within the Digital threat, it involves some of the operations processes such as [33]: A physical object's environment at large is both sources of data that are transferred to the central repository. Data is produced for feeding to the digital threat after analysis. The digital twin uses new data to assess what would happen if the environment changes, discover bottlenecks, and mimic the object's operation in real-time. AI algorithms can be used at this stage to make product design adjustments, identify harmful tendencies, and avert expensive downtimes. The dashboard displays and visualizes analytics insights. Stakeholders make decisions based on actionable data. Accordingly, the physical object's parameters, procedures, or maintenance plans are modified [34].

Tandem Twinning Experts can evaluate the strength, adaptability, energy efficiency, and other characteristics of the various components that make up an item credit to the necessary degree of twinning [35]. To analyze how the part in question will behave under static or heated pressure and in other real-world circumstances, they can use reenactment programming.

Resource or item twinning the full item's replication reveals how various components work together under various conditions and how greater execution and dependability might be achieved. Instead of creating new models, advanced twinning can be used to develop new specialized arrangements [36]. This shortens the progression period and accounts for quicker emphasis.

Twining of the creation and cycle Advanced twinning applies to processes in addition to physical resources [37]. You create complete virtual models of the creation procedures for this scenario. This method helps to provide preferable answers to important questions like: How long will it take to produce a specific item? What will the price be? What should each machine accomplish? Which processes are automatable? Is there any way that a certain thing can be developed? Additionally, it is easier to avoid expensive free time when you can visualize the entire organizing process.

Device twinning Complex item and cycle interconnections and dependencies are made perceivable by a digital twin of the framework [38]. The twinned framework, which can be thought of as an arrangement of frames, can be practically as large as a multistory building, electrical lattice, or even an entire city. However, the risk involved in building such a reproduction typically does not equal the expected return. Because of this, framework twinning is typically not as flexible as other digital twin types.

#### IV. SENSOR AND ACTUATOR IN DIGITAL TWIN

Data from the physical system is collected by the digital twin and converted into digital data via the sensor and actuator [39]. The sensor and actuator are depicted in Fig. 5 and collaborate with IoT and digital twins. A sensor is a device that converts actual events or qualities into electrical signals [40]. This piece of technology converts the contribution that the weather makes and uses it to support the structure. As an illustration, a thermometer converts the temperature from a real sensor into electrical signals for the system. An actuator is a device that converts electrical signals into real-world events or characteristics.

Fig. 5. General representation of sensor and actuator.

Every sensor, including electromagnetic, capacitor, resistive, and others, has a different operating principle [41]. They often perceive the climate's contrasting quality and translate it into an electrical sign of corresponding size. A latent sensor doesn't require an additional power source to function, but a detached sensor does. A working piezoelectric sensor transforms strain into an electrical signal [42]. A potentiometer is an example of a detachable sensor since its resistance varies with location but needs additional power to convert it into an electrical signal.

#### V. IOT IN DIGITAL TWIN

Especially, the explosion in IoT sensors is crucial to the possibility of digital twins. Additionally, as IoT devices develop, advanced twin scenarios can involve less complex and modest products, providing additional benefits to businesses [43]. Digital twins can be used to predict different outcomes in light of varying knowledge. Computerized twins may usually enhance an IoT setup for maximum efficiency with additional programming and information analysis [44]. They can also help designers determine where things should go or how they should function before they are ever dispatched.

IoT is a technological revolution that represents the future of computing and communications, and its success is dependent on rapid technological advancement in a variety of sectors, from wireless sensors to nanotechnology [45]. It can essentially turn those items or appliances into 'smart' things that can transmit and receive data as well as communicate with one another. This can help with data collecting, automation, and allowing various devices to be managed or monitored from a single location, such as a phone or table. Its customization makes people feel special and since the primary aim of the hospitality industry revolves around providing the ultimate guest experience, this is what IoT should be embraced as shown in Fig. 6 [46]. While the concept of the IoT has been around for a long time, recent breakthroughs in a variety of technologies have made it a reality.

More liable technology: IoT innovation is turning out to be progressively open to additional producers on account of the accessibility of minimal expense, and high-dependability sensors.

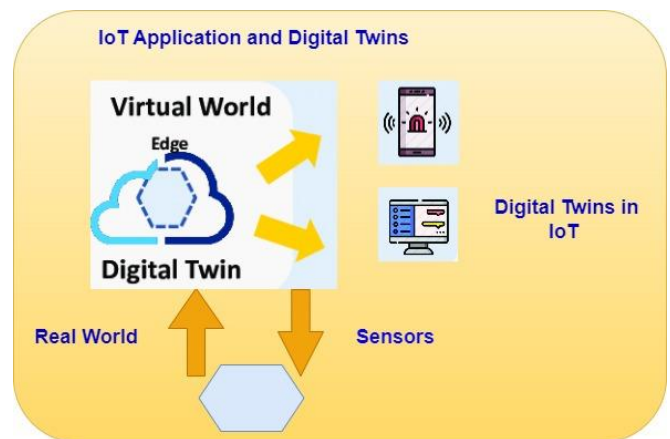

Fig. 6. General representation of IoT and its significance.

**Connectivity:** A variety of internet network protocols have made it simple to connect sensors to the cloud and other "things" for data transfer.

**Platform for Cloud computing:** As cloud platforms become more widely available, organizations and individuals can gain access to the infrastructure they need to scale up without having to manage it all.

**Analytics and Machine learning:** Organizations can obtain experiences quicker and all the more essentially on account of improvements in AI and examination, as well as admittance to different and huge volumes of information put away on the cloud. The development of these connected innovations keeps on pushing the outskirts of IoT, and IoT information takes care of these advances also.

**Conventional AI:** Natural language processing (NLP) has been brought to IoT gadgets (like computerized individual aides Alexa, Cortana, and Siri) because of advances in brain organizations, making them engaging, reasonable, and practical for home use.

## VI. AR AND VR IN DIGITAL TWIN

AR/VR has recently become a big idea in the hospitality industry since it allows hotels and other associated businesses to improve the actual environment they are offering or to enhance the experience of exploring the surrounding area [47]. AR is the perfect fusion of the real world and the electronic one to create a fake environment. Applications that use AR technology are developed for mobile devices or workspaces to integrate cutting-edge components into the current world [48]. A computer-produced reproduction of an alternate reality or environment is known as VR shown in Fig. 7. It is used in computer games and 3D movies [49].

AR shows the client relevant content by using computer vision, planning, and depth following. With the use of this functionality, cameras may collect, transmit, and interpret data to display cutting-edge material that is appropriate for the client being viewed [50] [51]. A VR headset screen must be placed in front of the client's eyes to remove any participation with our current reality in this way [52]. The built-in reality is vivid in augmented reality because you can also use visual, audible, and haptic excitement. AR and VR are used in hospitality management applications for various purposes [53].

Fig. 7. Virtual reality in hospitality industry.

## VII. DIGITAL TWIN IN HOSPITALITY INDUSTRY

A Digital twin is a representation of anything virtually [54]. This concept is evolving into an element of the dynamic process for increasing efficiency. In order to handle an item's nearly continuous state, operating condition, or position, digital twins use information from sensors that have been installed on the actual item [55]. This concept glorifies the replication processes of computer assisted design and computer assisted engineering. Any component of a physical object or process can be replicated using digital twins. The digital twin can reflect a new product's engineering drawings and measurements as well as all the subcomponents and associated lineage in the larger supply chain from the design table to the end user [56]. They might also appear in "as maintained" form, which would be a physical representation of the machinery on the factory floor.

The simulation depicts how the machinery works, engineers maintain it, or even how the consumer interacts with the products this machinery produces. Although digital twins can take many different forms, they all use and record data that simulates the real world. You can experiment with much iteration in the digital hotel sector to develop the scenarios that are most applicable to your company. New era industry 4.0 is the new revolution in hospitality industry to develop the simulation system on large scale to serve the society [57]. The hospitality industry has a wide range of uses for digital twins, which makes them a highly sought-after tool for investigating different market potential in this specialized area.

Real-time animation of the hospitality working process is also possible with the 3D plant model, which may be utilized to pinpoint the difficulties faced by this industry [58]. The primary factors that relate to the client for quality and service purposes are as illustrated in Fig. 8. Digital twin enables a virtual process to evaluate each step of the hospitality industry and provide an explanation of why a hotel and its services should be used [59]. The virtual facility gives a brief summary of all the features and amenities offered by the hotel as well as how the service provider addresses all the criteria in Fig. 7.. Over the coming years, it is anticipated that digital twin [60] applications will spread widely and no longer be restricted to activities or procedures exclusive [61] to the hotel business [62]. All types of hotel operations that want to stay competitive in their respective industries will use the technology. We can observe some instances of hospitality businesses that have already seized this chance. KFC Spain has joined MAPAL Data [63] Labs as the first business unit in the world to collaborate on a ground-breaking Digital Twin [64] project that uses cutting-edge digital [65] simulation to maximize labor and operational efficiencies [66]. It seems clear that digital twin technology will endure. The instrument has endless potential and offers numerous commercial advantages. Furthermore, although this technology [67] is currently viewed as a "nice-to-have," it will soon be necessary for companies that want to remain competitive and appealing to customers [68].

Fig. 8. Digital Twins for hospitality industry and simulation points.

### VIII. CONCLUSION

Digital twins play a crucial part in the technological advancement that has the potential to build a new foundation for the future. The merging of the physical and digital worlds makes it possible to make wise judgments at every stage of operations and hospitality, which can promote a data-driven smart hospitality environment. The use of the digital twin in the hospitality sector has drawn a lot of interest as a result of the facts mentioned above. In context of this purpose, the study's goal is to examine the value and potential applications of digital twins in the hospitality sector for the creation of cutting-edge digital infrastructure. The study also highlights many components that are important for the digital twin. The study concludes by summarizing and offering critical advice for the implementation of digital twins in the hospitality sector.

### IX. FUTURE WORK AND RECOMMENDATIONS

The research also examines technologies that benefit from and enable digital twinning. In-depth predictions are also included in the research for a variety of market areas and use cases, such as hotel service and simulations, production analytics, and others. A virtual object representation of a physical object that is mapped to actual objects in the real world, such as machinery, robots, or essentially any linked

business asset, is what is known as a "digital twin". IoT systems and software that are used to build a digital representation of the physical asset allow this mapping in the digital realm. A physical asset's digital twin can offer information about its status, including its physical state and disposition. The proposed digital architecture of the Hospitality Industry with digital twins is shown in Fig. 9.

On the other hand, tele-operation allows a digital object to be utilized to manipulate and control a real-world asset. This technology serves the hospitality industry in many ways such as:

- Future predictions from the digital twin solution: Planners can adjust for the following event iteration, improve operations, boost efficiency, and resolve any difficulties before they occur in a real-world setting by using digital twins, which frequently behave as a living, breathing model of the venue.
- Determine market obstacles and chances for digital twinning: By precisely recording their physical qualities, reproducing their actions, and altering their scale, a digital twin technology should be able to mimic both basic things and complex object relationships.
- Recognize the function of virtual twinning in product development, quality, and guest services: The ability to control quality and services is made possible by the vitality in digital twins, which will aid the hospitality business in the future. It makes the work faster to control and give the ability to handle the future challenges.
- Virtual simulations aid in understanding future plans and facilitate smooth decision-making with the least amount of money and effort: The hospitality industry can improve operational decision-making by utilizing the digital twin idea. Virtual reality has the functionality to help people make decisions more quickly in order to correct flaws.

Fig. 9. Proposed architecture of the digital twin and hospitality industry.

# Design of a Hypermodel using Transfer Learning to Detect DDoS Attacks in the Cloud Security

Marram Amitha, Dr.Muktevi Srivenkatesh

Department of Computer Science, GITAM Deemed to be University, Visakhapatnam, India

**Abstract**—The present research proposes a detective approach to analyzing the performance of various algorithms used for more accurate detection of Distributed Denial-of-Service (DDoS) attacks in cloud computing. From the start, this study uses machine learning and deep learning to explore whether information security has evolved in recent years. The deployment of intrusion detection systems and distributed denial-of-service attacks are then discussed. The most common DDoS attack types were summarized. In addition, this study reviewed the existing approaches and techniques for DDoS attack detection. Various pre-processing subsystems as well as attribute-based selection techniques for preventing the detection of DDoS were briefly described. The proposed Intrusion detection system uses transfer learning for detecting DDoS attacks in the Networks. The proposed system used for the data set for the Network Intrusion Detection System is SDN Dataset which has more features and is suitable to use to detect in Network Intrusions. It contains 23 features that are used to detect intrusions in the network SDN Dataset which consists of training and testing data to detect the attacks in the network. The detection and prevention subsystems through ML and DL strategies were briefly discussed. The proposed deep learning model for DDoS attack detection in cloud storage applications is explained. After that, various preprocessing strategies employed in the detection are described, among them rebalancing data, data cleaning, data splitting, and data normalization like min-max normalization. The author created a hypermodel that consists the parameters of baseline classifiers like Support Vector Machine, K-Nearest Neighbors Algorithm, XGboost, and other various machine learning models. The proposed model gives very good accuracy compared to other machine learning models.

**Keywords**—Machine learning; deep learning; support vector machine; k-nearest neighbors algorithm

## I. INTRODUCTION

Intrusion relates to every collection of connected operations performed by a malevolent adversary that affects a target system. Regarding the detection of DoS and DDoS attacks, intrusive activities are usually adaptable and can be categorized based on the attacks.

The primary threat from these four intrusion activities involves a DoS and DDoS attack that either consumes computer and communication facilities or takes advantage of the system's vulnerabilities to make the system accessible for authorized users. This leads to a significant loss of resources, money, and data. When numerous systems overwhelm the internet connection of a targeted system, which includes one or more web servers [1], a Distributed Denial-of-Service (DDoS) assault occur. Such an attack usually arises with traffic

overloading of the targeted system resulting from many compromised systems. Distributed Denial of Service attacks are different from different kinds of attacks in that can carry conduct a damaging attack on Internet-connected resources.

### A. Phases of DDoS Attack

Two phases are followed in DDoS attacks. The attacker seeks to gain access to the network's vulnerable machines first. With the compromised hosts of other networks, the attacker or master establishes his own network and describes them as slaves. The 'intrusion phase' occurs when that occurs. The attacker then selects which victim server to target and starts delivering packets in that direction. With DoS attacks, which start from a single host, DDoS attacks originate from a number of dynamic networks that were previously hacked. The 'DDoS attack phase' [2] corresponds to what this is recognized as.

Based on the way methods work, DoS and DDoS attacks can be roughly classified into three categories (Ali et al., 2019). These involve assaults based on connection utilization, bandwidth consumption, and vulnerability exploitation.

### B. Connection Consumption-based Attacks

A connection-oriented protocol is the Transmission Control Protocol (TCP). In advance of data exchange, it establishes a connection between the client and the server. A limited quantity of connection requests can be accepted and processed by any server. In an effort keep those with authorization considering accessing the service offered by the organization, the attacker establishes an enormous amount of connections with the server. The operating system's kernel [5] resources required for setting up connections have been drained by this type of attack. One of the most frequently used attacks under this category is the SYN Flood attack.

Fig. 1. Flood attack.

Fig. 1 shows the process of a SYN Flood attack, during which the attacker establishes an extensive amount of TCP connections with connections only partially accessible to deplete the connection pool. Due to how it operates, a cluster

of servers may be configured to function slower than normal through using slow network connections.

### C. Bandwidth Consumption-based Attacks

Every network has an established amount of accessible bandwidth. The network's bandwidth limit has been exceeded, which will impact up the response times of the servers and the various devices linked to it. Attacks based on computation-based DoS and DDoS are started by making use of this primary bandwidth. In order to generate a massive flood, the attacker uses established handler machines to control an enormous quantity of preconfigured zombie devices connected to the internet. User Datagram Protocol (UDP) flood is a prevalent attack in this type of attack. Fig. 2 shows the visualization of continuous features with respect to packet count protocol and type of attack.

This paper explains the procedure of transfer learning to train a model to get higher accuracy. In this research, authors used A.DDoS attack SDN Datasets from Mendeley website.

## II. RELATED WORK

Deep learning is gaining popularity these days because of its higher accuracy and performance. Its implementations in this field are being researched by a community of scholars. Automotive architecture, healthcare, manufacturing, and law enforcement are some of the well-known realms. The study that has already been completed by various scholars is mentioned below. Asad et al. [2020] [1] equate the effects of the machine learning methodology to those of others The Naive Bayes categorization methodology and the decision-tree categorization methodology are two examples of machine learning techniques. The researcher mostly attempted to act in a version that was not online. If the scale of the dataset grows larger, the output disparity becomes more pronounced. Deep Intelligence was introduced by Bhuvanewari Amma N.G et al [2023] [2]. The knowledge was derived using a radial base function with a variety of abstraction levels. The research was conducted on well-known datasets such as NSL-KDD and UNSW NB15 that included 27 functions. In comparison to other existing methods, the researcher believed that his method was more accurate. Muhammad Aamir et al. used a clustering technique to apply a feature selection process. Five related machine-learning methodologies were used to compare the algorithm. For preparation, SVM and RF methodologies were utilized. The best accuracy was attained by RF, which was about 96 percent.

Mishra et al. [3] classified packages depending on their characteristics. Through inspecting the IP header, the protection strategy attempts to identify IP addresses. These IP addresses are utilized to distinguish between spoofed and legitimate addresses. As the scale of the assault becomes larger, firewalls are ineffective. For separating the regular and assaulted traffic, Narasimha et al utilize anomaly identification and machine learning methodologies. Real-time datasets were utilized in the research. For classification, the well-known naive Bayes ML methodology was utilized. The outcomes were compared to those of other methodologies such as J48 and RF.

A. Haddaji et al [2023] [4] combined intellectual-stimulated computation and the entropy methodology in their research. For the classification, Support Vector Machine Learning was utilized. The platform's flow chart was being mined for information. In terms of identification precision, the outcomes were satisfactory. Omar E. Elejla et al. used an IPv6 classification strategy to incorporate a methodology for the identification of DDoS assaults. The findings were compared to 5 different well-known machine learning methodologies by the scientist. DT, SVM, NB, KNN, and NN were the methodologies utilized. The research was conducted on a well-known dataset. According to the source, the KNN methodology achieved a precision of about 85 percent.

Farhan ulla et al. [2023] [5] used the ML methodology to create an entropy-depend semi-supervised methodology. Unsupervised and supervised designs are used in this development. Unsupervised techniques have high precision and low false-positive rates. Supervised methods, contrarily, minimize the number of false positives. The datasets utilized in the research were NSL-KDD, UNB ISCX 12, and UNSW-NB15. For the recognition of the assault, Nathan Shone et al. use a DL methodology. It also utilized the NDAE function for unsupervised instruction. On the well-known KDD Cup 99 and NSL-KDD datasets, the proposed methodology was executed on a GPU utilizing TensorFlow. The researcher believed that he was able to get more precise identification outcomes.

## III. INTRUSION DETECTION SYSTEM MODEL

The Internet is a global network of computers connected through various media and a standard protocol. Among many additional essential elements in modern life, people nowadays depend on the World Wide Web for their education, trade, social ability, and recreational activities. Evidently, the Internet brought perhaps the greatest advances in communication and computing.

Attacks on the web may involve in many different possible dangers, such as financial loss, identity theft, loss of confidential data or information, theft of network resources, damage to a person's brand and reputation, and a decrease in consumer confidence in online banking and e-commerce.

Most security issues differentiate themselves from their earlier equivalents in non-network infrastructures since data and business logic are located on a remote Network server with transparent supervisors. One of these attacks, the Denial of Service (DDoS) attack, has been extremely aggressive and extremely intrusive to web servers. Denial of Service (DDoS) assaults frequently target the server a network of computers that provide consumers a service. DoS attackers seek to consume servers that are operational in an approach that leads the service stop functioning because of an excessive number of outstanding requests in the service queue.

DDoS attacks can be performed on government departments, educational institutions, and home systems that have been hacked. These computer programs are referred to as bots. Usually, DoS assaults begin at the network layer by sending many UDP, SYN, or ICMP packets of data. Attackers migrate to the application layer and flood it with HTTP GET requests, which is referred to as application-layer DDoS, after

network layer attack fails. According to Bhardwaj et al. (2020) [6], DDoS attacks can use TCP SYN, UDP flood, DNS reflection, HTTP flood, and ICMP flood. Based on information research on security, distributed denial-of-service (DDoS) attacks recently cost companies and governments all through the world a large amount of revenue. On the other side, the attackers use more advanced techniques to amplify attacks and overload their targets by taking benefit of their geographic distribution and computing power provided possibly by the wide variety of devices and their various movements, which are frequently incorporated within IoT network scenarios. Therefore, a practical and effective DDoS detection method must be developed and has been optimized, and functional in IoT-based smart environments with major constraints on processor power, reaction time, and data processing volume. Thus, conventional IDSs might out to be completely appropriate for applications in the Internet of Things. IoT security is a continuously significant issue that requires the creation of mitigation techniques and an increasing understanding of IoT safety concerns system (Catak FO et al., 2020) [7]. In order to guarantee that client data is stored in a safe fashion, security is another crucial component of network-based IoT data. Network security is crucial for both commercial and personal users. Everyone wants to remain certain regarding the integrity of their personal data. Businesses are legally required to protect customer information, and certain industries require more stringent regulations around data storage. Various difficulties with the value multi-tenancy, data loss and leaking, network accessibility, identity management, harmful APIs, inconsistent service levels, patch management, and internal threats are associated with the issue of network computing security. Some safety features that cannot be sufficiently scalable, incompatible, and appropriate are missing from conventional basic cryptographic algorithms. With these requirements in mind, an IDS mechanism with the indicated encryption approach has been established to defend the network from DDoS attacks.

#### A. DDoS Attack SDN Dataset

Machine learning and deep learning algorithms use this smaller net emulator-generated data set that has been modified with SDN, to categorize traffic. At the start of the project, ten smaller networks with switches connected to a single Ryu controller are established. Network simulation was utilized for imitating malicious traffic, such as TCP Syn assaults, UDP flood incidents, and ICMP assaults, as well as normal traffic including TCP, UDP, and ICMP. A total of 23 features in everything, some of which have been determined and some of which were obtained from the switches, in the data set. Among of the characteristics that have been obtained are Switch-id, Packet\_count, Byte\_Count, Duration\_sec, Duration\_nsec, which is Duration in Nanoseconds, Source IP, Destination IP, and Total Duration. The port symbol while rx\_bytes indicates the number of bytes received on the switch port, tx\_bytes indicates the number of bytes carried from the switch port. The dt field shows the time and date prior to the are transferred to values, and a flow is tracked every 30 seconds. Packet per flow examines the entire amount of packet in a single flow, while bytes per flow examines the total amount of bytes in a single flow. The data transfer and reception accelerates are tx\_kbps

and rx\_kbps, respectively, whereas port bandwidth is the product of tx\_kbps and rx\_kbps. The packet rate, which is determined as the number of packets sent per second, can be determined by dividing the number of packets provided per flow by the monitoring interval, Packetins message measure, and the total number of flow entries in the switch. The last column's category proof of identity, which decides whether the traffic type is malicious, is shown. Label 1 indicates malicious traffic, while Label 0 indicates benign traffic. The result of a 250-minute network simulation produced 1,04,345 rows of statistics. Repeating the simulation for a longer amount of time allows for the gathering of more data.

Fig. 2. Visualization of continuous features with respect to packet count, protocol, and type of attack.

#### IV. PROPOSED METHODOLOGY

A sophisticated model based on DLNN which employs optimized values in the hidden layers to differentiate among normal and attacked network data is developed for recognizing DDoS attacks.

### A. Deep Learning Neural Network

One of the most advanced artificial intelligence methods for tackling computer vision's 11 challenges is the Deep Convolutional Neural Network (Deep CNN). As a feed-forward artificial neural network, the Deep CNN established a class of deep learning and has been utilized for different agricultural image classification research. Deep CNN's convolutional layer, which is vital, employs filters to extract data from the input images. An enormous amount of training data must be collected for the purpose of enhancing the performance of Deep CNN. Fig. 3 shows the architecture of the Deep CNN technique.

One of the primary advantages of using Deep CNN for image classification is avoiding the requirement for feature development. Deep CNN's numerous levels each contain multiple convolutions. They provide many kinds of visuals for the training data in the quicker, more detailed layers, acquiring to more intricate ones in the deeper layers. The pooling layers, which initially serve as methods to extract features from the convolutional layers' performance as feature extractors, are then used to decrease the dimensionality of the training data. In the words of Chen J et al. (2019) [8], the convolutional layers transform an assortment of lower-level features into additional discriminative features. The vital elements of Deep CNN are the convolutional layers in addition. In contrast to traditional machine learning, feature engineering is an essential part of deep learning. The down-sampling process gets carried out along the spatial dimensions through the pooling layer. It promotes having fewer parameter choices. The pooling component of the proposed model uses the max-pooling process. In the proposed Deep CNN model, max pooling outperforms average pooling in processing performance. Dropout, which explains removing entities from the network, is another important layer. It follows the overfitting reducing regularization strategy. Using dropout values that ranged from 0.2 to 0.8, the proposed model was trained and compared. Applying the convolutional and pooling layers results, the dense layer follows up with the classification.

Deep CNN is a highly iterative process that requires developing an assortment of models while deciding on the most effective one (Morgan Kaufmann, et al. 2019) [9].

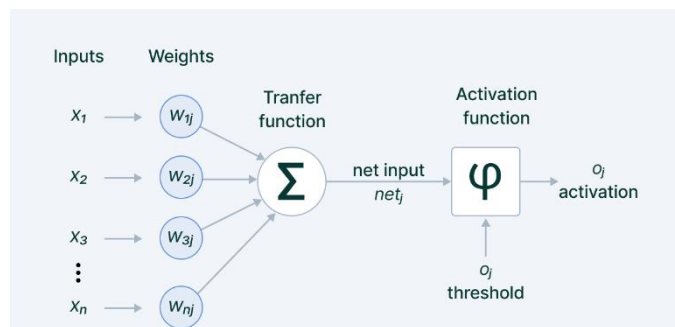

Fig. 3. The architecture of the deep CNN technique.

### B. Transfer Learning

An approach for transmitting knowledge from one machine learning model to another is referred to as transfer learning by collecting bias and weight values from present models, it

reduces the initial model construction phase of the new model. For instance, a machine learning model developed for task A could be used as a foundation for a model for task B. Current pre-trained models are used through transfer learning to gather knowledge that can be applied to new models.

In the research of Panigrahi R et al. (2018), AlexNet, Visual Geometry Group Network (VGGNet), Residual Network (ResNet), and Inception Network are among the most frequently utilized pre-trained deep learning models. A popular pre-trained deep convolutional neural network model is AlexNet.

The Alex Net comprises five convolutional layers with a ReLU activation function and three fully connected layers. The Alex Net contains 62,000,000 trainable variables.

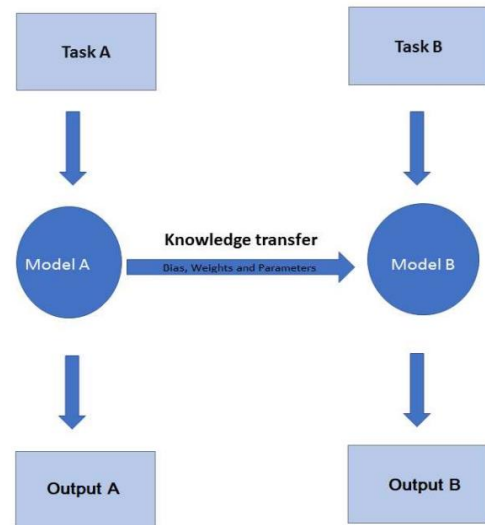

Fig. 4. Transfer learning techniques.

An example of an approach to transfer learning is shown in Fig. 4. In comparison with AlexNet, VGGNet increases performance while requiring less time to train. The convolutional and pooling layer kernels employed by VGGNet were lower than those utilized by AlexNet, indicating an important difference between the two networks. During the entire training phase, the kernel's size is fixed. VGG16 and VGG19 constitute two among the 14 distinct types of VGGNets. The number shows the number of network levels they are. There are 138 million trainable parameters in the VGG16. The ResNet addresses the vanishing gradient problem during the deep convolutional neural network training process. The ResNet makes use of a shortcut connection to improve network performance. In an entire network, there are only two pooling layers. ResNet18, ResNet50, and ResNet101 are the most common ResNet models. A total of eleven million trainable parameters in the ResNet18. In addition, the parallel kernel methods for handling flexible kernel values are presented for the inception net [10]. Google Net is the Inception Net's simplest iteration. In Google Net, there are 6.4 million trainable parameters.

DDoS volumetric attack constitutes the most harmful malicious internet traffic. This volumetric attack aims to

overwhelm the victim's computational capacity internet connections by having numerous attackers coordinate the transfer of a high rate of void data [11].

The proposed intrusion detection system for the detection of DDoS attacks and the Elliptic Curve Cryptography (ECC) - based secure encryption scheme. This method undergoes training and testing phases. In the training phase, the SDN dataset undergoes preprocessing where data nominalization, replacement of missing attributes and data normalization has been done. The proposed classification is carried out on the training phase to identify or classify the data to be normal or attacked data. Then the procedure is followed by preprocessing and classification as like in the training phase. Then if the classified data is normal, it can be further prevented from the attackers by encrypting the data using the ECC technique and stored in the network. If any need of encrypted real data in future will decrypt the data in the network and make use of it. Otherwise, the attacked (hacked) data is stored as a log file in the network for future attack detection. SDN-Data set which consists of forty-one features of is considered as normal and attacked type. Each feature is categorized into three types of attribute value types namely nominal, ordinal.

### C. Hyperparameter Optimization

It is necessary for machine learning model training to offer optimal performance. Hyperparameters are parameters that are set before training begins and control aspects of the training process that are not learned from the data. These parameters can significantly affect a model's performance, generalization, and convergence [12].

Here are the steps and techniques involved in hyperparameter optimization:

**Identify Hyperparameters:** Start by identifying the hyperparameters that need to be optimized. Depending on the type of model you are training, these could involve learning rate, batch size, number of layers, number of units in each layer, dropout rates, regularization strength, etc.

### D. Optimization Methods

**Grid Search:** For each hyperparameter, a grid of possible values needs to be specified, and all possible combinations should be thoroughly examined. It is easy to set up and can work well for a small parameter space, but it can be computationally expensive.

**Random Search:** Instead of trying all possible combinations, random search randomly selects parameter combinations to evaluate. It is more efficient than grid search for larger parameter spaces.

**Bayesian Optimization:** This is a more advanced approach that models the underlying function that maps hyperparameters to model performance. It uses this model to intelligently choose the next set of hyperparameters to evaluate, potentially reducing the number of evaluations needed.

**Gradient-Based Optimization:** Some libraries offer methods that use gradient-based optimization techniques to tune hyperparameters.

Fig. 5. Hyper parameter tuning process.

### E. Implement Hyperparameter Search

For grid search or random search, loop through different hyperparameter combinations, train the model on the training set and evaluate it on the validation set using the chosen evaluation metric. For Bayesian optimization, use a library like scikit-optimize, or Bayesian Optimization.

**Iterate and Tune:** Based on the results of the validation performance, adjust the range or values of the hyperparameters and repeat the optimization process. Fig. 5 shows the hyperparameter tuning process.

**Evaluate on Test Set:** Once you have found the best hyperparameters using the validation set, evaluate the model on a separate test set that was not used during the optimization process to get an unbiased estimate of the model's performance.

## V. EXPERIMENTAL RESULTS

After Steps to be followed

- Feature extraction.
- Data modification
- Classification
- Decision making

### A. Tools

We used i7 processor, a 256 SSD laptop TensorFlow, and Google Colab tools to train our model. We conduct perform manual attacks on DDoS and collect the data sets. We collect data sets of real-time attacks that have taken place previously from internet data sources.

### B. Preprocessing

For the purpose of minimizing noise in the data and improving the efficacy of the previously mentioned technique, preprocessing should be done on the data. Feature extraction and data transfer to numerical values are the two phases of data preparation.

### C. Feature Extraction

Feature extraction is the main step for data classification. In this project, three characteristics—packet length, delta time, and protocol—are considered in account.

D. Classification and Modification

With Data then, a numerical representation for these characteristics is created. The numerical values are fed to the ML models, with 30% utilized as training data and 70% for model testing. Each ML model is processed concurrently.

E. Decision Making

The voting majority among all algorithms determines the result.

Fig. 6 shows the training of the hyper model and Fig. 7, Fig. 8 shows the graph drawn between accuracy of the hyper model and epochs and loss vs. Epoch graphs.

```

Epoch 89/100

```

Fig. 6. Training of proposed model.

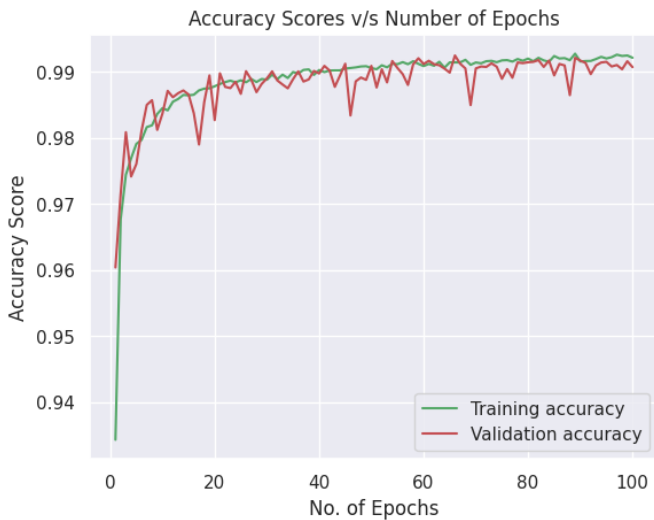

Fig. 7. Accuracy v/s Epochs in hyper model.

F. AUC and ROC

Evaluation of performance is an essential function in machine learning as shown in Fig. 9. So, we can depend on an AUC-ROC Curve when it comes to the classification their task. The AUC (Area Under the Curve) and ROC (Receiver Operating Characteristics) curves is employed to evaluate or show the performance of the multi-class classification trouble.

Fig. 8. Loss Vs Epochs.

It is one of the most essential criteria for assessing the efficiency of any classification model. AUROC (Area Under the Receiver Operating Characteristics) is a different method of expressing its contents.

Fig. 9. ROC curve of Hyper model.

The accuracy of the proposed algorithm is compared with other standard machine learning algorithms in Table I.

TABLE I. COMPARISON OF ACCURACY OF DIFFERENT MODEL

S.no	Model	Accuracy
1	XGBoost	98.179892
2	KNN	96.809194
3	Decision Tree	96.619800
4	Proposed Hypermodel	99.072289

## VI. CONCLUSION

Nearly all the work needs to be done manually while utilizing traditional methods, and the results are often inaccurate and difficult to identify risks. However, by employing a Machine Learning strategy, we can spot risks much more quickly than with traditional methods. Three neural network (ML) algorithms—Naive Bayesian, KNN, and Random Forest were employed in our proposal. The suggested hypermodel produced highly excellent precision and other output metrics like AUC and ROC by utilizing the hyper-tuning method in machine learning. We will be mounting it on all networks such routers, firewalls, and server since it has a limited resource consumption and can run on inexpensive components. The current system simply detects DDoS attacks, but in the future, we will improve it to a DDoS-avoiding model to improve server security. As technology advances, we will boost this model's efficiency.

**Abstract**—Globalization is certainly a blessing for us. Still, this term also brought such things that are constantly not only creating social insecurities but also diminishing our mental health, and one of them is Cyberbullying. Cyberbullying is not only a misuse of technology but also encourages social harassment among people. Research on Cyberbullying detection has gained increasing attention nowadays in many languages, including Bengali. However, the amount of work on the Bengali language compared to others is insignificant. Here we introduce a Hybrid ensemble method using a voting classifier in Bangla Cyberbullying detection and compare this with traditional Machine Learning and Deep Learning Classifiers. Before implementation, Exploratory Data Analysis was performed on the dataset to gather better insight. There are lots of papers that have already been published in other languages where it is seen that the hybrid approach provides better outcomes compared to traditional methods. Thus, we propose a highly well-driven method for Cyberbullying detection on the Bangla dataset using the hybrid ensemble method by voting classifier. The overall deployment consists of three Machine Learning classifiers, three Deep Learning classifiers, and a Hybrid approach using the voting classifier. Finally, the Hybrid ensemble method yields the best performance with an accuracy of 85%, compared with other Machine and Deep Learning methods.

**Keywords**—Bangla dataset; cyberbullying; exploratory data analysis; machine learning; deep learning; hybrid ensemble method

## I. INTRODUCTION

Globalization impacted Bangladesh immensely a long time ago, and we're moving forward with this new era and keeping ourselves up-to-date with technology, which is a blessing and positive news for us. But now the major concern is cyberbullying, which is also spreading drastically in the Bengali language. People got so aggressive while bullying others, and it is high time we should be concerned and do more research [1] on our language to prevent and detect those nonsocial texts. Research says, this type of behavior recurrently arose on YouTube, Facebook, and Twitter sites (Eric Rice, Cyberbullying perpetration and victimization among middle-school students., 2015). There are about 126.21 million internet consumers in Bangladesh [2], and the majority of active internet consumers are young. Also, Bengali is in the 6th rank as the most spoken language around the globe [3],

which accelerates the use of Bangla over social media. Which also increases the devastating amount of bullying on the internet. The expression "cyberbullying" can refer to a variety of behaviors, including hostile material, harassment, toxic commenting (such as gibe, triggered, sexual, or religious), and so on. And these sorts of aggressive behavior most lead to terrible mental health issues, such as self-harm anxiety, depression, social and emotional perplexity even suicidal thoughts or attempted suicide [4]. In Bangladesh, a survey stated, about 85 percent of youths believe that online bullying is an unadorned problem and 8 percent of youths have faced online bullying, at least one time a week or more since the pandemic [5].

Therefore, to mitigate such heinous acts of cyberbullying, many global preventive and intervention approaches have been introduced to improve the safety of internet users all around the world, and we should also be concerned about our Bangla language. Thus, we are approaching a new method to prevent this vile activity. Due to the numerous benefits the hybrid approach has over traditional machine learning algorithms, researchers are moving away from traditional machine learning techniques and toward them in the detection of cyberbullying. That's why, focusing on detecting bully on Bengali Language using a Hybrid Ensemble approach. The following are main highlights of this paper:

1) Introducing and proposing a hybrid ensemble approach that combines all the traditional approaches utilized in this study and uses a voting classifier to detect cyberbullying in the Bangla dataset.

2) The proposed method outperforms the currently used worldwide for classification and analysis, including Dense Architectural, LSTM, Bi-LSTM, KNN, Logistic Regression, and Decision Tree.

3) Performed exploratory data analysis (EDA) to get the appropriate insights and visuals for the desired cyberbullying model in the Bangla dataset.

4) Performed visualization and comparative analysis on the classification performance of three traditional machine learning and deep learning algorithms.

5) Evaluated various feature extraction methods to identify the optimal strategies for feature extraction and text

embedding for both conventional machine learning and neural network-based techniques.

Our whole work is divided into two parts:

- Performing Exploratory Data Analysis (EDA) to get insight from the dataset.
- And then introducing a hybrid ensemble method to detect cyberbullying in the Bangla dataset.

## II. RELATED WORKS

Cyberbullying is indeed like a parasite in our modern tech world. There are so many works and activities being practiced preventing this. Recently, the amount of work has been increased in the field of Cyberbullying detection in the Bangla dataset. But the progress is not comprehensive; we should enrich our research by doing more work to prevent this aggressive vulnerability on social media.

For English language, tons of work already been done in text categorization or Cyberbullying detection using text mining by classifying posts or conversations. Yin et al. text classification by using supervised learning [6]. In [7], they proposed unsupervised method for bully detection. Haidar et al. detect Cyberbullying by proposing a multilingual system in the Arabic language by using Machine Learning [8]. Dadvar et al. they proposed a Hybrid approach to detect Cyberbullying, where they show that the hybrid approach provides better performance than the expert systems [9]. Zhao et al. proposed an automatic Cyberbullying detection using bullying features on social media [10]. Mohammed Ali Al-garadi et al. proposed a model that provides a practical explanation for Cyberbullying detection in social media. This is an offensive language detection approach equipped with a lexical syntactic feature only [11]. Dalvi et al. they introduced a method to recognize and stop Cyberbullying on Twitter using machine learning [12]. Muneer et al. proposed an automatic bully detection system where they used more than 35,000 distinctive tweets as a dataset [13]. Herath et al. presented an automated bully detection system against immigrants, women, and cross-domain adaptability [14]. Robin M. Kowalski et al. came out social media bullying between Middle School Students, their results disclosed that about 84% of school students have experienced bullying in this study [15]. In a previous study conducted by Prathyusha et al. [16], a novel approach was proposed that integrates the Multiple Correlation Coefficient and the Support Vector Machine. In Bengali language, some noteworthy works been seen for Cyberbullying detection. Mahmud et al. [17] Utilizing the Bangla dataset, we were able to come up with a visualization method work on the Bangla corpus is specifically used for sentiment analysis [18]. In [19], Shahin Akhter et al. performed Cross-validation using ML classification models with 2400 data labeled as bullied and non-bullied and achieves superior performance on Bangla text with a detection accuracy of 97%. This study shows a very insignificant amount of data, that's why it's over fitted. In [20], Ahmed et al. used 44,001 users' comments from popular public Facebook pages and came out with a binary classification model of 87.91% accuracy. They proposed binary classification model which isn't well suited for text classification. In [21], Chakraborty et al. used several ML and

DL approach to analyze Bangla texts. In [22], Ahammed et al. proposed a Machine Learning approach with an accuracy of 72%. Again in [23] [24], Ahmed et al. used Bangla, Romanized Bangla and Meme Detection [25] text for Cyberbullying detection using traditional ML, and DL Classifiers.

In terms of bullying detection, the above approaches are all good, but they got a few lacking like, using insignificant amount of dataset, implementing traditional approach for bully detection, and the approach that doesn't help to classify text accordingly. Hence, we're introducing a new approach for Cyberbullying detection on the Bangla dataset: Hybrid Ensemble Method using the voting classifier. The detailed methodology is discussed in Section III. Section IV presents the Results analysis and the conclusion is given in Section V.

## III. RESEARCH METHODOLOGY

This research mainly focuses on introducing a new approach for Cyberbullying detection in the Bangla dataset.

### A. Dataset

There is total number of 10,512 data on our dataset and the dataset consists of three columns - comments, class, and gender. The class column categorized into- Gibe, Triggered, Sexual, Religious, and not bully. And the Class and Gender section is specifically used to perform Exploratory Data Analysis to get insight from the Bangla dataset. Fig. 1, a complete portrait of how the bully is differing from gender to gender.

Gender	Class				
	Gibe	Not bully	Religious	Sexual	Triggered
Female	1,321	1,101	286	251	873
Male	1,824	3,174	439	242	1,021

Fig. 1. Different types of bullies among gender.

### B. Model Procedure

In the proposed work, introducing Hybrid Ensemble approach for bully detection in the Bangla dataset. The overall reasearch is divided into four parts or sections:

- Exploratory Data Analysis to get proper insight from the dataset,
- Machine Learning deployment,
- Deep Learning deployment, and
- Hybrid Ensemble approach deployment.

To get an accurate and precise model, one need to know the dataset precisely that's why exploratory data analysis is must to do part before any model implementation. In our work, we use the table for our data visualization and find out proper insight through this visualization. The Bangla comments are collected from social media platform. Since

dataset is in raw format, contain noisy elements, unwanted data, null value which could degrade our model evaluation. So, lots of data preprocessing method been applied to sort out the dataset and remove those unwanted part from the Bangla dataset. A classifier is a function that uses an example's values as predictor variables or independent variables to determine the class to which the example belongs (the dependent variable). A computational software called machine learning is able to learn without being told where to look. In our work, Machine Learning Classifier perform one part which helps to understand further classification. New and robust deep learning (DL) algorithms have been developed as a result of advancements in computing technology, and they have shown promising outcomes in a variety of applications. Further implemented a few Deep Learning model in order to get overview from the dataset.

Finally introduced a Hybrid Ensemble method and compare between these three methods, to find out best performance. Illustrating overall workflow in below Fig. 2. Based on split data, the program then trains each classifier to develop a method of classifying. Three columns from dataset is taken for further analysis. They are- comments, Gender, and class. The class column divided comments into five categories:

Comments can be in different formats, like:

- Not bully,
- Triggered,
- Gibe,
- Sexual,
- Religious, etc.

Fig. 2. Diagram of the proposed workflow for the research.

So, Not Bully are the type of comments which are in general comments on a post or write as well wishing. Then others four types of comments are basic criteria of bully comment or language. For better clarification triggered comments are like make some pointing negatively publicly, gibe means spreading some rumors about other user, sexual mean abuse someone or eve teasing female through social media and the religious bullies are like contradicting with religious and conflict with each other and so on.

For further implementation and evaluation, we used three ML classifiers and three DL classifiers and Hybrid Ensemble approach using voting classifier. The accuracy, precision, recall, f1 score, validation loss, and accuracy of each of the classifiers used in these models have been evaluated in order to choose the optimal model for implementing the Cyberbullying detection on the Bangla dataset. The model procedure is detailed below.

1) *Exploratory data analysis:* The Exploratory Data Analysis (EDA) is performed on Tableau and came out with some important points and insights from our dataset. Dashboard of the overall Exploratory Data Analysis is shown in Fig. 3. Which is a collection or assembly of multiple worksheets. Worksheet are made by importing Class and Gender columns in Tableau.

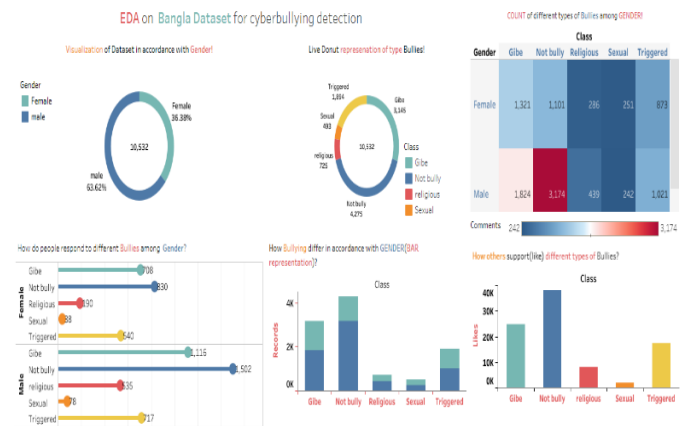

Fig. 3. Exploratory data analysis (EDA) on the Bangla dataset, and dashboard using tableau.

2) *Data analyzing and preprocessing:* For analysis, first dropped all the unwanted columns from the dataset. Before implementation, data analysis is mandatory for getting a clean and accurate model. The BNL corpus is used to remove Bangla stop-words, letters, and digits from the Bangla comments. The dataset was also cleaned of any duplicate information, links, or URLs, as well as numerals, punctuation marks, and emojis. The next step is to clean, instance selection, remove noisy data, unwanted value, feature extraction, and selection are among the steps that are involved.

3) *Feature extraction:* Machine Learning and Hybrid Ensemble approach feature extraction, we used Term Frequency & Inverse Document. It is stated that, in Machine Learning strings is converted into number by using TF-IDF and then provide a numerical format for the Machine Learning models. Using the text vectorizer term frequency-inverse document frequency, text is transformed into a vector format. The concepts of Term Frequency (TF) and Document Frequency are integrated (IDF).

4) *Split processed dataset:* The dataset was divided into training and testing data using the sklearn model selection module for subsequent implementation. A total number of 10,512 data is in the dataset and split them for further training and testing using several approaches.

### C. Machine Learning Classifiers

Here three Machine Learning classification models been used for the bully detection purpose and they are: Logistic Regression (LR), K-Nearest Neighbor (KNN), and Decision Tree (DT).

1) *Logistic regression (LR)*: Logistic Regression (LR) been widely used for classification algorithm (two-class classification). Logistic Regression estimates the probability of an event occurring by using the sigmoid function which maps any real value into another value between probability 0 and 1. The sigmoid function is written in Eq. (1).

$$\text{Logit}(x) = 1/(1 + \exp(-x)) \quad (1)$$

2) *K-Nearest neighbor (KNN)*: The k-nearest neighbors' algorithm (KNN) is a supervised learning and a non-parametric classifier, which uses propinquity where they group distinct data point to make prediction. Although it can be applied to classification or regression problems, it is commonly employed as a classification algorithm because it assumes that comparable points are located close to one another.

3) *Decision tree (DT)*: Decision Tree is also a supervised learning classifier. When it comes to classification issues, decision tree is often used. In DT, internal nodes outline dataset appearances, branches signify decision rules, and each leaf node denotes the result.

### D. Deep Learning Classifiers

For our research purpose, we used three Deep Learning approaches, like- Dense architecture model, LSTM, and Bi-LSTM.

1) *Dense architecture model*: The proposed approaches run 30 epochs to find out the upmost accurate performance for Dense Architectural model. It can be observed that, by the time each cycle or epoch running the performance of the model also enhances, which means decreasing validation loss of model and increasing validation accuracy of the model. The model summary provides the layer, shape, and number of parameters used in each layer. Fig. 4 below demonstrating, overall Dense Architectural Model summary, which includes that the model is running sequentially, the embedding layer got total 8000 parameters, dense layer got 408 parameters, there is no dropout in the dense layer. It also indicates that the total parameters are 8433 and all of them are trainable.

2) *Long short-term memory (LSTM)*: Long short-term memory (LSTM) is a type of recurrent neural network that was created specifically to stop the neural network output for a particular input from expanding up as it rotates with the feedback loops. Recurrent networks were able to outperform other neural networks at pattern identification thanks to these feedback loops. Another popular advanced recurrent neural network (RNN) structure that was created with long-range dependencies and temporal sequences in mind is known as Long Short-Term Memory. Fig. 5, Number of epochs and validation accuracy and loss scores in our LSTM model.

Model: "sequential"

Layer (type)	Output Shape	Param #
embedding (Embedding)	(None, 50, 16)	8000
global_average_pooling1d (G1)	(None, 16)	0
dense (Dense)	(None, 24)	408
dropout (Dropout)	(None, 24)	0
dense_1 (Dense)	(None, 1)	25
Total params: 8,433		
Trainable params: 8,433		
Non-trainable params: 0

3) *Bi-LSTM*: Bidirectional recurrent neural networks are the combination of two independent RNNs together for further implementation. With the help of this Bi-LSTM structure, the networks can vividly have both forward and backward information at every stage of the process. Using a bidirectional will run inputs in two ways: one from the past to future and another one from the future to past and where LSTM that only runs backward (unidirectional). Fig. 6 illustrates the number of epochs and validation accuracy and loss scores in our Bi-LSTM model.

### E. Hybrid Ensemble Method

Hybrid Ensemble Method is one of the popular methods used nowadays for better predicted outcome. It's also called the heterogeneous assembly of weak learners. Lots of Machine Learning classifiers are combined in this task to come up with a classification problem. Ensemble learning techniques got a long record and history of showing handsome performance comparing with any other traditional

ML approaches. The domains of these applications include classification and regression problems. Fig. 7 shows how the hybrid ensemble method works in a simple way.

Fig. 7. Basic working procedure of hybrid ensemble method.

#### IV. RESULT ANALYSIS

##### A. ML Models Result Analysis

The performance of the Machine Learning models was further examined through the utilisation of Receiver Operating Characteristic (ROC) curves and the Area Under the ROC Curve (AUROC). In Fig. 8, the receiver operating characteristic (ROC) curve and the area under the ROC curve (AUROC) are depicted for our machine learning classifiers. It is observed that the logistic regression (LR) model achieved the highest AUROC score of 88%. It has been noticed that Logistic Regression achieved the greatest AUROC score. It's stated that, highest AUROC means better classifier. Summary of ROC curve with AUROC score: Logistic Regression AUROC score is 0.88, K-Nearest Neighbor AUROC score is 0.832, and Decision Tree score is 0.551. According to the measurements of AUROC, Logistic Regression is the best classifier amongst the three ML classifiers.

Fig. 8. Receiver operating characteristic, and area under-ROC curve and scores of ML classifiers.

##### B. DL Models Result Analysis

For Deep Learning models, the visualization shown below is the result in validation loss and accuracy curve for comparison. Both Validation loss and Validation accuracy of Dense Architectural Model are illustrating in Fig. 9. For Dense Architectural Model with increasing number of epochs validation loss also decreasing and in mean-time validation accuracy increased. For the Dense Architectural Models Training and Validation evaluation, where employed a total number of 12 epochs. In below graph, validation accuracy versus the number of epochs provides a visual. Where blue line represents as Training accuracy score and yellow line representing Validation Accuracy score. This is time series analysis of visualizing how accuracy scores of Dense Architecture model increasing with number of epochs. Highest accuracy for both training and validation is highlighting in epoch number 12, where Training accuracy score around 0.775 and Validation accuracy score is around 0.770.

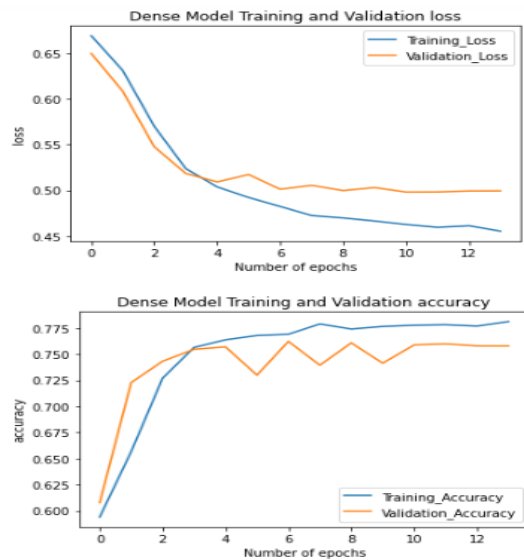

Fig. 9. Time series representation Dense Architectural model (Validation loss and accuracy scores with respect to number of epochs).

LSTM model Validation loss and accuracy in below Fig. 10 Validation accuracy as a function of the total number of epochs. Where blue line represents as Training accuracy score and yellow line represents Validation Accuracy score. This is a time series analysis of visualizing how accuracy scores of LSTMs (Long Short-Term Memory) model increasing with number of epochs. Highest accuracy for both training and validation is highlighted in epoch number 5, where Training accuracy score around 0.78 and Validation accuracy score is around 0.76 in the 4th epoch.

Bi-LSTM model Validation loss and accuracy in the Fig. 11. Where blue line represents as Training accuracy score and yellow line represents Validation Accuracy score. This is a time series analysis of visualizing how accuracy scores of Bi-LSTM (Bidirectional) model increase with number of epochs. Highest accuracy for both training and testing is highlighted in epoch number 7, where Training accuracy score around 0.78 and Validation accuracy score is around 0.7 at the 7th epoch.

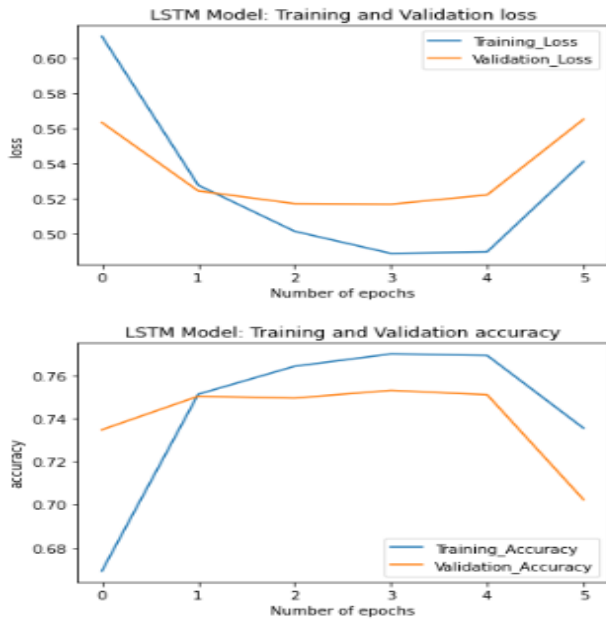

Fig. 10. Time series chart of LSTM model (Validation loss and accuracy scores with respect to number of epochs).

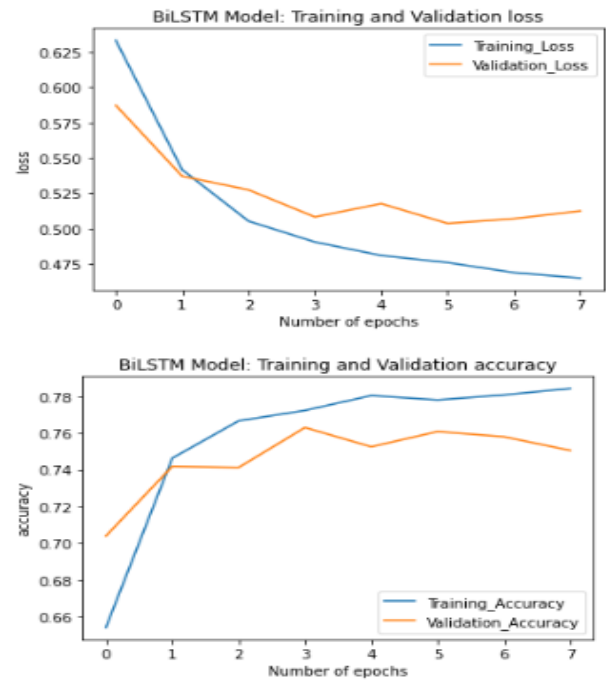

Fig. 11. Time series representation Bi-LSTM model (Validation loss and accuracy scores with respect to number of epochs).

C. Hybrid Ensemble Models Result Analysis

Now finally comparing and analyzing the proposed Hybrid ensemble model with ML and DL Models result. In Fig. 12, a bar chart representation to compare performance measurement scores of Machine learning classifiers and the proposed Hybrid Ensemble model is shown. Where it reflects that Hybrid Ensemble model performs better than Machine Learning classifier.

Fig. 12. Comparing our proposed hybrid ensemble approach with machine learning models.

Fig. 13. Time series chart of deep learning models.

Fig. 13 illustrates a short time series chart comparing Deep Learning models with our approached Hybrid Ensemble method. Where blue line representing accuracy scores and yellow line representing loss performance scores of the deep learning models.

V. CONCLUSION

The primary objective of this study is to priorities efforts towards the identification of Cyberbullying using the Bangla dataset, while also emphasizing the importance of raising awareness using visualization techniques. This research presents a novel methodology for identifying instances of bullying in the Bengali language. The Hybrid Ensemble approach was presented, which use a voting classifier and achieves an accuracy rate of 85%. In addition, conventional machine learning classifiers and deep learning classifiers were utilized for comparison with the proposed methodology. Ultimately, after doing a comparative analysis of the three ways, it has been determined that the Hybrid Ensemble approach exhibits superior performance. The primary objective and approach of this study are to foster increased participation among researchers in their respective native languages and mitigate societal obstacles such as Cyberbullying. In subsequent investigations, there is potential for the expansion of research through the utilization of Unsupervised or Reinforcement Learning methodologies. This

approach might be employed to further boost the efficacy of the bully detection model by using a Bangla dataset.

**Abstract**—The monkeypox virus, a species of the Orthopoxvirus genus within the family Poxviridae, is answerable for inflicting monkeypox. The symptoms of monkeypox last for about two to three weeks, which is often a self-limiting infection. There may be extreme cases. Recently, the case fatality rate has been in the region of 3-6. When developing a clinical medical diagnosis, it is vital to incorporate different rash diseases such as pox, measles, bacterial skin infections, scabies, syphilis, and medically connected allergies. Pathology at the symptom stage of the sickness could aid in distinctive monkeypox from chickenpox or smallpox. The dataset's machine learning model should not be used for clinical diagnosis, but rather for developing a new model to identify illness fast. The gray scale versions of the original photos in the Monkeypox grey file could make it easier to figure out training more quickly. The channel-wise feature responses that are adaptively re-calibrated are handled by the "Squeeze-and-Excitation" (SE) block. To do this, cross-channel dependency must be explicitly modeled. To demonstrate how these architectures are put together and how these building pieces may be layered to produce SE-Resnet designs in monkeypox image sets that generalize very well. Also, demonstrate that employing SE blocks significantly enhances the performance of current state-of-the-art CNNs while incurring just a little computational cost.

**Keywords**—Squeeze-and-Excitation (SE); monkeypox; poxviridae; prodromal; chickenpox; prodromal

## I. INTRODUCTION

As a result of the outbreak of COVID-19 in 2020, the whole globe was put in jeopardy; however, the emergence of monkeypox in 2022, which was reported by a number of countries, reveals the existence of yet another global danger. The Zoonotic Orthopoxvirus is responsible for the infectious illness known as monkeypox. The virus that causes monkeypox may be a member of the Poxviridae family (a member of the genus Orthopoxvirus) and is closely associated with each chickenpox and smallpox. However, transfer from person to person is also highly prevalent [1]. Rats and monkeys are the major disease transmission vectors. The virus was first found in an exceedingly monkey's body by researchers in a facility in Copenhagen, Denmark, in 1958 [17]. In 1970, amid a significantly additional aggressive plan to eliminate smallpox, the Democratic Republic of the Congo reported the primary human case of monkeypox [19]. This happened all during the campaign. Many people who live in close proximity to tropical rainforests are susceptible to contracting monkeypox, which is often spread across the central and western regions of Africa. By having direct touch with an infected animal, person, or object, a person can catch the virus. Direct body-to-body contact, animal bites, respiration

droplets, or mucus from the eyes, nose, or mouth are all approaches that it would spread [18].

Fever, body pains, and exhaustion are some of the early-stage symptoms that people who have been infected with monkeypox may experience. The long-term impact of monkeypox is a red bump that appears on the skin [5]. In 1996, several villages in Zaire's Kasai Oriental region reported receiving instances of monkeypox, according to the Katako-Kombe Health Zone. These communities existed inside its boundaries. For instance, the Democratic Republic of the Congo. In conjunction with the Centers for Disease Control and Prevention (CDC), the World Health Organization (WHO) appeared into this incidence. They extracted MPV from the lesions of active patients after identifying 92 likely instances that first appeared between February 1996 and February 1997. Between February 1996 and February 1997, all of the cases got started. In response to the continued reporting of instances, the World Health Organization and the Centers for Disease Control and Prevention (CDC) started a fresh inquiry in October 1997. The field investigation's findings, which are summarized in this article, show that the current monkeypox outbreak is the most serious one ever recorded in humans [2]. Phylogenetic analysis imply that the virus has been circulating outside of locations where it has been prevalent for some time without being recognized, perhaps disguising itself as other sexually transmitted illnesses (STIs) [20]. Individuals with a polymerase chain reaction-verified illness who were identified in sixteen different countries across five continents during the months of late April and late June 2022 were evaluated for probable exposures, demographic features, clinical findings, and outcomes. Although it was not possible to prove it, sexual transmission was thought to have occurred in 95% of patients but could not be proven. The data from 23 people were used to find that seven days was the median length of time spent in the incubation phase. In all, 13% of the people who contracted the illness were admitted to the hospital, most often for pain treatment. There were no recorded fatalities [4]. There is evidence that monkeypox can be passed from humans to their dogs based on the timing of the start of symptoms in both the human patient and their dog after the human patient became infected. The dog had sores on its skin and mucosa, and a test for monkeypox virus was positive.

PCR records from anal and mouth swabs exhibit that the sickness is existing in puppies and that it is now not simply transferred there via close contact with humans or by means of airborne transmission (or both). The results of this study should spark discussion regarding whether it is necessary to keep people with the monkeypox virus segregated from their

pets [22]. There is a possibility that the monkeypox virus belongs to not one but two distinct families. The West African clade affords a greater wonderful outlook with a case fatality price of much less than 1%. The most hazardous of the groups on the different aspect is the Central Basin clade, additionally referred to as the Central African clade. A case fatality rate of up to 11% may also observe to kids who have no longer acquired their vaccines. A full recovery for the remaining individuals often occurs four weeks following the commencement of their symptoms, with the possible exception of scarring and skin discoloration [21].

Patients often complete their recuperation within this time range. There is presently no treatment that is known to be effective against an infection caused by monkeypox. Treatment for viral infections consists on relieving the patient's symptoms as well as possible. Nevertheless, there are preventative measures that may be performed in order to avert an epidemic. The contaminated person must continue to be isolated, put on a surgical mask, and maintain lesions blanketed as lots as is virtually viable till all crusts on lesions have naturally fallen off and a sparkling pores and skin layer has grown. During this time, the infected person should also keep lesions covered. Research may additionally be achieved to decide the viability of the usage of components that have already been demonstrated to be really helpful in opposition to Orthopoxvirus in animal trials and extreme vaccinia vaccine sequelae in extra intense conditions. It is not known if the intravenous vaccinia immune globulin, the intracellular viral release inhibitor tecovirimat, or the oral DNA polymerase inhibitor brincidofovir will be effective against the monkeypox virus [14].

## II. RELATED WORK

Monkeypox provides challenges to public health officers and healthcare authorities in the areas of surveillance, laboratory capability, disease management, and treatment. Monkeypox cannot be recognised, diagnosed, treated, or prevented from spreading in many countries because to a lack of knowledge and experience in these fields. Disease monitoring systems demand initial and long-term financial and human resources. Mandatory illness reporting has enhanced Disease Surveillance and Response system reporting. Alerts are routine, but diagnostic samples and preventative techniques like contact tracing and patient seclusion are not. Human and animal health sectors must coordinate efforts and share information because monkeypox is a zoonotic disease [3]. Image analysis will be used as a method for training and developing machine learning models to classify the monkeypox illness. In addition to this, a modified VGG16 model is constructed, and it is tested for its capacity to identify between individuals who have monkeypox illness and those who do not. The fact that it was such a huge network in terms of the amount of parameters that needed to be trained was the most significant drawback [13]. In 2003, the Midwest saw an outbreak of monkeypox. Rats that were infected with the disease were acquired from a business that sold exotic pets and residential homes. After being killed, the rats had been taken to the United States Army Medical Research Institute of Infectious Diseases for investigation. Real-time polymerase chain reaction (PCR), enzyme-linked

immunosorbent assays (ELISA), and viral way of life had been used to analyse and prepare rodent tissue samples. For the purpose of identifying monkeypox viral DNA, we created and examined two distinct real-time PCR procedures. These methods used the F3L and N3R genes of the Vaccinia virus as their respective targets. The DNA of the orthopox virus and other bacteria were used to verify the assays. The presence of orthopoxvirus in rodents was shown by electrochemiluminescence (ECL) using panorthopox. Both the specific PCR test and the pan-orthopox test revealed that seven out of 12 (58%) of the animals had monkeypox (in at least one tissue). The outcomes of the PCR and the ECL were different. Both the PCR and the ECL tests came out positive in one hamster and three gerbils. Our team also used immune histology, electron microscopy, and culture on a variety of different cell lines to verify the monkeypox virus's existence. The samples' PCR findings revealed that the Zaire-96-I-16 monkeypox virus was present in each occasion (a human isolate from the Congo). Techniques that can be used to identify orthopox viruses include real-time PCR and ECL. Early detection is essential for both naturally occurring outbreaks and bioterrorism due to recent viral transmissions of the monkeypox virus [12]. Following an experimental MPXV infection, squirrels were observed for both the severity of the disease's clinical signs and the amount of virus that was expelled from their bodies through their body fluids. This was carried out to ascertain whether the virus could spread from an animal to a human. The outcomes of this study revealed that while some rope squirrels were unable to recover from their very minor illnesses, others were. They can expel a sizable amount of the virus through their lips, nostrils, eyes, and bowel movements. This information aids epidemiologists and public health experts in their understanding of the potential risks that interacting with rope squirrels may provide to local communities in Africa. Disease ecologists will additionally advantage from this discovery considering that it will assist them recognize how the MPXV virus is maintained and transferred from animals to humans [8].

When employing the MPXV PCR technique to screen for gonorrhoea and chlamydia, samples collected from four different males revealed the presence of monkeypox virus (MPXV) DNA. Through the use of serology, it was discovered that all three people had been subjected to MPXV, and the virus was successfully cultured from samples taken from two of the patients. These findings suggest that some incidences of monkeypox have not yet been identified, and they signal that testing and quarantining those who report symptoms might not be adequate to prevent the breakout of the illness [7]. However, it might also be investigated a wide variety of antiviral pills that had been first created for the remedy of smallpox and different viral infections [6]. There are no specific medications approved to treat monkeypox virus infection at this time. Cases in the continuing monkeypox pandemic in 2022 have been discovered to have peculiar clinical features. They consist of the absence of prodromal symptoms (such as lymphadenopathy and fever) and a propensity for early lesions to develop on the vaginal and perianal areas of the body. This methodology's novelty lies in its comprehensive clinical diagnosis approach, considering various similar diseases when identifying monkeypox. It

introduces a rapid, precise machine learning model for illness detection, especially monkeypox. It enhances efficiency by using grayscale images and “Squeeze-and-Excitation” (SE) blocks for Convolutional Neural Networks (CNNs) in medical image analysis, all while maintaining diagnostic accuracy. Combining clinical insights, machine learning, and innovative image processing, this approach has the potential to advance healthcare diagnostics and patient care. The treatment of symptoms will vary according to the systems involved or the individual syndromes. Patients who are at a high risk of developing severe illness or who already have high-risk disease characteristics may benefit from antiviral medication that alleviates severe disease and lowers risk. We are the guardians of the body that we inhabit. It is imperative that we take the necessary steps to adopt healthy living habits in order to forestall, mitigate, or otherwise take control of diseases and illnesses [16]. We used the SQUEEZE- AND- EXCITATION-Resnet layer of a convolutional neural network to find the monkeypox disease. This reduces the high risk of getting a serious illness.

### III. METHODS

The performance of any basic design may be enhanced by using this simple yet efficient add-on module, and the extra computational weight is only slightly increased by doing so. Squeeze-and-Excitation (SE) blocks were used in this approach to calculate the channel attention. The effect of squeeze- and- excitation (SE) blocks on traditional architectures will subsequent be examined, alongside with SE blocks’ overall performance in a range of computer vision applications. In present day designs of convolutional neural networks, the frames are equal to the channels in a tensor produced by using a convolutional layer. Typically, the dimensions of this tensor are (B, C, H, W), the place B stands for the batch size, C for the channels, and H and W for the corresponding spatial dimensions of the feature maps. In different words, the notation (B, C, H, W) may additionally be used to point out the dimensions of this tensor (H represents the height and W represents the width). Convolutional filters were used to extract a range of properties from the input data, which led to the creation of channels. In spite of this, there is a distinct possibility that the channels may not all possess the same degree of representational value. Because it’s likely that certain channels are more important than others, it’s a good idea to give each one a weight that’s proportionate to its value before the information is passed on to the next layer. This will ensure that the most important information gets sent.

#### A. Channel Attention

In a convolutional neural network, the two primary components are as follows:

- The dimensions provide a representation of the input tensor, which is typically a four-dimensional tensor (B, C, H, W).
- The weights for each layer are stored inside the trainable convolutional filters.

The convolutional filters are the ones that are in charge of generating the feature maps, and they do this by basing those maps on the learned weights that are contained inside

those filters or to put it another way, the feature maps are constructed by the convolutional filters. Together, these filters learn several feature representations of the target class data that the input tensor includes in the image. While other filters are taught to learn textures, some are taught to learn edges. Therefore, the variety of channels determines the range of convolutional filters that are used to study the distinctive feature maps of the input. These feature maps also have varied degrees of usefulness, based on what we know about frame selection in photography at this point in time. This shows that certain feature maps have high value than others do. A feature map that learns background texture transitions, for example, can be less useful and required for the learning process than a feature map that learns edge information since the latter already has the edge information. As a direct result, it is essentially suitable to supply the extra significant feature maps with a higher degree of relevance in contrast to the related feature maps. This lays the groundwork for how attention will be directed. We prefer to focal point our “attention” on the channels that supply the best significance, which, in practise, implies that we favor to prioritise some channels above others and provide them extra importance. The most straightforward strategy for achieving this objective is to apply a bigger scaling factor to the channels that carry a greater amount of significance. The Squeeze-Excitation Networks theory makes the exact same prediction about the likelihood of this happening.

#### B. Squeeze-and-Excitation Blocks

An architectural element called the Squeeze-and-Excitation Block permits dynamic channel-wise feature recalibration, which boosts a network’s representational power. This was done by the network being able to squeeze and stimulate information [11]. The procedure is as follows:

- As an input, the block makes use of a convolutional block.
- When employing average pooling, each channel is “squished” into a single numerical number.
- A dense layer that is then followed by a ReLU will increase non-linearity, and the complexity of the output channel will be lowered by a ratio.
- A sigmoid follows another thick layer, creating a smooth gating function for each channel.
- Last but not least, we assign a weight based on the side network, often referred to as the “excitation,” to each feature map of the convolutional block. Fig. 1 and 2 explains the Squeeze-and-Excitation Block.

Fig. 1. (A) Rudimentary SE-ResNet core module (B) Congestion SE-ResNet module. (C) Trifling SE-ResNet module.

Fig. 2. Squeeze-excitation module.

- The SE-block, also known as the Squeeze-and-Excite block, is a straightforward plug-in module made up of three components:
- Squeeze Module
- Excitation Module
- Scale Module

1) *Squeeze module*: To maximise channel attention, it would be preferable if the feature maps' scale should be modified to fit the maps themselves. As a consequence, the best channel attention would be obtained. In a nutshell, the output tensor from a convolutional layer is the feature map set. The letters B, C, H, and W, in the well-known tensor notation stand for the batch size, channels, height, and width of the feature mappings (B, C, H, W). For the purpose of simplicity, let's think of it as a three-dimensional tensor of type (C, H, W). In essence, what things is the depth (the quantity of channels or feature maps contained in the tensor) and geographic dimensions of every feature map. We must be concerned with HW pixels (or values) as a whole in order to make the attention paid to channels flexible to each channel taken independently. In order to make the interest genuinely adaptable, this would effectively suggest that you would be dealing with a whole of C, H, and W variables. This is due to the previous statement. Given that the number of channels in modern neural networks increases proportionally to the network depth, this figure will grow to be quite large. Therefore, in order to simplify the computation requirements of the whole operation, the usage of a feature descriptor that may condense the data included in each feature map to a single value is required [10]. The Squeeze Module was created as a result. Convolutional neural networks often make use of the pooling approach to minimize the quantity of space that the features occupy, even if the spatial dimensions of the feature maps can also be decreased to a single cost utilizing a range of distinct feature descriptors. Both the maximum pooling method and the average pooling method are widely used methods of pooling. While the second approach gets the greatest pixel value inside the same specified frame, the first method determines the average pixel values within a given window. Both have advantages and disadvantages in proportion to how beneficial they are overall. Although max pooling performs a decent job of protecting the pixels that are most likely to activate, it also has the potential to be highly noisy and ignores the neighboring pixels. Despite no longer maintaining the information, common pooling creates a smoother average of all the pixels covered inside that window

[15]. As shown in Fig. 3, we conducted an ablation inquiry to assess each descriptor's performance: Global Average Pool (GAP) and Global Max Pool (GMP). By averaging out each and every pixel that makes up the feature map, the Global Average Pool (GAP) process, which is employed via the Squeeze Module, essentially compresses the entire feature map to a single value. The Global Average Pool (GAP) operation allows for this. This option is chosen because, in contrast to the other two options, it produces a less chaotic atmosphere. As a consequence, if the input tensor is (CHW), the GAP operation will be performed, yielding an output tensor of shape (Cx1x1), which is simply a vector of length C with every feature map decreased to a single value. The output tensor that is created after it has been subjected to the GAP operator has the shape (Cx1x1) after doing so. In addition, the application of the GAP operator to the input tensor will determine the shape of the output tensor (Cx1x1).

Fig. 3. Global Average Pool (GAP) and Global Max Pool (GMP).

The findings of our comparison between the Squeeze version and the No-Squeeze variant are shown in the table that follows. They did this so they could evaluate the significance of the Squeeze operator. Fig. 4's No-Squeeze variant, which demonstrates that the tensor protecting the feature maps was once no longer condensed to a single pixel and that the Excitation module worked on the full tensor instead of simply a component of it, serves as an illustration of this idea [9].

Fig. 4. Squeeze variation.

2) *Excitation module*: The second stage of the module includes gaining knowledge of the adaptive scaling weights for each of these channels after the input tensor used to be reduced in size to a good deal greater sensible measurement of (Cx1x1). We locate that the first-rate approach for mapping the

scaling weights for the Excitation Module, which is existing in the Squeeze-and-Excitation Block, is a fully connected Multi-Layer Perceptron (MLP) bottleneck structure is shown in Fig. 5. The input and output layers and one hidden layer combine to form this MLP bottleneck. The three levels all have the same form. As a reduction block, the hidden layer takes the input space and reduces it in line with the reduction factor to a more manageable size (which is set at 16 by default). Then, in order to use it as the input tensor, the previously compressed region is inflated back to its original size. The following three factors may additionally be used to summarily illustrate the adjustments in dimensionality that take region at every layer of the MLP:

Fig. 5. Multi-Layer Perceptron (MLP) structure.

- The form that the input takes is  $(C \times 1 \times 1)$ . As a direct consequence of this, the input layer has some neurons of type  $C$ .
- This is reduced by a factor of reduction denoted by the letter  $r$  in the buried layer, which brings the total number of neurons to  $C$  raised to the power of  $r$ . When the output is projected again into the equal dimensional area as the input, the whole number of neurons grows to  $C$ .
- The last stage involves projecting the output back into the same dimensions space as the input.

In conclusion, the output is a weighted version of the same tensor with the same form, and the input is a tensor with the form  $(C \times 1 \times 1)$  that is used as the input. Fig. 6 displays the outcomes of their studies on how a SE module integrated into ResNet-50 architecture functions while utilising a variety of reduction ratios.

In a perfect world, the value of  $r$  would be set to 1, which would transform the network into a square that is totally linked on all levels and maintains the same width throughout. This would lead to improved information transfer as well as more interaction across channels (CCI). However, there is a trade-off that can be made between increasing the complexity of the system and enhancing its performance with a lower  $r$ . The trade-off may be made in any direction. As a consequence of this, we reach the conclusion that the default figure for the reduction ratio should be 16, and we base this conclusion on the Fig. 6 was shown before. This is a hyper parameter that can be adjusted further in order to achieve a higher level of performance. There is room for

more adjustment.

Fig. 6. Cross channel information

3) *Scale module*: Initial processing of the “excited”  $(C \times 1 \times 1)$  tensor is carried out with the aid of a sigmoid activation layer, which limits the values to a range that lies between zero and 1. This is done after the tensor has been acquired via the Excitation Module. Following that, the output is right away utilized to the input the usage of a basic broadcasted element-wise multiplication. Each channel or feature map in the input tensor is scaled the usage of the splendid learned weight from the MLP in the excitation module. This is done in the subsequent phase. More study was once carried out on ablation, with a unique center of attention on the results of a number of non-linear activation functions that might also be used as the excitation operator. In Fig. 7, the research’s conclusions are displayed. Since we conclude from the data that it gives the highest level of performance, the sigmoid activation function is chosen as the scale module’s default excitation operator. In conclusion, the Global Average Pooling (GAP) algorithm is used through the Squeeze Excitation Block (SE Block) to limit an input tensor with the shape  $(C \times H \times W)$  to a tensor with the shape  $(C \times 1 \times 1)$  earlier than the Multi-Layer Perceptron (MLP) bottleneck structure receives the  $C$ -length vector and makes use of it to create a weighted tensor with the identical shape  $(C \times 1 \times 1)$ . The inner spatial convolution of the block is accompanied by way of the squeeze-excitation block, which takes place earlier than the last convolutional layer. As a result, rather than functioning as the add-on that was initially planned, it now functions more like an integrated component. The default configuration, which covered including a SE-block after the eleven convolutions that have been performed, was once eventually chosen by way of SE-Net in spite of the reality that they had carried out ablation experiments and evaluated this integration technique. The most recent method for distinguishing monkeypox from other illnesses by analysing the images in the dataset is state-of-the-art (SOTA) detection utilising effective nets. The importance of being aware of the channels being used as well as the strength of Squeeze Excitation blocks are highlighted by this.

Fig. 7. Scale module.

#### IV. PERFORMANCE EVALUATION

The full set of test findings is investigated and analysed the use of the statistical methods now used by means of the majority of researchers, inclusive of accuracy, precision, recall, F1-score, sensitivity, and specificity. Due to the small range of lookup participants, the typical statistical effects are mentioned as a self-assurance interval with a 95% level of significance. This is followed by previously published research that also used a small dataset. Monkeypox may be classified for the purposes of our dataset as either true positive (Tp) or true negative (Tn), depending on how accurately people are diagnosed; alternatively, it may be classified as either false positive (Fp) or false negative (Fn), depending on how accurately people are diagnosed. Fig. 8 displays the True positive rate and False positive rate AUC scores. Fig. 9 displays the testing accuracy, validation accuracy, and testing accuracy with respect to the number of epochs. In this comparative analysis of algorithms for the detection of monkeypox disease, the focus was on evaluating their performance in conjunction with the SE-Resnet architecture. The dataset used for this evaluation consisted of a total of 228 images, with 102 of them falling into the 'Monkeypox' category, while the remaining 126 represented cases of 'Others,' encompassing diseases like chickenpox and measles.

Several methodologies and algorithms were assessed in terms of their accuracy in distinguishing monkeypox cases from others. Notable among these was the application of pre-trained deep learning (DL) models, as outlined in the study by Sitaula and colleagues in 2022. In this approach, these pre-trained models were fine-tuned using custom layers, and their performance was meticulously analyzed using four well-established metrics. This method yielded an accuracy rate of 87.13%, indicating its effectiveness in monkeypox detection.

Other algorithms included widely recognized deep convolutional neural networks (CNNs), such as ResNet-18 and GoogLeNet, which had 73.33% and 77.78% accuracy, respectively. Furthermore, more complex models like EfficientNet-B0 with 91.11% accuracy and NasnetMobile with 86.67% accuracy demonstrated their capability in monkeypox detection. Shuffle Net, MobileNetv2, CNN (with 3 layers), and LSTM (with 3 layers) also underwent evaluation, with accuracy percentages of 80%, 91%, 64%, and 94%, respectively. These results displayed the varying degrees of success in identifying monkeypox using different architectures.

Fig. 8. True positive rate vs False positive rate.

Fig. 9. Accuracy/Loss vs number of Epochs.

However, the most promising performer in this analysis was the proposed SE-Resnet architecture. SE-Resnet leverages the Squeeze-and-Excite block, composed of three critical components: the Excitation Module, Squeeze Module, and Scale Module. This innovative approach demonstrated an exceptional accuracy rate of 96%. The SE-Resnet architecture outperformed all other methods, highlighting its efficacy in enhancing the accuracy and reliability of monkeypox disease detection. In summary, this comprehensive comparison underscores the significance of the SE-Resnet architecture in achieving a remarkable accuracy rate of 96% in monkeypox detection, thereby offering a promising avenue for improving the efficiency of disease diagnosis and potentially enhancing patient care in the field of healthcare.

#### V. CONCLUSION

In this approach, we created a unique dataset for machine learning model training and development that may be utilised to categorise the monkeypox illness using image analysis techniques. The inadequacy of older architectures to accurately characterise channel-wise feature dependencies is something that is made clearer by the introduction of SE blocks. We have high hopes that this new information will be helpful in the categorization of monkeypox images, which calls for highly discriminative characteristics. In addition, a version of the SE-ResNET model is built, and its capacity to distinguish between patients who have and do not have monkeypox illness is investigated in two distinct investigations. Our suggested model, SE-ResNET, was able to attain an accuracy of around 95% with a score of 0.5% AUC. Some of the boundaries of our work can be overcome by means of consistently accumulating new images of monkeypox-infected patients, updating the dataset, checking out the overall performance of the proposed SE-ResNET model on highly skewed data, evaluating the overall performance of our model,

and the use of the proposed model to construct mobile-based prognosis tools.

#### ACKNOWLEDGMENT

I would like to express our sincere gratitude to all individuals and organizations who have contributed to the successful completion of this research article. First, I extend my deepest appreciation to our research advisor Dr. K. Selvakumar, Head and Professor, whose guidance, expertise, and continuous support were invaluable throughout the entire research process. Their valuable insights and constructive feedback significantly enhanced the quality and rigor of this study. Furthermore, we would like to acknowledge the contribution of Dr. S. Vairachilai, Dr. R Suban, and Dr. Pasupathy, who provided assistance with data collection, analysis, and interpretation. Their expertise and dedication played a crucial role in the successful execution of this research. Once again, I express my sincere gratitude to everyone involved, and we hope that our research contributes to the advancement of knowledge in this field. Feel free to modify and adapt this acknowledgment text to suit your specific circumstances and the individuals and organizations you wish to acknowledge in your journal article.

**Abstract**—One of the more prevalent and severe cancer kinds is thought to be skin cancer. The main objective is to detect the melanoma in initial stage and save millions of lives. One of the most difficult aspects of developing an effective automatic classification system is due to lack of large datasets. The data imbalance and overfitting problem degrades the accuracy. In this proposed work, this problem can be solved using a Generative Adversarial Network (GAN) by generating more training images. Traditional RNNs are concerned with overcoming memory constraints. By using a cyclic link on the hidden layer, these models attain Long short-term memory. However, RNNs suffer from the issue of the gradient disappearing, which affects learning performance. To overcome these challenges this work proposes Bidirectional Long Short-Term Memory (Bi-LSTM) deep learning framework for skin cancer detection. The dataset which is collected from the International Skin Imaging Collaboration were used in image processing. A novel metaheuristic enthused by the routine of African vultures is proposed in this proposed work. The African Vulture Optimisation Algorithm (AVOA) algorithm is designed to select optimum feature of skin image. The accuracy of the proposed method obtains 98.5%. This comprehensive framework, encompassing GAN-generated data, Bi-LSTM architecture, and AVOA-based feature optimization, contributes significantly to enhancing early melanoma detection.

**Keywords**—Skin cancer; generative adversarial network; Bi-LSTM; African Vulture Optimisation (AVO); deep learning (DL)

## I. INTRODUCTION

Skin cancer has become difficult to diagnose because of apparent similarities. Melanoma is the well-known type of skin cancer, have been caused for a significant number of deaths in recent years. Recent surveys show that in contrast

with various cancer types, the number of skin cancer patients is growing annually. Melanocytes, the skin external cells, are affected by it. It has several cell types that result in the skin becoming darker. It irregularly comes in a variety of dark tones. It can also be noticed on the skin in colorless or in shades of rosy pink in color, royal purple, azure, and more. It is more deadly and hazardous because it spreads quickly. Melanoma can be discovered everywhere on the human body, despite the fact that it typically develops on the lower limb's backside [1]. According to data from the World Health Organization (WHO), there are several thousand cases worldwide with a high risk of death by the year 2020. According to that, 324,635 new cases have been reported globally, of which 57,043 have resulted in death. The researcher also demonstrate that, of every 100 persons with melanoma, 18 will not survive [2]. Melanocytes in the epidermal layer have the potential to produce excessive amounts of melanin at a high rate in several circumstances. For instance, melanin is produced when strong UV radiation from sunlight is exposed for an extended period of time. Melanoma, a deadly kind of skin cancer, is the outcome of melanocytes' unusual growth. For successful treatment of melanoma, an early diagnosis is crucial. The survival percentage for 5 years is approximately 92% if the skin cancer is sensed at an earlier phase [3]. Accurate and timely diagnosis of melanoma, a deadly form of skin cancer, remains a pressing challenge in the field of dermatology and healthcare. Despite advancements in medical technology, the current diagnostic methods are often subjective and error-prone, leading to delayed diagnoses and poorer patient outcomes. The need for a more reliable and efficient approach to melanoma detection is evident, especially considering the increasing incidence of skin cancer worldwide. This research endeavors to address

these critical issues by developing an automated melanoma detection system that leverages the power of deep learning and convolutional neural networks.

Historically, skin cancer diseases have been diagnosed and detected by manual examination and inspection by sight. These methods for skin doctor to visually assess and screen lesion photographs are time-consuming, difficult, and error-prone [4]. Use of the ABCDE rule, which stands for asymmetry, boundaries, color, diameter, and evolving, is a typical way for spotting melanomas [5]. To diagnose melanoma, these warning indicators are monitored. The first warning indicator is a mole that is very asymmetrical or has uneven border patterns, as well as one that is larger than 6 mm in diameter and has an odd color. All of these indicators are tracked in order to study how researcher changes over time which determines the presence of melanoma. This methodology could be inaccurate and prone to measurement mistakes [6]. Effective feature extraction, classifiers, and color capture are required for the detection of skin lesion images. Recent developments have made it possible to diagnose melanoma accurately by molecular dermatopathology, which necessitates a discussion between a pathologist and a dermatologist. Even though the majority of dermatopathologists can determine the histological evaluation of melanocytic lesions by performing a traditional microscopic examination, some melanocytic neoplasms known as typical melanocytic proliferations require expert opinion before categorized as benign or malignant. The investigation of the histopathological features in relation to the clinical and microscopy data is also required because of this. If molecular diagnostics is used incorrectly to decide whether a condition is benign or malignant, it may also be deceptive and lose some of its greatest value [7]. However, this method can only be executed effectively by skilled medical specialists. These complications boost the scientific people to generate innovative systems for melanoma visualization and diagnosis. Melanoma cancer is diagnosed with the use of a computer-aided diagnosis (CAD) system. CAD diagnostic tool evidence can be utilized as a backup diagnosis for melanoma malignancy [8]. The expanding use of machine learning and AI in the disciplines of medical and health care has attracted a lot of study attention in recent years [9]. Clinical image of skin lesions with the existence of artefacts such as hair, veins, and texture and other issues might be challenging to identify melanoma lesions away from non-melanoma lesions. Consequently, the need for imagery preparation is crucial [10]. Early detection has been proven to significantly improve patient survival rates, with a five-year survival rate of approximately 92% when melanoma is detected at an earlier stage. By addressing the shortcomings of current diagnostic methods, this research aims to contribute to saving lives and reducing the burden of melanoma on individuals and healthcare systems.

Convolutional neural networks with deep learning recently entered the field of image-based skin cancer diagnosis and demonstrated diagnostic performance comparable to that of dermatologists. It would be ideal if doctors had assistance in the diagnosis of difficult-to-diagnose melanomas with unique localizations and uncommon subtypes [11]. The segmentation

is a vital step in creating an automated melanoma detection system. However, when there is no variation in image contrast or when there are just slight variations in illumination in the image content, the region of interest or thresholding-based algorithms perform well [12]. ResNet-50 Convolutional Neural Network (CNN) architecture was designed. CNN model employed a varied learning rate for each CNN layer. To slow down learning rates, novel techniques based on the cosines function is applied. The success percentage for the categorization had a sensitivity rate of 82.3% [13]. In deep CNN SoftMax classifier were used. This approach worked effectively for lesion images that were blurry and had many sizes. This method was calculated using skin lesion samples from PH2 and ISIC 2018 and yielded respectable accuracy and dice coefficients of 95% and 93%, for each [14].

The existing diagnostic methods for melanoma are beset by several limitations that hinder their effectiveness. Manual examination, reliant on visual inspection, is not only time-consuming but also susceptible to human subjectivity. The widely-used ABCDE rule, which assesses asymmetry, boundaries, color, diameter, and evolution, can introduce errors due to its reliance on qualitative observations. The presence of noisy images with artifacts like hair, veins, and variations in color makes accurate diagnosis even more challenging. These limitations underscore the need for a more objective, automated, and robust approach to melanoma detection. And also often struggle to accurately detect and segment melanoma lesions due to factors such as inadequate image segmentation, vanishing/exploding gradients in deep learning architectures, and difficulty in handling noisy images with variations like hairs or color changes. The current landscape of melanoma diagnosis is characterized by a conspicuous gap between the pressing need for accurate and timely detection and the limitations of existing methods. While deep learning and CNNs have shown immense potential in image-based tasks, their application to dermatology, especially for melanoma detection, remains a relatively unexplored territory. This research aims to bridge this gap by introducing an innovative approach that combines advanced technology with the critical domain of skin cancer diagnosis. Moreover, certain techniques suffer from computational intensity during feature extraction, leading to time-consuming analyses. In this work AI driven African Vulture optimization with GAN based Bi-LSTM deep framework for melanoma detection is projected. The primary contributions of the suggested work include:

- **Data Collection and GAN Augmentation:** The utilization of skin cancer images from the International Skin Imaging Collaboration (ISIC 2018) addresses the challenge of limited data availability. The integration of Generative Adversarial Networks (GANs) to generate additional synthetic images serves as a solution for data imbalance, enhancing the diversity and size of the dataset.
- **Advanced Preprocessing Techniques:** The implementation of Contrast Limited Adaptive Histogram Equalization (CLAHE) and Weiner filtering on input images aids in enhancing image quality and reducing unwanted artifacts such as hair, veins, and

noise. This preprocessing pipeline ensures that the subsequent analysis is based on clean and standardized data.

- **Precise Skin Contour Segmentation:** The application of Kapur thresholding for skin contour segmentation generates binary images that precisely isolate the skin lesions from the background. This step is pivotal in isolating the region of interest and improving subsequent feature extraction.
- **Optimal Feature Selection:** The introduction of African Vulture Optimization (AVO) algorithm for selecting optimal features from skin images adds a novel contribution. This technique helps to streamline and enhance the feature extraction process, potentially leading to more effective and efficient classification.
- **Hybrid CNN-Bi-LSTM Architecture:** The design of a Convolutional Neural Network (CNN) with Bidirectional Long Short-Term Memory (Bi-LSTM) layers offers a robust architecture for detecting melanoma. This combination enables the model to capture both spatial features from images and sequential patterns, potentially improving accuracy and diagnostic capabilities.

Overall, the key contributions encompass data augmentation, advanced preprocessing, precise segmentation, innovative feature selection, and a sophisticated deep learning architecture, collectively aiming to boost the accuracy and effectiveness of early melanoma detection and diagnosis. The leftover portion of this work is organised as follows: Section II contains comparable work as well as a thorough examination of them. Section III contains information about the problem statement. The proposed AVO-CNN architectures are discussed in detail in Section IV. In Section V, the outcomes of the experiments are presented and examined, and a full comparison of the suggested strategy to current best practises is given. Section VI, is the final section, where the paper is concluded.

## II. RELATED WORKS

Albert [15] proposed the combination of Predict-Evaluate-Correct K-fold (PECK) algorithms and Synthesis and Convergence of Intermediate Decaying Omnigradients (SCIDOG). MED-NODE data set were used to diagnose melanomas via digital image analysis. In the PECK algorithm 153 non-dermoscopic images of lesion were deep ensembled. On that data the state-of-the-art methods were educated and estimated. Considerable improvement in diagnostic performance over the most effective earlier approaches was achieved through introspective learning of the PECK ensemble to increase precision from sparse but high-dimensional training data.

Jiang, Li, and Jin [16] introduced a light-weight based deep learning outline called DRANet to distinguish between 11 dissimilar categories of skin diseases using a factual histopathology data set amassed over the past ten years. DRANet outperforms baseline models (such InceptionV3, ResNet50, VGG16, and VGG19) by a significant margin with

identical parameter sizes and comparative accuracy with fewer parameters. Vanishing/exploding gradients are a concern, and several stacked layers can occasionally have substantial training error. Shorfuzzaman [17] suggested a comprehensible ensemble stacked structure with CNN for early malignance skin tumor detection. Multiple sub-models of CNN which performs the similar classification are collected in the loading ensemble outline, which employs the transfer learning idea. All of the predictions from the sub-models are combined into a novel model termed a meta-learner, which produces the final prediction outcomes. Stacking ensemble model was trained and validated using skin lesions Kaggle dataset obtained over the International Skin Image Collection. The dataset includes 1497 and 1800 pictures of benign and cancerous moles, respectively. According to evaluation results, the ensemble model has better accuracy of 95.76%, sensitivity of 96.67%, and AUC of 0.957. Low-quality prediction results from inadequate image segmentation.

Wei, Ding, and Hu [18] suggested a simple model for detecting skin cancer that uses feature discrimination and the fine-grained classification principle. Two sets of training samples of the recognition model are first introduced in Lightweight CNN. This technique can extract additional discriminatory lesion characteristics and progress the performance in a bit of time. Next, two sets of output from CNN unit are used for training of two-feature group and differential networks simultaneously. Accuracy of 96.2% achieved by fusion performance can be improved by efficient discrimination network. Wang et al. [19] proposed an information that alert deep framework that imposes several clinical knowledge to feature segmentation and melanoma recognition unit. Lesion-based pooling and shape extraction (LPSE) structure is developed to move the data gained from image partition to detection unit. Also transmit data from recognition to segmentation units simultaneously. An efficient diagnosis guided feature fusion (DGFF) approach and recursive learning, is proposed which iteratively enhances the learning capability and boosts the performance It is more time consuming and labor intensive.

A lot of computer-aided diagnosis mechanisms have been created in the earlier. Due to the skin lesion images complicated visual qualities, which include irregularly shaped features and fuzzy edges, had trouble performing. Adegun and Viriri [20] suggested a deep learning technique to automate melanoma lesion detection and segmentation that gets over these restrictions. For efficient learning and feature extraction, an enhanced encoder-decoder structure with independent networks coupled through a number of skip pathways is proposed. This network increases the level of semantics of the feature encoder maps closest to decoder. In addition, SoftMax and Lesion-classifier were used. On International Skin on Biomedical Imaging (ISBI) 2017 dataset, proposed approach was accurate, with 95% and 92% dice coefficients. While on Pedro Hispano (PH2) dataset, it had an accuracy of 95%, dice coefficient of 93%. Some current state-of-the-arts are outperformed by this approach. This method needs better accuracy.

Manzo and Pellino [21] implemented deep CNN structures using prior training for visual representation with the aim of

predicting melanoma in skin lesions. To extract image features using a transfer learning strategy. The transfer learning features were then used in a grouping of classifications framework. The model precisely learns different classifiers then uses statistical techniques to grouping the supplied predictions. The primary weakness is the computing difficulty associated with the features extraction step, which is known to be time-consuming, especially as the amount of data to be analyzed increases. A hybrid classification method was created by İlkin et al. [22] combining a heuristic optimization technique and the SVM algorithm. It has certain advantages, but it also has some big disadvantages. Images with noise, such as hairs or colour changes, degrade performance. When a wounded area extends beyond the image's boundaries, the classifier's effectiveness in capturing the model's acquired characteristics diminishes.

### III. PROBLEM STATEMENT

When applying classification methods on Melanoma images, data imbalance was challenging. Data imbalance

causes overfitting problem [16], poor accuracy [20] and training error. Overfitting problem can be solved by increasing the size of dataset which accomplished through GAN (Generative Adversarial Network). CLAHE and Weiner filter which potentially remove noises and artifacts interfering with the classification. The existing work suffers from the issue of the gradient disappearing, which affects learning performance. To overcome these challenges this work proposes Bi-LSTM Deep Learning framework for skin cancer detection. The time consumption could be reduced by implementing African Vulture Optimization (AVO).

### IV. PROPOSED GAN BASED BI-LSTM WITH AVO

Research must automatically discover class-preserving changes to generate valid and representative samples in order to combat the imbalanced class problem and further improve classification accuracy. However, the samples of skin lesion should have high resolution for classification to detect the presence of malignant in skin lesion. Fig. 1 illustrates the proposed GAN-Bi-LSTM with AVO.

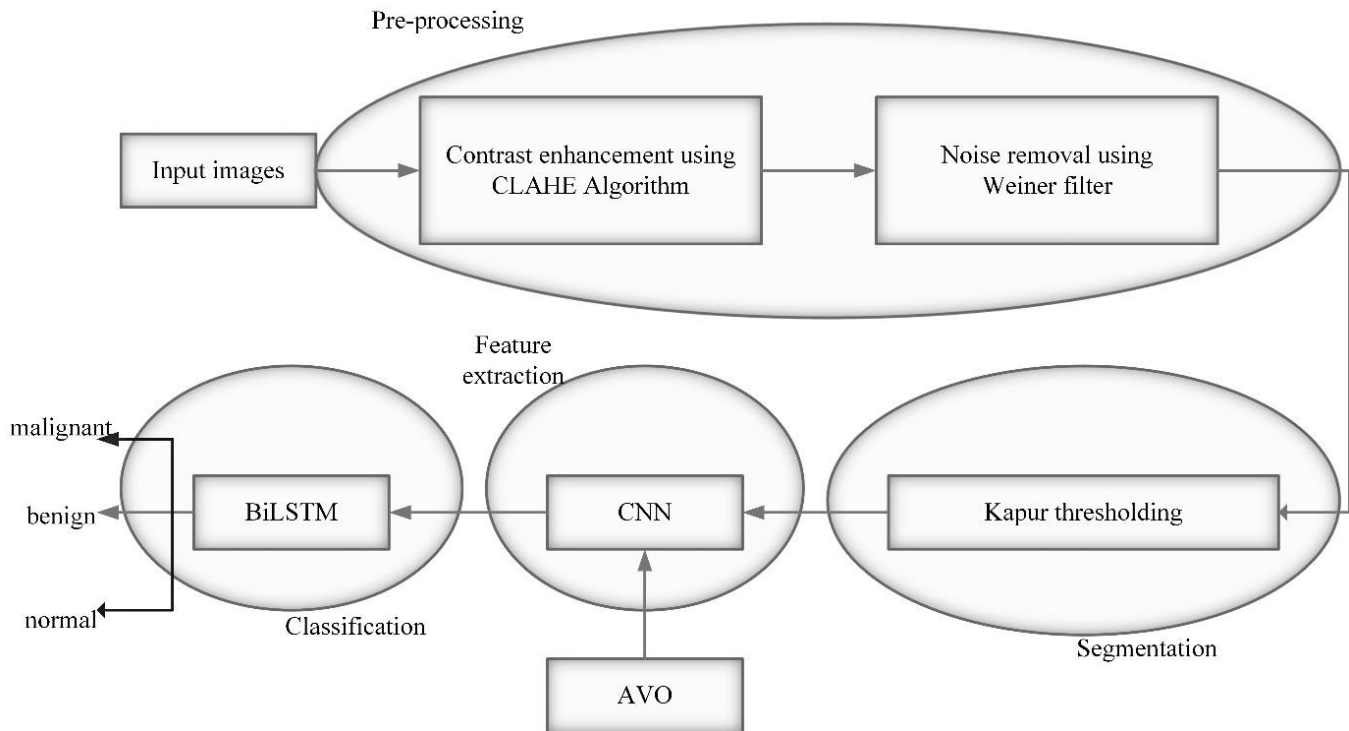

Fig. 1. Proposed AVO with GAN based Bi-LSTM.

The skin cancer images are grouped from ISIC 2018 and the fake images were generated using GAN to overpower the problem of data imbalance. The input images were preprocessed with CLAHE algorithm then filtered by Weiner filter to eliminate unwanted artifacts such as hair, veins and other noise factors. Then the skin contour is segmented by kapur threshold as binary images. The special features of skin images were extracted and optimum feature is selected in African Vulture Optimization (AVO). CNN with Bi-LSTM were designed to detect the melanoma from the skin lesion.

#### A. Data Collection

The International Skin Imaging Collaboration (ISIC 2018) provided the dataset for research which has challenges [23]. The objective is to automatically detect melanoma using dermoscopic pictures. There are three components to the challenge: Segmentation of Lesion, Visual Dermoscopic Features/Patterns Detection & Localization, and melanoma Classification. The proposed concentrate on the third job, which requires you to categorize lesion images into three different groups: melanoma, benign and normal. The dataset contains of images with multiple resolution. Although researcher chooses the test images at random, make sure that the class distribution is maintained and that the proportion of images from each class is comparable in the train and test sets.

B. GAN-based Data Augmentation

GAN is one of the generative techniques in deep learning. GAN framework consists of two neural networks. They are simultaneously guided discriminator and generator. A generator network G produces images from noise n and given to discriminator network D which identify the difference

between real image y and synthetic images generated by generator G. The images with better resolution are ready for further process. If the image produced by generator is not identical to the real image again it is given to discriminator and generator network. The construction of GAN is depicted in Fig. 2.

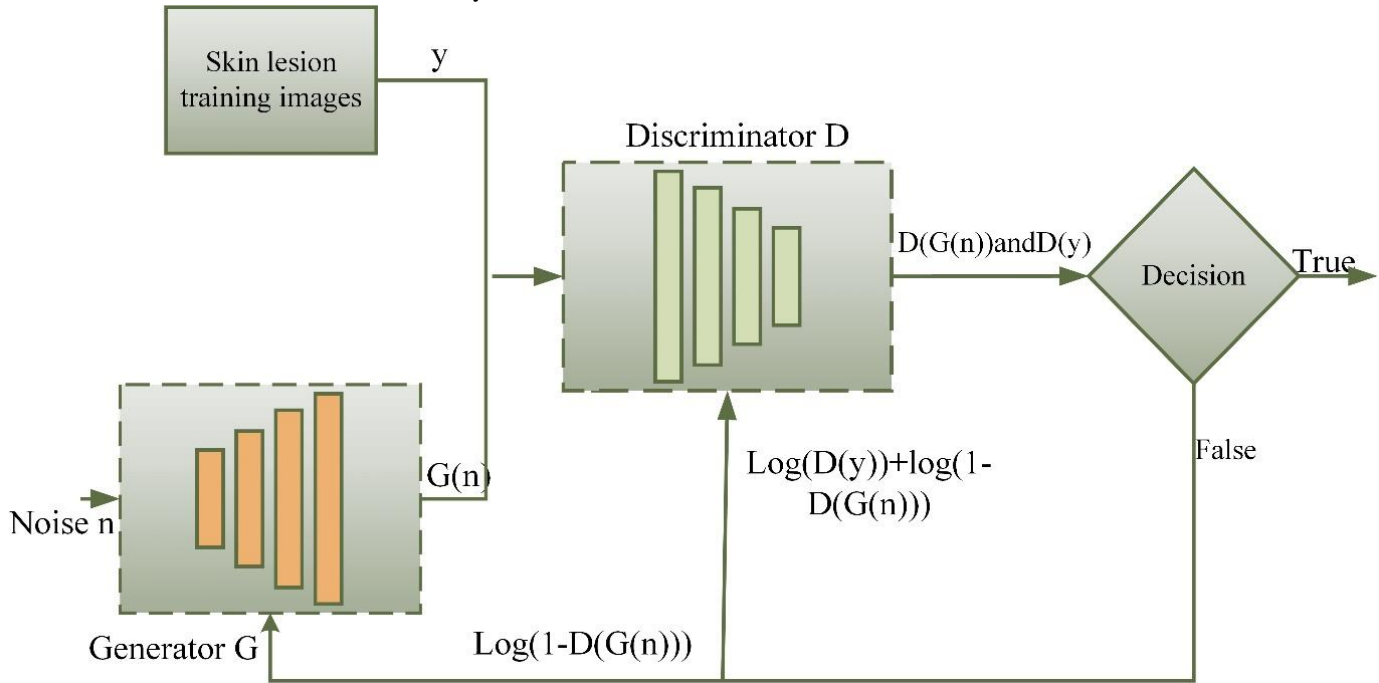

Fig. 2. Construction of GAN.

1) *Generator*: A convolution neural network serves as the generator based on unsupervised learning. The generative model that creates images that is comparable to the training images. In order to produce samples with a distribution that is similar to that of real samples, this artificial neural network assesses the probable distribution of the raw data and updates its parameters. The generator gets noise that is random and provides outputs information. There is some noise in the distribution as well. Now, the distribution of noise can be normal, uniform, or any other type. The generator feeds the discriminator network with its fake image output, and the discriminator performs its training and determines whether the input is real or fake.

2) *Discriminator*: A convolution neural network is a discriminator with supervised learning. It works as binary classifier that is learned on training images and forecasts whether the test image is a genuine or one that has been manufactured. Real images from the original training samples as well as generated image produced by the generator are included in the discriminator's training samples. During the training process, these fake images are utilised as negative examples. The generator works effectively creating genuine images. Only the discriminator can fail to discriminate among the first and generated samples.

3) *Loss function*: The loss function is found to evaluate error then it restores variations. It is specified for the generator

as well as the discriminator. The difference among the delivery of data generated by the generator and the delivery of the real images is calculated using the GAN loss function [24]. The discriminator tries to lower the negative log-likelihood. However, the generator just maximises negative log-likelihood since it wants to trick the discriminator. Since it can use the discriminator's cost function, the discriminator loss function is given in Eq. (1) as:

$$\max_D V(G, D) = E_{y \sim P_{data}(y)} [\log D(y)] + E_{y \sim P_n(n)} [\log(1 - D(G(n)))] \quad (1)$$

To minimize  $\log(1 - D(G(n)))$ , the Generator is trained. It produces images as similar to the real training images as possible. The generator loss function is expressed in Eq. (2) as,

$$\min_G V(G, D) = E_{y \sim P_n(n)} [\log(1 - D(G(n)))] \quad (2)$$

The generator and discriminator are optimized by the following Eq. (3),

$$\min_G \max_D V(D, G) = E_{y \sim P_{data}(y)} [\log D(y)] + E_{n \sim P_n(n)} [\log(D(G(n)))] \quad (3)$$

C. Image Preprocessing

Progressed images with interrelated masks for rotation, resizing, reflection and brightness were designed for each image. The less quality of the input lesion images delivered by electronic detectors restricts detection and evaluation. Up

sampling was used on the lesion images to solve the imbalanced class distribution. The ISIC2018 dataset was partitioned into three distinct groups for training, testing, and analysis to deal with the overfitting problem carried on by the smaller quantity of used training images.

1) *Image enhancement using contrast-limited adaptive histogram equalization (CLAHE)*: The pixel spreading can be realised in the image histogram. The contrast of image can be improved by rearranging the pixel distribution. Histogram equalisation, which can improve the variety of every pixel grey amount, is a mapping transformation of the original image 's grey level. So that image contrast is enlarged. An adaptive histogram equalisation (AHE) technique has a

tendency to overamplify noise in the areas of the image that are reasonably uniform. The CLAHE approach was suggested as a solution to this issue. Divide the image into parts that are non-overlap. Typically, the area dimension is established to 8 by 8. Obtain the histogram for each region, then trim the histogram using the threshold. By clipping of histogram with a predetermined threshold prior to calculating the Cumulative Distribution Function (CDF), the CLAHE algorithm attains the purpose of restricting the amplification [25]. This restricts the transformation function's slope as well. Redistribute pixels, then uniformly Spread the values of the clipped pixels under the histogram. local histogram equalisation is carried out on each region is shown in Fig. 3.

Fig. 3. Histogram equalization (a) before cutting (b) after cutting.

The linear interpolation is used to reconstruct the pixel value. Consider  $v$  as a grey value of image's sample point  $R$  and  $v'$  is the new grey value of that by performing linear interpolation. Let the sample points for surrounding regions are  $R_1, R_2, R_3$  and  $R_4$ .  $gr(v)$  is grey-level mapping for  $v$ .

The new grey value for pixels in the corners corresponds to the grey-level mapping for  $v$ . The new grey

value is expressed in Eq. (4),

$$v' = gr_1(v) \tag{4}$$

New grey value of pixels in edges is the mapping of grey level for  $v$  of two samples is expressed in Eq. (5),

$$v' = (1 - \alpha)gr_1(v) + \alpha gr_2(v) \tag{5}$$

New grey value of pixels in centre is the mapping of grey level for  $v$  of four samples is given in Eq. (6),

$$v' = (1 - \beta)((1 - \alpha)gr_1(v) + \alpha gr_2(v)) + \beta((1 - \alpha)gr_3(v) + \alpha gr_4(v)) \tag{6}$$

where, the normalized distances are  $\alpha$  and  $\beta$  with regards to the point  $R_1$ .

Due to the reason that a few of the images have tiny pixel counts and which need to be resized. This leads to

considerable changes in the image's luminance and size. There are many sets of parameters for various acquisition instruments. All pixel density was normalized within the range  $[-1, 1]$  to ensure that the data were reliable and noise-free. Eq. (7)'s normalization computation made the model less sensitive to minute weight changes. Normalization of image  $I_{Norm}$  is given in Eq. (7) as,

$$I_{Norm} = (I - min_i) \left( \frac{2}{max_i - min_i} \right) - 1 \tag{7}$$

Where,  $min_i$  and  $max_i$  are minimum image and maximum image.

2) *Noise removal by wiener filters*: The method used to remove unwanted data from the image is statistical. It achieves ideal trading among noise flattening and reverse filtering which filter the blurring and noise existing in the image [26].

Filter function is given in Eq. (8) as,

$$f(y, z) = \left[ \frac{H(y, z)^*}{H(y, z)^2 + \frac{S_n(y, z)}{S_i(y, z)}} \right] G(y, z) \tag{8}$$

Where  $G(y, z)$  represents degraded image,  $H(y, z)$  is degradation function,  $S_n(y, z)$  is a power spectra of noise and  $S_i(y, z)$  shows the original image's power spectrum.

#### D. Image Segmentation by Kapur Thresholding Technique

When taking a picture in many medical circumstances, negative impacts imposed to the skin image, causing image examination challenging for the computational approaches. In the case of input, portion of the skin image is essential and the rest of the image is not significant. To eliminate these negative consequences, kapur thresholding was applied. The image thresholding is used to keep the essential parts and eliminate the unwanted. Image thresholding is an image separation method that converts an image's pixel values to zero and one. In general, a threshold level value for the picture pixel points which overall value as threshold for all or each pixel may have different threshold value. The image's pixels are then compared to that level, and if the pixel intensity is more than the threshold, it is turned white; otherwise, it is turned black. As an outcome, a grayscale image is transformed into an image that is binary (black and white). Typically apply thresholding to choose portions of an image and eliminate those that aren't significant to us. Consider an image with L levels and N pixels ranging between 0 and L-1, If  $g(j)$  indicates the gray-level number and j describes image existences then median value of image is given in Eq. (9).

$$Mean = g(j)/N \quad (9)$$

The dermoscopy pictures were threshold using the Kapur technique. This procedure determines the limit using entropy  $T(u)$  boosting and histogram data, which can be computed using Eq. (10) to (14):

$$Max T(u) = A(0, u) + A(u, L) \quad (10)$$

$$Where \quad A(0, u) = - \sum_{j=0}^{u-1} \frac{P_j}{W_0} \ln \frac{P_j}{W_0} \quad (11)$$

$$W_0 = \sum_{j=0}^{u-1} P_j \quad (12)$$

$$A(u, L) = - \sum_{j=u}^{L-1} \frac{P_j}{W_1} \ln \frac{P_j}{W_1} \quad (13)$$

$$W_1 = \sum_{j=u}^{L-1} P_j \quad (14)$$

The ideal threshold value is calculated by maximizing the function  $T(u)$  and u number of grey levels was considered.

#### E. Extraction and Classification using AVO based CNN -Bi-LSTM

1) *Feature extraction using CNN*: Convolution, fully connected (FC) and pooling layers are stacked to form a CNN architecture. Each convolution layer has a set of filters that are learnable which is to acquire local features from the image being processed using the knowledgeable filters. It is probable to reduce computing complication while improving performance by constructing filters that conduct convolution actions based on two important ideas, namely weight division and local linking. The pooling layer is in charge of the down sampling process. One of the pooling layer's distinguishing characteristics is that it reduces the overall dimension of the image and avoids overfitting. Typically, FC layers are employed in the final CNN layer design to learn features returned by the layer of convolution; it is then utilised to construct the output.

2) *Feature selection using African vulture optimization (AVO)*: The latest metaheuristic technique developed through vulture tracking is called AVO. Vultures are a type of bird that may be found all over the world. Vultures are typically carnivorous; nevertheless, these birds are unable to divide the flesh and must rely on a different meat-eating to do it. African vultures may reach altitudes that exceed 11000 meters, and they travel great distances and rotate to locate food. They usually have difficulties after discovering a food source. The weaker vultures encircle the healthier vultures, delaying their activity; as that vulture fatigue, they begin to seek food. This way of living motivates to create a novel metaheuristic approach for tackling an optimization issue [27].

**Stage 1:** Increasing the size of the population, achieving similar values for each vulture, identifying the greatest vulture in each group, and selecting the best result for each group. This is explained in Eq. (15).

$$S(k) = \begin{cases} Best \ vulture_1, & if \ Z_k = f_1 \\ Best \ vulture_2, & if \ Z_k = f_2 \end{cases} \quad (15)$$

$f_1$  and  $f_2$  specify the parameters that are examined before to optimization, which must be between 0 and 1, where  $f_1+f_2=1$ .

**Stage 2:** Calculating the vulture famine rate. Vultures soar over the sky in quest of food. When there is insufficient energy, the vulture approaches stronger to grab a free meal. This is mathematically modelled in Eq. (16) and (17) as,

$$V = (2 \times \delta + 1) \times N \times \left(1 - \frac{iter_k}{max_{iter}}\right) + l \quad (16)$$

Where,

$$l = d \times \left(\sin\left(\frac{\pi}{2} \times \frac{iter_k}{max_{iter}}\right) + \cos\left(\frac{\pi}{2} \times \frac{iter_k}{max_{iter}}\right) - 1\right) \quad (17)$$

Where  $\delta$  denotes a random value ranged between [0,1],  $iter_k$  denotes the current iteration, N denotes a fixed number which displays the procedure of the optimization and makes the investigation and process stages,  $max_{iter}$  denotes the overall number of iterations, and d indicates an amount that is limited between -2 and 2. If N falls below zero, the vulture is hungry, and if it rises over one, the vulture is fulfilled.

**Stage3:** Enquiry.

In this method vultures contain random segments with two potential designs and a variable  $R_1$  with a value ranging from zero to one to determine the plane. The mathematical procedure for finding a meal for vultures is given in Eq. (18) and (19) as follows:

If  $R_1 \geq randR_1$

$$S(k+1) = BV(k) - T(k) \times S \quad (18)$$

If  $R_1 < randR_1$

$$S(k+1) = BV(k) - S + rand_2 \times ((ub - lb) \times rand_3 + lb) \quad (19)$$

where S identifies the vultures that diverge from others at randomly in search of food., lb and ub are the variables' lower

and upper bounds,  $BV$  contains the best vultures, and  $rand_2$  and  $rand_3$  define two random standards among 0 and 1.

**Stage 4: Utilization.**

This happens if  $|S| < 1$  divides the phase into two halves with two strategies that are determined by two R2 and R3 constraints that are in the range  $[0, 1]$ . The first portion of utilization begins at  $0.5 < |S| < 1$ . Both designs include rotational flights. If  $|S| \geq 0.5$  indicates that a vulture is spirited; in this stage, weak bird attempt to ingest food on stronger vultures.  $S(k + 1)$  represents the vulture's present location and can be designed using Eq. (20), (21), (22) as follows:

$$S(k + 1) = \frac{B_1 + B_2}{2} \quad (20)$$

Where,

$$B_1 = Best\ vulture_1(k) - \frac{Best\ vulture_1(k) \times S(k)}{Best\ vulture_1(k) - S(k)^2} \times S \quad (21)$$

$$B_2 = Best\ vulture_2(k) - \frac{Best\ vulture_2(k) \times S(k)}{Best\ vulture_2(k) - S(k)^2} \times S \quad (22)$$

The initial step of optimization is to specify the algorithm's minimal and maximum rate boundaries for avoiding system failures. The least acceptable value for the maximum pooling

is taken to be 2, and the highest value is considered as moving width. The proposed CNN's half-value accuracy has been used as an objective function in this case. The algorithm was initialized, updated, and reached the end state before the procedure was ended. Weights and biases, which make up a CNN's main building blocks, are thought to be enhanced.

3) *Skin cancer classification through Bi-LSTM:* Bidirectional LSTM layers extract hidden and sequential features from images in both forward and reverse time directions. RNN involves memory and data storage limitations. It is incapable of learning long-term, which might lead to gradient disappearance. As a result, to overpower the insufficiencies of algorithm, the LSTM approach was devised. This construction is formed on the usage of memory cells which store long-term and gate mechanisms to control this information. A basic LSTM unit contains three types of gates: Input gate  $i_t$ , Forget gate  $m_t$ , and output gate  $o_t$ . Each gate controls the state of memory cells by executing point-wise multiplication and sigmoid operations on the image  $y_t$ . The architecture of LSTM is exposed in Fig. 4.

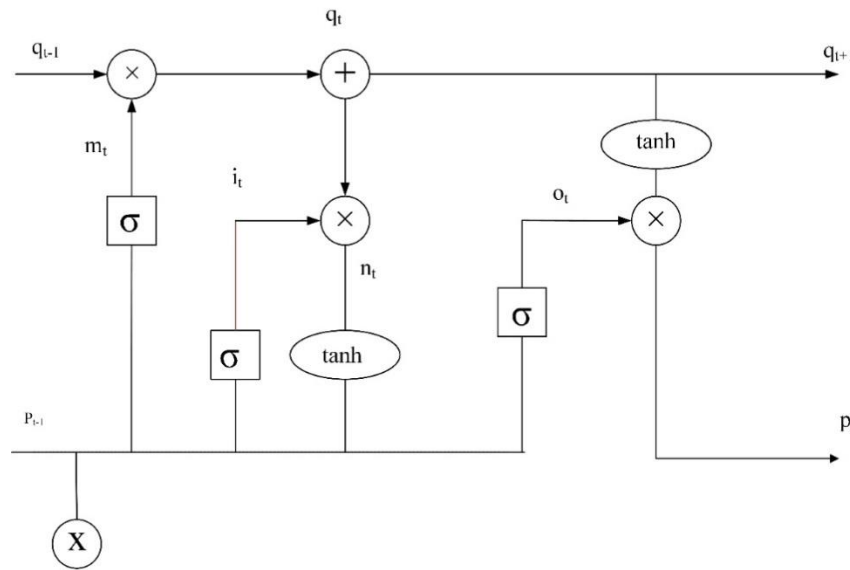

Fig. 4. LSTM architecture.

When input data  $y_t$  at its present state and output  $p_{t-1}$  from the preceding layer's hidden state are both entered, all gates are triggered. A forget gate specifies what information should be retained and which data should be ignored. The data gathered from the present input is used by sigmoid functions  $y_t$  to convey information from the present input  $y_t$  to the previous hidden state  $p_{t-1}$ . The forget gate's output value is between 0 and 1. When the rate is near to zero that indicates the data will be removed. More knowledge tends to be kept closer to oneself. The following procedures must be followed to calculate the forget gate formula using Eq. (23) input gate formula using Eq. (24) and output gate formula using Eq. (27) as follows:

$$m_t = \sigma(w_m \cdot [p_{t-1}, y_t] + b_m) \quad (23)$$

$$i_t = \sigma(w_i \cdot [p_{t-1}, y_t] + b_i) \quad (24)$$

$$\hat{q}_t = \tanh(w_q \cdot [p_{t-1}, y_t] + b_q) \quad (25)$$

Current state equation is expressed in eqn. (26),

$$q_t = m_t \odot q_{t-1} + i_t \odot \hat{q}_t \quad (26)$$

$$o_t = \sigma(w_o \cdot [p_{t-1}, y_t] + b_o) \quad (27)$$

Hidden state formula is given in eqn. (28),

$$p_t = o_t \odot \tanh(q_t) \quad (28)$$

Fig. 5. Bi-LSTM architecture.

Bidirectional LSTM (Bi-LSTM) links the two LSTM hidden layers to the output layer. Combining two LSTM as a single layer stimulates enhance the learning long-term dependence and model performance. Fig. 5 depicts the

structure of an unfolded Bi-LSTM layer with LSTM layer in forward and a backward direction. It classifies the input images as melanoma, benign and normal. Thus, the melanoma is detected from the input images.

---

The GAN-AVO algorithm is designed for the discovery of melanoma in skin lesion images. It begins by taking an input image containing a skin lesion and applies image

augmentation through a Generative Adversarial Network (GAN) for data enhancement. Subsequently, the image undergoes preprocessing, involving contrast enhancement

using the CLAHE method and noise removal through a Weiner filter. Image segmentation is performed by computing a threshold value. To retrieve relevant features, a Convolutional Neural Network (CNN) is employed to capture color, border, diameter, and shape information. AVO is utilized to select pertinent features, followed by the computation of fitness for vultures. If the number of selected features ( $|s|$ ) is greater than or equal to 1, the algorithm

upgrades vulture locations using Eq. (19); otherwise, it utilizes Eq. (20). Finally, the algorithm employs a Bi-LSTM network for classification, culminating in melanoma detection. This comprehensive approach integrates GAN-based augmentation, preprocessing, segmentation, feature extraction, AVO feature selection, and Bi-LSTM classification to effectively identify melanoma in skin lesion images. Fig. 6 shows flowchart of this research.

Fig. 6. Flowchart of proposed method.

## V. RESULTS

The proposed study aimed to enhance the accuracy of melanoma detection in skin images by employing a novel AI driven African Vulture optimization with GAN based Bi-LSTM deep framework for melanoma detection. The approach used GANs to create realistic and variety fake images, which were then mixed with the original dataset to supplement training images and improve model generalisation. AVO was used to optimise the network design and hyperparameters,

improving the model's overall performance. Extensive tests on a large-scale image were carried out, and the findings showed a considerable improvement in skin cancer diagnosis and localization accuracy. The following metric was used to assess the model efficiency of the strategy.

For comparison, the following segmentation of skin lesion evaluation criteria was used: precision, recall, F1-score, and accuracy. These parameters were used to assess the model. These are depicted below:

**Accuracy:** It calculates the fraction of real outcomes including true positives and true negatives across all cases investigated. It is expressed in Eq. (29),

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (29)$$

**Precision:** The ratio of exactly anticipated positive outcomes to overall predicted positive occurrences is defined as precision. The precision is calculated using Eq. (30).

$$Precision = \frac{TP}{TP+FP} \quad (30)$$

**Recall:** The recall measures the proportion of genuine positive samples that were projected to be positive. Using Eq. (31), calculate the value recall.

$$Recall = \frac{TP}{TP+FN} \quad (31)$$

where, FP represents false positive pixels, FN signifies false negative pixels, TP symbolizes true positive pixels, and TN describes true negative pixels.

**F1-score:** In the categorization task, recall and accuracy relate to one another. Although a high value for both is ideal, the reality is generally great accuracy with low recall, or high recall with low accuracy. To account for both recollection and accuracy, the F1-score, which is a mean of recall and accuracy, can be employed. Eq. (32) shows the definition of F1-score.

$$F1 - score = 2 * \frac{Precision*Recall}{Precision+Recall} \quad (32)$$

TABLE I. PERFORMANCE METRICS OF PROPOSED METHOD

Proposed GAN-BiLSTM with AVO	
Performance Metrics	Values (%)
Accuracy	98.5
Precision	98.1
Recall	98
F1-score	98

The assessment results of the created skin cancer detection system employing the combined strategy are shown in Table I. At 98.5%, the accuracy is exceptionally high. Precision, which measures the percentage of accurate positive predictions compared to all positive forecasts, is an outstanding 98.1%. The system's capacity to accurately detect real positive cases is demonstrated by the recall measure, also known as sensitivity which is remarkably high at 98%. At 98%, the F1-score, which balances recall and accuracy, is very impressive.

With high values across key performance parameters, these findings show precise and reliable skin cancer diagnosis. Fig. 7 illustrates the performance assessment of proposed GAN-Bi-LSTM with AVO.

Table II shows the Accuracy, Recall Precision and F1-score of the proposed approach with existing methods. The accuracy of the suggested method GAN-Bi-LSTM with AVO (98.5%) is higher than the existing approaches convnet (91.03%), Inception RESNET (91%) and RESNET-18(94.47%). Fig. 8 depicts the graphic depiction of the

performance metrics of proposed with existing approaches. The precision of the suggested method GAN-Bi-LSTM with AVO (98.1%) is higher than the existing approaches convnet (91.09%), Inception RESNET (91%) and RESNET-18(93.57%). The recall of the suggested method GAN-Bi-LSTM with AVO (98%) is higher than the existing approaches convnet (90.96%), Inception RESNET (91%) and RESNET-18(94.01%). The F1-score of the suggested method GAN-Bi-LSTM with AVO (98%) is higher than the existing approaches convnet (91.01%), Inception RESNET (91%) and RESNET-18(94.45%).

Fig. 7. Performance assessment of proposed GAN-Bi-LSTM with AVO.

TABLE II. PERFORMANCE METRICS OF PROPOSED METHOD IS EVALUATED WITH EXISTING METHODS

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)
Convnet [28]	91.03	91.09	90.96	91.01
Inception RESNET [29]	91	91	91	91
RESNET-18 [30]	94.47	93.57	94.01	94.45
Proposed method	98.5	98.1	98	98

Fig. 8. Graphical illustration of the performance metrics of proposed with existing approaches.

Fig. 9. Graphical depiction for training and validation accuracy of proposed method.

Fig. 10. Graphical representation of loss in proposed AVO-Bi-LSTM.

The accuracy level and loss rates fluctuation graphs for the entire GAN-based AVO-Bi-LSTM model procedure are displayed in Fig. 9 and 10. The accuracy ratio and loss ratio overall graph has stabilized at the training intervals of the GAN-based AVO-Bi-LSTM are at 100, and it is clear that the GAN-based AVO-Bi-LSTM fits data more quickly.

Fig. 11. Fitness improvement over iterations (AVO).

Before optimisation the value of accuracy for proposed GAN based AVO-Bi-LSTM is 98%. The accuracy achieved after optimisation using AVO is 98.5%. The fitness of AVO is depicted in Fig. 11. Using Eq. (33), the Area Under the Curve (AUC) has been calculated to estimate AVO-Bi-LSTM's overall performance. Fig. 12 shows ROC curve for the GAN-based AVO-Bi-LSTM model, and it can be seen that the ROC area is nearly close to 1, confirming the model's good stability and potential for usage as classification model for skin cancer diagnosis.

$$AUC = \frac{1}{2} \left( \frac{TP}{TP+FN} + \frac{TN}{TN+FP} \right) \quad (33)$$

AUC of proposed GAN based AVO-Bi-LSTM is compared with existing model (mAlexNet + Bi-LSTM) is given in Table III.

TABLE III. AUC OF PROPOSED GAN BASED AVO-Bi-LSTM IS COMPARED WITH EXISTING MODEL

Architecture	AUC
mAlexNet + Bi-LSTM	0.97
Proposed AVO + Bi-LSTM	0.985

In Table III, two distinct architectures are evaluated for their melanoma detection capabilities. The first architecture, which combines modified AlexNet (mAlexNet) with a Bi-LSTM network, achieves an Area Under the Curve (AUC) of 0.97. This indicates a strong ability of the mAlexNet and Bi-LSTM combination to victimize melanoma. In comparison, the proposed approach, utilizing Artificial Vulture Optimization (AVO) for feature selection in conjunction with a Bi-LSTM network, outperforms the former with an AUC of 0.985. The higher AUC value achieved by the proposed AVO + Bi-LSTM architecture underscores its superior ability to effectively distinguish melanoma cases from non-melanoma instances, highlighting its potential as an advanced and promising model for accurate melanoma detection in skin lesion images.

Fig. 12. ROC curve for proposed AVO-Bi-LSTM.

## A. Discussion

The proposed study aimed to significantly enhance the accuracy of melanoma detection in skin images by employing a novel AI-driven approach combining African Vulture optimization (AVO) with a Generative Adversarial Network (GAN)-based Bidirectional Long Short-Term Memory (Bi-LSTM) deep framework. This innovative approach harnessed GANs to generate realistic and diverse synthetic images, augmenting the original dataset to improve model generalization. AVO was utilized to optimize network design and hyperparameters, resulting in a substantial boost in the overall performance of the model. Extensive testing on a large-scale image dataset yielded highly promising results, showcasing a remarkable improvement in skin cancer diagnosis and localization accuracy. The evaluation of the model's efficiency was based on standard segmentation criteria, including precision, recall, F1-score, and accuracy. The results were exceptionally favorable, with an accuracy rate of 98.5%, precision at 98.1%, recall reaching 98%, and an impressive F1-score of 98%, indicating the model's precision and reliability in skin cancer diagnosis.

Comparing the proposed approach with existing methods, the superiority of the GAN-Bi-LSTM with AVO method was evident. Its accuracy of 98.5% outperformed other methods such as Convnet (91.03%), Inception RESNET (91%), and RESNET-18 (94.47%). Similarly, the precision, recall, and F1-score of the proposed method were significantly higher than those of existing methods, reaffirming its effectiveness in accurate melanoma detection. Visual representations of performance metrics, as depicted in Fig. 7, 8, 9, and 10, further illustrated the consistent and stable performance of the GAN-Bi-LSTM with AVO model. Moreover, AVO optimization yielded an even higher accuracy of 98.5%, compared to the initial accuracy of 98%, as shown in Fig. 11. The Area Under the Curve (AUC) analysis also indicated the superiority of the proposed AVO + Bi-LSTM architecture over an existing model, with an AUC of 0.985 compared to 0.97, underscoring its potential as an advanced and reliable model for accurate melanoma detection in skin lesion images.

## VI. CONCLUSION

The research introduces an AI-powered framework that combines African Vulture Optimization with Generative Adversarial Networks (GANs) and Bidirectional Long Short-Term Memory (Bi-LSTM) networks for melanoma detection. This study serves as an illustrative example of Bi-LSTM's application in identifying skin cancer from lesion images. GANs are harnessed to address data imbalance, generating additional data to enhance detection. Furthermore, the research devises an ensemble model that synergizes Bi-LSTM and GANs, surpassing the performance of the standalone deep learning model. Employing an iterative AVO evolutionary method enhances a population of solutions via fitness assessment. Depending on outcomes, this approach could potentially outperform existing artificial intelligence methods. Ultimately, the proposed hybrid deep learning framework, incorporating GANs and AV optimization, notably improves the accuracy of skin cancer detection and localization within skin images. The integration of GANs and AV optimization

effectively tackles data limitations and optimizes deep learning models, contributing to the advancement of melanoma diagnosis. The future work explores the integration of other imaging modalities, such as dermoscopy or infrared imaging, alongside the proposed framework to enhance the model's ability to detect melanoma across various imaging sources.

**Abstract**—Diabetes is a potentially sight-threatening condition that can lead to blindness if left undetected. Timely diagnosis of diabetic retinopathy, a persistent eye ailment, is critical to prevent irreversible vision loss. However, the traditional method of diagnosing diabetic retinopathy through retinal testing by ophthalmologists is labor-intensive and time-consuming. Additionally, early identification of glaucoma, indicated by the Cup-to-Disc Ratio (CDR), is vital to prevent vision impairment, yet its subtle initial symptoms make timely detection challenging. This research addresses these diagnostic challenges by leveraging machine learning and deep learning techniques. In particular, the study introduces the application of Restricted Boltzmann Machines (RBM) to the domain. By extracting and analyzing multiple features from retinal images, the proposed model aims to accurately categorize anomalies and automate the diagnostic process. The investigation further advances with the utilization of a U-network model for optic segmentation and employs the Squirrel Search Algorithm (SSA) to fine-tune RBM hyperparameters for optimal performance. The experimental evaluation conducted on the RIM-ONE DL dataset demonstrates the efficacy of the proposed methodology. A comprehensive comparison of results against previous prediction models is carried out, assessing accuracy, cross-validation, and Receiver Operating Characteristic (ROC) metrics. Remarkably, the proposed model achieves an accuracy value of 99.2% on the RIM-ONE DL dataset. By bridging the gap between automated diagnosis and ophthalmological practice, this research contributes significantly to the medical field. The model's robust performance and superior accuracy offer a promising avenue to support healthcare professionals in enhancing their decision-making processes, ultimately improving the quality of care for patients with retinal anomalies.

**Keywords**—Optic disc (OD); Optic cup (OC); U-network; restricted Boltzmann machines; squirrel search algorithm

## I. INTRODUCTION

Diabetes mellitus, a common metabolic problem characterized by increased blood sugar levels, can cause diabetic retinopathy, a chronic and progressive eye condition. The retina, the light-sensitive tissue at the back of the eye in charge of conveying visual information to the brain, is especially impacted by this disorder that poses a threat to eyesight [1]. The primary cause of adult blindness globally is diabetic retinopathy, which is of great public health concern. The slow destruction of the tiny blood vessels that supply the retina is the defining feature of diabetic retinopathy. Long-term exposure to high blood glucose levels, a characteristic of diabetes, can erode and potentially harm these vulnerable blood vessels. As a result, they can start to leak, causing fluid and lipid deposits to build up in the retina. Alternately, they may narrow and reduce the retina's blood supply, causing the release of growth hormones that promote the development of aberrant blood vessels. Because these aberrant blood vessels are weak and prone to bleeding, the retina might sustain additional harm.

In order to properly manage diabetic retinopathy, early identification and prompt care are essential. Regular eye exams and specialized imaging methods, such as fundus images and optical coherence tomography (OCT), are crucial for identifying this problem and tracking its development. The development of automated methods for diabetic retinopathy screening has also been aided by developments in artificial intelligence and machine learning, which have the potential to enhance the accessibility and effectiveness of early diagnosis and treatment. Understanding and resolving the complexity of diabetic retinopathy remain crucial in preventing vision loss and raising the quality of life for people with diabetes as diabetes incidence rises internationally [2]. Recently, automated diabetic retinopathy identification using retinal

scans has shown promise thanks to machine learning. Machine learning algorithms are capable of classifying the severity of diabetic retinopathy with amazing accuracy after analysing large datasets of retinal images and extracting pertinent information. Achieving consistently excellent performance across various patient demographics and image quality situations still presents a number of obstacles. The diagnostic accuracy of traditional machine learning algorithms can be hampered by the difficulty with which complicated, hierarchical patterns in retinal images can be captured. This has motivated academics to investigate more sophisticated deep learning techniques, such as CNNs and RBMs, to improve the identification of diabetic retinopathy.

The retina was a sphere located on the retina's inner side at the eye's rear. Its purpose has been to interpret visual data using the cones and rod and other image receptors found in the eye. The macula, or retina's central region, has a black, rounded area. Sharp eyesight was provided by the macula's fovea, which is located at its centre. The body's circulatory supplies blood to the retinal cells, just like it does for any other type of tissue. Each of the veins and main arteries enter and depart the eye through the optical disc, which is formed by an optic cup. It also serves as an organ wherein the optical nerve exits the eye. The efficacy of treatments in the medical sector is increased by early illness identification. Whenever the pancreas doesn't create enough insulin, diabetes looks to be a disorder that becomes progressively. A severe public health issue, diabetes mellitus currently affects 463 million individuals globally and is expected to reach 700 million in 2045. Diabetic retinopathy (DR), a commonly prevalent eye condition associated with diabetes, affects at least 1/3<sup>rd</sup> of people who have the condition [3]. No matter how severe their diabetes has been every patient with diabetes may acquire DR, which is characterised by increasing vascular disturbances in their retinas. Non-proliferative DR (NPDR) and PDR are the two common stages of DR [3]. Among the most popular clinical measures, the International Clinical DR (ICDR) dimension, has five DR severity levels: regular, mild, serious, moderate, and excessive [4]. There has been thought to be 93 million individuals living with DR globally, making it the main causes of blindness amongst working-age individuals. These numbers are expected to rise even higher, largely as a result of rising prevalence of diabetes in emerging Asian countries like China and India [4]. Whereas the early phases of DR are typically asymptomatic, neuronal retinal injury and clinically undetectable microvascular alterations advance during this time [5]. As a result, people with diabetes should undergo routine eye exams because prompt identification and treatment of the problem are crucial [4]. Flashes and floaters, vision loss, and blurred vision have been the main signs and manifestations of DR [4]. The macula is impacted by DR, which is brought on by metabolic changes inside retinal blood cells, caused because of abnormal blood flow, and blood components and blood leaks throughout the retina. As a result, the retinal membrane swells and causes vision to become hazy or blurry. The condition damages both eyes, and with continued untreated diabetes for an extended period of time, diabetic maculopathy results in blindness [6]. Early recognition of DR has been even more crucial given that the primary preventive approach was the treatment of

hyperlipidemia, hypertension, and hyperglycemia [5]. Additionally, if diabetic maculopathy and proliferative retinopathy have been cured in the initial phases of the illness, there is a considerable reduction in the risk of blindness with currently accessible therapies, including laser imageocoagulation. It becomes clear that early identification and suitable therapy are crucial for delaying or even preventing blindness from DR [7].

With the aid of specific medically recognised and authorised comparing agents that have been inserted towards the retina, the pupil elongation occurs in order to monitor the retinal structure, including the RBVs, macula, fovea, and Optic Disc (OD). This approach makes use of a mydriatic foundation video or the fluorescein catheterization (FA). This helps to collect fundus images from people with diabetes so they may be examined for the accurate diagnosis as well as the detection of DR. Manual techniques, including bio-microscopy, fundus retinal images, Optical Coherence Tomography (OCT), Adaptive Optics, Retinal Oximetry, Scanning Laser Ophthalmoscopy (SLO), OCT Angiography, Doppler OCT, Retinal Thickness Analyzer (RTA), and many others, can be used to identify DR early on [8]. Nevertheless, the manual analysis of the disease using these traditional approaches is laborious, time-consuming, and extremely error-prone. Additionally, it necessitates an advanced task force, which is occasionally impractical given the current situation. Therefore, it is not possible to carry out manual identification for DR early identification at any moment or location. As a result, the magnitude of these difficulties has spurred extensive study and the creation of methods that instinctively analyse data and detect the DR onset. This is mainly due to the desire to lower the expense of treating the illness. The common objective of increasing the effectiveness of healthcare services has been supported by developments in medical technology [9]. e-Health structures, for instance, have been effective being employed in an assortment of healthcare routes [10], [11]. In the biomedical imaging discipline, computer vision-oriented systems are becoming more significant. They offer the radiologist valuable decision support data that improves the prognosis and effectively informs medical personnel on the optimum efficient therapies for important medical diseases. Various image modalities, including 7-field colour fundus images (CFPs), ultra-wide-field-SLO (UWF-SLO), and colour fundus images (CFIs), were employed for the evaluation and therapy of DR in the particular medical imaging realm. Benefits could include less labour for the ophthalmologist as well as a lower risk of human miscalculation. Additionally, compared to manual detection, a computerised system might be far more effective and easily able to spot lesions and anomalies. Automated of DR identification is therefore crucial. Artificial Intelligence (AI) techniques can be used to create the DR automation systems.

Development in research and innovation has improved the quality, safety, and liveability of individual life. For example, a cutting-edge field of study called automatic medical imaging assessment uses imaging technologies to spot dangerous disorders. These Computer-Aided Diagnostic (CAD) tools, also known as automatic diagnosis systems (ADSSs), offer

amenities for the benefit of people. The use of CAD systems was acknowledged in a wide range of clinical diagnoses, including the identification of brain tumours, DR, gastrointestinal problems, glaucoma, macular oedema, and many others [12]. With personal observations, such CAD technologies have generated outcomes that are comparable. The creation of CAD tools depends on the image attributes that are computationally retrieved from images [13]. Clinical staff must manually examine DR abnormalities and retinal anatomy characteristics. Furthermore, observing intra- or inter-changes in retinal elements needs technical domain expertise because human examination of DR has been subjective. As a consequence, earlier DR screening programmes with colour fundus images must be carried out by CAD technologies. Clinical staff may spend less time, money, and effort manually analysing retinal images thanks to these CAD tools [14], [15]. AI offers the ability to completely alter how eye diseases have been now diagnosed and have a profound therapeutic effect on advancing ophthalmic treatment. Prior research on automatic DR identifications has been conducted. A useful method for the automatic identification and evaluation of DR has grown up: deep analysis of fundus images. The patients in physically underserved regions where there are few ophthalmologists and scarce medical facilities could benefit from the efficient deep learning (DL) system's ability to accurately and automatically recognise more severe DR with comparable or superior reliability than learned instructors and retina experts [16].

Machine Learning (ML) is a subgroup of DL that has grown stronger and increasingly effective as a weapon. DL is also an ideal complement to ML. The DL architecture is made up of a multifaceted, hierarchical design. Classifying, segmenting, localising, and identifying medical images are major DL tasks in clinical image assessment. DL offers more promising and outstanding outcomes in the diagnosis and categorization of DR diseases using a variety of techniques. Convolutional Neural Networks (CNN), Auto encoders, Generative Adversarial Networks (GAN), Recurrent Neural Networks (RNN), Deep Boltzmann Machines (DBM), Deep Belief Networks (DBN), and Deep Neural Networks (DNN) have been a few examples of DL-based approaches. The model performs better when there has been additional training information since both low-level and high-level characteristics have been automatically retrieved and trained [17]. Convolutional Neural Networks (CNN), a fundamental framework of DL in computer-vision, have produced outstanding results with regard to forecasting and detection in the medical images categorization. By autonomously segmenting the region-of-interests (ROIs) from the initial images, DL methods streamline the feature retrieval procedure. Additionally, these methods offer a complete answer for developing and assessing the categorization model. In DL methods, The DR images have been initially gathered. The acquired DR images have been then subjected to preprocessing methods like contrast enhancement, lighting modification, and scaling to remove noisy features. After being pre-processed, those images have been sent to the DL design, which uses the learning images' distinctive characteristics as input and the retrieved attributes and their scores to acquire categorization rules. In DL training, the

attribute weights have been recursively optimised to get the optimal characteristics weight and more precisely categorise the images. These optimised weights have been finally examined on unlabelled images via a categorization layer. The use of cloud computing has permeated almost every element of human life. Cloud computing, on the other hand, has limits in terms of prolonged delays, which are detrimental to IoT activities that require real-time responses [18]. The key contribution is discussed as follows:

- The research highlights the critical importance of early diagnosis for diabetes-related retinal conditions, which can potentially lead to blindness if not identified and managed in a timely manner.
- The paper recognizes the challenges posed by labour-intensive and time-consuming traditional methods of diagnosing diabetic retinopathy and the subtlety of early glaucoma symptoms. It underscores the need for more efficient diagnostic techniques.
- The study integrates machine learning and deep learning techniques to address these challenges. Notably, the introduction of Restricted Boltzmann Machines (RBM) showcases an innovative approach to enhance the accuracy and efficiency of the diagnostic process.
- The proposed model extracts and analyses multiple features from retinal images using RBMs, facilitating the accurate categorization of anomalies. This approach holds the potential to significantly expedite the diagnostic process.
- The research further extends its impact by introducing a U-network model for optic segmentation, contributing to more precise and reliable diagnostics.
- The application of the SSA to fine-tune RBM hyper parameters demonstrates a commitment to achieving optimal model performance.
- Rigorous experimentation using the RIM-ONE DL dataset substantiates the effectiveness of the proposed methodology. The high accuracy achieved serves as a testament to the model's robustness and potential clinical relevance.
- The comprehensive comparison against previous prediction models, incorporating metrics like accuracy, cross-validation, and ROC, underscores the model's superiority in diagnostic capabilities.

The structure of this article is organized as follows: Section II reviews previous research on prediction problems using various optimization methodologies. Section III, image pre-processing improve and adjust the brightness. The OD and OC are segmented using a Threshold U-Network. Section IV discusses the rim-one-dl dataset results. Section V, experimental evaluation comprises mathematically developed system models for sensitivity, specificity, accuracy, and AUC. Section VI concludes the paper.

## II. RELATED WORKS

A computer vision-based method to analyse and forecast diabetes from input retinal images was proposed by Mini Yadav et al. [19]. This facilitates the early identification of DR. Pre-processing, feature extraction, and segmentation techniques are used in the aforementioned image processing stage. Following the image processing procedures, the categorization step using ML is carried out. Python is employed for better research outcomes. For designing the coding for the empirical outcomes' platform, investigators use Jupyter. The framework created was tested on databases from open access public repositories, and it used CNN to obtain 98.50% accuracy as opposed to SVM's 87.40% accuracy. These outcomes outperform a number of sophisticated unsupervised ML approaches. It leads to a reduction in procedure complexity and enhanced evaluation metrics, making it appropriate for application in the DR detection employing retinal image assessment. The study asserts that their unsupervised ML approach outperforms previous methods, but in order to judge the robustness and generalizability of the suggested method, it must be tested on independent databases. The dependability of the outcomes might not be ensured in the absence of external testing.

The multi-scale attention network (MSA-Net) was proposed by Mohammad and Yasmine [20] for DR categorization. The suggested method uses an encoding network to place the retinal images in an upper-level representational space, enriching the representation by combining middle- and the highest-level information. The retinal morphology in a distinct locale is then described using a multi-scale characteristic hierarchy. A multi-scale attention system is added on the highest of the upper-level structure in order to improve the feature depiction's ability to discriminate. The cross-entropy loss has been employed to learn the framework in a conventional manner, and it is used to categorise the DR seriousness level. In addition, the model is instructed to distinguish between healthy and unhealthy retinal images employing the poorly annotated information. This stand-in exercise aids the model in improving its ability to distinguish between unhealthy retinal images. When used, the suggested strategy produced remarkable outcomes on the APTOS and EyePACS public databases. The study discusses the application of poorly labelled data to help the algorithm distinguish among retinal images that are healthy and those that are ill. However, if the annotations have not been precise or thorough adequate to capture the entire spectrum of abnormal retinal images, the efficacy of this method may be constrained. The training process may become biased and noisy due to insufficient annotations.

A CNN-oriented strategy was suggested by Worapan et al. [21] as a means of identifying and evaluating DR from retinal images. It could categorise the retinal images that were supplied into a normal group or atypical group that would then be automatically divided into four levels of anomalies. The suggested solution has been predicated on DeepRoot, a recently suggested CNN framework. It has one major branch and two subsidiary branches that link it. The principal feature generator for both upper- and lower-level attributes in retinal images resides in the central branch. The characteristics

produced from the central branch are then subsequently extracted by additional branches to provide more intricate and comprehensive characteristics. They use customised zoom-in/out and attenuation stratum to record the fine details of minuscule remnants of DR within retinal images. Moreover, the Kaggle database is used to train, verify and test the suggested approach. Using examples of unknown information that the researcher independently acquired from an actual circumstance in a hospital, the learned model's regularisation is assessed. Under the two categories scenario, it performs admirably, with 98.18% sensitivity. Although the research suggests evaluating the regularisation of the trained model using samples of unknowable information obtained from a healthcare facility, the specifics and extent of this verification have not been given. To guarantee that the model's performances comply with the desired purpose and to gauge its efficacy in practical contexts, rigorous real-world verification studies must be carried out in clinical settings.

Employing CNN, Raja and Balaji [22] created a reliable automated diabetic identification system for retinal images. The proposed system primarily consists of five components like preprocessing, exudates segmentation, blood vessels segmentation, extraction of textural features, and diagnosis of diabetes. The input retinal image is initially enhanced during the preprocessing stage employing adaptive histogram equalisation (AHE). As a result, fuzzy c-means clustering (FCM) and CNN have been employed for segmenting exudates and blood vessels, respectively. Following that, exudates and blood vessels are used to extract textural properties. Following extracting features, a support vector machine (SVM) is used to classify diabetic patients. The experimental findings show that, when compared to other methodologies, the suggested approach achieves improved diabetic diagnosis outcomes (sensitivity, specificity, and accuracy). To guarantee the suggested method's suitability for various populations and changes in retinal images, its efficacy and adaptability should be tested on separate databases. If various datasets were utilised to show the system's durability, the assessment should have been done on many databases, and this should be specified in the study.

The likelihood of vision loss may be considerably reduced by early diagnosis and treatment with DR. Analysis of retinal image has gained popularity as a method of disease detection in contemporary ophthalmology. Fundus angiography has been frequently used by ophthalmologists and computerised systems to find DR-based clinical indicators for DR earlier detection. Because of the imaging situations complexity, like imaging in a range of angles and lighting circumstances, fundus images are frequently exposed to inadequate contrast, sound, and inconsistent illumination problems. By lowering the noise and boosting the contrast, Saif Hameed et al. [23] proposed an algorithm for enhancing image quality that will reinforce the norm for colour fundus imaging. The method involves two primary steps: shrinking the images to eliminate extraneous information, followed by performing the shape cropping as well as gaussian smoothing to boost contrast and reduce noise. MESSIDOR and EyePACS represent two common datasets used to assess the research outcomes. It has been amply demonstrated that the findings of improved image

feature retrieval and categorization surpass those obtained without using the enhancement technique. As an IoMT usage, the updated algorithm has also been evaluated in smart hospitals. Although the research includes evaluating the revised method in smart hospitals, it is vital to take into account the practical difficulties and prerequisites for clinical deployment in the actual world. This entails integration with currently in use medical imaging equipment, regulatory authorizations, and professional acceptability. These issues should be covered in the study together with information on the difficulties and possible clinical advantages of applying the method in a clinical context.

Anas Bilal et al. [24] proposed an innovative two-stage method for automatic DR categorization. Data augmentation and pre-processing methods have been utilised to improve the image clarity and quantity because the asymmetric blood vessels (BV) and Optic Disc (OD) identification system has a low percentage of positive cases. For BV and OD segmentation during the first stage, two distinct U-Net algorithms are used. Subsequent to preprocessing for extracting and selecting the most discriminating characteristics after BV and OD extraction employing Inception-V3 depending on transfer learning (TL), the symmetrical integrated CNN-SVD framework has been developed in the secondary phase. It recognises DR by identifying retinal indicators like exudates, haemorrhages, and microaneurysms. The suggested approach displayed cutting-edge efficiency on the Messidor-2, DIARETDB0, and EyePACS-1 tests, with mean accuracy readings of 94.59 per cent, 93.52 per cent, and 97.92 per cent, correspondingly. The effectiveness of the recommended approach has been demonstrated through extensive evaluations and comparability with benchmark methods. The low affirmative case prevalence for asymmetric BV and OD recognition can make it difficult to train and assess the algorithms. The accuracy and generalizability of the suggested strategy, especially for identifying certain abnormalities connected to DR, may be impacted by the dearth of positive instances.

Phridviraj et al. [25] presented a bi-directional LSTM-oriented DR diagnosis model employing retina fundus images. The Bi-directional LSTM approach uses retinal fundus images to identify and categorise various categories of DR. The Multiscale Retinex alongside Chromaticity Preservation (MSRCP) technique is used in the suggested framework as a preprocessing stage to raise fundus image disparity and advance short discrepancy of pharmaceutical perspectives. Moreover, MSRCP is utilised to create results that are adequate for processing images. The key challenge regarding the Retinex method is setting the values for the variables, including the gain, offset, Gaussian scales, etc. Such parameters need to be altered to produce a useful result. The major objective of the presented approach is to get the ideal settings for the MSRCP procedure's variables. Additionally, an effective net-based characteristic extraction that makes of DL is used to create feature vectors from already processed images. The standard MESSIDOR database is used in numerous experiments. The outcomes are examined in light of several evaluating criteria. The findings demonstrate that the Bi-LSTM-MSRCP methodology is superior to more

contemporary techniques for DR diagnosis. Even if the research shows better results than current methods, it's crucial to take the comprehension of the suggested model into account. Since bi-directional LSTM models are frequently regarded as "black-box" models, it might be difficult to comprehend how decisions are made and the particular characteristics that contribute to DR diagnosis. The clinical acceptance and confidence in the paradigm may be constrained by its lack of comprehension.

For the purpose of DR identification, Loheswaran [26] suggested the Optimised Kernel-oriented Fuzzy C-Means (OKFCM) based Segmentation and RNN-based Categorization scheme. OD elimination and KFCM Separation performed using Modified Ant Colony Optimisation (ACO) are the two primary stages within the recommended segmentation portion. GLCM and time-built characteristics have been utilised for the grading of DR. The OKFCM-MACO-RNN was another name for the suggested framework. The OKFCM-MACO-RNN technique's sensitivity, accuracy, and specificity have values of 81.65 percent, 99.33 percent, and 99.42 percent, accordingly, have been adjusted to finish the OKFCM-MACO-RNN categorization assessment procedure in the diaretDB1 database. The OKFCM-MACO-RNN approach can be relied upon to reliably detect exudates. The OKFCM-MACO-RNN based Segmentation are evaluated with jacquard coefficient, accuracy, and dice coefficient having values of 72.84, 85.65, and 93.15 correspondingly. The quantity and variety of the database employed for learning and evaluation have a significant impact on how well the suggested framework performs. The diaretDB1 dataset has been mentioned in the study, but it is crucial to evaluate the dataset's representativeness and determine whether it effectively accounts for the variety of DR situations that are experienced in real-world circumstances. The algorithm might not work as well on other databases.

It is quite challenging to diagnose DR through laborious physical diagnosis because of the variety and complexities of DR. As a result, Spoorthi and Rekha [27] concentrated on employing an RNN-LSTM and Deep CNN (DCNN) integration to categorise a specific collection of fundus images into four phases. This method recognises all DR phases instantly. This mixture takes a lot of details from the fundus image. To create the integrated model, over 2000 fundus images have been utilised overall. This work shows that the precision of forecasting the DR phases has been greatly increased by the retrieval of those characteristics from fundus images employing RNN-LSTM and DCNN. To determine the combined model's suitability for use with various populations and changes in retinal images, its efficacy and generalizability should be examined on separate databases. To show the approach's resilience and dependability across various datasets, additional verification is required.

### III. PROBLEM STATEMENT

This study focuses on improving diabetic retinopathy diagnostic accuracy and efficiency using machine learning and RBMs. Diabetic retinopathy is a major consequence of diabetes that, if not identified early, can result in blindness.

Current approaches for detecting diabetic retinopathy frequently rely on ophthalmologists doing manual assessments, which can be expensive, time-consuming, and prone to inter-observer variability. Additionally, existing automated methods sometimes have trouble recognizing retinal abnormalities with high sensitivity and specificity. The suggested strategy tries to use RBMs, a class of neural network capable of learning hierarchical representations of data, to improve the automated identification of diabetic retinopathy in order to overcome these constraints. By doing this, it hopes to provide an alternative to current techniques that is more precise, effective, and consistent [24].

However, the limits of existing diabetic retinopathy detection techniques call for improvements. First off, the diagnostic accuracy of traditional machine learning algorithms is sometimes constrained by their inability to grasp the complex patterns and subtle elements seen in retinal images. Additionally, the lack of extensive, diverse datasets for training and testing might limit the capacity of present models to generalize, particularly when faced with differences in retinal images that occur in the real world. The promise of deep learning methods like RBMs, which can build intricate, hierarchical representations from data, is also underutilized in many current approaches. The need to build a strong, RBM-based solution that can not only exceed existing approaches in terms of accuracy but also adapt successfully to changes in image quality, illness development, and patient demographics is therefore appealing.

#### IV. PROPOSED METHODOLOGIES

Retinal image analysis is essential to perform mass screening, even if there is a lack of experienced doctors. This work presents RBM images, the analysis uses numerous features to predict formation in images. The steps used are image acquisition, pre-processing, segmentation, and glaucoma classification. Initially, retinal fundus images are obtained from the public data source. Pre-processing is necessary to eliminate unwanted image features such as speckles, blind spots etc. The OD and OC is performed using a Threshold U-Network (Two-stage TUNet). Next, the deep features such as contrast, homogeneity, mean disc, correlation, SD (standard deviation) disc, energy disc, entropy disc,

entropy cup, SD cup, mean cup, energy cup, etc., are extracted. Fig. 1 shows flow diagram of deep learning based retinal image analysis.

##### A. Dataset Collection

Some confusion and incorrect usage of the three published versions prompted the proposal to update and integrate DL (rim one for deep learning), an updated version of them, was created using them. With profound learning in mind, it is designed to meet the standards mentioned earlier for the environment. The outcome of integrating the three previous versions is rim-one DL. This gives each patient and each eye a separate image. Additionally, all images were correctly cropped around the head of the optic nerve, utilizing the exact same parallelism criterion, which was not done in earlier versions.

##### B. Pre-Processing

Pre-processing techniques such as cropping, channel separation, and data enhancement are used to input images. A image is the removal of external parts by cropping to improve encircling, change the proportions of an angle, or emphasize a subject and resizing image results in a change in its physical size. A tile is divided into the portion of data that is lost due to cropping. The original dataset contained only a limited number of images that could be used as training data. A neural network could not be applied and trained with such an amount of data. Flipping and data rotation has been used as augmentation techniques to overcome this problem. To increase the dimension of the test set, the images first had to be vertically flipped. Images are then flipped vertically, an additional increasing amount of data available. Flipped images were rotated from 0° to 180° in 20° increments after flipping. As a result, the model was effectively trained with a larger data set.

##### C. Segmentation of Images

The technique of splitting an image into its component sections using a segment/part of an image is known as image segmentation. The task of objects is to find a certain subdivision among the provided images. Segmentation is also used in retinal fundus images to investigate structures like the optic disc and optic cup.

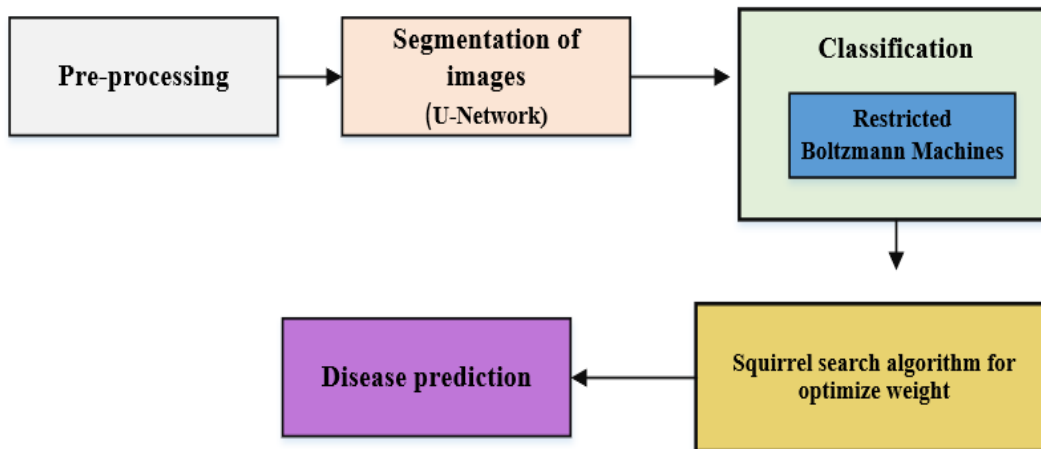

Fig. 1. Flow diagram of deep learning based retinal image analysis.

1) *OD*: The optic nerve head OD is where ganglion cells and axons leave eye to form visual cortex. If there are no shafts or cones, there is a blind zone. Because receptor rods and cones in this region are dull, the corresponding point of tiny blind spot at OD is increased. The OD is widely employed in to determine the cup-to-disc ratio.

2) *OC*: It is located in middle of the optic disc, which appears to be shaped like a white cup. The optical curve is responsible for the mobility of the retina in the human eye. The greater the distance from the optic curve's diameter, the greater the chance of developing glaucoma.

3) *Threshold U-network*: The OD and OC are segmented using a threshold U-network (TUNet). During processing, both OD and OC segmentation are two-stage thresholds [28]. A fundamental image processing approach is threshold segmentation. Varying tissues in medical imaging are often displayed at different levels of intensity. The threshold eliminates the uninteresting areas while also reducing noise interference. This process is both required and efficient. The threshold value must be chosen carefully. The region of interest will be impacted if the threshold range is too tiny; as a result, the experimental results are inaccurate. Noise reduction becomes difficult if the threshold range is set too high. The threshold range is often defined by experience. The two-stage U-Net design is used for the threshold interval computations. As glaucoma detection must be divided into two groups, it is challenging to segregate glaucoma data in real time (OD and

OC).To simplify and reduce the complexity of the problem, a two-stage U-Net framework is used and composed of total glaucoma segmentation and glaucoma substructure segmentation (the second step). The primary goal of the U-net architecture is the segmentation of the many substructures of the system [29]. Fig. 2 illustrates the U-Net framework.

*D. Restricted Boltzmann Machines (RBM) Diabetic Retinopathy Classification*

Using input vector  $f$ , concealed units  $s$ , weights matrices  $C$ , visible biases  $y$ , plus hidden biases  $z$  as shown, the RBM may be shown as a graph that is undirected.

$$L(s = 1|f) = \sigma(z + C.f)$$

$$L(f = 1|s) = \sigma(y + C.s) \tag{1}$$

The binary data acquired by applying the CLBP descriptors is transformed into actual value matrices in our process using RBMs. This information comprises image characteristics which the first set of CNN filters that have been trained under supervision often recognise, such as edges, blobs, or basic forms. Utilising RBMs enables bypassing these layers, leading to a reduced architecture to address a particular image categorization job. As a result, we are able to analyse more complicated features in the initial convolutional layers thanks to our prior processing and the RBM layers. Fig. 4 shows the restricted Boltzmann machine.

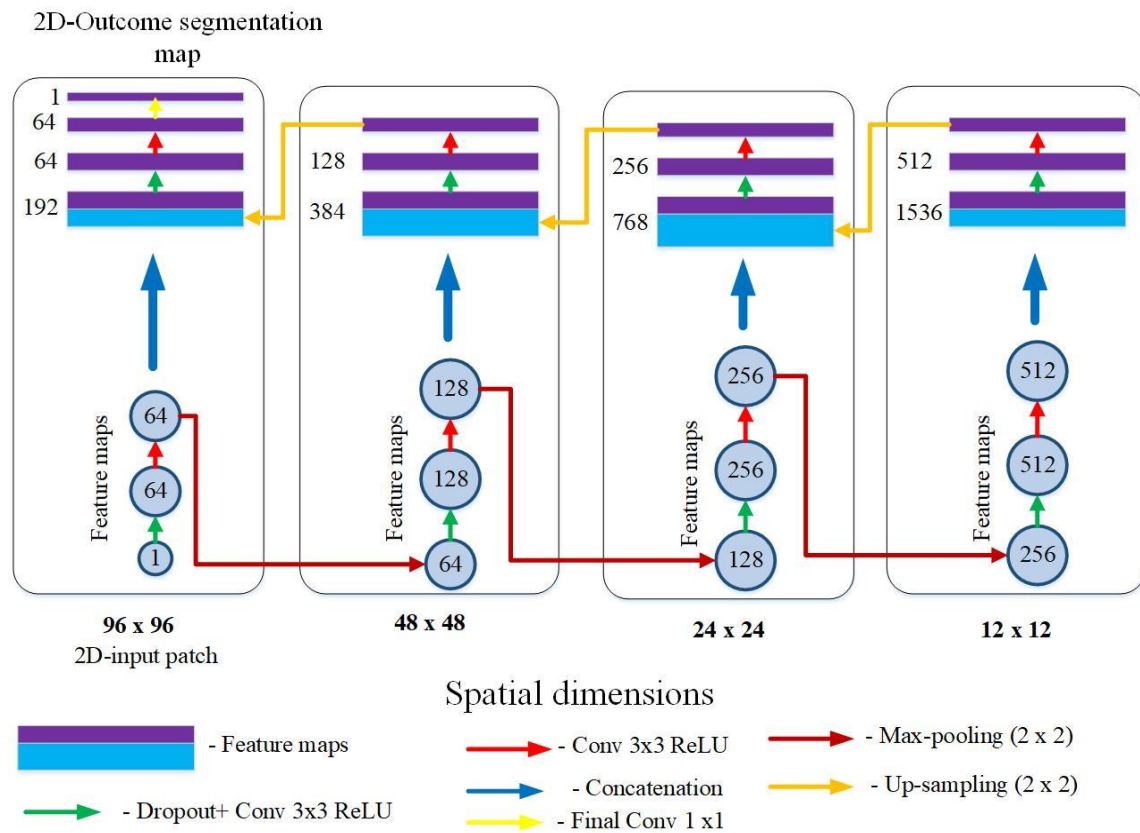

Fig. 2. U-net architecture.

The RBM analyses the information once the CLBP step is complete. The total amount of observable subunits is 16 in the most basic version since descriptor values are supplied immediately to the RBM, and bigger receptivity areas are possible by combining CLBP characteristics from a kernel of size P. The dimension of an output matrix as well as the overlapping sections may be modified using the stride length G. The RBM output vector  $v$  has a length of  $m = P^2$ .

Fig. 3. Illustration of a restricted Boltzmann machine.

The input vector for the RBM is shown in Fig. 3 being created for  $P = 2$ . The RBM layer's feed is a matrix created as following.

$$RBM_{1/P} = \begin{bmatrix} f(1,1) & f(1,2) & \dots & f(1,m) \\ f(2,1) & f(2,2) & \dots & f(2,m) \\ \vdots & \vdots & \vdots & \vdots \\ f(m,1) & f(m,2) & \dots & f(m,m) \end{bmatrix} \quad (2)$$

The numerical value within the  $s_i$  component corresponding to the accessible vector  $f$  is given by because the RBM in this design de facto transforms into a typical neural network feeding forward with the activation function of sigmoid.

$$s_i = \sigma(z_i + \sum_j c_{ji} f_j) \quad (3)$$

In matrices recording, the final solution that describes the RBM level is

$$\sigma(Z + C \cdot RBM_{1/P}) \quad (4)$$

The scope that the vector produced by the preparation workflow relies on the number of hidden elements (RH) or cadence (S), which determines how multidimensional the resulting data is,

$$\left[ \frac{C}{G} \times \frac{S}{G} \times RH \right] \quad (5)$$

wherein, the supplied image's parameters are  $[C \times S]$ . The whole pretreatment workflow and the CLBP-RBM translation are shown in Fig. 4.

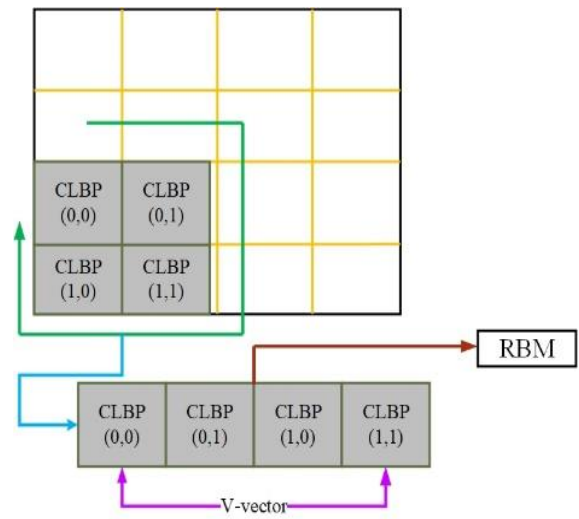

Fig. 4. CLBP kernels.

1) *Squirrel search algorithm for weight optimization*: The proposed method has 2 search methods: the first is jumping method, and second is a broadminded method. As part of evolutionary process, the practical method is automatically selected through the selection strategy of linear regression, which increases the robustness of a squirrel search algorithm. The escape process sufficiently creates a searching area, and the demise procedure uses the leaping mechanism in order to examine the created space. The capacity of SSA to evolve and explore is balanced. Regarding the incremental search approach, mutations operation maintains the present historical data and gives greater consideration to maintaining population diversity.

a) *Random initialization*: Initial population  $W$  was generated randomly with  $k$  number of flying squirrels.

$$W = \begin{bmatrix} W_{1,1} & W_{1,2} & \dots & \dots & W_{1,d} \\ W_{2,1} & W_{2,2} & \dots & \dots & W_{2,d} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ W_{m,1} & W_{m,2} & \dots & \dots & W_{m,d} \end{bmatrix} \quad (6)$$

In this case,  $W_{i,j}$  indicates the  $j^{th}$  dimension of  $i^{th}$  flying squirrel. In a forest, flying squirrels are allocated their initial locations according to a uniform distribution.

$$W_i = W_L + U(0,1) \times (W_U - W_L) \quad (7)$$

A distributed uniformly random number in the range  $[0, 1]$  is  $U(0,1)$ , and  $W_L$  and  $W_U$  represent lower and upper bounds for  $j^{th}$  dimension  $i^{th}$  flying squirrel.

b) *Fitness evaluation*: To calculate the localization, fitness values of the defined by users fitness coefficient has choice parameters (solution vectors) placed into it. The following table contains the values that were obtained:

$$f = \begin{bmatrix} f(|W_{1,1}, W_{1,2}, \dots, W_{1,d}|) \\ f(|W_{2,1}, W_{2,2}, \dots, W_{2,d}|) \\ \vdots \\ f(|W_{n,1}, W_{n,2}, \dots, W_{n,d}|) \end{bmatrix} \quad (8)$$

The value of fitness neural network layer weight depicts the quality of optimal weight. Here  $W = (w_t^c, w_t^{cap}, w_t^{GRU})$ , after storing the fitness values, array is sorted in ascending order. The squirrel with a minimum chestnut nut tree declares itself to have a fitness value. Afterwards, best three flying squirrels are thought to move to hickory nut trees from acorn trees.

c) *Generating location:*

Case 1: Hovering squirrels may move from acorn nut trees  $(W_{i,j})_{ant}$  to hickory nut trees  $(W_{i,j})_{hnt}$ . It is possible to determine the new location of squirrels in this case by following these steps:

$$(W_{i,j})_{ant} = \begin{cases} (W_{i,j})_{ant} + x_g \times s_c \times ((W_{i,j})_{hnt} - (W_{i,j})_{ant}) & \text{if } R_1 \geq P \\ \text{random location} & \text{otherwise} \end{cases} \quad (9)$$

Where  $x_g$  indicates a distance of random gliding,  $R_1$  indicates a random number in range of [0,1],  $(W_{i,j})_{hnt}$  denotes location of squirrel reached hickory nut tree and  $t$  represent current iteration. In mathematical model, the gliding constant  $s_c$  is used with the purpose of striking a balance amid exploration and extraction.

Case 2: A squirrel on a normal tree  $(W_{i,j})_{nort}$  can move towards an acorn tree; new location of the squirrel can be determined as follows:

$$(W_{i,j})_{nort} = \begin{cases} (W_{i,j})_{nort} + x_g \times s_c \times ((W_{i,j})_{ant} - (W_{i,j})_{nort}) & \text{if } R_2 \geq P \\ \text{random location} & \text{otherwise} \end{cases} \quad (10)$$

Case 3: In some cases, squirrels that have already consumed acorns on normal trees may settle in hickory trees to stockpile beech nuts which might be eaten during famine. Thus, the following information may be used to find new squirrel locations:

$$(W_{i,j})_{nort} = \begin{cases} (W_{i,j})_{nort} + x_g \times s_c \times ((W_{i,j})_{hnt} - (W_{i,j})_{nort}) & \text{if } R_3 \geq P \\ \text{random location} & \text{otherwise} \end{cases} \quad (11)$$

In this case,  $R_3$  represents a random number in the range of [0, 1]. The optimization algorithm was designed using an approximated model of the gliding behaviour. Flying squirrel fitness values are computed, and the locations are updated on

each iteration until the maximum number of iterations is reached.

V. RESULT AND DISCUSSION

The experimental setup, performance measurement, evaluation datasets, and experimental outcomes are all described in this section. The discussion of the results includes an evaluation of the proposed SSA algorithm. OD and OC were trained with the original data and merged with the image to demonstrate the effectiveness of the system based on deep feature extraction and classification.

A. *Simulation Environment*

Evaluate the proposed early-stage glaucoma disease prediction technique using the Python software in a simulated environment utilizing rim-one-dl datasets. The test is run on a machine equipped with an Intel(R) Core (TM) i5 CPU @ 3200 Mhz, 3 core(s), 4 logical pro. And micro software 10 pro, a micro soft corporation, is an OS manufacturer installed physical memory (RAM) 8GM. Table I shows simulation parameters for the rim-one-dl datasets.

TABLE I. SIMULATION PARAMETERS OF BOTH DATASETS

Simulation parameters for Rim-one-dl	Values
Batch size	2
Epoch	100
Activation function	Sigmoid
Dropout	0.5
Kernel size	(3,3)

B. *Performance Evaluation*

Fig. 5 compares the accuracy plot of the proposed ensemble DeepNet with conventional pre-trained models such as CapsNet, VGG 16 and DenseNet for the rim-one-dl datasets. An epoch in artificial neural networks is one loop that covers the whole training dataset. Training a neural network typically takes many epochs. The plot of CapsNet, shows a larger difference between validation and training accuracy. This shows that the model may be overfitted. Furthermore, the improvement in accuracy has not been constant. There are substantial gaps between training and validation at a few epochs. Furthermore, the training accuracy is significantly lower at the last epoch than the validation accuracy.

Furthermore, in the DenseNet plots in figures, the training accuracy is higher than the validation accuracy. This indicates that the model is overfitting, and the peaks are not increasing consistently. The training accuracy of DenseNet is continually rising; however, the validation accuracy is not. There is also a decrease in validation accuracy after a few epochs, which is undesirable. As a result, the model underperforms and is unsuitable for predicting abnormality.

Fig. 5. (a) Accuracy plot.

Fig. 6 depicts the overall performance of several criteria, such as accuracy, specificity, recall, and precision, using the rim-one-dl datasets. It is based on deepnet ensembles such as deep CNN with multi-pooling layer, dual part scaled cross dense network, and graph CapsNet. Accurate is the ratio of correct predictions to the total prediction or true value. It is usually multiplied by 100 to express it as a percentage. It quantifies the accuracy of the classifier model and is scientifically calculated as

$$accuracy = \frac{TP + TN}{P + N} = \frac{TP + TN}{TP + TN + FP + FN} \quad (12)$$

Where  $TP$  denotes True positive,  $TN$  denotes True negative,  $FP$  denotes false positive and  $FN$  denotes false negative. Fig. 6 clearly shows that the proposed one provides the highest accuracy, which is determined to be the rim-one-dl dataset. In contrast, other classifiers provide significantly lower accuracy. In terms of specificity, it again takes the lead regarding values compared to other classifiers. In the KGD dataset, the Capsnet is found to provide an accuracy that is somewhat close to the designed accuracy. CapsNet is an ANN machine learning system that may be used to better simulate hierarchical connections. CapsNet’s slow training and testing, lacks of spatial information is its drawback. As a result, its performance is reduced compared to the proposed model.

Fig. 6. Comparison graph for accuracy.

Also, a DenseNet is a convolutional neural network that uses dense connections between layers through Dense Blocks, which connect all levels directly. Each layer’s DenseNet feature maps are spliced with the previous layer, and the data is copied numerous times. However, the existing dense blocks did not consider the hierarchical features or concatenate the hierarchical features merely without removing the redundant features. As a result, its performance is not high as possible. The VGG16 network is large, implying it takes longer to train its parameters. Also, using the Max pooling layer in VGG16 caused information loss. The proposed model has tackled these issues using multi pooling layer, dual-part scaled cross-dense block and graph CapsNet. Hence, the proposed ensemble model outperforms all the pre-trained models shows in Fig. 6.

The rim-one-dl dataset utilized in the proposed research is one example of a dataset with varied comparison results that might vary due to a number of circumstances. The intrinsic diversity of data properties among datasets, including changes in image quality, resolution, noise levels, and the occurrence of certain retinal disorders, is a significant determining factor. Additionally, the design and training methods of the suggested algorithms might affect how well they function, which can make them more effective at managing particular kinds of data. On datasets with related features, algorithms designed for particular data qualities, such as those optimized for high-resolution retinal scans or skilled at managing noisy datasets, may perform better. Conversely, when applied to datasets with diverse properties, algorithms that lack the capacity to adapt to individual data changes may function inconsistently or with lower efficacy. The accuracy and generalizability of diabetic retinopathy detection systems can be enhanced by better understanding the specifics of each dataset and optimizing algorithms in accordance with those details.

The Jaccard Index is a statistical metric used to compare the similarity of samples. It is commonly referred to as the “Crossroads above the Union”. The Jaccard Index is the ratio of the intersection’s size to the samples’ union. It can have a minimum value of “0” and a maximum value of “1”. It is described mathematically as follows:

$$jaccard\ index, J(Gr, Sg) = \frac{Gr \cap Sg}{Gr \cup Sg} \quad (13)$$

Fig. 7. Segmentation performance.

Fig. 8. Cross validation graph.

The k-fold cross-validation approach has several variants. The following are regularly used variants: Training and testing split: In the extreme, k can be set to 2 (rather than 1), resulting in a single train/test split for model evaluation. The cross validation for the rim-one-dl dataset and the KGD dataset is shown in the above Fig. 7. A typical procedure for testing the performance of a k-fold cross-validation model is the entire data set is randomly divided into independent k-folds without replacement. Fig. 8 shows the cross validation graph.

ROC curves in Fig. 9 were displayed to visually evaluate ensemble approaches based on the association between true positive and false positive rates for each deepNet. The graph shows better outcomes when such a curve is closer to the top-left corner. Using the rim-one-dl, the AUC value outperforms the existing Deepnet CapsNet, DenseNet, and VGG16. As a baseline, a random classifier is expected to give points along the diagonal (FPR = TPR). Below Fig. 9 shows the ROC curves of ensemble methods using deep CNN with multi pooling layer, dual part scaled cross dense network, and graph CapsNet.

Fig. 9. ROC graph.

Plateaus or occasional dips might indicate challenges or local optima. Overall, the graph provides insight into the optimization's progress and efficiency in enhancing the solution's fitness over successive iterations.

Fig. 10. Fitness improvement graph.

Above Fig. 10 illustrates how a certain fitness metric evolves across multiple iterations of an optimization process. The x-axis represents the iterations or time steps, while the y-axis represents the fitness metric. The graph demonstrates how the fitness value changes as the optimization algorithm refines its solution. Generally, the graph shows an initial steep improvement as the algorithm quickly converges towards better solutions, followed by a gradual slope as further improvements become harder to achieve.

C. Discussion

When compared to current techniques, the suggested method shows a lot of potential for the identification of

diabetic retinopathy. Traditional methods, which frequently rely on ophthalmologists' manual evaluation or crude automated algorithms, can be time-consuming, prone to human error, and unscalable in light of the expanding prevalence of diabetes worldwide. Contrarily, using the strength of RBMs is a state-of-the-art innovation that enables the automatic extraction of complex, hierarchical information from retinal images. This deep learning method offers a robust solution that can adapt to a variety of patient demographics and varied image quality situations, with the potential to significantly improve the accuracy and efficacy of diagnosing diabetic retinopathy. This suggested method, which uses RBMs, not only performs better than current methods but also represents a substantial advance in the early and accurate diagnosis of diabetic retinopathy, thereby assisting in the preservation of eyesight and the efficient use of healthcare resources.

## VI. CONCLUSION

In conclusion, this research presents a promising approach for automated diagnosis of diabetic retinopathy using restricted Boltzmann machines (RBMs) and retinal fundus images (RFIs). The proposed model incorporates various elements of prediction in retinal images, with a particular focus on the segmentation of using a thresholds U-network model. This segmentation step is crucial for identifying specific regions of interest in the retinal images and enables the subsequent classification process. To optimize the performance of the RBM, the research employs the Squirrel search algorithm (SSA) for selecting optimal hyperparameters and minimizing the weight of the RBM. The use of SSA helps improve the overall accuracy and efficiency of the automated diagnosis system. The evaluation of the model on the Rimone-dl dataset showcases promising results, achieving an accuracy of 99.2%. This high level of accuracy demonstrates the potential of the proposed system in accurately categorizing anomalies and aiding ophthalmologists in early and precise prediction of diabetic retinopathy. Future research may look at the integration of deep learning architectures, like CNNs, to increase feature extraction from retinal images and better classification accuracy for improving diabetic retinopathy diagnosis using machine learning using Restricted Boltzmann Machines. An interesting research direction may also involve investigating the possibility of federated learning and transfer learning techniques to use large-scale, heterogeneous datasets for better model generalisation in actual clinical scenarios.

**Abstract**—Ovarian cancer is a major cause of mortality among gynecological malignancies, emphasizing the critical role of early detection in improving patient outcomes. This paper presents an automated computer-aided design system that combines deep learning techniques with an optimization mechanism for accurate ovarian cancer detection that utilizes pelvic CT images dataset. The key contribution of this work is the development of an optimized Bi-directional Long Short-Term Memory (Bi-LSTM) model which is introduced in the layers of CNN (Convolutional Neural Network), enhancing the learning process. Additionally, a feature selection method based on Lion with Grey Wolf Optimization (LGWO) is employed to enhance classifier efficiency and accuracy. The proposed approach classifies ovarian tumors as benign or malignant using the Bi-LSTM model, evaluated on the Ovarian Cancer University of Kaggle dataset. Results showcase the effectiveness of the method, achieving remarkable performance metrics, including 98% accuracy, 99.7% recall, 93% precision, and an impressive F1 score of 98%. The proposed method's efficiency is validated through comparison with validating data, demonstrating consistent and reliable results. The study's significance lies in its potential to provide an accurate and efficient solution for early ovarian cancer detection. By leveraging deep learning and optimization, the proposed method outperforms existing approaches, highlighting the promise of advanced computational techniques in improving healthcare outcomes. The findings contribute to the field of ovarian cancer detection, emphasizing the value of integrating cutting-edge technologies for effective medical diagnosis.

**Keywords**—Ovarian cancer; deep learning; bidirectional long short term memory; CT images; convolutional neural network; lion grey wolf optimization

## I. INTRODUCTION

Ovarian cancer is the occurrence of irregular cells in the ovary which reproduce uncontrollably and then causes tumor malignancy in the tissues [1]. This can be categorized into three major types namely sex-cord- stromal, epithelial and

germ cell. In this epithelial ovarian cancer has a secondary type namely clear cell, mucinous, serous and endometriosis. Serous tumors are segregated into low-grade serious carcinomas (LGSC) and high-grade serous carcinomas (HGSC). By analysis it shows that 70-80% people cause epithelial cancer, clear cell in addition with mucinous are induced to less than 5% people and 10% people cause endometriosis. The first sign of ovarian cancer is epithelial cancer, which must be detected early to prevent death. Ovarian cancer should be detected in early stage, for detecting involves various methods and this paper proposed the ovarian cancer through deep learning [2]. Epithelial ovarian cancer made up of diverse ancient subsets with peculiar genomic features, they are enhancing the accuracy and effectiveness of healing treatment. It enables the detection of reaction such as ovarian cancer susceptibility genes BRCA2 and BRCA1 and also corresponded combining deficiency with damage in DNA response pathway resistance either inhibitor. This procedure is to process genomic transformation in tumors along with blood to evaluate sensitivity, therapy resistance and precise residual disease indicator. Around 230000 women shall be analyzed and 150000 women are died. This signifies that EOC is the seventh usually detected cancer in women. Genetic syndromes comprise Peutz-Jegher along with uncommon disorders and they are nevoid basal cell sign. Their causative factor includes an embryonic pregnancy, initial menarche, fallen age menopause, smoking, polycystic ovary syndrome [3].

Ovarian cancers are predicted by two medical examinations they are serum cancer antigen 125(CA125) and transvaginal ultrasound. Specificity along with sensitivity is restrictions. CA125 is frequently raised in benign stage including endometriosis and ovarian cysts. It is not determined in initial stage. This test evaluates the quantity of protein named CA-125 within the blood. High stages of CA-125 are occurred in women. This test is beneficial as tumor marker to identify as ovarian cancer. High level of CA125 persons fails

to validate ovarian cancer because it might be endometriosis and pelvic inflammatory disease. Person with abnormal CA-125 level, medical practitioner again examines the report. CA-125 is widespread in countries such as Canada, Australia, United States and Ireland as an prediction for ovarian cancer [4]. Transvaginal Ultrasound (TVUS) is a checkup that utilizes sound waves to monitor the uterus, fallopian tubes and ovaries by fixing ultrasound wand inside the vagina. It detects massive tumor or benign take placed [5]. The most present worldwide statistic calculates 295,414 recently predicted cases of ovarian cancer all year and also this disease causes 184799 yearly dead. Moreover, in an advanced phase 75% of ovarian cancer patients are difficult to diagnose properly. The treatment of chemo resistant ovarian cancer by targeting mitochondria has observed. It is developed under the terms where cancer cells modify and swap to mitochondrial respiration this turns severe to endurance so that perfect metabolic focus for chemo resistant ovarian cancer. In ovarian cancer tumor metastasis together with chemoresistance are allied in mitochondria spatial redistribution. Aberrant dependence of mitochondrial pathways are caused by specific sets of genetic mutation [6].

Recent treatment strategies include by combining debulking surgery, radiation therapy and drug treatment. Some sophisticated remedies are immunotherapy, hormone therapy and targeted therapy. OC treatment mainly involves chemotherapy. Repeatedly applied chemotherapeutic agents employed for curing of ovarian cancer includes platinum comprising drugs i.e., carboplatin along with cisplatin and tiane family i.e., docetaxel together with paclitaxel. In recent days, scientists have been providing an immunotherapy approach to treat gynecologic cancers. From ascites, tumor and blood of ovarian cancer patients the T cells and Antibodies are predicted in immunotherapy [7]. The machine learning algorithms are involved in several data mining applications which include ovarian cancer. Although these algorithms don't perform suitably due to inaccurate computational complexity, data imbalance, and missing values. Recently deep learning-based process has gained advantage in computer vision related applications and data mining over machine learning. Deep Learning Network utilized in several regions such as speech recognition, computer vision, healthcare, image processing [8]. In this research, emphasize on developing a deep learning established system for classification of ovarian cancer. The systematic study highlights the Bi-LSTM classifier which effectively worked and maintained more accuracy than other classifier such us CNN, 3D-CNN, KNN and Random Forest classifier. The deep learning handles the data by various phases including convolution layer, dense layer and pooling layer. Commonly deep learning have sequential architecture pursued by feature extraction, feature selection and classification [9]. Deep learning is frequently used invading detection of ovarian cancer. Deep learning scheme Bi-LSTM network performs a vital function to enhance the classification [10]. Optimization algorithms can be used to automatically identify and extract important features from the data in the image especially size, shape, and area of the tumor occur in ovary. This helps to remit the time required and potential for manual analysis, and can also develop the accuracy of the detection process.

Optimization algorithms can also be used to train deep learning models that can automatically classify medical data as either containing a tumor or not. These models can be optimized to improve their performance, such as by adjusting their parameters or optimizing their training process.

The key contribution of the described outline is given as follows:

- The development of an optimized Bi-LSTM model for the early detection of ovarian cancer.
- The novelty of this work lies in the development of an optimized Bi-LSTM model for ovarian cancer detection, which enhances the learning process and achieves impressive performance metrics.
- By utilizing deep learning techniques and an optimization mechanism, this model enhances the learning process and improves the accuracy of classification.
- Additionally, a feature selection method called Lion with Grey Wolf Optimization (LGWO) is employed to further enhance the efficiency and effectiveness of the classifiers.
- The combination of the Bi-LSTM model and the LGWO feature selection method allows the system to accurately classify ovarian tumors as either benign or malignant.
- To validate the efficiency and reliability of planned method, its presentation metrics are compared with the validating data, demonstrating consistent and reliable results.

The configuration of this essay is as accompanies: Section II contains the related work that is framed to understand the proposed paper with the existing methods while Section III elaborates the problem statement. Section IV depicts the proposed LGWO-Bi-LSTM architectures. The results and performance metrics are tabulated and graphically represented in Section V. Finally, in Section VI, conclusion and future works are presented.

## II. RELATED WORK

Srivastava et al. [11] outlined adjusted VGG-16 deep learning, ovarian cyst detection was accomplished approach. Pretrained deep learning method consists of VGG-16 model. To understand the VGG-16 model keenly a multiple of 3×3 kernel sized filters are obtained. This explains the established VGG-16 prototype fine-tuned with the data-set of ultrasonic images. Modifying the VGG-16 model's top four layers allows for fine-tuning. Distinct women's sample ovarian images are gathered to detect if ovarian cyst is occurred or not. The accuracy of 92.11% is obtained. The downside of VGG-16 deep learning network is slower than the ResNet architecture. Meng et al. [12] Intended virtual historical method of staining with deep generative adversarial mechanism to determine the ovarian cancer. Here hematoxylin and also Eosin staining method are used. Depending upon GAN, here autofluorescence images are created to develop a weakly supervised learning method of unstained ovarian tissue

regions depending upon E and H staining portion of ovarian tissues. The characteristic of the result predicted by the approach is more precise. This paper proposed a valid autofluorescence image generation of algorithm in the insufficient data which can consume time and laborious data representations in many situations. Through doctors determined the accurate unstained fluorescence image of ovarian cancer can be generated by this mechanism is 93%. The existing algorithm involves several complexities to predict the ovarian cancer. The visual evaluation established through deep learning method reaches an accuracy of 95%. Lu et al.[13] Proposed the determination of ovarian cancer by machine learning. It detects the exact of benign and ovarian tumors. In this method includes several processes like blood test, demographics, tumor markers and general chemistry. 349 Chinese individuals' information regarding 49 characteristics were obtained, and 235 patients' data were processed using the machine learning Minimum Redundancy - Highest Relevancy approach. The MRMR adopts 10 noteworthy characteristics, including human epididymis protein 4 (HE4) and cancer-embryonic antigen (CEA) are top featured by the decision tree model. It shows that machine learning is mostly incredible in detecting the complex diseases. The accuracy of trained data of ROMA, Decision Tree, and Logistic Regression is 79.6%, 87.2%, 84.7% and the accuracy of test data of ROMA, Decision Tree, and Logistic Regression is 92.1%, 95.6%, 97.4% respectively. This method is largely unstable contrasted with the other decision approaches. Schwartz et al.[14] Proposed an automated structure to recognize ovarian cancer in transgenic mice through optical coherence tomography (OCT) recordings. Classification is achieved by a neural network that distinguishes structurally ordered sequence of tomograms. It consists of three neural networks they are 3D convolutional neural network, VGG-supported feed-forward network and convolutional long short-term memory network. The outcome indicates that it can accurately output manual tuning although there is a default in noise inherent OCT images. It obtained a mean of  $0.81 \pm 0.037$ .

Yang et al. [15] Proposed the detection of ovarian cancer by combining the clinical significance of salivary mRNAs together with carcinoembryonic antigen. It is a liquid biopsy method and it can be used to predict many types of cancers. Here we determined a discriminatory study of ovarian cancer by uniting CEA and salivary mRNA biomarkers. Using two methods this technique is achieved. They are independent validation phase and discovery phase in which finding and evaluating of multiple biomarkers is enabled by discovery phase, independent validation phase confirms the availability of the finest bio-markers. Discovery phase categories blood's CEA level and five mRNA biomarkers in saliva are noted. Novel panel of biomarkers is used to segregate ovarian cancer patients and healthy people with high specificity of 82.9% and also with high sensitivity of 89.3% are obtained. In validation phase it acquires sensitivity 85% and simplicity 88.3%. Lemmings et al. The author in [6] proposed the treatment of chemo resistant ovarian cancer by targeting mitochondria. It is developed under the terms where cancer cells modify and swap to mitochondrial respiration this turns severe to endurance so that perfect metabolic focus for chemo resistant ovarian cancer. In ovarian cancer tumor metastasis together

with chemoresistance are allied in mitochondria spatial redistribution. Zhang et al. [16] For manufacturers to offer more advanced and inexpensive, high-quality Ultrasonic Flaw (UT) technology that could improve maternity medical services, it is recommended that we tackle the requirement to establish sustained sonar criteria with tolerably high pregnant and neonatal death rates. A group of artificial intelligence techniques, like the most recent advances in training to learning for maternal ultrasonography, is growing in acceptance and sparking excitement across a number of industries, such processing images for artificial intelligence. In this study, sophisticated artificial intelligence (AI) algorithms that use logistic reconstruction classifiers (LRC) and convolution neural networks (CNNs) to associate the original input picture to the intended outcome image are of special interest. Additionally, they employed the Internet of Medical Things (IoMT) to divide up maternal tumour imaging and identify tumours for specialists. The experimental findings demonstrate that the LRC based on CNN may be utilised for predicting the outcomes of maternity ultrasounds with enhanced levels of paternal and neonatal movement.

Kaggie et al. [17] proposed Ovarian cancer is one of several tumour subgroups that may be characterized using multiparametric magnetic resonance imaging (MRI). Despite the limitations of traditional anecdotal T1- and T2-weighted scans, quantified mappings of MRI relaxation values, including T1 and T2 the mapping process, shows promise for improved tumour evaluation. Nevertheless, due to the ordered measurement of several parameters, quantitative MRI relaxation mapping approaches sometimes need lengthy scan periods. Fast qualitative MRI is made possible by a novel technique called magnetic resonance fingerprinting (MRF), which takes use of transitory signals brought on by changes in the parameters that make up of a pseudorandom programme. Statistical correspondences are subsequently created by matching these temporary signals to a computed lexicon of T1 and T2 elements. The capacity of the MRF to monitor several factors concurrently may provide a novel method for identifying malignancy and evaluating the effectiveness of treatments. Using ovarian cancer as an illustration structure, this practical research examines MRF for concurrent T1, T2, and relative proton density (rPD) mapping. Negi et al. [18] proposed In comparison to monolayer OLED design, a unique three hole block layer (HBL) arrangement of the OLED is presented that exhibits improved luminosity of 25285 cd/m<sup>2</sup>. The 74% increase in illumination power efficiency is partly to blame. The internal circuit evaluation is used to confirm an extensive numerical analysis built on the Poisson and drift dispersion model. The results of the examination show that the suggested gadget has a higher rate of recombine. A higher amount of recombination is a result of effective whole shielding as well as elevated particle input. Consequently, ovarian cancer is diagnosed by triple HBL OLED. The gadget produced an ultimate photon current level of 93 mA and had good responsiveness to different bands. According on their urine's ability to shine, a healthy individual can be distinguished from an oncological cancer survivor.

### III. PROBLEM STATEMENT

The detection of ovarian cancer is crucial for preventing patient mortality. However, there are several challenges associated with this process, such as the risk of infection, bleeding, blood clot formation, swollen legs, fatigue, infertility, and bowel changes. To aid in the detection process, a fine-tuned VGG-16 model has been developed to categorize ovarian cysts based on their forms, cysts, HOC, dermoid cysts, and PCOS. However, the current system lacks a user interface that allows pathologists to conveniently upload and predict images, which needs to be addressed and improved [19]. The

fine-tuned VGG deep learning network more time to train its parameters [11].

### IV. PROPOSED LGWO-BASED BI-LSTM

Initially the ovarian cancer dataset is preprocessed through weaned filter and then image segmentation is employed by Fuzzy C-means clustering. In this way feature is extracted using Grey Level Co-occurrence Matrix and feature is adopted by hybrid Lion Grey Wolf optimization and also categorized by Bi-LSTM model. Block diagram of hybrid Lion Grey Wolf Optimization through Bi-LSTM model is depicted in Fig. 1.

Fig. 1. Block diagram of hybrid lion grey wolf optimization through Bi-LSTM model.

#### A. Data Collection

The research utilizes pelvic CT image datasets affiliated with China's Qingdao University, specifically from a Class 3 hospital. After screening the obscured data, it acquired a totality of about of 5100 CT images of 223 patients containing pelvic CT images with highlights were gathered and utilized. The images were divided into two equal sets, with 50% used as training data and the other 50% used as testing data. This means that 2550 images with highlights were utilized for training and 2550 CT images with highlights were utilized for testing. The dataset consists of 2000 pelvic CT images collected from 223 patients. It contains three types of pelvic CT images containing clear cell, mucinous, endometriosis and serous. Pelvic CT images taken for mucinous, clear cell and endometriosis is 2000, 1500, and 1600 for ovarian cancer [20].

#### B. Pre-processed by Weinmed Filter

The most crucial stage for the best categorization outcomes is pre-processing. It is frequently carried out on data before classification to make sure the desired outcomes are reached [21]. The CT images that obtained are pre-processed to get more relevant for further process. The preprocessing step includes smoothing, toughen the edges of the image and noise removal. The objective of pre-processing enhances the image quality. Each pixel replaced weinmed filter with average value of intensities in region. Median filter removes salt and noise accurately. Weinmed filter probes to construct an optimal determination of the original image by enforcing the minimum mean square error limit between estimate and original image. The purpose of the weinmed filter is to reduce

the mean square error and it also de-blurs the image and reverses filtering. This filter also opens morphological operation and contrast enhancement to image enhancement and reduce noise. Individual background noises calculate the contrast of each region. By preserving the edge information of unclear areas, the background noise is removed shall highlights the digital prototype. Both the degradation function and noise are managed by weinmed filter. Through the degradation model, the error among the estimated signal and the input signal is provided.

Weiner filter formula is expressed in Eq. (1),

$$F_{X(u,v)} = \frac{|H(u,v)|^2}{|H(u,v)|^2 + S \frac{P_n(u,v)}{P_f(u,v)}} G(u,v) * \frac{1}{H(u,v)} \quad (1)$$

$P_n(u,v)$  - Noise power spectrum

$P_f(u,v)$  - Power Spectrum of the original image

$H(u,v)$  -Fourier Transform of the point spread function

$G(u,v)$  -Power Spectrum with the Fourier change of the noisy point cloud image

$F_{X(u,v)}$  -Result Value After restoration

The computed de-noising equation is given below.

Let FUV stand for the collection image parameters in a k-by-1-inch square sub image windows centered at the two points (u, v). The following phase in preparation is to remove and normalize the surrounding data during processing itself, albeit this might affect the results of segmentation. During this

moment, the edge from the CT ovarian equation is identified using a clever edge detecting approach Eq. (2) [22].

$$f(u, v) = \text{Median}\{F_{X(u,v)}\} \in Fu, v \quad (2)$$

The above equation (2) is termed as Weinmed filter.

### C. Segmentation using Fuzzy C-means Clustering

The segmentation process involves identifying and labeling the different regions in the CT images, such as the mucinous, clear cell, endometriosis, and serous. This task can be challenging due to the complex and heterogeneous nature of ovarian cancer, which can exhibit variations in size, shape, location, and intensity. In addition, there can be variability in the imaging protocols and noise artifacts that can affect the quality of the images. Segmentation of ovarian cancer using CT images can be performed using a variety of techniques, such as threshold, region-growing, active contours, and machine learning-based approaches. Here, Fuzzy clustering method is adopted to perform the task. In the context of ovarian cancer detection, image segmentation using fuzzy clustering can be used to separate the tumor region from the ovarian cancer. The segmentation result can then be used for quantitative analysis and clinical decision-making. Several studies have reported promising results using fuzzy clustering for ovarian cancer segmentation.

Fuzzy C-means clustering is preferable optimization for feature segmenting the CT images. It is the most common fuzzy algorithm which is extremely delicate to outliers, noise, and size of the clusters. It starts by randomly initializing the cluster centroids and the fuzziness parameter, and then iteratively updates the centroids and the degree of membership until convergence. The segmentation result is obtained by assigning each pixel to cluster with highest degree of membership. After initializing degree of membership values, the cluster centroids are calculated and then according on how far there is among every point of data to the geographic center of every cluster, the range of membership metrics associated with each observation point was modified. The levels of values for membership have been updated the cluster centers are re-computed using the weighted average of the data points. Repeat the process until convergence. Once, the algorithm converges, the final assignment of each data point to a cluster is based on the highest degree of membership value [23].

Let us consider a number of finite dataset be 'n' and A = (a<sub>1</sub>, a<sub>2</sub>, ..., a<sub>n</sub>). The dataset A is divided in to group of cluster by using FCM algorithm. Formula for FCM algorithm is given in Eq. (3).

$$J_s = \sum_{p=1}^n \sum_{q=1}^c u_{pq}^s \|A_p - C_q\|^2 \quad (3)$$

Where,  $u_{pq} = \frac{1}{\sum_{k=1}^c \left(\frac{d_{pq}}{d_{kq}}\right)^{\frac{2}{s-1}}}$  is the degree of membership

value of  $x_p$  in  $q^{th}$  cluster,  $x_p$  is  $p^{th}$  data points and  $c_q = \frac{\sum_{q=1}^n u_{pq}^s x_p}{\sum_{q=1}^n u_{pq}^s}$  is  $q^{th}$  cluster center, s denotes the fuzzy parameter and Euclidean distance is represented as  $\| \cdot \|$ .

Where,  $d_{pq}$  indicates the aloofness among data points  $x_p$  and  $q^{th}$  cluster focus and  $d_{kq}^*$  is distance between  $k^{th}$  cluster focus and  $q^{th}$  cluster center.

### D. Feature Extraction using Scale-Invariant Feature Transform (SIFT)

Finding the initial corresponding characteristics is the aim of the initial phase. The starting imagery A and those perceived image B, both of whom are fed to SIFT to extract and characterize local characteristics, are two separate images that need to be registered  $F_A$  and  $F_B$ , accordingly.

The prospective features are found by scanning across all of the available sizes and places of residence for extracted features. The regional maximal and minimal values of E(x), which can be described as the combination of the function using an image, i.e.,  $F_A$  or  $F_B$ , are used to discover scale-space extreme. Another thorough match to the neighboring data points is carried out to determine the precise positions of the characteristics [24]. Some prospective feature points have inadequate contrast elements or edge locations with poor localization, thus the contrasting values and primary curved proportions are utilized to exclude the unstable characteristics. After reliable prospective characteristics are discovered, every key point is given a dominant orientations determined by the current picture gradients directions histogram to achieve image rotational consistency [25]. A description matrix that is calculated for every distinctive point comes next. A 3-D histogram of grade dimensions and directions serves as such a description. To create a 128-D descriptor, the gradients alignment angle is compressed into eight orientations increments and the placement is compressed into a 4 4 placement grid.

$$\theta = \cos^{-1} \left( \frac{Z_p^H Y_p}{\|Z_p\| \|Y_p\|} \right) \quad (4)$$

where,  $Z_p$  represents the p th feature descriptors vector in that the sensed imagery,  $Y_p$  represents the p th feature descriptor vector in the reference image, and represents the angle among the two variables. The primary maximum degree versus the second minimum angle ratio, represented by the symbol proportion, is utilized to increase the accuracy of matching the initial characteristics. Initial match characteristics are disregarded if their angle ratios of distance are higher than a threshold value.

The combination of entropy together with the mean value of Fourier co-efficient is obtained to provide feature vector in AGLCM algorithm.

### E. Feature Selection using Hybrid LGWO

The Lion with Grey Wolf Optimization algorithm is employed to reducing the errors in training data and detects the malignant portion. Here the leader may be male or female indicated as alpha which enables hunting, sleeping, time to wake, location. Alpha makes decision and Beta handles.

Omega is the lower section of the grey wolf and for further wolves on every occasion [26]. Omega ( $\omega$ ) is noticed as the leftover provision [27]. In Lion optimization the parameters include learning rate ( $\alpha$ ), weight values ( $w$ ), number of layers ( $L$ ), kernel sizes ( $k$ ) and dropout rate ( $\gamma$ ).

1) *Initialization process*: At first the preprocessed output data is initialized as a, B and C as coefficient vectors.

Fitness evaluation:

Eq. (5) evaluates the fitness utility and predicts the result

$$Fit_i = \max accuracy \quad (5)$$

Differentiate the solution depend on filters:

Let the initial fitness be  $d_\alpha$ , the second finest fitness be  $d_\beta$ , the third finest fitness be  $d_\delta$

a) *Roaming*: In this process the territory is visited by every male lion where the total location to number of this location is %S. When the Lion find the best location it reforms the location during roaming. Lion shifts to improved location is denoted in Eq. (6) [28]

$$\gamma \sim U(0,2) \times g \quad (6)$$

Where,  $g$  – Male lion' current location and selected location from the territory and  $U$  – Uniform Distribution

$P_{si} = 0.1 + \min\left(0.5, \frac{Y_i - Y_{best}}{Y}\right)$ ,  $i=1, 2, 3 \dots$ no. of nomad lions

Where,  $P_{si}$  = the chance detected for seperation of all nomad lions  
 $Y_i = i_{th}$  Lion's fitness value and  $Y_{best}$  = Fitness value of the best nomad lion.

b) *Encircling prey*: Together with these three contenders by  $\alpha, \beta, \delta$  and also  $\omega$ . In addition for the group to track a prey is by surrounding their location. Encircling or trapping behaviour of grey wolves for pray during hunting is computed using the following Eq. (7) and (8) [29].

$$d(t+1) = d_{ps}(t) = \vec{B} \cdot \vec{K} \quad (7)$$

$$\vec{K} = |\vec{C} \cdot d_{ps}(t+1) - d_{ps}(t)| \quad (8)$$

Where,  $\vec{B} = 2\vec{c}r_1 - \vec{c}$  and  $\vec{C} = 2r_2$ , and  $d_{ps}(t)$  - The prey position,  $B$  and  $C$  – The coefficient vector,  $\vec{c}$  - Linearly lowered from 2 to 0,  $r_1$  and  $r_2$ - Random vector[0,1], and  $t$  - The iteration n numbers.

c) *Hunting*: Hunting is done based upon Lion Optimization. In every pride the female concentrates on a prey in a cluster to feed their pride. To surround the victim and to preserve pride it follows certain mechanisms. All lions fine-tuned their localities to rely on particular locality and the group associates' localities. Due to this reason the seekers surround the victim and apply relative training, assaults from locality conflict. For this the seekers are classified into three subdivisions. In the centroid of seekers, a prey is engaged. During hunting the hunters are chooses in sequence, a false victim is assaulted by decided seekers in order with the crowd

which decides lion to belong it. If a searcher enhances its fitness a false victim escape from searcher and new locality of prey is detected in Eq. (9) [30].

$$d_{ps}' = p + \text{ran}(0,1) \times PI \times (p - h) \quad (9)$$

Hunter represents the present locality seeker who hit to victim and PI denotes the objective seekers increasing rate in Eq. (10).

$$h' = \begin{cases} \text{rand}((2 \times p - h), p) & \text{if } (2 \times p - h) < ps \\ \text{rand}(p, (2 \times p - h)) & \text{if } (2 \times p - h) > ps \end{cases} \quad (10)$$

The new localities of centroid seekers are given bin Eq. (11)

$$h' = \begin{cases} \text{rand}(h, p) & \text{if } (2 \times p - h) < ps \\ \text{rand}(p, h) & \text{if } (2 \times p - h) > ps \end{cases} \quad (11)$$

The above equation produces an arbitrary value from b to c which is upper and lower limits, respectively.

Understanding and improving the effectiveness of the suggested model depends on research into how the HLGWO's characteristics affect the identification of ovarian cancer. These parameters include a wide range of factors, including population size, convergence standards, crossover and mutation rates, and trade-offs between exploitation and exploration. It is feasible to fine-tune the HLGWO algorithm to increase its efficiency and efficacy in optimizing the deep learning model for ovarian cancer diagnosis by carefully modifying and analyzing these parameters. The model's convergence rate and solution quality can be considerably impacted by striking the correct balance between exploration and exploitation. Additionally, preventing premature convergence and finding the most illuminating characteristics for precise identification may be achieved by optimizing parameters like mutation rates and crossover rates. To further improve HLGWO's potential as a diagnostic tool for ovarian cancer, it is crucial to refine and adapt the model for practical clinical applications. This requires understanding how these parameter adjustments influence the model's sensitivity, specificity, and overall accuracy.

#### F. Classification using Bi-LSTM

Classifications of RNN include Bi-LSTM it is enabled for processing of natural language like text classification. The context is captured as it is a powerful model and words depend on sequence [31]. In ovarian cancer classification, Bi-LSTM networks can be used to predict sequences of MRI or CT scans to classify ovarian cancer as benign or malignant. The input sequence can consist of images from different angles, slices, and time points and the network can learn to recognize patterns and features that are indicative of specific ovarian cancer types. Bi-LSTM model is represented in Fig. 2. In addition, Bi-LSTM networks can also be concatenated with other DL techniques, such as CNNs, to enhance the accuracy of the classification. Convolution neural networks are commonly used to extract data from medical images, while Bi-LSTM networks can learn the temporal dependencies between these features. Overall, Bi-LSTM networks are a promising tool for brain tumor classification because they can model the complex relationships and patterns in sequential

data, thus improving the accuracy of classification by utilizing backward hidden states, which contributes to the enhancement of LSTM network learning [32].

Four gates in LSTM neural network are represented in Eq. (12) to (15).

$$c_t = \sigma(M_f x_t + E_f h_{t-1} + c_c) \quad (12)$$

$$d_t = \tanh(M_g x_t + E_g h_{t-1} + c_d) \quad (13)$$

$$e_t = \sigma(M_i x_t + E_o h_{t-1} + c_e) \quad (14)$$

$$f_t = \sigma(M_o x_t + E_o h_{t-1} + c_f) \quad (15)$$

where, Ef, Eg, Ei, Eo represents the weight matrices of the preceding short-term state ht-1. Mf, Mg, Mi, Mo represents the weight matrices of the present input state xt, and cd, ce, cf,

and co are the bias terms. Where, pt-1 represents the previous long-term state.

The present long-term state of the network gt can be evaluated by using Eq. (16), and yt can be evaluated using Eq. (17).

$$g_t = f_t * p_{t-1} + e_t * d_t \quad (16)$$

$$y_t = h_t = f_t * \tanh(g_t) \quad (17)$$

The classification architecture is depicted in below by given Fig. 2. Similar to this, the LSTM layer gains knowledge of the dependencies among various time steps in sequence data.

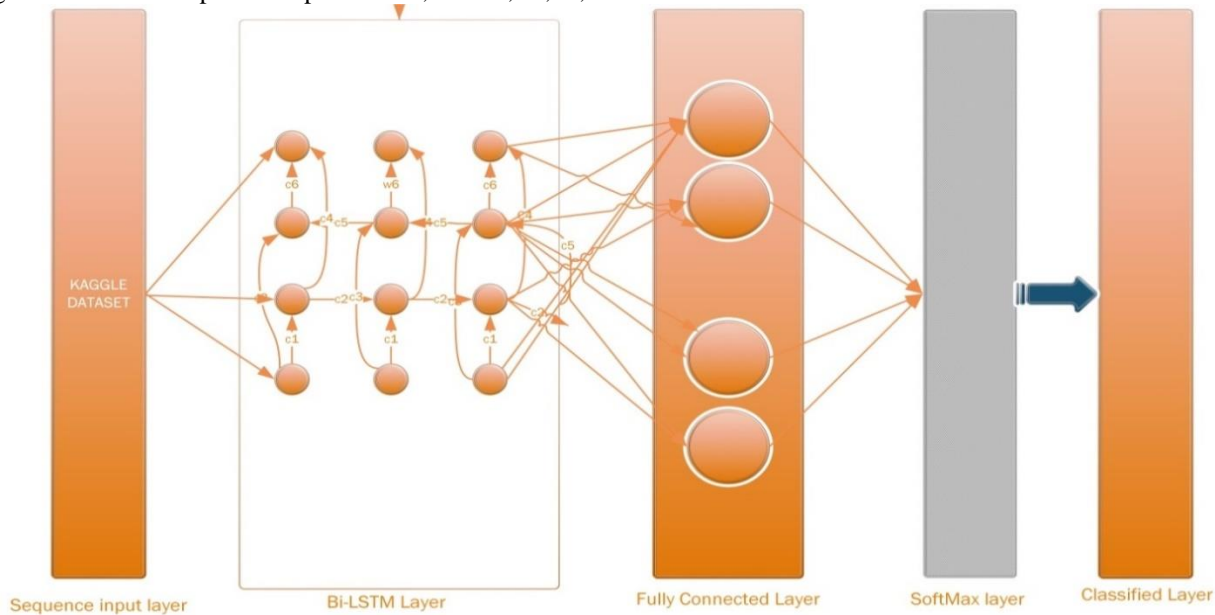

Fig. 2. Bi-LSTM classification of architecture.

**Algorithm 1: LGWO- Bi-LSTM mechanism**

INPUT: CT images from Kaggle dataset

OUTPUT: Classifying the type of ovarian cancer (clear cell, mucinous, serous and endometriosis)

Load input image data

$C = \{c_1, c_2, c_3, \dots, c_n\}$  //Image acquisition

Pre-processing of images

Toughen the edges of the image //Weiner filter

Removes the salt and noise effectively //Median filter

Segmentation of images

Choose the initial cluster and membership matrix //Fuzzy C-means Clustering

Calculate new cluster and new membership matrix

If (Difference in cluster center)

< threshold

Stop

Else

>threshold

Repeat

Feature Extraction

Feature Selection //LGWO

Calculate roaming using the fitness of Lion

Calculate encircling using the fitness of Grey Wolf

Calculate hunting using the fitness of Lion

Classification //Bi-LSTM

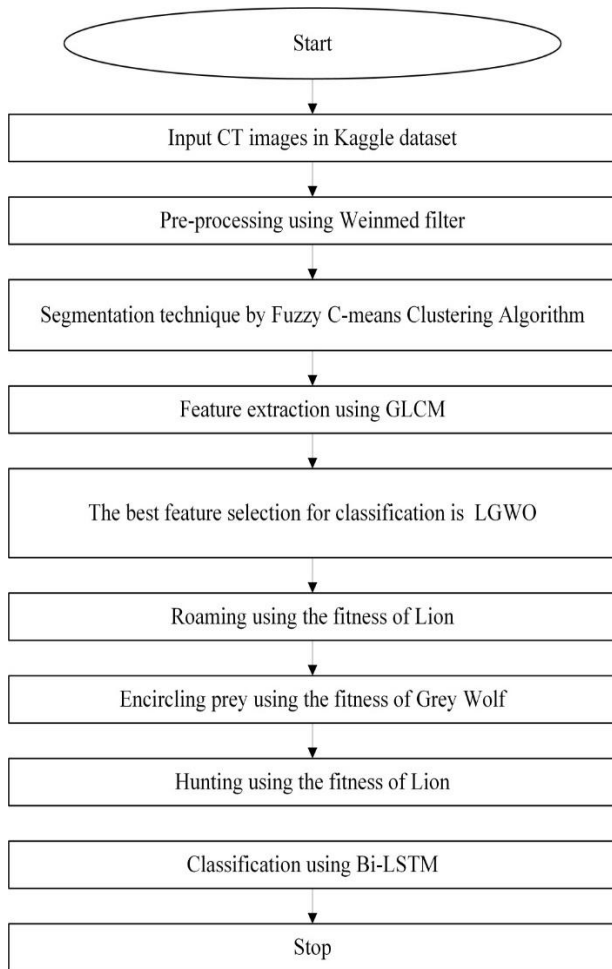

Fig. 3. Flow diagram of HLGWO -BI-LSTM model.

The above Fig. 3 elaborates the overall work flow of the entire proposed model. Main steps involved in detecting and classifying the ovarian cancer shown in flow with algorithmic conditions. This flow chart helps for quick understanding of the presented research.

### V. RESULT AND DISCUSSION

This study provides a detailed explanation of the experimental results obtained from the proposed method, using numerical terms to quantify the outcomes. The validation process was conducted on the CT images. The Kaggle dataset comprising 223 patient’s datasets containing 5100 CT images were separated 50% as testing along with training data. The proposed system’s evaluation was compared with three classification methods: ML-CNN, HOG-ANN, and UBOC. Performance evaluation of the Bi-LSTM classifier and LGW optimization algorithm is carried out using four metrics such as accuracy, F1 score, precision, recall. Entire experimental process is implemented by using MATLAB software in windows 10 platform.

#### A. Evaluation of Performance Metrics

The experiment assessed the models using four evaluation metrics: accuracy, F1-score, precision, and recall. These parameters are specifically defined in Eq. (18) to (21).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (18)$$

$$Recall = \frac{TP}{TP+FN} \quad (19)$$

$$Precision = \frac{TP}{TP+FP} \quad (20)$$

$$F1score = \frac{2*Recall*Precision}{Recall+precision} \quad (21)$$

In above equations, *TP* refers to the no. of data finely classified as positive out of all the data that were actually positive. *TN* Refers to the no. of data finely classified as negative out of all the data that were actually negative. *FN* is the number of data that were mistakenly classified as negative by the model even though they were actually positive in the dataset. *FP* is the number of data that were mistakenly classified as positive by the model even though they were actually negative in the dataset, Recall is defined as the ratio of the no. of data classified as positive by the model to the actual no. of data that were positive in the dataset. Precision is the ratio between no. of data that were correctly classified as positive by the model and the total no. of data defines positive. Finally, F1-score is the harmonic mean of recall and precision, as explained in [33].

TABLE I. EXPERIMENTAL RESULT ANALYSIS FOR DIFFERENT PARAMETERS WITH OTHER METRICS

Method	Accuracy	Recall	Precision	F1-score
ML-CNN[34]	96.5	96	98	97
CNN-DenseNet[35]	94.73	98.9	91	95
AlexNet[36]	84.45	90	75	87
Proposed Bi-LSTM-LGWO	98	99.7	93	98

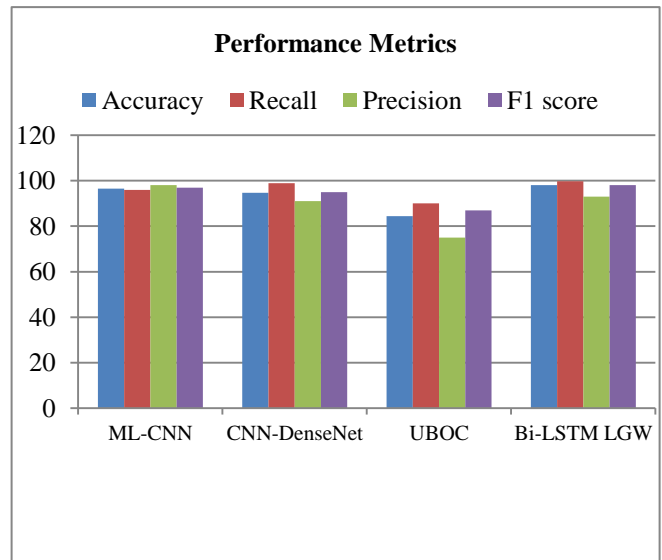

Fig. 4. Performance evaluation of various methods of classification.

In Table I, the performance evaluation of the proposed system is tabulated. The proposed Bi-LSTM-FFO shows higher accuracy when compared with other classifiers. Average of Precision and recall of the existing methods is higher than the proposed method. Mean value of precision

and recall gives a significant measure of classification called F1-score; the graphical identification of performance analysis is shown in Fig. 4.

TABLE II. COMPARED RESULT IN TERMS OF SENSITIVITY AND SPECIFICITY

Method	Specificity	Sensitivity
ML-CNN[34]	89.7	90.57
CNN-DenseNet[35]	96.94	95
AlexNet[36]	95	72
Proposed Bi-LSTM-LGWO	96.4	98

Fig. 5. Comparison of sensitivity and specificity for existing and proposed methods.

Comparison of the proposed model performance results with the existing methods is mentioned in Table II. For clear understanding comparative analysis of sensitivity and specificity are graphically represented in Fig. 5.

Fig. 6. ROC comparison.

Fig. 6 displays the ROC curve for different models used in ovarian cancer detection. The x-axis represents the FPR, and the y-axis represents the TPR. The proposed Bi-LSTM-LGWO model achieves the highest TPR of 0.7, outperforming

ML-CNN, CNN-DenseNet, and AlexNet, which have TPR values of 0.4 and 0.3.

Fig. 7. Fitness improvement.

Fig. 7 shows optimization, fitness improvement refers to the enhancement of the objective function's value or performance metric being optimized. This can be achieved by applying various optimization techniques, such as evolutionary algorithms, gradient descent, or simulated annealing, to iteratively search for better solutions.

**B. Discussion**

The findings of the suggested Bi-LSTM-LGWO model are highly encouraging, with a great sensitivity of 99.7% and an amazing accuracy of 98%. These results indicate that the model performs very well in detecting ovarian cancer properly, which is essential for early diagnosis and management. However, it's important to recognize that the suggested task has certain limits. First off, as larger and more diverse datasets are frequently needed for reliable performance, this may have an impact on how generalizable the model is. Second, the Bi-LSTM-LGWO model's computational complexity could make it impractical to use in real-time clinical situations. Future research should focus on overcoming these constraints by enlarging the dataset and streamlining the model. The model's credibility and suitability for use in clinical practice would also be further increased by investigating new performance indicators and carrying out external validation on various datasets.

**VI. CONCLUSION**

The suggested method is more effective than current classifiers and provides a better level of accuracy, making it a potential direction for further study. With accuracy of 98%, recall of 99.7%, precision of 93%, and F1-measure of 98%, the provided model exceeds the existing model. In comparison to the MNN-CNN method, the adopted classifier in the suggested model is more effective. In this approach Bi-LSTM model was employed for classification. The suggested methodology makes a significant addition to the field of ovarian cancer identification and classification overall. The suggested approach will then be examined by running tests on data sets from various sources and industries. Exploring

various topologies, optimization methods, and hyper parameters can improve the Bi-LSTM classifier and LGWO optimization algorithm's performance. In future proposed methods, performance should be validated through larger-scale clinical trials and collaborations with healthcare professionals to assess its reliability and effectiveness in practical medical settings.

**Abstract**—A key element of contemporary computer vision, image fusion tries to improve the quality and interpretability of images by combining complimentary data from several image sources or modalities. This paper offers a unique method for multi-modal image fusion, combining the benefits of Deep Convolutional Neural Networks (CNNs) and Non-Negative Matrix Factorization (NMF), by using current developments in deep learning and matrix factorization techniques. Deep CNNs have shown to be remarkably effective in extracting features from images, capturing complex patterns and discriminative data. A group of deep CNNs are trained using this suggested technique on a varied dataset of multi-modal images. With the help of these networks, which extract and encode pertinent characteristics from several modalities, information-rich representations may then be combined. Concatenating, the features that were derived from the CNNs throughout the fusion process results in a fused feature representation that perfectly expresses the input modalities. The main novelty is the two-stage integration of NMF: first, breaking down the fused feature representation into non-negative basis vectors and coefficients, and then, using NMF to further extract important patterns from the fused feature maps. The non-negativity requirement in NMF guarantees the preservation of the natural structures and characteristics present in the source images, resulting in fused images that are both aesthetically pleasing and semantically intelligible. Visual examination of the merged images demonstrates the method's capacity to successfully extract important information from several modalities. The better performance and robustness of the suggested approach, which has an accuracy of roughly 99.12%, are highlighted by comparison with existing fusion approaches.

**Keywords**—Image fusion; deep convolution network; non-negative matrix factorization; multi-modal images; vector space model

## I. INTRODUCTION

Image fusion has a wide range of uses in both commercial and non-industrial sectors, including security. Due to technical or optical imaging limitations, only a portion of the information may be recorded in an image using a certain type of detector or firing configuration. For example, reflecting

illumination data that has intensity in a constrained range and falls within a predetermined depth-of-field is a classic example of insufficient data. By combining complimentary data gathered from many source images that were taken with various sensors or optical settings, image fusion aims to create a synthesized image [1]. Following visual assignments, including video monitoring, scene comprehension, target acknowledgment, etc., benefit from a single fusion image with greater environment representations and better perception of sight. It is challenging to efficiently and rapidly explore image on image-sharing systems due to the enormous volume of images submitted to services like Flickr and Picasa. This issue can be resolved using gathering images summarization. The goal of the image collection overview is to portray a huge, multi-modal library using only a small subset of the images and labels. The small subset shows the different elements of the initial collection, such as the attribute of interest and scene category. Image collection summarization may be employed for a variety of multimedia projects, such as automatic album building, search outcome optimization, etc. [2].

Different kinds of medical images serve an essential part in clinical diagnosis in contemporary medicine and are quite helpful in identifying disorders. Doctors typically need to integrate numerous different kinds of medical images from the same location in order to gather sufficient data for an appropriate evaluation, which frequently causes significant difficulty. When a doctor simply uses his or her own theories and conceptions to analyze a variety of medical visuals, the evaluation's objectivity is compromised and it's possible that some of the image's data is overlooked. Techniques for image fusion offer a practical solution to these problems. The collected healthcare images from various modes contain supplementary as well as duplication of data as the range of medical imaging technologies grows [3]. Other research has used a combination of verbal and graphic data to create image representations [4]. To create the visual short, the investigator developed an overview challenge that involved locating subset image examples using a homogeneous and heterogeneous message transmission technique. The image summary challenge was transformed into a hyper-graph division issue

through research, which took into account both visual and textual aspects. It suggested a max-margin assistance vector machine-based technique to extract visual ideas from multimodal dataset [5].

An imaging equipment, such as a digital single-lens reflex the device, frequently finds it challenging in the field of electronic imaging to take an image in which all the objects are sharply focused [6]. Only subjects in the depth-of-field (DOF) of an optically lens will usually look crisp in a shot at a given focal length; subjects outside the DOF will most likely to be blurry. Multi-focus image fusion, which combines many images of the same subject captured at various focal lengths to create an all-in-focus appearance, is a common approach. Additionally, a significant area within the field of image fusion is multi-focus fusion of images [7]. Many techniques for merging multi-focus images may be used, regardless of alterations, for additional image fusion applications like visible-infrared image fusion and multi-modal healthcare image synthesis. Investigating multi-focus image fusion has dual significance from this perspective, making it an explosive subject in the image computing field. Several image fusion techniques have been developed in recent years, and these techniques may be loosely divided into two distinct groups: transformation area techniques and spatially domain technique [8]. Data fusion and mining include integrating and analysing many data sources to draw out insightful conclusions and patterns. To get a complete picture of the data landscape, it aggregates data from multiple heterogeneous sources, including databases, sensors and social media. When data from many sources are combined, conflicts are resolved, and a single dataset is produced that more accurately depicts the underlying phenomenon [9]. Then, using data mining techniques, relevant relationships, trends, and patterns are identified from the pooled data. Using techniques from machine learning as well as statistical methodologies, anomalies, hidden trends, and predictions or suggestions are found in this process. Data fusion and mining are widely used in a variety of industries, such as health care, banking, marketing, and cybersecurity, and they allow companies to make data-driven decisions that improve productivity, efficiency, and decision-making [10].

To generate the multi-modal overview successively, Camargo and Gonzalez i [11] used convex non-negative matrix factorization (convex NMF) to visual modalities expressed as BoW and textual modalities expressed as vector space model (VSM). However, they did consider the sequential association between the images and labels. The characteristics of the literary topic were first taken into account. Next, images were used as inspiration for the visual concept. The sequential method, however, limits the dissemination of information from various data. They primarily relied on the textual aspects of visual summaries, ignoring the visual aspects of the literary issue and the diverse interactions between the two mediums. As a result, older summary techniques are unable to generate outcomes that exactly match the initial collection. Early spatial domain approaches frequently employed block-based fusion. Depending on the subject of the images, blocks of various sizes can be created adaptively from the images. The concept of block-based techniques is shared by a different

class of spatial domain techniques that rely on image segmentation. However, the effectiveness of the classification has a big influence on how effectively these tactics work together. Many unique gradient-based, pixel-based spatial domain approaches have been created recently that can produce state-of-the-art multi-focus image fusion results. These approaches usually use rather complex fusion strategies (which can be thought of as rules in a broad sense) to their computation findings from activity degree analysis in order to boost the fusion efficacy.

The key contributions of the Multi-Modal Image Fusion using Deep Convolutional Neural Networks (CNNs) and Non-Negative Matrix Factorization (NMF) approach are:

- By concatenating the features obtained from the CNNs during the fusion process, a fused feature representation is produced that accurately captures the essence of the input modalities, improving image quality and interpretability.
- Deep CNNs are used to extract features from multi-modal images, showcasing their exceptional ability to capture intricate patterns and discriminative data, which are crucial for producing informative fused images.
- The integration of NMF in two stages is the primary innovation. In order to improve the fusion process, two steps must be taken: first, the fused feature representation must be broken down into non-negative basis vectors and coefficients; and second, NMF must be utilized to extract important patterns from the fused feature maps.
- The non-negativity condition in NMF makes sure that the fused images retain the organic shapes and traits that are present in the source images, resulting in fused images that are both aesthetically pleasing and semantically significant.

This article's remainder is organized as follows: In Section II, a summary of related research is provided. Section III presents the problem statement. The suggested approach's methodology and architecture are explained in Section IV of the article. The findings and subsequent discussion are covered in Section V. The conclusion is covered in Section VI.

## II. RELATED WORK

Although multi-model neuroimaging and gene identification technologies have advanced, attempts to integrate the two in order to investigate the virulence traits of schizophrenia (SZ) have been unsuccessful. Researchers suggest a unique approach known as grouping dense of joint non-negative matrices factorization on orthogonal domain to address this problem. The approach combines data from three models, single nucleotide polymorphism, and functional magnetic resonance imaging to identify risk genes, aberrant brain areas, and SZ-related epigenetic elements. For the purpose of eliminating unnecessary characteristics from the row of correlation matrix structures, researchers actively place diagonal constraints on the foundation matrix. Because data from genome-scanning provide extensive group information, researchers use three coefficients vectors that are densely

packed to enhance the features discovered. Our approach is tested using both the made-up and actual Mind Clinical Imaging Consortium (MCIC) datasets. Simulation results demonstrate that our approach outperforms rival tactics. GJNMFO identifies a set of risk genes, epigenetic variables, and aberrant brain functioning regions through the use of MCIC data in the study. These findings have significant economic and ecological ramifications, which science has proven [12].

For ground-based cloud recognition, deep neural networks have recently attracted a lot of attention. The entire focus of these techniques, however, is on extrapolating global features from visual input, which results in approximations for ground structures that are erroneous. The multi-evidence and multi-modal fusion network (MMFN), which is described in this article, is a unique technique for ground-based cloud identification that can increase cloud knowledge by fusing various signals in an integrated framework. By utilizing the attentive network and the main system, MMFN specifically uses a number of data points, such as global and local visual characteristics, from ground-based clouds images. Local visual qualities are gathered using the attention maps of the attentive system, which are constructed using fine-tuned salient aspects of convolutional stimulating structures. The multi-modal networking in MMFN is now studying the multi-modal properties of ground-based clouds. Researchers developed two fusion stages in MMFN to combine multi-modal features with local and global visual properties in order to fully fuse the multi-modal and multi-evidence visual qualities. The first multi-modal ground-based cloud database, or MGCD, is also made possible by study. It includes both the ground-based cloud images themselves as well as the multi-modal data that goes with each cloud image. When measured against state-of-the-art techniques, the MMFN obtains an identification performance of 88.63% on MGCD, proving its suitability for ground-based cloud recognition. The current study forbids the use extra factors, such as cloud basal height, for cloud characterization [13].

To achieve human-robot collaboration (HRC) in manufacturing processes, multimodal robot management must be intuitive and trustworthy. In earlier works, multimodal robotic control strategies were established. The technologies make it possible for human employees to control robots naturally without having to write brand-specific programming. However, because characteristics are not depicted consistently across multiple paradigms, the bulk of multimodal controlling robots' approaches are unreliable. In order to solve this problem, the research on reliable multimodal HRC production systems suggests a multimodal fusion architecture that makes use of deep learning. The proposed design consists of three modalities: verbal authority, hand gesture, and body motion. Three single-modal systems' characteristics are first trained to be retrieved, after which the characteristics are combined to swap representations. Tests show that the proposed multimodal fusion paradigm performs superior to the three unimodal models. The paper emphasizes the potential for applying the suggested multimodal fusion architecture to produce dependable HRC systems. The architectural concept paradigm wasn't made clear enough [14].

Radar electronic surveillance has new difficulties as a result of the emergence of cognitive wireless and electronic warfare; recognizing the signal generated by radar is a crucial component of this work. Research suggests a new radar signal recognition technique that uses non-negative matrix factorization network (NMFN) and ensemble learning. This system is capable of reliably recognizing radar signals under low signal-to-noise ratio conditions. Research investigates a method for extracting features based on a convolutional neural network at the beginning, which uses transfer learning as a way to address the issue of small sizes of samples. In order to extract characteristics and eliminate redundant data, research also suggests a non-negative matrix factorization system. In the third step, research create a feature fusion method utilizing stacked autoencoders (SAE), which can collect key feature expressions and condense feature dimensions. Last but not least, researcher suggests the improved artificial bee colony algorithm (IABC) as an ensemble learning technique that can increase the recognition rate. According to the simulation outcomes, recognition rates are 94.23% at 4 dB and 99.82% at 6 dB [15].

Dynamic MRI was used as a technique to record the body's various organs successive anatomy as they change over time. Nevertheless, due to mechanical and physiological limitations, its uses are restricted by shorter acquisition times. It has been demonstrated that dynamic MRI has spatio-temporal heterogeneity in its frequency spectrum (k-space). Lowering the number of k-space examples can greatly shorten the acquisition duration, yet at the expense of introducing artefacts into the associated image realm. To speed up the whole acquisition procedure, Shashidhar and Subha [16] created a cascaded Convolutional Long Short-Term Memory (ConvLSTM) framework for T2-weighted dynamic MRI patterns restoration from significantly under-sampled k-space information. Particularly, a Cartesian inadequate sampling mask could be used to under-sample completely sampled information obtained from the ADNI dataset. The aliasing artefacts caused by inadequate sampling are then eliminated using the ConvLSTM framework that has been suggested. In order to rebuild the imagery effectively and more accurately than CNN-based restoration, the ConvLSTM framework also learns the imagery's temporal and spatial connections. The utilization of medical databases presents ethical issues about data protection and informed approval, like the ADNI database. It is crucial to confirm that the research complies with ethical standards and has gotten the necessary rights and authorization for the use of the data.

### III. PROBLEM STATEMENT

The requirement for efficient multi-modal image fusion to improve image quality and interpretability across many applications is the issue this research attempts to solve. Integrating data from several sources while preserving the accuracy of the original data are difficult. Complex patterns and distinguishing traits are frequently difficult to capture using traditional techniques. The work suggests a remedy that combines the capacities of CNNs and NMF to address this. Utilizing CNNs' feature extraction abilities, the idea is to produce a fused feature representation that is then improved by NMF to uncover useful patterns. Since the non-negativity

requirement in NMF, the fused images are coherent and meaningful since their inherent structures are preserved. The suggested approach's capacity to maintain crucial diagnostic data and improve fusion quality is assessed by quantitative metrics and visual evaluations, demonstrating its potential to help precise decision-making and analysis in areas like medical imaging [17].

#### IV. PROPOSED FRAMEWORK

There are multiple steps in the suggested methodology for Deep Convolutional Neural Networks (CNNs) to fuse multimodal images. The process for Multi-Modal Image Fusion using Deep Convolutional Neural Networks and Non-Negative Matrix Factorization is depicted in Fig. 1. The input images are first preprocessed by converting them to a standard scale and using the proper transformations to improve image details. Then, using a sizable dataset of aligned multi-modal images and a fusion-specific loss function, CNN architecture is created, consisting of shared and modality-specific convolutional layers. From each modality, high-level feature maps are retrieved using the trained CNN. NMF is used to decompose extracted feature maps into non-negative basis vectors and coefficients in the setting of non-negative matrix factorization (NMF) feature extraction. The most discriminative basis vectors capturing the essential features of each modality are selected, and fusion weights are learned or fusion rules are applied to combine them. The fused basis vectors are multiplied with the corresponding coefficients to reconstruct the fused feature maps, which are then aggregated to generate the final fused image. Post-processing techniques like denoising or sharpening can be applied for further enhancement. This methodology is primarily used for multi-modal image fusion, where images from different modalities, such as infrared and visible, are combined to provide a comprehensive understanding of a scene. On the other hand, non-multi-modal image fusion is utilized in feature fusion scenarios where features from the same modality but captured under different conditions, such as exposure or focus, are fused to create a more comprehensive feature representation.

##### A. Data Collection

MRI brain images of 1000 datasets including healthy and unhealthy are used in the research. Among these 50% of images are used as training data and 50% of images are used as testing data. The collected brain cancer images were existing on the Kaggle depository website [18]. The datasets are distributed in Table I.

##### B. Data Preprocessing

Magnetic Resonance Imaging (MRI) imageries were impacted by unrelated and erratic noisy data, such as Gaussian noise and Speckle sound, which reduced the analysis value of those sample imageries. Speckle sounds have a significant impact on the contrast resolution of MRI brain imaging. Therefore, the original Hannmean filter is used to reduce noise in MRI brain images. A Hannmean filter is a filter that combines the Hanning window and Mean filters. The established Hannmean filter is used to minimize the noise in an image as well as any spatial intensity derivatives that may be present. In order to exchange each pixel's value with its surrounding neighbours' mean image values and ignore the

unreliable pixel value of their image background, the Hannmean filter is used. Noises are produced in MRI brain scans by the device's inhomogeneity dis a magnetic region afforded by temperature, the malfunction of the scanner, and the patient's movement throughout the scanning process. Both noiseless methods and image resolution were used to get a crisp MRI brain image [19].

Fig. 1. Proposed framework.

TABLE I. THE COLLECTED DATASETS

	Training data	Testing data
Unhealthy	250	250
Healthy	250	250
Overall data	500	500

##### C. Feature Extraction using CNN

Deep CNNs are remarkably good at capturing hierarchical representations and complicated patterns. In order to begin the feature extraction process, a series of deep CNNs are trained on a variety of datasets made up of multi-modal images. These networks learn to recognize distinguishing elements that are pertinent to each input modality since they are designed to the specifics of the input modalities. CNNs extract features that capture detailed textures, forms, and structures unique to each modality by utilizing both low-level and high-level filters. The cross-modal linkages are preserved while modality-specific subtleties are captured in the learnt features. Concatenating the retrieved features from the different CNNs results in the formation of the fused feature representation, this completely embodies the essence of the multi-modal inputs. The basis for further processing, such as the usage of NMF to hone and extract more abstract patterns, is this fused feature representation. The suggested framework improves the fusion

process by utilizing CNNs' advantages in extracting valuable features, thereby assisting in the creation of high-quality fused images that capture the complimentary information available in the multi-modal data.

The suggested medical image fusion architecture contains three primary phases, which are depicted in Fig. 2. To begin, it creates the same-size weight map (m) for source images X and Y of arbitrary size using Siamese network architecture. The produced weight map X is then subjected to Gaussian gradient deconstruction to produce the matching multi-scale sub-decomposed image Gm, which is used to establish the fusion operation in the coefficient calculation merger procedure. The top layer and the remaining layers of the sub-decomposed

image are represented by the symbols  $G_{M,i=N}^{i,s}$  and  $G_{M,0\leq1\leq N}^{i,s}$  [20]. The contrast gradient is used to break down the source images X and Y. For the following coefficient fusion technique, the multi-scale sub-decomposed images  $Q_x$  and  $Q_y$  are acquired. The top layers of the sub-decomposed images  $Q_x$  and  $Q_y$  are  $Q_{X,i=N}^{i,s}$  and  $Q_{Y,i=N}^{i,s}$  correspondingly. In order to denote the other layers of the sub-decomposed images  $Q_x$  and  $Q_y$ , accordingly, research adopts the notation  $Q_{X,i=N}^{i,s}$  and  $Q_{Y,0\leq1\leq N}^{i,s}$ . Finally, distinct thresholds are established, one for the top level and the other for the layers that make up sub-decomposed image  $F_q$ .

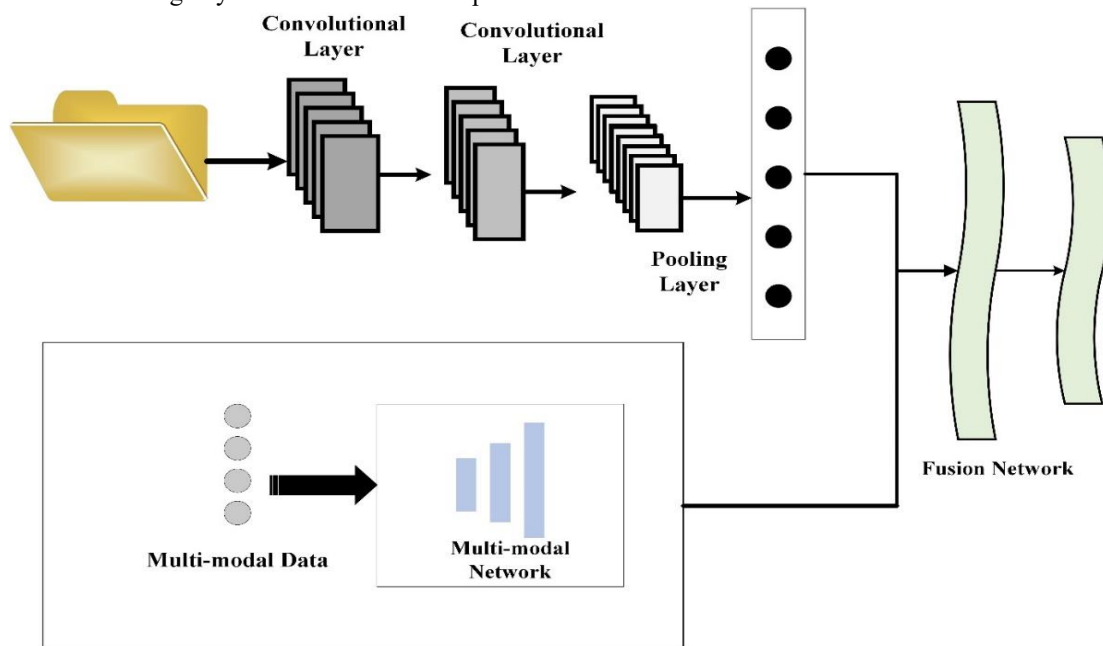

Fig. 2. Multi-modal fusion based deep convolution network.

The Fig. 2 represents a Multi-Modal Image Fusion based Deep Convolution Network, a powerful technique that combines information from different image modalities to generate a fused image with improved quality and interpretability. The network consists of input layers for each modality, followed by convolutional layers that extract relevant features from the images. Pooling layers down sample the feature maps, while fusion layers combines the extracted features from different modalities to create a comprehensive representation. Fully connected layers further transform and abstract the fused features, leading to an output layer that generates the final fused image. This architecture allows the network to leverage the strengths of each modality and enhance the understanding of the scene, making it a valuable tool in various applications [21].

The suggested technique uses CNN to accomplish an estimation of the ideal pixel level of activity and distributed weight by obtaining a weighted map of pixel activity details from numerous source images. In this study, Siamese networks are used to increase the effectiveness of CNN instruction. The Siamese system has two divisions. There are three convolutional layers and one max-pooling layer on each

branch. Convolutional neural networks comprise the top two layers. The input image's non-negative matrix factorization feature extraction is done on the first layer. There are more feature maps in the second layer. The top convolutional layer extracts the characteristics of the output map. In the proposed methodology, a max-pooling layer is included as the third layer in the network architecture. This layer serves to further reduce the number of parameters and remove unnecessary samples from the feature map. By down sampling the input feature map, the max-pooling layer retains the most significant information while discarding less relevant details, effectively reducing the computational complexity. Following the max-pooling layer, a fourth layer is introduced as a convolution layer. This layer extracts more intricate and detailed information from the pooled feature map, capturing finer patterns and features. To minimize the training complexity and memory usage, a lightweight network structure is employed for this convolutional layer [22].

Specifically, the feature maps from each branch are concatenated together in the network's final stage. Concatenation gives a more thorough representation by allowing the integration of knowledge gained from several

branches. The concatenated feature maps are then immediately coupled to a two-dimensional vector using a completely connected layer. The next bi-directional SoftMax layer uses this vector as its input. The two-dimensional vector is categorized based on probability values by the bi-directional SoftMax layer, which also forecasts the probability distribution of several qualities. This forecast is essential for estimating the probability that various attributes will appear in the input data. In order to predict attributes, the network outputs a probabilistic classification by mapping the two-dimensional vector to the SoftMax layer. Overall, to extract and express complicated information from the input data, this technology combines max-pooling, convolutional layers, and concatenation of feature maps. Accurate attribute prediction based on learned representations is made possible by the fully connected layer, the bi-directional SoftMax layer, and the probability-based categorization. This method is appropriate for a variety of applications requiring attribute prediction or classification since it minimizes the number of parameters, optimizes training complexity, and increases memory efficiency [23].

This study uses a SoftMax classifier to determine the categorization probability using Eq. (1) in order to achieve categorization in the DCNN network:

$$f(r_u) = \frac{e^{r_u}}{\sum_{v=1}^n e^{r_u}} \quad (1)$$

The mapping between each element of one ( $r_u$ ) will be approximately 1 and the rest will be closest to 0, normalizing all input matrices if one  $\pi_i$  is greater than every other component  $r$ . The SoftMax loss curve is found as Eq. (2) when the number of batches is set to 128:

$$B = \sum_{u=0}^{size} -\log f(r_u) \quad (2)$$

Stochastic gradient descent is utilized to minimize the loss function with the SoftMax loss value serving as the optimization objective. The acceleration loss and weight decay are established as the initial parameter values, respectively. Consequently, the weights are updated using Eq. (3):

$$s_{u+1} = s_u + t_u + 1 \quad (3)$$

In Eq. (3) the dynamic factor is defined as  $t_u$  and the weight is denoted as  $s_u$  at  $u^{\text{th}}$  iteration.

#### D. NMF for Multi Modal Image Fusion

By permitting the breakdown of fused feature representations into non-negative basis vectors and coefficients, NMF plays a crucial role in the field of Multi-Modal Image Fusion. This decomposition technique perfectly reflects the properties of image data, where pixel values are always positive. NMF makes it easier to create a fused image while maintaining the underlying natural structures and attributes existing in the input modalities by imposing this non-negativity requirement. The basis vectors, which depict fundamental patterns shared by all modalities, identify crucial characteristics that are similar to all inputs. By permitting the breakdown of fused feature representations into non-negative basis vectors and coefficients, NMF plays a crucial role in the field of Multi-Modal Image Fusion. This decomposition technique perfectly reflects the properties of image data,

where pixel values are always positive. NMF makes it easier to create a fused image while maintaining the underlying natural structures and attributes existing in the input modalities by imposing this non-negativity requirement. The basis vectors, which depict fundamental patterns shared by all modalities, identify crucial characteristics that are similar to all inputs.

Non-negative matrix factorization (NMF) is a powerful technique for multi modal fusion that aims to decompose a given data matrix into two non-negative matrices: a basis matrix and a coefficient matrix. In the context of feature extraction, NMF allows the extraction of meaningful and interpretable features by representing the input data as a linear combination of basis vectors. The basis matrix captures the fundamental components or patterns present in the data, while the coefficient matrix indicates the contribution of each basis vector to reconstruct the original data [24]. NMF assures that the extracted features are additive and non-competitive by applying non-negativity restrictions. This can be helpful for a variety of applications, including text mining, audio analysis, and image processing. The resulting basis vectors give the input data a condensed representation by emphasizing the key traits and bringing down the dimensionality, making it easier to perform further analysis or classification tasks. Overall, NMF-based feature extraction provides a practical method for identifying latent characteristics in data, enhancing the representation, comprehension, and use of complicated datasets [25].

For the assessment of non-negative matrices, the non-negative matrix factorization is used.  $A \in U_{G \times U}^+$  and  $B \in U_{U \times J}^+$  in which the two-matrix multiplication is similar to non-negative matrix  $C \in U_{G \times U}^+$  could be computed using the Eq. (4):

$$C = AB + F \quad (4)$$

Where  $F \in U_{G \times J}$  is an error matrix. The cost function connecting C and AB is minimized to predict the matrix of A and B as:

$$A = \arg \min_A Y(C|AB) \text{ for fixed } B \quad (5)$$

$$B = \arg \min_B Y(C|AB) \text{ for fixed } A \quad (6)$$

In Eqs. (5) and (6) the space between the two matrices of K and L is defined as  $V(K|L)$ .

The magnitude spectrogram of the signals is frequently used as the input matrix I in various applications of non-negative matrix factorization (NMF) for acoustic signals. In this instance, the frequency content of the acoustic wave over time is represented by the matrix I. Two non-negative matrices, A and B, are created by factorizing the matrix V. The spectrum features are represented by the matrix A, where each column vector represents a particular frequency structure or spectral component. The matrix B, on the other hand, reflects the temporal activations of acoustical events. Each row vector in this matrix represents the temporal envelope of a particular event. Research has been able to roughly reconstitute the magnitude spectrogram by multiplying matrices A and B. Consider a musical signal made up of three musical events to demonstrate this idea. Each column vector in matrix A would

be able to represent a different spectral pattern or frequency structure connected to the occurrences. The temporal envelopes of the various musical events would be represented by the row vectors of the matrix B, which would show how their amplitudes changed over time.

A conversion phase is used during the image testing and fusion process on the entirely linked layer to allow processing of sources of any size. The fully connected layer is converted into two identical convolutional layers with the same kernel size. Afterwards, the network may process any size images X and Y together in order to create a dense prediction map I. Each forecast  $I_s$  on the map has a two-dimensional vector with values ranging from 0 to 1. To make the weights assigned to corresponding image blocks simpler, if one dimension of a prediction is larger than the other, it is normalized to 1 while the other dimension is set to 0. This ensures that the weight of every image block is decreased with an output dimension value of 1. In their related image blocks, two close forecasts in S have overlapped areas. The mean value of the overlapping image blocks is obtained by adding the weights of the images in these overlapped sections. With the help of this method, the network can be fed images of any size, both X and Y, and a weight map W of the same size is produced. This makes sure that each image block's weight is reduced with an output dimension value of 1. The linked image blocks of the two close forecasts in I have overlap sections. The weights of the images in these overlapped portions are added to determine the mean value of the overlapping image blocks. Using this method, the system can produce a weight map W that is the same size as an image and accept images of any size, X and Y [19].

## V. RESULT AND DISCUSSION

Accuracy, Recall, Precision, F1-score, False Detection rate, Sensitivity, and Specificity are a few of the metrics used to verify the effectiveness of the projected model. True positive ( $t_p$ ), false negative ( $f_n$ ), false positive ( $f_p$ ), and true negative ( $t_n$ ) values are the fundamental variables that need to be computed.

### A. Accuracy

It gauges how precisely the system paradigm functions. In general, it refers to the ratio of correctly observed measurements to all data. The accuracy is presented in Eq. (7) as,

$$Accuracy = \frac{t_p + t_n}{t_p + t_n + f_p + f_n} \quad (7)$$

### B. Precision

The number of right positive estimates multiplied by the total number of positive guesses is used to measure precision. It is the percentage of precisely fused multi-modal medical images. Using Eq. (8), the precision is calculated as,

$$Precision = \frac{t_p}{t_p + f_p} \quad (8)$$

### C. Recall

Recall is defined as the ratio of true positives and false negatives to correct positive forecasts. It indicates the percentage of predictions that were accurate. multiple-modal image fusion. Eq. (9) is used to represent recall:

$$Recall = \frac{t_p}{t_p + f_n} \quad (9)$$

### D. Sensitivity

It is a measure of the proportion of correctly foretold true positives. Eq. (10) is used to calculate sensitivity as,

$$Sensitivity = \frac{t_p}{t_p + t_n} \quad (10)$$

### E. Specificity

The degree gauges how many precisely identifiable true negatives there are. Eq. (11) is used to calculate the specificity value as,

$$Specificity = \frac{t_n}{f_p + t_n} \quad (11)$$

TABLE II. COMPARISON OF PERFORMANCE METRICS

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Wavelet Transform	98.34	93.12	94.36	98.33
Fuzzy Logic	97.55	96.77	95.76	97.52
PCA	98.11	98.14	97.87	96.85
Proposed CNN-NMF	99.12	98.56	98.33	98.25

Fig. 3. Comparison of existing and proposed methods.

The Table II displays the accuracy, precision, recall, and F1-score performance evaluation of several image fusion techniques. The suggested CNN-NMF fusion strategy stands out among the tested techniques with the best accuracy of 99.12%, illustrating its capacity to successfully integrate multi-modal data. Additionally, this approach achieves impressive accuracy, recall, and F1-score values of 98.56%, 98.33%, and 98.25%, demonstrating its competence in accurately recognizing positive cases and minimizing false positives and negatives. The proposed CNN-NMF approach outperforms competing techniques like Wavelet Transform, Fuzzy Logic, and PCA, but it also has the potential to improve multi-modal image fusion tasks by capturing intricate patterns and preserving the integrity of the original data. It is depicted in Fig. 3.

TABLE III. MEDICAL IMAGE FUSION COMPARISON

Methods	Tsallis entropy	Gradient-based quality	Information ratio	Mutual information	Processing Time
MST-SR	64%	39%	36%	97%	15.05

CNN-LIU	62%	62%	28%	87%	14.58
Proposed	98%	45%	41%	92%	12.86

For the fused model with trainable and non-trainable weights, Fig. 4 and 5 displays the training accuracy and loss. Fig. 4 and 5 can be compared, and it is obvious that the model with trainable weights exhibits a faster improvement in accuracy and loss than the model with non-trainable weights. However, both networks achieve a point of convergence after around 40 epochs, with a training accuracy of about 98.07% and a loss of 0.0496. The fused model achieves a remarkable accuracy of 99.58% for the test dataset. These results show that both models eventually perform at a similar level in terms of accuracy and loss, however the model with trainable weights shows faster early development

A comparison of various methodologies based on various evaluation indicators and processing time is presented in Table III and Fig. 6. The NSCT-PC, CNN-LIU, ASR, MST-SR, and proposed algorithms are the ones that were tested. The Proposed technique receives the best score of 98% for Tsallis entropy, demonstrating its efficacy in maintaining information during the fusion process. While MST-SR, ASR, and CNN-LIU score lower with 64%, 66%, and 62% correspondingly, NSCT-PC comes in second with 71%. CNN-LIU receives the greatest score for gradient-based quality (62%), demonstrating its capacity to catch fine gradients in the fused image. The Proposed technique and ASR score 45% and 35%, respectively, whereas NSCT-PC scores 44%. The Proposed method achieves a 41% information ratio, showing a balanced preservation and utilisation of information. Following with 40% is NSCT-PC, followed by ASR with 39% and CNN-LIU with 28%. The Proposed technique receives a 92% for mutual information, demonstrating a high degree of mutual dependence between the input images in the fused result.

Following with 90% is NSCT-PC, and CNN-LIU comes in at 87%. The scores for MST-SR and ASR are lower, at 97% and 68%, respectively. In terms of processing speed, NSCT-PC performs the best with a time of 3.77. The Proposed approach achieves 12.86, whereas ASR comes in second with 6.15. The processing times for MST-SR and CNN-LIU are 15.05 and 14.58, respectively. The Proposed method achieves competitive scores for gradient-based quality and stands out in terms of Tsallis entropy, information ratio, and mutual information. A promising method for multi-modal image fusion, it surpasses competing techniques in most assessment measures despite taking a little longer to process data than NSCT-PC.

F. Discussion

The proposed research offers a novel method for multi-modal image fusion within the context of modern computer

vision that makes use of both Deep CNNs and NMF's advantages. Deep CNNs have been shown to be adept at extracting minute details and identifying subtle patterns in images, making them an invaluable tool for working with multi-modal data. The paper suggests using these deep CNNs in a two-stage fusion process. First, the neural networks are trained to extract significant features from various modalities, and then the features that were extracted are concatenated to provide a thorough fused picture of the input data. This method stands out due to the creative ways in which NMF is applied in two different phases: first, to break down the fused representations of features into non-negative basic vector and coefficients, and subsequently, to further extract significant patterns from the resulting fused feature maps. The inherent non-negativity requirement in NMF guarantees the preservation of organic structures and inherent qualities in the source images, producing fused images that are visually beautiful and semantically comprehensible. The method excels at extracting critical information from many modalities, as shown by a visual analysis of the fused images. Its amazing accuracy also stands out as a noteworthy accomplishment, beating other fusion techniques and demonstrating its better performance and resilience. As a result of the partnership between deep CNNs and NMF, this work offers an appealing method for multi-modal picture fusion that yields a reliable and highly precise fusion technique. The suggested method successfully collects and combines data from several modalities, producing combined images that are not only aesthetically pleasing but also semantically relevant. This is made possible by successfully merging both cutting-edge deep learning methods with matrix factorization techniques. This multi-modal fusion invention is poised to make major strides in a number of sectors that depend on picture processing and interpretation and where it is crucial to accurately extract complementing information from many sources.

Fig. 6. Objective evaluation comparison.

## VI. CONCLUSION

In this research, a unique and efficient multi-modal image fusion approach that makes use of Deep CNNs and NMF is provided. The suggested method tackles the fundamental problem of improving image quality and interpretability through fusion by taking use of current developments in deep learning and matrix factorization techniques. Deep CNNs have been shown to be effective in extracting features from a variety of input modalities, underscoring its importance in this situation by capturing complex patterns and discriminative data necessary for successful fusion. The approach creates information-rich representations that are then smoothly merged via the fusion process by training a series of deep CNNs on a variety of datasets. By allowing the extraction of crucial patterns from fused feature representations while conserving the inherent structures of the source images, the dual-stage integration of NMF represents a singular invention. This preservation, which is grounded in NMF's non-negativity condition, produces fused images that are both aesthetically cohesive and semantically understandable. The visual proof of information effectively collected from many modalities supports the approach's potential even more. This study's overall findings represent a substantial improvement in multi-modal image fusion, with potential applications in industries that need precise data integration and image enhancement.

**Abstract**—Image encryption is a crucial aspect that helps to maintain the images' confidentiality and security in diverse applications. Ongoing research is focused on improving the efficiency and effectiveness of encryption. Image encryption has many practical applications in today's digital world, such as securing confidential images transmitted over networks, protecting sensitive personal information stored in images, and ensuring the privacy of medical images. The suggested work represents a breakthrough in image encryption by proposing a model that leverages the power of DNA, RSA, and chaos. This model has three phases: key generation, confusion, and diffusion. The key generation phase employs a hash function and hyperchaotic technique to generate a strong key. During the confusion phase, the positions of pixels are rearranged, either at the image level or within blocks, using the Duffing chaotic map. Once the scrambling level is determined, each pixel undergoes two successive scrambling steps, with Henon and Arnold's chaotic map to change its location. During the diffusion phase, the encryption model employs a two- approach to ensure maximum security. Firstly, it utilizes dynamic DNA cryptography for non-adjacent bits, followed by robust RSA cryptography. The experimental results indicate that the model possesses a strong security level randomness and can withstand different attacks.

**Keywords**—Cryptography; image encryption; hash function; chaotic map; DNA encoding; DNA operations; RSA algorithm

## I. INTRODUCTION

In today's digital era, digital images are widely used for personal, professional, or commercial purposes. Therefore, these images require protection from unauthorized access. Image encryption and information hiding are the two basic approaches for securing digital images. Image encryption prevents hackers from recognizing the images by employing complex mathematical operations to transform image data into an unreadable form. Therefore, the hacker's attempts are wasted. There is a need to design and implement an algorithm characterized by its security and efficiency to succeed in withdrawing the different attacks. There are two phases in image encryption: diffusion and scrambling. The pixel positions are altered during the scrambling phase, whereas the pixel values are changed during the diffusion phase.

Various methods are employed during the confusion phase. Some of these works used the Arnold transform [1-3], Zigzag transformation [4,5], Fisher-Yates [6], and Josephus traversal

[7]. Other works implemented scrambling over two steps, such as L-shape and Arnold transforms as in [8], new filling curve design and Josephus traversal [9].

In terms of diffusion, S. Wang. et al. [10] suggested using the DNA sequence in the diffusion phase. Four sequences were derived from a 4D chaotic system and utilized to select the rules for encoding, computing, and decoding. They utilized higher dimensional chaos to offer a large key space. J. Yu et al. [11] began with the diffusion phase. They encoded the three matrices of RGB image using DNA sequence where a chaotic system chooses the rule. A new operation, known as DNA triploid mutation, was introduced to achieve cryptographic translation of DNA bases. Finally, they permuted the image using row-column permutation. C. Zou et al. [12] utilized two types of DNA strands: long and short. The image was permuted using two short DNA strands, while the long DNA strand was used in the diffusion stage. If the DNA sequence follows the property of the Watson-Crick base pairing, the XOR operation of DNA is performed; otherwise, the DNA addition operation is used.

B. Jasra and A. Moon [13] split the color image into three planes and encoded each plane using a DNA sequence based on the chosen row-level. A substitution algorithm relies on elliptic curves to accomplish effective encryption and authentication. J. Wang et al. [1] suggested a new type of chaos; Logistic-Sine self-embedding. They proved this type's chaotic features and adopted a 0-1 test to find the chaos's presence in the time series. They encrypted the plain image using a Logistic-Sine self-embedding chaotic system. Similarly, X. Li [14] introduced another chaotic sequence, which was 5D, and they showed that the 5D chaotic did not have a prominent Lyapunov exponent yet possessed several good characteristics. The 5D chaotic sequence was utilized to choose the DNA encoding, computing, and decoding.

The encryption model presented in [15] depended on a fused magic cube produced by fusing two magic cubes. The cipher image's pixels value was obtained from the plain image's pixels value by employing the fuse magic cube. J. Zheng and Q. Zeng [16] constructed an S-box using the obtained key from the Logistic map, generating a 16 x 16 matrix ranging from 0 to 255 with no repeated values. The image was diffused by traversing the scrambled image in order according to the generated keys.

A technique for encrypting color images was introduced in [17], which employs 3D chaos, RSA, DNA, and LSB. The image is initially encrypted using a DNA method and Lorenz chaotic map. The secret key is then encrypted employing RSA and hidden within a cipher image using LSB. In another approach proposed by M. Liu and G. Ye [18], image encryption is achieved by utilizing dynamic DNA alongside a hyperchaotic system. The dynamic DNA coding selects DNA rules in a randomized manner, guided by the employed chaotic map. This study also incorporates RSA to protect the secret key's confidentiality during transmission and management. U. Mir et al. [19] introduced an encryption method for color images using RSA and chaos in the domain of Hartley. The image is first ciphered utilizing RSA and then transformed from the time to frequency domain using a Hartley domain.

K. Jiao et al. [20] introduced an encryption approach combining RSA and a generalized Arnold chaotic map. The RSA algorithm obtains the map parameters, generating the keystream for a diffusion operation on the plaintext image. The confusion operation is then employed to conceal the image data and produce the cipher image. Babu M et al. [21] used chaotic Maps, RSA, and DNA sequences to encrypt images. This paper divided the plain image into several blocks. Secondly, different encryption schemes were utilized on each block, such as Secure Force, DNA Sequence, Arnold Map, and RSA encryption. Thirdly, a discrete cosine transformation algorithm was applied to the merged blocks, after which an XOR operation was conducted with a randomly generated key to produce the encrypted image.

This paper aims to enhance image encryption security by minimizing pixel correlation, maximizing randomness and unpredictability, and withstanding various types of attacks. The proposed encryption approach has three phases: key generation, confusion, and diffusion. The integration of different chaotic maps leads to a substantial expansion of the key space and makes encryption impervious to brute-force attacks. A robust key generation process achieves cryptosystem robustness against various attacks. Chaos and hash functions, SHA and MD5, produce the encryption key. The advantages of the SHA function are its irreversibility and a one-time pad key, while the chaos is characterized by randomness and unpredictability. The final encryption key is obtained by applying these hash functions to the user-specified key and the plaintext image. The encryption security approach is strengthened by utilizing the plaintext image and the user key.

Scrambling a pixel's locations can be done over the whole image or the divided blocks of the whole image, depending on the Duffing chaotic map. Moreover, two levels of confusion are implemented using Arnold and Henon's chaotic maps. The scrambling phase achieves high randomness between the pixels and decreases the correlation between the pixels to the minimum compared to the previous research, as illustrated by the results of the suggested method. The final phase is diffusion, implemented over two steps: DNA and RSA. In the DNA algorithm, the pair of bits to be replaced with the DNA sequence is not successive as customary in state-of-the-art research. The proposed algorithm incorporates dynamic DNA to select various rules for each pixel and DNA computations to improve its efficiency. The encoding, computation, and

decoding rules are determined using a 4D hyperchaotic sequence.

The second diffusion level is to implement the RSA algorithm, which is different from the state-of-the-art research where most of the paper used RSA along with DNA utilized RSA outputs as the initial values of chaotic sequences. Despite using multiple steps and various types of chaotic maps, we tried to keep the algorithm's runtime comparable to previous research. We conducted experimental testing and analysis to demonstrate the proposed approach's superiority and feasibility, showcasing its resilience against multiple attacks such as differential, plaintext, brute-force, occlusion, and noise attacks. Moreover, the correlation is lower than in the most recent research.

The paper's structure is as follows: the second section provides an overview of chaos and DNA cryptography. The third section outlines the suggested approach for image encryption/decryption, followed by the fourth section thoroughly explores the results, conducts in-depth analysis, and compares them with similar research. Lastly, the fifth section introduces the paper's conclusion.

## II. BACKGROUND

### A. Chaotic

Chaotic systems are characterized by unique features appropriate in encryption, like sensitivity to initial conditions, irregular behavior, and unpredictability. Therefore, using the chaotic sequence in the encryption system can give a high-security degree and robustness against attacks. Our suggested algorithm employs various types of chaotic systems at different stages to increase the key space and enhance security.

The 1D logistic map [22] generates chaotic dynamics in a discrete-time system. The Logistic chaotic map provides high speed, low arithmetic operations, and low computational overhead. It is a nonlinear recursive function defined by Eq. (1).

$$x_{n+1} = rx_n(1 - x_n) \quad (1)$$

Where  $r$  is a parameter that determines the map behavior.  $x_0$  should be  $\in [0,1]$  and  $r$  has to be within interval  $0 < r \leq 4$  to produce the chaotic behavior.

The Henon Chaotic Map [19] refers to a discrete-time dynamical map in 2D. Eq. (2) and (3) define the equations of the Henon map:

$$x_{n+1} = 1 - a x_n^2 + y_n \quad (2)$$

$$y_{n+1} = b x_n \quad (3)$$

To attain chaotic behavior in the Henon Chaotic Map, the control parameters  $a$  and  $b$  need to be assigned the values (1.4, 0.3).

The Arnold Chaotic Map [23] is often employed to scramble and alter pixel locations. It is described in Eq. (4) and (5).

$$x_{n+1} = (2x_n + y_n) \bmod m \quad (4)$$

$$y_{n+1} = (x_n + y_n) \bmod m \quad (5)$$

The "mod m" operation ensures that the coordinates do not exceed the image size.

Quantum Chaotic Map [24] is a classical dynamical system that is described to develop the function for solving computing of the quantum. It is used to generate many random numbers. The quantum map mathematical expression is given in Eq. (6)-(8).

$$x_{n+1} = r(x_n - |x_n|^2) - ry_n \quad (6)$$

$$y_{n+1} = -y_n e^{-2\beta} + e^{-\beta} r[(2 - x_n - x_n^*)y_n - x_n z_n^* - x_n^* z_n] \quad (7)$$

$$z_{n+1} = -z_n e^{-2\beta} + e^{-\beta} r[2(1 - x_n^*)z_n - 2x_n y_n - x_n] \quad (8)$$

Where  $x \in [0,1]$ ,  $y \in [0, 0.1]$ ,  $z \in [0, 0.2]$ ,  $r \in [0,4]$ ,  $\beta \in [6, \infty)$ ,  $x^*$  and  $z^*$  are complex conjugates of  $x$  and  $z$ .

Duffing Chaotic [23] produces chaotic dynamics in a discrete-time system. The Eq. (9) and (10) represent this map. It can be utilized to design damped oscillators.

$$x_{n+1} = y_n \quad (9)$$

$$y_{n+1} = -b x_n + a y_n - y_n^3 \quad (10)$$

Its control parameters,  $a$  and  $b$ , should be 2.75 and 0.2 to maintain chaotic behaviour in the Duffing Chaotic system.

### B. DNA

Images are encrypted using nucleic acid bases via a DNA encryption system, which subsequently carries out several additional DNA operations. The four nucleic acid bases identified by the Watson-Crick basic pairing principles are C (Cytosine), A (Adenine), T (Thymine) and G (Guanine). Every two bases complement each other; A is the complement of T and likely C and G. These four bases can be represented in binary using the numbers 00, 01, 10, and 11. There are 24 possible combinations for the DNA bases represented in binary. However, only eight satisfy the Watson-Crick complementary rule. Table I lists these eight coding principles. An illustration of the encoding process is as follows: Suppose a pixel value of 90 is represented in binary as 01011010. This number is then encoded as the AATT sequence if rule 4 is applied. There are a different number of operations according to the binary system. The operations used in this paper are addition, subtraction, multiplication, XNOR, XOR, right rotate and left rotate [10].

TABLE I. THE RULES OF DNA

Rule	1	2	3	4	5	6	7	8
A	00	00	01	01	10	10	11	11
T	11	11	10	10	01	01	00	00
C	01	10	00	11	00	11	01	10
G	10	01	11	00	11	00	10	01

## III. PROPOSED CRYPTOSYSTEM APPROACH

This section will showcase the construction of our suggested algorithm, which comprises three phases: key generation, confusion, and diffusion. The complete layout of our suggested algorithm is introduced in Fig. 1, and each phase will be elaborated in further detail in the preceding subsections. Our suggested approach is applicable to both grayscale and color images. For a color image with a size of  $M \times N \times 3$ , the three colors are separated into three matrices with an  $M \times N$  size, and each matrix is processed as a plain image.

### A. Key Generation

The immunity of the cryptosystem to various attacks is based on producing a solid key. The suggested algorithm employs the hash functions and chaotic sequence to generate the encryption key. The hash function has the advantage of its irreversibility and is a one-time pad key, while the chaos is characterized by randomness and unpredictability.

We chose to use MD5 and SHA-256 as the hash functions. The MD5 is faster than the SHA-256, but the SHA-256 is more complex than MD5. A hash value  $H_k$  is generated based on combining the original image and a random user-specified key. Generating the key from the original image enables the system to withstand chosen/known-plaintext attacks. The final key value,  $K_i$ , consists of 32 bits decimal.

The final key is used to generate the second input of DNA operation using the hyperchaotic map, Eq. (11)-(14). To enhance the approach's resistance to brute force attacks, we opted for the hyperchaotic map, which offers a large key space. The hyperchaotic initial values are calculated according to Eq. (15)-(18) and utilizing the final key,  $K_i$ . The matrix  $M \times N$  constitutes the representation of the second input, possessing identical dimensions to those of the original image.

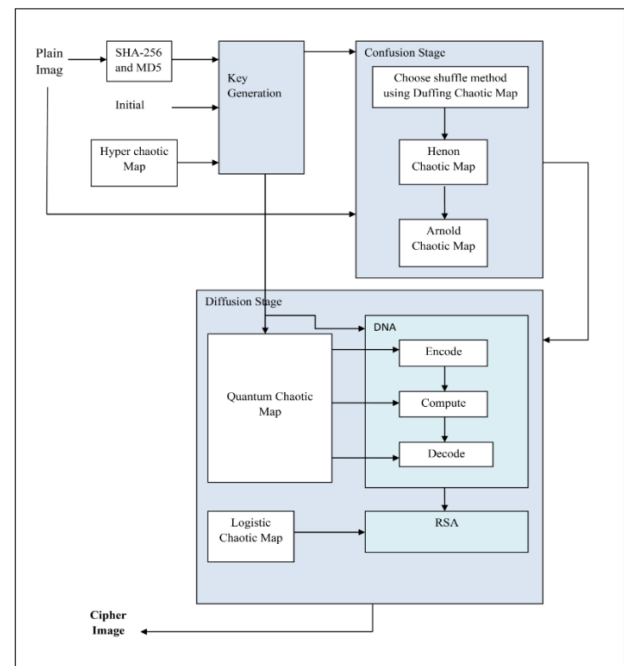

Fig. 1. The proposed image encryption approach's block diagram.

$$x_{n+1} = a(x_n - y_n) + r w_n \quad (11)$$

$$y_{n+1} = b x_n + x_n z_n - q y_n \quad (12)$$

$$z_{n+1} = -x_n y_n - c z_n \quad (13)$$

$$w_{n+1} = d x_n z_n - k w_n \quad (14)$$

$$x_0 = \frac{((((k_1 \oplus k_2) \wedge k_3) \oplus k_4) \wedge k_5) \oplus k_6}{256} \quad (15)$$

$$y_0 = \frac{((((k_7 \oplus k_8) \wedge k_9) \oplus k_{10}) \wedge k_{11}) \oplus k_{12}}{256} \quad (16)$$

$$z_0 = \frac{((((k_{13} \oplus k_{14}) \wedge k_{15}) \oplus k_{16}) \wedge k_{17}) \oplus k_{18}}{256} \quad (17)$$

$$w_0 = \frac{((((k_{25} \oplus k_{26}) \wedge k_{27}) \oplus k_{28}) \wedge k_{29}) \oplus k_{30}}{256} \quad (18)$$

Where  $k_i$  is XOR between the generated hash value and the initial secret key.

### B. Confusion Stage

This stage aims to change the pixel locations. Two alternatives were presented to achieve this goal: either process each pixel across the entire image or partition the image into blocks and rearrange the position of pixels within each block. The option number is calculated by Eq. (19), where  $y$  is determined from Duffing chaos in Eq. (9) and (10). Eq. (20)-(23) are utilized to compute the Duffing map's initial values and control parameters.

$$sh_{n0} = \text{floor}(\text{mod}(\text{avg}(y), 2)) \quad (19)$$

$$x_0 = \frac{k_{19} \oplus k_{20} \oplus k_{21} \oplus k_{22} \oplus k_{23}}{16} \quad (20)$$

$$y_0 = \frac{k_{25} \oplus k_{26} \oplus k_{27} \oplus k_{28} \oplus k_{29} \oplus k_{30} \oplus k_{31}}{64} \quad (21)$$

$$a = \frac{(k_{15} \oplus k_{16}) \oplus (k_{17} \wedge k_{18})}{16} \quad (22)$$

$$b = \frac{k_1 \oplus k_2 \oplus k_3 \oplus k_4 \oplus k_5 \oplus k_6}{512} \quad (23)$$

If the option number is one, we will change the pixel locations on the image's level depending on two chaotic systems: Arnold and Henon maps. The first step is to convert the original location,  $i$  and  $j$ , of each pixel to  $i_h$  and  $j_h$  locations using Henon, as shown in Eq. (24) and (25). The final locations,  $i_f$  and  $j_f$ , are generated using Arnold chaotic using the generated locations from the previous step, as illustrated in Eq. (26) and (27).

$$i_h = \text{mod}(\text{round}(|1 - a i^2 + j|), M) + 1 \quad (24)$$

$$j_h = \text{mod}(\text{round}(i + c), N) + 1 \quad (25)$$

$$i_f = \text{mod}(i_h - 1 + j_h - 1, M) + 1 \quad (26)$$

$$j_f = \text{mod}(i_h - 1 + 2(j_h - 1), N) + 1 \quad (27)$$

The other alternative is to modify the pixel location at the block level. The initial step involves partitioning the image into four blocks and shuffling their positions. Then, the pixel location within the block is rearranged by applying the same procedures as in the first method.

### C. Diffusion Stage

The confusion stage alone did not meet the encryption security requirements, necessitating the addition of a diffusion stage. The diffusion stage effectively conceals the original image information and increases attack resistance. In our proposed system, this stage consists of two steps, DNA and RSA, to offer more security to the cryptosystem.

1) DNA: In the DNA step, the encryption algorithm converts each pixel into its corresponding binary representation. Then, every pair of bits is substituted with a DNA sequence of four bases based on one of the eight DNA encoding rules shown in Table I. The DNA rule choice is made dynamically and calculated from Eq. (28), depending on the quantum map. The generated key is employed to obtain the quantum sequence's initial values, as shown in Eq. (29)-(31). The number of the generated quantum sequences equals the number of pixels to confuse the attacker, which rule is chosen and makes the cryptographic system unpredictable. Unlike the previous research, we did not replace the adjacent bits in each pixel; instead, we constitute a pair from the bit  $i$  and bit  $i+2$ , not  $i+1$ .

$$R_i = \text{floor}(8|x_i|) + 1 \quad (28)$$

$$x_0 = \frac{(((((((k_1 \oplus k_2) \oplus k_3) \oplus k_4) \oplus k_5) \oplus k_6) \oplus k_7) \oplus k_8) \oplus k_9)}{512} \quad (29)$$

$$y_0 = \frac{(((((((k_{10} \oplus k_{11}) \wedge k_{12}) \oplus k_{13}) \wedge k_{14}) \oplus k_{15}) \wedge k_{16}) \oplus k_{17}) \wedge k_{18})}{512} \quad (30)$$

$$z_0 = \frac{(((((((k_{19} \oplus k_{20}) \wedge k_{21}) \oplus k_{22}) \wedge k_{23}) \oplus k_{24}) \wedge k_{25}) \oplus k_{26}) \wedge k_{27})}{512} \quad (31)$$

$$op_i = 7 * \text{floor}(10^8|z_i|) \quad (32)$$

An illustration of the encoding process is as follows: Suppose a pixel value of 90 is represented in binary as 01011010. This number is then encoded using rule 4 as the GCCG sequence, not AATT. Here, the first A is determined using the first and third bit, which gives pair 11, equivalent to A according to rule 4.

After the encoding step, we apply a DNA operation on the encoded DNA sequence and the generated input from the previous stage to obtain another DNA sequence. The DNA operation,  $op_i$ , is selected based on the quantum sequence, as shown in Eq. (32). Finally, we perform the DNA decoding, which is the encoding reverse. The DNA sequence is converted to its equivalent binary using the rules in Table I. The rule is selected according to the quantum sequence shown in Eq. (28). The corresponding binary bits are reordered in odd and even positions, not as successive bits. For example, if the sequence is ATCG and the used rule is 8, the binary equivalent is 11001001, then it is reordered to 10101001. Finally, the decimal equivalent of the binary number is produced to use as the input of the RSA step.

2) RSA: The RSA step involves generating random prime numbers  $p$  and  $q$  using a Logistic chaotic map. The public and private keys are then calculated based on the result generated from the Logistic chaotic map, as shown in Algorithm (1). Afterwards, image encryption is achieved using the public

key, and decryption using the private key is illustrated in Algorithm (2).

---

**Algorithm (1) Public and private key generation**

---

Input: The prime numbers (p, q)  
 Output: Public key (PU), Private key (PR)  
 $x=q*p$   
 $\Phi(x)=(q-1)*(p-1)$   
 Choose e in condition that  $1 < e < \Phi(x)$  and  $\gcd(\Phi(x), e) = 1$   
 $d \equiv e^{-1} \pmod{\Phi(x)}$   
 PU = {x, e}  
 PR = {x, d}

---

**Algorithm (2) Encryption/Decryption of the image**

---

Input: Public key (PU), Private key (PR)  
 Output: Cipher image (C), Plain image (P)  
 $C = P^e \pmod{x}$   
 $P = C^d \pmod{x}$

---

**D. Image Decryption**

In the decryption phase, the encrypted image is converted back to its initial form, and the decrypted image reproduces the original image. This process follows a pattern inverse to that of encryption. The encrypted image first undergoes the diffusion phase, utilizing RSA followed by DNA techniques. Next, it enters the confusion phase, where Arnold and Henon chaotic maps are used, and the key generated from chaotic and hash functions, MD5 and SHA-256, is applied. The final output of this process is the original image.

**IV. EXPERIMENTAL RESULTS AND ANALYSIS**

The effectiveness and robustness of the suggested algorithm through various security tests are demonstrated in this section. Using MATLAB R2021a, the algorithm was simulated on a computer with an Intel(R) Core (TM) i5-6200U CPU @ 2.3GHz 2.4GHz and 8 GB of memory. There are different colors and grey images with different sizes utilized for testing. The grey images used in testing are Male 1024x1024, Lena 512x512, Barbara 512x512, Lake 512x512, Cameraman 256x256, and Kitten 256x256. The color images are Shreveport 1024x1024, Lena 512x512, Baboon 512x512, Lena 256x256, and Couple 256x256. Most of the images used in the study were sourced from the USC-SIPI database. Illustrations depicting the plaintext, cipher, and decrypted images are presented in Fig. 2 and Fig. 3 (a, c, and e). The right keys can be utilized to restore all images during the decryption tests. Any change in the secret keys, even if slight, leads to incorrect image decrypting, as will be proved in the following subsections. According to [25], there are four categories to estimate the proposed algorithm's performance.

- The visual perception evaluation

This category aims to generate an uncorrelated cipher image from the plain image. The performance metrics included in this category are PSNR, MSE, Correlation, Entropy, and Histogram analysis. Another test carried out within this category is the similarity test using the SSIM performance, which is adopted to evaluate the matching degree between the plaintext and cipher images.

- The high-performance evaluation

The goal of this category is to evaluate the diffusion characteristics. The tests to accomplish this goal are NPCR and UACI.

- The processing time.
- The strength of the cryptosystem evaluation

The cryptosystem strength is measured through key space, key sensitivity, and attack resistance.

**A. The Visual Perception Evaluation**

1) *Histogram analysis*: The distribution of tones inside an image, made up of pixels with various grey values, is essential. The histogram, which can adequately depict the amount of each pixel value, represents the tonal distribution of an image. An image's histogram gives statistical information that can be used to assess how strong an encryption system stands up to statistical attacks. Any plain image's histogram is covered by an angled or curved bar. There is much information in this bar. Hackers can use this bar to further their harmful goals. The cipher's task is to modify the pixel intensity values to produce a histogram with a uniform bar above it. Any information leaking in the image is greatly discouraged by the histogram's uniformity of the bar.

Additionally, it intimidates hackers and prevents them from succeeding with histogram attacks. Fig. 2 and 3(b,d) introduces the plain and encrypted images histogram. Apparently, the pixel distribution in cipher images is relatively uniform across all channels, but plain images have several peaks.

2) *PSNR and MSE*: Several measures are used to evaluate image quality, including PSNR and MSE, which quantify the level of difference between the original and cipher images. Equations (33-34) provide the mathematical expressions for PSNR and MSE.

$$PSNR = 10 \times \log_{10} \frac{p^2}{MSE} \quad (33)$$

$$MSE = \frac{1}{M \times N} \sum_{i=1}^M \sum_{j=1}^N |O(i,j) - C(i,j)|^2 \quad (34)$$

The maximum pixel value, represented by 8 bits, is denoted by  $p = 255$ . The plaintext and cipher images are denoted by  $O(i,j)$  and  $C(i,j)$ . The higher MSE and lower PSNR values determine the method's efficiency and security. Table II presents the PSNR and MSE values for grayscale and color image channels. As elaborated in Table II, the suggested algorithm achieves low PSNR and high MSE values, indicating its strong security and efficiency. Moreover, Table III compares the suggested algorithm's performance with previous research, pointing to its better performance relative to other techniques concerning both PSNR and MSE.

3) *SSIM*: SSIM is a test used to indicate how much the cipher image is similar to the plaintext image depending on the amount of structural information modification of the plaintext image. The SSIM is obtained as indicated in Eq. (35). A decrease in the similarity index indicates a decrease in

the match between the original and encrypted images and an increase in the degree of changed structural information.

The calculated values of the SSIM index are introduced in Table II. Table III shows that lower SSIM values close to zero indicate the lower similarity of the suggested algorithm. Moreover, the suggested algorithm gives better results than the other research, meaning the proposed algorithm offers less similarity to the other research, as indicated in Table III.

$$\begin{cases} SSIM(O, E) = \frac{(2 \mu_O \mu_E + C_1)(2 \sigma_{OE} + C_2)}{(\mu_O^2 \mu_E^2 + C_1)(\sigma_O^2 \sigma_E^2 + C_2)} \\ C_1 = (K_1 L)^2 \\ C_2 = (K_2 L)^2 \end{cases} \quad (35)$$

Where the  $\mu_O$  and  $\mu_E$  are the original and cipher images mean.  $\sigma_O^2$  and  $\sigma_E^2$  are the plaintext and cipher image variance. The original and cipher images covariance is denoted by  $\sigma_{OE}$ . L is set to 255, while  $K_1$  and  $K_2$  are set to 0.01 and 0.03, respectively.

	B	16261.35	6.0192	0.0002

4) *Correlation analysis:* Correlation analysis is a measure of how closely two variables are related. In plaintext images, adjacent pixels tend to be highly correlated, which can be utilized to attack the image. If the neighboring pixels correlation is excessively high, it makes it easier for attackers

to predict the next pixel value. By breaking the correlation between pixels, statistical attacks can be prevented. As the correlation between pixels approaches zero, it becomes progressively more challenging for a potential attacker to deduce any insights into the original plaintext image. The correlation values mathematical formulas in three directions are computed by Eq. (36). In Table IV, the correlation coefficients between the original and cipher images are depicted for all three directions. As depicted in the table, the original image coefficients are near one, meaning a solid correlation between pixels.

$$\begin{cases} R_{xy} = \frac{cov(x,y)}{\sqrt{V(x)V(y)}} \\ cov(x,y) = \frac{1}{N} \sum_{i=1}^N (x_i - E(x))(y_i - E(y)) \\ V(x) = \frac{1}{N} \sum_{i=1}^N (x_i - E(x))^2 \\ E(x) = \frac{1}{N} \sum_{i=1}^N x_i \end{cases} \quad (36)$$

Where the pixel total number is denoted by N, the values of the neighboring pair are x and y. The variance, mean, and covariance are V(x), E(x), and Cov(x,y), respectively.

The correlation values within the encrypted images approach zero, indicating a minimal correlation among pixels. Moreover, Table V shows that the correlation values for the proposed algorithm outperform the previous methods, which satisfies our objective of minimizing the correlation. In Fig. 4, the correlation distribution among adjacent pixels is depicted for the three directions of the 512 x 512 color Lena image. The figure shows the equal cipher image distribution, meaning the correlation between pixels is low. Moreover, scrambling over pixels on the block's level gives better results than scrambling pixels on the image's level, as introduced in Table VI.

5) Entropy: Entropy is a metric that indicates an image's level of randomness and unpredictability. The entropy can be calculated as given in Eq. (37).

$$Entropy = - \sum_{i=0}^{2^n-1} P(x_i) \log_2(P(x_i)) \quad (37)$$

Where the probability of x is P(x).

An entropy value of approximately eight is considered the ideal value for a cipher image [30]. Table VII presents the entropy value of the suggested algorithm, while Table VIII compares it with the recent work. The comparison reveals that the proposed method gives a better or similar result than the recent work, which satisfies our goal of maximizing the randomness and unpredictability of the image.

### B. The High-Performance Evaluation

In a differential attack, an attacker aims to uncover the differences between encrypted images produced from two slightly varied versions of the original image. The attacker looks for non-random areas in the encrypted images and then looks for changes in these areas that would conclude the key

used in image encryption. In slight alterations to the original image, the encryption procedure produces two cipher images: one for the original image and a second for the modified version. If a single-bit change in the original image causes the encrypted images to differ by at least 50%, then the differential attack cannot decrypt the cipher images. Two performance metrics are utilized, UACI and NPCR, to estimate the algorithm's resistance to differential attacks. The mathematical expressions for these two metrics are in Eq. (38) and (39).

$$NPCR = \frac{\sum_{x,y} D(x,y)}{N \times M} \times 100\% \quad (38)$$

$$UACI = \frac{\sum_{x,y} |E_1(x,y) - E_2(x,y)|}{255 \times M \times N} \quad (39)$$

Where  $E_1(x, y)$  and  $E_2(x, y)$  are two encrypted images of the same original image, but only one pixel value is changed.  $D(x,y)$  is calculated as follows:

$$D(x, y) = \begin{cases} 0 & E_1(x, y) = E_2(x, y) \\ 1 & E_1(x, y) \neq E_2(x, y) \end{cases}$$

Table VII showcases the NPCR and UACI values obtained through the proposed algorithm, whereas Table VIII provides a comparative evaluation of its performance against state-of-the-art methods. The NPCR and UACI values, approaching 99.6094% and 33.4635%, respectively, are considered close to the ideal benchmarks. The two metric values achieved by the suggested algorithm are in close proximity to the ideal values, demonstrating the suggested method's robustness against differential attacks.

### C. The Processing Time

Time evaluation is necessary in assessing the efficacy of cryptographic systems, with efficient systems expected to exhibit minimal encryption processes. To assess the time efficiency of our suggested algorithm, we conducted time measurements for each encryption step of the Kitten image, as shown in Fig. 5. The most consumable time is the key generation stage, as introduced in Fig. 5. Table IX displays a comparison of the encryption time consumed by the suggested approach with that of other approaches. The results show that our suggested method gives better time encryption for Lena with size 512. However, in the case of Lena's image with size 256, the results are higher than the two works as these works did not treat each color channel as a separate matrix as in our case.

TABLE VIII. THE ENTROPY, NPCR, AND UACI COMPARISON WITH PREVIOUS WORK

#### D. The Strength of the Cryptosystem Evaluation

1) *Key space analysis*: There are different types of attacks to obtain the original image. One type of attack that hackers can use is Brute force, where they try to decrypt the cipher image by employing all possible keys until the correct one is found. A key space with a large size can be a good defense against brute-force attacks, which refers to the entire set of keys used for image encryption. The researchers have determined that a minimum key space of 2100 [31] is required to resist brute-force attacks. The image cryptosystem's secret key was generated using 24 parameters from different chaotic maps in the suggested method—additionally, the hash function used 256 bits.

Following the IEEE 754 floating-point standard (double), the substantial precision amounts to 53 bits, necessitating 15 decimal digits for representation. Consequently, the key space of the proposed system stands at  $10^{437}$ , demonstrating resilience against brute-force attacks by surpassing the threshold of  $2^{100}$ .

2) *Key sensitivity*: A cryptosystem is considered effective if it is extremely sensitive to keys. Key sensitivity means any minor change in key value results in a significant change in output. There are two ways to test key sensitivity. The first is by making a faint change in the key value; the result should be two different encrypted images. The other way is that the slight change in key-value results in not retrieving the original image correctly from the encrypted one. In this paper, we test the key sensitivity in two ways. In the first test, we changed the key slightly and then encrypted the plain image to get another cipher image using two different keys. We change the initial value of x and y in the hyperchaotic used to generate the final key by adding to each value  $10^{-14}$ . The results illustrated in Fig. 6 show the robustness of the suggested algorithm regarding the slight change in key as parts c and e show the difference between the cipher image generated from the valid key and the cipher image produced from the modified keys.

The alternative approach for conducting the key sensitivity test encompasses encrypting the original image with the accurate key and decrypting the resulting cipher image using an altered key. Fig. 7 illustrates the distinction between the decrypted image derived from the correct key and the decrypted image obtained from the two adjusted keys. The difference between the two images proves the suggested algorithm's high sensitivity against a minor key change. Based on the two test results, the suggested method can resist brute-force and statistical attacks.

Fig. 6. Testing key sensitivity in encryption stage (a) image ciphered by the original key (b) image ciphered by the first modified key  $1(x0+10^{-14})$  (c) difference between a and b (d) image ciphered by the second modified key  $2(y0+10^{-14})$  (e) difference between c and d.

Fig. 7. Testing key sensitivity test in decryption (a) original image (b) decrypted image utilizing the first modified key  $(x0+10^{-14})$  (c) decrypted image utilizing the second modified key  $(y0+10^{-14})$ .

3) *Classical attacks*: Classical attacks include four attack types: chosen-plaintext, known-plaintext, chosen-ciphertext and ciphertext-only attack. The most harmful attacks are chosen and known plaintext attacks. In these two attacks, the attacker has access to plaintext and encrypted images and tries to deduce the keys. If the cryptographic system can withstand these attacks, it would be immune to the other two types.

The cryptographic system would be immune to the known and chosen plaintext attacks if it is sensitive to the key change, which is proved in subsection 2 of section D. Moreover, the suggested system is a one-time pad system that utilizes the SHA-256 function to produce the key. Another test in measuring the immunity to the attacks of known and chosen plaintext is to use all black and all-white images as the original, as shown in Fig. 8 (a) and (d). The corresponding cipher images for these two images and their histogram are displayed in Fig. 8 (b-c) and (e-f). The entropy and correlation values of the black and white images are depicted in Table X. From the results, the suggested algorithm shows strong immunity to the attacks of chosen and known plaintext attacks.

4) *Image processing attacks resistance*: During transmission, the cipher image may be exposed to several disruptions, and some attacks on cipher images will result in data loss. The decryption of a corrupted cipher image may thus lead to distorted or even unnoticeable results. The most famous image processing attacks are data and noise loss attacks. Minimizing the impact of data and noise loss attacks on the restored image is crucial for achieving an efficient image encryption algorithm.

The effectiveness of the proposed algorithm in withstanding noise attacks was assessed by introducing various levels of salt and pepper noise (0.5, 0.05, and 0.005) and then calculating the PSNR values between the original images and their decrypted counterparts. The results, presented in Table XI, affirm that the proposed algorithm effectively resists salt and pepper attacks.

Fig. 8. Classical attack test(a-c) black image, its cipher, and its cipher histogram (d-f) white image, its cipher, and its cipher histogram.

TABLE X. THE ENTROPY AND CORRELATION OF THE WHITE AND BLACK IMAGES

image		Entropy	Correlation		
			V	H	D
White	plain	-0.000000	-	-	-
	cipher	7.9993	-0.00005	-0.0034	-0.00199
Black	plain	0.0012	-	-	-
	cipher	7.99938	0.00088	0.0011	-0.0033

Furthermore, the algorithm's ability to withstand occlusion attacks was assessed by applying varying masks to the cipher images (1/16, 1/8, and 1/4). The decrypted images resulting from this masking process are displayed in Table XI, showcasing the algorithm's robustness against cropping attacks. Despite occlusion attempts, the algorithm demonstrates its capability to recover a portion of the image's information.

TABLE XI. THE PSNR VALUE OF THE PLAINTEXT IMAGES AND THEIR DECRYPTED IMAGES AFTER APPLYING NOISE AND DATA LOSS ATTACKS

Attack	Parameters	PSNR		
		R	G	B
Salt and pepper	0.005	27.3081	27.8380	27.8922
	0.05	20.3436	20.8994	21.9327
	0.5	10.8365	11.5345	12.5723
Cropping	1/16	19.1520	20.9261	21.9408
	1/8	16.3463	17.9376	18.8688
	1/4	13.4978	14.8659	15.8419

### V. CONCLUSION

The suggested technique in this paper employs DNA, RSA, and chaotic maps to produce an extremely robust and secure image encryption method. The approach encompasses three phases: key generation, confusion, and diffusion. The hash function and hyperchaotic are used to generate a robust key as the hash function is a one-time pad and chaotic produces unpredictable and random numbers. The suggested algorithm uses the original image and a user-defined key to generate the encryption key, thereby preventing the chosen/known-plaintext attack. In the confusion phase, there are two options to change the pixel's locations, either changing the location on the image's level or the block's level based on the Duffing map. After that, each pixel is subjected to two consecutive confusion steps: Henon and Arnold map. In the diffusion phase, the confusion phase output undergoes two successive diffusion steps: DNA followed by RSA cryptography. Using two steps in each phase maximizes the security and unpredictability of the suggested approach. Moreover, the suggested approach can withstand different attacks. Various security tests demonstrate the approach's effectiveness in withstanding attacks and achieving low correlation between neighboring pixels.

In future research, we will explore multi-model image encryption by combining color, texture, and depth data. Additionally, we aim to integrate machine learning techniques to optimize encryption parameters and enhance security. Another priority is reducing encryption time.

**Abstract**—Due to diverse backdrops, scale fluctuations, and a lack of annotated training data, the identification and recognition of objects in remote sensing images present major problems. In order to overcome these difficulties, this work suggests a novel hybrid technique that blends GAN and CNN. The suggested approach expands the small labelled dataset by synthesising realistic training examples using the generative abilities of GANs. The samples generated capture the various variances and backgrounds found in remote sensing photos, improving the object identification and recognition model's capacity to generalise. Additionally, CNNs, which are recognised for their outstanding feature extraction skills, are incorporated into the hybrid approach, enabling precise and reliable object identification and recognition. The model's CNN component is developed using both real and synthetic data, effectively combining the advantages of both fields. Several experiments are conducted on a large dataset of satellite photos to evaluate the performance of the proposed method. The results demonstrate that the hybrid model, with accuracy 97.32%, outperforms traditional approaches and pure CNN-based approaches in terms of dependability and resilience. The model may be efficiently generalised to unknown remote sensing images thanks to the GAN-generated samples, which bridge the gap among synthetic and actual data. The hybrid methodology used in this study demonstrates the possibility of merging GANs and CNNs for item detection and recognition using deep learning in remote sensing images.

**Keywords**—Object detection; Generative Adversarial Networks (GAN); Convolutional Neural Networks (CNN); deep learning; remote sensing; satellite images; hybrid model

## I. INTRODUCTION

Remote sensing images captured by satellites and aerial platforms provide a wealth of valuable information about the Earth's surface. Analysing these images for object detection and recognition tasks is of utmost importance in various domains such as environmental monitoring, urban planning, and disaster management [1]. Deep learning algorithms have

the potential to significantly increase the precision and effectiveness of item recognition and detection in this field when applied to remote sensing photos. Conventional methods to identifying and recognising objects in remote sensing photos frequently depend on rule-based algorithms and hand-crafted features, which have difficulties capturing the intricate and varied aspects of the data. The identification and classification of objects based upon their visual patterns and properties is made possible by deep learning techniques, which excel at autonomously learning hierarchical representations straight from the data [2].

In recent years, deep learning-based approaches have gained traction in remote sensing applications, leveraging the power of CNNs to learn discriminative features from large-scale remote sensing datasets. These models can effectively detect and recognize various objects, such as buildings, roads, vehicles, vegetation, and water bodies, in remote sensing images. By learning from a vast amount of data, CNNs can capture intricate spatial and spectral information, enabling accurate and robust object detection and recognition [3]. The advantages of deep learning in remote sensing imagery include its ability to handle complex scenes with diverse backgrounds, variations in lighting conditions, and different sensor characteristics. Additionally, deep learning models can learn from a wide range of remote sensing data sources, including optical imagery images and multispectral/hyperspectral data, making them versatile for different remote sensing applications [4]. By employing deep learning techniques, one can anticipate significant improvements in object detection and recognition performance in remote sensing images. The automated and efficient nature of deep learning models will enable faster analysis of large-scale datasets, leading to timely and accurate decision-making in various domains [5].

Additionally, the adaptability of deep learning approaches allows for transfer learning, where models trained on one remote sensing dataset can be fine-tuned on another dataset,

reducing the need for extensive annotation efforts. The effectiveness of the deep learning-based object identification and recognition system will be assessed throughout this research using benchmark satellite imagery datasets, comparing it with current state-of-the-art techniques [6]. One will consider metrics such as detection precision, recall, and computational efficiency to assess the accuracy and efficiency of our proposed approach. By advancing the state-of-the-art in deep learning-based object detection and recognition in remote sensing images, this research has the potential to greatly enhance our understanding of the Earth's surface and enable informed decision-making in a wide range of applications. The accurate identification and classification of objects in remote sensing images contribute to improved land cover mapping, infrastructure monitoring, disaster response, and environmental assessments, ultimately leading to more effective and sustainable management of our planet's resources [7].

A fundamental aspect of a computer vision job, object detection has a wide range of uses in automation, autonomous vehicles, and surveillance. By extracting discriminative characteristics from big datasets, deep learning models in particular CNN have achieved extraordinary performance in object recognition over time [8]. However, traditional CNN-based approaches often struggle with detecting objects in challenging scenarios, such as occlusions, small object sizes, and cluttered backgrounds. To address these challenges and improve object detection performance, a hybrid approach that combines the power of GANs and CNNs has gained significant attention. Generative Adversarial Networks have demonstrated their effectiveness in generating realistic synthetic data that follows the same distribution as the real data. GANs consist of a generator network and a discriminator network that engage in a competitive learning process [9]. The generator network synthesizes samples, aiming to fool the discriminator into classifying them as real, while the discriminator network tries to accurately distinguish between real and synthetic samples. This adversarial training leads to the generation of synthetic data that closely resembles the real data distribution [10].

By leveraging the generative capabilities of GANs, the hybrid approach aims to improve object detection performance by generating additional training samples. These synthetic samples provide the CNN-based object detection model with a more diverse and comprehensive understanding of object classes, augmenting the training data and enhancing the model's ability to generalize to different variations and challenging scenarios [11]. The hybrid approach involves two main stages. In the first stage, a GAN is trained on a large dataset of real object images, learning the underlying data distribution and generating synthetic samples that closely resemble real objects. These synthetic samples, combined with the real training data, create an augmented dataset for training the CNN-based object detection model. In the second stage, the CNN learns discriminative features from the augmented dataset, enabling accurate and robust object detection [12].

Fig. 1 represents the hybrid approach which offers several advantages in object detection. Firstly, it addresses the challenge of limited training data by synthesizing additional samples that capture a broader range of object variations. This augmentation leads to improved generalization and better handling of rare or underrepresented object classes. Secondly, the adversarial training process in GANs encourages the generation of realistic and diverse synthetic samples, effectively enhancing the model's ability to handle variations in object appearance, scale, and background clutter. Lastly, the hybrid approach promotes the transferability of learned features across different datasets and domains, enabling the model to adapt and generalize well to unseen data [13]. This approach focuses on developing and evaluating the hybrid approach of GANs and CNNs for object detection. This work will conduct extensive experiments using benchmark object detection datasets, comparing the performance of the hybrid approach against traditional CNN-based methods. This work will evaluate metrics such as detection accuracy, precision, recall, and robustness to challenging scenarios to assess the effectiveness of the hybrid approach [14].

CNN and GAN have revolutionized the field of object detection by providing powerful tools for accurate and robust identification of objects in images and videos. CNNs are extensively used in the early stages of object detection to extract relevant features from the input data. These deep neural networks are trained on large datasets to learn hierarchical representations of objects, enabling them to recognize patterns and objects at different levels of abstraction [15]. The convolutional layers of CNNs perform local feature extraction, while the fully connected layers analyze the extracted features and classify the objects. On the other hand, GANs play a crucial role in enhancing object detection by generating realistic and high-quality synthetic data. By training a GAN on a large dataset, it learns to generate images that closely resemble real-world objects, even in complex scenarios or rare situations. These synthetic images can be combined with the original dataset to augment the training data, thus increasing the diversity and robustness of the object detection model [16]. The improved accuracy and robustness of object detection have implications in various real-world applications, including autonomous systems, surveillance, and object recognition [17]. The findings from this research contribute to advancing the field of object detection and pave the way for more effective and reliable computer vision systems in practical applications [18]. The goal of this project is to create an effective recognition and detection of objects system for satellite or other aerial platform-derived remote sensing photos. In order to overcome issues like changing lighting circumstances and sensor noise, the project intends to automate the detection and classification of things like roads, structures, and automobiles in these photos. To increase the effectiveness of analysing remote sensing data for uses like urban planning as well as disaster assessment, a precise and scalable system is being developed.

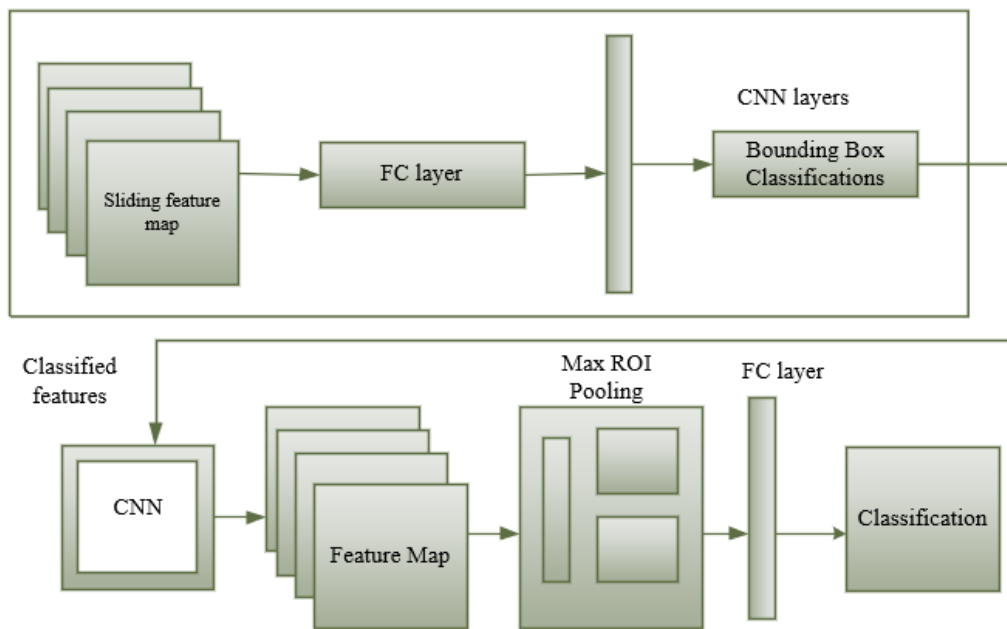

Fig. 1. CNN-GAN approach for object detection.

The following are the research's main contributions:

- The GAN-CNN approaches have been employed by other researchers, the proposed method stands out by introducing a distinctive data augmentation strategy that leverages GANs to generate authentic training examples, effectively addressing the challenges posed by diverse backgrounds, scale fluctuations, and limited annotated training data in remote sensing imagery.
- This hybrid strategy effectively augments the small annotated dataset and captures a variety of background fluctuations by harnessing the generative powers of GANs to create realistic training samples.
- The method makes the most of both domains by training the CNN components on both real and artificial data.
- The hybrid model significantly outperforms traditional and pure CNN-based approaches, according to experimental results.
- The potential of the hybrid technique for reliable and effective remote sensing item detection and recognition is demonstrated by the bridges of synthetic and actual information through GAN-generated samples, which improves the model's generalization to unknown remote sensing images.

The rest of the paper is structured as follows: Section II is described as related works while problem statement is explained in Section III. Similarly, Section IV is described as proposed methodology and Section V described as results and discussion and the conclusion is described as Section VI.

## II. RELATED WORKS

Li et al. [19] proposed a novel lightweight CorrNet is an ORSI-SOD approach. In CorrNet, first a compact subnet is

created for feature extraction and lessens the core network (VGG-16). Then initial crude prominence map is created using semantic features that are high-level in the correlation module, according to the coarse-to-fine technique. The granular scalar maps act as a geographical cue for low-level characteristics. Using the cross-layer association procedure the object position information is mined between high-level semantic characteristics. Finally, using low-level detailed characteristics, the coarse prominence map in the refinement subnet was refined to create the final fine saliency map. By lowering the requirements and calculations for each component, CorrNet ends up with only 4.09 million parameters and uses 21.09 gigaflops to execute. Results from tests on two open data sets demonstrate that lightweight CorrNet outperforms 26 modern techniques, including 16 huge methods based on CNN and two ultralight techniques, while saving a substantial amount of memory and runtime. Compact CorrNets are less suited to tackling difficult tasks involving the need for a greater capacity model because they are often built to contain less information. A lightweight CorrNet might not have enough capacity to catch such subtleties if the problem you're attempting to solve contains complex patterns or necessitates a lot of data presentation.

Sun et al. [20] created a part-based convolution neural network (PBNet) for integrated composite object detection in remote sensing pictures. PBNet evaluates an amalgamated object as a collection of parts and integrates component variables with contextual data to improve composite object recognition. Accurate ingredient knowledge can aid in the forecasting of an integrated item and help with problems resulting from various shapes and sizes. In order to provide accurate part information, a part placement module is developed that teaches the classification and localization of component positions using solely a boundary annotation. From a publicly available dataset, three representative categories of composite items are chosen for conducting

operations to test the effectiveness and generalizability of this method's identification capabilities. This dataset includes sewage treatment facilities from seven Yangtze Valley cities, encompassing an extensive variety of geographic areas. Extensive testing on two datasets demonstrates that PBNNet outperforms the current detection methods and reaches cutting-edge accuracy. Part-based models, however, primarily rely on precise part identification. The component detection process' noise or imprecision can have a negative impact on how well the PBNNet performs. Because of its reliance on precise component localization, the model may be more susceptible to mistakes or noise during the part identification process, which might result in poorer robustness and generalization.

Zhang et al. [21] proposed the Feature Pyramid Network which makes use of the built-in multiple scales rounded characteristics as well as incorporates the strong-semantic, and the weak-semantic, excellent quality features simultaneously, has been proposed as an efficient region-based VHR remote sensing imagery identification framework. The DM-FPN is made up of two modules that may be trained end-to-end: a multi-scale region suggestion network and a multiple habitats object detection network. To broaden the range of training data and get beyond input image size limitations, a number of multi-scale training methodologies are presented. To improve detection performance, particularly for tiny and dense objects, multi-scale prediction techniques are presented. Extensive tests and thorough analyse on a sizable DOTA dataset show how successful the suggested architecture. DM-FPN introduces an additional level of complexity compared to the original FPN. The inclusion of double multi-scale features requires more computational resources, including memory and processing power. This increased complexity can impact training and inference times, making it less suitable for real-time or resource-constrained applications.

Chen et al. [22] proposed a CNN for object recognition that combines scene-contextual data. The environment-contextual feature pyramidal network (SCFPN), in particular, seeks to improve the bond among the objective and the scene and address issues brought on by fluctuations in target size. The network is created by repeating an accumulated remnant block in order to enhance the ability to perform extracting features. With the help of this block, the receptive field may harvest targets' deeper information and perform very well in terms of tiny object recognition. Additionally, group normalization, which separates each channel into group and determines the variance and mean for normalization within each group, is utilized to overcome the batch normalization's limitation and enhance the efficacy of the suggested model. A tough public dataset is used to validate the suggested approach. The experimental findings show that our suggested approach outperforms existing cutting-edge object identification techniques. To include scene-level contextual data, SCFPN adds further layers and calculations. This could result in higher computing demands for both inference and training. SCFPN may be less appropriate for actual time or limited in resources applications as a result of the extra complexity.

Yan et al. [23] Developed the full-scale object detection network (FSOD-Net), which is comprised of a suggested multiscale enrichment network backbone transmitted with scale-invariant regression layers (SIRLs), is a one-stage scanner. First, by integrating the Laplace kernels with less concurrent multiscale layers of convolution, MSE-Net offers the multiscale characterization improvement. Second, because SIRLs have three distinct independent extrapolation branch layers (small, medium, and large scales), full-scale object information is covered by the default discrete scale bounding boxes (bboxes) in the regression technique. A further approach employs an oval-specific scale joint loss that combines a strong L1 norm restriction with the soft max function for each regression branch layer. It can also hasten convergence and boost anticipated b-box classification results. The findings of extensive research conducted on challenging sets of data over identifying objects in aerial images (DOTA) and object identification in visual imagery from remote sensing (DIOR), which include numerous examples from various imaging platforms, show that FSOD-Net is capable of performing better than other cutting-edge one-stage detectors. FSOD-Net, tend to have a higher computational complexity compared to simpler tasks like image classification. Object detection involves not only classifying objects but also accurately localizing their positions and generating bounding box predictions. This increased complexity can result in longer training and inference times and require more computational resources.

Ming et al. [24] proposed a Critical Feature Capturing Network (CFCNet) enhancing the accuracy of detection by focusing on three areas: developing robust visualization of features, fine-tuning pre-anchored patterns, and label assignment optimization. For instance, while constructing robust key features specific to a task, researchers first isolate the classification and recurrence elements using the Polarization Attention Module (PAM). The Rotation Anchor Refinement Module (R-ARM) performs localization improvement on preset perpendicular anchors to create superior rotation anchors using the retrieved selective regression characteristics. After that, high-quality anchors are adaptively chosen using the Dynamic Anchor Learning (DAL) technique based on their capacity to capture crucial information. The proposed system achieves outstanding performance immediate time object recognition and more potent conceptual representations for structures in remote sensing pictures. Experimental finding on three remote sensing datasets which demonstrate that this technique outperforms numerous state-of-the-art methodologies in terms of detection performance. Attention mechanisms often require additional memory to store the attention maps or weights. If PAM generates attention maps with high spatial resolution, it can significantly increase the memory usage of the network, making it less suitable for memory-constrained environments or large-scale applications.

Lu et al. [25] proposed a feature-fusion SSD and an end-to-end network called attention. First, a complex feature fusion framework is created to improve the shallow features' semantic information. The feature information is then screened by the introduction of a dual-path attention module. The background noise is muted and the main feature is

highlighted in this module using spatial focus and channel attention. A multiscale responsive field module follows, which improves the network's capacity for feature representation even more. In order to correct the imbalance among both the positive and negative samples, the loss function is lastly optimized. The results of this method's experiments on the data sets demonstrate its efficacy. Integrating attention mechanisms and feature fusion techniques into the SSD framework can introduce additional computational overhead. This may lead to increased training and inference times, making it less suitable for real-time or resource-constrained applications. SSD is designed to handle objects of different scales using a set of predefined anchor boxes. The introduction of attention and feature fusion mechanisms may introduce additional challenges in effectively handling scale variation. If not properly designed, the architecture may struggle to accurately detect objects at various scales, leading to potential detection errors. Attention mechanisms and feature fusion techniques introduce additional learnable parameters into the model. This increased parameter count may make the model more prone to overfitting, especially when the training dataset is limited or regularization techniques are not effectively employed. Careful parameter initialization and regularization strategies are required to mitigate these issues.

Fu et al. [26] suggested a feature-fusion architecture that uses a top-down pathway to add semantic descriptions to depth layer characteristics and an upward pathway to integrate top layer map features with low-level data to produce a multiple scales feature hierarchy. It is possible to create a potent representation of characteristics for numerous scales objects by mixing features from many levels. Axis-aligned boxes, which may include nearby instances and backdrop regions, have been used by the majority of prior approaches to find objects with variable directions and dense spatial distributions. This method creates a rotation-aware entity detector that locates items in remote sensing pictures by using oriented boxes. The region suggestion network adds more default angles to the anchors to better cover orientated objects. Instead of using horizontal proposals, which only imperfectly locate oriented objects, it uses oriented suggestion boxes to contain objects. For obtaining the characteristic maps of oriented suggestions for the next R-CNN subnetwork, the orientation-based RoI pooling procedure is implemented. On a public dataset, extensive tests are run for oriented object recognition in remote sensing photos. Feature-fusion architectures typically rely on having access to multiple modalities or sources of information. If one or more of these modalities are missing or inaccessible, the model may not be able to effectively perform feature fusion, limiting its performance or applicability.

### III. PROBLEM STATEMENT

The problem addressed in this research is the development of a robust and efficient object detection and recognition system for remote sensing images. Remote sensing images, acquired from satellites or aerial platforms, provide valuable information for applications such as land cover mappings, urban planning, and disaster assessment. However, manually

analysing these images is time-consuming and impractical, necessitating automated methods to identify and classify objects of interest [27]. The objective of this study is to design an accurate and scalable system that can detect and localize various objects in remote sensing imagery, such as buildings, roads, vehicles, and natural features, and subsequently recognize and categorize them into relevant classes. The system should be able to handle the challenges associated with remote sensing data, such as varying lighting conditions, sensor noise, and the large-scale nature of the datasets. By addressing these challenges, the proposed system aims to enhancing the efficiency and accuracy of object detection and recognition in remote sensing images, facilitating the analysis and interpretation of these critical data sources.

### IV. PROPOSED GAN-CNN APPROACH

For object detection and recognition in remote sensing images, the suggested methodology combines GANs with CNNs. The studies make use of two datasets, DOTA and UCAS-AOD, totalling 2900 and 1500 aerial photos with labelled items, respectively. By producing fake remote sensing photos, GAN-based data augmentation is used to broaden the dataset's variety and generalisation. An object generation network plus an image interpretation network makes up the GAN model known as RDAGAN. The image interpretation network makes sure that the generated pictures approximate the specified domain while the object generation network creates realistic objects. In order to handle multiscale objects, the CNN-based object identification employs a Faster R-CNN architecture with multilayer Region Proposal Networks (RPNs). The RPNs improve the detection of both tiny and large objects by using various CNN levels to create object suggestions. Additionally, CNN feature map fusion is included in the suggested approach to improve the representation of tiny objects without the need of up sampling. Overall, to accomplish precise and reliable object detection and recognition, the hybrid strategy includes GAN-based data augmentation, CNN-based object detection, and specialised algorithms for remote sensing images. Fig. 2 shows the Overall architecture of the proposed methodology.

#### A. Dataset Collection

DOTA and UCAS-AOD are two datasets used in the study's experiments [28]. The responsibilities for oriented (OBB) and horizontal bounding boxes (HBB) are included in both. The DOTA dataset, which now comprises 2900 aerial images with pixel sizes ranging from 800 x 800 to 4000 x 4000 and objects belonging to fifteen different groups with an overall number of 196171 occurrences, is the biggest dataset for object recognition in aerial imagery. It is divided into three sets: training (1/2), validation (1/6), and testing (1/3). UCAS-AOD includes 15683 occurrences of each of the two classifications (Plane and Car) and 1500 aerial images, each measuring roughly 1000 by 1000 pixels. For training and assessment, the research randomly chose 1220 images. Employing the authorized development kit for DOTA, the study divided images into  $1024 \times 1024$  squares with 512 pixels of overlaps. The datasets for identifying objects and recognition using remote sensing are displayed in Table I.

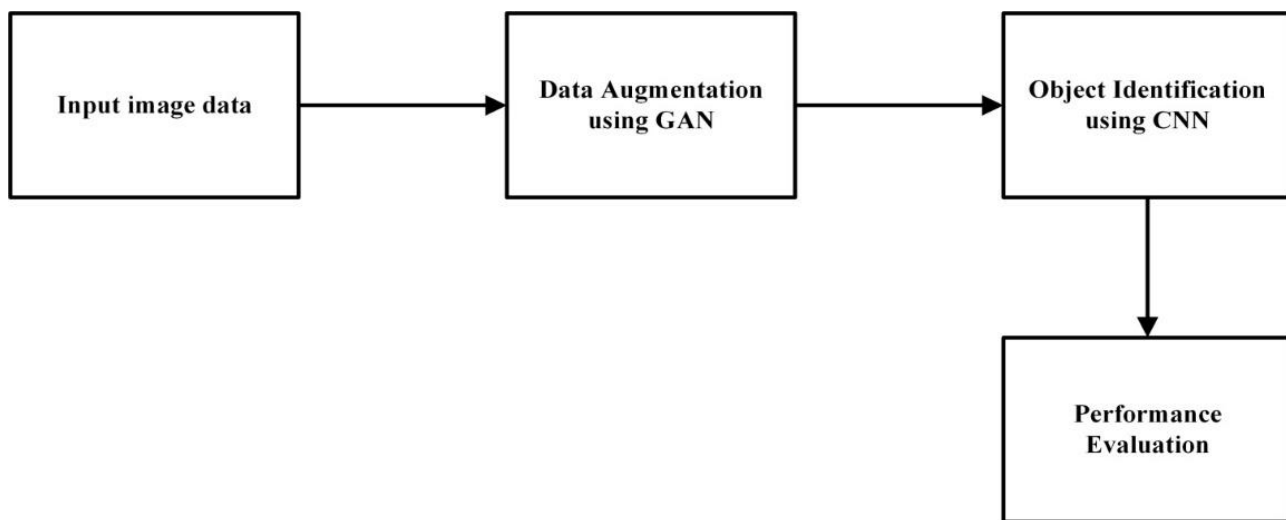

Fig. 2. Overall architecture of the proposed methodology.

TABLE I. REMOTE SENSING OBJECT DETECTION AND RECOGNITION DATASETS

Datasets	Total number of images	Categories	Instances	Image Sizes (Pixels)	Image Type
DOTA	2900	15	196171	800x800 to 4000x4000	RGB
UCAS-AOD	1500	2	15683	1000x1000	RGB

### B. GAN based Data Augmentation

In several industries, including remote sensing and medical imaging, an image data augmentation technique based on GAN is frequently employed. Because neural networks in these domains need a lot of training data, it might be challenging to collect enough of it. It is simple for models to over fit or fall victim to the class imbalance problem when there are few data points. By creating fresh samples from a data distribution, the GAN-based picture data augmentation techniques can solve these issues. Fig. 3 shows the overall design of RDAGAN.

Fig. 3. The overall design of RDAGAN.

RDAGAN operates by training a GAN to generate synthetic data samples that closely resemble the true data distribution. This process significantly expands the available training data, mitigating the risk of over fitting and enhancing model generalization. The suggested robust data augmentation GAN (RDAGAN) model does the data augmentation. The objective was to create a framework that maps targeted images in the desired image domain ( $i_s \in S$ ) to cleaned images in the image cleanliness domain ( $i_r \in R$ ). The proposed algorithm was trained employing a dataset for object recognition with few images, most of which contained occlusions. The proposed framework uses the divide-and-conquer strategy, splitting the framework into two networks. The model tries to add realistic objects to the image ( $i_r$ ), but it also tries to change the overall image to seem like it belongs in the domain that it is targeting ( $S$ ). A single GAN structure makes it difficult to accomplish these objectives since the training process becomes unpredictable.

To be placed into  $i_r$ , the target object's image is created by the object creation network. The visualization created by the object creation network is sent into the image interpretation network as a source of input. Due to the objectives of object formation and image interpreting, the imagery reduces the training instabilities in the image interpretation network. In order to generate a separated illustration of the target object, the network utilizes the InfoGAN architecture. The image interpretation network creates a loss function using the separated representations it received from the object development network. The crop and resize modules  $C$  were used to crop and resize object images  $C(i_c)$  from image  $i_r$  in order to train the algorithm. The hidden code  $r$  and indestructible noise  $x$ , which are obtained by sampling from a normal distribution, are inputs to the generator  $E_{obj}$ . In addition to validating the input images, the discriminator  $M_{obj}$  also forecasts the input hidden code  $r'$ .

The framework's goal  $N_{obj}$  includes two losses since the object formation network utilizes the InfoGAN design: an adversarial loss  $N_{GAN}^{obj}$  and an information loss  $N_{Info}^{obj}$ .

The negative outcome Eq. (1) explains how to utilize  $N_{GAN}^{obj}$  to ensure that the created patch  $E_{obj}(x, r)$  resemble the domain of the intended images  $C(i_s)$ .

$$N_{GAN}^{obj} = G_{C(i_s) \sim S} \log M_{obj}(C(i_s)) + G_{C(i_r) \sim R} \log(1 - M_{obj}(E_{obj}(x, r))) \quad (1)$$

The interaction of data between the produced image  $G_{C(i_r)}$  and the hidden code  $c$  is measured by loss of data  $N_{Info}^{obj}$ . Eq. (2) explains how to compute it employing the mean squared error of the projected code  $r'$  from the discriminator  $M_{obj}$  and the input hidden code  $c$ .

$$N_{Info}^{obj} = G_{r \sim L(0,1), r' \sim M_{obj}(E_{obj}(x, r))} (\|r - r'\|^2) \quad (2)$$

Eq. (3) states that the total goal,  $N_{obj}$ , is the aggregate of prior losses.

$$N_{obj} = N_{GAN}^{obj} + \lambda N_{Info}^{obj} \quad (3)$$

Where the extent of the data loss is represented by minimizing the overall aim, a simulation was trained.

The intended image  $i_s \in S$  is created by combining the freshly processed images  $i_r \in R$  and the object patch  $E_{obj}(x, r)$  produced by the object patch network using the image interpretation network  $i_r$ . However, utilizing the standard GAN model and a single adversarial loss, it is difficult to carry out these difficult tasks at once. To lessen the load of difficult jobs, the suggested model contains a local discriminator and extra loss functions.

1) *Generator*: Similar to the generator employed in CycleGAN, the image interpretation network generator  $E_{sc}$  features encoder-decoder architecture with blocks from the residual network (ResNet) in the center. However, because every characteristic are down and up sampled, the generator has adaptability in the form variance of the output imagery.

The generator needs a bounding box mask  $d_a$ , which identifies the place of flame insertion, and to produce the image. Eq. (4) demonstrate that the place where the mask's value is 0 denotes the background and the position where its value is 1 denotes the flame's location. The bounding box region is determined using no special techniques. The height and breadth of the images are used to sample discrete uniform randomness at each location in the bounding box region.

$$d_a = \begin{cases} 1 & \text{for flame} \\ 0 & \text{for background} \end{cases} \quad (4)$$

By resizing the object patch and placing it in the region where the integer value of the bounding box mask is one, the resized object patch  $i_q := \text{Resize}(E_{obj}(x, r))$  is created. The generator input is created by concatenating the scaled object patch with a clean imagery. By automatically combining the six-channel combined imagery and interpreting them such that they resemble the intended domain image  $i_s \in S$ , the generator produces the produced image  $E_{sc}(i_q, i_r)$ .

2) *Discriminator*: The global  $M_{sc}^{global}$  and the local  $M_{sc}^{local}$  discriminators make up the image interpretation network. The image interpretation network responsibilities of image interpretation and natural merging are carried out by these discriminators.

The images produced by the generator,  $E_{sc}(i_q, i_r)$ , are evaluated by the global discriminator,  $M_{sc}^{global}$ . The PatchGAN discriminator, which analyses portions of the image rather than the entire one, serves as the foundation for its construction. It determines if the imagery is comparable to the intended domain image  $S$ . An adversarial loss results from this assessment outcome.

When utilizing the mask of the created image  $E_{sc}(i_q, i_r)$ , the local discriminator  $M_{sc}^{local}$  decides if the object patch  $C(E_{sc}(i_q, i_r))$  is realistic and whether it can be acquired through the scaling and cropping operation  $R$ . The local discriminator's architecture is comparable to that of the global discriminators. However, similar to the InfoGAN discriminator, it also has a separate auxiliary layer that

generates the anticipated code  $r'$  from the image's map of characteristics. The adversarial loss contains the local discriminator's authentic assessment outcome.

3) *Adversarial loss*: In order to illustrate the generator for the mapping from R to S, the study employed adversarial loss  $M_{GAN}^c$ . Eq. (5) represents the goal as follows:

$$\begin{aligned} M_{GAN}^{sc} = & \\ & G_{i_s \sim q_s} \log M_{sc}^{global}(i_s) + \\ & G_{i_q \sim E_{gen}(x,r), i_r \sim Q_r} \log M_{sc}^{local}(E_{sc}(i_q, i_r)) \\ & + G_{i_s \sim q_s} \log(1 - M_{sc}^{global}(C(i_s))) + G_{i_q \sim E_{gen}(x,r), i_r \sim Q_r} \\ & \log(1 - M_{sc}^{local}(C(E_{sc}(i_q, i_r)))) \end{aligned} \quad (5)$$

Where the global discriminant  $M_{sc}^{global}$  seeks to separate the produced image  $E_{sc}(i_q, i_r)$  from the images acquired from the intended domain S, whereas  $E_{sc}$  attempts to produce images identical to those received from the targeted domain S and object targets look as genuine objects. In order to distinguish the created object  $C(E_{sc}(i_q, i_r))$  from the object acquired from S, the local discriminator  $M_{sc}^{local}$  makes a determination.

### C. CNN-Based Object Detection

The foundation for CNN-based object detection is introduced in this section. In contrast to categorization, the problem of object detection requires the prediction of both the precise location and labelling of numerous objects inside an image. R-CNN was initially a very effective method of object detection in the fields of computer vision. Three processes make up R-CNN: categorization, representation of characteristics obtained by CNN, and area proposal produced by selective search. Without having to calculate each ROI, Fast R-CNN can speed up object identification. In order to create fixed-dimensional characteristics from every ROI, it applies a ROI-pooling layer. The Hyper Region Proposal Network (RPN) now includes the production of object proposals because of the Faster R-CNN. Improved accuracy is achieved via faster R-CNN, which unifies object identification and recognition into a single network. It has influenced other creative and profitable item detectors for special instances.

The objective is to develop a unique detection network that can recognize both tiny and large items by utilizing the quicker R-CNN, which identifies objects employing high-level semantics. Faster R-CNN cannot be immediately implemented in remote sensing objects recognition because to recognize the distinctions between natural and remote sensing imagery. There are other optimization techniques suggested, such as multilayer RPNs and detecting subnetworks. The characteristic representation of the image is recovered using a sequence of convolution layers in the quicker R-CNN framework. RPN employs a number of anchors with predetermined sizes and aspect ratios over the map of characteristics to generate object proposals. Convolutional characteristics along with object suggestions are used in the categorization step to determine the labelling's

and bounding box of various objects. Due to the distinctions among natural and remote sensing images, it is difficult to recognize certain tiny objects in large remote sensing images, such as vehicles and ships, and it is also important for balancing these multiscale objects because certain large objects, such as ground track fields, must be identified. The CNN built on quicker R-CNN along fails to operate well on remote sensing information in regard to all the difficulties.

1) *Multilayer RPNs*: In the attempts, the bases are raised first taking into account the RPN principles. The original CNN bases employ three ratios of aspect and three scales,  $\{128^2, 256^2, 512^2\}$ . Extremely small bases have been included to the collection of bases because small objects can be seen in remote sensing images. The study finally uses five scales  $\{32^2, 64^2, 128^2, 256^2, 512^2\}$  to accurately fit the ground truth after multiple failed tries. There are now fifteen bases instead of the previous nine bases. The reliability of particular small object detection has increased as a result of this improvement. Although adding additional bases is an easy and basic technique to find more small components, the precision still cannot be improved upon. The size of the characteristic map gets smaller as the CNN advances, and typically the last layer characteristics are input into the RPN. This causes smaller components in a big image to lose information. There may be no information about this object in the characteristic map of the previous layer. The study assumes that lowering network levels have reduced receptive fields and therefore better suited for tiny item identification. On the other hand, larger objects can be detected better at higher levels.

The VGG16 model and ResNet-101 framework are the foundations of the proposed SAPNet. There are 13 convolution layers in the VGG16. The four pooling layers can split all of the convolution layers into five segments. Faster R-CNN generates proposals using the conv5\_3 layer, although it is challenging to include the characteristics of small objects. By creating a second RPN network, the study employs conv4\_3 to forecast ROIs, in contrast to earlier techniques that exclusively used conv5\_3 to create recommendations. Considering that conv5\_3 in VGG16 acquires more characteristics to obtain huge objects whereas conv4\_3 in VGG16 has additional characteristics concerning smaller objects. These two layers are suggested for adoption by multilayer RPNs.

There are two RPNs in the proposed network, as seen in Fig. 4. The first, RPN1, utilizes the conv5\_3 layer, whereas the second, RPN2, employs the conv4\_3 layer. While RPN1 concentrates on large proposals, RPN2 concentrates on modest proposals. The multilayer RPNs may provide multiscale remote sensing object suggestions through two RPN branches. When fitting huge objects in RPN1, the scale set  $\{128^2, 256^2, 512^2\}$  is used. When generating tiny object suggestions in RPN2, the scale set  $\{32^2, 64^2, 128^2\}$  is used. RPN1 utilizes the characteristics map produced by block 5 for ResNet-101, whereas RPN2 employs the characteristic map produced by block 4.

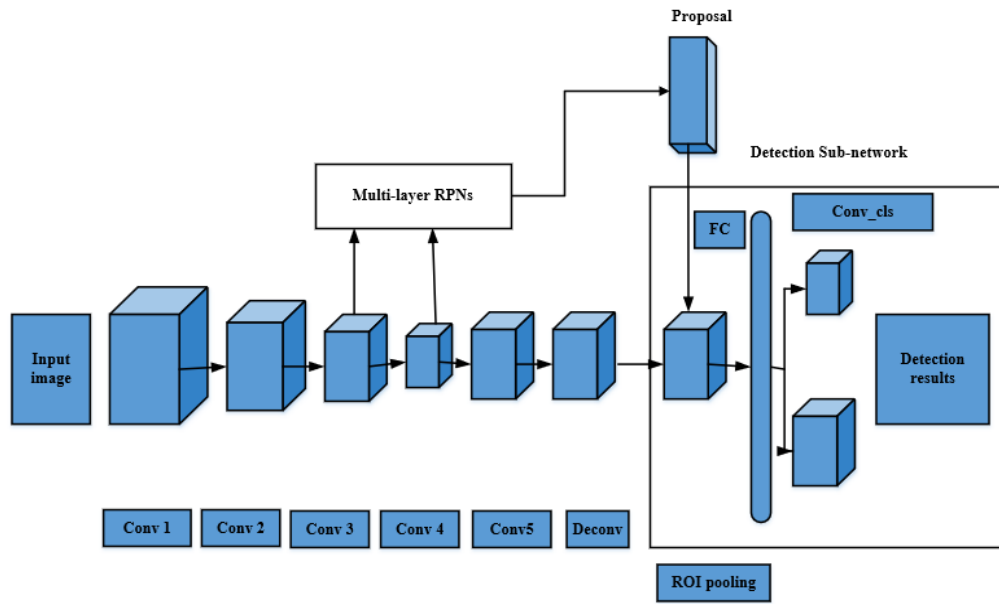

Fig. 4. Multilayered RPNs and a detection sub network.

The final identification subnetwork is where the anticipated bounding boxes and the labels of items originate from. A discrete probability,  $q = (q_0, q_1, \dots, q_k)$ , over  $K+1$  classifications ( $K$  object classes and one background class), is present in each ROI during the training phase. A ground truth label  $y$  is assigned to each ROI. In this case, the first category has been configured as the background, while classes'  $1-K$  corresponds to the classes of the ground truth. The bounding box regression target is denoted by the expression  $\hat{t} = (\hat{t}_u, \hat{t}_v, \hat{t}_x, \hat{t}_y)$ , the regressed bounding box by  $t = (t_u, t_v, t_x, t_y)$ , and the loss of every recognition layer by the expression is given in Eq. (6) and (7).

$$N(q, x, t, \hat{t}) = N_{els}(q, x) + \lambda[x \geq 1]N_{loc}(t, \hat{t}) \quad (6)$$

Where,

$$N_{loc}(t, \hat{t}) = \sum_{i \in \{u, v, x, y\}} smooth_{N_1}(t - \hat{t}) \quad (7)$$

In which,

$$smooth_{N_1(y)} = \begin{cases} 0.5y^2 \\ |y| - 0.5, & otherwise \end{cases}$$

The bounding box loss and classification loss are counterbalanced by the hyperparameter  $\lambda$ . During the test,  $\lambda$  is set to 1.

2) *CNN feature map fusion*: Certain methods simply exaggerate the input images before feeding them into the network because the pretrained CNN model only accepts input with a predetermined size ( $224 \times 224$  in VGG16, for example). These methods have an impact on the effectiveness of the detection, particularly for tiny items. Some techniques up sample the input images to correct for scale inconsistencies, but this uses more memory and slows down processing. The quicker R-CNN network's ROI pooling layer is still being studied. The network can analyse pictures of any

size thanks to its structure, which pools proposal regions into a fixed resolution of  $7 \times 7$ . Utilizing low level features is an effective approach to boost the information of tiny objects rather than up sampling the input images. The higher-level characteristics must be up sampled before being merged with the low-level characteristics since the size of the high-level characteristics is lower than that of the low-level characteristics.

## V. RESULTS AND DISCUSSION

### A. Evaluation metrics

Having into consideration the needs for practical engineering purposes, the approach was assessed using accuracy, average precision (AP), recall, frames per second (FPS), and the precision-recall (PR) curve. To clearly illustrate the results, a distinct matching rule precision-recall (PR) curve was created, and a new PR was created according to it.

1) *Precision and Recall (PR)*: PRC is a commonly employed metric utilised in numerous studies on object detection. Both the recall and accuracy measures can be written below, given that TP, FN, and FP stand for the amount of true positives, false negatives, and false positives, namely in Eq. (8)-(10)

$$\text{Precision} = TP / TP + FP \quad (8)$$

$$\text{Recall} = TP / TP + FN. \quad (9)$$

$$\text{F1 score} = 2 \times \frac{\text{precision} \times \text{recall}}{\text{precision} + \text{recall}} \quad (10)$$

If a detection results has an intersecting over union (IOU) to a baseline value of at least 0.5, it is projected to be a true positive; alternatively, it is regarded as a false positive [29].

IoU refers to the intersection area over the union region between the two boxes with boundaries in the context of object detection. A projected boxes is considered a true

positive (TP) if the IoU corresponding to the ground-truth box ( $G_0$ ) and forecasted box ( $D_0$ ) exceeds than the standard threshold, and a false positive (FP) else. IoU is characterised by Eq. (11)

$$IoU = G_0 \cap D_0 / G_0 \cup D_0 \quad (11)$$

A ground-truth box is said to be false negative (FN) when it is unable to locate the corresponding anticipated container. One may create a PR curve using these numbers for TP, FP, and FN, accuracy, and recall following calculating dynamic recall and precision at various scoring thresholds.

**B. Average precision (AP)**

The region underneath the PR curve is known as AP. They assess the detection outcomes of the suggested strategy using the mean average precision (mAP) in Eq.. (12) [30].

$$mAP = \frac{1}{N_0} \sum_{i=1}^N AP_{0_i} \quad (12)$$

1) *Intersection-over-Detection (IoD)*: They create an additional challenging matched rule to compute TP in order to test the capacity to forecast the entire composites object. The intersection across the region of the outcome of detection is characterised by a new IoD, that is indicated by the following:

$$IoD = G_0 \cap D_0 / D_0 \quad (13)$$

IoD is more capable to show the superior performance of PBNNet than IoU. As an outcome, when  $IoD > 0.5$ , an additional PR curve (dubbed PR-IoD) can be built.

TABLE II. PERFORMANCE METRICS OF PROPOSED GAN-CNN

Metrics	Proposed Method GAN-CNN
Accuracy	97.32
Precision	96.53
Recall	94.42
F1 score	92.27

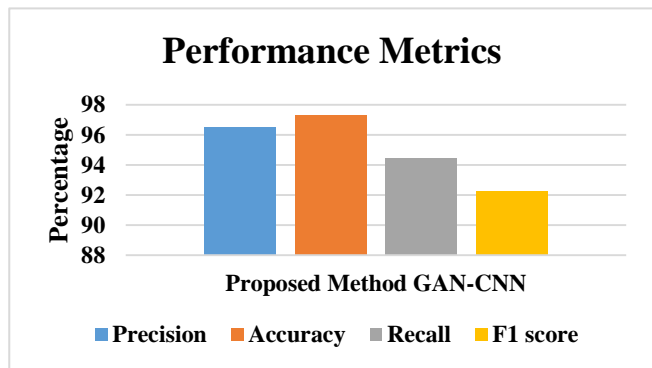

Fig. 5. Performance metrics of proposed GAN-CNN.

On the remote sensing picture dataset, the suggested GAN-CNN hybrid technique displayed outstanding results across key evaluation measures. The hybrid approach in Table II demonstrated its exceptional capacity to produce high accuracy, precision, and recall, culminating in a strong F1 score, with an accuracy of 97.32%, precision of 96.53%, recall of 94.42%, and an F1 score of 92.27% which is shown in Fig. 5. The metrics presented in Table II represent the average

performance of the proposed GAN-CNN method across both the UCAS-AOD dataset and the DOTA dataset. These findings highlight the hybrid methodology's ability to greatly increase the accuracy of object detection and recognition, giving it an attractive option for strengthening the interpretation and analysis of remote sensing data in a variety of applications.

TABLE III. PRECISION, RECALL, F1-SCORE OF EXISTING METHODS AND PROPOSED GAN-CNN [31]

Methods	Recall	Precision	F1 score	Accuracy
YOLO v3	78.09	84.62	81.22	84.86
SSD	77.35	83.36	80.24	85.94
CFF-SDN	87.23	93.11	90.07	94.68
Faster R-CNN	83.32	89.65	86.37	87.64
GAN-CNN	94.42	96.53	92.27	97.32

The YOLO v3 model demonstrated a recall of 78.09%, precision of 84.62%, F1 score of 81.22%, as well as accuracy of 84.86% in the evaluation of object recognition methods using the specified metrics on a remote sensing image dataset in Table III. Similar results were shown by the SSD model, which had an accuracy of 85.94%, a recall of 77.35%, and precision of 83.36%. With a recall of 87.23%, precision of 93.11%, F1 score of 90.07%, as well as accuracy of 94.68%, the CFF-SDN approach in particular produced better results. Recall was 83.32%, precision was 89.65%, F1 score was 86.37%, and accuracy was 87.64% for the Faster R-CNN model. The proposed GAN-CNN hybrid strategy, with recall of 94.42%, precision of 96.53%, F1 score of 92.27%, as well as accuracy of 97.32%, however, Fig. 6 demonstrated the most astounding performance across all parameters. These results highlight the hybrid approach's clear superiority over more traditional approaches, emphasising its potential to achieve extraordinarily accurate and dependable item recognition and detection in remote sensing images.

Fig. 6. Comparison chart of Precision, Recall, F1 score, Accuracy.

Fig. 7. PR curve of existing vs. proposed methods.

Variable performance across several approaches was demonstrated by a precision-recall curve assessment of the examined object detection algorithms on the remote sensing picture dataset in Fig. 7. While SSD demonstrated a precision of 83.36% and a recall of 77.35%, YOLO v3 attained an accuracy rate of 84.62% at a recall rate of 78.09%. The precision and recall numbers for the CFF-SDN technique were noticeably higher, with a 93.11% precision translating to an 87.23% recall percentage. Faster R-CNN achieved a recall of 83.32% and a precision rate that was 89.65%. With a precision of 96.53% and a phenomenal recall of 94.42%, the proposed GAN-CNN hybrid technique stood out as having the highest precision and recall rates. These trade-offs between high precision and recall, which are crucial for successful recognition and detection of objects activities in remote sensing images, offer insightful information about how well the models perform across various thresholds.

YOLO v3 scored a mAP of 82.73 among the investigated object detection techniques on the remote sensor image dataset in Table IV. SSD came in second with an overall rating of 81.53. With a mAP of 87.81, faster R-CNN displayed excellent performance. Notably, CFF-SDN fared better than the other approaches, obtaining a noteworthy mAP of 91.51. The maximum mAP of 94.32 was demonstrated by the suggested GAN-CNN hybrid strategy, outperforming all other approaches in Fig. 8. These findings emphasise the efficacy of the hybrid strategy and demonstrate its potential to greatly outperform both conventional single-model CNN methods and other cutting-edge methods in item recognition and detection in remote sensing images.

TABLE IV. MAP VALUES OF DIFFERENT METHODS

Methods	mAP
YOLO v3	82.73
SSD	81.53
CFF-SDN	91.51
Faster R-CNN	87.81
GAN-CNN	94.32

## VI. CONCLUSION

The authors propose a novel hybrid GAN-CNN approach for object detection and recognition in remote sensing images, aiming to address the challenges of diverse backgrounds, scale fluctuations, and limited annotated training data. Their method stands out through a data augmentation strategy that leverages GANs to generate realistic training examples capturing remote sensing photo variations, effectively expanding the labeled dataset. Notably, they integrate both real and synthetic data into their CNN component, combining the strengths of both domains. Their approach achieves superior performance, with an accuracy of 97.32%, surpassing traditional and pure CNN-based methods, while also showcasing the ability to generalize to unknown remote sensing images, bridging the gap between synthetic and actual data and demonstrating the potential of merging GANs and CNNs for remote sensing object detection and recognition. The evaluation's findings show how this hybrid approach can improve efficiency in comparison to more conventional CNN-based techniques. The hybrid technique solves issues particular to remote sensing images, including a lack of data annotations, unbalanced class distributions, and complicated backdrops, by introducing GANs into the learning pipeline. The GAN element creates artificial examples that accurately reflect the geographic distribution of targeted objects, enhancing the variety of the information and enhancing the generalisation abilities of the CNN component. Researchers found increased object detection precision, higher identification rates, and greater adaptability to difficult backdrops through empirical assessments. The combined methodology demonstrated its supremacy in remote sensing recognition and detection of objects tests by outperforming state-of-the-art techniques. The combined technique lowers the dependency on large-scale labelled datasets, which are frequently difficult to get in the satellite imagery area, by producing artificial data using GANs. This characteristic makes the technique realistic and adaptable to real-world circumstances by enabling more effective inference and training. Although the hybrid strategy has produced encouraging results, more study is needed in several areas. The accuracy and realistic nature of samples produced might be improved by adjusting the GAN design and investigating various GAN versions. Exploring various CNN designs, hyper parameters, and training methods would also offer insightful information for enhancing the efficiency of the hybrid technique. New opportunities for effective and

precise analysis of remote sensing imagery are made possible by its capacity to handle issues unique to remote sensing data, enhance performance, and lessen the reliance on data with annotations. The use of accurate item identification and recognition in decision-making processes is crucial in many programmes, such as urban planning, agriculture, environmental monitoring, and disaster management.

**Abstract**—Predicting underwriting risk has become a major challenge due to the imbalanced datasets in the field. A real-world imbalanced dataset is used in this work with 12 variables in 30144 cases, where most of the cases were classified as "accepting the insurance request", while a small percentage classified as "refusing insurance". This work developed 55 machine learning (ML) models to predict whether or not to renew policies. The models were developed using the original dataset and four data-level approaches resampling techniques: random oversampling, SMOTE, random undersampling, and hybrid methods with 11 ML algorithms to address the issue of imbalanced data (11 ML× (4 resampling techniques + unbalanced datasets) = 55 ML models). Seven classifier efficiency measures were used to evaluate these 55 models that were developed using 11 ML algorithms: logistic regression (LR), random forest (RF), artificial neural network (ANN), multilayer perceptron (MLP), support vector machine (SVM), naive Bayes (NB), decision tree (DT), XGBoost, k-nearest neighbors (KNN), stochastic gradient boosting (SGB), and AdaBoost. The seven classifier efficiency measures namely are accuracy, sensitivity, specificity, AUC, precision, F1-measure, and kappa. CRISP-DM methodology is utilised to ensure that studies are conducted in a rigorous and systematic manner. Additionally, RapidMiner software was used to apply the algorithms and analyze the data, which highlighted the potential of ML to improve the accuracy of risk assessment in insurance underwriting. The results showed that all ML classifiers became more effective when using resampling strategies; where Hybrid resampling methods improved the performance of machine learning models on imbalanced data with an accuracy of 0.9967 and kappa statistics of 0.992 for the RF classifier.

**Keywords**—Risk assessment; machine learning; imbalanced data; rapid miner; CRISP-DM methodology

## I. INTRODUCTION

Insurance underwriting is a critical process that assesses and selects risks. In exchange for a premium payment, an insurance company agrees to compensate the insured for financial losses under the terms of a contract between the person or organization and the insurer. Insurance is a vital risk management tool that protects individuals and businesses from unforeseen occurrences that could cause financial losses. Car insurance is one of the most important types of insurance, as it protects owners and drivers financially from a variety of dangers and uncertainties [1].

Risk assessment in the insurance sector is a critical process for evaluating the likelihood and severity of potential losses or damages for a specific policyholder. In auto insurance, risk assessment considers several factors that may increase the likelihood of an accident, such as the driver's age, driving record, vehicle type, and location. Risk assessment is essential in the world of auto insurance for accurately pricing policies and ensuring financial viability [2].

The global usage-based auto insurance market is projected to grow from \$57.86 billion in 2023 to \$174.33 billion by 2030, at a compound annual growth rate (CAGR) of 17.1%. This growth is being driven by the increasing adoption of usage-based insurance (UBI) programs by consumers, as well as the growing availability of telematics devices that can collect the data needed to calculate UBI premiums. The total direct written premium for private passenger auto insurance in the United States was \$247.1 billion in 2020, which underscores the significant size of the car insurance industry and the importance of risk assessment in ensuring that insurance companies can cover losses and remain financially stable [3] [4].

Machine learning (ML) has been used to improve the accuracy and effectiveness of risk assessment in auto insurance. ML algorithms are trained on large amounts of data to identify patterns and trends that would be difficult to find using traditional methods. This information can then be used to make more accurate predictions about the likelihood of an accident occurring, which can help insurers to price their policies more accurately and make better underwriting decisions [5].

Imbalance learning is a long-standing challenge in machine learning. In the context of auto insurance risk assessment, the majority class would be the group that reflects the majority of risks. The minority class, on the other hand, would be the group that makes up less of the total, such as policyholders who are denied insurance renewal. This category may have very little data. As a result, the data distribution across dataset classifications is often inconsistent in real-world settings. To improve the reliability of risk assessment, it is necessary to correct erroneous data. Data imbalances can be addressed using resampling techniques [6].

RapidMiner Studio is a data science platform that provides a graphical user interface for designing and deploying ML

models. It enables users to preprocess data, build ML models, and apply reshaping techniques for unbalanced data. RapidMiner supports a wide range of ML algorithms and provides tools for evaluating model performance and selecting the best model. It is an important tool for handling ML algorithms and applying reshaping techniques for unbalanced data because it provides a user-friendly interface for implementing these techniques without the need for advanced programming skills [7] [8].

The motivation for this paper is the need for accurate risk assessment in auto insurance. Risk assessment is critical for accurately pricing policies and ensuring the financial viability of insurance companies. However, traditional risk assessment methods are often inaccurate due to imbalanced datasets, which makes it difficult to predict the risk of underwriting a new policy. Machine learning (ML) techniques have been proposed to improve accuracy, but they are also susceptible to data imbalance problems.

This paper proposes a new approach to address the challenge of imbalanced data in auto insurance datasets by using resampling techniques to create a more balanced dataset. This could lead to more accurate risk predictions and better pricing decisions for insurance companies. Additionally, the proposed approach could help reduce the risk of losses and automate the risk assessment process, thereby improving underwriting efficiency.

The paper is divided into five sections. Section I introduces the topic, followed by Section II, which reviews the related work. Section III discusses the methodology, which separately describes the phases of the proposed model. Section IV, Results and Discussion presents the final steps of the methodology and its results. Section V presents the conclusion, and discusses the future research directions.

## II. RELATED WORK

In this section, the current work will review previous research efforts in risk assessment, claim prediction, and the use of machine learning algorithms and resampling methods. In the study of [9], the authors investigated the use of data mining tools and methods to develop models for analyzing risk levels for the Ethiopian Insurance Corporation (EIC). The study found that a decision tree model achieved an accuracy rate of 0.75 in classifying 3100 policies, while a neural network model achieved an accuracy rate of 58. And in [10], they investigated the use of telematics data to predict accident claims. They compared the effectiveness of XGBoost and LR methods. LR was found to be a suitable model for this task because it is interpretable and has good predictive performance with accuracy rate of 0.8397. XGBoost requires more effort to interpret and requires several model-tuning strategies to match the predictive performance of logistic regression. And in [11], the authors aimed to classify participants in the insurance renewal process to help companies reduce the claim ratio by being more selective in approving them. The proposed method involved classifying insurance participants' data using 3,803 datasets with four attributes and five algorithms to find significant features when generating the model. The study found that the decision tree (DT) algorithm was the most accurate, with an accuracy rate of 0.9540. The DT algorithm

also showed that the most significant feature in defining prospective company assessment was the average age. And in [12], the authors used bootstrapping for resampling to evaluate two classifiers, RF and SVM, using four metrics: Accuracy, Precision, Recall, and F-measure. The experimental results showed that the two classifiers scored an overall accuracy of 0.9836 and 0.9817, respectively.

And in [13], the authors investigated the use of machine learning techniques by auto insurance companies to analyse large amounts of insurance-related data and forecast claim incidence. They applied a variety of machine learning techniques, including LR, XGBoost, RF, DT, NB, and K-NN. They also applied the random over-sampling technique to address the problem of unbalanced data. The results of the study showed that the RF model outperformed all other approaches with an accuracy of 0.8677. And in [14], they developed 32 machine learning models using various data-level approaches to address this challenge. The study found that the AdaBoost classifier with oversampling and the hybrid method had the most accurate predictions. The study concluded that the AdaBoost classifier, using oversampling or the hybrid process, can generate more accurate models for analyzing imbalanced data in the insurance industry than other models.

## III. METHODOLOGY AND PROPOSED MODEL

CRISP-DM (Cross Industry Standard Process for Data Mining) methodology is adopted to develop the proposed model called AIRA-ML (Auto Insurance Risk Assessment-machine learning) shown in Fig. 1 for predicting risk assessment in car insurance. This methodology is used to ensure that the model is developed correctly and that it meets the needs of the business [15]. AIRA-ML consists of six phases: Business Understanding, Data Understanding, Data Preparation, Modeling, Evaluation, and Deployment [15] that will be explain in this sections and the following two sections in details:

### A. Business Understanding

This phase focuses on understanding business needs, which is then used to create an accurate predictive model using machine learning techniques. This phase consists of the following two sub phases:

1) *Determine business objective*: Classify customers using historical data such as insured data, vehicle data, and claims data for a deeper understanding of the data due to its different sources as shown in Table I. The Remark column in Table I provides additional insights such as relationships between independent variables were determined by preliminary examination and expert opinions to identify the dependent variable.

2) *Determine machine learning goals*: ML techniques in auto insurance can provide valuable information but face challenges like risk assessment using unbalanced data. Thus, this work aims to illustrate the effects of imbalanced data and select the most effective resampling technique.

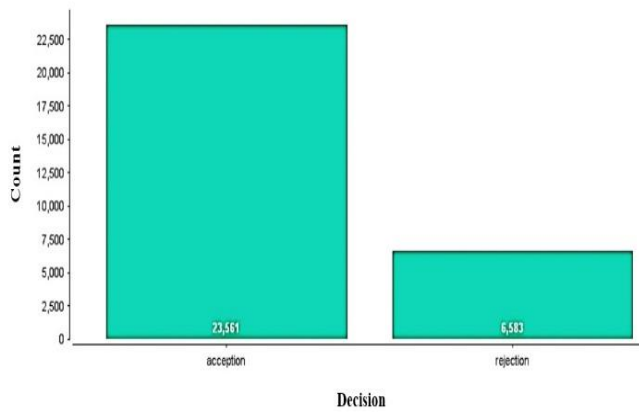

Fig. 1. Imbalanced data in the dataset.

TABLE I. SUMMARY OF THE ATTRIBUTES USED WITH THEIR DESCRIPTION

No.	Factors Group	Features Name	Description	Remark
1	Insured data	Age	Age of Policyholder	Independent
2		Location	Address	
3		Job	Class of business	
4		Hstatus	Health status	
5		Qualification	Educational Qualification	
6	Vehicle data	Make	Make of vehicle	
7		Model	Model of vehicle	
8		Body	Body type of vehicle	
9		Cc	Horsepower or CC	
10		Vage	Age of vehicle	
11		Use	Sub class of business (based on the purpose of use of vehicle)	
12		Availparts	Availability of spare parts	
13	Mileage	Mileage		
14	Claim data	Premium	Premium (averaged)	
15		Tclaimc	Total claim cost	
16		Insurance Val	Insurance Value	
17		Category	The level of probability of risk	
18	Decision	Decision	The decision to accept or refuse a policy	

**B. Data Understanding**

This phase focuses attention on finding, gathering, and analyzing the data sets that are used in AIRA-ML model phases. This phase is composed of four main tasks:

1) *Collect initial data*: a real-life data from an Egyptian car insurance company's policy and claims database were used, as well as manual formats for collecting vehicle and owner information during underwriting and claim requests.

2) *Describe the data*: The features in the dataset are 18, as shown in Table I, and 30144 records for insurance policy renewal that construct the used dataset, where insurance policy for 23561 client were renewed and 6583 were refused as shown in Fig. 2. This figure shows an imbalanced dataset problem that this work will address.

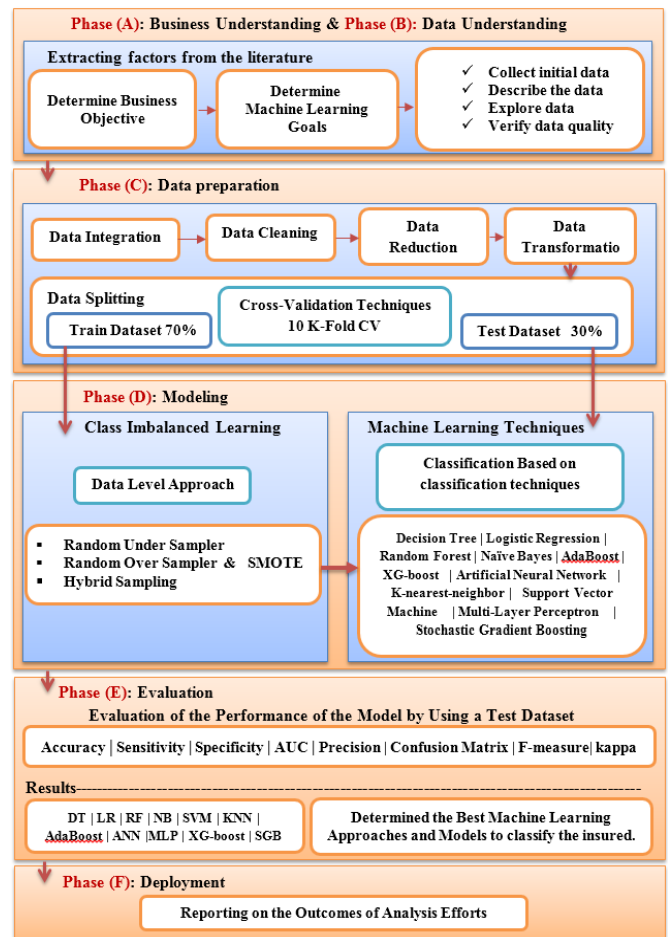

Fig. 2. AIRA-ML model.

3) *Explore data*: It is possible to infer remark column to explains that relationships between the independent variables and determine the dependent variable through preliminary examination and expert opinions. The insurance policies were classified into one of three possible categories risk (low, medium, or high) based on an annual assessment made by the insurance company. 17 features were used to classify the policies, including "accept the insurance request" and "refusal of insurance" as illustrated in Table I.

4) *Verify data quality*: This process plays a crucial role in enhancing the quality and integrity of the data, through checking out data completeness and correctness to enable more effective data-driven decision-making and insights extraction for the AIRA-ML model.

**C. Data Preparation**

Data preparation involves cleaning, transformation, feature engineering, integration, reduction, and splitting the organizing raw data for ML algorithm, which form training of classification model [8] [16]. These processes were conducted through a data science platform offering tools called RapidMiner that will be also used throughout all phases of AIRA-ML model.

1) *Data cleaning*: Data cleaning is a critical process that was performed on identifying and correcting or removing errors, inconsistencies, and inaccuracies within a dataset. By eliminating duplicate entries, handling missing values, correcting formatting issues, and dealing with outliers. In order to ensure that the dataset is accurate, reliable, and ready for further analysis.

2) *Data transformation*: The data transformation is performed on the feature that captures whether a car is used privately or commercially, which determines a specific feature. To facilitate analysis, the "Nominal to Numerical" operator is employed to convert categorical feature into numerical values. For example, in Table I, "private" is denoted as (1) and "commercial" as (0) for car usage. This conversion is applied to all categorical features in the analysis and in integral sub-process step within the AIRA-ML model, as depicted in Fig. 3. This ensures that the knowledge obtained from this transformation can be effectively utilized across the categorical features.

3) *Data integration*: This step "Join" combines data from different sources, as in the Factors Group in Table I, collecting vehicle and owner information during underwriting and claim requests. As shown in Fig. 3.

4) *Data reduction*: The "Select Attributes" selects only the most relevant features for analyzing relationships between the independent variables and determining the dependent variable through preliminary examination and expert opinions, as shown in Table I, and this can be determined through the RapidMiner as shown in Fig. 3.

5) *Data splitting*: The "Split Data" divides datasets into training and testing sets in the AIRA-ML model, splitting the data into 30% for testing and 70% for training [14], improving model performance and accuracy by ensuring data format and relevant features. This comprehensive tool helps organize raw data for machine learning training model as illustrated in Fig. 3[8].

#### D. Modeling

1) *Imbalanced data and a data-level approach*: Learning from imbalanced data is a challenging problem in machine learning, as real-life datasets often have imbalanced class distributions where a minority class has fewer samples than the majority class. As illustrated in Fig 2. This leads to biased results in standard machine learning algorithms. Minority classes may have more critical information and higher value, making it crucial to distinguish them. To overcome the bias, various techniques have been proposed in the field of imbalanced learning [16] [17].

Unbalanced data has a big impact on classification algorithm performance [8]. So this paper discusses resampling techniques like Random OverSampler, Random

UnderSampler, and SMOTE to address data imbalance and improve machine learning algorithms' performance. The authors compare these techniques and suggest improvements in classification algorithm performance.

a) *Data level methods*: The data-level approach involves oversampling and undersampling techniques to maintain balance between classes before classification [18]. And this is what it was applied for in the AIRA-ML model, as shown in Fig 1, and the implementation is illustrated in Fig. 3.

- Under-Sampling Methods

Under-sampling, also known as random under-sampling, is a technique to address unbalanced data by removing cases from the majority class of the training dataset [18].

- Over-sampling methods

Random Over-Sampling is a bootstrap-based technique for binary classification in imbalanced classes. It creates synthetic samples using conditional density estimation, working with continuous and categorical data. The technique maintains constant sample diversity without creating new samples [19].

SMOTE (Synthetic Minority Oversampling Technique) is a method of oversampling that creates fresh minority samples by mixing two minorities with one of their K nearest neighbours [6].

- Hybrid methods

Hybrid methods are a mixture of over-sampling and under-sampling methods at the data level. Hybrid sampling combines oversampling and undersampling to increase minority class numbers while decreasing majority class numbers.

#### 2) Implementing the data-level methods

a) *RUS (Random Under Sampling)*: RUS was implemented by simply choosing a random sample from the acceptance class ("majority class") that corresponds to the number of samples from the rejection class ("minority class"). Random undersampling of the majority class was accomplished as illustrated in Fig. 3.

b) *ROS (Random Over Sampling)*: To implement ROS, a procedure that produces an equal number of replicants of the minority class as samples of the majority class was developed. The bootstrapping operator in step resampling Techniques, as shown in Fig. 3. By doing several resamples of the original dataset using random oversampling of the rejection class with replacement, this operator generates a bootstrapped sample from the original dataset.

c) *The ROS/RUS (Random Over Sampling / Random Under Sampling)*: The aforementioned approach is modified in the ROS/RUS, where a sample size of the acceptance class and rejection class is selected in the step with resampling techniques as illustrated in Fig. 3.

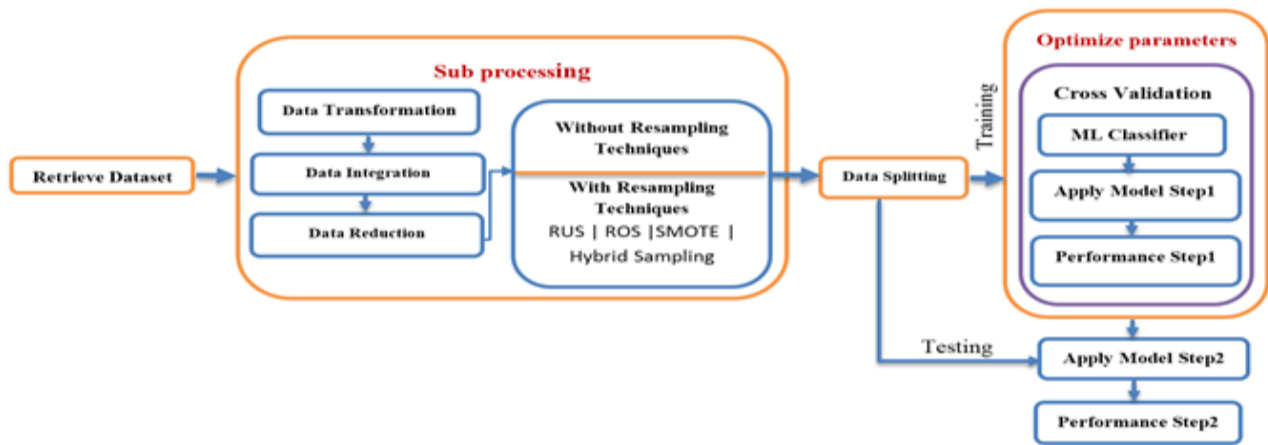

Fig. 3. The Process performed in RapidMiner with AIRA-MI Model.

d) *SMOTE (Synthetic Minority Oversampling Technique)*: The SMOTE technique was used on the dataset until the ratio of minority samples to majority samples is equal as illustrated in Fig. 3.

3) *Modeling techniques*: In the AIRA-ML model, 11 machine learning classifiers are used, as previously stated in Fig. 1. The AIRA-ML model incorporates 10-fold cross-validation to ensure fair comparisons by selecting machine learning parameters for each model. RapidMiner parameter optimization feature is employed to determine the ideal values for the chosen parameters, resulting in optimal outcomes across various machine learning models. The 10-fold cross-validation method is utilized by dividing the data into two groups: approximately 30% for test data and 70% for training data. Models are developed using the training data and evaluated using the test data.

#### IV. RESULTS AND DISCUSSION

##### A. Evaluation

Evaluation techniques calculate the effectiveness of classifiers in selecting the best applied model. Accuracy alone may not solve classification problems due to bias in majority class results, especially in imbalanced data [13] [16]. Consequently, Confusion Matrix evaluation criteria are used for measuring accuracy, sensitivity, specificity, precision, recall, AUC stands for "Area Under the Receiver Operating Characteristic Curve". It is a metric used to evaluate the performance of a binary classifier, and F-Measure, are utilized, beside Kappa Statistics to accurate more precise insurance policy renewal acceptance/ rejection.

1) *Confusion matrix*: A confusion Matrix is employed in binary classification problems to ensure accurate predictions of class outputs and facilitate the comparison between predicted and actual classes [16]. The matrix, as shown in Table II, displays the proportions of correctly classified samples (TP) and incorrectly classified samples (FP/FN). In other words, TP signifies renewal acceptance, while TN indicates rejection.

TABLE II. CONFUSION MATRIX

	<i>Predicted Positive</i>	<i>Predicted Negative</i>
<i>Actual Positive</i>	True positive (TP)	False negative(FN)
<i>Actual Negative</i>	False positive (FP)	True negative (TN)

Accuracy is the fraction of predictions rate for insurance state are correct which is calculated in "(1)", Sensitivity is the true positive ratio of positively classified cases that are actually positive for rejected insurance policies. Which is calculated using "(2)" Specificity is true negative rate of negatively classified cases that are actually negative for accepted insurance policies which is calculated using "(3)" [13] [20].

$$\text{Accuracy} = (\text{TP} + \text{TN}) / (\text{TP} + \text{FP} + \text{TN} + \text{FN}) \quad (1)$$

$$\text{Sensitivity} = \text{TP} / (\text{TP} + \text{FN}) \quad (2)$$

$$\text{Specificity} = \text{TN} / (\text{FP} + \text{TN}) \quad (3)$$

The metric "(4)" is the percentage of the relevant outcomes that assess the reliability of the classification and determine the appropriateness of acceptance or rejection decision. A recall "(5)" is a measurement of how many positive instances were correctly identified as positive, especially for imbalanced datasets [13] [20].

$$\text{Precision} = \text{TP} / (\text{TP} + \text{FP}) \quad (4)$$

$$\text{Recall} = \text{TP} / (\text{TP} + \text{FN}) \quad (5)$$

The F-measure also known as the F1 score "(6)" is a measure of a model's performance that takes into account the averaging of precision and recall.

$$\text{F-measure} = (2 * \text{Precision} * \text{Recall}) / (\text{Precision} + \text{Recall}) \quad (6)$$

2) *Kappa statistics*: Kappa statistics play a valuable role in assessing prediction success for both class acceptance and rejection, considering factors beyond accuracy. This is particularly important when dealing with datasets that exhibit significant imbalance class. Kappa "(7)" takes into account the agreement between model predictions and actual labels, providing a measure of agreement that goes beyond accuracy alone [13].

$$K=(Pr(a)-Pr(e))/(1-Pr(e)) \quad (7)$$

Where:

Pr(a) represents the observed agreement between the raters, which is the proportion of cases where the raters agree.

Pr(e) represents the expected agreement between the raters by chance.

Results of 11 machine learning classifiers on unbalanced data without any resampling models applied are shown in Fig. 4. The result highlights the highest accuracy rate in the classifiers with DT achieving an accuracy of 0.9015, because of machine learning techniques often ignore the minority class (rejection class) and allocate most cases to the majority class (acceptance class). Moreover, a direct proportion relationship can be seen between accuracy and specificity, whenever accuracy is high, the specificity of 0.949 is high as well due to the model consistently predicting the majority class, but reduced sensitivity to 0.6333. Precision is low at 0.8768 because the model frequently predicts the minority class incorrectly. The F-measure is also low at 0.1482 due to the combination of low precision and recall of 0.6333. Among the classifiers, kappa is low at 0.3267 because the model is not very good at predicting the minority class, and AUC is misleading because it is high and the model is not very good at predicting the minority class. On the other hand, the MLP classifier had the lowest performance measures (accuracy = 0.6888, sensitivity = 0.0825, specificity = 0.92121, AUC = 0.5021, precision = 0.7294, F1-measure = 0.14823, and kappa = 0.0871).

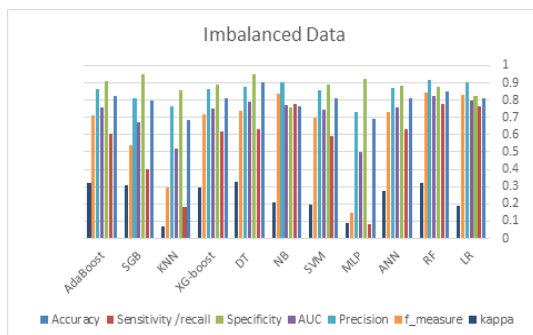

Fig. 4. Classifiers metrics for imbalanced data.

Fig. 5 shows the results of machine learning algorithms on imbalanced data that has been resampled using random oversampling. The accuracy results are not significantly improved, with the SVM classifier achieving an accuracy of 0.8736. This is understandable given that most models predict with poorer accuracy on balanced data, as they consider all classes at the same time. Accuracy is a simple metric to understand, but it overlooks several important factors that must be considered when evaluating a classifier's output. Therefore, we used additional metrics. Additionally, it is noteworthy that the sensitivity for all models with imbalanced data is lower than the sensitivity for balanced data created by random oversampling. This is because random oversampling does not address the class imbalance problem in a principled way. It simply increases the number of minority class samples lead to overfitting. The specificity for the SVM classifier is 0.8601,

with a high F-measure of 0.9366. This is due to the combination of high precision 0.9662 and recall 0.9087. The kappa is low 0.4514 because the model is not very good at predicting the minority class. The AUC is also not very good 0.8841. The KNN classifier has the lowest performance measures. The accuracy is 0.5563, the sensitivity is 0.4594, the specificity is 0.5934, the AUC is 0.5261, the precision is 0.7444, the F-measure is 0.5681, and the kappa is 0.112.

Overall, the results show that random oversampling is not an effective way to address the class imbalance problem in machine learning. Other principled approaches, such as SMOTE or hybrid method, are applied to improve the performance of imbalanced data.

Fig. 5. Classifiers metrics using the ROS method.

The results of machine learning algorithms on imbalanced data that has been resampled using random undersampling are shown in Fig. 6. The high precision for many classifiers, such as random forest (RF) 0.9823 and Artificial Neural Network ANN 0.9505, is because the model frequently predicts the minority class correctly. The F-measure is also high for RF 0.9669 due to the combination of high precision and recall 0.9521, the kappa is high with comparison with Fig. 4 and Fig. 5. Moreover, such as ANN 0.4514, the model is very good at predicting the minority class. The AUC is 0.8391, and accuracy is 0.8713, specificity is 0.799. On the other hand, the KNN classifier has the lowest performance measures. With accuracy of 0.5001, sensitivity of 0.6913, specificity of 0.4268, AUC of 0.5591, precision is 0.7833, F1-measure of 0.7344, and kappa of 0.254.

Additionally, Random undersampling is a technique that reduces the number of majority class samples in a dataset. This can help to improve the performance of machine learning models on imbalanced data, as it reduces the bias towards the majority class. However, the results show that random undersampling can be an effective way to address the class imbalance problem in machine learning.

The best performance with SMOTE is DT classifier as shown in Fig. 7 With an accuracy of 0.8575, sensitivity of 0.9521, specificity of 0.8212, AUC of 0.9521, precision of 0.8871, F1-measure of 0.9184, and a kappa of 0.483, while the lowest performance at SMOTE is the KNN classifier with an accuracy of 0.5844, sensitivity of 0.4159, specificity of 0.6490, AUC of 0.4159, precision of 0.5321, F1-measure of 0.4668, and kappa of 0.225. The result of the SMOTE resampling method has shown the improvement for sensitivity and specificity of the model. For example, the ANN classifier of

the SMOTE results has significantly improved with a sensitivity of 0.9087 and a specificity of 0.8212; in comparison with the ANN classifier without SMOTE, which has a sensitivity of 0.6333, and a specificity of 0.8823 as shown in Fig. 4. The SMOTE resampling method is also improving the performance of other classifiers, such as the DT classifier and the KNN classifier. Overall, the results show that the SMOTE resampling method is an effective way to improve the performance of machine learning models on imbalanced data, which leads to a more accurate and reliable model.

The hybrid resampling methods are more effective than random oversampling or undersampling alone. This is because they are able to create a more balanced dataset without overfitting the models.

Fig. 6. Classifiers metrics using the RUS method.

The results are shown in Fig. 8. The random forest (RF) classifier with hybrid resampling has the best performance, with an accuracy of 0.9967, an AUC of 0.994, a precision of 0.9977, an F-measure of 0.9975, and a kappa of 0.992. This means that the RF classifier is very accurate in predicting whether accept or reject the renewal of the policies. It also has the smallest gap between sensitivity of 0.9977 and specificity of 0.9959, which is an important performance indicator while

the MLP classifier has the lowest performance, with an accuracy of 0.5242, a sensitivity of 0.5029, a specificity of 0.5323, an AUC of 0.5171, a precision of 0.7388, an F-measure of 0.5984, and a kappa of 0.0497.

Table III compare the purposed model (AIRA-ML model) with earlier studies that used other model and resampling technique. The data was preprocessed in both its balanced and unbalanced states to improve the accuracy of training result and the effectiveness of machine learning algorithms.

×- Not used;

Finally, the hybrid approach performs is much better than the results of the earlier research. This approach, which is very accurate with predicting the decision of policies renewal at the same time as an essential performance indicator, that has the smallest gap between sensitivity and specificity. AUC, F1-score, and Kappa statistics are used as other Performance Measures to ensure that the model is effective as a trustworthy instrument for risk assessment and insurance policies activities in the insurance industry.

### B. Deployment

The deployment of the model is beyond the scope of this work and is the responsibility of the insurance company. The purpose of the model is to increase knowledge of the data, and the knowledge gained will need to be organized and presented in a way that the customer can use it. The research in this paper was conducted primarily for academic purposes, but the results can be used by the financial sector to apply machine learning technology to improve their business practices and gain a competitive edge.

However, the research has identified a task that needs more consideration in future work. Proper handling and concern for information are strongly recommended in data mining research.

## V. CONCLUSION AND FUTURE WORK

The insurance industry faces a significant challenge in predicting risk assessment in insurance policies. Thus, this paper proposes an accurate predictive model using machine learning (ML) and resampling techniques to assist insurance companies in making better pricing decisions. The results demonstrate that ML can be used to create an accurate predictive model for auto insurance risk, which can improve insurance acceptance and pricing decisions. Additionally, the results demonstrate that ML can be effective in addressing data imbalance problems in the auto insurance sector. The hybrid resampling technique outperformed all other resampling techniques, achieving an accuracy of 99.6% for the random forest (RF) classifier. This suggests that the hybrid resampling method is a promising approach for dealing with class imbalance problems in ML.

Further research is required to compare the efficiency measures using various datasets from various fields to prove the prediction efficiency of a random forest classifier with resampling methods to solve the imbalanced data problem. And future work may be done in the following directions: Using hybrid resampling techniques to improve comparison and performance with machine learning classifiers, apply this methodology to other sectors of insurance or any other sector with the same problem, which has an imbalance of data.

# An MILP-based Lexicographic Approach for Robust Selective Full Truckload Vehicle Routing Problem

Karim EL Bouyahyioui, Anouar Annouch, Adil Bellabdaoui

ITM-Information Technology and Management, ENSIAS-Mohammed V University in Rabat, Morocco

**Abstract**—Full truckload (FTL) shipment is one of the largest trucking modes. It is an essential part of the transportation industry, where the carriers are required to move FTL transportation demands (orders) at a minimal cost between pairs of locations using a certain number of trucks available at the depots. The drivers who pick up and deliver these orders must return to their home depots within a given time. In practice, satisfying those orders within a given time frame (e.g., one day) could be impossible while adhering to all operational constraints. As a result, the investigated problem is distinguished by the selective aspect, in which only a subset of transportation demands is serviced. Furthermore, travel times between nodes can be uncertain and vary depending on various possible scenarios. The robustness subsequently consists of identifying a feasible solution in all scenarios. Therefore, this study introduces an MILP-based lexicographic approach to solve a robust selective full truckload vehicle routing problem (RSFTVRP). We demonstrated the proposed method's efficiency through experimental results on newly generated instances for the considered problem.

**Keywords**—Vehicle routing problem; full truckload; robust optimization; MILP-based lexicographic approach; uncertain travel time

## I. INTRODUCTION

The vehicle routing problem (VRP) is one of the various investigated combinatorial optimization problems [1]. Its tendency is due to its concrete application in the logistics and transportation domains. These fields play an essential role in the modern market economy by assuring the movement of goods from factories to customers. The FTVRP is a variation of the VRP that has previously garnered limited scientific interest. This problem has a significant application to the truckload industry, where the carriers must service FTL transportation demands (known in the literature as orders or commodities) at a minimal cost between pairs of locations utilizing an available fleet of trucks. They are given a network of sites with FTL orders to be shipped between some pairs of locations. These orders must be shipped using a certain number of trucks available at the depots. The drivers who pick up and deliver these orders must return to their home depots (domiciles) within a given time. The problem is determining the least-cost truck routes so that every order is picked up at its source and shipped to its destination. A typical truck would leave the depot, pick up a commodity, deliver the commodity, travel empty, pick up another commodity, deliver the commodity, and so on. Finally, after picking up and delivering some orders, the truck returns to its domicile. Moreover, each order must be picked between certain hours only. In other

words, every pickup must only be made between a specific pickup time window. Once the order is picked up, it must then be delivered to its destination. Depending on the specific problem, the delivery can be made at any time or within a specified delivery time window only. If a driver reaches a pickup location early, he usually has to wait until the open time. In some instances, the driver may be paid based on a certain hourly rate for staying. The integration of the time constraints in the FTL transportation problem gives rise to the FTVRP with time windows (FTVRPTW). Furthermore, trucking companies can service their clients through numerous depots, with each client assigned preferentially to one depot (multi-depot FTVRP, FTMDVRP).

On the one hand, meeting all of the aforementioned attributes may prevent the trucks from honoring all orders. Therefore, the selective feature of the problem is introduced by relaxing the requirement of servicing all transportation demands within a limited time (selective FTVRP, SFTVRP). The goal may be the maximization of the collected total profit, in which a profit is associated with each order, the minimization of the whole travelling costs, in which the assignment covers as many feasible orders as possible, or the optimization of a combination of both.

On the other hand, travel between a pair of locations might be made via multiple paths. However, the optimal one with the shortest travel time will usually be traversed. In practice, the travel time is uncertain and dependent on specific circumstances (peak traffic hours, weather conditions, accidents, and so on). As a result, this paper investigates a robust selective full truckload multi-depot vehicle routing problem with time windows (RSFTMDVRPTW) under uncertainty in transportation time as a set of discrete scenarios. Each one illustrates an eventual situation that could occur throughout the shipping period. In each scenario, we consider that a fixed number of edges connecting locations are perturbed, and the travel times along those edges differ from the ideal ones. In this study, we formulate the RSFTMDVRPTW as a mixed-integer linear programming (MILP) model under uncertainty and the multi-objective facet, which addresses two functions: an economic component to be maximized and a component related to the worst observation of the total travel time over all scenarios to be minimized. These two objectives are conflicting in that increasing profit necessitates servicing more commodities, resulting in a longer transit time.

Many papers in the literature have been devoted to introducing, formulating, and solving FTVRP variants. Among them, the SFTVRP was solved using mathematical models,

exact solvers, meta-heuristics, and hybrid methods. The novelty of the problem under consideration is that the SFTVRP is treated in a robust backhaul trucking context while considering two objectives. As a result, combining the robust and selective aspects helps to bring the model closer to reality.

The remainder of this study is organized as follows: Section II describes some of the related works. Section III then formulates the RSFTMDVRPTW, while Section IV describes our MILP-based lexicographic approach. Section V presents the experimental findings. Finally, Section VI concludes the paper and suggests some future research directions.

## II. RELATED WORKS

Over the last two decades, many researchers have studied various FTVRP variants by adding constraints to the fundamental problem to better match real-world applications. Different approaches are used to solve these variants. Interested readers are referred to [2] for a detailed review of FTVRPs. To position our study in relation to the literature, we classified the various contributions of selective FTVRP (SFTVRP) variants based on whether the routes primarily contain the FTL shipment, transportation demand selection, multiple depots, time window constraints (TWs), and uncertainty. Table I outlines the most critical SFTVRP-related works and the current study features.

Ball et al. [3] were the first to introduce the multi-depot SFTVRP (SFTMDPDP). The problem consists of constructing routes for private vehicles and subcontracting chemical product commodities to common carriers with the goal of decreasing total cost while meeting a maximum time limit on truck routes. For resolving the FTMDPDP, three heuristics are proposed: a greedy insertion strategy (GI) and two algorithms based on the route-first, cluster-second (RF-CS) technique. Wang and Regan [4] investigated an SFTVRP with time windows (SFTPDPTW) considering only loading TWs, in which the objective is to minimize the empty travelling cost while serving the maximum number of orders within their time constraints. They devised an iterative strategy for resolving the problem by employing the window-partition-based (WPB) algorithm. Miori [5] proposed a TS algorithm for solving a similar SFTVRPT without TWs and with the same later goal. Li and Lu [6] presented a hybrid GA based on improved savings for an SFTVRP with split orders and the objective of maximizing the total profit. Liu et al. [7] developed a memetic algorithm to solve an SFTVRP in collaborative transportation. Another SFTVRPT in the collaborative logistics context was presented in [8]. The authors formulated the problem as an MILP model with the objective function of minimizing the total cost. They proposed a branch-and-cut-and-price-based heuristic to solve the model. Wang et al. [9] considered an SFTVRP with heterogeneous fleet application in the petrochemical industry that involves rich features, including multiple loading locations, optional orders, and loading dock capacity

limitations. They presented an MILP mathematical model for the problem, which is solved using the commercial solver Gurobi.

Yang et al. [10], Tjokroamidjojo et al. [11], and Zolfagharinia and Houghton [12] used some rolling horizon approaches (variants of re-optimization or heuristics) to deploy dynamic SFTVRP variants. A fraction of orders to be carried in a given day become known only a short time before service is needed, truck movements are added to the system as the day advances, and orders must periodically be reassigned. Li et al. [13] addressed a dynamic SFTVRP in a collaborative context in which the carrier can dynamically select its collaborative requests based on the surplus of its transport capacity in the collaborative process. The authors proposed a mixed integer programming (MIP) model for the problem, aiming to maximize the carrier's total profits after outsourcing requests. The model is solved through CPLEX software. Annouch and Bellabdaoui [14] proposed an adaptive GA to solve the open FTMDVRPTW with split delivery (FTOVRPTWSD) in the liquefied petroleum gas (LPG) distribution industry. The FTVRP variant addressed in this study is not selective, and the robustness aspect is not considered.

In our previous studies, we investigated a mono-objective variant of the selective FTMDVRPTW (SFTMDVRPTW) in an empty return context. The objective is to maximize the total profit of selective routes. The resolution of this problem is based on the development of mathematical models, exact solvers, meta-heuristics, and hybrid methods. We described a mathematical formulation of the SFTMDVRPTW as an MILP model [15]. Numerical results on small and medium-size instances are presented using the CPLEX solver. To solve larger instances, we developed, adapted, and applied some heuristic methods: an ant colony system (ACS) [16], a genetic algorithm (GA) [17-18], and a reactive tabu search (RTS) [19].

To the best of our knowledge, while uncertainty is present and relevant, it is rarely addressed for SFTVRP variants. Hammami et al. [20] investigated an SFTVRP with uncertain clearing prices. They developed an exact non-enumerative algorithm to obtain optimal solutions for small instances and a two-phase hybrid heuristic to solve larger instances.

The main contributions of this paper can be summarized as follows:

- Formulate the RSFTMDVRPTW as an MILP model under uncertainty and the multi-objective facet, which addresses two conflicting functions: an economic component to be maximized and a component related to the worst observation of total operation time to be minimized.
- Introduce a MILP-based lexicographic method for solving the RSFTMDVRPTW.

TABLE I. POSITION OF OUR STUDY IN RELATION TO THE FTVRP LITERATURE

Reference		Constraints									Objective function	Area	Solution approach

### III. A MATHEMATICAL FORMULATION OF THE RSFTMDVRPTW

#### A. Problematic

This study addresses a variant of the full truck vehicle routing problem under uncertainty in transportation time (RSFTMDVRPTW). The position of the problem is as follows. Assume a set of  $n$  orders to be served by a fixed fleet of  $m$  trucks. Each truck  $k$  is characterized by a starting point  $D_k$ , an ending point  $A_k$ , an earliest service start date  $D_k^{min}$  and a latest service end date  $D_k^{max}$ . Each order  $O_i$  ( $i = 1, \dots, n$ ) is characterized by a collection point  $L_i$  (origin) and a delivery point  $U_i$  (destination), a profit  $p_i$  (determined on the basis of the distance between origin and destination), a loading time window  $[L_i^{min}, L_i^{max}]$ , and an unloading time window  $[U_i^{min}, U_i^{max}]$ . The travel time for each arc  $(i, j) \in \{(D_k, LU_i)\} \cup \{(LU_i, LU_j)\} \cup \{(LU_i, A_k)\} \cup \{(D_k, A_k)\}$  is described by a set of  $NS$  scenarios  $t_{ij}^\xi$  ( $\xi = 1, \dots, NS$ ), where

each scenario reflects a potential time requirement for a truck traversing arc  $(i, j)$ .

The problem consists of selecting a subset of orders to be served and assigning them to trucks, thus finding an optimal sequence of orders assigned to each truck while maximizing total profit, minimizing the worst observation of the total travel time over all scenarios and respecting availability and time window constraints. Fig. 1 depicts a solution representation for an RSFTMDVRPTW instance with two trucks and 14 orders.

#### B. A discrete Scenario-based MILP Model

In this section, we propose an MILP model of the RSFTMDVRPTW, in which a set of discrete scenarios represents the uncertain travel times. The distribution of the uncertainty parameters is assumed to be unknown. As a result, all scenarios are generated uniformly. Table II defines all data and variable notations. Next, the objectives and constraints are introduced and explained.

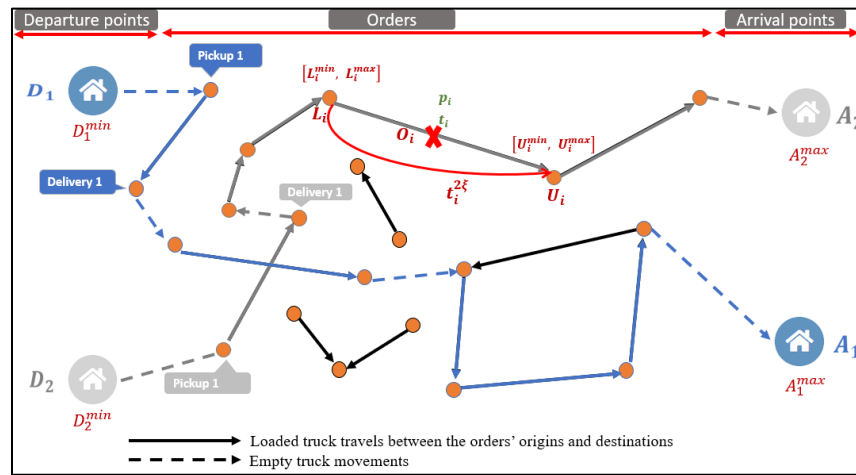

Fig. 1. An illustration of the RSFTMDVRPTW.

TABLE II. DECISION VARIABLES AND PARAMETERS OF THE MILP MODEL OF THE RSFTMDVRPTW

Notation	Meaning
$m$	Number of trucks
$D_k$	Departure depot of truck $k$
$D_k^{min}$	Earliest service start time of truck $k$
$A_k$	Arrival depot of truck $k$
$A_k^{max}$	Latest service end time of truck $k$
$n$	Number of commodities
$\{O_1, \dots, O_n\}$	Set of commodities
$L_i$	Collection point (origin) of the commodity $O_i$
$U_i$	Delivery point (destination) of the commodity $O_i$
$p_i$	profit associated with commodity $O_i$
$L_i^{min}$	Earliest time to load the commodity $O_i$
$L_i^{max}$	Latest time to load the commodity $O_i$
$U_i^{min}$	Earliest time to unload the commodity $O_i$
$U_i^{max}$	Latest time to perform the unloading of the commodity $O_i$
$NS$	Number of scenarios
$\Xi$	Set of possible scenarios
$t_i^\xi$	Travel time between collection and delivery points of the commodity $O_i$ under scenario $\xi \in \Xi$
$t_{ij}^\xi$	Empty travel time from the collection point of commodity $O_i$ to the delivery point of commodity $O_j$ under scenario $\xi \in \Xi$
$t_{oi}^{k\xi}$	Empty travel time from departure depot $D_k$ to the collection point of commodity $O_i$ under scenario $\xi \in \Xi$
$t_{i,n+1}^{k\xi}$	Empty travel cost from the delivery point of commodity $O_i$ to the arrival depot $A_k$ under scenario $\xi \in \Xi$
$M$	A big number
<b>Decision variables</b>	
$x_{ij}^k$	Binary decision variable that indicates whether the truck $k$ visits commodity $O_j$ immediately after commodity $O_j$
$t_{i,L}^{k\xi}$	Start time of the loading of commodity $O_i$ on truck $k$ under scenario $\xi \in \Xi$
$t_{i,U}^{k\xi}$	Start time of the unloading of commodity $O_i$ from truck $k$ under scenario $\xi \in \Xi$
$a_{i,L}^{k\xi}$	Amount of time to wait before the loading of commodity $O_i$ of truck $k$ under scenario $\xi \in \Xi$
$t_{0,L}^{k\xi}$	Departure time of service of truck $k$ from its starting depot $D_k$ under scenario $\xi \in \Xi$
$t_{n+1,U}^{k\xi}$	Arrival time of truck $k$ at its finishing depot $A_k$ under scenario $\xi \in \Xi$

The MILP model of the RSFTMDVRPTW is given as follows:

$$\text{Maximize } f_1 = \sum_{k=1}^m \sum_{i=1}^n \sum_{j=1}^{n+1} p_i x_{ij}^k \quad (1)$$

$$\text{Minimize } f_2 = TT_{\text{worst}} \quad (2)$$

Subject to:

$$\begin{aligned} & \sum_{k=1}^m \sum_{i=1}^n \sum_{j=1}^{n+1} t_{ij}^\xi x_{ij}^k \\ & + \sum_{k=1}^m \sum_{j=1}^{n+1} t_{0,j}^{k\xi} x_{0,j}^k + \sum_{k=1}^m \sum_{i=1}^n \sum_{j=1}^n t_{ij}^\xi x_{ij}^k + \sum_{k=1}^m \sum_{i=1}^n t_{i,n+1}^{k\xi} x_{i,n+1}^k \\ & + \sum_{k=1}^m \sum_{i=1}^n (w_{i,L}^{k\xi} + t_{i,U}^{k\xi} - t_{i,L}^{k\xi} - t_i^\xi) \leq TT_{\text{Worst}}, \forall \xi = 1, \dots, NS \end{aligned} \quad (3)$$

$$\sum_{j=1}^{n+1} \sum_{k=1}^m x_{ij}^k \leq 1 \quad \forall i = 1, \dots, n \quad (4)$$

$$\sum_{i=0}^n \sum_{k=1}^m x_{ij}^k \leq 1 \quad \forall j = 1, \dots, n \quad (5)$$

$$\sum_{j=1}^{n+1} x_{0j}^k = 1 \quad \forall k = 1, \dots, m \quad (6)$$

$$\sum_{i=0}^n x_{ih}^k - \sum_{j=1}^{n+1} x_{hj}^k = 0 \quad \forall h = 1, \dots, n, \quad \forall k = 1, \dots, m \quad (7)$$

$$\sum_{i=0}^n x_{i,n+1}^k = 1 \quad \forall k = 1, \dots, m \quad (8)$$

$$x_{i,0}^k = 0 \quad \forall k = 1, \dots, m, \quad \forall i = 0, \dots, n+1 \quad (9)$$

$$x_{n+1,i}^k = 0 \quad \forall k = 1, \dots, m, \quad \forall i = 0, \dots, n+1 \quad (10)$$

$$D_k^{\min} \leq t_{0,L}^{k\xi}, \quad \forall k = 1, \dots, m, \quad \forall \xi = 1, \dots, NS \quad (11)$$

$$t_{n+1,U}^{k\xi} \leq A_k^{\max} \quad \forall k = 1, \dots, m, \quad \forall \xi = 1, \dots, NS \quad (12)$$

$$L_i^{\min} \leq t_{i,L}^{k\xi} \leq L_i^{\max}, \quad \forall i = 1, \dots, n, \quad \forall k = 1, \dots, m, \quad \forall \xi = 1, \dots, NS \quad (13)$$

$$U_i^{\min} * \sum_{j=1}^{n+1} x_{ij}^k \leq t_{i,U}^{k\xi} \leq U_i^{\max}, \quad \forall i = 1, \dots, n, \quad \forall k = 1, \dots, m, \quad \forall \xi = 1, \dots, NS \quad (14)$$

$$t_{i,L}^{k\xi} + t_i^\xi \leq t_{i,U}^{k\xi}, \quad \forall i = 1, \dots, n, \quad \forall k = 1, \dots, m, \quad \forall \xi = 1, \dots, NS \quad (15)$$

$$t_{0,L}^{k\xi} + t_{0,i}^{k\xi} + w_{i,L}^{k\xi} \leq t_{i,L}^{k\xi} + M * (1 - x_{0i}^k) \quad \forall i = 1, \dots, n, \quad \forall k = 1, \dots, m, \quad \forall \xi = 1, \dots, NS \quad (16)$$

$$t_{0,L}^{k\xi} + t_{0,i}^{k\xi} + w_{i,L}^{k\xi} \geq t_{i,L}^{k\xi} - M * (1 - x_{0i}^k) \quad \forall i = 1, \dots, n, \quad \forall k = 1, \dots, m, \quad \forall \xi = 1, \dots, NS \quad (17)$$

$$t_{i,U}^{k\xi} + t_{i,j}^\xi + w_{j,L}^{k\xi} \leq t_{j,L}^{k\xi} + M * (1 - x_{ij}^k) \quad \forall i, j = 1, \dots, n, \quad \forall k = 1, \dots, m, \quad \forall \xi = 1, \dots, NS \quad (18)$$

$$t_{i,U}^{k\xi} + t_{i,j}^\xi + w_{j,L}^{k\xi} \geq t_{j,L}^{k\xi} - M * (1 - x_{ij}^k) \quad \forall i, j = 1, \dots, n, \quad \forall k = 1, \dots, m, \quad \forall \xi = 1, \dots, NS \quad (19)$$

$$t_{i,U}^{k\xi} + t_{i,n+1}^{k\xi} \leq t_{n+1,U}^{k\xi} + M * (1 - x_{i,n+1}^k) \quad \forall i = 1, \dots, n, \quad \forall k = 1, \dots, m, \quad \forall \xi = 1, \dots, NS \quad (20)$$

$$t_{i,U}^{k\xi} + t_{i,n+1}^{k\xi} \geq t_{n+1,U}^{k\xi} - M * (1 - x_{i,n+1}^k) \quad \forall i = 1, \dots, n, \quad \forall k = 1, \dots, m, \quad \forall \xi = 1, \dots, NS \quad (21)$$

$$x_{ij}^k \in \{0,1\} \quad \forall i, j = 0, \dots, n+1, \quad \forall k = 1, \dots, m \quad (22)$$

$$t_{i,L}^{k\xi} \geq 0, \quad \forall i = 0, \dots, n, \quad \forall k = 1, \dots, m, \quad \forall \xi = 1, \dots, NS \quad (23)$$

$$t_{i,U}^{k\xi} \geq 0, \quad \forall i = 1, \dots, n+1, \quad \forall k = 1, \dots, m, \quad \forall \xi = 1, \dots, NS \quad (24)$$

$$w_{i,L}^{k\xi} \geq 0, \quad \forall i = 1, \dots, n, \quad \forall k = 1, \dots, m, \quad \forall \xi = 1, \dots, NS \quad (25)$$

$$TT_{worst} \geq 0 \quad (26)$$

The problem represents a bi-objective optimization problem. The first objective function (1) seeks to maximize the total profit obtained from the selected commodities and the second objective function (2) aims to minimize the worst total operation time of all trucks over all considered scenarios.

Constraints (3) ensure that for all scenarios, the total operation time (empty travel time (first term), full travel time (second, third, and fourth terms), and waiting time before loading and unloading commodities (fifth term)) needed by all trucks does not exceed  $TT_{worst}$ . Constraints (4) and (5) imply that each collection and delivery location can be visited at most once. Constraint (6) guarantee that each truck must begin its journey from its starting depot. Constraints (7) ensure the conservation of flow; once a truck has packed an order, it must unload it at the corresponding delivery location. Constraint (8) guarantee that each truck finishes its route at the arrival depot. Constraints (9) and (10) ensure that each truck cannot return to its departure depot and cannot visit any point after its arrival depot. Inequalities (11)-(21) are used to compute the truck start time, the start time of the loading/unloading of commodities, and the time to wait at loading points in all scenarios. The time window constraints are respected using Inequalities (11)-(14). Constraints (15) require, at a commodity level, that the unloading time be greater than the sum of the loading time and the time from the commodity's collection location to its delivery location. Constraints (16) and (17) impose that loading a commodity onto a truck can only start after the truck has left its departure depot. Constraints (18) and (19) ensure that a truck can only pick up the next commodity after unloading the previous one, and displacement occurs. Constraints (20) and (21) guarantee that a truck can only unload a commodity if it can arrive at the arrival depot before the latest service end time. Finally, constraints (22)-(26) specify the appropriate values for decision variables.

#### IV. MILP-BASED LEXICOGRAPHIC APPROACH FOR THE RSFTMDVRPTW

Multi-objective optimization (MOO) problems involve optimizing more than one objective function simultaneously, which is usually in conflict, so improving one leads to worsening another. The lexicographic approach is a widely used solution method for MOO [21]. Fig. 2 depicts a general example of the lexicographic method in which the decision maker begins by ranking the objective functions in order of importance and then solves sequentially mono-objective problems starting with the most critical function and progressing to the least critical function. The lexicographic approach, similar to other methods (epsilon constraint, weighted sum, and so on), does not require any parameter configurations. Moreover, once the decision maker has prioritized one objective function over the other, it can provide a Pareto-optimal solution for the MOO problem.

## V. COMPUTATIONAL EXPERIMENTS

The computational experiments were performed using the AMPL programming language with CPLEX solver (version 12.7) on a laptop computer Intel Pentium Core i7- 4790 with 3.6 GHz and 16 GB of RAM memory.

The experiments are conducted across adapted SFTMDVRPTW instances proposed by EL Bouyahyious and Bellabdaoui [17], which are generated based on three classes  $R / C / RC$  of Solomon's VRPTW benchmark instances [22]. 'C' means that the points are clustered, 'R' indicates that the points are random, and 'RC' denotes that the points are both clustered and random.

In this study, the tests were restricted to the  $R$  problem class since it is most relevant to the FTVRP variant and the most difficult to solve. We used eight different instances from the datasets of El Bouyahyious and Bellabdaoui [17] with two different types of time windows ( $SFT1-4\_R25\_20\_2$  and  $SFT1-4\_R100\_50\_5$ ). We have adapted these instances to the RSFTMDVRPTW by adding a number of scenarios. A fixed number of arbitrary edges is selected in each scenario, and their travelling times are perturbed. Therefore, 96 new instances are generated and solved with the MILP-based lexicographic method.

Each instance is labelled as  $Ri\_n\_m\_NS\_l\_p$ , where:

- $i$  is the instance ID.
- $n$  gives the number of orders,  $n \in \{25, 50\}$ .
- $m$  gives the number of trucks,  $m \in \{2, 5\}$ .
- $NS$  denotes the number of scenarios,
- $NS \in \{10, 50, 100\}$ .
- $l$  denotes the uncertainty level,  $l \in \{50, 100\}$ . The travel time on each perturbed edge for each scenario varies on the interval  $[d(i, j), (1 + l\%)d(i, j)]$ , where  $d(.,.)$  denotes the Euclidean distance between any two points (shortest time)
- $p$  denotes the number of perturbed edges for every scenario, representing 10% or 20% of the total edges for each instance.

Table III summarizes the results performed on the 96 generated instances.  $TT_{worst}$  denotes the worst observation of the total travel time over all scenarios, and CPU represents the running time for CPLEX. For each instance, CPLEX is run for two-hour-time limits.

Table III shows the following observations:

- The proposed MILP-based lexicographic method performs well in all instances with 20 commodities where the CPLEX solver can provide optimal solutions in a relatively short time. When the number of commodities is increased to 50, CPLEX is unable to solve some instances optimally within 2 hours.
- As expected, the CPU time is significantly impacted by the number of commodities, the width of the time windows, and, in particular, the selective aspect (i.e.,

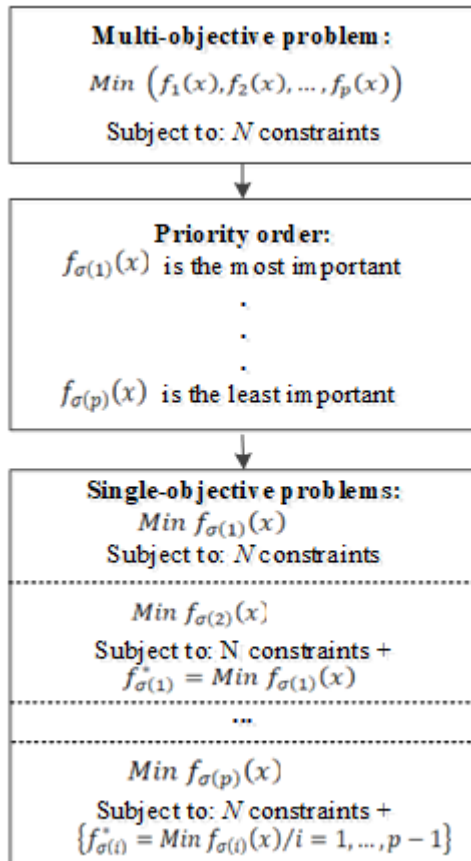

Fig. 2. Principles of the lexicographic optimization approach.

In this study, we use a lexicographic method based on the MILP formulation already defined. The selective aspect facilitates the ranking of the objective functions. This ranking was chosen on the grounds that maximizing the profit can reflect a higher quality of service, as well as on the grounds that beginning with the minimization of total travel time will generate a solution where no delivery commodity is assigned to trucks, where each route of a truck  $k$  will be the shortest path from departure point  $D_k$  to end depot  $A_k$  to obtain the lowest travel time. Therefore, we maximize the first objective  $f_1$  (the collected profit) first and then minimize the second objective  $f_2$  (the total travel time) based on the obtained solution for  $f_1$ . As a result, the original MILP model is transformed into two sequential models ( $P_1$ ) and ( $P_2$ ) as follows:

$$(P_1): f_1^* = \text{Min } f_1$$

$$\text{Subject to: Constraints (4) – (25)}$$

$$(P_2): f_2^* = \text{Min } f_2$$

$$\text{Subject to: } \begin{cases} \text{Constraints(3) – (26)} \\ f_1 \geq f_1^* \end{cases}$$

the number of unselected commodities in the obtained optimal solution). In all cases, as the number of unselected orders grows, the trucks cannot select some orders, resulting in increased CPU time.

- Furthermore, the number of scenarios and the uncertainty level directly affect the CPU time. As the values of these two parameters grow, so does the difficulty of resolving the instances.
- If the uncertainty level is set to 100, the travel time will likely be doubled. Utilizing many scenarios can diminish the uncertainty of travel time, resulting in more conservative estimates of the total worst-case travel time for all assumed scenarios.

- When comparing two different instances, a larger number of perturbed edges does not always imply a lower profit because those edges are selected randomly (e.g.,  $R1_{50_5_100_100_10}$  and  $R1_{50_5_100_100_20}$  have optimal profits of 5852 and 5841, respectively).

The robust aspect can significantly increase the problem's complexity, impacting the CPU time required to obtain a Pareto-optimal solution. Furthermore, the reported solutions are still worse than or equal to the non-robust solutions computed employing just the ideal scenario [17]. However, the feasibility of the obtained solution, over all scenarios, is the main advantage of robust optimization.

TABLE III. RESULTS OF THE PROPOSED MILP-BASED LEXICOGRAPHIC METHOD ON THE 92 GENERATED INSTANCES

Instance	Profit	TT <sub>worst</sub> *	CPU (s)	Instance	Profit	TT <sub>worst</sub> *	CPU (s)

## VI. CONCLUSIONS AND FUTURE RESEARCH

In this work, we have studied an essential variant of the full truck vehicle routing problem under uncertainty in transportation time, notably a robust selective full truckload multi-depot vehicle routing problem with time windows (RSFTMDVRPTW), in which a set of discrete scenarios represents uncertain travel times. We have proposed a discrete scenario-based MILP model for the RSFTMDVRPTW under the multi-objective facet, which addresses two conflicting functions: an economic component to be maximized and a component related to the worst observation of total operation time to be minimized. To solve the RSFTMDVRPTW, we have used an MILP-based lexicographic method, which maximizes the collected profit first and then minimizes the worst observation of total travel time based on the obtained solution for the first objective.

The considered approach was solved using CPLEX 12.6 and tested on 96 newly generated instances of up to 50 orders and five trucks adapted from the literature. The encouraging results demonstrate that the proposed lexicographic method provides a plausible Pareto-optimal solution for all instances with 20 commodities within an acceptable computing time. However, when the number of commodities is increased to 50, CPLEX cannot solve some instances optimally within 2 hours. Indeed, we remarked that the selective aspect, the values of the number of scenarios, and the uncertainty level strongly impact the proposed lexicographic method. Furthermore, the reported solutions are still worse than or equal to the nonrobust solutions computed employing only the ideal scenario. However, the feasibility of the solution over all scenarios is the main advantage of robust optimization.

As the problem is quite complex, only small instances can be solved optimally by CPLEX. Therefore, in future works, we will design an efficient metaheuristic algorithm to solve large instances of the problem with a large number of scenarios.

**Abstracts**—Scientific research is becoming more and more crucial to contemporary society as the backbone of the nation's innovation-driven development. The rapid growth of information technology and the rise of information technology in scientific research both contribute to the globalization of scientific research. Small research groups still don't have a place to showcase and share their accomplishments, though. In order to integrate scientific research information and combine personalised recommendation technology to suggest developments of interest to users through their historical behaviour data, the study proposes a personalised recommendation and sharing management system for scientific and technological achievements based on the Ruby on Rails framework. According to the testing results, the system had a 299ms request response time, a maximum 1KB request resource size, and a 20ms data transfer time. Additionally, the study's user-based collaborative filtering recommendation algorithm has an accuracy rate of 41% when the nearest neighbor parameter is set to 50, there are 10 information suggestions, and there are 0.7 training sets, which essentially satisfies the system criteria. In conclusion, the research suggested that a personalised recommendation and sharing management system for scientific and technological accomplishments can essentially satisfy the needs of small research teams to communicate and share scientific accomplishments, as well as realise the sharing of scientific achievements.

**Keywords**—Research management; personalised recommendations; WebSocket; ruby on rails; informatization

## I. INTRODUCTION

As the scope and extent of scientific research grow with the advancements in information technology and [1] technology, research has become increasingly diverse and intricate. Along with managing projects and delivering their results, researchers need to scrutinise data, design experiments and locate literature from a vast range of information [2]. In this scenario, research management systems (RMS) offer an efficient, automated and standardised alternative [3]. In order to automate and standardise research management, an RMS can aid researchers in managing information, designing experiments, analysing data, managing projects, and efficiently presenting research results [4]. Nevertheless, the current state of RMS in China is still nascent, and a shortage of academic platforms for the exchange of innovative research between teams makes it difficult to adapt research outcomes

[5].

## II. RELATED WORK

Real-time push and real-time communication are enabled by WebSocket technology, which is widely used in web applications that require a high degree of real-time, such as live chat, games, stock quotes, etc. Bisták P. proposes a new architecture for building virtual and remote laboratories using WebSocket communication technology to develop a remote control laboratory for three-tank hydraulic systems. The results showed that the remote laboratory had been visualised in 3D on the client side and was capable of comparing non-linear feedback control with dynamic feed-forward control [6]. To address the issue of exponential growth in IoT data traffic, Al-Joboury I.M. et al. proposed an IoT blockchain architecture using WebSocket communication. They found that proof-of-stake is more streamlined and advantageous for IoT applications than proof-of-work and Byzantine fault tolerance [7]. Pala Z et al. designed a network using machine learning to overcome the problem of synchronous system operation, which affects application efficiency, by analysing and transmitting data using WebSocket technology [8]. Abdelfattah A. S. et al. suggested a dependable approach using middleware and WebSockets technology to address the problem of Web service request timeouts in the mobile experience. The methodology improved the mobile experience by reducing network consumption time to seven times that of the straight cloud approach, according to the results [9]. To promote a multi-user real-time co-reading system using WebSocket technology, Chang C.T. et al. proposed a collaborative learning co-reading performance. Experiments revealed that the system significantly impacted students' learning outcomes during co-reading and that six out of seven hypotheses were supported [10].

In e-commerce, social networking, music, and other industries, CFRA, or a Personalised Recommendation Algorithm (PRA), is frequently utilised. When evaluated using independent datasets, Lim H et al.'s newly proposed Weighted Impulse Neighbourhood Regularised Three-Factor Decomposition One-Class Collaborative Filtering algorithm (CFA) demonstrated accuracy of the first 37 predicted associations of 8.495% with an enrichment factor of 4.19 compared to random guesses [11]. A recommendation framework that integrates local differential privacy (LDP)

with collaborative filtering has been developed by Bao T et al. to address the problem of dishonest server behavior or user privacy disclosure in case of failure. The results showed that the method outperformed other differential private recommendation methods [12]. In contrast to other fuzzy algorithms and traditional algorithms, Wu Y et al. proposed an interval fuzzy number-based CFRA. This algorithm is experimentally proven to be more effective and practical in sparse datasets with more users than items, and effective in improving prediction accuracy and ranking accuracy [13]. To address the issue of malicious user reviews and the issue of a small number of reviews affecting the accuracy of recommendations, Zheng G et al. proposed a CFRA with item labelling features [14]. Experiments revealed that the algorithm could successfully address the issue of cold-start data and that the interpretation of recommendation results was convincing. Zhang J et al. suggested a unique CFRA with item labelling features, and studies revealed that the proposed method was superior to existing methods [15].

The utilization of Websecurity technology and CFA is currently under investigation by various researchers from multiple perspectives; however, its practical application design in RMS is uncommon. To construct an RMS for scientific information PR, this study incorporates Websocket technology built on the Ruby on Rails framework and ronAJAX technology for CFRA. This study analyses the use of personalised recommendation (PR) algorithms based on WebSocket technology to recommend scientific and technological achievements of interest to users. The aim is to develop a management system for PR and information sharing that is objective, comprehensible, and logically structured. The conventional dissemination of scientific and technological advancements is frequently disseminated without sufficient personalized services. This research employs a customised recommendation system founded on network socket technology, which supplies individualised suggestions for scientific and technological advancements according to the users' requirements. This initiative aims to elevate users' curiosity and acceptance of scientific and technological developments, hence improving their utilization and market penetration. The research is categorised into four primary sections: analysis of pertinent research findings, core technology design and architecture, feasibility confirmation of the recommendation system, and a summary of the obtained results.

### III. DESIGN OF A PR AND SHARING MANAGEMENT SYSTEM FOR SCIENTIFIC AND TECHNOLOGICAL ACHIEVEMENTS BASED ON WEBSOCKET TECHNOLOGY

The sharing and interchange of scientific and technological advancements has become a crucial component of the growth of the scientific research area as a result of the ongoing development of data processing and artificial intelligence technologies. This part compares the benefits and drawbacks of popular recommendation algorithms (RA) in order to further choose the best RA for the research system. It also focuses on the essential technologies and architectural design of the research sharing management system.

#### A. Design of the Key Technology and Overall Architecture of the Research Sharing Management System

The main objective of the Research Sharing Management System is to enhance collaboration and information sharing among researchers, while facilitating the advancement of scientific research. It serves as a platform for storing, managing and sharing the results of scientific research. In order to help small research teams achieve result sharing and communication, the study will design the Research Sharing Management System from three aspects: system requirements, key technologies, and overall architecture. The system requirements are divided into two sections: business requirements and performance index requirements. The business requirements need to meet the purpose of research users to use information to achieve resource sharing, so the study adopts web research sharing system with simple interaction and unified interface. The system is divided into five modules: user authentication, team management, dynamic management, RA and private information management, and the specific structure is shown in Fig. 1.

The performance indicator requirements mainly meet the user experience, so the study combines the characteristics of the research system to design a system that should meet the performance requirements of strong real-time, operability, high reliability and high security during operation. After determining the system framework through requirements analysis, a number of development techniques are required to realise the submission, acquisition, storage, publication and notification of information. The first study uses Asynchronous JavaScript and XML (AJAX) asynchronous request technology to count user likes, favourites and comments, with page content rendered in HTML and CSS, dynamic display and interaction implemented by the DOM, and data exchanged between the browser and web server in JSON data exchange format. AJAX data exchange works with several technologies to load the system on demand, reducing unnecessary data transfer and thus speeding up the response time of the interface. The study then uses WebSocket technology to synchronise information between the browser and the server. The information transfer process between the browser and the web server is shown in Fig. 2.

The research then uses a recommendation system to complete the information filtering, which builds a user preference model based on user interaction data to recommend content of interest to the user. The RA essentially connects the user to information in a certain way, helping the user to discover content of interest while pushing content to the user, often in the form of friend recommendations, history, user characteristics and personal information. The final study uses Ruby on Rails framework technology to integrate AJAX technology, WebSocket technology, RA technology and other unmentioned technologies in an orderly manner, while abstracting simple and reusable design artefacts. The Ruby on Rails framework is designed with agile development ideas such as convention over configuration, chef selection and do not repeat. It is a typical Model View Controller (MVC) framework for mapping traditional input, processing and output logic. When a user submits a request via a browser, the server uses a route to locate the appropriate controller, which

then parses the user's request and interacts with the database using the model. Once the data has been retrieved, the controller provides the information to the view layer. This information is used by the view layer to create the finished web page, which is then returned to the browser as resources such as HTML, CSS and JavaScript. Fig. 3 shows the overall system architecture after integrating the core technologies to build the RMS.

As shown in Fig. 3, the study combines the business requirements and key technologies of the system based on following the design principles of the application while meeting the requirements of scalability, high stability, ease of operation and practicality, using the ActiveJob backend job module of the Ruby on Rails framework to create the PR system.

### B. PRA Design for Scientific and Technological Achievements based on WEBSOCKET Technology

After developing the shared management system's architecture, the study progresses to incorporate socket technology to enhance and design PRA technology accomplishments. Research users have relatively fixed research areas when doing research activities, resulting in a tendency to overlap information when searching for keywords and retrieve less available information. Although PRA serves as the foundation of PR technology, each algorithm has a unique application scenario, making it crucial to pick the best RA to suit research users' demands. Content-based algorithms, tag-based algorithms, knowledge-based algorithms, and CFRA are some examples of common RAs. The similarities between feature vectors and user preference vectors are computed by content-based RAs, which gather features from both people and items before making suggestions. Cosine similarity, as in Eq. (1) [16], is the formula used to determine similarity most frequently.

$$\cos(F_u, F_i) = \frac{F_u \cdot F_i}{\|F_u\| \times \|F_i\|} \quad (1)$$

In Eq. (1),  $F_u$  is the preference feature of a user and  $F_i$  is the preference feature of a candidate item. The closer the cosine similarity value is to 1, the closer the candidate item is to the user's preference, and the closer its value is to -1, the less suitable the candidate item is for that user. The advantages of content-based PRA are that only the user's interest features and resource attributes need to be compared online, and the similarity can be performed offline. The disadvantages are the difficulty of extracting information features from complex resources and the inability to detect similarities between similar synonyms [17]. The user's interest in the resource is determined using Eq. (2), and the tag-based RA analyzes the user's level of interest based on the number of times the user has tagged the resource. The tag-based RA then generates suggestions based on the interest matrix between the user and the resource.

$$p(u, i) = \sum_b n_{u,b} n_{b,i} \quad (2)$$

In Eq. (2),  $u$  is the user,  $i$  is the resource,  $b$  is the tag,  $n_{b,i}$  is the number of times the resource has been tagged, and  $n_{u,b}$  is the number of times the user has been tagged. The tag-based RA has the benefit of being able to comprehend the user's interests and easily obtaining the user's tags, but the drawback is that it requires work to develop the habit of tagging resources and the research user is not motivated to tag [18]. The knowledge-based RA is a system that provides a solution in response to the user's stated demands. Fig. 4 [19] illustrates the precise suggestion process.

Knowledge-based RAs are mainly applicable to specific domains and have a high recommendation accuracy rate, but the implementation process is complicated for users and not suitable for scientific users. Collaborative Filtering Architecture (CFA) is based on the user's evaluation of resources to jointly filter information and recommend content of interest to the user, which is mainly divided into user-based CFRA and item-based collaborative filtering recommendations [20]. User-based collaborative filtering uses the user's interest similarity score to make recommendations, which has no special requirements for recommended resources and can handle a variety of complex objects, while item-based CFA uses the similarity of items to make recommendations. A comparison of the advantages and disadvantages of each RA, combined with the usage scenario of the system, the study selected user-based CFRA and the specific algorithm recommendation process is shown in Fig. 5.

The complete collaborative filtering recommendation system consists of three modules: behaviour collection for collecting user information, a model for analyzing user interests, and an RA. The behaviour collection module mainly collects and classifies the operation behaviour of the user interface, and the research designs a user behaviour collection form to collect the user's research direction, likes, favourites, comments and other historical data, which is transferred to the server and then stored in the database through interface

interaction after collection. The study adopts a weighted average to infer the user's interest level, calculated as in Eq. (3).

$$\bar{p} = \frac{\sum_{i=0}^n m_i f_i(x_i)}{\sum_{i=0}^n f_i(x_i)} \quad (3)$$

In Eq. (3),  $n$  is the user action behaviour,  $m_i$  is the corresponding action behaviour weight, and  $f_i(x_i)$  is the corresponding score of the user action behaviour. The user browsing behaviour is calculated as in Eq. (4).

$$f_i(x) = \begin{cases} 1, & (\text{has viewed}) \\ 0, & (\text{has't viewed}) \end{cases} \quad (4)$$

The calculation of users' liking, favouriting and sharing behaviour is shown in Eq. (5).

$$f_i = \begin{cases} f_i(x), & (\text{thumb up}) \\ 0, & (\text{thumb down}) \end{cases}, \quad (i = 2, 3) \quad (5)$$

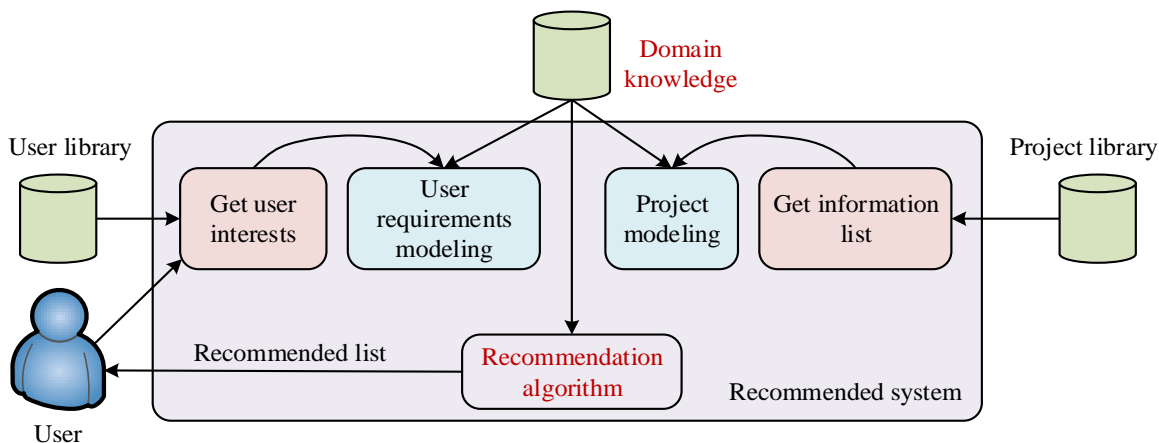

Fig. 4. Knowledge-based recommendation block diagram.

Fig. 5. CFRA structure diagram.

User objection to comment behaviour is calculated as in Eq. (6).

$$f_4(x) = x, (\text{comment statistics}) \quad (6)$$

The Euclidean distance was utilized to determine the similarity between users after the study generated the users' score matrices for each dynamic via the weighted average approach, as shown in Fig. 6. The Euclidean distance refers to  $n$  as the actual distance between two points in space.

Fig. 6. Schematic diagram of the distance between two points in the three-dimensional space coordinate system.

The Euclidean distance between the user score vectors is given by Eq. (7), since the user score for each dynamic can be regarded as a multidimensional vector.

$$D(u, v) = \sqrt{\sum_{k=1}^n (x_k - y_k)^2} \quad (7)$$

The  $u$ ,  $v$  in Eq. (7) are the sets of user  $u$ ,  $v$ 's ratings of all resource actions, and  $x_i$ ,  $y_i$  are the vectors of user  $u$ ,  $v$ 's ratings of all resources respectively. The closer the Euclidean distance, the higher the similarity, and for the convenience of calculation the normalisation process is performed as in Eq. (8).

$$\begin{cases} s(u, v) = \frac{1}{1 + D(u, v)} \\ 0 \leq s(u, v) \leq 1 \end{cases} \quad (8)$$

The user with the highest similarity to the user is identified and the difference set of the rating dynamics between these two users is determined. This process is repeated until all users have been compared. The study uses accuracy, recall, coverage and Mean Absolute Error (MAE) as performance indicators to evaluate the RA. Accuracy is assessed using Eq. (9).

$$\text{Accuracy} = \frac{\sum_u |R(u) \cap T(u)|}{\sum_u T(u)} \quad (9)$$

In Eq. (9)  $R(u)$  is the set of  $N$  resources recommended to user  $u$ , and  $T(u)$  is the set of resources preferred by user  $u$  on the test set. The recall is calculated as in Eq. (10).

$$\text{Recall} = \frac{\sum_u |T(u) \cap R(u)|}{\sum_u |T(u)|} \quad (10)$$

The coverage ratio is calculated as in Eq. (11).

$$\text{Coverage} = \frac{U_{u \in U} R(u)}{|I|} \quad (11)$$

In Eq. (11),  $U$  is the set of users and  $I$  is the total number of resources.  $MAE$  is calculated as in Eq. (12).

$$MAE = \frac{\sum_{r_{u,i} \in T} |p_{u,i} - r_{u,i}|}{r_{u,i}} \quad (12)$$

In Eq. (12),  $T$  is the test set and  $r_{u,i}$  is the rating of item  $i$  by user  $u$ . In conclusion, the system RA's analysis and design are finished.

#### IV. PERFORMANCE ANALYSIS OF A PR AND SHARING MANAGEMENT SYSTEM FOR SCIENTIFIC AND TECHNOLOGICAL ACHIEVEMENTS BASED ON WEBSOCKET TECHNOLOGY

To verify the effectiveness of the designed RMS and the feasibility of the PRA, this section is designed for comparative experiments of key system technologies and tests of the accuracy and resistance to attack of the user-based CFA.

##### A. Performance Analysis of Key Technologies for Technology Sharing Management System

To verify the feasibility of the AJAX data exchange technology selected for the study, the study used AJAX and traditional HTTP on the system to respond to the same operation respectively, and the response results of both were counted. The training of the model utilises Adam as the optimizer and employs a preheating training methodology. The batch size has been established as 254, with a total iteration count of 3000 and an initial learning rate of 0.0001.

Table I shows a comparison of the results of AJAX and HTTP request responses. The comparison shows that the response time for a single HTTP request is 1613ms and the request resource size is above 40KB, while the response time for AJAX containing the request header and request body is 299ms and the request resource size is no more than 1KB. The results show that AJAX has no additional data transfer of HTML and CSS resources during page loading, which speeds up the response speed of the interface and the study. The use of AJAX data exchange instead of traditional HTTP request

interfaces is effective. To verify the efficiency of the WebSocket real-time push technology selected for the study, the study was tested at a broadband of 30MB/s, counting the throughput of the AJAX polling and WebSocket networks and the data transfer time of the HTTP and WebSocket protocols.

Fig. 7(a) shows the comparison between AJAX polling and WebSocket network throughput. Compared to AJAX polling, WebSocket data requirements are smaller for concurrent client requests below one million and minimal for concurrent requests above one million. In terms of the amount of data communicated, WebSocket has a significant advantage with better concurrency performance. Fig. 7(b) shows the data transfer time comparison between HTTP protocol and WebSocket protocol, the data transfer time in HTTP protocol is basically around 35ms, the transfer time starts to increase when the concurrent working time is 5min and then decreases to around 30 when the data transfer time is mid 10min. The data transfer time in the WebSocket protocol is around 20ms, which varies in line with the HTTP protocol, which is known to consume time each time a connection is established and released during the transfer process. The comparison between the two shows that the WebSocket protocol has a faster

transmission time and faster real-time push. The study divided the generated CiteULike-a dataset into test sets A and B based on user-document interaction records in the CiteULike document management platform, each test set includes 2500 users, 7000 papers and 100000 user-document interaction records, the study proposed the system with the traditional RMS in two the test set was tested on two test sets, using ROC and AUC as evaluation metrics, with AUC being the area below the ROC curve.

The ROC curves and AUC values for the two systems on test sets A and B are displayed in Fig. 8. The findings reveal that on test sets A and B, the suggested RMS has AUC values of 0.973 and 0.986, compared to 0.726 and 0.667 for the conventional RMS. The results show that the AUC values of the proposed RMS on test sets A and B were 0.973 and 0.986 respectively, compared to 0.726 and 0.667 for the conventional RMS. The AUC values of the proposed system increased by 34% and 48%, indicating that the improvement of key technologies has improved the accuracy of the system recommendations and made it easier for researchers to share information and communicate their results.

**B. Performance Analysis of the PRA for Scientific and Technical Achievements**

To verify the effectiveness of the user-based CFRA selected for the study, offline experiments were conducted on the Movielen dataset to generate TopN recommendations for each user, using accuracy, recall, coverage and popularity as performance measures, specifying the nearest neighbour parameter as the K users with the most similar interests to the recommended user, and recording the test results.

Table II shows the results of the experimental tests using user-based CFRA. The experimental results show that the accuracy of information recommendation increases with the increase of the nearest neighbour parameter K. The best recommendation is achieved when K=50. When K is constant, the accuracy of information recommendation decreases and the recall, coverage and popularity increase as the number of resources recommended to the user increases. When the training set is 0.7, the accuracy of information recommendation can basically reach 41%. In conclusion, the

accuracy of information recommendations may essentially satisfy the system requirements when K=50, the number of information suggestions is 10, and the training set is 0.7. The study included the classic CFRA based on user (CF), CFRA based on user (UserCF), content-based recommendations (CB), and knowledge-based recommendation algorithm (KR) were tested on test sets A and B to confirm the algorithms' accuracy in making recommendations. The four algorithms' recommendation accuracy was compared using the MAE as a performance evaluation metric.

Fig. 9(a) and (b) show a comparison of the recommendation accuracy of the four RAs on test sets A and B. The results show that the MAE values of UserCF on the two test sets are significantly smaller than those of CF, CB and KR algorithms, and its recommendation accuracy is the highest, with the recommendation accuracy of UserCF improving by about 13.46% compared to KR, and its recommendation accuracy improving by about 10.38% compared to CB. This shows that the research selection of UserCF algorithm can meet the needs of RMS and improve the quality of system information recommendation. To further compare the attack resistance of the four algorithms, the study added mixed attack data to the original Movielen dataset, selected K=50, with fill size of 3%, 5% and 10%, and attack size of 1%, 2%, 3%, 4%, 5%, 6%, 7%, 8%, 9% and 10%, and tested the change of recommendation accuracy of the four algorithms as the fill size and attack size kept increasing situation.

Fig. 10(a) to (c) show a comparison of the prediction bias of the four algorithms at 3%, 5% and 10% fill size. The results show that when the fill size is the same, the prediction deviation of the four algorithms fluctuates more as the attack size increases. In conclusion, the user-based CFA used for the study is better suited for RMS, which can increase the accuracy of the system's recommendations and satisfy the demands of scientific user information sharing.

TABLE II. CFRA EXPERIMENTAL TEST RESULTS

### V. RESULTS AND DISCUSSION

With the ongoing advancements in science and technology and the rising prevalence of intelligent devices, there is a growing desire for personalized recommendations and shared management of scientific and technological accomplishments. The conventional approach to recommending and managing these accomplishments presents challenges such as information imbalance, imprecise recommendations, and burdensome administration. Designing a personalised system

for recommending and sharing scientific and technological achievements based on network socket technology has the potential to address these issues effectively, enhancing the efficiency of utilisation and improving the overall user experience. The study's experimental results demonstrated that implementing AJAX and WebSocket technologies can substantially enhance the system's response time and data transfer efficiency. Additionally, the UserCF approach proved to be more accurate in terms of information recommendation

and MAE value. The study adopted network socket technology and proposed corresponding system design and algorithm optimization based on the requirements of personalized recommendation and shared management. This holds immense importance in driving innovation and utilization of network socket technology, while also playing a guiding and exemplifying role in advancing the dissemination and collaboration of scientific and technological progress.

## VI. CONCLUSION

With the continuous development of science and technology, China has made significant progress in the field of scientific research. However, while the field of scientific research is steadily developing, the management of scientific research faces the problem of insufficient standardisation, automation and information management, so the construction and promotion of RMS is imperative. This paper proposes a scientific and technological achievement publicity and sharing management system based on WEBSOCKET technology to solve the problem of the lack of a professional platform for scientific communication and exchange among small scientific research teams. The trial results demonstrated that the system using AJAX technology has a response time that is 1314ms faster than that of traditional HTTP, that no request resource exceeds 1KB in size, and that the WebSocket technology used to transmit data demands is more efficient, with data transmission times of roughly 20ms. According to the study, the system has AUC values of 0.973 and 0.986 on the same test set, which is an improvement of 34% and 48% over conventional RMS, respectively. The UserCF method selected for the study also satisfies the system requirements for scientific research with an accuracy rate of about 41% for information recommendations at K=50, several information recommendations of 10, and a training set of 0.7. The recommendation accuracy of UserCF is around 13.46% higher compared to KR and about 10.38% higher compared to CB, which has the highest recommendation accuracy and the strongest resilience to attacks. The MAE of UserCF on the test set is much lower than that of the CF, CB and KR algorithms. In conclusion, the study claims that RMS-based systems can facilitate communication between small research teams and enable the dissemination of results. However, the study still has some shortcomings in that it collected too little information about users' personal lives, making it difficult to provide non-personalised dynamic recommendations. Future research can focus on the front-end interface of the system, user interaction, data collection and other in-depth research topics.

**Abstract**—The exploration of the universe is progressively increasing, within this inquiry, the planet Mars and the Moon remain a mystery and challenge, as well as its colonization and civilization. Thus, in the extravehicular activities (EVA) where the astronaut will be in extreme environments performing activities such as exploration, and collection of rock and soil samples for later analysis, it should be noted that when he performs these activities, he will be exposed to extreme environmental parameters such as radiation, temperature, gravity, and many other extreme conditions. Therefore, the Center of Space Emerging Technologies (C-SET) proposed a project called T-EVA, developed into the Research Line: Space Suits and Assistive Devices, and in the Research Area: Biomechatronics and Life Support Systems, with the aim of astronaut temperature monitoring during their work outside the base station, being able to know how much their body is measuring and if they are at risk of hypothermia or hyperthermia, which could cause irreparable damage. The electronic design was made for testing both in the laboratory and outside, as well as the implementation of the lycra to mount the design, resulting in a feasible prototype that can be implemented in real situations with easy access to temperature reports.

**Keywords**—Extravehicular-activities astronauts; spacesuits; body temperature; Mars; space

## I. INTRODUCTION

The journey to Mars is a major undertaking, as it is fraught with obstacles from the start of the mission to its completion, including challenges related to the atmosphere, geology, and

distance involved (Fig. 1). This has motivated both governments and private space companies to be interested in sending manned missions to Mars or the Moon, investing resources, and sending robotic missions to explore solutions to make these planets habitable and safe for humans [1]-[3]. Among these solutions are space biomedical mechatronics projects developed by the Center for Space Emerging Technologies, on which the T-EVA Project is based [4]-[9].

Extravehicular activities (EVAs) are a fundamental part of space exploration and have been a regular feature of manned missions since the earliest days of the space program. EVAs are planned activities that take astronauts outside the spacecraft or space station to perform specific tasks in space, such as repairs, maintenance, science equipment installation, or sample collection. Extravehicular activities are extremely complex and challenging due to the extreme environment of space. These activities are inherently dangerous because astronauts performing EVAs are exposed to many hazards, such as lack of gravity, extreme temperatures, cosmic radiation, and micrometeorites [15].

Successful EVAs require meticulous planning and coordination, as well as close collaboration between astronauts and the ground control team. As space exploration continues to expand to new horizons, EVAs will remain an essential part of our journey into the universe, allowing us to conduct scientific research and develop skills and technologies for future space missions, such as those planned to explore Mars and other celestial bodies [28].

Fig. 1. Average communication delay between Earth, LEO, cislunar space, and Mars.

The lunar environment is characterized by approximately  $\frac{1}{6}$  Earth g, and surface temperatures ranging from  $-143^{\circ}\text{C}$  to  $+127^{\circ}\text{C}$  due to direct sunlight or shading in an ambient vacuum. The temperature Lunar [10], [11] seen in the image collected from Quickmap, selected Artemis 3: Candidate Landing Regions and LRD DIVINER, Polar Winter Max Temp and selected temperature range  $-173.1^{\circ}\text{C}$  to  $31.8^{\circ}\text{C}$  and LOR WAC Basemaps, WAC+NAC+NAC\_ROI\_MOSAIC.

Space studies have determined that Mars has a thin atmosphere, which does not protect the surface from dangerous

cosmic rays and micrometeorites, a problem for astronauts traveling on the surface. In addition, the presence of 95%  $\text{CO}_2$  and 0.17%  $\text{O}_2$  in the atmosphere also makes it difficult for astronauts to breathe outside their spacesuits. Extreme temperatures [12], Fig. 2(a) are also a problem for the astronauts because they range from  $-153.1^{\circ}\text{C}$  near the poles to  $19.8^{\circ}\text{C}$  near the equator [13]. The cold climate of Mars is due to the low conductivity of the surface, the sparse atmosphere, and the great distance from the sun Fig. 2(b).

Fig. 2. (a) Temperature zones on the Moon from QUICKMAP and (b) Sea temperature from JMARS.

The human body can be conceptualized as a thermal machine that exchanges energy with its environment through moisture and heat. Likewise, thermal comfort implies a balance between the heat produced and the mechanisms of heat transfer through the effector system (vasoconstriction or vasodilation), depending on the constraints [14]. This means that exposure to adverse environments (environmental heat stress) can be detrimental to human health, especially when the environment is unknown [15]. As a result, in this temperature range in Fig. 3(a), it can be difficult for the crew to maintain the thermal

stability of both habitat and internal body temperature to conserve heat against hypothermia and its effects [16]. To solve this problem, the Extravehicular Mobility Unit (EMU) was designed to provide the necessary functions to keep the user alive [17], during extravehicular activities (EVA). As shown in Fig. 3(b), research in simulated Mars EVAs has shown that surface temperature on the suit may spatially vary by as much as 50°C depending on the astronaut's orientation relative to the sun, and atmospheric effects.

Fig. 3. (a) Thermoregulation in the human body and (b) Suit surface temperature varies throughout a simulated Martian EVA.

If the body's core temperature is exposed to extreme temperatures, it can develop hypothermia ( $<35.5\text{ }^{\circ}\text{C}$ ) or hyperthermia ( $>37.5\text{ }^{\circ}\text{C}$ ), and in peripheral parts, these effects can also occur at different degrees ( $<10^{\circ}\text{C}$ ), ( $>44^{\circ}\text{C}$ ) which can manifest in multiple symptoms [18]. Also, Table I presents a quantitative range of peripheral (skin) and core (thoracic) temperatures in relation to effects on the body and limits of thermal comfort in a thermoneutral environment [19], [20].

TABLE I. THERMOREGULATION IN HUMAN BODY

Temperature		Effects
Periphery	Body Core	
$>44-46\text{ }^{\circ}\text{C}$	$42\text{ }^{\circ}\text{C}$	Death
$36-43\text{ }^{\circ}\text{C}$	$41\text{ }^{\circ}\text{C}$	Hyperthermia
	$38-40\text{ }^{\circ}\text{C}$	Evaporation Vasodilation
$30-34\text{ }^{\circ}\text{C}$	$37\text{ }^{\circ}\text{C}$	Thermal Comfort
$24-28\text{ }^{\circ}\text{C}$	$36\text{ }^{\circ}\text{C}$	Vasoconstriction Thermogenesis
	$35\text{ }^{\circ}\text{C}$	Hypothermia
$<10\text{ }^{\circ}\text{C}$	$25\text{ }^{\circ}\text{C}$	Death

## II. PROPOSED APPLICATION FOR THE EARTH

### A. Firefighter Suit

In firefighting, activities with different levels of intensity are performed such as: throwing ladders, climbing ladders with heavy loads, performing a search, advancing a line, applying water, ventilating a roof, forcing a door, and searching a room [21]-[23]. Firefighters regularly face stress in their work, and their job performance that is directly related to saving or losing human lives, including their own [24]. The magnitude of these heat effects depends on individual factors such as age, health status, hydration, and physical fitness.

1) *Environmental conditions*: In firefighting, conducted a study compared physiological responses to an overhaul task in ambient conditions with no fire ( $15^{\circ}\text{C}$ ) to the same task performed with live fires in the structure ( $90.5^{\circ}\text{C}$  at chest level). Heart rate increased to an average of 139 bpm in the ambient conditions and to 175 beats per minute in the live-fire condition. Tympanic temperatures increased by slightly more than  $5.4^{\circ}\text{F}$  in the live-fire condition and less than  $1^{\circ}\text{F}$  in the ambient conditions as shown in Fig. 4(a), [25].

2) *Personal protective equipment (PPE)*: Protects firefighters from burn and inhalation injuries; however, due to its weight and restrictive properties, a laboratory study comparing 15 min of treadmill walking in the firefighter's uniform and 15 min of walking in fully encapsulated PPE found that the heart rate was 50 beats per minute higher while wearing the fully encapsulated gear [26].

3) *Individual characteristics*: A firefighter's age, gender, and body size all affect physiological responses to firefighting activities. In general, the risk of a heart attack while fighting a fire increase as the age of the firefighter increases.

4) *Medical condition*: High blood pressure, high cholesterol, and obesity are all well-established risk factors for cardiovascular disease. By prioritizing their cardiovascular health, firefighters can reduce their risk of experiencing cardiac events on the fire-ground and improve their overall quality of life.

5) *Fitness level*: A high level of physical fitness is necessary to successfully and safely perform demanding physical activities [27]. It increases the efficiency of the heart, improves thermal tolerance, provides cardioprotection by increasing the anticoagulant activity of the blood, and increases blood vessel dilation capacity to allow more blood to reach the muscles as shown in Fig. 4(b).

6) *Environmental control and life support subsystem*: Space is a hostile place, charged particles, solar radiation, vacuum, and free fall are potentially harmful, even fatal, to unprepared humans. Future space exploration missions will take astronauts far from Earth into extreme thermal environments, where temperature control of spacesuits will be a critical life support function. Due to wide oscillations of temperature swings, we need to balance the heat flow in, plus the heat generated internally, with the heat flow out humans, have their own, specific temperature range, where they function best. Existing thermal control technology relies on venting water to space to provide the required cooling. This approach is extremely costly, and possibly unsustainable, for future exploration missions [28].

The spacesuits have thermal regulation systems that ensure astronauts' comfort and protection by maintaining a stable internal temperature. These systems also allow the temperature of the suit to be adjusted according to external environmental conditions and the amount of heat generated by the astronauts during their metabolic activity. It has been observed that performance decrements manifest above 480 Btu/hour heat storage and tissue damage begins at 800 Btu heat storage. During the Apollo lunar surface EVAs, heat expenditure rates ranged from 780 to 1200 Btu/hour. It is important to understand and measure the estimated amount of heat expenditure prior to planetary spacewalks to ensure crew health, as the duration and requirements of the task can significantly affect heat output. Thermal management technology is an uncelebrated but nonetheless essential requirement for all spacesuits, spacecraft, and space habitats. During extravehicular activity (EVA), spacesuits must remove metabolic heat produced by the astronaut, residual heat from the suit's electronics, and absorb heat from the external environment [29]. Spacesuit design encompasses both the material selection of the spacesuit, which is important to

consider for radiation shielding and dust mitigation, as well as all the internal systems that support the regulation and monitoring of physiological health [30] as shown in Fig. 5(a).

In recent years, stretchable sensors for wearable applications have demonstrated their ability to continuously monitor health with a high level of fidelity and comfort (Table II) [31]. The integration of these elastic sensors into spacesuits could provide valuable information about astronauts' movements during EVA maneuvers, which could be combined with our proposed T-EVA to safeguard the astronaut's integrity [32]–[33] as shown in Fig. 5(b).

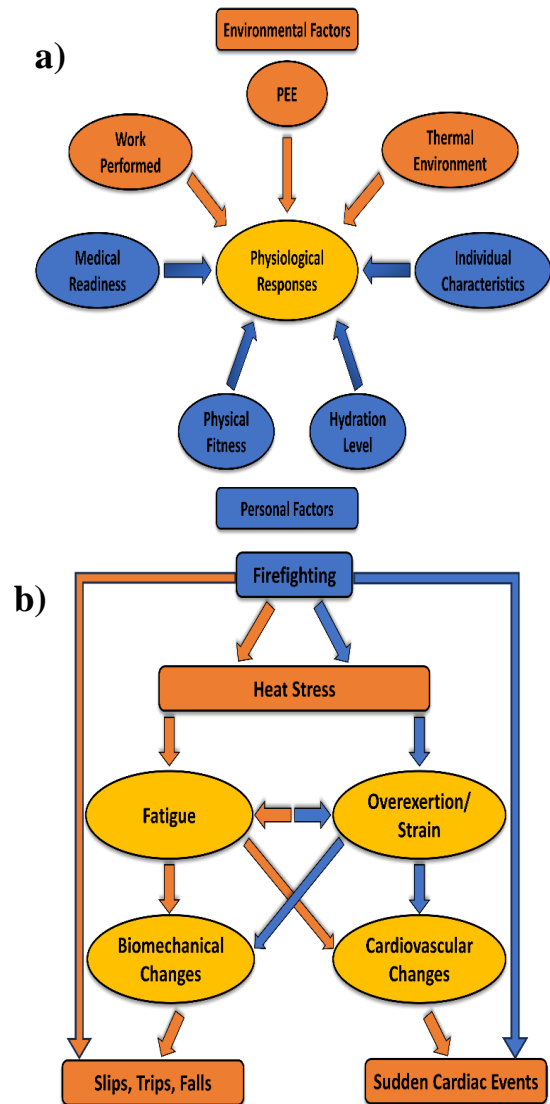

Fig. 4. (a) Factors that affect the way the body responds to firefighting activities and (b) Risk of heat stress in firefighters.

TABLE II. PLSS FUNCTIONS, RECOMMENDED TECHNOLOGIES OF CHOICE, RATIONALE, AND STRENGTHS & WEAKNESSES

Functions	Technology of Choice	Rationale	Strengths & Weaknesses
Oxygen Supply	High-Pressure Gaseous Oxygen Storage	Rechargeable on orbit, lighter & fewer parts	<b>Strengths</b> Reduced Volume Reduced System Mass Robustness Operability Reliability Less logistic <b>Weaknesses</b> Poor on-suit Mass
Thermal Control	Suit Water Membrane Evaporator	Less water contamination & can operate on Mars	
CO2 & Moisture Removal	Rapid Cycle Amine	Reduce logistics and resupply	
Power	Li-ion Polymer Batteries	Increase battery life & higher energy density	

Fig. 5. (a) Spacesuit with the sensor of T-EVA and (b) The system can control the temperature inside a spacesuit without venting water.

### III. PROPOSED METHOD

This section shall describe the steps for the development of the prototype of the temperature measurement system for extravehicular activities. The proposed methodology consists of 3 phases as shown in Fig. 6.

#### A. Phase 1 / Inputs

First, as it is very well described in the methodological diagram, it is a design project focused 100% on the user. As background, one could analyze and study the success that OMEGA watches have had in the space conquest, watches that NASA astronauts have used for more than 50 years in all their space explorations. Thanks to all these experiences, one was able to define the problems of visually assisted communication and control that astronauts currently lack information assistance systems that the astronaut will need to be able to carry out high-risk extravehicular activities, and more significant challenges unknown until now. One found three immediate needs that need to be resolved, such as:

- 1) Thermoregulation

- 2) Extreme temperatures

- 3) Monitoring of physiological parameters.

#### 1) Project objectives:

a) *General Analysis:* Analysis of the context in which the project performance will be carried out, Environmental analysis, Background analysis of presented congresses and workshops, Package Evaluation, Material Evaluation, and Manufacturing evaluation.

b) *Sensor Suit:* Anthropometric Evaluation to see the anatomical shape of the sensor case. Points Location to get the temperature variation correctly.

c) *T-EVA System:* Electronic package analysis, Performance analysis, Sensor analysis, Temperature analysis, Network analysis.

d) *T-EVA Bracelet:* Electronic package analysis, Performance analysis, Visual communication analysis.

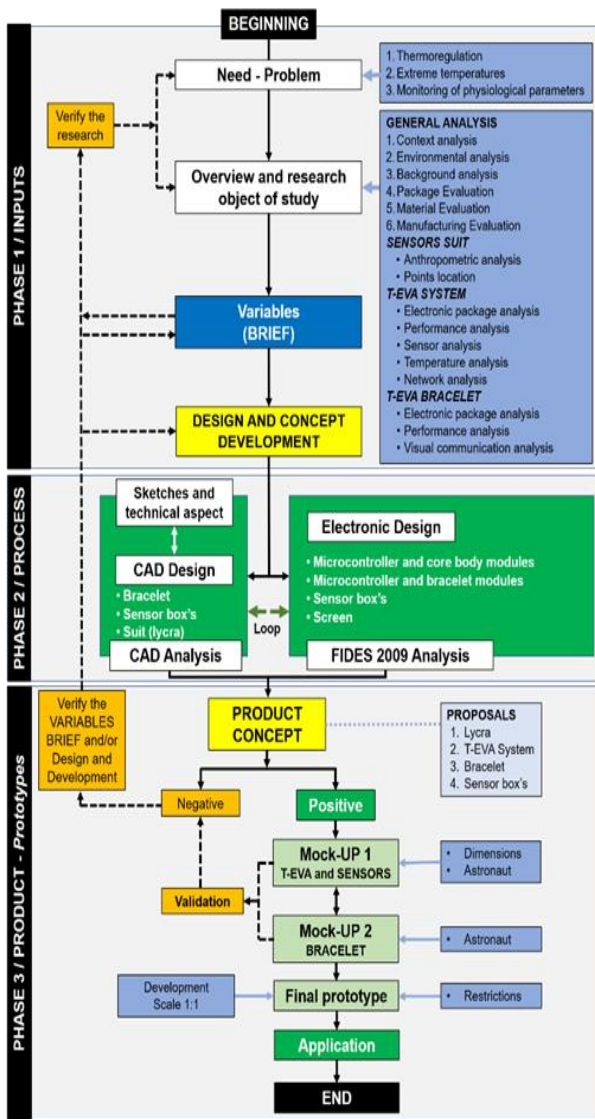

Fig. 6. Development diagram of T-EVA / I+P+p.

### B. Phase 2 / Process

In this phase, designs such as Sketches and technical aspects were made, which included analysis and CAD design with feedback from electronic design (Microcontroller and core body modules, Microcontroller and bracelet modules, Sensor boxes, Screen) [Fig. 7(a)]. This phase is divided into 3 parts.

1) *Bracelet*: The first part is a bracelet where the astronaut will be able to visualize the temperature in real-time as well as several pre-established alarms [Fig. 7(b)].

- a) Brushed titanium - Case – Grade 2.
- b) Black ceramic coated titanium -Top Ring - Grade 5.
- c) Special quartz - Glass Dome - that does not fragment.
- d) Black-coated brushed titanium-Side Push Button-Grade
- e) Titanium – Screws - Grade 2.
- f) Brushed Titanium - Bracelet Ring - Grade 2.
- g) Velcro Strap.

Fig. 7. (a) Bracelet in explosion view and (b) Bracelet implemented in a spacesuit.

2) *Sensors box*: The second part is the temperature sensor boxes (Fig. 8), which have an anatomical shape to capture any temperature variation, which is pretending to be manufactured based on FDA guidelines for medical devices [34], [35].

Fig. 8. Sensor Box.

3) *Central box*: The third part consists of the central box (Fig. 9), which contains the data processing board, a temperature sensor, and an RF module for sending the information to the bracelet and the base station.

Fig. 9. Central Box.

C. Phase 3 / Product - Prototypes

1) *Implementation specifications*: Lycra being a flexible and adaptable material to the human anatomy, it is established that the measures of this would be the Latin American 95th percentile [36], Fig. 10(a) shows the location of the sensors and twisted pair wires in the lycra. In Fig. 10(b), one can see the connection. See Table III.

2) *Electronics specifications*

a) *Sensor DS18B20*: The analog temperature sensor DS18B20 [Fig. 11(a)] was used, whose voltage output is linearly proportional to temperature, generates 10mV for every 1°C, has an accuracy of  $\pm 3/4^\circ\text{C}$  in the configured range of  $-55^\circ\text{C}$  to  $150^\circ\text{C}$  [Fig. 11(b)] and has a power consumption of 60  $\mu\text{A}$ , generating a self-heating of less than  $0.1^\circ\text{C}$ , Fig. 11(c) [37].

TABLE III. SENSOR LOCALIZATION IN HUMAN BODY

SENSOR	PERIPHERY – UPPER LIMBS				BODY CORE (THORACIC)	FOREHEAD
	LEFT SIDE		RIGHT SIDE			
CODE	Upper Arm	Fore Arm	Upper Arm	Fore Arm	BC-T	FH
	L-UA	L-FA	R-UA	R-FA		

Fig. 10. (a) Sensors in the body and (b) a Bracelet mounted on the arm of the space suit.

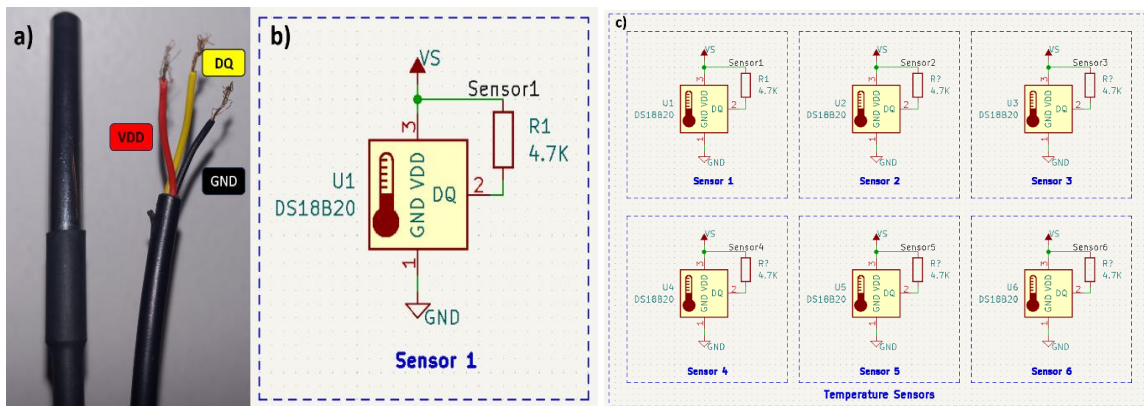

Fig. 11. (a) Sensors in the body and (b) a Bracelet mounted on the arm of the space suit.

b) *Microcontroller ESP32*: The ESP32 microcontroller was selected [Fig. 12(a), 12(b)], it has integrated wireless connectivity (WiFi and Bluetooth) to generate a communication network, has an operating temperature range of -40°C to 125°C, 30 pinouts, 512 KB RAM and the consumption specifications are shown in Table IV [38]–[41].

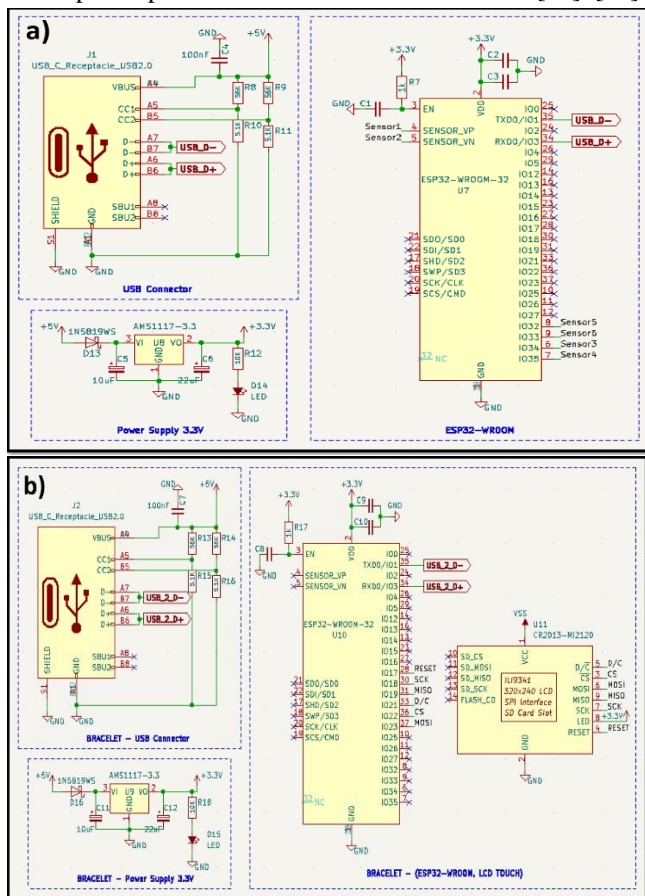

Fig. 12. (a) Schematic body core (ESP32, power supply, USB connector), and (b) Schematic bracelet (ESP32, power supply, USB connector).

TABLE IV. ELECTRONIC DESIGN OF T-EVA

Nº	Components and Consumption		
	Body Core Sensor Box	Consumption	Total
1	ESP 32 (SENDER)	180 mA	180 mA
2	DS18B20 (6)	5 mA	30 mA
3	Battery 3.7V DC – 1.4 A	Autonomy: 7.5 horas	
<b>Bracelet</b>			
1	ESP32 (RECEIVER)	80 mA	80 mA
2	TFT 2.4" – ILI9341	150 mA	150 mA
3	Battery 3.7V DC – 1A	Autonomy: 6 horas	

3) *Communication protocol*: ESP-NOW is a protocol invented by Espressif that allows connecting many devices without Wi-Fi. It is very versatile and can have unidirectional or bidirectional communication in different low-power 2.4 GHz wireless configurations. It is comparable to WiFi in the sense that pairing takes place before communication. After pairing, it becomes a secure peer-to-peer connection that does not require a handshake. This means that if one of the boards

suddenly shuts down or reboots, it will automatically connect to the other board at that time and continue to communicate. In addition, ESP-NOW can carry a payload of up to 250 bytes and can be configured to inform the application layer of the success or failure of transmission through the functions listed in Table V [42].

TABLE V. FUNCTIONS ESP-NOW

Nº	ESP-NOW PROTOCOL	
	Functions	Description
1	esp_now_init()	Wi-Fi must be initialized before initializing ESP-NOW.
2	esp_now_add_peer()	This function is used to pair a device and pass the MAC address of the peer as an argument.
3	esp_now_send()	Sends data with ESP-NOW.
4	esp_now_register_send_cb()	Registers a callback function that is triggered when sending data. This function returns whether the delivery was successful or not.
5	esp_now_register_rcv_cb()	Registers a callback function that is triggered when data is received. A specific function is called when data is received.

The configuration of an ESP32 "RECEIVER" (R) microcontroller receiving data from an ESP32 "SENDER" (S) microcontroller has been used. The communication network is unidirectional, which means that the information flows only from the sender to the receiver.

With this configuration, it is possible to collect the data from the four temperature sensors (1\_L-FA, 2\_L-UA, 3\_R-FA, and 4\_R-UA) from the sender ESP32 microcontroller and send it wirelessly to the receiver ESP32 microcontroller. After receiving the four temperature readings from the sending ESP32 microcontroller, the receiving ESP32 microcontroller displays the values on a 2.4" LCD display, as shown in Fig. 13.

Fig. 13. Diagram of connection.

#### IV. RESULTS AND DISCUSSIONS

Once the connections and operation of the sensors and microcontroller were verified, tests were performed on a breadboard to check the code and then the system was mounted on a lycra where first one sensor was inserted and then 4 sensors (Fig. 14 and 15).

a) *First Test:* Fig. 17(a), (b) shows the sending and receiving of the 4 temperature values using the ESP-NOW protocol and the Arduino IDE serial monitor. It is observed that the data (1\_L-FA = 35.28°C, 2\_L-UA = 35.75°C, 3\_R-FA = 35.37°C and 4\_R-UA = 35.67°C) reach their destination without loss of information.

b) *Second Test:* Fig. 18 shows the sending and receiving of the 4 temperature values using the ESP-NOW protocol and the Arduino IDE serial monitor. It is observed that the data (1\_L-FA = 35.35°C, 2\_L-UA = 35.77°C, 3\_R-FA = 35.41°C and 4\_R-UA = 35.68°C) reach their destination without loss of information.

c) *Third Test:* Fig. 19 shows the sending and receiving of the 4 temperature values using the ESP-NOW protocol and the Arduino IDE serial monitor. It is observed that the data (1\_L-FA = 35.39°C, 2\_L-UA = 35.79°C, 3\_R-FA = 35.44°C and 4\_R-UA = 35.73°C) reach their destination without loss of information.

d) *Fourth Test:* Fig. 20 shows the sending and receiving of the 4 temperature values using the ESP-NOW protocol and the Arduino IDE serial monitor. It is observed that the data (1\_L-FA = 35.45°C, 2\_L-UA = 35.76°C, 3\_R-FA = 35.46°C and 4\_R-UA = 35.72°C) reach their destination without loss of information.

## V. CONCLUSION AND FURTHER WORK

The results of this study demonstrate the feasibility of designing and implementing a prototype to measure astronaut body temperature during extravehicular activities (EVA). Body temperature ranges remained stable under normal conditions, and although problems arose with the LM35 temperature sensors, the choice of the DS18B20 sensors proved to be more successful, providing more stable and reliable readings. These sensors feature encapsulated probes that are ideal for skin contact and are water resistant, which increases their robustness when astronauts sweat. Constant temperature monitoring translates into easy-to-read reports, which is essential for preserving astronaut health during EVAs.

As a part of future work, it is intended to carry out further tests, in addition to those already performed, and to optimize the 3D printed prototype. These tests will be conducted at the Mars Desert Research Station (MDRS) in the deserts of Utah, USA, and in environments with lunar-like conditions.

The Center for Space Emerging Technologies (C-SET) is known for pursuing dual applications in every project. In this case, the T-EVA device could be employed on Earth to monitor the upper body temperature of firefighters when they face extreme heat exposure in urban or rural environments. This would provide them with real-time readings of their temperature, which would be crucial to take safety measures and protect their life and health in these challenging situations.

## ACKNOWLEDGMENT

The research has been managed, supervised by the Center for Space Emerging Technologies ([https://linktr.ee/cset\\_space](https://linktr.ee/cset_space)). Also, special thanks to the Institute of Electrical and Electronics Engineers – IEEE and to the American Society of Mechanical Engineers – ASME.

# Artificial Intelligence-based Volleyball Target Detection and Behavior Recognition Method

Jieli Huang, Wenjun Zou\*

Physical education institute, Nanchang Jiaotong University, Nanchang 330100, China

**Abstract**—Volleyball has limitations in relying on judges' subjective judgments alone to call penalties for infractions in the court. While video detail enhancement technology is extremely useful for target tracking and extraction in sports video, the current research on video detail enhancement technology does not pay much attention to the development of ball game violation tracking and recognition. Therefore, the study uses the fusion algorithm of wavelet exchange method and three-frame difference method and background subtraction method to detect and extract the motion targets, and uses the improved CamShift tracking algorithm and HMM to track and identify the tracking targets for the violation actions. Comprehensively, the study constructs a tracking recognition model for volleyball violation based on video enhancement technology to achieve accurate penalty in intense rivalry games. Through experimental analysis and comparison, the tracking F-measure value of the model constructed by the study is 0.89, which can achieve a good tracking effect, the recognition accuracy is 99.76%, and the average error is 0.003, which can effectively realize the tracking recognition of players' illegal actions during volleyball, and objectively make court penalties to guarantee the fairness and justice of the game.

**Keywords**—Volleyball; video detail enhancement; hmm; CamShift tracking; detection; recognition

## I. INTRODUCTION

In competitive competitions, the subjective judgment of the referee may be influenced by different perspectives and observation results, leading to doubts about the accuracy of the judgment. Video detail enhancement technology has become an important research direction for achieving accurate punishment of illegal actions in volleyball matches. However, despite the rapid development of computer and network technology, significant progress has been made in related research fields; the application of video detail enhancement technology in sports video still faces some challenges [1]. Due to the uncertainty of lighting conditions at the competition site, limitations of collection equipment, and the presence of noise interference, the quality and clarity of volleyball game video images are often low. This poses a challenge to the effectiveness of video detail enhancement algorithms. In addition, as the competition progresses, moving targets may experience problems such as rapid movement, deformation, and occlusion, which also increases the difficulty of tracking and recognizing moving targets. In addition, due to the individual differences of different athletes and the complexity of game rules, further research is needed on the identification methods for illegal actions [2]. With the current computer and networking skills, video detail enhancement has matured. In

the process of image and video acquisition, due to the lighting environment, acquisition equipment, noise interference and other factors, it will lead to the degradation of image and video visual effects, so detail enhancement algorithms need to be used to highlight some of the detailed information in the image and video for subsequent processing [3]. There are two main types of video detail enhancement algorithms, namely, detail enhancement based on multiple input images and detail enhancement based on single input images [4]. While video detail enhancement techniques are extremely useful in the tracking and extraction of targets in motion video, not much research attention has been paid to video detail enhancement techniques [5]. The study uses video detail enhancement techniques to process video images in volleyball and to achieve detection and tracking of motion targets, and to identify the offending actions accordingly. The images are first preprocessed using the wavelet variation algorithm RGB. After pre-processing, the motion targets are detected and extracted using a fusion algorithm with three-frame difference method and background subtraction method. After the motion targets are detected and extracted, the motion targets are tracked and identified using CamShift tracking algorithm and Hidden Kolff (HMM), which is found to be lost when the target tracking may be obscured. To address this, the study adjusts the position of the CamShift algorithm's finding glass by introducing a Kalman filter (Kalman) to predict the motion parameters of the target. As a result, the study constructs a volleyball motion violation tracking recognition model based on video detail enhancement, which realizes the intelligence of game penalty and effectively solves the penalty problem caused by viewing angle and other reasons during the game. The importance of research lies in improving the accuracy and fairness of competition judgments, optimizing the effectiveness of video image processing and object tracking, and providing useful references for penalty issues in other sports. The innovation lies in the refinement of the application of video detail enhancement technology. Through the combination of various algorithms and models, a volleyball movement violation tracking and recognition model based on video detail enhancement has been constructed. This study has important practical significance in improving the accuracy of competition judgments. This study is mainly divided into five sections. The second section summarizes the research on video tracking, motion recognition, and other technologies both domestically and internationally. The third section is to construct a proposed volleyball foul action tracking and recognition model, analyzing image data processing, image detection, and target tracking. The fourth section is to analyze the performance of the constructed model and verify the

superiority of the proposed model. The fifth section discusses the results and analyzes deeper conclusions. The final section summarizes the results and proposes the shortcomings of the research and future research directions.

## II. RELATED WORKS

In the process of image and video acquisition, under the influence of lighting environment, acquisition equipment, noise interference and other factors, it will lead to the degradation of image and video visual effect, and need to use detail enhancement algorithm to highlight some information in the image and video for easy discrimination and processing. For this, many scholars conducted research to improve the image visual effect. Xue et al. [6] found that most video enhancement algorithms depend on optical flow to enroll frames in video sequences, but flow estimation is difficult, so they proposed a TOFlow to achieve enhancement of image data, and found excellent optimization by comparing three functional tasks, frame interpolation, video denoising/denoising, and video super-resolution, with conventional optical flow for standard benchmark tests. Guan et al. [7] proposed a MFQE method for the lower house video and designed a new MF-CNN to improve the quality of compressed video by addressing the problem that existing methods to improve the quality of compressed images/videos mainly focus on improving the quality of individual frames without considering the similarity between consecutive frames, which effectively improves the effectiveness and generalization in terms of the latest image quality of highly compliant videos. Wang et al. [8] found that the key challenge of video SR is to effectively exploit the correlated asphyxia among consecutive frames, and that available deep learning-based methods typically estimate the optical flow among LR frames to provide temporal dependence, proposing an end-to-end video SR network to super-resolve optical flow and image. Zheng et al. [9] constructed an unsaturated magnetic excitation-based MFL measurement device by converting MFL information to image representation through the Zaitong pseudo-color imaging protocol, and the maximum modulus method was used for the point location of wire breakage to extract color moments, statistical texture features, and spectral texture features from the image. Tang et al. [10] proposed a new ship detection model that can be called FLNet by combining image processing methods and deep learning target detection methods in order to solve the problem that there is a large amount of background information and noise information similar to the ship in the image due to the mechanism of imaging by SAR, which badly affects the ship detection model performance.

In intelligent video analysis systems, motion target tracking is widely used in intelligent surveillance, human-computer interaction, and autonomous driving. In order to be able to track and recognize with high accuracy despite the challenges such as environmental changes, occlusion deformation and scale changes of the tracking target, the research on motion tracking recognition has been increasing. Kim et al. [11] tracked the excavator by using a pre-trained detector to locate the excavator and correlate the detection results, tracked the excavator by the tracking learning clean toilet algorithm, and finally used a hybrid deep

learning algorithm to model the visual features of the excavator and the operation cycle of the sequential patterns were modeled and trained to propose a vision-based framework for animal recognition. Jaouedi et al. [12] proposed a hybrid deep learning model-based approach for human action recognition using gated recurrent neural networks to classify sequence data and videos, and upper and lower feature data extraction using evaluation algorithm. Angeliniet al. [13] proposed a hybrid deep learning model-based approach for HAR due to the gap between the deep learning data requirements and the functionality provided by the framework that needs to provide the application in terms of data recording devices, a new 2D pose based pose level HAR approach (ActionXPose) was proposed by reducing the gap using the human pose provided by OpenPos. Zhang et al. [14] proposed a new pose level HAR approach (ActionXPose) in order to deal with the gaps with different temporal context information for long duration time series features and enhance spatio-temporal attention, the human action recognition problem was solved by using Conv-LSTM and FC-LSTM, and a STDAN was designed. Ge et al. [15] effectively represent the spatial static and temporal dynamic information of videos, using GoogleNet to extract the features in the video frames, processed by a spatial transformer network then modeled the sequential information of the features by convolutional LSTM, and proposed a new attention mechanism based convolutional LSTM action recognition algorithm.

In summary, the CNN model is used as the mainstream direction in speech recognition technology. Although this model can improve the performance of speech recognition, the subsequent structure construction is complicated and is not conducive to improving the operation efficiency of the model. Therefore, the research starts from neural network and proposes OPGRU to simplify the structure of speech recognition model and improve the recognition accuracy and operation efficiency of the model.

## III. VOLLEYBALL FOUL ACTION TRACKING RECOGNITION MODEL CONSTRUCTION

### A. Image Data Pre-Processing and Target Detection

Common penalty errors and misjudgments have been the trigger for conflicts on the court. The requirement of action specification in volleyball is very high, in order to ensure the reduction of errors and wrong calls in volleyball and the accurate detection of fouls committed by players. The ball game video is processed and analyzed using video detail enhancement technology [16]. Before tracking and recognition of ball game violation actions, pre-processing of sports video image data is required to improve the accuracy and recognition precision of tracking afterwards. Firstly, the image is converted to grayscale image by RGB and the image is weighted, and the processing formula is shown in the following Eq. (1).

$$I_i(x, y) = \alpha r(x, y) + \beta g(x, y) + \gamma b(x, y) \quad (1)$$

The values  $\alpha$ ,  $\beta$ , and  $\gamma$  in Eq. (1) are the values for weighting the action images of volleyball players. When the

athlete action image is an action image captured in natural light is, the image weight is set to 1. When the action image is captured in a single light, the image weight is set to 0 to eliminate the shadow of the volleyball player's body, and the wavelet transform algorithm is used to reduce the noise of the data signal after the image is grayscale processed and weighted, and the wavelet transform formula is shown in Eq. (2) below.

$$WT(a, \tau) = \frac{1}{\sqrt{a}} \int_{-\infty}^{\infty} f(t) \cdot \varphi\left(\frac{t-\tau}{a}\right) dt \quad (2)$$

In Eq. (2),  $a$  denotes the variable scale and  $\tau$  denotes the variable translation. After multiple wavelet transforms, the obtained signal components are shown in Eq. (3) below.

$$S = A_n + D_1 + D_2 + \dots + D_n \quad (3)$$

In Eq. (3),  $S$  denotes the original signal,  $D_n$  denotes the noisy signal obtained after  $n$  wavelet transforms, and  $A_n$  denotes the effective signal obtained after  $n$  wavelet transforms. After verification, it is found that the 3-layer wavelet transform has the best denoising effect. According to the above, the denoising and grayscale processing of volleyball sports video action data is realized. After processing the image need to detect the motion target, motion target detection is to take the target color, shape, position and size information in each frame of the video stream, and the video sequence is essentially three-dimensional data containing a time dimension, the study uses the three-frame difference method to extract the motion target, the three-frame difference method is illustrated in Fig. 1.

In Eq. (8),  $\alpha$  is the number, which is fed into the section as needed,  $w$  is the degree, and  $h$  is the figure. Eq. (9) is obtained by "summing" the background subtraction method with the motion target information obtained from the three-frame difference method.

$$D(x, y) = DI(x, y) \otimes DB(x, y) \quad (9)$$

After obtaining the target information, the background adaptive update is performed, and the update expression is shown in Eq. (10).

$$B(x, y) = \begin{cases} B(x, y) & D(x, y) = 0 \\ uB(x, y) + (1-u)I_k(x, y) & D(x, y) \neq 0 \end{cases} \quad (10)$$

The best value of  $u$  in Eq. (10) is 0.997, which is obtained after the study. The flow chart of the fusion algorithm of the three-frame difference method and the background subtraction method is shown in Fig. 2.

Firstly, the three adjacent frame degree values  $I_{k-2}$ ,  $I_{k-1}$  and  $I_k$  are collected for the operation of the neighboring two

difference absolute, and the difference map formula is obtained as shown in Eq. (4).

$$\begin{cases} D_1(x, y) = |I_{k-1} - I_{k-2}| \\ D_2(x, y) = |I_k - I_{k-1}| \end{cases} \quad (4)$$

Binarizing the two neighbor-dual differences, the expression is shown in Eq. (5).

$$\begin{cases} T_1 = d_1 + \beta\delta_1 \\ T_2 = d_2 + \beta\delta_2 \\ D_1(x, y) = \begin{cases} 255 & d_1 \geq T_1 \\ 0 & d_1 < T_1 \end{cases} \\ D_2(x, y) = \begin{cases} 255 & d_2 \geq T_2 \\ 0 & d_2 < T_2 \end{cases} \end{cases} \quad (5)$$

In Eq. (5),  $d$  is the mean value of the difference map,  $\delta$  is the standard deviation of the difference map, and  $T$  represents the threshold value. The two binarized images are subjected to or operation to obtain the motion target information, as shown in Eq. (6) below.

$$DI(x, y) = D_1(x, y) \oplus D_2(x, y) \quad (6)$$

The above equation is used to process the image, but in the process of research, it is found that there are still some limitations, and the motion target in the extraction will produce a hole phenomenon, for this problem, the study combines the background subtraction method and the three-frame difference method. The Eq. (7) is obtained from the background subtraction method.

$$DB(x, y) = |I_k(x, y) - B(x, y)| \quad (7)$$

In Eq. (7)  $I_k(x, y)$  is the current degree value,  $B(x, y)$  is the back pixel gray value.  $d(x, y)$  is the difference absolute value image  $DB(x, y)$  value image  $DB(x, y)$  pixel point of  $\bar{d}$  and standard  $\delta$ , with and standard deviation set to a value of  $T$ , into the binarization, to obtain the expression (8).

$$\begin{cases} \bar{d} = \frac{\sum_{x=0}^{w-1} \sum_{y=0}^{h-1} d(x, y)}{wh} \\ \delta = \sqrt{\frac{\sum_{x=0}^{w-1} \sum_{y=0}^{h-1} [d(x, y) - \bar{d}]^2}{wh}} \\ T = \bar{d} + \alpha\delta \\ DB(x, y) = \begin{cases} 225 & d \geq T \\ 0 & d < T \end{cases} \end{cases} \quad (8)$$

Fig. 1. Diagram of three frame difference method.

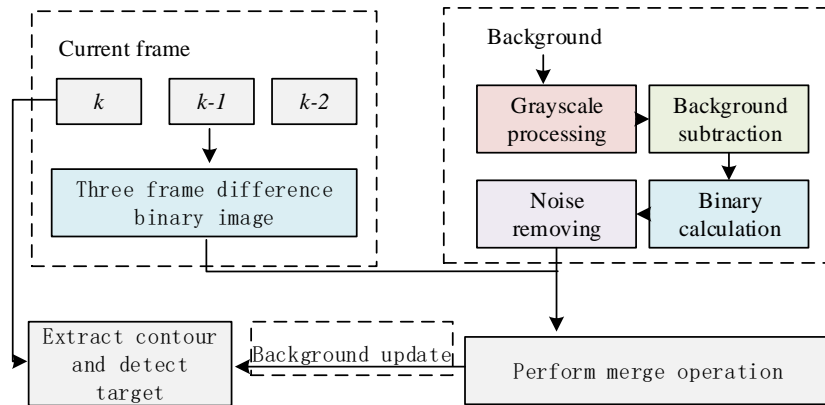

Fig. 2. Flow chart of fusion algorithm for target detection.

Combining the above, the study implements the pre-processing of volleyball sports action video images, and detects and extracts the image targets using an algorithm fused with the three-frame difference method and the background elimination method.

### B. Target Tracking based on Improved CamShift Algorithm

After the target is detected and extracted, it needs to be tracked so that the subsequent violation movements during volleyball sports can be identified in real time. The CamShift is a successive self-adaptive Meanshift algorithm. The Meanshift algorithm that finds and iterates over the pixels of a single image for optimal results, the CamShift mainly iterates processing of video sequences, where each frame in the video is called using the Meanshift algorithm. The Meanshift algorithm belongs to the kernel density estimation method, which describes the model of the target and the candidate model by the probability of the pixel feature values in the region and in the candidate region. Given a sample of points in the d-dimensional space  $R^d$ , the Meanshift vector of points has the basic form shown in Eq. (11).

$$M_h(x) = \frac{1}{k} \sum_{x_i \in S_h} (x_i - x) \quad (11)$$

In Eq. (11),  $x_i$  is the sample points in the interval,  $k$  denotes the sample falling into the  $S_h$  region, and  $S_h$  is the high-dimensional spherical region of radius  $h$ , which is the set of  $y$  points satisfying the relationship in Eq. (12) below.

$$S_h(x) = \{y : (y-x)^T (y-x) \leq h^2\} \quad (12)$$

The study extended the basic Meanshift form by introducing a kernel function in order to take into account the effect of the distance of each pixel point during the calculation, as shown in Eq. (13) below.

$$M_h(x) = \frac{\sum_{i=1}^n G\left(\frac{x_i - x}{h}\right) \omega(x_i) (x_i - x)}{\sum_{i=1}^n G\left(\frac{x_i - x}{h}\right) \omega(x_i)} \quad (13)$$

In Eq. (13)  $G(x)$  is a unit kernel function and  $\omega$  is the weight assigned to the sampled points. Using Eq. (13) for iteration, the following Eq. (14) is obtained.

$$m_h(x) = M_h(x) + x \quad (14)$$

After calculating the value of  $m_h(x)$ , assign it to  $x$ , and then calculate  $M_h(x)$  again. If the absolute value of  $M_h(x)$  is less than the tolerance error, end the cycle to get the final target position. If not, continue the calculation. The meanshift tracking algorithm is shown in Fig. 3.

Fig. 3. Schematic diagram of MeanShift tracking algorithm.

The CamShift utilizes the modalities of the probability distribution image detected by the Meanshift algorithm in continuous video detection by introducing a feedback loop in which the previous detection result is used as input to the next detection process and restricting the search area to the surroundings of the latest known target location. After the color tracking probability model is established, the video image is transformed with a color probability distribution map. The model initializes a search window (SW) in the first frame of the image, and adjusts the window size and position according to the tracking target in the way shown in Eq. (15).

$$\begin{cases} \hat{p}_k(W) = \frac{1}{|W|} \sum_{j \in W} p_j \\ \hat{p}_k(W) - p_k \approx \frac{f'(p_k)}{f(p_k)} \end{cases} \quad (15)$$

In Eq. (15)  $W$  is the SW of size  $s$  in the color probability distribution map,  $p_k$  is the initialized centroid of the SW,  $f(p)$  is the Meanshift climbing gradient equation, and the new centroid  $\hat{p}_k$  is found by dynamic iteration, and this is cycled until convergence to achieve adaptive change of the window. During the study, it is found that the target tracking may be obscured during the target tracking resulting in target loss. To address this, the study adjusts the position of the SW of the CamShift by introducing the Kalman filter (Kalman) to predict the motion parameters of the target to compensate for the temporary target loss due to occlusion. In two stages, prediction and correction, the components of the predicted state vector are used to set the center position of the SW of the CamShift, and the center of gravity position output by the CamShift is used as the measurement value to correct the predicted state vector and achieve the optimization improvement of the CamShift.

### C. HMM-based Foul Play Analysis Identification

Judgment of foul actions and near-foul actions in volleyball by the eyes of the referee alone usually leads to errors. The study has already used a fusion algorithm combining the three-frame difference method and the background elimination method to detect and extract the motion targets in the previous paper, and the improved CamShift has been used to achieve the tracking of motion targets in ball game sports videos. The HMM recognition process is shown in Fig. 4.

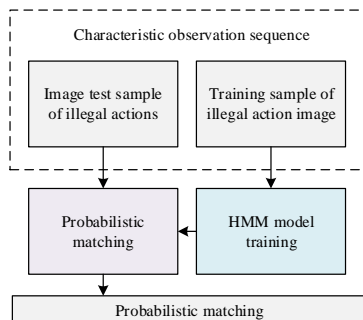

Fig. 4. HMM violation action identification process.

The data set of foul actions of volleyball players is divided into different types, firstly, each violation is modeled in a targeted way, and the study sets the amount of data for each violation to 120 and decomposes the action into  $n$  meta-actions. These meta-actions during the motion are temporal in nature, so each game violation is considered as a sequence of observations of length  $n$ . Training and learning are performed for this sequence of observations to find the best HMM parameters for each action model [17]. After finding the best parameters, the extracted observation sequence data is used as the input data of the HMM, and the probability of the best state sequence occurrence of the action in the current video under each action model is obtained using the Viterbi algorithm. The action which corresponds to the model with the largest probability of output is the identification outcome of the current observed sequence. HMM is expressed as the following Eq. (16).

$$\lambda = (A, B, \pi) \quad (16)$$

In Eq. (16),  $A$  is the state probability distribution,  $B$  is the observation probability distribution, and  $\pi$  is the initial probability distribution. To find the appropriate HMM parameters, the study uses the Baum-Welch algorithm to train each parameter of the HMM so that the probability of the observed sequence in the model is maximized. The state sequence data is considered as unobservable hidden data  $I$  as shown in Eq. (17) below.

$$P(O|\lambda) = \sum_I P(O|I, \lambda) P(I|\lambda) \quad (17)$$

In Eq. (17),  $O$  is the observed sequence data. The maximum expectation algorithm (EM) is used to implement the HMM algorithm for parameter learning.  $Q$  function, as follows in Eq. (18).

$$Q(\lambda, \bar{\lambda}) = \sum_I \log P(O, I|\lambda) P(O, I|\bar{\lambda}) \quad (18)$$

In Eq. (18),  $\bar{\lambda}$  denotes the current estimate of the model parameters and  $\lambda$  is the maximized model parameters. After obtaining the value of the  $Q$  function, the parameters of the HMM were obtained by maximizing the  $Q$  function, combined with the Lagrange multiplier method. In volleyball violation recognition, after the training of the violation model is completed, the study uses the Viterbi algorithm to find the optimal solution of the HMM. For a given HMM model and observed sequence data, the optimal path  $I^* = (i_1^*, i_2^*, \dots, i_T^*)$  is solved, and  $T$  denotes the length of sequence  $I$ . Through the above operation, the analysis of the recognition of ball game violation actions is completed. The principle of the Viterbi algorithm is shown in Fig. 5.

Comprehensive above, the research uses video detail enhancement technology to detect and track the target of the game video image, and finally uses the action model for recognition, and constructs a volleyball foul action tracking recognition model based on video detail enhancement technology, which effectively makes accurate judgment on each violation action remembered in volleyball.

Fig. 5. Principle of viterbi algorithm.

#### IV. TRACKING RECOGNITION MODEL PERFORMANCE ANALYSIS

The study conducted performance analysis on the constructed model, using the Volleyball Dataset for training and analysis. The dataset consists of 55 videos, with 4830 keyframes annotated with athlete positions, as well as their individual and group actions. The study divided 4830 keyframes into training and testing sets, with a ratio of 8:2 between the training and testing sets. The study was conducted to improve the accuracy and recognition precision of tracking. The wavelet transform noise reduction process was performed on the image, and to verify the noise reduction process effect, the study used the same set of violating actions. The noise reduction effect of the image of the x-axis acceleration of the violation action is compared as shown in Fig. 6.

Fig. 6. Effect before and after wavelet change noise reduction.

As can be seen from Fig. 6, before the use of wavelet denoising, there is a lot of redundant data and noise in the image of the offending action, which is difficult to extract and identify subsequently, after the wavelet transform noise reduction eliminates the redundant data removal in the x-axis acceleration of the foul action, and maintains the original curve direction while noise reduction, which makes the waveform graph clearer and improves the accuracy of tracking and identification of subsequent video images. To verify the tracking effect of the tracking algorithm, the research improved CamShift tracking algorithm is compared longitudinally with the currently popular and superior performance tracking algorithms: CT, TLD, IVT, and LIPAG to verify the tracking of a subset of target deformation, a subset of illumination changes, and a subset of background interference, a subset of the three interference cases using the algorithm. The distance accuracy curves (precision plot) for comparing different cases are shown in Fig. 7.

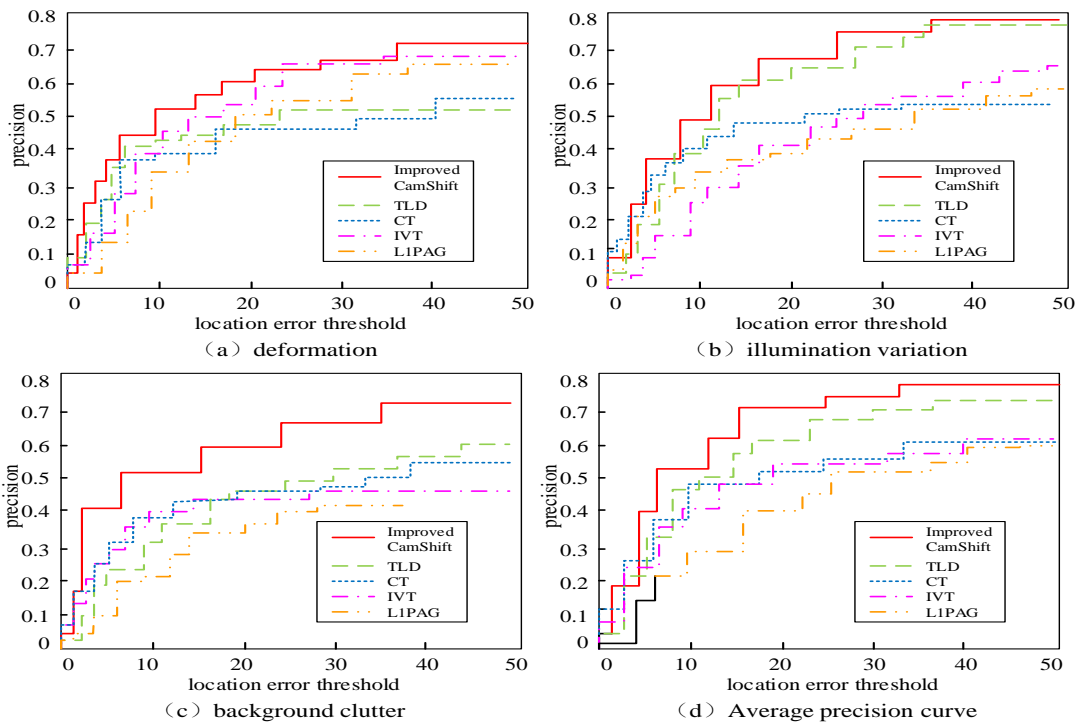

Fig. 7. Comparison of Accuracy Curves.

In Fig. 7, the tracking distance precision of each algorithm is affected by different effects under different interference scenarios, and increases with the increase of the positioning error threshold, among which the improved CamShift tracking algorithm is the least affected by interference, and the average tracking precision is 0.79 under each interference scenario at a positioning error threshold of 50. The TLD tracking algorithm is at a positioning error threshold of 50. The average tracking precision of the TLD tracking algorithm is 0.73 at a positioning error threshold of 50, which is 8.2% less than the precision of the improved structure. The average tracking precision of the CT tracking algorithm is 0.59 at a positioning error threshold of 50, which is 33.9% less than the precision of the improved structure. The average tracking precision of the IVT tracking algorithm is 0.61 at a positioning error threshold of 50, which is 29.5% less than the precision of the improved structure. The average tracking precision of the LIPAG tracking algorithm is 0.59 at a positioning error threshold of 50, which is 29.5% less than the precision of the improved structure; and the average tracking precision of the LIPAG tracking algorithm is 0.61 at a positioning error threshold of 50. The average tracking precision of the LIPAG tracking algorithm is 5.7 when the localization error threshold is 50, which is 38.6% less than the algorithm precision. The above figure shows that the proposed algorithm has better tracking effect in complex scenarios such as target deformation, light change, and background disturbance. To further verify the performance of the algorithms, the study introduces recall (Re), precision (Pr), and comprehensive performance (F-measure) to compare the performance of the five tracking algorithms under three different scenarios of multimodal background, light change, and bad weather with quantitative metrics, as shown in Table I.

TABLE I. COMPARISON OF AVERAGE PERFORMANCE OF TRACKING ALGORITHMS

Algorithm	Scene	Re	Pr	F-measure
Improved CamShift	Highway	0.90	0.88	0.89
	Fountain	0.88	0.87	0.87
	Wet Snow	0.92	0.91	0.91
TLD	Highway	0.82	0.81	0.81
	Fountain	0.84	0.80	0.82
	Wet Snow	0.76	0.79	0.78
CT	Highway	0.82	0.83	0.82
	Fountain	0.79	0.80	0.79
	Wet Snow	0.80	0.81	0.80
IVT	Highway	0.73	0.75	0.74
	Fountain	0.69	0.70	0.69
	Wet Snow	0.77	0.79	0.78
LIPAG	Highway	0.74	0.72	0.73
	Fountain	0.71	0.74	0.72
	Wet Snow	0.68	0.69	0.68

Table I shows that the improved CamShift tracking algorithm using particle filtering significantly improves the ability of the improved algorithm to handle complex backgrounds including light changes and multimodal backgrounds, and the performance index value of this algorithm is the highest in all scenes. The improved CamShift tracking algorithm has an average Re value of 0.90, an average Pr value of 0.89, and an F-measure value of 0.89 for the three scenes. Slightly higher than the TLD tracking

algorithm, which has an average Re value of 0.81, an average Pr value of 0.80, and an F-measure value of 0.80. The CT tracking algorithm has an average Re value of 0.81. The average Re value of the CT tracking algorithm is 0.81, the average Pr value is 0.81, and the F-measure value is 0.81; the other two algorithms have lower values of quantitative indicators. The comprehensive table above shows that the research improved CamShift tracking algorithm has high comprehensive performance and good robustness. To verify the recognition effect of the volleyball violation recognition model (model 1) constructed by the study, the recognition models constructed by convolutional neural network (CNN) (model 2) and support vector machine (SVM) (model 3) and BP neural network (model 4) were used for violation recognition using volleyball sports videos from video websites, and the recognition effect was compared for training and testing, and the results are shown in Fig. 8 is shown.

Fig. 8. Comparison of recognition effects of four recognition models.

In Fig. 8, the recognition rate of the offending actions in models 1, 2, 3, and 4 decreases as the sample size increases. When the sample reaches at 500, the precision of model 1 was 99.76%, the recognition precision of model 3 was 98.68% lower than that of model 1 by 0.08%, the recognition precision of model 2 was 99.21%, lower than that of model 1 by 0.55%, and the recognition precision of model 4 was 98.89%, lower than that of model 1 by 0.87%. When the sample was increased to 4000, the precision of the four model precision all decreased, but model 1 decreased the least, the recognition precision was 99.52%, model 3 recognition precision was 98.39%, 1.13% lower than model 1, model 2 recognition precision was 98.49%, 1.03% lower than model 1, model 4 recognition precision was 98.32%, 1.20% lower than model 1. The comprehensive content of Fig. 6 shows that model 1 has high stability and the highest recognition precision among the four recognition models. To further verify the recognition model performance, the recognition errors of the four models are recorded and compared, as shown in Fig. 9.

From Fig. 9, the highest error of recognition error curve of model 1 is 0.009, the lowest error is 0.001, and the average error is 0.003. It can be seen that the overall curve of this model is lower than the other three models, among which the highest recognition error of model 3 is 0.012, the highest recognition error of model 4 is 0.018, and the highest recognition error of model 2 is 0.016. The volleyball violation tracking recognition model constructed by the study can effectively track and identify the violations during the game, providing a strong guarantee for the fairness of the game.

Fig. 9. Identification error of four models.

## V. DISCUSSION

Through the above experimental results, it was found that wavelet transform denoising of images can effectively eliminate redundant data and noise, maintain the original curve direction, and make the waveform clearer. This is crucial for the tracking and recognition of subsequent video images. Compared with popular tracking algorithms such as CT, TLD, IVT, and LIPAG, the improved CamShift tracking algorithm has higher tracking accuracy and robustness in subsets of illumination changes, background interference, and target deformation. Similarly, accuracy, recall, and comprehensive performance indicators also demonstrate its superiority. Compared with popular tracking algorithms such as CT, TLD, IVT, and LIPAG, the improved CamShift tracking algorithm has higher tracking accuracy and robustness in subsets of illumination changes, background interference, and target deformation. Similarly, accuracy, recall, and comprehensive performance indicators also demonstrate its superiority. The recognition error of Model 1 is the smallest, indicating that the model has high robustness and accuracy, and is suitable for use in actual competitions to accurately track and identify violations that occur during the competition. In summary, the improved CamShift tracking algorithm and volleyball violation recognition model constructed in the study have been compared and tested, showing high accuracy and stability. This will have a significant impact on the fairness of actual matches and open up a path for subsequent research, indicating that important positions should be given to data preprocessing and model optimization in such research.

## VI. CONCLUSION

In volleyball, referees are very prone to subjective judgment errors due to different observations from different angles during the game viewing process. For this reason, the study uses RGB to grayscale the image and wavelet variation algorithm to noise reduce the video image, and then uses the fusion algorithm of three-frame difference method and background subtraction method to detect and extract the motion target in the image. After the motion target is detected and extracted, the CamShift tracking algorithm is used to track the motion target and it is found that the target may be lost due to the occlusion of the tracking target during the target tracking. To address this, the study adjusts the position of the SW of the CamShift by introducing the motion parameters of the Kalman prediction target to achieve improved optimization. The set of images that have been extracted from the offending actions are input to the HMM recognition model to track and identify the offending actions that appear in the motion video. As a result, the study constructs a volleyball

motion violation tracking recognition model based on video detail enhancement. Through the analysis of experimental verification, the recognition accuracy of the research constructed tracking recognition model is 99.76%, and the average error is 0.003, which can effectively realize the tracking recognition of players' illegal actions during volleyball sports and realize the fairness of the penalty in the court game. At present, the model is only used in sports competitions and has not been put into more fields, which can be further explored in the future research.

# Deep Learning-based Multiple Bleeding Detection in Wireless Capsule Endoscopy

Prof. Ouiem Bchir, Ghaida Ali Alkhudhair, Lena Saleh Alotaibi,  
Noura Abdulhakeem Almhizea, Sara Mohammed Almuhanha, Shouq Fahad Alzeer  
Collage of Computer Science and Information, King Saud University, Riyadh, Kingdom of Saudi Arabia

**Abstract**—Wireless Capsule Endoscopy (WCE) is a diagnostic technology for gastrointestinal tract pathology detection. It has emerged as an alternative to conventional endoscopy which could be distressing to the patient. However, the diagnosis process requires to view and analyze hundreds of frames extracted from WCE video. This makes the diagnosis tedious. For this purpose, researches related to the automatic detection of signs of gastrointestinal diseases have been boosted. In this paper, we design a pattern recognition system for detecting Multiple Bleeding Spots (MBS) using WCE video. The proposed system relies on the Deep Learning approach to accurately recognize multiple bleeding spots in the gastrointestinal tract. Specifically, the You Only Look Once (YOLO) Deep Learning models are explored in this paper, namely, YOLOv3, YOLOv4, YOLOv5 and YOLOv7. The results of experiments showed that YOLOv7 is the most appropriate model for designing the proposed MBS detection system. Specifically, the proposed system achieved a mAP of 0.86, and an IoU of 0.8. Moreover, the results of the detection were enhanced by augmenting the training data to reach a mAP of 0.883.

**Keywords**—Wireless Capsule Endoscopy (WCE); Multiple Bleeding Spots (MBS); Gastrointestinal (GI) disease; deep learning; pattern recognition

## I. INTRODUCTION

The digestive system disorders have been a concern for physicians over years. In fact, millions of people around the world suffer from gastrointestinal (GI) diseases. Specifically, among more than 73 thousand participants in a worldwide study, 40% of them have functional gastrointestinal disorders. In addition, disorders such as digestive system cancer are considered fatal and a major cause of mortality according to 2020 United States statistics. Several pathogens can affect the gastrointestinal tract such as inflammations, infections, cancers, benign tumors, ulcers, and hemorrhoids. Some of these pathogens have similar symptoms. Specifically, cancer, benign tumors, ulcers, and hemorrhoids may yield Multiple Bleeding Spots (MBS) in the gastrointestinal tract. The latter symptom consists of a loss of blood in the GI tract because of ruptured vessels indicating the presence of an abnormality [1]. These MBS appear as small dark red spots or as small light spots next to the red dark ones. Fortunately, with the emergence of new diagnostic techniques, it is possible for physicians to detect GI abnormalities. Endoscopy is the most common diagnostic technique for GI tract. Nevertheless, it is inconvenient and painful for the patient. In order to alleviate this inconvenience, Wireless Capsule Endoscopy (WCE) developed in 2000, emerged as a new diagnostic technique.

The diagnosing process consists of the patient swallowing a capsule. The latter contains a camera to record the journey of the capsule internally to the GI tract. Then, the physician analyses the record to diagnose the patient by looking for abnormal spots. WCE generates an eight-hour video. In other words, 60,000 frames need to be visualized by the physician. However, due to the small size of the lesion region and the visual fatigue, the disease diagnosis may be missed at an early stage. In light of this, a diagnostic technology related to image processing and pattern recognition would help in the rapid and accurate detection of the disease. Nevertheless, due to the likeness of the MBS and other intestinal characteristics such as, bubbles, holes, or small food debris, etc. It is challenging to extract visual descriptors able to distinguish MBS pattern from the other ones. It is even more arduous due to the background clutter. In fact, MBS can occur in all parts of the GI tract exhibiting large variety of background in terms of color, and texture. One way to tackle this problem is through the use of Deep Learning (DL) models which learn automatically suitable features.

In this paper, we develop a multiple bleeding spot detection system for Wireless Capsule Endoscopy (WCE) videos. More specifically, we design a pattern recognition system based on deep learning models that are able to detect the bleeding spots through the GI tract. In particular, deep learning models adopted for pattern recognition were utilized. These models are designed to localize and categorize the object of interest. For this purpose, we employ the You Only Look Once (YOLO) deep learning approach [2]. In this regard, we propose to compare different versions of YOLO. These are YOLOv3 [3], YOLOv4 [4], YOLOv5 [5], and YOLOv7 [6].

## II. RELATED WORKS

Recent researches have proposed aided-diagnosis systems for bleeding anomalies within the intestinal tract using WCE images. They can be categorized into classification-based approaches, and detection-based approaches. The former approaches classify the whole WCE frame as including bleeding spots or not including bleeding spots. Whereas, the detection approaches not only classify the frame but also localize the bleeding spots within the frame. Moreover, each of these two categories bifurcates into conventional and deep learning approaches according to the machine learning paradigm that have been adopted. More specifically, conventional approaches use “engineered” features (also referred to as hand crafted features). Alternatively, deep

learning approaches automatically extract the feature while training the deep learning model.

#### A. WCE Frame Classification System

1) *Conventional approaches:* The work in [7] propose to classify WCE frames into “Bleeding” and “No Bleeding”. For this purpose, it extracts a hand-crafted feature, namely, the color moment feature from WCE frames. Then, it is conveyed to a Support Vector Machine (SVM) [8] classifier. The choice of the visual feature to be adopted has been made through empirical experimentation. In fact, MPEG-7 visual descriptors, “color moment”, “Discrete Wavelet Transform”, “Edge Histogram Descriptor”, “Gabor”, and a combination of “Discrete Wavelet Transform” and “color moment”. Similarly, the proposed system in [9] extracts hand crafted features. More specifically, MPEG-7 features [10] are considered. These are the “color moments”, the “color histogram”, the “local color moments”, the “Gabor filter”, the “Discrete Wavelet Transform” (DWT) and the “Local Binary Pattern” (LBP) features [10]. The extracted features are then conveyed to a machine learning approach to categorize the frames as “Bleeding” or “No Bleeding”. This is performed by clustering each of the training “Bleeding” frames, and the training “No Bleeding” frames into similar groups using Fuzzy C-Means (FCM) [11]. As such, in the testing phase, the unknown frame is compared to the obtained cluster centroids from the training phase. It is then assigned to class of the closest centroid.

2) *Deep learning approaches:* The authors in [12] use a well-known CNN model that won of the ImageNet Large Scale Vision Recognition Competition (ILSVRC). Specifically, it exploits LeNet-5 [13] architecture. Alternatively, the work in [14] uses deep learning CNN models for feature extraction. In particular, VGG-19 [15], ResNet50 [16], and InceptionV3 [17] are adopted. Similarly, these are well known CNN models which won the ILSVRC competition. Nevertheless, inceptionV3 is an evolved version of InceptionV1 used in GoogleNet displays the architecture of inceptionV3. The obtained features from the three considered models are concatenated. Then, a feature selection is performed to select the most distinctive features. The selected features are conveyed to SVM classifier [8] to categorize the frames as “Bleeding” or “No Bleeding”. The study in [18] proposed a system to diagnose the abnormalities in the GI. This study proposed a model which utilizes MobileNet [19]. The latter is a lightweight deep learning model. Specifically, it uses the independent convolutions for each depth dimension, then employs  $1 \times 1$  pointwise convolution to recover the depth. The output of MobileNet [19] is fed to a custom built convolutional neural network model. It is constituted of 64 filters with a kernel size of  $3 \times 3$ . The resulting feature map is passed to a three fully connected layers for classification purpose. In [20] authors proposed to classify WCE frames as “Bleeding” and “No Bleeding”. They employ a customized CNN model architecture. It consists of an eight-layer convolutional neural network that is composed of three

convolutional layers (C1-C3), three pooling layers (MP1-MP3) and two fully connected layers (FC1, FC2). Moreover, Support Vector Machine (SVM) [8] classifier is utilized instead of the Softmax layer.

#### B. Bleeding Detection System

1) *Conventional approaches:* The study in [21] extracted color and texture features. These features are used to generate bag of words using K-means clustering algorithm. Next, the Expectation Maximization (EM) is employed on the “Bag-of-Visual-Words” for super-pixel segmentation. From the region of interest, geometric features like centroid, area, and eccentricity are extracted and fed to the SVM classifier [8]. The authors in [22] proposed an approach based on statistical color feature analysis. First, the frame is split into blocks. After that, dark or light blocks are excluded. Moreover, canny operator [23] is applied to discard the edges. Furthermore, Wavelet db2 with soft thresholding [24] is applied to reduce noise. The Red channel of the RGB color space is exploited to detect bleeding regions. More specifically, red ratio is computed for individual pixels. Finally, Support Vector Machine (SVM) is used to classify WCE frames into bleeding and non-bleeding classes. Alternatively, the system described in [25] performs semantic segmentation by classifying the pixels as a “Bleeding” or “No Bleeding” pixel. This results in detecting the bleeding pixel within the frame. More specifically, the proposed system in [26] extracts the Red-Green-Blue (RGB) color feature [26] and the Gray-Level Co-occurrence Matrix (GLCM) texture feature [26]. These two features are combined and fed to Random Tree (RT) [27], Random Forest (RF) [28], and Logistic Model Tree (LMT) [29] classifiers.

2) *Deep learning approaches:* The authors in [30] use AlexNet [31] CNN model to classify the frames as “Bleeding”, or “No Bleeding”. This is a well-known CNN model, which is one of the earliest models that won the ILSVRC run by ImageNet. Once the bleeding frames are separated, they are segmented using SegNet [32] in order to detect the “Bleeding” areas. It is a deep learning model designed for image segmentation. It is constituted of convolutional stacked auto-encoder. Similarly, the authors in [33] use U-Net deep learning segmentation approach to detect “Bleeding” regions in the small intestines. The model architecture has a “U” shape. The model down-samples the input image to a small feature map. Next, it up-samples it. The up-sampling process use skip connections to benefit from the down-sampling process. In fact, at each level, the down-sampled feature map is concatenated to the up-sampled one to generate the next up-sampled feature map. The work in [34] employs a Cascade Proposal network to generate region of interest proposals. These are regions susceptible to include bleeding pattern. The proposed regions are then fed to the Region Proposal Rejection (RPR). The latter is a small network consisting of one convolutional layer, one fully connected layer, and two output layers. It is used to rank the regions based on a score. Its output

is fed to a detection module which predicts the bounding box and the corresponding class. For the testing phase, the unseen image is provided to both a Salient Region Segmentation (SRS) and a Multiregional Region Combination (MRC). While SRS captures the exact location of the regions [34], and MRC that gains adequate coverage of the concerned region and apply the SRS to locate region of interest's positions. Moreover, object boundaries are refined using the Dense Region Fusion (DRF) approach by checking the density of a specific area [34].

### C. Discussion

As it can be noticed, the related works in [7], [9], [12], [14], [18], and [20] classify the frames into “Bleeding” and “No Bleeding”. While the earliest studies in [7] and [9] are based of extracting “hand crafted” features that are fed to a classifier, the works in [12], [14], [18], and [20] exploit deep learning models befitting therefore from the automatic learning of the features. In fact, using deep learning paradigm alleviates the problem of selecting the suitable features which is usually performed through empirical comparison of the features. Nevertheless, classification approaches do not localize the bleeding within the frame. Alternatively, the works in [21], [22], [25], [30], [33], and [34] perform bleeding detection. In particular, the studies in [21], [22], and [25] utilize “hand crafted” features. While the work in [21] and [22] splits the frame into blocks to transform the problem into a set of local problems and identifies in which block the bleeding occurs, the work in [25] perform semantic segmentation through pixelwise classification. The deep learning detection-based approaches in [30] and [33] are segmentation approaches. In fact, they exploit well known deep learning segmentation approaches SegNet and U-Net. Nevertheless, these two approaches are known to be very slow and not suitable for real world applications [35]. On the other hand, the work in [34] is not employing segmentation. It learns a bounding box to localize the anomaly. Specifically, it is based on a customized CNN. Thus, the adopted model could be fit the considered datasets. Moreover, it includes several modules, namely, SRS, MRC, RPR, and detection modules. This is advantageous when compared to end-to-end model. In fact, the error inducted by one of these modules affects all other modules. Moreover, the error of the different modules gets accumulated.

## III. PROPOSED APPROACH

Computer aided-diagnosis can lessen the visualization task and help detecting automatically the MBS. As shown in the related works investigation, MBS aided diagnosis systems are based on image processing and machine learning techniques. In particular, most of the reported works related to detecting MBS employ segmentation techniques. As a result, “hand crafted” features for the segmentation task and for the classification task are required. This can be alleviated by the use of deep learning approaches designed for object detection. Nonetheless, to the best of our knowledge, deep learning models have not been explored for MBS detection. In particular, the end-to-end state of the art YOLO models were not investigated.

YOLO deep learning detection model outperformed the other object detection approaches in many pattern recognition

applications [36], [37]. Moreover, the success of YOLO model and its applicability to real world applications, yield the evolution of the model and the publication of different versions. However, a throughout comparisons of these versions in terms of performance and efficiency needs to be performed. In this regard, YOLO model, specifically, its latest versions YOLOv3 [3], YOLOv4 [4], YOLOv5 [5], and YOLOv7 [6] are investigated for detecting MBS in the GI tract. In the following, we describe the four considered models.

### A. YOLOv3 Architecture

YOLO version 3 (YOLOv3) [3] is an improved version of YOLO which seeks to enhance the performance through the use of residual blocks and different scale feature maps. Inspired by Residual Networks [38] YOLOv3 employs alternatively  $3 \times 3$  and  $1 \times 1$  convolutional layers to form a residual unit. This unit aims at avoiding the vanishing gradient problem faced by very deep network. YOLOv3 is composed of five residual block which incorporate a number of residual units. Since a stride of 2 is used at each residual block, the input is down-sampled five times. In particular, the last three down-sampled feature maps are used for the prediction task. Specifically, after the third residual block, the feature map is down-sampled by factor 8. It is exploited for small object prediction. On the other hand, the output of the fourth residual block is down-sampled by a factor of 16, and it is utilized to generate scale 2 feature map. The latter is employed for medium object prediction. Alternatively, big objects, referred to as scale 1 objects, are predicted using the last residual block for which the feature is down-sampled by a factor of 32. Furthermore, YOLOv3 performs feature fusion to benefit from the feature maps at the different scales. As such, it up-samples scale 1 feature map and concatenate it with scale 2 feature map. The obtained feature map is then up-sampled, and concatenate with scale 3 feature map [38].

### B. YOLOv4 Architecture

YOLOv4 [4] is the fourth version of the YOLO model family. YOLOv4 model architecture is composed of multiple sections. Namely, they are the Input, the Backbone, the Neck, and the Head (dense prediction, and the sparse prediction). The backbone and the neck sections are responsible for feature extraction and aggregation, respectively. In particular, the CNN deep learning model, CSPDarkNet53 [39], is used as a feature extractor in the backbone section. Alternatively, Spatial Pyramid Pooling (SPP) and Path Aggregation Network (PANet) were utilized in the neck section to fuse the features using Bag of Specials (BoS). Finally, the head which is responsible for both localizing the object in the image and classifying it, amounts to YOLOv3 models. It consists of two stage detectors. The first one is the one stage object detector and the second one is the one is the two-stage object detector [4]. Compared to the previous versions of YOLO, YOLOv4 mainly introduced two additional concepts. Bag of Freebies (BoF) and Bag of Specials (BoS). Bag of freebies are a set of techniques that alters the training framework or perform data augmentation. Many techniques can be incorporated for the purpose of enhancing the model performance without affecting on the inference cost [10]. Alternatively, BoS are strategies such as enlarging the receptive field, integrating features, incorporating attention modules, or post-processing.

These strategies aim at significantly enhancing the performance of accuracy at the expense of increasing the inference cost [4].

### C. YOLOv5 Architecture

YOLOv5 [5] is implemented using PyTorch which allows faster training [40]. As such, YOLOv5 allows rapid detection with the same accuracy as YOLOv4. Specifically, YOLOv5 has been proved to have higher performance than YOLOv4 under certain circumstances and partly gained confidence in the computer vision community besides YOLOv4. YOLOv5 model architecture is similar to YOLOv4 architecture. It employs CSPDarknet53 [40] for the backbone section as feature extractor. The latter aims at addressing the gradient in deep networks and decreases the inference time through the use of cross-layer connections between the network's front and back layers. Moreover, it seeks improving the accuracy and utilizing lightweight model. Furthermore, the SPP module referring to the Spatial Pyramid Pooling module, performs maximum pooling with several kernel sizes and then fuses the features by concatenating them together. Additionally, YOLOv5 exploits Path Aggregation Network (PANet) in the neck section as feature aggregator to increase the flow of information and to enhance the object localization. Besides, PANet incorporates a Feature Pyramid Network (FPN) [41]. On the other hand, the head is designed in the same way as YOLOv3 and YOLOv4. Specifically, it produces three different scale feature maps. The CSP network in the backbone is made up from one or more residual units, whereas the CSP network in the neck is made up of new module called CBL modules that replace the residual units. The CBL module consist of Convolution layers, Batch normalization layers, and Leaky ReLU activation function modules [42]. YOLOv5 introduces a new layer referred to as Focus layer [43]. It takes the place of the first three layers of YOLOv3. Therefore, it reduces the GPU requirement and decreases the number of layers.

### D. YOLOv7 Architecture

The most recent YOLO architecture, YOLOv7 [44], is based on YOLOv4 version. The main modifications consist of (i) the introduction of the Extended Efficient Layer Aggregation Network (E-ELAN), (ii) the incorporation of model scaling component, (iii) the use of planned re-parameterized convolution, (iv) the employment of auxiliary head, and (v) the exploration of label assigner mechanism. E-ELAN is a computational component in YOLOv7 backbone part. It enhances the prediction performance continuously by employing “expand, shuffle, merge cardinality”. Alternatively, the model scaling optimizes the number of layers, the number of channels, the number of stages in the feature pyramid, and the resolution of the input image in order to meet the requirements of various problems. Nevertheless, YOLOv7 introduces a new model scaling paradigm which optimizes the scaling factors jointly, not independently one from the other. Similarly, YOLOv7 modifies RepConv by discarding the identity connection. In fact, it uses RepConvN in order to prevent the presence of identity connection for re-parameterized convolution. Moreover, YOLOv7 exploits the Deep Supervision training technique. More specifically, YOLOv7 uses an auxiliary head in the intermediate layers to guide the

training. The head responsible for the final prediction is referred to as lead head. Additionally, to further enhance the training, YOLOv7 outputs soft labels instead of hard one referring to the ground truth.

We propose to compare the performance between different YOLO approaches which are YOLOv3 [3], YOLOv4 [4], YOLOv5 [5], and YOLOv7 [6] in recognizing in recognizing “Bleeding” spots. For this purpose, the considered models need to be trained. Therefore, each YOLO model is fed with images indicating the bleeding areas, if any. Specifically, the coordinates of the bounding boxes surrounding the MBS patterns are provided as input along with the “Bleeding” images. They consist of the upper left corner coordinates (X, Y), the width, and the height of each box. Concerning the “Non-Bleeding” images, no boundary box is specified. To determine the best version of YOLO, the considered YOLO models are evaluated using the test set. Specifically, the different models are tested in terms of the inference time, MBS localization and classification. The best performing model is adopted to build the required system.

## IV. EXPERIMENT

Kvasir-Capsule dataset [45] is considered in this project. It is a dataset of WCE videos collected from clinical examinations performed at the Department of Medicine, Bærum Hospital, and Vestre Viken Hospital Trust in Norway. It consists of 406 “Bleeding” images representing bleeding spots of different size, color, and texture. In addition, it includes 34338 “Non-Bleeding” images representing normal GI tract frames (without bleeding). According to [46], it is not recommended to add images without region of interest (“non-bleeding” images) to the training set. More specifically, “non-bleeding” images should not exceed more than 10% of the total number of images in the training set. As such, only 328 non-bleeding images are first considered. This results in the distribution reported in Table I, where the images are divided into 60% for training, 20% for validation, and 20% testing sets. Nevertheless, in order to get a glimpse of the models’ performance on the real-world, 6000 non-bleeding images are used in the test set. More specifically, both test sets which are the test set after omitting most of non-bleeding images (Test 1) and the test set that containing 6000 background images (Test 2) are assessed.

The available Ground Truth consists of labeling the whole image as including bleeding or not. Nevertheless, in order to train YOLO, a different ground truth should be provided. In fact, the coordinates of the bounding boxes surrounding the bleeding spots should be fed to model to be trained. As such, the dataset is labeled using labeling software tool [47]. As a result, 960 bleeding regions are considered.

TABLE I. DATASET DISTRIBUTION

	<i>Training set</i>	<i>Validation set</i>	<i>Testing set without additional non-bleeding (Test 1)</i>	<i>Testing set with additional non-bleeding (Test 2)</i>
<b>Bleeding</b>	231	75	100	100
<b>Non-bleeding</b>	328	108	86	6000

Two performance measures are considered to evaluate the performance of YOLOv3 [3], YOLOv4 [4], YOLOv5 [5], and YOLOv7 [6] in terms of recognizing MBS. Specifically, we considered Intersection over Union (IoU) [48] and mean Average Precision (mAP) [49], since the localization and the categorization of the object of interest are assessed using these performance measures. Moreover, Floating Point Operations per second (FLOP) [50] is also considered to compare the time efficiency of the considered YOLO models. Fig. 1 shows a comparison between the performances of the considered YOLO models on Test 2 in terms of both mAP and IoU.

As illustrated in Fig. 1, YOLOv3 performs better than YOLOv4 and YOLOv5 in terms of recognition with mAP equal to 0.828. This is an expected outcome since the architecture of YOLOv3 consists of residual blocks. One of them is exploited specifically for small object detections which concord with the small pattern of the bleeding spots. Moreover, in terms of IoU, YOLOv4 achieves an IoU of 0.736 which is better than 0.589 for YOLOv3 and 0.727 for YOLOv5. In fact, YOLOv4 is better in localizing bleeding spots since it incorporates two stage detectors. The first one is called the one stage object detector and the second one is the two-stage object detector. Nevertheless, YOLOv5 exploits path aggregation network that enhances the model localization ability. Alternatively, YOLOv7 achieved the highest IoU and mAP equal to 0.8 and 0.86 respectively. This makes YOLOv7 the most appropriate model to design the proposed approach.

Fig. 1. Performance comparison of YOLOv3, YOLOv4, YOLOv5, and YOLOv7 in terms of mAP and IoU.

Moreover, data augmentation is employed to increase the size of the training data set conveyed to the best performance model, namely YOLOv7 [6]. This is achieved by adding more images to train the model. These images were created by flipping and rotating existing training images. The augmented dataset contains “1056” images. The performance of YOLOv7 without using the augmented data is compared with its performance when training the model with additional data. Table II depicts the performance of YOLOv7 when including and excluding data augmentation. As it can be seen, the augmented dataset improved YOLOv7 performance in terms of mAP.

Furthermore, we compare YOLOv3 [3], YOLOv4 [4], YOLOv5 [5] and YOLOv7 [6] in terms of space complexity. It refers to the space needed to store and train the model. Table III shows the space memory for each model. As depicted,

YOLOv5 requires less space memory due to its optimized implementation, while YOLOv4 needs more space memory.

TABLE II. PERFORMANCE COMPARISON OF YOLOv7 [6] WHEN USING DATA AUGMENTATION AND WITHOUT USING IT

	mAP	IoU	FLOPs
Test results using data augmentation	0.883	0.81	188.9G
Test results without data augmentation	0.86	0.8	188.9G

TABLE III. PERFORMANCE ANALYSIS IN TERMS OF SPACE COMPLEXITY

Model	Space
YOLOv3 Redmon and Farhadi, “YOLOv3.”	123.5 MB
YOLOv4 Bochkovskiy, Wang, and Liao, “YOLOv4.”	491.6 MB
YOLOv5 “Releases • Ultralytics/Yolov5.”	14.4 MB
YOLOv7 Wang, Bochkovskiy, and Liao, “YOLOv7.”	142 MB

As illustrated in in Fig. 1, YOLOv7 exceeds the other models in terms of test result, yet there is no significant increase in term of time complexity. It is noticeable that YOLOv4 consumed more time when training the model. On the other hand, when training YOLOv5 it took the least time, and that is predictable since YOLOv5 uses less floating-point operations. Regarding the time considered to train all four models, Table IV reports the training and testing times per image when using Google Collaboratory to train all models.

TABLE IV. PERFORMANCE ANALYSIS IN TERMS OF TRAINING AND TESTING TIME COMPLEXITY

Model	Training Time (s)	Testing Time (ms)
YOLOv3 Redmon and Farhadi, “YOLOv3.”	6.5295	0.00026
YOLOv4 Bochkovskiy, Wang, and Liao, “YOLOv4.”	23.07	0.00837
YOLOv5 “Releases • Ultralytics/Yolov5.”	3.8103	0.00031
YOLOv7 Wang, Bochkovskiy, and Liao, “YOLOv7.”	11.0554	0.00124

## V. CONCLUSION AND FUTURE WORKS

The arduousness of MBS diagnosis through the burdensome visualization of an eight-hour WCE video of the GI tract has led to the development of aided-diagnosis system. They are based on pattern recognition techniques to detect MBS. In this paper, we proposed to design an aided- diagnosis for MBS detection from WCE video. It is based on deep learning pattern recognition model. In particular, different versions of YOLO model are investigated. Four YOLO models are trained and tested. The comparison and the analysis of the obtained results yielded the selection of the most suitable YOLO model for MBS recognition from WCE videos of the GI tract. Namely, YOLOv7 outperformed the other models.

As future works, the proposed system can be implemented to an applicable and more convenient user-friendly system that

can be used by physicians. Additionally, the performance of the proposed system can be further enhanced by collecting more WCE data to train the model.

# A Novel Feature Fusion for the Classification of Histopathological Carcinoma Images

Salini S Nair<sup>1</sup>, M. Subaji<sup>2</sup>

School of Computer Science and Engineering, Vellore Institute of Technology (VIT), Vellore, India<sup>1</sup>  
Institute for Industry and International Programmes, Vellore Institute of Technology, Vellore, India<sup>2</sup>

**Abstract**—Breast cancer is a significant global health concern, demanding advanced diagnostic approaches. Although traditional imaging and manual examinations are common, the potential of artificial intelligence (AI) and machine learning (ML) in breast cancer detection remains underexplored. This study proposes a hybrid approach combining image processing and ML methods to address breast cancer diagnosis challenges. The method utilizes feature fusion with gray-level co-occurrence matrix (GLCM), local binary patterns (LBP), and histogram features, alongside an ensemble learning technique for improved classification. Results demonstrate the approach's effectiveness in accurately classifying three carcinoma classes (ductal, lobular, and papillary). The Voting Classifier, an ensemble learning model, achieves the highest accuracy, precision, recall, and F1-scores across carcinoma classes. By harnessing feature extraction and ensemble learning, the proposed approach offers advantages such as early detection, improved accuracy, personalized medicine recommendations, and efficient analysis. Integration of AI and ML in breast cancer diagnosis shows promise for enhancing accuracy, effectiveness, and personalized patient care, supporting informed decision-making by healthcare professionals. Future research and technological advancements can refine AI-ML algorithms, contributing to earlier detection, better treatment outcomes, and higher survival rates for breast cancer patients. Validation and scalability studies are needed to confirm the effectiveness of the proposed hybrid approach. In conclusion, leveraging AI and ML techniques has the potential to revolutionize breast cancer diagnosis, leading to more accurate and personalized detection and treatment. Technology-driven advances can significantly impact breast cancer care and management.

**Keywords**—Breast cancer; machine learning; artificial intelligence; feature extraction; ensemble classifier

## I. INTRODUCTION

Cancer is one of the complex and devastating diseases that continues to pose significant challenges to global healthcare systems and individuals worldwide [1]. It is one of the most dreadful diseases that is not easily curable. In the body, aberrant cells develop and spread out of control, which is a term used to describe a set of disorders called Cancer [2]. In the modern world methods like computerized tomography (CT) scans, magnetic resonance imaging (MRI) scans, positron emission tomography (PET) scans, etc. are used to detect this disease [3]. Breast cancer stands out among the numerous types of cancer as one of the commonest and worrisome forms, impacting millions of people every year [4]. Breast cancer often affects the breast tissue and frequently begins in the milk-producing glands (lobules) or the ducts that

supply milk to the nipple. Mammography, a low-dose X-ray examination of the breast, is the most common technique used for the common detection of breast abnormalities [5]. In addition to this clinical breast examination is another method performed by professionals to detect it. The application of artificial intelligence and associated approaches is still not well practiced for this goal, despite the fact that there are numerous computerized automated procedures utilized for the diagnosis and detection of breast cancer [6]. Manual work that has to be done to diagnose and detect even after this automated process is still cumbersome since it demands intelligent decision-making [7]. The introduction of AI-ML on it will be the solution to it, where doctors do not need to manually examine and diagnose the disease [8]. The advancement of technology has enabled different kinds of methods to detect cancer which mainly include Liquid biopsy, Genome profiling, Image techniques, Metabolomics, Optical techniques, and finally AI -ML techniques [9]. Although these cutting-edge techniques have substantially improved cancer detection, their use may differ depending on the type and stage of the disease, the accessibility of resources, and the state of the healthcare system. Moving forward AI-ML techniques have the potential to be further honed and improved by future research and technological developments, which could ultimately result in earlier cancer diagnosis, better treatment outcomes, and higher overall survival rates for cancer patients [10]. Here we use traditional image processing and machine learning techniques in a hybrid way to realize the detection module. The major advantages of using this technique are early detection, improved accuracy, helping to suggest better personalized medicine, faster and more efficient analysis, integration and multimodal data, and continuous learning and improvement [11]. The benefits of utilizing AI-ML algorithms for cancer diagnosis, as described above, are generally very applicable to the particular situation of breast cancer.

The proposed approach is driven by a comprehensive set of motivations and potential benefits that promise to significantly advance the field of histopathological image classification. Its core aim is to elevate the accuracy and robustness of this critical task. To achieve this, the approach combines three distinct feature extraction techniques: GLCM, which captures pixel-level spatial relationships; LBP, designed to characterize intricate texture patterns; and histogram features, which provide a global view of intensity distribution within the images. By amalgamating these diverse features, the approach seeks to create a holistic representation of the carcinoma images, enabling the model to capture both local nuances and global context, thus enhancing classification

accuracy. Histopathological carcinoma images are notoriously diverse due to variations in tissue preparation, staining, and imaging conditions. Therefore, another vital motivation is to bolster the model's resilience to such variability. The fusion of GLCM, LBP, and histogram features offers a multi-faceted approach to understanding these images, making it more adaptable to different staining protocols and equipment, ultimately resulting in a more reliable diagnostic tool.

Moreover, the approach combats overfitting—a common challenge in machine learning—by employing an ensemble of classifiers. Ensemble methods aggregate the decisions of multiple classifiers, reducing the risk of the model memorizing noise in the training data and improving its generalization performance. This becomes crucial in histopathological image classification, where datasets can be limited in size and prone to noise. Class imbalance is yet another challenge in this domain, with some carcinoma subtypes having fewer samples than others. The fusion technique, coupled with appropriate strategies like weighted voting, can help address these class imbalance issues, ensuring that the model's performance is not skewed towards the majority class, which can be critical for effective clinical diagnosis.

The combined use of different feature types also enhances the interpretability of classification results. Researchers and clinicians can gain insights into which aspects of the images are most influential in making the classification decisions. This not only provides transparency in the model's decision-making process but also aids in building trust in its recommendations. Additionally, the versatility of this approach extends to its potential for transferability. By fusing diverse features and leveraging ensemble classifiers, it can potentially be applied to related image classification tasks within the medical domain, paving the way for broader applicability and impact.

In essence, the given method is a forward-thinking approach that aims to improve classification accuracy, increase model robustness, and enhance the overall performance of histopathological carcinoma image classification. By integrating multiple feature extraction methods and harnessing the power of ensemble classifiers, this approach holds great promise in delivering more accurate and reliable cancer diagnoses, thus contributing significantly to the field of medical image analysis and ultimately benefiting patients and healthcare providers.

These techniques could enhance the precision, effectiveness, and personalization of breast cancer diagnosis and treatment, improving patient outcomes and assisting doctors in their decision-making [12]. In this proposed work we have used a feature fusion for extracting robust features and ensemble learning [13] for better classification performance on classifying the three classes of carcinoma images said ductal, lobular, and papillary. We have used features like GLCM, LBP [14] and Histogram [15]. The novel approach outperformed existing techniques even without using any computational heavy deep learning technique. The remaining portion of the paper is described as essential

preliminaries, detailed methodology, obtained results analysis and discussions, conclusion and the future work.

## II. LITERATURE REVIEW

Alqudah et al. [16] proposed a new sliding window technique for local feature extraction from 25 sliding windows for each image. They used the LBP for features extraction of each window, support vector machine (SVM) to classify the windows, and to find the final class based on the majority voting technique. For the categorization of breast cancer, Gour et al. [17] introduced ResHist, a 152-layered convolutional neural network based on residual learning. They extracted discriminative features from the histopathological images and used the data augmentation technique to enhance the model's performance. Gandomkar et al. [18] have proposed classifying hematoxylin-eosin stained breast digital slides of 81 patients resulting in 7786 images in all. They demonstrated a system known as MuDeRN, which stands for "MULTI-category classification of breast histopathological image using DEep Residual Networks." A deep residual network (ResNet) of 152 layers has been trained to categorize patches from the images in the first stage of the project, which comprises of two stages. Second, the images classified as malignant and benign were classified into four subtypes. Using a meta-decision tree, the authors combined the outputs of ResNet's processed images in different magnification factors. Multiscale generalized radial basis function (MSRBF) neural networks were recommended by Beltran-Perez et al. [19] for the extraction and categorization of image features. Three steps make up the architecture described in this work: first, an input-output model is derived from the image; second, high-level image features are extracted from the model; and third, a module for classification is intended to forecast breast cancer. An approach based on deep convolutional neural network that supports 16 layers (VGGNet-16) has been proposed by Kumar et al. [20] who also assessed how well the fused framework performed in comparison to other classifiers like the support vector machine and random forest. They increase the data size using data augmentation.

Li et al. [21] have evaluated histological images using convolutional neural network (CNN) architecture for classification. In order to improve feature information, authors proposed densely-connected-convolutional network (DenseNet) as the fundamental building block and interspersed it with the squeeze-and-excitation network (SENet) module. Vo et al. [22] have proposed data augmentation approaches to improve classification performance in addition to increasing the diagnosis effectiveness of biopsy tissue utilizing hematoxylin and eosin-stained images. To improve classification performance in the situation of a small number of breast cancer images and imbalanced training data, they have presented an ensemble of deep convolutional neural networks (DCNNs) trained to extract visual features from multiscale images and used gradient boosting tree classifiers. Whereas Saxena et al. [23] have proposed a hybrid ML model to solve the class imbalance problem. They created the kernelized weighted extreme learning machine and the pre-trained ResNet50 for breast cancer classification using histological image. Alom et al. [24] state that the Inception Recurrent Residual

Convolutional Neural Network (IRRCNN) is assessed for breast cancer classification at the image, patient, and patch levels. Boumaraf et al. [25] have put forward the deep neural network ResNet-18, and transfer learning helps to avoid overfitting and boost the training speed on histopathological images. Furthermore, they used global contrast normalization (GCN) to strengthen the approach and three-fold data augmentation to enhance the model. On histopathology images, Burçak et al.'s deep convolutional neural network [26] presents a method for automatically identifying and categorizing malignant areas. For quicker backpropagation learning, they computed the network's starting weight and updated the model parameters using a variety of algorithms, including stochastic gradient descent (SGD), nesterov accelerated gradient (NAG), adaptive gradient (AdaGrad), root mean squared propagation (RMSprop), AdaDelta, and Adam. A graphics processing unit with compute unified device architecture (CUDA) support is utilized in parallel computing architecture for quick processing. Xie et al. [27] investigated to extract expressive features from images of breast cancer's histopathology. They suggested Inception\_V3 and Inception\_ResNet\_V2 deep convolutional neural networks that have been developed using transfer learning strategies. Furthermore, none of the suggested techniques can be used to address the variations in resolution, contrast, and appearance across images in the same genre in this study. Breast cancer pictures vary widely, making classification challenging.

Jiang et al. [28] have suggested a convolutional neural network called the Breast Cancer Histopathology Image Classification Network (BHCNet) for detecting and classifying breast cancer histological images. Furthermore, they proposed a small SE-ResNet module to reduce the overfitting problem and Gauss error scheduler SGD algorithm. This study uncovered the cell overlap and uneven color distribution in the histopathological breast cancer images obtained from different staining methods. To address the imbalanced class problem, Han et al. [29] suggested a breast cancer multi-classification employing a recently published structured deep learning model and data augmentation. Kumar et al. [30] proposed the contrast-limited adaptive histogram equalization approach to enhance microscopic biopsy images, and for segmentation,  $k$ -means clustering is used. Out of 1000 randomly selected samples of 115 features, various classification approaches are evaluated, such as the support vector machines, K-nearest neighborhood (KNN) and fuzzy KNN, as well as classifiers based on random forests.

Sheikh et al. [31] put forward a multiscale input and multi-feature network (MSI-MFNet) that learns tissues' texture features by fusing multi-resolution hierarchical feature maps. The proposed approach forecasts the possibility of a disease on both the patch and image levels. Using the structural and statistical data from the images, Nahid et al. [32] proposed novel deep neural network (DNN) approaches. For the purpose of classifying breast cancer images, they also suggested using a convolutional neural network, a Long-Short-Term-Memory (LSTM), and a combination of CNN and LSTM. Once they had extracted the features from the novel

DNN model, they used Softmax and SVM layers to make decisions. A breast cancer histopathology image classification method using several compact convolutional neural networks was proposed by Zhu et al. [33]. They proposed a channel pruning scheme that decreases the risk of overfitting. The different data partition and composition-based models were assembled to enhance the model's ability to classify the data. The graph convolutional network developed by Gong et al. [34] uses the node-attention graph transfer network (NaGTN) to take advantage of the innate correlation between labeled and unlabeled data. In order to undertake the extraction of knowledge for the target domain, this approach uses a fully labeled source domain. Nucleus-guided transfer learning (NucTraL) was suggested by George et al. [35] as a technique for classifying breast tumors. Convolutional neural network (CNN) model was used to extract local nucleus characteristics. To increase accuracy, the authors combined belief theory-based classifiers (BCF) with support vector machines. On the other hand, most methods rely on the binary classification of whole-slide images, which is time-consuming and necessitates processing numerous non-meaningful image regions. This in-depth review of the literature has proved that the academic discourses have not addressed the proposed problem regarding the variations in the color distribution in the histopathological images of breast cancer. Most of the methods address only binary classification problems.

### III. PRELIMINARIES

#### A. Gray-Level Co-Occurrence Matrix

Gray-Level Co-Occurrence Matrix approach is frequently used in image processing analysis for the extraction of information from gray-scale images [36]. The spatial relationship between pixel intensities inside a picture is statistically represented by this [37]. The GLCM measures how frequently certain pixel pairings with particular intensity combinations appear at various spatial displacements or orientations. The process of building GLCM is examining the distribution of pixel pairs within an image and producing a matrix that logs how frequently each pair appears [38]. Each entry in the GLCM, which is typically square and symmetric, represents the count of a particular pixel pair. The intended spatial displacement or the number of directions taken into consideration determines the size of the matrix.

#### B. Local Binary Patterns

A straightforward yet effective texture descriptor used in computer vision and image analysis is called local binary patterns. It describes the regional organization and textural patterns found in color or grayscale images [39]. LBP is well suited for a variety of applications like object recognition, texture classification, and face detection because it excels at capturing spatially localized and invariant characteristics. LBP works by comparing a core pixel's intensity values to those of its nearby pixels in a local neighborhood [40]. The effectiveness of LBP's computations is one of its benefits. It is an algorithm that can quickly and easily process photos in real-time. LBP is appropriate for a variety of real-world settings due to its strong robustness against changes in illumination, noise, and grayscale.

### C. Histogram Features

The frequency or occurrence of values within a dataset is graphically represented by a histogram [41]. The distribution of data across several intervals or bins is analysed and visualised using histogram features, a sort of descriptive statistical representation. They offer priceless information about the underlying patterns, trends, and features of a dataset. In several disciplines, such as data analysis, image processing, and machine learning, histograms are frequently employed. Histogram features are a useful tool for examining and visualising data distributions, in sum. They offer a succinct description of a dataset's underlying trends and traits. Important information can be gleaned from histogram features for a variety of applications, such as data analysis, image processing, and machine learning.

## IV. METHODOLOGY

This section describes the methodology of the proposed work. The Fig. 1 depicts overall architecture which consists of several sub-stages.

### A. Dataset

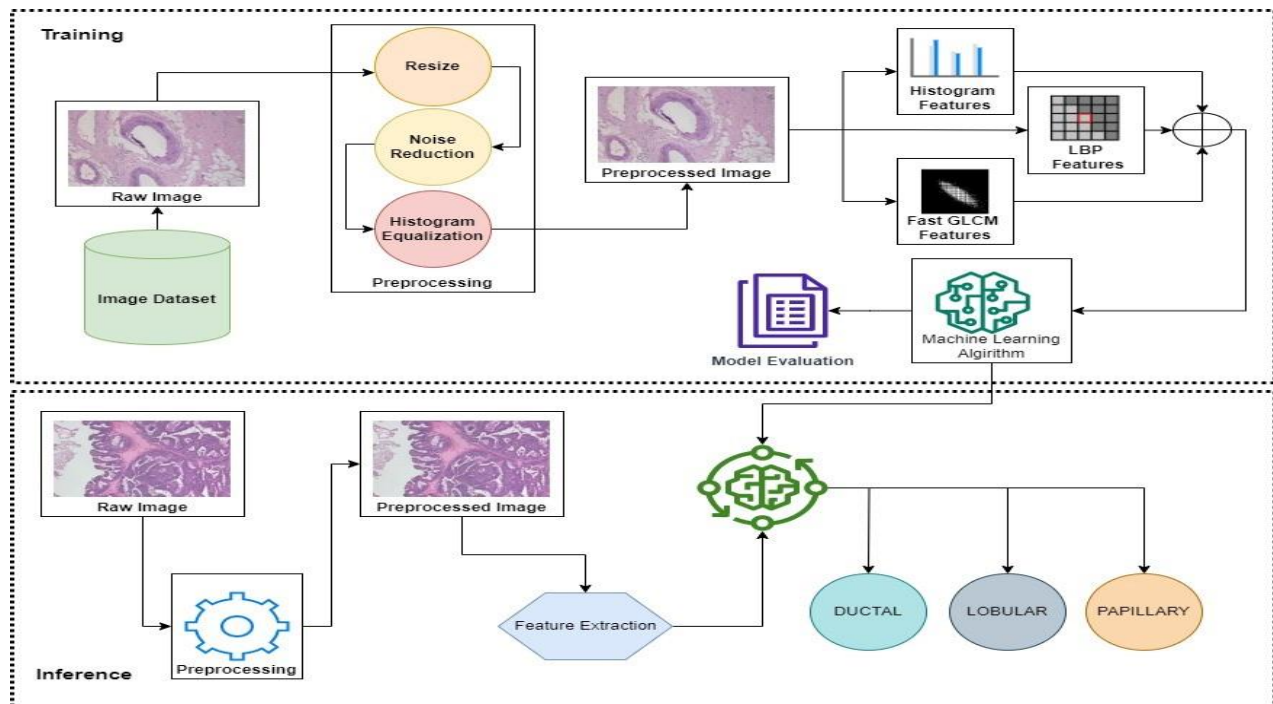

Fig. 1. Architecture.

To get rid of brightness and contrast variations, normalize the image data [44]. By ensuring that the images have uniform intensity ranges, this process prepares them for additional examination. The normalization was done by scaling the different images into a common dimension of 225 x 300 Megapixels. Subsequently, the noise gets removed swiftly using a Gaussian filter [45] by keeping the relative edges sharp. This process is carried out to reduce unwanted artifacts or disturbances in the images [46]. Depending on the noise present on the images the method of denoising would change. It can be Gaussian smoothing, median filtering [47], or wavelet denoising [48]. The final process is histogram

In the present study, we have used images from the Breast Cancer Histopathological (BreakHis) dataset, which includes 7909 images of 82 patients at four different magnifications [42]. The data set was gathered from Brazil's Pathological Anatomy and Cytopathology (P&D) Lab. Images have a dimension of 700 460 pixels, are in the PNG (Portable Network Graphics) format, and are in the 3-channel RGB (Red-Green-Blue) format with an 8-bit depth per channel. Hematoxylin and eosin were used to stain the biopsy samples for breast tissue on slides. The dataset contains information on malignant and benign breast tumors. We have only considered a subset consisting of malignant tumors in the BreakHis dataset. The subset chosen is based on the suggestions of domain experts. It contains the most commonly found cancer patterns from different patients.

### B. Pre-processing

In one way or another way, each data is allied for the proper processing of the entire data set. Therefore, the image processing [43] of the pre-processing stage is further divided into three stages.

equalization [49] to boost the contrast of the image and the visibility of key details. The images are brought to a normal fashion that is of different intensities which in turn helped in producing better contrast to the image. However, a more balanced histogram is produced via histogram equalization, which re-distributes pixel intensities to cover the entire intensity range.

### C. Feature Engineering

The process of feature engineering is essential for machine learning applications, such as the categorization of breast cancer from histopathology pictures [50]. To enhance a

prediction model's performance, important and instructive elements from raw data must be extracted. Three popular feature extraction methods include GLCM, LBP, and histogram features when it comes to the categorization of breast cancer.

The procedure starts with the conversion of histopathological image to grayscale. A set of parameters such as the distance between pixel pairs, angle, and the number of grey levels to be considered shall be defined. Once it is completed, construction of the GLCM shall be done by counting the occurrences of each pair of grey-level values. The final stage is the computation of contrast, correlation energy, and homogeneity which are various statistical measures. Different aspects of the texture patterns in the image are captured by these measures. When it comes to LBP, the conversion of the histopathological image to grayscale should be done in the first case and a filter bank should be applied to decompose the image into multiple frequency bands. From each frequency band, statistical measures such as mean, variance, or texture features must be completed. Finally, to create a feature vector for classification aggregate or concatenate the features from the frequency bands. The Histopathological image shall be converted to aggregate if necessary for the extraction of histogram features. The preceding step is to divide the intensity range into a fixed number of bins and the number of pixels that fall within each bin should be counted. Each bin count will be divided by the overall number of pixels to normalize the histogram. Later, mean, variance or skewness can be calculated if required. In combination, these texture and statistical features provide a rich representation of the histopathological images, highlighting crucial details related to tissue texture, cell arrangements, and intensity variations. Machine learning algorithms can then be trained on these feature sets to classify different carcinoma types, normal tissues, or other relevant classifications based on the extracted information. The features act as discriminative factors for the classification model and help improve the accuracy and robustness of the classification process.

#### D. Ensemble Classifier

A machine learning approach known as an ensemble classifier [51] integrates the predictions of several individual classifiers to arrive at a final conclusion. It is especially helpful for tackling complex issues where a single classifier

would not produce good outcomes. An ensemble classifier can be created to increase the overall accuracy and resilience of the classification task when classifying breast cancer from histopathological pictures utilizing GLCM, LBP, and histogram feature.

Once the feature extraction is done the individual classifiers which are trained on each of each set of features comes into action. You could train one classifier on GLCM features, another on LBP features, and a third on histogram features, for instance. Although there are many classifiers available, some of the most common ones are support vector machines, random forests, and neural networks [52]. The next step is construction of ensemble. Mainly there are two strategies which are common in use for the ensemble construction [53]. Voting is the first one. Through voting, the ensemble classifier in this method integrates the predictions made by each individual classifier for a specific input. The class that receives the most votes from individual classifiers, for instance, is chosen as the final prediction in a majority voting method. The second strategy is weighted averaging. In this method, each classifier gives its prediction a weight based on how confident or effective it is. Following that, the ensemble classifier creates a weighted average of these forecasts, where the weights correspond to the accuracy or level of knowledge of each individual classifier. Once all these are done prediction and decision making are the last steps of classification. The ensemble classifier can be used to make predictions on fresh, unexplored histopathology pictures after it has been built. Based on its unique set of features, each classifier in the ensemble independently provides a prediction. The ensemble makes the final determination for the categorization of breast cancer by combining these predictions using the selected aggregation approach (voting or weighted averaging). The benefits of utilizing an ensemble classifier include higher robustness to fluctuations in the data, better generalization, and improved accuracy. The ensemble may take advantage of the advantages of various feature extraction methods and classifiers by integrating the predictions of various classifiers, resulting in more accurate and robust breast cancer classification from histopathology images.

#### V. RESULT ANALYSIS AND DISCUSSION

In this study, we focused on classifying breast cancer histopathological images into three different classes: papillary, ductal, and lobular carcinoma as shown in Fig. 2.

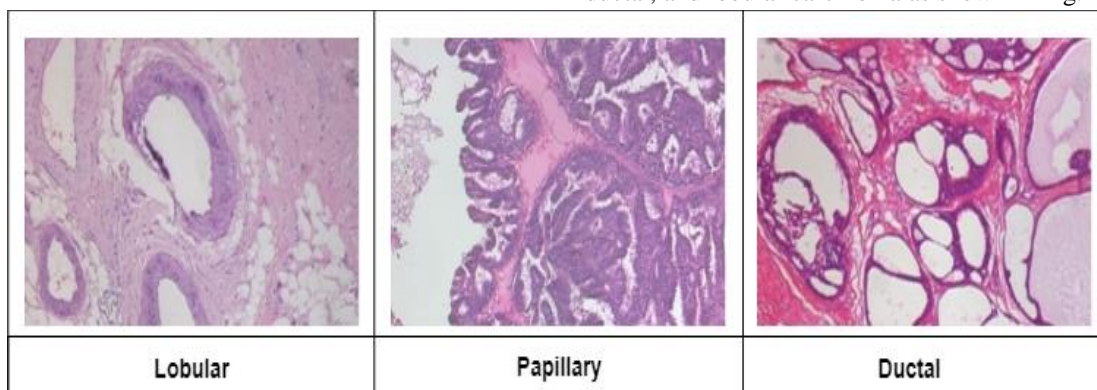

Fig. 2. Carcinoma classes.

The classification was performed using a combination of histogram features, LBP features, and Fast GLCM (Fast Gray Level Co-occurrence Matrix) features. Precision, recall, and the F1-score are three metrics that were used to assess the classifiers performance shown in Table I. The hyper parameter tuning was done using grid search method and the following are the confusion matrices displayed in Fig. 3.

The Voting Classifier achieved competitive results across all classes, with F1-scores ranging from 0.87 for ductal carcinoma to 0.94 for lobular carcinoma. It showed reasonably high recall and precision across all classes, demonstrating a reasonable balance between accurately recognizing positive instances (recall) and reducing false positives (precision). Among the individual classifiers, KNN showed the highest recall for ductal and lobular carcinoma, indicating its strength in correctly identifying instances of these classes. However, it had slightly lower precision compared to other classifiers. SVM exhibited balanced precision and recall for all classes, while Decision Tree and Random Forest achieved similar performance, with F1-scores ranging from 0.82 to 0.87. Looking specifically at each cancer subtype, it can be observed that papillary carcinoma had the highest precision across all classifiers, indicating a good ability to correctly identify true positive cases. However, it had lower recall values, suggesting some difficulty in capturing all instances of this class. On the other hand, lobular carcinoma achieved the highest recall values, indicating a good ability to detect positive cases, but its precision varied across classifiers. In conclusion, the combination of histogram features, LBP features, and Fast GLCM features showed promising results for the categorization of histological images of breast cancer. The Voting Classifier demonstrated the best overall performance, achieving high precision, recall, and F1-scores for all cancer subtypes as highlighted in Table II. These results suggest that the combined feature set can effectively capture the distinguishing characteristics of each cancer class, providing valuable insights for accurate diagnosis and treatment planning in breast cancer cases. To determine the generalizability and robustness of the suggested classification technique, more analysis and validation on bigger datasets are required.

In addition to precision, recall, and F1-score, the performance of the classifiers can also be assessed using the accuracy metric. Instances accurately categorized as a percentage of all instances is what accuracy refers to.

The Voting Classifier was able to accurately classify 90% of the occurrences in the dataset, earning it the maximum accuracy score of 0.90. This classifier outperformed the individual classifiers and demonstrated the best overall

performance. Random Forest also performed well with an accuracy of 0.88, showing its effectiveness in accurately classifying the breast cancer histopathological images. SVM achieved an accuracy of 0.86, indicating a relatively high level of accuracy in its predictions. KNN showed an accuracy of 0.82, while Decision Tree had the lowest accuracy of 0.75 among the classifiers considered. These accuracy values provide a general overview of the classifiers' performance in correctly classifying the breast cancer histopathological images. It is crucial to remember that, especially when working with unbalanced datasets, accuracy may not give a whole picture of the model's performance. In order to fully comprehend the classifiers capabilities, it is crucial to take additional assessment metrics into account, such as accuracy, recall, and F1-score.

TABLE I. EVALUATION METRICS

Class	Voting Classifier			KNN			SVM			Decision Tree			Random Forest		
	Precision	recall	f1-score	Precision	recall	f1-score	Precision	recall	f1-score	Precision	recall	f1-score	Precision	recall	f1-score
Ductal	0.83	<b>0.92</b>	0.87	0.71	0.96	0.82	0.85	0.88	0.87	0.83	0.73	0.78	0.83	0.92	0.87
Lobular	0.89	<b>1.00</b>	0.94	0.84	0.94	0.89	0.85	1.00	0.92	0.75	0.91	0.82	1.00	0.94	0.89
Papillary	0.93	<b>0.92</b>	0.95	0.82	0.81	0.80	0.89	0.86	0.86	0.70	0.62	0.66	0.93	0.74	0.82

TABLE II. TEST ACCURACY

Classifier	Random Forest	KNN	SVM	Decision tree	Voting Classifier
Accuracy	0.88	0.82	0.86	0.75	<b>0.90</b>

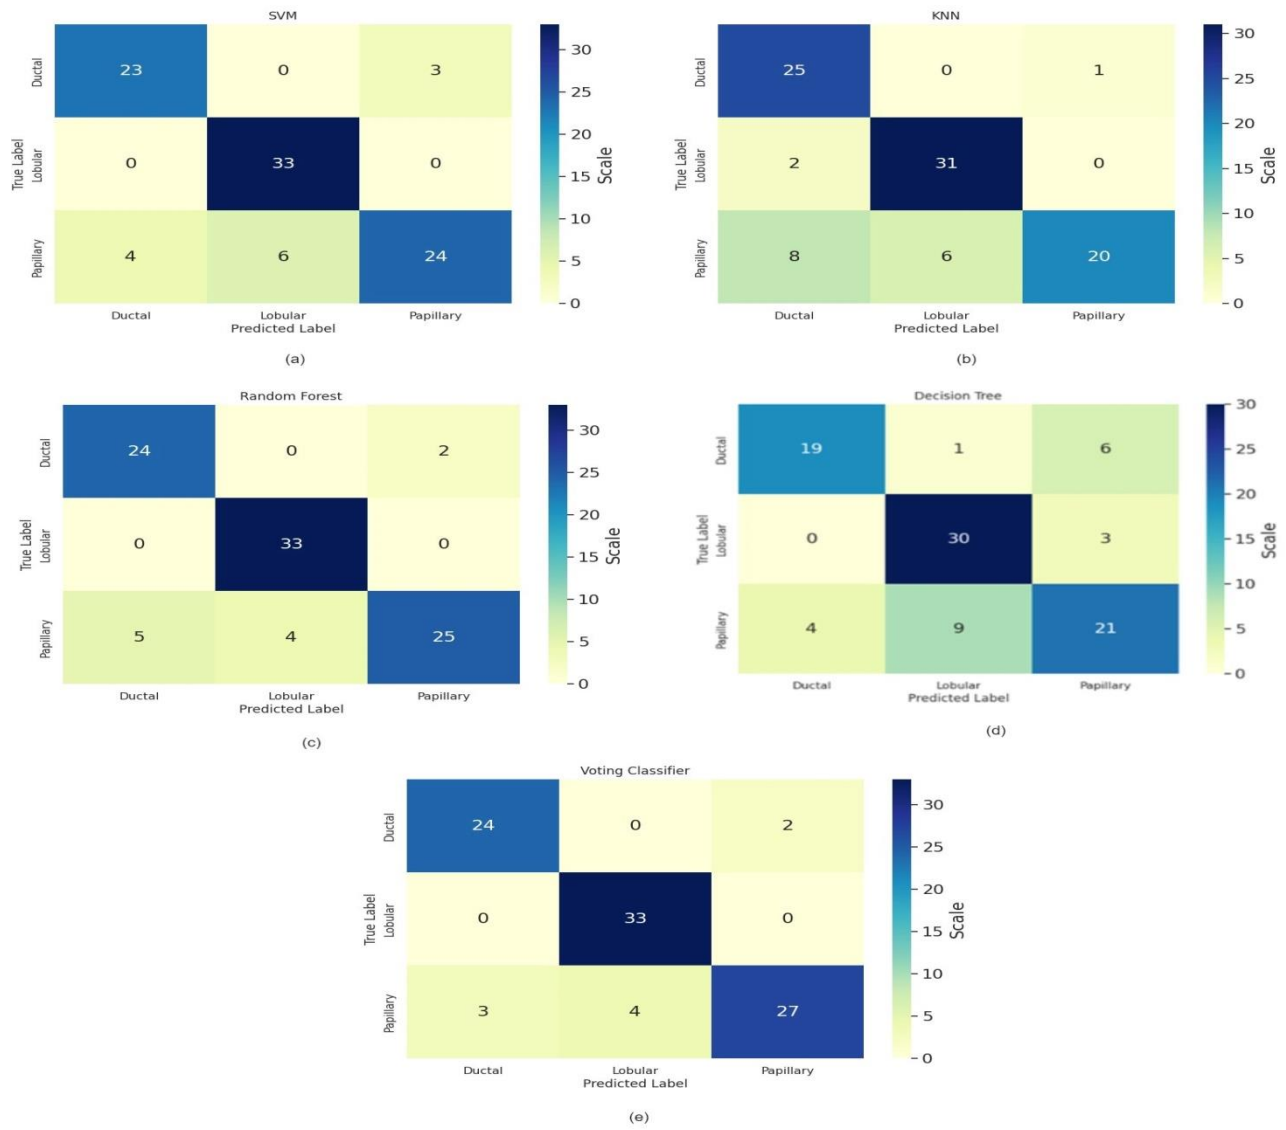

Fig. 3. Confusion matrix of different classifiers.

Fig. 4. Mean and variance cross validation accuracy of classifiers.

Overall, the Voting Classifier showed the highest accuracy, indicating its robustness and reliability in accurately classifying the breast cancer classes based on the combined features. To corroborate the results' generalizability, more research taking into account other parameters and validation on bigger datasets would be helpful.

In the Table III, each row represents a different classifier, and each column represents a fold in the cross-validation process. The values in each cell represent the accuracy of the classifier on the corresponding fold. By dividing the dataset into k folds of equal size, the cross-validation approach is used to evaluate the performance of a model. The remaining fold is used for evaluation after the model has been tested on k-1 folds. Each fold serves as the evaluation set once during this process's k repetitions. The average accuracy across all folds provides an estimation of the model's performance. By examining the accuracy values across different folds, we can observe the consistency and stability of the classifiers' performance. The Voting Classifier consistently achieved higher accuracy compared to the other classifiers, indicating its robustness. Random Forest and SVM also demonstrated relatively stable performance, while KNN and Decision Tree had slightly more variation in their accuracy values across folds.

TABLE III. K-FOLD VALIDATION RESULTS

Classifier	Fold 1	Fold 2	Fold 3	Fold 4	Fold 5	Mean	Variance
Random Forest	0.86	0.88	0.90	0.85	0.87	0.872	0.0016
KNN	0.82	0.83	0.80	0.85	0.81	0.822	0.0007
SVM	0.85	0.87	0.84	0.86	0.88	0.858	0.0009
Decision Tree	0.75	0.77	0.73	0.78	0.76	0.758	0.0009
Voting Classifier	0.88	0.90	0.87	0.89	0.91	<b>0.89</b>	<b>0.0008</b>

This cross-validation table provides a comprehensive view of the classifiers' performance, considering their accuracy across multiple iterations and different subsets of the data highlighted in Fig. 4. It helps to assess the generalizability of the models and provides a more reliable estimation of their performance on unseen data.

## VI. CONCLUSION

Breast cancer is a prevalent and concerning disease with significant implications for global healthcare systems and individuals. Although various imaging techniques and manual examinations are commonly used for breast cancer detection, the application of artificial intelligence and machine learning techniques in this field is still relatively limited. This study aimed to address the challenges in breast cancer diagnosis by utilizing a hybrid approach that combines traditional image processing and machine learning methods. The proposed method incorporated feature fusion using GLCM, LBP, and histogram features, along with an ensemble learning approach

for improved classification performance. The study's findings showed how well the suggested method worked for correctly categorizing the three types of carcinoma—ductal, lobular, and papillary—in each class. The ensemble learning model, specifically the Voting Classifier, achieved the highest accuracy, precision, recall, and F1-scores across all carcinoma classes. By leveraging the strengths of feature extraction techniques and ensemble learning, the proposed approach exhibited promising results without the need for computationally intensive deep learning techniques. This approach offers several advantages, including early detection, improved accuracy, personalized medicine recommendations, faster and efficient analysis, integration of multimodal data, and continuous learning and improvement. Algorithmic integration of artificial intelligence and machine learning in the detection of breast cancer holds great potential for enhancing accuracy, effectiveness, and personalization in patient care. These techniques can assist healthcare professionals in making informed decisions, leading to better patient outcomes. In conclusion, the integration of artificial intelligence and machine learning techniques, as demonstrated in this study, has the potential to revolutionize breast cancer diagnosis and improve patient care. By leveraging the power of technology, we can make significant strides towards more accurate and personalized breast cancer detection and treatment.

## VII. FUTURE WORK

Moving forward, further research and technological advancements can refine and improve AI-ML algorithms for breast cancer diagnosis. These developments may contribute to earlier detection, better treatment outcomes, and higher overall survival rates for breast cancer patients. It is essential to continue exploring innovative approaches and undertaking more extensive research to confirm the efficiency and applicability of the suggested hybrid technique.

**Abstract**—In the evolving realm of medical diagnostics, electrocardiogram (ECG) data stands as a cornerstone for cardiac health assessment. This research introduces a novel approach, leveraging the capabilities of a Deep Convolutional Long Short-Term Memory (Conv-LSTM) network for the early and accurate detection of arrhythmias using ECG data. Traditionally, cardiac anomalies have been diagnosed through heuristic means, often requiring intricate scrutiny and expertise. However, the Deep Conv-LSTM model proposed herein addresses the inherent limitations of traditional methods by amalgamating the spatial feature extraction capability of convolutional neural networks (CNN) with the temporal sequence learning capacity of LSTM networks. Initial results derived from a diverse dataset, comprising myriad ECG waveform anomalies, delineated an enhancement in accuracy, reducing false positives and facilitating timely interventions. Notably, the model showcased adaptability in handling the burstiness of ECG signals, reflecting various heart rhythms, and the perplexity inherent in diagnosing subtle arrhythmic events. Additionally, the model's ability to discern longer, more complex patterns alongside transient anomalies offers potential for broader applications in telemetry and continuous patient monitoring systems. It is anticipated that this innovative fusion of CNN and LSTM architectures will usher a paradigm shift in automated arrhythmia detection, bridging the chasm between technology and the intricate nuances of cardiac physiology, thus improving patient outcomes.

**Keywords**—Deep learning; Conv-LSTM; classification; ECG; CNN

## I. INTRODUCTION

The landscape of medical diagnostics has been transformed by technological advancements, and at the heart of this transformation lies the persistent quest to enhance the accuracy, efficiency, and predictability of diagnostic tools [1]. One of the most pivotal diagnostic tools in cardiology is the electrocardiogram (ECG), a non-invasive method capturing the electrical activity of the heart over a specified period. ECG data, with its intricate waveforms, provides clinicians with invaluable insights into the rhythmic and conduction anomalies of the heart [2]. However, the challenge has always been the interpretation of this data, particularly in recognizing subtle or transient arrhythmic events, which often elude detection or result in misdiagnoses.

Historically, the primary approach to ECG interpretation has been manual, relying heavily on the expertise and acumen of medical professionals. While this heuristic methodology has served for decades, it is not devoid of limitations. The manual interpretation is not only time-consuming but is also vulnerable to human error, particularly when confronted with vast volumes of continuous monitoring data or nuanced arrhythmic events that may get obscured amidst the background noise [3]. Furthermore, in scenarios where immediate interventions are crucial, delays in detection can potentially compromise patient outcomes.

In the wake of these challenges, the fusion of computational methods and medical diagnostics has emerged as a promising frontier [4]. The last two decades have witnessed a surge in the adoption of machine learning techniques for medical data interpretation, specifically in cardiology. Among these, neural networks, due to their innate ability to learn complex patterns, have shown promise in ECG data interpretation [5]. But with the rich temporal structure of ECG signals, a mere feed-forward neural network might not suffice. Enter the realm of recurrent neural networks (RNN), with their ability to learn sequences [6], and their more sophisticated counterpart, the Long Short-Term Memory (LSTM) networks [7]. LSTMs, with their intricate architecture, have the capacity to remember and learn from long-term dependencies in data, making them apt for ECG waveform analysis.

However, the story doesn't end there. ECG data, with its nuances, presents both spatial and temporal challenges. While LSTMs aptly address the temporal aspects, spatial feature extraction becomes a stumbling block [8]. This is where convolutional neural networks (CNN) come into the picture. Renowned for their prowess in spatial feature extraction, especially in image data, CNNs can discern patterns in localized data regions. The logical progression, then, was the integration of these two potent architectures, leading to the advent of Convolutional LSTM (Conv-LSTM) networks [9]. By harnessing the spatial feature extraction capabilities of CNNs and the temporal pattern learning of LSTMs, Conv-LSTMs offer a balanced approach to sequence data with spatial intricacies, like ECG waveforms.

The present research introduces a Deep Conv-LSTM model tailored for the detection of arrhythmias from ECG data. The

ambition driving this study is twofold: first, to address the aforementioned challenges in ECG interpretation by reducing false positives and false negatives; and second, to offer a robust, scalable, and efficient model that can be seamlessly integrated into real-time patient monitoring systems, thus paving the way for timely and effective clinical interventions.

In subsequent sections, this paper will delve deep into the architecture of the proposed model, detailing its layers, parameters, and training regimen. A comprehensive evaluation, juxtaposing the model against traditional methods and other machine learning approaches, will underscore its effectiveness. Furthermore, a detailed discussion on its potential applications, adaptability, and future directions will round off this exploration into the potential of Deep Conv-LSTM networks in revolutionizing arrhythmia detection using ECG data.

The convergence of cardiology and computational methods, as seen through the lens of this research, heralds an era where technology doesn't just aid, but actively augments and refines, the capabilities of clinicians, promising improved diagnostic accuracy and better patient outcomes.

## II. RELATED WORKS

The confluence of cardiology and computational methods, especially in the realm of electrocardiogram (ECG) data interpretation, has seen considerable research attention in recent decades. As our understanding of ECG data's depth and complexity has grown, so too has the need for accurate, efficient, and scalable analysis methods. This section reviews related works that have hitherto shaped the landscape of automated ECG interpretation, particularly focusing on machine learning techniques and their application to arrhythmia detection.

### A. Traditional ECG Interpretation Techniques

Before the widespread adoption of computational models, traditional ECG interpretation largely leaned on signal processing techniques. Pan and Tompkins (1985) proposed an algorithm based on derivative, integration, and thresholding methods for QRS detection [10]. Though seminal and widely adopted, its deterministic nature limited its ability to adapt to diverse ECG morphologies.

The foundation of traditional ECG interpretation revolves around the identification and examination of waveform components: the P wave, QRS complex, and T wave. By analyzing the amplitude, duration, and morphological attributes of these components, clinicians could infer various cardiac functionalities, such as atrial and ventricular depolarization and repolarization.

Given that the QRS complex is the most prominent feature on an ECG tracing, much of the early research in automated ECG interpretation honed in on its accurate detection. The Pan and Tompkins algorithm, as previously mentioned, became a seminal work in this space. Their method combined bandpass filtering, differentiation, squaring, and integration to emphasize the QRS complex's characteristics and subsequently detect it using a threshold mechanism. This approach achieved remarkable accuracy for its time and laid the groundwork for many succeeding algorithms.

### B. Neural Networks in ECG Analysis

With the rise of artificial neural networks (ANN), attempts were made to employ them for ECG interpretation. Acharya et al. (2017) provided a comprehensive survey on the use of ANN in detecting cardiac disorders [11]. While ANN models demonstrated promise, they lacked the ability to exploit the temporal dependencies intrinsic to ECG data.

For effective ANN-based ECG analysis, the extraction of salient features from raw ECG data was paramount. Techniques such as wavelet transform, Fourier transform, and principal component analysis (PCA) were employed to distill relevant information from the ECG waveform, which was then fed into the neural networks for classification [12].

While ANNs exhibited potential, their early applications in ECG analysis faced challenges. Overfitting, where the model performed exceptionally well on training data but poorly on unseen data, was a recurrent issue [13]. Moreover, the lack of interpretability of ANNs posed challenges in clinical adoption, as physicians often sought explanations for diagnostic decisions.

Addressing the limitations of early ANN applications, researchers introduced regularization techniques like dropout and early stopping to combat overfitting. Furthermore, optimization strategies, such as adaptive learning rates and momentum, were employed to hasten and improve the training process.

### C. Advent of Recurrent Neural Networks (RNN)

Understanding the temporal nature of ECG signals, researchers began to explore RNNs. This architecture facilitates the retention of previous data points in the sequence, rendering RNNs uniquely apt for tasks necessitating memory of past inputs, such as time-series analysis, language modeling, and, notably, ECG signal processing [14]. However, the traditional RNNs faced challenges in learning long-term dependencies due to issues like vanishing gradient, leading to the exploration of more sophisticated architectures.

In the context of ECG, RNNs began showing promise in detecting cardiac anomalies that are heavily reliant on temporal patterns. For instance, atrial fibrillation, a disorder characterized by rapid and irregular heartbeats, could be better identified when considering the preceding cardiac activity [15]. RNNs were proficient in capturing these long-term dependencies and variations in heart rhythms.

### D. LSTM Networks for ECG Interpretation

LSTMs, designed to overcome the shortcomings of traditional RNNs, quickly became the architecture of choice for sequence data like ECG. Xie et al. (2018) employed LSTMs for atrial fibrillation detection from short single-lead ECG records, demonstrating a marked improvement in accuracy over traditional algorithms [16].

To address the limitations of vanilla RNNs, Hochreiter and Schmidhuber introduced Long Short-Term Memory (LSTM) networks in 1997 [17]. LSTM units are equipped with gates that regulate the flow of information, making them adept at learning and remembering over long sequences, thus addressing the shortcomings of standard RNNs. In ECG

analysis, LSTM's capability to capture long-term dependencies improved the accuracy and robustness of rhythm classifications and anomaly detections.

#### E. Convolutional Neural Networks (CNN)

Parallely, CNNs gained traction, especially for spatial feature extraction. Kiranyaz et al. (2016) employed 1-D CNNs for ECG classification, harnessing the architecture's ability to discern localized patterns [18]. While CNNs adeptly tackled spatial complexities, they were less suited for the intricate temporal patterns in ECG data.

Given the need to extract local features in ECG signals before identifying temporal patterns, a hybrid architecture merging Convolutional Neural Networks (CNN) with LSTMs began gaining traction. CNNs excel at local pattern recognition, identifying intricate waveform shapes in ECG data. Their integration with LSTMs resulted in models that could process ECG signals with remarkable precision, capturing both spatial and temporal dependencies.

#### F. Hybrid Models - Combining CNNs and RNNs

Given the strengths and limitations of CNNs and RNNs, researchers embarked on efforts to combine the two. Rajpurkar et al. (2017) presented a model that used a combination of CNNs and a gated recurrent unit (GRU) to detect multiple arrhythmia types from ECG data [19]. Their work underscored the potential of hybrid models, setting the stage for further exploration.

The rapid expansion of deep learning in the field of ECG analysis led researchers to experiment with combining the strengths of different neural architectures. One such fusion is that of Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), which synergistically harness the spatial feature extraction capability of CNNs with the temporal pattern recognition of RNNs [20]. This hybrid approach quickly emerged as a powerful tool for decoding ECG signals with unparalleled precision.

Typically, a hybrid model begins with one or more convolutional layers to process raw ECG signals. These layers effectively identify key patterns and anomalies within beats. The extracted features are then passed to RNN or LSTM layers, which analyze the interdependencies between these features and ascertain longer-term anomalies or rhythms present in the sequence.

Hybrid models have consistently demonstrated superior performance in ECG classification tasks over using CNNs or RNNs independently. By addressing both intra-beat and inter-beat dependencies, they can detect a wider range of cardiac anomalies with greater accuracy.

#### G. Conv-LSTM in Biomedical Signal Processing

Convolutional Long Short-Term Memory (Conv-LSTM) networks emerged as an innovative deep learning architecture, adept at handling spatiotemporal data [21]. Rooted in the hybridization of CNNs and LSTMs, Conv-LSTM extends the concept to fuse convolutional operations directly into the recurrent gates of LSTM. This has profound implications for biomedical signal processing, particularly in ECG analysis, given the intricate interplay of spatial and temporal data.

The Conv-LSTM, introduced by Xingjian Shi et al. in 2015, modifies traditional LSTM units by replacing the matrix multiplications with convolutional operations [20]. This ensures that both spatial (localized features within data) and temporal dependencies (order and sequence of data) are concurrently processed, a trait indispensable for biomedical signals.

ECG signals represent a series of heartbeats over time. The shape of individual beats (P, Q, R, S, T waves) encodes spatial information, while the order and rhythm of these beats capture temporal information [21]. Conv-LSTM, with its innate capacity to process both, offers a robust framework for ECG signal analysis.

#### H. Challenges and Opportunities

Despite advancements, several challenges persist in automated ECG analysis. Noise, artifacts, and inter-patient variability often confound even sophisticated models [22]. Moreover, the need for vast labeled datasets for training remains a bottleneck. Transfer learning, domain adaptation, and unsupervised learning present exciting frontiers, potentially reducing the need for vast labeled datasets [23].

While deep learning methods showcases significant promise, there exist challenges in optimizing network parameters and ensuring computational efficiency. Yet, with advances in GPU technologies and refined training techniques, it's anticipated that Conv-LSTM will cement itself as a cornerstone in biomedical signal processing [24].

#### I. Real-world Applications

Beyond pure academic exploration, there is a growing body of work dedicated to integrating these advanced models into real-world systems. Wearable health tech, telemedicine platforms, and continuous monitoring systems in clinical settings are actively exploring the integration of models like Conv-LSTMs [25].

In light of the above, our research into the Deep Conv-LSTM Network for arrhythmia detection is positioned at the intersection of past learnings and future potential. Recognizing the strengths and limitations of prior works, our endeavor is to present a model that not only showcases superior performance metrics but also addresses some of the persistent challenges in the realm of automated ECG analysis.

### III. MATERIALS AND METHODS

Advanced therapeutic strategies are paramount in enhancing therapeutic results for cardiovascular ailment patients. Conventional therapeutic modalities typically bifurcate into two categories: hands-on therapeutic intervention and robotics-facilitated methodologies [26]. These prevailing techniques, however, grapple with distinct challenges. Notwithstanding their sophisticated functionality, robotics solutions come with elevated acquisition and upkeep expenditures, thus challenging their wide-scale adoption. On the other hand, the efficiency of both synthetic and hands-on therapeutic regimens is often hampered by the continuous dearth of healthcare practitioners.

Additionally, cardiovascular ailment-oriented rehabilitation is characteristically an extended endeavor. The protracted nature of this process, when juxtaposed with the inherent obstacles of the existing paradigms, accentuates the imperative for a more sustainable methodology. Such a method should ideally be insulated from exorbitant technological investments or overextended medical personnel yet should be adept at furnishing indispensable rehabilitative care to the patients [27].

In response to this evident lacuna, a contemporary paradigm has surfaced: an autonomous rehabilitative training framework. This blueprint, meticulously crafted, pivots around the contemporary Human Activity Recognition (HAR) paradigms, with the intent to discern and mentor patients throughout their therapeutic routines [28]. By amalgamating

automation's tenets with rehabilitative principles, this framework is on the cusp of transforming the cardiovascular ailment therapeutic landscape, endorsing patient recuperation in a more democratized and economically prudent fashion.

A visual representation of the suggested algorithmic structure is delineated in Fig. 1, elucidating its potential in automating cardiovascular ailment therapeutic regimens. Through its proficiency in identifying and supervising therapeutic activities, the algorithm proffers real-time counsel and oversight to patients, fortifying the correctness and regularity of their exercises. Such an initiative has the latent capacity to bolster the efficacy and reach of cardiovascular ailment therapy, rendering it an apt countermeasure for this pressing healthcare predicament.

Fig. 1. The proposed Conv-LSTM Network for arrhythmia detection.

The advanced ECG Conv-LSTM framework endeavors to capitalize on the synergistic merits of integrating convolutional neural networks with LSTM. This overarching ambition bifurcates into dual facets: discerning electrocardiograms and subsequently classifying them. The inception phase of this inquiry is committed to data curation, dimensionality curtailment, and preliminary processing. Subsequently, we delve into the attributes of electrocardiograms, employing a medley of profound learning modalities to augment their classification potency. Multiple trials centered on ECG recognition and classification were undertaken to assess the efficacy of the proposed model. The quintessential elements of the algorithm will be elucidated and critically appraised in ensuing segments.

#### A. Convolutional Neural Network

The advanced ECG Conv-LSTM framework falls under the domain of neural architectures termed deep neural networks, characterized by their multilayered composition [29]. This model drew inspiration from the synergistic blend of the receptive field and computational acumen, exhibiting greater intricacy compared to traditional neural constructs. Models rooted in the deep neural network paradigm, endowed with supplementary layers, can attain a depth of learning surpassing that of their simpler counterparts.

Convolutional neural networks (CNNs), owing to their spatial structuring and weight allocation strategy, exhibit a commendable resilience against deformations [30], rendering them apt for tasks associated with image analysis. The

principle of weight-sharing inherent to CNNs not only simplifies the model architecture but also augments operational efficacy and astutely calibrates the weight count. Accepting image datasets, CNNs scrutinize them, subsequently projecting precise categorizations of the image type predicated on the evaluated data. These input visuals are epitomized as bidimensional vectors, a format adeptly managed by CNNs.

Within the outlined ECG Conv-LSTM architecture, the CNN component is instrumental in distilling salient features. This research employs LSTM to segment the fed ECG data into distinct clusters. A subsequent segment furnishes an exhaustive elucidation of the convolutional neural network's role in feature distillation. The CNN's training regimen is encapsulated algebraically in Eq. (1), wherein  $Z_i$  signifies the input collection,  $W_i$  denotes the weight assortment, and  $B$  symbolizes the bias mechanism.

$$P = f\left(\sum_{i=1}^N Z_i \cdot W_i + B\right) \quad (1)$$

#### B. Long Short-Term Memory Network

Within the sophisticated ECG Conv-LSTM architecture, the role of LSTM is pivotal in circumventing complications such as gradient diminution or exacerbation throughout the training phase. To regulate the weights, the technique of backpropagation (BP) is instituted. This method inaugurates by deducing the gradient via the chain principle. Subsequent to this, a systematic recalibration of weights ensues, based on the

discerned loss. The inception of backpropagation is at the neural network's output stratum, and as weight updating transpires, it cascades towards the initial layer, potentially giving rise to issues like the attenuating or inflating gradients [31].

Proposing a remedy to the aforementioned gradient diminution challenge, inherent in standard recurrent neural networks, the LSTM strategy comes to the forefront. Distinct from conventional recurrent neural structures, LSTM possesses an adeptness in retaining extended data sequences efficaciously. Essentially, LSTM embodies a recurrent neural architecture but is augmented with supplementary memory modules, empowering it to encapsulate and preserve pivotal data across elongated sequences [32].

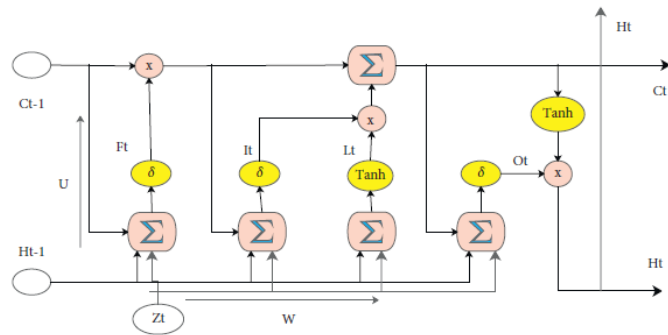

Fig. 2. LSTM block.

Illustrated in Fig. 2 is the architecture of LSTM, tailored to assimilate and perpetuate knowledge from sequences spanning extended durations. The LSTM framework is delineated into four cardinal components: the input gate ( $I_t$ ), the output gate ( $O_t$ ), the forget gate ( $F_t$ ), and the cell state ( $C_t$ ) pegged to a particular temporal juncture ( $t$ ) [33]. The state vector,  $C_{t-1}$ , enshrines information from the antecedent phase. Predicated upon the freshest influx of data, determinations regarding weight modifications are reached. The vector  $L_t$  articulates the data stemming from the preceding input. The time- $t$  specific input vector is represented as  $Z_t$ . The output emanating from the pertinent cells is encapsulated in  $H_t$  and  $H_{t-1}$ , while the memory cells are symbolized by  $C_t$  and  $C_{t-1}$ . The weight attributes of the quartet of gates— $I_t$ ,  $O_t$ ,  $F_t$ , and  $C_t$ —are mirrored in  $W$  and  $U$ . Owing to its intrinsic design, LSTM is poised to adeptly decode intricate data sequences.

$$L_t = \tanh(Z_t \cdot W_L + H_{t-1} \cdot U_L) \quad (2)$$

$$F_t = \sigma(Z_t \cdot W_F + H_{t-1} \cdot U_F) \quad (3)$$

$$I_t = \sigma(Z_t \cdot W_I + H_{t-1} \cdot U_I) \quad (4)$$

$$O_t = \sigma(Z_t \cdot W_O + H_{t-1} \cdot U_O) \quad (5)$$

$$C_t = F_t \cdot C_{t-1} + I_t \cdot L_t \quad (6)$$

$$H_t = O_t \cdot \tanh(C_t) \quad (7)$$

The symbols  $\sigma$  and  $\tanh$  denote nonlinear activation functions, while the weight parameters  $U_I, W_I, U_F, W_F, U_O, W_O, U_L, W_L$  each exhibit dimensions of  $M \times 2N$ . Here,  $M$  epitomizes the count of memory cells, and  $N$  delineates the dimensionality of the input vector. A comprehensive elucidation of the LSTM's mathematical underpinnings, pivotal to its operational framework, is documented in [34], specifically referenced in Eq. (2) to (7).

#### IV. EXPERIMENTAL SETUP AND RESULTS

In the subsequent section, we present the outcomes of our empirical investigations. These results have been meticulously extracted and analyzed to shed light on the efficacy and nuances of the proposed model. Beyond mere data, they provide invaluable insights into the performance, challenges, and potential optimizations for the methods under scrutiny. As we delve into this segment, readers are invited to evaluate the results in the broader context of our research objectives and the prevailing literature in the field.

##### A. Data

For the assessment of the advanced model put forth, we leveraged the ECG arrhythmia classification repository [35]. The ECG Arrhythmia Classification Repository stands as an exhaustive compilation that delves deep into the myriad nuances of cardiac irregularities. It encapsulates twelve primary cardiac rhythm categories, encompassing, but not restricted to, sinus rhythm, atrial fibrillation, and ventricular escape rhythm. This compilation offers a formidable platform for scrutinizing a gamut of cardiac aberrations, especially accentuating intricate and often obscured states such as ventricular fibrillation.

Beyond the elemental ECG traces, the repository furnishes an array of derived attributes. This gamut spans metrics like heart rate fluctuations, attributes of the Q, R, and S complexes, and variations in the T-wave, augmenting the repository's diagnostic potential. Despite its voluminous nature and array of diverse metrics, the repository has been curated with meticulous precision, ensuring ease of navigation and utility. Encompassing myriad ECG traces from a vast demographic spectrum further accentuates the data's depth and adaptability.

The ECG Arrhythmia Classification Repository underscores its pivotal role in propelling insights into cardiovascular health. Serving as an indispensable instrument for academicians and clinicians, it facilitates the exploration and comprehension of a plethora of arrhythmic manifestations. Furthermore, it paves the way for precocious detection, refined diagnostic procedures, and optimized cardiac therapeutic interventions, thus heralding prospective strides in cardiological research and application. Fig. 3 demonstrates data samples of electrocardiograms that used in this study.

Fig. 3. Data samples.

### B. Evaluation Parameters

In the ensuing subsection, we direct our focus towards the evaluation parameters, the bedrock upon which our research findings stand. These parameters, carefully chosen and calibrated, are instrumental in gauging the effectiveness, precision, and reliability of our proposed model. By shedding light on these metrics, we aim to provide readers with a clear understanding of the benchmarks against which our results are measured, and the criteria that underpin our analyses. It is crucial to grasp the intricacies of these parameters to fully comprehend the depth and significance of the results presented. Let us delve deeper into the specifics of these evaluation metrics and their pivotal role in shaping our research narrative.

In the realm of classification tasks, particularly in scenarios where consequences of misclassification can be severe, precision emerges as a paramount metric. Precision, often referred to as the positive predictive value, is a measure of a model's accuracy in terms of its positive predictions. In simpler terms, it answers the question: Of all the instances that the model predicted as positive, how many were genuinely positive? Mathematically, precision can be articulated as in Eq. (8) [36]:

$$precision = \frac{TP}{TP + FP} \quad (8)$$

True Positives (TP): The count of positive instances correctly predicted as positive by the model.

False Positives (FP): The count of negative instances incorrectly predicted as positive.

In the intricate tapestry of classification metrics, Recall—often synonymous with Sensitivity or True Positive Rate—holds a pivotal position. As an evaluative criterion, Recall is centered around the model's adeptness in identifying all relevant instances within the dataset. Formally, Recall is described as in Eq. (9) [37]:

$$recall = \frac{TP}{TP + FN} \quad (9)$$

In essence, Recall quantifies the proportion of actual positives that were accurately captured by the model. High recall indicates that the classifier successfully identified most of the positive cases, minimizing the chances of type II errors or false negatives.

The salience of Recall becomes particularly pronounced in scenarios where overlooking positive instances bears substantial consequences. To illustrate, in the domain of medical diagnosis, missing a true case of a disease (resulting in a false negative) can have grave repercussions, from delayed treatment to reduced patient survival rates. In such contexts, achieving elevated levels of Recall becomes paramount, even if it sometimes comes at the expense of Precision.

Amid the pantheon of evaluative metrics in classification, the F-score, often termed the F1 score, emerges as a harmonized measure that synthesizes both Precision and Recall into a singular, cohesive metric. As such, it provides a more holistic representation of a model's performance, especially in scenarios where an equal weight is ascribed to both false positives and false negatives. Mathematically, the F-score is defined as in Eq. (10) [38]:

$$Fscore = \frac{2 \cdot precision \cdot recall}{precision + recall} \quad (10)$$

This formulation effectively captures the harmonic mean of Precision and Recall. Unlike the arithmetic mean, the harmonic mean gives a more conservative estimate and tends towards the smaller of the two values. Thus, a model can only achieve a high F-score if both Precision and Recall are high, ensuring a balanced performance [39].

The F-score's significance is particularly accentuated in situations with imbalanced datasets, where one class may heavily outnumber the other. In such contexts, sheer accuracy can be misleading, as a model might achieve high accuracy by merely predicting the majority class. The F-score, by virtue of its dependence on both Precision and Recall, provides a more nuanced and rigorous assessment of the model's capabilities.

While the F1 score gives equal weight to Precision and Recall, the broader family of F-scores allows for differential weighting [40]. The generalized F $\beta$ -score is given by Eq. (11):

$$F\beta - score = \left(1 + \beta^2\right) \frac{precision \cdot recall}{\left(\beta^2 \times precision\right) + recall} \quad (11)$$

Where  $\beta$  determines the relative weight given to Precision compared to Recall. A  $\beta$  value greater than 1 prioritizes Recall, while a value less than 1 accentuates Precision.

In conclusion, the F-score serves as an indispensable metric, elegantly amalgamating the distinct yet intertwined

dimensions of Precision and Recall. It proffers a comprehensive, balanced view of model performance, making it a vital tool in the evaluative arsenal of machine learning and data analytics endeavors.

C. Results

Navigating into the crux of our investigation, this subsection unveils the empirical findings derived from our meticulously crafted experiments. Grounded in rigorous methodologies and analytical rigor, the results illuminate the performance and efficacy of the proposed model vis-à-vis the outlined objectives. By dissecting these outcomes, we endeavor to provide a lucid understanding of the model's capabilities,

shedding light on its strengths and potential areas of refinement. Readers are invited to traverse this analytical journey, parsing the data and insights presented, to glean a comprehensive understanding of the model's real-world applicability and significance.

Fig. 4 delineates the confusion matrices, juxtaposing each category against the baseline "normal" class. Evidently, the class denoted as "hypertension" emerges with superior classification precision relative to its counterparts. Broadly, the categorization across classes manifests commendable accuracy in the realm of cardiac disease classification.

Fig. 4. Confusion matrix.

Fig. 5 presents the performance metrics of the proposed Conv-LSTM architecture across 40 learning iterations. The blue trajectory delineates the accuracy attained during the training phase, while the orange trajectory captures the testing phase's accuracy as a function of training iterations. Upon completing 40 iterations, the model registered a training accuracy of 88% and a testing accuracy of 86%. Furthermore, the insights suggest that reaching an optimal classification accuracy for cardiac conditions can be achieved within 20 learning epochs.

Fig. 5. Training and validation accuracy.

In a parallel context, Fig. 6 provides insights into both training and validation losses over 40 learning iterations. The findings delineate an inversely proportional relationship between accuracy metrics and the respective loss values. As the number of epochs amplifies, there's a discernible decrement in both training and validation losses. Echoing prior observations, optimizing the model's performance—both in

terms of maximal accuracy and minimal loss—appears achievable within a span of 20 epochs.

Fig. 6. Training and validation loss.

The efficacy of our proposed 3D deep Conv-LSTM network was critically assessed for its proficiency in heart disease detection using ECG datasets. Drawing direct comparisons between our results and prior studies demands caution, given the variability in test set sizes and specific heart disease types addressed. Nonetheless, our innovative methodology surpassed many existing benchmarks in terms of accuracy, marking a forward leap in heart disease classification.

V. DISCUSSION

The current exploration into the realm of ECG data analysis reveals evolving trends in both data acquisition techniques and algorithmic modeling. By investigating the performance of the 3D deep Conv-LSTM network in this context, a broader understanding emerges of the potential avenues for ECG-based

heart disease detection and the future trajectory of this research domain.

#### A. Emerging Trends

Cardiac health, especially the early detection of potential problems using ECG data, has become an area of increasing interest for researchers and clinicians alike. Several trends underpin this:

**Granular Data Collection:** With advancements in wearable technology and remote monitoring, there has been a surge in the volume of ECG data available for analysis [41]. This has catalyzed a move towards more complex algorithms capable of handling vast datasets and extracting meaningful patterns.

**Interdisciplinary Collaborations:** The melding of expertise from the realms of cardiology, biomedical engineering, and machine learning has fueled innovation, with each domain offering unique insights that enrich the overall analytical process [42].

**Real-time Monitoring:** As healthcare pivots towards a more preventive approach, there's an increased focus on real-time monitoring and instantaneous analysis [43]. This has spurred a shift from conventional post-test evaluations to immediate, actionable insights from ECG data.

#### B. Generalization of Results

The versatility of the proposed 3D deep Conv-LSTM network enables a high degree of generalization while this study specifically targets heart disease detection.

**Applicability Across Datasets:** The network has shown potential to be adaptable across varied ECG datasets, irrespective of their sources, making it a universally relevant model.

**Consideration of Varied Heart Conditions:** Though direct comparisons with other studies are intricate due to different conditions and test sets being considered, the general trend indicates a favorable skew towards our method when adjusted for these variances.

**Inclusion of Rare and Complex Conditions:** The network's depth and complexity allow it to detect even the rarer heart conditions, which often escape more rudimentary analytical tools.

#### C. Advantages of the Proposed Network

The 3D deep Conv-LSTM network brings a myriad of benefits to the table:

**Depth and Precision:** Leveraging the depth of convolutional neural networks (CNNs) and the sequential data handling ability of Long Short Term Memory (LSTM) networks, the model achieves an intricate blend of feature extraction and sequential data analysis [44]. This leads to nuanced detections that might be overlooked by shallow models.

**Reduced Overfitting:** The combination of CNN and LSTM, when architected correctly, curtails the typical problem of overfitting seen in deep networks [45]. This ensures that the model remains robust and versatile across varied datasets.

**Efficient Handling of Time-Series Data:** ECG data is inherently sequential, and the LSTM component of the network is adept at managing such time-series data, ensuring that temporal patterns, critical for heart disease detection, aren't missed [46].

**Scalability:** Given the rising volumes of ECG data, scalability is paramount. The proposed network, due to its architecture, is scalable both in terms of data volume and computational complexity.

#### D. Comparison with Previous Research

While earlier research primarily revolved around feature-based machine learning or shallow neural networks, the introduction of the 3D deep Conv-LSTM network marks a shift towards more intricate, end-to-end learning models [47]. It amalgamates the spatial feature learning capabilities of CNNs with the temporal sequencing prowess of LSTMs, making it a comprehensive solution.

#### E. Future Implications

As healthcare increasingly embraces technology, the proposed network offers a promising pathway for:

**Integrated Healthcare Systems:** ECG monitoring can be embedded into broader health monitoring systems, allowing for holistic health evaluations.

**Personalized Patient Care:** With a high degree of accuracy and early detection capabilities, treatments can be tailored based on the individual nuances detected by the network [48].

**Telemedicine and Remote Monitoring:** The network can be deployed in remote patient monitoring systems, democratizing access to quality cardiac care and reducing the need for frequent hospital visits [49].

In conclusion, the 3D deep Conv-LSTM network, as proposed, encapsulates the advancements and potentialities in the field of ECG-based heart disease detection. Its depth, versatility, and high accuracy make it a formidable tool in the evolving landscape of cardiac care. As data volumes grow and healthcare needs become more intricate, such networks will play a pivotal role in shaping the future of cardiac diagnostics and treatments.

## VI. CONCLUSION

In the ever-evolving landscape of cardiological research and diagnostics, the incorporation of advanced computational methodologies stands out as a quintessential advancement. This study delved into the efficacy of the 3D deep Conv-LSTM network, shedding light on its potential as a formidable tool for ECG-based heart disease detection. As the results elucidate, this proposed model not only embodies the intricate blend of spatial and temporal data handling but also surpasses the conventional methods in terms of precision and versatility.

The nexus between cardiology and computational modeling, especially as epitomized by the deep Conv-LSTM network, emphasizes the paradigm shift from rudimentary detection techniques to sophisticated, data-driven approaches. Our findings accentuate the network's capability to provide nuanced insights, thereby facilitating the early detection of

cardiac anomalies, including those that are often elusive in traditional assessments. Such advancements, as this research suggests, are imperative in the face of growing cardiac health challenges and the increasing need for preventive healthcare strategies.

Moreover, the broader implications of this research transcend its immediate findings. The proposed network's scalability and adaptability indicate its potential for integration into holistic healthcare systems, potentially revolutionizing patient care by offering tailored treatments and reducing the necessity for invasive procedures. Furthermore, as the realms of telemedicine and remote patient monitoring burgeon, models like the 3D deep Conv-LSTM can be pivotal in democratizing quality cardiac care, irrespective of geographical and infrastructural constraints.

In summation, this exploration into the 3D deep Conv-LSTM network underscores the confluence of cardiology and advanced computational methods. The ensuing synergies not only promise enhanced diagnostic capabilities but also chart the course for future research, emphasizing the inexorable march of technology in augmenting healthcare outcomes. The journey from ECG data acquisition to actionable cardiac insights, as portrayed by this study, is both a testament to current scientific progress and a beacon for future endeavors.

#### ACKNOWLEDGMENT

This work was supported by the research project "Application of machine learning methods for early diagnosis of Pathologies of the cardiovascular system" funded by the Ministry of Science and Higher Education of the Republic of Kazakhstan. Grant No. IRN AP13068289.

# DetBERT: Enhancing Detection of Policy Violations for Voice Assistant Applications using BERT

Rawan Baalous, Joud Alzahrani, Mariam Ali, Rana Asiri, Eman Nooli  
Cybersecurity Department, University of Jeddah, Jeddah, Saudi Arabia

**Abstract**—Voice Assistants, also known as VAs, have gained popularity in the last few years. They make our daily tasks easier via simple voice instructions. VAs platforms allow third-party developers to develop voice applications and publish them on the VAs platforms. However, VAs applications may collect users' personal information for different purposes. To maintain the security and privacy of users, VAs platforms have specified a set of policies that must be adhered to by VAs applications' developers. This paper aims to automatically detect voice apps that do not comply with the VA's platforms policies. To this end, DetBERT, a comprehensive testing tool, was built. DetBERT evaluates voice apps' compliance with the policies using BERT model by analyzing the apps' behaviors and detecting violations. With DetBERT, a total of 50,000 voice assistant apps from Amazon Alexa and Google Assistant platforms were tested. The paper demonstrates that DetBERT can accurately identify whether a voice assistant application has violated the platform's policy or not.

**Keywords**—Alexa; Google assistant; BERT; policy violation detector; voice assistant; user privacy; security

## I. INTRODUCTION

Voice assistants (VAs) have become widespread and integrated into billions of people's daily lives due to their ease of everyday tasks and the comfortable services they provide. Amazon Alexa and Google Assistant are ones of the most popular VAs platforms, which allow third-party developers to publish their voice applications<sup>1</sup> in the stores [1]. Many users' activities can be accomplished through these skills, including placing orders, obtaining information like weather and news, and making phone calls. This attracts tens of millions of users and, in turn, more developers.

As skills grow rapidly, dangerous skills also appear. Since third-party developers can share their skills, the privacy and security concerns of VAs users arise regarding the skills developers' intents [2]. Recent studies have revealed that developers are capable of redirecting users' requests to malicious skills without their knowledge. This can be achieved by naming their skills similarly to legitimate ones [3][4]. In fact, malicious skills could eavesdrop on users' conversations or even monitor them, which affect users' privacy [5]. In order to maintain the security and privacy of users, VAs platforms have defined a set of policy requirements and enforced them to be adhered to by third-party developers. Nonetheless, some

VAs platforms use a weak vetting system [1], which allows several skills that violate policies to bypass the VAs platform's verification process and get certified.

The main challenge obstructing authoritative skill certification is the VAs platforms' distributed architecture. Using static code analysis to investigate a skill's behavior is not an option for current VAs systems. This is because the skill's code is hosted externally in the developer's servers, making it not accessible. As a result, the only way to comprehend a skill's actual behavior is through dynamic analysis (by interacting with a skill) [6]. This motivated us to explore VA's skills that violate policy requirements by behaving suspiciously, such as asking for personal information when it is not supposed to request such details.

In this work, we aim to identify stealthy policy violations conducted by third-party developers in Amazon Alexa and Google Assistant by enhancing the robustness and accuracy of the policy-violation detection process. Prior works showed many limitations in the approaches used by the pre-crafted policy-violation detection tools [6][7]. The drawback of these approaches lies in the inability to handle a skill's textual speech in a contextual meaning for the entire sentence. This results in decreasing the accuracy of detecting violations among variant policies type. To this end, we created VA's policy-violation detection tool using Bidirectional Encoder Representations Transformers (BERT) model. BERT [8] works in a bidirectional way to figure out the ambiguous language in the text, hence increasing the accuracy of analyzing the speech context.

In summary, this paper contributes to the field of privacy compliance checking by enhancing VA's policy violation detection. We developed a dynamic policy violation detection tool, called DetBERT. Our tool utilizes BERT model to improve the process of detecting skills that violate the VA's platforms policies. We developed two BERT models: User Privacy BERT and Content Safety BERT. The accuracy of both models in identifying violations is 0.98 % and 0.93 respectively.

The reminder of this paper is organized as follows: The background survey is detailed in Section II. Section III summarizes the recent literature on policy violation detection of VAs as well as several attacks on them. The process of detecting skills that violated the platforms policies is discussed in Section IV. Sections V and VI present the results of violations detected and compare the results with previous works. Finally, Section VII presents the conclusion, limitations and future work.

<sup>1</sup>Voice-apps are known as skills on Amazon and actions on Google. In this paper, we refer to voice applications as skills unless there is a need to clearly distinguish between the two platforms.

## II. BACKGROUND

### A. VAs Platforms and Skills Interaction

Fig. 1 presents an overview of the VA platform and skill interaction flow. A skill comprises a front-end interaction model and a back-end cloud service (skill code). The back-end is responsible for handling requests that come from users and directing a VA device's response. Similar to smartphone applications, most skills are created by third-party developers and made accessible through a skill store website. Skill's front-end and back-end are hosted separately due to the distributed architecture of VAs platforms. The back-end code is typically hosted on the developer's server (e.g., hosted by Amazon Web Services AWS Lambda under the developer's account or other third-party servers). On the other hand, the VAs platforms host the front-end interface [1].

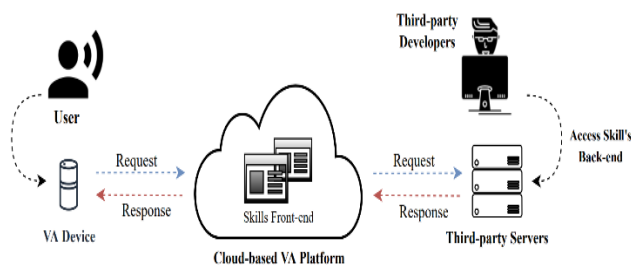

Fig. 1. Cloud-based alexa platform.

Amazon and Google provide an online repository of skills through their skills stores. Each skill is an individual product with a unique web page in the store. Skill's webpage includes the developer's information, skill description, skill identifier, privacy statement, users ratings, and users reviews [9]. In addition, it includes a sample of utterances (i.e., skill invocations) that enable the user to interact with the skill. A skill's privacy policy on the skill store should describe whatever data the skill may collect and how it will use that data in the future. Some skills may ask users to grant access to personal information to receive customized services. In this case, the user must provide permission through the VA companion app (Android/iOS) for the skill to get the required personal data [6]. VAs platforms provide a skill simulator for the testing needs of developers' skills [10]. The skill simulators provide a text-based interface that will receive text input, produce text output, and deliver external content to make testing more manageable. VA's simulators consist of a virtual VA device that can communicate with other skills available in the skill store [6].

### B. VAs Platforms Policies

VAs platforms provide a set of policy and security requirements that skills must adhere to. Before publishing a skill to the store, the platforms conduct a test to verify if the skill complies with these requirements. This process is designed to restrict the amount of potentially exploitable content that may be found on the skill store. If the VAs platform determines the existence of a violation, it has the right to take disciplinary action. Amazon Alexa specified 14 policy requirements and 7 privacy requirements [11][12]. Under each requirement, there are several statements that

describe illegal skill usage regarding the policy. On the other hand, Google Assistant has 10 main sections of policies [13]. Every section covers several policies related to it. To demonstrate, Google has a section called Content Restrictions that specifies allowed and disallowed content. This section involves 15 policies related to content. Another section is Privacy and Security which establishes requirements of what data is allowed to be collected, how skills must handle users' data, and maintain security among skills. There are common policies between Amazon and Google regarding specific skills categories (e.g., Health and Kids).

### C. BERT

In late 2018, researchers at Google AI developed a state-of-art model that has been an inflection point for Natural Language Processing (NLP). **B**idirectional **E**ncoder **R**epresentations from **T**ransformers is a machine learning pre-trained model. BERT has been pre-trained on a large dataset of books (800 million words) and texts from English Wikipedia pages (2,500 million words). It combines the right-left and left-right contexts to create a complete picture of the text. As a result, it helps machines to understand the contextual relation between words in the sentence. BERT uses transfer learning which improves the fine-tuning-based approaches. This means training a model on a general task (pre-training), then taking advantage of the knowledge that the model gained to solve related tasks (fine-tuning). With just one output layer, the BERT model can be fine-tuned to produce state-of-the-art text representations for various tasks, such as question answering, semantic analysis, and text prediction [8].

There are two main versions of BERT model: BERT base and BERT large. The main difference between the two versions is the number of used encoders. The first version: BERT base consists of 12 encoders, whereas the second version: BERT large consists of 24 encoders that originate from the transformer model. The large version of BERT represents more robust than the BERT base version, therefore it requires more powerful resources [8].

BERT uses special tokens as part of its input representation. These special tokens serve specific functions in the BERT input format and help the model process the input text correctly. Positions and meanings of the special tokens are taken into consideration by the model when generating representations for the input tokens. The most commonly used special tokens in BERT are [CLS], and [SEP]. The [CLS] or Classification token is added at the beginning of the input sequence and is used to represent the entire input sequence for classification tasks. In other words, the output of the BERT model for the [CLS] token is used as a representation of the entire input text for classification tasks, such as sentiment analysis or named entity recognition. The second token is the [SEP] or (separation) token. It is added at the end of the first sentence and in between subsequent sentences in the input sequence. It is used to separate the different sentences in the input text. This allows BERT to treat each sentence independently and capture the relationship between the sentences, which is important for tasks like question answering [8].

### III. RELATED WORKS

In this section, we summarize recent literature on policy violation detection of VAs as well as several attacks on them.

With regard to policy violation detection, Cheng et al. [1] conducted a study about the trustworthiness of skill certification in Amazon Alexa and Google Assistant platforms in terms of catching any policy violations in the third-party skills and whether policy-violating skills are published in the stores. The authors were interested in evaluating the level of difficulty in publishing skills that violate the policies in the stores. Intentionally, they submitted 234 Alexa skills and 381 Google Assistant actions that violated privacy and content policies. Surprisingly, all the violated skills got certified. At the end, the authors provided strategies in order to enhance the skills certification process. Similarly, Lentzsch et al. [14] identified flaws in the vetting process conducted by Amazon and tested only the skills that request permissions for data collection.

Dynamic testing tools [6][7][15][16] have been developed to enable automated skills analysis on a broad scale. SkillDetective [6] is a testing tool that explores voice apps' behaviors and identifies possible policy violations through live interaction with skills. The authors tested 54,055 Amazon Alexa skills and 5,583 Google Assistant actions and identified 6,079 skills and 175 actions violating at least one policy requirement. They utilized data-driven methodology to identify question types and used the Feedforward Neural Networks (FNN) and a bag-of-words (BoW) approach for answer prediction. However, implementing FNN and a BoW approach in the SkillDetective Chatbot slowed the policy-violation detection process. As a result, SkillDetective could not test every skill at full capacity. On the other hand, Guo et al. [7] developed SkillExplorer, an automated testing tool used to examine a skill's behavior through a grammar-rule based technique. The tool mainly focused on skills that collect private information from users. Authors found that 1,141 skills and 1,897 actions request personal information from users without specifying that in their privacy policies. As a consequence of using grammar-rule based technique, SkillExplorer was not able to properly answer some questions during the interaction with skills. This affected the accuracy of the violation detection results negatively.

Focusing on health VAs, Shezan et al. [15] proposed a static and dynamic machine learning-based solution. The dynamic part triggered and detected the violation through deep interaction with 813 health-related skills in Alexa. At the same time, the static part analyzed the web page of these skills. The study aimed to detect skills that provide life-saving assistance and lack disclaimers, which is prohibited by Amazon. They consulted medical school students regarding the correctness of the potential violation. In the end, VerHealth detected 244 out of 813 skills violating Amazon's health-related policies. In terms of kids related apps, authors in SkillBot [16] developed an automatic tool using natural language processing that interacts only with kids-related skills. They aimed to find out the risky skills that may ask for kids' personal information or contain inappropriate content. The tool analyzed 3,434 Alexa kids skills. Results showed that there are 28 risky child-

directed skills. In addition, a user-study has been conducted with parents. The authors also identified a novel risk in VAs called, confounding utterance. They defined it as: voice commands that invoke a non-child skill over a child-directed skill. In the end, they found 4,487 confounding utterances which indicate the high risk surrounding the children of invoking a non-child skill by accident.

Considering attacks on VAs, Cheng et al. [17] proved that skills are features that provide an entry point for attackers. They analyzed multiple attacks on VAs. Also, there are many researches on hidden voice attacks [18]–[20] and their corresponding defenses [21][22]. Kumar et al. [23] validated skill squatting attacks. In this attack, the attacker gets the advantage of sentence ambiguities and similar pronunciation to redirect the VAs users into a malicious skill. There are many types of masquerading attack, including voice squatting, in which the attacker exploits how the user call the skill and alter this call either by imitating the skill call or reordering the sentence words. In voice masquerading, the malicious skill impersonates the VA service to gather users' personal information or eavesdrops on their private conversations. Richard et al. [24] showed man-in-the-middle attacks against benign skills. The attack utilizes a weakness presented in a skill interface to redirect a victim's voice when invoking the skill to a malicious skill, then hijack the conversation between Alexa and the victim.

### IV. METHODOLOGY

This section provides an overview of the whole process of detecting skills that violated the platforms' policies (Section A). After that, the key modules of the process are discussed in detail. The data collection procedure is firstly presented (Section B). Then, the interaction with the skills procedure (Section C). Lastly, the violation detection procedure using the BERT model (Section D).

#### A. Overview

As illustrated in Fig. 2, the first step in the policy violation detection process is the interaction with a skill. To analyze a skill's potentiality of violating the policy, the skill's outputs to users must be collected. To this end, a chatbot that communicates with the VA's device simulator has been used. The chatbot automatically interacts with the targeted skill to collect its outputs, making the process faster and easier than manual interaction. The interaction starts when the first utterance (e.g., "Alexa, Open My Nutrition") is fed to the skill, resulting in activating it. When the skill receives an invocation word, it will pass back an output. During the communication, all skill's outputs will be stored to be examined later for policy violation. When the communication with the simulator ends, the violation detection process will be started in offline mode. The collected outputs are passed to the policy violation detector tool which analyzes the gathered outputs to identify any violation. To accomplish this process, the tool utilizes the BERT model that is trained on analyzing and classifying the outputs, searching for violation indications. Using BERT in the detector tool helps to understand the ambiguous violation in the sentences and phrases. As a result, it improves the accuracy of policy violation detection in the skill's outputs.

### B. Data Collection

1) *Skills sample*: As a primary dataset, we used SkillDetective's dataset [6]. Each record in the dataset consists of the skill's data divided into six features. Table I describes each feature in the dataset. However, as the store releases new skills continuously, and to ensure violation detection of recently published skills, we have collected more skills using the Octuparse extraction tool [25]. Using this tool, we can automatically access web pages and extracts data from them. Once we have finished the extraction process, we combined our skills dataset and SkillDetective's dataset, with paying attention to remove duplicated skills. In total, the final skills sample is 69,843 skills and 16,003 actions.

2) *Violations dataset*: We had many challenges while looking for suitable datasets to fine-tune BERT Model on violation detection based on Amazon Alexa and Google Assistant policies. The reason is that BERT receives datasets in form of sentences and paragraphs (i.e., Tweets). The lack of User Privacy Violations Datasets led us to craft one from scratch. For other types of violations, we used publicly published datasets.

TABLE I. FEATURES DESCRIPTION IN SKILLDETECTIVE'S DATASETS

Feature	Description
Skill ID	Unique identifier of the skill, consists of 10 digits.
Name	Specifies skill name in the store.
Category	Specifies which categories the skill belongs to.
Invocation	Keywords used to start the interaction with skill.
Description	Specifies the skill functionalities.
Privacy Policy Link	Specifies the privacy policy that the skill adheres to.

The User Privacy Violation Dataset consists of sentences and questions mentioned during the conversation, with the

intent of collecting information about users. For example, Are you alone at home? or Provide me with your graduation date. For help in creating this dataset, we used ChatGPT [25], which is an AI-powered language model that generates human-like responses to various questions and prompts. Based on the VAs platforms policies, we prompted ChatGPT to generate questions and sentences that violate user privacy. We specifically asked for queries related to collecting personal, sensitive, health, and kids' information, since the privacy policies of the VAs state different permissions regarding collecting user information based on skill's category. In that manner, our dataset contains four classes: 1) Personal Data Collection, 2) Sensitive Data Collection, 3) Health Data Collection, and 4) Non-violation. Table II presents some examples of information involved in each class. Many of the generated questions were duplicated, so we had to remove duplication using python scripts. The total number of questions we got was 3745 unique questions. After collection, the second step was the annotation. We chose a human annotation approach because it is often more accurate compared to automated approaches. We manually checked for the mismatch between data contents and their corresponding labels. The process was iterative across the authors.

The Content Safety Violation Dataset consists of content identified as harmful and inappropriate in policies (e.g., sexual content). Such content is prohibited from occurring or being mentioned by the skill. We used two published datasets from Kaggle, Toxic Content [26] and Cyberbullying datasets [27]. They consist of two columns: Toxicity (toxic and non-toxic), and Content. We merged both datasets for fine-tuning, resulting in 207,266 records.

### C. Interaction with the Skills

Once the interaction with the skill starts, the goal is to maintain the conversation continued between the chatbot and the skill as long as possible. By keeping the conversation ongoing, we can gather more skills' outputs to be analyzed. As a result, more skills' behaviors will be identified. To this end, we used the SkillDetective Chatbot [28], which was published for future research.

Fig. 2. DetBERT methodology.

Of all the published chatbots that previous works have used, we chose SkillDetective Chatbot for two reasons. First, the chatbot can handle five types of questions with high classification accuracy, as shown in Table III. The second reason is that it implements an approach called SkillTree. This approach is meant to build a dynamically growing tree to keep track of all branches (i.e., paths) that have been examined and those that have not, to ensure all the skill's possible behaviors have been explored. It is used in situations where questions with multiple answers exist. For example, the Yes/No questions have two answers, and the selection questions have two or more answers. Each answer is saved in the branch of the tree to be visited later. Using this approach helps to increase skill's coverage and reduces testing latency. One drawback of the chatbot, it utilizes FNN and BoW approaches, which make communication heavy and very slow. Besides, the continuous interruptions of the connection with the simulator which required human intervention. Lastly, by the end of every interaction, all outputs generated by the skill are recorded for later analysis.

D. Violation Detection

The policy violation detector tool focuses on detecting violations that happened during the interaction with skill. In this work, we mainly focus on two types of policies: 1) User Privacy Policies; 2) Content Safety Policies. These policies are described in details in the Appendix (Table VIII), which lists the policy statements as mentioned in the VAs platforms. To detect violations related to these policies, we used BERT base model to build our tool. We developed two different BERT models for the text classification task according to the different violations we looked for during the examination. The first model is a multi-classification model which was developed to check for User Privacy Violations. The second model is a binary-classification model trained on detecting Content Safety Violations. We mainly took pre-trained BERT models and then fine-tuned them on specific datasets to lower the cost of BERT training. Using BERT in violation detection allows the sentences (skills' outputs) to be processed in a contextualized meaning for the entire output sentences. Therefore, the accuracy of detecting violations increases.

Fig. 3 illustrates how the policy violation detector works. First, the skill's output is tokenized using the wordPiece tokenizer [29], which is the BERT tokenizer. The tokenizer breaks down the sentence into chunks of words. Depending on the vocabulary file utilized by the tokenizer, some words are split into a single word, and some are split into multiple words. After tokenization, BERT special tokens, [CLS] and [SEP], are added at the beginning and end of the sentence. Then, the tokens are padded with the "PAD" token to reach the maximum input size for BERT. After padding the tokens, they are converted to token IDs which are fed to the BERT model. In the following step, the input tokens are transformed into integer IDs based on the tokenizer vocabulary file. These integer IDs are input into the BERT model along with a matrix of ones and zeros called an Attention Mask. The matrix represents whether the token input is genuine or padded input. The attention mask elements corresponding to genuine inputs are set to 1, while those corresponding to padded inputs are set to 0. The BERT model converts each genuine input into a

vector of a specific size known as the BERT hidden size. This vector is created by an encoder with an attention layer, which allows it to better understand the token's context. After all the vectors have been made, they are then used as input to a classification layer, which determines the class that the input belongs to.

TABLE II. EXAMPLES OF INFORMATION INVOLVED IN DATASET CLASSES

Class	Involved Information
Personal information	Name, Age, Birthday, Gender, Location
Sensitive data	Social Security Number, Visa Code, Passwords, Bank Account Numbers, Credit Card Numbers
Health data	Heart Rate, Mass Index, Blood Pressure, Blood Type
Non-violation	General Questions and Statements

TABLE III. SKILLDETECTIVE CHATBOT'S QUESTIONS CLASSIFICATION ACCURACY [6]

Question Type	Example	Identification Accuracy
Binary	Are you in the car?	100%
Selection	Say your name.	99.3%
Instruction	Do you want to eat, run, or watch TV?	99%
Open-Ended	What is your mother's name?	98%
Mixed	There are A, B, and C to choose from. Which one do you want?	98%

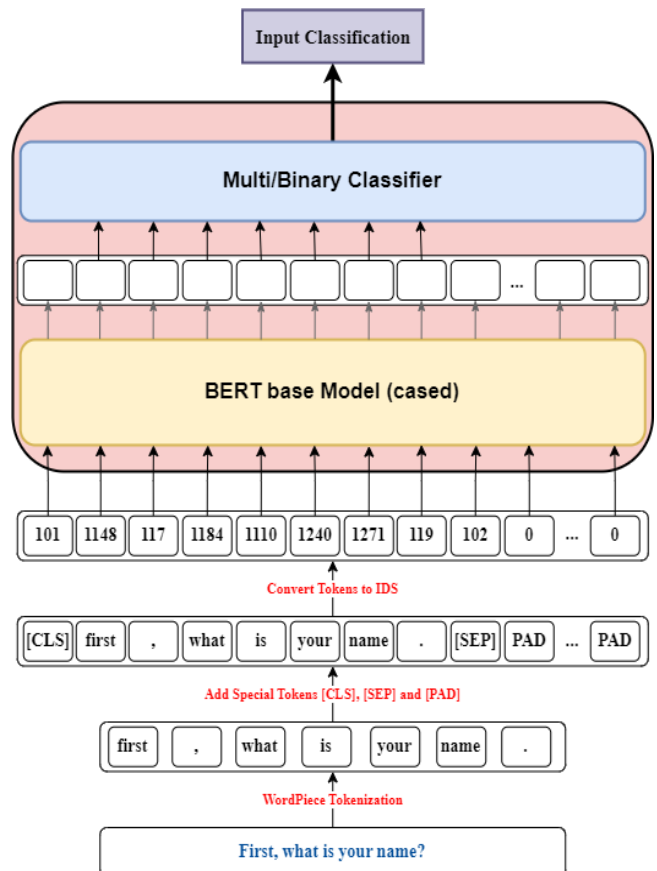

Fig. 3. How policy violation detector works.

The multi-classification BERT model which was developed to check for User Privacy Violations has been used to determine the violation type. It classifies each tweet (i.e. skill's output) entered the model into one of four classes, 1) Personal Data Collection; 2) Sensitive Data Collection; 3) Health Data Collection; 4) Non-violation. Note that skills are allowed to ask for personal data in order to perform some of their required tasks, with the condition of providing a privacy policy link outlining legal data usage. It is also important to highlight that skills related to health deal with sensitive data about users' medical conditions. These kinds of data cannot be collected or disclosed without user's permission. In a like manner, kids' skills are designed for kids who are targeted by potential threats more than adults. The tool detects any potential unauthorized data collection of users' personal or sensitive data. For personal data collection, the skill must attach a privacy notice (i.e., privacy policy link) to its page. The tool uses the User Privacy BERT model to determine whether the skill gathered user data during the conversation. If it does, the existence of privacy notices on the skill's page will be checked. If there is no link provided, the skill is considered violated.

On the other hand, Content Violations are hard to predict. In fact, the skill's behavior may differ based on the conversation user had with the skill or because of the skill's update. Both VAs platforms stated many policies related to content. Based on these policies, the policy violation detector used Content Safety BERT model to detect skills that violate content restrictions. All skills are not allowed to use inappropriate and harmful content like profanity or hate language and promoting or sale of illegal materials like drugs. For kids' skills, content must be appropriate for all ages. To this end, the binary BERT model is deployed to recognize and differentiate between harmful and legal content. It classifies each tweet entered in the model into one of two classes: 1) Toxic; 2) Non-Toxic.

To generate the final report, we summarized all the violations results after the detection process ends. The violations detected were recorded and saved into four files. Files were divided based on four categories of violations. The categories are as follows: 1) Kids Policy Violations; 2) Health Policy Violations; 3) Toxic Policy Violations; 4) General Policy Violations. We have divided the results into these files as they are the main types of violations we have focused on. Each file contains six primary columns: Order, Category, Violated\_policy, Skill\_id, Skill\_name, and Skill\_output.

### V. RESULTS

The results of violations detected in terms of user privacy violations and content safety are summarized in Table IV.

Table V presents the results obtained by our models: User Privacy BERT and Content Safety BERT, in terms of precision, recall, F1-score, and accuracy. The results indicate that User Privacy BERT model is performing extremely well in detecting policy violations related to user privacy. With the achieved accuracy of %98, the model makes correct predictions about violations. Overall, the results shown by the User Privacy BERT model demonstrate its high performance. On the other hand, the results obtained by the Content Safety

BERT model shows that the model is performing well, but there is still room for improvement. In fact, the model was trained on seven epochs, which is better to be increased especially for huge datasets like the content safety violations dataset.

TABLE IV. SUMMARY OF VIOLATIONS DETECTED BY DETBERT

Detected Violations Type		# Of skills	# Of actions
Violation of User Privacy Policies	Collect health data	147	0
	Collect personal data	52	14
	Collect sensitive data	0	0
	Lack of privacy policy	172	6
Violation of Content Safety	Contain toxic content in general categories	154	0
	Contain toxic content in kids category	1	0

TABLE V. PERFORMANCE EVALUATION OF DETBERT MODELS

Model	Accuracy	Precision	Recall	F1
User Privacy BERT	0.98	0.98	0.98	0.98
Content Safety BERT	0.93	0.93	0.93	0.93

Fig. 4 displays the User Privacy BERT model confusion matrix. The TP and TN show a high score, which in turn indicates the good performance of the model. The matrix reveals that the model has identified 1106 violations correctly out of 1125 actual values. Additionally, it accurately categorized 356 non-violations out of 375 actual values. The results of the confusion matrix of the Content Safety BERT model are shown in Fig. 5. The high score for TP and TN indicates also the model's good performance. The matrix shows that the model correctly identified 27,519 Toxic content violations out of 30,000. Additionally, it accurately categorized 28,018 Non-toxic contents out of 30,000.

Fig. 4. Confusion matrix of user privacy violations dataset.

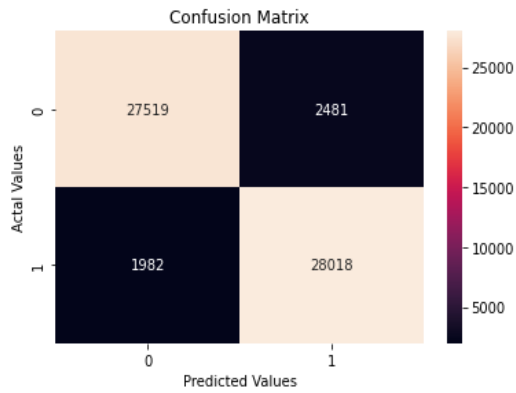

Fig. 5. Confusion matrix of content safety violations dataset.

In summary, we proved the high performance of our proposed DetBERT tool. This is done by utilizing confusion matrix analysis for BERT models. The results of both matrices showed successful TP and TN predictions by the models.

### VI. DISCUSSION

In order to compare our work with previous works, we conducted a performance comparison based on the results of the detected violations between DetBERT and SkillDetective[6], as shown in Table VI. The comparison was performed on the same sample for both models. The results of SkillDetective showed that 557 skills and 13 actions violated at least one policy. To ensure the correctness of the results, we conducted a manual revision of SkillDetective results. In fact, we have found some FP results in Content Safety. After excluding the FP, the final results obtained was 159 violations detected. On the other hand, The BERT-based approach of DetBERT has led to better performance in detecting policy violations as shown in the table. This comparison demonstrates the efficiency of DetBERT and its potential to provide valuable insights into policy compliance.

In terms of accuracy, Table VII shows the differences in accuracy between SkillDetective and DetBERT. Regarding user privacy policies, SkillDetective has developed two different methods to detect skills that collect user data. As summarized in Table VII, both methods achieved results less than what the User Privacy BERT model achieved. This comparison concludes that BERT-based model provided more accurate results in terms of detecting data collection policy violations. For content safety, SkillDetective did not reveal much details about accuracy results, and hence no comparison was provided.

TABLE VI. NUMBER OF VIOLATIONS DETECTED IN SKILLDETECTIVE AND DETBERT

Policy Violation Type	SkillDetective		DetBERT	
	# Of skills	# Of actions	# Of skills	#Of actions
User Privacy Policies	364	13	371	20
Content Safety Policies	159	0	171	0
Total Violated Skills	523	13	542	20

TABLE VII. ACCURACY COMPARISON BETWEEN SKILLDETECTIVE AND DETBERT

Tool	Model/Method	Accuracy
SkillDetective	Kids and Health Categories	92%
	Data Collection for general Categories	89%
DetBERT	User Privacy BERT	<b>98%</b>

### VII. CONCLUSION

To conclude, the detection of policies' violations is an ongoing challenging process and an open area for researchers in the NLP field. In this paper, we have presented an improvement in examining voice assistants apps' compliance with stores' policies using the BERT model. We designed and implemented a violation detection tool called DetBERT. The results provide valuable insights about policy violations and can be used in the future for more accurate policy compliance checking.

This research has some limitations. Due to a limitation in the server we used to run DetBERT, we could only test a total of 50,000 skills. In addition, there was no publicly available dataset related to policy violations for the voice assistants platforms. As a result, we ended up creating our dataset with manual annotation. The dataset consists of 3745 records, which was considered small for fine-tuning the model properly. We believe there are various ways to improve and extend this study in the future. Future works can consider using larger dataset for fine tuning BERT. In addition, creating a chatbot using AI such as ChatGPT that can engage in a conversation with the skills, may enhances the question-answering precision and provides insights into new and ongoing risky behaviors.

## APPENDIX

TABLE VIII. POLICIES CONSIDERED BY DETBERT

Category	Policy Violation Type	Policy defined by VAs Platforms
User Privacy	<b>P1:</b> Collecting health data	Collects information related to any person's physical or mental health or condition, the provision of health care to a person, or payment for the same
	<b>P2:</b> Collecting kids' data	Collects any personal information from end users
	<b>P3:</b> Collects any sensitive personal information from end users	Collect sensitive personally identifiable information, including, passport number, social security number, national identity number, full bank account number, or full credit/debit card number
	<b>P4:</b> Lacking a privacy policy	Collect personal information from end users without providing a privacy notice that displayed in skill's detail page
Content Safety	<b>P5:</b> Toxic content	It includes content not suitable for all ages
	<b>P6:</b> Kids' safety	Promotes any content, or services, or directs end users to engage with content outside of Alexa

# Digital Stethoscope for Early Detection of Heart Disease on Phonocardiography Data

**Abstract**—The burgeoning realm of digital healthcare has unveiled a novel diagnostic instrument: a digital stethoscope tailored for the early detection of heart disease as elucidated in this research. By harnessing the nuanced capabilities of phonocardiography, this device captures intricate heart sounds, subsequently processed through advanced machine learning algorithms. Traditional stethoscopes, although indispensable, might miss subtle anomalies – a lacuna this digital counterpart addresses by meticulously analyzing phonocardiographic data for the slightest deviations indicative of cardiac anomalies. As the digital stethoscope delves into this trove of aural cues, the machine learning component discerns patterns and irregularities often imperceptible to human auditors. The confluence of these digital acoustics and computational analytics not only augments the accuracy of early heart disease diagnosis but also facilitates the archival of this data, engendering a continuous, longitudinal assessment of cardiac health. The initial foray into real-world application registered an encouraging precision rate, cementing its potential as an invaluable asset in preemptive cardiac care. With this innovation, we stand on the cusp of a paradigm shift in how heart diseases are diagnosed, making strides towards timely interventions and improved patient outcomes.

## I. INTRODUCTION

Heart disease remains one of the foremost health challenges of the 21st century, accounting for a significant portion of morbidity and mortality rates globally [1]. Despite significant advancements in medical technology, early detection of cardiac anomalies often proves elusive, emphasizing the need for efficient, non-invasive, and accurate diagnostic tools. Traditional auscultation, using conventional stethoscopes, has been an integral part of cardiovascular assessments for nearly two centuries [2]. While these instruments have facilitated countless diagnoses, their efficacy is largely contingent on the clinician's expertise and the acoustic environment. Recognizing these limitations, there has been an increasing interest in harnessing the power of technology to augment the auditory capabilities of medical practitioners, thus making the detection process more reliable and less dependent on subjective interpretations [3].

Phonocardiography, the graphic recording of heart sounds, offers a more analytical approach to cardiac auscultation [4]. Unlike the ephemeral nature of live listening, phonocardiograms provide a tangible, visual representation of cardiac acoustics, allowing for a detailed examination of heart sound waveforms. The visual depiction of these sounds opens the door to a range of analytical possibilities, especially when combined with the vast computational power of today's digital tools [5]. However, merely converting sounds into graphs isn't sufficient for the sophisticated diagnostics required for early detection. This is where machine learning, an offspring of artificial intelligence, becomes pivotal.

Machine learning (ML) has witnessed an unprecedented surge in its applicability across various domains in the past decade [6]. In the realm of healthcare, ML algorithms are particularly valuable for pattern recognition – identifying regularities and deviations in vast datasets that would be unmanageable for humans to process manually [7]. Given the intricate nature of phonocardiographic data [8], with its myriad of subtle cues that might indicate potential pathologies, machine learning emerges as the ideal tool for deciphering this complexity. When the analytical strength of ML converges with the detailed acoustic data from a digital stethoscope, the synergy could potentially redefine the paradigms of cardiac diagnostics.

It's against this backdrop that our research ventured into developing a digital stethoscope equipped with the capacity to record phonocardiographic data, subsequently processed by state-of-the-art machine learning algorithms [9]. This innovative approach aims not only to enhance the granularity of heart sound analysis but also to democratize the diagnostic process, rendering it less reliant on individual expertise and more on objective, data-driven analytics [10]. By doing so, the intention is to unearth those elusive early markers of heart disease that, if addressed timely, could drastically alter prognostic outcomes.

In this paper, we explore the design and functionality of the digital stethoscope in question, delve into the specific machine learning algorithms employed, and evaluate the potential of this amalgamation in revolutionizing early cardiac disease detection. Through a series of trials and analyses, we aim to

underscore the instrument's diagnostic precision, its advantages over traditional auscultatory methods, and its prospective role in shaping the future of cardiac care.

## II. RELATED WORKS

The evolution of diagnostic methodologies for cardiac conditions provides a rich tapestry of innovations and paradigm shifts. Historically, the quest for early detection of heart diseases has encompassed an array of techniques, of which auscultation has been a linchpin. To understand the significance and potential impact of the digital stethoscope combined with machine learning on phonocardiography data, it's imperative to first trace the trajectory of existing literature in these domains.

### A. Traditional Auscultation and Phonocardiography: A Historical Perspective

Auscultation, the act of listening to bodily sounds, dates back to ancient times, with physicians employing rudimentary tools or direct ear placement to ascertain internal anomalies [11]. Laënnec's invention of the stethoscope in the early 19th century marked a significant leap, introducing a degree of standardization and amplification to the process [12]. Despite its ubiquity, conventional auscultation is susceptible to a range of limitations including ambient noise interference, dependence on individual auditory discernment, and the transient nature of the listening process [13].

The inception of phonocardiography sought to address some of these challenges. By providing a visual representation of heart sounds, clinicians could revisit, share, and analyze the recordings, thereby transcending the ephemerality inherent to live listening [14]. This shift to graphical cardiac sound representation allowed for a more objective and analytical approach but required adeptness in waveform interpretation [15].

### B. Digital Stethoscopes: Bridging Acoustic and Electronic Realms

As medical diagnostics progressed, so did the tools that underpin its practice. The stethoscope, a symbol of medical professionalism since the 19th century, hasn't been immune to this evolution. Its traditional acoustic counterpart, while invaluable, presented constraints in terms of sound clarity, susceptibility to ambient interference, and lacked the capability for longitudinal data recording [16].

The advent of digital stethoscopes marked a watershed moment in auscultatory practices. By incorporating electronic components, these devices promised—and often delivered—superior auditory fidelity, adeptly filtering out extraneous noises and enhancing the salience of crucial cardiac sounds [17]. Beyond mere amplification, the transformative aspect of digital stethoscopes lay in their ability to interface seamlessly with computational platforms. This not only facilitated real-time visual representation of cardiac acoustics but also opened avenues for persistent data storage, rendering sporadic health assessments a continuum of insightful cardiac monitoring [18]. While the foundational principle of listening remained unchanged, the digital shift accentuated the depth, clarity, and analytical potential of this time-honored diagnostic ritual.

### C. Machine Learning in Healthcare: A New Frontier

In the lexicon of contemporary healthcare, machine learning (ML) has rapidly ascended as a transformative force. This subset of artificial intelligence, distinguished by its capacity to autonomously evolve through data-driven insights, has opened vistas of opportunities across myriad medical domains [19].

The allure of ML in healthcare is multi-faceted. Central to its appeal is its profound capability for pattern detection, particularly salient in complex datasets where nuanced anomalies might elude human analysis [20]. Such pattern-recognition prowess has been harnessed in diverse medical terrains, from the precision of radiographic interpretations to the predictive capabilities in patient prognosis [21].

With phonocardiographic data being inherently intricate, laden with auditory subtleties indicative of potential pathologies, ML's integration in this domain has emerged as a promising frontier [22]. While the potential of machine learning is vast, its implementation in healthcare isn't merely a technological endeavor; it represents a confluence of computational excellence and clinical acumen, aspiring to reshape the contours of patient-centric care in the digital age.

### D. Integrating Machine Learning with Phonocardiography: Preliminary Endeavors

The synergy between phonocardiography and machine learning (ML) stands as an epitome of interdisciplinary convergence in modern medical research. Historically, phonocardiography, with its graphic representation of cardiac sounds, provided a tangible avenue for detailed acoustic analysis, albeit demanding meticulous human interpretation [23].

The proposition of integrating ML into this domain was fueled by the algorithmic promise of discerning intricate patterns and anomalies within these auditory datasets. Initial scholarly forays were primarily anchored in leveraging ML for extracting salient features from phonocardiographic recordings, differentiating normative heart rhythms from their pathological counterparts [24].

Subsequent research endeavors cast a wider analytical net, navigating the complexities of diverse cardiac anomalies and iterating across a spectrum of ML algorithms to optimize diagnostic accuracy [25]. Notwithstanding the promise these preliminary investigations showcased, they were often hamstrung by challenges—primarily, the quality of the phonocardiographic inputs, which were at times marred by environmental interferences or sub-optimal recording devices. Yet, these early ventures underscored the potential of this amalgamation, paving the way for the sophisticated diagnostic methodologies we envision today.

### E. Challenges and Opportunities: A Synthesis

While the confluence of digital stethoscopes and machine learning augurs well for cardiac diagnostics, challenges abound. Data privacy, especially with digitized medical records, remains a concern [26]. Additionally, ensuring algorithmic transparency and explicability in healthcare is paramount, given the stakes involved [27].

On the flip side, opportunities for this interdisciplinary venture are vast. Beyond mere diagnostics, there's potential for predictive analytics, long-term cardiac health monitoring, and even integration with telemedicine platforms, paving the way for remote diagnostics and consultations.

The literature underscores a clear trajectory: from the rudimentary act of listening to heart sounds to harnessing advanced computational tools for intricate cardiac sound analysis. The marriage of digital stethoscopes with machine learning isn't just the next step in this evolution, but potentially a giant leap, promising a future where heart disease detection is more precise, timely, and democratized.

### III. CHARACTERISTICS OF HEART SOUNDS

The cardiac sounds S1 and S2 predominantly fall within the high-frequency spectrum, optimally discerned using the diaphragm aspect of a stethoscope. A typical S1 frequency ranges from 50 to 60 Hz, while an S2 usually varies between 80 to 90 Hz [28]. On the other hand, S3 is characterized as a low-amplitude, pre-diastolic signal with a frequency band approximating 20-30Hz. S4, manifesting towards diastole's conclusion, is perceptible distinctly when utilizing a stethoscope. A deviant S4 resonates at frequencies below 20 Hz [28].

While S1 and S2 are generally detectable, their amplitude displays variability. In certain instances, due to underlying cardiac abnormalities, their audibility might be compromised. It's noteworthy that S1 and S2 do not resonate at constant frequencies but fluctuate across different cardiac cycles. These intrinsic complexities in cardiac sound demarcation have spurred scholars to architect specialized analytical methodologies [28].

Fig. 1 delineates the comprehensive categories and roles of HSs. Typically, each cardiac ailment is associated with one or two HSs. Certain anomalous heart sounds manifest as an elevated frequency noise subsequent to the primary tricuspid stenosis (TS) sound. Notably, the ejection sound (ES) is a prevalent early systolic noise, attributed to the abrupt halting of the semilunar cusps as they initiate their movement in early systole. During mid-systole, the mid-systolic click (MSC) emerges due to the abrupt cessation of prolapsing mitral valve leaflets' movement into the atrium, restrained by chordae [29].

Clinicians pay heed to these atypical cardiac sounds, recognizing their potential in providing diagnostic insights.

Fig. 1. Heart sounds.

### IV. ELECTRONIC STETHOSCOPE STRUCTURE

Fig. 2 presents a conceptual framework of the envisaged stethoscopic apparatus incorporating machine-learning methodologies. Heart sounds, as captured by the stethoscope, undergo amplification and filtration via an analog interface prior to their digital conversion and relay to the analytical subsystem. It's imperative for this analog interface to exhibit a superior signal-to-noise quotient, efficient common-mode suppression, and minimal baseline deviations or saturation tendencies. The pre-amplification mechanism enhances the subtle cardiac acoustic signals, initially picked up by the microphone, to a more discernible magnitude.

Fig. 3 delineates the architecture of a computer-integrated cardiac monitoring apparatus leveraging an electronic stethoscope, compartmentalized into three pivotal segments: data acquisition, pre-processing, and signal analysis. The electronic stethoscope actively records heart sounds (HS), subsequently digitized by the pre-processing segment. Within this segment, the full-frame HS signal, having undergone noise mitigation and interference reduction, is both normalized and partitioned. Signal analysis tools undertake the tasks of feature extraction and pattern categorization. The resultant structure culminates in clinically-informed diagnostic determinations. An exhaustive breakdown elucidating the intricacies and sub-components of these principal sections is provided.

#### A. Heart Sound Acquisition

Heart Sound Data Acquisition Module. The initial phase of heart sound retrieval yields automated cardiac acoustic data, serving as the foundation for subsequent processing stages.

Electronic Stethoscope Sensory Mechanism. Patient-derived cardiac acoustics are captured via a digital stethoscope, as illustrated in Fig. 4. Within this apparatus, some may employ a digital audio mechanism, a piezoelectric plate, or an aerodynamic suction module. This instrument then converts the heart's electrical impulses into auditory signals.

Fig. 2. Diagram of the proposed heart disease detection system.

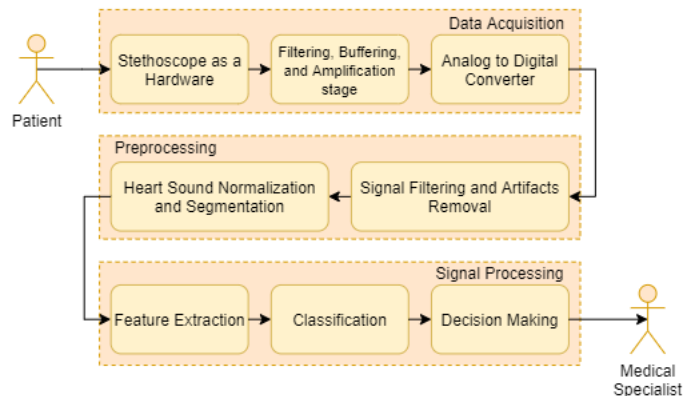

Fig. 3. Typical flow chart for heart sound signal acquisition, processing and analysis.

Fig. 4. Electronic sensor stethoscope.

**Amplification and Filtration Mechanism.** In diverse communication frameworks, amplification and filtration instruments are indispensable. To mitigate noise disturbances originating from power sources, a low-pass filter is employed. Subsequently, an anti-aliasing filter is integrated to reduce potential aliasing effects. Within specific system blueprints, the filtration mechanism is conceptualized as a low-pass filter, tailored to encompass the frequency spectrum of most rapid cardiac acoustics. Band-pass filtering is invoked for passband delineation, effectively countering aliasing. Post amplification, the signal undergoes digitization through an analog-to-digital transformation.

**Analog-to-Digital Transduction.** This component effectively transmutes analog signals into their digital counterparts. The parameters for this conversion can be predetermined by the equipment fabricator. Elevated bit rates and sampling frequencies can augment precision, all while economizing on bandwidth and energy consumption.

### B. Data Collection

In this stage, the digital cardiac acoustic signal undergoes reduction, standardization, and segmentation.

**Denosing Mechanism.** Typically, a digital filtration system is employed to isolate the desired signal from its embedded noise within the pertinent frequency domain. Advanced denosing methodologies are generally adopted to enhance the signal-to-noise ratio (SNR), thereby furnishing the apparatus with superior noise attenuation capabilities.

**Normalization and Cycle Division.** Diverse sampling points and processing locales often introduce variances in the captured signal during data acquisition. Consequently, cardiac sound signals undergo normalization to a predetermined scale, ensuring that data acquisition positions and multiple samples do not skew the anticipated amplitude of the signal. Post-normalization, these signals are partitioned into distinct cycles, priming them for component recognition within the heart sound and subsequent feature extraction.

### C. Heart Sound Signal Processing Module

During this phase, feature delineation and categorization activities are undertaken.

**Feature Delineation.** Signal manipulation necessitates the conversion of analog information into a digital paradigm. Such

a parametric portrayal is subsequently harnessed for in-depth analyses and applications.

**Categorization Mechanism.** After the amassed features are integrated into a classification system, it serves as a tool for data discernment, aiding healthcare practitioners in diagnostic determinations and therapeutic strategy formulations.

The processor core hubs, as depicted in Fig. 4, constitute the primary entities of an apparatus equipped to handle the digitized signal and its ensuing processing. From our meticulous investigations, it became evident that the discourse predominantly gravitates towards three pivotal phases concerning the automated identification of varied cardiac anomalies and acoustic signal afflictions: (1) Heart Sound (HS) data capture and sensory blueprinting, (2) noise attenuation and cardiac sound signal partitioning, and (3) proficient feature extraction coupled with autonomous HS analysis.

## V. PROPOSED NETWORK

For a nuanced evaluation of heart tones—encompassing rhythm, boundaries, duration, and intensity—a robust database is paramount. We curated a dataset, drawing samples primarily from heart failure patients, notably those affiliated with the Cardiology Department of the Almaty Cardiology Center. Heart tone biometric measurements were captured using an electronic stethoscope. For each individual, quintuple recordings were procured from the cardiac apex, as visualized in Fig. 5.

Ensuring database integrity is crucial for efficacious model training. Consequently, only the cardiac tones from individuals with clinically validated heart conditions were cataloged.

### A. Detection of Special Characteristics

Feature delineation serves to illuminate the distinct attributes of heart tones, facilitating differentiation of standard and anomalous cardiac sounds. An algorithm tailored for this extraction was conceived using Python, a choice made for its adeptness at signal processing functions. This algorithm, spanning eight meticulous steps, is poised to extract a rich set of attributes from a singular cardiac sound. This richness ensures individualized representation of each patient during the optimal analysis phase. It leverages a series of preset resolutions and thresholds to perform an in-depth analysis of cardiac acoustics.

Fig. 5. Working principle of the smart stethoscope.

Fig. 6. Key components of cardiac sound [30].

Prevailing academic sources provide methodologies to discern the cardinal components of heart sounds, notably the primary cardiac signal (S1) and the secondary tone (S2), as well as to demarcate the boundaries of S1, S2, systole, and diastole (as depicted in Fig. 6).

In the inaugural step, a standardized root-mean-square trajectory spanning a duration of 10 seconds is derived. Given the inherently transient nature of heart sounds, 10-second segments are extracted from the primary recording to circumvent the omission of sporadic features dispersed within anomalous heart sounds. Subsequent to this, consistent RMS energy trajectories of the procured segments are crafted, primarily to accentuate the peaks of S1 and S2 whilst concurrently diminishing noise perturbations.

Step 2: Peak Recognition. The primary objective was to distinguish prominent peaks between S1 and S2 tones. Parameter resolution was employed to discern these peaks. In the event that inter-peak distances failed to align within a stipulated range, the identification process was iteratively revisited, altering the resolution to secure a consistent peak count. This iterative mechanism [31] acknowledges the variability in heart tone frequencies across individuals, correlating the resolution to each individual's unique heart rhythm. Hence, a myriad of resolutions is assessed for each cardiac sound until an optimal fit is established.

Step 3: Demarcation of Dominant Peaks. Initial steps involved assessing zero-crossings at the stipulated threshold, subsequently mapping approximate peaks for the upper boundary. If the segmented peaks did not achieve satisfactory numbers, the algorithm looped back, using a divergent resolution for prominent peak identification.

Step 4: Identification of Minute Peaks. Waves trapped between the demarcated dominant peak boundaries were analyzed, with the zenith of each wave being recognized as the minor peak. Disparities between these minor peaks and their corresponding dominant peaks were assessed. Adjustments were made if deviations exceeded acceptable ranges, and the process cyclically reverted to the dominant peak phase if necessary [32].

Step 5: Minor Peak Segmentation. Zero-crossings of the waves within the dominant peak boundaries were examined in relation to the identified minor peaks. Should any discrepancies arise in the demarcation of minor peaks, thresholds were adjusted and the segmentation was re-evaluated.

Step 6: Temporal Estimation & Validation. Consolidating prior findings, peaks were chronologically arrayed, both in terms of prominence and brevity. Rigorous validation ensured the elimination of any misaligned or overlapping peaks. In scenarios where peak counts were suboptimal, the protocol reverted to the dominant peak classification stage. This loop, targeting absolute accuracy, was exceptionally applied to cardiac tones heavily masked by noise.

Step 7: Categorization of Cardiac Tones. All segregated segments and intervals were labeled as S1, S2, systole, or diastole, resonating with the observation that systolic duration typically undercuts diastolic intervals in heart sounds.

Step 8: Feature Derivation. Post the validation process, features were distilled solely from those samples that met the requisite criteria.

### B. Applying Machine Learning for Abnormal Heartbeat Detection

Fig. 7 elucidates the amalgamation of the classification architecture alongside the signal pre-processing schematic, further incorporating machine learning methodologies. The procured heart sound data was bifurcated into datasets earmarked for model calibration and evaluation. Employing Python, both signal refinement and autonomous segmentation were executed, leading to the statistical analysis and the machine learning-driven training and categorization of cardiac tones. An overview of these pre-processing activities is delineated in the subsequent section. From the partitioned cardiac audio data, a plethora of attributes was extracted spanning time (t)-domain, frequency (f)-domain, and Mel frequency cepstral coefficients (MFCC). Prior to its introduction into the machine learning paradigm for assessment, the designated training dataset was subjected to a series of pre-processing stages.

Fig. 7. Machine learning-based heart sound abnormality detection.

For the purpose of categorization, we employed the k-nearest neighbor (k-NN) classifier. Within this study, the number of neighbors and distance served as pivotal hyperparameters. Upon the meticulous extraction and mitigation of noise from the signals, we proceeded with heart sound identification. As previously highlighted, the dataset was divided, allocating 200 atypical heart sounds juxtaposed with 200 typical ones. Concurrently, the dataset was apportioned into 80% for training and 20% for testing.

The dataset bifurcation catered to two primary subsets: a training dataset and a validation dataset. The former educates the machine learning architecture utilizing samples furnished with benchmark values, aiming to curtail potential errors. In contrast, the latter evaluates the model's efficacy on previously unencountered samples, ascertaining the model's applicability to novel data. For the preliminary analysis encompassing 12 subjects, the training subset comprised 48 impulse responses, while the validation subset accounted for 46.

### C. Classification of Heart Sounds

For real-time execution, the cardiac audio data was subjected to a 10-second buffering [33-34], subsequently undergoing baseline drift rectification, segmentation into individual cardiac beats, and filtering within a specified bandwidth using Python 3.5. A multi-threaded script, penned in Python, was developed to facilitate the acquisition, buffering, real-time preprocessing, and identification of cardiac audio

data on the primary computing device. Signal preprocessing and segmentation tasks were executed on a personal computer, leveraging libraries such as Numpy, scikit-learn, and Matplotlib. The most efficacious algorithm, identified through benchmarking, was then instantiated on the personal computer for real-time classification, employing both PyBrain and Scikit-learn libraries.

## VI. EXPERIMENTAL RESULTS

### A. Hardware

The rapid advancement of mobile technologies paves the way for enhancing routine healthcare practices. Potential applications encompass leveraging mobile gadgets for clinical data collection, provisioning diagnostic information to physicians, researchers, and patients, real-time monitoring of patients' vital signs, and facilitating immediate healthcare interventions.

The designed system prioritizes minimalism, encompassing just three essential components: a stethoscope, a dedicated smartphone application, and a compact device. Within the stethoscope's chamber, an electronic microphone is strategically positioned for sound capture. To attenuate extraneous noise, all other extremities of the hose are sealed, barring the intake section. Fig. 8 delineates the constituent elements of the conceptualized stethoscope.

Fig. 8. Components of the proposed stethoscope.

Fig. 9 presents a comprehensive illustration of the systematic process employed for the identification of cardiac anomalies using a mobile device, following the acquisition of the heart's acoustic imprints via a stethoscope.

The initial phase entails a meticulous analysis of the audio signals captured from the stethoscope. This is succeeded by the application of a refined algorithm specifically designed to discern and neutralize extraneous ambient noise. Transitioning to the subsequent stage, a detailed classification protocol is employed to interpret these processed signals. Culminating this sequence, the analysis yields insights, upon which a potential diagnostic recommendation is formulated, providing a holistic understanding of the cardiac state.

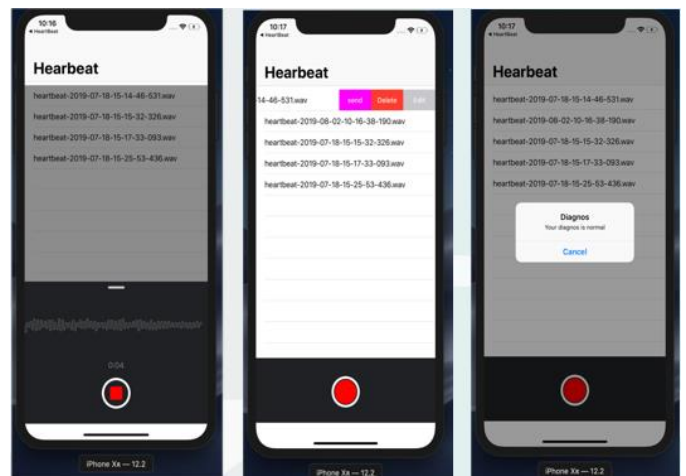

Fig. 9. Heartbeat abnormality detection process.

B. Classification Results

Fig. 10 depicts various cardiac acoustic patterns. These include: Normal: Typical sounds indicative of a healthy heart. Murmur: Additional auditory phenomena resulting from perturbations in blood flow, producing discernible vibrations. Extrahls: An ancillary auditory signature. Artifacts: A diverse array of distinct auditory emissions.

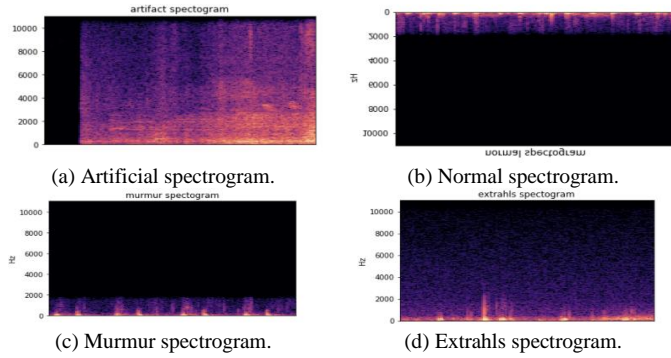

Fig. 10. Time domain PCG trace and its power spectral density for different types of heart sounds.

Fig. 11 depicts the training and validation processes utilized for the identification of atypical heart rhythms. This representation provides insights into both training and validation accuracy metrics over a span of 300 epochs. In Fig. 12, the evolution of training and validation loss metrics across the training epochs is showcased. Notably, post approximately 100 epochs, both the training and validation losses appear to stabilize.

Fig. 11. Model training and validation for abnormal heartbeat detection.

Fig. 12. Model training and validation for abnormal heartbeat detection.

Fig. 13 presents a confusion matrix detailing the classification outcomes for five distinct cardiac conditions: normal heartbeat, murmur, extrasystole, extrahls, and artifacts. The findings underscore a commendable level of precision in classifying cardiac sound patterns and pinpointing abnormal heart rhythms.

Fig. 13. Confusion matrix.

VII. DISCUSSION

The examination of heart sounds, especially as an early diagnostic tool, has been a significant area of interest in cardiological research. This study's central tenet sought to harness the technological capabilities of today's world, combined with the intricacies of cardiac acoustics, to devise a model that could reliably identify and classify abnormal heart rhythms.

One of the most notable findings of this study was the efficacy with which the model was able to delineate between different heart conditions. With the increasing prevalence of cardiovascular diseases globally, having an accessible and precise diagnostic tool can potentially revolutionize cardiac care, especially in areas where specialized cardiac care remains elusive. The use of smartphones, as indicated in this research, points towards a trend in telemedicine and mobile health (mHealth) solutions, which have gained substantial traction over recent years.

The study's multi-step approach, starting from data collection using an electronic stethoscope to signal preprocessing, feature extraction, and final classification, ensured a comprehensive review of the heart sounds. The detailed steps, as represented in the figures, allow for a meticulous understanding of how the model refines and uses the data. This approach is essential, especially given the critical nature of the data in question; heart sounds are not only diverse but also nuanced.

One of the primary challenges faced in many similar studies is the noise interference in heart sound recordings. Our methodology, which incorporated sophisticated noise reduction techniques, was able to significantly improve the signal-to-noise ratio (SNR). The pre-processing of heart sound signals, as delineated in our study, presents a robust method of ensuring the integrity of the data, further enhancing the model's reliability.

The utilization of Python, a versatile and widely adopted programming language, underscores the scalability and adaptability of the proposed method. The integration of multiple libraries like Numpy, scikit-learn, and Matplotlib not only facilitated rigorous data processing but also ensures that the model can be integrated or adapted into various other platforms or studies.

The training, testing, and validation datasets' demarcation ensures that the model is not just accurate but also generalizable. Often, machine learning models might overfit to the training data, making them less reliable when exposed to new, unseen data. Our model, after undergoing rigorous training and validation, demonstrated a commendable degree of accuracy, pointing towards its robustness.

However, it is also essential to note the limitations of this study. The presented model, while advanced, is primarily dependent on the quality of the initial recordings. Factors like the positioning of the stethoscope, the ambient environment, and the patient's physical condition can introduce variances in the recorded sounds. Furthermore, while the study encapsulated multiple heart conditions, there remains a wide variety of cardiac anomalies, each with its unique acoustic signature, which might not be entirely accounted for in this research.

Additionally, while smartphones and mobile applications promise a more democratized healthcare landscape, their efficacy is inherently tied to factors like smartphone penetration in a region, digital literacy, and the reliability of digital infrastructures. Hence, while the model offers promise, its large-scale application would require a more ecosystem-driven approach, ensuring that all potential bottlenecks are addressed.

In conclusion, the presented research underscores the potential of merging technology and cardiology, offering a glimpse into the future of cardiac diagnostics. The methodology, marked by its rigor and attention to detail, sets a precedent for further studies in this domain. Future research might look into integrating more varied heart sound datasets, exploring the potential of real-time diagnostics, and even combining this acoustic data with other diagnostic metrics for a more comprehensive assessment. The horizon of cardiac care, augmented by technology, seems promising, and this research serves as a beacon in that journey.

## VIII. CONCLUSION

This research undertook the ambitious endeavor of bridging the realms of advanced technological tools with the intricate field of cardiology, underscoring the transformative potential such intersections hold for modern medicine. The primary focus was the identification and classification of heart sounds, tapping into the ever-evolving capabilities of machine learning and the widespread accessibility of smartphones.

The developed model, as showcased in this study, demonstrated notable accuracy in deciphering and distinguishing between various heart conditions. These findings are of paramount importance, especially considering the global rise in cardiovascular diseases and the resultant need for accessible, accurate, and timely diagnostic tools. The utility

of a smartphone-based diagnostic mechanism extends beyond mere convenience; it potentially democratizes cardiac care, paving the way for early interventions even in areas bereft of specialized healthcare infrastructures.

However, it is essential to recognize that while the results are promising, the journey is only just beginning. The marriage of technology and healthcare, though filled with potential, also demands a rigorously holistic approach. Factors ranging from the quality of data acquisition to the challenges associated with the mass adoption of smartphone-based medical tools must be addressed for this research's broader implications to fully materialize.

In summary, this study has laid down a robust foundation, emphasizing the confluence of technology and cardiology as a potent avenue for future research and applications. As we look ahead, it becomes evident that the future of cardiac care, supported by technological innovations, has the potential to reshape healthcare landscapes, making diagnostics more accurate, accessible, and timely. This research stands as a testament to that potential, signaling an exciting trajectory for both cardiac care and medical technology.

# Predicting the Level of Safety Feeling of Bangladeshi Internet users using Data Mining and Machine Learning

Md. Safiul Alam, Anirban Roy, Partha Protim Majumder, Sharun Akter Khushbu

Department of Computer Science and Engineering, Daffodil International University, Dhaka, Bangladesh

**Abstract**—An amazing combination of cutting-edge data mining and machine learning methodologies to predict the level of safety feeling among Bangladeshi internet users, which is a significant departure in this subject. By leveraging cutting-edge algorithms and innovative data sources, this work provides previously unheard-of insights into how this demographic perceives online safety, shedding light on an essential yet underappreciated aspect of their digital lives. This exceptional study's original research increases the body of knowledge of online safety and sets the road for policy recommendations and intervention tactics that will enable Bangladesh to become a global leader in internet security.

**Keywords**—Bangladesh; data analysis; data mining; important factors; machine learning; prediction; performance evaluation metrics; safety level

## I. INTRODUCTION

Every day, more people are using the internet than ever before, all over the world [1]. This rate is increasing in Bangladesh too [2]. Because recently Bangladesh has seen growth in internet usage [3]. At present, the Internet has become a massive part of people's daily lives in Bangladesh [4]. As a result, communication, business, education, banking, service, jobs, etc. are turning online day by day in Bangladesh [5]. In March 2021 Internet users in Bangladesh increased to 116 million whereas the population of Bangladesh at the time was 167 million which means 70% of the population had access to the internet [6]. People want to feel safe, secure, and devoid of any bullying, harassment, and illegal activity when using the internet [7]. According to a UNICEF survey, 32% of Bangladeshi children, aged 10 to 17, are familiar with and have encountered online abuse, harassment, and cyberbullying. 25% of them have access to the internet by the age of 11. Additionally, according to a Telenor Group and Grameenphone report, online bullying is a serious problem for 85% of Bangladeshi youngsters. According to the report, 18% of them experienced worse bullying as a result of the shocking COVID-19 epidemic [8]. So, it is very important to know people's safety feelings at the time of using the internet [9]. The advent of the digital era has created possibilities and challenges never before experienced, altering how people connect, communicate, and access information throughout the globe. As the internet continues to permeate every area of our daily lives, online safety and security have become a huge concern [10]. For that it is essential for the user to feel safe while using the internet [11]. There is a great depiction of an

accurate prediction of an individual's safety level at the time of using the internet is indispensable with prior knowledge about the important factors, which have a great impact [12]. Moreover, it is necessary for private and public organizations, industries, banks, and IT companies to find out people's safety level at the time of using the Internet [13]. Because it will make their services more secure and effective [14]. In that case, safety level prediction will act as a guide to making an appropriate safety level which has been fulfilled in this research.

This work closes a huge knowledge gap that has mostly gone unfilled up to this point. Despite the abundance of research on online safety, there are surprisingly few that focus on the unique viewpoints and experiences of internet users in Bangladesh [15]. Because of its geographical emphasis and dedication to illuminating the intricacies of online safety in the context of Bangladesh, this study is a pioneering effort that stands out [16]. This work's significance extends beyond the sphere of academic research; it has a significant impact on Bangladesh's evolving digital ecosystem and tackles urgent problems that have not yet been fully investigated [17]. This groundbreaking study demonstrates its importance in a number of ways. In the age of digital transformation, where internet access is nearly widespread, it is imperative to provide Bangladeshi internet users with the knowledge and tools they need to properly navigate the online world [18]. By predicting people's safety feelings and fostering a sense of control and confidence in the face of online hazards, this study strengthens people's agency in safeguarding their digital experiences [19]. For Bangladeshi internet service providers, regulators, and legislators, the novel approach of this study offers a once-in-a-lifetime chance to tailor safety measures and actions [20]. Knowing the specific factors influencing safety feelings may help them develop more effective strategies and policies that match the local context, which will eventually lead to a safer online environment. The integration of data mining and machine learning in this study has increased the prevalence of data-driven decision-making in the area of internet safety. The efficacy of organizations and authorities may be improved by using the information gathered from this study to assist them in allocating resources and choosing initiatives based on actual evidence. The lack of study on the perspectives of Bangladeshi internet users on online safety highlights the novelty and significance of this endeavor [21]. This study investigates an understudied area, filling a large gap in the literature and setting the stage for future studies that have an

emphasis on regional and local variability. As Bangladesh embraces digitization, developing a culture of cybersecurity becomes increasingly important [22]. This work has the potential to promote best practices among internet users, academic institutions, and businesses by igniting dialogues on online safety. Also, this study combines data mining and machine learning, fusing cutting-edge technology with real-world applications. The innovative approaches adopted might serve as a paradigm for future studies on the intersection of data science and cybersecurity in Bangladesh and elsewhere in the world [23]. Even though this study's findings are anchored in the context of Bangladesh, they may still be applicable to other developing nations that are going through rapid digitalization [24]. This research's importance transcends national boundaries since the technique and results developed here may be changed and applied in similar situations. There isn't a single, universal approach to online safety [25]. This unique piece of work is actually innovative since it allows for the customization of safety precautions. By anticipating Bangladeshi users' safety attitudes and allowing interventions and assistance to be personalized to individuals' particular concerns and experiences, online safety is made more pertinent and effective. It also reveals the attitudes and beliefs of Bangladeshi internet users, shedding light on a hitherto unresearched facet of online safety. This highlights the emotional and intangible aspects of cybersecurity that are occasionally overshadowed by technology solutions [26]. By detecting and evaluating these emotions, this approach improves our understanding of the human side of cyber security. The originality of this work opens the door for future research initiatives that focus on the feelings and experiences of internet users in a variety of contexts. It sets a precedent for appreciating the importance of the human element in cybersecurity and might ignite a larger conversation about the psychological aspects of online safety [27]. Along with being creative, it may help the Bangladeshi online community understand online safety by making it more pertinent, relatable, and human.

Additionally, this approach combines the strengths of machine learning and data mining. By exploiting the capabilities of this cutting-edge technology, the research proposes a creative way of predicting safety feelings that are tailored to the Bangladeshi environment. Combining these methods should result in conclusions that are more accurate, and practical, and represent a novel contribution to the field of internet safety.

Data mining and machine learning, a subfield of artificial intelligence (AI), employ statistical techniques to give computers the capacity to learn from data and improve their performance on certain tasks [28]. Data mining and machine learning are used to enable learning and inference across a heterogeneous mix of devices, including PCs, smartphones, IoT devices, and edge devices [29]. A data mining and machine learning probabilistic system is a complex tool that may be used to evaluate obtained data, provide predictions or judgments based on that data, and then present those findings to the user [30].

As Bangladesh continues its journey toward digital transformation, the findings of this study have the potential to

inform governmental decisions, empower internet service providers to enhance user safety, and ultimately create a more secure online environment. By bridging the gap between data-driven insights and the specific problems faced by Bangladeshi internet users, this research provides a groundbreaking contribution to maintaining the online experiences of an expanding online community. Here, emphasis has been given to the analysis of some empirical factors of an individual's data to perform the safety level prediction.

In this research, safety level predictions have been done and several factors behind this have been analyzed. Moreover, extensive research and analysis have been conducted. Here, several data mining techniques have been applied for experimentation, and several performance evaluation metrics to evaluate this work. Twelve popular data mining classifiers, including Logistic Regression, MLP, KNN, Decision Tree, Naive Bayes, Search Vector Machine, Gradient Boosting, Linear Discriminant Analysis, Stochastic Gradient Descent, Ada Boosting, Bagging, and Random Forest, have been experimented with on a survey dataset. Several performance evaluation metrics have been calculated to determine the best classifier in the working context, and a result comparison is presented here. From the analysis of the obtained result, it is confirmed that the Decision Tree classifier achieves the best result in terms of metrics.

These are the order of this paper: Section II gives an exhaustive overview of relevant studies. The study methodology is presented in Section III along with a brief overview of the dataset, data analysis, implementation process, classifiers, the outcome of the experiment, and additional findings while the conclusion is given in Section IV. Finally, Section V provides future work.

## II. LITERATURE REVIEW

The ultimate purpose of this research work is to the safety level of the user. After going through several articles, it is discovered that there has been no existing work like this done before. However, it has been unable to locate a compass in the large ocean of scholarly works that might direct us through the uncharted area of understanding how Bangladeshi internet users view their online safety [31]. This absence emphasizes the originality and importance of this research, which aims to address this important gap and improve not only the scholarly community but also the daily lives of countless Bangladeshi internet users [32]. The awareness that addressing the safety concerns of internet users goes beyond academic study and constitutes a necessary first step in establishing a more secure and safe online environment for everyone has steered this research down an innovative route [33]. To implement this unique model, some papers have been studied. All of them are described below as per the research paper's theme:

Syeda et al. [34] applied seven approaches of data mining i.e. KNN, Decision Tree, SVM, NN, Naive Bayes, Logistic Regression, and Random Forest to predict user satisfaction and dissatisfaction. They have taken different parameters which are produced with high accuracy. The accuracy for KNN, Decision Tree, SVM, NN, Naive Bayes, Logistic Regression and, Random Forest were 96%, 93.33%, 93.3%,

86%, 89.3% and, 96%. Though the highest accuracy is achieved by three algorithms, they have chosen Random Forest because it shows better precision, recall, and f1 score rather than others.

In order to identify phishing websites, Kaytan et al. [35] suggested a clever model based on extreme learning machines. Website forms differ from one another in terms of how they perform. Therefore, they must make use of special web page features to prevent phishing assaults. Additionally, they proposed a template based on computer training methods for identifying phishing web pages. The model has one output and 30 inputs. In this application, the 10-fold cross-validation test was run. The classification's total accuracy was 95.05 percent.

Salehin et al. [36] Karim advocated combining LSTM and artificial intelligence to produce a straightforward rainfall forecast model. The correctness of the deep learning approach is essential for this manner of application has been established. They used 6 parameters in their article. The accuracy was increased to 76% by looking at all the data integrating LSTM and artificial intelligence to produce a straightforward rainfall forecast model. They used 6 parameters in their article. The accuracy was increased to 76% by looking at all the data.

Salehin et al. [37] recommended utilizing RHMCD as a model to assist machine learning algorithms accomplishes the intended goal. Naive Bayes classifiers, logistic regression, and support vector machines are the algorithms that were tested. The sentiment analysis method was employed to gather information on mental health issues. The amount of depression was assessed using the decision tree method.

Salehin et al. [38] predicted the severity of depression caused by excessive cell phone use. Depression is detected using the Linear Regression technique and two machine learning algorithms, decision trees.

Technologies for agriculture have been created by Salehin et al. [39]. Various viral, fungal, and bacterial illnesses result in a significant loss of agricultural produce. In this research, they categorize crop situations based on various datasets by using the Scale Invariant Transform Feature (SIFT) technique. Finally, the solution was made available through live online portals and SMS services.

Talha et al. [40] draw attention to the significant drawback and its many root causes, including emotional instability, despair, stress, and loneliness. Physical, virtual, and medical reports were the three approaches that were used to collect the data. The detrimental impact of human behavior is demonstrated by the 71% optimistic theorem of Naive Bayes. For measurement purposes in search vector machine (SVM), negative and positive parameters are set. Last but not least, they compare the outcomes of our suggested specialization to those of the three fundamental points of reference.

Syeda et al. [41] used educational data mining to forecast the pupils' success. The entirety of the projection was based on the students' current location and general academic standing.

Yeasin et al. [42] suggested using the data mining approach to forecast students' careers. Only CS grads have had this task completed for them. They used a number of classifiers, and the accuracy varied according on each classifier. Just 506 data records were used in this study, and no distinct training or testing datasets were indicated.

Alonzo et al. [43] provided a thorough analysis of how different machine learning algorithms are used to predict and rate the quality of coconut sugar.

Perez et al. [44] provided examples of the findings from a case study on educational data analytics that was focused on identifying undergraduate students majoring in systems engineering who had dropped out after six years of attendance. Their experimental findings demonstrated that straightforward algorithms may identify dropout predictors with sustained levels of accuracy. Here, the output of four algorithms—decision trees, logistic regression, naive bayes, and random forest—was examined to suggest the best course of action. The major findings are presented here to lower the dropout rate by identifying probable causes. In addition, they provided some evaluations of the data's quality to help the students refine their data collection techniques.

With the purpose of resolving the dropout prediction problem, Mi et al. [45] developed different temporal models. Specifically, based on substantial research conducted with a few massive open online courses (MOOCs) accessible through edX and Coursera. They claimed that one logical improvement to the model, which would include a max pooling layer before the output layer, would further their work. They anticipated that their model's expansion would increase its robustness.

Aksenova et al. [46] reported an enrollment prediction research that uses support vector machines and rule-based predictive models with the aim of predicting the overall enrollment headcount, which is made up of continuing, returning, and new (freshman and transfer) students. The core prediction findings are generated using a machine learning approach called SVM, which is then applied by a program called Cubist to create simple rule-based predictive models. Lastly, they provided some experimental findings about the forecasting of student enrolment.

### III. METHODOLOGY

This section is parted into Data Description, Data Collection, Data Preprocessing, Data Analysis, Classifier Description, Implementation Procedure, Result and Discussion, and Evaluation. This section basically presents the approach taken to accomplish this work.

Fig. 1. Methodology diagram.

For this work, several steps have been performed, as presented in Fig. 1. A detailed description of all the subsections is presented below.

### A. Data Description

Information that approximates and characterizes is referred to as qualitative data. It is possible to notice and document qualitative data [47]. In statistics, qualitative data is sometimes referred to as categorical data since it can be categorized based on the characteristics and traits of an object or phenomenon [48]. Any information that can be quantified and employed in statistical or mathematical calculations is referred to as quantitative data [49]. Making judgments in real life using mathematical inferences is aided by this type of data [50]. So, in this work, all the data are qualitative before preprocessing, and after preprocessing, they are converted to quantitative data for analysis and to build a machine learning model for prediction. A decision has been made after evaluation.

### B. Data Collection

Data is survey-based data. The survey has been performed. Most of the data has been collected by physical survey and some of the data has been collected through an online survey. A total of 5,321 individual records are used here to accomplish this work. The survey mainly consists of 8 questions.

### C. Data Preprocessing

After checking for null values, it has been found that there have been no missing values in the dataset as all the answers to the 8 questions have been obtained from the respondents and the information has been carefully compiled to make the dataset. Fig. 2 shows that there are no missing values. The data type information has been checked, and it has been observed that 6 columns have object-type values. The label encoding pre-processing technique has been used to convert these object-type values into numeric. Among the 8 questions, 7 questions

Fig. 2. Heatmap for checking null values.

Fig. 3. Correlation matrix.

(How safe you feel about your information, when you are online? How safe you feel about your information, when you are messaging? How safe you feel about your information, when you are e-mailing? Do you feel unsafe in online banking? What is your age? How much time you use internet on a day (in hours)? which area do you live in?) This has been used as the independent variable and only one question (Safety\_Level) has been used as the dependent variable.

To prevent overfitting, the dataset has been split into training and testing sets. The correlation of the independent variables in the training dataset has then been determined, as shown in Fig. 3. A total of 73% of the data has been used for the training of the classifier and 27% has been employed for testing purposes. To retrieve appropriate attributes, a threshold value of 0.78 has been set. Using this value, it has surprisingly been found that the 8 features that have been used as the independent variables do not need to be changed.

D. Data Analysis

Data analysis is the process of cleansing, converting, and modeling data to discover useful information for commercial decision-making. The goal of data analysis is to gather useful data and make decisions based on that analysis. When determining what is occurred most recently in real life or how something plays out when making a certain decision, a simple illustration is provided of how the data is interpreted.

In a survey of 5,321 respondents, it is discovered that 31.20% of individuals feel extremely safe about their information when they are online, 32.14% of people feel no safety at all, and 36.65% of people feel poor safety about it. These results are depicted in Fig. 4.

Fig. 5 shows the results of a survey of 5,321 people, which is revealed that 35.38% of respondents feel only moderately safe about their information when messaging, 32.33% of respondents feel no safety at all, and 32.29% of respondents feel extremely safe about their information when messaging.

Fig. 6 illustrates the results of a survey of 5,321 respondents, which is surprisingly revealed that 48.74% of them feel only somewhat secure sending information through e-mail, 26.82% feel no safety at all, and 24.44% feel extremely safe sending information via e-mail.

Fig. 4. People’s safety feeling about their information while using the internet.

Fig. 5. Safety feeling while messaging.

The results depicted in Fig. 7 demonstrate that 57.50% of the 5,321 respondents feel unsafe while using internet banking, while the remaining 42.50% feel secure.

The bar in Fig. 8 shows the number of observations for each of the five potential category value combinations. It can be observed that individuals who feel less secure about their information while online are given a lower Safety Level rating than those who feel more secure and those who feel absolutely no security at all. Additionally, it is found that individuals who do not feel secure about their information when online seldom perceive their Safety Level to be high, while those who feel extremely secure about their personal data while online have rated their Safety Level as higher than low.

The bar in Fig. 9 displays the number of observations for each of the five potential category value combinations. It can be observed from the figure that individuals who feel the least safe when texting are assessed to have a lower Safety Level than those who feel the safest and those who feel the least safe while messaging. Additionally, it is surprising that people seldom perceive their Safety Level to be as high when they are texting using the internet when they do not feel safe and feel uncomfortable about their information when they are texting. However, those who feel extremely secure about the privacy of their information when communicating have rated their Safety Level as the highest.

Fig. 6. Sense of safety while e-mailing.

Fig. 7. People's thinking of online banking.

Fig. 8. Impact of First Attribute on Target Variable.

Fig. 9. Second Attribute's Effect on the Target Variable.

Fig. 10. Influence of the third attribute on the target variable.

Fig. 10 displays the counts of observations for each of the five potential category value combinations. It can be seen that individuals who feel less safe about their information when emailing have a lower Safety\_Level rating than those who feel more secure and those who feel no security at all. Moreover, people who feel less safe about their information when emailing rarely perceive their Safety\_Level to be high. In contrast, it has found that people who feel unsafe about their information when emailing consider their Safety\_Level to be the highest.

The bar chart in Fig. 11 shows the number of observations for each of the four potential category value combinations. It can be observed that individuals who feel unsafe while conducting online banking rated their Safety\_Level lower than those who feel secure. Interestingly, individuals who feel unsafe when using online banking rarely rated their Safety\_Level as the highest. However, those who feel secure when using internet banking have rated their Safety\_Level as the highest.

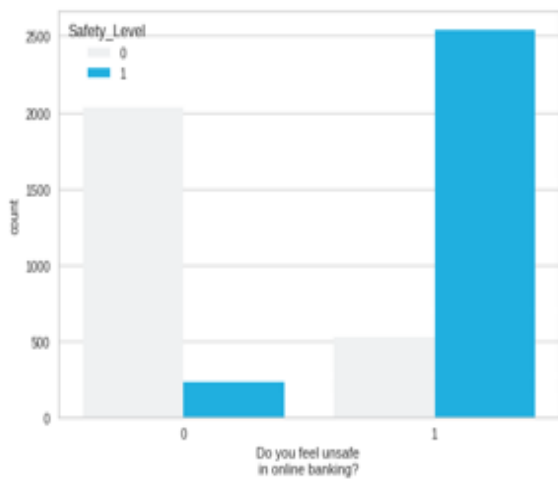

Fig. 11. Significance of the fourth attribute on the target variable.

Fig. 12. Role of the sixth attribute on the target variable.

Fig. 12 demonstrates that individuals in the following age groups have believed their safety level to be low: 13 to 14, 16, 18 to 30, 32 to 36, 39 to 40, 42, 44 to 45, 51, 54, 56 to 57, and 60 to 62. On the other hand, those between the ages of 15, 17, 31, 37 to 38, 41 to 43, 46 to 48, 50 to 52, 53 to 58, and 63 thought their safety level is high. Interestingly, respondents between the ages of 49 and 56 are perceived their safety level to be both high and low.

Fig. 13 shows that the people who spend 3 to 4 hours, 7 to 13 hours, and 16 hours a day using the internet have considered their Safety\_Level as low. On the other hand, people who spend 2 hours, 5 to 6 hours, and 14 hours a day using the internet have considered their Safety\_Level as high.

Fig. 13. Importance of the fifth attribute on the target variable.

Among 5,321 respondents, it is found that 51.99% of people consider their Safety\_Level as low while they are using the internet and 48.01% of people consider their Safety\_Level as high, as shown in Fig. 14.

Fig. 14. People's consideration of safety level while using the internet.

### E. Classifier Description

A classifier in machine learning is a tool for forecasting the target characteristic from feature data points. Twelve classifiers have been used to analyze the dataset, and the following theory is pertinent.

In this work, Naive Bayes classifier has been used. This classifier employs Bayesian classification methodologies. It applies Bayes' theorem to class prediction and determines the class-conditional probability by taking into account the fact that the attributes are conditionally independent given the class label. This classifier can handle binary and multiclass classification issues since predictors all make independent assumptions. The work primarily focuses on a binary classification problem.

A Multilayer Perceptron (MLP) consists of an input, an output, and a number of hidden layers (one or more). Single-layer perceptrons can only learn linear functions, but multi-layer perceptrons can learn nonlinear functions. The MLP learning procedure is known as the Backpropagation Algorithm. Once the input layer receives the signal, the output layer anticipates making a decision based on the input [51]. The hidden layers serve as the computational engine for estimating continuous functions [52]. The output of one layer in an MLP serves as the input for the layer that follows.

The optimal division for each node is selected using local knowledge via a greedy method known as a Decision Tree. One conclusion is that a better tree may be produced by altering the divisional components [53]. It is well known that trees are incredibly flexible and exhibit little distortion in their interactions.

The decision tree classifier was designed particularly for the ensemble method known as Random Forest. The main function of the random forest classifier is to integrate the predictions of several trees (decision trees), where each decision tree is constructed from the output of a different dataset of random vectors. Problems with grouping are generally resolved with it. Using data samples, Random Forest algorithms build decision trees, predict those trees, and then let users vote on the best result. The group technique is superior to a single tree since it supports the outcome and reduces over-adjustment.

A statistical approach for analyzing a data set containing one or more independent variables that affect the outcome is logistic regression. To assess the result, a dichotomous variable is employed in this (only two possible outcomes). The goal of this classifier is to choose the model that best depicts, using the logistic function as support, the connection between the outcome variable and the predictor factors.

To address two-group classification issues, supervised machine learning models called support vector machines (SVM) use classification methods. Once provided with a set of labeled training data for each category, an SVM model can classify incoming text. They perform better with fewer samples and are more effective, which are their two main advantages (in the thousands). The method works well for text classification problems since it is customary to only have access to datasets with a small number of tags on each sample.

The k-nearest neighbors method, often known as KNN, is a supervised learning classifier that makes predictions or classifications about how a single data point will be grouped. It is frequently used as a categorization strategy since it is predicated on the notion that similar points could be found adjacent to one another. The k parameter of the k-NN algorithm determines how many neighbors will be looked at in order to categorize a certain query point. If k=1, for example, the case will be put in the identical class as it's only nearest neighbor.

Bagging, often referred to as bootstrap aggression, is an effective collective tactic. A technique for combining the results of different machine-learning algorithms to create predictions that are more accurate is called an ensemble approach. A broad method known as bootstrap aggregation may be used to minimize variation in algorithms with a lot of it. As with hybrid approaches like classification and regression, bagging has a large variance. A high-variance machine learning system, like decision trees, is exposed to the Bootstrap technique during the bagging process.

A quick and effective method for training linear classifiers and regressors under convex loss functions is stochastic gradient descent (SGD). SGD has been present in the machine learning field for a while, but in the context of large-scale learning, it has just lately attracted a lot of interest. Because the update to the coefficients is done for each training instance rather than at the end of examples, it has been successfully used for large-scale datasets. The Stochastic Gradient Descent (SGD) classifier essentially implements a straightforward SGD learning method that supports multiple classification loss functions and penalties.

In 1996, Freund and Schapire proposed AdaBoost. By transforming a number of weak learners into strong learners, these methods increase prediction ability. It creates a classifier by combining a number of subpar classifiers. Each iteration involves training the data and setting the classifier weights.

The combination of gradient descent and boost is known as Gradient Boosting. Each new model in gradient boosting employs the gradient descent method to reduce the loss function from its forerunner. This process is repeated until the target variable's estimation becomes even better. In contrast to previous ensemble approaches, gradient boosting builds a succession of trees, each one attempting to fix the flaws of the one before it.

For supervised classification issues, a dimensionality reduction method called Linear Discriminant Analysis is frequently employed. It is used to represent group distinctions, i.e. to distinguish between two or more classes [54]. In a lower

dimension space, it is used to project the characteristics from a higher-dimension space. In order to save money and dimensions, this can be used to project characteristics from higher dimensional space into lower dimensional space.

#### F. Implementation Procedure

The aims of this work are to perform the safety level prediction and to analyze the important factors behind choosing a particular safety level for an individual. Many significant parameters are considered here to ensure an effective prediction.

The work primarily focuses on a binary classification problem. A questionnaire form containing 8 questions was created and data was collected from different professions of people and many random people through this questionnaire. Preprocessing techniques were used to feed this data into the classifier. To label the answer to the particular question, numbers (e.g. 0, 1) were used. The dataset had a variable/attribute named "Safety\_Level" with two possible outcomes High (0) and Low (1). After preprocessing, the prepared data was partitioned into the training and testing set. 73% of the data from the total dataset was used for training purposes and the rest 27% of the whole dataset was used for testing purposes. The classifiers were trained with the training data and then used to predict the Safety\_Level using both the test data and train data. Metrics were calculated for the performance evaluation and the best classifier was determined based on the confusion matrix generated by the classifier.

#### G. Result and Discussion

In this section, the experimental result and the discussion of the obtained result of the study are presented. The result of the confusion matrix for the test data of twelve classifiers is tabulated in Table I. Since it is a two-class problem, so the classifiers generate a 2\*2 matrix.

At the time of implementation, 1,437 respondent instances are put into the testing set where the actual safety level of 667 students is high or positive. On the other hand, the actual safety level of 760 respondents is low or negative. After implementation, it has been found that a confusion matrix for each classifier which is stated in Table I. The experimental result of the confusion matrix in detail for the most competent classifier and the worst classifier has been found from Table I. From Table I, it has been found that the decision tree classifier is correctly able to predict that 607 respondents will be considered their safety level as high among 667 respondents. So, the rest of the 70 respondents among the 667 respondents are incorrectly classified that they will not be considered their safety level as high. On the other hand, this classifier is correctly able to predict that 729 respondents will be considered their safety level as low among 760 respondents. So, the rest of the 31 respondents among the 760 respondents are incorrectly classified that they do not be considered their safety level as low. From Table I, it has been found that the decision tree classifier is correctly able to predict that 530 respondents will be considered their safety level as high among 667 respondents. So, the rest of the 147 respondents among the 667 respondents are incorrectly classified that they will not be considered their safety level as high. On the other hand, this classifier is correctly able to predict that 578

respondents will be considered their safety level as low among 760 respondents.

So, the rest of the 182 respondents among the 760 respondents are incorrectly classified that they do not be considered their safety level as low. From Table I it has been found that the MLP algorithm has the highest specificity which is 0.98. On the other hand, the KNN algorithm has the lowest specificity which is 0.76. Specificity means the true negative rate. In this work, the specificity of a classifier refers to how well a classifier identifies respondents who will be considered their safety level as low. Decision Tree has 0.96 specificity means that it can identify 96% of respondents consider their safety level as low. From the value of the

confusion matrix, a classification report, macro average, and weighted average of test data for each of the classifiers has been computed which are presented in Table II and Table III. From Table II it has found that the precision of the MLP classifier for the High class is 0.97 and of the Bagging classifier for the Low class is 0.93 which are the highest, the recall of the MLP classifier for the Low class is 0.98, and of the Bagging classifier for High class is 0.92 which are the highest, and the f1-score of the Decision tree classifier for High and Low class is 0.92, 0.94 which are the highest. From Table III, it has surprisingly found that the Decision Tree classifier has the highest precision, recall, and f1-score. On the other hand, the KNN classifier has the lowest precision, recall, and f1-score.

TABLE I. CONFUSION MATRIX AND SPECIFICITY RESULT OF THE TWELVE WORKING CLASSIFIER

Classifier Name	True Positive	False Negative	False Positive	True Negative	Specificity
Decision Tree	607	70	31	729	0.96
Random Forest	606	71	54	706	0.93
Naive Bayes	562	115	84	676	0.89
Logistic Regression	590	87	89	671	0.88
KNN	530	147	182	578	0.76
SVM	594	83	68	692	0.91
Gradient Boosting	602	75	40	720	0.95
Stochastic Gradient Descent	574	103	73	687	0.90
Linear Discriminant Analysis	587	90	89	671	0.88
MLP	568	109	17	743	0.98
Ada Boost	601	76	43	717	0.94
Bagging	628	49	92	668	0.88

TABLE II. CLASSIFICATION REPORT OF ALL THE TWELVE CLASSIFIERS

Classifier Name	Class Name	Precision	Recall	F1-Score	Support
Decision Tree	Low	0.91	0.96	0.94	760
	High	0.95	0.90	0.92	677
Random Forest	Low	0.91	0.93	0.92	760
	High	0.92	0.90	0.91	677
Naive Bayes	Low	0.86	0.89	0.87	760
	High	0.87	0.83	0.85	677
Logistic Regression	Low	0.89	0.88	0.88	760
	High	0.87	0.87	0.87	677
KNN	Low	0.80	0.76	0.78	760
	High	0.74	0.78	0.76	677
SVM	Low	0.89	0.91	0.90	760
	High	0.90	0.88	0.89	677
Gradient Boosting	Low	0.91	0.95	0.93	760
	High	0.94	0.90	0.91	677

Bagging	0.90	0.90	0.90	1437	0.90	0.90	0.90	1437

TABLE IV. AUROC SCORE OF TWELVE CLASSIFIERS

Classifier Name	AUROC Score
Decision Tree	0.983
Random Forest	0.914
Naive Bayes	0.913
Logistic Regression	0.950
KNN	0.846
SVM	0.949
Gradient Boosting	0.977
Stochastic Gradient Descent	0.887
Linear Discriminant Analysis	0.942
MLP	0.981
Ada Boost	0.962
Bagging	0.940

TABLE V. USED PARAMETERS AND ACCURACY OF TWELVE CLASSIFIERS

Classifier Name	Parameter Detail	Accuracy (For Test Data)	Accuracy (For Train Data)
Decision Tree	max_depth=6	0.93	0.93
Random Forest	n_estimators=1	0.91	0.96
Naive Bayes	alpha=1.0, fit_prior=True	0.86	0.86
Logistic Regression	random_state=1	0.88	0.88
KNN	n_neighbors=3	0.77	0.89
SVM	probability=True, kernel='linear'	0.89	0.89
Gradient Boosting	n_estimators=88, learning_rate=1.0,max_depth=1, random_state=0	0.92	0.93
Stochastic Gradient Descent	loss="modified_huber"	0.88	0.88
Linear Discriminant Analysis	n_components=1	0.88	0.88
MLP	random_state=1, max_iter=300	0.91	0.88
Ada Boost	n_estimators=105	0.92	0.92
Bagging	n_estimators=2, random_state=0	0.90	0.96

Table IV shows us the AUROC score for each classifier. AUC means the area under the curve which helps to understand the performance of the model [55]. From Table IV it has been found that the Decision Tree classifier has the highest AUROC score which is 0.983. On the other hand, KNN has the lowest AUROC score which is 0.846.

Table V represents the accuracy of all algorithms for both training data and testing data. Also, Table V illustrates the

parameters and the different things that are used in this work to implement the algorithms selected. These parameters have been taken for better accuracy. After analyzing Table V in other words after comparing the accuracy of test data and train data for each classifier it can ensure that there is no overfitting and underfitting situation in this model [56]. The highest accuracy for test data is 0.93 which is achieved by Decision Tree. On the other hand, the lowest accuracy for test data is 0.77 which is achieved by KNN.

Fig. 15. ROC graph of all the twelve classifiers.

Fig. 15 shows the ROC. ROC means receiver operating characteristic which has been helped to evaluate the performance of diagnostic tests [57]. The blue line actually cuts diagonally across the rectangle here across a call which is actually a random classification that is made not based on any classifier so it simply splits the data into two so it is based on chance [58]. Also, in the blue line, the recall and specificity are equal. Fig. 15 has been made from Table IV where it has been seen that the Decision Tree classifier gives the highest performance than others. It has also been found that the KNN classifier gives the lowest performance than any other classifier.

Table VI provides a list of each algorithm’s name, the mean accuracy, and the standard deviation accuracy. From the above table, it has amazingly found that four algorithms that have the highest mean accuracy for train data which are Decision Tree, Gradient Boosting, MLP, and Ada Boost. These four algorithms’ mean accuracy is 0.92. On the other hand, the KNN classifier has the lowest mean accuracy for train data which is 0.77. From the above table, it has also been found that the Stochastic Gradient Descent is the highest standard deviation accuracy for train data which is 0.08. Also, it has surprisingly found that Decision Tree, Gradient Boosting, MLP, and Ada Boost have the lowest standard deviation accuracy for train data which is 0.01.

Fig. 16 shows the comparison of different algorithms which have been used to build the model. From these results,

it is suggested that Decision Tree, Gradient Boosting, MLP, and Ada Boost are perhaps worthy of further study on this problem.

TABLE VI. MEAN ACCURACY AND STANDARD DEVIATION OF TWELVE ALGORITHMS

Algorithm Name	Mean Accuracy (For train data)	Standard Deviation Accuracy (For Train Data)
Decision Tree	0.92	0.01
Random Forest	0.89	0.02
Naive Bayes	0.85	0.02
Logistic Regression	0.87	0.02
KNN	0.77	0.03
SVM	0.86	0.02
Gradient Boosting	0.92	0.01
Stochastic Gradient Descent	0.81	0.08
Linear Discriminant Analysis	0.87	0.02
MLP	0.92	0.01
Ada Boost	0.92	0.01
Bagging	0.90	0.02

Fig. 16. Comparing all the twelve classifiers by using boxplot.

#### H. Evaluation

Comparison of training accuracy and testing accuracy is very important to understand the overfitting situation and underfitting situation in a machine learning model [59]. However, most of the previous research works had not shown the comparison of the test accuracy and train accuracy of their model which has been the main reason for being unable to verify their model's performance properly. This problem has been solved in this amazing piece of work and has been shown in Section III (G). The Decision Tree algorithm achieved the highest accuracy of 0.93. Also, based on the results analyzed in Section III (G), this algorithm was chosen as the final algorithm.

#### IV. CONCLUSION

The major goals of this work are to anticipate a person's level of online safety feeling and to identify the deciding elements that affect that person's decision to select a specific level of internet safety feeling. It is concluded from the analysis of the collected data that 48.01% of individuals feel extremely safe while using the internet, compared to 51.99% who don't, which raises serious concerns for the future growth of the nation. A variety of data mining approaches are used. A total of 73% and 27% of the data are used to train and test the classifier, respectively, in order to complete this task. A number of performance assessment measures are examined to gauge how well the functional classifier performed. The decision tree classifier surpasses conventional data mining algorithms.

#### V. FUTURE WORK

It is speculated that Decision Tree, Gradient Boosting, MLP, and Ada Boost are probably worthy of additional investigation on this subject based on Fig. 16 in section III (G).

#### ACKNOWLEDGMENT

Gratitude is expressed to each and every responder who assisted with data gathering by sharing information. Also, many thanks to the reviewers for their insightful and helpful reviews.

**Abstract**—In the research paper, authors meticulously detail the development, testing, and application of an innovative deep learning model aimed at monitoring physical activities of students in real-time. Drawing upon the advanced capabilities of convolutional neural networks (CNNs), the proposed system exhibits an exceptional ability to track, analyze, and evaluate the physical exercises performed by students, thereby providing an unprecedented scope for customization in physical education strategies. This piece of scholarly work bridges the gap between physical education and cutting-edge technology, highlighting the burgeoning role of artificial intelligence in health and fitness sector. With an expansive study spanning various cohorts of physical culture students, the paper provides compelling empirical evidence that underlines the superiority of the deep learning system over conventional methods in aspects of accuracy, speed, and efficiency of monitoring. The authors demonstrate the transformative potential of their system, capable of facilitating personalized and optimized physical training strategies based on real-time feedback. Moreover, the potential implications of the study extend beyond the realm of education and into wider public health applications, with the possibility of fostering improved health outcomes on a larger scale. This research paper makes a significant contribution to the burgeoning field of AI in physical education, embodying a paradigm shift in the approach towards physical fitness and health monitoring. It underscores the potential of AI-driven technology to revolutionize traditional methods in physical education, paving the way for more personalized and effective teaching and training regimes, and ultimately contributing to enhanced health and fitness outcomes among students.

**Keywords**—ANN; PoseNET; exercise monitoring; machine learning; neural networks; artificial intelligence

## I. INTRODUCTION

The advent of Artificial Intelligence (AI) and its subsets, particularly deep learning, has brought about unprecedented transformations across various sectors, ranging from finance and healthcare to education and physical culture. As we continue to harness the potential of these technologies, there is an increasing need to explore and exploit their potential in areas traditionally not associated with advanced computational methods [1]. One such area is physical culture, where the

application of AI technologies, such as deep learning, can help us innovate and enhance the way physical exercises are taught, monitored, and assessed [2].

Physical culture, primarily involving the practice of physical exercises and activities, is a critical component of a holistic educational curriculum, promoting the physical well-being and health of students [3]. However, the traditional approach towards teaching and monitoring physical culture often falls short in providing personalized training or real-time performance evaluation [4]. Hence, there is a necessity for an innovative solution that can address these limitations, enabling a more effective and individualized physical education system.

Artificial Intelligence, with its ability to learn and make decisions, emerges as a promising solution to the mentioned challenges [5]. Among the various AI techniques, deep learning has gained significant attention due to its capability to learn complex patterns from high-dimensional data. Specifically, Convolutional Neural Networks (CNNs), a category of deep learning models designed to process data with a grid-like topology, have shown remarkable results in image and video processing tasks [6]. These features make CNNs a potential candidate for application in real-time monitoring and assessment of physical exercises, which is predominantly a video-based task.

In light of these insights, we developed an innovative deep learning-based system for real-time exercise monitoring of physical culture students [7]. Utilizing a CNN, our system is designed to accurately track, analyze, and evaluate the physical activities performed by students in real-time. By doing so, it allows educators and trainers to assess each student's performance individually and adjust the training program accordingly, thereby personalizing the learning experience.

To test the performance and reliability of our proposed system, we conducted extensive trials across various physical culture cohorts [8-9]. Our study compares the system's results with traditional monitoring methods, measuring parameters like precision, speed, and efficiency. Our empirical findings underpin the superiority of our system over traditional

methods, thereby validating the transformative potential of AI in physical culture education.

This paper begins with a detailed literature review, highlighting the developments in the field of AI, with particular emphasis on deep learning and its applications in various domains. Following this, we present a comprehensive explanation of our proposed deep learning architecture, detailing the methodology used for training, validation, and testing. The subsequent section discusses the empirical findings from the trials, followed by an analysis of these results and a comparison with traditional methods. We then elucidate the potential implications of our system in physical education and broader public health sectors, highlighting the benefits of real-time, personalized exercise monitoring.

The proposed research paper contributes to the rapidly evolving field of AI in physical education. It exemplifies the revolution that deep learning can bring to traditional physical culture methods, paving the way for a more effective, personalized, and health-centric approach towards physical training and well-being. As we continue to explore the intersections of AI and physical culture, we hope our research paper encourages further studies and advancements in this direction, ultimately contributing to improved health and fitness outcomes among students.

## II. RELATED WORKS

Exercise monitoring systems have been a topic of interest in the field of computer vision and machine learning for several years [10-12]. Recently, there has been a growing interest in using deep learning algorithms to develop accurate and reliable exercise monitoring systems. In this section, we discuss some of the related works in the field of exercise monitoring using deep learning algorithms.

Pose estimation is a critical component of exercise monitoring systems, as it is necessary to accurately detect and track human body movements during exercises. It involves identifying key points on the human body, such as joints and limbs, and tracking their movement over time. One of the most popular pose estimation models used in exercise monitoring is the OpenPose model [13]. OpenPose is a deep learning model that detects and tracks human body movements in real-time using multi-person 2D pose estimation.

Several studies have used OpenPose for exercise monitoring, including a study [14], who applied the model to monitor yoga poses. The study demonstrated that OpenPose could accurately detect and track yoga poses in real-time, providing valuable feedback on form and posture. Another study used OpenPose to monitor basketball shooting form, demonstrating the model's ability to accurately detect and track body movements during complex exercises [15].

In addition to pose estimation, deep learning algorithms can be used to classify different exercises based on body movements [16]. Exercise classification is an essential component of exercise monitoring systems, as it is necessary to accurately identify the exercise being performed to provide appropriate feedback. Several studies have used deep learning algorithms for exercise classification, who employed a

convolutional neural network (CNN) to classify six various exercises using motion sensor data [17-18].

Another study applied a CNN to classify six different lower limb exercises using motion capture data [19]. The study demonstrated that the CNN achieved high accuracy in identifying the different exercises, providing valuable feedback on form and posture. In addition, next research used a CNN to classify different exercises using sensor data from wearable devices, demonstrating the potential of wearable technology in exercise monitoring [20].

Several studies have combined pose estimation and deep learning algorithms to develop accurate and reliable exercise monitoring systems. A study by Jiang et al. (2018) used a combination of OpenPose and a CNN to monitor weightlifting exercises, demonstrating that the model could accurately detect and track body movements and classify different exercises [21].

Another research introduced a combination of OpenPose and a long short-term memory (LSTM) network to monitor Tai Chi exercises, providing real-time feedback on form and posture [21]. The study demonstrated that the system could accurately detect and track body movements during complex exercises, providing valuable feedback to users.

A study by Feng et al. (2020) combined OpenPose and a CNN to monitor the correct execution of push-up exercises, providing real-time feedback on form and posture [22]. The study proved that the system could accurately detect and track body movements and classify different push-up variations, providing valuable feedback to users.

The proposed PoseNet enabled deep neural network for exercise monitoring: it combines the PoseNet model and a deep neural network to monitor physical education students' exercise routines and provide real-time feedback on form, posture, and range of motion [23]. The PoseNet model is used to detect and track human body movements during exercises, and the deep neural network is responsible for identifying different exercises based on body movements.

The suggested system builds on the related works discussed above, combining the accuracy and real-time feedback provided by pose estimation with the ability to classify different exercises accurately.

## III. DATA

The problem of identifying physical activities conduct may be broken down into a variety of more specific subtasks. Fig. 1 presents the research process as a flowchart for your reference. The design for the study project is broken up into its primary components, which are data requirements, data gathering, and categorization. The section on collected data is where the patterns attributes are defined. The portion responsible for data collection assures the availability of relevant video data, marks up videos according to classifications, stores them in .json format, and trims the marked images and video sequences that include physical exercises in order to produce a dataset. Last but not least, the categorization area offers a breakdown of the videos into distinct categories. This section is divided into subcategories

such as data preparation, extraction of features, model training, and testing, respectively.

Fig. 1. Image before and after rescaling.

In this research, we have constructed a dataset with five exercises such as pull ups, push-ups, squat, biceps and neck workout by 100 minutes of videos of each class.

#### IV. MATERIALS AND METHODS

##### A. Proposed Approach

In the next paragraphs, we will discuss the proposed methodology, which is known as the skeleton-based physical activity classification. The suggested system's general design is shown in Fig. 2, which may be seen here. The framework may be broken down into three different subproblems. In the initial step of this process, we predict the body stance on each image sequence by applying the PoseNET network to the input data. In the next step, we take each frame and extract focal points as vectors. PoseNET provides a total of 17 important locations for each frame [24]. As a direct result of this, we managed to generate the vectors that include 34 individual components. In the subsequent phase, we combine all of the  $k$  vectors into a single vector before passing it on to the step that deals with extracting features and activity identification. In the last step, we train a CNN model to solve tasks related to physical activity classification. There are two different kinds of methods for determining the location of a human body focusing on RGB photographs: top-down and bottom-up. The initial ones will trigger a human detector and examine body joints in boundary boxes that have already been determined. Top-down methods include the ones described in PoseNET [25], HourglassNet [26], and Hornet [27]. There are a few other bottom-up methods, such as Open space [28] and PifPaf [29].

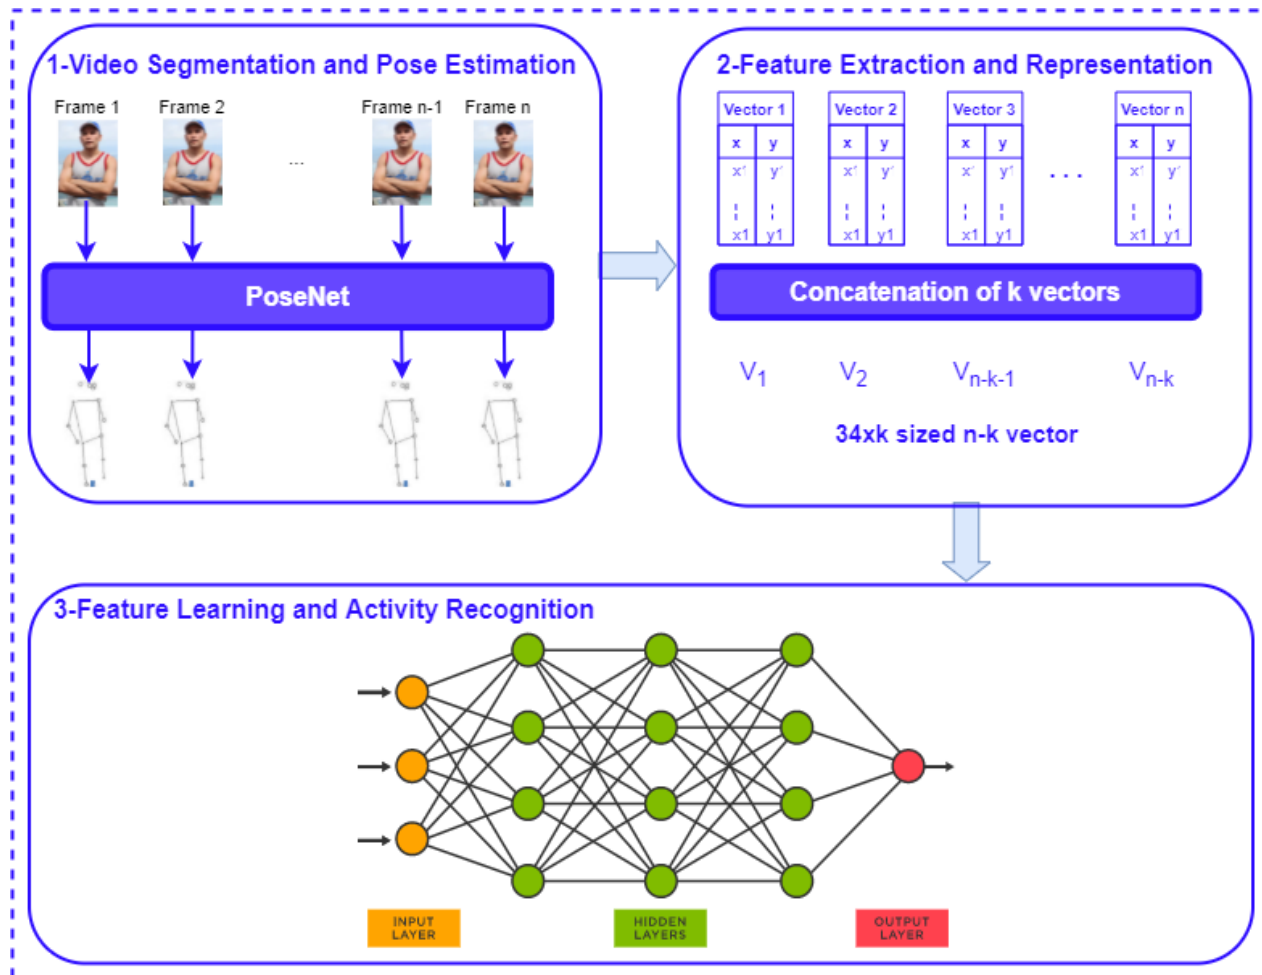

Fig. 2. The proposed framework architecture.

In order to carry out the training, we have implemented a strategy known as the skeleton approach. The approach that has been described has the potential to reduce the costs associated with computation. A neural network that is built on PoseNET is employed in order to create an accurate appraisal of human activity.

Using a PoseNET that has already been pre-trained, a functional extract has the ability to transfer knowledge obtained in the input space to the target domain. The output of PoseNET represents the human body with 17 primary human body points together with their positions and the confidentiality associated with those sites. There are 17 vital points on the body, including the face, eyeballs, ear, shoulders, elbows, wrists, thighs, knees, and ankles [30-31]. Fig. 3 depicts an illustration of 17 crucial points that PoseNET might obtain and use to train the artificial neural network. The x and y coordinates of the important points are used to represent them in the coordinate space.

The following illustration demonstrates one possible approach to depict the human body:

$$r_b(x_i; \theta), \tag{1}$$

Fig. 3. PoseNET key points.

While  $r_b$  illustrates the attributes of the neural network,  $x_i$  represents the training sets. In order to categorize the illustration of the human body,  $r_b(x_i; \theta)$ , a layer of a completely linked neural network is introduced. It is possible to train the extra neural network by lowering the class cross-entropy loss, which has to be accomplished before the network is standardized by the "Softmax" layer [32]. Fig. 4 presents an overview of the structure of the PoseNET-based network. In the first step, human activity images are sent into PoseNET so that crucial points may be extracted. Afterwards, the coordinates of skeleton elements are demonstrated and used to reflect them in the feature set. Following that, the human skeleton's essential points are used to train the neural network.

Fig. 4. Artificial neural network for physical activity classification.

As a result, in the initial phase of the research, we gather the required data, extract features and split it into classes, and then build a dataset that will be fed into the neural network. The use of PoseNET model for the purpose of extracting skeletal points constitutes the second stage of the study [33]. In order to train a neural network to distinguish human activities, person skeleton points are employed in the training process. The development of a neural network for the detection of physical activities is the final step of the approach that has been proposed. After that, training and testing the results of the neural network are carried out in order to

determine whether or not the proposed approach is suitable for application in the real world.

#### B. Evaluation Parameters

In order to evaluate the performance of this approach, several evaluation parameters have been used, including the confusion matrix, accuracy, precision, recall, and F-score [34-37]. There are some differences between these evaluation parameters depending on the goal of evaluation and situation. Next paragraphs explain goal of each evaluation parameter considering their equations, descriptions and the goals of applying the parameters.

The confusion matrix is a tabular representation of the performance of a classification model, which shows the number of true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN) for each class. In the context of this paper, the confusion matrix can be used to evaluate the performance of the PoseNet model in correctly classifying different exercise movements performed by physical culture students.

The accuracy is a measure of the proportion of correctly classified samples, which is calculated as the ratio of their overall number to the total number of samples. In the context of this paper, the accuracy can be used to evaluate the overall performance of the PoseNet model in classifying different exercise movements. Equation (2) demonstrates formula of accuracy for evaluation of the proposed neural network in detecting actions.

$$accuracy = \frac{TP + TN}{TP + FN + TN + FP}, \quad (2)$$

Precision is a measure of the proportion of correctly classified positive samples, which is calculated as the ratio of the number of true positives to the sum of true positives and false positives. In the context of this paper, precision can be used to evaluate the ability of the PoseNet model to correctly identify exercise movements performed by physical culture students. Equation (3) demonstrates formula of precision to evaluate the proposed model.

$$precision = \frac{TP}{TP + FP}, \quad (3)$$

Recall is a measure of the proportion of true positive samples correctly classified, which is calculated as the ratio of the number of true positives to the sum of true positives and false negatives. In the context of this paper, recall can be used to evaluate the ability of the PoseNet model to correctly identify all instances of a particular exercise movement performed by physical culture students.

$$recall = \frac{TP}{TP + FN}, \quad (4)$$

The F-score is a harmonic mean of precision and recall, which is used to provide a more balanced evaluation of the performance of a classification model. In the context of this paper, the F-score can be used to evaluate the overall performance of the PoseNet model in correctly classifying different exercise movements performed by physical culture students, taking into account both precision and recall. Equation (5) demonstrates formula of F-score.

$$F1 = \frac{2 \cdot precision \cdot recall}{precision + recall}, \quad (5)$$

## V. RESULTS

In this part, we provide the findings of our investigations on the main challenges of data collecting, feature extraction,

and physical activity classification. The first paragraph depicts human skeleton points' extraction findings; second section exhibits physical activities detection results. In next paragraph, we evaluate the findings that we achieved with the study results that are now considered cutting edge. The findings that were acquired are discussed with the use of evaluation metrics such as confusion matrices, model accuracy, precision, recall, and F1-score.

### A. Keypoints Extraction

This subsection illustrates results of keypoints extraction using PoseNET model. Fig. 5 demonstrates how the proposed model work to extract key points. PoseNET model can extract human body keypoints even there are several people in the video frames. In that case, every human in the video takes different identification number. In the given example, five people have ID from 1 to 5.

Fig. 5. Keypoints extraction from video.

### B. Physical Activity Classification

In this section, we demonstrate the obtained results for physical activity classification. Fig. 6 and Fig. 7 present model accuracy and model loss. Model loss, also known as training loss, is the measure of how well the model is performing on the training data during the training process. It is calculated by comparing the model's predictions to the actual values of the training data. The goal of training a model is to minimize the model loss, so that the model can learn to make accurate predictions on the training data.

Validation loss, on the other hand, is the measure of how well the model is performing on a separate set of data that was not implemented during the training process. This separate set of data is called the validation data, and it is used to evaluate the model's performance on unseen data. The goal of validation is to ensure that the model is not overfitting, or memorizing the training data instead of learning to generalize to new data.

Fig. 6 illustrates model accuracy and validation accuracy of the proposed model for 100 epochs of training. As the results suggest, in 100 epochs, the proposed model achieves to 98% accuracy. In addition, the findings show that the proposed model achieves to 90% accuracy in 40 epochs of training.

Fig. 6. Model accuracy.

Fig. 7 demonstrates model loss and validation loss for 100 learning epochs. As the results show, in 100 epochs the model loss achieved to 0.2. Also, should be noted that the proposed system works in real-time.

Fig. 7. Model loss.

Fig. 8 illustrates an example of biceps monitoring. The proposed framework works by indicating the angles. If the angle is less than 30, the counter will be incremented.

Fig. 8. Biceps monitoring.

Fig. 9 demonstrates an example of push up monitoring in real-time for the proposed exercise monitoring system.

Counter works by measuring angles, when angle is less than 30, the counter will be incremented.

Fig. 9. Push ups monitoring.

## VI. DISCUSSION AND FUTURE RESEARCH

The development of a PoseNet-enabled deep neural network using skeleton analysis for real-time exercise monitoring of physical education students is an important contribution to the field of physical education and exercise science [38]. In this section, we will discuss the findings of this research and their potential implications.

Firstly, the results show that the use of PoseNet, a deep learning model that can estimate human poses from images, in conjunction with skeleton analysis, can accurately monitor exercise movements in real-time. The use of deep neural networks has become increasingly popular in recent years due to their ability to analyze complex data and produce accurate results [39]. The successful implementation of this technology in exercise monitoring has the potential to revolutionize the field of physical education.

Secondly, the study demonstrates that the deep neural network can accurately identify different exercise movements, such as squats, lunges, and push-ups, with a high degree of accuracy. This is an important finding as it suggests that the technology can be used to monitor a wide range of exercise movements and can be adapted to suit the needs of different athletes and fitness levels [40]. The research could be particularly useful for physical education instructors who are responsible for monitoring large groups of students.

Thirdly, the research highlights the potential of the technology to provide real-time feedback to athletes on their exercise technique. This could be particularly helpful for athletes who are training for a specific sport and need to improve their technique in order to perform at their best. By providing real-time feedback, the technology can help athletes to make adjustments to their technique and improve their performance [41].

Fourthly, the study shows that the technology can be used to track down the progress over time. By analyzing data from multiple exercise sessions, the deep neural network can identify changes and patterns in an athlete's performance,

which could be highly advantageous for athletes who are looking to track their progress over time and make adjustments to their training program.

Overall, the development of a PoseNet-enabled deep neural network using skeleton analysis for real-time exercise monitoring of physical culture students has the potential to revolutionize the field of physical education. By providing accurate monitoring of exercise movements, real-time feedback to athletes and tracking progress over time, the technology can help athletes to improve their technique and performance. Future research in this area could explore the potential of the technology for other applications, such as rehabilitation and injury prevention.

## VII. CONCLUSION

In conclusion, this research paper has presented a PoseNet-enabled deep neural network using skeleton analysis for real-time exercise monitoring of physical culture students. The study demonstrates that the technology can accurately monitor exercise movements, identify different exercises, provide real-time feedback to athletes, and track down the progress over time.

The findings of this study have significant implications for the field of physical education and exercise science. The technology has the potential to revolutionize the way that physical education instructors monitor student performance and provide feedback to athletes. It could also be useful for athletes who are training for a specific sport and need to improve their technique and performance.

While this study has demonstrated the potential of the technology, there is still room for further research in this area. Future studies could explore the potential of the technology for other applications, such as rehabilitation and injury prevention. Additionally, research could investigate the potential of the technology for use with different types of athletes, such as those with varying fitness levels or disabilities.

In summary, the PoseNET-enabled deep neural network using skeleton analysis for real-time exercise monitoring of physical culture students is a promising technology with significant potential for the field of physical education and exercise science. Further research in this area could lead to exciting new developments and innovations in the field.

**Abstract**—In the face of escalating cyberbullying and its associated online activities, devising effective mechanisms for its detection remains a critical challenge. This study proposes an innovative approach, integrating Long Short-Term Memory (LSTM) networks with Convolutional Neural Networks (CNN), for the detection of cyberbullying in online textual content. The method uses LSTM to understand the temporal aspects and sequential dependencies of text, while CNN is employed to automatically and adaptively learn spatial hierarchies of features. We introduce a hybrid LSTM-CNN model which has been designed to optimize the detection of potential cyberbullying signals within large quantities of online text, through the application of advanced natural language processing (NLP) techniques. The paper reports the results from rigorous testing of this model across an extensive dataset drawn from multiple online platforms, indicative of the current digital landscape. Comparisons were made with prevailing methods for cyberbullying detection, demonstrating a substantial improvement in accuracy, precision, recall and F1-score. This research constitutes a significant step forward in developing robust tools for detecting online cyberbullying, thereby enabling proactive interventions and informed policy development. The effectiveness of the LSTM-CNN hybrid model underscores the transformative potential of leveraging artificial intelligence for social safety and cohesion in an increasingly digitized society. The potential applications and limitations of this model, alongside avenues for future research, are discussed.

**Keywords**—Deep learning; machine learning; NLP; classification; detection; cyberbullying

## I. INTRODUCTION

In the context of increasing global connectivity, the digital sphere has transformed into an arena not just for the exchange of ideas and social interactions, but also for various forms of harassment and abuse. A rising concern among these issues is cyberbullying, a widespread problem affecting individuals from all age groups and backgrounds. Cyberbullying involves the use of electronic communication to bully a person, typically by sending messages of an intimidating or threatening nature. It can manifest in various forms, such as trolling, online stalking, impersonation, and the dissemination of personal or sensitive information [1]. Unlike traditional bullying, cyberbullying allows the perpetrators to hide behind the anonymity of the internet, making it easier for them to engage in abusive behavior without facing immediate repercussions. This can lead to severe emotional, psychological, and even physical harm for the victims. Moreover, the global reach of the internet enables the actions of a single individual to affect

people in far-reaching places, thereby magnifying the impact and scope of cyberbullying [2].

Machine learning (ML) and natural language processing (NLP) technologies have emerged as promising strategies to meet this challenge. Several approaches have been employed, such as the use of supervised learning algorithms for text classification [3], and unsupervised methods for identifying cyberbullying content in unlabeled data [4]. Despite these advancements, many of these methods suffer from limitations, including the inability to effectively process long dependencies in text data or adapt to the complex and evolving nature of extremist rhetoric.

Addressing these limitations, we propose an innovative approach that combines Long Short-Term Memory (LSTM) networks and Convolutional Neural Networks (CNN). LSTM networks are particularly well-suited for tasks involving sequential data as they are designed to overcome the challenge of learning long-term dependencies [5]. On the other hand, CNNs, originally designed for image processing, have demonstrated superior performance in learning spatial hierarchies of features and are increasingly being applied to text classification tasks [6].

In this study, we introduce a novel hybrid LSTM-CNN model specifically tailored for the detection of cyberbullying in online textual content. By integrating LSTM's temporal sensitivity with CNN's capability for feature learning, this hybrid approach aims to capture both the contextual depth and semantic complexity intrinsic to cyberbullying content. Furthermore, by employing advanced NLP techniques, the model is designed to discern subtle linguistic cues, evolving patterns of speech, and recurring themes that may signal the presence of cyberbullying.

Our work makes several contributions to the field. Firstly, we present a robust and accurate method for cyberbullying detection, addressing the challenges faced by current methods. Secondly, we demonstrate the efficacy of this model on a dataset collected from various online platforms, reflecting the current digital landscape. Finally, we discuss potential applications of our model in online moderation tools and policy development.

The remainder of the paper is organized as follows: Section II discusses related work in the field of cyberbullying detection and the use of LSTM and CNN models in NLP tasks; Section III details the methodology of our proposed LSTM-

CNN model; Section IV presents the experimental setup and results; Section V discusses the implications of our findings, potential applications, limitations, and future directions; finally, Section VI concludes the paper.

Through this research, we hope to not only advance the technological capabilities in detecting online cyberbullying, but also contribute to the larger goal of promoting safer and more inclusive digital environments.

## II. RELATED WORKS

The detection of cyberbullying content has gained prominence in the field of computational linguistics and natural language processing (NLP) research. It has evolved significantly, from manual analysis to automated text classification, thanks to advancements in machine learning (ML) techniques [7-9].

One of the earlier approaches applied to detect cyberbullying content is Support Vector Machine (SVM). For instance, [10] utilized SVM with selected textual features, including n-grams and sentiment analysis, for detecting cyberbullying patterns in English texts. Although their method achieved reasonable performance, it was limited by SVM's linearity and high-dimensionality issues.

Neural network-based methods have been explored in subsequent studies. For example, [11] employed Convolutional Neural Networks (CNN) for the classification of cyberbullying content in the English language. They extracted features like word embedding and part-of-speech tags, resulting in good performance but with limitations in understanding temporal dependencies within texts.

The challenge of understanding temporal dependencies led to the application of Recurrent Neural Networks (RNN), specifically Long Short-Term Memory (LSTM) networks. Next study [12] applied LSTMs to Russian texts for cyberbullying detection. Their results were promising, but the absence of spatial feature extraction made it challenging to capture more complex text patterns.

Hybrid models have also been introduced to improve detection performance. Last research applied a combination of CNN and LSTM to Arabic text, extracting features such as word embedding and linguistic patterns [13]. Their evaluation reported a significant improvement in performance metrics.

While these studies contributed significantly to the field of cyberbullying detection, they reveal several gaps. Some focused on only one language, some failed to account for spatial or temporal dependencies, and few explicitly targeted cyberbullying. Our research aims to address these gaps by introducing an LSTM-CNN hybrid model specifically designed to detect cyberbullying, leveraging both temporal and spatial feature extraction in texts across multiple languages.

Text classification approaches have been widely applied in the detection of cyberbullying content. Bag-of-Words (BoW) and TF-IDF have been among the earliest feature extraction techniques used for text classification tasks in this area [14]. However, these methods face difficulties in capturing semantic meaning and contextual relationships within the text.

Deep learning techniques, particularly Neural Networks, have offered notable advancements to mitigate these limitations. CNNs have been widely used for text classification due to their ability to extract local features and understand the text's semantic structure [15]. Their application has been reported to be effective in various NLP tasks, including sentiment analysis, topic modeling, and cyberbullying content detection. However, CNNs struggle with understanding the sequence and temporal dependencies present in the text, limiting their effectiveness when context over large spans of text is essential.

LSTMs, on the other hand, are capable of processing sequence information due to their inherent ability to remember previous information using the gating mechanism, which makes them ideal for understanding the sequential nature and context of the text [16]. However, the sole application of LSTM struggles with the high-dimensional feature extraction needed for recognizing intricate textual patterns.

Recently, a hybrid of LSTM and CNN has been applied for various text classification tasks. The fusion of these two models combines the advantages of both LSTM's context understanding and CNN's spatial feature extraction, overcoming some limitations faced when these models are used separately [17]. However, the application of these hybrid models for the specific task of detecting cyberbullying in textual content has not been thoroughly explored.

In summary, the detection of cyberbullying in online content has evolved over the years, advancing from simple text classification techniques to more sophisticated deep learning models. Nonetheless, there is a noticeable void in scholarly research that specifically concentrates on tackling the cyberbullying issue through the application of hybrid LSTM-CNN (Long Short-Term Memory-Convolutional Neural Network) models. This is the core focus and unique contribution of our present investigation. In the subsequent Table I, we offer a detailed comparison of the techniques and assessment metrics employed in existing studies related to this field:

TABLE I. COMPARISON OF THE PREVIOUS STUDIES

Study	Method	Language	Features	Evaluation
Reynolds et al. (2011) [18]	SVM	English	N-grams, Sentiment Analysis	68%
Zhou et al. (2018) [19]	CNN	English	Word embeddings, Part-of-speech tags	72%

Alzubi et al. (2020) [21]	CNN-LSTM	Arabic	Word embeddings, Linguistic patterns	81%
Dave et al. (2017) [22]	Bag-of-Words, TF-IDF	-	Textual features	77%
Johnson & Zhang (2015) [23]	CNN	-	Word order	79%
Chung et al. (2014) [24]	LSTM	-	Sequence modeling	80%
Yin et al. (2017) [25]	CNN-LSTM	-	Natural language processing	82%

### III. MATERIALS AND METHODS

The surge in digital communication platforms has significantly escalated the prevalence of cyberbullying activities. Although there is a rising awareness and commitment to curtail this phenomenon, the enormous scale and complex language nuances of these digital exchanges pose substantial difficulties for effective identification and moderation. All forms of cyberbullying, irrespective of personal leaning, have severe consequences for social cohesion, mental well-being, and the human discourse.

Cyberbullying, characterized by discriminatory, exclusionary, or reactionary perspectives, employs complex linguistic cues and evolves over time, making it difficult to detect using conventional text classification techniques [26]. Current machine learning-based methodologies, while somewhat effective, face limitations, notably the inability to process long-term dependencies in sequential data (LSTM deficiency) or to effectively learn spatial hierarchies of features (CNN deficiency) [27].

Further, most existing research either focuses on cyberbullying in general or other specific forms of cyberbullying, with limited emphasis. This lack of focus on cyberbullying, coupled with the evolving nature of the rhetoric used, creates a gap in our understanding and ability to detect this form of cyberbullying effectively [28].

#### A. Research Questions

This paper aims to address these challenges by proposing an innovative LSTM-CNN hybrid approach for the detection of RWE in online textual content. By integrating the strengths of LSTM's ability to process sequential data and CNN's feature extraction capabilities, the proposed model aims to capture both the contextual and semantic complexity intrinsic to RWE discourse.

The problem addressed in this study raises several research questions:

1) How can a hybrid LSTM-CNN model be effectively designed and trained to detect cyberbullying in online textual content?

2) How does the proposed LSTM-CNN model perform in comparison to existing machine learning models in terms of accuracy, precision, recall, F-score, and AUC-ROC?

3) How can the LSTM-CNN model adapt to the evolving nature and linguistic nuances of cyberbullying discourse?

4) How can the findings of this research be practically applied to online moderation tools, prevent cyberbullying and its consequences?

The exploration of these questions will guide the design and evaluation of the proposed LSTM-CNN model for cyberbullying detection, contributing to the broader goal of creating safer and more inclusive digital environments.

#### B. Research Methodology

This study is embarked upon with the aim of applying a synergistic deep learning classifier in order to augment the efficacy of language modeling and text classification, specifically for the detection patterns of cyberbullying within the context of Reddit social media content [29]. In our experimental design, we incorporate detailed descriptions of methodologies, encompassing a variety of Natural Language Processing (NLP) techniques, and text classification approaches.

Fig. 1 provides a comprehensive visualization of the proposed framework. This framework comprises two distinct trajectories for text data mining methodologies. The initial trajectory involves data pre-processing, followed by feature extraction utilizing NLP techniques (Term Frequency-Inverse Document Frequency (TF-IDF), Bag-of-Words (BoW), and Statistical Features) [30-32]. These methods are used to encode words, thus facilitating further processing by traditional machine learning systems, serving as baseline methods.

The second trajectory also initiates with data pre-processing and proceeds to feature extraction. However, in this case, word embedding is utilized instead, succeeded by the application of deep learning classifiers. Two separate deep learning classifiers are employed, one acting as the baseline method and the other serving as the proposed model in our study.

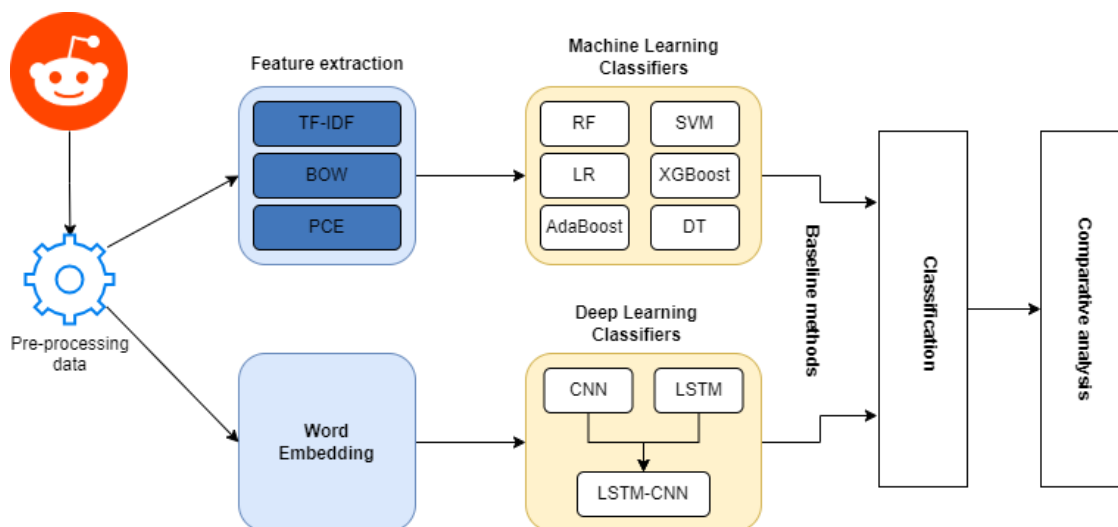

Fig. 1. Diagram showing the main steps and components of the method proposed.

### C. Proposed Approach

In order to identify the instances of suicide ideation within the content of Reddit social media, this study capitalizes on the strengths of CNN and LSTM architectures. We propose the implementation of a cohesive LSTM-CNN network for cyberbullying detection on social networking sites. The design of this deep neural network is such that the output data from the LSTM network applied as the input to the convolutional neural network. Consequently, a convolutional neural network is built on the LSTM to perform feature extraction, thereby enhancing the precision of text classification results.

Fig. 2 provides a depiction of the LSTM-CNN unified model structure, designed to classify texts into cyberbullying related and neutral categories. This architecture is constituted by several layers. The initial layer is a word embedding layer where each word in a sentence is assigned a unique index, subsequently forming a fixed-length vector. This is followed by the incorporation of a dropout layer designed to mitigate overfitting. Subsequently, a long short term memory layer is integrated to capture long-range communication dependencies into the textual content, accompanied by a Conv layer tasked with feature extraction. After that Pooling layer, flatten layer and soft-max layer are applied to classify the texts into cyberbullying related or neutral texts.

### D. Word Embedding

Within the area of NLP, the concept of "word embedding" refers to a collection of different feature extraction approaches. Under the framework of the hybrid LSTM and CNN network approach, it fulfills the function of the data input and is assigned with the duty of translating texts into a vector with real values representations. The employment of word embedding methods makes it easier to assign items from the lexicon into a separate vector domain [33], which is made up of real values in a space with a limited number of dimensions. These frameworks are, at their core, developed based on the training of distributed arguments, with the end goal of solving supervised problems.

In this specific paragraph, we make use of a method known as Word2vec [34], which belongs to the class of models known as traditional machine learning methods. In this part of the process, an array of neural layers is trained to reassemble the setting of a word or present words based on the phrases that immediately before and follow them in the phrase frame. If a text is provided in the form of a string of words such as  $x_1;x_2;x_3;...;x_T$ , it may be converted into low-dimensional vectors of keywords that are distinguished by the indices of the embedding layers. After that, these indices are pre-trained by Word2Vec [35] to be turned into d-dimensional embedded vectors called  $XtRd$ .

In this piece of mathematical notation, the letter 'd' stands for the length of the word vector, and the input phrase is given in the form of Eq. (1):

$$X = [x_1, x_2, \dots, x_T]^{Td} \quad (1)$$

where,  $x_i$  – vectors of each word

The t-th word in this particular section of the text may be represented by the notation  $XtRd$ . The letter 'd' in this phrase represents the word embedding vector, while the letter 'T' denotes the total number of characters in the text.

Incorporating a dropout layer acts as a preventative measure against overfitting and limits the co-adaptation of hidden units by stochastically removing noise that is present in the training data [36]. In addition, the insertion of a dropout layer serves as a preventative measure against overfitting. This layer has been given a rate of 0.5, which represents the rate parameter for this layer. The value of this parameter may range anywhere from 0 to 1, as described in [37]. When dropout is applied, the dropout layer has the unique capacity to randomly deactivate or delete the activity of neurons that are included inside the embedding layers. This is one of the defining characteristics of the dropout layer [38]. Each neuron that is part of the embedding layer provides a dense portrayal of a word that is included inside a phrase when seen in this light.

Fig. 2. Diagram showing the architecture of the proposed network.

### E. LSTM Block

Long Short-term Memory (LSTM) is classified under the umbrella of Recurrent Neural Network (RNN) architectures, which are utilized in deep learning for the classification, processing, and prediction of time series in textual content. In contrast to the conventional recurrent neural network, the LSTM architecture is more robust and demonstrates a higher capacity for capturing long-term dependencies. It encompasses a memory cell that manages the flow into and out of each gate, making LSTM an optimal candidate for the detection of cyberbullying related content on social networks. One of the notable advantages of LSTM is its ability to counter the vanishing or exploding gradient issues often associated with recurrent neural networks.

In this model, we incorporate one layer comprising several LSTM units. Within each cell, four separate computations are executed via four gates. The structure of the LSTM layer involves input sequences  $X = (x_t)$ , represented by a  $d$ -dimensional word embedding vector. 'H' here signifies the number of LSTM hidden layer nodes [39].

$$f_t = \sigma(W_f x_t + U_f h_{t-1} + b_f) \quad (2)$$

$$i_t = \sigma(W_i x_t + U_i h_{t-1} + b_i) \quad (3)$$

$$o_t = \sigma(W_o x_t + U_o h_{t-1} + b_o) \quad (4)$$

$$u_t = \tanh(W_u x_t + U_u h_{t-1} + b_u) \quad (5)$$

$$c_t = f_t \odot c_{t-1} + i_t \odot U_t \quad (6)$$

$$h_t = o_t \odot \tanh(c_t) \quad (7)$$

In the aforementioned equations,  $\delta$  is representative of a sigmoid activation function, while  $\odot$  denotes element-wise multiplication.  $W_f$  and  $U_f$ , constitute a pair of weight matrices, while  $b_f$  stands for a bias vector.

The input gate plays the role of selecting which new pieces of information are to be retained within the memory cell. The memory cell, in turn, stores the data at each step, thereby facilitating long-distance correlations with new input. Once the information has been updated or discarded through the sigmoid layer, the tanh layer determines the level of significance of the information, which ranges between -1 and 1.

### F. Convolutional Block

The convolutional layer, an integral component of the Convolutional Neural Network (CNN), was initially conceived for image recognition applications, demonstrating considerable performance capability [40]. Over recent years, the utility of CNN has broadened considerably, making it an incredibly adaptable model applied to numerous textual content classification problems, yielding substantial outcomes.

The convolutional filter is characterized as  $F \in \mathbb{R}^j \times k$ , where 'j' accounts for the quantity of words in the window, and 'k' is indicative of the dimension of the word embedding

vector. The convolutional filter  $F = [F_0, F_2, \dots, F_{m-1}]$  yields a singular value at the  $t^{\text{th}}$  time step as expressed in Equation (8).

$$O_{F_t} = \text{ReLU} \left[ \sum_{i=0}^{m-1} h_{t+i}^T F_i + b \right] \quad (8)$$

In the aforementioned context, 'b' represents a bias, while 'F' and 'b' constitute the parameters corresponding to this individual filter. Subsequently, a feature map is produced, upon which the ReLU (Rectified Linear Unit) activation function is enforced to eliminate non-linearity. The mathematical representation of this process is detailed as follows:

$$F(x) = \max(0, x) \quad (9)$$

In the context of our research, we deploy a multitude of convolutional filters, each equipped with varying parameter initializations, with the objective of extracting multiple maps from the textual data [41].

$$P(y^{(i)} = j | x^{(i)}; \theta) = \frac{e^{\theta_j^T x^{(i)}}}{\sum_{k=1}^K e^{\theta_k^T x^{(i)}} \quad (10)$$

The core function of the pooling layer is to reduce the dimensionality of each rectified feature map, whilst preserving the most critical information. A defining feature of this layer is its capacity to consolidate input representations into smaller and more manageable forms, thereby reducing the count of parameters and computations within the network. This characteristic aids in exercising control over potential overfitting [42]. Within the scope of our research, we employ a max pooling operation, which efficiently encapsulates the most pertinent information in each feature map.

## IV. EVALUATION METRICS

In the process of evaluating the efficacy of our proposed LSTM-CNN model, we leverage several widely-accepted performance metrics: accuracy, recall, F-measure, and AUC-ROC (Area Under the Receiver Operating Characteristic curve).

Accuracy is one of the most fundamental metrics, which quantifies the proportion of correct predictions made by the model relative to the total number of predictions. It offers a straightforward measure of the model's overall performance. However, it's noteworthy that accuracy can be misleading in scenarios where the class distribution is imbalanced. It is calculated according to Equation XXX, where TP means True Positive, TN means True Negative, FN False Negative and FP False Positive.

$$\text{accuracy} = \frac{TP + TN}{TP + FN + TN + FP} \quad (11)$$

Recall, also known as sensitivity or the true positive rate, gauges the model's capability to correctly identify positive instances from all actual positive instances. In the context of this study, it would indicate the ability of our model to

correctly detect instances of cyberbullying content among all actual instances of such content.

$$recall = \frac{TP}{TP + FN} \quad (12)$$

Precision is a metric used to evaluate the quality of a model. Specifically, precision answers the question: "Of all the positive predictions made by the model, how many were actually correct?"

$$precision = \frac{TP}{TP + FP} \quad (13)$$

F-measure, or F1-score, provides a harmonic mean of precision and recall. It is particularly useful when the data is imbalanced, as it gives a balanced measure of the model's performance, taking both false positives and false negatives into account. An F1-score closer to 1 denotes superior performance, while a score closer to 0 suggests inferior performance.

$$F1 = \frac{2 \cdot precision \cdot recall}{precision + recall} \quad (14)$$

Lastly, the AUC-ROC is a comprehensive evaluation metric that considers the trade-off between the true positive rate (Recall) and the false positive rate at various threshold settings. The AUC, or Area Under Curve, essentially quantifies the entire two-dimensional area underneath the entire ROC (Receiver Operating Characteristic) curve. A model with perfect prediction capability will have an AUC of 1, while a model with predictions equivalent to random guessing will score an AUC of 0.5.

Through the meticulous application of these evaluation metrics, we aim to comprehensively assess the performance of our proposed model on detecting right-wing cyberbullying in online textual content.

## V. EXPERIMENTAL RESULTS

### A. Feature Engineering

Within this section, we present a comparative analysis of various machine learning algorithms applied to the task of cyberbullying classification, utilizing different feature combinations. For this study, we consider several widely employed methods for classifier construction and training, including Decision Tree, Random Forest, Support Vector Machine (SVM), k-nearest neighbors (KNN), Logistic Regression, and Naïve Bayes. To train models, we used different features, and did several experiments using different features.

Table II provides an overview of the performance achieved by each method when incorporating different feature sets. Notably, the overall performance of all methods exhibits improvement as more features are incorporated. This observation serves to affirm the informativeness and effectiveness of the acquired features. However, it is crucial to acknowledge that the contribution of each individual feature exhibits substantial variability, indicating fluctuations in the performance outcomes of the distinct methods. Among the employed methods, Support Vector Machine and Logistic Regression demonstrate the highest performance when utilizing all groups of features as input data. Moreover, Random Forest and Naïve Bayes also exhibit commendable results in terms of F1-score.

TABLE II. COMPARISON OF THE PREVIOUS STUDIES

Approach	Applied Feature	Accuracy	Precision	Recall	F-measure	AUC-ROC
<b>Proposed LSTM-CNN</b>	-	<b>0.9752</b>	<b>0.9687</b>	<b>0.9896</b>	<b>0.9828</b>	<b>0.9867</b>
Random Forest	Statistic	0.5846	0.5728	0.5828	0.5710	0.5764
	Statistic + TFIDF	0.5972	0.5946	0.5916	0.5934	0.5908
	Statistic + TFIDF + LIWC	0.5992	0.5987	0.5972	0.5929	0.5934
Decision Tree	Statistic	0.5629	0.5687	0.5638	0.5618	0.5607
	Statistic + TFIDF	0.5793	0.5781	0.5719	0.5764	0.5718
	Statistic + TFIDF + LIWC	0.5892	0.5875	0.5816	0.5817	0.5871
KNN	Statistic	0.6235	0.6219	0.6187	0.6172	0.9128
	Statistic + TFIDF	0.6381	0.6346	0.6324	0.6308	0.6305
	Statistic + TFIDF + LIWC	0.6398	0.6357	0.6318	0.6327	0.6309
Naïve Bayes	Statistic	0.5246	0.5164	0.5129	0.5134	0.5109
	Statistic + TFIDF	0.5264	0.5218	0.5207	0.5231	0.5203
	Statistic + TFIDF + LIWC	0.5316	0.5306	0.5294	0.5234	0.5219
Logistic Regression	Statistic	0.6786	0.6734	0.6726	0.6716	0.6708
	Statistic + TFIDF	0.7102	0.7164	0.7106	0.7126	0.7131
	Statistic + TFIDF + LIWC	0.7193	0.7164	0.7128	0.7146	0.7148
Support Vector Machines	Statistic	0.6989	0.6978	0.6946	0.6942	0.6982
	Statistic + TFIDF	0.7093	0.7064	0.7048	0.7028	0.7042
	Statistic + TFIDF + LIWC	0.7223	0.7208	0.7203	0.7207	0.7206

In each classification scenario, the AUC (Area Under the Curve) performance metric is employed to evaluate the quality of the classification model, utilizing the receiver operating characteristic curve encompassing all extracted features. Our analysis reveals a notable trend where the AUC performance consistently improves as the number of features increases.

Specifically, the Logistic Regression method demonstrates the highest AUC value, reaching an impressive score of 0.9759.

Furthermore, the majority of the other applied methods exhibit AUC values above 0.9, indicating strong discriminatory capabilities. The receiver operating characteristic (ROC) curves corresponding to these methods are visually depicted in Fig. 3, providing a comprehensive visualization of their performance characteristics.

Fig. 3. Obtained results.

Fig. 4 vividly portrays the Area Under the Receiver Operating Characteristic Curve (AUC-ROC) for the proposed hybrid Long Short-Term Memory and Convolutional Neural Network (LSTM-CNN) model. The Fig. 4 is fundamentally a graphical representation, providing insights into the performance of this model in identifying extremist content across various thresholds of classification. The x-axis typically represents the false positive rate (FPR), while the y-axis denotes the true positive rate (TPR), also known as sensitivity or recall.

Fig. 4. AUC-ROC curve in.

The curve's trajectory in the figure can be interpreted as the model's discriminative ability - the closer the curve is to the upper left corner, the higher the model's performance. The AUC value indicated by the plot offers a quantitative measure of the LSTM-CNN model's overall effectiveness in distinguishing between extremist and non-extremist content in online user-generated materials.

## VI. DISCUSSION

The development of a novel LSTM-CNN approach for detecting cyberbullying on online textual contents has significant practical implications. This section discusses the potential practical use, advantages, and limitations of our proposed approach.

### A. Practical Use

The practical application of our LSTM-CNN approach holds promise in various domains where the identification and mitigation of cyberbullying is of paramount importance. Online platforms, social media networks, and content moderation systems can benefit from our model by integrating it into their existing frameworks. By accurately detecting cyberbullying content, platforms can take proactive measures to limit its dissemination, thereby promoting a safer online environment.

Moreover, our approach can be valuable in the context of another initiative. It provides a tool to identify and monitor

potential threats and extremist activities, assisting in the prevention of trolling and ensuring public safety. Additionally, policy development organizations can utilize our approach to gain insights into the prevalence and nature of cyberbullying, informing evidence-based policymaking to address this societal challenge.

### B. Advantages of the Proposed Model

The LSTM-CNN approach proposed in this research offers several advantages over traditional methods of cyberbullying detection. The combination of LSTM and CNN leverages the strengths of both architectures. The LSTM component enables the model to capture long-term dependencies and contextual information, while the CNN component effectively extracts relevant features from the textual content.

Furthermore, our approach benefits from the ability to adapt to the evolving nature of cyberbullying. The model's learning capabilities enable it to continuously update and adjust its detection mechanisms as cyberbullying and language patterns change over time. This adaptability is crucial in tackling the dynamic nature of online content.

Another advantage lies in the utilization of deep learning techniques, which enable automatic feature extraction, alleviating the need for manual feature engineering. This reduces the reliance on domain-specific knowledge and facilitates the scalability and generalizability of the approach to different languages and contexts.

### C. Limitations

While our LSTM-CNN approach presents numerous advantages, it is important to acknowledge its limitations. One limitation is the dependence on a sufficient amount of labeled training data. Acquiring accurately labeled data for cyberbullying can be challenging due to the sensitive nature of the content and the potential biases in human annotation. Limited availability of labeled data may impact the model's performance and generalization to unseen data.

Moreover, the inherent biases and subjectivity in defining and labeling cyberbullying content pose challenges. Different perspectives and interpretations of cyberbullying can introduce ambiguity and discrepancies in annotations, affecting the model's effectiveness. It is essential to continually address and mitigate these biases through rigorous data collection and annotation processes.

Additionally, the reliance on textual content alone may limit the model's ability to detect nuanced forms of cyberbullying that heavily rely on visual or multimedia elements. Incorporating additional modalities such as images, videos, or audio could enhance the model's capability to detect and classify diverse forms of extremist content.

Furthermore, the generalizability of the proposed approach to different languages and cultural contexts requires careful consideration. Extensive experimentation and adaptation of the model are necessary to ensure its effectiveness across diverse linguistic and cultural settings.

## VII. CONCLUSION

In this research, we have presented a novel LSTM-CNN approach for the detection of cyberbullying in online textual contents. Our approach leverages the combined power of Long Short-Term Memory (LSTM) and Convolutional Neural Network (CNN) architectures, capitalizing on their respective strengths in capturing long-term dependencies and extracting relevant features from textual data.

Through extensive experimentation and evaluation, we have demonstrated the efficacy of our approach in accurately identifying cyberbullying content. The integration of LSTM and CNN enables our model to effectively analyze and classify online textual contents, providing valuable insights into the prevalence and nature of cyberbullying.

The practical implications of our research are significant. Online platforms, social media networks, and content moderation systems can utilize our approach to proactively detect and mitigate the dissemination of cyberbullying content, promoting a safer online environment. Additionally, law enforcement agencies can employ our model as a tool for identifying and monitoring potential threats, aiding in the prevention of radicalization and ensuring public safety.

Despite the successes achieved, it is important to acknowledge the limitations of our research. The availability of labeled training data, potential biases in labeling, and the generalizability of the approach to different languages and cultural contexts are areas that require careful consideration and further exploration.

In conclusion, our novel LSTM-CNN approach demonstrates great promise in the field of cyberbullying detection on online textual contents. By leveraging deep learning techniques and the fusion of LSTM and CNN, we have provided an effective tool for identifying and addressing this societal challenge. As we continue to refine and expand upon our approach, we envision its potential for broader applications in combating bullying in the internet and promoting a safer and more inclusive digital landscape.

**Abstract**—In the ever-evolving realm of infrastructure management, the timely and accurate detection of road surface damages is imperative for the longevity and safety of transportation networks. This research paper introduces a pioneering framework centered on the Mask R-CNN (Region-based Convolutional Neural Networks) model for real-time road surface damage detection. The overarching methodology encapsulates a deep learning-based approach to discern and classify various road aberrations such as potholes, cracks, and rutting. The chosen Mask R-CNN architecture, renowned for its proficiency in instance segmentation tasks, has been fine-tuned and optimized specifically for the unique challenges posed by road surfaces under diverse lighting and environmental conditions. A diverse dataset, amalgamating urban, suburban, and rural roadways under varied climatic conditions, served as the foundation for model training and validation. Preliminary results have not only underscored the model's robustness in real-time detection but also its superiority in terms of accuracy and computational efficiency when juxtaposed with extant methods. Concomitantly, the framework emphasizes scalability and adaptability, positing it as a frontrunner for potential integration into automated road maintenance systems and vehicular navigation aids. This trailblazing endeavor elucidates the potentialities of deep learning paradigms in revolutionizing road management systems, thus fostering safer and more efficient transportation environments.

**Keywords**—Deep learning; CNN; random forest; SVM; neural network; prediction; analysis

## I. INTRODUCTION

Road infrastructure remains a pivotal element in the socio-economic fabric of nations, serving as the backbone of trade, transportation, and daily commuting [1]. As urbanization and globalization continue to expand, so does the reliance on a durable and well-maintained road network. While the necessity of pristine road infrastructure is universally recognized, it's equally undeniable that roadways are persistently subjected to degradation [2]. Factors such as climatic extremes, vehicular stress, and natural wear-and-tear all contribute to the deterioration of road surfaces [3]. The consequent damages, ranging from innocuous surface irregularities to perilous potholes, pose significant safety risks to motorists, exacerbate vehicular wear, and escalate maintenance costs. Hence, timely

and accurate damage detection is a sine qua non for effective road maintenance and ensuring commuter safety.

Historically, the task of road surface damage detection was primarily relegated to manual inspections. Field engineers and surveyors would periodically inspect stretches of road, logging visible damages for subsequent repair. However, such methods are inherently fraught with shortcomings. Human inspections are not only labor-intensive and time-consuming but are also marked by subjective biases and are often limited by the perceptual constraints of the human eye. Furthermore, large-scale road networks make manual monitoring a logistical challenge, often leading to significant delays between damage occurrence and its eventual rectification [4].

Emerging from this backdrop, technological solutions began to surface, attempting to alleviate the limitations of manual inspection. Early endeavors in this direction exploited image processing techniques to detect road anomalies [5]. While promising, these rudimentary techniques often grappled with issues of low accuracy, particularly in diverse environmental and lighting conditions [6]. More advanced techniques leveraging pattern recognition and machine learning offered an uptick in detection capabilities but remained hamstrung by their inability to perform adequately in real-time scenarios and their frequent misclassifications in complex road environments [7].

The recent upswing in the adoption of deep learning models across diverse domains signaled a transformative potential for road damage detection. Deep learning, a subset of machine learning, empowers models to learn and make decisions from vast amounts of data, often surpassing human-level performance in specific tasks [8]. In the context of road damage detection, Convolutional Neural Networks (CNNs) have emerged as a favored tool due to their adeptness in handling image data [9]. However, while CNNs are proficient in classification tasks, the intricate nature of road damage detection demands a more nuanced approach, one capable of instance segmentation—a task that goes beyond mere classification and seeks to delineate and identify specific objects within images.

This is where the Mask R-CNN model [10] enters the fray. An evolution of the established R-CNN [11] and Fast R-CNN [12] architectures, Mask R-CNN has proven its mettle in

instance segmentation tasks across various domains. Its unique architecture, which seamlessly integrates the strengths of both its predecessors, enables precise object localization and pixel-wise mask prediction. Such capabilities render it an intriguing prospect for the intricacies of road surface damage detection.

This research paper aims to exploit the prowess of the Mask R-CNN model in developing a comprehensive framework for real-time road surface damage detection. Drawing upon a meticulously curated dataset encompassing a myriad of road types and conditions, the study seeks to optimize and fine-tune the Mask R-CNN model for this specialized task. Moreover, this investigation delves deep into the challenges inherent in road damage detection, such as variable lighting, shadow effects, wet surfaces, and other environmental nuances. By addressing these complexities, the paper aims to elevate the discourse on automated road damage detection and present a robust, scalable, and efficient solution.

In doing so, this paper positions itself at the intersection of advanced deep learning paradigms and pressing infrastructural challenges. It aspires not just to contribute to academic discourse but also to catalyze tangible shifts in how road maintenance authorities across the globe approach the monumental task of road upkeep and safety assurance. By marrying the Mask R-CNN model's capabilities with the real-world demands of road damage detection, this study embarks on a journey to redefine the standards of road infrastructure management in the age of artificial intelligence.

## II. RELATED WORKS

The journey of automating road surface damage detection has been a progressive one, punctuated by incremental innovations and paradigm shifts. As this research navigates the waters of the Mask R-CNN model for real-time road surface damage detection, it is imperative to contextualize its approach within the broader framework of previous efforts in this domain. This section endeavors to provide a comprehensive review of related works, elucidating the trajectory of technological advances that have shaped the discourse on automated road damage detection.

### A. Traditional Image Processing Techniques

The inception of automated methodologies for road surface damage detection is deeply rooted in traditional image processing techniques. In the nascent stages, simple, yet effective algorithms such as edge detection, thresholding, and morphological operations were employed to discern road anomalies, primarily cracks and potholes. Pioneering research, exemplified by the work of [13], and made strides in this domain by harnessing wavelet transforms for enhanced crack detection. While these early techniques represented a significant leap from manual inspection, they were not without their limitations. Particularly, their susceptibility to variable environmental conditions, such as fluctuating lighting and shadows, frequently resulted in a high rate of false positives. Consequently, despite their foundational contributions, it became evident that more sophisticated approaches were needed to achieve the precision and reliability demanded by real-world applications in road maintenance.

### B. Machine Learning and Pattern Recognition

Transitioning from the foundational image processing methodologies, the domain witnessed a paradigm shift with the advent of machine learning and pattern recognition techniques. Here, the emphasis transitioned from raw image manipulation to extracting discernible features, which could then be classified using algorithms. A seminal contribution in this realm was made by [14], who adeptly combined texture-based feature extraction with Support Vector Machines (SVM) to pinpoint road cracks. This strategy elevated the accuracy of detection substantially. However, it also introduced the intricacy of manual feature engineering, a labor-intensive endeavor with potential for inconsistencies. Despite the undeniable advancement in damage detection these methods brought about, the challenges they posed emphasized the need for more automated and adaptive solutions, paving the way for the exploration of deep learning techniques in subsequent research.

### C. Deep Learning and CNNs

The renaissance of neural networks, especially Convolutional Neural Networks (CNNs), ushered in a new era for road damage detection. The beauty of CNNs lies in their ability to automatically learn features from raw image data without explicit manual feature engineering. Significant contributions in this realm include the work of [15], who developed a road damage detection and classification system based on deep CNNs. Their model was not only adept at identifying damages but also categorizing them into types like cracks, potholes, and patches. However, while CNNs were proficient in classifying damaged regions, delineating the exact boundaries of these damages remained a challenge.

### D. R-CNN and its Evolution

The introduction of Region-based Convolutional Neural Networks (R-CNN) signaled a quantum leap in object detection tasks. R-CNN and its evolutionary offshoots, Fast R-CNN and Faster R-CNN, integrated region proposal networks with CNNs, allowing precise object localization within images [16-18]. In the context of road damage detection, this meant an enhanced ability to identify and demarcate specific damaged regions within a broader road image. The works of [19] stand testament to the efficacy of Faster R-CNN in detecting and segmenting road damages.

### E. Instance Segmentation with Mask R-CNN

Delving deeper into the world of object detection, the Mask R-CNN model emerged as a revolutionary tool, bringing the nuance of instance segmentation to the fore. Building upon the foundation laid by its predecessors, the Faster R-CNN, the Mask R-CNN transcended mere object localization, offering pixel-wise mask prediction for each identified entity within an image [20]. This level of granularity made it an optimal candidate for tasks requiring meticulous delineation, such as road damage detection. Early explorations into the model's applicability, highlighted by studies like those of [21], exhibited promising outcomes. The ability of the Mask R-CNN to pinpoint and define road surface anomalies with precision underscored its potential to set a new benchmark in the domain, promising a convergence of accuracy and granularity hitherto unseen in earlier methodologies.

### F. Real-Time Detection Challenges

While the evolution of detection techniques marked notable advancements, the exigencies of real-time processing remained a pivotal concern. The operational demands of road maintenance necessitate not just accuracy, but also timeliness in damage detection. Architectures like YOLO (You Only Look Once) and SSD (Single Shot MultiBox Detector), as elucidated by researchers such as [22-23], respectively, heralded solutions emphasizing real-time object detection. Though not tailored explicitly for road anomalies, the underlying principles of these frameworks provide invaluable insights. They spotlight the intricate balance and potential trade-offs between detection speed and accuracy. Such considerations are paramount when envisioning a model that operates in dynamic real-world settings, reinforcing the need for an optimal blend of precision and promptness in any prospective road damage detection system.

### G. Adaptive Learning and Transfer Learning

With vast and diverse road networks, training models from scratch becomes computationally expensive. The concept of transfer learning, where models pre-trained on large datasets are fine-tuned for specific tasks, gained traction. The author in [24] explored transfer learning for road damage detection, leveraging models initially trained on datasets like ImageNet and adapting them to the specific nuances of road images.

In synthesizing the above, one discerns a clear trajectory: from basic image processing to the intricacies of deep learning, and from the broad strokes of object detection to the finesse of instance segmentation. This research positions itself at this evolving frontier, seeking to harness the potential of Mask R-CNN, not just in terms of detection accuracy but also in meeting the demands of real-time processing.

## III. MATERIALS AND METHODS

A comprehensive review of pertinent literature underscores the unparalleled efficacy of deep convolutional neural networks (DCNNs) in current scholarly investigations. A pivotal initial step involves segmenting roadway imagery to demarcate relevant classes, crucial for defect identification. Presently, CNN architectures, such as the SegNet [25] and U-Net [26], are gaining traction for their effectiveness in this domain. The challenge arises from the subtle grayscale variations in road imagery and the minimal contrast between the intended subject and its backdrop, compounded by incidental noise and unrelated elements. To navigate these challenges, a fully convolutional neural network (FCNN) employing an "encoder-decoder" configuration is utilized, yielding a binary output image [27]. The FCNN bifurcates into a convolutional segment—transforming the primary image into a feature-rich representation—and a segment producing the segmented output from these features. This architecture encompasses a series of convolutional strata, augmented by filters and subsequent sub-discretization tiers. By integrating upsampling with convolutional stages, the architecture reconstructs the initial image dimensions, subsequently crafting a likelihood matrix.

The CrackForest dataset comprises 117 snapshots, partitioned into training, testing, and validation subsets. For each image, 64x64 segments are extracted arbitrarily from both training and test sets. Image quality amplifies with gamma correction, enhancing neural network performance. A 95:5 ratio, emphasizing defects constituting at least 5% of the image, is deemed optimal. With 15,200 training fragments juxtaposed against 3,968 test fragments, the balance is deemed propitious for the deep learning process. The network's evaluation employs intersection over union metrics, complemented by binary similarity metrics. Weight initialization within FCNN layers leverages the Glorot technique, normalizing each layer's input distributions, thus mitigating internal covariance shifts. Optimization ensues via the Adam optimizer. Research concludes that an optimal 25-epoch training duration—split between an initial 5 epochs and a subsequent 20—is effective. Execution of the FCNN blueprint leverages both Keras and TensorFlow platforms. Upon training completion, the artificial neural network undergoes rigorous testing and validation using sample data.

In this study, an enhanced methodology trained existing Mask R-CNN models via TensorFlow's Object Detection API, aiming to augment road defect detection efficiency. These refined models subsequently underwent rigorous evaluations utilizing meticulously curated annotation datasets.

### H. Data Collection and Preparation

Traditionally, road surface damage detection relied on aerial images or imagery sourced from vehicle-mounted cameras. Aerial imaging poses practical challenges due to the intricacies involved in capturing such images, restricting its widespread application. Conversely, using imagery derived from vehicle-mounted cameras offers more pragmatic utility, considering the ease of data acquisition. This positions commonly available devices, like smartphones, as potential tools for damage detection, whether the processing occurs in situ or is offloaded to a remote server. Consequently, we developed a unique dataset encompassing six distinct categories of road damage, with each image meticulously annotated by hand.

Fig. 1 presents a visual guide to the diverse damage types, denoted by specific class names such as D20. The subsequent illustrative table segregates these damages into six primary categories, distinguishing between cracks and other deformities. Crack-based damages further bifurcate into linear and alligator cracks, while other categories span potholes, ruts, and anomalies like faded lane markings. Notably, the breadth of damage categories explored in our study outstrips the limited scopes of prior works. For instance, the approach proposed by [28] merely detects potholes under the D40 label, while Jana et al. [29] differentiates damages strictly as longitudinal or transverse. Further, preceding deep learning studies [30-33] primarily focus on identifying the mere presence or absence of damage.

Fig. 1. Road damage photos and classes for a model training.

### I. Annotation and Classification for Enhanced Damage Detection

To facilitate a refined categorization, our annotation data delineates 12 distinct classifications of road damage and associated features captured in the photographs. The Microsoft Visual Object Tagging Tool (VoTT) was instrumental in annotating these color images. Within each image, specifically its lower two-thirds, every discernible feature within our predefined classes was segmented and appropriately labeled. Table I elucidates the compiled annotation data.

Among these classifications, "Scratches on Markings" emerged as the most prevalent, boasting 3,360 segments. This was closely followed by "Linear Cracks" at 3,080 segments. On the rarer end, "Grid Cracks in Patchings" registered the least at 252 segments, succeeded by "Stains", "Manholes", and

"Potholes". For analytical rigor, the data segments were stratified into training, validation, and testing datasets at a proportion of 0.6:0.2:0.2, respectively.

In our comprehensive research, we established a refined taxonomy of annotation data that encompasses 12 unique classifications pertinent to road damage and its corresponding features as depicted in the photographic evidence. The intricacies of the annotation process were adeptly managed using the Microsoft Visual Object Tagging Tool (VoTT), which proved pivotal for effective categorization within the color images. A keen focus was directed towards the inferior two-thirds of each image. Within this portion, every feature that aligned with our pre-established categories was diligently segmented and given an appropriate label. For a detailed scholarly overview, readers are directed to Table I, which presents a thorough synthesis of the amassed annotation data.

TABLE I. ROAD IMAGES ANNOTATION DATA

Class ID	Classes	Training	Validation	Testing	Total
1	Linear crack	3080	660	660	4400
2	Grid crack	658	141	141	940
3	Pavement joins	854	183	183	1220
4	Patchings	448	96	96	640
5	Fillings	1344	288	288	1920
6	Pot-holes	406	87	87	580
7	Manholes	336	72	72	480
8	Stains	266	57	57	380
9	Shadow	1190	255	255	1700
10	Pavement markings	1414	303	303	2020
11	Scratches on markings	3360	720	720	4800
12	Grid crack in patchings	252	54	54	360
0	Total	13608	2916	2916	19440

Among these classifications, "Scratches on Markings" emerged as the most prevalent, boasting 3,360 segments. This was closely followed by "Linear Cracks" at 3,080 segments. On the rarer end, "Grid Cracks in Patchings" registered the least at 252 segments, succeeded by "Stains", "Manholes", and "Potholes". For analytical rigor, the data segments were stratified into training, validation, and testing datasets at a proportion of 0.6:0.2:0.2, respectively.

#### IV. PROPOSED NETWORK

In pursuit of an integrated solution for crack identification and their granular pixel-wise delineation, the contemporary Mask R-CNN convolutional network architecture was chosen. Delving into its foundation and operational mechanics, one finds that the Mask R-CNN is rooted in a lineage of convolutional neural networks designed for localized region processing. This lineage encompasses the Region-based Convolutional Neural Network (R-CNN), its subsequent iterations in Fast R-CNN, and the even more refined Faster R-CNN.

Fig. 2 portrays our adoption of the Mask R-CNN architecture tailored for road surface damage identification. At its core, the Mask R-CNN framework is intrinsically intricate in its block configuration. The initial phase involves the input image being processed through the network, highlighting a

feature map. Common feature extractors employed for this purpose include VGG-16, the 50-layer Residual Neural Network (ResNet50), and the more extensive 101-layer Residual Neural Network (ResNet101), with layers focused on classification being omitted. An evolutionary distinction of this architecture, setting it apart from earlier iterations, is the incorporation of the Feature Pyramid Network (FPN) methodology. This technique is pivotal in harvesting feature maps across varied scales. Within this paradigm, consecutive layers of the network, characterized by descending dimensions, are perceived as a stratified "pyramid", where lower tier maps are high-resolution, and the apex tiers possess enhanced semantic abstraction.

Post this feature map extraction, the Region Proposals Network (RPN) segment takes center stage. Its primary objective is to pinpoint hypothesized regions within the image that potentially harbor objects. This is achieved by sliding a 3x3 neural network window over the feature map, with the output anchored on predefined 'k anchors' – essentially frameworks with specified dimensions and orientations. For every such anchor, the RPN forecasts the object's presence and, if detected, fine-tunes the coordinates of the object's bounding box. This stage's ultimate goal revolves around spotlighting regions brimming with potential object presence. Consecutively, overlapping regions are eliminated, courtesy of the non-maximum suppression operation.

Fig. 2. Proposed mask R-CNN model for road surface damage detection.

In the subsequent phase, the Region of Interest (ROI) Align mechanism comes into play, selecting values pertinent to these regions from the feature maps and standardizing them to a uniform size. These harmonized values then undergo final processes including classification, adjustment of bounding box coordinates, and mask prediction. Notably, the emergent mask, despite its considerably diminished size, retains real values. Once the mask is scaled congruent to the object's dimensions, the precision achieved is commendable.

## V. EVALUATION

To ascertain the efficacy of the suggested model, it's evaluated against key metrics, specifically the mean average precision (MaP) and the average recall (AR), both scrutinized at varying thresholds of intersection over union (IoU). In scenarios involving classification paired with object localization and detection, the ratio derived from the areas of the bounding boxes frequently serves as a determinant metric, reflecting the accuracy of the bounding box placement.

Embedded within the Mask RCNN is a region proposal network layer, adept at executing parallel inferences concerning class categorization, segmentation, and mask territories, leading to a resultant of six distinctive loss metrics. Complementing these inherent model-specific metrics, both average precisions and average recalls, benchmarked at an IoU value of 0.5, are employed across all twelve delineated road object categories, as referenced in [34].

$$IoU = \frac{S(A \cap B)}{S(A \cup B)} \quad (1)$$

Given A as the forecasted bounding box and B as the reference bounding box, the Intersection over Union (IoU) serves as a metric. The IoU value stands at zero when the bounding boxes do not intersect, and reaches its zenith of one when the bounding boxes perfectly coincide.

A pivotal aim of evaluation is maximizing the detection of instances within a given population using a screening method. It's imperative that false negatives are curtailed, even if it necessitates an uptick in false positives. This emphasis necessitates the careful consideration of three fundamental metrics: the true positive rate (TPR), false positive rate (FPR), and overall accuracy (ACC). Within the realm of medical terminologies, TPR often finds its synonym in sensitivity (SEN) and is represented as seen in equation (2), as documented in [35].

$$TPR = SEN = \frac{TP}{P} \quad (2)$$

Let TP represent the count of true positives, while P signifies the total positive instances in the dataset.

The quantification of the subsequent metric, the false positive rate, is articulated in equation (3), as delineated in [36]:

$$FPR = \frac{FP}{N} \quad (3)$$

Where N denotes the aggregate count of negative cases in the population and FP symbolizes the number of false positives. Furthermore, the true negative instances are also represented by N. However, a more intuitive understanding of this metric is the fraction of true negatives out of the actual negative cases. In medical terminology, this metric is often referred to as specificity (SPEC), articulated as equation (4), as cited in [37]:

$$TNR = SPEC = \frac{TN}{N} = 1 - FPR \quad (4)$$

Ultimately, the metric of accuracy encapsulates the equilibrium between true positive and true negative outcomes. This metric becomes particularly insightful when there exists an imbalance between positive and negative instances within the dataset. This is quantitatively represented in equation (5), as referenced in [38]:

$$ACC = \frac{TP + TN}{P + N} \quad (5)$$

## VI. EXPERIMENTAL RESULTS

Within this segment, the experimental findings are bifurcated into two distinct subsections. The initial subsection elucidates the results pertaining to road damage detection, followed by an exposition on road damage segmentation outcomes. The subsequent section delves into the real-time performance of the proposed model, accompanied by visual demonstrations. This encompasses both original imagery and annotated representations of road conditions. In the third subsection, a comprehensive assessment of the model is presented, detailing evaluative metrics such as precision, recall, and F-score for the respective categories of road surface impairments.

### A. Road Damage Detection Results

Leveraging the intricacies of the Mask R-CNN architectural framework, we developed a nuanced system tailored for road damage detection. This state-of-the-art approach is adept at swiftly and accurately discerning multiple forms of roadway degradation, encompassing anomalies like cracks and spalling, as evidenced in the images procured using digital photographic equipment. To facilitate an insightful understanding and comparison of the system's performance, Table II meticulously catalogs the results of the damage detection endeavor. This tabulation emphasizes evaluative metrics, notably precision, recall, and the F1-score, underscoring the robustness and precision of the devised methodology.

### B. Road Damage Segmentation Results

In the process of isolating the segment of the image associated with the roadway, pixels within the road mask are accentuated. Subsequently, an 8-connected region search algorithm is employed on the resultant binary mask. The region boasting the highest pixel count is subsequently identified as the coverage mask, as depicted in a gray shade in Fig. 3.

TABLE II. EVALUATION OF THE PROPOSED METHOD BY CLASSES

Model	Precision	Recall	F1-score
<b>Proposed model</b>	<b>0.9214</b>	<b>0.9876</b>	<b>0.9571</b>
Fully convolutional encoder–decoder network [39]	0.9130	0.9410	0.9270
Deep learning-based semantic segmentation [40]	0.8340	0.6855	0.7524
UNet-based concrete crack detection CrackUnet19 [41]	0.9145	0.8867	0.9004
Two-step light gradient boosting machine [42]	0.6801	0.7578	0.6950
Semantic segmentation using deep learning [43]	0.4044	0.7847	0.4994
Automated vision-based detection [44]	0.9236	0.8928	0.9079

Fig. 3. Marked up road images.

To assess the proficiency of the devised methodology for defect detection, a curated dataset comprising 50 authentic images showcasing road cracks was meticulously assembled. Fig. 4 juxtaposes the outcomes of manual crack delineation against the segmentation outcomes achieved through the proposed neural network's granular pixel-wise selection on an actual image.

Fig. 4. Marked up pixel-wise selection of road images.

Fig. 5 presents the outcomes of model evaluation over 100 epochs. In Fig. 5, the accuracy and validation accuracy of the advanced model are delineated. It can be inferred from the data that our model achieves an approximate accuracy of 90% within 60 epochs, indicative of its robustness and applicability in real-world scenarios.

Fig. 6 depicts the training and validation loss associated with the model. The observed minimal loss suggests that the model is poised to commit minimal errors in practical applications.

Fig. 5. Accuracy in road damage detection.

Fig. 6. Loss in road damage detection.

Various strategies employing deep learning paradigms aim to enhance road safety. Contemporary research offers innovative solutions to this issue [45]. For instance, [46] introduced a Vehicle Re-Identification technique to address challenges stemming from significant intra-class variances due to changing vehicle viewpoints during motion and pronounced inter-class resemblances due to analogous appearances. Our model is tailored to identify road surface imperfections using smartphone cameras or any equipment capable of capturing real-time road footage. Based on the results from the conducted experiments, it can be posited that deep learning techniques hold promise in addressing road safety and security challenges.

Table III presents the metrics associated with the model concerning bounding boxes and segmentation masks. For bounding boxes, the metrics for mAP at various IoU thresholds (IoU=.50:.05:.95), mAP (IoU=.50), and mAP (IoU=.75) register as 0.2432, 0.4382, and 0.2482, respectively. In contrast, these metrics for segmentation masks are discerned to be 0.1600, 0.3257, and 0.1279, marking a noticeable decline. The Precision mAP (small) for minuscule objects manifests as markedly lower values, being 0.0365 and 0.0133 for bounding boxes and segmentation masks, respectively, especially when juxtaposed against the Precision mAP for larger and medium-sized entities. The Average Recall metrics for small, medium, and large entities on bounding boxes are quantified as 0.1166, 0.3132, and 0.4717 respectively, whereas the corresponding values for segmentation masks are 0.1021, 0.2528, and 0.2732. Pertaining to our designated damage categories such as linear cracks (denoted as Crack1), grid cracks (labelled as Crack2), potholes, scratches on road markings, and grid cracks in surface repairs, the detection precision metrics at an IoU threshold of .50 are 0.4085, 0.4958, 0.5714, 0.5934, and 0.4000, respectively.

TABLE III. EVALUATION OF THE PROPOSED METHOD BY CLASSES

Classes	Precision @ 0.5 IoU (Bounding box)	Recall @ 0.5 IoU (Bounding box)	Recall @ 0.5 IoU (Segmentation)	Recall @ 0.5 IoU (Segmentation)
Linear crack	0.5383	0.3847	0.3583	0.2639
Grid crack	0.6256	0.7140	0.5920	0.6744
Pavement joins	0.4900	0.5179	0.2498	0.2531
Patchings	0.7644	0.5584	0.8161	0.5843
Fillings	0.6071	0.4667	0.3040	0.2528
Pot-holes	0.7012	0.4155	0.7012	0.4155
Manholes	0.9596	0.8798	0.9596	0.8798
Stains	0.1798	0.1484	0.1191	0.1282
Shadow	0.5273	0.4317	0.3285	0.2713
Pavement markings	0.7522	0.7460	0.5065	0.5002
Scratches on markings	0.7232	0.7531	0.4863	0.4944
Grid crack in patchings	0.5298	0.2474	0.7298	0.3063

## VII. CONCLUSION

## REFERENCES

This research delved deeply into the realm of road surface damage detection, harnessing the potential of the Mask R-CNN architecture. The imperative need to develop robust, accurate, and real-time systems for detecting and classifying road damages stems from the crucial role such systems play in ensuring roadway safety and aiding in timely maintenance. A cornerstone of infrastructure management, road health significantly impacts both economic metrics and public safety.

The Mask R-CNN model showcased its prowess in detecting various types of surface damages with commendable precision. Emphasis was placed on understanding its structural nuances and ensuring optimal parameter selection to refine the resultant models. Features like the Region Proposals Network and the integration of the Feature Pyramid Network brought depth and versatility to the proposed method, allowing it to contend with complex road scenarios.

Key metrics used in assessing the model, including mAP and Average Recall across varying IoU thresholds, offered insightful perspectives into the model's performance. The observed results were heartening, with the model showcasing proficiency, especially in differentiating between minor and significant road damage categories.

Comparative analyses with extant literature reinforced the efficacy of the proposed approach, especially considering the challenges posed by real-time, on-ground situations. The model's capacity to work with images and footage from commonplace devices, such as smartphones, stands testament to its applicability in real-world scenarios, democratizing road damage detection to a broader user base.

In summation, while the world of deep learning and neural networks continues to evolve, the application of these technologies in solving pertinent, real-world challenges, as showcased in this study, remains paramount. The presented work not only contributes a robust solution to road surface damage detection but also lays down a pathway for further refinement and innovation in the domain. As future directions, the integration of more advanced architectures and real-time response mechanisms can further elevate the impact and utility of such systems in global infrastructure management.

# Osteoporosis Detection and Classification of Femur X-ray Images Through Spectral Domain Analysis using Texture Features

Dhanyavathi A, Veena M B

Department of Electronics and Communications, BMS College of Engineering, Bengaluru, India  
Visvesvaraya Technological University, Belagavi-590018, India

**Abstract**—Osteoporosis commonly diagnosed as a bone disorder that affects the significant portion of the population. The Dual X-ray Absorptiometry (DXA) is one of the most accepted standard methods of analyzing the bone disorder, but it is exorbitant. However X-ray is a cost effective, therefore the proposed work introduces a new technique to improve osteoporosis detection and classification of femur bone X-ray image. The spectral based sub band images texture features are used to analyze the Region Of Interest (ROI) femoral head trabecular bone. A spectral domain based on the Two-Dimensional Discrete Wavelet Transform (2D-DWT) is used to represent variations in finer details in the image. Trabecular femur bone texture is determined only by horizontal, vertical, and diagonal sub bands of DWT coefficients. The sub band images are further enhanced by applying the maximum response filter (MRF) at different scales, thereby enhancing the most significant responses. Consequently, the sum of the MRFs of different scale images is considered as the supervised database. To detect osteoporosis, the test and supervised images are analyzed to calculate two significant attributes such as Zero Mean Normalized Cross-Correlation (ZMNC) and Sum Squared Difference (SSD). Based on experimental results, the performance metrics measure is improved in all aspects over current methods.

**Keywords**—Classification; feature; femur; images; normal; osteopenia; osteoporosis; texture

## I. INTRODUCTION

This The disease osteoporosis causes loss of bone density and increases the risk of fractures in millions of people worldwide [1][2]. Debilitating fractures can be effectively managed and prevented with early detection. Osteoporosis is often diagnosed with X-ray imaging, but traditional methods often rely on visual assessment, which may be subjective and subject to human errors [3]. A Convolution Neural Network (CNN) model was used to assess osteoporosis based on hip radiographs. An ensemble model with clinical covariates was also investigated [4]. From a single Dual-Energy X-Ray Absorptiometry (DXA) image of the proximal femur, reconstruct both the 3D bone shape and the Three Dimension Bone Mass Density (3D-BMD) distribution [5]. A set of Quantitative Computed Tomography (QCT) scans, a statistical model of the combined shape and BMD distribution is constructed to detect osteoporosis [6]. A method of estimating the apparent physical BMD of the proximal femur from CT images with good accuracy when evaluating post-menopausal

osteoporosis. The proximal femur radiographs were analyzed using Gabor filters, wavelet transformations, and fractal dimensions-based texture analysis methods to identify osteoporosis [7]. The volumetric estimation of femur bone based on an x-ray image using a computer-based algorithm to detect osteoporosis [8]. A comparison of BMD of CT scan and BMD revealed a difference of 4.53 percent in volume. An analysis was conducted to examine how they related with BMD and anthropometric factors such as height and weight [9]. In recent study, 34% of Indian women had osteoporosis and 20% had osteopenia, respectively. The study measured the energy of the proximal femur trabecular bone as a result of osteoporosis postmenopause using dual-tree complex wavelet transforms (DT-CWT) [10]. DT-CWT has been successfully used to analyze the trabecular pattern on the right proximal femur on radiographs. The Gabor filter was used to calculate features from the trabecular pattern recorded on proximal femur radiographs in the assessment of osteoporosis [11]. In order to justify the classification result, Singh indexes of trabecular pattern are used. An expert system designed for diagnosing osteoporosis based on measuring bone texture using fuzzy X-ray images [12]. A fuzzy X-ray imaging technique analyzes trabecular bone texture and thus calculates bone density by combining resolution enhancement algorithms and edge detection algorithms. Both algorithms are efficient at calculating disease severity. An image of a femur bone can be classified using morphometric features from the image segmented [13]. The femur bone structure is segmented using active contour method from a 2D X-ray radiograph and morphometric measurements are calculated in pixel values for head diameter, head height, neck diameter, and intertrochanteric distance in the proximal femur and neck. Several images of patients with osteoporotic, osteopenia, and normal conditions are collected using computer tomography (CT) [14]. MIMICS software is used to analyze the condition more effectively. Initially, the images must be imported into the MIMICS software for analysis. An effected, normal femur bone is generated in 3D by MIMICS software and osteopenia and normal patients can use the analysis as a precaution. Gradient Harmony Search (GHS) optimization based deep networks are used for classification [15]. A Harmonic Search (HS) algorithm is incorporated with a Gradient Descent (GD) algorithm is used to build GHS. Utilizing machine learning and image processing techniques to detect early-stage fractures caused by osteoporosis in femur image [16]. The Fracture Risk Assessment tool (FRAX) calculations were performed

retrospectively on 560 volunteers (age at least 50 years) who underwent hip-spine X-rays, BMD scans and FRAX tool calculations [17]. To determine whether Cortical Thickness Index (CTI) and Canal Flare Index (CFI) are used to calculate neck BMD (nBMD) on anteroposterior radiographs, both indices were measured on anteroposterior radiographs. Based on characterization of BMD and trabecular bone microarchitecture, an automated approach was developed to predict biomechanical bone strength in proximal femur specimens [18]. As a diagnostic biomarker for osteoporosis diagnosis, tracking disease progression, and evaluating the response to therapeutic intervention, the automated and objective way trabecular bone microarchitecture is analyzed, and the subsequent reduction performance achieved suggest that it may be utilized in this manner. Two Deep learning Convolution Neural Networks (DCNNs) i.e., Alex Net and Google Net were trained on anteroposterior hip radiograph images to detect risk in the neck of femur [19]. Feasible element analysis (FEA) of the hip guided by high-resolution magnetic resonance imaging (MRI) has been developed to assess subject-specific bone strength [20]. If technique is further validated, management of hip fracture risks in the clinic may be useful. Researchers evaluated the involvement of spinal and hip flexion discordances in Korean patients with a typical femoral fractures and femur neck fractures [21]. Discordances might be affected by osteoporotic fracture locations. Using conventional radiographs obtained for various indications, a robust opportunistic screening tool for osteoporosis and fracture risk assessment was demonstrated to provide vertebral compression fractures detection, BMD estimation, and fracture risk estimation in a fully automated manner [22]. In assessing fracture risk, parameters and their interactions are analyzed [23]. In a multiple regression analysis, bone density and the loading directions in a sideways fall have been considered as independent variables along with the fracture risk index as a dependent variable. As independent variables, angle about the femoral neck axis at the coronal and transverse ends of the shaft was measured in both coronal and transverse planes. In the interaction analysis of parameters, bone density appears to have a greater effect on fracture risk. Although analyzing the current techniques for detecting osteoporosis in femur images helps to a definite conclusion, while several challenges remain, there is a need for the work to be advanced. To produce more comprehensive work and enhance system performance, a new approach of osteoporosis detection in femur image based on spectrum analysis is introduced in this work.

## II. METHODOLOGY FOR PROPOSED WORK

The Fig. 1 illustrates the proposed work analysis is on the basis of spectral domain, 2D-DWT spectral domain analysis is introduced to analyze texture features of the X-ray of ROI femur images, offering valuable insights beyond the visual representation.

An analysis of the spectral features of image texture in two dimensions is carried out by one level decomposition of 2D-DWT [24][25]. Detecting osteoporosis involves two steps: the first is analyzing texture features on ROI images of femur bones and then deciding whether the given test image is normal (healthy bone) or abnormal (osteopenia or osteoporosis). By focusing on Horizontal Coefficients (HC), Vertical

Coefficients (VC), and Diagonal Coefficients (DC), the feature dimension in 2D-DWT can be reduced substantially. As a result, the proposed system model can detect bone diseases effectively with this reduced set of image texture. Ultimately, this work aims to obtain meaningful information from texture features by using symmetric wavelet family. With wavelet transformations, extracting texture information at different directions depending on how it is oriented. Further the image texture analysis of 2D-DWT is executed using MRFs at different scales. In order to classify normal or abnormal images, test and supervised images are matched based on attributes of ZMNCC and SSD of MRFs.

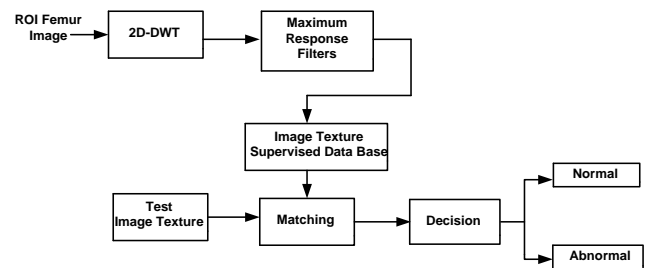

Fig. 1. Block schematic for the suggested work.

### A. Two Dimension Discrete Wavelet Transform

The 2D-DWT is a versatile and powerful tool for analyzing and processing 2D data like images, and its significance be situated in its capability to provide a compact and meaningful representation that facilitates various texture analysis in spectral domain. There were four sub band images in a one level decomposed 2D-DWT is illustrated in Fig. 2. Rows of the input image matrix are first transformed with an LPF and HPF, then its columns are treated with an LPF and HPF to produce sub band images are like approximation coefficients i.e., AC and three detail sub band images like HC, VC, and DC correspond to horizontal, vertical, and diagonal coefficients, respectively and each sub band images size are quarter of the input image. All three detail coefficients are represented half-resolutions of the input image and edge variations are almost exclusively visible in these three images. These three sub band images are considered in this study because of their texture information gives significant variations of intensity for analyzing the trabecular micro architecture of the femur bone.

The Symlet-4 wavelet is the basis function used in this work, due to its higher-scale detail coefficients are captured as finer details and texture patterns, while lower-scale detail coefficients capture broader texture patterns. The Symlet-4 is a type of wavelet that is used due to its balance between compact support and frequency localization. The sym in Sym4 stands for symmetric, which means that it has a symmetric shape. It is like Daubechies wavelets but have slightly different properties. The significance of using the Symlet-4 wavelet for image texture analysis lies in its ability to capture both low-frequency and high-frequency information effectively.

### B. Two-Dimensional Maximum Response Filter

A two-dimensional maximum response filter (2D-MRF) is introduced in this work to extract fine and coarse detail information of HC, VC and DC and its kernel is based on a Gaussian filters [26][27] at different scales. Each pixel location

must be analyzed in order to obtain the response values, first convolve the image with the Gaussian filter at multiple scales. Thus, the filtered output is calculated by taking the maximum value from the responses for each pixel location.

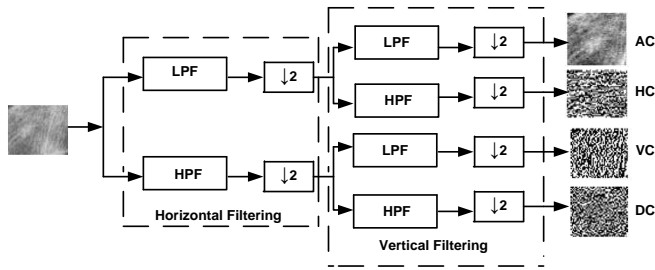

Fig. 2. First level 2D-DWT decomposition structure.

The MRF can help improve the robustness of feature extraction methods to noise and variations in the image. By emphasizing the most prominent responses and suppressing less significant ones, the filter helps in reducing the influence of noise or unwanted artifacts on the extracted features. The MRF can exhibit scale properties i.e., it can be effective in detecting the same pattern at different scales within the image. It helps in reducing the computational load by focusing on the most relevant features, this results in a faster processing and analysis of image datasets. Eq. (1) is the 2D-MRF using a Gaussian function, given an input sub band images  $S_B(x, y)$ , which are HC, VC and DC.

$$G(x, y) = \frac{1}{(2\pi\sigma^2)} e^{-\frac{(x^2+y^2)}{(2\sigma^2)}} \quad (1)$$

However, the Gaussian filter is characterized by a standard deviation, which is a scaling factor of the filter to compute the response values at each pixel location in the image i.e., where is the different scales and perform convolution operation ( $*$ ) between the image and the Gaussian filter at multiple scales shown in (2).

$$R_V(x, y, S) = S_B(x, y) * G(x, y, S) \quad (2)$$

Each pixel location is evaluated at multiple scales after obtaining the response values, a maximum response filter selects the response value that is the highest i.e., from the set of responses for each pixel demonstrated in (3).

$$R_{max}(x, y) = \max(R_V(x, y, 1), R_V(x, y, 2), \dots, R_V(x, y, S)) \quad (3)$$

The total number of scales used in this work are two different sets i.e., [0.3, 0.6, 0.9] and [5, 10, 15] to get fine and coarse detailed texture information respectively. Finally, the filtered output  $F_o(x, y)$  as in (4) represents the maximum pixel value at each location.

$$F_o(x, y) = R_{max}(x, y) \quad (4)$$

The MRFs process efficiently highlights the most salient features across different scales and emphasizes significant structures while suppressing less important ones. The scale

values determine the filter output i.e., Gaussian filter standard deviation ( $\sigma$ ) can be adaptable to for fine and coarse image texture requirements. The total texture image  $T_I(x, y)$  is a supervised image texture data in this proposed work, its value is calculated at each pixel location  $(x, y)$  in the image using the following algorithm.

**Algorithm :** Determination of fine and coarse texture image information

**Step1:** Fine texture analysis

$$\text{Find, } F_1(x, y) = R_{max}(x, y)$$

$$R_{max}(x, y) = \max(R_H(x, y, 0.3), R_V(x, y, 0.3), R_D(x, y, 0.3))$$

The  $R_H(x, y, 0.3)$  is filter response due to HC input at 0.3 scale, the  $R_V(x, y, 0.3)$  is filter response due to VC input at 0.3 scale and  $R_D(x, y, 0.3)$  is filter response due to DC input at 0.3 scale.

Similarly, find  $F_2(x, y) = R_{max}(x, y)$  at 0.6 scale

and  $F_3(x, y) = R_{max}(x, y)$  at 0.9 scale.

**Step 2:** Determine fine texture sum i.e.,  $S_F(x, y)$

**Step 3:** Coarse texture analysis

Repeat Step 1: to find  $F_4(x, y)$  at 5 scale,

$F_5(x, y)$  at 10 scale and  $F_6(x, y)$  at 15 scale.

**Step 4:** Determine coarse texture sum  $S_C(x, y)$

$$S_C(x, y) = F_4(x, y) + F_5(x, y) + F_6(x, y)$$

**Step 5:** Determine total texture image i.e.,  $T_I(x, y)$

$$T_I(x, y) = S_F(x, y) + S_C(x, y)$$

**C. Matching and Decision process**

A general match is based on finding test features that correspond to supervised databases [28]. In the matching process in which the test images and supervised images texture features are matching based on two attributes such as Zero Mean Normalized Cross-Correlation (ZNCC) and Sum of Squared Difference (SSD), which are obtained from total texture image i.e., The classification of the input test image is developed on having the highest possible value of ZNCC and lowest value of SSD, which are considered as the matching test classes. Pixels are compared based on their intensity values. These attributes help quantify the similarity between two images. Based on their intensity values, these attributes help quantify the similarity between two images.

- Zero Mean Normalized Cross-Correlation (ZNCC): Using the ZNCC, the cross-correlation between two images can be normalized. An image's similarity can be measured with it, where a value close to 1 indicates high similarity, while a value close to -1 indicates high dissimilarity.

Eq. (5) is the ZNCC between two images supervised i.e. test given by:

$$ZNCC(S_I, T) = \frac{\sum [(S_I(i, j) - \mu_{(S_I)}) (T(i, j) - \mu_{(T)})]}{\sqrt{\sum (S_I(i, j) - \mu_{(S_I)})^2} \sqrt{\sum (T(i, j) - \mu_{(T)})^2}} \quad (5)$$

Where:  $S_I(i, j)$  is the intensity value of supervised image  $S_I$  at position  $(i, j)$ . The  $T(i, j)$  is the intensity value of test image  $T$  at position  $(i, j)$ , The  $\mu_{(S_I)}$  is the mean intensity value of image. The is the mean intensity value of image  $T$ , the  $\sum$  denotes the summation over all pixel positions  $(i, j)$  in the images.

- Sum of Squared Difference (SSD): It measures the difference between corresponding intensity of the supervised image and the test image by summarizing their squares. Using the (6), it measures the degree of two images diverge from one another.

$$SSD(S_I, T) = \sum (S_I(i, j) - T(i, j))^2 \quad (6)$$

where, the summation is performed over all pixel positions in the images. In SSD case, test and supervised images are more similar when the value is lower. Based on SSD and ZNCC, the test input ROI image class is identified by reflecting on  $D1 = \text{Max}\{ZCCC\}$  and  $D2 = \text{min}\{SSD\}$ , if both D1 and D2 conditions are satisfied, that class is reflected as prediction class. The three classes are employed in this work as abnormal labeled as class-1 (osteopenia), class-2 (osteoporosis) and class-3 (normal).

### III. PERFORMANCE METRICS

The confusion matrix provides valuable insights into the model performance by quantifying different types of classifications [29]. The Table I displays the general confusion matrix used in the field of medicine to categorize the patient's positive and negative health conditions. From the confusion matrix, calculate various evaluation metrics, such as accuracy, precision, recall, and F1 score, which help assess the model effectiveness in different aspects.

TABLE I. GENERAL REPRESENTATION OF CONFUSION MATRIX

	Predicted Negative	Predicted Positive
Actual Negative	TN (True Negative)	FP (False Positive)
Actual Positive	FN (False Negative)	TP (True Positive)

- 1) *True positive (TP)*: Indicates that, number of samples were positive predictions made correctly.
- 2) *True negative (TN)*: Number of negatively predicted samples that were correct.
- 3) *False positive (FP)*: Incorrectly predicted positive samples are measured by this metric.
- 4) *False negative (FN)*: Number of negative samples predicted incorrectly.

In accordance with the confusion matrix, here are various evaluation metrics: Model accuracy measures how accurate the predictions as in (7),

$$Accuracy = \frac{(TP + TN)}{(TP + TN + FP + FN)} \quad (7)$$

Precision (Positive Predictive Value, PPV), estimates the positive samples predicted correctly by the model using (8),

$$Precision = \frac{TP}{(TP + FP)} \quad (8)$$

Recall (Sensitivity, True Positive Rate, TPR) measures the model ability to correctly identify positive samples among all actual positive samples as in (9),

$$Recall = \frac{TP}{(TP + FN)} \quad (9)$$

Specificity (True Negative Rate, TNR) measures the model's ability to correctly identify negative samples among all actual negative samples measured in (10),

$$Specificity = \frac{TN}{(TN + FP)} \quad (10)$$

The F1 score represents in (11) is a balanced measure of the model's performance by combining precision and recall together.

$$F1\ score = \frac{2(Precision * Recall)}{(Precision + Recall)} \quad (11)$$

Analyzing the performance of a model using these metrics provides valuable insight into different aspects. A high accuracy indicates overall good performance, it indicates good class predictions when precision and recall are high. As it incorporates both precision and recall, the F1 score is particularly useful when both are equally important. Interpretation of these evaluation metrics must consider the context. If there is an imbalanced dataset, accuracy might not be a reliable measure, and other metrics like precision-recall curve or area under the receiver operating characteristic (AU-ROC-) curve might be more informative [30]. This curve plots between two parameters: True Positive Rate (TPR), False Positive Rate (FPR).

### IV. DATASET DESCRIPTION

Total 51 X-ray femur images were collected with the focal distance was set at 0.812 m. The X-ray parameters were 75-80 kV and 80 mAs for all patients. This study used images supplied by a reputed Bangalore hospital, Karnataka state, India. The image data consist of 2D radiographic images in JPEG format of size 2140×1760. In that 23 are normal, 10 are osteopenia and 18 are osteoporosis femur images. Table II listed the region of interested (ROI) femur bone of left and right of size 170×114, the total 102 ROI images including both left and right, which are considered to verify the proposed system experimentally.

TABLE II. DESCRIPTION OF DATA SET

Total ROI images: (23×2) + (10×2) + (18×2)=102					
Normal femur bone		Abnormal femur bone			
		Osteopenia femur		Osteoporosis femur	
Left	Right	Left	Right	Left	Right
23	23	10	10	18	18

A. Experimental Dataset Division

The proposed model can be experimentally tested by dividing the 102 total ROI of the image dataset into different cross-folding schemes, in the following Table III. A comparison between this and a previously conducted study on cross-folding methods reveals how well the proposed model performs.

TABLE III. EXPERIMENTAL DIVISION OF DATASET

Data - folding	Total number of samples of ROI images = 102					
	Supervised set			Test set		
	Normal	Abnormal		Normal	Abnormal	
	Osteopenia	Osteoporosis		Osteopenia	Osteoporosis	
Two-fold	12+12	5+5	9+9	11+11	5+5	9+9
	24+10+18=52			22+10+18=50		
Three-fold	16+16	7+7	12+12	7+7	3+3	6+6
	32+14+24=70			14+6+12=32		
Four-fold	18+18	8+8	14+14	5+5	2+2	4+4
	36+16+28=80			10+4+8=22		

V. RESULTS AND DISCUSSION

The input image of femur is a very low-quality image because the X-ray image of inner trabecular bones micro-architecture is not visible to distinguish between healthy bone and osteoporotic bone. Because of its versatility, DWT has become a very useful method for the process of decomposing an image into several resolutions through wavelet decomposition. By concentrating the wavelet energy in time and keeping its periodic properties, wavelets can simultaneously analyze both time and frequency of pixels intensity in the image. By decomposing a digital image into different sub bands, the 2D-DWT can resolve frequencies more precisely and time resolutions more coarsely at lower frequencies. Fig. 3 shows 2D-DWT output AC, HC, VC and DC. The approximation coefficient is same as the input image, Horizontal coefficient sub band is giving the horizontal information of texture features, vertical coefficient sub band gives the vertical information of texture features similarly the diagonal sub band gives the diagonal texture features. Only HC, VC and DC are texture information is sufficient to analyze the texture features of inner trabecular bones micro-architecture of femur bone.

Fig. 3. First level 2D-DWT decomposition structure.

2D-DWT followed by Maximum Response Filter (MRF) based sub band image texture analysis is a technique used in order to extract meaningful texture features from an image as shown in Fig. 4, Multi-resolution analysis. In 2D-DWT, the image is decomposed into multiple frequency bands, representing different levels of detail or textures. This multi-resolution property is well-suited for texture analysis as textures often exhibit varying degrees of complexity at different scales. By applying the MRF at two sets of scale as [0.3, 0.6, 0.9] and [5, 10, 15] and filter size is technique after the 2D-DWT of HC, VC and DC, the most significant texture information from different sub bands can be extracted. MRF highlights regions with the maximum texture response, enhancing the representation of dominant texture patterns.

Fig. 4. First image texture (a) sum of MRFs scale at [0.3, 0.6, 0.9] (b) sum of MRFs scale at [5, 10, 15] (c) sum image of (a) and (b).

The matching is taking place between the supervised image database and test images based on SSD and ZNCC attributes and then decision is made on these attributes to decide whether the test ROI is abnormal (osteoporosis or osteopenia) or normal bone based on maximum ZNCC and minimum SDD.

According to the Table IV, different data cross-folding methods result in different confusion matrices. By applying cross-validation techniques, whether the model will perform well on unseen data and avoid over fitting or under fitting issues. As a result of supervised dataset for four folding, that is, 80 samples and the test dataset is 22 samples, the method achieves better results for four folding because of a greater number of supervised datasets. The system will have a larger number of texture patterns to decide whether an image is normal or abnormal, however osteoporosis and osteopenia bones both are included as abnormal in this proposed work. Actual positive sample (abnormal) set in test data set is 12 (osteoporosis and osteopenia) and actual negative sample set is 10 (normal). In the case of four folding, the model gives TP=12 and FP=0, which gives better results, however in normal case gives TN=9 out of 10 and FN=1.

TABLE IV. CONFUSION MATRIX FOR DIFFERENT FOLDING

Data Folding	TP	FP	TN	FN
Two-fold	11	3	4	4
Three-fold	12	2	5	3
Four-fold	12	0	9	1

Using graphical representation of non-normalized confusion matrix, system performance can easily assess at a momentary look as shown in Fig. 5 for four folding data. The diagonal of the confusion matrix (from top-left to bottom-right) represents correct predictions, while off-diagonal elements indicate misclassifications. This graphical representation helps in understanding the model strengths and weaknesses in terms of classifying different instances. The observation of four folding data from Table IV gives the TP=4+8=12 i.e., abnormal bone = Osteopenia (class-1) + Osteoporosis (class-2) and TN=10 i.e., normal bone (class-3). The system predicts better results with false negative was the only one sample, which is actually normal (healthy) bone showing it as abnormal.

Fig. 5. Graphical representation confusion matrix for four folding data.

On all metrics measures, four folding achieves better results than the other folding, as revealed in Table V. Model performance metrics provide quantitative measures to evaluate how well a machine learning model is performing on a dataset. Metrics like accuracy, precision, recall, and other characteristics are essential for evaluating model. The choice of data folding (i.e., cross-validation method) can impact the way these metrics are computed.

TABLE V. MODEL PERFORMANCE METRICS FOR DIFFERENT DATA FOLDING

Data Folding	Precision	Recall	Specificity	F1 Score	Accuracy
Two-fold	78.57%	73.33%	57.14%	75.85%	68.18 %
Three-fold	85.71%	80.00%	71.42%	82.75%	77.27%
Four-fold	100%	93.33%	100%	96.54%	95.45%

Testing of the proposed model includes a general classifier technique in machine learning [31]: K-Nearest Neighbor (KNN), Discriminant Analysis (DA), Naive Bayes (NB), Decision Tree (DT), Support Vector Machine (SVM), and Random Forest (RF). For each classifier and proposed method, total twenty-one experiments were conducted including two, three, and four data folding. Comparing the system accuracy

for different classifiers is an essential step in selecting the most suitable classifier for a specific task. The accuracy metric provides an overall measure of how well the classifier performs in terms of correctly classifying instances. The Table VI shows that the proposed model is more accurate than other classification techniques, due to the effectiveness of the texture analysis method, so the system could be able to distinguish between normal and abnormal.

TABLE VI. FOUR-FOLD OF DATA COMPARISON OF SYSTEM ACCURACY FOR DIFFERENT CLASSIFIERS

Classifiers	Accuracy		
	Two-fold	Three-fold	Four-fold
KNN	58%	59%	61 %
DA	62%	64%	73 %
NB	60%	64%	66%
DT	67%	67%	68%
SVM	74%	75%	75%
RF	68%	68%	68%
<b>Proposed method</b>	<b>68.18 %</b>	<b>77.27%</b>	<b>95.45%</b>

The Table VII indicates that the proposed method for texture analysis performed better than other classification techniques, allowing the system to distinguish normal from abnormal behavior based on the performance evolution results.

TABLE VII. FOUR-FOLD COMPARISON OF PERFORMANCE EVALUATIONS FOR DIFFERENT CLASSIFIERS

Classifiers	Precision	Recall	Specificity	F1 Score	AU-ROC value
KNN	60 %	72 %	57%	65%	0.6128
DA	65%	72 %	60 %	68%	0.6789
NB	54%	60 %	67%	66%	0.6534
DT	60 %	60 %	60 %	60 %	0.5934
SVM	94 %	91%	93%	94%	0.9489
RF	92 %	92%	93 %	94 %	0.9393
<b>Proposed method</b>	<b>100%</b>	<b>93.33%</b>	<b>95.45%</b>	<b>96.54%</b>	<b>0.9659</b>

The An AU-ROC (Area Under the Receiver Operating Characteristic) plot is a graphical representation used to compare the performance of different classifiers in classification tasks. When comparing different classifiers using AU-ROC plots, the classifier with the highest AU-ROC value is generally considered as best performance. AU-ROC plot of the proposed system with two classification techniques is revealed in Fig. 6, in which the proposed occupies a larger area under the curve than the other two.

It is critical to compare the performance of different methods for determining osteoporosis in the femur bone when analyzing image data. Various methods or algorithms are employed to solve a particular problem, and comparing their performance helps in selecting the most effective one. As an illustration of the system performance for the different methods is as revealed in Table VIII, nevertheless proposed method performs better when data is folded four times.

Fig. 6. An AU-ROC plots.

TABLE VIII. PERFORMANCE COMPARISON WITH DIFFERENT METHODS

Ref. No.	Specificity	F1 Score	Accuracy	Sensitivity	AU-ROC
[4]	88.24%	89.43%	88.50%	88.19%	89.01%
[15]	93.70%	93.39%	93.39%	93.90%	92.37%
[17]	84.20%	85.39%	91.39%	92.80%	86.50%
[22]	94.19%	90.28%	91.27%	80.29%	93.43%
Proposed Method	95.45%	96.54%	95.45%	93.33%	96.59%

## VI. CONCLUSION

The spectral based analysis of texture features of ROI femur X-ray images produces very good results because the 2D-DWT gives pixel intensity variation at different scale. Therefore, the texture features are helpful in obtaining the significant texture using MRFs. The various scales in image texture benefit from the MRFs, contributing to its effectiveness and the capability to process fine and coarse information efficiently. By calculating the two attributes as ZNCC and SSD of the test and supervised images in the matching process helps to classify the test image. The best matching between the test and the supervised database is considered as the maximum correlation and minimum sum difference which is exactly the test predicted classes. The proposed work achieves better osteoporosis detection with less error.

In future the evaluation can be made in spatial domain so that the system can be in contrast with proposed one however requiring extra database to boost the system performance. The femur X-ray images must be derived from a customary public dataset to make this work useful in medical disciplines for early detection of osteoporosis. A generalized X-ray image dataset for the femur is not available to make the proposed work more significant for detecting osteoporosis.

# A Systematic Review on Blockchain Scalability

Asmaa Aldoubaee, Noor Hafizah Hassan, Fiza Abdul Rahim

Razak Faculty of Technology and Informatics, Universiti Teknologi Malaysia, Kuala Lumpur, Malaysia

**Abstract**—Blockchain is an exciting new technology that has garnered attention across multiple industries. This new technology offers several advantages, including decentralization, transparency, and immutability. However, several issues limit the effectiveness of this technology, such as scalability, interoperability, and privacy. A systematic review of blockchain scalability research was conducted using three primary databases: ACM, Science Direct, and IEEE. The review examined the state of the art in blockchain scalability, identifying the most important research trends and challenges. The solutions that have been established can be categorized into two main groups: those that pertain to block storage and those that pertain to the underlying blockchain mechanism. Numerous solutions were suggested for each main group. The most common proposed solutions for improving the scalability of blockchain networks in the literature are improving the consensus algorithm and using sharding. Most of the solutions were proof of concept and need more investigation in the future.

**Keywords**—Blockchain; scalability; sharding; consensus algorithm

## I. INTRODUCTION

Blockchain is another form of digital value exchange that has gained attention from different sectors [1]. The idea of blockchain was first introduced by Haber and Stornetta in 1991. Nakamoto later used blockchain in 2008 as the most well-known example: cryptocurrencies [2],[3]. This technology has found its way into various industries and applications, including banking, insurance, supply chain management, healthcare, identity verification, stock market analysis, IoT, energy, and intellectual property management. According to [4], the reasons for its popularity are its advantages, which include decentralization, security, immutability, efficiency, and transparency.

Despite the many advantages of blockchain technology, researchers and developers have identified several challenges and bottlenecks that need to be addressed before blockchain can be widely adopted, as [4] mentioned. Scalability is a significant challenge preventing the system from growing up. Scalability issue occurs for many reasons. According to [5], the main two are the blockchain mechanism and the block size.

To address this challenge, researchers and developers have made significant efforts to improve the scalability of blockchain technology [5]. Efforts can be categorized based on the areas they focus on. Some solutions aim to enhance the chain mechanism, while others, such as [6], concentrate on managing stored data.

This paper aims to review current blockchain scalability solutions and research trends systematically. This systematic literature review (SLR) briefly overviews blockchain

technology and its scalability problems. The different ways blockchain scalability has been addressed and the results of performance evaluations of these solutions are categorized. The paper identifies several potential areas for future research on blockchain scalability, such as improving the consensus mechanism, using sharding, and off-chain scaling.

This systematic review article consists of seven sections. Section I specifically covers the introduction and significance of this review. Section II provides a background about the blockchain and the scalability challenge. This is followed by Section III, highlighting the related reviews and surveys conducted on this topic. Section IV underlines the reasons for conducting this review. The following is Section V, which highlights the methodology of this review, including the research questions, study selection, and the inclusion and exclusion criteria. The results of this study, including the answers to the research questions, are discussed in Section VI. Lastly, this article is concluded in Section VII.

## II. BACKGROUND

### A. Blockchain

A blockchain is a chain of blocks that serves as a public ledger and contains complete records of all transactions committed [7], as illustrated in Fig. 1. The list of transactions in this chain expands as new blocks are added. This record of the list continues to grow.

Fig. 1. A Standard structure of a blockchain [8].

Blockchain technology was first used in the field of cryptocurrencies in 2008. The success of blockchain technology in the world of cryptocurrencies has led other industries to explore and adopt it. The idea of blockchain was first introduced by Haber and Stornetta in 1991. Nakamoto later used blockchain in 2008 as the most well-known example, cryptocurrencies. This technology has found its way into various industries [12].

The success of blockchain technology is limited due to its inability to be implemented on a large scale [9]. In simple terms, scalability issues exist due to the limited block size and the current blockchain mechanism. This issue grows as the number of transactions increases, demanding additional nodes to maintain the network while also increasing the number of

steps required for the transaction to travel and attain full consensus with every node. For instance, according to [10], Bitcoin, which utilizes the Proof of Work (PoW) consensus algorithm, has a peak limit of processing only seven transactions per second.

Blockchain systems have lower throughput and latency performance than non-blockchain system [11]. The number of transactions completed per second is called throughput [10], while the delay between making a blockchain data request and getting a response to that request is referred to as latency.

This scalability issue has been studied, and many solutions have been proposed to enhance the ability to scale up the blockchain, which will be tackled later. It is not easier to propose a scalability solution because the features of blockchain will be affected, like decentralization and security [12]. Therefore, creating a trade-off between the proposed solution and the other related aspects is necessary, as illustrated in Fig. 2. The proposed solution must provide a trade-off between scalability, decentralization, and security. These characteristics can be challenging to balance, but it is essential to consider them when making decisions.

Fig. 2. Scalability trilemma [4].

### III. RELATED WORKS

With the growth of blockchain in various sectors, warning bells ring about the scalability issue. As a progression of this issue, researchers have thoroughly probed into this problem, and tens of papers have been published regarding this issue. Furthermore, scalability issues have been widely investigated recently. Tens of papers were published on this bottleneck. Moreover, reviews and surveys were conducted on this issue. Table I illustrates the relevant reviews and surveys on this SLR. Some related works focused on a special domain like healthcare [13] or the Internet of Medical Things [14]. This paper thoroughly explores blockchain scalability issues in general and evaluates proposed solutions to determine their effectiveness in practice rather than just as a proof of concept.

### IV. REASON FOR CONDUCTING SYSTEMATIC REVIEW

The reason for doing this Systematic Review is the critical importance of the scalability challenge within the blockchain. Extensive research has been conducted, and numerous attempts have been made to address the issue. However, there is still a need for enhancing and discovering more efficient methods to enhance the scalability of the blockchain. Therefore, within this

systematic review, we seek to highlight findings, identify gaps, and pave the way to discovering innovative, more effective methods to improve blockchain scalability. The output of this research may help to assist blockchain technology in evolving and changing, making it even more reliable, scalable, and flexible to meet the many demands of modern applications and industries.

### V. REVIEW METHOD

A systematic literature review identified, evaluated, and interpreted all available research related to a specific research question, topic area, or phenomenon of interest. The authors used guidance from [16], as a step and guide for doing the review, which served as a framework for their methodology. The goal of following this guidance was to ensure the review process was methodical and precise. The authors followed the suggested procedures, methods, and instructions in Fig. 3. An explanation for that will be provided.

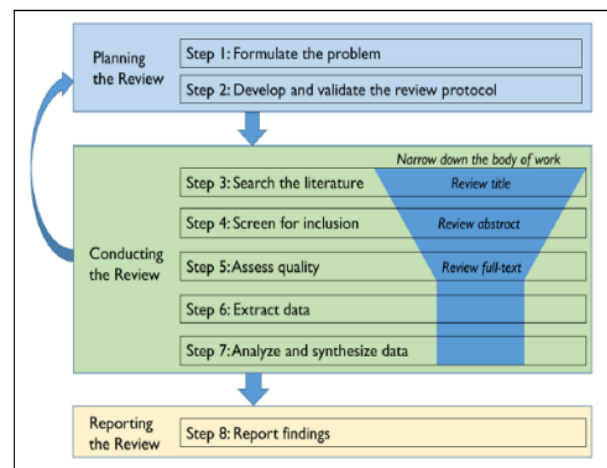

Fig. 3. Systematic review steps.

#### A. Research Question

The goal of this study is to investigate the scalability challenge of blockchain. The following research questions were formulated to conduct the investigation:

- RQ1: Where are the studies on the scalability of blockchain being conducted?

This research question aims to understand the current research and study trends on blockchain scalability.

- RQ2: How the scalability issues in blockchain have been addressed? What are the techniques and aspects used to address the scalability?

The second research question is to identify the current approaches and solutions by looking at the techniques and aspects used to solve blockchain scalability.

- RQ3: How did the proposed solutions succeed in achieving scalability?

The last research question is to evaluate the impact of prior efforts and pave the way for more effective and scalable blockchain systems in the future.

TABLE I. RELATED REVIEWS AND SURVEYS

Ref	Year	Title	Summary	Main Future direction
[12]	2021	A systematic review of blockchain scalability: Issues, solutions, analysis, and future research	In this review, the available solutions were categorized according to their performance in three areas: writing, reading, and storage.	This paper proposes integrating two or more scalability solutions to create a more effective and secure scaling solution. The goal is to enhance the read performance of the blockchain and optimize the query language. Additionally, it recommends implementing more robust cross-shard communication methods.
[14]	2021	A Survey on Blockchain-Based IoMT Systems: Towards Scalability	The survey presented the various factors that can affect a blockchain's ability to scale, whether directly or indirectly. Additionally, it categorized the potential solutions into two types: on-chain and off-chain.	<ul style="list-style-type: none"> <li>• They recommend two methods to solve the scalability issue: either through on-chain or off-chain solutions.</li> </ul>
[15]	2020	A Review on Scalability of Blockchain	<ul style="list-style-type: none"> <li>• The review outlined the key approaches and technologies put out to address the scalability issue in the blockchain.</li> <li>• There are three primary factors that contribute to blockchain scalability bottlenecks. These include performance inefficiency, significant confirmation delays, and function extension limitations.</li> </ul>	<p>The review provided suggestions for further studies as below:</p> <ul style="list-style-type: none"> <li>• Studying a large-scale, high-performance peer-to-peer (P2P) network. Without advancements in network technology, enhancing the performance of blockchain systems will remain challenging.</li> <li>• A high-performance programmable computing engine is crucial for utilizing various smart contracts that are written in different programming languages.</li> </ul>
[13]	2020	Scalability Challenges in Healthcare Blockchain System—A Systematic Review	<ul style="list-style-type: none"> <li>• Defined the main reasons leading to healthcare scalability issues: the block size, huge amounts of data, the number of nodes, and the consensus protocol.</li> <li>• It provided a map of the main 16 proposed solutions according to the reasons. This review covers 16 solutions that fall into two main categories: storage optimization and blockchain redesign. There are three solutions for storage optimization and 13 solutions for blockchain redesign, including blockchain modeling, read and write mechanisms and bi-directional network.</li> </ul>	NA
[16]	2022	Scalable blockchains — A systematic review	<ul style="list-style-type: none"> <li>• This review classified the current solutions into solutions related to payment Channel Networks like lightning networks, sharding, blockchain delivery networks, hardware-assisted networks, Parallel Processing, and blockchain redesigning.</li> <li>• It highlighted the sharding as the main potential solution.</li> </ul>	<p>This review offers these recommendations.:</p> <ul style="list-style-type: none"> <li>• Developing new consensus algorithms.</li> <li>• Exploring the use of off-chain solutions.</li> <li>• Investigating the potential of sharding and sidechains to improve the scalability of blockchains.</li> <li>• Developing new metrics evaluate scalability of blockchains.</li> <li>• Investigating the impact of blockchain scalability on various application domains.</li> <li>• Developing new tools and frameworks to facilitate the development and deployment of scalable blockchain applications.</li> </ul>
[4]	2021	Systematic Literature Review of Challenges in Blockchain Scalability.	<ul style="list-style-type: none"> <li>• This review analyzed the main factors that affected the scalability of blockchain: the number of transactions per second, and the consensus mechanism and how it affects the scalability.</li> <li>• The review explores the on-chain and off-chain solutions to the scalability issue. Consensus algorithm and sharding were the most important solutions.</li> </ul>	NA
[6]	2020	Solutions to Scalability of Blockchain: A Survey	The scalability problem with blockchain systems is discussed in this study along with a number of suggested solutions. Some of the suggested solutions include sharding, sidechains, cross-chain solutions, DAG-based solutions, and off-chain solutions including payment channels and state channels. These solutions are grouped into many typical blockchain layers. The authors also go through alternative consensus techniques and how they can help blockchain systems become more scalable, including Proof of Work (PoW), Proof of Stake (PoS), and Delegated Proof of Stake (DPoS).	Future work will involve building more effective and safer sharding approaches, researching the possibilities of off-chain solutions like payment channels and state channels, and examining alternative consensus mechanisms that might increase the scalability of blockchain systems. The authors also advise investigating the use of artificial intelligence and machine learning methods to enhance the functionality of blockchain systems. Finally, they advise looking into the possibility of combining blockchain with other cutting-edge technologies like edge computing and the Internet of Things (IoT).

### B. Study Selection

Through a systematic review process, various research works have been found in published papers to explore the research trends and state-of-the-art advancements in blockchain scalability. The initial search used ACM, Science Direct, and IEEE databases. They were chosen based on the availability of these papers as full texts through the Universiti Teknologi Malaysia library. This phase was conducted by using the following search string: (“blockchain scalability” OR “scalable blockchain”), which is summarized in Table II. After conducting an initial search of the three databases, a total of 146 papers were found. These papers went through different stages of filtering, based on the criteria shown in Fig. 2. Finally, the 35 studies were reviewed to identify trends and advancements in blockchain scalability.

### C. Inclusion and Exclusion Criteria

Inclusion criteria are established in the SLR to find papers related to the research goals. These standards guarantee that studies directly related to the study issue are included, whereas studies that do not conform to the established standards or are irrelevant to the research emphasis are excluded. The paper selection process is illustrated in Fig. 4. The main inclusion criteria for this study are:

- Being published in English.

- Being cited at least once.
- Describing the scalability issue on a blockchain.
- Providing solutions for scalability obstacles.

The exclusion criteria are:

- Papers that are written in another language rather than English
- Papers in which the concept is not described clearly.
- Do not specifically address scalability challenges in the blockchain.
- Papers that are not cited in other studies.

TABLE II. PAPERS SELECTION FROM THE DATABASES

Data Source	Documentation	
	No. of Articles Found on Primary Search	Selected Articles
ACM (Journal)	304	9
Science Direct	307	6
IEEE	109	20
Total	720	35
Total		35

Fig. 4. Papers selection process.

## VI. RESEARCH FINDINGS

In this section, we will discuss the results of our systematic review to answer the research questions listed below.

RQ1: Where are the studies on the scalability of blockchain being conducted?

The issue of scalability has captured the attention of researchers, resulting in the publication of numerous papers in both journals and conferences. These studies explained the reasons that lead to the scalability issue, and accordingly, Numerous techniques have been proposed to address the scalability problem in blockchain from various perspectives.

Previous reviews on this issue have commonly classified the solutions based on their relationship to the blockchain, distinguishing between on-chain and off-chain approaches. On-chain solutions primarily focus on improving scalability by modifying elements within the blockchain, while off-chain solutions prefer to conduct transactions outside the network [4] or based on the purpose or objective of the proposed solution [11].

The approaches presented in this systematic review were broken down into two groups: related to the Blockchain mechanism and related to block storage. The largest share of proposed solutions dealt with the mechanism of the blockchain, followed by those that dealt with block storage, as illustrated in Fig. 5.

Fig. 5. Distribution of the founded solutions.

RQ2: How the scalability issues in blockchain have been addressed? What are the techniques and aspects used to address the scalability?

As mentioned previously, there are two main classifications in this systematic literature review. Under each main classification, several techniques were employed to address the issue of scalability. Fig. 6 illustrates the classification, whereas Fig. 7 illustrates the distribution of the proposed technique. The techniques found under each group are illustrated below:

A. Related to the Blockchain's Underlying Mechanism

1) *Optimizing the consensus algorithm*: The consensus protocol is a crucial component of blockchain that facilitates the creation of new blocks and the maintenance of the network. It involves reaching an agreement among network users on sustaining the network. The consensus protocol outlines the process for selecting the author of a new block [10].

Various applications have been implemented to utilize these techniques to improve the scalability of the blockchain. Based on the findings of this SLR, the consensus protocol is most frequently discussed to propose solutions to the scalability issue. Many studies concluded that the ineffectiveness of the consensus protocol primarily causes the main blockchains' scalability problems. So, to address the

scaling issue, researchers have looked for novel consensus methods [4].

The consensus algorithm has been developed from different aspects: reducing the complexity [17], scaling according to the incoming traffic rate [18], and using checkpoints that allow the block to have its own hash chains to add more transactions [19]. The implementation results encourage more investigation and development to generate a better scaling rate. Table III shows the major consensus solutions found in this review.

2) *Using sharding*: The concept of sharding has gained popularity, particularly because it has been successfully applied in the field of databases in the past. It is becoming more well-known as one of the viable ways to improve blockchain performance [16]. Sharding has been used widely as a solution for scalability bottlenecks in the blockchain. It enables blockchains to expand effectively. Furthermore, it divides the workload across different subsets of nodes to handle different parts of the blockchain to reduce the overhead of consensus protocol [20] [21]. As a result, each node is no longer required to process the whole network's transactional load. Each node only stores the information relevant to the partition or shard responsible for it. Among all the other scaling solutions, sharding seems the most effective solution as it holds the core functionalities of blockchain with it. Each shard works like a separate blockchain network, operating completely as Satoshi Nakamoto envisioned a blockchain to work[22]. However, applying sharding to the blockchain presents several difficulties, and there are no fully prepared methods to increase the blockchain's scalability. For instance, security inside the sub-shards and the inter-shard communication method are issues [23]. Furthermore, researchers found a problem with sharding with the node generation process [24]. Finally, many shard-based solutions were proposed with different benefits for increasing the scalability of the blockchain. Many are still theoretical concepts that need real implementation for further evaluation, as is clear in Table IV.

Fig. 6. Proposed solutions classifications.

Fig. 7. The distribution of the proposed solution.

TABLE III. MAJOR SOLUTIONS BASED ON CONSENSUS ALGORITHM

Ref	Year	Protocol	Improve scalability by	Goal	Implementation	Results
[17]	2022	Byzantine Algorithm Group	Reducing the communication complexity	reducing complexity from $O(n^2)$ to $O(n_2^3)$	-	-
[25]	2019	Byzantine Fault Tolerant	Randomly select root	Selecting root randomly will reduce the mining time.	-	Providing constant latency
[18]	2021	Dynamic Proof of Work (PoW)	mining Scaling according to the IoT traffic	Checkpoint mechanism for mining that	NA	
[26]	2019	Byzantine Fault Tolerant	Reduce communication on each node	Cloud service integrated with the blockchain	-	-
[27]	2018	Delegate Proof of Stake (PoS)	Randomize delegated		-	-
[28]	2021	Hybrid protocol (Pow) and (PoS)	Transactions from external sources can be processed through this protocol, which then sends the final outcomes back to the main layer for storage in the distributed ledger.	The Hybrid Lightning Protocol can scale blockchain networks to handle more transactions.	√	maximized the throughput to 1,668,000 Transactions per second
[29]	2019	Distributed Time-Based consensus algorithm	Proposed algorithm that could minimize the processing overhead	To minimize the confirmation time	√	Successfully decreasing the processing time

TABLE IV. SUMMARY OF SHARDING-BASED SOLUTIONS

Ref.	Idea	Improve scalability by	Goal	Implementation	Results
[30]	Muti level sharding	Providing architecture for multi-level sharding and proposed a mechanism for interacting between sub-nodes	Enabling efficient cross-chain transactions in high scalability and extensibility.	NA	NA
[31]	Reducing the inter shard communication	Dividing the assignments, validation, verification, & storage responsibilities between nodes	Minimizing the need for inter-shard communication	NA	NA
[32]	Using the Verification Random Function	Utilizing a sharding strategy to share the random values created by participating nodes within a smaller group of nodes rather than directly among all node	Decreasing the computation and communication overhead	NA	NA
[20]	The scheme simultaneously achieves linear scaling in throughput, storage efficiency, & security.	Each node stores and computes in a coded shard of the same size that is generated by linearly mixing uncoded shards.	Achieving throughput efficiency as well as improving security.	Simulation	performing better than both uncoded Sharding and complete replication in throughput, storage optimization, and security.

3) *Changing the structure of blockchain:* The architecture of blockchain has a high computational complexity and needs a considerable amount of computing and storage space. These characteristics make it difficult to scale up. From that angle, many research studies proposed solutions to redesigning blockchain, like using a sub-chain [24]. Additionally, other researchers defined three types of blocks, and according to these types, block generation and consensus were updated [33]. However, this review observation shows that this solution has received relatively fewer citations. Therefore, we recommend conducting further studies soon to explore and investigate this area deeply.

4) *Improving the scalability from the second network layer:* Working on the network layer is an effective scaling option for blockchain. However, as it is an off-chain solution, it lacks the fundamental features of blockchain technology [22]. It became obvious how much scalability could be increased by using second-layer state channels [34]. The second layer channel works as an extra channel that can increase transactions per second and improve blockchain scalability by bypassing the consensus process.

5) *Updating the blockchain mechanism:* The suggested mechanism and solution focused on the activity inside the blockchain network, such as message passing between nodes. This reduced the amount of data held in each block and improved its scalability [35]. One way to achieve this is by altering the method of selecting the neighboring block [26]. The evaluation of these solutions shows better scalability in terms of reducing the time of confirmation.

6) *Changing the linear sequence of the blockchain:* Previous solutions have considered factors such as block size, block generation, and consensus. These solutions operate within the linear sequence of the blockchain network. Alternatively, altering the order of the block sequence may improve scalability [9]. Researchers suggested using a Directed Acyclic Graph-based blockchain model, which could enhance the scalability of large-scale networks [9]. A single solution was found in this review as a suggestion for enhancing the scalability. Furthermore, due to the limited

amount of published experimental findings and open-source implementations, this solution needs more investigation in the future.

### B. Related to Block Storage Capacity

One of the main factors affecting blockchain's scalability is the block storage capacity. This problem has been addressed with several proposals that try to expand the space available within blocks and permit more transactions. Here are some significant solutions that were discovered in this SLR:

1) *Using Segregated Witness (SEGwit):* Adding more space to the block allows more transactions to be done as SEGwit [36]. The concept involves restructuring transactions through forking, resulting in a four-fold increase in block size. Additionally, the block signature will be kept separate from the block, allowing for improved scalability and increased transaction capacity.

2) *Using Interplanetary File System (IPFS):* Many proposed solutions use InterPlanetary File System (IPFS) for storing data [37], while others use it for storing transactions [38]. One way to improve scalability is by using IPFS, which reduces the amount of data stored in a block by only including the hash value while the actual data is stored in IPFS. According to the analysis, this technology could play a significant role in scaling blockchain without affecting the core mechanism of blockchain [39].

RQ3: How did the proposed solutions succeed in achieving scalability?

This review found that the available studies have improved scalability by analyzing the factors that caused this obstacle. These factors were the block storage capacity and the mechanism of the blockchain. Most of the studies that suggested solutions could enhance scalability by dealing with these factors. Furthermore, some studies' initial results show incremental scalability improvement in throughput and latency. The studies contributed to enhancing scalability by analyzing the factors and providing theoretical-based solutions. The available solutions can serve as a roadmap for achieving improved scalability. Most of the studies still prove the

concept, lacking implementation in real scenarios. Scalability bottlenecks in blockchain still need further investigation. Table V summarizes all the research articles included in this SLR.

TABLE V. SUMMARY OF THE SELECTED STUDIES

Library	Ref.	Aspect	Simulation	Implementation	Improve scalability idea	Domain
ACM	[40]	Scalable consensus algorithm (BFT) and integration blockchain into cloud-based services	√	×	reducing the intra-plant communication complexity from $O(n^2)$ to $O(n)$ .	Industrial Plant
	[17]	The new consensus algorithm for reducing the complexity	√	×	reducing the communication complexity from $O(n^2)$ to $O(n^3)$	Commercial Blockchain
	[38]	Using IPFS	√	×	A theoretical manner for distributing transactions between on-chain and off-chain. Only the hash address is stored in the block, and using IPFS for storing the transactions.	Blockchain-base crypto computing
	[41]	New architecture	×	×	The maximum workload that may be handled varies with the number of nodes which increases the scalability by preventing broadcast in all cases	NA
	[9]	The DAG-based model includes greater scalability and lower transaction fees	×	×	Improving linear sequence and Separating the workload into a different level	NA
	[42]	New consensus algorithm : Proof of Property	×	×	Allowing participants to validate the transaction without downloading the complete blockchain which enhances the storage.	NA
	[21]	Using Sharding + enhancing consensus algorithm	√	√	The consensus protocol in each shard has been improved to achieve more than 3,000 transactions per second, resulting in increased effectiveness. This has been implemented across multiple shards.	NA
	[27]	Using randomize consensus algorithm for subchains	×	×	By using subchain technology, scalability is enhanced as it allows for additional blockchain nodes to become block producers and receive rewards.	NA
IEEE	[30]	Sharding	×	×	By facilitating efficient cross-chain transactions, multi-level sharding can be enabled to achieve high scalability and extensibility.	NA
	[43]	Using New architecture	√	×	Integrating with cloud storage for storing transactions to solve storage	NA
	[37]	Using IPFS	×	×	Improving scalability by utilizing IPFS to store patient records outside of the blockchain.	Medical Records
	[32]	Randomness protocol via sharding	×	×	Eliminating the use of heavy cryptography	Large-scale IoT applications
	[18]	Using new consensus algorithm	√	×	Using dynamic Proof Of Work consensus with checkpoint mechanism for mining Scaling according to the IoT traffic	Industrial Internet of Things
	[26]	Algorithm for choosing the block's neighbor	×	√	Reducing propagation time by 20-40%	NA
	[35]	using the data compression scheme	×	√	Reducing the data on the block by compression. Scalability improved by reducing the creation time .	Trading Platforms
[33]	New Blockchain Architecture	×	√	Reducing the consensus complexity will lead to better scalability.	NA	
[20]	Sharding with Lagrange-Coded Computing	×	×	We are enabling scaling without increasing the number of nodes by reducing the node's storage workload and increasing the verification outside the system.	NA	
[44]	Blockchain Architecture	×	√	They are reducing the resource	Massive devices of	

					utilization by updating the architecture for better scalability rate.	IoT
	[45]	Blockchain Architecture focuses on all layers	×	√	Reducing the storage need which operates via DHT	NA
	[25]	Consensus algorithm	×	√	Randomly selecting committees to improve on the quadratic message complexity

## VII. CONCLUSION

In this paper, a systematic review was conducted to define the state of the art on blockchain scalability issues. The researchers attempted to analyze the studies through the literature extracted from the three databases. Introducing a solution for blockchain scalability bottleneck is not a simple process due to the complexity of the blockchain architecture and the distributed nature. Thus, proposed solutions must provide a trade-off between keeping the blockchain scaling and keeping its robust features like the decentralization and security. The consensus algorithm is the most critical component developed by researchers. Moreover, the Proposed solutions show improved scalability regarding throughput and latency. Additionally, sharding techniques come second as a critical solution that could significantly enhance scalability. Finally, most of the solutions are still proof of concept, and the recommendation is to apply these solutions in real scenarios for

the best investigation and analysis. Blockchain's scalability problem is a major obstacle to its widespread adoption. More research and better solutions must be developed to make widespread use of blockchain possible.

## ACKNOWLEDGMENT

The study was funded by the Encouragement Research Grant (Vote No. Q.K130000.3856.20J96) awarded by Universiti Teknologi Malaysia.

ENSATE, Abdelmalek Essaadi University, TIMS LABORATORY, Tetuan, Morocco<sup>2</sup>

**Abstract**—In light of the growing global diabetes epidemic, there is a pressing need for enhanced diagnostic tools and methods. Enter machine learning, which, with its data-driven predictive capabilities, can serve as a powerful ally in the battle against this chronic condition. This research took advantage of the Pima Indians Diabetes Data Set, which captures diverse patient information, both diabetic and non-diabetic. Leveraging this dataset, we undertook a rigorous comparative assessment of six dominant machine learning algorithms, specifically: Support Vector Machine, Artificial Neural Networks, Decision Tree, Random Forest, Logistic Regression, and Naive Bayes. Aiming for precision, we introduced principal component analysis to the workflow, enabling strategic dimensionality reduction and thus spotlighting the most salient data features. Upon completion of our analysis, it became evident that the Random Forest algorithm stood out, achieving an exemplary accuracy rate of 98.6% when 'BP' and 'SKIN' attributes were set aside. This discovery prompts a crucial discussion: not all data attributes weigh equally in their predictive value, and a discerning approach to feature selection can significantly optimize outcomes. Concluding, this study underscores the potential and efficiency of machine learning in diabetes diagnosis. With Random Forest leading the pack in accuracy, there's a compelling case to further embed such computational techniques in healthcare diagnostics, ushering in an era of enhanced patient care.

**Keywords**—Machine learning; support vector machine; artificial neural networks; decision tree; random forest; logistic regression; Naive Bayes; principal component analysis; classification; diabetes

## I. INTRODUCTION

In recent times, diabetes has prominently risen as a pervasive and potentially lethal ailment, with its effects resonating across age groups and genders. This condition, fundamentally shaped by the body's compromised insulin production, interferes with carbohydrate metabolism. This interference results in heightened blood sugar levels, precipitating a slew of symptoms such as augmented thirst, hunger, and frequent urination [1]. A concerning facet of this disease is its accentuated and adverse impact on women, as reflected in their lower survival rates and compromised quality of life [2].

The malaise manifests in three main forms: Type 1, Type 2, and gestational diabetes. Type 1 is predominantly an autoimmune disorder seen in children, leading to the annihilation of pancreatic insulin-producing cells. In contrast, Type 2 emerges when there's heightened insulin resistance

across various organs, eventually pushing the pancreas beyond its production capacities. An added layer of complexity is gestational diabetes, which particularly afflicts pregnant women owing to their pancreas's insufficient insulin output during pregnancy [2]. Furthermore, the diabetes spectrum has more grim facets, capable of inducing long-term harm and malfunctioning in diverse organs like the eyes, kidneys, heart, blood vessels, and nerves [4].

Given the multifarious nature of this disease, physicians find themselves navigating a diagnostic labyrinth. Early diagnosis becomes paramount, serving as the linchpin in circumventing and mitigating potential complications [5]. Fortunately, recent technological strides, predominantly within the machine learning spectrum, proffer novel solutions. Machine learning, a potent sub-discipline of artificial intelligence, harnesses algorithms and statistical frameworks to parse voluminous datasets, unveiling patterns and correlations that often remain concealed from conventional statistical techniques [3].

Positioned against this backdrop, our study delves into the potential of machine learning as a transformative tool in diabetes diagnostics. Six pivotal machine learning classification paradigms - namely, Support Vector Machine, Artificial Neural Networks, Decision Tree, Random Forest, logistic regression, and Naive Bayes - are meticulously examined using the PIDD dataset. By anchoring our assessment on accuracy, we render a holistic comparison of these algorithms' performance nuances.

The paper is structured to facilitate a coherent reader journey. Post this introduction in Section I, Section II immerses into the expansive realm of related works, detailing classification modalities used previously in diabetes prediction. Section III sheds light on our chosen methodologies and intricacies of the PIDD dataset. The crux of our findings unfolds in Section IV, with Section V diving into discussions and implications of these outcomes. Finally, Section VI encapsulates our conclusions, while also hinting at prospective research trajectories.

As we traverse this research landscape, our study is guided by the pressing questions: How do these machine learning paradigms stack against each other for diabetes prediction on the PIDD dataset? Furthermore, can they truly emerge as reliable instruments for diabetes diagnostics?

## II. RELATED WORK

In the annals of modern healthcare research, the strategic deployment of machine learning to grapple with the monumental challenge of diabetes classification has unfailingly occupied a spotlight [6]. The intrigue and allure of this intersection between computational prowess and medical insight have galvanized countless researchers to charter previously unexplored terrains.

Vandana Bavkar, with an academic rigor that's now cited extensively, delivered a magnum opus—a systematic review that scrutinized the versatile applications of machine learning, data mining techniques, and tools in the expansive canvas of diabetes research [6]. His explorations weren't just confined to the realms of prediction and diagnosis. They ventured further, diving deep into the intricacies of diabetic complications, the mystique of genetic predispositions juxtaposed against environmental triggers, and the labyrinth of healthcare management. It was in the revelations of Bavkar's investigation that the bedrock importance of prediction and diagnosis was underscored, positioning them as cornerstone applications of machine learning in the diabetes research tapestry [7].

Parallel to Bavkar's seminal work, Hassan et al. [8] charted their own research trajectory, focusing on the prediction dynamics of diabetes mellitus. Armed with a range of machine-learning classifiers, their study served as a testing ground for techniques such as K-nearest neighbors, Support Vector Machine, and Decision Tree. The metrics they employed—precision, accuracy, sensitivity, and specificity—offered a comprehensive lens through which to evaluate the performance of these classifiers.

Further enriching this research milieu, Kaur et al. delineated a study wherein a quintet of predictive models was brought to the fore [9]. These included stalwarts like Decision Tree, Support Vector Machine, and Naive Bayes. The Pima Indian Diabetes dataset and the R Data Manipulation Tool became their canvas. In a different vein, Zhang et al. concocted a rather innovative approach, introducing a hybrid model that synergized random K-means with Decision Tree, specifically tailored to forecast diabetes risk [10]. Other scholarly forays in this domain have seen the inception of predictive architectures grounded on the Weighted Feature Selection of Random Forest and the XGBoost Ensemble Classifier [11]. Yet another groundbreaking initiative leaned into a logistic regression model, ingeniously augmented by the feature transformation capabilities of XGBoost [12].

Each of these studies, while diverse in methodology and focus, echoes a singular sentiment: the paramount importance of machine learning's role in not just predicting and classifying diabetes, but also in unearthing the intricate dance of genetics and environment, and in revolutionizing healthcare delivery for diabetic patients.

But herein lies an undeniable truth. Despite the richness of insights and the plethora of methodologies that have emerged from these academic odysseys, the horizon of diabetes classification using machine learning still holds vast expanses yet to be charted. The quest for impeccable prediction accuracy

continues, as does the endeavor to spotlight risk factors in their nascent stages. With this study, our ambition is lucidly clear: to augment the extant knowledge reservoir by meticulously assessing the efficacy of a spectrum of machine learning algorithms, all in the context of the revered Pima Indians Diabetes Data Set [13].

To punctuate our intentions and situate our efforts in the grander scheme of academic pursuits, it's paramount to acknowledge the teeming body of studies that have previously addressed this challenge. This dense and rich academic tapestry underscores both the significance and the complexity of the diabetes classification conundrum.

## III. DATASET AND METHODS

### A. Dataset Description

In this study, we utilized the Pima Indians Diabetes Data Set [14], which is a widely used dataset in diabetes research. This dataset was originally collected by the National Institute of Diabetes and Digestive and Kidney Diseases and is available for public use from the UCI Machine Learning Repository. The dataset consists of 768 instances, each containing information about female patients of Pima Indian heritage. The dataset includes various attributes such as age, BMI, blood pressure, skin thickness, insulin level, and diabetes pedigree function, along with the target variable indicating whether the patient has diabetes or not.

The clinical descriptors for these attributes are presented in Table I.

TABLE I. THE CLINICAL DESCRIPTORS OF THE VARIABLES

Number	Attribute	Description	Type
1	Npreg	Number of pregnancies	Numeric
2	Glu	Plasma glucose concentration	Numeric
3	BP	Diastolic blood pressure (mm Hg)	Numeric
4	SKIN	Triceps skinfold thickness, (mm)	Numeric
5	Insulin	Insulin dose, (mu U/ml)	Numeric
6	BMI	Body Mass Index (weight in kg/ (size m) <sup>2</sup> )	Numeric
7	PED	Diabetes pedigree function (heredity)	Numeric
8	Age	Age (Year).	Numeric
9	class	Target variable (0 or 1)	Numeric

### B. Methods

The intellectual pursuit of understanding diabetes through the prism of machine learning necessitates the application of a robust and multifaceted methodology. In light of this, our investigation unfurled in a series of calibrated steps, each meticulously designed to serve a specific purpose within the broader research framework.

1) *Data preprocessing*: Central to the fabric of any data-driven study is the sanctity of the data itself. Recognizing this, our first port of call was to refine and purify the data landscape. We embarked on a rigorous journey of data preprocessing, which, at its core, was about ensuring the

reliability and accuracy of the outcomes. Recognizing the potential pitfalls of missing values, these were diligently identified and addressed with a strategic blend of imputation or outright deletion, depending on the context.

2) *Feature selection*: Beyond just raw data, the richness of features often dictates the nuances of the results. With this philosophy in mind, we ventured into the realm of feature selection. The objective was straightforward yet critical: to streamline the dataset by spotlighting the most consequential attributes for diabetes classification. From the vast repertoire of available techniques, we leaned on the classical Principal Component Analysis (PCA). It's a tool that elegantly navigates the dimensions of data, projecting from a higher-dimensional space to a lower one, all while retaining features pivotal to dataset variance.

3) *Machine learning algorithms*: With the data landscape prepped, the stage was set to deploy the titans of machine learning. Six algorithms, each renowned for its distinctive virtues and latent challenges, were chosen for the diabetes classification task:

a) *Support Vector Machine (SVM)*: The SVM stands tall as a supervised classifier, renowned for its prowess in both regression and classification tasks [15]. Fig. 1 shows SVM algorithm. Originated by Vapnik [16], SVM's genius lies in its capacity to delineate data into classes, both linearly and non-linearly. At its core, SVM conjures hyperplanes in a high-dimensional milieu. The ultimate aspiration? A hyperplane that segregates data classes with the widest possible margin. Non-linear classification gets a boost through a bouquet of kernel functions, each striving to maximize hyperplane margins [17].

Fig. 1. Support vector machine algorithm [18].

b) *Artificial Neural Networks (ANN)*: Channeling inspirations from the intricate mesh of human neural architecture, ANNs exemplify the confluence of biology and computation [19]. Introduced in the 1950s, ANNs mirror the workings of the human brain's myriad neurons, with artificial neurons and weighted interconnections taking center stage [20]. There are three essential layers in a neural network: input layer, hidden layer, and output layer. The input layer is in charge of accepting data from the user. Fig. 2 shows an example of MLP network with two inputs, five neurons in the

hidden layer. The output layer will provide us with the results. The hidden layer is the layer that sits between the input and output layers. On the same layer, there is no interaction between neurons [21]. If the input vector is  $\vec{x}$ , the weight vector is  $\vec{w}$ , and the activation function is a sigmoid function, the output is as follows:

$$y = \text{sigmoid}(\vec{x} \cdot \vec{w}) \quad (1)$$

and the sigmoid is as follows:

$$\text{sigmoid}(x) = \frac{1}{1+e^{-x}} \quad (2)$$

Fig. 2. Example of an MLP network with a hidden layer with two inputs, five neurons in the hidden layer, and one output.

c) *Decision Tree*: Decision Trees, both elegant and insightful, offer a flowchart-like structure to visualize and make decisions. Whether for classification or regression, they rely on a series of attribute tests, guiding data from root to leaf, ultimately culminating in a class prediction [22]. The algorithmic underpinnings encompass three operations: determining terminal nodes, associating non-terminal nodes with tests, and assigning a class to terminal nodes (see Fig. 3) A plethora of algorithms, from ID3 to CTREE, have been proposed for decision tree formulation [23].

Fig. 3. Example of a decision tree.

d) *Random Forest*: Emerging from the shadows of decision trees is the Random Forest—a brainchild of Breiman [24]. It's an ensemble approach, creating a 'forest' of decision trees from randomly chosen data subsets (see Fig. 4) The collective wisdom of this forest then votes or averages, producing classifications or regressions, respectively [25][26][27].

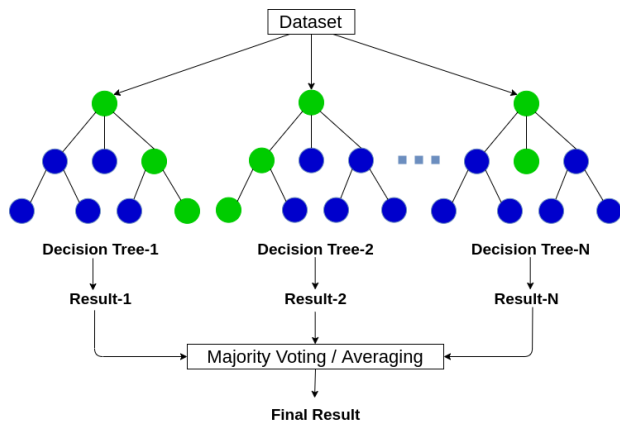

Fig. 4. Random forest.

e) Logistic Regression:

A stalwart in the classification domain, Logistic Regression evaluates probabilities through the sigmoid function, discerning relationships between binary dependent and independent variables. The sigmoid's magic rests in its ability to produce binary outputs based on weighted inputs. If the sigmoid output surpasses 0.5, the prediction is 1; otherwise, it's 0. The sigmoid/logistic function is calculated as follows:

$$y(x) = \frac{1}{1+e^{-x}} \quad (3)$$

where, y is the output which is the result of the weighted sum of the input variables x.

f) Naive Bayes: Grounded in the probabilistic paradigm, the Naive Bayes classifier champions the Bayes Theorem [1]. It presumes that each class feature exists in isolation—hence the "naive" tag. The algorithm computes the posterior probability,

$$P(C|X) = \frac{P(X|C)P(C)}{P(X)} \quad (4)$$

where, P(C|X) is the posterior probability of the target class.

- P(X|C) is the probability of the predictor type.
- P(C) is the probability that class C is correct.
- P(X) is the prior probability of the predictor.

In many intricate real-world scenarios, Naive Bayes has showcased exceptional classification prowess.

IV. EXPERIMENTAL RESULTS

The selection of the Pima Indians Diabetes Data Set for this study was a deliberate choice. This dataset, which has garnered significant attention in the data science community, offers intricate nuances and a wealth of attributes that allow for an exhaustive evaluation of machine learning algorithm performances.

- 1st Experiment: Comprehensive Approach with All Variables.

Our first experiment was anchored in a holistic approach, wherein all available features from the dataset were utilized.

This comprehensive method was designed to create a baseline performance, which future models in our study would either strive to match or surpass. The accuracy metrics corresponding to this experiment, for various algorithms, are tabulated in Table II.

TABLE II. ACCURACY WHEN USING ALL VARIABLES.

Methods	Accuracy validation
Random Forest	0.982
Decision Tree	0.966
SVM	0.954
Logistic Regression	0.794
ANN	0.948
Naïve Bayes Classifier	0.788

As evinced from the results in Table II, the Random Forest classifier emerged as the frontrunner, delivering an impressive accuracy of 0.982, thereby setting a solid benchmark for subsequent experiments.

- 2nd Experiment: Exploring the Power of PCA for Dimensionality Reduction.

Principal Component Analysis (PCA) stands as a testament to the efforts of countless researchers aiming to refine large data volumes into their most significant components. With the aspiration to condense the dataset into its primary four components, representing 71% of its inherent variance, there was an optimistic expectation for data efficiency without sacrificing critical information.

The performance outcomes derived from this approach are detailed in Table III.

TABLE III. ACCURACY WHEN USING THE PCA.

Methods	Accuracy validation
Random Forest	0.97
Decision Tree	0.962
SVM	0.888
Logistic Regression	0.728
ANN	0.826
Naïve Bayes Classifier	0.744

A glance at Table III reveals a pivotal observation: while the Random Forest algorithm continued to exhibit stellar accuracy at 0.97, it was clear that the unmodified data carried nuanced intricacies not entirely captured by PCA. It's a gentle reminder of the delicate balance between data reduction and the preservation of intricate patterns.

- 3rd Experiment: A Deep Dive into Correlation Dynamics.

One of the guiding principles of this experiment was to unearth the relationships and patterns present among the dataset's variables. As machine learning models continue to advance in complexity, a nuanced comprehension of how variables interact and influence each other is paramount.

Fig. 5 and 6 graphically depict the interactions between the class variable and other attributes, as well as the overarching correlation matrix respectively.

Fig. 5. The class variable as a function of the other variables.

Fig. 6. Correlation matrix.

The metrics arising from this correlation analysis, especially when excluding the 'BP' and 'SKIN' attributes are enumerated in Table IV.

TABLE IV. ACCURACY WITHOUT THE USE OF 'BP' AND 'SKIN'.

Methods	Accuracy validation
Random Forest	0.986
Decision Tree	0.974
SVM	0.964
Logistic Regression	0.792
ANN	0.806
Naïve Bayes Classifier	0.784

An illuminating discovery from this analysis was the marginal contribution of the 'BP' and 'SKIN' variables. By sidelining these variables, the Random Forest algorithm, known for its dynamic adaptability, achieved an apex accuracy of 0.986, highlighting the value of informed feature selection in machine learning.

- 4th Experiment: Spotlight on Prime Features.

The emphasis of this experiment was on identifying and evaluating the predictive power of four critical attributes: number of pregnancies, plasma glucose concentration, body mass index, and age. These features, singled out for their perceived significance, were put to the test to determine their collective predictive prowess.

The outcomes, with focus solely on these attributes are presented in Table V.

TABLE V. ACCURACY WHEN USING THE NUMBER OF PREGNANCIES, PLASMA GLUCOSE CONCENTRATION, BODY MASS INDEX, AND AGE.

Methods	Accuracy validation
Random Forest	0.984
Decision Tree	0.97
SVM	0.964
Logistic Regression	0.788
ANN	0.78
Naïve Bayes Classifier	0.78

While these select attributes showcased substantial predictive capability, the Random Forest algorithm highlighted a noteworthy point: focusing exclusively on them, albeit impactful, didn't outperform its previous benchmarks. The model's accuracy, in this context, peaked at 0.984, subtly reminding us of the intricate dynamics within data.

## V. DISCUSSION

At the confluence of scientific inquiry, we find an unyielding drive towards understanding, clarity, and the quest for tangible insights. Embedded within the heart of this exploration, our study not only aligns with previous findings but also brings forth novel perspectives in the realm of diabetes research [1,15].

One of the standout revelations was the prowess of the Random Forest classifier. Consistent with the observations by Breiman [24] and further corroborated by Liaw and Wiener [27], the Random Forest's consistent performance with the PIMA dataset reaffirms its position of prominence in machine learning applications.

While our experiments were rooted in rigorous methodologies, they were not without their illuminating moments of introspection. Notably, the outcomes from our dimensionality reduction experiment with PCA deviated from what one might expect from theoretical postulations. Such moments, humbling as they are, serve to underline the subtle yet critical chasm that can exist between abstract mathematical formulations and their tangible manifestations in real-world datasets. This deviation nudges us to approach data science with a blend of both rigor and adaptability, being open to unexpected insights.

Diving further into the dataset's granular details, the number of pregnancies, plasma glucose concentration, body mass index, and age have revealed themselves as potential linchpins in diabetes prediction, much in line with previous research findings [5,8]. Yet, the more subtle role of the 'BP' and 'SKIN' attributes reminds us of the broader landscape of attribute interplay and the importance of not viewing any single attribute in isolation.

Conclusively, this exploration has been an enlightening journey, one that reiterates the power of machine learning but equally underscores the necessity for nuanced, iterative data analysis. As the realms of medical diagnostics and data science continue to intersect, it is these intricate dances between data, theory, and application that will pave the way for transformative insights.

## VI. CONCLUSION AND FORWARD PATHWAYS

Throughout our research, we rigorously applied various machine learning methodologies to the PIMA dataset. A consistent standout was the Random Forest classifier, not merely for its algorithmic prowess but for its adaptability and robustness when pitted against intricate datasets like PIMA. The nuanced roles of attributes, especially 'BP' and 'SKIN', underscore the layered complexity within the dataset and the intricacies of diabetes as a medical condition.

Upon deeper examination, it became evident that while some attributes such as the number of pregnancies, plasma glucose concentration, body mass index, and age played pivotal roles in diabetes prediction, others demanded a more careful evaluation. This balance between attribute importance and the broader attribute interplay deepens our understanding and offers a refined perspective on the dataset's potentials and pitfalls.

Looking ahead, there's a wealth of opportunity. The idea of melding deep learning techniques, such as convolutional and recurrent neural networks, with traditional machine learning offers a promising avenue. As medical datasets continue to expand, they will benefit from architectures designed to handle vast amounts of data and extract intricate patterns. This integration could redefine the landscape of medical predictive modeling, particularly for conditions as multifaceted as diabetes. To encapsulate, our findings have been both affirming and enlightening, and the journey ahead in the realms of medical diagnostics and data science is full of promise. Each step we take is more than just academic progression; it is a stride towards enhancing medical prediction and, ultimately, patient outcomes.

New Horizon College of Engineering, Bangalore, India<sup>1</sup>  
Department of MCA, New Horizon College of Engineering, Bangalore, India<sup>2</sup>

**Abstract**—Human organ transplantation is a lifesaving process for many of the patients suffering from end stage diseases. Transplantation surgeons are often confronted with the question of the expected survival prognosis for this expensive and perilous process. The aim of the work is to identify an optimal model for predicting the survival of the recipient based on the available organ. This study identifies important features of the recipient and donor parameters for training the model. The study compares the performance of the Random Survival Forest (RSF), which is a machine learning method, and the Cox Proportional Hazard (CPH) model, which is a statistical model, to identify the more accurate model for survival prediction. Variations of the C-index, Brier score, and cumulative Area Under Curve evaluate the survival models considered. This study suggests that CPH which is a statistical method is a better option for forecasting graft and patient survival for an improved clinical outcome.

**Keywords**—Cox proportional hazard model; random survival forest; C-index; brier score; area under curve; organ transplantation; survival prognosis

## I. INTRODUCTION

Kidney transplantation is the only option for those patients identified that the dialysis is no longer a viable solution. According to Organ Procurement and Transplantation Network (OPTN), while there were 88,901 patients waiting for kidney transplantation in US, only 25,499 transplantations were performed in year 2022 [1]. In India, there are around 2 lakhs kidney patients waiting for transplantation per year. However only 10,000 transplantations are performed in a year [2]. Kidney from deceased donor has proven to be a better source to reduce the waiting time for the transplant recipients. There was a huge leap in the number of transplantations in United States due to increase in deceased organ donation. But the Delayed Graft Function (DGF) continues in an upward trend and occurred in 24% of adult kidney transplants in 2021 [3]. Increased DGF is a concern, as it increases the risk of acute rejection and death [4]. To reduce the risk of DGF by taking precaution in the selection of donor kidneys, minimizing cold ischemia time, and monitoring of the recipient after transplantation [5]. In this post pandemic era, especially as it is very difficult to procure an organ, transplant surgeon has to select an ideal recipient for the available organ. Despite having a variety of technologies and infrastructure, relatively little of it is used in such crucial life-saving procedures. The reason and motivation for selecting this topic for research work is mainly as a result of the lack of transplantable organs. As the

availability of organs is very less, we have to make sure that each organ is allocated to the right recipient who can ensure maximize life expectancy. Computer algorithms which suggest the best match for a better survival prognosis helps to increase the success rate of post-transplantation.

Exploiting the new-age technologies to identify the correct recipient for the available organ helps to achieve a better survival prognosis. Sophisticated method helps to find a correct patient in less amount of time promoting interinstitutional organ transplantation without affecting the preservation time of the deceased organ [6]. Implementation of an organ harvesting and transplantation network using IoT and Blockchain improve the efficacy of the organ allocation system. It also monitors the pathophysiological changes in donors and recipients which help in improving the overall quality of organ transplantation [7].

There are numerous survival prediction algorithms that use statistical or machine learning algorithms which are suitable for respective field of study. Random Survival Forest is a machine learning algorithm which predicts by leveraging an ensemble of multiple decision tree. RSF is the machine learning method used for survival prediction particularly while handling complex, high-dimensional data and when making predictions is the key objective. Cox proportional hazard is the statistical method used for survival prediction particularly when there is censored data and when understanding the impact of covariates is the primary goal. The Cox Proportional Hazards (CPH) model and the Random Survival Forest (RSF) algorithm are both significant in the field of survival analysis and have distinct advantages and applications. Selection between them is usually based on the specific characteristics of the data and research objectives. The objective of this paper is to compare the accuracy of survival prediction done by CPH which is a statistical method with RSF which is a machine learning method.

The following section summarizes the review and key findings of related works. The following section after the literature review explains the details regarding the dataset and the methods used. In the material and method section selects the two most significant algorithms based on the review of papers involving survival prediction. The following sub-sections of evaluate the performance of the statistical and machine learning models. The discrimination assessment of the models is done by the calculation of Concordance-index. Time-dependent Brier score is as an alternative method to assess the calibration, of both the methods. Even though, Random

\*Corresponding Author

Survival Forest and Cox's proportional hazards model were performing equally well in terms of discrimination (c-index) and in terms of calibration (IBS), there is notable difference in terms of time dependent Receiver Operating Characteristic (ROC) curve or the cumulative Area Under Curve obtained. This paper suggests CPH as an optimized survival prediction method for kidney transplant recipients.

## II. LITERATURE REVIEW

Lentine, Krista L et al., [3] reflected in their paper that amid COVID-19 pandemic, the field of kidney transplantation faced both successes and challenges in broader geographic organ distribution. The United States witnessed a record number of kidney transplants, mainly due to the increase in deceased donor kidney donation. However, disparities in access to living donor kidney transplant persist, especially for non-White and publicly insured patients. Delayed graft function (DGF) continues an upward trend and occurred in 24% of adult kidney transplants in 2021. Five-year graft survival for deceased donor transplant was 88.6% versus 80.7% for recipients aged 18-34 years, and 82.1% versus 68.0% for recipients aged 65 years or older. The rate of deceased donor transplants among pediatric candidates recovered in 2021 from a low in 2020.

In this paper, the authors Grant, Shannon et al. evaluate various goodness-of-fit tests for the Cox proportional hazards model with time-varying covariates [8]. The Cox proportional hazards model is used in survival analysis to assess the relationship between covariates and the hazard rate. However, when the covariates are time-varying, traditional goodness-of-fit tests may not perform well. The authors propose and compare several alternative tests to assess the model's fit to the data. The key findings of the paper may include insights into the accuracy and reliability of different goodness-of-fit tests when applied to this particular scenario. This research is valuable for improving the assessment of how well the Cox model fits the data when dealing with covariate changes over time, which is a common occurrence in survival analysis studies.

Spooner, A., Chen, E., Sowmya, A. et al. did a comparative study of, ten machine learning algorithms that can perform survival analysis [9]. In this study performance and stability of high dimensional and heterogeneous clinical data was carried out. The researchers developed new prediction models that incorporated immunological factors, recipient, and donor variables, and compared their performance with conventional models. They analyzed data from 3,117 kidney transplant recipients in a multicenter cohort. The results showed that using a survival decision tree model significantly increased the accuracy of graft survival prediction compared to a conventional decision tree model. The occurrence of acute rejection within the first-year post-transplant found to be associated with a 4.27-fold increase in the risk of graft failure.

Yoo, K.D., Noh, J., Lee, H. et al. in their work discusses the challenges in analyzing data from clinical trials and cohort studies, particularly those related to dementia [10]. Such data is often high-dimensional, censored, and heterogeneous, making traditional statistical methods insufficient. Machine learning models that can predict the time until a patient develops

dementia have become essential in understanding dementia risks. They offer more accurate results when dealing with complex clinical data. The study compares ten machine learning algorithms combined with eight feature selection methods to analyze high-dimensional and heterogeneous clinical data. The models predict survival to dementia using baseline data from two different studies: the Sydney Memory and Ageing Study (MAS) and the Alzheimer's Disease Neuroimaging Initiative (ADNI). The models achieved promising performance values, with a maximum concordance index of 0.82 for MAS and 0.93 for ADNI.

The authors K. Suresh, C. Severn, and D. Ghosh [11] discuss various types of discrete-time survival models, such as the Cox proportional hazards model, the logistic regression model, and parametric models like the Weibull and exponential models. The authors emphasize the potential benefits of using machine learning algorithms for more accurate and robust predictions, while also acknowledging the challenges and complexities involved in these approaches.

## III. METHODS AND MATERIALS

Random Survival Forest is a well-known Machine learning algorithms to explore the time to event, in order to study the survival prognosis. Cox Proportional Hazard is a classic statistical approach used on deidentified medical data which may have a high proportion of censored data. While handling censored observations, it can parallelly predict hazard ratio to investigate the association between covariates and survival time of a patient [12]. The aim of the study is to compare the accuracy of survival prediction of the two methods. Training using same dataset gives a better comparison of performance for both Random Survival Forest (RSF) model and Cox Proportional Hazard (CPH) model.

### A. Dataset

The proposed study, use the dataset from United Network for Organ Sharing (UNOS). Standard Transplant Analysis and Research (STAR) files consist of de-identified patient-level information of the transplant recipients and waiting list applicants. The dataset covers patient information starting from January 10, 1987. For the purpose of research, a request sent to UNOS for the STAR dataset. UNOS allowed downloading of STAR dataset from file server on signing a non-disclosure agreement. The data for each type of transplantation covers various attributes of both recipient and donor including survival timeline information. A subset of about 2000 patient data, were used for the comparison study. Attributes selected for training the model includes five features of the transplantation data, along with one event indicator and another attribute indicating the time to event. The event indicator, PX\_STATUS is labelled in four classes, to represent DEAD, ALIVE, RETX or LOST. Mapping to binary representation, the value 'False' assigned to ALIVE status and value 'True' assigned to remaining three status. The five features selected are age of the recipient (AGE), age of the donor (AGE\_DON), BMI of the recipient (BMI\_CALC), HLA mismatch number between recipient and donor (HLAMIS) and cold ischemia time (COLD\_ISCH\_KI) for the organ. The attribute time to event PTIME is the time interval between the transplantation

date and the date at which the event happened, indicated in number of days.

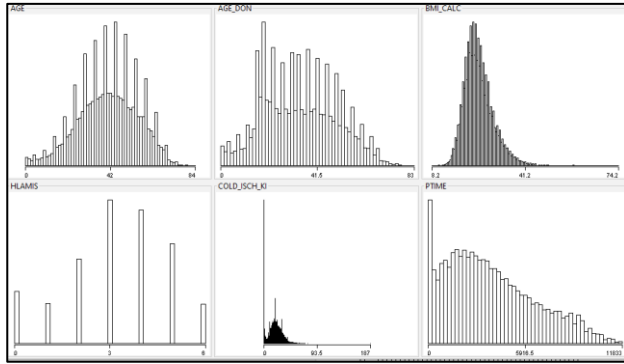

Fig. 1. Feature distribution against time.

Fig. 1 depicts the distribution of selected features against the time span event of patient survival time in days (PTIME).

**B. Staistical Method based Analysis**

Cox proportional-hazards (CPH) model is the statistical method to analyze the risk of several features towards the time to event. This method measures the hazard ratio of covariates on the survival of an individual. Hazard function  $h(t)$  or instantaneous failure rate shows the risk of an event occurring for an individual at any point of time [13]. In case of an individual who has undergone transplantation, the event can be death or re-transplantation at time  $t$ . Calculation of Hazard function  $h(t)$  is as follows [12]:

$$H(t) = H_0(t) \times \exp(b_1x_1 + b_2x_2 + b_3x_3 + \dots + b_kx_k)$$

where  $H_0(t)$  is the cumulative baseline hazard function and  $x_1, x_2, \dots, x_k$  are the subset of predictor variables considered.

The calculation of survival function  $S(t)$ , using CPH model is as follows [12]:

$$S(t) = \exp(-H_0(t) \times PI)$$

where PI, the Prognostic Index. Calculation of PI is as follows:

$$PI = x_1b_1 + x_2b_2 + x_3b_3 + \dots + x_kb_k$$

Survival times are subject to right-censoring. Therefore, we need to consider an individual’s event indicator (PX\_STAT) in addition to survival time (PTIME) [14]. CoxPHSurvivalAnalysis is the python library which is fully compatible to do the required statistical analysis on the dataset and hence used in current analysis of data. PX\_STATUS and PTIME are stored as a structured array. The first field is an indication of observed survival status. Occurrence of event indicated as, ‘True’ value, and ‘False’ value to indicate the remaining status. The second field denoting the observed survival time (PTIME), which corresponds to the number days between the transplantation date and the time of death (if PX\_STATUS == ‘True’) or person contacted last time (if PX\_STATUS == ‘False’).

Cox proportional-hazards model estimates the hazard ratio of a covariate and the effect on the survival of the patient. The extracted hazard ratio and specific distribution generates the

survival time of a patient. Features are used to predict the survival time of an individual. The method overcomes the disadvantage of directly estimating survival time from censored data.

**C. Machine Learning Method based Survival Analysis**

Random survival forests, is an ensemble tree method for analysis of right-censored survival data. Predictions using Random Survival Forest predictions are an aggregation of the predictions of individual trees in the ensemble. Aggregation of the tree-based Nelson-Aalen estimators leads to the construction of the ensemble in Random Survival Forest [15]. The ensemble survival function from random survival forest is as follows:

$$\hat{S}^{rsf}(t|x) = \exp\left(-\frac{1}{B} \sum_{b=1}^B \hat{H}_b(t|x)\right)$$

Corresponding to covariate value  $x$ ,  $\tilde{N}_b^*(s, x)$  is the count of the uncensored events until time  $s$  and  $\tilde{Y}_b^*(s, x)$  is the number of risks at time  $s$ . The estimated conditional cumulative hazard function in each terminal node of a tree using the Nelson-Aalen estimator is as follows:

$$\hat{H}_b(t|x) = \int_0^t \frac{\tilde{N}_b^*(ds, x)}{\tilde{y}_b^*(s, x)}$$

RandomSurvivalForest is the python library used for RSF model creation.

**D. Performance Evaluation of Stastical and Machine Learning Models**

Sample data of six real-world clinical datasets from UNOS evaluates the performance of Cox proportional-hazards model and Random survival forests. Table I shows the clinical dataset used for the analysis. The discriminatory power of five features used to evaluate the predictions done by these predictive models. 20% of training data assess the prediction of the model to predict the survival of a patient after transplantation.

TABLE I. SAMPLE DATA – UNOS DATASET FOR THE FEATURES

	AGE	AGE_DO N	BMI_CAL C	HLAMIS	COLD_ISCH_KI
Sample 1	4	30	21.3	4.0	1.0
Sample 2	10	27	21.3	6.0	9.0
Sample 3	14	5	16.0	5.0	37.0
Sample 4	72	37	22.5	3.0	2.0
Sample 5	72	16	24.1	2.0	17.0
Sample 6	72	62	22.4	5.0	21.0

Graphs generated visualized the evaluation of the results for the given dataset.

a) *Survival Probability Graph*: The survival probability graph in Fig. 2 shows the probability of survival against the number of days, using Cox Proportional Hazard model.

Fig. 2. Probability of survival using Cox PH.

The survival probability graph in Fig. 3 shows the probability of survival against the number of days, using Random Survival Forest model.

Fig. 3. Probability of survival using RSF.

Fig. 2 and Fig. 3 show that younger recipient is having more survival rate in comparison to older recipient. Both CPH and RSF show similar trends.

b) *Hazard Graph*: The graph in Fig. 4 shows the Cumulative hazard function against survival time in days, using Cox Proportional Hazard model. The graph in Fig. 5 shows the Cumulative Hazard function using Random Survival Forest [16].

Fig. 4. Cumulative hazard using Cox PH.

Cumulative hazard function reconfirms the finding identified in the survival probability graph.

Fig. 5. Cumulative hazard using RSF.

c) *Permutation Importance*: The feature importance of estimators for a given dataset is determined by the permutation importance function. The permutation feature importance measures the increase in the prediction error of the model as a result of permuting the values of a feature. Computation of the permutation importance [17][18],  $i_j$  for the feature  $f_j$ , is as follows:

$$i_j = s - \frac{1}{k} \sum_{k=1}^K s_{k,j}$$

where,  $s$  is the reference score for the data  $D$ , on predictive fitted model  $m$ , calculated for  $K$  repetition for each feature  $f_j$ . The results of permutation feature importance for both the model shows that age of the recipient variable is the main driver of prediction. The variation of data in these columns causes the mean square error in both models to increase. Compared to CPH model, RSF model depends mostly on this variable. Table II shows the permutation feature importance of CPH model and Table III shows the same using RSF model.

TABLE II. PERMUTATION IMPORTANCE-CPH

Permutation Importance-CPH		
	Importance mean	Importance std
AGE	0.024935	0.016718
AGE_DON	0.023710	0.012844
BMI_CALC	0.002368	0.007720
HLAMIS	-0.001456	0.002062
COLD_ISCH_KI	-0.005284	0.007599

TABLE III. PERMUTATION IMPORTANCE-RSF

Permutation Importance-RSF		
	Importance mean	Importance std
AGE	0.049249	0.019136
AGE_DON	0.015333	0.006105
BMI_CALC	0.003339	0.003046
HLAMIS	0.001181	0.004930
COLD_ISCH_KI	0.000656	0.004182

d) *Concordance Index (C-Index)*: C-Index or C-statistic is a measure of predictive accuracy of a model particularly used for survival analysis. C-Index value indicates, a higher risk should result in a shorter time to the adverse event. Therefore, if a model predicts a higher risk score for the first patient ( $\eta_i > \eta_j$ ), we also expect a shorter survival time in comparison with the other patient ( $T_i < T_j$ ).

$$c = \frac{\sum_{i,j} I(T_i > T_j) \cdot I(\eta_j > \eta_i) \cdot \Delta_j}{\sum_{i,j} I(T_i > T_j) \cdot \Delta_j}$$

Split the dataset in training and test sets. Fit the models on the training set. Evaluate the model performances (C-index) on the test set. The desirable values range is between 0.5 and 1. Closer the value towards 1, the more the model differentiates between early events (higher risk) and later occurrences (lower risk). The C-index maintains an implicit dependency on time [19]. The C-index becomes more biased when the amount of censoring is more [20]. CPH gave a Concordance Index of 0.5505 while using RSF, the C-index is calculated as 0.5427. As the number shows CPH gives a better performance than RSF in terms of C-Index.

e) *Brier Score*: Brier Score or Brier Probability score is a measure of the accuracy of the forecast done by a model. The score particularly evaluates the probabilistic prediction. The time-dependent Brier score is an extension of the mean squared error to right censored data. Inverse probability of censoring weights ( $1/\hat{G}(t)$ ) and the model's predicted

probability of upcoming events up to the time t ( $\hat{\Pi}(t|x)$ ), estimates the Brier score as given below [21].

$$BS^{\wedge}(t) = \frac{1}{n} \sum_{i=1}^n \frac{\hat{s}^2(t|x_i)I\{T_i \leq t\}\delta_i}{\hat{G}(T_i - |x_i)} + \frac{(1 - \hat{s}(t|x_i))^2 I\{T_i > t\}}{\hat{G}(t|x_i)}$$

The integrated Brier score at time T is as follows:

$$IBS(T) = \frac{1}{T} \int_0^T BS(t) dt$$

Lower values for the Brier score indicate better prediction performance. Using the Brier score we can calculate the continuous rank probability score (CRPS), defined as the Integrated Brier Score (IBS) divided by time. CPH gave an Integrated Brier score of 0.1958, and 0.1967 while using RSF. In terms of Brier Score, both CPH and RSF are equally performing, however CPH is having slightly better prediction performance.

f) *Receiver Operating Characteristic Curve (ROC)*: Another performance metric to compare the models is time dependent ROC curve [21]. The time-dependent ROC curve is a graphical representation used in survival analysis. This is used to evaluate the performance of predictive models designed to estimate the probability of an event occurring at a specific time in the future. It is also known as the dynamic or cumulative Area Under the Curve (AUC). In the graphical representation of the curve, the x-axis represents time, and the y-axis represents a measure of the model's performance at that specific time. As seen in the Fig. 6, the CPH performance is better than the RSF. The mean value for CPH is 0.602 which is higher than the RSF mean 0.568.

Evaluation of Cumulative hazard function at a time interval of 1000 days calculates the time-dependent risk scores. The plot of CPH shows that the model is doing moderately well on average, with an approximate AUC of 0.602. However, there is a clear difference in prediction performance between the AUC curve of RSF and that of CPH. The performance prediction on the test data increases 15 years after the transplantation surgery. It remains high during the initial 4 to 5 years soon after the surgery and also after 15 years of transplantation. Thus, we can conclude that the model is most effective in predicting death both at the low-term and at high-term using the time-dependent AUC curve.

CPH classify and prioritize parameters using multivariate analysis. The model considered the parameters prioritized for the risk of hazard by Cox Proportional Hazard model. These include CIT, Age of the recipient, HLA mismatch, and BMI calculated. Cox proportional hazard prediction model predict survival days. Prediction accuracy of models evaluated by comparing the predicted survival graph against the actual survival days available as part of the UNOS dataset. Including a fitted model-based prediction in the current allocation policy can enhance the outcome of organ transplantation.

Fig. 6. Comparison of mean AUC -CPH and RSF.

#### IV. RESULTS

Comparing the result with the predictive performance of the Random Survival Forest model, the Cox proportional hazard model performs impartially better on average, mostly due to the better performance in the intervals 4–5 years, and 15–20 years. Even during the period above 5 years, CPH has equally or better performance than RSF. This shows that even though it is convenient to assess overall performance, using mean AUC, even without considering the mean AUC, CPH is a better method to predict the survival prognosis of transplant recipients.

#### V. CONCLUSION

For evaluating survival models considered, variations of the C-index, Permutation Importance, Brier Score, and Cumulative AUC curve proposed over the time are analyzed [21]. The result indicates that both models perform equally well, achieving a concordance index of  $\sim 0.55$ . Evaluation of the prediction of the models is done using alternative methods. Time-dependent Brier score assess the discrimination and calibration, of both the methods. Here again, both the models had the same score of  $\sim 0.196$ . Despite Random Survival Forest and Cox's proportional hazards model performing equally well in terms of discrimination (c-index) and in terms of calibration (IBS), there seems to be a notable difference in terms of time dependent ROC curve or the cumulative AUC. The mean value of AUC with Cox's proportional hazards model outperformed Random Survival Forest. Thus, this paper suggests CPH as an optimized survival prediction method for kidney transplant recipients.

# Analyzing RNA-Seq Gene Expression Data for Cancer Classification Through ML Approach

Abdul Wahid, M Tariq Banday  
Department of Electronics & Inst. Technology  
University of Kashmir, Srinagar, India

**Abstract—Purpose:** Ribonucleic Acid Sequencing (RNA-Seq) is a technique that allows an efficient genome-wide analysis of gene expressions. Such analysis is a strategy for identifying hidden patterns in data, and those related to cancer-specific biomarkers. Prior analyses without samples of different cancer kinds used RNA-Seq data from the same type of cancer as the positive and negative samples. Therefore, different cancer types must be evaluated to uncover differentially expressed genes and perform multiple cancer classifications. **Problem:** Since gene expression reflects both the genetic make-up of an organism and the biochemical activities occurring in tissue and cells, it can be crucial in the early identification of cancer. The aim of this study is to classify the RNA-Sequence data into five different cancer forms, such as LUAD, BRCA, KIRC, LUSC, and UCEC, through an ensemble approach of machine learning algorithms. RNA-Seq data for five different cancer types from the UCI Machine Learning Repository are examined in this research. **Methods:** As a first step, the relevant features of RNA-Seq are extricated using Principal Component Analysis (PCA). Then, the extricated features are given to the ensemble of machine learning classifiers to classify the type of cancer. The ensemble of classifiers is built using Support Vector Machine (SVM), Naive Bayes (NB), and K-Nearest Neighbor (KNN). **Results:** The results demonstrated that the proposed ensemble classifier outperformed the existing machine-learning approaches with an accuracy of 99.59%.

**Keywords—RNA-Sequence; gene expression; feature extraction; voting classifier; ensemble approach**

## I. INTRODUCTION

Cancer is a complex disease characterized by the uncontrolled division and growth of abnormal cells in the body, often forming tumors and potentially spreading to other tissues. When cells behave abnormally and divide abnormally, they can damage neighboring cells and form tumors that can be lethal depending on the circumstances. Early detection and appropriate therapy can reduce the chances of harming other cells. Researchers are working to evolve new systems for preliminary cancer detection and categorization in response to the high cancer mortality rate. However, it is challenging to diagnose cancer early due to the disorganized nature of cancer cells. As a result, RNA-Seq analysis can be instrumental in this case [1]. RNA (Ribonucleic acid) is a molecule that plays a critical role in protein synthesis in cells. RNA is made up of a sequence of four different nucleotide bases: adenine (A), guanine (G), cytosine (C), and uracil (U). RNA sequencing (RNA-Seq) is a powerful technique used to study gene expression by determining the sequence of RNA molecules in a sample. In RNA sequencing, RNA is first isolated from the sample and then converted into complementary DNA (cDNA)

using reverse transcription. Next, the cDNA is sequenced using high-throughput sequencing technologies to generate extensive RNA sequence data. RNA sequential datasets can be used for various purposes, such as studying gene expression, identifying genetic mutations, and developing new disease therapies. These datasets can be generated through various techniques, such as RNA sequencing, microarrays, and hybridization. RNA-Seq is a recent and well-liked method for discovering new transcripts and isoforms by delivering more normalized and less noisy data for prediction and classification purposes. The most crucial role of transcriptome profiling is identifying the differentially expressed genes in the body or finding gene variances at various levels. Using RNA-sequencing, identification and quantification may be done all at one spot. To categorize diseases like breast invasive carcinoma (BRCA), colon adenocarcinoma (COAD), renal chromophobe, etc. RNA-Seq data are freely accessible from many databases [2]. However, many dimensions, complexity, and duplication of features make studying RNA gene expression data particularly challenging. Thus, Machine Learning (ML) and deep learning algorithms can be used to extract features [3], [4] automatically.

Machine Language is a subset of Artificial Intelligence (AI) which is accustomed to identifying underlying patterns in data to identify associations between them [5], [6]. In the age of big data, ML is becoming crucial since it is becoming increasingly difficult for humans to recognize trends and patterns in data to make predictions [7], [8]. ML is thus taking over from humans when identifying and forecasting unseen data to enable informed decision-making. By retrieving features from a database without human input, ML generates predictions. There is a growing use of ML almost everywhere [9]. Its common uses include natural language processing, forecasting, aviation management, and biology to identify protein and RNA sequences [10], [11].

The most crucial aspect of RNA-Seq analyses is differential analysis [12]. Traditional differential analysis techniques often match tumor samples to standard samples of the same tumor kind [13], [14]. However, due to its ignorance of additional tumor forms, such a technology could not distinguish between distinct tumor types [15]. Therefore, conducting an in-depth analysis using RNA-Seq data is necessarily better for understanding the causes of different cancers [16]. Furthermore, most studies attempt to locate genes with differential expression to extract the most pertinent properties. Therefore, developing a strategy that incorporates an understanding of various tumors kinds in the study is essential.

Although RNA-Seq data help detect changes at the gene level, working with RNA-Seq data can be difficult due to its spatial properties [17]. Feature engineering, a technique used to address the challenges of high dimensionality and the relatively small number of samples in gene expression data, is a crucial part of computer approaches for gene expression research. In the current study, gene expression features are extracted in order to overcome the curse of dimensionality and an ensemble of three ML methods for cancer classification using gene expression data have been applied with hard voting strategy. Five tumors of RNA-Seq data are used in this investigation. The current study has applied an ensemble of three ML methods for cancer classification using gene expression data. Five tumors of RNA-Seq data is used in this investigation.

The key contributions of this study are following:

- The proposed framework applies multiple ML models to produce a final ensemble model that is rich in diversity.
- Relevant features extricated from the RNA sequence dataset for cancer prediction.
- RNA Sequence data has been analyzed and visualized to infer knowledge.
- Receiver operating characteristics analysis and state-of-the-art analysis has been done to prove the superiority of the proposed approach.

The remaining paper is organized as follows: The literature relating to the current investigation is discussed in Section II. In Section III, the proposed method is covered. The experimental findings are covered in Section IV, and the article is wrapped up in Section V.

## II. LITERATURE REVIEW

First, to categorise cancer, Sterling Ramroach et al. used various machine learning techniques [18]. A dataset for several cancer kinds was downloaded for their study from the online data portal COSMIC. The machine learning models that were used were support vector machine (SVM), neural networks, K closest neighbour (KNN), and random forest (RF). For various cancer types and primary sites, the authors conducted numerous tests. In contrast to other algorithms, RF distinguished itself by achieving significant classification accuracy and being simple to tune.

The boosting deep cascade forest (BCDForest) deep learning algorithm was presented by Yang Guo et al. as the preference for deep neural networks for categorising the cancer RNA. This strategy was used to publicly available microarray data sets encompassing adenocarcinoma, brain, and colon cancer and RNA-Seq data sets containing BRCA, GBM, pan cancers, and LUNG. Each deep forest in this ensemble methodology worked well in predicting the classification outcomes. First, Cascade forests are built using decision tree-based random forests trained to find relevant characteristics in raw data. Next, this result was placed against state-of-the-art classifiers like SVM, KNN, LR, RF, and the original gforest [18]. The authors claimed that their suggested approach produced more precise results.

Yawen Xiao et al. suggested that the multimodal ensemble technique includes KNN, SVM, DTs, RFs, and Gradient Boosting Decision Trees (GBDTs) [19]. Three different cancers were treated using their suggested approach: LUAD, stomach adenocarcinoma (STAD), and BRCA. This tactic was used to train each classifier individually using the supplied data to produce predictions, which were then used to inform a multimodal ensemble approach using deep learning. This technique predicts cancer more accurately than data produced by a single classifier.

Using Voom, Dincer Goksuluk et al. developed a new range of classifiers termed “voomNSC”, “voomNBLDA”, and “voomPLDA” to classify and assess RNA-Sequencing data. VoomNSC uses the NSC approach in conjunction with voom transformation to create classifiers that are more reliable and accurate [3]. Because VoomDLDA and voomDQDA are not sparse bases, they take advantage of all the model’s properties. The sparse base classifier voomNSC uses only the subset of features in the model. The results showed that voomNSC produced the best outcomes compared to PLDA, NBLDA, and NSC.

Paul Ryvkin et al. provided a brand-new numerical method for CoRAL (classification of RNA by analysis of length) [20]. For this reason, the authors sequenced databases of short RNA sequences. Three trimmed adapter sequences were then applied to the dataset, and a FASTA file was generated after completing numerous pre-processing steps. Next, aligned reads were recorded in SAM files by comparing them to a reference file. A SAM file was then created based on the mismatch rate of the readings. Finally, a BAM file containing the aligned and matched genes was created and delivered to CoRAL. CoRAL categorises various RNA sequence types and draws out salient traits from them. This technique categorises short RNA sequences and gives the user a more significant direction.

Hamid Reza Hassanzadeh et al. suggested a cutting-edge pipeline technique to predict the prognosis of cancer patients [21]. The proposed method used Laplacian Support Vector Machines for semi-supervised learning. This technique predicted the survival of patients with neuroblastoma (NB) and kidney cancer (KIRC). It involved four steps where pre-processing is the first step which includes feature metric storage and data analysis. The second step is feature extraction and then next step removes overfitting problems. Using a generalisation strategy as the final step will enable to assess the precision of each model and determine the weights accordingly. In terms of accuracy, this pipeline method performed better than supervised SVM.

Jiande Wu et al. have suggested using several machine-learning algorithms to detect triple-negative breast cancers [5]. In this study, TCGA data were used to evaluate the gene expression levels of 110 breast cancer samples that were triple-negative with 992 non-triple-negative samples. SVM, KNN, Naive Bayes (NB), and DT were the machine learning classification models that were employed. Due to the enormous dimensions of the data, a further step known as feature selection was carried out before classification to obtain the essential features. The categorisation job had accuracy rates of

90%, 87%, 85%, and 87%, respectively. The results demonstrate that SVM outperformed the other techniques.

GeneQC (gene expression quality control), a machine learning-based technique, was proposed by Adam McDermaid et al. to determine the reliability of expression levels precisely from RNA sequencing datasets [15]. The authors used data from seven plant and animal taxa's RNA sequencing. Three different types of information were entered into GeneQC. A SAM file is read by the first mapping, a reference genome FASTA file by the second, and a species-specific annotation file by the third. GeneQC uses two processes: a Perl script to extract features and an R programme to model the mathematical relationships between those features. GeneQC then categorises the reading alignment category for each Genome.

Yawen Xiao et al. presented a stacked sparse auto-encoder, utilising a semi-supervised deep learning methodology [19]. LUAD, STAD, and BRCA were just a few of the cancer types that this approach predicted. This model integrated supervised classification methods with semi-supervised feature extraction techniques to handle labelled and unlabelled data and extract more precise information for cancer prediction. The results demonstrated that the suggested method gave more accurate prediction results when compared to several cutting-edge machine learning classifiers, including SVM, RF, NN, and auto-encoders. In addition, several studies have considered using technologies, including wireless sensor networks, networks, software-defined networking, and the Internet of Things (IoT) [22].

To find biomarkers in high throughput sequencing, Brian Aevermann et al. suggested combining feature selection and the binary manifestation method of a random forest [23]. The authors' analysis supports this by using the NS-Forest version 2.0. Identifying active cell types and under investigation are two goals for which the most recent iteration of NS-Forest is effective. Their study sent a cell with a clustered gene expression assignment to the RF, from which significant features were gleaned using the Gini index. To overcome unfavourable indicators, genes were further prioritised. The top-ranked genes were then determined using a binary expression score. To adjudicate the least number of features, a criterion based on a decision tree and F-Beta score was employed to investigate various combinations of biomarkers. Finally, the human middle temporal gyrus (MTG) was used in tests to gauge the technique's efficiency [24].

Barbara Pes used the homogenous ensemble approach and applied the selection algorithm to several diversified datasets derived from the original set of records. The author worked on high-dimensional benchmarks from various domains, and this ensemble approach led to a significant gain without any degradation of the predictive performance [25].

Table I tabulates the existing literature on cancer classification with advantages and disadvantages, which pave the way to propose a novel ensemble machine learning technique in this study. Compared to the current cancer

classification approaches, the proposed method is different in the way that the RNA features are extricated using PCA and the type of cancer is classified using the proposed ensemble classifier that reduces the computation complexity as the model is constructed using the extricated features alone.

### III. PROPOSED APPROACH

Most traditional cancer classification systems use a single classification method, relying heavily on a specific classification algorithm for accuracy. The performance of a particular classifier may differ depending on the dataset. Therefore, to increase prediction accuracy, a framework must be developed for combining complementary information from different classifiers. The proposed approach is the hybridization of feature extraction and an ensemble of machine learning classifiers that classify cancer using RNA sequence data. Fig. 1 illustrates the block diagram of the proposed approach. This approach consists of the following modules: feature extraction, data splitting, model selection, and voting ensemble classification.

#### A. Feature Extraction

Feature extraction is an essential step in machine learning. It involves selecting and transforming the most relevant information from the input data to create a set of new, more informative features. This can help improve machine learning algorithms' performance by reducing the data's dimensionality and removing noise or irrelevant information. There are many techniques for feature extraction, including Principal Component Analysis (PCA), Linear Discriminant Analysis (LDA), and Independent Component Analysis (ICA). PCA identifies the directions of maximum variance in the data and projects the data onto a new coordinate system defined by these directions, called principal components. The first principal component is the direction of maximum variance in the data. Each subsequent principal component is orthogonal to the previous components and captures the maximum remaining variance. The data is first standardised by performing PCA to have zero mean and unit variance. Then, the covariance matrix is computed, and its eigenvectors and eigenvalues are calculated. The eigenvectors represent the directions of the principal components, and the eigenvalues represent the amount of variance explained by each component. The data can then be projected onto the principal components by multiplying the original data matrix by eigenvectors [34], [35].

Let the dataset be  $D$  consisting of  $x+1$  dimensions. Ignore the labels such that new dataset become  $x$  dimensional.

The mean for every dimension of the whole dataset is computed as follows:

$$D_{\mu} = \frac{x}{D_{size}} \quad (1)$$

The covariance matrix of the whole dataset is computed as follows:

$$Cov_{mat}(D_A, D_B) = \frac{1}{n} \sum_{i=1}^n (A - \bar{A})(B - \bar{B}) \quad (2)$$

TABLE I. REVIEW OF EXISTING CANCER CLASSIFICATION SYSTEMS

Ref.	Methodology	Used Dataset	Metrics	Advantages	Disadvantages
Goksuluk et al., 2019 [3]	Microarray-based classifiers	Synthetic dataset	Accuracy, sparsity, sensitivity, specificity	User-friendly and simple	Prior knowledge of packages is required
Khalifa et al., 2020 [4]	Optimised deep learning	Tumour gene expression dataset	Precision, recall, F1-score, accuracy	Less complex and requires less time to train	Performance is low
Wu et al., 2021 [5]	SVM, KNN, NB, and DT	Cancer Genome Atlas dataset	Accuracy, recall, specificity, precision, F1-score	Efficient	Complexity is high
Ramroach et al., 2020 [9]	RF and Gradient boosting machine	Cancer Genome Atlas dataset	Accuracy	High performance	Complexity is high
Arowolo et al., 2020 [26]	Ensemble classifier	RNA sequence dataset	Accuracy, sensitivity, specificity, precision, recall, F1-score	Less complex	Low accuracy
Yu et al., 2020 [27]	NB, RF, SVM	RNA sequence dataset	Sensitivity, specificity, accuracy, F1-score, AUC	Complexity is low	Interpretation is low
Garcia-Diaz et al., 2020 [28]	Grouping genetic algorithm	RNA sequence dataset	Standard deviation, accuracy	Computation speed is fast	Incomplete exploration of solution space
Mohammed et al., 2023 [29]	Reinforcement learning	Omics dataset	Accuracy	High processing speed	The optimisation is done partially
Arowolo et al., 2021 [30]	KNN and Decision tree	Western Kenya RNA sequence dataset	Accuracy, sensitivity, specificity, precision, recall, F-score	Less complex	Low accuracy
Arowolo et al., 2021 [31]	Genetic algorithm and Ensemble classification	Anopheles Gambiae dataset	Accuracy, sensitivity, specificity, precision, recall, F-score	High specificity	Works for only small datasets
Ramamurthy et al., 2020 [32]	Deep learning	Synthetic dataset	Recall Jaccard index, dice index, correlation coefficient, specificity, F1-score, computational time	High accuracy	More complex
Mohammed et al., 2021 [33]	Stacking ensemble	Cancer Genome Atlas dataset	Accuracy, F1-score, precision, sensitivity, AUC	High accuracy	Less inference

The eigenvectors and the corresponding eigenvalues are computed as follows:

$$\det(D-\lambda I)=0 \quad (3)$$

A  $d \times k$  dimensional matrix is created by selecting the  $k$  eigenvectors with the most significant eigenvalues after the eigenvectors are sorted in decreasing order. Next, the samples are transformed into the new subspace using the eigenvector matrix, yielding the principal components.

### B. Data Splitting

Training and test sets are created from the primary component data. The test set assesses how well each classification model performed, and the training set is used to create classification models. The total sample size determines the ratio for dividing the data into two portions. For example, 70% of the training set is typically used in research, and the remaining 30% is used as the test set. However, the split ratio can be lowered to 50% when there are fewer samples [36] [37]. Like the last example, this ratio might be raised to 80% or 90% if the total number of samples is high enough. The fundamental idea behind determining the ideal splitting ratio is to select a splitting ratio with a sufficient number of samples in both the training and test sets to generate a trustworthy fitted model and test predictions. The test accuracy is sensitive to unit

misclassifications even though the fitted model is ultimately reliable. In our proposed approach, data has been split on the ratio of 70:30.

### C. Model Selection

Selecting the right classifier for a particular machine-learning task is essential to the modelling process. There are a variety of classifiers to choose from, each with its strengths and weaknesses. The factors to consider when selecting a classifier include the type of problem, dataset size, data complexity, and interpretability and performance metrics. Some commonly used classifiers in machine learning are Logistic Regression, K-Nearest Neighbors, Support Vector Machines, Decision Trees, Random Forests, and Naive-Bayes. It is often a good idea to try multiple classifiers and compare their performance on the given task to determine the best option. The ensembles of multiple classifiers can often perform better than a single classifier. After building these machine learning models, only the top-performing models are considered for proposed ensemble model building.

### D. Ensemble of Classifiers

The ensemble of classifiers is built by combining the advantages of three classifiers such as SVM, NB, and KNN.

- Support Vector Machine

The SVM is mainly used for categorisation due to its excellent accuracy and capacity for managing enormous amounts of data. It is a supervised ML algorithm. The goal of the SVM method is to find a hyper-plane that divides the data set into distinct groups in a suitable way for training sets [38]. Linearly separable data can be divided into two groups by a straight line. A line can separate data that are linearly separable in two dimensions. The function of the line can be represented as follows:

$$y=ax+b \quad (4)$$

The above equation can be re-written as follows by replacing  $x$  with  $x_1$  and  $y$  with  $x_2$ :

$$ax_1-x_2+b=0 \quad (5)$$

If  $x$  and  $w$  are defined as  $x = (x_1, x_2)$  and  $w = (a, -1)$ , then (4) is defined as follows:

$$wx+b=0 \quad (6)$$

It is the equation of the hyperplane, which is derived from two-dimensional vectors. This hyperplane is used to make predictions. For example, cancer is defined as having a point above or on the hyperplane and not having a threshold below the hyperplane.

- Naive Bayes

Naive Bayes (NB) classifiers are scalable because the number of parameters required is linear in the learning process's number of variables (features/predictors). A closed-form expression, which takes linear time, can be evaluated to perform maximum-likelihood training [39]. The classifier is a function that is computed as follows:

$$NB_{cl}=\operatorname{argmax}_{k \in \{1, \dots, K\}} P(C_k \pi_{i=1}^n p(x_i|C_k)) \quad (7)$$

- K Nearest Neighbor

K-Nearest Neighbor (KNN) is a supervised algorithm based on the distance function. The distance function, which assesses the degree of similarity or difference between two

samples, is the basis of this classifier. The Minkowski distance metric is computed as follows:

$$MD(x,z)=\left(\sum_{r=1}^d \|x_r-z_r\|^p\right)^{\frac{1}{p}} \quad (8)$$

With KNN, the function is locally approximated, and all computation is delayed until the function is assessed. Normalising the training data can significantly improve accuracy if the features represent different physical units or sizes because this technique relies on distance for classification. In addition, applying weights to neighbour contributions can help classification and regression because it encourages neighbours closer to one another to contribute more to the average than neighbours farther away. When utilising KNN classification or KNN regression, the neighbours are selected from a group of objects for which the class or object property value is known [40].

#### IV. RESULTS AND DISCUSSION

The experiments were evaluated on an Intel(R) Core(TM) i7-6700 processor with 8 GB of RAM under Windows 10. The proposed approach was implemented in Python using the available machine learning packages. The UCI Machine Learning Repository hosts an RNA sequencing dataset containing gene expression data obtained from RNA sequencing of cancer cells and healthy cells. The gene expression levels are measured for over 20,000 genes, and more than 5,000 samples are in the dataset. The dataset used for experimentation is the RNA sequence dataset. This dataset is from the UCI Machine Learning Repository. The dataset contains information on the gene expression levels of five different cancer forms [41]. They are listed as follows:

- Lung ADenocarcinoma (LUAD)
- BRest invasive CArcinoma (BRCA)
- KIdney Renal Clear cell CArcinoma (KIRC)
- Lung Squamous Cell CArcinoma (LUSC)
- Uterine Corpus Endometrial CArcinoma (UCEC)

- 15: hardvotingclassifier.fit(Traindata, Trainlabel)
- 16: classification=hardvotingclassifier.predict(Testdata)
- 17: Return RNACancerclass

---

There are 20531 attributes over 801 occurrences. The most dangerous type of cancer for women is BRCA. The most common type of kidney carcinoma, known as KIRC, accounts for 70–80% of instances of the disease and has a high mortality rate globally. LUAD is a common type of cancer. Around 40% of all lung cancer diagnoses are due to it. It primarily attacks non-smokers. LUAD is typically discovered by accident and spreads more slowly than other forms of lung cancer. Smokers are likelier to get LUSC, the second most prevalent lung cancer. Airborne smoke particles often reside in the middle of the lung and transmit LUSC cancer. Undiagnosed in its early stages, UCEC is a recurrent prenatal malignancy. It affects more women than any other type of cancer. Due to the lack of information on its biomarkers for early detection and treatment, it has a high mortality rate. Fig. 2 depicts the distribution of cancer classes.

**E. Principal Component Analysis**

Fig. 3 depicts the scatter plot of principal components. The dimension of the RNA sequence data is high and in order to improve the performance of the classification task, the dimension of the dataset has been reduced and features are extricated using PCA. Experimentation has been done with varying number of principal components and using trial and error approach the number of principal components used in the proposed approach is five. The reason behind the achievement of significant results using five principal components is that the dataset consists of five cancer classes. It is observed from the scatter plot that there are similarities in LUAD, BRCA, and COAD cancer classes. The KIRC and PRAD are scattered separately as there are dissimilarities exist in these classes compared to LUAD, BRCA, and COAD.

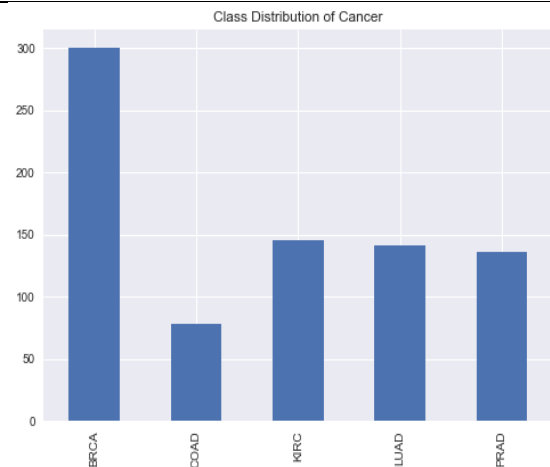

Fig. 2. Distribution of cancer classes.

Fig. 3. Scatter plot of principal components.

### F. Performance Evaluation

Performance evaluation in machine learning is assessing the accuracy and effectiveness of a trained model. It is essential to evaluate the performance of a machine learning model to determine its effectiveness in solving a specific problem [42]. The model's performance can be improved by tuning the hyper-parameters. Various metrics for evaluating a model's performance include Accuracy, Confusion Matrix, Precision, Recall, F1-Score, AUC (Area- Under-the-Curve)-ROC.

Fig. 4 depicts the confusion matrix for the classification of cancer RNA sequences. There are  $n$  columns and  $n$  rows in a confusion matrix, where each column represents a predicted classification, and each row represents the true classification [43]. To determine the model's accuracy, it is possible to examine the values along the diagonal - a good model will have a high diagonal value and low values off it. Furthermore, one can determine where the model is having difficulty by examining the highest values, not on the diagonal. These analyses help identify cases where the model's accuracy is high but consistently misclassifies the same data.

A classification report is a technique used to evaluate the performance of machine learning models in multiclass classification problems. It comprehensively summarises the model's performance on various evaluation metrics such as precision, recall, F1-score, and support. Fig. 5 depicts the classification report with the considered performance metrics. The precision, recall, f1-score, and support are computed for all the cancer classes. Furthermore, the macro average and weighted average are also computed to know the performance of the studied cancer ensemble classifier. The accuracy obtained is approximately 100% using the proposed ensemble approach for classifying the cancer RNA sequences.

Table II compares training and testing scores of the existing and proposed cancer classifications. It is seen that the proposed approach performed significantly well in training, but the performance is not significant in terms of testing compared to the proposed hybrid ensemble approach.

TABLE II. TRAINING AND TESTING SCORE ANALYSIS

Model	Training Score (%)	Testing Score (%)
LR	99.46	98.59
NB	98.75	99.17
RF	99.46	98.76
KNN	99.46	98.75
DT	98.75	97.51
<b>Proposed</b>	<b>99.64</b>	<b>99.59</b>

### G. ROC Analysis

The ROC (Receiver Operating Characteristic) curve is a graphical representation of the performance of the classifier, showing the trade-off between sensitivity (true positive rate)

and specificity (true negative rate) at different classification thresholds [44], [45]. To create a ROC curve, the classifier is applied to a dataset with known outcomes (i.e., a labelled dataset), and the true positive rate (TPR) and false positive rate (FPR) are calculated for different classification thresholds. The TPR is the proportion of true positive predictions among all positive cases in the dataset, and the FPR is the proportion of false positive predictions among all negative cases in the dataset. These rates are plotted on the y-axis and x-axis for different thresholds, resulting in a curve that starts at the origin (TPR=0, FPR=0) and ends at (TPR=1, FPR=1). The area under the ROC curve (AUC) is a standard metric summarising the classifier's overall performance. For example, an AUC of 0.5 indicates random performance, while an AUC of 1 indicates perfect performance. A higher AUC value indicates better classifier performance distinguishing between the positive and negative classes.

The One-vs-Rest (OvR) classifier and the One-vs-One (OvO) classifier are two common approaches for multiclass classification problems [46]. In the OvR approach, a separate binary classifier is trained for each class, which distinguishes that class from all the other classes. In contrast, the OvO approach trains a binary classifier for each pair of classes. Both approaches can be used to generate ROC curves for multiclass classification problems. In the case of OvR, the ROC curve is generated by computing the false positive rate (FPR) and true positive rate (TPR) for each class's binary classifier. The overall ROC curve is then obtained by combining the individual curves for each class. In the case of OvO, the ROC curve is generated by comparing the predicted class probabilities for each pair of classes and computing the FPR and TPR based on the number of correct and incorrect predictions for each pair.

Finally, the overall ROC curve is obtained by combining the FPR and TPR values for all the pairs of classes. When applied to gene selection methods, OvR and OvO can help to improve the results by reducing the number of false positives and false negatives in the classification process. By treating each class as a separate binary classification problem or training separate models for each pair of classes, OvR and OvO can help to better capture the subtle differences between the different classes, leading to more accurate classification results.

Fig. 6 depicts the ROC analysis for One-vs-Rest (OvR) classifier. The AUC is high for the proposed approach compared to the existing approaches such as LR, NB, RF, and KNN. The reason behind the high performance of the proposed approach is that the extracted features are used for classification. Furthermore, the advantages of the existing classifiers are combined to build the ensemble classifier.

Fig. 7 depicts the ROC analysis for One-vs-One (OvO) classifier. All the plots depict high AUC except COAD versus LUAD, as these cancer classes have high similarity by which classifier cannot differentiate these two classes efficiently.

### H. State-of-the-Art Analysis

The state-of-the-art analysis with respect to the reported results of existing cancer RNA classification systems is tabulated in Table III. The proposed approach is compared with optimized deep learning, ensemble classifier, SVM, grouping genetic algorithm, marker gene selection,

dimensionality reduction with neural network, and dimensionality reduction with SVM. It is evident that the proposed approach surpasses the existing cancer classification systems. The reason behind the significant performance is that the curse of dimensionality problem existing in gene sequence data has been overcome using the feature extraction process

and extracted features are utilized for the ensemble classification task. Furthermore, a hard voting classifier has been built using the combination of best-performing classifiers that are chosen based on the trial-and-error process. Thus, the superiority of the proposed approach has been proved.

TABLE III. STATE-OF-THE-ART ANALYSIS

Method	Year	Accuracy (%)
Optimised deep learning [4]	2020	96.9
Ensemble classifier [26]	2020	93.3

## V. CONCLUSION

The study successfully classified the RNA cancer types from a huge database using the proposed voting ensemble classifier approach. The RNA cancer sequence features were extracted using feature extraction process of PCA to reduce the dimension of the sequence data. The extracted features were used for ensemble classification model building and a hard voting ensemble classifier was effectively applied. In this work a dataset from the UCI Repository was used that includes 801 samples and 20,531 attributes representing five forms of cancer (Breast, Kidney, Colon, Lung, and Prostate). The proposed system used to find an ideal response for the classification of cancer RNA sequences. The accuracy percentage for ensemble categorization is 99.59%. The ROC analysis had been performed with respect to one versus one class and one versus rest of the classes. It is evident that the AUC for the proposed approach is high. Furthermore, the state-of-the-art analysis proved that the proposed ensemble approach outperforms the existing RNA cancer classification systems. In future, the work can be improved by employing a wider variety of exhaustive and thorough techniques, which might be used with other kinds of high-dimensional datasets.

## ACKNOWLEDGMENT

All data were collected and handled in accordance with ethical standards, including anonymization and secure storage, to ensure the protection of participants' privacy and confidentiality.

The dataset used and analyzed during the current study are available in the UCI Machine Learning Repository, <https://archive.ics.uci.edu/ml/datasets/gene+expression+cancer+RNA-Seq>. The data is available publicly and can be used by the machine learning community for the empirical analysis of machine learning algorithms.

Moreover, the first author receives the grant under FDP scheme of UGC India. The second Author has no conflict of Interest.

# Historical Building 3D Reconstruction for a Virtual Reality-based Documentation

Ahmad Zainul Fanani, Arry Maulana Syarif

Faculty of Computer Science, Universitas Dian Nuswantoro, Semarang, Indonesia

**Abstract**—An innovative preservation approach was proposed to document historical buildings in 3D model, and to present it virtually. The approach was applied to the Lawang Sewu building, one of the architectural masterpieces that is part of Indonesian history. Virtual Reality (VR) technology was used to create a Lawang Sewu VR application program that allows users to virtually walk around the building. A new method for 3D reconstruction was proposed, where data of photo, video and miniature documentation, as well as notes collected from observations were used as the main reference. Meanwhile, architectural record data was used in cases where information cannot be obtained through the main reference. The proposed method focuses on traditional techniques, both at the data acquisition and 3D modelling stages. Poly modelling techniques were chosen for 3D reconstruction. The poly modelling technique was chosen based on its ease and flexibility in controlling the number of polys in 3D models, and was suitable to be applied for repetitive spatial typologies, such as the Lawang Sewu building. After given textures, the 3D model was sent to the VR editor. In addition of running on the desktop platform, Head Mounted Device (HMD) that supports the creation of an immersive experience, was also chosen to run the Lawang Sewu VR. The evaluation carried out to measure the level of similarity of the 3D model to the original building and the sensation of an immersive experience felt by the user shows good achievements.

**Keywords**—Virtual reality; immersive presentation; 3D reconstruction; historical heritage building preservation

## I. INTRODUCTION

Lawang Sewu is a historic building that became one of the markers of the city of Semarang, Central Java, Indonesia. This building is the work of the famous Dutch architect, C. Citroen from the J.F. Firm. Klinkhamer and B.J. Quendag in 1903 and completed in 1907 for the headquarters of the Dutch colonial railway company, or Nederlandsch Indische Spoorweg Naatschappij. The Lawang Sewu building was designed to have a lot of windows and doors as an air circulation system, and this is where the term Lawang Sewu, which in Javanese means a thousand doors, came from. The Lawang Sewu complex which stands on an area of about 18,232 square meters consists of five buildings, which are buildings A, B, C, D, E, and lavatory. Fig. 1 shows the photo collection of the Lawang Sewu building.

An innovative approach was proposed to support the preservation of the Lawang Sewu building as an architectural masterpiece which is currently functioning as a tourist destination. The proposed approach allows users who have not had the opportunity to visit the Lawang Sewu building can see the architectural details of the building virtually. VR

technology based on 3D reconstruction was proposed to create a Virtual Lawang Sewu program application that can document architectural details of buildings in 3D format. Therefore, users can walk around the building virtually. VR is an immersive technology that allows users to interact subjectively with the virtual world so that they can feel the sensation of their physical present. VR is an environment that is displayed in the form of media that is able to create a sensation for users who seem to be physically in their surroundings [1], and 3D reconstruction techniques are developing rapidly to meet the needs of geometric 3D models for the film, game and virtual environment industries, such as works [2-5]. In this study, for the purpose of the documentation and virtual presentation, the Lawang Sewu building was reconstructed into a 3D model to be applied to VR applications that can be run in the desktop and HMD platforms. The main problem was to reconstruct the building into a 3D model as precisely as possible. In order to maintain the number of polys in the 3D model, traditional 3D modelling techniques was chosen to create the 3D model. The technique has consequences for the process of selecting data sources and analyzing them, which are also carried out manually, such as carrying out careful photography sessions to obtain information from the building profile, or measuring every detail of the building profile directly or other approaches. After that, carry out an analysis of the information obtained to calculate the shape and size of the building. The proposed traditional 3D modeling technique can be used to reconstruct buildings into 3D models with precision.

Fig. 1. The Lawang Sewu building.

The remainder of this paper is organized as follows: Section II discusses a review of some related work, Section III describes the proposed methodology which includes techniques in the data collection, techniques in the 3D reconstruction and 3D model texturing, VR programming, and evaluation. Section IV analyzes results. Section V covers the conclusion.

## II. RELATED WORK

There are various types of sensations of user presence in a virtual world (immersion), which are tactical to feel experience in carrying out tactical operations that require skill, strategic to feel mental challenges, narrative to feel being in a story, spatial to feel being in the real world, psychological to feel anxiety over the game with real life, and sensory to feel being in a unity of time and place based on the virtual environment [6]. VR consists of hardware components including computer sets, sensor embodiments (head mounted displays, binocular orientation monitors, and monitors), process acceleration cards, tracking systems, input devices, and software components including 3D modelling software, graphics, audio, and virtual reality simulation [7].

3D reconstruction is one of the challenges in developing VR applications. The challenge in 3D reconstruction is to formulate the right method in creating a 3D model that is as close as possible to the original object [8]. 3D reconstruction research was conducted for building objects [9-10], underwater environments [1, 5], small objects [11], and other objects. 3D reconstruction can be grouped by time (time-based reconstruction). For example, 3D reconstruction that aims to visualize objects based on their current construction such as works [2-3, 12-15], and 3D reconstructions that aim to visualize objects that have been damaged into their intact form such as works [16]. Research on 3D reconstruction for the Coliseum building in Rome, Italy, was carried out by [17], and the Great Wall in China by [18]. Both studies used tourism photo data from the [www.flickr.com](http://www.flickr.com) site. The Coliseum building model was generated from 2106 photos, while the Great Wall model was generated from 120 photos. Further, it was explained that the challenge of this research is matching and 3D reconstruction of information from hundreds or thousands of photos consisting of variations in perspective, illumination, weather, resolution, and others that have the potential for clutter and outliers. The real-time room environment reconstruction technique uses an octre-based surface representation for Kinect Fusion, where the space is represented as a signed distance function and stored as a uniform grid of voxels [18].

Technological developments have enabled VR application programs to be presented through stationary displays (desktop-VR or CAVE), head-based displays (HMD-VR or smartphone-VR), and Hand-based displays (Handheld VR) [9]. This supports the so-called Second Chance Tourism that utilizes digital technology, such as VR technology, which allows tourists to get the experience of visiting tourist sites without physically having to be on site [4]. On the other hand, the appearance of an attractive 3D model is one aspect of building the absorptive experience that the user gets, and the absorptive experience has an influence on the level of immersive felt by the user in a virtual environment [19]. Therefore, the use of VR

technology for the preservation of cultural heritage needs to consider the design of attractive 3D models. Meanwhile, multi-experiential which includes learning and educational experiences, including emotional experiences, has become part of the existence of cultural heritage preservation [20]. Therefore, VR application programs also need to be designed to be able to provide various experiences for users while in a virtual environment.

## III. METHODOLOGY

Workflow used in this study was designed based on eight challenges in developing the model of tangible 3D-based cultural heritage preservation identified by [8], which are time-based 3D reconstruction, typology, 3D reconstruction method, application category, research objective, data management, presentation method and research evaluation. Based on the time, there are two types of time in the 3D based preservation of historical objects, which are 3D reconstruction based on the current environment that uses data from the current condition of historical objects, and based on the past environment that uses data from historical objects that have been damaged, even extinct [8]. The proposed 3D reconstruction for the Lawang Sewu building referred to the current physical condition of the building, where the current physical data of the building was analyzed for use in its 3D modelling. Typological analysis was carried out to design data collection techniques based on the detailed characteristics of the building. Data was collected through: 1) direct observation by documenting the architectural details of the Lawang Sewu building in records, photos and videos; 2) the building miniature observation; 3) the building blueprint analysis. After determining the time-based 3D reconstruction method and performing typological analysis, the data management stage was carried out to design the data flow for the process before, after and during the 3D reconstruction. Based on the chosen time-based 3D Reconstruction, typology analysis, and data management design, traditional 3D modelling techniques was chosen to create the Lawang Sewu 3D model. The technique was chosen based on its ease and flexibility in controlling the number of polys in 3D modelling to reconstruct buildings with repetitive spatial typologies, such as the Lawang Sewu building.

In addition to measuring the physical building, a new method proposed to measure the area of the building in 3D reconstruction is to use the size of one of small elements of the building, and then count the number of the chosen element in a room. For example, given a tile chosen for the element to measure area of a room with a size of 30 x 30 cm; the length and width of the room uses 10 tiles; and the area of the room is 900 x 900 cm. The tile order index is also used to identify the position of other elements, such as doors, windows, poles. For example, given the door in a room, the door is in the order of tiles 4 to 7, so the door size is around 120 cm. The proposed method uses calculations based on the size of the element of the building that is the reference for measurement and its number. Moreover, the proposed method can facilitate texturing work, where the texturing process for building elements, such as tiles, can be appropriate based on the number of elements. On the other hand, there are building elements that still require size data based on architectural records, such as building height, or building elements that require physical

measurements for comparison data or because their position is disconnected from the elements used as measurement references, such as poles in the building yard.

Accurate building size is not the target, because this 3D reconstruction project aims to document historical buildings for virtual presentation purposes. Therefore, visual similarity is the target, and not the accuracy of the building's size. Later, evaluation results show that this method is effective for 3D reconstruction which can create 3D objects with a size scale that is close to real objects. The workflow of the Lawang Sewu VR development consists of five stages, which are data collection, 3D reconstruction, 3D texturing, VR programming, and evaluation.

### A. Data Collection

In addition to direct observation to the location of the Lawang Sewu building, the data sources used include a collection of photos, videos, miniatures and blueprints of the building. First of all, direct observation to the location was conducted in order to get a general picture of the environment, such as the layout, shape and structure of the building. Furthermore, an analysis of the building blueprint was carried out to sharpen the understanding of the building information from an architectural perspective. The building blueprint is displayed in one of the rooms used as a museum in the Lawang Sewu building. The building miniature which is also displayed in the museum was a medium to better understand the layout, shape, and structure of the building in a 3D perspective. Furthermore, photo and video sessions were conducted on every detail of the building, including physical measurements of the building. Physical measurements of buildings were not carried out on all building constructions, but on certain parts, such as doors, windows, stairs, tiles, and several other parts. Fig. 2 shows some blueprints of the Lawang Sewu building, while Fig. 3 shows the illustration of the miniature buildings.

All data sources were treated like puzzles in working on 3D reconstruction, where data serve to complement each other. The data acquisition method in 3D reconstruction proposed in this study adopts a puzzle game.

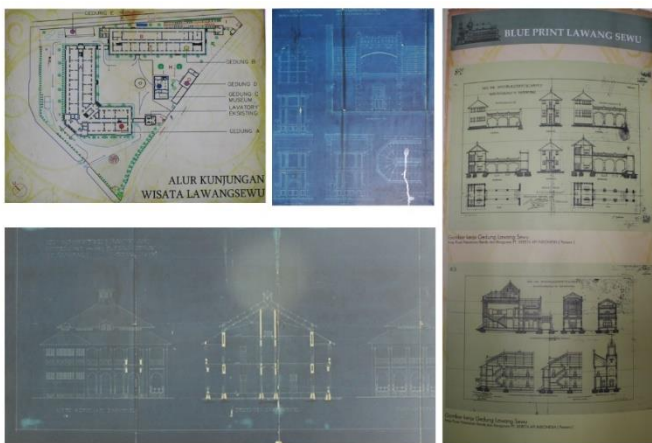

Fig. 2. Example of the blueprint of the Lawang Sewu building

Fig. 3. Example of the blueprint of the Lawang Sewu building

### B. 3D Reconstruction

The Lawang Sewu building consists of buildings A, B, C, D, and E, including the basement which is located under building B. In this study, 3D reconstruction was targeted at the two main buildings, which are building A and B, including the Lavatory connected by a bridge to building A. The 3D reconstruction phase started from building B, continued with building A and Lavatory including the connecting bridge between them. Fig. 4 shows the layout of the Lawang Sewu building based on its blue print.

Fig. 4. The blueprint of the buildings.

Building B has a size of 22x77 m<sup>2</sup> or an area of 4,145.21 m<sup>2</sup> with two main floors and one roof space. 3D reconstruction begun by identifying the size of the one room at the very end. The design of building B has a repeating pattern of rooms with almost all rooms being the same size. There are different sized rooms that are twice the size of the other rooms. The 3D reconstruction process in building B which consists of three floors was started from the first floor by identifying the size of

the tiles and counting their number like cells in a matrix, where the number of cells in a row represents the width of the room, and the number of cells in a column represents the length of the room. Furthermore, as long as it is still accessible by hand, physical measurements of building elements were also carried out, such as the thickness of walls, the size of doors, windows, poles and stairs. In order to reduce the amount of poly, the ceiling of the room was not 3D reconstructed, but created using image textures from the original photo. Meanwhile, the height of the room was identified using architectural records data. After one room at the very end has been reconstructed in 3D, the process continues with the next room, and so on until the room at the other end. The method was also applied to obtain size, shape and layout data of other objects in the building. Fig. 5 shows illustration of using the size and number of tiles to identify the area of the room and the position of elements in it, while Fig. 6 shows example of an object that require physical measurement.

Fig. 5. Illustration of using the size and number of tiles to determine the area of the room and the position of the profiles in it.

Fig. 6. Example of an object that require physical measurement.

After obtaining the data and information of building B, the process continued with the creation of a 3D model of the building using the 3Ds Max application program. Stages in the process of making 3D models were carried out as in the stage of data acquisition for buildings. Starting from the very end of the room, then it was duplicated to complete the design of the

first floor of building B, and continued with corridors and terraces. Other editing, such as merging two rooms into one room, and making stairs objects were carried out with the support of photo documentation data. After the first floor was completed, the 3D reconstruction was continued to the second and third floors using the same methods and techniques. Meanwhile the 3D reconstruction for the roof of the building was carried out using data obtained based on observations and analysis on the miniature building. Next was applying a cleaning process to remove unnecessary vertices and polygons.

Fig. 7. The comparison illustration between the original photo of building B and the 3D model of building B.

The cleaning process was performed to maintain the number of vertices and polys in the 3D model for its size does not swell and the application program can be lighter when being played. The cleaning process produced a 3D model of building B with a total of 75,209 polygons and a total of 107,619 vertices. Fig. 7 shows a comparison illustration between the original photo of building B and the 3D model of building B. Further, the 3D model of building B was used as a reference in the 3D reconstruction of building A.

Building B has a size of 22x77 m<sup>2</sup> or an area of 4,145.21 m<sup>2</sup> with two main floors and one roof space. Building A is a three-story main building that has a shape like the letter L with an area of 5,473.28 m<sup>2</sup>, and the floor of the office and lobby is tiled with a size of 16x16 m<sup>2</sup>. Meanwhile, the 2-story Lavatory has an area of 242.60 m<sup>2</sup>. The same methods and techniques were applied in the 3D reconstruction of building A. The 3D reconstruction of the bridge connecting building A and Lavatory was carried out by continuing, or embedding, in the 3D model of building A. The wall of building B which is at the end of the building that connects to building A was used as the starting point.

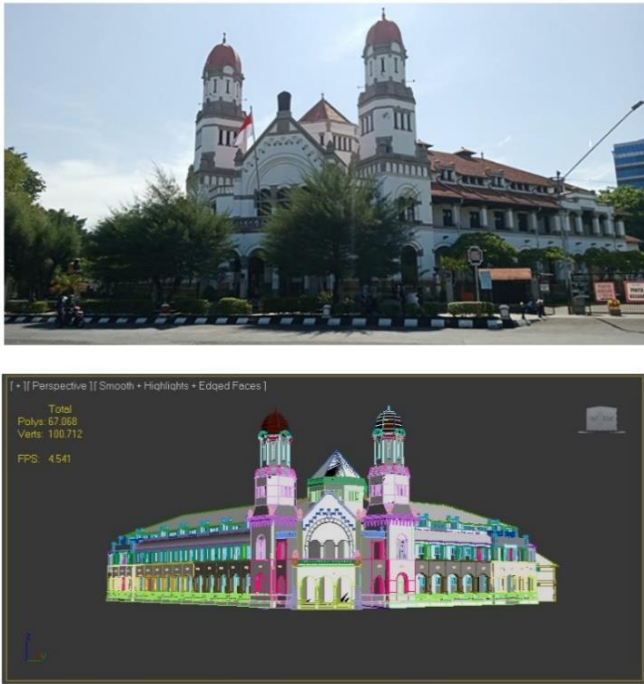

Fig. 8. Comparison illustration between the original photo of building A and the 3D model of building A.

The cleaning process produced a 3D model of building A and the lavatory with a total of 67.068 polys and a total of 100.712 vertices. Fig. 8 shows a comparison illustration between the original photo of building B and the 3D model of building B. The 3D model of the Lawang Sewu building consisting of buildings A, B, and Lavatory produced has a poly count of 142,227 and a vertex of 208,331. Fig. 9 shows an illustration of the results of making the model.

Fig. 9. A Results of the 3D model of the Lawang Sewu building consisting of buildings A, B, and Lavatory.

### C. Texturing

The 3D texturing process was carried out using the Unwrap UVW modifier tool in 3Ds Max. The tool is for applying and controlling more than one texture on various parts of the object. First of all, the details of the surface of the real object were photographed. Furthermore, the 3D object is applied with the unwrap technique to produce a pattern of parts of the object in the form of an outline. The pattern image is saved in PNG format and sent to the Adobe Photoshop application program to be textured using a warp technique based on the photo details

of the real object. Fig. 10 shows an illustration of an unwrap image resulted from the 3Ds Max application program which was then applied to the warp technique in the Adobe Photoshop application program using photo details of the real object.

The 3D texturing process was also carried out using the image texture mapping technique. This technique can keep the number of polygons from swelling in making 3D models more realistic and attractive, in which 3D objects are applied with color patterns [21]. Some objects, such as doors and windows, were manipulated using the image texture bump mapping technique. 3D models for doors and windows were formed using boxes, a primitive shape type, consisting of six polygons and eight vertices. Details of the original object profile were photographed, then edited using an image editor application program, Adobe Photoshop. Image of the object profile, then used to give texture to the object. Fig. 11 shows an illustration of the application of the image texture mapping technique to create a 3D door model. Details of the door profile, including the surface look realistic although it is built from a 3D box object consisting of a small number of polygons and vertices with a flat surface.

Fig. 10. Illustration of an unwrap image resulted from the 3Ds Max application program which was then applied to the warp technique in the Adobe Photoshop application program (a) using photo details of the real object (b).

Fig. 11. Illustrations of (a) that is the door profile image used in the image texture mapping implementation for a 3D box object (b).

#### D. VR Programming

The Lawang Sewu VR computer program was developed to run on the desktop and the HMD platforms with a consideration that desktop applications are still popular and widely used by users, while HMD-VR applications, although currently gaining popularity, not many users have the devices. A teleportation feature that allows users to change locations from building A to building B, or vice versa, including building floor selection is added to the Lawang Sewu VR. This feature makes it easy for users to get around the building virtually. The challenge in implementing 3D assets into the virtual environment presented through HMD is determining the proportion of users and 3D objects. The traditional technique was used by comparing the proportions of humans and objects in the real environment with the proportions of avatars and objects in the virtual environment through certain poses.

Fig. 12. Illustration of setting a 3D model scale to make it proportional to the original object.

In this case, a person was asked to pose with his arms stretched out in a door of the Lawang Sewu building in the real environment, and the pose was documented through photographs. After that, the person was asked to play Lawang Sewu VR using Oculus Quest 2, and pose in the same location as in the real world. Comparison of photos in the real environment and visualization of user games through casting were the benchmarks in scaling the 3D model so that it is proportional. Fig. 12 shows an illustration of setting a 3D model scale to make it proportional to the original object. Fig. 13 shows user's activities in playing the program using Oculus Quest 2.0, while Fig. 14 shows screenshots of the Lawang Sewu VR played in the desktop platform.

Fig. 13. Illustration of user's activities in playing the Lawang Sewu VR using Oculus Quest 2 HMD.

Fig. 14. Screenshots of the Lawang Sewu VR for desktop.

#### E. Evaluation

User acceptance test was carried out to measure the achievement of the goal of developing the Lawang Sewu VR computer program, which are documenting historical buildings and presenting them virtually using VR technology. The performance of the Lawang Sewu run in desktop-VR and HMD-VR platforms was measured by evaluating the level of visual similarity and the level of area proportionality between the 3D model of buildings and the original objects. An additional evaluation was carried out on the Lawang Sewu HMD-VR which was the level of immersion evaluation in order to measure the sensation of the user presence in the virtual environment of the Lawang Sewu building.

Respondents who work as tour guides were selected based on their profession in taking tourists every day to tour the Lawang Sewu building. They were assumed to have knowledge of the physics of the Lawang Sewu building. The other 15 respondents were those who had visited the Lawang Sewu building in the past month. Out of 30 respondents, 12 of them were women, and the rest were men. The youngest respondent was 11 years old and the oldest was 51 years old. Respondents were asked to rate the performance of the Lawang Sewu VR by providing opinions.

Results of the user acceptance test for each the Lawang Sewu run in desktop-VR and HMD-VR platforms were measured using the Mean Opinion Score (MOS) technique with the following formula, where R is the individual rating for the stimulus given by subject N:

$$MOS = \frac{\sum_{n=1}^N R_n}{N} \quad (1)$$

Results of the calculation of the MOS value were converted to a range of values 0 - 1 representing bad performance, 1.1 - 2.4 representing poor performance, 2.5-3.4 representing good

performance, and 3.5-4 representing excellent performance. The following are statements (S) judged for gaining opinions of users:

- S1: The 3D model of the Lawang Sewu building has a high level of visual similarity to the original building.
- S2: The 3D model of the Lawang Sewu building has a high degree of similarity in size proportion to the original building.
- S3: The sensation of being in the virtual environment of the Lawang Sewu building really feels like being in the original environment.
