The user acceptance test was carried out in two sessions, where the first and second sessions were to provide opinions on the Lawang Sewu desktop-VR, and the Lawang Sewu HMD-VR, respectively. In the first session, each respondent was guided in playing the Lawang Sewu desktop-VR. After getting used to playing the application, each respondent was asked to play it by walking along the usual route for an

unlimited duration. After the respondent completes the usual route taken virtually, respondents were asked to provide an opinion on the S1 and S2 statements in the range of values of 1-4 which represent Strongly Disagree, Disagree, Agree and Strongly Agree, on each statement based on their experience when playing the application. Meanwhile, the second session took place the next day. The evaluation mechanism was the same as in the first session, but in this session the respondents used the HMD device. In this session, respondents were asked to provide an opinion on the S1, S2, and S3 statements.

Evaluation in the first session that measured the Lawang Sewu desktop-VR performance resulted that out of 30 respondents, MOS scores for the statement S1 and S2 were 3.5, and 3.3. Meanwhile, evaluation in the second session that measured the Lawang Sewu HMD-VR performance resulted that out of 30 respondents, MOS scores for the statement S1, S2, and S3 were 3.5, 3.2, and 3.6, respectively. Table I and Table II show MOS results of the performance of the Lawang Sewu run in desktop-VR and HMD-VR, respectively.

TABLE I. MOS RESULTS OF THE LAWANG SEWU DESKTOP-VR

Statements	Opinion Score				MOS Score	
	1	2	3	4		
Visual Similarity (S1)	0	0	14	16	3.5	Good
Size Proportionality (S2)	0	0	22	8	3.3	Good

TABLE II. MOS RESULTS OF THE LAWANG SEWU HMD-VR

Statements	Opinion Score				MOS Score	
	1	2	3	4		
Visual Similarity (S1)	0	1	14	15	3.5	Excellent
Size Proportionality (S2)	2	3	13	12	3.2	Good
Immersion Level (S3)	0	1	11	18	3.6	Excellent

#### IV. RESULTS AND DISCUSSION

An application program based on VR technology was developed to document historical buildings and present them virtually. The application program called The Lawang Sewu VR documents the historic Lawang Sewu building located in Indonesia by reconstructing the building into a 3D model and providing a texture similar to the current condition of the building. Furthermore, the Lawang Sewu 3D Model was sent to the game engine editor to be developed into a VR-based application program that allows users to go around the Lawang Sewu building environment virtually. Desktop and HMD platforms were the targets for running The Lawang Sewu VR, considering that many users already have devices to play desktop-based applications, while HMD-based applications provide a strong immersive sensation.

Based on the typology of buildings that have repetitive patterns, data acquisition and 3D reconstruction were more focused on the use of traditional methods and poly modeling techniques. Photo and video data including architectural records obtained through direct observation were used as references for 3D reconstruction. Some of the data that cannot be obtained through observation were collected through the blue print of the building. The solution in the use of the poly modelling technique was proven to be able to control the number of polys and vertices in the details of the curve of the

building in the 3D model of the Lawang Sewu building which includes buildings A, B and Lavatory. The development of the Lawang Sewu VR application program lasted three months which was divided into one month for data acquisition, one and a half months for 3D reconstruction, and half a month for VR programming. The 3D reconstruction phase involves the most human resources. Ten students from Universitas Dian Nuswantoro, were involved in this stage.

The achievement of the goal of documenting the Lawang Sewu building and presenting it virtually was measured based on the visual similarity and size proportionality of the 3D model to the real building. The traditional 3D modelling technique was conducted based on information obtained from carrying out careful photography sessions, measuring every detail of the building profile directly and the building blueprint analysis. The proposed 3D reconstruction technique is appropriate for building objects with profile and visual characteristics that have symmetry patterns that can be easily identified and measured, such as having tiles of the same size, the same distance between building pillars, or others. The proposed 3D modeling technique is proven to be able to appropriately reconstruct buildings with repetitive spatial typologies, such as the Lawang Sewu building. The user acceptance test measured using the MOS technique on the Lawang Sewu desktop-VR shows that both visual similarity and size proportionality reach a good level. Meanwhile, the

visual similarity in the Lawang Sewu HMD-VR reached an excellent level, and size proportionality reached a good level. This achievement shows that the documentation of the Lawang Sewu building into a 3D model format with visuals and sizes that are close to real objects can be carried out well, and VR technology that supports users around the location virtually can perform well. Especially in the Lawang Sewu HMD-VR, the measurement of the immersive level, the sensation of the user's presence in the virtual world, can achieve an excellent MOS score. Although it still requires further testing, it can be assumed that in 3D reconstruction of historic buildings as assets in HMD-based VR application programs, the relationship between visual similarity and size proportionality has a significant role on the level of immersive perceived by the user. Through some light discussions after trying the Lawang Sewu HMD-VR, some users tried to compare the visuals and sizes of several building elements in a 3D model with real objects, such as doors, windows, stairs and others.

## V. CONCLUSION AND FUTURE WORK

The 3D reconstruction method and the use of VR technology proposed in this study are proven to be able to document historic buildings in 3D model format and present them virtually and interactively. However, the 3D reconstruction technique used in this research is appropriate for building objects with profile and visual characteristics that have repetitive spatial typologies, such as the Lawang Sewu building.

At this time, the functionality of the Lawang Sewu VR is still limited to documentation and virtual presentation of the physical building based on its current condition. The story telling functionality that is able to visualize the physical and historical conditions in the past is the target for further development, including the addition of a multi-user feature that allows more than one user to interact in a virtual Lawang Sewu environment.

## ACKNOWLEDGMENT

Thank to Ministry of Research, Technology, and Higher Education of The Republic Indonesia for financial support through the second year of Applied Research Grant 2022 (Hibah Penelitian Terapan 2022).

# Identifying and Prioritizing Digital Transformation Elements Using Fuzzy Analytic Hierarchy Process

Mohammed Hitham M.H, Hatem Elkadi, Neamat El Tazi

Faculty of Computers & Artificial Intelligence, Cairo University, Cairo, Egypt

**Abstract**—Digital transformation addresses multiple aspects of the organization. These aspects are the elements to be addressed for the digital transformation in any organization and are categorized as dimensions and sub-dimensions. In this work, these elements are collected from a wide range of related literature (56 publications). The most relevant elements were then identified through expert survey; involving 12 experts. The weights for these elements were identified using multi-criteria decision-making (MCDM) techniques. The Analytical Hierarchy Process (AHP) is one of the most often used MCDM techniques to incorporate individual and subjective preferences when conducting analysis and convert complex issues into a clear hierarchical structure. This work applies fuzzy AHP to take into consideration the treatment of uncertainty issues (in AHP), using the geometric mean method, and through an iterative process, calculate the weights of various dimensions and sub-dimensions, and prioritize them within the proposed roadmap for digital transformation implementation. Sensitivity analysis and comparison with AHP were used to validate our findings and the robustness of our approach. The proposed approach identified 9 main dimensions and 42 sub-dimensions which align with the majority of the literature. However, the advantage of this approach is the prioritization of these nine dimensions and their sub-dimensions as per the weights assigned to each one of them, allowing the project manager to allocate the available resources to the dimensions with the highest priority. The results show that the strategy and business process dimensions are the most crucial ones in the implementation of digital transformation.

## I. INTRODUCTION

Digital Transformation (DT) has become an essential part of human life, and it is necessary for almost every private and public sector seeking growth, expansion, quality, and sustainability [1]. It can also change our life, work, increase productivity, save money, and reduce effort. In order to benefit from these advantages, several countries have started launching digital transformation projects such as [2-3]. Moreover, private sectors have also embraced DT, with organizations implementing their own DT programs [4]. However, it is important to note that every organization operates in a unique context and may be at a different stage of implementing DT. Therefore, it is essential for both public and private sectors to have an approach that allows them to assess their current position in DT implementation, identify strengths and weaknesses, and develop strategies to overcome any challenges [5]. By understanding their current state and addressing weaknesses, organizations can enhance their DT efforts and achieve greater success in embracing the advantages of DT.

This approach is called digital maturity model, readiness tests, or frameworks. It has two objectives: 1) the first objective is used to define the current position in the context of DT, and 2) the second objective is to propose a roadmap for implementation of DT. Organizations need a roadmap to clearly understand the DT concepts involved and effectively implement DT. The formulation of the roadmap poses a major challenge given the large variety of frequently occurring dimensions and sub-dimensions (criteria) that necessitate the use of a decision support technique called Multiple Criteria Decision Making (MCDM) [6]. To handle the large variation between the decision makers' opinions, Saaty [7] proposed AHP in order to streamline complex multi-decision-making processes and make them more systematic. AHP resolves complicated scenarios, including multiple criteria in the decision-making process by converting to a hierarchical structure [7-8]. Following the creation of the hierarchical structure, any two criteria are compared using pairwise comparison. There are three primary steps that make up the AHP: 1) define the goal and hierarchical structure of the study, 2) construct pairwise comparisons between criteria at each level of structure, and 3) calculate weight and ranking. AHP is the most widely used among MCDM techniques in domains, such as software [7] and industry [8]. Downsides with uncertainty associated with the decision-makers judgment can be solved by combining AHP and fuzzy set theory [10], [11-14].

To the best of our knowledge, the majority of studies look at how to evaluate digital transformation by defining the dimensions and sub-dimensions of digital transformation in the private or public sector and setting priorities for their implementation, but no study has taken more attention to a comprehensive approach that takes into account both. The study aims to address the gap in research by taking a comprehensive approach to evaluating DT in both the private and public sectors. It encompasses two key aspects: Firstly, the comprehensive synthesis of diverse elements, including dimensions and sub-dimensions, to DT within both the private and public domains. Secondly, the introduction of a hybrid approach—the combining of the Fuzzy Analytic Hierarchy Process (FAHP) with the Analytic Hierarchy Process (AHP)—designed to effectively prioritize the implementation of digital transformation components. The output of this prioritization will serve as the basis for a future roadmap proposal. Conducting such a study could help identify commonalities and differences between sectors, enabling a more effective allocation of resources and prioritization of implementation strategies. The rest of the paper is organized as follows: Section II presents a literature review of the relevant literature

on the topic. Section III discusses the research methodology employed in the study is discussed in detail; Section IV discusses the results of our approach. Section V validates the results of the hybrid approach by using sensitivity analysis and comparison with AHP, and in the finally section, the conclusion and future work are presented.

## II. LITERATURE REVIEWS

Selecting the appropriate maturity components, such as dimensions and sub-dimensions, and computing the weights requires an analytical and scientific approach, as follows in our work:

### A. Approaches to Weight Dimensions and Sub-Dimensions in DT

According to our literature review, there are two most common methods for defining weights for dimensions and sub-dimensions:

- The first method involves calculating the arithmetic mean.

In this procedure, specialists assign a separate value to each dimension and sub-dimension [15-18]. These values are then used to calculate mean values, which are considered as weights for each dimension and sub-dimension.

- The second method relies on MCDM

The second approach employs Multi-Criteria Decision Making (MCDM) techniques. In this method, experts assign comparative values to each dimension relative to the other dimensions. Likewise, they assign values to each sub-dimension relative to other sub-dimensions within the same dimension. Several studies have proposed various methodologies for prioritizing DT in different domains. For instance, [8] introduced an AHP-based approach for Industry 4.0, [13] employed Fermatean AHP for Supply Chain prioritization, [19] presented a method for technology selection in DT, [20] combined SF-AHP and SF-TODIM approaches in the defense industry, [21] devised a DEMATEL-based method for assessing DT in the health sector, [22] utilized ANP for evaluating DT in manufacturing, [23] introduced a fuzzy TOPSIS-based approach for supplier evaluation in DT within production systems and [24] employed Shannon entropy to calculate Business digital maturity in Europe. Analysis of previous research reveals that many studies focused on the private sector, and there is not the same level of interest in the public sector.

### B. Determining the DT Dimensions and Sub-dimensions

The literature review encompassed a thorough examination of assessment frameworks related to DT. This involved extracting DT maturity dimensions and their corresponding sub-dimensions from various studies [25-73]. The selection of these studies was based on their relevance to DT assessment requirements. The outcome of the literature review revealed a total of nine main dimensions and 168 corresponding sub-dimensions related to DT maturity. However, in order to streamline the assessment framework, only the most frequently occurring sub-dimensions, with a frequency of two or more,

were chosen. As a result, the sub-dimensions were reduced to a more manageable number of 70.

The results of the literature review to define dimensions and sub-dimensions can be summarized in Table I.

## III. RESEARCH METHODOLOGY

Based on a thorough study of the literature [25-73], including comparisons of digital maturity assessment in the field of DT and expert reviews. This research employs an iterative and tested approach to construct an assessment framework in DT [14-15] and [8]. Overall, research methodology has a two-phase process, namely:

- Defining dimensions and sub-dimensions in DT
- Derivation of weights via a hybrid approach (FAHP with AHP)

The output of phase one is used as an input to phase two. Each phase will be discussed as follows:

### A. Defining Dimensions and Sub-dimensions in DT

In Section II (B), drawing on the literature review, a first draft of the dimensions and sub-dimensions is defined. As described earlier, we need a way to identify the most relevant sub-dimensions for evaluating digital transformation. To achieve this, a review of the first draft with DT specialists (12) was conducted to capture the final relevant dimensions that were identified for further weight derivation. The summary of the methods used in this phase is shown in Fig. 1.

Fig. 1. Flow diagram of the first phase.

### B. Deriving Weights Using Hybrid Approach

As mentioned before, the aim of this research is to use the MCDM approach to prioritize the implementation of DT dimensions and sub-dimensions. This is done by proposing a hybrid approach that combines fuzzy group theory with the AHP method. Fig. 2 shows the proposed methodology. An overview of our approach will be given as follows:

- Step 1: Defining Problem and Planning: Define the objective of the study, define DT elements, and decompose the problem into a hierarchical structure.
- Step 2: Construct pair-wise comparisons at each level of the hierarchy structure by using fuzzy numbers.

The fuzzy scale used in the research [13] was employed to facilitate pairwise comparisons between DT elements, such as dimensions or sub-dimensions).

A is a  $n \times n$  pairwise matrix in which the relative importance of pairwise comparisons is determined on a scale of 1 to 9.

$$\tilde{A}^k = \begin{bmatrix} \tilde{d}_{11}^k & \tilde{d}_{12}^k & \dots & \tilde{d}_{1n}^k \\ \tilde{d}_{21}^k & \dots & \dots & \tilde{d}_{2n}^k \\ \dots & \dots & \dots & \dots \\ \tilde{d}_{n1}^k & \tilde{d}_{n2}^k & \dots & \tilde{d}_{nn}^k \end{bmatrix} \quad (1)$$

Where  $\tilde{d}_{ij}^k$  indicates the Jth decision maker's preference of ith criterion over the jth criterion, via fuzzy a triangular numbers. It is fuzzy number (l, m, u) [13], for reciprocal:

$$d_{ij} \tilde{k}^{-1} = (l, u, m)^{-1} = \left( \frac{1}{u}, \frac{1}{m}, \frac{1}{l} \right) \quad (2)$$

Twelve decision makers "experts" consist of DT consultants and academics, which are considered experts in their respective fields abbreviated as E1, E2, E12. By collecting the opinions of these decision-makers and constructing the pairwise comparison matrix using Eq. (1), it becomes possible to determine the relative of each dimension and sub-dimension Pairwise comparisons of the fuzzy judgment matrix "i" are frequently inconsistent because they are prone to bias and inaccuracy in preference for expert responses. Therefore, AHP is used to avoid inconsistencies in responses. The consistency index for pairwise comparisons was calculated by using Eq. (3).

$$\lambda_{max} = \frac{1}{n} \sum_{j=1}^n \frac{A_{wi}}{w_i} \quad (3)$$

$$CI = \frac{\lambda_{max} - n}{n - 1} \quad (4)$$

Where n is the number of dimensions or sub- dimensions

Eq. (5) is used to calculate the consistency ratio, where CI is compared with a random index.

$$CR = \frac{CI}{RI} \quad (5)$$

- Step 3: Check consistencies (for the most likely value)

This random index (RI) value [12] is correlated to the number of dimensions or sub-dimensions compared and used to calculate the consistency ratio, as shown in Eq. (5). The level of consistency is acceptable if the CR is less than 0.1. If not, there will likely be a lot of inconsistency, so the opinion of the decision-maker will be deleted. In this study, the CI is calculated for the middle value (most likely value "m") [11], even though the pairwise comparison indices (relative importance) of the judgment matrix are TFNs for each decision-maker separately. In this work, we calculate the consistency ratio for each expert separately. If the consistency index exceeds 0.1, the opinion of this expert will be deleted.

- Step 4: Aggregate expert opinions

If there are many decision makers accepted  $\tilde{d}_{ij}$ , the average"  $\tilde{d}_{ij}$  "is calculated using Eq. (6) [13].

$$\tilde{d}_{ij} = \frac{\sum_{k=1}^k \tilde{d}_{ij}^k}{k} \quad (6)$$

According to averaged preferences, pair wise contribution matrices are updated as shown in Eq. (7).

$$\tilde{A} = \begin{bmatrix} \tilde{d}_{11}^k & \dots & \tilde{d}_{1n}^k \\ \vdots & \ddots & \vdots \\ \tilde{d}_{n1}^k & \dots & \tilde{d}_{nn}^k \end{bmatrix} \quad (7)$$

- Step 5: Calculate CR to Aggregate Expert Opinions

Pair-wise comparisons were constructed for the opinions of decision-makers based on Eq. (6), and then a new CR was calculated for this matrix using Eq. (5).

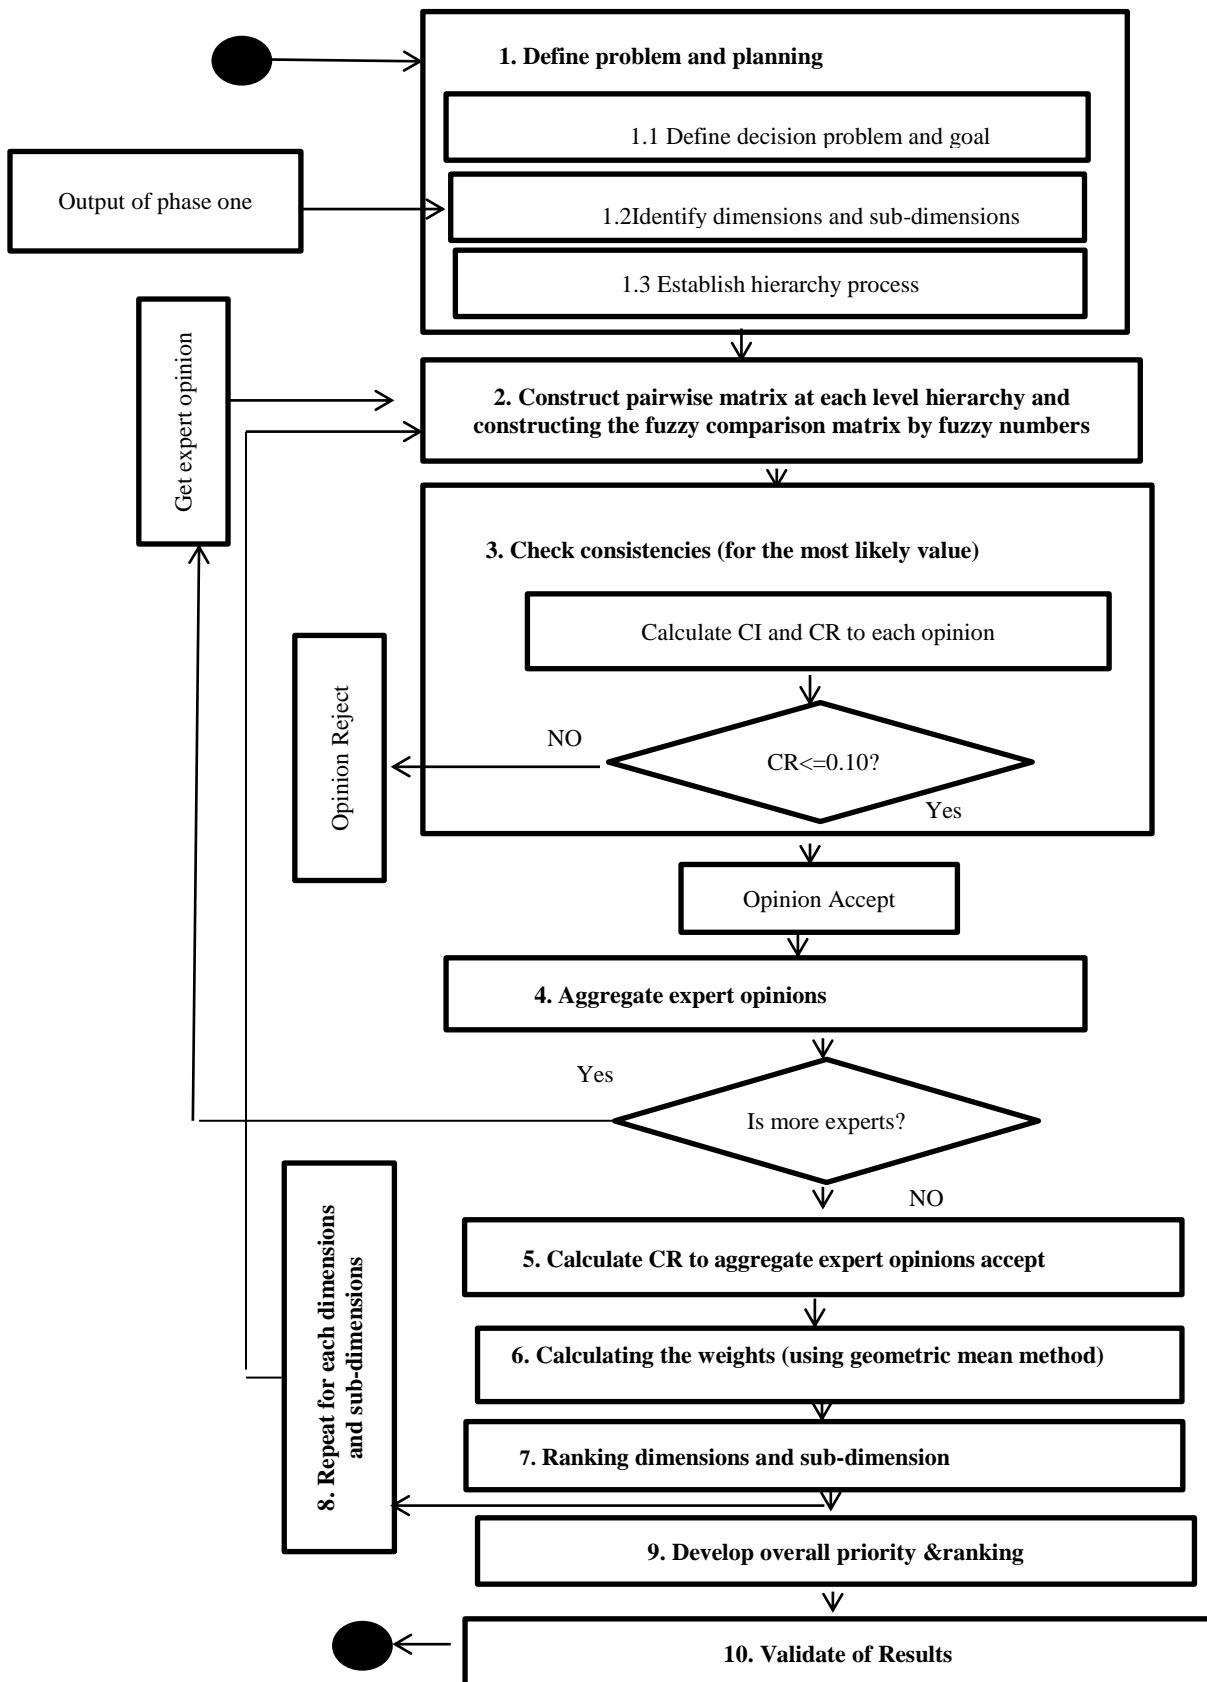

Fig. 2. Flowchart of the proposed methodology of the second phase.

- Step 6: Calculating the weights Using Fuzzy Geometric Mean Method.

As mentioned before, the major problem of AHP has been enhanced by utilizing fuzzy logic since it does not include vagueness for subjective judgments. There are several approaches to F-AHP, such as the geometric mean [11], [14], [64-65], and the extent analysis method [66]. In this work, the fuzzy geometric mean method was used to calculate the weights.

The sixth step contains several sub-steps that can be summarized as follows:

Step 6.1: According to [64] and [13], the fuzzy geometric mean value of each sub-dimension or dimension is calculated using Eq. (8). Here  $\tilde{r}_i$ , it still represents triangular values.

$$\tilde{r}_i = \left( \prod_{j=1}^n \tilde{d}_{ij} \right)^{1/n}, i = 1, 2, \dots, n \quad (8)$$

Where n is the number of dimensions or sub-dimensions.

Step 6.2: Find the vector summation of each  $\tilde{r}_i$ .

Step 6.3: Find the (-1) power of the summation vector. Replace the fuzzy triangular number, to make it in an increasing order [13].

Step 6.4: The fuzzy weight of dimensions or sub-dimensions was calculated as shown in Eq. (9).

$$\tilde{w}_i = \tilde{r}_i \otimes (\tilde{r}_1 \oplus \tilde{r}_2 \oplus \dots \oplus \tilde{r}_n)^{-1} = (lw_i, Lw_i, mw_i, uw_i) \quad (9)$$

Step 6.4: The weights that have been calculated by using Eq. (8) are still fuzzy triangular numbers, so we need to defuzzified them by the Centre of Area (COA) as shown in Eq. (10) [13].

$$W_i = \frac{l+m+u}{3} \quad (10)$$

Step 6.5: The weights that come from Eq. (9) were normalized as shown in Eq. (11).

$$N_i = \frac{M_i}{\sum_{i=1}^n M_i} \quad (11)$$

- Step 7: Ranking of dimensions and sub-dimensions.

Based on the outputs of step seven, the dimensions and sub-dimensions can be ranked according to weights.

- Step 8: Repeat steps 3, 4, and 5 for all levels of the hierarchy.
- Step 9: Develop overall priority & ranking.

According to [9], the total weight of sub-dimensions can be calculated according to Eq. (12), where “I” is the weight of dimensions and “j” is the weight of sub-dimensions in each dimension.

$$t_{ij} = g_i \times w_{ij} \quad (12)$$

- Step 10: Validate of Results

The Sensitivity analysis and comparison with AHP were used to validate of our approach.

#### IV. RESULTS AND DISCUSSION

In this section, we used the proposed method presented in Section III, as illustrated in in Fig. 1 and 2 to define and prioritize the dimensions and sub-dimensions of digital transformation. It will be discussed as follows:

##### A. DT Dimensions and Sub- dimensions

The results of the review with experts (applying Method 1 in Fig. 1) to define relevant dimensions and sub-dimensions are summarized in Table II. After conducting the review with experts to determine the most important sub-dimensions in evaluating digital transformation, the sub-dimensions were reduced to 42.

TABLE II. DT DIMENSIONS AND SUB-DIMENSIONS AFTER REVIEW WITH EXPERTS

Dimensions	Sub-dimensions
Customer	Customer training, Customer centricity, Customer integration
Technology	IT Architecture, Technology driven, Technologysecurity ,IT governance, Exploitation new technology,Use technology for data collection ,Digital Capabilities, IT Infrastructure, IT standard, Effective technology planning
Strategy	Coordination of digital transformation activities, Strategic governance, Technology investments, Risk assessment for digital transformation , Ecosystem Management, Stakeholder Management, Strategic alignment (Business-IT alignment) ,Digital transformation vision, Transformation in Digital Leadership
Organization	Transformation in digital leadership, Organization governance, Digital change management, Cross functional collaboration
Processes process	Business process Integration, Business process performance management , Business process standard, Business process security , Transformation in digital leadership
Culture]	Innovative culture, Openness to change,Communication, Everyone is allowed to make decisions
Data	Data analysis, Data management ,Data security and privacy,Data governance
Employees	Openness to new technology, Willingness to change, Employee training
Citizen	Citizen training, Citizen skills, Citizen centricity

##### B. Weights of DT Dimensions and sub-dimensions

In this section, the proposed method presented in Section III in Fig. 2 is used to prioritize the implementation of the dimensions and sub-dimensions of digital transformation by calculating weights. Fig. 3 illustrates this hierarchical structure involving the objective of the study, dimensions, and sub-dimensions.

In Fig. 3, the first level relates to the objective goal of the study. The second level corresponds to dimensions, and the last level corresponds to sub-dimensions of each dimension. In this paper, a pairwise comparison matrix will be created between elements (dimensions) in level 2. Similarly, a pairwise comparison matrix will be created between elements (sub-dimensions) in level 3 that have the same parent in level 2. Due to space constraints, the results of the steps involved in the proposed method are presented for the main dimensions on level 2, as shown in subsection A.

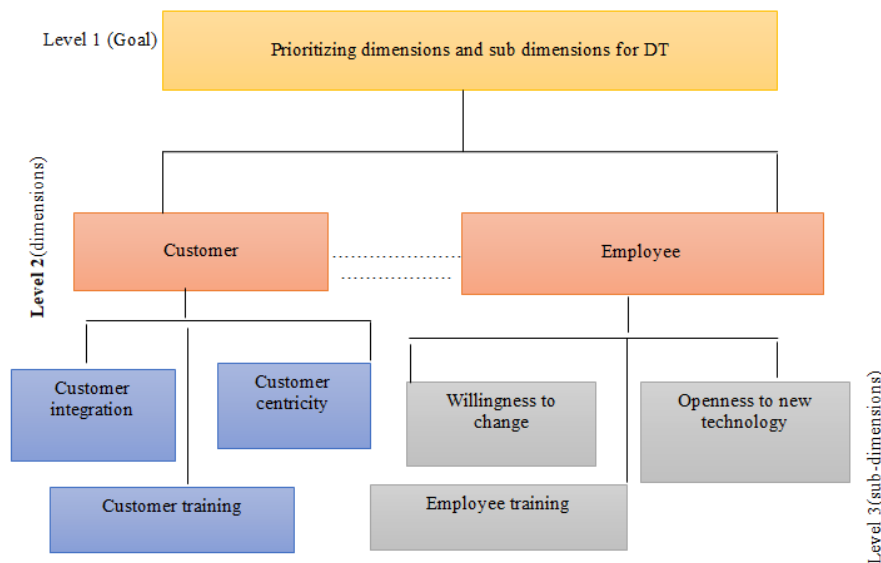

Fig. 3. Example DT Hierarchy structure of the problem.

### C. Weights of DT Dimensions

The results of the steps involved in the proposed method are presented for the pairwise comparison matrix between the main dimensions on level 2, as well as the output of each step. For each expert out of 12, a pairwise matrix was created, but due to the difficulty of displaying all of them, it was sufficient to present a matrix for one expert, as shown in Table III. Then consistency is checked for each expert (E) separately, as shown in Table IV. Only four expert opinions were accepted, while eight expert opinions were omitted, as shown in Table IV. The opinions of the experts accepted in the previous step were collected, as shown in Table V. The consistency ratio of the opinions of the accepted experts is calculated based on Table V. Consistency ratio = 0.064003. The outputs of applying Eq. (8), (9), and (10) and Step 7 are summarized in Table VII. From Table VI, it can be noticed that the strategy dimension has the highest weight (priority) "0.341" followed by the business process with a weight "0.215". Thus, the strategy dimension will rank first, followed by the business process. It can also be seen that the citizen dimension has the least weight (0.030).

### D. Weights of Sub-dimensions

As previously mentioned, due to space limitations, the results of the steps involved in the proposed method will not be presented for the main dimensions at Level 3, but the final results for the respective weights for each sub-dimension will be shown in Table VII.

### E. Total Weights of each Sub-dimensions

As we mentioned before, the total overall weight of each sub-dimension (t) can be calculated according to Eq. (12). The results of applying step eight can be summarized in Table VIII. For example, in "digital transformation vision",  $g_i=0.341$ ,  $w_{ij}=0.355$ , so  $t_{ij}=0.121$ . After calculating  $t_{ij}$  for all, it can be ranked. Based on the outputs of Table VII, it is possible to arrange the implementation of the sub-dimensions in relation to digital transformation. "Digital transformation vision" was first ranked, "business process standard" was placed second, and

"integration of citizens" came in last ranked. So it can be said that "digital transformation vision" is the leading factor for DT, followed by "business process standard". One other salient sub-dimension is willingness of employees to change" followed by "business-IT alignment". The consistency analysis of this research is summarized in Table VIII. Fig. 4 shows an incremental comparison of the total weights of all sub-dimensions (t) in detail.

## V. RESULTS VALIDATIONS

In this section, our work will be evaluated by identifying the advantages of this work compared to the research that is most similar to it [8] and comparing the results of our work with the results of AHP, in addition to using the Sensitive Analysis.

### A. Comparison with Prior Study

In order to contextualize our research, it's imperative to draw comparisons with a prior study [8]. This prior research shares the commendable attribute of employing a coherent methodology to delineate and assign weights to DT elements. Nonetheless, the preceding study harbors three notable limitations: it confines its focus solely on the private sector for the definition of DT elements, employs the AHP to prioritize these elements despite inherent uncertainties, and regrettably omits result validation. In response to these challenges, this research endeavors to address them comprehensively. The first limitation was overcome by the comprehensive identifying of elements relevant to DT evaluation in general (both segments). The second challenge is strategically navigated by adopting a combined approach, unifying AHP with FAHP to bolster consistency and mitigate the uncertainties often associated with expert judgments. Furthermore, a rigorous sensitivity analysis was performed to validate the results, critically addressing the last limitation. In doing so, our research not only endeavors to provide a comprehensive solution but also contributes to the broader scholarly discourse on digital transformation assessment methodologies.

**B. Comparison Results (Ranking)**

A comparative analysis is performed to validate the effectiveness of our proposed approach by comparing the results of our approach with those of AHP as follows:

- Comparing the ranking between the main dimensions

Based on the results obtained, it can be observed that the ranking of the main dimensions using the Analytic Hierarchy Process (AHP) is the same as the ranking using fuzzy AHP, with the exception of the business process and employee dimensions as shown in Fig. 5. In AHP, the business process dimension is ranked third, whereas in fuzzy AHP, it is ranked second. Similarly, the employee dimension is ranked second in AHP and third in fuzzy AHP. Comparative analysis of the

results indicates that our approach is 80% compatible with AHP in terms of dimensional order. This suggests that there is a significant level of agreement between the two methods, except for the specific dimensions mentioned above.

- Comparing the ranking between the sub-dimensions in each dimension

Due to space limitations, only the sub-dimensions rank of the data dimension was compared. Based on the comparative results shown in Fig. 6, it can be concluded that our approach is 100% compatible with AHP in terms of the ordering of sub-dimensions in the data dimension. This indicates that our proposed approach accurately orders the implementation of dimensions in the decision tree (DT).

### C. Sensitivity Analysis

A sensitivity analysis is a tool to determine the effects of potential modifications in the dimension or sub-dimension weights on the prioritization of DT [13]. A sensitivity analysis was applied to the FAHP approach results based on dimensions. The X-axis represents the change in important values between 1 and 9 (that have been assigned by 12 experts) of the main dimensions or sub-dimensions, and the Y-axis represents the ranking of dimensions. We can observe the effects on the ranking of the dimensions and sub-dimensions as follows:

- Sensitive analysis in dimensions

In this analysis, the weights of a certain dimension for each expert will be changed between 1 and 9, while the weights of other dimensions are fixed. For example, when the weight of the strategy dimension with respect to the business process dimension is changed between 1 and 9, strategy has always been placed in the first rank, except for one time when business process came first, as shown in Fig. 7. This will be iterated by changing the strategic dimension values for each of the remaining dimensions. By conducting a sensitivity analysis, it was determined that the weights assigned to the primary dimension have only a slight impact on the overall results. Additionally, the order of choices does not change significantly even with variations in the weights of the primary dimensions.

- Sensitive analysis in sub-dimensions (customer as example)

Due to space constraints, only sensitivity in customer sub-dimensions was examined, as shown in Fig. 8, 9, and 10.

- ✓ Sensitive analysis in customer training with respect to the customer centricity

When the weight of the customer training with respect to the customer centricity is changed, the customer training has always been placed in the first rank and the customer centricity has always been placed in the second rank except one time, as shown in Fig. 8.

- ✓ Sensitive analysis in customer training with respect to the customer integration

When the weight of the customer training with respect to the customer integration is changed, the customer training has always been placed in the first rank and the customer integration in the second rank, as shown in Fig. 9.

- ✓ Sensitive analysis in customer centricity with respect to the customer integration

When the weight of customer centricity with respect to customer integration is changed, customer centricity has always been placed in the second rank, as shown in Fig. 10.

Sensitivity analysis shows that weights for the customer sub-dimensions have only a limited effect on the results, and there is no significant change in the order of the sub-dimensions.

Fig. 7. Results of sensitivity analysis strategy dimension with respect to the technology dimension.

## VI. CONCLUSION

The core objective of this study was to establish a systematic framework for prioritizing the implementation of dimensions and sub-dimensions within the context of digital transformation. This was achieved through two distinctive phases. The initial phase involved defining the key dimensions and sub-dimensions, drawing from prior research and expert evaluations. A comprehensive set of 42 sub-dimensions was assembled under nine primary dimensions. Subsequently, the study progressed into the second phase, where the weights of both main dimensions and sub-dimensions were meticulously computed. In this research, the integration of the fuzzy geometric mean method with AHP provided the basis for identifying priority areas of focus for organizations. The application of the fuzzy scale and geometric mean method to allocate weights to dimensions and sub-dimensions effectively handled uncertainties in the decision-making process. The inclusion of AHP further bolstered decision consistency. The findings underscored that "strategy" (0.341) and "business process" (0.215) emerged as the two pivotal dimensions within the realm of digital transformation. The sub-dimension "digital transformation vision" held the foremost position, closely trailed by "business process standard. This study carries significant implications for organizational decision-makers across both the private and public sectors. It offers a tangible pathway for identifying the priority of sub-dimensions, thereby

amplifying the likelihood of successful digital transformation endeavors. Sensitivity analysis was then employed to validate the outcomes of our approach. Notably, the ranking of alternatives remained largely unchanged even when the weights of primary dimensions or sub-dimensions were modified. Furthermore, a comparative analysis was executed between our proposed approach and AHP. Through sensitivity analysis and consistency ratio calculations, the robustness and effectiveness of our approach were both established. In summation, this research introduces a methodological paradigm that guides the strategic sequencing of dimensions and sub-dimensions in digital transformation initiatives. It not only empowers decision-makers but also underscores the reliability and effectiveness of the proposed approach through rigorous analysis and validation.

- Limitation

The hybrid approach used in this paper was created exclusively for digital transformation. As well, this is a general approach and does not apply to case studies.

- Future work

Several experiments will be carried out using different MCDM techniques as well as applying our approach in many areas. The next step will be to use these findings to suggest a roadmap for the organizations when they are being evaluated.

**Abstract**—With the rapid advancement of technology in Malaysia, the number of cybercrimes is also increasing. To stop the increase in cybercrimes, everyone, including normal citizens, needs to know how secure they are while using digital appliances. A system is developed to predict the risk of users based on their behaviour when they are online using real-life behavioural data obtained from a private university's 207 undergraduates. Five supervised machine learning methods are being tested which are: Regression Logistics, K-Nearest Neighbour (KNN), Decision Tree (DT), Support Vector Machine (SVM), and Naïve Bayesian Classifier with the aid of a tool, RapidMiner. The algorithms are used to construct, test, and validate three categories of cybercrime threat (Malware, Social Engineering, and Password Attack) predictive models. It was found that KNN model produces the highest accuracy and lowest classification error for all three categories of cybercrime threat. This system is believed to be crucial in alerting users with details of whether the consumer behaviour risk is high or low and what further actions can be taken to increase awareness. This system aims to prevent the rise in cybercrimes by providing a prediction of their risk levels in cybersecurity to encourage them to be more proactive in cybersecurity.

**Keywords**—Cybersecurity threat; cybersecurity risk; predictive modeling; undergraduates; cybercrime

### I. INTRODUCTION

Malaysia has entered the digital age, with online meetings and classes or cashless payments becoming more popular [1]. However, as the number of digital users has increased over the years, it may also lead to a surge in cybercrimes. Although most Malaysians have a good level of awareness of cyber threats and risks, only a few who act against it due to a low understanding in cybersecurity and the severity of cyber threats and attacks [2] [3]. This high number of cyberattacks has been estimated to cost the global economy USD 1 trillion in 2020, that is, 50% more than in the previous year [4]. According to researchers, the increase in cybercrimes is also happening in Malaysia [5] [6]. Malaysia's cybersecurity is currently slow to catch up with the pace of advancement, and people lack of knowledge in cybersecurity due to the consequences and impacts of Malaysia's organisation, in the private or public

sector [5]. Cyberattacks go beyond the loss of money and reputation but remain a failure in finding a global systematic way to confront [7]. With numerous reports claiming that there is an increase in cybercrimes that are not only targeting important organisations and government but also normal citizens [7][8][9], there are various studies to warn digital users the don'ts and dos without certainly proclaiming how much precaution is needed to be considered safe in cyberspace.

The rise of cybercrimes in Malaysia has caused a lot of damage not only in terms of financial and reputation. However, as a normal citizen without any background knowledge in cybersecurity, it could be difficult for him to know and keep up to date with the latest cybersecurity news and may not even know where to start. One would need to read and listen to stories of victims of cybercrimes and learn from their mistakes to know the risks, but this is not enough because the sources of stories are limited as they were usually from the same social circle. This method of learning may be inaccurate and insufficient, as technology is advancing rapidly and may not be up to date with the latest cybersecurity methods. This concludes that there are no concrete means to prove one's knowledge of cyber risks in the current cybersecurity measures.

There are companies that offer cybersecurity services for companies to predict cyber threats and attacks using artificial intelligence (AI) and machine learning. Having that said, there is no need for normal citizens to hire a company just to know their risk levels in cybersecurity. Thus, the competition is scoped down to simple websites asking visitors a sample of questions to predict their awareness, as it is more non-tech-savvy friendly. These websites, however, do not have official databases and are opinion-based; no research is done in the prediction of results, but rather in a pop quiz-like structure. In general, these websites do not describe risks based on varied behaviours.

Furthermore, very little research was done among Malaysians and some existing research was outdated. Therefore, this study aims to fill this gap by helping researchers with cybersecurity prediction based on user

behaviour. Hence, the system would predict the user's risks based on real-life data sets and can give users an idea of which aspect of cyber risk is greater rather than only scores.

Predictive modelling of cybersecurity threats predicts the risks of a user while using a digital device such as a mobile phone, laptop and personal computer by using machine learning algorithms tested and validated by user behaviour data acquired from undergraduates in Malaysia. Therefore, the objective of this study is to identify the factors that affect users' security awareness (in terms of malware attacks, social engineering, and password attacks); build a predictive model of cybersecurity threats for undergraduates using the Internet in Malaysia; and develop a website to implement the predictive model.

This project has two main parts, data modelling and website deployment. Python is used to programme the machine learning part of the system, coded using Jupyter, with the dataset, while the website serves as a medium for users to predict their risks, who can access the Python files to make predictions. The results will then be displayed on the website. Web pages are structured using HyperText Markup Language(HTML) and the layout is formatted using Cascading Style Sheet(CSS) with JavaScript to give the web pages a final touch to make it more appealing in an integrated development environment (IDE), Visual Studio Code (VSC).

Young adults have a low understanding of the basics of cybersecurity as they are unfamiliar with common cyber threats [3]. The findings suggest that exposing cybersecurity knowledge at a young age can ensure healthy habits online, reducing the chance of cyber attacks and threats [2]. As gender does not affect prediction results because the prediction is entirely based on behaviours, this expands the system's target of the system to both genders.

This paper is constructed in four sections: Section II about literature review of current research in cybercrime prediction; Section III describes the methodology used in this present study; Section IV presents the study result and discussion; and Section V concludes the present study with limitation and future works.

## II. LITERATURE REVIEW

The digital economy dominates Malaysia in business transactions, as more than 40% of these transactions are made digitally. Research found that the future of Malaysia will depend on the digital economy; therefore, the digital space in Malaysia needs to be trusted to allow parties including enterprises, customers, public sectors and individuals to have a reliable digital space [1][10]. According to the Malaysia Computer Emergency Team, there is a visible increase in cyberattacks from January 2022 to July 2022 [11]. One of the recommendations to reduce the risk of cyber threats and attacks is the need to increase public awareness of risks, threats, and

vulnerabilities in cyberspace. Therefore, increasing awareness of cyber threats is one of the objectives of the system and is achieved by providing a prediction of user risk in cyberspace using predictive modelling with machine learning techniques.

Since there are various types of cyber threats, three threats, namely malware attack, social engineering, and password attacks, are selected due to the high likelihood of these threats against individuals. Other threats include advanced persistent threats (APT), where attackers gain unauthorised access to a network and try to become a part of the network to prevent detection for an extensive period of time, and Man-in-the-middle attack (MitM), where attacker intercepts users when they are remotely accessing a system over the Internet. APT requires attackers to possess a high knowledge of the victim, and therefore these attacks are usually launched towards nation states, large organisations, companies, or very important people. [12] As the target of this project is young undergraduate Internet users, they are less likely to connect their device remotely online, making MitM not in scope.

There are no equivalent research studies to the proposed project, but similar studies have been found that predict the cyber risk of software [13] [14]. Both projects use machine learning techniques to identify weak points or vulnerabilities in the system and the risk that the software becomes infected or corrupted at a certain time. Zhang et al. [13] built the predictive model with data from the National Vulnerability Database (NVD), which is a public data source for reported software vulnerabilities. They tested the data with various approaches for predictive modelling to find the best techniques for their prediction model, as their study results show that the current approach is not accurate except for a few vendors. Bilge et al. [14] on the other hand, got their data from 18 enterprises for a year, which contains information about binaries appearing on machines with fully and semi-supervised machine learning. Semi-supervised machine learning is a technique that uses machine learning machine learning that uses both supervised, where labelled data is used, and unsupervised, where unlabelled data are used [15].

Other work closely related to cyber risk prediction is cyberattack predictions and cyberattack detection. The prediction is usually overlooked by the research community opposed to cyberattack detection. Ben Fredj explored the prediction of cyberattacks using a deep learning approach [16]. It is a subgroup of the machine learning approach in which multiple layers of neural networks are used to build the model [15], which simulates how neuronal nerves work in a human brain. In addition to that, there is a study that surveyed not only machine learning approaches, but also data mining approaches in terms of prediction and prediction methods used in cybersecurity [17]. Regarding cyberattack detection [18][19][20], most studies use Deep Learning (DL) to model their data to detect which attacks will occur in given situations and the rate of these attacks (Table I).

TABLE I. SUMMARY OF RELATED WORKS

### A. Malware

Malware means malicious software which refers to any software that intrudes on a system developed by cyber-attackers. This software can penetrate the device of a user ranging from viewing to modifying private data, such as user's personal photos, operating systems, and other data that the attacker can find on the victim's device [21]. Malware types include, but are not limited to, viruses, spyware, backdoor, and keyloggers, each with different threats and dangers. Viruses can attach themselves, using macros, to Microsoft Office software such as Words. Therefore, it infects the victim's computer when it is opened or viewed. Students will use Words frequently for various reasons such as completing assignments or recording notes, which pose a high possibility of becoming a victim. Other great possibilities include downloading free software online to avoid purchasing.

Malware is a programme that is inserted into a system with the intention of compromising the confidentiality, integrity, or availability of the victim's data, applications, or operating system, or otherwise annoying or disrupting the victim. Therefore, measuring risk in malware infection can be simplified to the ability to prevent malware from entering the system and the ability to mitigate threats if prevention fails. First, the ability to prevent malware can be measured by how many techniques the user knows about how a malware can enter a system and the depth of understanding of these techniques (MW1). Second, the ability to mitigate threats can be measured by how quickly the user can detect that malware has already entered the system, identified the source of the malware, and remove malware and its techniques (MW2) [22] [23]. Therefore, the system should collect the user response for the following regarding user's behaviour to avoid different malware threats:

- M1. Is antivirus software, firewall, and anti-spyware available on the user computers? (MW1, MW2)
- M2. What is the user's confidence level of antivirus software in their computers? (MW1, MW2)
- M3. How inclined is the user to download materials from unsecure sites? (MW1)
- M4. How inclined is the user to download freeware on the Internet? (MW1)
- M5. How inclined is the user to scan removable drives before using them on computers? (MW1)
- M6. How inclined is the user to apply security patches as soon as possible? (MW2)
- M7. Is the user able to sense that something is wrong if the computer runs oddly slow? (MW2)

### B. Social Engineering

The art of persuading people to breach information systems is known as social engineering. Instead of launching technical assaults on systems, social engineers use influence and persuasion to persuade people with access to information to reveal secret information or even carry out hostile actions. Most successful attacks on systems are rarely required to find technical vulnerabilities; hacking the human is usually sufficient [24]. Social engineering is the most successful when combined with other methods, such as phishing [25]. Phishing is the act of sending links that link victims to their website that do what cybercriminal programmes to do. For example, attackers send links decorated with official names and formatting to make them appear to come from a legitimate source to play mind tricks and get victims to click on the link. In addition to sending links, attackers can act as an advertiser trying to advertise a product and ask the victim to scan a QR code (quick response) that links to their malicious attack. Both situations are likely to occur amongst anyone.

Social engineering is a method of tricking victims to help compromise their own system. Therefore, user measurement of the risks in social engineering attacks can be simplified into the level of understanding of social engineering techniques and the ability to respond to these techniques correctly. First, how many social engineering techniques can the user know that can be used to measure the level of understanding (SE1). Second, whether the user knows how to respond to these techniques can be used to measure the ability to respond (SE2) [23] [26]. Therefore, the system should collect the user response for the following:

- S1. Is the user interested in learning social engineering issues? (SE1, SE2)
- S2. Does the user establish a trusted relationship with strangers on-line? (SE1, SE2)
- S3. How inclined is the user to click hyperlinks in email messages? (SE1, SE2)
- S4. How inclined is the user to check the authorisation of the interlocutor? (SE1)
- S5. How inclined is the user to check URL spellings? (SE1)
- S6. Does the user trust any benefit winning emails, calls, or SMS? (SE1)
- S7. Does the user trust in any information online? (SE1)
- S8. Is the user aware of the latest scam and phishing techniques? (SE1)
- S9. Does the user feel intimidated by questions by any interlocutor? (SE2)
- S10. How inclined is the user to provide details to authorities? (SE2)

S11. How inclined is the user to respond to calls, SMS, or email from strangers? (SE2)

### C. Password Attack

Password attacks occur when attackers attempt to gain access to a victim's system using the victim's password. This attack is different from the above two threats, as this threat attacks through the 'front door' rather than in secret or stealthily by guessing and trying repetitively until it is correct. User passwords are easy to guess, since they are related to the victim or the password is an actual word or phrase [27], which can be easily obtained using social engineering techniques. As Malaysia is moving toward a digital era, account creation can be common and logging in or signing up requires a password. Other techniques of password attacks include, but are not limited to, brute force, where the attackers try every possible password combination, or dictionary attack, where attacks steal the encrypted data during transmission containing the victim's password and decrypt it using their encryption library.

Password attack is a method to legitimately enter the victim's system through victim passwords. Therefore, to measure the risks of users in password attacks, it can be measured by how securely users keep their passwords and complexity [23] [28]. Therefore, the system should collect the user response for the following:

- P1. Does the user's password follow a keyboard pattern?
- P2. Does the user share passwords with other people?
- P3. Does the user create different passwords for different applications?
- P4. Is the user's password consisting of lowercase, uppercase, numbers, special characters?
- P5. Is the user password longer than 8 characters?
- P6. Is the user's password created based on personal/information?
- P7. Does the user change the password?
- P8. Does the user use the 'Recall password' option?
- P9. Does the user write the password?
- P10. Does the user use 'hint' to recover forgotten passwords?
- P11. Does the user check for a padlock symbol on browsers?

### D. Conceptual Framework for Measuring Ability to Avoid Cyberattacks

Based on the literature review, Fig. 1 summarises the measurement criteria of ability to avoid cyberattacks of three categories of threats – malware, social engineering, and password attack.

### E. Web Projects

Moving from research-based projects to web projects, three web services, namely ProProfs, W3Schools, and the Federal Trade Commission (FTC), are being compared as follows. This predictive modelling is built for young people in Malaysia, which is the scope that is not covered by these three websites.

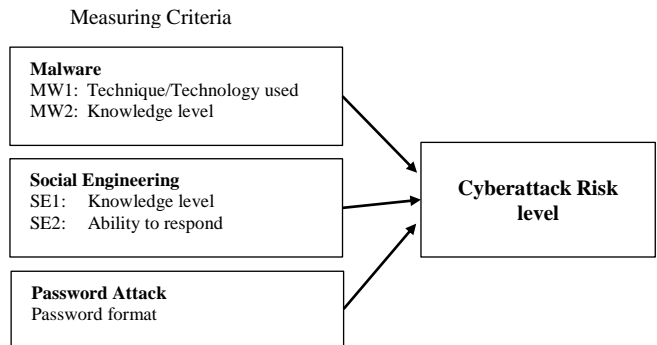

Fig. 1. Conceptual framework of measuring criteria for cyberattack risk level.

First, ProProfs is a website that allows any user to create quizzes and post them online on the ProProfs website itself (Fig. 2). Therefore, this website has a variety of quizzes from different domains, which, of course, includes cybersecurity. However, most of the questions of these quizzes are focused on cybersecurity as a course instead of a test for user risks on-line. The questions asked are technical and not suitable for general users who do not consider cybersecurity as their focus. On the ProProfs website, a quiz is found that tests for users' cyber health and security, but it seems to have the same results for all responses entered. Since it is available to everyone, most of these quizzes do not have concrete backing of data to support the claims of the results.

Fig. 2. Screenshots of the ProProfs website.

Next, W3Schools is a free educational website to learn Python coding (Fig. 3). However, this website is controlled by two entities namely Refsnes Data and W3schools Network instead of a central point for everyone to submit their viewpoints. As mentioned, this website is built for educational purposes and the cybersecurity quiz is one of the many quizzes found, which is also for people who want to make a revision of cybersecurity courses. Therefore, it does not inform users about the cyber risks that could occur to users.

Fig. 3. Screenshots of W3Schools' website.

The Federal Trade Commission is an official website of the United States (USA) government that is built to protect American consumers (Fig. 4). It contains cybersecurity quizzes for small businesses to help guide them. The topics in the cybersecurity quizzes are the basics of cybersecurity, physical security, ransomware, phishing, vendor security, and secure remote access. In addition to quizzes, it also provides other means of guidance, such as but not limited to downloadable publications and videos of cybersecurity, which are all accessible in the additional resource's subsection of the page. Table II summarises the three websites in terms of owner, target users, location, and content(s).

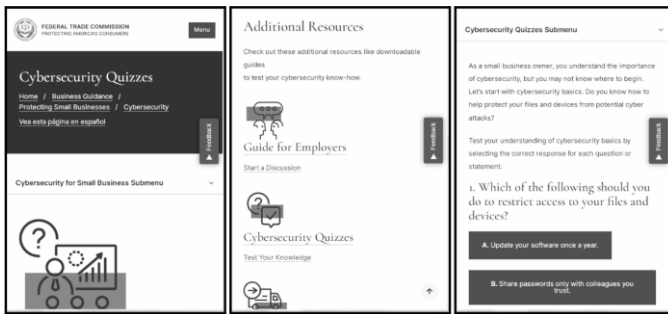

Fig. 4. Screenshots of FTC's website.

TABLE II. COMPARISON OF 3 WEB SERVICES WITH THE PROPOSED PROJECT

	ProProfs	W3Schools	FTC
<b>Owner(s) of Content</b>	Anyone	Refsnes Data and W3schools Network	US Government
<b>Target Users</b>	Not specific	Learner	Small business
<b>Location</b>	Not specific	Not specific	US
<b>Content(s)</b>	Quizzes	Quizzes Guidance	Quizzes Guidance

### III. METHODOLOGY

Questionnaire items are modified to avoid multiple-choice types of questions. Its purpose is to overcome the limitations of multiple-choice questions, which are the excessive words that make users feel more like an exam and will try to give a 'correct answer' instead of their genuine online behaviour. The data entry designs are shown in Table III.

In this study a private university in Malaysia in the age group of 15 to 30 years constituted the population. The sampling plan implemented in this investigation is the simple random sampling method (SRS). A total of 207 undergraduates participated in the study.

TABLE III. MODIFIED QUESTIONS

ID	Question	Response Type	Measured Questions
<b>Malware</b>			
L1	Is your device's operating system (OS) up-to-date?	5 likert scale	M6, M2
L2	Do you scan removable drives?		M5
L3	Do you download freeware online?		M3, M4
L4	Do you feel something is wrong if your device is running slow?		M7, M2, M4
L5	Is your device protected by any cybersecurity measures?		M1, M4
<b>Social Engineering</b>			
E1	Are you interested in learning about social engineering issues?	5 likert scale	S1,S8
E2	Do you establish a trusted relationship with strangers online?	5 likert scale	S2, S11, S8
E3	Do you click on links in emails?	5 likert scale	S3, S7, S8
E4	Do you check the authorisation of the authorities?	5 likert scale	S4, S7, S8
E5	Which link is the right URL to the Google website? www.google.com; google.com; https://google.com; g00gle.com; http://google.com		S5, S8
E6	Do you feel intimidated by questions from any authority?	5 likert scale	S9, S11
E7	Do you provide details to the authorities?	5 likert scale	S10, S8
<b>Password Attacks</b>			
A1	Create a password that you will use.	Open ended	P1, P4, P5
A2	Is the password created based on personal/ information?	5 likert scale	P6
A3	Do you change your password?		P7
A4	Do you use password management features?		P8, P10
A5	Write the password?		P9
A6	Do you share passwords?		P2
A7	Do you check for a padlock symbol on browsers?		P11
A8	Do you create different passwords for different applications?		P3

Participants responded to the questionnaire based on a 5-point Likert scale, which divides into 5 categories (strongly agree, agree, neither agree, disagree, strongly disagree). The questions are then analysed to determine whether they are good or bad practises. For questions classified under good practises, the mark is allocated accordingly based on the options (“Strongly agree”-5, “Agree” - 4, “Neutral” - 3, “disagree”- 2, “Strongly disagree” - 1) while for questions classified under bad practises, the mark allocated for each option is the opposite of good practises (“Strongly agree”-1, “Agree” - 2, “Neutral” - 3, “disagree”- 4, “Strongly Disagree” - 5). The responses to every question may vary; however, they generally have the same meaning. The scores for each question for each category are summed up as a total score. Thus, the highest scores attainable on the questionnaire for Malware, Social Engineering, and Password Attack are 25, 35, 40 respectively (best cybersecurity practises implemented), and the lowest scores are 5, 7, 8 respectively (worst cybersecurity practises implemented). Data are then statistically transformed into maximum scores of 35, 55, 55 and lowest 7, 11, 11 respectively.

Questions are either the main question itself, thus not needing to be processed, or are paired with other questions. Questions that are paired with others are calculated using the mean of all questions related to it, except questions A1 and A4. For example, questions L1 and L4 also have value for question M2. Therefore, the value of M2 to be given to the model is the mean value of L1 and L4.

For question A1, the input text will be used to measure 3 parameters.

1) For input text that follows a keyboard pattern, will be marked as low score, while a text that does not will be marked as a high score.

2) The length of the text will determine the score for P4. To achieve the best score (5), users must have an input text of more than 16 characters, while less than 4 characters will be marked as low score(1).

3) The number of character types will determine the score for P5. Text input will be marked as the best score (5) if it contains all types of character (lower case, upper case, numbers, special characters) and the lowest score(one) if it only contains one type of character.

Regarding questions A4, P8 and P10, they point to similar features that most applications provide, which are ‘remember password’ and ‘forget password’. Thus, both scores will be equal. The model will receive the user's behaviour in cyberspace as input to determine its awareness and then predict the user's risk of cyber threats (Fig. 5).

Fig. 5. Predictive Modelling components of Cyber Threats.

#### IV. RESULT AND DISCUSSION

##### A. Model Performance

Based on several related works that have been studied, a supervised machine learning method has been selected for the predictive model (Fig. 6). Five supervised machine learning methods are being tested, Regression Logistics, K-Nearest Neighbour (KNN), Decision Tree (DT), Support Vector Machine (SVM), and Naïve Bayesian Classifier with the aid of a tool, RapidMiner. K-fold cross-validation, where the dataset is divided into 5 groups with each group being the test data set after training the machine with other groups, is used to assess every method above. Of the above five, KNN is selected as the machine learning methodology, as it has the highest accuracy among the other methods (Table IV). KNN is an algorithm that calculates the distance between the new data point and the nearest available data point, where k is a positive integer. The new point is then classified according to which class has the most data points closest to the new data point. The contingency table or confusion matrix is used to help display the accuracy of all the above-mentioned methods. The accuracy is calculated with formula 1 and simplified with formula 2 into percentage (%).

Formula 1:

$$\frac{TruePositives}{TotalPredictedYes} + \frac{TrueNegatives}{TotalPredictedNo} = Accuracy$$

Formula 2:

$$TruePositives + TrueNegatives = Accuracy$$

Fig. 6. Supervised machine learning model.

TABLE IV. SUMMARY OF 5 MODELS FOR EACH CATEGORY OF CYBERATTACKS

Model	Malware		Social Engineering		Password Attack		Average Accuracy (%)
	Accuracy (%)	Classification Error (%)	Accuracy (%)	Classification Error (%)	Accuracy (%)	Classification Error (%)	
Naïve Bayesian Classifier	79.5	20.5	89.8	10.2	91.4	8.6	86.9
Regression Logistics	79.5	20.5	88.2	11.8	91.4	8.6	86.4
KNN	92.9	7.1	93.8	6.2	97.6	2.4	94.8
DT	83.0	17	91.5	8.5	79.5	20.5	84.7
SVM	83.0	17	91.5	8.5	81.2	18.8	85.2

**B. Model Fit**

Python has been selected as the programming language for the machine learning part of the system. Python is selected because it has built-in libraries and frameworks suitable for data science. The libraries used for this project are pandas, NumPy, and Scikit-learn. Pandas library is used to read data tabulated in excel sheets, NumPy is used to process the data into machine learning parameters for the model to train, and Scikit-learn is used to implement machine learning models. A built-in Python module, pickle, is used to save the model as a non-readable binary file to be placed in the server and accessed by the webpage. Two parameters are needed to train the model, the first being the data to test, while the second being the K values.

To get the first parameter, the data is loaded into memory with pandas extracting data from excel sheets. Numpy is then used to convert the data into arrays. These arrays are then divided into training and test data with a ratio of 5: 1 (80% training, 20% testing). Training data will be used to fit the model while test data are used to measure the accuracy of the model.

The next parameter is to find the best K-value for the model. For this, another two-array list is created, namely a set of K values, from 3 to 30, and an empty list to store the results. The model is trained 28 times, and its result score is stored in the empty array list. The least K value with the highest accuracy is then selected as the K value. A lower value of K means that the classification is close to the original value and will not include further away data points, thus increasing precision. K values are evaluated as shown in Fig. 7, 8, and 9. The K values are 4, 5 and 3 for malware attack, social engineering, and password attack model, respectively. After splitting the data set and finding the optimal K values, the model is ready to be saved as a binary file using pickle.

Fig. 7. Accuracy score of K values for malware attacks.

Fig. 8. Accuracy score of K values for social engineering.

Fig. 9. Accuracy score of K values for malware attacks.

**C. Validity and Reliabilty Consideration**

Prior to this actual study, the instrument (questionnaire) was pilot tested with a group of 30 students from the same research site. The researchers ensure that the participants for the pilot test do not participate in the actual study. Data collected from the pilot test were measured for reliability using the Cronbach alpha reliability coefficient, formula 3.

Formula 3:

$$a = \frac{k}{k - 1} \left( 1 - \frac{\sum V_i}{V_t} \right)$$

Where a is the reliability coefficient, k is the number of questions,  $V_i$  is the variance of the responses of each question, and  $V_t$  is the variance of the total score of each respondent. The reliability measurement of the questionnaire is shown in Table V where all categories show good reliability.

TABLE V. RELIABILITY MEASUREMENT

Cyber Security Categories	Number of Items	Reliability Coefficient
Malware	5	84.3%
Social Engineering	7	81.0%
Password Attack	8	80.2%

D. Demographic Variable Effect

This study is specifically aimed at the demographics of users (age, geography). The variable (gender) is not used in the prediction; however, this variable is still being tested by independent samples T-Test to compare the means of two independent groups (male and female) to prove that this variable does not affect the accuracy of the prediction (Table VI). Data are statistically analysed using the SPSS programme. A total of 207 Malaysians participated in the study, of whom 98 of the respondents are male and 109 of the respondents are female.

TABLE VI. VALUES OF THE T-TEST FOR DIFFERENCES IN THE LEVEL OF CYBER SECURITY BEHAVIOUR BY GENDER IN THE ASPECT OF MALWARE, SOCIAL ENGINEERING, AND PASSWORD ATTACK

	Group statistics		T-Test	
	Mean	Std Deviation	t-value	Sig.
<b>Malware</b>				
Male	33.60	5.49	0.05	0.963
Female	33.57	4.76		
<b>Social engineering</b>				
Male	34.28	5.27	-1.02	0.306
Female	34.99	4.76		
<b>Password Attack</b>				
Male	33.46	5.79	0.26	0.796
Female	33.25	5.96		

Based on the three tables above, there are no significant gender differences in the level of cybersecurity behaviour in all three aspects (malware, social engineering, password attack); thus, gender does not affect the accuracy of the prediction of the model.

E. Comparing Proposed Website with Existing Websites

1) *Similar existing website:* Three previously mentioned websites are studied for their functionalities to choose those that are applicable for this project. All of them follow the same flow, that is, to introduce what and how important cybersecurity is and a navigation panel or menu which links to other functionalities.

The Proprofs website allows users to view the list of questions of the selected quiz, contact the author of the quiz, take the quiz, edit the settings of the webpage, to search for other quizzes from any domain, to share the selected quiz, in embedding the quiz to another website. The Proprofs website also allows users to create quizzes with the precondition of having an account with Proprofs, thus needing users to log in prior to creating quizzes [29].

The W3schools website allows users to view an introduction of cybersecurity, search for other services that w3school provides, log into a w3school account, take the quiz,

quick link to access other tutorials, change the theme of the website, translate the website to another language. The W3schools website also allows users to subscribe to their services under the condition that the user has an account with w3schools, which requires that the users log in [30].

The FTC website allows users to translate the website into another language, report fraud, sign up for FTC newsletters, search for other documents in a legal library, give feedback, view Introduction to Cybersecurity, print the website, take the risk assessment, and access to other services [31].

Based on the study above, all websites have similar design and functions; therefore, to be consistent with the existing websites, the Predictive Modelling of Cyber Security Threats website should display an introduction to cybersecurity and explanation of its importance (Fig. 10). The navigation menu should also be added to this website for easy navigation between other web pages, which includes displaying the information page and the methodology page. Users can also choose to share this website. Feedback from user functions should also be included so that this website can interact with users for future improvements. Lastly, the website should allow users to assess their cyber risks. Other functions such as searching, log-in or log-out, and printing are omitted in this website, as they serve no purpose for their functions on this website. For example, this website does not need a search function, as this project has only cyber risk prediction as its focus. The comparison is summarised in Table VII.

Fig. 10. Screenshot of the project website prediction result page.

## V. CONCLUSION

This project uses five machine learning algorithms (Regression Logistics, K-Nearest Neighbour (KNN), Decision Tree (DT), Support Vector Machine (SVM), and Naïve Bayesian Classifier) to predict the risk of cyber threats in the aspects of malware attack, social engineering, and password attacks among Internet users based on their online behaviour. During the development of this present study, it was also found that gender does not play a role in the perception of cybersecurity in Malaysia. KNN predictive model produced the highest accuracy and the lowest classification error. Therefore, KNN model is further improved using Python.

Given the absence of previous studies utilizing machine learning techniques for predicting users' cyberattack risk levels, this present study introduces a conceptual framework that includes measurement criteria for assessing risk levels. Most of the previous studies are predicting the cyberattacks of organisation websites or companies' networks instead of individual risk level. This study serves as guidance for future researchers to continue the study in other cyberattacks such as MitM. New behaviours can also be incorporated to investigate cyber risks. Furthermore, this present study only focused on a data set of young people, since all participants in this project were in the age group of 15 to 30. More efforts are needed in this domain, as predicting human behaviour is a complex task [10]. Techniques to detect potential cyberattacks are crucial to ensure a safe world of the Internet for global users.

# Enterprise Marketing Decision: Advertising Click Through Rate Prediction Based on Deep Neural Networks

Luyao Zhan

Faculty of Business and Accountancy, Henan Open University, Zhengzhou, 450008, China

**Abstract**—With the high-speed growth of modern information technology, online advertising, as a new form of advertising on the Internet, has begun to emerge, demonstrating enormous development potential. To improve the accurate estimation of advertising placement and improve the operational efficiency of the advertising placement system, an improved deep neural network model for forecasting advertising click through rate was studied and designed. Meanwhile, the values of the activation function and the parameter dropout are determined, and the prediction accuracy of the deep neural network model and the improved model is compared and analyzed. The experimental results show that the training time of the improved prediction model has been shortened by about 73.25%, resulting in a significant improvement in computational efficiency. When the number of iterations is 110, the logarithmic loss function value is 0.208, and the logarithmic loss function value of the improved model is 0.207, with an average loss reduction of 0.4%. In the area comparison under the receiver operating characteristic curve, the pre improved model was 0.7092, and the improved model was 0.7207. Meanwhile, compared to before the improvement, the prediction accuracy of the improved model increased by 1.6%. The data validates that the optimized model has high prediction precision and efficiency, and has certain application potential and commercial value in marketing.

**Keywords**—Click through rate prediction; deep learning; deep neural network; online advertising; marketing

## I. INTRODUCTION

Nowadays, the growth of internet companies has been inseparable from advertising marketing, and Click Through Rate (CTR) prediction remains a key issue in the advertising field. With the continuous improvement of internet commerce and search engines, online advertising has become one of the main ways for businesses to promote and market [1]. With the development of information technology such as the Internet and intelligent terminals, the scale of the domestic advertising industry market has been continuously expanding in the past few years. The consecutive expansion of the advertising industry has driven the sustained growth of internet advertising. In internet marketing, CTR is the ratio of the click numbers on a certain content on a website page to the quantity of times. It shows the level of attention paid to a certain content on a webpage and is taken to measure the attractiveness of advertisements [2]. Based on information such as user behavior attributes and advertising characteristics, a prediction model can be constructed using deep learning methods for advertising CTR prediction [3]. Deep learning

methods have achieved good results in speech and image recognition, and can also reduce manual repetition in the field of advertising CTR prediction, controlling the accuracy and efficiency of advertising production [4]. The advantage of Deep Learning Model (DLM) in automatically extracting higher-order features improves accuracy, but it lacks a certain degree of interpretability compared to manually extracted features [5]. Therefore, this study designed the advertising CTR prediction model of the Deep Neural Network based on Sampling (SDNN), and determined the activation function and the parameter dropout. This article also compares and analyzes the prediction accuracy of four models: Deep Neural Network (DNN), SDNN, DNN trained with dropout, and SDNN trained with dropout. The research aims to improve the operational efficiency of the advertising placement system, so that enterprise marketing can determine more accurate decisions. The research content mainly includes six sections. The second section is a review of the current research status of advertising CTR prediction and deep learning both domestically and internationally. The third section constructs an improved DNN advertising CTR prediction model. Under this, the first sub-section designs an advertising CTR model, and the second sub-section proposes an SDNN advertising CTR prediction model. Section four analyzes the results of the improved DNN advertising CTR prediction model. The fifth section is a discussion on improving the advertising CTR prediction model of DNN. Section six is the conclusion.

## II. RELATED WORKS

The high accuracy of CTR prediction can help advertisers and advertising platforms increase revenue and gain greater benefits. Many researchers have proposed various ideas and methods here. Cai et al. constructed a neural network and global attention mechanism model to precisely forecast the possibility of users clicking on advertisements, achieving interaction between low and high order nonlinear features, while promoting optimization of deep structures. This model has good predictive performance [6]. Xue and other professionals have constructed adaptive hash algorithms and DNN models to reduce redundant features in deep CTR prediction problems. It can automatically select practical features for high-order interaction. This model has good performance, low complexity, and requires less training time [7]. Liu and other scholars proposed an A-CTR-P that combines big data analysis to achieve mobile computing of advertising CTR logs, and used power-law distribution for log preprocessing and category feature extraction. This model has

good prediction accuracy [8]. Zhou's team proposed a model that combines advertising topic distribution network and recurrent neural network to control data transmission for e-commerce product advertising recommendation. This model has high accuracy while reducing computational complexity [9]. To improve advertising profits and promote user experience, Ghorbel et al. built the upper confidence limit and A-CTR-P of GA built on the LSTM network to improve the feature selection of micro targeting technology and optimize hyper-parameter. The accuracy of this method reaches 87%, the precision reaches 89%, and the recall rate reaches 92% [10]. Liu et al. designed a user preference network model for a recommendation system that combines attention for CTR prediction under video recommendation. This model has good predictive performance and solves the time series problem of user feedback information [11].

Deep learning has made good progress in the image and natural language processing, and is widely used in daily life. Hung's team proposed an early warning model that combines machine learning and deep learning algorithms to identify learners at risk in order to analyze student behavior performance. This model captured 59% of high-risk students, with an overall accuracy of 86.8% [12]. Ma et al. built transfer learning and deep learning models for the prediction of residual life transfer of batteries with different formulations to avoid the loss of battery information. It saved testing costs and ensures high temperature robustness, with high prediction accuracy, while optimizing batteries with different formulations [13]. To avoid employee turnover, professionals such as Ozmen EP have constructed a hybrid extended convolutional decision tree model with good classification accuracy based on convolutional neural networks and grid search optimization [14]. Deng and other scholars designed a topology optimization method combining geometric depth learning to elaborate the density distribution function for compliance and pressure constraints. It ensured the boundary smoothness and effectively reduces design variables and controls structural complexity, making it very practical [15]. Hu et al. raised a deep reinforcement learning method driven by curiosity to optimize intelligent and interconnected automotive power control systems to accelerate training speed and achieve a good balance of universality. Under this algorithm, the control behavior rate had been optimized by 50.43%, and the learning productivity had been improved by 74.29% [16]. To optimize the energy efficiency of cooperative spectrum sensing, He H's team has built a high-performance reinforcement learning and deep learning framework for graphical neural networks to promote the improvement of system energy efficiency and spectrum efficiency [17].

In summary, many professionals have conducted research on CTR prediction and deep learning, and applied them to various fields. However, there are still few research results on using deep learning to predict CTR, and this direction has strong potential application value for lifting the accuracy of advertising prediction.

### III. A-CTR-P BASED ON DNN

To rise the advertising prediction accuracy and the operational efficiency of the advertising delivery system,

A-CTR-P is designed to improve DNN, and the activation function and dropout values are determined.

#### A. Construction of A-CTR-P

In today's era, traffic monetization and product promotion depend on advertising. The precise recommendation of advertisements helps to improve user experience and the ability to monetize platform traffic. The key factor in achieving precise recommendations is CTR estimation. The accuracy of CTR estimation affects the decisions of advertisers and advertising platforms regarding advertising placement, thereby determining bids based on user click behavior. When advertising platforms calculate the bidding price of each advertiser, CTR estimation is the core link. The relationship between internet platform users and advertisers is Fig. 1.

Fig. 1. Calculate the tripartite relationship of advertising.

In Fig. 1, internet platforms enhance user experience and increase user stickiness through personalized and precise recommendations. The user's click behavior on the pushed product is used as feedback to promote the optimization of the push product mechanism on various internet platforms. This can increase platform revenue while improving user experience. The data related to CTR prediction comes from the Criteo dataset. 0 means the user without clicking, and 1 indicates that the user clicked. There are 13 numerical features and 26 string features in the data [18]. Before building a prediction model, it is necessary to complete data processing and feature engineering. The data preprocessing process involves descriptive statistics of the overall data, as Fig. 2.

In Fig. 2, first of all, the data is processed separately according to the type in the database, and the string data is characteristic processed, that is, One-hot coding. The data that has been uniquely hot coded will become a high-dimensional sparse matrix [19]. Next, data normalization and descriptive statistics were performed on the processed string and numerical data, and the data was segmented into a test and a training set in a 1:4 ratio. Feature engineering includes feature processing and feature selection. Before establishing a prediction model, the first step is to standardize the features, scale the original data proportionally, and map it to the inter cell range. The expression of the Max Min standardized transformation is Eq. (1).

$$x = \frac{x - x_{\min}}{x_{\max} - x_{\min}} \quad (1)$$

In Eq. (1), after feature processing, the numerical data is uniformly normalized to the range of [0,1] intervals. The technical process of feature selection is Fig. 3.

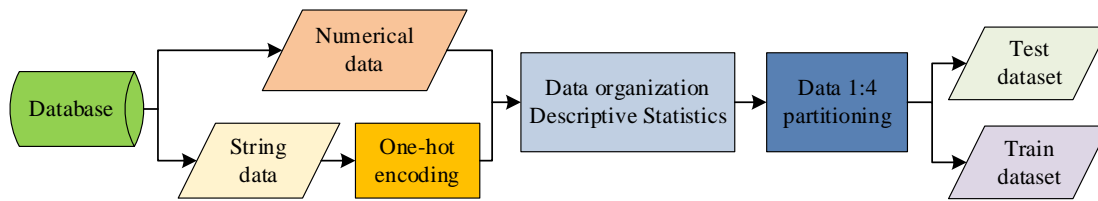

Fig. 2. Data preprocessing flowchart.

Fig. 3. Feature selection technical process.

In Fig. 3, a part of the feature subset is generated from the original feature set, and the optimal feature subset is generated by evaluating the selected subset that meets the criteria. If the criteria are not met, continue selecting in the feature subset. In the process of calculating advertising click logs, there are extremely few cases where users click on the logs, with the vast majority being cases where users have not clicked. There is a problem of category imbalance in CTR prediction. Category imbalance refers to the significant difference in the number of training samples for sample data in classification tasks. To avoid imbalanced class distribution, data sampling uses an under sampling method that removes the number of multiple class samples. The CTR prediction results only have two possibilities: clicking or not clicking, which belongs to the binary classification problem: user clicks are represented by  $y=1$ , and user clicks are represented by  $y=0$ . Table 1 shows the binary confusion matrix on the obtained test set.

TABLE I. DICHOTOMOUS CONFUSION MATRIX

Predictive Value \ True Value	Regular Class ( $y=1$ )	Negative Class ( $y=0$ )
Regular class ( $\hat{y}=1$ )	TP	FN
Negative class ( $\hat{y}=0$ )	FP	TN

TP represents the amount of correctly predicted positive samples. FP is the prediction error numbers for negative examples. FN represents the quantity of prediction errors for active samples. TN refers to the correct negative example amounts predicted. From the confusion matrix, the total evaluation index of the method is Eq. (2).

$$accuracy = \frac{TP + TN}{TP + FN + FP + TN} \quad (2)$$

In Eq. (2), Accuracy, Precision and Recall rate are all used as measurement indicators. Precision is the possibility of true prediction in the positive sample predicted by the model, expressed as follows.

$$Precision = \frac{TP}{TP + FP} \quad (3)$$

The recall rate represents the proportion of all active examples, as expressed in Eq. (4).

$$Recall = \frac{TP}{TP + FN} \quad (4)$$

The ROC indicator is connected with True Positive Rate (TPR) and False Positive Ratio (FPR), where the TPR calculation formula is Eq. (5)

$$TPR = TruePositiveRate = \frac{TP}{TP + FN} \quad (5)$$

The FPR calculation formula is Eq. (6).

$$FPR = FalsePositiveRate = \frac{FP}{FP + TN} \quad (6)$$

TPR and FPR are interdependent, and the larger the TPR and the smaller the FPR, the more superior the classification performance. Logloss index of the logarithmic loss function measures the prediction accuracy of the classifier, and can also be used as the standard of the classification effect, as shown in Eq. (7).

$$\log loss = -\frac{1}{N} \sum_{i=1}^N \sum_{j=1}^M y_{ij} \log(p_{ij}) \quad (7)$$

In Eq. (7),  $N$  is the gross samples, and  $p_{ij}$  represents the predicted CTR of users to advertisements. The logarithmic loss of all samples represents the average logarithmic loss of each sample, and the smaller the value, the better the model performance. The evaluation indicator Area Under Curve (AUC) of the method is expressed as the area enclosed by the coordinate axis under the ROC curve. In terms of CTR prediction, the larger the AUC, the better the training effect. The smaller the Logloss value, the higher the accuracy of the prediction model [20].

### B. DNN-based Prediction of Advertising CTR

On the basis of constructing A-CTR-P, further research is conducted on the use of DNN for CTR prediction. DNN is a multi-layer unsupervised neural network that uses the output features of the previous layer as inputs to the next layer for feature learning. After layer by layer feature mapping, the features of existing spatial samples are mapped to another feature space to learn better feature expression for existing inputs. DNN has multiple nonlinear mapping feature transformations that can fit highly complex functions [21]. The structure is Fig. 4.

Fig. 4. DNN model structure.

In Fig. 4, DNN includes input, hidden and output layers. In CTR prediction, i.e. the binary classification  $\{0,1\}$  problem, the DNN input layer with an L-layer hidden layer is Eq. (8).

$$X = \{X_1, X_2, X_3, \dots, X_n\} \quad (8)$$

$n$  in Eq. (8) means the input quantities. The hidden layer is Eq. (9).

$$h^{(l)} = f(W^{(l)}h^{(l-1)} + b^{(l)}) (\forall l \in 1, 2, 3, \dots, L-1) \quad (9)$$

In Eq. (9),  $h^{(l)}$  represents the input vector of L+1,  $f(\cdot)$  is the activation function.  $W^{(l)}$  represents the weight matrix of L-1.  $b^{(l)}$  is the offset vector of L. The output layer is Eq. (10).

$$y_{pre} = \arg \max_C P(y = C, X; w, b) \quad (10)$$

In Eq. (10),  $X$  represents the input vector, and  $P(y = C, X; w, b)$  represents the probability that the output is equal to  $C$ .  $y_{pre}$  is the output of the final model and the corresponding category  $C$  when  $P(y = C, X; w, b)$  is at its maximum, resulting in category 0 or 1. The key solution  $\{w, b\}$  of DNN model calculation makes the loss function the smallest, and the DNN weight could be trained through Stochastic Gradient Descent (SGD). SGD is an optimization algorithm used to update DNN parameters on a gradient basis. Each iteration will randomly select a small batch of samples to calculate the gradient of the loss function, and use the gradient to update the parameters. This random characteristic makes the algorithm more robust, avoiding getting stuck in local minima, and also accelerates training speed [22]. Random

gradient descent is the average extraction of a small batch of samples  $B = \{x^{(1)}, \dots, x^{(m)}\}$  from the training set.  $m$  is usually a relatively small number. When the amount of data is large, it is necessary to iterate with abundant samples to gain the optimal solution, as expressed in Eq. (11).

$$g = \frac{1}{m} \nabla_{\theta} \sum_{i=1}^m L(x^{(i)}, y^{(i)}, \theta) \quad (11)$$

Eq. (11) uses samples from a small batch of  $B$ . To obtain the minimum cost function and the optimal parameters, the weight update rules used in the training of DNN are Eq. (12).

$$\varpi^{(r+1)} = \varpi^{(r)} - \nabla E(\varpi^r) \quad (12)$$

In Eq. (12),  $\varpi$  is the weight,  $\nabla$  is the gradient, and  $E$  is the error function. The selection of activation function includes Sigmoid and Rectified Linear Unit (Relu). In the sigmoid function, when any input value is  $x$ , the output value is between the intervals (0, 1). When the input value is 0, the output value is 0.5. The sigmoid function can be represented as Eq. (13).

$$f(x) = \frac{1}{1 + \exp(-x)} \quad (13)$$

The Relu function is Eq. (14).

$$g(x) = \max(0, x) \quad (14)$$

The derivative of  $g(x)$  can be obtained from Eq. (14), which can be gained as Eq. (15).

$$g(x) = \begin{cases} 1, & x \geq 0 \\ 0, & x < 0 \end{cases} \quad (15)$$

In Eq. (15), if the input value  $> 0$ , the output is equal to it; If it  $< 0$ , the output = 0. DNN can handle high-dimensional sparse category features, but its ability to learn samples with multiple parameters, longer training time, and fewer categories is limited. SDNN is a research on random undersampling of data based on DNN, in order to improve the noise and imbalance of the data. Random undersampling can improve runtime and solve storage problems by reducing the number of samples. The SDNN structure is listed in Fig. 5.

In Fig. 5, the input numeric data and string data are normalized and heat coded respectively to obtain a normalized numeric matrix and a sparse matrix. The two are connected by a matrix to form training data. The training data will be normalized using resampling techniques. Input the resampled data for deep feature learning of DNN, and then output the predicted value probability and corresponding predicted labels. SDNN is a new method improved in DNN. After normalizing and encoding the input data, a random under sampling process is added to the data, thereby improving the impact of data imbalance on DNN and mining complex association relationships in features. The process framework of the SDNN algorithm is Fig. 6.

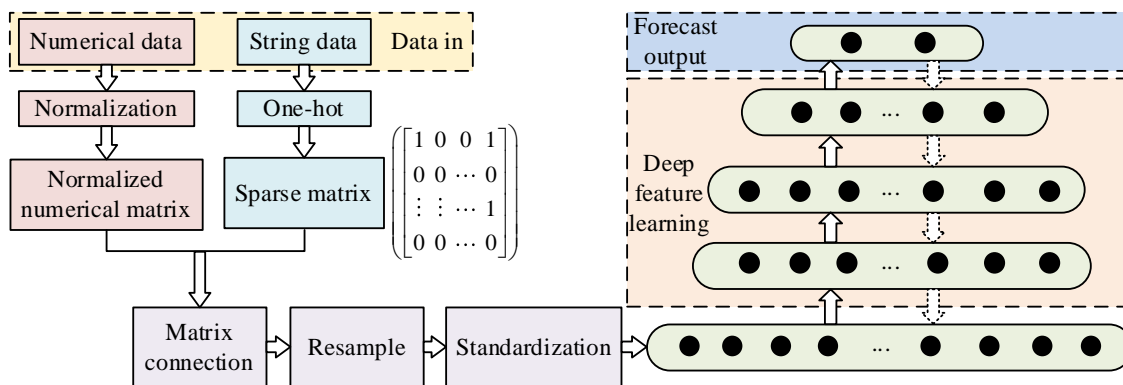

Fig. 5. SDNN structure.

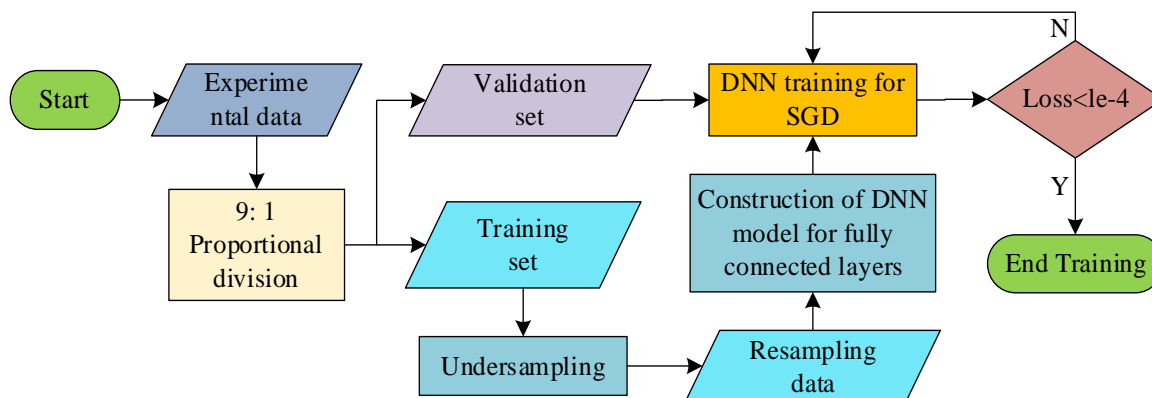

Fig. 6. SDNN algorithm process.

In Fig. 6, the input training data is separated into a training and a validation set in 9:1. Before constructing the DNN, a random under sampling technique is taken to the training set, and then a fully connected DNN is established on the resampled dataset. In training, the loss function on the verification set needs to be calculated. When the number of iterations increases and the loss function no longer changes or changes very little, that is,  $loss < 1e-4$ , the training ends. For parameter issues, the study adopts the dropout technique proposed by Hinton. Dropout can ensure that weight updates no longer rely on the joint action between hidden layer nodes. Overall, the network structure undergoes changes during each DNN training session. The general effect of the final model depends on the synthesis of different model predictions each time.

#### IV. ANALYSIS OF A-CTR-P RESULTS BASED ON DNN

Starting from DNN, to construct a prediction model and first conduct model exploration experiments based on DNN. To comprehensively verify the effectiveness of the DNN, the DNN model and the improved model SDNN were studied and designed. The activation function ReLU and Sigmoid were compared and analyzed, and the key parameter dropout was effectively explored. First, a comparative analysis of the activation function ReLU and Sigmoid is carried out, as listed in Fig. 7.

Fig. 7. ReLU and sigmoid activation function and gradient comparison diagram.

In Fig. 7(a), the input value of the sigmoid activation function is less than 0 and approaches 0, while the output value is greater than 0 and approaches 1. In the process of backpropagation, only when the input is around 0 has good activation. In Fig. 7(b), the sigmoid function makes the neural network better at feature recognition, but generally causes the gradient to disappear within five layers. The ReLU activation function is constant at gradients greater than 0, effectively avoiding the matter of gradient disappearance. The gradient of the ReLU function is relatively stable compared to the sigmoid function, indicating that the AUC value of the ReLU is relatively stable. To study the feature learning ability of hidden layers, the effects of the model structures of ReLU DNN/SDNN and Sigmoid DNN/SDNN on AUC were compared and analyzed, as displayed in Fig. 8.

Fig. 8. Comparison rendering Relu/sigmoid activation function and gradient comparison diagram.

In Fig. 8(a), the AUC values of Sigmoid and Relu are similar when the hidden layers are 2. The AUC curve of Sigmoid DNN gradually deducts as the hidden layers increases. When the hidden layer amounts are 5, the AUC value is the lowest, at 0.5417. The AUC values of Relu DNN are all around 0.70, and the curve is relatively stable. The AUC reaches its peak at 0.7181 when the layers are 3. The AUC of Relu DNN has significantly lifted, and Relu represents the relative stability of the prediction effect. In Fig. 8(b), until the layers are 5, the AUC value of Sigmoid SDNN is the lowest, at 0.5242. The AUC value of Relu SDNN is relatively stable, reaching a peak of 0.7369 when the number of hidden layers is 3. Under the same model structure, the AUC value of SDNN is higher than that of DNN, indicating that DNN random under sampling helps to improve the AUC value. The Relu SDNN model was selected for the study, and the parameter settings are Table II.

TABLE II. DNN PARAMETER SETTINGS

Items	Settings
Model structure	2022-1024-1024-800-2
Objective function	Mean_squared_error
Max-iterations for training	200
Activation function	Relu
Regularizer	L2

To ensure the effectiveness of the algorithm, research was conducted under GPU parallel acceleration. The training time of the DNN model is 277.1801s, and the SDNN is 74.1490s, which is approximately four times that of the SDNN. The training time of SDNN has been reduced by about 73.25%, greatly improving the computational efficiency of DNN. DNN trained on the original data and reduced the data samples by 60% after under sampling. The training scale of SDNN has decreased. However, the reduction of training data did not make the prediction performance of SDNN worse; on the contrary, it also improved the computational efficiency of the algorithm. Considering that the number of network layers and the number of iterations in the training phase of SDNN also have an impact on the prediction results of the model, in order to obtain more reasonable parameter values, the experiment was trained on a training set with a data size of 400000 samples. In the experiment, different network layers and

iterations were selected to obtain the AUC values of the model, as shown in Table III.

TABLE III. AUC VALUES OF THE MODEL UNDER DIFFERENT NETWORK LAYERS AND ITERATIONS

Number of layers	Iterations					
	50	70	90	110	130	150
2	0.8103	0.8213	0.8237	0.8251	0.8248	0.8242
3	0.7821	0.8103	0.8194	0.8215	0.8202	0.8214
4	0.8215	0.8327	0.8392	0.8482	0.8501	0.8503
5	0.7979	0.8267	0.8372	0.8380	0.8376	0.8371
6	0.8064	0.8132	0.8158	0.8263	0.8257	0.8278

In Table III, regardless of the number of iterations, the AUC of the model is the highest when the number of network layers is 4. Regardless of the number of network layers, when the number of iterations is less than 110, the AUC value of the model remains increased. When the number of iterations is 110 or above, the AUC value of the model is relatively stable and does not change much. To determine the values of the key parameter dropout in the DNN model, the study was conducted from 0.2 to 0.9 in steps of 0.1. The impact of adjusting the dropout parameter on the prediction performance of SDNN, as well as the comprehensive comparison of the four models with a dropout of 0.5 is exhibited in Fig. 9.

In Fig. 9(a), as the dropout increases, the AUC curve gradually rises and gradually decreases after reaching its peak. When the dropout is greater than 0.8, the AUC curve sharply decreases. When the dropout is 0.5, AUC reaches its peak at 0.7394. When the dropout is less than 0.8, the AUC curve is relatively stable. Therefore, the parameter dropout value is set to 0.5. In Fig. 9(b), the AUC value of DNN is 0.7092, the AUC value of DNN model trained with dropout is 0.7300, and the AUC value of SDNN is 0.7207. The SDNN model trained with dropout has the highest AUC, which is 0.7394. The AUC value of SDNN has been improved, indicating that resampling can achieve the goal of eliminating data imbalance. Balanced data categories have a certain effect on improving prediction performance. As a result of the large size of the data itself, the SDNN was selected for comparative analysis between the training and the test set. When the dropout parameter is 0.5, the training iteration process of SDNN is Fig. 10.

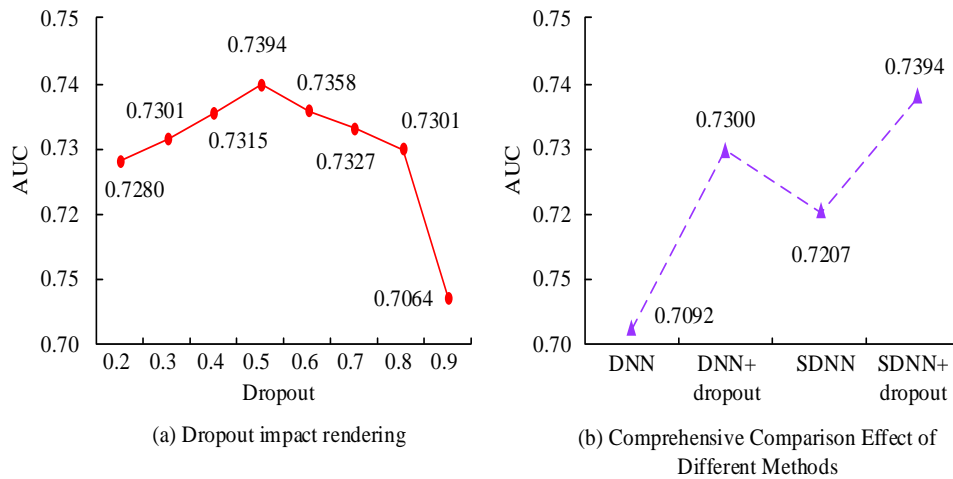

Fig. 9. Comprehensive comparison chart.

Fig. 10. The training iteration process of SDNN.

In Fig. 10(a), when the number of iterations of the SDNN model training set trained with dropout is 200, the loss function curve still shows a downward trend, and the loss function is 0.085. In Fig. 10(b), when the number of iterations of the verification set is the 110th, the loss function converges, and the value of the loss function is 0.201. The number of iterations decreases rapidly before 110, and after 110, the curve oscillates and no longer decreases. SDNN is effectively trained. To evaluate the predictive precision, a comparative analysis was performed on four models: DNN, SDNN, DNN trained with dropout, and SDNN trained with dropout. The AUC and Logloss values of the four methods are listed in Fig. 11.

In Fig. 11(a), the SDNN trained with dropout has the highest average AUC, reaching convergence at 110 iterations with an AUC of 0.7375. The DNN trained with dropout

converges at 130 iterations, with an AUC of 0.7300. SDNN converges at 120 iterations, with an AUC of 0.7260. The average AUC of DNN is the lowest, and it gradually converges when the number of iterations is 140, at which point the AUC is 0.7255. In Fig. 11(b), the Logloss curve of the SDNN trained with dropout converges at 110 iterations, with a Logloss value of 0.201. When the number of iterations is 110, the Logloss value of DNN is 0.208, the Logloss value of SDNN is 0.207, and the Logloss value of DNN trained with dropout is 0.203. At this point, the Logloss value of SDNN decreased by 0.4% compared to DNN. The application effects of the four models in the test training set are represented by ROC curves. At the same time, to compare the relationship between the ROC curves of various models more clearly, the area of curve FPR0.2 to 0.3 is enlarged. The comparison of ROC curves and ROC partial curves of the four models are demonstrated in Fig. 12.

Fig. 11. Comparison of convergence rates under different models.

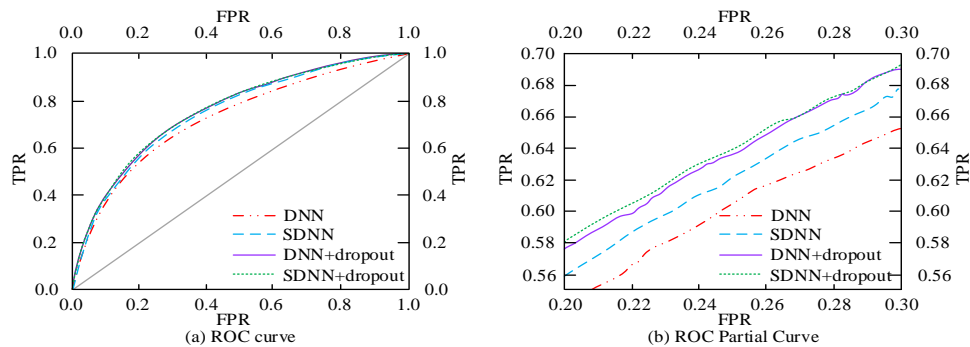

Fig. 12. Comparison between ROC curve and ROC local curve.

In Fig. 12(a), the area under the ROC of DNN is the smallest, at 0.7092, indicating that its AUC is the smallest among the four models. The area under the ROC curve of DNN and SDNN trained with dropout is similar to that of SDNN trained with dropout. In Fig. 12(b), the AUC value of DNN trained with dropout is 0.7300, SDNN trained with dropout is 0.7394, and SDNN is 0.7207. Compared to DNN, SDNN increased AUC by 1.6%. Although the improvement is not significant solely in terms of numerical values, the CTR prediction problem of internet advertising companies involves massive amounts of data every day. Due to the difficulty in estimating costs, any slight increase in AUC value will result in significant advertising effectiveness.

## V. DISCUSSION

The complexity of the model is related to its performance. The higher the complexity of the model, the more accurate the error of the training set at the end of the month, and the resulting model accuracy. However, higher complexity may lead to an increase in the computational workload and training time of the model, leading to an increase in research costs. Therefore, it is necessary to study and select the appropriate number of network structure layers and iterations. The study selects a network layer of 4, iteration number of 110, and parameter dropout value of 0.5. Under these conditions, the model studied can improve the predictive accuracy of advertising placement in a targeted manner, which plays a certain role in making marketing decisions for enterprises.

## VI. CONCLUSION

To improve the prediction accuracy of advertising placement, an improved DNN based A-CTR-P: SDNN was studied and designed, while the activation function and parameter dropout were determined. The prediction accuracy of DNN, DNN trained with dropout, SDNN, and SDNN trained with dropout were compared and analyzed. The results indicate that when the hidden layers have 5, the AUC of Sigmoid DNN is the lowest, at 0.5417. When there are 3 hidden layers, the AUC of Relu DNN reaches its peak at 0.7181, and the AUC is relatively stable at around 0.70. The AUC value of Relu DNN has greatly lifted, and Relu represents the relative stability of the prediction effect. Under the same model structure, the AUC value of SDNN is higher than that of DNN, and the improvement effect of SDNN on DNN is conducive to the improvement of AUC. When the dropout is around 0.5 and the SDNN prediction model training

set has 200 iterations, the loss function curve still maintains a downward trend, at which point the loss function is 0.085. The loss function curve does not decrease until the 110th time of the validation set, at which point the function value is 0.201. When the number of iterations is 110, the Logloss value of DNN is 0.208, and the Logloss value of SDNN is 0.207. At this time, the Logloss value of SDNN decreases by 0.4% compared to DNN. Comparing the ROC curves of DNN and SDNN, the AUC of DNN is 0.7092 and that of SDNN is 0.7207. The prediction accuracy of SDNN is higher than that of DNN, with an increase of 1.6% in AUC. This research result can accurately target users and save the operating costs of the advertising placement system, providing a new direction for advertising companies' marketing and effectively ensuring corporate profits. One of the future research directions is to integrate user social information into advertising CTR prediction models, enrich user information, and improve user expression information. However, due to equipment limitations and limited training data, the advantages of deep learning cannot be fully utilized. So in the future, the amount of training data will be increased so that the model can perform better.

# Design and Development of an Intelligent Rendering System for New Year's Paintings Color Based on B/S Architecture

Zaozao Guo

Faculty of Art, Sustainable and Creative Industry, Sultan Idris Education University, 35900, Perak Darul Ridzuan, Malaysia  
Department of Computer Science, Nankai University Binhai College, Tianjin 300270, China

**Abstract**—With the arrival of the synthetic talent era, laptop technological know-how for the safety and inheritance of intangible cultural heritage has added a new way of thinking, and the range of intangible cultural heritage additionally offers greater chances for laptop technology, the utility of laptop talent science to New Year's Eve artwork of the applicable lookup there are many gaps. Training of Cyclic Generative Adversarial Network (CycleGAN) realize the task of extracting plots of different site types from planar maps and the Rendering generation from planar color block map to color texture map. This paper first introduces the B/S community architecture, Python programming technological know-how and Django framework. Then the unique approach of using pc Genius to the project of rendering Chinese New Year artwork is clarified via modeling, studying algorithms, and community architecture. Finally, a hierarchical fusion generative adversarial neural community structure is designed primarily based on generative adversarial neural networks. The structural and textural features of the image are fused by texture GAN and then rendered to generate the New Year paintings. The test results show that this kind of algorithm draws clear texture, realistic images and full color of the New Year's pictures, and the IS index reaches 3.16 in the quantitative analysis, which is higher than other comparison algorithms.

**Keywords**—B/S architecture; intelligent rendering; adversarial neural network; Chinese New Year painting

## I. INTRODUCTION

There are two essential standard approaches to instructing painting: one is the way of offline teaching, and the different is the way of online video teaching. Offline introduction is an expert instructor and college students face-to-face teaching; this offline coaching is the most common way of educating artwork education [1-3]. The online video instructing technique is that the instructor documents the video in advance, and then the college students pay to get the instructing video. The two present regular portray teaching strategies have the following disadvantages.

1) *Offline* teaching methods of one-on-one teaching is the teacher to meet the requirements of the students at the designated location of the class; this class is expensive; if it is a one-to-many teaching mode, although the cost can be relatively reduced, the teaching effect cannot be guaranteed;

2) *The* relevant video teaching method is the teacher to meet the requirements of the students to the designated location of the class.

3) *Fewer* relevant professional teachers, but the market demand, resulting in several students still in the school stage for unregulated training courses, resulting in uneven teaching levels.

4) *Teachers* and students offline teaching methods by space, time limitations, teachers and students or student's parents must be based on the designated time to the designated place of class teaching.

5) *The* traditional video teaching method is usually that the teacher records the video in advance, and then the students watch the video to learn. This teaching method lacks interaction between the teacher and the students and is passive.

Painting is one of the oldest types of art, and its content material has advanced all through human records and exclusive cultures. In modern times, with the popularization of electronic information technology, all kinds of electronic drawing board software and hardware have gradually become the main tools for people to create paintings, such as Adobe's Photoshop, Apple's iPad, Apple Pencil, etc., and the digital form of photographs produced by them have been widely used in various aspects of production and life, such as news dissemination, prototyping, film and television creation, etc. In general, portraying wholly demonstrates human nature, and it is the essential painting shape, focusing on realism. In general, representation wholly shows human knowledge and creativity and is a critical potential in visible conversation for humans regardless of its shape and tools. In the modern-day community era, the digital shape of portray can be very handy to disseminate and use, is one of the major types of contemporary media, and consequently, has a very realistic fee and realistic significance [4, 5].

The main manifestation of program communication, the canonical representation of the floor plan with the advancement of AI technology, the design drawing and high-quality rendering based on the design is crucial for the design presentation [4]. Therefore, machine learning (Machine Learning) of the setup data makes it possible for Artificial Intelligence Aided Design (Artificial Intelligence Aided planner often spends a lot of time to collect plan cases that can

be drawn from, Design, AIAD), which, Deep Learning and rendering of the floor plan using a variety of software. At present, computer vision (Deep Learning) has been in the design of image analysis and generation of consciousness (Computer Vision) in the field of image recognition; generation technology shows great potential for application. In recent years, in architecture and graphic arts has been more mature, so that AI recognition case plane and rendering cartography design field, professional image data sets and deep learning applications do not become possible. And the realization of this automated analysis and mapping of the front break emerges, designers rely on interdisciplinary cooperation to develop AIAD field mentioning is a high-quality landscape garden floor plan training set. Unlike common face or object image databases, Landscape Architecture Flat View to improve the efficiency of design analysis and mapping. And landscape architecture discipline to carry out this type of research limitations mainly from the interdisciplinary cooperation and the number of face database has outstanding professionalism: 1) the variety of land types: the lack of data sets. 2) drawing expression both normative and artistic; 3) access to the threshold of the image is to present the design scheme is an important carrier of the Landscape Garden high, the need for professionals to carry out careful screening and data annotation Lin design floor plan is the designer case to draw upon, Concept presentation and Data Labeling.

Artificial intelligence is an important engine for future economic development, and machine learning technology is a major research field of artificial intelligence; the current machine learning technology, according to the different learning modes, is roughly divided into three categories: supervised learning, unsupervised learning and reinforcement learning. Supervised gaining knowledge is a studying technique that depends on statistics labeling, primarily the use of statistics labeling statistics to supervise the coaching model and then using the dummy to predict the new data, in general, used in classification, regression and different tasks [6]. In general, supervised and unsupervised learning focus on the perception and understanding of data; in contrast,

As shown in Fig. 1, the overall architecture of Python can be divided into three parts: Python module libraries, commonly used standard libraries and runtime environments. For the commonly used syntax standard libraries of Python, (see Table I).

TABLE I. COMMON SYNTAX STANDARD LIBRARY OF PYTHON

Grammar Library	Related Explanations
atexit	Functions that are allowed to be called when the program exits
argparse	A function that parses a command run
bisect	Providing a binary lookup algorithm for sorted lists
calendar	Date-related functions
codecs	Functions related to coding and decoding data
collections	Useful data structures
copy	Functions for copying data

reinforcement learning methods not only realize the perception and understanding of data but also focus on generating intelligent decisions and actions according to the task goals, which can realize more complex functions and become a hot research topic in recent years.

## II. RELEVANT THEORIES AND TECHNOLOGIES

Technology is the basis for realizing various functions. In building a platform for processing and analyzing painting images, some important theoretical techniques provide important support for the platform's design. This paper adopts the Python+Django technology framework for design and uses PyCharm for design and debugging. The B/S architecture is used for system design to facilitate subsequent upgrading and maintenance [7, 8]. Before introducing the platform, the theoretical technologies involved are first introduced and summarized.

### A. Python Technology

Python is a high-level and broadly used programming language. It has the benefits of excessive efficiency, low overhead, open source, portability, sturdy interpretability, etc., and has been preferred to utilize builders quickly. Python's fusion of several algorithmic programs determines that it can play a necessary position in unique fields. The general architecture of Python's distribution of functions is shown in Fig. 1 as follows:

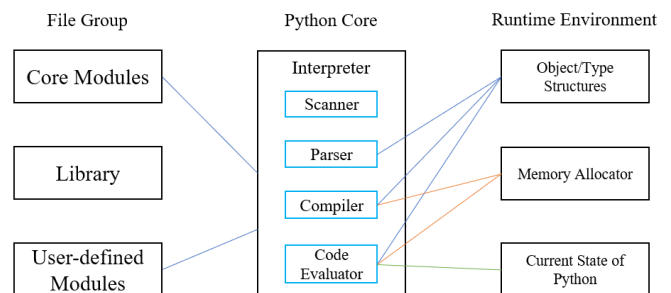

Fig. 1. Python overall architecture diagram.

### B. Cornerstone Image Support Technology

Cornerstone.js is a medical image viewing tool written in Js script to support the display and interaction of medical images. As its name suggests, it has a “cornerstone” role in the image display field, and many image reading systems for artistic paintings are based on Cornerstone.js. Rich scripts provide powerful technical support for browsing image data. Basic operations such as zooming and panning of image data can be realized.

Currently, most home portray exhibition structures mixed with AI are also developed primarily based on Cornerstone.js. The Internet web page multi-threaded decoding used in this script quickens the show of snapshots and helps the Internet to practice compression strategies such as JPEG to transmit images. Modularity (component design) allows it to be embedded in extraordinary front-end frameworks for convenient invocation through developers. As proven in the following code, it can recognize the show of DICOM portray images [9, 10].

```
const
element=document.getElementById('demo-element');
const imageUrl='http://example.url.com/image.dcm?';
cornerstone.enable(element);
cornerstone.loadAndCacheImage(imageId).then(function(i
```

```
mage){
cornerstone.displayImage(element,image);
cornerstoneTools.mouseInput.enable(element);
```

The flow when Cornerstone performs image display is shown in Fig. 2.

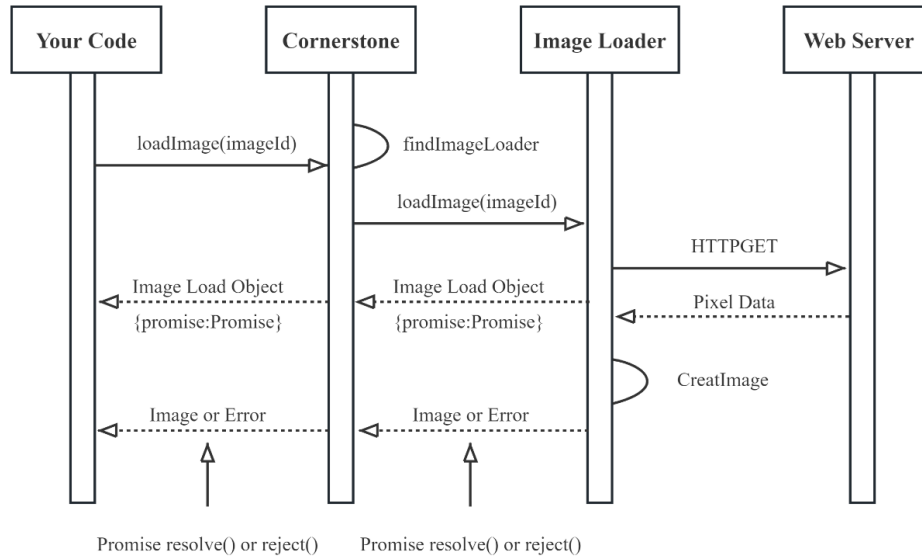

Fig. 2. Cornerstone flowchart.

C. Web Framework Technology

Web framework technological know-how is a disbursed utility software architecture, which is ordinarily divided into two foremost parts: client-side and server-side. The customer aspect frequently includes Html language, script program, CSS style, plug-in technological know-how and so on [11].

Each element on the “active” page has a variety of labels. web server development technology is also from static to dynamic gradual development, gradually being perfected. Server-side technologies include servers, CGI, ASP, Servlet and JSP technologies [12, 13]. Fig. 3 shows the Web application processing flowchart.

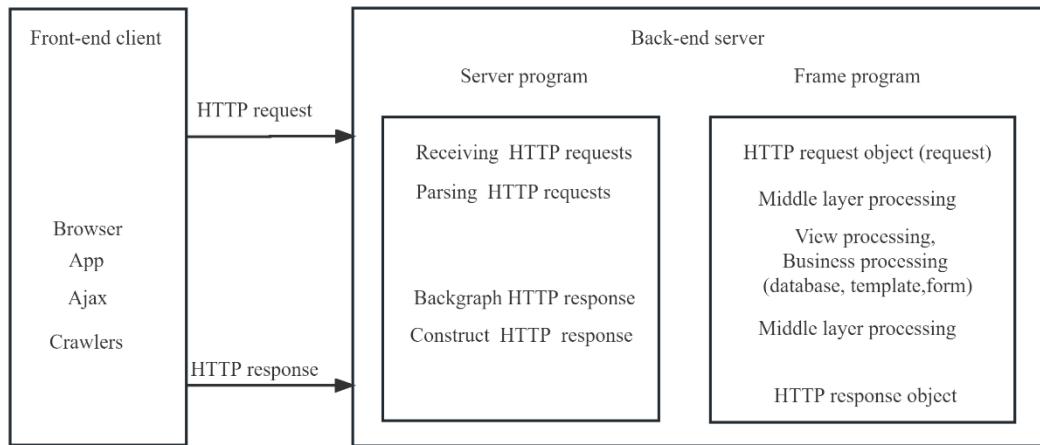

Fig. 3. Web application processing flow chart.

Web technology is more in line with the current technical requirements and is an important direction for the future development of network architecture. Therefore, this paper adopts the B/S architecture model that satisfies Web technology for the research and development of image processing systems [13].

D. MVT Framework

Generally, in improving the project, it is fundamental to first classify the functions, a massive piece of the task damaged down into many small tasks, and as a way as viable to comprehend the low coupling of the range of modules to beautify the scalability and portability.

MVC's full spelling for Model-View-Controller, after continuous development and integration, the idea of MVC has been applied to Web development. It plays an important role, known as Web MVC framework. In MVC, M is model (business logic layer), V is view (interface layer), C is controller (controller), used to schedule View layer and Model layer.

Python language Django framework uses the MVT architecture pattern. In Django for web development, this framework also follows the MVC idea. However, in Django, this architecture is called MVT, but the essence of the MVC pattern is the same.

The operational logic between the three MVTs is shown in the following Fig. 4.

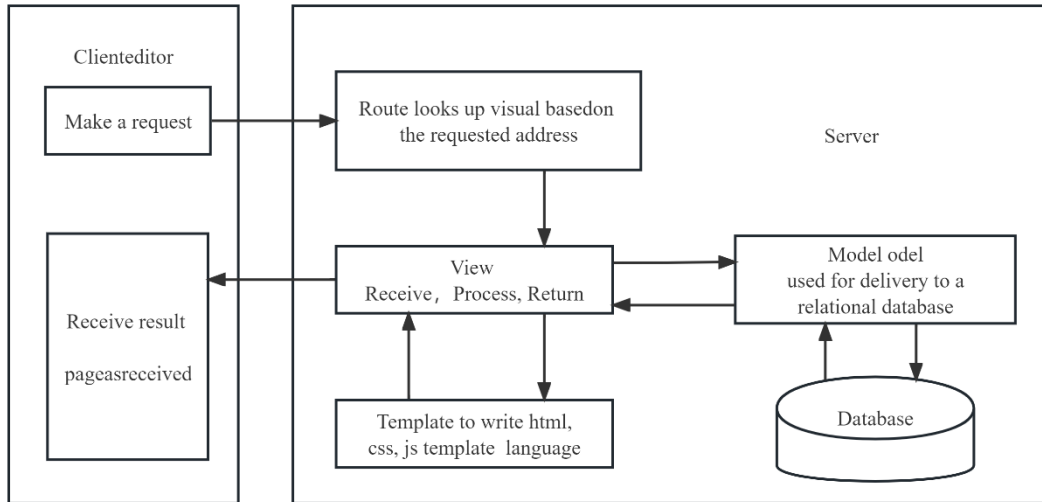

Fig. 4. MVT operation logic diagram.

Various supporting technologies are indispensable in the design and development, and the intermingling of different technologies lays a cornerstone foundation for the design and development of the platform [14]. Coordinating the different technologies to achieve the desired effect is an important and complex process. The role of different technologies are skillfully combined, in line with the needs of the current form of social development, to provide the necessary technical support for the exchange and integration of different fields.

#### E. Architecture Mode

The b/s structure is a famous community shape mode after the upward job of the Web. b/s shape comprises the show, characteristic, and statistics layers. This mannequin unifies the patron and centralizes the core implementation of the device on the server side, simplifying improvement and maintenance [15,16]. The statistics layer strategies and calculates the request based on the user's conduct.

The network structure of the b/s model is shown in the following Fig. 5.

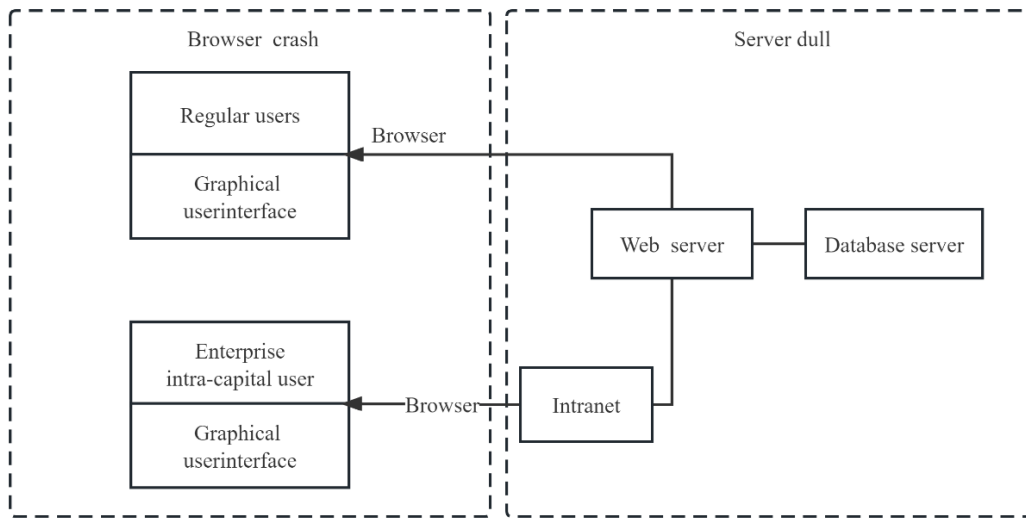

Fig. 5. Schematic diagram of the b/s architecture network structure.

The final processed page information or data is returned to the browser, and the browser displays the results to the browser by rendering the information returned by the server. The page information or data is returned to the browser, and the browser, by rendering the information returned by the server to display the results on the page [17].

Compared with the c/s model, the b/s model has more prominent advantages and is, therefore, more popular.

1) *Easy maintenance and upgrading*: In the common c/s model, upgrading the gadget requires upgrading each the customer and the server. After upgrading the software, every consumer desires to improve his/her purchaser to use it. If widely widespread improvements are required, the work of gadget directors in retaining the gadget will be very time-consuming and poorly maintained. But b/s structure solely wants to focus on upgrading the machine saved on the server can be, all the purchasers, that is, the browser, do no longer want to do any maintenance.

2) *Superior performance*: With the development of the Web, b/s architecture is widely used, but also promotes the development of Ajax technology, which makes part of the data processing in the client can be carried out, greatly reducing the burden on the Web server, and can realize the page local real-time refreshing, improve the interactive performance of the page.

3) *Low development costs, more options*: Software development based on b/s architecture generally only needs to be installed on a Linux server, so there are many choices of servers and high security. The Linux operating system and the database's connection are free, so this not only greatly reduce the cost of software development but also many choices.

4) *High reusability*: The c/s architecture of the program needs to consider the whole software design from the whole; when there is a problem, or the system needs to be upgraded

and changed, it may need to be redesigned to make a completely new system. Software with b/s architecture can be largely divided into different components by functional modules to achieve high reusability.

When the software is changed from c/s architecture to b/s architecture, the system software no longer needs the developers to specialize in the development of the client software. Still, it only needs to focus on the update of the program to free up the labor force [18]. At the same time, the use of the browser as a client, the development of a more friendly interface, while the newly developed system does not require users to learn from scratch, greatly reduces the user's learning costs.

### III. REINFORCEMENT LEARNING BASED STROKE PAINTING SIMULATION

#### A. Model-based DDPG Algorithm

Fig. 6 shows the general framework of the algorithm, which is generally a Model-based Deep Deterministic Policy Gradient (Model-based DDPG). At the core of the framework is a drawing intelligence, whose goal is to decompose a given target image into a number of strokes, and let these strokes reconstruct the target image on the drawing board by means of a renderer, which is "model-based" in the sense that it utilizes the explicit model of a discriminator and a neural renderer [19, 20]. In order to simulate the human drawing process, this paper will use a sequential Markov decision process to model it: in the inference phase, the intelligent body decides the control parameters (i.e., actions) for the next stroke in each step based on the observed target image and the current state of the drawing board, and the renderer receives the control parameters and draws the strokes on the drawing board; in the training phase, the training samples are randomly sampled from the empirical recall cache, and then the discriminators and neural renderers are used to reconstruct the target image with the strokes [21].

Fig. 6. The general framework of the algorithm (left, inference phase; right, training phase).

#### B. Neural Renderer

1) *Task definition*: In the reinforcement learning drawing simulation framework, the task of the neural renderer is to

render the input stroke control parameters (i.e., the action produced by the drawing intelligences) into a rasterized image of the stroke, which is then added to the current drawing

board. Specifically, neural renderers are used for three reasons.

a) Due to the differentiable nature of the neural renderer, the errors of the strokes can be back-propagated through the renderer, which is crucial for the model-based DDPG algorithm used in this paper;

b) The neural renderer can be trained by a supervised learning algorithm to mimic a real renderer rendering strokes. In this way, existing real renderers can be used to train the neural renderer, avoiding repetitive manual design [22, 23].

2) *Learning algorithm:* In this paper, we use the supervised learning method to train the neural renderer. For each stroke, suppose the corresponding stroke renderer is  $R_{GT}$ , the learning goal of the neural renderer R is to hope that for any drawing board state C and stroke control parameter a,

its rendering result is as similar as possible to  $R_{GT}$ , and ideally, the two are equal, i.e. (as shown in Fig. 7).

$$R(C, a) = R_{GT}(C, a) \quad (1)$$

For the rendering process designed in this paper, the output  $S_t$   $a_t$  of the neural renderer subject network is independent of the drawing board state, taking into account that different strokes have different degrees of prominence in different board states (e.g., black strokes are almost invisible in the black drawing board, while very obvious in the white drawing board). Therefore, during the training process, this paper defines two standard states for the board,  $C_B$ ,  $C_W$ , which denote the empty boards of pure black and pure white, respectively, and then measures the gap in rendering results using the  $L_2$  distance, and ultimately constructs the objective function of the learning as,

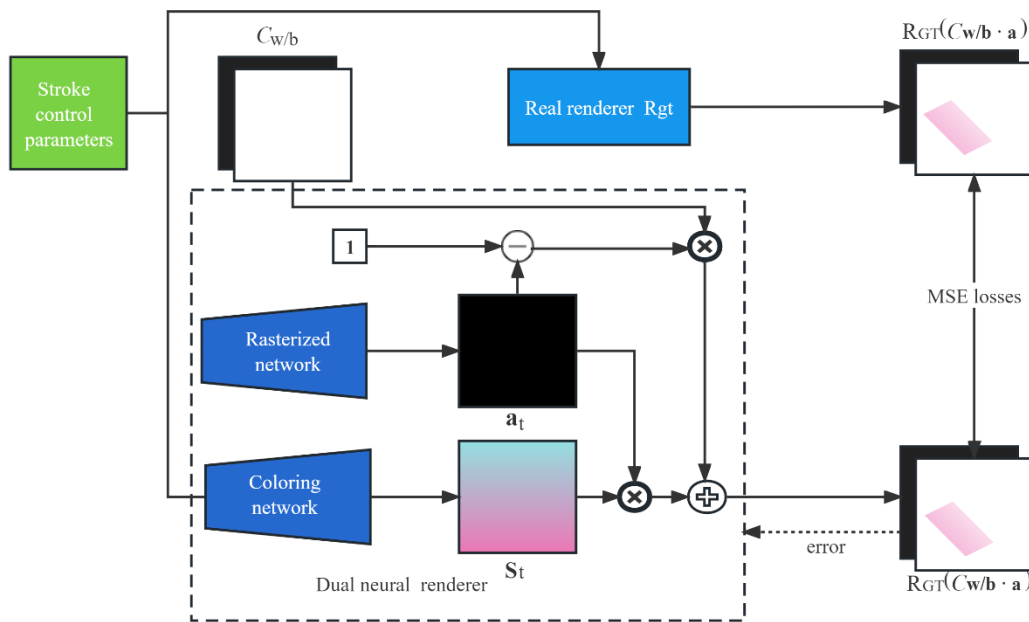

Fig. 7. Neural renderer training approach.

$$J(\mathbf{W}^R) = \mathbb{E}_{a \sim U(A)} \left[ |R(C_B, a) - R_{GT}(C_B, a)|^2 + |R(C_W, a) - R_{GT}(C_W, a)|^2 \right] \quad (2)$$

Where  $\mathbf{W}^R$  denotes the parameters of the neural renderer,  $U(A)$  denotes the uniform distribution defined on the stroke control parameter space A. The learning process of the neural renderer is to minimize the objective function.

$$\min_{\mathbf{w}} J(\mathbf{W}^R) \quad (3)$$

In practice, this paper uses a stochastic gradient descent algorithm to solve this optimization problem and complete the training of the neural renderer. As in Fig. 7, the sampled stroke control parameters will be sent to the real renderer  $R_{GT}$ ,

which renders the stroke on the blank drawing board  $C_{W/B}$  with the result  $R_{GT}(C_W, a)$ , and the neural renderer synthesizes the  $S_t$ ,  $a_t$  internally according to the same control parameters, and then obtains the rendering result  $R_{GT}(C_W, a)$  according to Eq. 3, and finally calculates the  $L_2$  of the two results distance (i.e., MSE loss) to update the network parameters of the neural renderer.

3) *Network structure:* The neural renderer in this paper uses a two-way architecture divided into a shading network and a rasterization network. The shading network is used to output the stroke image  $S_t$ , whose input is the complete stroke control parameters, and the network consists of six layers of inverse convolutional layers. The rasterization network is used to output the transparency image  $a_t$ , whose

input is the part of the stroke control parameter that does not contain color, and the network consists of four fully-connected layers and three Shuffle convolutional layers.

### C. Stroke Translator

1) *Task definition:* The undertaking of the stroke translator is to translate the managed parameters of one variety of strokes into these of any other by means of the capacity of a neural network so that the rendering consequences of the two sorts of strokes are as visually comparable as possible [24]. After the intelligent body has been trained to master one type of stroke, the control parameters of the stroke generated by the intelligent body during the painting process can be collected and then converted into the control parameters of another type of stroke using a stroke translator, and finally rendered by a renderer to obtain the painting results of another type of stroke. In this way, the painting results of multiple styles of strokes can be obtained with less time and computational resources [25, 26]. Let the control parameter of the source stroke A be  $a_A \in A_A$  and the control parameter of the target stroke B be  $a_B \in A_B$ ; the translator  $T_{AB}$  translates the source stroke into the target stroke, i.e.

$$a_B = T_{AB}(a_A; \mathbf{W}^T) \quad (4)$$

Where  $\mathbf{W}^T$  denotes the parameters of the translator.

2) *Learning algorithm:* In this paper, we use a supervised learning method to train a stroke translator. Assuming that the renderer of the source stroke A is  $R_{GT}^A$  and the renderer of the target stroke B is  $R^B$ , where  $R^B$  is a neural renderer, the learning goal of the translator is to hope that for any source stroke  $a_A \in A_A$  and any drawing-board state C, the renderer is able to find a corresponding target stroke  $T_{AB}(a_A; \mathbf{W}^T) \in A_B$  so that the rendering results of the two strokes  $R_{GT}^A(C, a_A)$  and  $R^B(C, T_{AB}(a_A))$  are as similar as possible visually. For this, this paper defines two standard drawing board states,  $C_B$ , and  $C_W$ , which denote pure black and pure white empty drawing boards, respectively, and then measures the gap between the rendering results using the  $L_2$  distance and finally constructs the learned objective function as,

$$J(\mathbf{W}^T) = E_{a_A \sim U(A_A)} \left[ \begin{aligned} & \left| R^B(C_B, T_{AB}(a_A; \mathbf{W}^T)) - R_{GT}^A(C_B, a_A) \right|^2 \\ & + \left| R^B(C_W, T_{AB}(a_A; \mathbf{W}^T)) - R_{GT}^A(C_W, a_A) \right|^2 \end{aligned} \right] \quad (5)$$

Where  $U(A_A)$  denotes the uniform distribution defined on the stroke control parameter space  $A_A$ , and the learning process of the translator is to minimize the objective function, i.e.

$$\min_{\mathbf{W}^T} J(\mathbf{W}^T) \quad (6)$$

Due to the differentiable property of the neural renderer  $R^B$ , this optimization problem is solved by stochastic gradient descent algorithm in this paper to complete the training of the stroke translator. For the sampled control parameter  $a_A$ , the corresponding neural renderer  $R_{GT}^A$  is first used to render the stroke  $R_{GT}^A(C_{W/B}, a_A)$  on a blank drawing board  $C_{B/W}$ , then the control parameter  $a_A$  is converted to  $a_B$  by the translator  $T_{AB}$ , and then the renderer  $R^B$  is used to obtain the rendering result  $R^B(C_{W/B}, T_{AB}(a_A; \mathbf{W}^T))$ , and finally calculate the  $L_2$  distance (i.e., MSE loss) of the two results to update the network parameters of the translator [27].

3) *Network structure:* Since the translation process of the two-stroke control parameters is equivalent to completing a kind of mapping, this paper adopts a four-layer fully-connected network to construct the stroke translator, the size of the input layer is the number of control parameters of the source stroke, and the size of the output layer is the number of control parameters of the target stroke.

## IV. DESIGN OF INTELLIGENT RENDERING GENERATION ALGORITHM BASED ON IMAGE TEXTURE

At present, although it is possible to render images, the processing of image details and textures is not satisfactory. In order to solve this problem, an intelligent painting generation algorithm based on image texture drawing technique is proposed and a hierarchical fusion generation countermeasure neural network is constructed. It renders the image using structural GAN and texture GAN, which further generates the texture details of the image and makes the image clearer and more realistic.

### A. Generative Adversarial Neural Network

Generative Adversarial Networks (GAN) is a new kind of deep generative mannequin proposed by using Goodfellow et al. It has been effectively utilized to picture generation, video generation, picture fashion migration and picture complementation and different scenarios.

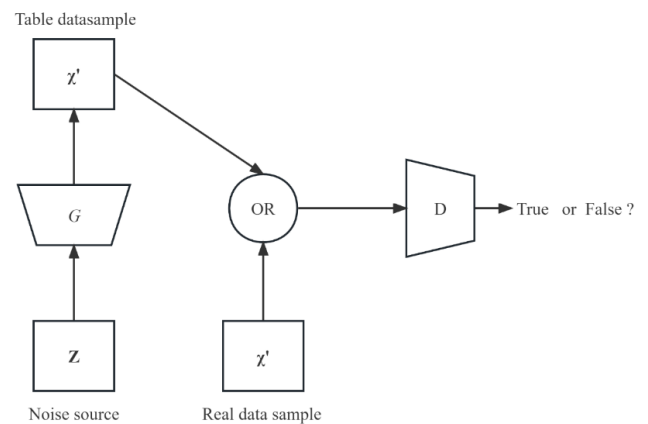

Fig. 8. Schematic diagram of GAN structure.

The generative adversarial community is stimulated via the zero-sum sport in recreation theory, which regards the trouble of producing sport statistics as a disagreement and sport between two networks, the discriminator and the generator. The position of the generator is to synthesize statistics in a given uniformly dispensed noise or generally dispensed noise [28, 29]. The two networks are trained, improved in the confrontation, and then continue the confrontation after repeated confrontations to obtain progress so that the generated data is constantly close to the real data until it cannot be distinguished from the real data so that the desired data content can be obtained. The principle of the GAN structure is shown in Fig. 8.

Definition G is a network to generate images, which can be called a generator, and z represents a random noise through the noise generated by the image can be recorded as G(z). D is a discriminative network, also known as a discriminator, whose role is to distinguish whether the noise generated by the image is real. If x represents an image, when the input parameter value x, the output D(x) represents the probability value that this image is a real image. When the value is equal to 1, it means that x must be a real image; and when the value is 0, it means that the image x is not a real image. During the training process, the generator and the discriminator play with each other; the mathematical relationship between the two can be expressed as follows:

$$\min_G \max_D V(D, G) = E_{x \sim p_{data}(x)} [\ln D(x)] + E_{z \sim p_z(z)} [\ln(1 - D(G(z)))] \quad (7)$$

Where E is the probability function, x is the real data, z is the noise,  $p_{data}(x)$  denotes the distribution of the real data set,

D() denotes the discriminator,  $p_z(z)$  denotes the defined a priori noise, and G() denotes the generator.  $D(G(z))$  characterizes the probability of the D network to judge whether the image generated by G is real or not, and G, in order to make the image it generates converge as much as possible to the real image, needs to deceive the D network. G, in order to make the image generated by itself as close as possible to the real image, it needs to deceive the D network. Given any function D and G, there is a unique solution, and when G can generate a false image  $G(z)$ , the value of  $D(G(z))$  is always 0.5. As a result, the overall model can reach the global optimal state. In practice, it is found that maximizing  $\ln D(G(z))$  is better than minimizing  $\ln(1 - D(G(z)))$ .

Unlike typical coaching models, GAN implements two exclusive networks and an adversarial education method. It makes use of the returned propagation mechanism, in which a clearer and greater sensible pattern can be synthesized besides the complicated Markov Chain, and the computation is surprisingly simple Model Design

1) *Model architecture:* The paper proposes to generate an adversarial neural network based on the hierarchical fusion of image structure and texture to realize the intelligent generation of painting images so as to assist the creators to create better works. Its main model architecture is shown in Fig. 9

The sketches drawn are first fed into the system model for normalization preprocessing to ensure that the image conforms to the model.

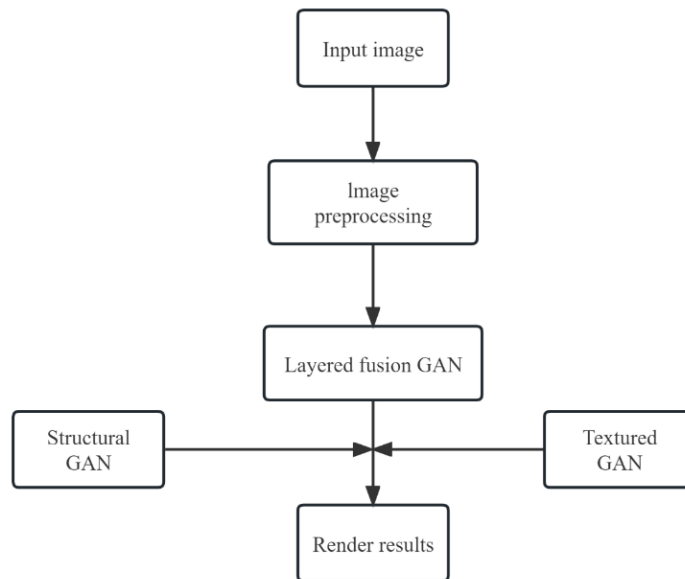

Fig. 9. The model architecture of the paper.

2) *Structural GAN:* The input of the generative network G is collected from uniformly distributed noise, and the output is

a structural line drawing. A 100-dimensional vector is used to represent the input noise z, and the size of the output image is

72×72×3. The discriminative network D will classify the generated structural line drawings based on the real images obtained from deep learning. The generative network adopts a 10-layer model and performs convolutional operations after passing through the fully connected layers to finally generate the structural line drawings. In the setup, batch normalization is used in each layer, and the ReLU activation function is used except for the last layer, which uses the Tanh activation function [30].

3) *Texture GAN*: The generated network is modified as a conditional GAN, that is, the conditional information is used as additional input for generator G and discriminator D. As an addition to discriminator D, the structure line map not only makes the generated image more real after input, but also requires the generated image to match the structure line map to ensure its controllability. When training the discriminator, only the real image and its corresponding structural line drawings are considered as positive examples, so that a higher resolution 128×128×3 image can be generated by texture GAN.

For example, if the image  $x=(x_1, \dots, x_M)$ , its corresponding structural line drawing is  $C=(C_1, \dots, C_M)$ , and the uniformly distributed noise is  $\hat{z}=(\hat{z}_1, \dots, \hat{z}_M)$ , the generating function can be changed from  $G(\hat{z}_i)$  to  $G(C_i, \hat{z}_i)$ , and the discriminative function can be changed from  $D(x_i)$  to  $D(C_i, x_i)$  losses of the discriminative network can be rewritten as follows, respectively.

$$L_{\text{cond}}^G(C, \hat{z}) = \sum_{i=M/2+1}^M L(D(C_i, G(C_i, \hat{z}_i)), 1) \quad (8)$$

$$L_{\text{cond}}^D(X, C, \hat{z}) = \sum_{i=1}^{M/2} L(D(C_i, x_i), 1) + \sum_{i=M/2+1}^M L(D(C_i, G(C_i, \hat{z}_i)), 0) \quad (9)$$

In the generator network architecture, a 128×128×3 textured line graph and 100-dimensional vector noise  $\hat{z}$  are taken as inputs to the network. The inputs to the network are the structured lines and the concatenation of images. The two will first go into the convolutional layer and the inverse convolutional layer, respectively, and then merge to form the 32×32×192 feature maps and further perform seven layers of convolution and inverse convolution on the top of these feature maps. The final output is a 128×128×3 image.

4) *Joint model*: The discriminator in the texture GAN treats the generated pattern line drawings and images as negative samples and the real structure line drawings and real images as positive samples [31]. As a result, the generator network loss function of the structural GAN can be expressed as follows:

$$L_{\text{joint}}^G(\hat{z}, \tilde{z}) = L^G(\hat{z}) + \lambda \cdot L_{\text{cond}}^G(G(\hat{z}), \tilde{z}) \quad (10)$$

Where  $\hat{z}$  and  $\tilde{z}$  represent two sets of uniformly distributed samples in structural GAN and texture GAN, respectively. The first term on the right side of the equation represents the adversarial loss of the structural GAN discriminator, and the second term on the right side of the equation represents the loss of the texture GAN.  $\lambda$  is a hyperparameter, and its value is set to 0.1 in this experiment, which is smaller than the learning rate of the texture GAN, so as to avoid the occurrence of the overfitting situation.

## B. Test Results and Analysis

1) *Experimental environment*: The experimental environment is Python 3.6, the processor is i7-6800k, the memory is 32 GB, the graphics card is GTX2080Ti, the operating system is Linux, and the experiment is based on the open-source deep learning framework PyTorch for simulation [32].

The experiments were optimized using Adam optimizer, where the momentum term  $\beta=0.5$ ,  $\beta_2=0.999$ , and the batch size M is 128, and the inputs and outputs of all the networks are scaled to [-1, 1]. The learning rate of both structural GAN and texture GAN is set to 0.0002. In joint learning, the learning rate of texture GAN is set to  $10^{-6}$ , and the learning rate of structural GAN is set to  $10^{-7}$ . In addition, the rest of the parameter settings are designed according to the parameters of the experiments in DCGANI.

2) *Experimental parameter settings*: All algorithms involving stochastic gradient descent in this paper were trained using the Adam optimizer. The neural renderer and translator learning rates are updated using an exponential update strategy every 100 Epochs, and the reinforcement learning uses a manual method to update the learning rates. The dimensions of both the drawing board and the target image are set to  $H \times W \times 3 = 128 \times 128 \times 3$ . Noting that the limited number of steps for the drawing intelligences is 40 and the size of the action combination is 5, which corresponds to a total number of strokes of  $40 \times 5 = 200$ .

3) *Experimental results*: It can be found that after the fusion of the generative adversarial neural network, the final image is more realistic in texture and does not change the original object that the painter is trying to depict, so the model works well.

In Fig. 10, as can be seen from the figure, according to the training method proposed in this paper, the model can converge to a stable value within 140 Epochs, which indicates the feasibility of the training method proposed in this paper. For different strokes, the neural renderer converges to different values: the point-like texture of chalk strokes is more complex, which is difficult for the neural renderer to learn. Watercolor strokes and oil strokes are relatively simple, and thus converge to higher precision, but due to the difficulty in learning the texture of the details of the oil strokes, the convergence precision is relatively low. This may be due to the fact that the strokes are relatively “light,” and thus, the absolute value of the noise is small, resulting in a high PSNR value.

Fig. 10. Stroke renderer training content.

The translator is further applied to the reinforcement learning drawing simulation framework to translate the stroke control parameters generated by the intelligent body, and the drawing results of different stroke styles can be obtained.

Overall, the translated drawing results can basically maintain the content of the original results, but the details may be lost, and the differences between different strokes are huge, as shown in Fig. 11.

Fig. 11. Stroke translator training process.

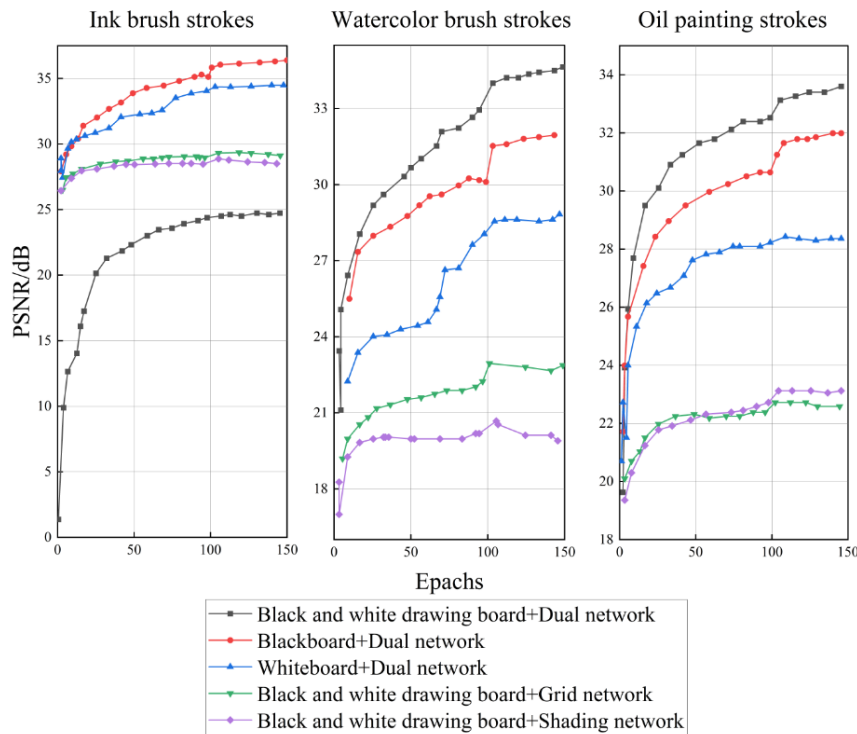

Fig. 12. Neural renderer ablation experiments.

In the case of training using black and white panels, neither the rasterization network nor the coloring network alone can achieve the best results, illustrating the effectiveness of the two-way network. In the case of using the two-way network, neither the black drawing board alone nor the white drawing board alone can achieve the best results, illustrating the effectiveness of the training method proposed in this paper (as shown in Fig. 12).

4) *Experimental analysis and comparison*: The paper also quantitatively analyzes the generated images and evaluates the

quality of the generated images by the international common evaluation index IS. The larger the value of IS, the higher the quality of the generated images and the more realistic the effect, which mainly examines two aspects of the image performance: 1) whether the generated images are clear or not; 2) whether the generated images are varied or not.

In GAN, the conditional probability  $p(y|x)$  is usually expected to be highly predictable. Where  $x$  denotes a given image, and  $y$  denotes a specific object contained in the image.

IS uses a fixed classification network, Inception Network, to realize the classification of the generated image and then predicts  $p(y|x)$ . In terms of diversity, the edge probabilities are computed using the following formula.

$$\int_z p(y|x = G(z)) dz \quad (11)$$

In summary, the formula for IS is as follows:

$$IS(G) = e^{E_{x \sim p} D_{kl}(p(y|\square) \| p(y))} \quad (12)$$

where,  $D_x$  is the discriminant function containing the KL-Divergence constraint. In order to better validate the effect of this experiment, 1000 images were also generated using DCGAN and ProGAN respectively, and 10 evaluations were done using MNIST samples to take the mean value. The experimental results obtained are shown in Table II.

TABLE II. IS ASSESSMENT RESULTS

arithmetic	IS
GAN	0.8
DCGAN	1.44
ProGAN	1.87
Methodology of this paper	2.30

As can be viewed from Table I, the IS fee of the paper's approach is the highest, which shows that the photo generated the usage of the hierarchical fusion facets is of greater nice and has clearer and extra practical important points.

In this section, the portray consequences generated by way of the techniques in this paper are in contrast (the goal photograph is from the take a look at dataset), the quantitative assessment is completed via calculating the similarity index between the portray consequences generated by way of every approach and the goal photograph (taking the common price of the complete dataset), and the qualitative evaluation is finished through examining the true portray effects of one of a kind methods.

The parameters of several comparison methods were set as follows:

Using ink strokes, in order to make the size of the output image 128×128, the grid is set to 3×3, 23 strokes per grid totaling 207 strokes, and the number of iteration steps is 50;

Using watercolor brushstrokes, the size of the board is 128×128; using the pre-training model and parameters provided in the original article, the number of painting steps is 40, corresponding to the number of strokes is 40×5=200;

Using oil brush strokes, the board size is 128×128, and the number of strokes is limited to 200.

To summarize the floor plan rendering capabilities of the model: 1) the quality of CyceGAN rendered floor plan meets the need for clear presentation; 2) Epoch50 rendering is flatter, Epoch300 is rich in detail but has a certain chance of producing pixelated details, 3) the rendering of the nature of the land is accurately expressed, but the rendering of the

structures is not prominent enough and needs to be manually further emphasized, and 4) the middle of the rendering colors is not as good as the middle of the rendering, and there is a certain lack of transition tones which are somewhat missing.

## V. CONCLUSION

With the rapid development of Web technology, basic application systems based on b/s architecture have been widely developed and applied, and software based on b/s architecture has become the trend of software development. As a common form of artistic creation, painting is an important means of visual communication in the fields of news dissemination, prototype design, movie and television creation. The content of digital painting is easier to disseminate in the current network era and has important research and application value. In this paper, based on the previous research work, an image generation algorithm is proposed based on the intelligent rendering algorithm of image texture, which generates the structural line drawing through the structural GAN, and then through the rendering of the texture GAN to generate the ideal effect of the painting. The main conclusions are:

1) *This* chapter mainly introduces the related technical theories involved in the art image processing platform, the B/S network architecture which is popular among developers nowadays, the Python programming technology which has a great momentum, and the Django framework which is convenient for researchers in Python technology.

2) *This* chapter first introduces the model-based DDPG reinforcement learning approach as the main framework and clarifies in detail how reinforcement learning is applied to the task of painting simulation through three aspects: modeling, learning algorithm, and network architecture. Then, we introduce a two-way neural renderer for constructing the drawing simulation environment and a stroke translator that can realize the conversion of stroke control parameters.

3) *Based* on the existing open-source drawing board and renderer technologies, this paper defines a variety of stroke rendering methods and integrates them into a unified renderer framework to construct various drawing simulation environments. On this basis, this paper uses a unified two-way neural network structure and training method to realize a neural renderer that can be used for different stroke rendering. From the experimental results, it can be seen that the two-way neural renderer used in this paper combined with the DDPG reinforcement learning framework can effectively generate the drawing content of multiple stroke styles and realize the simulation of the drawing process; the stroke translator proposed in this paper can complete the expected translation of stroke control parameters and realize the migration of multiple stroke drawing styles.

**Abstract**—Emotion is a complex phenomenon that originates from everyday issues and has significant effects on individual decisions. Electroencephalography (EEG) is one of the widely used tools in examining the neural correlates of emotions. In this research, two concepts of Granger causality and directional transfer function were utilized to analyze EEG data recorded from 36 healthy volunteers in positive, negative and neutral emotional states and determine the effective connectivity between different brain sources (obtained through independent component analysis). Shannon entropy was utilized to sort the brain sources obtained by the ICA method, and average topography helps to add spatial information to the proposed connectivity models. According to the obtained confusion matrix, our method yielded an overall accuracy of 75% in recognizing three emotional states. Positive emotion was recognized with the highest accuracy of 87.96% (precision = 0.78, recall = 0.78 and F1-score = 0.81), followed by neutral (accuracy = 82.41%) and negative (accuracy = 79.63%) emotions. Indeed, our proposed method achieved the highest recognition accuracy for positive emotion. The proposed model in the present study has the ability to identify emotions in a completely personalized way based on neurobiological data. In the future, the proposed approach in the present study can be integrated with machine learning and neural network methods.

**Keywords**—EEG; effective connectivity; granger causality; directed transfer function; emotion recognition

## I. INTRODUCTION

Emotion is a complex phenomenon that originates from everyday issues and has significant effects on individual decisions. The extent of these decisions can affect the personal and social life of the people of society [1]. Emotions are very important in learning and communicating, and their expression plays a big role in human relationships. Emotions can directly affect a person's performance, and therefore, it is important to try to understand their sources and control them [2]. A certain emotion is one of the brain states that is produced by the electrical activity of millions of neurons and is associated with physiological changes in the whole body [3]. When experiencing emotions, the brain's left and right hemispheres are involved in different ways [4]. For example, it has been shown that the left prefrontal area is more involved in dependent emotional reactions and the right prefrontal area is involved in withdrawal reactions [5]. Generally, it is hypothesized that the left hemisphere is dominant in positive

emotions, and the right hemisphere is dominant in negative emotions [6].

Electroencephalography (EEG) is one of the widely used tools in examining the neural correlates of emotions [7]. This instrument has many applications in cognitive neuroscience and psychiatry and improves our insight into various behavioral phenomena including depression [8], bipolar disorder [9-17] and hyperactivity [18-22]. Many researchers have applied various machine learning techniques to EEG data to develop an automated EEG-based emotion recognition system [23]. Zhang et al. applied the Empirical Mode Decomposition (EMD) technique to EEGs, calculated the sample entropy from the first four IMFs, and reported an average accuracy of 93.20% in classifying five distinct emotions [24]. Zheng and Lou trained deep belief networks by calculating entropy features from different EEG frequency bands and achieved an accuracy of 86.65% in detecting three negative, neutral and positive emotions [25]. Meng et al. proposed an EEG-based emotion recognition system based on entropy features and cascaded convolutional recurrent neural networks and achieved an accuracy of 94.85% in valence-based classification problems [26]. Hwang et al. utilized convolutional neural networks along with generating topology-keeping differential entropy features to prevent the loss of localized information and achieved an average accuracy of 90% in recognizing three negative, positive and neutral emotions [27]. Nawaz et al. proposed an EEG-based emotion recognition system based on various linear and nonlinear features such as fractal dimension and wavelet energy, feature selection by principle component analysis, and multiple classifiers such as SVM and KNN, and reported an average accuracy of 77.60%, 78.96% and 77.62% in detecting dominance, arousal and valence emotions, respectively [28]. Two recent reviews on EEG-based emotion recognition emphasized the importance of such systems for various scientific fields, such as psychology and cognitive neuroscience, and highlighted the necessity of developing these systems with a special focus on regional brain connectivity [29, 30].

In the last two decades, neuroscience studies have focused on the connections of different areas of the cerebral cortex and how these areas interact when performing a specific sensory-motor or cognitive action to better understand brain function [31]. Many attempts have been made to quantify these connections through EEG analysis [32]. Functional

\*Corresponding Author, e-mail: sxiaojing202305@163.com

connectivity is an observable phenomenon that can be quantified by measuring statistical dependencies such as correlation or transfer entropy [33]. On the other hand, effective connectivity refers to the model parameters that attempt to explain the observed dependencies (functional connectivity). From this point of view, effective connectivity refers to the concept of coupling or direct causal influence by examining the direction of information dissemination [34, 35]. Bagherzadeh et al. achieved a high accuracy of 99% in the classification of five emotional states using effective EEG connectivity and convolutional neural networks [36]. In another study, Bagherzadeh et al. used EEG frequency effective connectivity maps based on the transfer learning technique and achieved an accuracy of 95% in the classification of five emotional states [37]. Although these studies have shown the high potential of EEG effective connectivity as a biomarker for human emotion recognition, few studies have used this important feature of brain signals to develop EEG-based emotion recognition systems.

Therefore, in this research, we aim to process EEG signals to estimate effective connectivity in brain resources and provide models to investigate how brain resources influence each other in order to detect three emotional states: neutral, negative, and positive. For this purpose, we investigated the potential of Granger causality and directed transfer function to estimate effective cortical connectivity in different emotions. Our research showed that these approaches can reveal noticeable effective connectivity patterns in each emotion, which can be classified in order to emotion recognition.

## II. METHODS

Fig. 1 shows the work process of the current research. Considering that in this research, two concepts of Granger causality and directional transfer function are used in EEG data processing, it is necessary to briefly introduce these concepts first.

### A. Granger Causality

Granger causality is a technique to derive specific kinds of causal dependence among stochastic samples by reducing the

bias of predicting possible effects if past observations of the hypothesized causes are utilized to anticipate the effects plus previous observations of the possible effects. This concept was first proposed through Wiener and then reformulated through Granger based on linear autoregressive models. This algorithm considers two assumptions: (I) a cause should precede its effects, and (II) data on the past of a cause should enhance the anticipation of the effects above and beyond data on the collective past of the other observed samples. To estimate influences from the channel  $x_j$  to  $x_i$  for  $n$  channel autoregressive processes, we considered  $n$  and  $n-1$  multivariate autoregressive models. The model is fitted to overall  $n$ -channel system, resulting in the residual variance  $V_{i,n}(t) = \text{var}(E_{i,n}(t))$  for time series  $x_i$ . Then, a  $n-1$  multivariate model is fitted for  $n-1$  channels, except for channel  $j$ , which results in the residual variance  $V_{i,n-1}(t) = \text{var}(E_{i,n-1}(t))$ . So, Granger causality is given by:

$$Granger_{j \rightarrow i}(t) = \ln \left( \frac{V_{i,n}(t)}{V_{i,n-1}(t)} \right) \quad (1)$$

### B. Directed Transfer Function

This method is used to measure the direction and frequency content of brain activities. The directed transfer function is a multivariate approach that is formulated by multivariate autoregressive models to investigate the causal relationships between EEG channels and recognize the directed dissemination of EEG activities. This algorithm works in the frequency domain to characterize regional connectivity based on the factorization of the coherence between two EEG channels.

### C. Dataset

In this research, we utilized an EEG dataset on neutral, positive, and negative emotional states from [38]. This dataset includes EEG signals recorded from 36 young adults in the neutral, positive, and negative emotional states induced by standard images from the International Affective Picture System (IAPS). 16 Ag/AgCl electrodes were utilized to capture brain signals at a sampling rate of 512 Hz based on a 10-20 international recording protocol.

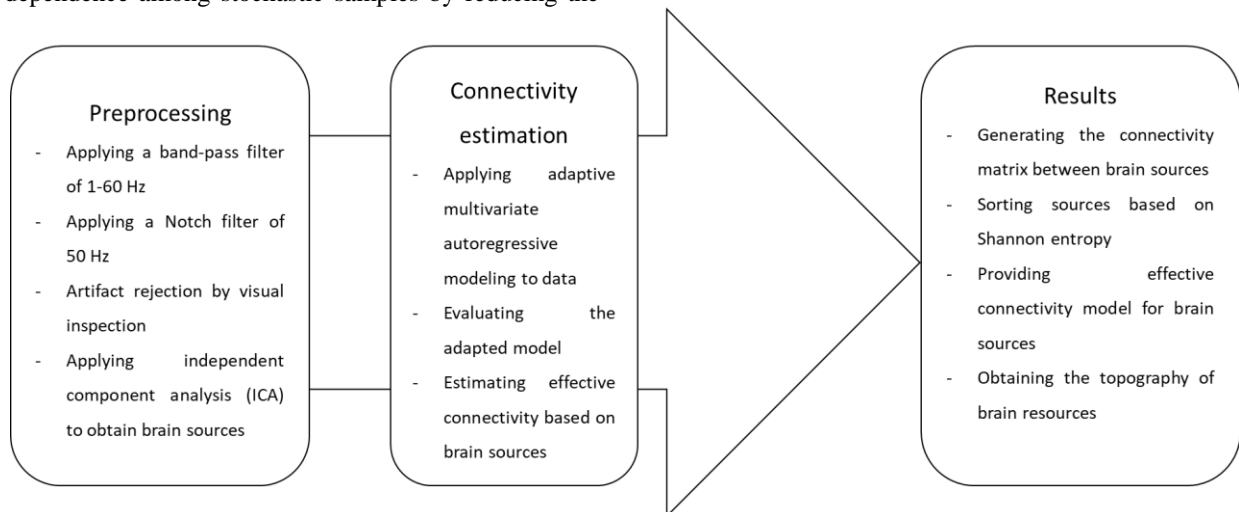

Fig. 1. Flow chart of the proposed method for EEG-based emotion recognition based on effective connectivity.

#### D. Data Preprocessing

First, we applied a Butterworth band-pass filter (order 4) with a frequency of 1–60 Hz to the signals to cancel unwanted noise. A 50 Hz notch filter was then applied to the signals to cancel power line interference. Next, an experienced neurologist checked all EEGs and rejected all parts of the signals contaminated with various artifacts, such as body motion and eye blinking. After obtaining a clean EEG signal for each subject, independent component analysis (ICA) was applied to the signals to decompose them into independent components. A fast ICA algorithm was utilized in this work to decompose 16 source components from EEG channels. However, we encountered a bad situation when using ICA because the order of the extracted components changes in every run of the algorithm. To solve this problem, Shannon's entropy of sources was used as a measure of information to sort brain sources. Sources are sorted according to Shannon entropy value and in ascending order. These brain sources obtained from ICA were used for further analysis.

#### E. Effective Connectivity Estimation

EEGLAB and SIFT toolbox were utilized to estimate effective connectivity [39]. The first step to estimate the connectivity value is to fit a model to the data using Adaptive Multivariate Autoregressive (AMVAR) modeling, which is acceptable for this purpose. To adapt this model, the length of the window, the step of the window, and the order of the model should be selected. After selecting the values of these parameters, the accuracy of the fitted model is evaluated. Table I shows the selected values for these parameters.

TABLE I. SELECTED VALUES FOR AMVAR MODEL PARAMETERS

Parameter	Value
Window length (second)	5
Window step (second)	1
Model order	10

It should be noted that the higher order of the model causes complexity, and the short length of the window leads to an increase in calculations. As a result, a trade-off should be made in choosing these parameters. If the model is sufficiently adapted to the data, the residual coefficients of the model should be small and uncorrelated relative to the real data. The presence of correlation in the residuals indicates the presence of correlated structures in the data that the model is unable to provide. To solve this issue, a null hypothesis with a significance level is considered, and the model is evaluated through it. To evaluate the whiteness of the residuals in this research, the autocorrelation function method with a significance level of 90% was utilized, as well as the consistency assessment through the percent consistency [40]. The stability of the model was evaluated with the stability index. A VAR model is stable if the augmented coefficient matrix of all stability indices is less than one [41].

Granger causality and direct transfer function methods were used to estimate the effective connectivity. In this study, effective connectivity was estimated in four EEG frequency bands: delta (1-4 Hz), theta (4-8 Hz), alpha (8-13 Hz), and beta

(13-30 Hz). In fact, for six sources sorted by Shannon entropy, effective connectivity was estimated in these frequency bands.

#### F. Performance Evaluation

To evaluate our proposed approach for emotion recognition, we utilized various classification metrics, including accuracy, precision, recall and F1-score. These metrics are given by:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (2)$$

$$Precision = \frac{TP}{TP+FP} \quad (3)$$

$$Recall = \frac{TP}{TP+FN} \quad (4)$$

$$F1 = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (5)$$

where TP, TN, FP and FN denote true positive, true negative, false positive and false negative elements for a specified emotional class obtained from the confusion matrix.

### III. RESULTS

First, the accuracy, stability, and consistency of the model were checked using the mentioned criteria. The results showed that the stability of all models was fully established, and the average model stability in all samples was about 78%. The average rejection of the null hypothesis was 93%. For each emotional state, the maximum number of connections in each frequency band was calculated. In each sample, a source can receive information from other sources. Fig. 2 shows a schematic of the calculation of the connectivity between sources as a sender or receiver of information.

Based on the schematic shown in Fig. 2, the sources with the most receiving and sending information in three emotional states were determined based on averaging in different frequency bands as shown in Table II.

Fig. 2. A schematic of the calculation of the connectivity between sources as a sender or receiver of information. Source 1 is the sender with 100%, and source 5 is the receiver with 100%.

Based on the results obtained in Table II, the proposed model based on Granger causality and directed transfer function for effective connectivity for neutral, negative, and positive emotional states is shown in Fig. 3. The models presented in Fig. 3 are obtained from the statistical analysis of the connection between different sources. In fact, in these

models, the information related to the location of brain sources is not included, so they cannot be used to identify the location of connections. To solve this problem, topographic images of sources were used.

TABLE II. SOURCES WITH THE MOST RECEIVING AND SENDING INFORMATION IN THREE EMOTIONAL STATES

Emotional state	Sending sources		Receiving sources	
	Source	Percentage	Source	Percentage
Neutral	5	54.2	9	52.1
	7	48.4	7	46.8
Negative	6	47.1	8	48.7
	10	44.3	6	44.5
Positive	10	66.2	6	66.2
	9	43.1	7	49.2

In this model, each circle represents a brain source, which is assigned a number based on Shannon entropy ranking.

Fig. 3. Proposed model based on Granger causality and directed transfer function for effective connectivity for (A) positive, (B) neutral, and (C) negative emotional states.

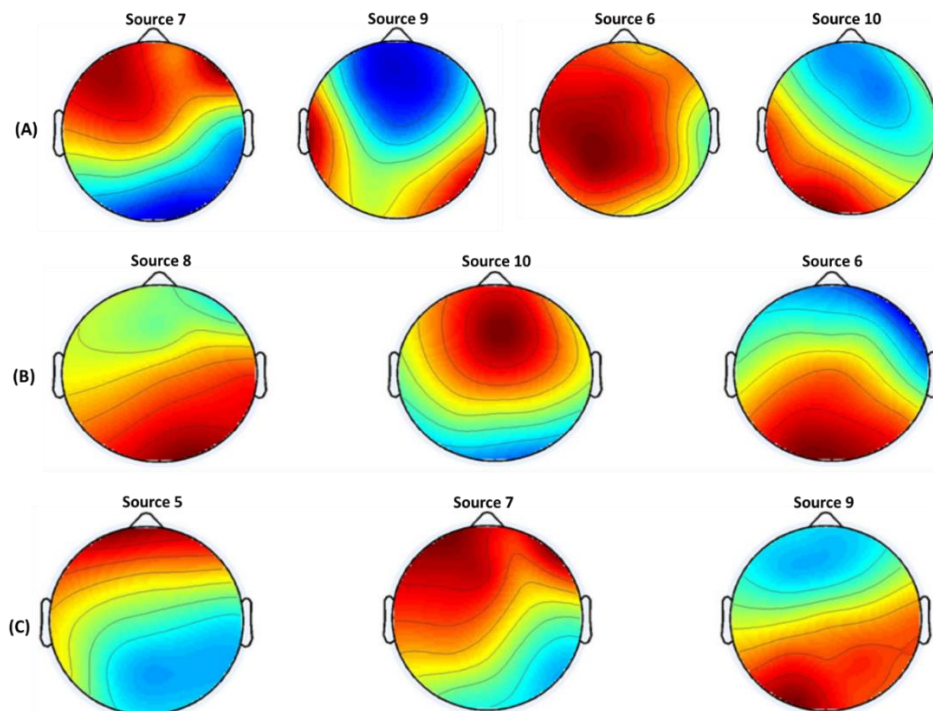

Fig. 4. Average topography images of 36 samples for sources with the most input and output connections, as specified in Fig. 3, extracted with independent component analysis, in (A) positive, (B) negative, and (C) neutral emotional states.

Arrows go from the source of the information transmitter to the source of the information receiver. The larger the diameter of an arrow, the greater the amount of information spread.

In addition to separating different sources from each other, ICA provides us with information about the location of these sources on the scalp by producing images called the topography of a source. These images are important in that they can show how a source spatially affects the entire scalp. As a result, by considering the assumptions about the location that is activated during specific stimuli, the location of their sources can be identified. Accordingly, the topography of the sources whose models were created in the previous section was determined, and their average topography was examined in all samples. It is worth mentioning that the selected sources are the same in terms of entropy. The topography of source 10 in the positive emotion belongs to source 10 in terms of entropy in all samples. Table II and Fig. 3 specify the sources with the most output and input connections in each emotion. Based on this, Fig. 4 shows the average topography of these sources for positive, negative, and neutral emotional states.

Fig. 5. The proposed models for effective connectivity in (A) positive, (B) negative, and (C) neutral emotional states with spatial information.

The images in Fig. 4 contain spatial information about brain sources. By combining these images with the information of the models from Fig. 3, other new models are presented that also contain spatial information about brain sources. Fig. 5 shows the presented model for effective connectivity between brain sources in positive, negative, and neutral emotional states with spatial information.

In this model, each circle represents a brain source, which is assigned a number based on Shannon entropy ranking. Arrows go from the source of the information transmitter to the source of the information receiver. The larger the diameter of an arrow, the greater the amount of information spread.

The models presented in Fig. 5 are the average of all samples. In the next step, similarity measurement and labeling operations were performed for each sample. In other words, each individual's connectivity model was compared with the average models presented in Fig. 5 and labeled based on its similarity to each of the average models. The total number of samples is 36 subjects with three emotional states: positive, negative, and neutral. Therefore, there are 108 models with similar distribution in different emotional states. To measure the similarity of each sample in all emotional states and frequency bands, first, the average input and output information of all sources of that sample was calculated. The rate of receiving and sending information from all sources was determined for each sample. Then, in each sample, two sources that had the highest amount of receiving and sending information were selected. In the next step, the emotional state label of 108 samples was removed, and the samples were shuffled. Two selected sources from each sample were compared with the proposed models and given a label according to their similarity to each of the models as shown in Table III.

TABLE III. THE RESULT OF LABELING SAMPLES FOR POSITIVE, NEGATIVE, AND NEUTRAL EMOTIONAL STATES IS BASED ON THE PROPOSED EFFECTIVE CONNECTIVITY MODELS

		Estimated label based on similarity with proposed models		
		Positive	Neutral	Negative
Real label	Positive	28	3	5
	Neutral	2	26	8
	Negative	3	6	27

Table III shows the confusion matrix obtained by the proposed approach based on effective connectivity to identify positive, negative, and neutral emotions. According to the

obtained confusion matrix, our method yielded an overall accuracy of 75% in recognizing three emotional states. Table IV shows the obtained classification criteria for each class. As shown, positive emotion was recognized with the highest accuracy of 87.96% (precision = 0.78, recall = 0.78, and F1-score = 0.81), followed by neutral (accuracy = 82.41%) and negative (accuracy = 79.63%) emotions.

TABLE IV. CALCULATED CLASSIFICATION CRITERIA FOR EACH POSITIVE, NEGATIVE, AND NEUTRAL EMOTIONAL STATE

Class	n (truth)	Accuracy (%)	Precision	Recall	F1-score
Positive	33	87.96	0.78	0.85	0.81
Neutral	35	82.41	0.72	0.74	0.73
Negative	40	79.63	0.75	0.68	0.71

#### IV. DISCUSSION

The aim of this study was to estimate cortical effective connectivity from the EEG signal of emotions based on Granger causality and directed transfer function for the recognition of different human emotions. Our proposed method achieved the highest recognition accuracy for positive emotion. In the proposed model for positive emotion, source 10 had the highest amount of receiving information from other sources. This finding is consistent [38], where source 10 achieves the highest recognition accuracy for positive emotion. In the proposed model for negative emotion, source 8 had the highest amount of sending information to other sources. Abdolssalehi et al. also achieved the highest recognition accuracy for negative emotion through source 8 [38]. However, in [38], the authors relied on recurrence quantification analysis for pattern recognition from brain sources.

In contrast, we utilized the effective connectivity between these sources and improved the results obtained in Abdolssalehi et al.'s work. In addition, as mentioned, sources 10 and 8 had the highest amount of information exchange in positive and negative emotional states, respectively. The average topography of sources 10 and 8 of all samples was located in the left posterior hemisphere and the right posterior hemisphere, respectively. This finding is consistent with the valence hypothesis, which assumes the opposite predominance of the right hemisphere for negative emotions and the left hemisphere for positive emotions [49, 50]. Table V compares the findings of the present study with previous studies. As can be seen, our proposed system performs better than most of the previous methods.

TABLE V. COMPARING THE FINDINGS OF THE PRESENT STUDY WITH PREVIOUS STUDIES

Reference	Algorithm	Results
[42]	Spectral features and SVM classifier	49.4% like, 55.7% arousal, 58.5% valence
[43]	Spectral features and SVM classifier	79.59% sadness, 74.11% anger, 86.15% joy, 83.59% pleasure
[44]	Spectral and statistical features and LDA classifier	62% anxiety, 50% engagement, 57% boredom
[45]	Spectral assymetry index, wavelet entropy and SVM classifier	82.5% negative excitement, 64% neutral
[46]	Spectral features, Gabor transform and probabilistic neural network	62.97% sadness, 69.74% disgust, 73.64% anger, 56.79% fear
[47]	Spectral features and SVM classifier	50.5% valence, 62.1% arousal
[48]	Spectral features and SVM classifier	61% sadness, 58% fear, 53% anger, 51% joy
Our proposed approach	Effective connectivity and confusion matrix	87.96% positive, 82.41% neutral, 79.63% negative

Most of the studies that have tried to recognize human emotions using EEG signals have used a variety of machine learning methods and artificial neural networks that provide us with a black box-like function [51-53]. Although some of these studies have reported very high detection accuracies, the process of pattern recognition in them is unclear and ambiguous [54]. However, in this research, we tried to choose and propose a transparent work process to overcome this important limitation of previous studies. Although we did not use learning machines and artificial neural networks for classification and pattern recognition, the obtained results are quite promising. Therefore, our proposed model can be very useful in various research fields, such as psychiatry, psychology, neuroscience, and cognitive science. The important thing to consider about our proposed model is that this model can work completely depending on a person, and it is a personalized model. Individual and cultural differences are very important issues in the development of emotion recognition systems. At the same time, most previous techniques ignore this important issue. However, the proposed model in the present study has the ability to identify emotions in a completely personalized way based on neurobiological data. In the future, the proposed approach in the present study can be integrated with machine learning and neural network methods and improve the proposed model.

## V. CONCLUSION

In this study, a new method based on effective connectivity using Granger causality and directed transfer function was able to successfully extract connectivity patterns related to positive, negative and neutral emotions and led to the detection of these emotions based on EEG signal analysis. The obvious advantage of our method is its transparency in all stages of analysis and not using black boxes related to machine learning and neural networks, which increases its clinical applicability compared to previous works. However, this method needs further validation using different databases. In addition, our proposed method should be integrated with an artificial intelligence system to automate emotion recognition. In this

study, only three emotions were investigated, and future studies should evaluate this method for other emotions as well.

**Abstract**—The goal of this study was to develop a robust image cryptographic scheme based on Latin Square Matrix and Logistics Map, capable of effectively securing sensitive data. Logistics mapping is a comparatively strong chaos system which enciphers with an unpredictability that significantly reduces the chance of deciphering. Additionally, the Latin square matrix stands out for its uniform histogram distribution, thereby bolstering its encryption's potency. The consequent integration of these algorithms in this study was therefore grounded in the scientific rationale of establishing a strong and resilient cypher technique. The study provides a new chaos-based method and extends the application of the probabilistic approach to the domain of symmetric key image encryption. Permutation and substitution approaches of image encryption were deployed to address the issue of images volume and differing sizes. The issue of misplaced pixel positions in the image was also adequately addressed, making it an effective method for image encryption. The hybrid technique was simulated on image data and evaluated to gauge its performance. Results showed that the algorithm was able to securely protect image data and the private information associated with them, while also making it very difficult for unauthorized users to decrypt the information. The average encryption time of 184( $\mu$ s) on seven (7) images showed that it could be deployed for real-time systems. The proposed method obtained an average entropy of 7.9398 with key space of  $1.17 \times 10^{77}$  and an average avalanche effect (%) of 49.9823 confirming the security and resilience of the developed method.

**Keywords**—Image encryption; algorithm; logistics map; Latin square matrix; chaos technology

## I. INTRODUCTION

As a result of the massive development of digital information technology, an ever-increasing volume of image data is being generated and distributed over the interconnected networks of computing infrastructure. These images typically contain confidential information such as trade secrets, military secrets, confidential medical reports and other types of secrets. It is therefore critical to protect sensitive data contained in these images from unauthorized access; many industries and fields rely on the secure transmission of such data [1]. As a

result, image transmission security has emerged as one of the most pressing topics in information sciences [1].

The method that is utilized to protect the confidentiality of images is known as cryptography. Cryptography is a method for safely transmitting data and communications by utilizing certain keys. This ensures that only the receiver to whom the information is addressed is aware of the true content of the message, hence preventing unauthorized access [2, 3]. It has a significant impact on the conversations that take place over mobile phones, as well as on e-commerce, the sending of emails, the transmission of financial information, and other areas of an individual's day-to-day life. The prefix "crypt" in the word "cryptography" refers to something that is "hidden" or "written" [4]. Information is encrypted by the use of mathematical presumptions and algorithms in the field of cryptography. These techniques are used to encode information before it is delivered, making it harder to decipher the information from its original form. Cryptography provides privacy by ensuring that transmitted data isn't known by external parties, it is reliable because it ensures there is no form of modification during storage and transfer of data from the sender to the receiver [4].

Encryption is a method of data security that entails encoding the data in such a way that it can only be deciphered by those who have been granted permission to do so. Examples of data that can be encrypted include multimedia files and sensitive papers [3]. Encryption and decryption are both possible outcomes of the usage of cryptography. Image encryption refers to the process of hiding an image using an encryption algorithm in such a way that its private information is protected and it is unavailable to attackers or unauthorized users [5]. Images are encrypted for a variety of purposes, including identifying the image's source, securing copyright information, preventing piracy, and preventing individuals who shouldn't have access to them from viewing them. Image encryption allows images to be shared via e-mail, the internet and other transmission media without worrying about these images being seen by unauthorized users. According to [6], all internet-connected citizens share more than 1.8 billion images

per day. This shows how much sensitive data can be lost just in a day and therefore shows the importance of encrypting these images. The development of good encryption algorithms has resulted from the necessity to meet the security needs of digital images [7, 8]. Therefore, in this study, a Latin square matrix and logistics mapping cryptographic scheme for image encryption was designed, simulated and implemented.

The study contributes significantly in advancing the frontiers of cryptography through the innovative integration of chaos-based and probabilistic encryption techniques, ensuring that the enciphering and deciphering phases are error-resistant. Chaos-based encryption techniques are known for their ability to provide high levels of security due to their inherent unpredictability, while the integration of probabilistic techniques ensures that the crypto processes are not deterministic but involves randomness, thus enhancing their resilience against various attacks. One other notable feature of the proposed method is its ability to handle images of varying sizes. This scalability is crucial in practical applications where images may have different dimensions. The developed technique also achieves semantic security, meaning that even with knowledge of parts of the plain images, it is computationally infeasible to recover the key or glean meaningful information from it. In summary, this study introduces a novel chaos-based image encryption method with a probabilistic approach, addressing the unique challenges posed by image data. Statistical, computational and differential attack evaluations conducted on the developed algorithm further highlight the effectiveness of the proposed method. The developed encryption method is secure, as it has a large key space, a high level of sensitivity to both cipher keys and plain images, and no known weaknesses.

The remaining sections of this study are highlighted as follows: Section II discusses the related work by previous researchers in the area of image encryption. Section III gives the details of the methodology used in this study. Section IV gives the obtained results. Section V concludes the study while Section VI provides the recommendation.

## II. RELATED WORK

Patel & Thanikaiselvan [9] presented a new image encryption algorithm that used Latin Square and Machine Learning techniques. The algorithm first generated a chaotic sequence using neural network-based pseudo-random number generator. This sequence was then used to create encryption key images, which were XORed with the input image to produce the encrypted image. The proposed algorithm was iterated a finite number of times to generate a cipher image population. A genetic algorithm was then used to optimize the population and find the least correlated cipher image. The model was resistant to communication channel attacks, such as noise addition, cropping, and JPEG compression.

Wang et al. [10] proposed a new image encryption algorithm that used Latin square matrices. The algorithm first generated a chaotic sequence using a Lorenz system. This sequence was then used to create a Latin square matrix, which was used to permute the pixels of the input image. The permuted was then diffused using a logistic map. The simulation results from the proposed image encryption

algorithm showed that it outperformed many existing image security algorithms. The algorithm was also resistant to communication channel attacks. A further investigation of this study is recommended, as it showed promises in protecting sensitive data in several applications.

Zhang et al. [11] introduced and implemented a Latin Square and random-shift based chaotic image encryption scheme. In some contexts, it was also referred to as the LSRS algorithm. The LSRS algorithm made use of a structure that consisted of pixel scrambling, replacement, and bit scrambling. The generation of Latin squares during the encryption process was correlated to the chaotic sequence, and this generation contributed to an increase in the system's overall level of security. In this line of study, the difficulty of decoding the method increased as a result of the fact that each encrypted image corresponds to a Latin square lookup table. The results of the simulation validated the LSRS algorithm's reliability as well as its efficiency.

Xu et al., [12], presented an algorithm that made use of self-orthogonal Latin Squares as its basis. This algorithm was also referred to as SOLS. In one cycle of encryption, the algorithm used the "permutation-substitution permutation" mode and the entire encryption procedure was carried out by a single SOLS. This research demonstrated that the substitution operation could be protected from differential attack by using permutation procedures at both the top and bottom levels during a single round of encryption. Therefore, at the bottom level, both substitution and permutation operations contributed to the diffusion effect. The results of the complexity analysis and simulation in the study demonstrates that the newly created algorithm was both secure and efficient, which demonstrates that it is suitable for use in real-time applications.

Zhang & Chen [13] developed a technique of encryption based on Henon chaotic maps. This encryption algorithm employed a two-phase encryption strategy. In the first step, the original image was fused with a key image, and the process was repeated in the second step. The authors asserted that their encryption approach was suitable and more resistant to brute force attacks than other similar methods since they employed both the key-image and the plain image back.

## III. METHODOLOGY

This study provides a new chaos-based method and extends the application of the probabilistic approach to the domain of symmetric key image encryption. It has been carefully developed to make certain that the cipher text is unpredictable. This method of image encryption made use of two different approaches, namely permutation and substitution, to encrypt square images. Permutation is referred to as the process of shifting around the locations of an image's pixels and substitution as a method for modifying the values of the pixels that are adjacent to one another. This approach addresses the issue of encrypting images with voluminous data because it is probabilistic and can accommodate images of any size. It generates a key stream using randomness, which is subsequently used in various phases to carry out operations of permutation and substitution thereby achieving semantic security. The processes of permutation and substitution was carried out without the need to wrongly misplace the pixel

positions in the image, making it an effective method for image encryption.

The encryption process which includes a fusion of the Latin Square Encryption (involving random key generation, generation of Latin Squares, Latin Square whitening, Latin Square permutation) and Logistic map Encryption. This process is represented algorithmically in Algorithm 1, while Fig. 1 depicts the framework of the proposed hybrid model.

Fig. 1. Proposed fused latin square - logistic map encryption model.

**Algorithm 1: Fused Latin Square - Logistic map Encryption**

**Input:** p: Original image

**Output:** C: ciphered image

1. Import image and essential libraries;
2. Define **RandomKey()** to generate a 256-bit key;
3. Using predefined **KeyedLatin()** produce  $n$  Latin squares of order  $d$  dependent on the random key  $K$ ;
4. Define a **lsq\_whitening()** and use it to perform Latin square whitening;
5. Use the predefined **lsq\_permutation()** to randomly rearrange the image's pixel values;
6. Define **bitget(x,y)** to obtain the bits from each row and column and perform **XOR** operations on the obtained bits  $B$  and previous matrix  $M$ ;
7. Set **colourImage = 0** and **grayscaleImage = 1**;
8. Define **getImageMatrix(imageName)** for colour images and **getImageMatrix\_gray(imageName)** for grayscale images to obtain the image matrix.
9. Encrypted image for the first time with the **hexadecimal key sequence K**.
10. Conduct substitution on the image that has already been encrypted;
11. **Return Cipher Image C**

**A. Random Key Generation**

Algorithm 2 presents the method for generating random key using the *dec2hex* function.

**Algorithm 2: Random Key Generation Algorithm**

**Input:** image matrix

**Output:** k: a 256-bit random key in HEX

1. Define a function **dec2hex()**;
2. Parse **dec2hex()** using the string and length as parameters;
3. Convert decimal string to a hexadecimal string **hex\_string**;
4. Define function **RandomKey()**;
5. **Return key k.**

**B. Permutation Phase**

1) *Generating latin square*: A Latin square of order  $n$  is a square matrix with dimensions  $n * n$ , whose entries consist of  $n$  symbols ordered so that each symbol appears exactly once in each row and column. An  $n$  Latin square  $L$  of order  $d$  that is dependent on the key  $K$  is generated in this phase of the process. The mathematical modelling of a Latin square  $L$  of order  $d$  that can be derived using a tri-tuple function  $FL$  of  $(r, c, i)$  is presented as follows:

$$F_L(r, c, i) = \begin{cases} 1 & \text{si } L(r, c, i) = S_i \\ 0 & \text{otherwise} \end{cases} \quad (1)$$

Where  $r$  denotes the index of a line of an element of  $L$ ;  $l \in N = 0; 1; \dots; N - 1$ ,  $c$  denotes the index of a column of an element of  $L$   $c \in N$ ,  $i$  denotes the index of a symbol element in  $L$  and  $S_i$  is  $i$ th symbol in the whole =  $\{S_0, S_1, \dots, S_{N-1}\}$ . This implies that each symbol appears exactly once in each row and each column of  $L$ .

2) *Latin square whitening*: The term "Latin square Whitening" refers to an operation that combines the plaintext "P" with a pseudo random sequence. With the aid of the *LatinSquareWhitening* function, a  $n$  Latin Square  $L$  of order  $d$  that is determined by the key  $K$  is produced. An example is the *XOR* operation. When it comes to image encryption, a plaintext message is represented by an image block denoted by the letter  $P$  and made up of a certain number of pixels. Multiple binary bits (a byte) are used to represent each individual pixel. Since the goal of key whitening is to combine plaintext information with encryption keys, we describe it as an encrypted text that operates over a finite field  $GF(2^8)$  and is applied to the image data. A computational illustration of this is provided below:

$$y = [x + 1]_{2^8} \quad (2)$$

where  $x$  represents a byte in the plaintext,  $i$  is the byte's appropriate position in the keyed Latin square, and  $y$  represents the outcome of the whitening. The computations performed over  $GF(2^8)$  are denoted by  $[.]_{2^8}$ . The whitening effect caused by the procedure described above can be easily undone by using;

$$x = [y + 1]_{2^8} \quad (3)$$

Plaintext byte  $x$  represents a pixel in image encryption; for example, it might be identified at the intersection of the  $r$ th row and the  $c$ th column (i.e.,  $x = P(r, c)$ .)

Now let  $l = L(r, c)$  be an element situated at the relevant position in the keyed Latin square  $L$ , and let  $y$  be the ciphertext byte with  $y = C(r, c)$ , and then we will get the pixel-level equation below which is consistently utilized in the process of key whitening;

$$\begin{cases} C_{(r,c)} = [SR(P(r, c), [D]_3) + L(r, c)]2^8 \\ P_{(r,c)} = SR([C(r, c) + L(r, c)]2^8, [D]_3) \end{cases} \quad (4)$$

where the rotating parameter is  $D = L(0, 0)$ , symbol  $n$  indicates the existing round number ( $n[0,7]$ ), and  $SR$  represents the spatial rotating function ( $X, d$ ), which rotates an image  $X$  in accordance with various values of the direction  $d$  as defined below;

$$y = SR(X, d) \begin{cases} x, & \text{if } d = 0 \\ \text{flip } X \text{ up} \rightarrow \text{down} & \text{if } d = 1 \\ \text{flip } X \text{ left} \rightarrow \text{right} & \text{if } d = 2 \end{cases} \quad (5a)$$

Observe that the following identity is always true if  $Y = SR(X, d)$ :

$$X = SR(Y, d) \quad (5b)$$

3) *Latin square permutation*: At this phase, the Latin square is utilized to permute the image's pixels. If we take both the input and output  $x$  and  $y$  in FRM (Forward Row Mapping) and IRM (Inverse Row Mapping) to be indices, then a FRM defines a mapping from  $[0,1,2, \dots, 255]$  to  $[0,1,2, \dots, 255]$ , and an IRM defines the matching inverse mapping to that FRM mapping. Consequently, the Latin square P-box row, also known as the PLCL, can be defined as follows:

$$PLCL = \begin{cases} C_{(x,y_a)} = P(x, FRM(L, x, y_a)) \\ P_{(x,y_b)} = C(y, IRM(L, x, y_b)) \end{cases} \quad (6)$$

$y_a$  and  $y_b$  represent the column indices before and after the mapping, respectively, in this equation. In a comparable way, the P-column Latin square box, often known as the PCCL, can alternatively be calculated with the aid of the following equations:

$$PCCL = \begin{cases} C_{(x_a,y)} = P(x, FRM(L, x_a, y), y) \\ P_{(x_b,y)} = C(ICM(L, x_b, y), y) \end{cases} \quad (7)$$

In this operation, the row indices both before and after the mapping are shown by the notation  $x_a$  and  $x_b$ , respectively. Using a cascading method for the row permutations PLCLs, in addition to the column permutations known as PCCLs in the following manner allows us to construct our Latin square permutation with the highest level of performance possible:

$$\begin{cases} C_{(x,y)} = C^*(x, FCM(L, x, y), y) \\ P_{(x_a,y)} = P(x, FRM(L, x, y)) \end{cases} \quad (8)$$

In a broad sense, the function of the Latin square permutation can be expressed in the following manner:

$$PCL = \begin{cases} C = Ecr_p(L, P) \\ P = Dcr_p(L, P) \end{cases} \quad (9)$$

4) *Substitution using logistics maps*: The logistic map examines discrete time steps using a nonlinear difference equation. It is named the logistic map because it translates the value of the population at each given time step to its value at the subsequent time step.

The utilization of key mixing is included in this implementation. Following the completion of each pixel encryption, the initial values of the chaos map are recalculated with the addition of the key value as well as the value of the previous encryption. Logistics map is defined as follows;

$$\begin{aligned} x_{i+1} &= \alpha x_i (1 - x_i) + \beta y_i^2 x_i + \gamma z_i^3 \\ y_{i+1} &= \alpha y_i (1 - y_i) + \beta z_i^2 y_i + \gamma x_i^3 \\ z_{i+1} &= \alpha z_i (1 - z_i) + \beta x_i^2 z_i + \gamma y_i^3 \end{aligned} \quad (10)$$

$x_i, y_i$  and  $z_i$  represent system variables,  $\alpha$  and  $\gamma$  are parameters, while  $i$  shows iterations. For  $3.57 < \mu \leq 4$ , the map turns chaotic and for  $\mu = 4$ , the chaotic values produce in the full range of 0–1. The flowchart for decryption is shown in Fig. 2.

### C. Decryption

The decryption process converts the enciphered image back to plain image via the following algorithmic process.

- 1) Load the enciphered image;
- 2) Define *LogisticDecryption (imageName, key)*;
- 3) Generate Key-dependent 256x256 Latin Squares  $L$ ;
- 4) Extract a keyed Latin square;
- 5) Perform Latin square permutation using  $CP = lsq\_permutation(input, L, decryption)$ ;
- 6) Perform Latin square whitening utilizing  $CW = lsq\_whitening(input, L, decryption)$ ;
- 7) Return  $P$ ;

Fig. 2 presents the flowchart of the decryption process.

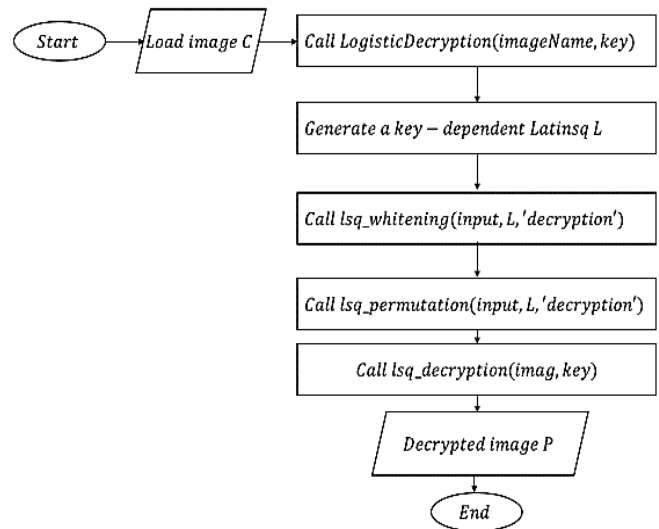

Fig. 2. Flow chart representation of the decryption process.

## IV. RESULTS AND DISCUSSIONS

### A. Simulation Results

The fused encryption algorithm was experimented on seven (7) image dataset (Baboon, Lena, Peppers, Man, Water Lilies, Airplane and Fruits) to demonstrate the performance of the technique in terms of complexity and security. The experimental results are presented as follows:

1) *Histogram analysis*: The act of making ciphertext more widely available is one that bears significant importance. To be more specific, it should conceal the excessive sections of the plain image and should not reveal any information about the image or the relationship between the image and the enciphered image. Additionally, it should conceal its redundant elements [14]. Algorithm 3 depicts the process of finding the image histogram.

---

#### Algorithm 3: Histogram Algorithm

---

**Input:** Image,

**Output:** Histogram graph.

1. Import cv2 and from matplotlib import pyplot as plt;
  2. set `img = cv2.imread('/image location path', 0)` to read the images from their location path;
  3. set `histr = cv2.calcHist([img], [0], None, [256], [0, 256])` to find the frequency of pixels in range 0 – 255;
  4. Display the plotting graph of an image using `plt.plot(histr)` and `plt.show()`;
- 

Fig. 3 and Fig. 4 contain the histograms of both the plain image and the encrypted form of those images respectively that were produced by the proposed approach. Both sets of histograms were generated by the proposed scheme. It is clear from the fact that the histograms of the cipher-images are relatively uniform, and they are notably different from that of the plain image. As a result, they do not present any signals that may be utilized to launch a statistical attack on the cipher.

Fig. 3. Plain image and it's histogram.

Fig. 4. Enciphered Fig. 3 and it's histogram.

2) *Key space analysis*: The larger the key space, the greater the ability to fight against an attack using brute force,

because the process of decryption is strenuous for the attacker, and the sophisticated nature of the information makes it impossible to retrieve [15]. However, if the key that is being encrypted is relatively simple, even the most robust encryption method can be broken using exhaustive search attack. This is not the case if the key is long [16]. The initial secret keys in the proposed approach were set to have a length of 256-bits. Because of this, the key space was 2256, which is equivalent to  $1.17 \times 10^{77}$ , making it sufficiently enormous to withstand any type of brute-force attack.

3) *An evaluation of the correlation between adjacent pixels*: A term referred to as an image's "intrinsic feature" describes the strong correlation that exists between the image's individual pixels. As a result, to increase resistance against statistical analysis, a secure encryption technique should remove it entirely. Within the scope of this work, visual autocorrelation analysis was conducted. Algorithm 4. depicts the process of plotting an auto-correlation pixel effect graph;

---

#### Algorithm 4: Auto-correlation pixel effect Algorithm

---

**Input:** Image,

**Output:** Histogram graph.

1. Import cv2, from matplotlib import pyplot as plt and pandas as pd;
  2. Declare data = pd.read\_csv("daily-minimum-temperatures-in-blr.csv",header=0, index\_col=0, parse\_dates=True, squeeze=True) to read the data from the csv;
  3. Display top 100 data using data.head(100);
  4. Display the plotting graph of an image using `pd.plotting.lag_plot(data, lag=1)`;
- 

Fig. 5 and Fig. 6 presents the autocorrelation results of both an original image and its enciphered version signposting the algorithms resilience to statistical analysis.

Fig. 5. Original image and its auto-correlation result.

Fig. 6. Cipher image and its auto-correlation result.

4) *Execution time*: The execution time (ET) of the fused algorithm was computed programmatically using the following formula:

$$ET = \text{run time} + \text{compile time} \quad (11)$$

The average execution time result for this algorithm was calculated to be 184μs demonstrating the algorithms efficiency for real time applications. Table I presents the ET for seven images.

TABLE I. EXECUTION TIME OF ALGORITHM RESULTS

Image	ET(μs)
Baboon	233
Lena	210
Peppers	190
Man	120
Water Lilies	155
Airplane	146
Fruits	245
<b>Average ET</b>	<b>184</b>

5) *Mean Square Error (MSE)*: The MSE value is the average difference between the pixels throughout the entire image. It is utilized to determine how accurate the pixel value is, and the error value is just the difference between the two. A larger value for MSE denotes a greater degree of dissimilarity between the processed image and the original image. In spite of this, it is important to apply appropriate precautions when working with the edges. The mean square error (MSE) can be computed using the formula that is provided in the following equation.

$$MSE = \frac{1}{AB} \sum_{M=1}^{M=A} \sum_{N=1}^{N=B} (O(m, n) - R(m, n))^2 \quad (12)$$

In this case, AB refers to the size of the image, O refers to the image before it was processed, and R refers to the image after it was processed.

The MSE was calculated for the seven images in this study, and the calculation returns an average result of 0.0, which indicates that there was no error done on the edges of the images while they were being encrypted.

6) *Peak Signal Noise Ratio (PSNR)*: When comparing the squared error of the original image and the modified version, the Peak Signal to Noise Ratio (PSNR) and the Mean Square Error (MSE) are useful metrics to use. There is a connection that works reversely between PSNR and MSE. Therefore, a greater PSNR number suggests that the image has a higher quality (better). The ratio of the PSNR values of the decrypted and original versions is used to measure the image's quality. In this study, the PSNR value for the seven images experimented reached infinity, indicating a superior image quality. It has been determined, based on measurements, to be represented as:

$$PSNR = 10 \log_{10} \frac{(2^n - 1)^2}{MSE} \quad (13)$$

Algorithm 5 shows the step-by-step process of calculating PSNR

### Algorithm 5: PSNR Algorithm

**Input:** Original image, decrypted image,

**Output:** PSNR value.

1. **Import cv2 and math, from skimage import metrics;**
2. **Set  $img = cv2.imread('image location', 1)$   $dec\_img = cv2.imread('image location', 1)$  to read the images from their location path;**
3. **Assign  $img = dec\_img$ ;**
4. **Set  $psnr\_skimg = metrics.peak\_signal\_noise\_ratio(dec\_img, img, data\_rang=None)$**
5. **Print ('PSNR = ',  $psnr\_skimg$ )**

7) *Root Mean Square Error (RMSE)*: The RMSE value approximates the MSE value that provides accurate and reliable results [17]. Root mean square error (RMSE) is used to measure the difference between the original image and the segmented image [18]. It can be expressed in mathematical terms as;

$$RMSE = \sqrt{\frac{\sum_{l=1}^A \sum_{j=1}^B [Or(l,m) - De(l,m)]^2}{AB}} \quad (14)$$

where the values of the coordinates are denoted by the letters  $i$  and  $m$  and the size of the array is  $A \times B$ . Both the original and the decrypted versions of the image are indicated by the notation Or and De, respectively [19]. The interval  $[0, \infty]$  denotes the range of the RMSE. The smaller the value of Root Mean Square Error (RMSE), the more effective the segmentation. In this work, RMSE as calculated on the image datasets resulted to 0.0, which indicates that there is effective image segmentation while the images were being encrypted.

8) *Structural Similarity Index (SSIM)*: The SSIM demonstrates the correspondence between the decrypted and original image. This number is an evaluation and estimate of the image's quality that was produced from several different areas of the image that were the same size. SSIM is represented mathematically in Eq. (15).

$$SSIM = \frac{(2\mu_1\mu_{De} + C1)(2\partial_{1De} + C2)}{(\mu_1^2 + \mu_{De}^2 + C1)(\partial_1^2 + \partial_{De}^2 + C2)} \quad (15)$$

Here,  $\mu_1$  symbolizes the average of the inputs (I), while  $\mu_{De}$  represents the images after they have been decrypted (De). The standard deviations of the I and the De are, respectively,  $\partial_1^2$  and  $\partial_{De}^2$ . " $\partial_{1De}$ " stands for the covariance of the values I and De, while " $C1$ " and " $C2$ " stand for the regularization using the values  $(0.01P)^2$  and  $(0.01P)^2$ , respectively. The results of the SSIM can range from 0 to 1, with 1 indicating an excellent match between the original image and the image that has been modified. Moreover, good encryption algorithms should have SSIM values that fall anywhere between 0.97 and 1. In this study, the average SSIM value is 1 indicating that there is an exact match between the two images.

9) *Relative Average Spectral Error (RASE)*: RASE is a method that is used to calculate the overall performance of

image fusion algorithms for each spectral band. The following is the formula that is used to calculate RASE:

$$RASE = \frac{100}{A} \sqrt{\frac{1}{L} \sum_{i=1}^L RMSE^2 (B_i)} \quad (16)$$

x is the total exposure value of the L band (Bi) in the original multispectral image, whereas RMSE is the minimal square error that evaluates the effectiveness of each band in the merged image. The perfect value would be 0. In this study, RASE was calculated to be 0, which indicates that the methodology used was effective.

10)Relative dimensionless global error in synthesis (ERGAS): ERGAS is a metric that determines the overall quality of the merged image. The inaccuracy when the quality of anything improves, shows that there is a substantial tendency for ERGAS to decrease. As a result, it is an effective measure of the quality. Cases that are considered to be of "high quality" have error ERGAS values that are equal to or lower than 3, whereas cases that are considered to be of "poor quality" have error ERGAS values that are greater than 3. 0 is the optimum value for it. The average ERGAS of this work was computed to be 0.057143. Table II shows results of the analysis. This demonstrates that the algorithm is efficient. It is denoted mathematically as:

$$ERGAS = 100 \frac{he}{l} \sqrt{\frac{1}{L} \sum_{i=1}^n \frac{RMSE^2(A_i)}{y_i}} \quad (17)$$

TABLE II. ERGAS RESULTS

Image	ERGAS
Baboon	0.00
Lena	0.10
Peppers	0.20
Man	0.50
Water Lilies	1.00
Airplane	0.00
Fruits	0.00
Avg ERGAS	0.057143

11)Information entropy analysis: The entropy of the information is a measure of how random the information is, and it may be computed as follows [19]:

$$H(m) = \sum_{i=0}^{255} -Pl(m_i) \log_2 Pl(m_j) \quad (18)$$

Each gray level in an image with 256 gray levels contains 8 bits of data associated with it [20]. When the probability of each gray level is the same, the encrypted image is able to obtain the ideal entropy of 8, which indicates that each gray level of the encrypted image is evenly distributed. The fused encryption's entropy analysis on the enciphered images showed that the average information entropy was 7.53302, which is relatively close to the number 8. Hence, cipher images have a stronger random distribution, and the risk of information disclosure is completely eliminated. Table III depicts the results of evaluation.

TABLE III. AVERAGE OF INFORMATION ENTROPY RESULTS

Image	Entropy
Baboon	7.8693
Lena	7.9976
Peppers	7.9943
Man	7.8997
Water Lilies	7.9907
Airplane	7.993
Fruits	7.8330
Avg entropy	7.9397

12)Differential attack analysis: In most cases, attackers will begin by making a few alterations to the plain image. Next, they will encrypt both the plain image and the modified plain image using the same encryption algorithm. Finally, they will compare the two cipher images in order to gain further insight into the connection between the plain image and the cipher image. The number of pixels change rate (NPCR) and the unified average change intensity (UACI) are calculated to enhance the anti-differential attack performance of the encryption algorithm. In order to test the effect of slightly changing the plain image on the corresponding cipher image, the equations for NPCR and UACI are as follows:

$$NPCR = \frac{\sum_{i=1}^A \sum_{j=1}^B D(i,j)}{A \times B} \times 100\% \quad (19)$$

$$UACI = \frac{\sum_{i=1}^A \sum_{j=1}^B |C_1(i,j) - C_2(i,j)|}{A \times B} \times 100 \quad (20)$$

If the height and breadth of the cipher image are denoted by A and B and C1, C2 are two cipher images, and there is a difference of one bit between each answering plain image and each cipher image. The values of NPCR and UACI that should be anticipated for an image are the following: NPCR = 99.6094% and UACI = 33.4094%, respectively.

During the simulation, we selected a pixel at random for each of the image data in order to alter the value of that pixel. After that, we encrypted the images both before and after the change in order to obtain two cipher images, then we computed the NPCR and UACI. It was deduced, based on the simulation result, that the NPCR of the encrypted image was 99.60983 % and that the UACI was 33.4235 %, both of which are extremely similar to the value that was anticipated. Hence, the encryption technique is sensitive to alterations and has the ability to withstand differential attack. Table IV indicates result of the analysis.

TABLE IV. RESULTS OF NPCR AND UACI ANALYSIS

Image	NPCR	UACI

Avg entropy	99.6074	33.43211

13) *Avalanche effect*: To examine key sensitivity and demonstrate the robustness of the suggested scheme against differential cryptanalysis, evaluations on avalanche properties were conducted. In [20], it was stated that the avalanche effect of the technique should always be  $\geq 50\%$ . As part of this study, the avalanche effect of encryption algorithm was evaluated. The pattern of the number of bits modified in cipher with a single bit change in the secret key revealed that, regardless of the position of the key bit altered, the average change in the number of bits in the cipher text was 49.98235%

14) *which is roughly 50%*. It shows in Table V that the proposed method has high key sensitivity, high confusion, and consistent and significant contributions from all key bits to the cipher bits. Algorithm 6 depicts the step-by-step process of this security analysis. Avalanche effect is calculated with the formula below:

$$\text{Avalanche Effect} = \frac{\text{No. of altered bits in the ciphertext}}{\text{No. of bits in the ciphertext}} \quad (21)$$

**Algorithm 6: Avalanche Effect Algorithm**

**Input:** Original image,

**Output:** Avalanche value.

1. **Def**  $x_0$  as first cipher;
2. **Def**  $x_1$  as second cipher after 1 bit change;
3. **Print bitwise xor operation;**
4. **Count 1s in binary;**
5. **Evaluate** equation of avalanche effect;
6. **Divide** result in step 5 by the longest **binary string**.

Table VI presents a comparison of this study with other state-of-the-art techniques, based on multiple evaluation metrics, while Fig. VII presents a comparative analysis of our techniques' encryption time with other authors. The comparison showed that our technique efficient and competes very favourably against other state-of-the-art techniques.

The plot displays the encryption time of the proposed method at 184( $\mu$ s) and plotted against various authors in the related work. The plot shows that the developed model achieves second best encryption time when compared to other state-of-the-art results. Fig. 8 shows the plot of average avalanche effect obtained from the experiment.

(Wu et al., 2018)	7.9196	$10^{88}$	99.6090	33.4227	1.00	0.0	0.2	187	49.9106
(Gan et al., 2018)	7.9993	2470	99.6000	33.4400	0.96	0.0	0.1	210	50.0736
(Li et al., 2017)	7.9272	2273	99.6100	33.4600	0.95	0.0	1.0	230	49.8735
(Pak et al., 2017)	-	2138	99.6236	33.3441	0.99	0.0	1.0	178	49.8807

The avalanche effect is considered as one the desirable property of any encryption algorithm. The effect ensures that an attacker cannot easily predict a plain-text through a statistical analysis.

## V. CONCLUSION

The study's objective was to develop a resilient encryption scheme to protect images from being decrypted. A strong algorithm for encrypting images should be resistant to attacks, and its efficiency should be unaffected by either the encryption key or the image that has been encrypted. It should have a large key space. This algorithm with all its component parts and stages, satisfies each one of these criteria, and it also has certain unique qualities. As this proposed algorithm is completely described in integers, it is computationally efficient in either software or hardware and does not lead to complications with finite precision or discretization. In addition, the suggested approach builds all encryption primitives based on a key generator. These encryption primitives include substitution and permutation, and because of changes, the proposed method achieves high sensitivity to any key change. The suggested technique additionally combines probabilistic encryption, which provides the conversion of a single plain image into numerous cipher images utilizing a single encryption key, and assures that the decoding phase is error-resistant up to a preset level. Statistical, computational and differential attack evaluations have been conducted on the developed algorithm. All experimental results indicated that the proposed encryption method is secure, as it has a large key space, a high level of sensitivity to both cipher keys and plain images, and no known weaknesses.

## VI. RECOMMENDATION

It is strongly suggested that this method be utilized whenever images need to be encrypted. In addition, more research can be done on the algorithm to enhance its current capabilities and make it even more powerful than it now is. Additional statistical analysis can be carried out computationally as well as visually.

**Abstract**—When an image undergoes hybrid post-processing transformation, detecting tamper region, localizing it and segmentation becomes very difficult tasks. In particular, when a copy-move attack with hybrid transformation has similar contrast and illumination parameters with an authenticated image it makes tamper detection difficult. Alongside, under small-smooth attack existing tamper identification model provides a very poor segmentation outcome and sometimes fails to identify an image as tampered. This article focused on addressing the difficulty through the adoption of the Deep Learning model. The proposed technique is efficient in detecting tampering with good segmentation outcomes. However, existing models fail to distinguish adjacent pixels' relationships affecting segmentation outcomes. In this paper, an Improved Convolution Neural Network (ICNN) assuring correlation awareness-based Tamper Detection and Segmentation (TDS) model for image forensics is presented. This model brings good correlation among adjacent pixels through the introduction of an additional layer namely the correlation layer alongside vertical and horizontal layers. The TDS-ICNN is very effective in localizing and segmenting tamper regions even under small-smooth post-processing tampering attacks by using a feature descriptor built using aggregated three-layer ICNN architecture. An experiment is done to study TDS-ICNN with other tamper identification models using various datasets such as MICC, Coverage, and CoMoFoD. The TDS-ICNN is very efficient under different post-processing hybrid attacks when compared with existing models.

## I. INTRODUCTION

Image authentication methods are characterized in the following two classes: (1) Active and (2) Blind or Passive. Digital Watermarking has been proposed as an active method using which an image can be authenticated [1]. The main aim of watermarking is to ensure the protection of copyright, authentication of content, ownership recognition, and data integrity. Watermarking ensures content from modification only and also provides data integrity and content authentication. Watermarks generally are indivisible from the digitized picture element they are embedded in. Further, the

watermarks undergo a similar transformation in the picture. The major drawback of using watermarking is that it prerequisites watermark to be embedded during capturing of the image. This also binds/restricts its applicability to real-time environment usage. Thus, they are used only in controlled surroundings such as in armed forces and surveillance environments. Furthermore, some watermarks may break down the image quality.

Passive or blind forgery detection considers images without any digital signature, digital watermark, or any other prior information and checks the authenticity and origin of the image. Image forgery may not leave any visual clues of tampering being done. But there are high chance that it most probably perturbs the underlying statistical characteristics of an original image or modifies the scene of an image. These inconsistencies are utilized for tampering identification. Since this method doesn't require any prior knowledge of the picture. Passive forgery authentication techniques are further divided into forgery-dependent techniques and forgery-independent techniques as shown in Fig. 1. Forgery-dependent methodologies are delineated to identify a particular class of tampering for example splicing, copy-clone, etc. which relies on the forgery class type used on a picture. Whereas latter, the independent methods identify tampering using artifact traces left in the procedure of carrying out light inconsistencies and re-sampling. Existing forgery detection techniques recognize various traces of forged segments and identify them and the forged segment is localized [2].

Over many years, several attempts have been made for the classification of whether given images are authenticated or forged. Nonetheless, just a couple of works [3] endeavor to localize tampering at the pixel level. Recent methodologies [4] have aimed at addressing the localization issue by characterizing patches as tampered. Establishing the location of the tampered region ring is an exceptionally difficult job and also well-crafted tampering of pictures doesn't leave any visual hints. A sample repetition of well-crafted image tampering is shown in Fig. 1, where image one and three defines the tampered image, and image two and four defines the ground truth of the respective image that has been forged through transformation attacks. In Fig. 1(a), a copy-clone

attack is presented where a set of objects is copied and pasted into the different regions within the image. Here one image is the source and the other is the copy-moved object. Fig. 1(b), defines the spliced attack, here an object within an image is spliced and copied into a different image. Fig. 1(c), shows an object removal attack, where an image is blended on top of some-other object.

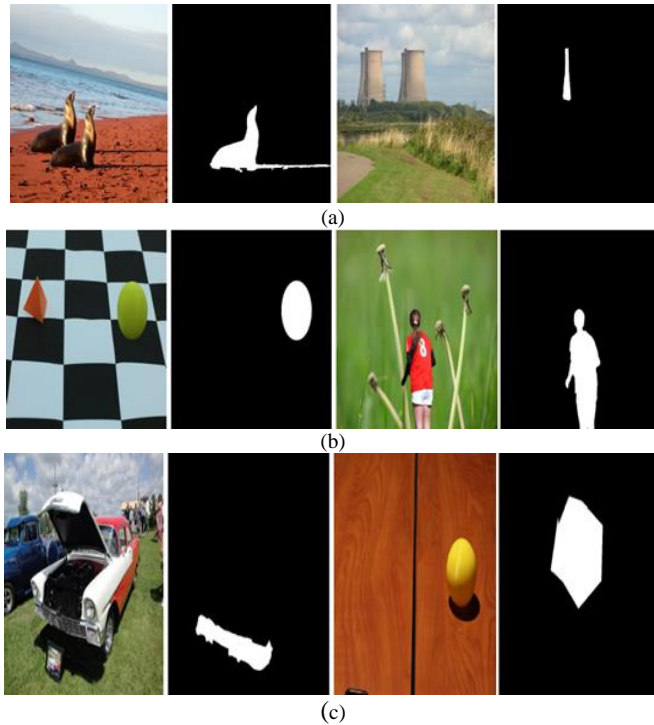

Fig. 1. Different types of tampering attacks [7].

The majority of the cutting-edge image forgery detection approaches uses statistical properties through frequency domain feature. In [5], the artifact was introduced by applying a different level of JPEG compression for the identification of tampered images. In [6], additional noisy information was added to images that were compressed through JPEG to work on the presentation of resampling identification. Recently, the DL method has provided some very good results in computer vision applications, for example, object detection, hyperspectral crop classification, image registration, and segmentation, etc. Recently, DL models like auto-encoders [7] and Convolutional Neural Networks (CNN) [8], [9] have been employed for image tampering detection with good results. Existing tampering detection models are predominantly designed to detect only one kind of attack [10], [11]. In this way, one methodology probably won't excel in different sorts of tampering attacks. Additionally, it appears to be not realistic to expect this sort of attack well in advance.

Segmenting the tampering region is more challenging as compared to object segmentation because here only the region that is tampered only must be segmented. Recently, CNN has been emphasized with good effect for object segmentation strategies [12], [13]. In [12], a fully connected CNN has been used for studying object features and shape features through the extraction of features in a hierarchical manner. The CNN-based method provides good performance in the field of

segmentation and object classification. In image tampering only the tampered region must be segmented and well-crafted tampered image differentiating between genuine and tampered is very difficult because they look very comparable. Although CNN produces spatial guides for various districts of sections, it can't sum up some different statistical noise made by various tampering methods. Consequently, the tampering region localization using a standard CNN-based design may not provide the ideal performance requirement of a realistic attack. In [13], studied different image forgery segmentation models were studied [14]. The study shows that the existing model performs badly in detecting copy-clone and object-removal. Using the resampling feature [4] the artifacts were created (i.e., resampling, compression) using tampered images can be learned [15]. The resampling attack generally occasionally allows correlation among pixels because of interpolation. The CNN-based [16], [17], image forgery identification model learns resampling features [18] very well using spatial maps produced through translation invariance of various regions of images [19], [20]. Thus, this research work aims to build an efficient resampling feature detection through CNN to detect hybrid attacks and achieve better-tampered region segmentation outcomes [21], [22]. The significance of the research work is as follows:

- This paper presented an improved CNN for tampering detection and segmentation in the image by adding to additional layer to retain the correlation between horizontal and vertical streams for exploiting good-quality resampling features.
- The TDS-ICNN model can work well considering different attacks such as scaling, compression, and rotation attacks.
- The TDS-ICNN is efficient in detecting multiple tampered regions within the same image.
- The TDS-ICNN can even detect image tampering attacks under noisy and small-smooth regions. An improved tampering area segmentation outcome using TDS-ICNN for tampering dataset with hybrid transformation attack is achieved. On the other side, the existing model works well i.e., good segmentation for some datasets, and for other datasets, very poor result is achieved.
- This shows the robustness of the TDS-ICNN model. An improved ROC performance is achieved using the TDS-ICNN model for carrying out classification tasks such as whether a given image is authenticated or tampered with considering diverse tampering datasets such as CoMoFoD, Coverage, and MICC.

The manuscript is arranged as follows: Section II discusses various current methodologies to detect tampering in multimedia content. Section III presents the material and method used for performing tampering detection methods. Section IV presents with working structure of the proposed tampering detection and segmentation model. Section V presents the experiment analysis of the proposed method with various other tampering detection methodologies. Section VI

concludes the research significance with future research direction.

## II. RELATED WORK

The section studies various recent methodologies for detecting tampering in multimedia content. In [8] developed a robust image tampering detection method using CNN, where an image undergoes double compression tampering attacks; the model attains an accuracy of 92% using the CASIA v2 dataset. Similarly, [9] used ResNet50v2 for constructing batchwise CNN to detect image tampering. Experiment outcomes show 99.3 accuracy on the Casia v1 dataset and 81% accuracy on the CASIA v2 dataset. In [11] designed a tampering detection by training CNN with both unseen noise and predictable noise for online social network platforms. The model works well for social platforms; however, considering other domains the model fails to accurately detect tampering in images. In [18] designed pulse-CNN model to extract the contour features of potential tampering that had undergone complex tampering attacks like noise, scaling, and rotation attacks. The experiment outcome shows the model achieved a precision of 95.27% and 95.3% on the CASIA and CoMoFoD datasets, respectively.

In [23] introduced an end-to-end deep neural network namely BusterNet with two layers to capture the tamper feature followed by a fusion layer to merge the feature for segmentation of copy-move tamper region. Experiments are done on CASIA and CoMoFoD and segmentation output is given at pixel-level. Similarly, in [26] designed adaptive-attention residual refined network (AR-Net) to extract tampered object features, and feature maps correlation is done after which the fusion of features is performed using pyramid pooling. The experiment is done using CASIA II, Coverage, and CoMoFoD. In [27] developed a copy-move tampering detection mechanism using source-target region distinguishment network (STRDNet) by extending BusterNet. The model additionally introduces a filter at the pooling layer with a double self-correlation layer for establishing feature matching hierarchically. The experiment is done using CASIA, CoMoFoD, and Coverage datasets and the segmentation outcome is given at the pixel level. In [29] introduced an effective block-level feature optimization trained with deep CNN. The deep CNN uses a feature pyramid for robust detection accuracy against scaling attacks. The experiment is done using CASIA II with 57.48% and the CoMoFoD dataset with a precision of 50.11% and the boundary pixel direction aids in the detection of segmentation edges and can tolerate noise, compression, blurring, and color addition.

In [24] designed a key-point-based clustering method to detect tampering attacks under small-smooth regions. Experiments are done on MICC, GRIP, FAU, and Coverage with good true positive rates of 97.5%, 100.0%, 100%, and 80.22%, respectively. In [25] designed a new SIFT key points extraction through effective clustering for identifying

tampered regions utilizing similarities. The clustering process to identify similarities is done considering color with different scales and smaller cluster size is considered to reduce computational overhead. In obtaining more quality outcomes pixel level similarity is done iteratively. The experiment is done using D0 datasets and pixel-level analysis segmentation accuracy is measured. In [30] combined both accelerated KAZE (A-KAZE) and speeded up robust features (SURF) for extraction of features by keeping the contrast level reasonably low. Then, to eliminate the mismatch density-based spatial clustering (DBSCAN) is used. Then, the affine matrix is applied to improve the tampering localization accuracy. The experiment is done with Ardizzone (D0) with 92.75% precision and the CoMoFoD dataset [31] with 95.23%. The overall survey shows key-point-based tampering detection is predominantly studied its performance using the MICC and DO dataset and the CNN-based model is predominantly studied using CASIA, Coverage, and CoMoFoD dataset.

The result attained using existing tampering detection methods have obtained satisfactory results; however, there is still wide scope to improve the results, as the existing model failed to provide good segmentation result under small-smooth robust tampering attacks which undergoes diverse post-processing attacks. Further, the model must be tested under different kinds of datasets; and most of the existing methods failed to provide pixel-level segmentation analysis. The current methods failed to extract feature correlation between horizontal and vertical layers; as a result, higher false positive is experienced with poor segmentation outcomes. In overcoming the research issues in the next section, the proposed methodology is presented.

## III. MATERIALS AND METHODS USED

### A. Dataset Used

The dataset used in this work is listed below:

1) *MICC*: The dataset is composed of 600 images out of which, 160 images are forged, and the remaining 440 images are authenticated. The dataset is composed of different attacks like scaling and rotation made of plants, artifacts, animals, etc.

2) *CoMoFoD*: The dataset is made of a total of 260 images where several post—processing attacks are done. The resolution images are 512×512 for 200 images where different post-processing attacks have been done to obtain a total of 10,400 images. The other 60 images have a resolution of 3000×2000 and different post-processing attacks like compression, blurring, scaling, rotation, and noise addition have been created to obtain a total of 3120 images.

3) *Coverage*: The dataset is composed of different copy-clone attacks with a total of 100 images of tampered and as well as authenticated ones. The image size is 400×486 with complex attacks like rotation, scaling, and illumination attacks.

Fig. 2. Architecture of tampering detection and segmentation using improved convolution neural network.

### B. Preprocessing

The work has used a total of three datasets; in this first, the image is resized to  $512 \times 512$  into the non-overlapping region of 64 (i.e.,  $8 \times 8$ ) similar to the work presented in [17]; thus, induces certain artifacts. In [17] used space-filling curve for extracting correlation among both horizontal and vertical streams; the model achieved good, tampered region detection accuracies; however, with poor segmentation accuracies; especially under small-smooth hybrid attacks. In addressing the segmentation problem, this paper introduces an improved CNN model that with an additional layer to obtain a good correlated features-map for achieving improved tampered region detection and segmentation outcome.

## IV. PROPOSED METHODOLOGY

The methodology to localize and segment tamper regions considering hybrid attacks using TDS-ICNN is presented in this section. The feature extraction process using TDS-ICNN. Lastly, extracted features are highly correlated and training is done to create a good descriptor in classifying whether a given image is authenticated or tampered with.

### A. System Model and Architecture

The preprocessed image are passed into proposed improved CNN model for extraction of resampling features and identify the tampered region and segment it. In this work

50% of images from three different dataset is taken as input during training process of ICNN and tampering detection and segmentation model is constructed. The architecture of TDS-ICNN is given in Fig. 2. The working of tampering detection using ICNN architecture is given in Algorithm 1.

---

### Algorithm 1: the ICNN-based tampering detection and segmentation.

---

**Step 1. Start**

**Step 2. Load the images.**

**Step 3. Preprocess image into  $512 \times 512$  into the non-overlapping region of 64 (i.e.,  $8 \times 8$ )**

**Step 4. Pass the image into a three-layer ICNN.**

**Step 5. The first layer extracts the multi-dimensional RSF with the presence of noise. The RSF is captured by considering the difference between adjacent pixels across vertically and horizontally directions.**

**Step 6. The middle layer extracts the high-level feature across vertical and horizontal directions. The features that are correlated across both horizontal and vertical directions are aggregated.**

**Step 7. The, using last layer i.e., SoftMax and sigmoid function takes aggregated features as input for learning diverse features and optimizing binary tampering detection problems in multimedia forensics, respectively.**

**Step 8. Store the result and segmentation outcome.**

**Step 9. Stop**

---

A detailed explanation of the different layers is given below.

### B. Extraction of Noisy Features

In multimedia forensic extraction of resampling features is difficult as it is dependent on the information presented in a respective image. Nonetheless, some existing methodologies showed RSF extraction is not dependent on an image by extracting RSF through spatial domain using redundant feature properties. In this work, the noise is modeled by interpolating the current pixel with neighboring pixels and the difference in estimates is computed considering the image size of  $256 \times 256$ . In extracting the initial resampling feature with minimal training overhead two high-pass filters are used CNN kernel namely horizontal  $3 \times 1$  and vertical  $1 \times 3$  filters. Then the image is convoluted with padding and stride set to 1 using these filters, after that the difference (i.e., correlation) between neighboring pixels in vertical and as well horizontal direction are extracted to obtain a residual map of  $256 \times 256 \times 1$ .

### C. High-level Feature Extraction

This layer takes input from the previous layer for extraction of high-level features. The standard tampered region detection and segmentation model extracts features and correlates through each direction individually; as a result, exhibits very poor performance. However, in this paper, the RSF features are extracted and weighted in both directions individually, where it is composed of five similar groups. The group encompasses 4-layer such as convolutional layer, batch normalize layer, activation layer, and pooling layer. The fifth group has correlated features collected from the middle layer of TDS-ICNN. Finally, the features from different layers are aggregated to obtain the final RSF feature to perform tapering detection classification.

The middle layer in TDS-ICNN fuses the correlated features from both directions. The middle layer is composed of 4 groups such as convolutional layer, batch normalize layer, activation layer, and pooling layer. The feature extracted from group 1 from horizontal and vertical streams is fused considering  $1 \times 1$  convolutional kernel with stride set to 1. The remaining three groups are utilized for the extraction of high-level RSF illustrations of aggregated tampering information. Finally, by interpolating in both directions backward the feature map is established.

### D. Classification

The ICNN introduces fully-connected CNN employing SoftMax/Sigmoid operation. The model takes input features from the middle layer and performs classification based on probability estimates that belong to the tampered or non-tampered group using the following equation.

$$P(z = 1|y) = \frac{1}{1+f^{-a}} \quad (1)$$

$$P(z = k|y) = \frac{f^{a_k}}{\sum_{l=0}^L f^{a_l}} \quad (2)$$

where Eq. (1) defines the sigmoid operation of a fully connected layer for performing classification of establishing whether an image is tampered with or not as output. The parameter  $P(z = 1|y)$  defines the probability of whether  $y$  is

classified into the respective group. Eq. (2) is used for detecting multiple tampered regions using SoftMax operation, where  $a_k$  is the fully connected layer output of the  $k^{th}$  neuron. The parameter  $P(z = k|y)$  defines the probability of whether  $y$  belongs to the  $k^{th}$  group.

### E. Convolution Layer

The feature extraction done using the convolutional layer is as follows

$$G_k^{(o)} = \sum_{l=0}^L G_l^{(o-1)} * \alpha_{lk}^{(o)} + c_k^{(o)} \quad (3)$$

where  $G_k^{(o)}$  defines the  $k^{th}$  feature-map established inside the  $o^{th}$  layer,  $G_l^{(o-1)}$  represents the  $j^{th}$  feature-map established inside  $(the\ o - 1)^{th}$  layer,  $\alpha_{lk}^{(o)}$  defines the  $l$  channel of  $k^{th}$  convolutional kernel inside the  $o^{th}$  layer, and  $c_k^{(o)}$  represents  $k^{th}$  bias parameter of  $o^{th}$  layers, and  $*$  represent two-dimension convolution operation. The convolutional layer is set to 3 filters with sizes of  $(1 * 1, 3 * 3, \text{ and } 5 * 5)$  and a stride of 1.

### F. Batch Normalization

The feature map extracted in the previous layer is normalized according to feature variance according to its distribution in the middle layer. The batch normalizer operates between activation and convolutional layers. The average between total information inside the batch is described as follows

$$\beta = \frac{1}{n} \sum_{j=0}^n y_j \quad (4)$$

where  $\beta$  defines the average,  $n$  defines the overall size of the feature used, and  $y_j$  represents the  $j^{th}$  information used. In a similar, manner the difference between the total features inside the batch is estimated as follows

$$\gamma^2 = \frac{1}{n} \sum_{j=0}^n (y_j - \beta)^2 \quad (5)$$

where  $\gamma^2$  defines the difference. In this work, normalization is done on each feature to obtain new feature sets  $\hat{y}_j$  with average initialized to 0 and difference initialized to 1 and is obtained using the following equation

$$\hat{y}_j = \frac{y_j - \beta}{\sqrt{\gamma^2 + \delta}} \quad (6)$$

where  $\delta$  defines a trivial floating-point parameter higher than 0 that is used for avoiding dividing by zero error. The final batch-normalized feature is expressed as follows

$$z_j = \varphi \hat{y}_j + \omega \quad (7)$$

where,  $\varphi$  and  $\omega$  are the CNN extracted features, and  $z_j$  defines batch normalization  $j^{th}$  output. In this work to obtain better features an activation function is used that is non-linear. The adoption of such a layer will not cause significant changes due to smaller fluctuations in prediction error.

### G. Activation

In this work, the TDS is represented in the form of different spaces for achieving better-tampered region detection in multimedia forensics. The work uses TanH as an activation

function instead of ReLu and Sigmoid because it works well for features with higher differences.

#### H. Pooling Layer

The element size is reduced by down-sampling the feature maps and establishing the hierarchical structure by observing continuous features' convolutional filter. The max pooling kernel size is set to 3×3 and stride of 2 and is applied to all pooling layers except the 5<sup>th</sup> layer of both streams for providing maximum parameter in each input feature-maps by capturing patterns on neighboring pixels. The average pooling is used in the last pooling layer of both streams for down-sampling the feature maps to 1 to minimize the model parameter of fully connected CNN. The adoption of such a mechanism significantly aided in achieving improved tampered region identification and segmentation using the proposed methodology.

### V. EXPERIMENTAL STUDY

In this section experiment is done to validate the performance of TDS-ICNN over existing tampering detection methodologies like copy-move forgery detection using binary descriptor feature (CMFD-BDF) [22], BusterNet [23], fast and efficient CMFD (FE-CMFD) [24], AR-Net [26], and STRDNet [27].

#### A. Setup and Metrics

The TDS-ICNN model is modeled utilizing Python, C++, and Matlab libraries. The Intel I-7 processor with 16 GB RAM running with Windows 10 platform is used for conducting the experiments. Performance is evaluated using MICC-600, Coverage, and CoMoFoD dataset. The MICC-F600 dataset undergoes scaling and rotation post-processing tamper attacks. The CoMoFoD dataset undergoes compression, scaling, and rotation post-processing tamper attacks. The coverage dataset undergoes compression, scaling, and post-processing tamper attacks. The ROC metrics used are recall/ true positive rate (TPR), false positive rate (FPR), and F1-score for validating different tamper identification models.

$$\text{False positive rate (FPR)} = \frac{FP}{(FP + TN)} \quad (8)$$

$$\text{True positive rate (TPR)} = \frac{TP}{(TP + FN)} \quad (9)$$

$$\text{F1 - Score} = \frac{2TP}{((2TP + FN + FP))} \quad (10)$$

$$\text{Accuracy} = \frac{((TN + TP))}{((TP + FP + TN + FN))} \quad (11)$$

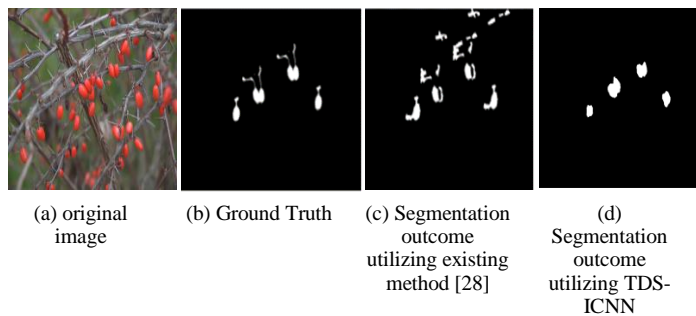

Fig. 3. Segmentation outcome of different methodologies.

Fig. 4. Recall performance for MICC-600 dataset.

#### B. MICC Dataset

The experiment is conducted using the MICC-F600 dataset. The tampering segmentation result utilizing TDS-ICNN and other recent tamper identification models is graphically represented in Fig. 3. From Fig. 3 it is seen that TDS-ICNN provides improved tampering region segmentation outcomes when compared with existing models. Fig. 4 shows recall performance achieved utilizing TDS-ICNN and other existing tampering detection methodologies. Fig. 5 shows false positive rate performance achieved utilizing TDS-ICNN and other existing tampering detection methodologies. Fig. 6 shows the F1-score at image level performance achieved utilizing TDS-ICNN and other existing tampering detection methodologies. Fig. 7 shows that the F1-score at pixel-level performance was achieved utilizing TDS-ICNN and other existing tampering detection methodologies. The outcome obtained from Table I shows that TDS-ICNN improves detection accuracy and reduces false positives; thus, it can be adapted to provide a reliable tamper identification model.

### C. Coverage Dataset

Here experiment is carried out using a coverage dataset. In the dataset is very difficult to classify which is authenticated and which is tampered one. The tampering segmentation

results utilizing TDS-ICNN and other recent tamper identification models are graphically represented in Fig. 8 and Fig. 9. The result proves improved tamper region segmentation outcomes utilizing TDS-ICNN concerning recent tamper identification models. Fig. 10 shows the accuracy of performance achieved utilizing TDS-ICNN and other existing tampering detection methodologies. Fig. 11 shows the F1-score utilizing TDS-ICNN and other recent tamper identification methodologies. The outcome obtained from Table II shows that TDS-ICNN improves detection accuracy and reduce false positive and hence, it can be adopted to provide a reliable tamper identification model.

### D. CoMoFoD Dataset

The CoMoFoD dataset is utilized for studying the performance of TDS-ICNN with other recent tamper identification models. The dataset has diverse post-processing attacks being accrued out; thus, making it extremely challenging to detect tamper regions and localize them. The tampering segmentation result utilizing TDS-ICNN and other recent tamper identification models is graphically represented in Fig. 12. From Fig. 12 it can be stated that TDS-ICNN improves tamper region segmentation outcomes when compared with existing models. Fig. 13 shows recall performance achieved utilizing TDS-ICNN and other existing

tampering detection methodologies. Fig. 14 shows the precision performance achieved utilizing TDS-ICNN and other existing tampering detection methodologies. Fig. 15 shows the F1-score result utilizing TDS-ICNN and other recent tamper identification methodologies. The outcome obtained in Table III shows that TDS-ICNN improves detection accuracy and reduces false positives; thus, can be adapted to provide a reliable tamper identification model.

## VI. CONCLUSION

The research work has presented a technique namely TDS-ICNN to identify whether an image is authenticated or tampered with. The preprocessing technique and feature extraction technique adopted in TDS-ICNN can retain spatial features concerning different patches. Alongside this, a good correlation exists among both horizontal and vertical curves through the introduction of a correlation layer. To eliminate spatial dependencies, the features extracted are aggregated and a descriptor is constructed to perform classification. The experiment is conducted using three datasets, such as MICC-600, Coverage, and CoMoFoD. For the MICC dataset the existing methods namely CMFD-BDF attains a TPR and F1-Score of 89.14% and 92.6%, respectively; however, the proposed TDS-ICNN attains a TPR and F1-score of 99.1% and 98.6%, respectively. For the Coverage dataset the existing methods namely AR-Net attain an accuracy of 84.88% and the proposed TDS-ICNN attains an accuracy of 85.63%, respectively. Similarly, the STRDNet attains an F1-score of 67.7%, and the proposed TDS-ICNN attains an F1-Score of 74.56%. For the CoMoFoD dataset the existing methods namely AR-Net attains a recall, precision, and F1-Score of 46.55%, 54.21%, and 50.09%, respectively; however, the proposed TDS-ICNN attains a recall, precision, and F1-Score of 89.0%, 76.54%, and 85.6%, respectively. The result attained shows that superior performance is achieved using TDS-ICNN in comparison with other standard tamper detection methods. A good ROC performance such as TPR, FPR, F1-Score, and accuracy in comparison with other existing tamper detection methodologies is achieved. The significant result provides a satisfactory benchmark for using it for real-time tampering image circulation in social media platforms and WhatsApp messenger; thereby can prevent misleading information circulation.

Future work would be focused on studying the model performance on other standard datasets like CASIA, and DO. The work would further investigate how the proposed model can be used to detect tampering in video. Further, would focus on developing an ensemble learning model to improve tampering detection accuracy with fewer false positives.

**Abstract**—Loss of life and property often occur due to natural disasters and other significant occurrences like earthquakes, which make manual damage assessment a time-consuming and inefficient process. In an attempt to address this challenge, researchers have been investigating the field of automated damage assessment in Remote Sensing. With time, this area of research has transformed from conventional machine learning techniques to more sophisticated deep learning techniques. The study puts forward the PRESSNet model as a solution for assessing building damage. The effectiveness of the proposed PRESSNet model is compared to that of a baseline model, PSPNet, and ResNet 50, across different types of damage. This study contributes by introducing the spatial attention module to the baseline model. The xBD Dataset was used both before and after the Palu earthquake disaster. The results show that PRESSNet performs similarly or slightly better than the baseline model in all damage categories. This illustrates the impressive ability of the proposed PRESSNet architecture to accurately detect and classify building damage. This research sheds light on the development of effective models for assessing disaster damage and lays the foundation for future progress in this crucial area.

**Keywords**—Remote sensing; deep learning; PSPNet; ResNet; spatial attention

## I. INTRODUCTION

In an era characterized by an increasing frequency of natural disasters, including earthquakes, floods, and hurricanes, which yield dire consequences, the importance of proficient crisis management becomes paramount. These catastrophic events result in not only the unfortunate loss of human lives but also substantial property damage [1]. Access to crucial information, both before and after a catastrophic event, proves to be of utmost importance in enhancing disaster response strategies and mitigating the impact on human lives and physical infrastructure [2]. In addition to enhancing the capacity for early detection and warning before the crisis begins, it is crucial to gather information about a disaster as soon as it occurs [3].

Assessing structural damage to buildings stands as a critical issue in the field of disaster response, as it has been identified as a prominent factor contributing to the loss of life during natural calamities [4]. The precise assessment of such harm is crucial to enhance emergency response efforts and ultimately preserve a greater number of lives. Recent advancements in remote sensing technology and the deployment of satellite constellations have greatly enhanced our ability to obtain high-resolution satellite (HRS) data [5]. Integrating this wealth of data with machine learning (ML) and deep learning (DL)

methodologies offers a promising approach for evaluating structural damage in the aftermath of a calamitous event [5].

Assessing structural damage to buildings stands as a critical issue in the field of disaster response, as it has been identified as a prominent factor contributing to the loss of life during natural calamities [4]. The precise assessment of such harm is crucial to enhance emergency response efforts and ultimately preserve a greater number of lives. Recent advancements in remote sensing technology and the deployment of satellite constellations have greatly enhanced our ability to obtain high-resolution satellite (HRS) data. Integrating this wealth of data with machine learning (ML) and deep learning (DL) methodologies offers a promising approach for evaluating structural damage in the aftermath of a calamitous event [5].

However, recent evaluations of the PSPNet model, which employs ResNet 50 as its underlying framework, have identified shortcomings in effectively gathering and leveraging contextual information at various scales, particularly in the intricate realm of building degradation [8]. To address this challenge, the present study introduces the PRESSNet framework, which utilizes spatial attention mechanisms to enhance the identification and prioritization of critical regions inside a building that exhibit signs of structural deterioration. PRESSNet's performance in accurately evaluating the extent of building damage surpasses that of the PSPNet + ResNet-50 model, showcasing its capacity to augment disaster response efforts.

The primary objective of this study is to underscore the importance of spatial attention mechanisms within deep learning models for the purpose of disaster response. PRESSNet's contribution to the advancement of computer vision research in disaster management lies in its emphasis on the effective identification and classification of different levels of damage. This study highlights the significance of attention mechanisms in improving the performance of convolutional neural networks, thereby contributing to the development of more efficient disaster response systems.

Furthermore, this study introduces the PRESSNet model as a solution for assessing building damage. It compares the effectiveness of PRESSNet to that of a baseline model, PSPNet, and ResNet 50, across different types of damage. The xBD Dataset is utilized both before and after the Palu earthquake disaster. The results demonstrate that PRESSNet performs similarly or slightly better than the baseline model in all damage categories. The baseline model exhibits strong performance with a macro-average F1 score of 89.5%, while

PRESSNet slightly outperforms it, achieving a macro-average F1 score of 90%. This illustrates the impressive ability of the proposed PRESSNet architecture to accurately detect and classify building damage. This research sheds light on the development of effective models for assessing disaster damage and lays the foundation for future progress in this crucial area.

## II. RELATED STUDIES

### A. Building Damage Assessment in High Resolution Satellite Imagery using Deep Learning

The assessment of building damage using deep learning models, particularly convolutional neural networks (CNNs), has been a prominent subject of investigation within the domain of remote sensing utilizing satellite and aerial photography. The authors, Garg et al. [8], introduced a deep convolutional neural network (CNN) that utilizes transfer learning to do building damage assessment using satellite photos. The model underwent training by utilizing a pre-existing VGG16 network, which was subsequently fine-tuned using a dataset specifically curated for earthquake-affected buildings. The results indicate that the suggested model had superior performance compared to standard machine learning techniques, achieving an accuracy of 87% on the test dataset.

The authors, Hu et al. [9], introduced an innovative methodology that uses deep learning techniques to evaluate structural harm in buildings through the analysis of aerial photography. The employed methodology involved the utilization of a Siamese network architecture to conduct a comparative analysis of aerial photos captured before and after a catastrophic event. The objective was to accurately detect and pinpoint areas where structural damage to buildings had occurred. The model achieved an overall accuracy of 92.65 percent on the test dataset.

Using satellite data, Shah et al. [10] created a deep convolutional neural network (CNN) method that makes use of transfer learning to assess the degree of building damage. The model under consideration utilized a pre-existing ResNet-50 network [11], which was subsequently refined through the process of fine-tuning. A dataset of buildings damaged by Hurricane Harvey served as the basis for this refinement. Waseem et al. [12] developed a system based on deep learning methods to assess the degree of building damage using satellite data. The proposed model integrates features derived from a pre-trained ResNet 50 network with manually engineered characteristics, including texture and color features.

### B. PSPNet

The assessment of building damage holds significant importance in the aftermath of disasters, as it serves to guide relief operations, optimize resource allocation, and ascertain the overall consequences of both natural and human-induced calamities. The assessment of building damage has been significantly improved with the application of convolutional neural networks (CNNs), thanks to recent breakthroughs in computer vision and deep learning. The Pyramid Scene Parsing Network (PSPNet) is a convolutional neural network (CNN) architecture that has gained significant recognition due to its capacity to effectively capture contextual information at several scales.

The Pyramid Scene Parsing Network (PSPNet) is a convolutional neural network that uses a pyramid pooling module to capture contextual information at many scales. Additionally, it incorporates a spatial attention module to enhance important features and suppress non-informative ones [13]. The inclusion of the pyramid pooling module in PSPNet facilitates the efficient extraction of features at different scales. This capability is crucial in accurately identifying zones of building damage that exhibit diverse sizes. The architecture of PSPNet incorporates a pyramid pooling module that effectively combines contextual information from multiple scales. The module presented in this study is designed to gather contextual information at many scales. This enables the model to effectively capture both global and local contextual information that is relevant for building damage assessment. The inclusion of the pyramid pooling module significantly contributes to the model's ability to effectively differentiate between regions that are damaged and those that are unaffected.

Dilated convolutions, which are also called atrous convolutions, are used in the PSPNet architecture to increase the receptive field while keeping the spatial resolution the same. Dilated convolutions enable the neural network to record a wider contextual range by introducing gaps inside the convolutional kernels, thereby maintaining the integrity of spatial details. The PSPNet employs a fusion technique to effectively integrate contextual information by merging elements at many scales. The final segmentation map is generated by combining and refining the multi-scale feature maps from the pyramid pooling module using convolutional layers.

The PSPNet model comprises three primary components, each serving distinct roles. By using ResNet 50 as the underlying framework, it is possible to create a feature map from an input image. The pyramid parsing module utilizes the feature map of the initial module, ResNet 50, to extract representations of four separate sub-representations. These sub-representations are obtained using convolution operations of sizes  $1 \times 1$ ,  $2 \times 2$ ,  $3 \times 3$ , and  $6 \times 6$ . The result of the representation that was restored in the preceding layer is increased in size and combined with all of the increased representations, together with the characteristics that were mapped in the initial module. The convolutional layer utilizes a representation of the input image produced from the second module in order to obtain the final semantic segmentation results.

The point-wise attention blinders used for the research conducted by Hamdi et al. [14] exhibit dissimilarities when compared to the blinders employed in other studies. The PSA module specifically instructs on the implementation of location- and category-sensitive masks that possess self-adaptive capabilities. The Public Service Announcement (PSA) acquires the ability to gather contextual information for each unique point in a manner that is flexible and tailored to the specific needs of the user.

The method of pooling known as shift pooling was introduced by Yuan et al. [15] and was implemented to enhance the performance of PSPNet. The repositioning of the pooling grid allows for the comprehensive acquisition of local

feature information by the pixels located at the edges and corners of the grid, resulting in enhanced segmentation outcomes.

### C. Spatial Attention Mechanism Module

The spatial attention mechanism (SAM) has been identified as a highly successful approach for evaluating building damage and other computer vision tasks. The Spatial Attention Module (SAM) is employed to consolidate comparable picture information and augment the network's capacity to depict these characteristics. The utilization of SAM allows the model to effectively allocate importance to informative traits while simultaneously suppressing non-informative ones through the selective concentration on pertinent regions. This approach has been widely employed in several deep learning models to evaluate the extent of building damage.

Chen et al. [16] introduced a novel approach for enhancing the precision and consistency of building damage assessment. Their proposed method involves utilizing a change detection feature extractor, which incorporates a pyramid spatial temporal attention module. The experiments showed that this module, called SAM, makes it possible for the network to capture similar features and highlight the unique features of damaged regions.

The domain of remote sensing through satellite and aerial imaging has witnessed significant research activity in the realm of building damage assessment. Deep learning models, particularly convolutional neural networks (CNNs), have emerged as a prominent approach in this subject. The authors, Garg et al. [8], introduced a deep convolutional neural network (CNN) that utilizes transfer learning to do building damage assessment using satellite photos. The model underwent training by utilizing a pre-existing VGG16 network and subsequently underwent refinement through the utilization of a dataset consisting of buildings impacted by earthquakes. The results indicate that the suggested model exhibited superior performance compared to standard machine learning techniques, achieving an accuracy rate of 87% on the test dataset.

Attention mechanisms are widely used in deep learning. An attention model was created by Mnih et al. [17] that picks a number of regions or sites for processing in an adaptive manner. Multiple attention masks were found by Chen et al. [18] to combine feature maps or forecasts from many branches. Pre- and Post-Disaster Imagery were recovered from a single model with the same weight in investigations conducted by Weber et al. [19], and the output features were layered (concatenated) to derive features between pre and post.

A self-attention machine translation model was developed by Vaswani et al. [20]. The correlation matrix between each spatial location in the feature map was calculated by Wang et al. [21] to identify attention masks. Zhao et al.'s [22] point-wise spatial attention network (PSANet) was suggested as a way to relax the local neighborhood constraint. A self-adaptively learnt attention mask connects each location on the feature map to every other location. Additionally, scene understanding is allowed through bidirectional information propagation. The

forecast of the current position can be aided by knowledge from previous positions, and the prediction of other positions can benefit from information from the current one.

## III. RESEARCH METHODOLOGY

### A. Dataset

The applied dataset is the 2018 Palu earthquake from the Tier 1 XBD dataset (<https://xview2.org>). Fig. 1. shows the map of Palu. No damage, minor damage, major damage, and destroyed are the four levels of damage. Pre- and post-disaster dataset images are distributed as follows: 80% to the training dataset and 20% to the test dataset.

### B. Data Preprocessing

The original dimension of the Palu dataset was 128 x 128 pixels, which has been reduced to 64 x 64. No Damage and Destroyed are the two classes or levels within this research. Pre- and post-disaster images for the Train Dataset increased from 54 to 3264. Pre and Post Images increased from 15 Images (1024x1024) to 1024 Images (256x256) in the test dataset. The training dataset is composed of 70% Training data and 30% Validation data. The training dataset is then rotated by 30 degrees to generate a new patch. The Steps per Epoch used for this research are 16000 for Training and 5000 for validation.

The training dataset was used to optimize the neural network, whereas the validation dataset was used to evaluate the network's training efficacy. Using the evaluation dataset, the effectiveness of the optimized neural network was determined. The validation and training images were read into (256, 256, 4) arrays of the form. The labels were interpreted as an array of shapes (256, 256, 1), with the values 1 or 0 indicating whether the item is damaged or not.

Fig. 1. Palu earthquake, 2018.

### C. Proposed Method

This study proposed the model PRESS-Net, which consists of the single segmentation model PSPNet[10] using ResNet[12] as a with different backbone using ResNet 50 and ResNet 101 with Hyperparameter Tuning and Spatial Attention

Module [23] to learn which feature and where the location of feature is important to be selected.

Fig. 2. Spatial attention module architecture.

The spatial attention map is generated by applying the interspatial relationship between features. When compared to channel attention, the spatial attention module architecture (see Fig. 2) emphasizes "where" as an additional information component. We first use average-pooling and max-pooling operations along the channel axis to compute spatial attention, and we then concatenate the results to provide an efficient feature descriptor. It has been proven that aggregating procedures applied along the channel axis can effectively highlight informative regions. We apply a convolution layer to the concatenated feature descriptor to generate a spatial attention map  $M_s(F) \in R^{H \times W}$  that encodes where to highlight or suppress.

The computation for spatial attention is as follows:

$$M_s(F) = \sigma(f^{7 \times 7}([AvgPool(F); MaxPool(F)])) \\ = \sigma(f^{7 \times 7}([F_{avg}^s; F_{max}^s]))$$

- Where  $\sigma$  denotes the sigmoid function and  $f^{7 \times 7}$  represents a convolution operation with the filter size of  $7 \times 7$  [23].

---

**Algorithm 1: Pseudocode for building segmentation using CNNs**

**Inputs:** xBD Dataset

**Output:** Segmented building damage

1. **Start:**
2. Load and preprocess the xBD Dataset
3. Apply noise removal to the Palu dataset
4. Initialize training loop counter  $i = 1$
5. Set maximum training loops as MAX\_LOOPS
6. Do while  $i \leq MAX\_LOOPS$ :
7. # Training Data Augmentation
8. Augment training data and masks
9. # Split dataset into training and validation sets
10. Split Augmented Data into  $X_{train}$ ,  $X_{val}$  and Augmented Masks into  $y_{train}$ ,  $y_{val}$
11. # Create the PSPNet model with ResNet-50 backbone and spatial attention
12.  $pspnet\_model = create\_pspnet(input\_shape, num\_classes)$
13. # Train the model
14. Train  $pspnet\_model$  on  $X_{train}$  and  $y_{train}$  for a specified number of epochs
15. # Evaluate the model's performance on validation set
16. Evaluate  $pspnet\_model$  on  $X_{val}$  and  $y_{val}$  to get validation loss and accuracy
17. # Print evaluation results (optional)
18. Print "Validation Loss:", validation\_loss
19. Print "Validation Accuracy:", validation\_accuracy
20. # Save the trained model (optional)
21. Save  $pspnet\_model$  to disk with a suitable filename
22. # Increment training loop counter
23. Increment  $i$

24. End do while
25. End

- The process begins by loading a dataset called xBD, containing images of building damage. These images are prepared for analysis by removing any distracting noise from them, which helps the algorithm focus on the key information. To train an accurate model, a training loop is set up. A loop counter named 'i' starts at 1, and a maximum number of loops (MAX\_LOOPS) is predetermined to manage the training process. Inside the loop, data augmentation is applied to the training images and their corresponding masks.
- This augmentation involves making small changes to the images, like flipping or rotating, to create a more varied dataset. This diversity helps the model learn better. The augmented data is divided into two parts: one for training ( $X_{train}$  and  $y_{train}$ ) and another for validation ( $X_{val}$  and  $y_{val}$ ). This separation helps evaluate how well the model performs on new, unseen data. Within the loop, a specialized model called PSPNet is constructed. It's designed to understand and segment building damage.
- This model uses a ResNet-50 backbone, which helps identify important features, and a spatial attention module to focus on critical parts of the image. The PSPNet model is trained using augmented training data. It learns from the images and their associated masks that indicate where building damage is present. This training process continues for a set number of cycles, improving the model's accuracy with each iteration. After training, the model's performance is tested on the validation dataset. This helps measure how well the model has learned to identify building damage. The results, such as validation loss and accuracy, can be printed out to assess the model's progress. If desired, the trained PSPNet model can be saved to the computer's storage. This way, the model can be reused later without needing to go through the training process again. The loop repeats as long as the loop counter 'i' is within the set maximum number of loops (MAX\_LOOPS). In each loop, the model's understanding of building damage is refined, leading to better performance.
- Once the desired number of loops is completed, the algorithm finishes its execution. This systematic approach helps create a reliable model for segmenting building damage from images, contributing to more accurate and efficient analyses.
- PRESSNet is a deep learning model that incorporates the PSPNet model, ResNet 50 architecture, and a spatial attention mechanism to improve image segmentation performance. The evaluation metrics for this research will be the macro-average F1 Score, which will be used to compare the baseline model and the proposed model. The architecture can be seen in Fig. 3.
- The ResNet 50 backbone functions as the network's foundation. Multiple residual blocks are layered to

create a deep convolutional neural network. Each residual block is comprised of multiple convolutional layers, enabling the network to learn increasingly complex characteristics.

The skip connections in the residual blocks permit gradient flow during training, thereby resolving the vanishing gradient problem and enhancing the network's capacity to acquire meaningful representations. The ResNet 50 backbone analyzes the input image and extracts multiple levels of hierarchical features, capturing both low-level details and high-level semantic information. The PSPNet (Pyramid Scene Parsing Network) module is incorporated into the architecture to collect contextual data at multiple scales.

The module operates on the ResNet 50 backbone's generated feature maps. It utilizes a pyramid pooling mechanism to combine spatially distinct features. Pyramid pooling is accomplished by dividing the feature maps into multiple regions of differing sizes and then performing pooling operations (such as average pooling) within each region. By combining features at various dimensions, the PSPNet module captures both local details and global context, giving the network a comprehensive understanding of the image.

Fig. 3. The PRESSNet architecture.

The spatial attention mechanism is implemented to selectively highlight informative image regions. It improves the network's discriminative ability by focusing on pertinent features and suppressing irrelevant or chaotic regions. Indicating the significance of each location, the mechanism allocates attention weights to various spatial locations in the feature maps.

During the training process, these attention weights are learned, allowing the network to automatically attend to informative regions. The spatial attention mechanism helps the network make more accurate predictions and improves its overall performance by focusing on pertinent features. The ResNet-50 backbone in the PRESSNet architecture extracts complex image features. The PSPNet module then processes these features to capture contextual information at multiple scales. Lastly, the spatial attention mechanism selectively accentuates significant regions, thereby enhancing the network's capacity to concentrate on pertinent features.

By integrating these elements, the architecture is able to effectively capture both local and global context, extract high-level characteristics, and selectively focus on informative regions. This improves the performance of various image comprehension tasks, such as semantic segmentation, where precise object boundary delineation and accurate pixel-level predictions are essential.

#### IV. RESULT AND DISCUSSION

PRESSNet made use of the Palu earthquake disaster dataset, which it acquired from the xBD dataset. The proposed method, which is called "PRESSNet," combines the effectiveness of the PSPNet model with the architecture of "ResNet-50" and adds a "spatial attention" mechanism to get great results in tasks that have to do with understanding pictures. The ResNet-50 architecture is part of the PRESSNet framework. It uses deep residual blocks to collect high-level features and get discriminative representations in a way that uses few resources. The PSPNet model improves network performance by incorporating a pyramid pooling module that effectively combines contextual information from several dimensions. This enables the model to capture both local and global context, leading to enhanced performance. Furthermore, the integration of a spatial attention mechanism into PRESSNet enables the network to prioritize informative regions within the input image. This capability allows the network to concentrate on pertinent characteristics while effectively reducing the impact of noise and distractions. Through the integration of several components, the suggested PRESS-Net exhibits remarkable performance in the field of image analysis, showcasing the efficacy of including the PSPNet model alongside ResNet-50 and spatial attention mechanisms for the purpose of enhancing image processing tasks. The test results are displayed in Table I.

The assessment of various damage classes was conducted using three models: the baseline model (PSPNet+ResNet50), PRESSNet, and the PSPNet + ResNet 101 + Spatial Attention model. The evaluation revealed that the baseline model achieved an F1 score of 98.6% for the "Background" class. PRESSNet demonstrated a little superior performance compared to the base model, as seen by its F1 score of 98.62%. The F1 score achieved by the enhanced model PSPNet+ResNet101+spatial attention was 94.3%. The baseline model attained an F1 score of 88.6% for the "No Damage" category. The performance of PRESSNet was somewhat inferior to that of F1, as evidenced by its score of 88.2%.

The combination of PSPNet, ResNet 101, and spatial attention achieved a notable F1 score of 75.1%. The baseline model obtained an F1 score of 81.2% in the "Destroyed" class. The performance of PRESSNet showed a slight superiority compared to F1, as substantiated by its score of 82.4%. The PSPNet+ResNet101+spatial attention model had a significantly diminished performance, as evidenced by an F1 score of 28.3%. The observed substantial decrease in the F1 score pertaining to the "Destroyed" class, resulting from the utilization of an alternative backbone (PSPNet+ResNet101+spatial attention) in comparison to the baseline model (PSPNet+ResNet50) and PRESSNet, raises the inquiry regarding the underlying reasons for the drop in performance.

Several factors may have contributed to this performance loss that the PSPNet+ResNet101+Spatial Attention model is more complicated than the base model. It includes a more advanced ResNet architecture (ResNet 101) and spatial attention. It may have been more difficult to learn effective

representations for the “Destroyed” class due to the increased model complexity, resulting in a lower F1 score.

If the “Destroyed” class is not adequately represented in the training data, the model may struggle to acquire meaningful patterns for this class. Insufficient data can result in inaccurate generalizations and diminished performance, especially when dealing with uncommon or underrepresented groups.

**Imbalance in Class Distribution:** If the dataset is imbalanced, i.e., there is a significant difference in the number of samples between classes, the model’s performance may be negatively impacted. If the “Destroyed” class is underrepresented relative to other classes, the model may not have had sufficient exposure to acquire its unique characteristics, resulting in a lower F1 score.

To resolve the low F1 score for the “Destroyed” class in the improved model, it may be advantageous to investigate and analyze the specific difficulties and constraints posed by this class in greater depth. Obtaining more representative training data, meticulously balancing the class distribution, and refining the model architecture and hyperparameters could be potential solutions for improving the model’s performance on the “Destroyed” class.

The baseline model (PSPNet+ResNet50) received an F1 score of 89.5% based on the macro-average F1 scores, which provide a comprehensive performance measurement. With an F1 score of 89.7%, PRESSNet outperformed the baseline model by a small margin. The performance of the improved model, PSPNet+ResNet101+spatial attention, was 66% on the F1 scale.

Fig. 4 shows the result between the baseline model, PRESS-Net, and PSPNet + ResNet 101 + Spatial Attention. In general, PRESSNet performs comparably or slightly better than the baseline model (PSPNet+ResNet50) across all damage classes. However, the model that used ResNet 101 backbone did not improve performance across all classes, with the "Destroyed" class experiencing a significant performance decline.

It is essential to observe that these results are dependent on the evaluation metrics and data set employed. To comprehend the factors contributing to the performance disparities between models, additional analysis and investigation are required.

TABLE I. THE TEST RESULT

Class	Deep Learning Model		
	Baseline Model (PSPNet + ResNet 50)	PSPNet + Resnet 50 + Spatial Attention	PSPNet + Resnet 101 + Spatial Attention
F1 Background (Class 0)	0.986	0.986	0.943
F1 No Damage (Class 1)	0.886	0.882	0.751
F1 Destroyed (Class 2)	0.812	0.824	0.280
Macro Average F1	0.895	0.900	0.659

Fig. 4. The test result.

## V. CONCLUSION

This paper presents the PRESS-Net methodology for developing semantic segmentation models, with a particular focus on leveraging the Palu earthquake disaster dataset obtained from the xBD dataset. The PRESS-Net model achieved remarkable results in the field of image understanding by combining the beneficial aspects of the PSPNet model with the ResNet-50 architecture while also incorporating a spatial attention mechanism. The examined technique has demonstrated enhanced performance in comparison to the baseline model (PSPNet+ResNet50), particularly in its capacity to capture both local and global context information.

Upon conducting a comparative analysis of different versions of the model, this research has come across surprising findings. The baseline model (PSPNet+ResNet50) demonstrated commendable performance, achieving an F1 Score of 89.5%. The percentage was elevated to 89.7% as a result of the intervention of PRESS-Net. The F1 Score of the more intricate model, which combines PSPNet, ResNet101, and spatial attention, experienced a decrease to 66.0%. This decrease was particularly notable in the "Destroyed" category. The potential cause for this reduction could be attributed to the model's excessive complexity or the inadequate availability of suitable instances for learning. In order to tackle this matter, the research proposes the acquisition of more photos that portray scenes of destruction, ensuring a balanced distribution of image categories, and making modifications to the structure of the model.

In the future, there are several exciting research possibilities for improving building damage assessment. One option is to explore different types of deep learning models that might be better at recognizing structural damage. This could involve trying out various model designs or new methods in deep learning. Using larger and more diverse datasets can also

help the model work better in different situations. These datasets should cover a wide range of disasters and locations. To truly understand how well the model works in the real world, we need to test it with actual aerial and satellite images. Additionally, ongoing efforts to improve the model, like transfer learning or fine-tuning, can make a big difference when working with larger datasets. We should also consider adding more types of data, like weather or location information, to make the predictions more accurate. Lastly, we should validate the model's results in real-life situations to ensure it works effectively in disaster management. These suggestions are intended to guide future research in making deep learning models for building damage assessment more effective and reliable.

**Abstract**—The challenge of how to further improve the accuracy of the system's recommendations in a data-limited environment is crucial as the use of group intelligence recommendation systems in everyday life increases. Through the fusion of different types of auxiliary information, this study develops a multi-feature fusion model based on the conventional recommendation model by introducing knowledge graphs. It also considers the homogeneity of push results caused by graph convolutional network smoothing when using knowledge graphs, and designs a fusion label propagation algorithm and graph convolution. The multi-feature fusion model had a maximum hit rate of over 80% and a normalised discount gain of up to 43% running time much lower than the conventional graph convolution recommendation model in the representation dimension interval [2, 32], while the fusion label propagation algorithm and graph convolution network model maintained a hit rate and normalised discount gain higher than the conventional model by 2 to 1 under 10 consecutive epochs. With a hit rate and normalised discount gain 2 to 10 percentage points higher than the conventional model, the coverage rate increased to 49.8%. This study is useful for research on group intelligence recommendation systems and can serve as a technical guide for improving the ability of group intelligence systems to make recommendations quickly.

**Keywords**—Knowledge graphs; recommendation system; graph convolutional networks; label propagation algorithms

## I. INTRODUCTION

Group Intelligence Recommendation (GIR) System research is expanding along with the field of group intelligence technology. The common GIR systems predict the user's past choice data using neural network-like algorithms to create suggestions [1]. There is a pressing need to lessen the reliance of the recommendation model (RM) on users' previous data as standard recommendation systems have a tendency to produce highly biased outcomes when data information is limited [2]. Since in the actual recommendation process, in addition to information about the interaction between users and items, there is also information about user profiles, items, some relevant environmental conditions, etc., knowledge graphs (KGs) containing a wide variety of information data have been noticed. Multiple pieces of information can be combined thanks to the properties of KGs, which also improve the scalability of the recommendation system (RS) [3]. This is because, as a directed heterogeneous

graph, KG uses edges to represent relationships between entities and nodes to represent entities that can represent both users and items. As a result, interactions between users and other users as well as interactions between users and items can be fused into the graph as auxiliary information, which can be used to make up for the information deficit brought on by a data-scarce environment [4]. In general, conventional suggestion models possess certain limitations whereby they may encounter the issue of data sparsity. This refers to a scenario in which there is minimal interaction data between users and items. As a result, the accurate modelling of the relationship between users and items is challenging and may impede the correctness and customisation of suggestion outcomes. When the recommendation system begins operating, it lacks adequate user behavior data or item attribute information, over-relies on users' historical behavior data, and disregards their present interests and requirements. Therefore, it struggles to offer dependable personalized recommendations for new users or items. To design a multi-feature fusion model based on the traditional RM, this study attempts to improve the traditional RM. It also attempts to introduce KG while taking into account the problems with graph convolutional smoothing and homogenization of recommendation results that are easily encountered when applying KG. Finally, it attempts to introduce Label propagation algorithms (LPA) to Graph convolutional networks (GCN) in order to further optimise the multi-feature model. This research content has the potential to advance the field of recommendation systems and enhance the quality of recommendation services for practical applications.

The study is broken up into six sections: The second section gives a summary of the most recent research findings; the third section describes the study's methodology and design elements; the fourth section presents the experimental findings and an analysis based on those findings; and the fifth section summarises the study's findings and the prospect is given in sixth section.

## II. RELATED WORKS

People use GIR systems frequently, and with the growth of the web sector, customised RS has become increasingly important. According to Zhan et al, current recommendation models (RMs) primarily consider item compatibility modelling and do not consider user profiles, resulting in a

system where knowledge is pushed in a one-dimensional way without linking to user preferences. By adding attention to attribute-aware KG, Zhan et al. subsequently created an association between users and things, and created user-relationship-aware attention layers and goal-aware attention layers to capture user preferences. The results demonstrate the superiority of the model over other models for capturing user preferences [5]. Although Chen et al. argue that the current usage of GCNRM typically involves recursive aggregation with neighbouring nodes and their subsets, there is uncertainty in determining whether said neighbours can provide vital information after graph convolution. The introduction of KG in GCNRM is indeed beneficial in handling diverse multi-information tasks. Chen et al. proposed the Neighbour Enhanced Graph Convolutional Network (NEGCN) to enhance graph refinement process based on GCNRM and designed the neighbour evaluation method for critical information assessment. NEGCN demonstrated significantly improved model performance compared to the traditional graph convolutional RM [6]. Jiang et al. claim that the current RS approach to information exploitation is still limited and often only considers neighbourhood-specific information. To improve the conventional RS recommendation model, Jiang et al. propose a social aggregation neural network model based on attention mechanisms (AM). The model enables optimal user model embedding by propagating global social influence and capturing heterogeneous influences through AM. According to the results, using multi-layered perception to simulate the interaction between users and things is more flexible and successful than using conventional linear interaction algorithms to produce recommendation results [7].

Sang proposes a new knowledge graph-enhanced neural collaborative RM that can operate on information aggregation from multi-hop neighbours, and can use AM to grade the importance of relationships, as well as to model users and items in the embedding by modelling them in the embedding dimensional connections. On the other hand, the use of KGs in RM has always been hampered by the difficulty of modelling higher-order connectivity in large KGs using traditional models. The results showed that the model somewhat reduced the challenge of applying KG to RM [8]. Zhang et al. proposed a new knowledge-aware representation of the Graph Convolutional Recommendation Network model, arguing that in real recommendation environments, data is often sparsely distributed and the use of neighbourhood information alone is not sufficient to support accurate recommendation prediction results. The model can fuse item information through the propagation of links between nearby nodes in the KG and quickly capture correlations between people and items. This allows the model to predict likely user choices over time. This model, which creates user profiles by establishing neighbourhood associations between people and user objects by sorting features with high similarity between different users, has been shown to significantly outperform classical RM on a large dataset [9]. Graph neural networks, on the other hand, are favourable in dealing with complicated transitions between entity interactions in the environment of limited information input, according to Gwadabe et al. As a result, Gwadabe et al. proposed a graph neural network-based RM that may use graph neural networks to learn the ordered interactions first,

followed by the unordered interactions, in the current session. Numerous studies have revealed that this model performs noticeably better than other models in addressing unpredictable user behaviour in a data-limited environment [10].

In summary, experts have studied both the improvement of conventional RM and the implementation of KG, but have focused on optimising RM to increase the accuracy of push results to users, relying on the substantial information compensation found in KG itself. In reality, another problem with KG in RM is that a significant proportion of graph nodes are susceptible to convolutional smoothing, which can lead to homogenization of push results. It is still important to conduct research on how to use the entities' own information as much as possible in a data coefficient environment, and how to solve problems with the use of KG.

### III. DESIGN OF THE GIR MODEL FOR THE INTEGRATION OF KG

The principle of traditional RM is to get user behaviour prediction by analysing historical data of users, but the results derived from this model will be more deviant in a data sparse environment, so KG, which can fuse various kinds of auxiliary information, needs to be introduced to make up for the lack of interaction information. However, the KG itself is large in scale and is prone to the problem of excessive smoothing of a large number of graph nodes in the GCN, which can lead to homogenisation of the model's recommendations to users [11]. To address these problems, a multi-feature fusion model based on KG and AM and a model that fuses LPA and GCN are proposed.

#### A. Design of KGARA Model for Multi-Feature Fusion based on KG and AM

To address the limitations imposed on RM by data sparse environments, this research proposes the KGARA model. The core principle of this model is to incorporate relationship-aware structures to enrich the preference relationships between users and objects, and users and users. Based on joint AM, the model uses KG to fuse adjacent objects with different relationship types to obtain rich feature information. A graphical neural network is also used as a deep learning algorithm in RS.

The semantic information is first modelled using the representation-based KG recommendation algorithm, which vector embeds the input user features to obtain the initial representation, and then uses AM to complete the portrayal of user preferences. In this process, the representation is generated by the KG encoding operation on its entity, which requires the use of Knowledge Graph Embedding (KGE) [12]. KG, the interaction matrix of the relationship between the user and the item, and other information are fused to generate the user representation  $u$ , and the item representation  $v$ , and then they are inner-producted to obtain the probability of the user choosing the item, which is described by (1) is described.

$$\hat{y}_{uv} = u^T v \quad (1)$$

$T$  in (1) denotes the inner product operation and  $\hat{y}_{uv}$  is the user selection probability. Fig. 1 shows the structure of the model. From left to right, the first layer is an embedding vector layer, from which the unique hot codes of user, relationship and item are input and formed into an initial representation by vector embedding operation; then the unweighted KG formed by the initial representation is

transformed into a weighted KG by the attention layer and stored in the adjacency matrix; the next layer is the feature propagation layer, where the item representation is trained by GCN and fused with the domain representation using an aggregator; finally, the probability of the user selecting the item is obtained by inner product operation on the obtained item representation  $e_v$ .

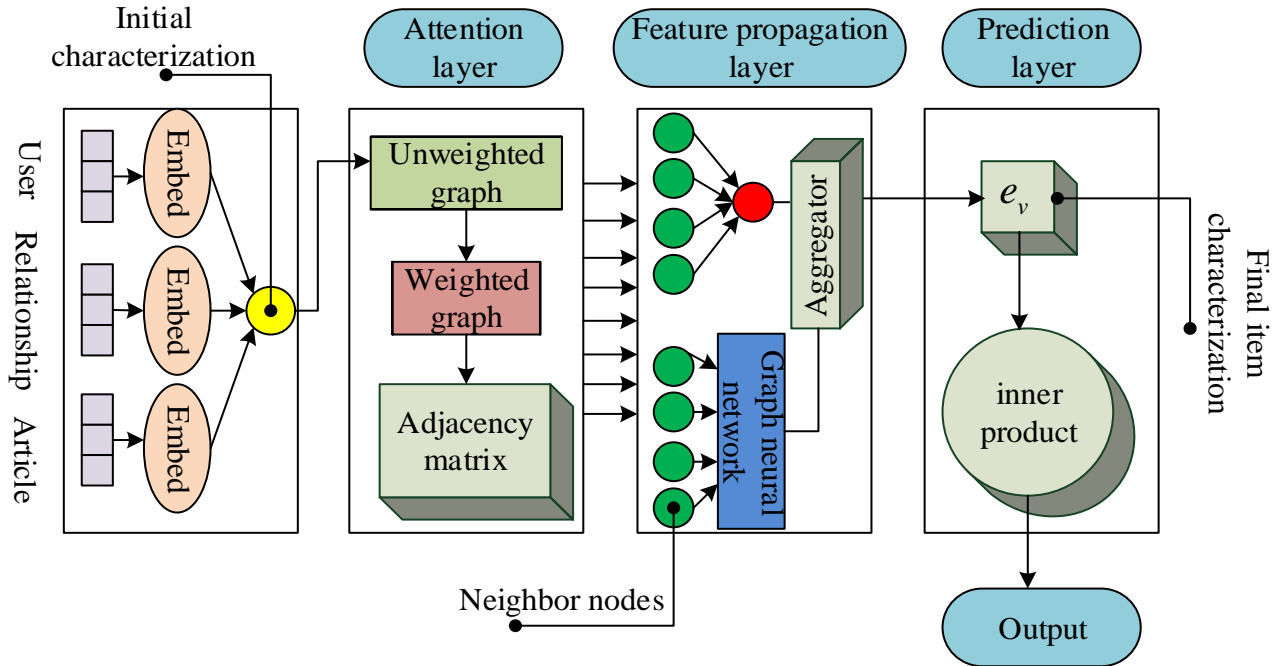

Fig. 1. Structure of the KGARA model.

In the relational attention network layer, the degree of importance between the relational representation and the user representation is obtained by doing an inner product operation on the two, described by (2).

$$c_u^r = e_u^T e_r \quad (2)$$

where  $e_r$  is the relational representation,  $e_u$  is the user representation and  $T$  denotes the inner product operation done on both. However, in the initial KG the edges can only describe the relationship but not the weight values, so the initial unweighted KG needs to be transformed into a weighted graph by (3).

$$y_{uv} = \begin{cases} 1, & \text{If } u, v \text{ interact;} \\ 0, & \text{If } u, v \text{ do not interact;} \end{cases} \quad (3)$$

$y_{uv}$  in (3) is a parameter in the user-item interaction matrix. The adjacency matrix resulting from the transformation into a weighted graph is denoted  $A_u$  and the relationship weights of entity  $i$  and entity  $j$  in row  $i$  and column  $j$  of this matrix are expressed in (4).

$$A_u^{i,j} = c_u^{r,i,j} \quad (4)$$

$c_u^{r,i,j}$  in (4) represents the entity relationships in the unweighted graph. Since the weighted graph itself can lead to an excessive computational burden, the KGARA model prioritises the nodes by attention weight values, which in turn yields the important nodes. The important nodes are weighted and summed by (5), which in turn gives the target entity representation.

$$e_{N(v)}^u = \sum_{\alpha \in N(v)} \hat{c}_\alpha^r e_\alpha \quad (5)$$

The set of target node  $v$  and neighbouring nodes in equation (5) is denoted by  $N(v)$ ,  $\alpha$  is a parameter taken from this set, and the normalised relational attention score is  $\hat{c}_\alpha^r$ . This indicates that nodes with a high relational attention score will be filtered out, as defined by (6) for them.

$$\hat{c}_\alpha^r = \frac{\exp(c_\alpha^r)}{\sum_{e \in N(v)} \exp(c_e^r)} \quad (6)$$

Next, at the feature propagation layer, the relational attention information is fused on the basis of the obtained weighted graph, and after all the rows in the matrix have been calculated, the individual entity representations are obtained,

denoted as  $h_k$ . The process is represented by equation (7).

$$\begin{cases} H_1 = \sigma(D_u^{-\frac{1}{2}} A_u D_u^{-\frac{1}{2}} H_0 W_0) \\ H_2 = \sigma(D_u^{-\frac{1}{2}} A_u D_u^{-\frac{1}{2}} H_1 W_1) \\ \dots \\ H_k = \sigma(D_u^{-\frac{1}{2}} A_u D_u^{-\frac{1}{2}} H_{k-1} W_{k-1}) \end{cases} \quad (7)$$

In (7), the representation matrix in row  $k$  is represented by  $A_u$ ,  $W_k$  is the parameter matrix in row  $k$ , and  $\sigma$  is the activation function. where there is a logarithmic matrix relationship between  $D_u^{-\frac{1}{2}}$  and  $A_u$ , described by (8).

$$D_u^{ij} = \sum_j A_u^{ij} \quad (8)$$

The item representation and the domain representation are aggregated by (8) to obtain the final item representation  $e_v$ . The final step of the model performs an inner product operation on the user representation and the item representation obtained from (8) to finally arrive at a probability value for that user to accept the recommended item, a process described by (9).

$$\hat{y}_{uv} = e_u^T e_v \quad (9)$$

### B. Design of A GCNLP Model Incorporating LPA and GCN

When applied to RM, the KG technique is computationally intensive due to the presence of tens of billions of edges and billions of nodes [13]. In GCNs, the large number of nodes can also cause the problem of smooth graph convolution and thus homogeneous recommendation results [14]. Therefore, in this study, the KGARA model is used to adjust the weight value of the edges of the GCN, and the attention network is used to filter the user's maximum weight on the items.

The structure of the GCNLP model is shown in Fig. 2. The structure of the feature propagation layer is improved from the structure of the KGARA model in Fig. 1, and the rest of the

embedding vector layer, attention layer, and prediction output layer are structured in the same way as the KGARA model. In the improved feature propagation layer, GCN operates on neighbouring nodes to derive item representations, while LPA is introduced to adjust the weight values for graph edges.

Specifically in the representation propagation layer, the model uses the GCN to make basic predictions and then uses the LPA to assist in adjusting the edge weights. As a multilayer feedforward neural network, the GCN is able to perform transformation and propagation operations on nodes in the graph, as described by (10).

$$P^{(k+1)} = \sigma(D^{-1} A P^k W^{(k)}) \quad (10)$$

In (9),  $\sigma$  is the activation function,  $\sigma$  is the parameter matrix of layer  $k$ , and the resulting  $P^{(k+1)}$  is the node representation of layer  $k$ . Present at nodes  $\sigma$  and  $v_j$ , the GCN to  $v_i$  update process is described by (11).

$$P_i^{(k+1)} = \sigma\left(\sum_{v_j \in N(v_i)} \alpha_{ij} p_j^{(k)} W^{(k)}\right) \quad (11)$$

In (11),  $P_j^{(k)}$  is the  $k$ th level node representation of the target node,  $\alpha_{ij}$  is the value of the  $i$ th row and  $j$ th column in the adjacency matrix, i.e. the weight value between nodes, and the  $i$ th node in the set of neighbours is represented by  $N(v_i)$ . After the domain nodes of the target node are aggregated to obtain the domain representation of the target node, they are then transformed into the next-order representation  $P_i^{(k+1)}$  of the target node, and (12) and Equation (13) provide a description of these two steps.

$$s_i^{(k)} = \sum_{v_j \in N(v_i)} \alpha_{ij} P_j^{(k)} \quad (12)$$

(13)  $\sigma$  is domain representation.

$$P_i^{(k+1)} = \sigma(s_i^{(k)} W^{(k)}) \quad (13)$$

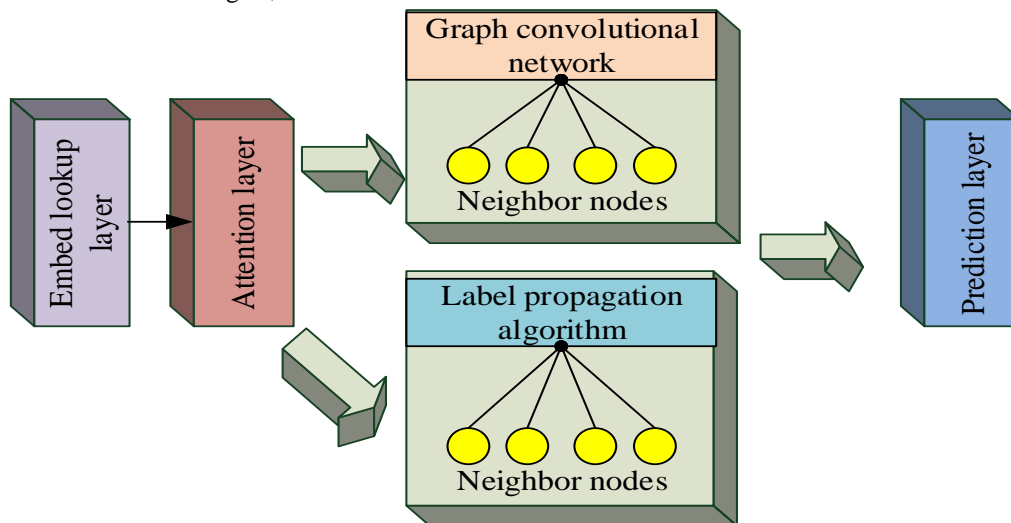

Fig. 2. GCNLP model structure.

The distance between  $v_i$  and  $v_j$  is defined as  $Q(p^{(k)})$ , and the distance between its domain representation  $s_i$  and  $s_j$  is defined as  $Q(s^{(k)})$ . After the aggregation operation on nodes  $v_i$  and  $v_j$ ,  $Q(s^{(k)})$  will be smaller than  $Q(p^{(k)})$  and similar nodes will be grouped into the same class, i.e. in the GCNLP model GCN places items of user attention in the same class to improve recommendation performance.

The propagation process of LPA at each level, i.e. according to the normalised edge weights, all nodes are subjected to label propagation by their neighbouring nodes and all nodes that already have labels are subjected to an initialisation operation by themselves to prevent the labels from disappearing [15]. The simulated label propagation process is shown in Fig. 3, assuming that the propagation process is performed only three times, with the goal of propagating from node a to node b. Red dots indicate with labels and colourless dots indicate without labels. In the first

execution (green line), node a passes the label to its neighbours node 3 and node 1, but node 1 already has a label, so the propagation path is inaccessible; in the second execution, node 3, which has already been propagated with a label, passes the label to its neighbours node b and node 4 (yellow line) and the first execution is completed, so node a initialises and propagates the label again (purple line); in the third execution, the nodes that already had labels in the previous execution also perform the initialization operation and continue to propagate the labels (blue line). Finally, the LPA must find all paths from node a to node b that are no longer than 3, as expressed by (14).

$$x_i^\infty = \sum_{j \in N(i)} a_{ij} x_j^\infty \quad (14)$$

In (13),  $x_i^\infty$  denotes the node in the label matrix,  $x_j^\infty$  is the value of column  $j$  of row  $i$  in the adjacency matrix, and  $N(i)$  is the set of neighbours of the node.

Fig. 3. Label propagation process.

The evaluation indicators introduced in this study were Hit Rate (HR), Normalized Discounted Cumulative Gain (NDCG) and Coverage, described by (15), (16) and (17) [16].

$$HR @ N = \frac{\text{Number of Hits @ } N}{|GT|} \quad (15)$$

*Number of Hits @ N* in equation (15) is the number of positive samples in the item sorting list in the recommendation task, and  $|GT|$  is the number of total samples in the test set.

$$NDCG @ N = \frac{\sum_{u \in U} NDCG_u @ N}{|U|} \quad (16)$$

Where  $|U|$  represents the number of users and  $\sum_{u \in U} NDCG_u @ N$  is the process of accumulating the normalised discounted gain in the test, resulting in a mean value of  $NDCG @ N$  [17].

$$\text{Coverage} @ N = \frac{|U_{u \in U} R(u)|}{|I|} \quad (17)$$

In equation (17)  $|I|$  is the set of items,  $U$  is the set of users, and  $RS$  is the list of items recommended by users

denoted by  $R(u)$ .

#### IV. EXPERIMENTAL RESULTS AND ANALYSIS

Performance testing experiments on the proposed KGARA model and the GCNLP model are conducted in the Book-Crossing environment, a book dataset, Movielens-1M, a film dataset, and Last FM, a music dataset [18]. For the model, the higher the value of HR and NDCG, the higher the quality. The Generalised Matrix Factorisation (GMF), Neural Matrix Factorisation (NeuMF) and Long Short-Term Memory R-GCN (LRGCN) were selected for the KGARA performance detection experiments [19]; the LRGCN, Ripple Net and Neural Graph Collaborative Filtering (NGCF) were selected for the GCNLP performance testing experiments [20]. An early termination strategy is implemented if HR@20 and NDCG@20 do not increase for 20 consecutive epochs on the test set, where an epoch is the process of training once using all samples in the training set.

##### A. Experimental Results and Analysis of the KGARA Model

First, parametric experiments were conducted to explore the effect of different representational dimensions on the model, followed by a comparison of the effect of the data sparse environment on the model performance. The parameter settings for the datasets in the experiments are given in Table I.

TABLE I. DATASET PARAMETER SETTINGS

Aggregator	BI-Interaction			
Data set	Learning rate	Batch size	Number of neighbors	Jump count
Configured parameters				
Book-Crossing	0.0002	32	8	1
Movielens-1M	0.02	2048	4	2
LastFM	0.0004	128	8	1

Fig. 4 shows the hit rate variation of the GMF, NeuMF, LRGCN and KGARA models on the three datasets under the representation dimension interval [2,32]. As can be seen from the figure, the overall hit rate of each model tends to increase as the representation dimension increases. However, compared to the Book-Crossing dataset and the Movielens-1M dataset, the increase for all models on the LastFM dataset varies between 1 and 3 percentage points, due to the fact that this dataset is less informative and can perform almost with sufficient information at lower representation dimensions. And in each dataset, compared to other models, the hit rate of KGARA proposed in this study is on average the highest, up to over 80% in the Movielens-1M dataset, which is on average 5 to 10 percentage points higher than the traditional graph neural network-based GMF and NeuMF; but in the Book-Crossing dataset, the average hit rate of LRGCN is

slightly higher than that of KGARA, which is also due to the simpler structural design of LRGCN than KGARA.

Fig. 5 shows the changes in the normalised discount gain of the GMF, NeuMF, LRGCN and KGARA models as the representation dimension increases on the three datasets. As can be seen in Fig. 5, the NDCG values of all models increase as the representation dimension increases, and although the increase in the NDCG metric is smaller, KGARA performs best when comparing both the initial NDCG values and the NDCG values at representation dimension 32: the initial NDCG value on the Movielens-1M dataset is around 42%, and as the representation dimension increases to 32, its NDCG value reaches around 43%. The average NDCG values of the KGARA model are much higher than those of the traditional graph convolution models GMF and NeuMF, ranging from 4 to 10 percentage points higher on average.

Fig. 4. Changes in hit rates of various models on different datasets.

Fig. 5. Normalized loss gain changes of each model on different datasets.

Fig. 6. Changes in hit rates of various models in data scarcity environments.

To test the performance of the KGARA model with the introduction of the KG feature fusion structure in a data sparse environment, the GMF, NeuMF, LRGCN and KGARA models were tested on the Movielens-1M dataset, and the hit rate variation of all models was compared by adjusting the proportion of the training set to the test set for this dataset. The experimental results are shown in Fig. 6, where  $r$  represents the proportion of the training set. As can be seen from Fig. 5, the hit rate of KGARA reached more than 78% when the proportion of the training set was only 10%, which was 2 to 10 percentage points higher than the other models, and as the proportion of the training set increased, the hit rate of KGARA also increased, stabilizing at 81.6% when the proportion of the training set reached 60%, with the highest hit rate reaching 81.8%. The other models basically stabilized after the training set percentage increased to 70%, and the final hit rate was still lower than KGARA by 2 to 8 percentage points.

Next, the runtimes of all models were examined on the

Fig. 7. The proportion of running time of each model on different datasets.

Fig. 8. Changes in hit rates of various models on different datasets.

three datasets at 1600MHz core frequency, RTX2080 graphics card and 8G video memory. Fig. 7 shows the results of the runtime comparison for all models. As can be seen from Fig. 7, although the runtime ratios of the models varied from dataset to dataset, the largest average runtime ratio was for the traditional graph convolution model GMF, which accounted for 56% of the four models; the model with the lowest runtime ratio was KGARA, which accounted for 4% on average, almost a tenth of the GMF runtime.

### B. Experimental Results and Analysis of the GCNLP Model Doing the Results Analysis

In addition to testing the basic performance of GCNLP in different data dimensions, this study also needs to test whether GCNLP can improve the problem that GCN is prone to homogeneous recommendation results due to graph convolution smoothing, so 10 consecutive epochs were analyzed for the GCNLP model in terms of three metrics: hit rate, normalized discount gain and coverage.

Fig. 8 shows the hit rate variation of the four models GCNLP, LRGCN, Ripple Net and NGCF on different datasets in the environment with representation dimensions {2,4,6,8,16,32}. As can be seen from the figure, although the hit rate on the Book-Crossing dataset is on average 2 percentage points higher than that of the GCNLP model due to the simple structure of LRGCN, the GCNLP hit rate is 2 to 4 percentage points higher than the other models on all other datasets, with the GCNLP hit rate on the Movielens-1M dataset being on average the highest, averaging in the upper 65% range with a maximum of 66%.

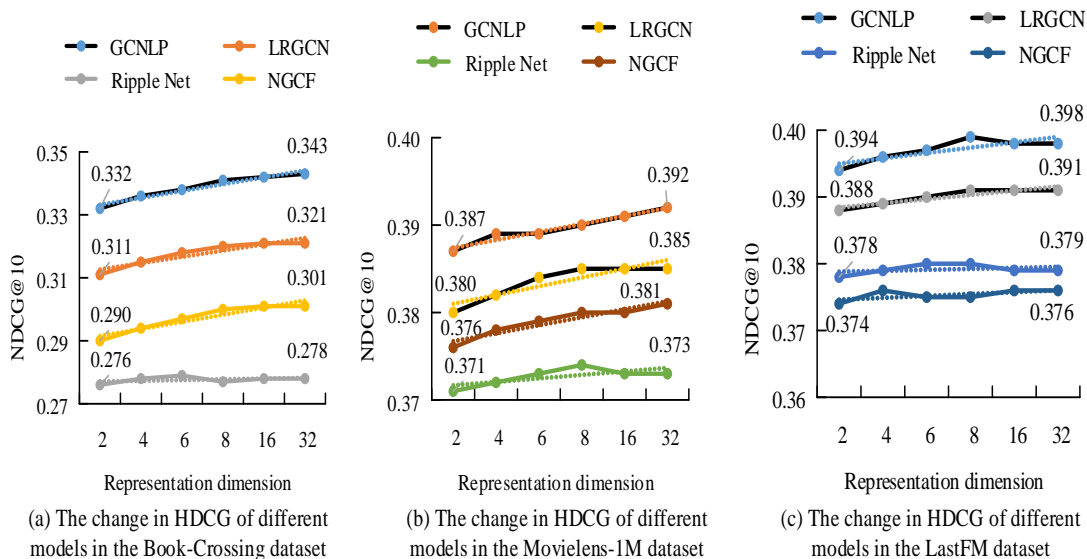

Fig. 9. NDCG changes of each model on different datasets.

Fig. 9 shows the variation in normalised discount gain for each model on the different datasets, and it can be seen that the NDCG values for all four models increase as the characterisation dimension increases on all three datasets, but the NDCG values for GCNLP are higher than the initial and final NDCG values for the other models compared to the other models. GCNLP had the highest NDCG values overall on the LastFM dataset, averaging around 36.5% and up to 40% over the period, while being one to two percentage points higher than the other models.

For GCNLP improvements made on the basis of the KGARA model, the metric coverage (Coverage) can be targeted to detect GCNLP performance. The higher the value of  $Coverage@N$ , the higher the coverage of the model and the less likely the problem of homogeneous recommendation results will occur. Fig. 10 provides a comparison between the mean coverage of all models under the low representation dimension and the mean coverage under the high

representation dimension based on three distinct datasets. As observed in Fig. 10, the coverage of each model increases as the representation dimension increases. The GCNLP and LRGCN show comparable coverage in the low representation dimension. However, in the high representation dimension, GCNLP exhibits a higher average coverage than all other models.

Table II displays comprehensive average coverage information for each model in both high and low representation dimensions. It is evident that, in the high representation dimension, the Book-Crossing dataset showed the highest coverage of GCNLP at 49.8%, while, in the low representation dimension, the Movielens-1M dataset presented the highest coverage of GCNLP at 41.2%. Overall, GCNLP's coverage was greater than the other models, indicating that the enhancements made to GCN using LPA improved the homogeneity of RM push results.

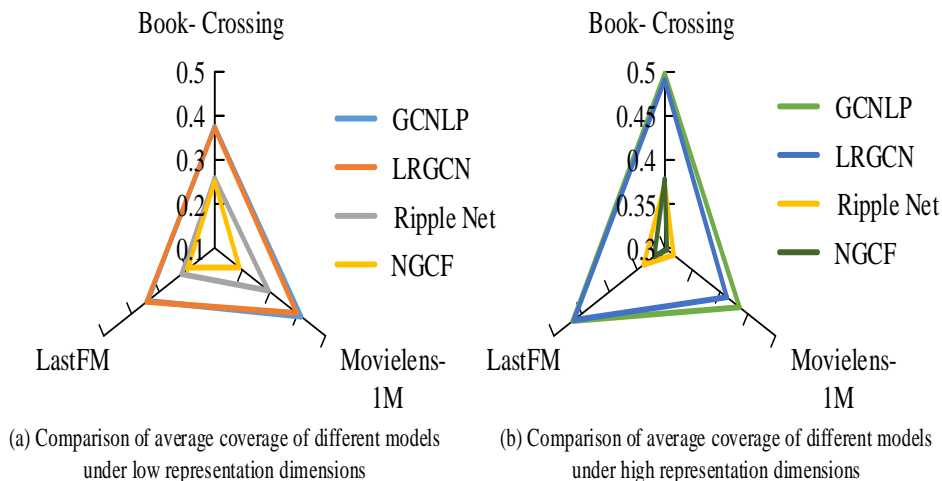

Fig. 10. Comparison of average coverage of various models.

TABLE II. DETAILED DATA ON AVERAGE COVERAGE OF EACH MODEL

Under low feature dimensions	Book-Crossing	Movielens-1M	LastFM
GCNLP	0.375	0.412	0.341
LRGCN	0.373	0.396	0.345
Ripple Net	0.258	0.294	0.219
NGCF	0.251	0.189	0.198
Under high feature dimensions	Book-Crossing	Movielens-1M	LastFM
GCNLP	0.498	0.435	0.466
LRGCN	0.491	0.412	0.464
Ripple Net	0.373	0.316	0.338
NGCF	0.378	0.304	0.319

## V. CONCLUSION

The aim of this study was to address the problem of large deviations in recommendation results in traditional GIR models within a data sparse environment. To achieve this goal, the study developed a multi-feature fusion model, KGARA, and improved its GCN structure by combining with LPA to obtain the GCNLP model. This approach enabled a more accurate and reliable model, thus mitigating the issue mentioned above. The study also introduced KG and AM based on traditional RM to compensate for the lack of interaction information. The results of 20 consecutive epoch trials show that the KGARA model has a maximum hit rate of over 80% and a normalised discount gain of over 43% when the characterisation dimension interval [2,32] is shifted, which is higher than other models. Furthermore, the proportion of the Movielens-1M training set was altered from 10% to 90%, with a maximum hit rate of 81.8%, ultimately illustrating the KGARA model's superior performance compared to all other comparative models in the data-scarce setting. Owing to its efficient nature and the shortest running duration among its counterparts, the KGARA model proves to be the most effective. Based on the results from 10 consecutive epochs of experimentation on the GCNLP model, the hit rate and normalised discount gain surpass other comparison models when the representation dimension is altered within the range of [2,32]. Specifically, the hit rate reaches up to 66% and the normalised discount gain reaches up to 40%, both of which are higher than those of other models. Moreover, the GCNLP model attained an average coverage of 41.2%, which outstripped the conventional graph convolution model's average coverage by a significant margin. This suggests that the addition of LPA to the GCN structure was a fruitful improvement and could potentially resolve the problem of homogenization in push outcomes. The study successfully enhanced the classic push model; however, it only considered user preferences' constant conditions and omitted dynamic shifts in user preferences. This aspect warrants future investigation.

## VI. PROSPECT

The KGARA and GCNLP models exhibit higher hit rates, normalized discount gains, and coverage performance when compared to other models. These outcomes suggest that the improved models are anticipated to outperform

recommendation systems, enhancing the standard and personalization of recommendation outcomes. Such accomplishments can offer motivation and establish benchmarks for the betterment and refinement of recommendation system models. One potential avenue for future research could involve the development of recommendation algorithms that rely on temporal data. Such algorithms could utilize users' past behavior and historical data to predict their future interests. This could involve the application of techniques including time series analysis, sequence modeling, and deep learning.

# Statistical Language Model-based Analysis of English Corpora and Literature

Wenwen Chai\*

School of Foreign Languages, Zhengzhou Normal University,  
Zhengzhou, 450044, China

**Abstract**—Despite widespread use of statistical language models in language processing, their ability to process natural languages is not advanced and they struggle to effectively capture linguistic information. Furthermore, there is a lack of automatic processing models in the field of natural language processing. In order to address these issues, and improve the processing ability of statistical language models for English language a statistical language model optimization algorithm has been proposed. This algorithm is based on an improved resorting algorithm and is specifically applied to process English literary texts. Experimental results indicate that the proposed algorithm outperforms the N-gram algorithm in a majority of texts, with a maximum accuracy improvement of 14.5%. Additionally, in terms of the grammar analysis model, there is a high level of consistency between the model's scoring and the expert manpower scoring, as reflected by a correlation coefficient of 0.7893. This high level of consistency between the grammar analysis model and expert analysis results holds significant importance for the advancement of natural language processing.

**Keywords**—Statistical language model; corpus; English literature; reordering; grammatical analysis

## I. INTRODUCTION

Currently, utilizing automated algorithms to process natural language is one of the important research topics in the fields of corpus and translation. Statistical language models are models that use statistics to calculate the probability distribution of word occurrences in a particular language or context, which users use as a basis for operations and predictions [1]. With the maturity of technologies such as machine translation and speech recognition, statistical language models have become more widely used [2]. However, as a data-driven model, a single statistical language model has limited ability to process natural language and cannot reflect the linguistic features of natural language [3]. Based on the limitations of the statistical language model, various natural language processing algorithms that have applied the model also tend to be far less capable than human analysis [4]. In order to effectively improve the statistical language model's ability to process natural language and to apply it to natural language processing work, a reordering algorithm based on an improved minimum error training method is proposed. The reordering is an optimization technique, which can optimize the output of statistical language models by reordering the phrases [5]. A grammar analysis algorithm for English literature is proposed based on the reordering algorithm. Overall, this study proposes an English prediction and literary analysis algorithm based on statistical language models. This model aims to effectively

enhance the processing ability of statistical language models for English natural language.

This article is divided into seven sections. The second section introduces the research progress in related fields. The third section introduces the construction ideas and process of the model. The fourth section is the display of experimental results. The fifth section is the discussion. The sixth section is the conclusion. Lastly, seventh section discusses the limitations and future work.

## II. REVIEW OF THE LITERATURE

Statistical language models, one of the most important models in the field of natural language processing, have been studied and applied currently. Desai and his team examined the eye and neural activity of forty subjects during reading activities based on statistical language models combined with medical tests and found that the processing cost of low-frequency words was reduced due to contextual cues. The meanings of high-frequency words were more easily accessible and integrated with context [6]. The research results provide results based on human science for the processing of natural language. Teks P led his research team to conduct a machine translation study for Lampung Nyo dialect and compared the approaches based on statistical language models [7]. The project aimed to help student immigrants in Lampung province to translate the Lampung dialect of Nyo through the model and the proposed method was adopted as a working model with an accuracy rate of 59.85%. Sreelekha and Bhattacharyya [8] provided a solution for machine translation of Indian languages where digital resources are scarce by using Indowordnet lexical database to extend statistical language models and evaluate 440 models for 110 pairs of languages for comparison. They found that using lexical database mapping helped to resolve linguistic ambiguities and improve translation quality. Collins et al. [9] provided a framework for processing communication language data based on statistical language models using generalized linear mixed models and Bayesian methods, which, based on the results of the sample analysis, was able to analyze and compare the discourse patterns of children who had experienced traumatic brain injury and typically developing children differences between them. This study has important implications for the field of language processing and the study of childhood brain injury. Ycel et al. [10] used statistical language models to construct a computer-based system for learning foreign language vocabulary. They used specified software to display various card sets constructed using the proposed algorithm and examined the polysemantic correlations between behavioral variables and difficulty levels

of different word categories. This study provides an effective method for learning foreign language vocabulary. The author in [2] investigated the specific case of word frequency effects decreasing with age based on word frequency theory in statistical language models and suggested that word frequency effects may occur at different stages of language production. Ge [11] proposed a hybrid research framework combining word frequency analysis from Google Books Ngram Viewer with other analyses in conjunction with statistical language models, aimed at developing a linguistic and cultural concept analysis. Their findings showed a strong correlation between languages in different regions and their cultural concepts, and the frequency of concept words indicated a stronger collectivist culture in China compared to the U.S. Poncelas et al. [12] proposed a feature decay extension algorithm based on a parallel corpus and a statistical language model in order to delve into feature decay algorithm techniques to achieve a better method of training data instance selection. This method can reduce the execution time of FDA and improve the translation quality when multiple computational units are available. This study provides an important reference for improving the performance of machine translation using FDA technology.

A review of recent research related to statistical modeling of language reveals that most of the research in this field focuses on machine translation. In addition, some studies have combined statistical language models with the fields of medicine and sociology. In the field related to statistical language models, there are fewer studies investigating how to improve their ability to recognize natural language, and there is a lack of related applications in the last three years. Based on this gap area, this research focuses on the improvement of statistical language models and their application in the field of natural language recognition.

### III. ENGLISH CORPUS OPTIMIZATION AND LITERARY ANALYSIS BASED ON STATISTICAL LANGUAGE MODELS

#### A. A Statistical Language Model-Based Algorithm for Reordering English Corpus Output

Statistical language models calculate the frequency of occurrence of these concepts in a corpus based on the historical data of a given sequence of words and the likelihood of each word in that sequence. Although this technique is currently widely used in areas involving language processing such as speech recognition, and its translation, statistical language models, as a data-driven model, have biases in the estimation of real natural language [13]. This is due to the limitation of data size and data content. Lexical models, N-gram models, and co-occurrence models are all reordering models that have emerged to make statistical language models closer to real natural language [14]. However, the degree of fit of these models to natural language still needs to be optimized. In this study, a reordering method based on minimum error rate training is proposed. Minimum error rate training is a theory applied to the field of machine translation, but it can be improved and applied to this English corpus optimization and

literary analysis. In the English to other languages literary analysis scenario, the results of the statistical linguistic model-based translation for a specific utterance are shown in (1).

$$\hat{R} = \arg \max \Pr(R|f) \quad (1)$$

In (1)  $\hat{R}$  is the output result,  $f$  is the original utterance to be processed, and  $R$  is the output target language utterance. To obtain the output with the lowest error rate, the log-linear model is used to compute the posterior probability of the sentence pair  $(R, f)$  and recalculate the score, i.e., the ranking basis. The calculation procedure is shown in (2).

$$S(R, f) = \Lambda \bullet \Phi(R, f) \quad (2)$$

In (2),  $S(R, f)$  is the score,  $\Phi(R, f)$  is the feature vector linking the log-linear model and the sentence pairs, and  $\Lambda$  represents the weights of all features. Then the posterior probability can be defined as (3).

$$P(R|f) = \frac{\exp(S(R, f))}{\sum_{R'} \exp(S(R', f))} \quad (3)$$

Based on the results of the recalculated scores and the posterior probabilities, the system reorders the candidate results and outputs the new optimal items as shown in (4).

$$\hat{R} = \arg \max \Pr(R|f) = \arg \max S(R, f) \quad (4)$$

In the process of minimum error rate training, feature parameter weights need to be tuned and determined. The session first requires giving each parameter an initial value of weight and debugging for individual parameters. The other non-object parameters are treated as constants during debugging. Next proceed to apply the parameter in to other sentences of the corpus. The process is shown in Fig. 1. Fig. 1(a) shows the tuning process of one parameter  $a$  on the optimal solution selection of sentence R1. Different parameters take different value intervals corresponding to different optimal solutions. Fig. 1(b) depicts the test results of parameter  $a$  corresponding to sentence R1 in other sentences.

After completing this test, all segmentation points are identified and the optimal values of all sentences are found between each segmentation point. The next step is to perform error statistics for the optimal values in each interval, as shown in Fig. 2. Fig. 2 shows the total number of errors statistics for parameter  $a$ . As the value of  $a$  varies, the total number of errors statistics also fluctuates significantly, with smaller total number of errors representing better results from the statistical language model output. After following this process for all parameters, the whole algorithm is iterated until the error value statistics tend to be stable, which is more desirable.

Fig. 1. Adjustment process of feature parameter weights.

Fig. 2. Count of total error of different parameters.

In order to further enhance the performance of reordering and optimize the results, two sub-models with embedded minimum error rate training are proposed. The sub-models include lexical indication model and lexical N-element co-occurrence model. The lexical indication model performs lexical classification work for the statistical language model. Accurate lexical classification is the basis for the statistical language model to work properly and perform correct literary analysis. There are many possible lexical sequences for a word string, and some of the traditional models directly output the most common lexical properties of words. This method is the most cost-efficient and fast, but the accuracy rate is not satisfactory. To improve this situation, a lexical indication model is considered using a hidden Markov model. The hidden Markov model is shown in Fig. 3, which consists of hidden sequences, observed sequences and different probability distributions. According to the structure of this model, the selection of parameters directly affects the model performance. It has three main parameters, which are noted here as  $\lambda = (\pi, a, b)$ . The lexical indication task can be analogized to a decoding problem, i.e., finding the optimal sequence of states based on a given word sequence to generate a sequence of observations and a set of parameters. Hidden Markov models can efficiently solve such decoding problems.

Fig. 3. Hidden Markov model.

The lexical N-element co-occurrence model is to integrate lexicality into the traditional word N-element co-occurrence model. The traditional word N meta model calculates the probability distribution by lexicon, while the lexical N meta co-occurrence model calculates it by lexicality, as shown in (5).

$$P(T) = \prod_{i=1}^n p(t_i | t_1, \dots, t_{i-1}) \quad (5)$$

In (5),  $p(t_i | t_1, \dots, t_{i-1})$  represents the lexical N\$ probability.  $t_i$  represents the different lexical properties. After obtaining the lexical N-probability, we need to deal with the co-occurrence relationship between different words. The co-occurrence is when two words appear together, and the more co-occurrence of two words in the text, the stronger the connection between them. In the lexical N meta co-occurrence model, instead of word-to-word co-occurrence, word-to-word co-occurrence is used, as shown in (6).

$$P(T|W) = \prod_{i=1}^n p(t_i | w_i) \quad (6)$$

In (6),  $W$  is a word sequence and  $T$  is its corresponding lexical sequence. Correspondingly, the co-occurrence frequencies of words and lexemes are shown in (7).

$$P(W|T) = \prod_{i=1}^n p(w_i | t_i) \quad (7)$$

The two sub-models are embedded in the minimum error training with linear interpolation, and the optimal results are re-output using linear re-ordering. Specifically, when the statistical language model based on minimum error training

outputs the ranking results, the two sub-models process the output word order with probability calculation, and then the probability calculation results are linearly interpolated with the ranking results of the statistical language model, as shown in (8).

$$P(W) = c_1 p_1(W) + c_2 p_2(2W) + c_3 p_3(W) \quad (8)$$

In (8),  $P(W)$  is the recalculated probability.  $c_i$  is the weight of the sub model, and  $P_i$  is its probability. This completes the construction of the proposed reordering algorithm, which utilizes two sub-models for optimization and is able to output results that are closer to natural language than the general reordering model.

### B. English Grammar Evaluation Model for Literary Analysis

The analysis of English literature has been one of the important application areas of statistical language models [15]. Due to the complexity and variability of natural language, algorithm-based literary analysis has been more difficult [16]. In this study, a grammar evaluation model based on statistical language models is proposed for the grammar evaluation aspect of English literary analysis. The model applies the proposed minimum error training reordering algorithm and incorporates the Transformer structure. The Transformer structure is an encoder-decoder model as shown in Fig. 4. The structure consists of six identical decoders with sub-layers. Each sublayer is connected with a normalization module and residuals between them [17]. There are two types of sub-layers, the fully connected network layer and the attention mechanism layer [18]. The number of layers of encoder and decoder is adjustable under this structure [19]. Considering the cost and

computational consumption, the number of layers of both encoder and decoder is set to 6 here.

In written English literature, most of its grammar is fluent and correct, and the problematic ones are usually small. Therefore, the Transformer model is used to move the sentences without grammatical problems directly to the target sentences, thus avoiding the interference of the grammar evaluation model with the sentences without grammatical problems. The mechanism of the probability distribution of words in the target sentence is shown in (9).

$$P_t(W) = a_t p_t^{copy}(w) + p_t^{gen}(w)(1 - a_t) \quad (9)$$

In (9),  $P_t(W)$  is the lexical probability distribution in the target sentence.  $P_t^{gen}$  is the probability distribution of grammar evaluation generation, and  $P_t^{copy}$  is the probability distribution of original utterance replication.  $a_t$  is the parameter used to control the probability of generation and replication at each time  $t$ . The Transformer structure is used in English grammar evaluation in the way shown in Fig. 5. The Transformer model itself is used to generate the probability distribution of the target vocabulary. The replication score is then calculated by the joint determination of the original utterance input this and the implicit state of the target word. The concept of attention mechanism of the Transformer model needs to be introduced here. The attention mechanism solves the problem of interaction, selection and integration between multiple information sources. It enables the model to focus more on the parts of high importance in the operation. Under the attention mechanism, sentences with a higher probability of grammatical problems are given higher weights.

Fig. 4. Transformer structure.

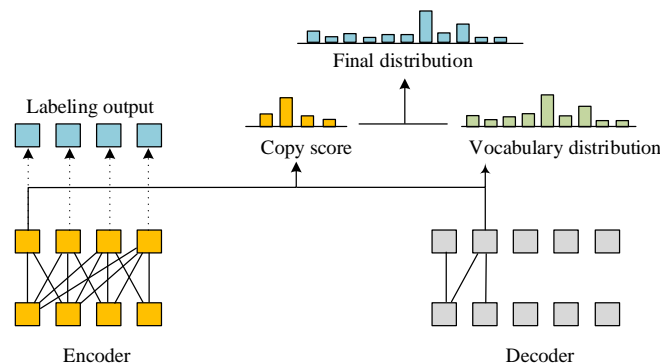

Fig. 5. Transformer structure in grammar evaluation.

Since the Transformer structure alone suffers from the problem of sparse gradients, optimization methods need to be utilized to improve this problem. Here, Adaptive moment estimation (ADAM) optimization is chosen in combination with Transformer structure. This is an adaptive learning rate optimization algorithm that is commonly used to train deep neural networks. The Adam algorithm is derived by combining the advantages of Adagrad and RMSProp algorithms to dynamically adjust the learning rate and track the exponential mean of each parameter and the exponential mean of the squared values. This adaptive learning rate can be automatically adjusted during the training process to ensure that the learning rate is neither too large nor too small, improving the training efficiency and convergence speed. Compared with the traditional gradient descent method, Adam's algorithm has faster convergence speed and higher efficiency, and is widely used in the optimization of various deep learning models. Suppose the objective function is  $f(\omega)$ , then the gradient of the objective function under Adam's algorithm for the current moment parameters  $g_t$  is shown in (10).

$$g_t = \nabla f(\omega_t) \tag{10}$$

After obtaining the gradient, it is also necessary to calculate the data of first-order momentum and second-order momentum in the process, where the solution process of first-order momentum is shown in (11).

$$m_{1t} = \phi(g_1, g_2, \dots, g_t) \tag{11}$$

Equation (11) in  $m_{1t}$  is the first-order momentum. The process of solving for second-order momentum is similar to first-order momentum, and the mathematical expression of the process is shown in (12).

$$m_{2t} = \psi(g_1, g_2, \dots, g_t) \tag{12}$$

In (12), the second-order momentum is denoted by  $m_{2t}$ . At a particular moment  $t$ , the gradient solution process of the algorithm is shown in (13).

$$\mu = l \frac{m_{1t}}{\sqrt{\mu}} \tag{13}$$

In (13),  $\mu$  represents the gradient.  $l$  represents the learning rate of the algorithm. Adam's algorithm also needs to update the parameters, and the mathematical procedure of parameter update is shown in (14).

$$\omega_t = -(\mu_{t-1} - \omega_{t-1}) \tag{14}$$

In (14),  $\omega_t$  represents the parameters at the time of  $t$ . Finally, the functions  $\phi(g_1, g_2, \dots, g_t)$  and  $\psi(g_1, g_2, \dots, g_t)$  for solving the first- and second-order momentum are defined as shown in (15).

$$\begin{cases} \phi(g_1, g_2, \dots, g_t) = lm_{1,t-1} + (1-l)g_t \\ \psi(g_1, g_2, \dots, g_t) = lm_{2,t-1} + (1-l)g_t^2 \end{cases} \tag{15}$$

This completes the construction of a grammatical analysis model for English literature based on statistical language models. The complete flowchart of the proposed algorithm can be summarized in the form shown in Fig. 6. The reordering algorithm based on minimum error training is used to adjust the output of the English corpus based on the statistical language model, while the lexical indication model and lexical N-element co-occurrence model are proposed to further optimize the output of the corpus. The proposed reordering algorithm is applied to the English corpus for English literary analysis, and it can analyze the utterances more effectively and make the output results closer to natural language. Applying this feature to English literary grammar analysis, the study combines the improved Transformer structure to propose an English grammar analysis model which can analyze and point out the grammars that may be problematic in English literature. In this part, the Transformer structure improved by Adam is used to process English literary texts and analyze them based on a corpus.

Fig. 6. Flow chart of proposed algorithm.

#### IV. MODEL TESTING AND RESULT PRESENTATION

This test focuses on the reordering algorithm for the English corpus and the grammatical analysis model of English literature combined with this algorithm. To ensure that the performance of the algorithm is fully exploited, adequate configurations as well as a large amount of data are required. The various environment configurations and the corpus used for the process of this test are shown in Table I. For system stability reasons, Windows 10 was chosen as the operating environment and Python was used as the programming environment. Four English corpora were selected, namely Gutenberg, Wikitext-103, News crawl 2018, and Tatoeba. The lowest of these databases contained 1. The lowest of these databases contains 1,000,000 statements and the highest contains 4,000,000 statements. The four databases have a total of 10,000,000 statements. The large volume of data eliminates the impact of various special cases in the experiment.

First, we measure the Perplexity of the English corpus based on the proposed reordering technique. Perplexity is an important index to evaluate the performance of linguistic statistical models, which represents the average number of branches of the target text. The reciprocal of Perplexity expresses the average probability of each word. When the language model has low Perplexity, it means that it has high performance. A high degree of Perplexity means that the model selection is more difficult and the performance is lower. Fig. 7 shows the test results of algorithm Perplexity. In order to get comparable results, N-gram algorithm and unimproved minimum error training method are used for comparison. Fig. 7(a) shows the Perplexity of several algorithms in the text with a large amount of data, and Fig. 7(b) shows their

performance in the text with a small amount of data. When the test text is a large text with a size of more than 100kb, the Perplexity of several algorithms fluctuates less. Their fluctuation range is between 400 and 550. When the text is a small file of 20kb or less, the Perplexity of several algorithms fluctuates greatly, ranging from 150 to 800. On the whole, the Perplexity of the proposed algorithm is lower than that of the other two algorithms under each TXT text, which shows that the proposed sub algorithm optimization can effectively reorder, thus controlling the complexity of the language model and ensuring the efficiency of the model.

After completing the evaluation of the perplexity, the accuracy of the algorithm output also needs to be evaluated. Since N-gram has been widely used in related fields, N-gram is directly used here as a comparison object. Fig. 8 shows the results of comparing the output accuracy of the proposed reordering algorithm with N-gram. The curves in the Fig. 8 indicate the difference in accuracy between the two on the same text, and positive values indicate that the accuracy of the proposed algorithm is higher than that of N-gram, while negative values indicate the opposite from the overall view of the curves. The majority of the accuracy curves are above 0, i.e., the proposed algorithm is more accurate than N-gram for most of the texts. The proposed algorithm is up to 14.5% more accurate than N-gram. In the few texts where its accuracy is lower than N-gram, its accuracy is no less than 5% of N-gram. A larger sample size eliminates accidental phenomena, so based on the results, although both perform negatively when dealing with different texts, the proposed algorithm has a higher reordering ability than the widely used N-gram algorithm in terms of accuracy.

TABLE I. TEST ENVIRONMENT CONFIGURATION AND CORPUS SELECTION

Item	Detail	
CPU	i5-13400f	
Memory	32 GB	
Operative System	Windows 10	
Programming Environment	Python	
Corpus	Wikitext-103	3,000,000 sentences
	Tatoeba	1,000,000 sentences
	Gutenberg	4,000,000 sentences
	News crawl 2018	2,000,000 sentences

Fig. 7. The degree of confusion of the algorithm in different environments.

Fig. 8. Accuracy difference between the proposed algorithm and N-gram.

In addition to the accuracy, the accuracy, recall and F0.5 values of different algorithms were also compared on the dataset and the results are shown in Table II. This test was performed on the accuracy, recall and F0.5 values of each N-gram, minimum error training and the proposed reordering algorithm. The tests were done on each of the four datasets to ensure the comprehensiveness of the results. On the Gutenberg dataset, the proposed algorithm has a precision rate of 57.98 and accuracy and F0.5 values of 25.68 and 52.23, which are higher than the other two algorithms in these three dimensions. Combining the test results on the four datasets, the proposed algorithm has the highest accuracy rate of 62.13, the highest recall rate of 37.43, and the highest F0.5 value of 54.32. The proposed algorithm consistently outperforms the N-gram and the minimum error rate training methods in several dimensions of accuracy rate, recall rate, and F0.5 value, both in terms of individual dataset comparisons and in terms of the dataset as a whole.

After completing the analysis of the proposed reordering algorithm, the testing of the English literary grammar analysis algorithm based on this algorithm is continued. Since grammatical analysis mainly deals with natural language,

human analysis from experts is currently the most correct way for natural language processing. Therefore, 750 texts were selected for the test and the results of human analysis from experts were compared with the results of the algorithm, and the results are shown in Fig. 9. The horizontal coordinates in this Fig. 9 represent the different texts and the vertical coordinates represent the scores of the two methods for the grammar. Looking at the overall distribution of scores, we can see that the distribution of scores scored by the algorithm is more concentrated than that scored by the expert human, but in general there is a certain correspondence. The expert scores are concentrated in the range of 98 to 75, while the algorithmic scores are concentrated in the range of 75 to 87. The mean score of expert scoring was 85.15 and the mean score of algorithmic scoring was 84.27. The correlation analysis of the results showed that the correlation coefficient of the two scoring methods was 0.7893, which means that there is a significant correlation between them. The change of the results indicates that the proposed English grammar analysis algorithm is somewhat synchronized with the results of the human analysis, and therefore its correctness is to some extent trustworthy.

TABLE II. COMPARISON RESULTS OF ALGORITHM PERFORMANCE

Corpus	Algorithms	Precision	Recall	F0.5
Wikitext-103	Proposed	66.54	37.43	38.42
	Minimum error training	60.78	32.84	33.43
	N-gram	57.31	30.11	29.75
Tatoeba	Proposed	60.84	23.52	54.32
	Minimum error training	53.13	20.18	43.81
	N-gram	51.27	18.60	41.58
Gutenberg	Proposed	57.98	25.68	52.23
	Minimum error training	50.55	21.14	47.64
	N-gram	47.83	18.93	42.41
News crawl 2018	Proposed	62.13	27.61	46.58
	Minimum error training	57.64	24.33	40.77
	N-gram	55.53	20.58	36.12

## V. DISCUSSION

The proposed model is an English natural language analysis model based on an English corpus, designed to analyze English corpora and literature. The reordering algorithm based on Minimum Error Training is employed to adjust the output of the English corpus using statistical language models. Additionally, the introduction of the part-of-speech indicator model and part-of-speech n-gram co-occurrence model further enhances the optimization of the corpus output. When applied to English literary analysis using the proposed reordering algorithm, it facilitates more effective sentence analysis, resulting in output that closely aligns with natural language. By incorporating this feature into English literary grammar analysis, a research study proposes an improved Transformer-based English grammar analysis model to identify potential grammar issues in English literary works. In this study, an enhanced Transformer structure, utilizing improvements from Adam optimization, is utilized to process English literary texts and perform analysis based on the corpus.

teaching platform's analysis algorithm was used as the comparison object. Three common types of grammar problems were used as the comparison objects: article questions, prepositional problems, and singular and plural problems. The test results are shown in Fig. 10, where Fig. 10(a) shows the comparison results of article questions, Fig. 10(b) shows the comparison results of prepositional problems, and Fig. 10(c) shows the comparison results of singular and plural problems. Compared with the education platform algorithm, the proposed algorithm is superior in precision, recall, and F0.5 in all three dimensions. The proposed algorithm achieved a precision rate of 64.37%, a recall rate of 40.32%, and an F0.5 value of 57.51% in singular and plural problems. For article questions, the precision rate of the proposed algorithm reached 60.79%, while the education platform algorithm only reached 58.82%. Through a comprehensive analysis of the comparison results, it can be seen that the proposed grammar analysis algorithm has a stable advantage over existing algorithms.

In the results display section, multiple datasets were used to compare the proposed model with other similar models. The reason for using multiple datasets is that this comparison method can to some extent eliminate randomness and increase the reliability of experimental results. According to the experimental results, the proposed model has the highest accuracy of 62.13, the highest recall rate of 37.43, and the highest F0.5 value of 54.32 on the four datasets used. From these indicators, the proposed model has stable advantages compared to similar algorithms. Due to the fact that manual analysis by humans is currently difficult for machines to replace in the field of natural language analysis, the results of expert human analysis are also entered here and compared with the results of algorithm analysis. After conducting correlation analysis on the statistical results, it was found that the correlation coefficient between the two analysis methods was 0.7893, indicating that the results of algorithm analysis and manual analysis are to some extent similar. This means that the proposed model is to some extent close to people's processing ability of English literature and natural language.

## VI. CONCLUSION

Aiming at the optimization of current statistical language models and English corpora, as well as the gaps in automatic algorithms in the field of English literature analysis, this research proposes an improved re-sorting algorithm based on the minimum error rate training. Based on the re-sorting algorithm, a grammar analysis model for English literature is also proposed. The test results show that in the vast majority of texts, the accuracy of the proposed algorithm is higher than that of the N-gram algorithm. The proposed algorithm has a maximum accuracy of 14.5% higher than N-gram. In a small portion of text with accuracy lower than N-gram, its accuracy is not less than 5% of N-gram. On the Gutenberg dataset, the accuracy of the proposed algorithm is 57.98, with accuracy and F0.5 values of 25.68 and 52.23, which are higher than the other two comparative algorithms in these three dimensions. In addition, in terms of grammar analysis models, the correlation coefficient between model scoring and expert manpower scoring results is 0.7893, indicating a significant correlation between the two. On Singular and plural problems, the accuracy of the model's scoring reached 64.37, the recall rate was 40.32, and the F0.5 value was 57.51, all higher than existing grammar analysis models. The results show that the proposed model has considerable application potential in the field of English literature analysis.

## VII. LIMITATIONS AND FUTURE WORK

This study has made certain contributions to relevant fields, but the research results still have limitations. The proposed algorithm is greatly influenced by the size of the text. When the text is too small, there will be significant fluctuations in the performance of the model. How to maintain stable performance of algorithms at any text size is the direction of future work. In addition, this study did not focus on the consumption of algorithms, so it is necessary to evaluate this aspect in future work to determine its practical value.

# Marginal Distribution Algorithm for Feature Model Test Configuration Generation

Mohd Zanes Sahid, Mohd Zainuri Saringat, Mohd Hamdi Irwan Hamzah, Nurezayana Zainal

Faculty of Computer Science and Information Technology,  
Universiti Tun Hussein Onn Malaysia (UTHM), Johor, Malaysia

**Abstract**—Generating test configuration for Software Product Line (SPL) is difficult, due to the exponential effect of feature combination. Pairwise testing can generate test input for a single software product that deviates from exhaustive testing, nevertheless proven to be effective. In the context of SPL testing, to generate minimal test configuration that maximizes pairwise coverage is not trivial, especially when dealing with a huge number of features and when constraints must be satisfied, which is the case in most SPL systems. In this paper, we propose an estimation of distribution algorithm, based on pairwise testing, to alleviate this problem. Comparisons are made against a greedy-based and a constraint handling based approach. The experiments demonstrate the feasibility of the proposed algorithm, such that it achieves better test configurations dissimilarity and at the same time maintain the test configuration size and pairwise coverage. This is supported by analysis using descriptive statistics.

**Keywords**—Estimation of distribution algorithm; marginal distribution algorithm; test configuration generation; pairwise testing; software product line

## I. INTRODUCTION

Many software products developed for various domains carries some similar functionality. This software shares similar functionalities since they have been developed based on the same kind of input and output types. The similarity in the internal program structure due to identical user requirements also contributes to the commonalities among these software products. Because of this scenario, and based on the benefit of reuse principles, Software Product Line (SPL) has been developed as a software development paradigm to produce software inspired by product line approach. Developing an SPL system enables us to create a software structure that is customizable to various needs, by maximizing software artefacts reusability [1]. Due to the highly variable and reusable nature of SPL artefacts, it is uneconomic to develop software based on distinct requirements separately, as some of the functionalities are similar. However, it is difficult to employ single product development paradigm to build various software products that fulfil the needs of diverse users of a similar domain.

A unit of system function in an SPL is represented as a feature, and explicitly defined as common or variable features and utilized throughout the SPL development process. One way to model the commonalities and variabilities in an SPL is using a Feature Model (FM), based on feature modeling technique [1]. Two or more features are combined and utilized

together in a single software product. This is known as feature configuration. The flexibility of feature configuration process could result in unspecified and unintended system behavior. This might lead to incorrect execution [1]. Hence, it is crucial to test all possible feature configurations to reduce the potential misbehavior of interacting features. But, to test all possible feature configurations is unfeasible. The number of feature configurations increases dramatically as the number of features increased, making full testing of feature configurations especially in large-scale FM impractical [2], [3]. In view of this, a number of techniques have been proposed to reduce the combinatorial explosion of feature configuration testing [4] that leveraged the potential of search-based techniques. More on this is presented in Section II.

In conventional meta-heuristics approaches, probabilities are implicitly employed in the selection and re-production operators, such as mutation operator, to produce offspring [5], [6]. We identified a research gap in feature configuration exhaustive testing, such that, one can explicitly build a probabilistic model of features distribution from an initial set of test configurations. This probabilistic model allows us to estimate the distribution of highly fit features and guide us in generating subsequent candidate solutions that maximize pairwise coverage. Towards that, in Section III we strategize the test configuration generation process, and our contributions are as follows:

- 1) We devise a set of algorithms based on bivariate marginal distribution in SPL context. This approach is perceived as a lightweight variant of estimation of distribution algorithm, in which only the statistics of the population are maintained across generation, instead of the actual population.
- 2) We introduce the notion of feature configuration dependency graph in part B of Section III, which contains the dependency information between pairs of features, extracted using statistical computation.
- 3) We implement the proposed approach using Java and conducted empirical studies. Results are reported and discussed in Sections IV and V.

## II. BACKGROUND AND RELATED WORKS

### A. Feature Model

Feature Modeling is a popular way to model SPL variability and it is by far the most reported in industry. In Feature Modeling, Feature Model (FM) notation has been developed to represent features and its dependencies [1]. The

tree representation of FM is known as Feature Diagram. It presents a feature as a node, and relationship between two features as an edge. Different types of edges can be assigned between features, which represent the relationship of type mandatory, optional, or, or alternative. Additionally, an FM might encompass some constraints which act as rules or conditions that limit the linking between features.

Fig. 1 shows a feature model named as OnlineBookstore SPL from Software Product Line Online Tools (SPLOT) [7].

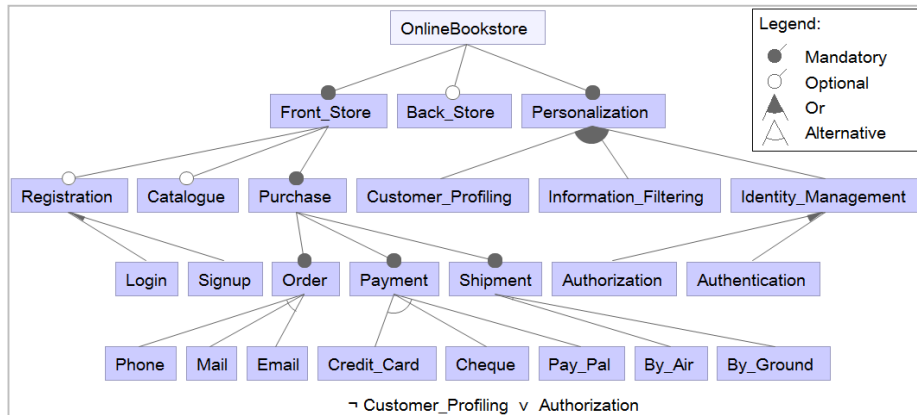

Fig. 1. A Feature Model of an OnlineBookstore SPL.

In the subsequent part of this paper, we refer each feature from our Feature Model as  $x$ . It is an integer where  $x \in [1, N]$ , having  $N$  as the maximum number of features in the FM.  $x$  can be of positive prefix (not written) to indicate the feature is included or negative prefix (explicitly written) to indicate the feature is not included.

For brevity, each feature in the feature model shown in Fig. 1 is mapped to a unique number, assigned sequentially from top to bottom, left to right. This gives us a representation as shown in Fig. 2, which is used throughout this paper.

Fig. 2. Number assignment of each feature.

### B. Test Configuration

Software products of an SPL are configured and produced by combining several features. These artefacts are called feature configurations. In view of testing, test case(s) can be defined for each feature. Thus, to test a feature configuration, Test Configuration (TC), which consists of many test cases, can be generated in the same way the feature configuration is generated. A test configuration, TC, is a list of all features,

This feature model defines some of the most common features that an online bookstore system should have. It consists of 25 features, including seven mandatory features. There is one cross-tree-constraint defined, which is  $\neg$  Customer\_Profiling  $\vee$  Authorization. This constraint signifies that feature Customer\_Profiling requires the presence of feature Authorization, but not conversely. Apart from that, a couple of variation points are defined. For example, we can choose to have Signup feature apart from Login; different types of Personalization features can be incorporated; and so on.

represented by its feature number. Each feature in a test configuration can have either positive or negative prefix.

### C. Pairwise Testing

Complete testing of all possible feature configurations is not feasible. For  $n$  number of features, it requires  $2^n$  number of test configurations to cover all possible combinations, because it is either selected or excluded. This makes it exponentially proportioned to the number of features. To alleviate this obstacle, pairwise testing has been widely used as a viable solution. The ultimate goal of pairwise testing is to cover all possible pair of features at least once [8]–[10]. Thus, testing can be focused on the interaction of both features. Pairwise testing is a kind of combinatorial testing, where we choose 2 features to be considered or included in our test pool. Generalization of pairwise testing is called t-wise testing, where  $t$  indicates the number of features to choose.

For its practicality and usability, SPL pairwise testing is governed by constraints. Considering two features (1 and 2) from OnlineBookstore SPL, four pairs of tuple have to be generated, i.e. (1,2), (1,-2), (-1,2) and (-1,-2), where negative prefix indicates that the feature is not selected in the feature configuration. Due to constraints (cross-tree-constraints and relationship of features in FM), some invalid pairs will be eliminated, e.g. (-1,2) is invalid, because root feature, i.e. 1, must always be selected. The same goes with mandatory features (2, 4, 7, and so on).

If we construct one Test Configuration,  $TC_i$ , for each pair of features,  $pf_{v,w}$ , (as an example, pair of feature 1 and -5), assigned as follows;

$$pf_{1,-5} = (1, -5); \quad TC_a = [ 1, ?, ?, ?, -5, ?, ?, ?, ? ]$$

we can set any arbitrary value for other variables in  $TC_a$  (marked as ?). However, these variables could possibly be matched with other pairs of features that we should cover. Thus, if we can systematically set the values of each variable in  $TC_i$ , we could maximize the number of valid pairs in each TC so that it can minimize the number of TC.

#### D. Related Works

SPL test configuration generation techniques that are based on greedy approach or applied meta-heuristics are discussed in the first part of this section. In the second part, few selected literatures of Estimation of Distribution Algorithms (EDA), including works related to its adoption in software engineering activities are presented.

Among others, multi-objective evolutionary algorithm has been proposed for SPL testing [6]. Their motivation was to minimize the tests suite by sorting the product lines. Henard et al. [2] also employed a search-based algorithm, (1+1) Evolution Strategy (ES), to generate and prioritise covering array, guided by a (dis)similarity measure. Henard et al. mentioned that t-wise approaches for SPLs are restricted to FMs of small sizes and t-wise coverage of low strength. Both are constrained by scalability issues that result from the intractable computation for very large FMs or high t-wise strength. Therefore, they formulated the feature configuration generation problem as a search-based where the search space consists of all valid feature configurations extracted from the FM. Dissimilarity between features is used as the fitness function during the searching for better populations.

Feature configuration testing is highly influenced by the effectiveness of constraint handling techniques that eliminate invalid test configurations. One of such prominent work is published by Yu, Duan et al. [11], whereby the validity checking of test configuration is achieved using minimum invalid tuples (MITs). This approach has been implemented as a tool named LOOKUP.

Hybrid of multi-objective crow search and fruitfly optimization has been studied and offers an optimal selection of the test suites at a fairly good convergence rate [12]. Haslinger et al. [13] applied a Simulated Annealing algorithm to generate t-wise covering array and demonstrated a tool to improve the performance of SPL testing. Haslinger et al. report a speedup of over 60% on 133 publicly available feature models, while preserving the coverage of the generated tests.

Johansen et al. published their solution [3] and a tool named ICPL, which capable of processing large feature models, better execution time and produced small covering array. They used the fact that a (t-1)-wise is always a subset of the t-wise, and employed this principle to recursively build up a higher strength covering array from a smaller one.

Estimation of Distribution Algorithms (EDA) is a kind of Evolutionary Algorithms that finds near optimal solutions based on the evolution of candidate solutions satisfying some fitness functions. EDA guide the search by explicitly building the probabilistic model of promising candidate solutions. The detail discussion on EDA is beyond the scope of this paper, but interested reader can refer to papers by Ceberio et al. [14], Shirazi et al. [15], Shakya and Santana [16], Simon [17] and

Pelikan [18]. In the area of Search-Based Software Engineering (SBSE), to the best of our knowledge, no attempt has been made to employ any variant of high-order EDA (which includes bivariate or multivariate statistics) in SPL testing.

EDA have been adopted to solve many optimization problems in single software-product development such as to optimize test data generation and test suites generation [19]–[21] and refactoring [22]. The work in [19] employs bivariate EDA named as COMIT [23], in which the combination of pair of variables are viewed as tree, therefore it has a single root node. They proposed integration with data mining techniques to predict the performance of a test data generator. In the context of testing for concurrent software, detecting faults can be improved by exploiting information discovered in EDA exploration that can save future test efforts [24]. EDA has also been employed to improve software reliability prediction [25]. They reported that EDA-based approach can optimize the parameters of support vector regression in predicting the software reliability, by introducing a chaotic mutation operator into traditional EDA. Prior to that, they define the software reliability prediction problem as a combinatorial optimization problem with constraints, in which, search-based are known to be a viable solution to that problem.

### III. PROPOSED APPROACH

This section presents an evolutionary-based algorithm that generates minimal and effective SPL test configuration that satisfies pairwise coverage of features, based on bivariate marginal distribution strategy.

#### A. Marginal Distribution Algorithms of EDAs

Estimation of Distribution Algorithms (EDAs) explores the space of potential solutions following the principle of survival of the fittest of individual and populations similar to Genetic Algorithm (GA) [16], [18]. However, in EDAs, crossover and mutation operators are removed and replaced by the estimation of a probability distribution. The Probability Distribution is a model of (1) the distribution of genes across all individuals, and (2) the dependence relations or independence relations of genes between individuals.

One way to estimate the distribution of genes from all the individuals in the population is by using marginal distribution. The simplest marginal distribution calculates the probability of each candidate solutions' genes independently. This strategy is called as univariate marginal distribution. This contrasts with bivariate marginal distribution, which calculates the estimation based on the dependency of two genes. The dependency that is of our interest is the statistically significant dependency, which can be computed using Pearson's chi-square statistics [26].

The probability distribution for the univariate marginal distribution is calculated using the frequency of each gene from all or truncated individuals and stored as Probability Vector (PV). The PV will be used to sample or generate new individuals in subsequent generations. For the bivariate marginal distribution, we start with calculating the frequency of each gene. Then, we calculate the joint probability of each pair of genes, using the previously calculated frequency value. Afterward, for each pair of genes, we calculate the Pearson's chi-square tests to establish links between interdependent

genes. The result of this is a set of genes dependency and we only consider two genes as interdependent if the value is statistically significant. Next, we generate a dependency graph to store this information. The graph is acyclic and not necessarily has to be connected. All genes that have no interdependency with other genes are assigned as a root node in the graph. Whereas, for those that have a link, if both genes are not yet added to the graph, choose any gene from that pair as the root node. Add the other gene as a child node and connect them using an edge. Among them, nodes that are added earlier are called as the parent node.

Based on the constructed graph, we generate a new population. First, populate genes for root nodes using univariate frequencies. Next, for each child nodes, populate the genes using conditional probability. Perform the same process for all child nodes. From there, the standard evolutionary step is applied, which is fitness evaluation of each individual in the new population. The population is truncated, and the process repeats until an acceptable solution is found. The intuition is, univariate-based EDA is considered as a lightweight evolutionary algorithm and require small memory footprint [27], whereas the bivariate EDA manifest possible variables interdependency [18].

**B. Bivariate Distribution of SPL Features**

This section presents the mechanism and illustration of a second-order EDA (bivariate distribution) to generate pairwise test configuration for SPL. Here, we named this approach as Combinatorial Testing using Estimation of Distribution (COTED).

The proposed strategy is generally outlined as follows:

- 1) Generate a set of test configuration as the initial population. Calculate the fitness of each test configuration using the number of covered pairwise. Then, we perform truncation to select highly fit candidate solutions.
- 2) Calculate univariate frequencies and bivariate frequencies of each feature number.
- 3) Create a feature configuration dependency graph using the calculated frequency.
- 4) Generate new test configurations based on the graph.
- 5) Repeat until termination criteria are matched.

We define our fitness function as the number of pairs of features covered by each test configuration, whereby, the more pairs covered, the better the fitness. The intuition is, during the search for fitter test configurations, the stronger the dependency of a particular pair of features present in the current fittest test configuration, the more frequent it should be included in the subsequent list of test configuration. For

example, if the dependency of features 5 and 7 are statistically significant in our 10 best test configurations, we should create more test configurations using the calculated conditional distribution of features 5 and 7 in the next iteration. The definition of best test configurations refers to those that cover a higher number of pairs from our list of all valid pairs.

By modeling the non-dependency between two features in a set of test configurations, we can search for possible dependency between two features. This dependency would suggest that the two features should be paired, and those that have strong dependency should be considered first. A variant of EDA that has the capability to find this dependency is called the Bivariate Marginal Distribution Algorithm (BMEDA) [17], [28]. It uses a factorization of the univariate marginal and joint probability distribution that able to expose second-order dependencies. For our test configuration generation problem, we define the univariate marginal and joint probability distribution as follows:

**Definition 1 (univariate marginal probability)**

The probability of a feature is selected,  $p(x_i)$ , is unconditional to other features. For example,  $p(5) = 0.7$ , means that the probability of feature number 5 to be selected is 70 per cent from all test configurations.

**Definition 2 (joint probability)**

Joint probability between feature  $v$  and feature  $w$ ,  $JP_{v,w}$ , is defined as the probability of feature  $v$  and feature  $w$  been considered (either selected or not selected).

In the remaining part of this section, we elaborate the details of the mechanism to generate test configuration that satisfies pairwise coverage of feature configuration.

Step 1. Feature configurations in FM are governed by constraints, so that only valid test configurations are generated. A SAT solver is utilized to populate the seed of our search space. Once a collection of valid test configurations is available, we calculate their fitness using pairwise coverage and remove unfit test configurations. To illustrate this, we make a list of valid pair of features that needs to be covered in Listing 1. We start by populating 20 test configurations from SAT solver and calculate the number of pairwise covered by each test configuration as its fitness value. We sort and select 10 fittest test configurations as our truncated initial population, which is presented in Fig. 3.

**Pair of features, pf = { (-3,20), (-3,21), (5,19), (-5,20), (5,22), (-5,23), (-6,18), (8,9), (8,19), (8,21), (-8,23), (-9,19), (9,23), (-10,20), (-10,23), (11,19), (11,22), (-11,23), (12,19), (12,22), (-12,23), (-16,23), (19,23), (20,22), (21,24), (21,-25), (22,-24), (22,25) }**

Listing 1. Pair of valid features that needs to be covered.

Test Configuration, TC	Fitness
01: [1,2, 3,4, 5, 6,7, 8, 9, 10,-11, 12,13,14,15, 16, 17,-18, 19,-20,-21, 22,-23,-24, 25]	8
02: [1,2, 3,4, 5, 6,7, 8,-9, 10, 11,-12,13,14,15, 16,-17,-18, 19,-20,-21, 22,-23,-24, 25]	8
03: [1,2,-3,4, 5, 6,7,-8,-9, 10, 11, 12,13,14,15,-16, 17,-18,-19, 20,-21, 22,-23,-24, 25]	7
04: [1,2,-3,4, 5, 6,7, 8, 9, 10, 11,-12,13,14,15, 16, 17,-18, 19,-20,-21, 22,-23, 24,-25]	6
05: [1,2, 3,4,-5, 6,7,-8, 9, 10,-11,-12,13,14,15, 16, 17,-18,-19, 20,-21,-22, 23,-24, 25]	6
06: [1,2,-3,4, 5,-6,7,-8, 9,-10, 11, 12,13,14,15,-16,-17, 18,-19,-20,-21, 22,-23,-24, 25]	6
07: [1,2,-3,4,-5,-6,7,-8,-9, 10,-11,-12,13,14,15, 16, 17,-18,-19, 20, 21,-22,-23, 24,-25]	5
08: [1,2,-3,4,-5,-6,7,-8,-9, 10,-11,-12,13,14,15, 16,-17, 18,-19,-20,-21,-22, 23, 24,-25]	5
09: [1,2, 3,4, 5,-6,7,-8, 9, 10, 11,-12,13,14,15,-16, 17,-18,-19, 20,-21,-22, 23, 24, 25]	4
10: [1,2,-3,4, 5,-6,7,-8, 9, 10, 11,-12,13,14,15, 16,-17,-18,-19, 20,-21,-22, 23, 24,-25]	4

Fig. 3. List of initial truncated population with fitness value.

Step 2. We calculate the univariate distribution for each feature. Each feature in each test configuration has either positive or negative prefix. We compute the mean of positive number for each feature from all test configurations. These processes are presented in Algorithm 1. The result of this process is the Probability Vector, PV of our initial population, as shown in Fig. 4.

**Algorithm 1. Calculate Probability Vector**

1. Load a population of candidate solutions
2. Select 10 test configurations according to its pairwise fitness
3. Let  $n$  be the length of a test configuration
4. For  $i = 1$  to  $n$
5. Calculate the mean of positive  $i$  as  $mean\_i$
6. Set the probability vector for feature  $i$ ,  $P(i) = mean\_i$
7. Next  $i$

<b>PV:</b> [1.0,1.0,0.4,1.0,0.7,0.5,1.0,0.3,0.6,0.9,0.6,0.3, 1.0,1.0,1.0,0.7,0.6,0.2,0.3,0.5,0.1,0.5,0.4,0.4,0.6]
--

Fig. 4. Probability vector of initial population.

The next step is to calculate the joint probability of all possible value in each pair of the feature. As an example, for features 5 and 11, we calculate the occurrences of all four pairs; i.e. (5,11), (5,-11), (-5,11) and (-5,-11). Based on the population in Fig. 3, we get the joint probability value of 0.6, 0.1, 0.0 and 0.3, respectively. This process is defined in Algorithm 2, line 2 to 8.

After that, calculate the Pearson’s chi-square statistics,  $C_{v,w}$ , for each pair of features using the following equation:

$$C_{v,w} = n * \sum_{\alpha,\beta} \frac{[JP_{\alpha v, \beta w} - P(\alpha v)P(\beta w)]^2}{P(\alpha v)P(\beta w)}$$

where  $n$  is the number of test configuration

$\alpha$  is either positive or negative prefix

$\beta$  is either positive or negative prefix

For example, for  $v=5$  and  $w=11$ :

$$C_{5,11} = 10 * \left( \frac{(JP_{5,11} - P(5)P(11))^2}{P(5)P(11)} + \frac{(JP_{5,-11} - P(5)P(-11))^2}{P(5)P(-11)} + \frac{(JP_{-5,11} - P(-5)P(11))^2}{P(-5)P(11)} + \frac{(JP_{-5,-11} - P(-5)P(-11))^2}{P(-5)P(-11)} \right) = 10 * \left( \frac{(0.6 - (0.7*0.6))^2}{0.7*0.6} + \frac{(0.1 - (0.7*0.4))^2}{0.7*0.4} + \frac{(0.0 - (0.3*0.6))^2}{0.3*0.6} + \frac{(0.3 - (0.3*0.4))^2}{0.3*0.4} \right) = 6.4$$

This step is defined in Algorithm 2, line 9 to 14. Based on our sampled population, the calculated bivariate frequencies are shown in Fig. 5. Here, we are only interested in chi-square value of at least 3.84 [17], based on the degree of freedom of 1 and p value of 0.05. By calculating the chi-square values of the initial population, we choose 11 feature pairs. These pairs are conceived as having a strong dependency, due to the high degree of correlation.

**Algorithm 2. Calculate Bivariate Frequencies**

1. Initialize joint probability,  $JP$
2. For  $v = 1$  to  $n - 1$
3. For  $w = 2$  to  $n$
4. For each test configuration,  $tc$
5. Calculate joint probability between feature  $v$  and  $w$ ,  $JP_{v,w}$ , group by combination of positive and negative prefix
6. Next  $tc$
7. Next  $w$
8. Next  $v$
9. Initialize chi-square,  $C$
10. For  $v = 1$  to  $n-1$
11. For  $w = 2$  to  $n$
12. Calculate the Pearson’s chi-square statistics  $C_{v,w}$
13. Next  $w$
14. Next  $v$

Feature Pair	Chi-square
(8,19)	10.0
(24,25)	10.0
(22,23)	6.6
(5,11)	6.4
(10,18)	4.5
(3,24)	4.5
(5,22)	4.4
(8,22)	4.4
(12,22)	4.4
(8,20)	4.4
(6,8)	4.4
Other pair	<3.84

Fig. 5. Bivariate frequencies of the initial population.

Step 3. The succeeding step is to create a Feature Configuration Dependency Graph (FCDG). We define FCDG as a forest and are specified in Definition 3.

Definition 3. (Feature Configuration Dependency Graph, FCDG).

$FCDG = (V,E)$ , where  $V$  is the set of all features available in the forest, and  $E$  is the set of all edges between some ordered pairs of features. FCDG contains a collection of possibly disconnected trees.

Each feature is represented by a node, and dependency between the pair of features is represented by an edge. The dependency between features is to be calculated based on conditional probability, thus its relationship is of type directional. Therefore, we link the respective nodes in our FCDG using directed edges.

We define the following six properties for the FCDG:

- 1) The indegree of a node is the number of edges directing to that node. Each node has zero or one indegree.
- 2) The outdegree of a node is the number of edges leading away from that node. Each node has zero or more outdegree.
- 3) A node with zero indegree and non-zero outdegree is called as a root node. FCDG can have more than one root node.
- 4) A node with non-zero indegree is called as a child node.
- 5) A node with non-zero outdegree is called as a parent node.
- 6) A node without a degree is called as a standalone node.

The generation process of FCDG starts by selecting a random feature and adds it to our graph. Then, add a dependent feature by finding another feature having the highest chi-square value of at least 3.84, and add it to the graph. Repeat this step until no more features fulfil this criterion. Then, select another random feature and repeat the whole process until all features are added to the graph. This process is defined in Algorithm 3.

**Algorithm 3. Create Feature Configuration Dependency Graph**

1. Let  $W$  as the set of all features
2. Let  $F$  as an empty graph, consists of empty  $V$  and  $E$
3. Select a random feature,  $r$ , from  $W$
4. Add  $r$  to the graph,  $V$
5. Remove  $r$  from  $W$
6. If there are no more features in  $W$ , goto end
7. For each remaining features in  $W$
8. Find a feature,  $s$ , that has the highest dependency to feature  $r$
9. If found
10. add  $s$  to  $V$
11. removes  $s$  from  $W$
12. add set  $\{r,s\}$  into  $E$
13. if not found
14. goto step 3
15. end if
16. End

Executing this algorithm against the values from Fig. 5 will result in a graph with the following attributes:

- The set of all features,  $V = \{1,2,3,\dots,25\}$
- Edges between some ordered feature pairs,  $E = \{ \{3,24\}, \{5,11\}, \{8,6\}, \{8,19\}, \{8,20\}, \{18,10\}, \{22,5\}, \{22,8\}, \{22,12\}, \{22,23\}, \{24,25\} \}$

In this case, the FCDG for our running example consists of 25 nodes with 11 edges. This can be graphically presented using a forest with three disconnected trees as shown in Fig. 6. All nodes in white colour are standalone nodes, in which no dependency to other nodes is discovered. The rest (coloured nodes) are nodes with dependency. As an example, it is shown that features 18 and 10 are highly dependent. From Fig. 3, feature 18 is always negative whenever feature 10 is positive, and the other way round. Another example is between feature 8 and 19. It is of high frequency that both having negative values in the same row. The same relationship (of a certain pattern) can be observed for the rest of the pairs.

Step 4. Once we have the dependency graph, we can proceed with generating a new population. It consists of two parts, (1) to populate root nodes, and (2) to populate child node.

Fig. 6. The feature configuration dependency graph of the initial population.

We start by populating all features correspond to the root nodes in our graph. The features are assigned with positive or negative values using univariate probabilities. Then, we populate the remaining features that correspond to the child nodes. This is performed by calculating the conditional probabilities of the child nodes given its parent nodes. We define the conditional probabilities for our strategy as follows:

**Definition 4. (conditional probability)**

Conditional probability of feature  $s$  and feature  $r$ ,  $CP(s/r)$  is defined as the probability of feature  $s$  to be selected, given feature  $r$  been selected. It is calculated using the joint probability of  $s$  and  $r$ ,  $JP_{s,r}$ , divide by the univariate probability of  $r$ , i.e  $P(r)$ .

$$CP(s | r) = \frac{JP_{s,r}}{P(r)}$$

This process is defined from line 3 to line 8 of Algorithm 4.

**Algorithm 4. Populate New Generation**

1. For each root nodes,  $r$ , in  $G$
2. Populate new generation having positive/negative value of  $r$  using univariate frequencies
3. For other nodes,  $s$ , in  $G$
4. If parent node of  $s$  has been populated
5. Populate positive/negative value of  $s$  based on the conditional probability of  $s$  given parent of  $s$
6. If all features have been populated, goto end
7. Next root node
8. End

To demonstrate the first part, which is populating all the root nodes, Fig. 7 shows a possible assignment for 20 test configurations of our new generation. For example, for feature 16, from our initial generation, the PV value for feature 16 is 0.7, hence 70% of the new generation should have the positive value of 16. This can be achieved by using random numbers generated from a uniform distribution between 0 and 1. As per shown in Fig. 7, the outcome of this strategy is the assignment of a positive value of 16 for test configurations TC01, TC04-TC08, TC10, TC11, TC14 TC16 and TC18 TC20. The remaining test configurations are assigned with -16. We apply the same strategy to populate the remaining root node features, and values are presented in Fig. 7. For non-root node features, which we mark with unfilled squares ( $\square$ ), will be populated later.

The second part populates the remaining features, with respect to the child nodes from our dependency graph, i.e. features 5, 6, 8, 10, 11, 12, 19, 20, 23, 24, 25. Let us choose feature 12 as an example. Since feature 22 has been assigned with values, we assign feature 12 given the respective values of feature 22, using conditional distribution. It can be calculated using the joint probability of both features having positive values in the initial population, i.e. 0.3. Then divide by the probability vector of feature 22, i.e. 0.5. This equates to 0.6. Thus, we populate 60% of feature 12 with positive values for test configuration having positive 22. Similarly, calculate the probability of positive 12 given the negative value of feature 22, and use the result to populate the value of remaining test configurations. Once all values for feature 12 have been

assigned, we use the same strategy to populate the remaining features. A possible outcome of this process is shown in Fig. 8.

Step 5. The final step in this iteration is to calculate the fitness of each individual in the new generation. We count how many pairs from Listing 1 matched with each pair of features in each test configuration. The fitness values are shown in the

right column of Fig. 8. It is observed that three test configurations (TC10, TC17, and TC18) have better fitness value (marked with \*) compared to the previous generation of test configuration (refer Fig. 3). Truncation is again applied to select only ten highly fit individuals. The whole process repeats from Algorithm 1 and continue until the intended pairwise coverage has been met.

Fig. 8. Populated non-root node features using conditional distribution and calculated fitness value.

#### IV. EXPERIMENT AND RESULTS

COTED has been implemented and executed on a set of feature models from Software Product Line Online Tools (SPLOT) [7]. The objective is to measure the efficiency and effectiveness of bivariate distribution approach based on EDA in generating test configuration satisfying pairwise testing. The comparison has been made against (1) a greedy-based approach, ICPL [3] and (2) a constraint handling approach based on the minimum-invalid-tuple strategy, LOOKUP [29].

The first part assesses the efficiency by measuring the minimum number of test configurations that the three approaches able to generate. The second part measures the

quality of the generated test configuration, in terms of the frequency of pairwise tuple, and test configuration similarity. During the experiments, 8 datasets of various sizes of constrained Feature Models (FMs) have been selected from SPLOT. COTED has been executed with the population of size 800 with truncation size 100, stagnancy count of 3 executions, maximum generations were 5000 and execution timeout of 1800 seconds.

##### A. Minimum Number of Test Configurations

This is the most used metric that evaluates the efficiency of the solution for SPL test configuration generation [12]. It calculates the number of test configurations generated using a particular approach that either fully satisfies the pairwise

coverage, or partially fulfil the coverage with a decent percentage. However, the latter does not conform to the definition of pairwise testing, i.e. to have all pairs covered at least once. Therefore, a complete pairwise coverage is often of the goal in any SPL test configuration exercise.

Fig. 9 shows that LOOKUP is the most outstanding tool in generating the most minimal test configurations. For J2EEWebArch and CocheEcologico, it outperforms the other techniques. For others, it produces an equal number of test configuration as generated by COTED, except for SPLSimulES dataset.

**B. t-wise Frequency**

This measure has been devised by Perrouin et al. [30] as the ratio between the occurrences of t-wise and the number of test configurations generated. This can be used to check whether the solution satisfies the t-wise principle, i.e., in the solution, every valid combination of t factors must be present at least once. An optimum solution consists of combination of t factors once. This, however, is hard to achieve.

Fig. 10 shows the box plots of all evaluated techniques calculated based on the median of t-wise frequencies of the generated test configurations for each benchmark datasets. In general, the average and the dispersion of the t-wise frequencies are stable for the three techniques. Most of the results show that the frequencies are maintained low, as depicted by the concentration on the low end of the scale, except for Ecommerce (Fig. 10(a)) and Billing (Fig. 10(g)) datasets. Low frequency of t-wise in the generated test configurations indicates that there are less pairwise

occurrences; hence lower the redundancy of feature of pairs. This is useful in the event of limited time and resources available for testing, which is often the case in SPL testing.

On average, as shown in Table I, the median and standard deviation ( $\sigma$ ) of the proposed techniques resides on the decent level, which is on par with the other approaches. Even though, on average, ICPL can demonstrate lower t-wise frequency (0.288), the deviation of the overall solution is worse than the rest. On the other side of the coin, LOOKUP and COTED managed to cover pairwise steadily, with low variations, on average, however, it covers higher frequency than ICPL. The differences between COTED and LOOKUP are relatively low. 50 per cent of the overall medians are equal for both techniques.

Datasets	Num. of Features	Num. of Constraints	TC Generation Techniques		
			COTED	ICPL	LOOKUP
Ecommerce	10	10	6	7	6

Graph Product Line	0.27	0.2280	0.29	0.2289	0.27	0.2263
J2EE Web Arch	0.26	0.1440	0.28	0.1566	0.29	0.1391
Billing	0.4	0.1530	0.36	0.1782	0.38	0.1553
Coche-ecologico	0.33	0.2488	0.13	0.3353	0.32	0.2530
Average	0.311	0.177	0.288	0.202	0.307	0.177

C. Test Configurations Similarity

The third measurement is test configuration similarity [30]. The objective is to assess the degree of similarity between test configurations among a different set of solutions. The similarity between two test configurations is calculated using Jaccard Index, *Jac*. Given a and b as the two test configurations, we calculate *Jac*(a,b) as follows:

$$Jac(a,b) = \frac{|a \cap b|}{|a \cup b|}$$

The presence of all mandatory features is a must in all test configurations. Since all solutions from the three techniques are of valid test configurations, we omit the similarity checking for mandatory features. Only optional features are observed.

This similarity measure can be used to measure the degree of diversity of the generated solutions. Lower Jaccard Index value indicates that the test configurations are less likely to be similar, hence more diversified. Fig. 11 shows the box plots calculated based on the median of the test configuration

similarity from the generated solutions for each benchmark datasets. Overall, the averages of the test configuration similarity are low and encouraging among all techniques, and the dispersions of the median are stable for all techniques. This is depicted in Fig. 11 based on the trend of right skewness, as most medians are closer to the first quartile than the third quartile. COTED performance is on par with LOOKUP, and in fact, it managed to outperform LOOKUP at SPL-SimulES dataset. Overall, COTED and LOOKUP outperform ICPL for most datasets.

With respect to the average and measure of dispersion, as shown in Table II, LOOKUP performed better than the rest, with the exception to three datasets (Cellphone, SPL SimulES and ArcadeGamePL) where COTED has a bit lower median values. Meanwhile, the median of COTED is better than ICPL, with lower median and  $\sigma$  on five datasets (ECommerce, Cellphone, ArcadeGamePL, Graph Product Line and Coche ecologico). This suggests, on average, it produces more dissimilar sets of test configurations.

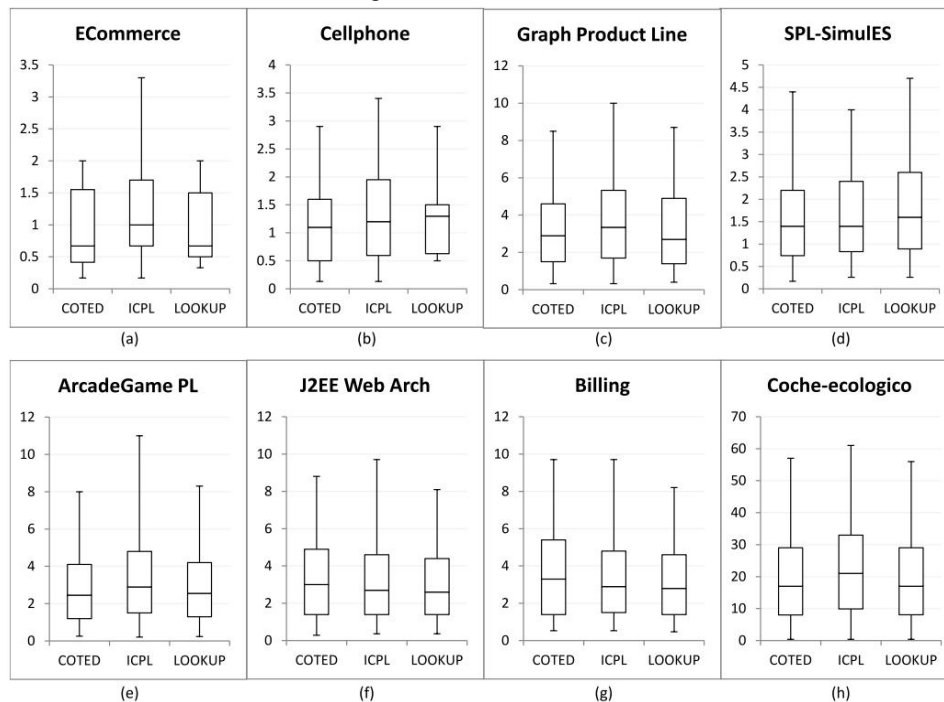

Fig. 11. Box plots for the median of t-wise similarity of the three approaches.

TABLE II. MEDIAN AND STANDARD DEVIATION ( $\sigma$ ) OF TEST CONFIGURATION SIMILARITY

Techniques Datasets	COTED		ICPL		LOOKUP	
	Median	$\sigma$	Median	$\sigma$	Median	$\sigma$
ECommerce	0.67	0.6581	1	0.8064	0.67	0.6489

Average	3.977	3.102	4.556	3.253	3.902	2.987

## V. DISCUSSIONS

By calculating the marginal distribution between every two features in a particular sample, we can infer its connection. And based on that strong assumption, the population evolve towards more frequently connected features. This can directly be translated to more pairwise coverage. The ability to maximize pairwise coverage at each evolution cycle results in the reduction in the overall cycles of exploration, and subsequently, reduce the number of generated test configuration that fulfil pairwise coverage.

This strategy has been evaluated against two current approaches, i.e. greedy-based and minimum invalid tuple based. Of the three strategies, the minimum invalid tuple-based strategy performed the best, but, competitively challenged by COTED, and this is supported by results analysis using descriptive statistics.

Even though the performance of COTED is shown to be comparable, if not better than other approach, it provides us with a set of knowledge on the problem structure. By analysing the evolution of the probability models during test configuration generation, we discover a set of data on how the problem is being solved. We also gain knowledge on how features are distributed in the population with respect to other features. We explicitly acquire this in the form of feature configuration dependency graph which stores a set of feature pairs that have strong dependency. This information is deemed crucial as it could help us (1) decide how to prioritize the test configurations in pairwise testing, and (2) infer a higher order marginal distribution based on the collection of dependency knowledge.

As compared to test generation, previous literature highlighted that test prioritization for SPL is insufficiently researched, especially on one that is based on feature reusability [31]. Reusable features are features that appear more frequently in final software products than the others. Hence, calculating the frequency might help in extracting the most reusable one. In view of interaction testing, two interacting features are of one main concern. Thus, to find those reusable interactions could mean to find common feature interactions.

The dependency knowledge in the form of a collection of feature configuration dependency graphs are acquired iteratively from second-order probabilistic model. As opposed to computing a higher-order probabilistic model (which involves multivariate computation), this process is more viable as it incurs much lower cost. Additionally, a higher-order probabilistic model is achievable by grouping or clustering lower-order dependencies which contains highly interacting sets of variables [32]. Therefore, we could leverage a lightweight second-order iterative computation for practical higher-order computation. This remains to be investigated and thus motivate our future work.

## VI. CONCLUSION AND FUTURE WORKS

Generating efficient and effective test configurations for SPL is difficult. One way to feasibly tackle the combinatorial explosions of feature configuration testing is by leveraging pairwise testing.

Based on the work we conducted throughout this study, we found that the marginal distribution algorithm-based approach is a feasible and competitive strategy. It allows us to reduce the number of required test configuration from an exhaustive approach by leveraging pairwise coverage as its fitness function. Our proposed strategy managed to generate the solution of similar quality in terms of t-wise frequency and test configuration diversity, compared to those generated by state-of-the-art approaches. The outcome of the proposed strategy is two-fold. First, it generates minimized test configuration for pairwise testing. Secondly, the inherent ability of the strategy to extract the dependency knowledge in the form of feature configuration dependency graphs. As per our knowledge, this is the first time a combinatorial interaction testing in software product line problem is being modelled and tackled by using probability based evolutionary algorithm.

**Abstract**—In today's computing era, the Internet of Things (IoT) stands out for its implementation of automation, high-quality ecosystems, creative and efficient services, and higher productivity. IoT has found applications in various fields, such as education, healthcare, agriculture, military, and industry, where diverse resource requirements present a major challenge. To address this issue, we propose a novel QoS-aware resource allocation method for IoT systems. Our approach combines the Ant Colony Optimization (ACO) and Tabu Search (TS) algorithms to manage resources effectively, minimize energy consumption, reduce communication delays, and enhance overall system performance. Experimental results demonstrate the efficiency and effectiveness of our approach, with significant improvements in QoS metrics compared to traditional methods. By merging ACO and TS algorithms, our research contributes to the advancement of IoT capabilities, energy conservation, and business optimization.

**Keywords**—Internet of things; resource allocation; virtualization; Ant Colony Optimization; Tabu Search

## I. INTRODUCTION

The Internet of Things (IoT) enables the integration of the virtual and physical worlds, facilitating communication between various devices without human intervention [1]. This has led to a growing interest in IoT research due to its ability to enable intelligent and ubiquitous services through data aggregation, processing, analysis, and mining [2, 3]. However, the performance of IoT systems is influenced by several factors and resources, such as user requirements, energy consumption, diverse applications, storage capacity, communication needs, network bandwidth, and computing power. These resources are heterogeneous in nature, meaning they vary in their capabilities and characteristics [4]. IoT networks face resource allocation challenges, particularly in networks with heterogeneous properties. Resource allocation involves effectively managing and allocating limited resources to achieve optimal objectives [5]. The resources in IoT networks are divided into two categories: node resources and channel resources. Node resources, also known as physical resources, include storage, computational power, and energy resources. On the other hand, channel resources pertain to communication channels and networks, encompassing aspects such as channel bandwidth, load balancing, and traffic analysis [6].

Resource allocation refers to the task of efficiently assigning available resources to complete a set of tasks while

considering specific conditions and constraints [7]. The target is to optimize resource utilization and enhance the performance of the IoT platform. The resources in IoT devices are often limited due to factors such as energy constraints, processing power, and storage capacity [8]. However, IoT devices have the potential to provide various services and functionalities. Efficient resource allocation is crucial for optimizing the utilization of these limited resources and ensuring that tasks are completed effectively [9]. The heterogeneous and distributed characteristics of the devices and resources complicate IoT resource allocation. IoT devices come in different types with varying capabilities and characteristics. They may have different energy levels, processing capacities, and storage capacities. The resource allocation algorithm needs to consider these differences and allocate resources accordingly [10].

Integrating machine learning, deep learning, Artificial Intelligence (AI), and urban public transportation systems plays a pivotal role in efficiently allocating resources in the IoT. These technologies collectively form the backbone of intelligent resource management in urban environments. Machine learning algorithms enable IoT systems to adapt and optimize resource allocation strategies by analyzing vast amounts of data [11, 12]. Deep learning, a subset of machine learning, excels in pattern recognition and feature extraction, making it invaluable for understanding complex urban dynamics [13, 14]. AI systems bring decision-making capabilities to IoT devices, allowing them to dynamically adjust resource allocation based on real-time conditions and user preferences [15, 16]. Urban public transportation systems are a prime example of IoT in action, encompassing connected vehicles, smart traffic management, and passenger information systems. By leveraging the data generated within these transportation networks, machine learning models can predict traffic patterns, optimize routes, and enhance energy efficiency, leading to reduced congestion and environmental impact [17].

In recent years, researchers have turned to nature-inspired meta-heuristic algorithms to tackle optimization problems in various domains, including IoT resource allocation. These algorithms mimic natural phenomena and use techniques such as solution perturbations and stochasticity to avoid local optima and achieve optimal or near-optimal solutions. Meta-heuristic optimization algorithms have gained popularity due to their ability to handle various applications and optimization problems. These meta-heuristic algorithms can be applied to IoT resource allocation problems to meet various objectives,

such as energy efficiency, bandwidth utilization, and task allocation. Previous research efforts have explored different optimization techniques for resource allocation in IoT systems. Genetic, ACO, and Particle Swarm Optimization (PSO) algorithms are some of the methods applied to address this challenge. However, these approaches often suffer from slow convergence or suboptimal solutions, particularly when dealing with complex, combinatorial optimization problems that arise in IoT resource allocation scenarios. Therefore, it is necessary to develop more efficient and effective algorithms to cope with the complexity and variability of IoT environments.

This paper proposes a novel QoS-aware resource allocation method for IoT systems that utilizes a hybrid approach that incorporates both the Ant Colony Optimization (ACO) and the Tabu Search (TS) algorithms. The ACO algorithm is derived from the foraging behavior of ants and effectively solves combinatorial optimization problems. It employs a population of artificial ants to construct solutions by probabilistically selecting resources based on pheromone trails and heuristics. On the other hand, the TS algorithm is a local search-based metaheuristic that intensifies the search process by maintaining a tabu list, preventing revisiting previously visited solutions and encouraging the exploration of new solutions. By combining these two powerful optimization approaches, we aim to overcome the limitations of conventional resource allocation methods and provide a more efficient and effective solution regarding QoS-aware resource allocation in IoT systems.

In this context, our motivation for this research lies in the critical need for efficient resource allocation in IoT systems. Managing limited resources becomes paramount as IoT applications continue to increase across diverse domains such as education, healthcare, agriculture, military, and industry. IoT systems rely on a multitude of resources, including but not limited to storage, computational power, and energy. These resources are heterogeneous and often constrained, posing significant challenges to resource allocation. Our proposed approach addresses these challenges by prioritizing Quality of Service (QoS) in resource allocation. The potential benefits of our research are multifaceted. By effectively managing resources, our method aims to minimize energy consumption, reduce communication delays, and enhance overall system performance. This not only leads to improved operational efficiency but also contributes to sustainability efforts by reducing energy usage. Furthermore, our approach holds the promise of enabling more reliable and responsive IoT applications. As IoT plays an increasingly integral role in critical domains such as healthcare and industrial automation, optimizing resource allocation can directly impact service quality and reliability. Our research makes several significant contributions to the field of IoT resource allocation:

- Novel hybrid approach: We propose a novel resource allocation method that combines the power of ACO and TS algorithms. This hybrid approach harnesses the strengths of both algorithms to address the limitations of conventional resource allocation methods.
- QoS prioritization: Our method places a strong emphasis on QoS, aiming to improve energy efficiency,

reduce communication delays, and enhance overall system performance. This contributes to a more reliable and responsive IoT ecosystem.

- Efficiency and effectiveness: Through extensive testing and experimentation, we demonstrate the efficiency and effectiveness of our approach. Our results indicate significant improvements in QoS metrics when compared to traditional resource allocation methods.

The rest of the paper is organized in the following manner. Section II presents an introduction to IoT and resource allocation and describes existing resource allocation methods. Section III discussed the proposed method. Simulation results are reported in Section IV. Section V summarizes the main contributions of the study.

## II. BACKGROUND

### A. IoT Resource Allocation

Resource allocation is of utmost importance in the IoT ecosystem, where a multitude of interconnected devices collaborate to provide diverse services and applications. In the IoT, resources such as network bandwidth, computational power, storage capacity, and energy are scarce and must be allocated efficiently among numerous devices and applications [18]. Effective resource allocation in the IoT involves determining the optimal assignment of resources to meet the diverse requirements of IoT applications while considering factors such as QoS, energy efficiency, and network stability. A major challenge of IoT resource allocation stems from the dynamic and heterogeneous nature of IoT environments. IoT devices possess varying capabilities, communication protocols, and QoS requirements, further complicating the allocation process.

Additionally, IoT networks encounter fluctuations in resource availability due to device mobility, changing network conditions, and varying demands from different applications. Resource allocation algorithms in the IoT must be adaptive, scalable, and capable of handling network dynamics. Furthermore, considering resource limitations in IoT deployments, efficient allocation strategies are essential to prevent bottlenecks, ensure optimal resource utilization, and enhance the overall performance of IoT systems [19].

To address the resource allocation challenges in the IoT, a range of approaches have been proposed, each tailored to specific IoT scenarios and requirements. These approaches span from centralized algorithms to distributed mechanisms. Centralized resource allocation methods involve a central entity or server that receives requests from IoT devices and allocates resources based on predefined criteria or optimization objectives [20]. These algorithms centralize the decision-making process and effectively manage resource allocation in certain IoT environments. Distributed resource allocation algorithms aim to distribute the decision-making process among IoT devices themselves, enabling them to collaborate and negotiate for resources autonomously [21]. These algorithms promote self-organization and adaptability in resource allocation, making them suitable for dynamic and decentralized IoT systems. Optimization techniques such as genetic algorithms, swarm intelligence, and game theory have

been applied to solve the resource allocation problem in the IoT [22]. These techniques consider QoS, energy efficiency, load balancing, and fairness while allocating resources to IoT devices. They provide efficient and optimized resource allocation solutions based on mathematical models and optimization objectives. Machine learning and artificial intelligence-based approaches are gaining prominence in IoT resource allocation. These approaches leverage historical data and real-time analytics to make intelligent resource allocation decisions. By learning from past experiences and adapting to changing IoT conditions, machine learning-based algorithms can optimize resource allocation to meet dynamic IoT requirements. Edge computing offers a promising model for resource allocation in the IoT. By deploying computation and storage capabilities closer to IoT devices at the network edge, edge computing reduces latency, optimizes bandwidth usage, and enables localized resource allocation decisions. This decentralized approach minimizes the reliance on cloud resources and enhances the overall efficiency and responsiveness of IoT systems [23].

### B. Related Work

Wang, et al. [24] focused on addressing the distributed resource allocation problem in energy-efficient data forwarding for resource-constrained Industrial IoT (IIoT) systems [9]. They approached this problem by formulating it as a Decentralized, Partially Observable Markov Decision Process (Dec-POMDP), taking into account the decentralized and partially observable nature of the system. To tackle this challenge, they proposed an innovative algorithm named Dual-Attention assisted Deep Reinforcement Learning (DADR) for energy-efficient resource allocation. The DADR algorithm leverages a dual-attention assisted deep reinforcement learning (DRL) model within the Convolutional Attention Module, Dual-Attention, and Experience Reconstruction (CTDE) framework. The actor-network of the DADR algorithm incorporates a multi-scale convolutional attention module (CAM) to extract feature information from local states across various dimensions. Introducing a novel critic network, which employs a dual-attention module and an experience reconstruction module, enables comprehensive and precise evaluation of the system state from a global perspective. This critic network effectively addresses non-stationary and partially observable issues in multi-agent systems while maintaining scalability in dynamic environments without requiring modifications to the model structure. By combining CAM and Multi-Head Self-Attention (MHSA), the DADR algorithm enhances the representation learning capability of the DRL model.

Consequently, it provides improved optimization directions for energy efficiency and data transmission reliability. To assess the performance of the DADR algorithm, the researchers conducted simulations. The results of these simulations demonstrate the superiority of DADR over existing resource allocation algorithms and Multi-Agent Reinforcement Learning (MAREL) models in terms of network stability, transmission reliability, and network lifetime.

Kim and Ko [25] introduced a service resource allocation approach that aims to minimize data transmissions among users' mobile devices while effectively addressing the

constraints associated with such environments. To address the resource allocation problem, they transform it into a variant of the degree-constrained minimum spanning tree problem. Subsequently, they apply a genetic algorithm to efficiently generate near-optimal solutions within a shorter timeframe. The authors devise a fitness function and an encoding scheme specifically tailored to optimize the application of the genetic algorithm. Through the utilization of these components, the proposed approach demonstrates a remarkably high success rate, achieving near-optimal solutions in an average of 97% of cases. Moreover, it surpasses the brute force approach by significantly reducing the time required for solution generation.

In the study conducted by Tsai [26], the challenges associated with resource allocation in IoT systems are addressed. These systems are characterized by diverse user requirements, different types of appliances, limited network bandwidth, and computation power, all of which pose limitations to the performance of IoT systems and necessitate effective resource allocation solutions. To tackle this problem, the author proposes an algorithm that combines the concepts of data clustering and metaheuristics. The algorithm focuses on allocating the large-scale devices and gateways within the IoT system in a manner that minimizes the total communication cost between them. By optimizing the resource allocation, the algorithm aims to enhance the overall performance of the IoT system. The proposed algorithm is evaluated through simulations, and the results demonstrate its superiority over other resource allocation algorithms considered in the study. Specifically, the algorithm outperforms alternative approaches in terms of reducing the total data communication costs, highlighting its effectiveness in optimizing resource allocation for IoT systems.

Deng, et al. [27] address the challenge of trustworthiness management in edge computing (EC) systems, which play a crucial role in handling the increasing number of IoT devices connected to the edge of the network. They focus on ensuring compliance with service-level agreements (SLAs), which serve as an important indicator of trustworthiness for IoT services. To tackle this challenge, the authors propose a solution that involves modeling the state of the service provisioning system and the resource allocation scheme as a Markov decision process (MDP). They encode the trustworthiness gain, measured by the degree of SLA compliance, and use it as the objective for resource allocation adjustments. To obtain an optimal resource allocation policy, the authors employ reinforcement learning (RL) techniques. They train a policy using RL methods, which enables the dynamic generation of resource allocation schemes based on the system's current state. The trained policy is designed to maximize the trustworthiness gain of the services by allocating resources appropriately. The proposed approach is evaluated through experiments conducted on the YouTube request dataset. The results demonstrate that the edge service provisioning system utilizing the proposed approach outperforms baseline approaches by at least 21.72% in terms of performance.

Nematollahi, et al. [28] have proposed a novel architecture for offloading jobs and allocating resources for the IoT by incorporating Fog Computing (FC). They aim to address the limitations of low processing power and the need for efficient

data processing and management in IoT applications. The architecture consists of three main components: sensors, controllers, and FC servers. The authors introduce the concept of the subtask pool approach in the second layer, which enables the offloading of work from IoT devices to FC servers. To optimize resource allocation, they combine the Moth-Flame Optimization (MFO) algorithm with Opposition-based Learning (OBL), forming the OBLMFO algorithm. In the second layer, a stack cache approach is implemented to ensure resource allocation is balanced and prevent system load imbalance. The authors also leverage blockchain technology to guarantee the accuracy of transaction data, enhancing the reliability and transparency of resource distribution in the IoT system. To evaluate the performance of the OBLMFO model, the authors conducted experiments using the Python environment with a diverse set of jobs. The results demonstrate that the OBLMFO model achieved a 12.1% reduction in the delay factor and a 6.2% reduction in energy consumption compared to existing approaches.

Nguyen, et al. [29] propose a generalized federated learning (FL) algorithm to address the challenges encountered in FL, including non-independent and identically distributed data and heterogeneity of user equipment (UE). The objective of their approach is to reduce the global communication burden and enhance the convergence rate of FL. The proposed FL algorithm builds upon the current state-of-the-art federated averaging (FedAvg) by introducing a weight-based proximal term to the local loss function. This modification enables the

algorithm to perform stochastic gradient descent in parallel on a sampled subset of UEs during each global round, effectively reducing the communication overhead. The researchers provide a convergence upper bound that illustrates the tradeoff between the convergence rate and the number of global rounds. The analysis shows that convergence can still be ensured even with a small number of active UEs per round.

Liu [30] proposed a resource allocation algorithm for mobile edge computing. The algorithm aims to optimize base station performance over the long term by considering various factors, such as cable channel congestion, energy consumption, latency, communication cost, and task arrival characteristics. An energy consumption deficit queue based on Lyapunov drift penalties is introduced. This queue couples the energy consumption and time of small base stations, ensuring that energy consumption constraints are met during optimization. To calculate the offloading weight for task allocation, the authors employ game theory and propose an offloading weight formula derived from the Shapley value. The offloading weight is computed impartially, factoring in the return of various tasks. Simulations on the MATLAB platform were used to evaluate the proposed algorithm's performance. The algorithm can attain Nash equilibrium within a finite number of iterations, according to the results. Furthermore, the algorithm outperforms other comparison strategies in terms of the number of successfully offloaded tasks, time delay, and energy consumption.

TABLE I. IOT RESOURCE ALLOCATION METHODS

Method	Approach	Key features	Performance
DADR	Deep reinforcement learning model based on partially observable Markov decision processes	Centralized training and distributed execution framework Actor-network with a multi-scale convolutional attention module. Novel critic network based on dual-attention module	Outperforms existing resource allocation algorithms and multi-agent reinforcement learning models
Genetic Algorithm	Transformation of the resource allocation problem into a variant of the degree-constrained minimum spanning tree problem	Fitness function and encoding scheme for optimization	Achieves near-optimal solutions in 97% of cases on average and outperforms brute force approach
Data clustering and metaheuristics	Algorithm leveraging data clustering and metaheuristics	Minimization of total communication cost. Optimization of IoT system performance	Outperforms other resource allocation algorithms and reduces total data communication costs
Markov decision process with reinforcement learning	Modeling of state of service provisioning system and resource allocation as MDP	Trustworthiness gain as objective. Dynamic generation of resource allocation schemes	Outperforms baseline approaches by at least 21.72%
Fog Computing with moth-flame optimization and opposition-based learning	Architecture incorporating fog computing for resource allocation optimization	Subtask pool approach. Stack cache approach. Blockchain technology for accuracy of transaction data	Achieves reduction in delay factor and energy consumption
Generalized federated learning	Weight-based proximal term in local loss function and parallel stochastic gradient descent on a sampled subset of user equipment	Convergence rate improvement. Reduction of global communication burden	Requires less training time and energy consumption compared to full user participation
Task offloading and resource allocation algorithm	Optimization of long-term performance of small base stations and consideration of various factors	Energy consumption deficit queue. Offloading weight model based on Shapley value	Achieves Nash equilibrium and outperforms other comparison strategies

Table I presents a summary of IoT resource allocation methods along with their key features and performance characteristics. The reviewed methods often exhibit limitations that make them less suitable for the resource allocation problem. Some optimization techniques, such as genetic algorithm, can suffer from slow convergence, especially in large-scale IoT systems. This can hinder real-time decision-making, which is essential in many IoT applications. PSO and

traditional heuristic methods may produce suboptimal solutions when dealing with the complex, combinatorial nature of IoT resource allocation problems. Many existing methods do not inherently prioritize QoS metrics. They may not effectively address the specific QoS requirements of diverse IoT applications. We chose the proposed hybrid method, which combines ACO and TS algorithms, for several compelling reasons:

- **Combinatorial optimization:** IoT resource allocation is inherently a combinatorial optimization problem, as it involves allocating limited resources to tasks with varying requirements. ACO excels in solving such problems by mimicking the foraging behavior of ants and constructing solutions through probabilistic resource selection. This aligns with the nature of the resource allocation problem in IoT systems.
- **Local search enhancement:** While ACO provides global exploration, TS offers local search capabilities by maintaining a Tabu list. TS intensifies the search process by preventing revisits to previously explored solutions, which is crucial for avoiding suboptimal solutions in IoT resource allocation.
- **QoS focus:** Our primary objective is to prioritize QoS in IoT resource allocation. Existing methods may lack the necessary mechanisms to give due consideration to QoS metrics, such as energy efficiency and reduced communication delays. Our hybrid approach allows us to explicitly address these QoS concerns.

### III. PROPOSED METHOD

This section introduces a novel resource allocation algorithm called ACO-TS, which combines the ACO and TS algorithms. ACO-TS offers improved efficiency in terms of cost and execution time compared to existing approaches. We delve into the details of ACO-TS in the following subsections: Firstly, we define the problem and outline the objective function. Next, we provide a comprehensive explanation of the

proposed method, highlighting its key features and mechanisms.

#### A. Problem Definition

The distributed nature of resources and the need for efficient access make resource allocation in IoT challenging. The integration of multiple applications and the heterogeneity of connectivity further complicate resource allocation. Efficiency in an IoT system is measured by factors such as allocation interval, response time, and processing time, which are important QoS constraints. This study focuses on the resource allocation problem involving resource nodes and gateways. Resources are allocated to service instances, and gateways are responsible for connecting to these resources. Gateways serve as the interconnection points for IoT systems, managing the traffic of multiple resources. Effective resource allocation requires optimizing the distribution of resources among gateways to minimize communication costs. Additionally, the connectivity between gateways is crucial, and minimizing communication costs is a key objective. Various connection models, such as ring or bus connections, can be considered to achieve this goal. Fig. 1 illustrates an example of a resource-gateway connection. Communication costs depend on the chosen communication model. The objective of the problem is to determine the resource allocation pattern that minimizes communication costs. Another important aspect is load balancing, which involves distributing resources among gateways to prevent bottlenecks. The objective function section describes how load balancing and communication costs are calculated in the problem.

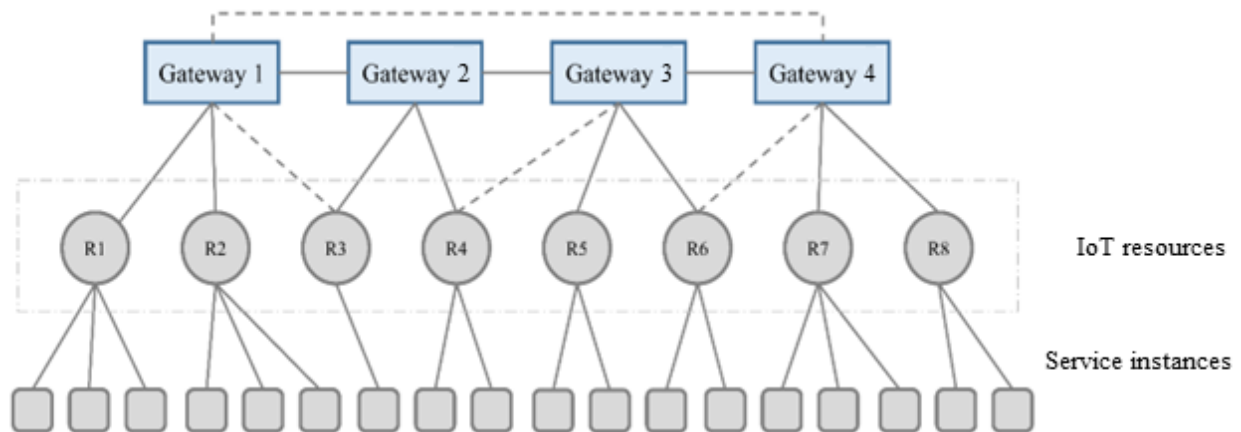

Fig. 1. An example of a resource-gateway connection.

#### B. Objective Function

In the considered network model, it is assumed that all resource nodes have the ability to communicate with each other. Therefore, to evaluate the different solutions to the resource allocation problem, it is necessary to calculate the total cost of network communications. It is assumed that all resources send messages to each other, and the objective function aims to minimize the total cost of these messages. The total cost is calculated using Eq. 1, which represents the mathematical expression for determining the cost. The proposed algorithm focuses on minimizing this objective function as its main goal.

$$T_c = \frac{\sum_{j=1}^{|V_g|} (d_j^r \times d^g)}{p} \quad (1)$$

In Eq. (1), the variable  $d^g$  represents the overall communication cost among gateways,  $d_j^r$  represents the total data transfer cost between the  $j^{th}$  gateway and all resources connected, and  $V_g$  represents the total number of gateways in the network. It is important to note that communication within a gateway can also result in messages being exchanged between gateways. The exponential nature of the communication cost within a gateway greatly affects the total communication cost. Thus, the equation  $(d_j^r \times d^g)$  is the most

appropriate way to calculate the maximum communication costs. The objective is to minimize the value of the objective function. Since gateways have the ability to send messages to all resources, we need to multiply  $d_j^r$  by  $d^e$ . By summing up these values for all gateways, we can obtain an estimation of the total communication costs for the gateways. The numerator part of the  $T_c$  fraction in the objective function can be calculated by performing this calculation for each gateway.

### C. Proposed Hybrid Algorithm

The proposed hybrid method combines the ACO algorithm and the TS technique to tackle the IoT resource allocation problem, considering QoS requirements. This combination leverages the strengths of both algorithms to achieve efficient and effective resource allocation. The ACO algorithm, which mimics the foraging behavior of ants, simulates the behavior of ants in search of food [31]. The algorithm constructs solutions by probabilistically selecting resources based on pheromone trails and heuristics. The pheromone trail represents the quality of each resource allocation solution, and ants deposit and update pheromone values as they move through the solution space. This behavior encourages the exploration of promising solutions and exploits the accumulated knowledge of previous solutions. By utilizing the ACO algorithm, the proposed method can efficiently explore the large solution space and identify potential resource allocation configurations that satisfy the QoS requirements. To further enhance the search process and overcome local optima, the TS technique is integrated into the proposed method. TS is a local search-based metaheuristic that intensifies the search by maintaining a tabu list [32]. The tabu list keeps track of recently visited solutions, preventing them from being revisited in subsequent iterations. This mechanism encourages diversification and exploration of new regions in the solution space, allowing the algorithm to escape local optima and search for better resource allocation solutions. Neighborhood search and diversification strategies are also applied within the TS framework to further improve the search process.

The proposed hybrid method balances exploration and exploitation by fusing the ACO algorithm and TS technique. The ACO algorithm explores the solution space using pheromone trails and heuristics, while the TS technique intensifies the search process by leveraging the tabu list and neighborhood search strategies. This combination enables the algorithm to efficiently converge towards optimal or near-optimal solutions that satisfy the QoS requirements of IoT applications. The ACO algorithm updates the pheromone trails based on the quality of each resource allocation solution. The pheromone update formula is given by:

$$\tau_{ij} = (1 - \rho)\tau_{ij}^{old} + \sum_{k=1}^m \Delta\tau_{ij}^k \quad (2)$$

where  $\tau_{ij}$  represents the pheromone level on edge  $(i, j)$  in the resource allocation graph,  $\rho$  is the evaporation rate that controls the decay of pheromone over time, and  $\Delta\tau_{ij}^k$  represents the pheromone increment for ant  $k$  on edge  $(i, j)$  in the solution construction phase. The ACO algorithm constructs solutions by probabilistically selecting resources based on the pheromone trails and heuristics. The probability of selecting resource  $j$  for ant  $k$  at node  $i$  is calculated using the following equation:

$$P_{ij}^k(t) = \begin{cases} \frac{[\tau_{ij}(t)]^\alpha [\eta_{ij}]^\beta}{\sum_{l \in N_k} [\tau_{il}(t)]^\alpha [\eta_{il}]^\beta} & \text{if } j \in N_k \\ 0 & \text{otherwise} \end{cases} \quad (3)$$

Where  $\alpha$  and  $\beta$  control the relative importance of pheromone trails and heuristics,  $\eta_{ij}$  represents the heuristic information, which captures the desirability of allocating resource  $j$  at node  $i$  based on factors such as energy consumption, network capacity, and QoS requirements. The TS algorithm maintains a tabu list to prevent revisiting previously visited solutions. The tabu list is updated using the following equation:

$$TL = TL_U(i, j) \quad (4)$$

Where  $TL$  represents the tabu list,  $(i, j)$  represents the resource allocation move (e.g., allocating resource  $j$  at node  $i$ ) that is added to the tabu list. The pseudocode for the proposed hybrid method is shown in Algorithm 1. The proposed algorithm begins by initializing the necessary variables and data structures, including the resource allocation graph, QoS requirements, and algorithm parameters. It then enters a loop that repeats for a specified number of iterations. Within each iteration, a set of ants is created to construct resource allocation solutions. Each ant starts at a random node and selects resources probabilistically according to the pheromone trails and heuristics. The constructed solutions are evaluated against the QoS requirements, and pheromone trails are adjusted accordingly. After the ACO phase, the algorithm proceeds to the TS initialization. In this case, the best solution is set as the current solution, and the tabu list is initialized as empty. The TS loop begins, continuing until a stopping criterion is met. In each iteration of the TS loop, neighboring solutions are generated by making resource allocation moves from the current solution, taking into account the tabu list restrictions. The best non-tabu solution is selected, and if it improves upon the current best solution, it becomes the new best solution. The corresponding resource allocation move is added to the tabu list, and the selected solution becomes the current solution for the next iteration. The algorithm repeats this process for the specified number of iterations, continuously improving the resource allocation solutions. Finally, the best resource allocation solution found is output as the final result.

#### Algorithm 1. Pseudocode of the proposed algorithm

<p><b>Initialize:</b></p> <ul style="list-style-type: none"> <li>- Initialize pheromone levels <math>\tau_{ij}</math> for all edges <math>(i, j)</math> in the resource allocation graph</li> <li>- Initialize an empty tabu list <math>TL</math></li> </ul> <p><b>Repeat</b> for a specified number of iterations:</p> <ul style="list-style-type: none"> <li>Create a set of ants:</li> <li>- For each ant <math>k</math>: <ul style="list-style-type: none"> <li>- Start at a random node <math>i</math></li> <li>- Initialize an empty resource allocation solution <math>S_k</math></li> </ul> </li> </ul> <p><b>Construct solutions:</b></p> <ul style="list-style-type: none"> <li>- For each ant <math>k</math>: <ul style="list-style-type: none"> <li>- While not all nodes are visited: <ul style="list-style-type: none"> <li>- Calculate the selection probability <math>P_{ij}^k</math> for unvisited neighboring nodes</li> <li>- Select a resource <math>j</math> based on the selection probability</li> <li>- Add resource <math>j</math> to the solution <math>S_k</math></li> <li>- Update the visited and unvisited node lists</li> </ul> </li> </ul> </li> </ul>
--

**Update pheromone trails:**

- For each ant  $k$ :
  - Calculate the solution quality metric  $Q_k$  based on QoS requirements
  - Update the pheromone trails:
    - For each edge  $(i, j)$  in the solution  $S_k$ :
      - Calculate the pheromone increment  $\Delta\tau_{ij}^k$
      - Update pheromone level  $\tau_{ij}$  using the pheromone update formula

**Evaporate pheromone trails:**

- For each edge  $(i, j)$  in the resource allocation graph:
  - Evaporate pheromone level  $\tau_{ij}$  using the evaporation rate  $\rho$

**Tabu Search:**

- Initialize the best solution  $S_{best}$  with the best solution found so far
- Set the current solution  $S_{curr}$  as  $S_{best}$
- Set the tabu list  $TL$  as empty
- Repeat until a stopping criterion is met:
  - Generate a set of neighboring solutions by making resource allocation moves on  $S_{curr}$ 
    - Select the best non-tabu solution  $S_{next}$  from the neighboring solutions
    - If  $S_{next}$  is better than  $S_{best}$ , update  $S_{best}$
    - Add the resource allocation move corresponding to  $S_{next}$  to the tabu list  $TL$
    - Set  $S_{curr}$  as  $S_{next}$

The overall time complexity of the combined ACO and TS algorithms can be expressed as a combination of the complexities of both algorithms. Assume the number of ants as  $N_a$ , the number of iterations as  $N_i$ , the size of the solution space as  $N_s$ , the number of resources available for allocation as  $M$ , the size of the neighborhood as  $N_n$ , and the diversification parameter as  $N_d$ . The time complexity of the ACO algorithm can be approximated as  $O(N_a * N_i * f(N_s))$ , where  $f(N_s)$  represents the complexity of constructing solutions. The ACO algorithm updates the pheromone trails based on the quality of each resource allocation solution, which has a complexity of  $O(M)$  since the pheromone values for each resource need to be updated. The time complexity of the TS algorithm primarily depends on the neighborhood search operation and the diversification strategies employed. Assuming the complexity of the neighborhood search operation is  $O(g(N_n))$  and the complexity of diversification strategies is  $O(h(N_d))$ , the overall time complexity of the TS algorithm can be approximated as  $O(N_i * (g(N_n) + h(N_d)))$ . Consequently, the time complexity of the combined ACO and TS algorithm can be represented as:

$$O(N_a \times (N_i \times O(f(N_s)) + M) + O(g(N_n)) + O(h(N_d))) \quad (5)$$

#### IV. RESULTS AND DISCUSSION

In this section, we present the simulation and evaluation of the suggested algorithm. The simulations were performed using MATLAB software on a desktop computer with a core i5 CPU and 4GB of RAM. The performance of the proposed resource allocation technique is assessed by comparing it with previous methods in two scenarios. The first scenario involves four experiments with varying numbers of gateway and source nodes. The details of these experiments are summarized in Table II. Each experiment is characterized by the number of gateway and resource nodes. These parameters allow for the evaluation and comparison of the proposed method under

different network configurations. The overall fitness of each mechanism is depicted in Fig. 2 to 5. From these figures, it can be observed that the proposed method consistently outperforms genetic, PSO, and ACO algorithms. Scalability is another important aspect considered in the proposed technique. Fig. 3 proves that as the network size increases, the convergence diagram of the proposed technique (blue line) diverges from the convergence diagrams of the ACO and genetic algorithms (red and black lines), indicating its scalability. The optimality of the convergence graph is determined by the communication costs in the network. The fitness function used in the evaluation takes into account execution time and energy consumption, which are crucial factors in determining the sub-function of fitness.

TABLE II. SIMULATION PARAMETER VALUES

Parameters	Experiment 1	Experiment 2	Experiment 3	Experiment 4
Number of gateway nodes	10	25	60	120
Number of resource nodes	30	100	500	800

We compare the proposed method with ACO and genetic algorithms in the second scenario. Similar to the first scenario, four experiments are conducted, following the setup described in Table II. Fig. 6 to 9 illustrate the performance of the algorithms in these experiments. From the figures, it can be observed that the genetic algorithm exhibits the highest execution time among the three algorithms. This prolonged decision-making process can lead to traffic congestion on the server, causing delays and inefficiencies. On the other hand, the ACO algorithm performs better than the genetic algorithm, as it takes less time to select the best resource. In comparison to existing benchmark algorithms, our proposed method demonstrates a faster decision-making process in selecting the best resource. This reduced time is beneficial in achieving efficient resource allocation and improving overall system performance.

Fig. 9. Execution time comparison (Fourth experiment)

In our evaluation of the proposed algorithms, we utilized multiple datasets that reflect diverse IoT scenarios and characteristics. These datasets differ in terms of size, complexity, and the specific application domains they represent. Such variations inherently contribute to differences in algorithm performance. For instance, in datasets characterized by large-scale IoT networks with numerous interconnected devices, the proposed hybrid algorithm may excel in optimizing resource allocation by leveraging ACO's global exploration capabilities. On the other hand, in smaller-scale networks or datasets representing resource-intensive IoT applications, the local search enhancements offered by the TS algorithm might yield more pronounced benefits. Moreover, the nuances of each dataset, including the nature of IoT devices, their energy constraints, and communication patterns, can significantly impact the suitability of the proposed algorithms. The variations observed in comparative results across these datasets suggest that our algorithms exhibit adaptability to different IoT contexts. These findings open avenues for future research in fine-tuning the proposed algorithms to specific IoT scenarios, as well as exploring adaptive resource allocation strategies that can dynamically adjust to the unique requirements of diverse IoT data types and application domains. In essence, the dataset variations shed light on the algorithmic flexibility of our approach, indicating its potential to cater to the evolving and multifaceted landscape of IoT resource allocation.

## V. CONCLUSION

This paper suggested a novel QoS-aware resource allocation method for IoT systems using a hybrid approach of the ACO and TS algorithms, called ACO-TS. It efficiently allocates limited resources in IoT systems in accordance with the QoS requirements of individual devices. Through the integration of the ACO algorithm and TS technique, we have demonstrated the effectiveness and efficiency of our approach in optimizing resource allocation decisions. The ACO algorithm leverages the behavior of ant colonies to explore the solution space, while the TS technique intensifies the search process to overcome local optima. By combining these two techniques, we achieve a balance between exploration and

exploitation, resulting in improved convergence speed and solution quality. Our experimental evaluations in realistic IoT scenarios have suggested the merits of the ACO-TS approach. In comparison with existing resource allocation methods, ACO-TS achieves significant improvements in energy consumption reduction, network capacity maximization, and satisfaction of QoS requirements.

# Artificial Rabbits Optimizer with Deep Learning Model for Blockchain-Assisted Secure Smart Healthcare System

Mousa Mohammed Khubrani

College of Computer Science and IT, Jazan University, Jazan, Saudi Arabia

**Abstract**—Smart healthcare is based on the electronic health and medical histories of residents, combined with information technology (IT) which can be used to construct a variety of systems including humanised health management systems and convenient medical service systems. The transparency, traceability, decentralization and security of BC technology and machine learning (ML) will enable the medical sector to upgrade and optimise different forms of quality and service. Therefore, this study introduces an artificial rabbit optimizer with deep learning for Blockchain Assisted Secure Smart Healthcare System (ARODL-BSSHS) technique. The presented ARODL-BSSHS technique designs a new healthcare monitoring technique by using blockchain (BC) technology and classifies the presence of malicious activities in the healthcare system, and takes needed actions to predict the disease. For intrusion detection, the ARODL-BSSHS technique exploits the ARO algorithm with Hop field neural network (IHNN) model. On the other hand, the ARODL-BSSHS technique applies a deep extreme learning machine (DELIM) model for disease detection purposes. Finally, the heap-based optimization (HBO) technique is exploited as a hyperparameter optimizer for the DELIM model. The ARODL-BSSHS technique involves BC technology for the secure transmission of healthcare data. A series of simulations were carried out on benchmark datasets: heart disease and NSL-KDD database for examining the performance of the ARODL-BSSHS technique. The experimental values highlighted that the ARODL-BSSHS method obtains superior performance than other approaches.

**Keywords**—Blockchain; smart healthcare; artificial rabbit's optimizer; deep learning; intrusion detection

## I. INTRODUCTION

The connection of clinically related technologies will have a major impact on healthcare professionals and patients [1]. Along with the diversified nature and fast growth of the health care atmosphere, protection becomes a major problem as advanced security problems develop and earlier security problems become more acute. Data protection can be defined as the capability to transmit and store data without enabling unauthorized access to make sure confidentiality, data consistency, legality, and legitimacy [2]. Only authorized users have access to the protected data. Due to their unauthorized access and unauthenticated users, cybercrime develops and often affects healthcare sensors and systems [3]. A considerable amount of healthcare data is distributed, collected and gathered among various health care sectors. The data transmission must take place in a protected manner. The

number of cyber-attacks is increasing drastically due to enormous data transformation. It denotes the demand for a reliable system for protecting health care datasets [4]. Potential mining methods are demanded to inspect clinical data to assist in enhancing patient care, disease discovery, and offering medical treatment [5]. ML can be a complex computational method that was employed in various fields like health care, image recognition, and language processing [6]. Still, ML methods obtain a higher level of accuracy with a large volume of the training set that can be vital in health care, where accuracy may, in some cases, denote the difference between losing and saving the life of the patient. In many cases, centralized training methods acquire a large quantity of data from robust cloud servers that result in major consumer privacy violations, particularly in the clinical domain [7]. As an accountable and open data protection system, the progression of the BC technology opens the way for novel ways to solve the main problems of ethics, privacy, and security in domains that require privacy, anonymity and security of records including health care system [8] [9]. But BC has attained remarkable achievement for different smart healthcare technologies like patient record access control, data distribution, etc. [10].

Today, BC and ML technology are preferred [11]. The security, traceability, transparency, and decentralization of these two technologies will assist the healthcare sector to upgrade and optimize in several aspects [12]. The implementation of and making the functioning of the health care sector more efficient [13]. Few studies have explored the implementation of ML and BC. For instance, a health management platform based on BC can allow users to track personal data securely, and smart contracts are utilized in clinical detection to automatically manage emergencies [14].

This research is driven by the urgent need to address the growing vulnerabilities in healthcare systems due to escalating cyber threats and the rapid advancements in healthcare technologies. This study introduces an Artificial Rabbit Optimizer with Deep Learning for Blockchain-Assisted Secure Smart Healthcare System (ARODL-BSSHS) technique. This novel technique focuses on creating a secure and intelligent healthcare system, specializing in intrusion detection and disease diagnosis. It strategically employs the Artificial Rabbit Optimizer (ARO) algorithm and the Hopfield Neural Network (HNN) model for intrusion detection, and a Deep Extreme Learning Machine (DELIM) model for accurate disease detection, with Blockchain technology incorporated to secure

data transmission. The efficacy and improved performance of the ARODL-BSSHS technique have been validated through extensive experiments on recognized datasets, showcasing its potential for real-world applications in enhancing healthcare security and efficiency.

## II. LITERATURE REVIEW

In [15], the authors introduced a smart BC Manager (BM) depends on the DRL for optimizing the BC behavior of the network in real-time while concerning clinical data needs, like security levels and urgency. Utilizing 3 RL-related methods like Dueling Double Deep Q-Network (D3QN), Double Deep Q-Networks (DDQN), and DQN, the optimization approach can be developed as a Markov Decision Process (MDP). Lakhan et al. [16] present a DRLBTS abbreviated as DRL-aware BC-related task scheduling structure with various goals. The presented method offers security and makespan potential scheduling for medicinal purposes. Singh et al. [17] modelled a DL-related IoT-based structure for the secured smart city where BC offers a dispersed atmosphere at the transmission stage of CPS, and SDN established the protocol for transporting data. A DL-related cloud was applied at the application layer of the presented structure to solve scalability, centralization, and communication latency.

Mantey et al. [18] presented a BC privacy system (BPS) as DL for diet recommendation mechanisms for patients. This study applied DL and ML approaches like MLP, RNN, LR etc., to the Internet of Medical Things (IoMT) data obtained. The product section contains a collection of eight attributes. The IoMT dataset features are examined with BPS and encoded in advance to the implementation of DL and ML-related structures. In [19], presented a BC-orchestrated DL method (BDSDT) for Secured Data transmission in IoT-based healthcare systems. First, a new scalable BC structure is devised to ensure secure data transmission and data integrity using Zero Knowledge Proof (ZKP) system. Afterwards, BDSDT integrated with the off-chain storage IPFS abbreviated as InterPlanetary File mechanism, to solve problems with data storing costs to solve data security problems. Sammeta and Parthiban [20] developed a new method HBESDM-DLD abbreviated as hyperledger BC-based secure clinical data management with DL-related diagnosis method. This method includes different stages of operations such as hyperledger BC-based secure data management, encryption, diagnosis and optimal key generation. For encryption, SIMON block cipher method can be implemented. For optimal key generation, a group teaching optimization algorithm (GTOA) was adopted.

In [21], the authors proposed a Decentralized Interoperable Trust framework (DIT) based on BC for the Internet of Things (IoT) platform. The DIT IoHT employs a private BC ripple chain to establish secure and reliable data transmission by authenticating nodes in relation to their interoperable structures. Purbey, Khandelwal, and Choudhary in [22] introduced a method for secure and efficient ontology generation using BC, named BOGMAS. This approach employs a semi-supervised technique to generate ontologies from structured or unstructured datasets. It combines techniques such as extra trees (ET) stratification and linear support vector machine (LSVM) for predicting variances.

Almaiah et al. [23] proposed a Deep Learning (DL) architecture integrated with BC to ensure dual levels of privacy and security. Firstly, they establish a BC model where participating entities undergo registration, validation, and verification through smart contracts using Proof of Work. Subsequently, they model BiLSTM for intrusion detection and apply a DL method incorporating a Variational Autoencoder (VAE) technique for privacy preservation.

The reviewed studies, despite their innovative contributions to blockchain and deep learning in healthcare, exhibit several overarching limitations. Many face issues related to scalability, adaptability, and specificity, which can restrict their applicability across diverse healthcare environments and requirements. Several solutions also struggle with the balance between complexity and user-friendly implementation, posing challenges in deployment and interpretation. Additionally, the methods proposed often focus narrowly on specific aspects of healthcare or technology, neglecting a holistic approach that addresses the multifaceted nature of healthcare systems, thus necessitating further holistic and integrative research endeavors.

## III. PROPOSED MODEL

In this study, the ARODL-BSSHS technique has been developed to accomplish security in the healthcare system. The presented ARODL-BSSHS technique involves the design of secured and smart healthcare system using two major processes, namely intrusion detection and disease diagnosis. To accomplish this, the ARODL-BSSHS technique follows a series of processes: HNN based intrusion detection, ARO based parameter tuning, DELM-based disease detection, and HBO based parameter optimization. Fig. 1 illustrates the workflow of ARODL-BSSHS algorithm.

### A. BC Technology

In this work, the ARODL-BSSHS technique involves BC technology for secure transmission of healthcare data. Electronic Health Records (EHR) are well functioning on smart contracts [24]. It developed the framework for a decentralized medical service stage and aids as an interface to the patient records that can be shared by suppliers and patients. BC is separated into research-centric and patient-centric BC network classes, as stated by "BC Technology in Healthcare". The security concern regarding EHR is tackled by the patient-centric BC network, which gives the authority over sharing medicinal data with multiple users. BC technology can be able to modernize healthcare management by permitting unambiguous and transparent data access through every stakeholder involved, comprising hospitals, therapists, medical experts, and general practitioners [25]. In such cases, several medicinal stakeholders do not necessarily use resource- and time-consuming information and verification progressions.

Furthermore, this approach could contribute to the early detection of health-related issues, thereby reducing instances of medical malpractice arising from coordination issues [26]. It instills trust in individuals regarding their comprehensive care, as the integrity of healthcare records from previous visits to different medical practitioners remains intact within the network. Additionally, BC serves as a valuable tool for

constructing patient-centric networks through various means, such as augmenting data availability, thereby enhancing data liquidity, establishing unique patient identifiers, and implementing digital access control. The Hyperledger Fabric system can be leveraged to establish a permissioned BC network. Within this system, two distinct types of peers exist: validating peers, responsible for ledger management, consensus procedures, and transaction validation. The data is stored within a distributed system, facilitating the upload of patient medical histories, verification of healthcare records, and the facilitation of data access requests and permissions.

Fig. 1. Workflow of ARODL-BSSHS approach.

### B. Intrusion Detection using Optimal HNN Model

For intrusion detection process, the HNN classifier is used. The HNN exhibits abundant dynamical behavior owing to its hyperbolic tangent function and special network structure [27]. The HNN with  $n$  neurons is defined by the series of dimensionless non-linear ordinary differential equations as in the following:

$$\dot{x} = -x + Y \tanh(x) + I \quad (1)$$

Where

$$x = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_i \\ \vdots \\ x_n \end{bmatrix}, I = \begin{bmatrix} I_1 \\ I_2 \\ \vdots \\ I_i \\ \vdots \\ I_n \end{bmatrix}$$

$$Y = \begin{bmatrix} y_{11} & y_{12} & \dots & y_{1j} & \dots & y_{1n} \\ y_{21} & y_{22} & \dots & y_{2j} & \dots & y_{2n} \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ y_{i1} & y_{i2} & \dots & y_{ij} & \dots & y_{in} \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ y_{n1} & y_{n2} & \dots & y_{nj} & \dots & y_{nn} \end{bmatrix} \quad (2)$$

In Eq. (2),  $\tanh(x)$  shows the neuron activation function,  $x_i$  embodies the  $i$ -th neuron membrane voltage,  $Y$  characterizes the synaptic weight matrix, and  $y_{ij}$  denotes the synaptic weight between  $j$ -th and  $i$ -th neurons. Moreover,  $I_i$  characterizes  $i$ -th neuron external stimulate current. In recent times, improved model has been created on the basis of original HNN models, namely HNN with time delay, fractional HNN, discrete HNN, HNN with dissimilar active functions, etc.

The ARO algorithm can be applied to improve the detection rate of the HNN model. The ARO can be stimulated by the survival skills of the rabbit [28]. Rabbits are herbivores which mainly consume leafy weeds and grass. Rabbits wouldn't eat the grass nearby the holes; rather, they find food far away from their nests to avoid predators identifying the nest. These foraging strategies are determined as exploration. Furthermore, to lessen the possibility of being captured by hunters or predators, they are skilled at digging a lot of holes for the nest and randomly choose one as a shelter. This random hiding approach can be assumed as exploitation in ARO. Rabbits must run faster to avoid dangers from the predator owing to their low level in the food chain, resulting in a decline in their energy, so they should shift between random hiding and detour foraging based on their energy status. The mathematical model of ARO is constructed with previous knowledge about the natural behaviors of rabbits, such as exploitation, exploration, and transition from exploration to exploitation.

Consider that every individual in the population has an individual area with burrows and few grass. In foraging activity, the rabbit has a tendency to move towards the faraway area of other rabbits in finding food and overlook what lies nearby, same as an old Chinese proverb says: "A rabbit doesn't eat grass close to their nests". These behaviors are named detour foraging, and they can be mathematically formulated as:

$$X_i(t+1) = X_j(t) + A \times (X_i(t) - X_j(t)) + \text{round}(0.5 \times (0.05 + R_1)) \times n_1, \quad (3)$$

$$i, j = 1, \dots, N \text{ and } i \neq j$$

$$A = L \times c \quad (4)$$

$$L = \left( e - e^{\frac{t-1}{T}} \right) \times \sin(2\pi R_2) \quad (5)$$

$$c(k) = \begin{cases} 1, & \text{if } k == g(l) \\ 0, & \text{otherwise} \end{cases} \quad k = 1, \dots, D \text{ and } l = 1, \dots, [R_3 \times D] \quad (6)$$

$$g = \text{randperm}(D) \quad (7)$$

$$n_1 \sim N(0,1) \quad (8)$$

Where  $X_i(t)$  and  $X_j(t)$  signify the location of  $i$ -th and  $j$ -th rabbits at the  $t$  existing iteration,  $X_i(t + 1)$  indicates the candidate location of  $i$ -th rabbit at  $t + 1$  the next iteration correspondingly.  $T$  denotes the higher iteration counts.  $N$  shows the size of population.  $t$  represents the existing iteration.  $\lceil \cdot \rceil$  refers to the ceiling function.  $D$  symbolizes the dimensional of specific problem.  $randperm(\cdot)$  shows the arbitrary value within 1 and  $D$ .  $R_1$ ,  $R_2$ , and  $R_3$  indicates the random integer within  $[0,1]$ .  $round(\cdot)$  indicates rounding to the nearby integer.  $L$  stands for the length of movement stage while implementing the detour foraging.  $n_1$  follows the uniform distribution.

Here, rabbits tend to conduct continuous detour foraging at the beginning of iteration; then, they often implement random hiding. The idea of rabbit energy  $E$  was introduced to retain a better balance between exploitation and exploration that is gradually reduced over time:

$$E(t) = 4 \left(1 - \frac{t}{T}\right) \ln \frac{1}{R_4} \quad (9)$$

In Eq. (9),  $R_4$  indicates the random integer having range of  $[0, 1]$ . The value of  $E$  energy co-efficient differs from zero to two. If  $E \leq 1$ , it shows that rabbit has lesser energy for physical activities. Hence it is necessary to carry out random hiding to escape from the predators, and the ARO method enters the exploitation stage. If  $E > 1$ , it shows that rabbit has sufficient energy to discover the foraging region of other individuals such that the detour foraging takes place, and this stage can be determined by the exploration. Rabbits are generally met with attack and chase from the hunters. To survive, they should dig several holes nearby their nests for shelter.

In Eq. (9), the variable  $R_4$  represents a randomly generated integer within the range  $[0, 1]$ . The energy coefficient  $E$  assumes values from zero to two. When  $E \leq 1$ , it indicates that the rabbit possesses limited energy for engaging in physical activities. As a result, the rabbit adopts a strategy of random hiding to evade predators, marking the onset of the exploitation stage in the ARO method. Conversely, when  $E > 1$ , the rabbit possesses sufficient energy to explore the foraging regions of other individuals. This condition triggers detour foraging and signifies the exploration stage. In their natural environment, rabbits often encounter threats from predators, leading to pursuits and attacks. To ensure survival, they create several burrows in close proximity to their nests, offering shelter from potential threats.

$$X_i(t + 1) = X_i(t) + A \times (R_5 \times b_{i,r}(t) - X_i(t)) \quad (10)$$

$$b_{i,r}(t) = X_i(t) + H \times g_r(k) \times X_i(t) \quad (11)$$

$$g_r(k) = \begin{cases} 1, & \text{if } k == \lceil R_6 \times D \rceil \\ 0, & \text{otherwise} \end{cases} \quad (12)$$

$$H = \frac{T-t+1}{T} \times n_2 \quad (13)$$

$$n_2 \sim N(0,1) \quad (14)$$

Where the parameter  $A$  is evaluated by Eqs. (4)-(7),  $R_5$  and  $R_6$  shows two random integers within  $[0,1]$ ,  $b_{i,r}(t)$  signify the arbitrarily chosen burrow of  $i$ -th rabbits in  $D$  burrows applied

to hide at  $t$  existing iteration, and  $n_2$  follows the uniform distribution.

Fitness selection is a crucial component of the ARO technique. Encoded outcomes are utilized to assess the quality of solution candidates. In this context, the accuracy value serves as the primary criterion for designing a fitness function (FF).

$$Fitness = \max(P) \quad (15)$$

$$P = \frac{TP}{TP+FP} \quad (16)$$

Where  $TP$  denote the true positive and  $FP$  specifies the false positive value.

### C. Disease Detection using DELM Model

At this stage, the DELM model is used to detect the presence of the disease. ELM is the first presented by Huang et al. that is utilized for SLFNs [29]. An input weighted and hidden layer (HL) biases can be arbitrarily allocated at first, so the trained databases for determining the resultant weighted of SLFNs are integrated. For  $N$  random various instances  $(x_i, t_i)$ ,  $i = 1, 2, \dots, N$ , whereas  $x_i = [x_{i1}, x_{i2}, \dots, x_{in}]^T$ ,  $t_i = [t_{i1}, t_{i2}, \dots, t_{im}]^T$ . Thus, the ELM technique is expressed as:

$$\sum_{j=1}^L \beta_j g_j(x_i) = \sum_{j=1}^L \beta_j g(w_j \cdot x_i + b_j) = 0_i (i = 1, 2, \dots, N), \quad (17)$$

Whereas  $\beta_j = [\beta_{j1}, \beta_{j2}, \dots, \beta_{jm}]^T$  states the  $j^{th}$  hidden node weighted vector, but the weighted vector among the  $j^{th}$  hidden node and the resultant layer is defined as  $w_j = [w_{1j}, w_{2j}, \dots, w_{nj}]^T$ . The threshold of  $j^{th}$  hidden node is expressed as  $b_j$ , and  $0_i = [0_{i1}, 0_{i2}, \dots, 0_{im}]^T$  refers to the  $i^{th}$  resultant vector of ELM.

It is estimated the resultant of DELM when the activation function  $g(x)$  with 0 error that implies as Eq. (18):

$$\sum_{i=1}^N ||0_i - t_i|| = 0. \quad (18)$$

Thus, Eq. (17) is termed as Eq. (19):

$$\sum_{j=1}^L \beta_j g_j(x_i) = \sum_{j=1}^L \beta_j g(w_j \cdot x_i + b_j) = t_i (i = 1, 2, \dots, N). \quad (19)$$

Eventually, Eq. (19) is easily defined as Eq. (20):

$$H\beta = T, \quad (20)$$

whereas,  $H$  defines the HL resultant matrix, and  $H = H(w_1, w_2, w_L, b_1, b_2, b_L, x_1, x_2, x_N)$ . So,  $h_{ij}$ ,  $\beta$ , and  $T$  are demonstrated as:

$$[h_{ij}] = \begin{bmatrix} g(w_L \cdot x_1 + b_L) & \dots & g(w_L \cdot x_1 + b_L) \\ \vdots & \ddots & \dots \\ g(w_L \cdot x_N + b_L) & \dots & g(w_L \cdot x_N + b_L) \end{bmatrix}, \quad (21)$$

$$\beta = \begin{bmatrix} \beta_{11} & \beta_{12} & \dots & \beta_{1m} \\ \vdots & \vdots & \ddots & \vdots \\ \beta_{L1} & \beta_{L2} & \dots & \beta_{Lm} \end{bmatrix} \quad (22)$$

and

$$T = \begin{bmatrix} t_{11} & t_{12} & \dots & t_{1m} \\ \vdots & \vdots & \ddots & \vdots \\ t_{N1} & t_{N2} & \dots & t_{Nm} \end{bmatrix}. \quad (23)$$

Afterwards, the minimal norm least-squares solution of Eq. (20) as:

$$\hat{\beta} = H^{\dagger}T, \quad (24)$$

Whereas  $H^{\dagger}$  implies the Moore Penrose generalization of the inverse of matrix  $H$ . The resultant of DELM is defined as Eq. (25):

$$f(x) = h(x)\beta = h(x)H^{\dagger}T. \quad (25)$$

From the above mentioned, the procedure of ELM is defined as follows. Initially, DELM is arbitrarily allocated the input weighted and HL biased ( $w_i, b_i$ ). Next, it can compute the HL resultant matrix  $H$  based on Eq. (21). Afterward, by employing Eq. (24), it attains the resultant weighted vector  $\beta$ . Lastly, it classifies the novel database based on the above-trained procedure. Fig. 2 represents the framework of ELM.

Fig. 2. Architecture of ELM.

#### D. Parameter Tuning using HBO Algorithm

At the final stage, the HBO algorithm was utilized for the optimal parameter tuning of the DELM Model. HBO algorithm was inspired by the social behaviours of human beings according to the hierarchy of organization [30]. This approach stimulates the corporate rank hierarchy (CRH), which implies that the member of the teamwork in the specific organization should be organized in a hierarchical form for completing the specific task. The presented method exploits the CRH model for hierarchically arranging the search candidate according to the fitness of this candidate. For the hierarchy construction, the heap-based data organization can be exploited. Besides the modeling of CRH, the whole concept involves three stages: (i) modeling of the collaborations between their direct manager and the subordinators; (ii) modeling of interactivity amongst the workers; and (iii) lastly, the modeling of self-contribution of the subordinators to accomplish the required task.

#### E. Modelling of the CRH Concept

The presented approach can be conceptualized as a population. In this context, each searching agent within the search space can be likened to a heap node, with the fitness

function (FF) of optimizer problems serving as the master key to access these heap nodes.

In a large organization that operates under a centralized infrastructure, laws and regulations are enforced unilaterally, flowing from senior leadership down to employees. In such a setup, employees are expected to adhere to the instructions of their superiors. With upgrading the place of searching candidate, this stage is mathematically defined:

$$x_i^k(t+1) = B^k + \gamma(2r-1)|B^k - x_i^k(t)| \quad (26)$$

In Eq. (26),  $x$  indicates the position of search agent;  $t$  and  $k$  show the existing iteration and the vector element, correspondingly; and  $B$  shows the parental node. The term  $(2r-1)$  symbolizes the  $k$ -th components of the vector  $\gamma$  and is produced randomly and defined as follows:

$$\lambda^k = 2r - 1 \quad (27)$$

In Eq. (27),  $r$  indicates the arbitrary parameter within  $[0,1]$  in a uniform distribution:

$$\gamma = \left| 2 - \frac{(t \bmod T)}{\frac{T}{4C}} \right| \quad (28)$$

In Eq. (28),  $T$  shows the maximal amount of iterations, and  $C$  indicates an adjustable parameter and relies on the iteration based on Eq. (29):

$$C = \frac{T}{25} \quad (29)$$

Colleagues (Subordinators) in a specific organization cooperate to accomplish official tasks. In the presented method, the nodes at a similar location from the heap are considered colleagues:

$$x_i^k(t+1) = \begin{cases} S_r^k + \gamma\lambda^k|S_r^k - x_i^k(t)|, & f(S_r) < f(x_i(t)) \\ x_i^k + \gamma\lambda^k|S_r^k - x_i^k(t)|, & f(S_r) \geq f(x_i(t)) \end{cases} \quad (30)$$

The self-contribution of every sub-ordinator from the organization was defined as follows:

$$x_i^k(t+1) = x_i^k(t) \quad (31)$$

In this section, the three position updating equation defined in the prior subsection is combined as one formula. A roulette wheel was exploited for making a balance among exploitation as well as exploration stages. The  $P_1, P_2,$  and  $P_3$  probabilities are used for achieving the balance between this phase. An initial probability  $p_1$  can be exploited to update the location of the searching agent from the population and is formulated as follows:

$$P_1 = 1 - \frac{t}{T} \quad (32)$$

The second proportion,  $p_2$  can be evaluated by Eq. (33):

$$P_2 = P_1 + \frac{1-P_1}{2} \quad (33)$$

Lastly, the probability  $p_3$  was evaluated by Eq. (33):

$$P_3 = P_2 + \frac{1-P_1}{2} = 1 \quad (34)$$

$$x_i^k(t+1) = \begin{cases} x_i^k(t), & P < P_1 \\ B^k + \gamma\lambda^k |B^k - x_i^k(t)|, & P_1 < P < P_2 \\ S_r^k + \gamma\lambda^k |S_r^k - x_i^k(t)|, & P_2 < P < P_3 \text{ and } f(S_r) < f(x_i(t)) \\ x_i^k + \gamma\lambda^k |S_r^k - x_i^k(t)|, & P_2 < P < P_3 \text{ and } f(S_r) \geq f(x_i(t)) \end{cases} \quad (35)$$

Where  $p$  shows a random value within  $[0,1]$ .

The HBO technique not only grows a FF to attain higher accuracy of classifier and determines a positive integer to represent the greater efficacy of candidate solutions. The decline of classifier error rate is assumed as FF.

$$\begin{aligned} fitness(x_i) &= ClassifierErrorRate(x_i) \\ &= \frac{\text{no.of misclassified instances}}{\text{Total no.of instances}} * 100 \end{aligned} \quad (36)$$

#### IV. RESULTS

##### A. Results Analysis on Intrusion Detection Dataset

In this section, the intrusion detection results of the ARODL-BSSHS approach were tested on the NSL database [31], including 2100 instances and five classes, as shown in Table I.

TABLE I. DETAILS OF NSL DATASET

Class	No. of Instances
Normal_Class	500
DoS_Class	500
Probe_Class	500
R2-L_Class	500
U2-R_Class	100
<b>Total Number of Instances</b>	<b>2100</b>

Fig. 3 illustrates the classifier outcomes generated by the ARODL-BSSHS technique when applied to the NSL dataset. Figs. 3(a) and 3(b) depict the confusion matrix derived from the ARODL-BSSHS method using a 70:30 split of Training and Testing Data Split (TRP/TSP). The outcomes indicate that the ARODL-BSSHS approach effectively identified and correctly categorized all five classes. Similarly, Fig. 3(c) showcases the Precision-Recall (PR) curve yielded by the ARODL-BSSHS approach. The findings suggest that the ARODL-BSSHS system achieved favorable PR performance across all five classes. Lastly, Fig. 3(d) displays the Receiver Operating Characteristic (ROC) curve resulting from the ARODL-BSSHS technique. This graph highlights that the ARODL-BSSHS approach yielded commendable results, exhibiting superior ROC values for all five classes.

The intrusion detection outcomes of the ARODL-BSSHS technique under 70:30 of TRP/TSS are demonstrated in Table II. The results reported that the ARODL-BSSHS technique recognizes five class labels effectually. For instance, with 70% of TRP, the ARODL-BSSHS technique obtains average  $accu_y$  of 99.73%,  $prec_n$  of 99.19%,  $sens_y$  of 99.18%,  $spec_y$  of 99.83%, and  $F_{score}$  of 99.19%. Additionally, with 30% of TSP, the ARODL-BSSHS method attains average  $accu_y$  of 99.75%,

$prec_n$  of 99.45%,  $sens_y$  of 99.46%,  $spec_y$  of 99.83%, and  $F_{score}$  of 99.45%.

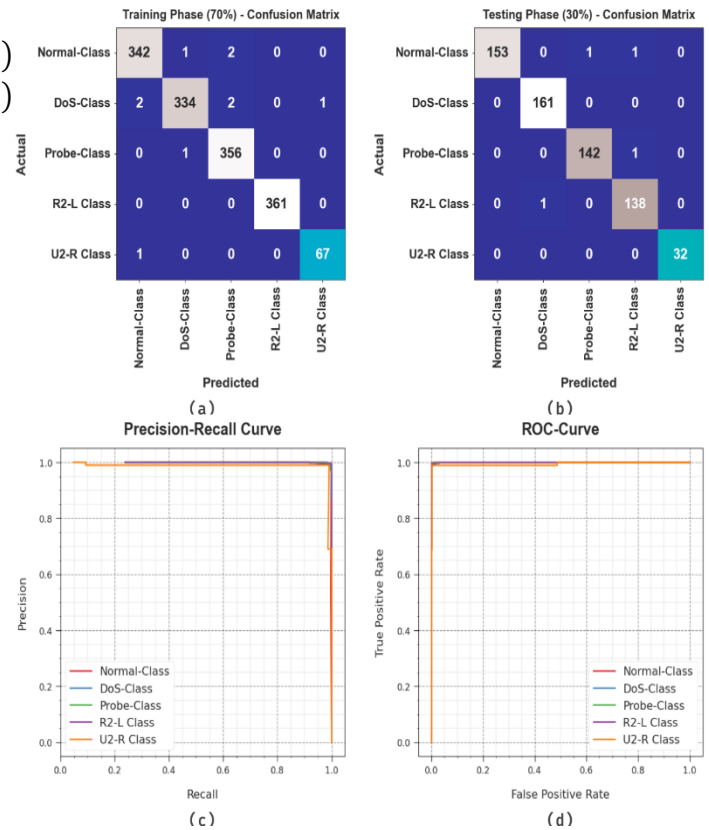

Fig. 3. Classifier outcome on NSL dataset (a-b) Confusion matrices, (c) PR curve, and (d) ROC curve.

TABLE II. INTRUSION DETECTION OUTCOME OF ARODL-BSSHS SYSTEM ON NSL DATASET

Class	$Accu_y$	$Prec_n$	$Sens_y$	$Spec_y$	$F_{score}$
<b>Training Phase (70%)</b>

Fig. 4. Accuracy curve of ARODL-BSSHS system on NSL dataset.

Fig. 4 examines the accuracy performance of the ARODL-BSSHS algorithm through the training and validation phases on the NSL dataset. The findings indicate that the ARODL-BSSHS system achieves peak accuracy values as the epochs progress. Notably, the higher validation accuracy in comparison to the training accuracy signifies the proficient learning capability of the ARODL-BSSHS system on the NSL dataset.

The evaluation of loss during both training and validation stages of the ARODL-BSSHS algorithm on the NSL dataset is presented in Fig. 5. The results suggest that the ARODL-BSSHS algorithm maintains similar values of training and validation loss. This observation underscores the effective learning of the ARODL-BSSHS approach on the NSL dataset.

Fig. 5. Loss curve of ARODL-BSSHS system on NSL dataset.

Table III and Fig. 6 reports the comparative intrusion detection results of the ARODL-BSSHS technique. The outcomes implied that the SVM model and LDA model achieves worse outcomes. Although the RF, NB, CART, and HNIDS models offer slightly improved results, the ARODL-BSSHS technique outperforms the other existing models with maximum  $accu_y$  of 99.75%,  $prec_n$  of 99.45%,  $sens_y$  of 99.46%, and  $F_{score}$  of 99.45%.

TABLE III. COMPARISON OF ARODL-BSSHS ALGORITHM WITH DIFFERENT METHODOLOGIES ON THE NSL DATASET

Classification Method	Accuracy	Precision	Sensitivity	F-Score
SVM Model	87.80	97.85	91.41	96.67
LDA Model	91.57	96.78	90.57	96.32
RF Model	97.50	97.85	94.67	97.48
Naïve Bayes	94.66	95.62	93.55	95.08
CART	94.59	96.55	92.78	95.62
LR Model	92.31	91.26	90.11	91.26
HNIDS	98.97	98.85	96.12	99.04
ARODL-BSSHS	99.75	99.45	99.46	99.45

Fig. 6. Comparative outcome of ARODL-BSSHS approach with other methods on NSL dataset.

The computation time (CT) examination of the ARODL-BSSHS technique with recent models on the intrusion detection process is reported in Table IV and Fig. 7. The outcomes reported that the ARODL-BSSHS approach gains least CT of 9.50s. On the other hand, the existing SVM, LDA, RF, NB, CART, LR, and HNIDS models obtain increased CT of 20.54s, 18.89s, 12.37s, 19.77s, 16.09s, 12.97s, and 11.21s respectively.

TABLE IV. COMPARISON OF CT OUTCOME OF ARODL-BSSHS APPROACH WITH OTHERS ON NSL DATASET

Classifier	Computational Time (sec)
SVM	20.54
LDA	18.89
RF	12.37
Naïve Bayes	19.77
CART	16.09
LR	12.97
HNIDS	11.21
ARODL-BSSHS	09.50

Fig. 7. CT outcome of ARODL-BSSHS approach with other methods on NSL dataset.

B. Results Analysis on Disease Diagnosis Dataset

The Cleveland heart dataset (CHD) [32] contains of 303 samples with 76 features, but only 14 features can be assumed that more appropriate for study experimental purposes. Table V illustrates the details on CHD.

TABLE V. DETAILS ON CHD

Class	No. of Samples
Absence	138
Presence	165
Total Number of Samples	303

Fig. 8 presents the classifier outcomes achieved by the ARODL-BSSHS algorithm when applied to the CHD dataset. Sub-figures 8a and 8b display the confusion matrix generated by the ARODL-BSSHS system using a 70:30 split of Training and Testing Data Split (TRP/TSP). The outcomes indicate that the ARODL-BSSHS system effectively recognized and accurately classified both of the available classes.

Similarly, Fig. 8(c) illustrates the Precision-Recall (PR) analysis performed by the ARODL-BSSHS model. The results reported demonstrate that the ARODL-BSSHS system achieved superior PR performance across the two classes. Lastly, Fig. 8(d) showcases the Receiver Operating Characteristic (ROC) analysis conducted by the ARODL-BSSHS approach. This graph demonstrates that the ARODL-BSSHS algorithm has delivered capable results, achieving maximum ROC values for the two classes.

The classification outcome of the ARODL-BSSHS method under 70:30 of TRP/TSS is established in Table VI. The outcomes stated that the ARODL-BSSHS system recognizes five class labels effectively. For example, with 70% of TRP, the ARODL-BSSHS method attains average  $accu_y$  of 95.07%,  $prec_n$  of 95.32%,  $sens_y$  of 95.07%,  $spec_y$  of 95.07%, and  $F_{score}$  of 95.19%. Furthermore, with 30% of TSP, the ARODL-BSSHS method acquires average  $accu_y$  of 97.83%,  $prec_n$  of

97.87%,  $sens_y$  of 97.83%,  $spec_y$  of 97.83%, and  $F_{score}$  of 97.80%.

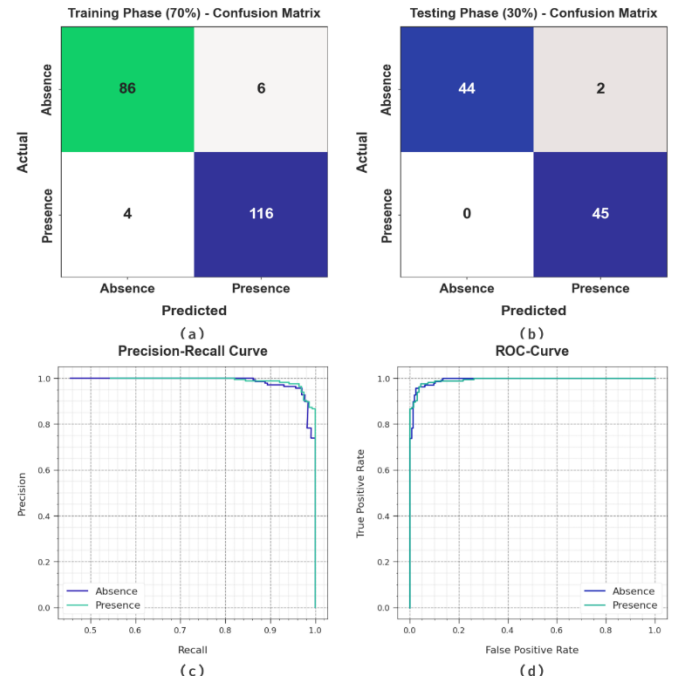

Fig. 8. Classifier outcome on CHD (a-b) Confusion matrices, (c) PR curve, and (d) ROC curve.

TABLE VI. CLASSIFIER OUTCOME OF ARODL-BSSHS SYSTEM ON CHD

Class	$Accu_y$	$Prec_n$	$Sens_y$	$Spec_y$	$F_{Score}$
<b>Training Phase (70%)</b>					
Absence	93.48	95.56	93.48	96.67	94.51
Presence	96.67	95.08	96.67	93.48	95.87
<b>Average</b>	<b>95.07</b>	<b>95.32</b>	<b>95.07</b>	<b>95.07</b>	<b>95.19</b>
<b>Testing Phase (30%)</b>					
Absence	95.65	100.00	95.65	100.00	97.78
Presence	100.00	95.74	100.00	95.65	97.83
<b>Average</b>	<b>97.83</b>	<b>97.87</b>	<b>97.83</b>	<b>97.83</b>	<b>97.80</b>

Fig. 9. Accuracy curve of ARODL-BSSHS system on CHD.

Fig. 9 examines the accuracy performance of the ARODL-BSSHS approach within the training and validation phases using the CHD dataset. The results highlight that the ARODL-BSSHS system achieves its highest accuracy values as the epochs progress. Furthermore, the notably superior validation accuracy compared to the training accuracy underscores the efficient learning capacity of the ARODL-BSSHS algorithm on the CHD dataset.

The analysis of loss during both the training and validation stages of the ARODL-BSSHS approach using the CHD dataset is depicted in Fig. 10. The findings suggest that the ARODL-BSSHS algorithm maintains closely aligned values for both training and validation loss. This observation emphasizes the capable learning behavior of the ARODL-BSSHS algorithm on the CHD dataset.

Fig. 10. Loss curve of ARODL-BSSHS system on CHD.

### V. DISCUSSION

In Table VII and Fig. 11, the comparative outcome of the ARODL-BSSHS approach is reported in [33][34]. The results implied that the RF algorithm gains worse performance. But, the NB, LR, SMO, AdaBoostM1 + DS, and Bagging + REPTree approaches offer somewhat higher outcomes; the ARODL-BSSHS system demonstrates the other existing models with maximal  $accu_y$  of 97.83%,  $prec_n$  of 97.87%,  $sens_y$  of 97.83%, and  $F_{score}$  of 97.80%.

TABLE VII. COMPARATIVE OUTCOME OF ARODL-BSSHS APPROACH WITH OTHER METHODS ON CHD

Classifier	Accuracy	Precision	Sensitivity	Specificity	F-Measure
NB Model	84.49	84.50	84.50	87.00	84.50
LR Model	84.49	84.50	84.50	87.00	84.50
SMO Model	86.14	86.20	86.10	90.00	86.10
AdaBoostM1 + DS	83.83	83.90	83.80	88.00	83.80
Bagging + REPTree	83.83	83.90	83.80	88.00	83.80
RF Model	81.19	81.20	81.20	85.00	81.10
ARODL-BSSHS	97.83	97.87	97.83	97.83	97.80

Fig. 11. Comparative outcome of ARODL-BSSHS approach with other methods on CHD.

The CT inspection of the ARODL-BSSHS approach with recent algorithms is reported in Table VII and Fig. 12. The outcomes inferred that the ARODL-BSSHS algorithm reaches a minimal CT of 8.17s. Also, the existing NB, LR, SMO, AdaBoostM1 + DS, Bagging + REPTree, and RF approaches reach maximum CT of 23.20s, 25.10s, 15.90s, 25s, 23.40s, and 20.30s correspondingly. These results analysis assured the better performance of the ARODL-BSSHS technique on the smart healthcare system.

TABLE VIII. CT OUTCOME OF ARODL-BSSHS APPROACH WITH OTHER METHODS ON CHD

Classifier	Computational Time (sec)
NB	23.20
LR	25.10
SMO	15.90
AdaBoostM1 + DS	25.00
Bagging + REPTree	23.40
RF	20.30
ARODL-BSSHS	08.17

The results of the comparative analysis illustrate the superior efficacy of the ARODL-BSSHS approach in securing healthcare systems over the studied alternative models. It was found that ARODL-BSSHS significantly outperforms other classifiers in terms of accuracy, precision, sensitivity, specificity, and F-measure, achieving a maximum accuracy of 97.83% and a minimal Computational Time (CT) of 8.17s. This implies that the ARODL-BSSHS not only is more accurate in predictions and classifications but also is more efficient, making it a preferable choice for real-time applications in smart healthcare systems. This superior performance of ARODL-BSSHS emphasizes the critical role of sophisticated techniques in addressing the complexity and diversity of healthcare requirements and environments. The increased accuracy and reduced computational time are indicative of its capability to deal with the multifaceted and dynamic nature of healthcare data more effectively and

efficiently. The discussed results reinforce the viability and superiority of the ARODL-BSSHS approach in enhancing security and optimizing performance in smart healthcare systems, presenting it as a promising solution for future integrations and developments in healthcare technology.

Fig. 12. CT outcome of ARODL-BSSHS approach with other methods on CHD.

## VI. RECOMMENDATIONS & FUTURE WORKS

It is recommended that future research on the ARODL-BSSHS approach should explore its adaptability across diverse sectors like finance, education, and supply chain management. Integration with emerging technologies such as Edge and Quantum Computing and 5G can be crucial to enhance the method's capabilities and to cater to the evolving needs of modern applications. Developing scalable and user-friendly implementations is imperative to ensure broader applicability and user acceptance.

The integration with Edge and Quantum Computing is being explored to optimize computational processes and solve complex problems efficiently [35]. There is also a heightened emphasis on developing robust security and privacy-preserving protocols due to the escalating concerns related to data breaches and cyber-attacks in healthcare systems. The application of Federated Learning and Decentralized AI is gaining traction, addressing the need for decentralized model training and decision-making processes that adhere to data privacy standards. Moreover, the utilization of AI for personalized and predictive healthcare is becoming pivotal, allowing for the development of individualized treatment plans and early detection of diseases.

## VII. CONCLUSION

The ARODL-BSSHS technique has been developed for accomplishing security in the healthcare system in this study. The presented ARODL-BSSHS technique involves the design of secured and smart healthcare system using two major processes, namely intrusion detection and disease diagnosis. To accomplish this, the ARODL-BSSHS technique follows a series of processes: HNN based intrusion detection, ARO based parameter tuning, DELM based disease detection, and HBO based parameter optimization. In addition, the ARODL-

BSSHS technique involves BC technology for secure transmission of healthcare data. A widespread experimental analysis is made on benchmark datasets: heart disease and NSL-KDD dataset to ensure the improved results of the ARODL-BSSHS technique. The experimental values highlighted that the ARODL-BSSHS technique obtains better performance than other approaches. In the upcoming years, the performance of the ARODL-BSSHS algorithm can be improved by multimodal DL techniques.

Henan Province, China

**Abstract**—A wide range of web-based applications uses the Transmission Control Protocol (TCP) to ensure network resources are shared efficiently and fairly. As wired and wireless networks have become more complex, various end-to-end Congestion Control (CC) schemes have been developed, offering solutions through their proposed TCP variants. Network tomography, a powerful analytical tool, offers a unique perspective by measuring end-to-end performance to estimate internal network parameters, including latency. This estimation capability proves valuable, especially in cases where precise protocol performance evaluation is essential. TCP protocol can be improved significantly by properly estimating RTT time. It has resulted in better network conditions and improved reliability, as well as a higher level of user satisfaction. In this study, we propose a method to infer the link delay using network tomography and then adjust the RTT based on the delay estimation obtained in the previous step. Simulation results performed using the NS2 software show that the proposed method significantly improves the TCP protocol's Round-Trip Time (RTT) estimation by more than 15%. It reduces congestion, improves information transfer efficiency, and ensures the highest level of service in the network.

**Keywords**—Latency; network tomography; end to end; depending on the probe

## I. INTRODUCTION

The landscape of networking technologies has evolved significantly over the years, witnessing advancements that span multiple generations, including the emergence of 5G and the anticipation of 6G. The need for efficient data transfer mechanisms becomes increasingly pronounced as wired and wireless networks expand in complexity and scale. The Transmission Control Protocol (TCP) has long been a cornerstone of network communication, ensuring reliable and adaptive data delivery in various applications [1, 2]. While high-speed networks have reached gigabit speeds, mobile wireless access networks have led to a proliferation of mobile hosts connected to the Internet via slow wireless links [3]. Further, the challenging characteristics of wireless links, such as the high packet loss rates or delays resulting from various factors, such as link-layer retransmissions or handoffs between connection points to the Internet, have posed significant challenges to Internet transport protocols [4, 5]. Today's Internet applications require a reliable mechanism to transfer data due to increasing performance requirements. TCP is extensively used as the transport protocol in many applications due to its ability to adapt to the properties of the network and

its robustness in the face of many types of failures [6, 7]. However, the closed nature of legacy switches, which do not provide accurate visibility of network events, has limited the improvement of the performance of applications that rely on TCP [8].

In this rapidly evolving landscape of complex systems and advanced technologies, research has been directed toward optimizing control strategies and enhancing performance across various domains. The integration of hierarchical optimization and fuzzy logic has yielded promising results in addressing challenges posed by time-varying delays and disturbances in discrete large-scale systems [9, 10]. Machine learning techniques have also emerged as a powerful toolset for analyzing and managing network dynamics. Notably, studies have delved into the analysis of Android ransomware using hybrid approaches [11] and explored machine learning-based network slicing for efficient 5G network management [12]. Additionally, predictive models and probabilistic neural networks have been harnessed to forecast idle slot availability in wireless local area networks [13], while innovative cell designs have been introduced to enhance data collection efficiency in green IoT networks [14]. The integration of machine learning into data conditioning and forecasting methodologies has showcased its potential in optimizing well-pad operations [15, 16]. In the rapidly evolving landscape of complex systems and advanced technologies, the fusion of association rule mining and urban public transportation assumes paramount importance. This synergy facilitates data-driven decision-making, offering insights into commuter behavior, traffic patterns, and service optimization. As urban areas continue to grow, leveraging these tools empowers city planners and transport authorities to navigate the complexities of modern urban mobility, fostering efficiency, sustainability, and improved quality of life for urban dwellers [17, 18]. Moreover, sustainable energy technology has embraced novel concepts, such as power harvesting through ambient vibrations and capacitive transducers [19]. This compilation of research endeavors exemplifies the diverse and impactful directions that contemporary studies are exploring, aiming to unlock new frontiers of knowledge and practical application.

TCP uses the fast retransmit mechanism to trigger retransmissions following the receipt of three consecutive duplicate acknowledgments (ACKs) [20]. As a backoff mechanism, the TCP retransmission timer expires if the TCP sender does not receive ACKs for a certain period of time. Upon expiration of the retransmission timer, the TCP sender

retransmits the first undelivered segment, assuming it is lost in the network [21]. Because retransmission timeouts (RTOs) can indicate that the network is heavily congested, the TCP sender resets its congestion window to one segment and gradually increases it in accordance with the slow start algorithm. Nevertheless, suppose the RTO occurs spuriously, and segments are still outstanding in the network. In that case, a false slow start may damage the potentially congested network by injecting additional segments at an increased rate [22]. One of the most crucial aspects of such a mechanism is how long after sending a package and receiving a receipt, the timeout must be announced. Network tomography offers the opportunity to actively measure link-level characteristics such as delay and loss on end-to-end paths at the link level [23]. Most network tomography techniques developed to date are based on one-way measurements, requiring cooperation from sending and receiving hosts. Consequently, the paths over which these techniques can be applied are severely limited [24]. This paper proposes a method for estimating link delay using network tomography, followed by adjusting the RTT in accordance with the delay value obtained in the previous step. Finally, the results from the study are used to improve the TCP retransmission mechanism to reduce latency and improve performance. The main contributions of this paper are summarized as follows:

- We propose a novel method that leverages network tomography to estimate link delays and adjust RTT values, significantly improving TCP protocol performance.
- Simulation results conducted using NS2 software demonstrate that our approach enhances TCP RTT estimation by over 15%, leading to reduced congestion, improved information transfer efficiency, and heightened service quality within the network.

The remainder of this paper is structured as follows. Section II presents a background of the problem. Section III provides a detailed description of the proposed method, outlining the key steps and innovative aspects of our approach. In Section IV, we present the results of empirical evaluations and comparisons, demonstrating the superiority of our method in terms of accuracy and efficiency. Finally, Section V summarizes our findings, highlights the contributions, and suggests potential avenues for future research.

## II. BACKGROUND

Performance parameters within a network are difficult to measure directly by internal nodes as some may not communicate proactively for security reasons. The network tomography method provides a very convenient means of measuring network parameters since it measures only the end-to-end characteristics of the network. In the end, the network is estimated based on its internal features. Many approaches are employed in network tomographies, such as estimating link level 1 parameters, determining network correlations, and calculating the network traffic matrix between the source and destination networks.

Several methods are presented for estimating link delay via a tomography network. In some cases, the delay distribution is

discrete. These methods assign end-to-end latencies and delay links based on assumed collections, and the probability of mass-delay links is calculated using the EM algorithm [25]. In a statistical model containing latent dependent variables that are imperceptible, the EM algorithm or maximum expected (expectation-maximization) is a repeatable method for finding the maximum value or estimate of the most likely value of an inductive (inferring from effects to causes) parameter set of parameters. The calculation will be repeated for most parameters in the expected results. Calculations and estimates are obtained in stage M to determine the distribution of latent variables used in the next iteration (E) [26]. The method used to estimate the delay of end-to-end latencies supposed links to collections are assigned. The possibility of mass-delay links is calculated using the EM algorithm. There are two limitations in the face of real networks:

- In a real network, because the traffic load on some of the links is heavier and lighter for the other part of the link, packet delay can be quite different. So, if you set that delays end-to-end, links have been assigned to the minor premise. In this case, the desired levels of accuracy are not achieved. Suppose these sets are assumed to be large. In that case, complex computational problems arise, so selecting the appropriate set to assign end-to-end latency and link latency is impossible for these methods.
- The large network size, usually with large amounts of complex data (sets assumed that the end-to-end delays and delays links are assigned to them) to obtain delays of all links face. However, the EM algorithm calculates the probability of each of the probe packets. However, if the input data set is large, these are time-consuming calculations and thus cannot link estimates on time delays for large-scale networks [27].

Unlike the discrete distribution models that estimate the delay, some methods are used to model continuous distribution delay. These methods assume that the distribution of the known delay follows. Examples of distributions include the Poisson distribution and Gaussian distribution compound [26, 28]. Peterson and Davie [29] The authors sought to improve the algorithm to Kaczmarz to take advantage of computing linear tomography systems in the network. The algorithm in linear systems, adaptive control, and tomography systems with wireless sensor networks is used in nature and later as an iterative algorithm in these cases. This algorithm is based on mathematics, potential events, and the full and complex.

In [30], routing and tomography have been amended using a series of evolutionary and biological matrices added and the idea of using algorithms. The framework of evolutionary algorithms solving the robustness and accuracy helps tomography. More studies in the area of network tomography are based on parametric models. The parametric model assumes that measuring data traffic depends on the number of defined parameters. For example, recent studies estimate the internal delay distribution. The probability mass distribution can be modeled as functions. In this context, parameters and the probabilities associated with each function are likely crimes. Some methods of inference delay focused on multicast

routing. The routing of packets sent from the sender to the recipient during an operation moved. During the probe packets, the paths split apart, double, and multiply [31].

### III. PROPOSED METHOD

With the advent of 5G and the impending rise of 6G, the networking landscape has been marked by transformative capabilities, promising higher data rates, lower latency, and greater network efficiency. These advancements are largely attributed to the proliferation of advanced wireless technologies, the expansion of device connectivity, and the integration of cutting-edge communication paradigms. As the industry shifts its focus toward ultra-low latency, these technologies are poised to reshape the dynamics of data transmission and drive the development of novel applications. In this dynamic context, the accurate estimation of Round-Trip Time (RTT) assumes heightened significance. RTT estimation plays a pivotal role in determining optimal retransmission timeouts, facilitating congestion control, and enhancing overall network performance. While conventional methods have sufficed in earlier network paradigms, the evolving landscape introduces new challenges and opportunities that necessitate innovative approaches.

In order to maximize network efficiency, accurate RTT estimation and optimal RTO quantification are essential. The RTO must be longer than the return time or RTT. The RTT is affected by many factors, such as transmission delay, propagation delay, header processing time, ACK production time, etc. Consequently, RTT is not a static value in real-world environments and will change over time. In this case, the change reflects the conditions mentioned in the examples. The RTO should not be set with more than enough, as this will lead to long delays. Additionally, there is an important question to be addressed: what happens if the route changes? What should be done if the network traffic situation and the status of the intermediate nodes change? It is, therefore, necessary to repeat this estimate regularly. The period can be repeated with an appropriate interval of time, such as 20 milliseconds. In order to send probes, a condition may be set, which will result in re-sending the packets if that condition is met. Network conditions will be estimated correctly again. Knowledge of any link to update, to help without sending the actual data and only based on the information provided by the source node is placed tomography, the parameters needed to set up protocols like TCP.

These parameters may also be estimated based on other ideas for calculating them. By estimating the RTT more accurately, the TCP can retransmit at better times and increase the number of these posts. In order to overcome the problems mentioned above, a method based on the unicast delay estimates tomography is recommended for improving TCP. Tomography is used in this way for both end-to-end and link-to-link tomography. Tomography can be used by any network node to calculate the delay on links, whether it is the transmitter or any other node on the network.

Furthermore, it can assist in improving the routing process. To estimate network delay, we first use tomography. To estimate the number of packet delay probe pairs, unreachable packets are sent from the source node to the destination node.

End-to-end packets are bursts that act as end-to-end communications. A delay equation is developed using the relationship between the delay and the delay link that routes packets of information to the probe. Our solution is derived from equations described in the previous chapter to estimate the quantity delay optimally. The route is calculated based on the number of nodes, and each node will have some delay in packets. In general, course delays are little more than the sum of the delays from link to link. As each node experiences a delay in processing, queuing, or propagation, connections are also created. The decision to send real-time packets may result in incorrect calculations and the loss of influence tomography performed to adjust the network RTT in the TCP protocol when the decision is made to send packets in real-time.

In spite of the fact that the processing delay may seem insignificant at first, it does not have any significant impact on large networks with high traffic, especially when there are a number of intermediate nodes and those with high and low processing power. Each node is given a delay. Additionally, it is also possible to have a significant other since it is always in the real world, with a variety of unforeseen and additional delays. Besides the low estimate of the time required for RTT retransmission, a high estimate of the real-time network and reach pass may help reduce the package's delay. When the estimate for the time is slightly larger, it is better to be low since a low estimate, increased network traffic, and poor network conditions can all contribute to delays. By sending and receiving information, each probe packet can help estimate the exact real delay.

For closed questions, the collection, analysis, and length of time from the time of receiving the low are examined, and the amount of delay is determined based on the link. A more appropriate RTT parameter is determined based on the level of probe tomography accuracy of information and links to the detailed estimate of the actual delay. The RTT value is calculated using probes that measure the RTT by tomography and real delay roadshows, achieving a much more accurate delay than TCP. Finally, we will use the results of this calculation to regulate better and improve our TCP retransmission mechanism. By using the proposed approach, better estimates of RTT TCP can be made, and thus, better performance may be achieved.

#### A. Approach Proposed Resolution

As RTT is the basis for accurately estimating probe tomography, multiple packets of burst tomography can be sent to different recipients using unicast protocols. These probes will be used to determine the answer depending on the sender and RTT. The following steps are followed to estimate the actual RTT.

In the first step, tree topology is considered for the network. Leaf nodes of the tree network are selected as the destination. To send pairs of probe packets, multi-packet probe packets are burst using unicast routing. Each packet transmits information about each link, including when it was sent and received by each node, enabling a more accurate estimate of the latency of the links and the route. Data collection and analysis of transmitter probe packets and the amount of time calculated by the probe packet are low. The amount of packet delay is

calculated according to the network. During the extraction and analysis process, we provide accurate, real-time probe data packet processing at each node to estimate the actual RTT at each node. The information obtained from the probe packets is used to calculate the actual delay based on the optimal number of links as follows:

$$\text{Path Delay} = (\text{Tomo Delay}) + ((2n-2) * (\text{Mean Node Delay})) \quad (1)$$

In Eq. (1), Tomo Delay is the optimal amount of delay quantity for links through tomography, n is the number of nodes between source and destination, and mean Node Delay represents the average delay of processing nodes. The probability does not decrease if the sweep is different and has a different number of nodes. If there were more nodes along the path, the equation was recalculated. By replacing parameter 2n with the number of nodes and the number of nodes in the path, the equation is modified as follows:

$$\text{Path Delay} = (\text{Tomo Delay}) + ((n_{\text{went}} + n_{\text{back}}) * (\text{Mean Node Delay})) \quad (2)$$

To improve the mechanism of retransmission of TCP, the result calculation shows that the actual delay replaces the RTT value calculated by the TCP protocol so that TCP will begin with a more accurate estimate of RTT. In practice, more complete equations may be available instead of replacing the equation. There is, however, an additional condition that can be met by a simple equation to estimate the actual delay. The routine can be effective for a network. A better match will always be required in computational experiments.

### B. Evaluation of the precision of the delay

This section provides information regarding the delay time, accuracy, and reliability. In addition to accurately representing scientific work, it indicates what they can contribute to other research endeavors. Estimated delay in TCP is considered an important issue, and its accuracy is crucial. We use the cumulative method to adjust and improve TCP RTT. If the estimates are correct, they will have a significant impact on the

performance of the network. Statistical analysis indicates that the proposed method effectively predicts the delay, and the results indicated they would be considerable. It is, therefore, necessary to compare the delay used to calculate the cumulative delay in the proposed method with the actual delay by the time an estimate is made regarding the links and integrated.

The complexity and variability of the network make it impossible to test with a definitive result. So, the effort involved here has been estimated at ten times. This means that every time, a predetermined scenario is applied to every package in exchange for the time a probe is sent, calculated, printed, and recorded at the outlet. Additionally, a comparison was made between the sent and received packets obtained and recorded, simultaneously with the actual delay time on the printed output. Because the two packages are sent on two separate paths, each package will experience two delays. Therefore, the two delays are calculated every time. The third scenario is somewhat busier in the network regarding the calculation. The traffic in this scenario consists of 21 TCP streams and 161 on-off Poisson streams transmitted over UDP. Statistics are collected from node one. It can be said that the accuracy of this method is relatively high, and errors in the tenth milliseconds. For more detailed calculations, each row of accuracy and the error rate can be calculated and then averaged. The packet error rate refers to the number of packets with errors divided by the number of packets transmitted, calculated by Eq. (3).

$$PER = \frac{\text{number of packet with errors}}{\text{number of packets transmitted}} \quad (3)$$

Table I provides a comparison of the actual delay and delay calculation for two batches of the probe. This data illustrates the accuracy of our proposed method in estimating delays accurately. Similarly, Table II presents the percentage of delay calculation error in the proposed method for two packs of probe data. Analyzing this data allows us to assess the precision of our approach in real-world scenarios.

TABLE I. COMPARISON OF ACTUAL DELAY AND DELAY CALCULATION FOR TWO BATCHES OF THE PROBE

Closed computational delay the first	Real delay packet first	Delay calculation package II	Real delay packet second
42/5 ms	23.5 ms	10.6 ms	18.6 ms
34.6 ms	87/6 ms	32.7 ms	92/6 ms
5.55 ms	90/5 ms	21/6 ms	7.17 ms
89.7 ms	11.8 ms	29/4 ms	80.4 ms
24/8 ms	91/7 ms	81.7 ms	63/7 ms
94/4 ms	18.5 ms	23.7 ms	65/7 ms
34.5 ms	49/5 ms	48/6 ms	11.7 ms
87.5 ms	08/6 ms	76/3 ms	45/3 ms
12.6 ms	67/6 ms	22/8 ms	59/7 ms
34.8 ms	79/7 ms	34/7 ms	8.57 ms

TABLE II. PERCENTAGE OF A DELAY CALCULATION ERROR IN THE PROPOSED METHOD FOR TWO PACKS OF PROBE

Percent packet error First	Packet error percentage of the second
60/3 percent	20.1 percent
70/7 percent	70/5 percent
90/5 percent	30/13 percent
71/2 percent	80.4 percent
60/10 percent	30.2 percent
60/4 percent	40/5 percent
70/2 percent	80/8 percent
40/3 percent	90/8 percent
20.8 percent	30.8 percent
00/7 percent	40.6 percent

### C. The potential of network tomography-based RTT estimation

In this backdrop, our proposed method offers a novel approach to RTT estimation, leveraging the power of network tomography. Traditional RTT estimation methods may confront limitations in accurately gauging RTT in scenarios with multiple physical paths, varying link delays, and changing network dynamics. Here, network tomography emerges as a promising avenue to address these challenges by providing end-to-end performance insights based on the measurement of delay characteristics. Our method, grounded in network tomography, introduces an additional dimension to RTT estimation. While advancements in networking technologies, such as 5G and 6G, and increased compute power contribute to RTT reduction, our method augments these efforts by enhancing accuracy and reliability. By considering link delays across multiple paths and leveraging network tomography's capabilities, our method provides a more comprehensive and nuanced RTT estimation. Fig. 1 shows the flowchart for actual RTT estimation.

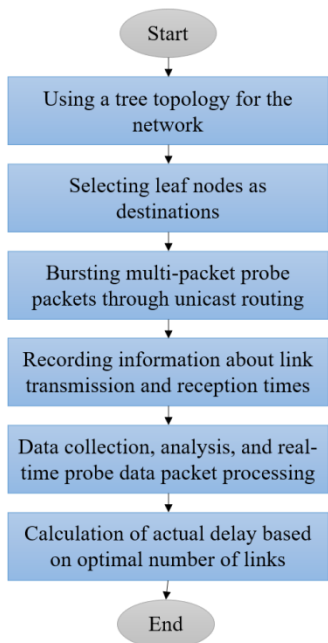

Fig. 1. RTT estimation.

### D. Relevance in evolving networking technologies

The evolving networking technologies, particularly 5G and the anticipated 6G, demand precision in RTT estimation to harness their full potential. While these technologies offer low-latency communication, our method's emphasis on accurate RTT estimation aligns with the quest for precision in data transmission. In environments where real-time applications, IoT devices, and mission-critical communications are paramount, our method's ability to adapt and estimate link delays across diverse paths becomes indispensable. In scenarios with multiple physical paths, MPTCP utilization, and the intricate interplay of network conditions, our method demonstrates its relevance by providing insights into delay characteristics that traditional methods may overlook. This nuanced estimation approach aligns well with the objectives of evolving networking technologies to minimize latency and optimize data transfer efficiency.

## IV. EXPERIMENTAL RESULTS

Simulation may take into account particular circumstances. Simulating and evaluating all possible scenarios is neither feasible nor logical. In each simulation, the actual network conditions should be considered, but the results should be reported as accurately as possible under the constraints. Furthermore, many scenarios are proposed for simulating various aspects of the proposed method. Simulations must also be conducted under conditions similar to those encountered in the review, compared with the method before using it or other suggested methods. In some contexts, a comprehensive network may not be necessary and may be subject to performance conditions. The algorithm is not random in nature, and its behavior is uncertain. Moreover, while improving the network from the perspective of all available parameters, other parameters may be affected. This is because certain reconciliation parameters, namely the balance between them, as well as improving all the parameters simultaneously, cannot be achieved.

The NS2 simulator is used to simulate the proposed method. In order to implement several networks, OTcl is used to create scenarios, and C++ code is used to simulate algorithms and protocols. Communication between scripting languages should be considered in this regard. Although the NS2 software is available on Linux, it can be used on Windows

via a software interface called Cygwin, a Linux virtual machine that can run NS2. The proposed method is simulated and evaluated on a wired network at a fixed time. At this time, seven of eight nodes are linked to a tree with a root node number of zero. Fig. 2 shows this package.

Fig. 2. A network of assessment.

Each link has a queue that is a FIFO algorithm. The simulation was performed with three types of traffic. Traffic is the most crucial first tomography is used, TCP traffic that RTT adjustment is considered. Two types of background traffic are assumed as the frequency of use. CBR traffic, Poisson traffic, and others with entirely different features. Poisson traffic is a traffic accident, while CBR traffic congestion is at the rate specified and is absolutely certain. The CBR traffic intended as a background other than CBR traffic that was initially closed probe is used to estimate RTT TCP traffic. The proposed and other methods and evaluations were conducted in two different scenarios.

#### A. Network Topology

The experimental setup involves a wired network comprising nodes connected in a tree topology, with a root node numbered zero. The nodes are connected through links equipped with a First-In-First-Out (FIFO) queuing algorithm. Two distinct scenarios are considered, each reflecting different aspects of network dynamics and traffic patterns.

Scenario 1 involves a multi-traffic flow setting, where TCP flows are established at rates of 21 units. These TCP flows coexist with background traffic consisting of CBR traffic and Poisson traffic, which is modeled using the UDP. This scenario creates a dynamic and diverse network environment by combining TCP flows with different rates and various types of background traffic, such as CBR and Poisson traffic. The primary objective of this scenario is to thoroughly evaluate and assess the adaptability of the proposed method under conditions of varying network loads and diverse traffic types. Scenario 2 explores the interplay between CBR and TCP dynamics, where TCP flows operating at rates of 21 are integrated with both CBR traffic and background Poisson traffic. The emphasis transitions towards evaluating the effectiveness of the suggested approach when contending with

clearly defined CBR traffic, contributing a heightened level of foreseeability to the network ambiance. This particular setting furnishes valuable observations regarding the method's proficiency in situations characterized by more predictable traffic arrangements. A tree topology governs data routing within the simulated network. The rationale behind this choice lies in its ability to capture a simplified representation of network structures, enabling controlled experimentation while providing a foundation for performance evaluation.

#### B. Results and Analysis

The proposed method's performance is evaluated under a network load with a mix of TCP flows, CBR traffic, and Poisson traffic in the first scenario. The goal is to assess how the algorithm adapts RTT adjustments to optimize network performance under diverse conditions. Fig. 3 and 4 illustrate the comparison of throughput and delay across multiple simulations. The results highlight the method's ability to maintain efficient data transfer despite varying traffic types and network load. The second scenario delves into the method's interaction with competing CBR traffic and effectiveness in a more deterministic setting. Fig. 5 and 6 show the throughput and delay comparisons. The method demonstrates its capability to achieve competitive performance under such conditions, albeit with varying degrees of effectiveness compared to scenario 1. The proposed method's performance is evaluated against different traffic types and rates in both scenarios. The nuanced results reflect the method's adaptability to diverse network conditions and the potential to optimize RTT adjustments effectively. The results underscore the method's potential to provide accurate RTT estimations and optimize data transmission despite varying network dynamics. As networking technologies evolve, our method's capacity to enhance RTT estimation remains relevant and valuable, contributing to optimizing data transfer mechanisms in the face of complex and diverse networking scenarios.

Our proposed method for RTT estimation through network tomography offers versatile, practical applications across diverse contexts. In real-time communication systems, such as telemedicine and remote surgery, where low latency is critical for seamless interactions, our method ensures accurate RTT estimation even in complex, multi-path networks. In IoT deployments, where devices often rely on efficient data exchange for timely decision-making, our approach enhances network reliability by precisely estimating RTT, leading to optimized device communication. Furthermore, in vehicular networks, where vehicles exchange safety-critical information, our method's adaptability to changing network conditions ensures reliable RTT estimation, contributing to safer road environments. In cloud computing environments, where data transfer efficiency impacts application performance, our method aids in precise RTT estimation, leading to enhanced user experiences. These use cases highlight the tangible benefits of our proposed scheme, underscoring its potential to revolutionize diverse industries by improving RTT estimation accuracy, network reliability, and overall performance.

Fig. 3. Comparison of the throughput in the first scenario.

Fig. 4. Comparison of the delay in the first scenario.

While our proposed method significantly enhances TCP's RTT estimation, it is essential to acknowledge that our approach primarily focuses on improving RTT accuracy and reducing congestion in the absence of packet corruption. In cases where packet corruption occurs during transmission, the TCP protocol is equipped with error detection mechanisms, such as checksums, to identify and request retransmission of corrupted packets. Our work primarily complements these

existing error detection and recovery mechanisms by providing more precise RTT estimations, which can lead to more efficient congestion control. However, in cases of severe packet corruption or loss, additional mechanisms at higher protocol layers, such as transport layer error correction codes or application-layer retransmission strategies, may be necessary to ensure data integrity and reliability.

Fig. 5. Comparison of the throughput in the second scenario.

Fig. 6. Comparison of the delay in the second scenario.

## V. CONCLUSION

Network tomography offers an invaluable method for analyzing a network's performance. To determine internal performance parameters, network tomography measures end-to-end performance, as opposed to methods that are based on internal communication. This method has the capability of estimating times in the event that it is necessary to evaluate a protocol's performance in a network by estimating times. The TCP protocol can be significantly improved by properly estimating the RTT time. The proposed method is a relatively flexible method that can be performed using different settings and conditions, and other formulas receive different results. The proposed method is a valuable mechanism for different

computer networks to estimate the rate of actual delay, which deals with network conditions and restrictions to ensure the quality of their service is targeted.

While our method significantly improves RTT estimation, it may not achieve absolute accuracy due to factors such as network variability and unforeseen delays. The sensitivity of our approach to rapid network dynamics necessitates periodic RTT updates, but it may not capture instantaneous changes. Moreover, computational complexities and resource requirements should be considered in resource-constrained environments. Real-world networking scenarios can introduce challenges beyond modeling capabilities, and the scope of our

empirical evaluations may not cover all possible conditions. These limitations provide valuable context for the application and interpretation of our research findings.

# Routing Strategies and Protocols for Efficient Data Transmission in the Internet of Vehicles: A Comprehensive Review

Yijun Xu\*

School of Automotive and Rail Transit, Nanjing Institute of Technology  
Nanjing, Jiangsu 211167, China

**Abstract**—The Internet of Vehicles (IoV) integrates wireless communication, vehicular technology, and the Internet to create intelligent transportation systems. Efficient routing of data packets within the IoV is crucial for seamless communication and service enablement. This paper provides a comprehensive review of routing strategies and protocols in the IoV environment, categorizing and evaluating existing approaches. Routing protocols are classified, their adaptability is assessed to network variations, and their performance is compared. Insights are drawn from researchers' experiences. The paper offers a taxonomy of routing protocols, highlights adaptability to network conditions, and presents a comparative analysis. Lessons from researchers shed light on practical implications. The review identifies key routing challenges in IoV and provides a valuable resource for understanding and addressing these challenges in future research.

**Keywords**—Internet of things; internet of vehicles; Vehicular Ad Hoc Networks (VANETs); routing; network adaptability; vehicular technology

## I. INTRODUCTION

The increasing number of users has led to a significant expansion of transportation systems in many countries [1]. However, these systems often suffer from inefficiency and high maintenance costs [2]. The global number of vehicles, including commercial and passenger vehicles, has slightly exceeded one billion, according to recent studies. Projections suggest that it will reach approximately two billion by 2035 [3]. In order to address these challenges, the development of Intelligent Transportation Systems (ITSs) aims to enhance traffic monitoring, road safety, and passenger comfort, ultimately reducing accidents [4]. Vehicular Ad hoc Networks (VANETs) are crucial in implementing intelligent transportation systems. VANETs enable real-time traffic information exchange between two modes of communication: Vehicle-to-Roadside (V2R) and Vehicle-to-Vehicle (V2V) [5]. By facilitating the transmission of warning messages and alerts, VANETs assist drivers in navigating through potential hazards [6]. The main goal of VANETs is to reduce travel time, cost, and pollutant emissions, which in turn enhances traffic safety and efficiency [7]. However, despite the potential benefits, modern vehicular networks face several challenges that must be addressed. Challenges are comprised of unstable internet service, personal devices' limited compatibility, commercialization restrictions, constrained processing capability, network architecture limitations, and no cloud

computing services [8]. Addressing these issues is crucial to harness the full potential of VANETs and to ensure the successful deployment of advanced vehicular networks. By overcoming these challenges, the development of intelligent transportation systems can significantly improve the efficiency, reliability, and overall performance of transportation systems worldwide [9].

Data transmission in the IoV is a critical aspect of modern transportation systems, relying on several innovative technologies to optimize operations and enhance efficiency. Smart grids play a fundamental role by intelligently managing the distribution of energy, enabling Electric Vehicles (EVs) to be a part of IoV seamlessly [10]. Machine learning and deep learning algorithms analyze vast amounts of data generated by vehicles, traffic signals, and urban infrastructure. They derive valuable insights, predicting traffic patterns, suggesting optimal routes, and facilitating efficient energy usage, thereby significantly improving IoV's functionality [11-13]. Artificial Intelligence (AI) acts as the backbone, integrating these technologies and enabling decision-making processes in real time. It enables automated responses to traffic conditions, mitigating congestion and enhancing safety [14-16]. Association rule mining, on the other hand, extracts hidden patterns and correlations from diverse data sources within IoV, revealing valuable information about vehicle behavior, urban mobility, and energy consumption patterns. This knowledge is vital for optimizing routes, managing energy resources, and improving overall transportation efficiency [17]. Urban public transportation is a vital component of IoV, providing sustainable, shared mobility options. Integrating IoV technologies into public transportation enhances services by predicting demand, optimizing schedules, and ensuring a smoother passenger experience. This synergy is paramount in addressing urban traffic challenges, reducing emissions, and transitioning towards smarter, sustainable cities [18].

The IoV network consists of distributed nodes, including vehicles, roadside units, and sensors, which enable local communication. This distributed system facilitates edge computing and the interaction between communication and computation [19]. Artificial Intelligence (AI) is crucial in accessing the IoV network. The IoV network collects information from roadside units and mobile applications, utilizing the bandwidth of the 5G mobile network to enhance internet communication [20]. IoV finds applications in traffic management systems and industrial settings. The future of IoV

research lies in leveraging big data algorithms to process data from IoT devices. It is an evolving field that attracts researchers' attention due to its relevance to human life. Routing protocols specific to the IoV environment are utilized, with SL-ZRP (Stable-Link State Zone Routing Protocol) being a significant communication protocol [21]. SL-ZRP is a function-based protocol that considers factors like speed, destination, and delay to determine optimal routes among vehicles, reducing network representation and overhead. The increasing number of road vehicles poses challenges such as accidents and associated expenses. IoV, originating from VANET, has been the subject of research for several years, addressing these issues. As people's lifestyles change, diverse requirements for vehicular networking have emerged, expanding the scale, structure, and applications of VANET. Large-scale and heterogeneous networks have been introduced, enabling services beyond safety information, including entertainment and environmental protection [22]. This paper proposes a routing protocol taxonomy and explores various IoV applications. This paper makes several significant contributions to the field of IoV:

- **Classification of routing protocols:** The paper provides a comprehensive classification of routing protocols specifically designed for the extreme and complex urban environment of IoV. This classification helps understand the different approaches and strategies employed by these protocols.
- **Adaptability to network density and throughput variation:** The paper recognizes the need for routing algorithms in IoV that can effectively handle low and high network densities while accommodating variations in throughput and delay. This highlights the importance of robust and adaptable routing solutions for the dynamic nature of vehicular networks.
- **Comparison of routing protocols:** The paper offers a comparative analysis of the various protocols in terms of their performance, scalability, reliability, and efficiency. This comparison assists in identifying the strengths and weaknesses of different protocols and aids in selecting the most suitable one for specific IoV scenarios.
- **Lessons learned from researchers:** The paper presents insights and lessons learned from researchers who have explored different challenges related to routing in IoV. This provides a deeper understanding of the practical implications and potential solutions for addressing the unique challenges faced in vehicular networks.

## II. BACKGROUND

### A. Internet of Vehicle

The Internet of Things (IoT) is an evolving technology that links the digital and physical worlds, allowing for communication between objects and humans [23]. This concept has revolutionized our daily lives, making communication more informative, processing more intelligent, and devices smarter [24]. With IoT, the vision of seamless and ubiquitous communication, anytime and anywhere, is

becoming a reality. IoT represents a significant transformation in our lifetime, following the universal accessibility of mobile devices and the world wide web [25]. IoT relies on key technologies such as short-range wireless communications, real-time localization, RFID, and sensor networks. These technologies enable various applications and research areas to flourish, particularly in smart transportation, smart industry, smart homes, and smart healthcare [26]. Integrating smartness in these areas has enhanced efficiency, convenience, and sustainability. Fig. 1 visually illustrates the diverse areas impacted by IoT, highlighting the interconnectedness of smart transportation, smart industry, smart homes, and smart healthcare. The widespread adoption of IoT transforms our environment into a smarter and more interconnected world, revolutionizing how we interact with objects and improving various aspects of our daily lives [27]. The Internet of Vehicles (IoV) is a concept that combines VANET and IoT technologies to establish connections between various devices within vehicles and smart infrastructure on roads [28]. This integration enables seamless communication and data exchange among these devices, leading to a comprehensive IoV-based system [29]. This system includes embedded processors, onboard units, vehicles, roadside units, fog and edge devices, and cloud servers [30]. In an IoV-based system, devices can sense and collect various types of data, such as environmental and traffic-related data. The collected data is then shared among the devices, allowing collaboration and information exchange [31].

Additionally, the data collected from IoV devices can be combined with other data sources, such as social media data, user-generated data, and open-source intelligence, to provide valuable insights for decision-making at different levels [32]. One practical application of IoV-based systems is providing real-time traffic-related information to residents. The system can generate and disseminate up-to-date traffic information by utilizing the data collected from vehicles and roadside units, helping individuals make informed decisions about their routes and travel plans [33].

Fig. 1. Diverse areas impacted by IoT.

The IoV is increasingly implemented in urban areas to provide network access to drivers, people, and traffic management personnel. As the transportation system expands, it becomes more challenging and costly to maintain [34]. According to recent reports, the usage of IoV is widespread globally, and it is projected to have over three billion users by 2030. The increased number of vehicles has resulted in traffic congestion and a higher incidence of accidents [35]. To address these issues, IoV is being utilized in urban areas to improve traffic safety. Routing is a crucial aspect of IoV and is vital in daily life. It involves selecting the most optimal path for traffic networks or across multiple networks, considering the dynamic changes in topology [36]. IoV systems detect shortcomings and analyze data to make informed decisions for driving vehicles. Intelligent devices equipped with embedded processors and wireless technologies are utilized in IoV to facilitate vehicle communication [37]. By leveraging various forms of communication, such as device-to-device and machine-to-machine, IoV environments aim to enhance traffic safety in urban areas. Integrating IoV in urban settings aims to reduce traffic accidents by leveraging intelligent technologies and efficient communication. Through real-time data analysis and decision-making processes, IoV systems contribute to improving overall transportation efficiency and enhancing road safety [38].

Incorporating advanced communication and information technology, IoV brings several advantages in resolving traffic and driving challenges, leading to increased passenger safety and a superior driving experience. The communication components of IoV can be categorized into three main types: vehicular mobile Internet, inter-vehicular communication, and intra-vehicular communication [39]. As a heterogeneous vehicular network, IoV involves communication across five different types: Vehicle-to-Infrastructure (V2I), Vehicle-to-Sensors (V2S), Vehicle-to-Personal devices (V2P), Vehicle-to-Vehicle (V2V), and V2R, as illustrated in Fig. 2 [40]. To

facilitate efficient communication in IoV, various wireless technologies are employed. These include vehicular communications such as Dedicated Short-Range Communications (DSRC) and Cellular Automata for Local Mobility (CALM), cellular mobile communication technologies like 4G/LTE, WiMax, and Satellite communication, as well as short-range static communication technologies like Zigbee, Bluetooth, and Wi-Fi [41]. The classification of these wireless communication technologies for IoV applications is depicted in Fig. 3. Fig. 4 provides a general overview of the structure of IoV, illustrating the interconnectedness and communication flow among vehicles, roadside units, sensors, and other components of the IoV ecosystem. This structure forms the foundation for efficiently exchanging information and data within the IoV network.

Fig. 2. Communications in IoV.

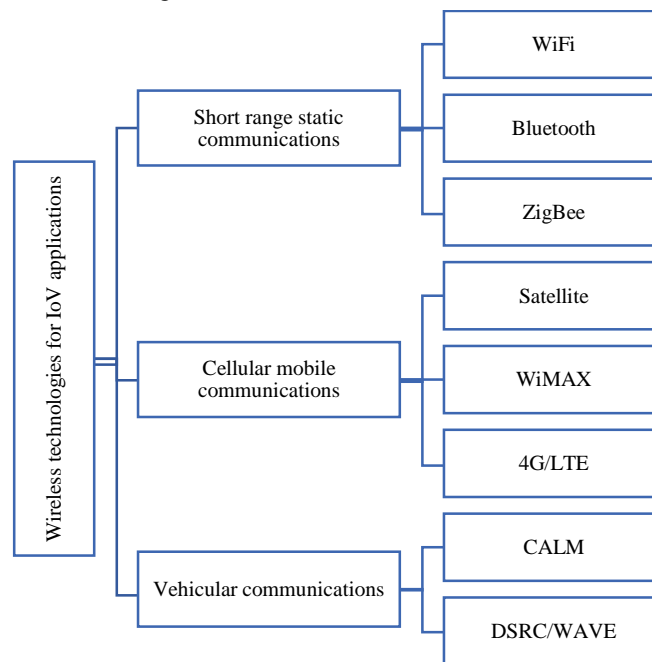

Fig. 3. Wireless communication technologies for IoV applications.

Fig. 4. A general overview of IoV.

The architecture of IoV is structured into four layers: the environment sensing and control layer, application layer, network access and transport layer, and coordinative computing control layer.

- Environment sensing and control layer: This layer plays a crucial role in implementing IoV services by focusing on vehicle control and the traffic environment. It involves sensing and gathering information from the vehicle's perspective and the surrounding environment. Vehicles utilize sensing technology to collect data about the environment, humans, and other vehicles to prevent accidents. Swarm sensing techniques gather dynamic information about the environment and facilitate cooperative decision-making.
- Network access and transport layer: Node management, data processing, remote monitoring, and data analysis are the main tasks in this layer. The IoV network provides every vehicle with diverse network access while taking into account network load constraints. The layer ensures efficient data transmission and handles the transportation of information between vehicles and infrastructure.
- Coordinative computing layer: This layer focuses on coordination within the IoV environment. It supports the interaction of cognitive computing capabilities and swarm intelligent coordinative computing capabilities. The coordinative computing layer facilitates data processing, resource allocation, and decision-making processes within the IoV system.
- Application layer: The application layer offers two types of services: closed and open services. Closed services are specific applications like control platforms and traffic command systems. Open services, provided by numerous internet service providers, include real-time traffic services and must support a suitable business model. Additionally, the application layer enables third-party providers to access open service capabilities, expanding the range of services available within the IoV ecosystem.

#### B. IoV vs. VANET

IoV, an advanced concept that combines VANETs and IoT, aims to enhance the capabilities of VANETs and strengthen ITS. While IoV and VANET technologies aim to improve driving experiences and reduce accidents, several parameters differentiate the two networks. These parameters include their goals, communication types, compatibility, range of usage, processing competence, market attention, network specifications, availability of internet facilities, data size, network connectivity, decision-making processes, the utility of applications, and network awareness [42]. VANETs primarily aim to enhance traffic safety and reduce travel time, costs, and pollutant emissions. However, it lacks entertainment features for passengers, leading to commercialization challenges [43].

On the other hand, IoV technology has broader goals, including improving traffic safety and efficiency and offering commercial infotainment services. IoV's entertainment provides passengers access to online video streaming, movies, file downloading, and other services, thus enhancing their

overall experience. VANETs support two types of communication: V2I and V2V communication [44].

In contrast, IoV enables five types of communication: V2V, V2R, V2I, V2S, and V2P. Each communication type relies on different wireless technologies to exchange information. While individuals widely use personal devices like smartphones, laptops, and tablets, they face compatibility issues within VANETs due to incompatible network architectures [45]. As a result, personal devices cannot effectively communicate information with other nodes in VANETs. In contrast, IoV addresses this compatibility issue, enabling personal devices to efficiently disseminate information among other nodes in the event of hazards, fostering an interactive environment.

The range of usage in VANETs is limited to local and discrete applications, such as providing alerts to drivers about road incidents or avoiding collisions. The nodes in VANETs, which are vehicles, are temporary, random, and unstable, leading to lower scalability compared to IoV [46]. In contrast, IoV offers a global scope and sustainable applications/services by incorporating intelligent vehicular networks with computing and communication capabilities [47]. This enables intelligent networking among vehicles on a larger scale. VANETs face resource constraints regarding computation and processing capacity, as they primarily handle local information collected by sensors in the surrounding environment [48].

In contrast, IoV can handle global information, including big data [49]. Processing and analyzing data in real-time without any delays is crucial. Intelligent computing platforms like cloud computing, fog computing, and edge computing are utilized in IoV for efficient big data analytics and faster processing. VANETs have not achieved the desired commercialization over the years for various reasons, including unreliable internet connectivity, incompatibility with personal devices, and limitations in local processing capabilities. As a result, VANETs have not received significant market attention, and their usage has stagnated. On the other hand, IoV has experienced substantial research advancements and commercial interest. It benefits from reliable internet connectivity, compatibility with personal devices, and the rapid evolution of communication and computation technologies.

VANETs have a singleton network architecture, which limits their usage by not collaborating with other existing networks [50]. This lack of collaboration restricts their connectivity and functionality. In contrast, IoV utilizes a heterogeneous vehicular network framework that enables collaborative networking [51]. IoV incorporates five different types of communications, including WAVE, Wi-Fi, 4G/LTE, and satellite networks, which enhance the flexibility and connectivity of the architecture. Internet connectivity is a fundamental requirement in modern production environments. VANETs face challenges in extending internet connectivity, as roadside infrastructure may be scarce or not fully networked in certain areas.

On the other hand, IoV enables vehicles to connect to the Internet at any time, providing Internet services to all nodes. Faster and reliable internet services in IoV facilitate the implementation of an IoV environment with low latency, high reliability, and increased bandwidth. In terms of data, VANETs

rely on limited local information for decision-making and lack collaboration with global data sources. In contrast, IoV is built on big data principles, as it generates a vast amount of real-time data regarding vehicle information. Additionally, the collaboration among various heterogeneous networks in IoV contributes to accumulating diverse data sources.

Vehicles in VANETs experience frequent disconnections from the ad-hoc network, resulting in a loss of network services. This is primarily due to the non-collaboration with other reachable networks and the pure ad-hoc network architecture. In contrast, vehicles in IoV remain connected to the best available network at all times, enabling efficient communication. IoV can easily collaborate with other reachable networks in case of any issues with the current network. In VANETs, the architecture imposes limitations on storage and computing, making it challenging to make intelligent decisions based on big data mining computations.

On the other hand, IoV architectures leverage Artificial Intelligence-based big data and data mining computations for decision-making. Due to the network disconnection issue in VANETs, the availability of ITS (Intelligent Transportation Systems) applications cannot be guaranteed. In IoV, ITS services are reliable and efficient due to using a client-server architecture with internet connectivity. In VANETs, network services and applications, such as safety messages, require exchanging event location and vehicle information. However, network awareness is limited to neighborhood awareness, as obstacles hinder the proper exchange of information. Additionally, vehicle processing and storage constraints contribute to reduced network awareness. In IoV, incorporating big data technologies like cloud computing and fog computing enhances the network's performance, allowing global network awareness.

### III. CLASSIFICATION OF IOV ROUTING PROTOCOLS

The routing protocols in IoV pose a significant challenge. While many routing protocols, such as DSDV, DSR, and AODV, are adapted from MANET, this article discusses specific geographical routing protocols like GPSR and GPCR. These routing protocols are classified based on their transmission strategies. Location-based routing protocols in IoV can be categorized into four types: hierarchical, geographic, broadcast, and geocast. Among these, geographical protocols are divided into unicast, broadcast, and geocast. The transmission strategy adopted classifies the routing protocols into unicast, geocast, and broadcast categories.

#### A. Transmission Strategy

The transmission strategy in routing protocols for IoV can be classified into three types: unicast routing protocol, geocast routing protocol, and broadcast routing protocol. Unicast routing protocol aims to transmit data from a single source to a single destination using a multi-hop technique through greedy forwarding. Intermediate vehicles can relay the data along a specific routing path from the source to the destination. The routing algorithm determines the forwarding decisions based on specific routing protocol characteristics. Unicast routing protocols can be further categorized based on the information they use into four types: topology-based, position-based, map-

based, and path-based routing protocols. Fig. 5 illustrates the routing strategy and different routing protocols in IoV. The primary objective of geocast routing protocol is to transmit data from a single source node to all destination nodes within a specific geographical region called the Zone of Relevance. It employs a multicast service known as location-based multicast routing. Geocast routing is particularly useful for many VANET applications. Vehicles in the network receive and drop packets based on their current location. Traffic lights can help

implement geocast routing. The broadcast routing protocol is commonly used for sharing information, such as traffic updates, weather emergencies, road conditions, advertisements, and announcements among vehicles. It is also used with unicast routing protocols to discover routes to destinations. Dissemination protocol for heterogeneous vehicular cooperative networks (DHVN) is an example of a broadcast routing protocol. Broadcast routing protocols rely on road topology and network connectivity to function effectively.

Fig. 5. Taxonomy of routing protocols in IoV.

### B. Information Required

Based on the information required, routing protocols in IoV can be classified into four types:

**Topology-based Routing:** Topology-based routing protocols utilize information about the network's underlying structure, such as the connectivity and topology of the vehicles or infrastructure nodes. These protocols make routing decisions based on the network's topology, including the links between nodes and their quality metrics. Examples of topology-based routing protocols include DSDV (Destination-Sequenced Distance Vector) and OLSR (Optimized Link State Routing). Position-based routing protocols rely on the location information of the vehicles or nodes to make routing decisions. Each vehicle determines its position using GPS or other localization techniques and includes this information in the routing process. Protocols like GPSR (Greedy Perimeter Stateless Routing) and GPCR (Geographic Position-based Routing) fall into the category of position-based routing.

Map-based routing protocols utilize detailed road network maps to make routing decisions. These protocols consider the geographical layout and attributes of the road network, such as road segments, intersections, and traffic conditions. Map data

is used to determine the optimal path for data transmission. Map-based routing protocols are commonly used in navigation and route planning applications. Path-based routing protocols focus on identifying specific paths or routes for data transmission. These protocols use predefined paths or routes, which can be determined based on factors like road conditions, traffic patterns, or specific requirements of the application. Path-based routing allows for more controlled and predetermined data routing. Examples of path-based routing protocols include AODV (Ad hoc On-Demand Distance Vector) and DSR (Dynamic Source Routing).

### C. Scenarios Routing

In addition to the mentioned protocols, there are several other routing protocols in the context of IoV, namely, vehicular routing protocol, Delay Tolerant Routing Protocol (DTN), and Disrupted Adaptive Routing (DAR). Table I shows the classification of IOV routing protocols. Vehicular routing protocol focuses on exchanging road information among vehicles to enable efficient routing. It utilizes techniques like ant colony optimization, where vehicles act as ants to find the optimal path based on local information and pheromone trails left by other vehicles. DTN is designed to handle intermittent or disrupted connectivity in the network. It employs a carry-

forward mechanism, where intermediate nodes store and forward data until a suitable connection becomes available for transmission. DAR is a routing protocol that aims to reduce network congestion and improve overall performance compared to traditional routing protocols. It achieves this by dynamically adapting the routing paths based on network conditions, thereby reducing transmission delays and improving packet delivery.

In IoV networks, routing scenarios are divided into three types: 1D, 2D, and 3D. 1D scenarios involve vehicles moving in a linear direction, such as on a highway or a single-lane road. Routing protocols are designed to facilitate efficient data transmission along this one-dimensional path. In 2D scenarios, vehicles can move in a two-dimensional space, such as urban or suburban areas with multiple lanes and intersections. Routing protocols consider the spatial relationships and connectivity between vehicles in these environments. 3D scenarios involve routing in complex environments where vehicles can move in three dimensions, such as in aerial or underwater vehicular networks. Routing protocols in these scenarios need to account for the specific challenges and characteristics of the respective environments.

#### D. Network Types

Routing is feasible in both homogeneous and heterogeneous networks within the IoV framework. In a

homogeneous network, vehicles and network elements have comparable characteristics and capabilities. The routing protocols for homogeneous networks assume that vehicles have similar communication ranges, transmission capabilities, and network behaviors. Examples of homogeneous networks in IoV include all vehicles equipped with the same communication technology (e.g., all vehicles use Wi-Fi or DSRC for communication). In a heterogeneous network, vehicles and network elements may have different characteristics, capabilities, and communication technologies. Heterogeneous networks in IoV may involve vehicles with different communication ranges, transmission powers, and technologies (e.g., a mix of vehicles using Wi-Fi, cellular networks, or satellite communication). Routing protocols for heterogeneous networks must consider these differences and ensure effective communication and data exchange among vehicles with diverse capabilities.

Routing protocols in homogeneous and heterogeneous networks aim to find the most efficient paths for data transmission, considering factors like network congestion, connectivity, data reliability, and quality of service requirements. The specific design and implementation of routing protocols may vary depending on the characteristics and objectives of the network. Still, the overall goal remains the same: to establish reliable and optimal routes for data transmission in IoV networks.

TABLE I. CLASSIFICATION OF IOV ROUTING PROTOCOLS

Routing protocol type	Information required	Scenarios routing	Network types	Strengths	Examples
Unicast routing	Topology-based	1D and 2D	Homogeneous	Reliable point-to-point communication	DSDV and AODV
	Position-based	1D and 2D	Homogeneous	Efficient use of position information	DSDV and AODV
	Map-based	1D and 2D	Homogeneous	Utilizes detailed road network maps	DSDV and AODV
	Path-based	1D and 2D	Homogeneous	Offers predetermined data routing	DSDV and AODV
Geocast routing	Position-based	2D	Heterogeneous	Efficient data transmission within a specific geographical region	GPSR and GPCR
Broadcast routing	Topology-based	1D and 2D	Homogeneous	Effective for sharing information among vehicles	DHVN
	Map-based	1D and 2D	Homogeneous	Utilizes road network attributes	DHVN
	Path-based	1D and 2D	Homogeneous	Provides controlled data routing	DHVN
Vehicular Routing	Various	Various	Various	Utilizes intelligent algorithms like ant colony optimization	Ant Colony, DTN, and DAR

#### IV. DISCUSSION

In this section, we provide a detailed discussion of the findings and insights gained from the classification of IoV routing protocols. Our comprehensive classification of IoV routing protocols offers a structured approach to categorizing and understanding the diverse strategies employed in vehicular networks. By grouping protocols into three main categories based on their transmission strategies (unicast, geocast, and broadcast), we facilitate a clearer view of their roles and functionalities. This classification provides researchers and practitioners with a valuable roadmap for selecting the most suitable routing protocols for specific IoV scenarios. Unicast routing protocols offer reliable point-to-point communication within IoV networks. Their strengths lie in efficient position-based routing, the utilization of detailed road network maps,

and the ability to provide predetermined data routing. These characteristics make them suitable for various IoV scenarios. Through multi-hop forwarding, intermediate vehicles can relay data, facilitating communication even when the destination is not in the direct transmission range of the source. Unicast protocols are adaptable and can be further categorized based on the information they use, such as topology-based, position-based, map-based, and path-based routing protocols. This flexibility allows for protocol selection that best suits the specific requirements of IoV scenarios. However, these protocols have their limitations. They may face challenges related to network congestion in scenarios with a high density of vehicles. Moreover, data reliability and latency can become concerns in scenarios with dynamic network conditions, necessitating the development of more robust routing algorithms.

Geocast routing protocols are specifically designed to transmit data from a single source to all destination nodes within a predefined geographical region known as the Zone of Relevance. Their strength lies in efficiently disseminating information to a targeted area, making them particularly useful for many vehicular applications. Geocast protocols leverage location-based multicast routing, where vehicles within the designated zone receive and process packets based on their current location. This approach ensures that only vehicles within the relevant geographical area receive the data, reducing unnecessary network traffic. However, geocast protocols have limitations concerning the definition and management of these geographical zones. The accuracy of defining such regions and handling scenarios with overlapping or rapidly changing zones can pose challenges.

Broadcast routing protocols play a crucial role in sharing real-time information among vehicles. Their strength lies in their ability to quickly disseminate critical updates, such as traffic conditions, weather emergencies, or road incidents, to a wide audience of vehicles. Broadcast protocols are often used in conjunction with unicast routing protocols to discover routes to destinations. However, they also have limitations. Broadcasting can lead to network congestion, especially in densely populated areas, where a large number of vehicles simultaneously receive and process broadcast messages. To mitigate this, efficient mechanisms for broadcast suppression and congestion control are necessary. Moreover, ensuring data reliability and minimizing redundant data reception are ongoing challenges in broadcast routing, as data packets may be received by vehicles multiple times.

Configuring routing protocols in the context of the IoV involves a range of parameters that influence how data is routed and communicated within the network. The choice of the routing algorithm is fundamental. IoV can employ various routing protocols, including proactive (table-driven) like OLSR or reactive (on-demand) like AODV. The selection depends on factors like network size, mobility, and application requirements. Parameters related to the network's physical layout, including the number of vehicles, their initial positions, and the road infrastructure, play a significant role. Realistic network topologies are essential for accurate simulations. The communication range of IoV devices, often determined by the technology used (e.g., DSRC, Wi-Fi, cellular), is crucial. It affects how far vehicles can communicate with each other and with roadside infrastructure. Some routing protocols allow for configuring transmission power levels. Adjusting transmission power affects the range at which a vehicle can communicate, influencing network coverage and energy consumption. Parameters related to packet generation, including packet size and transmission rate, can vary depending on the type of data being exchanged. Larger packets or higher transmission rates may require different routing strategies.

Different mobility models, such as Random Waypoint, Gauss-Markov, or real-world traffic data, can be used to simulate vehicle movements. The choice of mobility model affects how vehicles move and interact within the network. In wireless communication, propagation models define how signals propagate through the environment. These models consider factors like path loss, shadowing, and fading,

impacting signal strength and reliability. Parameters related to traffic patterns, such as the type of data generated (e.g., safety messages, multimedia), traffic density, and source-destination pairs, are essential for evaluating routing performance. If the IoV application demands specific QoS, parameters related to latency, jitter, and reliability thresholds may be configured to ensure that routing decisions meet these requirements. Routing protocols in IoV often include security features. Parameters for encryption, authentication, and key management may need configuration to ensure secure communication. Factors like vehicle speed, acceleration, and braking characteristics can be modeled as parameters. These parameters influence how vehicles move and interact in the network. The length of the simulation or data collection period can impact the stability and convergence of routing protocols. Longer simulations may be needed to observe certain network behaviors.

## V. FUTURE RESEARCH DIRECTIONS

- **Standardization and interoperability:** Standardization efforts are crucial to ensure widespread adoption and interoperability of routing algorithms in the IoV. Future research should focus on developing standardized routing protocols and interfaces that enable seamless communication across different vehicular networks and technologies.
- **Blockchain-enabled routing:** Blockchain technology offers decentralized, transparent, and tamper-resistant data management. Integrating blockchain into routing algorithms can enhance trust, security, and privacy in the IoV. Future research should explore the application of blockchain-enabled routing algorithms that can provide secure and reliable communication among vehicles and infrastructure.
- **Machine learning-based routing:** Machine learning techniques have shown promise in various domains. Applying machine learning algorithms to routing in the IoV can enable proactive decision-making, traffic prediction, and congestion control. Future research should investigate the use of machine learning-based routing algorithms that can adapt and learn from network dynamics to optimize routing decisions.
- **Edge computing and intelligent routing:** With the proliferation of edge computing in the IoV, there is an opportunity to leverage edge resources for intelligent routing. Future research should explore intelligent routing algorithms that can utilize edge computing capabilities, such as real-time data processing, decision-making, and resource optimization, to improve routing efficiency and responsiveness.
- **Quality of Service (QoS):** The IoV requires different communication services with varying QoS requirements. Routing algorithms should be able to provide differentiated services based on application-specific QoS metrics, such as latency, reliability, and throughput. Future research should investigate QoS-aware routing algorithms that can efficiently handle diverse application requirements.

- **Security and privacy:** Security and privacy are critical concerns in vehicular networks. Routing algorithms should incorporate robust security mechanisms to protect against attacks and ensure data confidentiality, integrity, and availability. Future research should focus on developing secure routing protocols and privacy-preserving techniques to mitigate threats and protect user privacy effectively.
- **Resilience to attacks:** Vehicular networks are susceptible to jamming, spoofing, and Sybil attacks. Routing algorithms should be resilient to such attacks and capable of detecting and mitigating them. Future research should explore routing algorithms that can enhance the network's resilience and ensure reliable communication in the presence of malicious entities.
- **Scalability:** As the number of connected vehicles increases, scalability becomes a major challenge. Designing routing algorithms that can efficiently handle large-scale networks is crucial. Future research should focus on developing scalable routing schemes that effectively handle increasing vehicles and data traffic.
- **Dynamic network conditions:** Vehicular networks are characterized by high mobility, intermittent connectivity, and dynamic network topologies. Routing algorithms must adapt to these conditions to ensure reliable and efficient communication. Future research should explore adaptive routing algorithms that dynamically adjust routing paths based on the current network state.
- **Energy efficiency:** Vehicles in the IoV are typically resource-constrained, especially in terms of energy. Routing algorithms should consider energy consumption and aim to minimize energy expenditure. Future research should focus on energy-aware routing algorithms that optimize energy consumption while maintaining reliable communication.
- **Integration with smart city infrastructure:** The IoV is closely linked to the concept of smart cities. Routing algorithms should be designed to integrate with existing smart city infrastructure, such as traffic management systems, intelligent transportation systems, and urban sensing networks. Future research should explore routing algorithms that can seamlessly integrate with smart city infrastructure to enable efficient and sustainable urban mobility.
- **Traffic load balancing:** In congested scenarios, routing algorithms should distribute traffic load evenly across the network to prevent congestion and ensure efficient resource utilization. Future research should focus on load-balancing routing algorithms that intelligently distribute traffic and optimize network performance.
- **Vehicular cloud computing:** Integrating cloud computing with vehicular networks offers opportunities for offloading computation and storage tasks to the cloud. Routing algorithms should consider the availability and utilization of cloud resources to optimize communication and resource allocation. Future research should explore routing algorithms that leverage vehicular cloud computing for enhanced scalability, resource management, and application performance.
- **Cross-layer optimization:** Traditional layered network architectures may not be suitable for the dynamic and resource-constrained IoV environment. To improve routing performance, cross-layer optimization techniques can leverage interactions between different layers (e.g., physical, MAC, and network). Future research should investigate cross-layer routing algorithms that optimize communication efficiency, reliability, and resource utilization.
- **Robustness to mobility:** Vehicles in the IoV are highly mobile, resulting in frequent topology changes and link disruptions. Routing algorithms should be robust to mobility-induced challenges and maintain connectivity even in highly dynamic environments. Future research should explore mobility-aware routing algorithms that can adapt to vehicle movements and ensure seamless communication.
- **Cooperative communication and collaboration:** Cooperative communication among vehicles and infrastructure can improve routing efficiency, reliability, and safety in the IoV. Research should focus on cooperative routing algorithms that enable vehicles to collaborate, exchange information, and assist each other in routing decisions, leading to enhanced network performance.
- **Context-aware routing:** The IoV is rich in contextual information, including vehicle positions, speeds, traffic conditions, and environmental factors. Incorporating context awareness into routing algorithms can optimize route selection based on the current context and improve overall network performance. Future research should explore context-aware routing algorithms that leverage contextual information for intelligent and adaptive routing decisions.
- **Multi-hop communication:** In the IoV, vehicles may need to rely on multi-hop communication to reach distant destinations or overcome connectivity gaps. Research should focus on developing efficient multi-hop routing algorithms that can optimize message forwarding and ensure reliable end-to-end communication.
- **Heterogeneous network integration:** The IoV encompasses various communication technologies, such as cellular networks, dedicated short-range communication (DSRC), and Wi-Fi. Integrating these heterogeneous networks poses challenges in terms of routing and seamless handover. Future research should explore routing algorithms that effectively integrate and manage heterogeneous networks to provide uninterrupted connectivity.

- Real-time traffic management: Routing algorithms in the IoV should consider real-time traffic information to make informed routing decisions. Future research should explore integrating real-time traffic data, such as congestion and traffic flow information, into routing algorithms to enable efficient traffic management and avoidance.

## VI. CONCLUSION

The IoV is a transformative technology that enables autonomous driving scenarios by connecting people, intelligent vehicle systems, and cyber-physical systems in urban environments. It has attracted significant commercial and research attention due to advancements in computation and communication technologies, such as edge computing, grid computing, parallel processing, big data analysis, web semantics, and artificial intelligence. The IoV network employs protocols like position, map, and path-based to enable intelligent applications related to road conditions, vehicle preemption, and information services. Maintaining routes in the dynamic IoV network, particularly in homogeneous networks like VANETs, presents challenges due to mobile node behavior. To address this, the IoV network is categorized into 1D, 2D, and 3D scenarios, with Plane-based routing focusing on the latter. However, plane-based routing has limitations in real-world scenarios due to the absence of the third dimension. The IoV network is further divided into homogeneous and heterogeneous networks to optimize vehicle utilization, offering the potential for future development. The paper emphasizes the IoV network's layered architecture, communication, data analysis, and recent challenges, providing valuable insights for researchers and industries. It acknowledges including traditional VANETs and large-scale heterogeneous network structures within the IoV network.

This study has certain limitations that provide opportunities for future research. Firstly, our classification and analysis of IoV routing protocols are primarily based on a theoretical framework. While this provides a structured understanding of these protocols, practical evaluations through extensive simulations and real-world experiments are necessary to validate their performance under varying network conditions. Secondly, the study focuses on existing IoV routing protocols but does not explore the development of novel routing solutions tailored to emerging IoV challenges, such as autonomous vehicles, the integration of 5G, and the proliferation of IoT devices in urban environments. Future research could delve into the design and evaluation of innovative routing protocols that effectively address these evolving demands. Moreover, the security aspects of IoV routing, including privacy preservation and protection against cyberattacks, remain a critical concern. Investigating the integration of robust security measures into routing protocols is essential for ensuring the integrity and confidentiality of data in vehicular networks. Lastly, the study primarily addresses routing at the network layer, and future work could explore the interactions between routing protocols and higher-layer applications, such as traffic management and autonomous vehicle coordination. These areas represent promising avenues for enhancing the efficiency, safety, and overall performance of IoV networks.

# Design and Implementation Submarine Cable Object Detection YOLOv4 based with Graphical User Interface (GUI) for Remotely Operated Vehicle (ROV)

Fikri Arif Wicaksana, Eueung Mulyana, Syarif Hidayat, Rahadian Yusuf  
School of Electrical Engineering and Informatics, Institut Teknologi Bandung, Bandung, Indonesia

**Abstract**—The use of submarine cables as underwater transmission channels for distributing electrical energy in Indonesian waters is crucial. However, the detection and maintenance of submarine cables still heavily rely on human observation, leading to limitations in time and subjective interpretations. This research aims to design and implement an underwater object detection system based on YOLOv4 integrated with a Graphical User Interface (GUI) on a Remotely Operated Vehicle (ROV) for submarine cable detection. The YOLOv4 model was trained using a balanced dataset, achieving performance with precision of 0.89, recall of 0.85, and f1-score of 0.87. Detection of Good Condition (SC-Good-Condition) achieved an Average Precision (AP) of 97.62%, while Bad Condition detection (SC-Bad-Condition) had an AP of 87.54%, resulting in an overall mAP of 92.58%. The implemented GUI successfully detected submarine cables in two test videos with FPS rates of 0.178 and 0.083. The designed underwater object detection system using YOLOv4 and GUI on ROV demonstrated satisfactory performance in detecting submarine cables. However, further efforts are needed to improve the GUI's FPS to make it more responsive and efficient. This research contributes to the development of underwater detection technology that supports environmental observation and electrical energy distribution in Indonesian waters.

**Keywords**—Submarine cable; object detection; GUI; ROV; YOLOv4

## I. INTRODUCTION

Electricity is a fundamental and crucial necessity for the livelihood of Indonesian society. As Indonesia's economic growth and population continue to expand, the demand for electricity increases. Furthermore, being an archipelagic nation with 17,504 islands, almost all activities in both rural and urban areas of Indonesia require electricity. Therefore, there is a need for a transmission medium that can distribute electricity from one island to another. Submarine cables are underwater transmission channels that can distribute electricity between Indonesian islands [1]. However, in practice, submarine cables require periodic maintenance to ensure their optimal condition. One stage in the process of maintaining submarine cables is underwater inspection to observe the surrounding environment of the cables.

A Remotely Operated Vehicle (ROV) is an underwater robot that can be controlled remotely [2]. Some ROVs are

equipped with computer vision technology-enabled cameras for underwater inspection purposes, including maintenance and observation in the vicinity of submarine cables [3]. Typically, the process of detecting submarine cables is visually performed by ROV operators who oversee the video feed from the camera mounted on the ROV. However, this approach has some limitations, such as dependency on human observation, which is susceptible to fatigue and time constraints, as well as subjective interpretation in identifying submarine cables [4].

To address these limitations, automated object detection techniques have been developed, including underwater object detection. One method that has shown good performance is YOLOv4 (You Only Look Once version 4), which enables fast and accurate object detection [5]-[7].

Additionally, implementing a Graphical User Interface (GUI) on the ROV can provide an intuitive and user-friendly interface for operators, facilitating cable observation and detection with higher efficiency [8]. However, despite several studies on underwater object detection using YOLOv4 and research on GUI implementation on ROVs, research specifically combining both aspects in the context of submarine cable detection is still limited.

Therefore, this research aims to fill this knowledge gap by designing and implementing an underwater object detection system based on YOLOv4, integrated with a GUI on the ROV, particularly in the context of submarine cable detection. This study is expected to enhance the effectiveness and efficiency of submarine cable detection more accurately and efficiently.

Several prior studies have explored submarine cable detection using various methods, including both Deep Learning and non-Deep Learning approaches, yielding reasonably accurate results.

One previous study employed CNN and YOLO model (YOLOv3) for submarine cable detection but lacked a desktop GUI application. The results were as follows: for the original image dataset, it achieved an Average Precision (AP) of 98.14%, an F1 Score of 95.79%, and an Average Time of 0.416 seconds. Meanwhile, after dataset enhancement, it achieved an AP of 98.95%, an F1 Score of 96.92%, and an Average Time of 0.452 seconds [9].

Another research used edge detection methods to detect submarine cables, utilizing the Hough Transform model. This study developed software for ROVs equipped with cameras for cable detection. It reported successful submarine cable detection using 100 scenes, resulting in 83 correct detections, 17 false detections, and a recognition rate of 83% in the first experiment. In the second experiment, out of 100 scenes, it achieved 98 correct detections, 2 false detections, and a recognition rate of 98% [10][11].

This research focuses on submarine cable detection using the more recent CNN model YOLOv4, enhanced by the inclusion of a GUI for computer vision on the ROV. This integration of YOLOv4 and GUI aims to improve the quality of ROV-acquired computer vision data compared to previous studies, providing a more advanced and comprehensive approach to submarine cable detection.

In line with the outlined objectives, this paper is organized as follows. Section I begins with an exploration of the background of the research, emphasizing the vital role of electricity in Indonesian nation, the challenges posed by its archipelagic nature, and the need for advanced techniques in submarine cable detection. It further elucidates the specific goals and contributions of this research, aiming to bridge the existing gap in the integration of YOLOv4-based object detection and GUI on ROVs for submarine cable detection. Moreover, this section provides a concise review of prior research endeavors related to underwater object detection, ROV applications, and GUI implementations in the marine domain.

Section II delves into the research design, detailing the methodologies, equipment, and procedures employed in developing the underwater object detection system using YOLOv4 and integrating it with the ROV's GUI. It sheds light on the technical aspects and considerations pivotal to the success of this innovative system.

Section III is dedicated to presenting the experimental findings and their subsequent analysis. The section elucidates the outcomes of deploying the YOLOv4-based system and GUI on the ROV during underwater cable inspections. It discusses performance metrics and GUI functionality test.

Section IV, we synthesize the findings into comprehensive conclusions and offer recommendations for future research in this field. We reflect on the implications of our work on the broader context of submarine cable maintenance and its potential contributions to the sustainability and efficiency of Indonesia's electricity distribution network. Furthermore, we suggest avenues for further research and improvements to enhance the capabilities of the integrated system, ensuring its continued effectiveness in the evolving landscape of underwater cable detection.

## II. RESEARCH DESIGN

### A. Research Stages

There are several steps carried out in this research, as shown in Figure 1.

Fig. 1. Research stages.

- **Literature Review:** Conducting a comprehensive literature review on underwater object detection methods and techniques, the YOLOv4 approach, GUI utilization on ROVs, and related submarine cable research to understand the foundational theories and related studies.
- **GUI Design:** Designing and developing the Graphical User Interface (GUI) using PyQt (Python QML) library to enable interaction between the ROV operator and the YOLOv4-based underwater object detection system.
- **Data Collection:** Gathering the necessary image data for training and testing the submarine cable detection model. The image data used in this research was obtained from underwater inspection videos conducted by PT Syergie Indoprima in the year 2022.
- **Data Splitting:** Dividing the image data into two classes: SC-Good-Condition (good cable condition) and SC-Bad-Condition (bad cable condition). The entire image data will be divided into two subsets, with 80% of the data used for model training and 20% for model testing, both for imbalanced and balanced datasets.
- **Data Annotation and Training:** Annotating the image data with appropriate labels, i.e., SC-Good-Condition or SC-Bad-Condition, indicating the condition of the submarine cable in each image. Next, training the underwater object detection model using YOLOv4 with the annotated image data.
- **Performing Cross-Validation:** Conducting cross-validation on the trained model to measure its performance and accuracy in detecting submarine cables. The data is divided into 5 subsets (folds), and the model training and testing will be repeated on each fold to obtain more reliable results.
- **Model Performance Evaluation and Analysis with Confusion Matrix:** Using the cross-validation results, a confusion matrix is created to depict the overall model performance. The confusion matrix provides information on the number of true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN) in detecting submarine cables. Through the confusion matrix, the model's performance is analyzed and evaluated, including calculation of evaluation metrics such as precision, recall, and F1-score, to gain a deeper understanding of the model's ability to detect submarine cable conditions.

- **Model Implementation into GUI:** The trained and evaluated underwater object detection model is then implemented into the previously designed GUI application. This process involves a seamless integration between the model and GUI to enable real-time and non-real-time submarine cable detection through the ROV using a user-friendly GUI that provides clear and understandable results for the ROV operator.

**B. GUI Design**

Figure 2 is a mock-up of the GUI designed in this research. This GUI functions to display real-time and non-real-time computer vision camera views for detecting submarine cables.

Fig. 2. Mock-up of ROV computer vision application GUI.

This GUI is equipped with 2 screen views, namely the "source video" screen to display real-time and non-real-time computer vision and the "YOLOv4 Processing Result" screen to show the submarine cable detection results from the trained YOLOv4 weights. Additionally, there is a status bar that displays the GUI duration, submarine cable detection class, AP (Average Precision) value, and bounding box dimensions.

**C. Data Collection**

The data used in this study was collected from underwater inspection video documentation by PT Syergie Indoprima. The documentation videos were converted into image frames using VLC Media Player. There are 4 underwater inspection videos used in this research, resulting in a total of 395 image frames. The data collection process is illustrated in Figure 3.

Fig. 3. Collecting data stages.

**D. Data Splitting**

After the data collection process, the data is divided into two classes: SC-Good-Condition and SC-Bad-Condition. This class division is based on the physical conditions observed in the underwater inspection videos that have been converted into 395 image frames. The following are some criteria for the submarine cable classes in this research, presented in Table I.

TABLE I. CRITERIA FOR SUBMARINE CABLE CLASSES

Criteria for SC-Good-Condition	Criteria for SC-Bad-Condition
The armor layer of the submarine cable is intact, with no peeling.	The armor layer of the submarine cable is peeling.
The submarine cable is not covered by underwater vegetation.	The submarine cable is covered by underwater vegetation [12]

Figure 4 is an example of SC-Good-Condition image, and Figure 5 is an example of SC-Bad-Condition image.

Fig. 4. Example of SC-good-condition image.

Fig. 5. Example of SC-Bad-condition image.

Out of the 395 submarine cable image frames obtained, the number of images for each class was imbalanced. Therefore, the image data was re-divided to create a balanced dataset for the research. The balanced dataset used is presented in Table II, and the data split between the training and testing sets is presented in Table III.

TABLE II. DATA IMAGE SPLIT INTO BALANCED DATASET

Class	Number of Images
SC-Good-Condition	100 Images
SC-Bad-Condition	100 Images

TABLE III. DATA IMAGE SPLIT BETWEEN TRAINING AND TESTING SETS

Number of Image Data	Training Data (80%)	Test Data (20%)
200 Images	160 Images	40 Images

Balanced and imbalanced datasets are important concepts in Deep Learning, including for object detection models like YOLOv4<sup>1</sup>. When collecting image data, it is crucial to pay

<sup>1</sup>Introduction to Balanced and Imbalanced Datasets in Machine Learning. (n.d.). Balanced and Imbalanced Datasets in Machine Learning [Full Introduction]. <https://encord.com/blog/an-introduction-to-balanced-and-imbalanced-datasets-in-machine-learning/>

attention to dataset balance, especially if there are differences in the number of examples between the SC-Good-Condition and SC-Bad-Condition classes. If the dataset is imbalanced, for instance, when there are fewer examples of bad submarine cables compared to good examples, the object detection model can become biased in learning relevant patterns and features of the bad submarine cables [13]. Therefore, it is necessary to perform proportional data splitting for training and testing the model effectively, enabling the model to accurately recognize both classes and avoid any undesired bias in submarine cable detection.

E. Data Annotation and Training

In this research, the tool LabelIm<sup>2</sup> was utilized for annotating the images used in submarine cable detection. This tool allows users to easily create annotations in the YOLOv4 format. It provides features to manually select and mark the positions and boundaries of submarine cables for both SC-Good-Condition and SC-Bad-Condition classes. The annotation process involves drawing bounding boxes around the cables in each image. These bounding boxes provide information about the coordinates (x, y) and dimensions (width and height) of the submarine cables.

For the training data process, custom configurations were used based on the number of classes being trained. A reference guide<sup>3</sup> was employed for the configuration of submarine cable detection, as presented in Table IV for yolov4\_train.cfg and Table V for yolov4\_test.cfg.

TABLE IV. CONFIGURATION FOR YOLOV4\_TRAIN.CFG

Reference	Used Configuration
$Filters = (number\ of\ class + 5) \times B$ B = number of bounding boxes	$Filters = (2 + 5) \times 3$ $Filters = 21$
$Max\ batches =$ $number\ of\ classes \times 2000$	$Max\ batches = 2 \times 2000$ $Max\ batches = 4000$
$Steps = 80\%, 90\% \text{ of } max\ batches$	$Steps = 80\%, 90\% \text{ of } 4000$ $Steps = 3200, 3600$
$Batch = 32$ $Subdivision = 16$	$Batch = 32$ $Subdivision = 16$

TABLE V. CONFIGURATION FOR YOLOV4\_TEST.CFG

Reference [14]	Used Configuration
$Filters = (number\ of\ class + 5) \times B$ B = number of bounding boxes	$Filters = (2 + 5) \times 3$ $Filters = 21$
$Max\ batches =$ $number\ of\ classes \times 2000$	$Max\ batches = 2 \times 2000$ $Max\ batches = 4000$
$Steps = 80\%, 90\% \text{ of } max\ batches$	$Steps = 80\%, 90\% \text{ of } 4000$ $Steps = 3200, 3600$
$Batch = 1$ $Subdivision = 1$	$Batch = 1$ $Subdivision = 1$

<sup>3</sup>A. (2023, June 20). GitHub - AlexeyAB/darknet: YOLOv4 / Scaled-YOLOv4 / YOLO - Neural Networks for Object Detection (Windows and Linux version of Darknet ). GitHub. <https://github.com/AlexeyAB/darknet>

- Filters: In the YOLOv4 configuration (cfg) file, the "filters" parameter refers to the number of filters needed in the last convolutional layer of the YOLOv4 network architecture. This number of filters is related to the number of object classes to be detected (plus 5), then multiplied by 3.  $Filters = (Number\ of\ classes + 5) \times B$  indicates that for each object class to be detected, plus 5 (representing bounding box coordinates and confidence score), it will be multiplied by 3. The result is the total number of filters required in the last convolutional layer.
- Max batches: In the YOLOv4 configuration (cfg) file, the "max\_batches" parameter determines the total number of iterations that will be used in the model training. Each iteration involves one batch of image data to train the model. The value of "max\_batches" indicates the limit on the number of iterations to be performed during training. Therefore, from the formula  $Max\ batches = Number\ of\ classes \times 2000$ , it can be concluded that in this research, the maximum number of iterations for each training session is set to 4000 iterations.
- Steps: In the YOLOv4 configuration (cfg) file, the "steps" parameter is used to control when the learning rate will be adjusted during the training process. The "steps" value, expressed as a percentage of "max\_batches," determines the points at which the learning rate will undergo changes. In this research, "steps" are set at 80% and 90% of "max\_batches," which means there are two points where the learning rate will change during training: (1) At 80% of "max\_batches": The learning rate will be adjusted when the training reaches 80% of the total scheduled iterations ("max\_batches"). This adjustment usually involves decreasing the learning rate to help the model reach an optimal point during training. (2) At 90% of "max\_batches": The learning rate will be adjusted when the training reaches 90% of the total scheduled iterations ("max\_batches"). This adjustment typically involves further decreasing the learning rate to smooth the model's convergence process and improve the final results. The purpose of adjusting the learning rate is to optimize the training process and aid the model in achieving a good convergence, thereby enhancing object detection performance.
- Batch and subdivision: In the YOLOv4 configuration (cfg) file, the "batch" and "subdivisions" parameters are used to control how training or testing data is processed in each iteration. Here is an explanation for both values: (1) For the "yolov4\_train.cfg":  $Batch=32$ : The "batch" value indicates the number of images processed in each training iteration. In this case, 32 images are processed simultaneously in one iteration. This means that 32 images are loaded into memory and used to update the model weights in one iteration.  $Subdivisions=16$ : The "subdivisions" value indicates how many weight updates will be performed before considering one iteration complete. In this case, every 16 weight updates will be performed before one

iteration is considered complete. This is useful to reduce memory load and speed up the training process. With this configuration, in each training iteration, 32 images are loaded and processed, and weight updates are performed every 16 times. This allows for YOLOv4 model training with efficiency and speeds up the training process. (2) For the "yolov4\_test.cfg": Batch=1: The "batch" value is set to 1, which means that in each testing iteration, only 1 image will be processed. This is done because during the testing phase, we want to test each image individually to obtain accurate detection results and precise evaluation. Subdivisions=1: The "subdivisions" value is set to 1, which means that weight updates are not needed during the testing process. Each image is tested separately without any weight updates because no training is done at this stage. With this configuration, each image in the testing data will be tested separately, one by one, without any weight updates performed. This allows for accurate testing and precise evaluation of the previously trained model.

#### F. Performing Cross-Validation

In this research, cross-validation method is used to evaluate and validate the performance of the underwater object detection model. Cross-validation is a statistical method employed to assess and validate a model on a limited dataset<sup>4</sup>. The following are the steps of cross-validation conducted in this study:

- **Data Splitting:** The dataset used is divided into several subsets called "folds". In this research, the dataset is divided into 5 folds, as shown in the data split in Table VI.
- **Cross-Validation Iterations:** The cross-validation is performed 5 times, where each iteration uses one fold as the testing data, and the remaining folds are used as the training data. For example, in the first iteration, fold 5 is used as the testing data, while folds 1 to 4 are used as the training data. In the second iteration, fold 4 is used as the testing data, and folds 5 and 1 to 3 are used as the training data, and so on.
- **Model Training:** In each iteration, the submarine cable detection model is trained using the designated training data. The training process is conducted using the predetermined techniques and parameters.
- **Model Testing:** After training the model in each iteration, the model is evaluated using separate testing data. The model's performance is measured using relevant evaluation metrics such as precision, recall, and F1-score.
- **Selecting the Best Iteration Result:** After completing the cross-validation iterations, the performance evaluation results of the model in each iteration are recorded. Then, the best iteration result is chosen based on evaluation metrics like precision, recall, and F1-

score. The best iteration result is selected as the final outcome representing the model's best performance.

TABLE VI. DATASET FOLD SPLITTING

Iteration	Fold 1 (20%)	Fold 2 (20%)	Fold 3 (20%)	Fold 4 (20%)	Fold 5 (20%)
Iteration 1	Train				Test
Iteration 2	Train			Test	Train
Iteration 3	Train		Test	Train	
Iteration 4	Train	Test	Train		
Iteration 5	Test	Train			

Through the cross-validation method, this research can obtain more stable and reliable estimations of the performance of the submarine cable detection model. By dividing the dataset into different subsets for training and testing, this study can objectively test the model on various data and identify its strengths and weaknesses.

#### G. Model Performance Evaluation and Analysis with Confusion Matrix

This stage involves using the confusion matrix to evaluate and analyze the performance of the submarine cable detection model. The following are the steps involved:

- **Building the Confusion Matrix:** Using the testing data, the submarine cable detection model will make predictions for the SC-Good-Condition and SC-Bad-Condition object classes. From the prediction results and the ground truth labels, the confusion matrix will be constructed. The confusion matrix is a table with four cells representing the number of correct and incorrect predictions for each object class. The cells in the confusion matrix include True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN) [14]. The visualization of the confusion matrix is shown in Figure 6.
- **Based on the visualization of the confusion matrix above, in the context of submarine cable detection with classes SC-Good-Condition and SC-Bad-Condition, the definitions of True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN) can be stated as follows:**
  - **True Positive (TP):** TP occurs when the model correctly detects a submarine cable in good condition (SC-Good-Condition). This means that the model predicts correctly that the example belongs to the SC-Good-Condition class and indeed represents a submarine cable in good condition.
  - **True Negative (TN):** TN occurs when the model correctly detects a submarine cable in bad condition (SC-Bad-Condition). This means that the model predicts correctly that the example belongs to the SC-Bad-Condition class and indeed represents a submarine cable in bad condition.

<sup>4</sup>Cross Validation: Teknik Evaluasi Machine Learning, 6 Metode. (2022, August 14). Digital Polar. <https://digitalpolar.com/cross-validation/>

- False Positive (FP): FP occurs when the model incorrectly detects a submarine cable in bad condition (SC-Bad-Condition) as a submarine cable in good condition (SC-Good-Condition). This means that the model mistakenly predicts that the example belongs to the SC-Good-Condition class, whereas it actually belongs to the SC-Bad-Condition class.
- False Negative (FN): FN occurs when the model incorrectly detects a submarine cable in good condition (SC-Good-Condition) as a submarine cable in bad condition (SC-Bad-Condition). This means that the model mistakenly predicts that the example belongs to the SC-Bad-Condition class, whereas it actually belongs to the SC-Good-Condition class.

Fig. 6. Confusion matrix visualization [15].

- Calculating Evaluation Metrics: Based on the confusion matrix, various performance evaluation metrics for the model can be calculated, such as precision, recall, and F1-score. Precision measures the extent to which the model's positive predictions are correct, while recall measures the extent to which the model can correctly identify positive objects. F1-score is a combined measure that takes into account both precision and recall to provide a balanced performance overview<sup>5</sup>. The calculation algorithms for each metric are presented in Table VII.

TABLE VII. ALGORITHM FOR CALCULATING EVALUATION METRICS

Metric	Calculation Algorithm
Precision	$\frac{TP}{(TP + FP)}$ (1)
Recall	$\frac{TP}{TP + FN}$ (2)
F1-score	$\frac{2 \times (Precision \times Recall)}{(Precision + Recall)}$ (3)
mAP	$\frac{1}{N} \sum_{i=1}^N AP_i$ (4) Note: N = Number of AP data AP = Average Precision

<sup>5</sup>Kumar, A. (2023, March 17). Accuracy, Precision, Recall & F1-score - Python Examples - Data Analytics. Data Analytics. <https://vitalflux.com/accuracy-precision-recall-f1-score-python-example>

- Interpretation of Results: Through the confusion matrix and calculated evaluation metrics, the performance results of the model can be interpreted. Analyzing the number of TP, TN, FP, and FN for each object class provides insights into the model's ability to detect submarine cables in both SC-Good-Condition and SC-Bad-Condition classes. Observing the values of precision, recall, and F1-score for each object class helps in understanding the strengths and weaknesses of the model in detecting submarine cables.
- Visualization of Confusion Matrix: To facilitate understanding, the confusion matrix can be visualized using graphs or heat maps. This helps to clearly visualize the distribution of prediction results and errors that occur across all object classes.
- Testing Submarine Cable Detection on 20 Image Samples: To ensure that the model can accurately detect submarine cable conditions, a test for submarine cable detection is performed on 20 images listed in Table VIII, which are then analyzed for their results.

TABLE VIII. DETAILS OF THE SUBMARINE CABLE DETECTION TEST IMAGES

File Name	Class
Sample01.png – Sample10.png	SC-Good-Condition
Sample11.png – Sample20.png	SC-Bad-Condition

Through the evaluation and performance analysis of the model using the confusion matrix, this research provides detailed insights into how the submarine cable detection model operates, the extent of errors that occur, and the model's performance across all object classes. This aids in understanding and reporting the model's performance more accurately and informatively.

#### H. Model Implementation to GUI

This stage involves integrating the object detection model for underwater objects into the previously designed GUI. The following are the steps involved in this implementation:

- Model Preparation: The trained and tested submarine cable detection model (weights) will be prepared for integration into the GUI.
- Integration with GUI Library and Framework: The model will be integrated with the GUI library and framework used in this research, which is PyQt (Python QML).
- Functional Testing: After the integration is complete, functional testing of the GUI will be conducted to ensure that the submarine cable detection model operates smoothly within the GUI. At this stage, non-real-time submarine cable detection will be tested on several videos, and the details of these test videos are presented in Table IX.
- Evaluation and Refinement: After testing the functionality, the performance of the GUI and the submarine cable detection model within the GUI

environment is evaluated. Several aspects that can be evaluated include the mAP of the detection results according to equation (4) and also the calculation of the GUI's Frames per Second (FPS) performance, which can be calculated using the following equation:

$$FPS = \frac{\text{Number of Detected SC Frames}}{\text{GUI Processing Time}} \quad (5)$$

TABLE IX. DETAIL OF SUBMARINE CABLE DETECTION TEST VIDEOS ON GUI.

File Name	Video Duration
SampelVideo1.mov	54 seconds
SampleVideo2.mov	60 seconds

Subsequently, areas that need improvement or enhancement can be identified, and refinements can be made as necessary.

By integrating the submarine cable detection model into the GUI, this research provides an intuitive and interactive interface for users to perform submarine cable detection practically and efficiently. The GUI facilitates both real-time and non-real-time usage of the model and streamlines the interpretation of detection results within a more structured environment.

### III. RESULT AND ANALYSIS

In this chapter, the results of the experiments, evaluation, and performance analysis of the model, as well as the functionality test of the GUI, are explained in accordance with the previously described design.

#### A. Experiment using Imbalanced Dataset

A total of 16 training experiments were conducted using the imbalanced dataset, wherein four datasets with varying numbers of images were used. The number of images in the SC-Good-Condition class was smaller compared to the number of images in the SC-Bad-Condition class, with a ratio of 40:60. The details of the image distribution for the imbalanced dataset are presented in Table X and Table XI.

From the division of the imbalanced dataset, training was conducted with varying numbers of iterations. Each dataset was trained using 1000, 2000, 3000, and 4000 iterations. The training results produced 16 metric outcomes, presented in Table XII and visualized in the graph in Figure 7.

TABLE X. THE NUMBER OF IMAGES IN THE SC-GOOD-CONDITION CLASS AND THE SC-BAD-CONDITION CLASS USED IN THE IMBALANCED DATASET

Dataset Name	Number of Images Data	SC-Good-Condition Class (40%)	SC-Bad-Condition Class (60%)
Dataset 1	395 Images	158 Images	237 Images
Dataset 2	790 Images	316 Images	474 Images
Dataset 3	1185 Images	474 Images	711 Images
Dataset 4	1580 Images	632 Images	948 Images

yolov4_imb_1580_4000	0.69	0.27	0.38	38.63%

Fig. 7. Graph of evaluation metrics from training using the imbalanced dataset.

From Table XII and Figure 7, it can be observed that there is variation in the performance metrics across different datasets and iterations. It is evident that increasing the number of images in the dataset and the number of iterations does not always result in consistent improvement in the measured metrics.

For example, in the mAP (mean Average Precision) column, it can be seen that some combinations have lower

values compared to others, even when using a higher number of images and iterations. For instance, in the "yolov4\_imb\_395" dataset, the mAP for 4000 iterations (87.67%) does not show a significant improvement compared to 2000 iterations (87.67%). This indicates that after reaching a certain threshold of images and iterations, further increases do not provide significant benefits in the measured metrics.

This highlights that performance improvement is not solely dependent on increasing the number of data and iterations. There are other factors that need to be considered, such as data quality, balance of data between classes, and algorithmic factors used in model training. In this experiment with the imbalanced dataset, the best metric results were achieved by the "yolov4\_imb\_395\_4000" weight.

**B. Experiment using Balanced Dataset**

A total of 20 training experiments were conducted with the balanced dataset using the cross-validation method. Among these experiments, the training process involved 5 iterations of cross-validation, with 5 fold data images for both training and testing data, as indicated in Table VI. Each cross-validation iteration utilized a different number of training iterations, similar to the training of the imbalanced dataset, which included 1000, 2000, 3000, and 4000 training iterations.

The number of images in the SC-Good-Condition class was balanced with the number of images in the SC-Bad-Condition class, with a 1:1 ratio. The details of image distribution for the balanced dataset are provided in Table II and Table III, as discussed previously. The training results from the balanced dataset yielded 20 sets of performance metrics, presented in Table XIII, and visualized in Figure 8.

TABLE XIII. TRAINING RESULTS USING THE BALANCED DATASET

Name of Weight	Precision	Recall	F1-score	mAP @0.5
yolov4_blc_itr1_1000	0.62	0.32	0.42	51.98%
yolov4_blc_itr1_2000	0.70	0.68	0.69	64.54%
yolov4_blc_itr1_3000	0.80	0.78	0.79	75.65%
yolov4_blc_itr1_4000	0.79	0.76	0.77	72.86%
yolov4_blc_itr2_1000	0.78	0.62	0.69	73.68%
yolov4_blc_itr2_2000	0.86	0.80	0.83	86.06%
yolov4_blc_itr2_3000	0.81	0.73	0.76	78.44%
yolov4_blc_itr2_4000	0.89	0.85	0.87	92.58%
yolov4_blc_itr3_1000	0.55	0.45	0.49	51.28%
yolov4_blc_itr3_2000	0.91	0.77	0.84	77.01%
yolov4_blc_itr3_3000	0.84	0.77	0.81	77.08%
yolov4_blc_itr3_4000	0.89	0.77	0.83	77.53%
yolov4_blc_itr4_1000	0.55	0.38	0.45	36.53%
yolov4_blc_itr4_2000	0.70	0.55	0.61	49.87%
yolov4_blc_itr4_3000	0.53	0.38	0.44	34.20%
yolov4_blc_itr4_4000	0.75	0.57	0.65	61.09%
yolov4_blc_itr5_1000	0.47	0.35	0.40	40.90%
yolov4_blc_itr5_2000	0.59	0.47	0.53	47.13%
yolov4_blc_itr5_3000	0.72	0.57	0.64	59.87%
yolov4_blc_itr5_4000	0.82	0.68	0.74	72.25%

Fig. 8. Graph of evaluation metrics from training using the balanced dataset.

From the table and graph above, there is data on the performance metrics from various dataset combinations with different iterations during the model training. Here are some analyses based on the available data:

- **Differences in Dataset Combinations:** It is evident that each dataset combination exhibits different performances in the measured metrics. For example, if we observe the Precision column, some dataset combinations like "yolov4\_blc\_itr2\_2000" (0.86) and "yolov4\_blc\_itr2\_4000" (0.89) show higher precision values compared to other combinations.
- **Influence of Iterations:** In some cases, increasing the number of iterations consistently improves the measured metrics. For instance, if we consider the dataset combinations "yolov4\_blc\_itr1" and "yolov4\_blc\_itr2," it can be seen that higher numbers of iterations result in better performance in metrics like precision, recall, and F1-score.
- **Interrelation of Metrics:** In certain cases, there is a connection observed between the measured metrics. For example, the dataset combination "yolov4\_blc\_itr2\_4000" exhibits higher values of precision (0.89), recall (0.85), and F1-score (0.87) compared to the dataset combination "yolov4\_blc\_itr2\_1000" (precision: 0.78, recall: 0.62, F1-score: 0.69). This indicates that improvements in precision and recall also contribute to an increase in the F1-score.
- **Dependency on Dataset and Iterations:** The analysis reveals that performance improvement is not solely dependent on the number of iterations but also relies on the dataset combination used. For instance, in the dataset combination "yolov4\_blc\_itr3," increasing the number of iterations does not lead to significant improvements in the measured metrics, particularly in precision and recall.

This analysis shows that performance enhancement cannot be guaranteed solely through increasing the number of iterations. Additionally, other factors such as dataset quality, data variation, and parameter tuning should be considered to improve the overall model performance.

Subsequently, from each cross-validation iteration, the best-performing weight was selected, and the results were

summarized in the cross-validation results table shown in Table XIV and visualized in Figure 9.

TABLE XIV. CROSS-VALIDATION RESULT

Iteration	Precision	Recall	F1-score	mAP @0.5
Iteration 1	0.80	0.78	0.79	75.65%
Iteration 2	0.89	0.85	0.87	92.58%
Iteration 3	0.89	0.77	0.83	77.53%
Iteration 4	0.75	0.57	0.65	61.09%
Iteration 5	0.82	0.68	0.74	72.25%

Fig. 9. Graph of evaluation matrix from cross-validation result.

From the cross-validation results above, several analysis can be drawn as follows:

- Precision: Precision measures how accurately the model classifies the positive class. The average precision from five iterations is 0.83, with the highest value reaching 0.89 in the second iteration. This indicates that the model tends to perform well in identifying the positive class.
- Recall: Recall measures how well the model recognizes instances of the positive class. The average recall from five iterations is 0.73, with the highest value reaching 0.85 in the second iteration. Although the average recall is relatively high, it should be noted that there is variation in recall values between different iterations.
- F1-score: The F1-score is a combined measure of precision and recall. The average F1-score from five iterations is 0.76, indicating a balanced performance between precision and recall in classifying the positive class.
- mAP @0.5: The mAP (mean Average Precision) at threshold 0.5 is a commonly used evaluation metric in object detection tasks. The average mAP from five iterations is 76.62%, with the highest value reaching 92.58% in the second iteration. This shows that the model has a good ability to detect objects with confidence levels that meet this threshold.

Thus, based on the cross-validation results, the model demonstrates good performance in classifying the positive class with a relatively high level of accuracy. Consequently, we select the weight associated with the best metric, which is the

metric from iteration 2: "yolov4\_blc\_itr2\_4000," for further analysis and comparison in our research.

### C. Comparison of Imbalanced Dataset and Balanced Dataset Experiment

After conducting training experiments on both imbalanced and balanced datasets, the best-performing weights from each dataset were selected for comparison. The comparison of these weights is presented in Table XV and the graph in Figure 10.

TABLE XV. COMPARISON OF EVALUATION METRICS FOR TRAINING ON IMBALANCED AND BALANCED DATASETS

Name of Weight	Dataset Type	Precision	Recall	F1-score	mAP @0.5
yolov4_imb_395_4000	Imbalanced	0.87	0.83	0.85	0.8767
yolov4_blc_itr2_4000	Balanced	0.89	0.85	0.87	0.9258

Fig. 10. Comparison graph of evaluation metrics for training on imbalanced and balanced datasets.

- Precision: The model with the balanced dataset has slightly higher precision (0.89) compared to the model with the imbalanced dataset (0.87). Precision measures how accurately the model classifies the positive class, and higher results indicate that the model with the balanced dataset is better at accurately recognizing the positive class.
- Recall: Recall in the model with the balanced dataset (0.85) is slightly lower than the model with the imbalanced dataset (0.83). Recall measures how well the model recognizes instances of the positive class. Although recall in the model with the balanced dataset is higher, the difference is not significant.
- F1-score: The model with the balanced dataset (0.87) has a higher F1-score compared to the model with the imbalanced dataset (0.85). F1-score is a measure of the harmonic mean between precision and recall, and the higher result in the model with the balanced dataset indicates better overall performance in classifying the positive class.
- mAP @0.5: The model with the balanced dataset has a higher mAP @0.5 (0.9258) compared to the model with the imbalanced dataset (0.8767). mAP @0.5 is a commonly used evaluation metric in object detection tasks, and the higher result in the model with the balanced dataset indicates better ability to detect objects with confidence levels that meet the threshold.

Based on the performance evaluation results in the table and graph above, the weight "yolov4\_blc\_itr2\_4000" using the balanced dataset outperforms the weight "yolov4\_imb\_395\_4000" using the imbalanced dataset in terms of precision, recall, F1-score, and mAP @0.5. The model with the balanced dataset has better ability to accurately classify the positive class, with higher F1-score and mAP @0.5.

In addition to better metric results, using the balanced dataset also provides several other advantages. By using a balanced dataset, we can avoid bias in the model as the dataset reflects an even distribution of data. Additionally, a balanced dataset can provide more balanced classification results and better control over prediction errors.

Therefore, based on the comparison results and the advantages obtained, the model with the balanced dataset ("yolov4\_blc\_itr2\_4000") can be chosen as the best in classifying SC-Good-Condition and SC-Bad-Condition.

**D. Model Performance Evaluation and Analysis**

After selecting the "yolov4\_blc\_itr2\_4000" weight using the balanced dataset as the best training result based on the metrics, the performance of the model will be further evaluated and analyzed using the confusion matrix.

From testing 40 validation images on the balanced dataset, a confusion matrix is constructed as a tool to analyze the trained classification model. Figure 11 displays the confusion matrix of the selected weight.

Fig. 11. Confusion matrix of the selected weight.

Based on the confusion matrix above, the model weight can be evaluated as follows:

- TP (True Positives): There are 20 images correctly detected as SC-Good Condition.
- TN (True Negatives): There are 15 images correctly detected as SC-Bad Condition.
- FP (False Positives): There is 1 image wrongly detected as SC-Bad Condition, whereas it should be SC-Good Condition.

- FN (False Negatives): There are 3 images misclassified as SC-Good Condition, whereas they should be SC-Bad Condition.

To improve the model's performance in handling false positives (FP) and false negatives (FN) cases, several additional improvements can be implemented:

- Increase the Amount of Data: Collecting more submarine cable images with a wider variation. Having a larger and more representative dataset allows the model to learn more complex patterns and enhance its detection capabilities for cases of false positives and false negatives.
- Further Data Augmentation: Perform data augmentation on submarine cable images with even broader variations, such as rotation, translation, zooming, cropping, and other distortions. This will help the model recognize various possible conditions in submarine cables and improve its adaptability.
- Hyperparameter Configuration Tuning: Perform hyperparameter tuning on the YOLOv4 model. Some hyperparameters that can be examined include learning rate, max\_batches, batch size, subdivision size, input image size, and other parameters related to the YOLOv4 architecture.

**E. Detection Test on Submarine Cable Image Samples**

In this stage, a detection test is conducted on 20 sample submarine cable images, comprising 10 images with good condition and 10 images with bad condition. These images are outside of the balanced dataset used for training. The results of the detection test on the sample images are shown in Table XVI. Additionally, the Average Precision (AP) graphs for the SC-Good-Condition and SC-Bad-Condition classes are presented in Figure 12 and Figure 13, respectively.

TABLE XVI. RESULTS OF THE DETECTION TEST ON SUBMARINE CABLE IMAGE SAMPLES

File Name	Detection Image Result	Class	AP @0.5
Sample01.png		SC-Good-Condition	0.87
Sample02.png		SC-Good-Condition	0.94
Sample03.png		SC-Good-Condition	0.87
Sample04.png		SC-Good-Condition	0.82

Sample05.png		SC-Good-Condition	0.94
Sample06.png		SC-Good-Condition	0.91
Sample07.png		SC-Good-Condition	0.95
Sample08.png		SC-Good-Condition	0.82
Sample09.png		SC-Good-Condition	0.96
Sample10.png		SC-Good-Condition	0.97
Sample11.png		SC-Bad-Condition	0.82
Sample12.png		SC-Bad-Condition	0.90
Sample13.png		SC-Bad-Condition	0.94
Sample14.png		SC-Bad-Condition	0.83
Sample15.png		SC-Bad-Condition	0.87
Sample16.png		SC-Bad-Condition	0.88
Sample17.png		SC-Bad-Condition	0.66
Sample18.png		SC-Bad-Condition	0.98

Sample19.png		SC-Bad-Condition	0.96
Sample20.png		SC-Bad-Condition	0.91

Fig. 12. Graph of average precision results for the detection test on SC-Good-Condition class image samples.

Fig. 13. Graph of Average Precision results for the detection test on SC-Bad-Condition class image samples.

Based on the table and graphs above, the AP (Average Precision) values indicate how well the model can detect and classify objects with high accuracy. The higher the AP value, the better the detection performance on those images. It can be observed that some SC-Good-Condition and SC-Bad-Condition images have high AP values, such as Sample10.png (SC-Good-Condition) with AP 0.97 and Sample18.png (SC-Bad-Condition) with AP 0.98. This indicates that the model has a good ability to detect and classify both conditions of submarine cables. There is variation in the detection performance among the submarine cable images. Some images achieve high AP values, showing accurate detection, while others obtain lower AP values, suggesting possible difficulties in detection for those images. Therefore, it is necessary to evaluate the causes of the low AP values and identify factors that may influence the detection results in those images. This may involve visual analysis and further investigation of the images to discover patterns or difficulties that the model may encounter in accurately classifying submarine cable images.

Here are some assumptions about the factors that may influence the detection results with low AP values on the submarine cable images:

- **Blurry or Unclear Image Quality:** Images with blurry or unclear quality can cause difficulties in detecting submarine cables. The lines or contours of the submarine cables may not be clearly visible, making it challenging for the model to classify accurately.
- **Inappropriate Image Scale or Size:** Image size that is either too small or too large can affect the model's ability to detect submarine cables accurately. Images that are too small may lead to the submarine cable object being too tiny to detect, while images that are too large may cause the details of the submarine cable object to be lost or distorted.
- **Variations in Lighting or Image Contrast:** Differences in lighting or contrast in submarine cable images can affect the model's ability to recognize and classify the submarine cables accurately. Low lighting or low contrast can make it difficult to see the details of the submarine cable object, leading to detection challenges.
- **Presence of Confusing Objects:** The presence of other objects that have visual similarities with submarine cables, such as other cables or structural elements, or the presence of other objects obstructing the submarine cable, such as fish, rocks, etc., can confuse the model and disrupt the process of accurate detection and classification.
- **Variations in Submarine Cable Shapes or Types:** Images in the dataset may have variations in the shape or type of submarine cables, which can pose challenges for the model in recognizing these variations. The model may struggle to understand the variations in texture, shape, or size of different types of submarine cables.

*F. GUI Functionality Test*

In this stage, the functionality of the GUI is tested by conducting non-real-time submarine cable detection on several videos presented in Table IX. The results of the GUI functionality test are presented in Table XVII and graph images in Figure 14 for the testing on the SampleVideo1.mov file.

TABLE XVII. RESULTS OF GUI FUNCTIONALITY TEST ON SAMPLEVIDEO1.MOV

Video Duration	GUI Processing Duration	Detected Class	AP Value @0.5
00:01	00:06	SC-Bad-Condition	0.75
00:01	00:11	SC-Bad-Condition	0.85
00:02	00:16	SC-Bad-Condition	0.89
00:03	00:20	SC-Bad-Condition	0.91
00:04	00:25	SC-Bad-Condition	0.97
00:05	00:29	SC-Bad-Condition	0.97

00:06	00:33	SC-Bad-Condition	0.98

00:18	01:44	SC-Good-Condition	0.93
00:19	01:48	SC-Good-Condition	0.94
00:20	01:52	SC-Good-Condition	0.91
00:21	01:57	SC-Good-Condition	0.94
00:25	02:16	SC-Bad-Condition	0.89
00:26	02:20	SC-Bad-Condition	0.90
00:27	02:25	SC-Bad-Condition	0.50
00:28	02:29	SC-Bad-Condition	0.85
00:30	02:38	SC-Good-Condition	0.75
00:30	02:42	SC-Good-Condition	0.78
00:31	02:47	SC-Good-Condition	0.79
00:32	02:56	SC-Good-Condition	0.66
00:34	03:00	SC-Bad-Condition	0.73
00:34	03:05	SC-Good-Condition	0.54
00:39	03:24	SC-Bad-Condition	0.82
00:39	03:28	SC-Bad-Condition	0.85
00:41	03:33	SC-Bad-Condition	0.32
00:42	03:42	SC-Bad-Condition	0.76
00:44	03:51	SC-Bad-Condition	0.89
00:44	03:55	SC-Bad-Condition	0.85
00:45	04:00	SC-Bad-Condition	0.90
00:47	04:09	SC-Bad-Condition	0.75
00:47	04:13	SC-Bad-Condition	0.71
00:48	04:17	SC-Bad-Condition	0.79
00:48	04:22	SC-Bad-Condition	0.79
00:50	04:26	SC-Good-Condition	0.41
00:51	04:35	SC-Good-Condition	0.78
00:52	04:40	SC-Good-Condition	0.54

Fig. 14. Graph of GUI functionality test results on SampleVideo1.mov.

Based on the table and graph above, the analysis is as follows:

- The GUI successfully detected SC-Good-Condition at the video timestamps: 00:18, 00:19, 00:20, 00:21, 00:30, 00:31, 00:32, 00:34, 00:50, 00:51, and 00:52. The GUI successfully detected SC-Good-Condition 11 times out of a total of 50 detection frames.
- The GUI successfully detected SC-Bad-Condition at the video timestamps: 00:01, 00:02, 00:03, 00:04, 00:05, 00:06, 00:07, 00:08, 00:09, 00:10, 00:11, 00:12, 00:13, 00:15, 00:16, 00:17, 00:18, 00:19, 00:25, 00:26, 00:27, 00:28, 00:34, 00:39, 00:41, 00:42, 00:44, 00:45, 00:47, and 00:48. The GUI successfully detected SC-Bad-Condition 30 times out of a total of 50 detection frames.
- Several frames are at the same second, such as frames of SC-Bad-Condition at video timestamps: 00:01, 00:06, 00:09, 00:12, 00:14, 00:18, 00:34, 00:39, 00:44, 00:47, and 00:48, which were detected twice at each second. As for SC-Good-Condition frames, there is only one video timestamp (00:30) with two frames detected in that second.
- Several frames are at the same second but have different detection classes. At video timestamps: 00:18 and 00:34, each has 2 frames with different detection classes, one frame of SC-Good-Condition, and one frame of SC-Bad-Condition.
- To calculate the GUI's FPS (Frames per Second) performance for SampleVideo.mov, the formula in equation (V) is used:

$$FPS = \frac{50 \text{ frame}}{280 \text{ detik}} = 0.178 \text{ fps}$$

From the calculations above, the GUI performance for detecting SampleVideo1.mov still has a low FPS, taking a total time of 4 minutes and 40 seconds (280 seconds).

- To calculate the mAP (mean Average Precision) performance, the formula in equation (IV) is used. The results of mAP calculations for each class in the GUI functionality test on VideoSample01.mov are shown in Table XVIII.

TABLE XVIII. RESULTS OF MAP CALCULATION FOR GUI FUNCTIONALITY TEST ON VIDEOSAMPLE01.MOV

Class Name	mAP @0.5
SC-Good-Condition	0.725
SC-Bad-Condition	0.861

Based on the table above, the detection and classification results of submarine cables using the GUI have achieved a good mAP value.

Next, the functionality test continues for the video SampleVideo2.mov. The results of the GUI functionality test for SampleVideo2.mov are presented in Table XIX and graph images in Figure 15.

TABLE XIX. RESULTS OF GUI FUNCTIONALITY TEST ON SAMPLEVIDEO2.MOV

Video Duration	GUI Processing Duration	Detected Class	AP Value @0.5
00:02	00:07	SC-Good-Condition	0.48
00:02	00:12	SC-Good-Condition	0.95
00:02	00:16	SC-Good-Condition	0.56
00:03	00:20	SC-Good-Condition	0.79
00:04	00:24	SC-Good-Condition	0.35
00:11	00:53	SC-Good-Condition	0.45
00:11	00:58	SC-Good-Condition	0.43
00:11	01:02	SC-Good-Condition	0.92
00:12	01:06	SC-Good-Condition	0.86
00:13	01:11	SC-Good-Condition	0.51
00:14	01:15	SC-Good-Condition	0.49
00:14	01:19	SC-Good-Condition	0.29
00:20	01:35	SC-Good-Condition	0.27
00:30	02:31	SC-Good-Condition	0.56
00:38	03:08	SC-Bad-Condition	0.39
00:44	03:43	SC-Bad-Condition	0.58
00:50	04:09	SC-Bad-Condition	0.41
00:51	04:14	SC-Bad-Condition	0.72
00:51	04:18	SC-Bad-Condition	0.94
00:52	04:22	SC-Bad-Condition	0.98
00:53	04:27	SC-Bad-Condition	0.90
00:54	04:31	SC-Bad-Condition	0.94
00:54	04:36	SC-Bad-Condition	0.74

Based on the table and graph above, the analysis is as follows:

- The GUI successfully detected SC-Good-Condition at the video timestamps: 00:02, 00:03, 00:04, 00:11, 00:12, 00:13, 00:14, 00:20, and 00:30. The GUI successfully detected SC-Good-Condition 9 times out of a total of 23 detection frames.

Fig. 15. Graph of GUI functionality test results on SampleVideo2.mov.

- The GUI successfully detected SC-Bad-Condition at the video timestamps: 00:38, 00:44, 00:50, 00:51, 00:52, and 00:54. The GUI successfully detected SC-Bad-Condition 6 times out of a total of 23 detection frames.
- Several frames are at the same second, such as SC-Bad-Condition frames at video timestamps: 00:51 and 00:54, which were detected twice at each second. SC-Good-Condition frames at video timestamps: 00:13 and 00:14 were detected three times in each second.
- To calculate the GUI's FPS (Frames per Second) performance for SampleVideo.mov, the formula in equation (V) is used:

$$FPS = \frac{23 \text{ frame}}{276 \text{ detik}} = 0.083 \text{ fps}$$

Based on the calculations above, the GUI performance for detecting SampleVideo2.mov still has a low FPS, taking a total time of 4 minutes and 36 seconds (276 seconds).

- From the testing of SampleVideo1.mov and SampleVideo2.mov, both GUI FPS performances are relatively low. The following are some assumptions that may cause the low FPS performance:
  - Model Complexity: The low FPS may be caused by the complexity of the YOLOv4 detection model used. Models with many layers and parameters may require longer processing time.
  - Computational Load: Object detection using the YOLOv4 model requires intensive processing and consumes a lot of computational power. This can reduce processing speed and result in low FPS.
  - Hardware Limitations: The use of less powerful hardware, such as a CPU with low computational power, can affect the GUI's performance and cause low FPS.
- To improve FPS and enhance the GUI's responsiveness in submarine cable detection, several efforts can be made:
  - Model Optimization: Optimize the YOLOv4 detection model by reducing the number of unnecessary layers or parameters and using a lighter model.

- Use More Powerful Hardware: Use GPUs with parallel processing capabilities to improve processing speed and FPS.
- Resolution Reduction: Reduce the video resolution or convert the video format to a lighter format to improve FPS.
- Data Streaming: Use data streaming techniques to process videos in real-time and enhance GUI responsiveness.

By implementing the above efforts, it is expected that FPS on the GUI can be increased, making the application more responsive and providing users with a better experience in submarine cable detection. Continuous and iterative evaluation is necessary to ensure optimal performance improvements.

- To calculate the mAP (mean Average Precision) performance, the formula in equation (IV) is used. The results of mAP calculations for each class in the GUI functionality test on VideoSample02.mov are shown in Table XX.

TABLE XX. RESULTS OF MAP CALCULATION FOR GUI FUNCTIONALITY TEST ON VIDEOSAMPLE02.MOV

Class Name	mAP @0.5
SC-Good-Condition	0.554
SC-Bad-Condition	0.681

### G. Comparison of Functionality Test Performance

From the two functionality tests with two different videos, VideoSample01.mov and VideoSample02.mov, two performances were obtained for comparison. The comparison of functionality test performances is presented in Table XXI.

TABLE XXI. COMPARISON OF GUI FUNCTIONALITY TEST RESULTS FOR VIDEOSAMPLE01.MOV AND VIDEOSAMPLE02.MOV

File Name	Video Duration	GUI Processing Time	Number of SC Frame Detected	FPS	mAP @0.5
VideoSample01.mov	00:54	04:40	50 frames	0.178	0.829
VideoSample02.mov	01:00	04:36	23 frames	0.083	0.605

Overall, the GUI has performed well in detecting submarine cables in both videos. This can be seen from the relatively high mean Average Precision (mAP) @0.5 values, which are 0.829 for VideoSample01.mov and 0.605 for VideoSample02.mov. mAP @0.5 measures the object detection accuracy at an Intersection over Union (IoU) threshold of 0.5, and the higher the mAP value, the more accurate the detection results.

However, there are differences in the number of detected submarine cable frames between the two videos. In VideoSample01.mov, the GUI successfully detected 50 SC frames, while in VideoSample02.mov, the number of detected submarine cable frames was only 23. This difference is due to the varying video conditions between the two samples.

VideoSample02.mov has a more blurry, shaky, and often unfocused video quality, making submarine cable detection more challenging. This affects the GUI's performance in detecting SC in that video. Another factor that can affect the number of detected submarine cable frames is the complexity of the background and the presence of other objects that are similar to the submarine cable, causing some submarine cable frames to go undetected.

Regarding FPS, both VideoSample01.mov and VideoSample02.mov have low FPS values. This indicates that the GUI's processing is still relatively slow, resulting in slow detection. Increasing the FPS is one of the efforts that need to be made to improve the quality and efficiency of the GUI in detecting submarine cables.

#### IV. CONCLUSION

In this research, a YOLOv4-based underwater detection system integrated with a Graphical User Interface (GUI) for Remotely Operated Vehicle (ROV) in submarine cable detection has been successfully designed and implemented. Based on the experimental results and analysis, the following are the conclusions drawn from this research:

1) *Development of Submarine Cable Detection Model:* The performance evaluation of the model on the balanced dataset weight showed satisfactory results with precision of 0.89, recall of 0.85, F1-score of 0.87, and mAP of 92.58%. This indicates the model's ability to recognize both classes effectively.

2) *Implementation of Graphical User Interface (GUI):* The performance evaluation of the designed GUI showed promising results. In VideoSample01.mov, the GUI successfully detected 50 frames of submarine cable images with an mAP of 0.829 and GUI FPS of 0.0178. In VideoSample02.mov, the GUI detected 23 frames of submarine cable images with an mAP of 0.605 and GUI FPS of 0.083. The implementation of the GUI with the submarine cable detection model on the ROV successfully reduces dependency on human observation. With this automated system, issues of fatigue and subjective interpretation in identifying submarine cable conditions can be addressed. This provides the benefit of facilitating the submarine cable maintenance process.

In light of the successful development and implementation of the YOLOv4-based underwater detection system integrated with a GUI for ROV in submarine cable detection, there are several key areas for future research and improvements:

1) *Future work* should aim to enhance the scalability and adaptability of the system. This could involve expanding the dataset to encompass a broader range of underwater environments and conditions. Additionally, exploring the integration of machine learning techniques for automatic parameter tuning, especially in varying lighting and water clarity conditions, would further bolster the system's performance and reliability. Furthermore, the system could benefit from the incorporation of real-time anomaly detection

algorithms to promptly identify potential cable issues and facilitate proactive maintenance.

2) *There* is potential to extend the application of this technology to broader marine infrastructure management. Researchers can explore its utility in tasks beyond submarine cable detection, such as pipeline monitoring, marine biodiversity assessment, and archaeological exploration. Adapting the system for these diverse applications could significantly contribute to the advancement of marine sciences and industries. Additionally, research efforts should be directed toward refining the user interface and operator interaction aspects of the GUI to ensure user-friendliness and efficiency. This includes incorporating features that enable operators to annotate and validate detected cable segments, fostering human-machine collaboration for more accurate results. By addressing these areas in future research endeavors, we can further enhance the capabilities and impact of this innovative underwater detection system.

# Research on Clothing Color Classification Method based on Improved FCM Clustering Algorithm

Jinliang Liu

School of Creative Design, Shanghai Industry of Commerce & Foreign Languages, Shanghai 201399, China

**Abstract**—In the apparel industry, apparel color is an important factor to enhance the market competitiveness of enterprise products. However, the current prediction samples of clothing fashion color styling information do not incorporate practical cutting-edge fashion information. Therefore, Self-adaptive Weighted Kernel Function (SWK) has been introduced to traditional Fuzzy C-Means (FCM) clustering algorithms. After improvement, the SWK-FCM clustering algorithm is obtained, which enhances the classification ability of fashion colors and hue. Two prediction models have been developed using the finalized data of the International Fashion Color Committee, along with the SWK-FCM clustering algorithm. The models have been tested via experiments to verify their accuracy. The experimental results show that the classification coefficients of SWK-FCM clustering algorithm are 0.9553 and 0.9258 under 5% Gaussian noise. They are higher than those of FCM (0.7063) and FLICM (0.8598). The classification entropy is lower than that of the comparison algorithm, while the same results are presented under other conditions and in the actual experiments. In addition, the overall MSE of the GM (1, 1) prediction model using the final case information is 0.00028, which is close to the order of  $10^{-4}$ . The MSE value of the BP neural network prediction model using the final case information ranges from 0.000529 to 0.011025. Overall, the clustering algorithm of SWK-FCM has good classification performance. Additionally, the GM (1,1) model based on SWK-FCM has better prediction results, which can be effectively applied in practical clothing color classification and popular color prediction.

**Keywords**—Fuzzy clustering; SWK-FCM; fashion color scheme; Gaussian noise

## I. INTRODUCTION

The development of the economy has driven changes in the overall consumption concept of the people. People's daily needs for clothing are gradually shifting towards pursuing quality and fashion [1]. Clothing color is an important element in improving the competitiveness of goods. Popular colors are the focus of attention in the clothing industry, and their effective prediction can promote the effective development of clothing enterprises [2]. Zhu D et al. constructed two neural models of perceptual data based on deep learning for the problem of popular color trends of Japanese women's clothing kawaii style [3]. In response to the difficulty of fashion designers in achieving realistic restoration of Yi clothing color images, Zhu Hai et al. proposed a Yi clothing color extraction classification and trend prediction based on the K-means algorithm [4]. Garcia C C C proposed a consumer preference data based on material culture for fashion culture prediction in response to the trend of fashion clothing color trends [5]. The

current methods for predicting fashion color trends are still in the exploratory stage, resulting in low prediction accuracy, high time consumption, and high actual cost. As a clustering algorithm, FCM algorithm can effectively solve the classification time and improve the accuracy of prediction. However, traditional FCM does not perform well in actual fashion color classification prediction. At the same time, although the color quantization space method among many current methods can predict clothing color systems based on final information, it has high requirements for data extraction and low practicality. The grey model in the popular color prediction model has low requirements for dyeing sample data, but the actual prediction accuracy is not high enough. In this context, this study improves the FCM clustering algorithm and obtains an FCM clustering algorithm based on mean space constraints and adaptive weighted kernel functions (Self-adaptive Weighted Kernel Fuzzy C-Means, SWK-FCM). Based on this, the Grey Model (1,1), GM (1,1) and Back Propagation (BP) neural network prediction model are constructed. The purpose of the model is to improve the classification quality of apparel hues and achieve effective prediction of apparel fashion colors, so as to give relevant enterprises the corresponding guidance. In addition, the application of data prediction in the textile industry is still in an exploratory state, and the application of classification methods in the clothing industry is relatively shallow. Therefore, the study of using SWK-FCM clustering algorithm to classify clothing hue is innovative.

This paper is divided into five sections in total. The Section I is a summary and discussion of the current research on clothing color classification at home and abroad. Section II is the related work. Section III analyzes the clothing color classification method proposed on the basis of the improved FCM clustering algorithm. Section IV is to analyze the performance of this method. Section V concludes the paper.

## II. RELATED WORK

Fashion colors are the most important part of fashion elements, and they are pivotal in enhancing brand image and sales [6]. Therefore, achieving effective prediction of apparel fashion colors can bring higher business value to stakeholders and also promote the development of the industry. However, the prerequisite for realizing fashion color prediction for apparel is the effective classification of apparel hues [7]. Based on this, a wide range of domestic and foreign scholars have conducted in-depth research on it. Zhou Ze et al. proposed a new clothing classification method based on parallel convolutional neural networks for color tone recognition and classification. This method improved the

stability and accuracy of clothing classification on the basis of effectively extracting clothing tone features in [8]. Mushtaque S et al. constructed an effective classification platform for online shopping of women's clothing in Pakistan based on the collection of top women's clothing brands in Pakistan [9]. Wu D et al. proposed a new method for apparel attribute recognition and prediction, and used it to classify apparel hues, thus improving the recognition efficiency and classification accuracy based on the constructed relational model. The accuracy of classification was improved based on the relationship model [10]. Dai Y et al. proposed five different experimental schemes to improve the accuracy of fashion color database and fashion color classification based on the collection of relevant data [11]. Han A et al. used machine learning to analyze fashion color data and determine whether fashion designers have used fashion colors proposed by relevant institutions to guide seasonal trends. This method of analyzing and classifying fashion color data effectively enhances the potential of fashion color trend analysis to guide production [12].

In addition, Mau T N et al. effectively created an optimization method for initial clustering based on location-sensitive hashing for fuzzy clustering of categorical data, thus improving the clustering effect while reducing the dimensionality of categorical data and providing help for data trend prediction [13]. Mersch B and Buchel S et al. proposed a pricing heuristic based on machine learning for large-scale optimization of images, which improves the image coloring problem while increasing the prediction accuracy [14]. The issue of sustainable development was comprehensively analyzed through a multi-level perspective system to provide a predictive direction for the strategic transformation of the fashion industry [15-16]. Wang Wei et al. constructed a hybrid color trend prediction model based on genetic algorithm and extreme learning machine to address the issue of future color trend prediction, effectively improving prediction accuracy [17].

From the research of above scholars, the application of prediction of data in textile industry is still in the state of exploration, while the application of classification method in apparel industry is still shallow. Therefore, the research on the classification of apparel color shades using the SWK-FCM clustering algorithm possesses a certain degree of innovation, while the prediction model constructed on its basis can provide objective and scientific support to the stakeholders. In addition, it can also provide guidance for guiding consumers to form correct consumption behaviors while improving the accuracy of apparel trend prediction.

### III. ANALYSIS OF CLOTHING COLOR CLASSIFICATION METHOD BASED ON IMPROVED FCM CLUSTERING ALGORITHM

#### A. Study on Clothing Color Classification based on SWK-FCM Clustering Algorithm

There is a problem of inconsistency between current fashion color case information and actual cutting-edge fashion information. In response to this, this study combined case information and improved the Fuzzy C-Means (FCM) clustering algorithm to construct a fashion color prediction model. Traditional clustering usually refers to the process of

clustering things using similarity. Cluster analysis uses mathematical methods for clustering research, using the degree of correlation between certain features of the tested object as the basis for classification, without considering other prior knowledge. Fuzzy cluster analysis is a clustering analysis method constructed on the basis of fuzzy theory. Its correlation analysis of data is performed on the basis of considering regional characteristics and classifying them [18]. In pattern recognition and image segmentation, this method can be used to describe fuzzy objects more objectively.

FCM clustering algorithm belongs to a kind of fuzzy clustering algorithm, which achieves automatic classification of sample data by optimizing each sample point and determining the class of each sample point [19]. The classification accuracy of the traditional FCM clustering algorithm is very effective in the actual clothing color classification. Therefore, the study obtained the SWK-FCM clustering algorithm by embedding the kernel function in the FCM clustering algorithm and weighting it. Compared with traditional FCM, the SWK-FCM clustering algorithm enhances inter sample features by introducing kernel functions. It effectively prevents misclassification of important details through adaptive weights, and improves the system's noise resistance by introducing spatial functions. Among them, the expression of the objective function of SWK-FCM is shown in Eq. (1).

$$T = 2 \sum_{i=1}^a \sum_{j=1}^n b_i^m \lambda_{ij}^m (1 - K(x_j, u_i)) + 2\gamma \sum_{i=1}^a \sum_{j=1}^n b_i^m \lambda_{ij}^m (1 - K(\bar{x}_j, u_i)) \quad (1)$$

In equation (1),

$$T = 2 \sum_{i=1}^a \sum_{j=1}^n b_i^m \lambda_{ij}^m (1 - K(x_j, u_i)) + 2\gamma \sum_{i=1}^a \sum_{j=1}^n b_i^m \lambda_{ij}^m (1 - K(\bar{x}_j, u_i))$$

denotes the objective function.  $i$  denotes the number of clusters, whose maximum value is  $a$ .  $j$  denotes the number of elements in the sample, whose maximum value is  $n$ .  $b_i$  denotes the dynamic weight of a class, which can express the importance of a certain class.  $\lambda$  denotes the affiliation degree.  $m$  denotes the fuzzy factor.  $J(x, u)$  denotes the inner product kernel function.  $\gamma$  denotes the control parameter. On this basis, the computational expressions of the clustering center and the affiliation function can be obtained by minimizing the objective function by the Lagrange multiplier method under the corresponding constraints. Among them, the expressions of the constraints are shown in Eq. (2).

$$\begin{cases} \sum_{i=1}^a b_i = 1 \\ \sum_{i=1}^a \lambda_{ij} = 1 \end{cases} \quad (2)$$

Therefore, the expression of the cluster center  $u_i$  is calculated as shown in Eq. (3).

$$u_i = \frac{\sum_{j=1}^n \lambda_{ij}^m J(x_j, u_i)(x_j, \bar{u}_j)}{(1 + \gamma) \sum_{j=1}^n \lambda_{ij}^m J(x_j, u_i)} \quad (3)$$

Similarly, the expression for the calculation of dynamic weights is shown in Eq. (4).

$$b_i = \frac{\sum_{j=1}^n \lambda_{ij}^m (1 - J(x_j, u_i))^{\frac{1}{m-1}}}{\sum_{i=1}^a \left( \sum_{j=1}^n \lambda_{ij}^m (1 - J(x_j, u_i))^{\frac{1}{m-1}} \right)^{\frac{1}{m-1}}} \quad (4)$$

Finally, the expression of the affiliation function is calculated as shown in Eq. (5).

$$\lambda_{ij} = \frac{b_i \left( 1 - J(x_j, u_i) + \gamma \left( 1 - J(x_j, \bar{u}_i) \right) \right)^{\frac{1}{m-1}}}{\sum_{k=1}^a b_k \left( 1 - J(x_k, u_i) + \gamma \left( 1 - J(x_k, \bar{u}_i) \right) \right)^{\frac{1}{m-1}}} \quad (5)$$

Therefore, the specific steps of the SWK-FCM clustering algorithm constructed in the study are shown in Fig. 1.

Fig. 1. Detailed steps of SWK-FCM clustering algorithm.

In Fig. 1, the SWK-FCM algorithm firstly sets the corresponding parameters and initializes the affiliation and clustering centers at the same time. Secondly, it calculates the clustering centers of all categories and the dynamic weights of each step using Eq. (3) and Eq. (4). Then it updates the affiliation and calculates the new affiliation using Eq. (5). It continuously updates the affiliation and calculates the new affiliation until it satisfies Eq. (6). The final step is defuzzification, thus completing the classification. Among them, the determination constraints embodied in the steps are shown in Eq. (6).

$$\max \left\{ \left| \lambda_{ij}^{old} - \lambda_{ij}^{new} \right| \right\} < \delta \quad (6)$$

In Eq. (6),  $\lambda_{ij}^{old}$  denotes the old affiliation.  $\lambda_{ij}^{new}$  denotes the new affiliation.  $\delta$  denotes the threshold value. In

addition, in the final deblurring equation, the classification of each pixel point needs to be achieved based on the corresponding point equation, which is expressed as shown in Eq. (7).

$$v = \arg \max x_i \{ \lambda_{ij}, i = 1, 2, \dots, a \} \quad (7)$$

In Eq. (7),  $v$  indicates the category to which it belongs. Since the color system of different popular colors itself is different, this leads to different methods of color classification. Therefore, in the actual process of popular color data processing, it is necessary to determine the popular color hue classification method. Based on Eq. (1) to (7), the proposed SWK-FCM algorithm can automatically classify the color hues of clothing fashions and gradually determine the relevant intervals of color hue values for further processing of the data. Its process in apparel color clustering is similar to Fig. 1. However, there is a slight difference in the last step. That is, according to Eq. (1), the objective function value is calculated and the minimum error value is set. Until the objective function value is less than the given minimum error value or the number of iterations exceeds the limit, the algorithm process ends. The expression of the minimum error value calculation is shown in Eq. (8).

$$\varepsilon = \frac{|T_t - T_{t-1}|}{T_t} \quad (8)$$

In Eq. (8),  $\varepsilon$  denotes the minimum error value.  $t$  denotes the number of iterations. By using the SWK-FCM clustering algorithm to cluster the hue and return to the hue center and hue affiliation matrix, the hue value interval of each color class of the garment can be obtained after the corresponding processing of the affiliation matrix. The individual unclustered hue values are automatically assigned with the hue value interval that spans the adjacent interval. At the same time, the frequency of each type of hue in different years can be obtained statistically. The corresponding formula is used to calculate the proportion. The calculation expression is shown in Eq. (9).

$$P_{i'} = \frac{f_{i'}}{F} \times 100\% \quad (9)$$

In Eq. (9),  $P_{i'}$  indicates the proportion of colors in the  $i'$  category in different years.  $f_{i'}$  indicates the frequency of colors in the  $i'$  category.  $F$  indicates the total number of colors announced in the fashion color scheme of a certain year.

### B. Construction of a Color Prediction Model for Fashionable Clothing Colors based on Final Case Information

After elaborating the SWK-FCM clustering algorithm, the processed data can be brought into GM (1,1) with BP neural network to achieve the prediction of clothing process color shades. Before that, it is necessary to design the process of garment process color trend prediction using the finalized information. The study uses the information of the apparel fashion color case issued by the International Color Council as the actual data source, and uses the SWK-FCM clustering

algorithm to classify the color shades of apparel, so as to redefine the color intervals. GM (1,1) and BP neural network are used to perform color shade prediction, and the specific process is shown in Fig. 2.

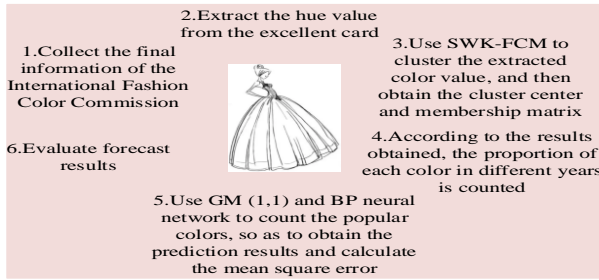

Fig. 2. Fashion color trend prediction process based on final information.

From Fig. 2, the process of predicting the trend of fashion colors using the case information is firstly to collect the historical case information of the International Color Council and extract the color phase values from the color cards. Secondly, it is to cluster the proposed color phase values by using SWK-FCM to obtain the cluster center and affiliation matrix. The next step is to count the proportion of each color in different years based on the results obtained. Then, GM(1,1) and BP neural network are taken to count the popular colors to obtain the prediction results and calculate the mean square error. Finally, evaluating the prediction results. Among them, the main steps of the prediction of the fashion color prediction model using GM (1,1) based on the final case information are shown in Fig. 3.

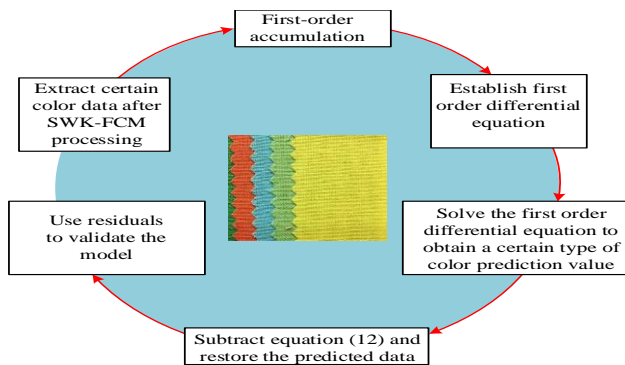

Fig. 3. Main steps of fashion color prediction based on GM (1,1).

From Fig. 3, the main steps are to first extract the original sequence of a certain type of color data after SWK-FCM processing and perform first-order accumulation to generate a first-order sequence; second, to establish a first-order differential equation and solve the first-order differential equation to obtain the predicted value of a certain type of color. Next step is to perform continuous accumulation of the equation to reduce the predicted data. Finally, the residual is used to verify the model. The expression of the original sequence and the first-order cumulative equation is shown in Eq. (10) [20-22].

$$\begin{cases} y^{(0)}(v') = y^{(0)}(1), y^{(0)}(2), \dots, y^{(0)}(v') \\ y^{(1)}(v') = \sum_{i'=1}^{v'} y^{(0)}(i') \end{cases} \quad (10)$$

In Eq. (10),  $y^{(0)}(v)$  denotes the original sequence.  $y^{(1)}(v)$  denotes the first-order sequence.  $i''$  denotes the color category whose maximum value is  $v'$ . And the computational expression of the established first-order differential equation is shown in Eq. (11).

$$\frac{dy^{(1)}(v')}{dv} + cy^{(1)}(v') = h \quad (11)$$

Eq. (11),  $c$  denotes the whitening coefficient, which reflects the trend of the variable.  $h$  denotes the endogenous control gray scale. In addition, the expression of the predicted value of a certain type of color obtained by solving this first-order differential equation is shown in Eq. (12).

$$\hat{y}^{(0)}(v'+1) = \left( y^{(0)}(1) - \frac{h}{c} \right) e^{-cv'} + \frac{h}{c} \quad (12)$$

In Eq. (12),  $e$  denotes the natural constant. Therefore, based on the stepwise representation of the GM (1,1) model, Eq. (12) is cumulated. The predicted data expression obtained by this reduction is shown in Eq.(13).

$$\hat{y}^{(0)}(v'+1) = \hat{y}^{(1)}(v'+1) - \hat{y}^{(1)}(v') \quad (13)$$

Finally, the model is validated using the nibbling formula, and the expression of the residual formula is calculated as shown in Eq. (14).

$$\eta(v') = \frac{y^{(0)}(v') - \hat{y}^{(0)}(v')}{y^{(0)}(v')} \quad (14)$$

In Eq. (14),  $\eta(v')$  denotes the relative error. The model is considered to meet the requirement when the relative error meets the corresponding condition, which is expressed in Eq. (15).

$$\begin{cases} |\eta(v')| < 0.1 \\ |\eta(v')| < 0.2 \end{cases} \quad (15)$$

In Eq. (15), when the relative error satisfies the first row of the equation, it means that the GM model achieves good accuracy. When the relative error satisfies the second row of the equation, it means that the GM model achieves general requirements. In addition to the GM model, the apparel popular color hue prediction model constructed by using the final case information also contains the BP neural network prediction model. BP neural network is a one-way propagation multilayer feedforward network, which is trained repeatedly by the samples of the network. Therefore, the weights and thresholds of the network can be gradually reduced on the negative gradient and achieve the expected results to a certain extent [23]. Because there is little color information of popular colors, and after analyzing the prediction results of current popular colors according to different network structures, the study chose a BP neural network for prediction. Its network topology is schematically shown in Fig. 4.

Fig. 4. Topological structure diagram of fashion colors based on BP neural network.

In Fig. 4,  $N$  denotes the color data related to a certain type of clothing color for the previous  $N$  years.  $O$  denotes the target value.  $W_{ij}$  denotes the weight value of the  $i$ -th neuron in the input layer relative to the  $j$ -th neuron in the hidden layer.  $W_{jk}$  denotes the weight value of the  $j$ -th neuron in the hidden layer relative to the  $k$ -th neuron in the output layer. From the figure, the topology of clothing fashion color using BP neural network contains the same three-layer structure. However, in the process of predictive modeling, the data related to each type of color needs to be trained separately. Firstly, the number of nodes in the input layer, output layer and should that layer needs to be set. The study sets the number of nodes in the input layer to 4, which are represented by A, B, C and D respectively. The number of nodes in the implicit layer is 7, and the number of nodes in the output layer is 1. Next, parameters such as excitation function, minimum learning rate, and maximum number of iterations are set. When the error associated with the training exceeds the expected value, it enters the backward propagation of the error, and then the gradient decreasing method is used to gradually correct the hidden layer weights to obtain the expected result. Finally, the completed training model is used to predict the color correlation data for the next year.

#### IV. PERFORMANCE ANALYSIS OF THE PREDICTION MODEL CONSTRUCTED BASED ON SWK-FCM CLUSTERING ALGORITHM

To verify the effectiveness of the garment fashion color shade prediction model constructed in the study, the study analyzed it using experiments. This study first evaluated the quality of clothing color classification using the SWK-FCM

clustering algorithm. Then, the fuzzy local information c-means (FLICM) clustering algorithm was introduced and compared with SWK-FCM clustering algorithm and traditional FCM clustering algorithm [24]. Before the experiment, the threshold value is set to 0.00001, the fuzzy factor is 2, the control parameter is 3.8, and the Gaussian kernel parameter is 110. In addition, based on the information of the international spring and summer women's fashion color definitions released by the International Color Council from 2017 to 2022, the study collects and organizes nearly 300 colors and uses the SWK-FCM clustering algorithm to find ten clustering centers. After data processing, the classification results and the contents of the classification intervals are shown in Table I.

TABLE I. TEN CLUSTERING CENTERS AND HUE INTERVALS OF HUE VALUES IN PANTONE COLOR SPACE

Hue classification	Name	Cluster center	Chromatic value range
1	Green	2	[1, 4].
2	Greenish yellow	6	[5, 8].
3	Yellow	10	[9, 11].
4	Yellow-red	13	[12, 15].
5	Red	17	[16, 21]
6	Red-purple	26	[22, 30]
7	Purple	39	[31, 40].
8	Purplish blue	44	[41, 48]
9	Blue	53	[49, 57].
10	Turquoise	61	[58, 64].

In Table I, a total of ten cluster centers were obtained in this study. The corresponding colors are mainly green, yellow, red, purple, blue, and five intersecting colors. On this basis, the classification quality assessment criteria are selected as classification coefficient (E) and classification entropy (F). The experimental clothing images are selected as 5% Gaussian noise and 10% pretzel noise. The comparison results of the performance parameters of the three algorithms classification criteria simulation are shown in Fig. 5.

Fig. 5. Comparison results of performance parameters of clothing color hue tested by three algorithm classification standards.

Fig. 5(a) shows the comparison results of the algorithms under 5% Gaussian noise. Fig. 5(b) shows the comparison results of the algorithms under 10% pretzel noise. From Fig. 5(a), the classification coefficient of SWK-FCM clustering

algorithm is 0.9553, which is higher than 0.7063 of FCM and 0.8598 of FLICM. Meanwhile, the classification entropy of SWK-FCM clustering algorithm is 0.1380, which is lower than 0.3324 of FCM and 0.2623 of FLICM. At the same time,

the classification entropy of SWK-FCM clustering algorithm is 0.1837, which is lower than that of FCM (0.3598) and FLICM (0.3157). This indicates that the SWK-FCM clustering algorithm has better classification quality and more robustness. To further verify the result, the study applies it to

the actual apparel color classification, in which three colors, green, yellow-red and purple, are randomly selected under ten clustering centers. The three colors are used as the clothing classification images for the experiment. The comparison results are shown in Fig. 6.

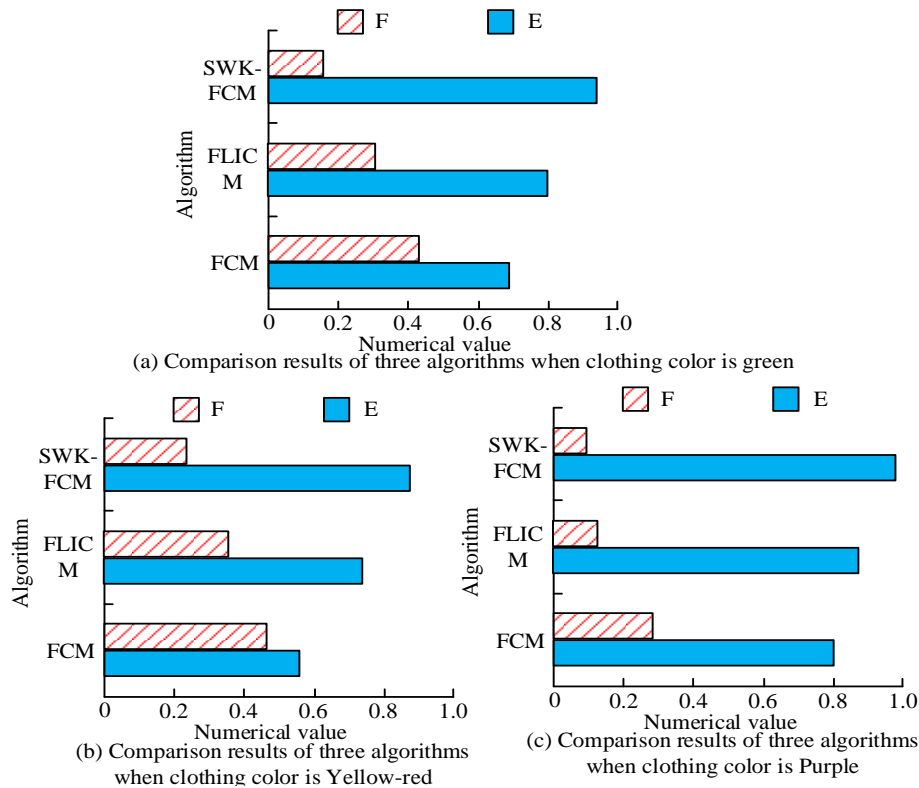

Fig. 6. Performance comparison results of three algorithms for clothing classification images.

Fig. 6(a) shows the comparison results of the three algorithms when the garment hue is green. Fig. 6(b) shows the comparison results of the three algorithms when the garment hue is yellow-red. Fig. 6(c) shows the comparison results of the three algorithms when the garment hue is purple. From Fig. 6(a), the classification coefficient of SWK-FCM clustering algorithm is 0.9388, which is much higher than that of the comparison algorithm. The classification entropy is 0.1540, which is significantly lower than that of the comparison algorithm. From Fig. 6(b), the classification coefficient of SWK-FCM clustering algorithm is 0.8967, which is higher than the comparison algorithm. The classification entropy is 0.2637, which is lower than the comparison algorithm. In Fig. 6(c), the classification coefficient of SWK-FCM clustering algorithm is 0.9778, which is also higher than that of the comparison algorithm. The classification entropy is 0.0946, which is lower than that of the comparison algorithm. Therefore, the SWK-FCM clustering algorithm is less susceptible to interference from noise and has higher classification accuracy in the actual clothing color classification. Therefore, the two prediction models constructed on the basis of SWK-FCM are studied to possess better performance in theory. To verify the performance of the GM (1, 1) prediction model and the BP neural network prediction model, the study analyzes the prediction results of both of them separately. In the

experiments, the study compares the absolute error, relative error, and Mean Square Error (MSE), which are denoted by e, d, and m, respectively. The results are shown in Fig. 7.

In Fig. 7, G (2022) denotes the original value in 2022. P (2022) denotes the predicted value in 2022. e denotes the absolute error; d denotes the relative error. m denotes the mean square error. Comprehensive Fig. 7 shows that the MSE values of the GM (1, 1) model color prediction using the final case information are very low, at 0.000004~0.001296. Its MSE can be as small as  $10^{-6}$  magnitudes, and the overall MSE is 0.00028, which is close to the magnitude of  $10^{-4}$ . This indicates that the GM (1, 1) model has higher prediction ability and higher accuracy rate. Meanwhile, based on the comparison between the prediction and the real curve in 2022, the average relative error of the popular colors in 2022 is 14.51%, which is very close to the actual value, except for the relatively large relative error of individual colors. This indicates that the GM (1,1) model using the final case information has a stronger trend inference ability. In addition, using the constructed BP neural network prediction model to determine case information, a time series is created for four consecutive years of raw color data from 2019 to 2022. It serves as the input feature vectors a, B, C, and D., The predicted results obtained through continuous training are shown in Fig. 8.

Fig. 7. Prediction results of SWK-FCM and GM (1,1) based on final information.

Fig. 8. BP neural network prediction results based on final information.

Comprehensive Fig. 8 shows that the MSE value of the BP neural network prediction model with 4-7-1 network structure for the popular color hues is between 0.000529 and 0.011025. While the MSE of the four colors, red, yellow-green, green, green-blue, and purple is of the order of  $10^{-4}$ , and the overall MSE is 0.0036, which is about the order of magnitude of  $10^{-2}$ . In summary, the prediction model using SEW-FCM and BP neural network is not as accurate as the GM (1,1) prediction model. But it can improve the prediction accuracy in comparison with other models. On this basis, to more comprehensively analyze the high accuracy of the prediction model of clothing fashion color built on the basis of SWK-FCM clustering algorithm, the study compares the two models built using the final case information with the prediction models built on the basis of traditional classification methods. The four models are represented by GM (1,1) (F), BP(F), GM and BP. Among them, the BP neural network uses relu as the excitation function, with a maximum number of iterations of 1000, 4 input feature vectors, 4 input layer nodes, 1 hidden node, and 1 output layer node. The minimum error of Xunyu is less than  $10^{-4}$ . The results are shown in Fig. 9.

The MSE value of the GM (1, 1) prediction model using the final case information is 0.00028, while the MSE value of the BP neural network prediction model using the final case information is 0.0036. Both of them are much lower than the 0.0071 of the GM model. The GM (1, 1) prediction model is

ideal, indicating that it can better predict the trend of popular colors.

Finally, to further validate the performance of the proposed SWK-FCM algorithm, a clustering algorithm using graph theory (a), a fuzzy kohlen clustering network algorithm (b), and a fuzzy covariance learning vector quantization algorithm (c) are introduced and compared with FCN (d) and SWK-FCM (e). Among them, the comparison indicators include accuracy, accuracy, recall, F1 value, and area under the curve, represented by 1-5. The results are shown in Table II.

From Table II, the algorithm proposed in the study has values of 98.95%, 98.65%, 99.01%, 99.63%, and 98.73% on indicators 1-5, respectively, which are higher than the comparative algorithms. This indicates the effectiveness and high performance of the algorithm in actual classification.

TABLE II. COMPARISON RESULTS OF DIFFERENT ALGORITHMS AND INDICATORS

-	A	B	C	D	E
1	92.41%	90.91%	95.45%	90.91%	98.95%
2	88.45%	92.34%	96.45%	89.65%	98.65%
3	90.21%	95.45%	97.11%	90.01%	99.01%
4	89.00%	93.16%	98.21%	89.51%	99.63%
5	82.06%	91.51%	94.63%	79.41%	98.73%

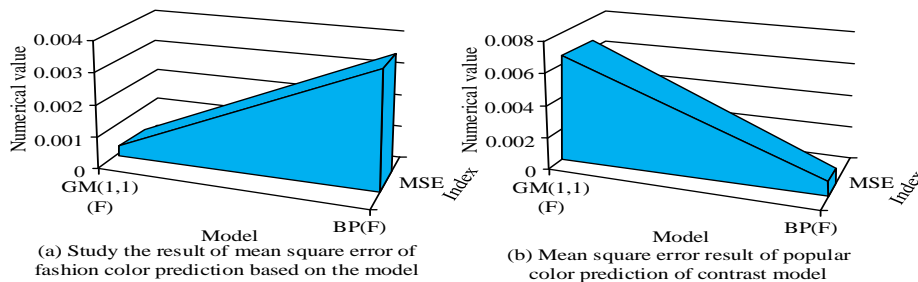

Fig. 9. Comparison results of popular color hue prediction based on final information with other models.

## V. CONCLUSION

To achieve the prediction of the actual cutting-edge fashion information of current fashion colors, the study obtained the SWK-FCM clustering algorithm by improving the traditional FCM clustering algorithm. Meanwhile, the prediction model of GM (1, 1) and BP neural network was constructed on the basis of this clustering algorithm combined with the final case information. The performance of SWK-FCM clustering algorithm and the effect of the two prediction models were analyzed by experiments. The experimental results showed that the classification coefficients of SWK-FCM clustering algorithm under different conditions were 0.9553 and 0.9258, and the classification entropies were 0.1380 and 0.1837, respectively. The same results were presented in the actual clothing color classification. In the GM (1, 1) prediction model experiments, the MSE of the GM (1, 1) model color prediction using definite case information was in the range of 0.000004 to 0.001296, and its MSE could be as small as  $10^{-6}$  magnitudes. In the experiments of the BP neural network prediction model, the MSE values ranged from 0.000529 to 0.011025 for the prediction of popular color shades, and the overall MSE was 0.0036, which reaches the magnitude of  $10^{-2}$ . Among the four models compared, the mean square error value of the GM (1, 1) prediction model using the final case information was 0.00028, which is lower than the other compared models.

Overall, the SWK-FCM clustering algorithm has better classification quality, is less susceptible to noise interference in actual color classification, and can automatically classify color phases. In theory, it can also be applied to other color spaces. Among the prediction models constructed on its basis, GM (1,1) has a better prediction effect, and both can provide corresponding guidance and assistance to stakeholders in the clothing ecosystem. However, the amount of popular color finalization information selected for the study is too small, which increases the difficulty of the study. Therefore, it is necessary to increase the amount of data in the future. At the same time, the study only analyzed the hue among the three attributes of color. In the future, a comprehensive prediction of popular colors should be made based on the saturation and purity of colors.

**Abstract**—Big data systems are expanding to support the rapidly growing needs of massive scale data analytics. To safeguard user data, the design and placement of cybersecurity systems is also evolving as organizations to increase their big data portfolios. One of several challenges presented by these changes is benchmarking real-time big data systems that use different network security architectures. This work introduces an eight-step benchmark process to evaluate big data systems in varying architectural environments. The benchmark is tested on real-time big data systems running in perimeter-based and perimeter-less network environments. Findings show that marginal I/O differences exist on distributed file systems between network architectures. However, during various types of cyber incidents such as distributed denial of service (DDoS) attacks, certain security architectures like zero trust require more system resources than perimeter-based architectures. Results illustrate the need to broaden research on optimal benchmarking and security approaches for massive scale distributed computing systems.

**Keywords**—Big data systems; zero trust architecture; benchmarking; distributed denial of service attacks

## I. INTRODUCTION

Big data systems are unified environments designed for massive-scale data analytics. Systems capable of handling large amounts of data are becoming more important as the volume of data created and communicated over the Internet increases [1]. Cybersecurity systems play an important role in ensuring the large quantities of data on the Internet remains safe. One dimension of several necessary to accomplish the latter are next-generation security devices. Intrusion detection and prevention systems (IDPSs) properly manage data accessibility, privacy, and safety. IDPS algorithms are able to identify cyber threats using several mechanisms. This includes using prior information from previous attacks, anomalies in network packets [1], and machine learning [2].

As big data systems become more common, their roles will continue to expand. This includes the capability to analyze and detect information security vulnerabilities at scale. For example, several big data frameworks exist that discover distributed denial of service (DDoS) attacks [3]. This expansion of roles offers many exciting opportunities for organizations. However, as the use of big data systems grows, the capability of attackers to leverage associated parallel computing power for nefarious reasons also increases [3]. A

systematic review of 32 papers pertaining to securing big data found that a critical need in future research is building more secure big data infrastructure [4]. Contributing to the latter objective, the researchers demonstrate how varying network architectures impact the security and performance of big data systems.

Organization of the paper is as follows. Section II reviews literature on intrusion detection and prevention methods for big data systems. Section III outlines the research design and methodologies used to test perimeter-based security and perimeter-less security applied to a big data system environment. Section IV describes the research results. Section V concludes the study by discussing the limitations and future outlook.

## II. LITERATURE REVIEW

Work is necessary to optimize both the information security and performance of distributed systems. Today, several open-source big data frameworks provide remarkable potential for solving challenging data science and related problems by leveraging powerful parallel and distributed data processing. However, securing these systems often carries performance penalties. The review of literature that follows explores research on the impact of various IT infrastructure security strategies and their influence on big data environments. It begins by reviewing comprehensive surveys most closely related to information security and big data systems.

### A. Surveys of Big Data and Intrusion Detection

Previous systematic reviews of literature focused on information security and big data provide a vast array of objectives. A prominent theme is using deep learning [1] and machine learning [2] to assist in detecting or preventing cybersecurity attacks. This line of research often utilizes deep learning or machine learning algorithms for near real-time data protection.

A recent and well cited comprehensive survey in [1] evaluates how deep learning is used for intrusion detection systems in the cybersecurity domain. It found notable contrasts between machine learning approaches in cybersecurity and deep learning. Conventional machine learning approaches utilized in cybersecurity were classified by approaches such as artificial neural networks (ANNs), Bayesian networks, decision trees, fuzzy logic, k-means clustering, k-nearest neighbor (kNN) algorithm, and support vector machines (SVMs). The

survey centered on deep learning focal intrusion detection methods that included autoencoders (AEs), convolutional neural networks (CNNs), deep belief networks (DBNs), generative adversarial networks (GANs), and long short-term memory (LSTM) recurrent neural networks [1].

AEs, DBNs, and GANs were highlighted in [1] for their unsupervised learning strengths. In the absence of gradient estimation, AEs can use gradient descent to train data. A strength of LSTM is its capabilities in analyzing time-series data. CNNs do not need as much data processing prior to evaluation as certain algorithms and is able to classify cyber-attacks using multiple characteristics well. Combined, the survey of literature finds that AEs, CNNs, DBNs, GANs, and LSTM networks each have potential to improve intrusion detection methods. Furthermore, the survey [1] outlined the importance of dataset reliability when evaluating deep learning intrusion detection effectiveness. Variance in cybersecurity attack datasets can introduce model bias when comparing multiple deep learning methods. Thus, any biases in attack datasets or data from live systems could increase spurious results [1].

A subsequent theme in the literature concentrates on cybersecurity and privacy prevention in big data applications. While this research again employs various data science methods to detect or prevent data breaches, it also illustrates how big data techniques can prevent information privacy issues. Research in [4] led to a proposed model for enhancing information privacy. The model highlights people, organizations, society, and government roles. It leverages IDS, IPS, and encryption as its primary techniques to prevent data breaches [4].

### B. Big Data Architectures and Information Security

As big data evolves, the supporting infrastructures will require proper encryption, intrusion detection, and intrusion prevention. Changing architectures within computer networks, messaging techniques, and undefined communication methods introduce numerous challenges. In a 2014 study Mitchel and Chen [5] recognized this paradigm. Their emphasis on cyber-physical systems (CPS) ranging from smart grids to unmanned aircraft systems led to the classification of four primary intrusion detection categories. These include legacy technologies, attack sophistication, closed control loops, and physical process monitoring. Each of the latter is narrow concepts as they relate to the broader field of intrusion detection, underlying the unique customization of IDSs for cyber-physical systems [5].

Three years later Zarpelo et al. [6] outlined a similar but distinct paradigm; intrusion detection focal to the Internet of things (IoT). The researchers stated that IoT has similar information security matters as the Internet, cloud services, and wireless sensor networks (WSNs). Despite similarities, IoT information security approaches are distinct, according to the authors due to concepts such as data sharing between users, the volume of interconnected objects, and the amount of computational power of the associated devices. Like cyber-physical systems, IoT presents diverse challenges to the design of intrusion detection systems [6].

Designing secure cloud computing environments poses several novel problems at multiple infrastructure layers. As an example, cloud resources can be leased by numerous vendors focused on varying as-a-service models such as infrastructure as a service (IaaS), platform as a service (PaaS), and/or software as a service (SaaS). Multi-cloud applications rely upon the seamless integration of cloud resources from providers focused on one or many as-a-service types, which continue to expand. In Casola et al. [7] a model is outlined for designing, creating, and implementing multi-cloud applications. The flexible approach accounts for varying as-a-service components. Security-by-design is a primary objective of the process lifecycle between the functional design of multi-cloud applications and the security design. The functional design phase defines the application logic, interconnections of services, and resource requirements. In the security design phase, each cloud element is assessed in terms of security risks and security needs. Security policies and controls are designed based on the latter requirements. Similar to CPS [5] and IoT [6], the multi-cloud application model is a subsequent example of how information security solutions play a prominent role due to the systems' distinct architectural and infrastructure layers.

Securing big data environments or leveraging associated techniques like machine learning to enhance information security intertwines numerous fields include but not limited to CPS, IoT, and cloud computing. Like big data systems, CPS requires cybersecurity protection [8] of private data [9]. Big data, IoT, and CPS often overlap through the ad hoc interfaces of systems such as smart vehicles, buildings, factories, transportation systems, and grids [10]. As a vulnerable attack surface, IoT advances the need for intelligent information security.

Machine learning [11], including ensemble intrusion detection [12], and IDS design [13] are proposed techniques to mitigate malicious cybersecurity attacks. Due in part to porous attack surfaces in cloud centric big data, IDSs may require collaborative frameworks [14]. In [15], fuzzy c means cluster (FCM) and support vector machine (SVM) were proposed as a collaborative technique for IDS detection rates. Compared to other mechanisms, the proposed hybrid FCM-SVM showed lower false alarm ratios and higher detection accuracy [15]. Furthermore, [16] illuminates the need for scaling IDS detection algorithms using the resources of parallel computing in the cloud.

In [17] the researchers propose the BigCloud security-by-design framework. The framework draws from the need to integrate big data security into the system development lifecycle. Its primary cloud application domain is focal to infrastructure as a service. It notes IaaS as one of the faster growing as-a-service options for big data. The model helps design and enforce secure authentication, authorization, data auditability, availability, confidentiality, integrity, and privacy. However, its IaaS concentration could provide greater benefits to as-a-service components specific to host operating systems, hypervisors, networking, and hardware [17]. Similar to IaaS, the evolution of serverless platforms and Function-as-a-service (FaaS) applications requires careful security design to overcome security threats that new services often suffer [18].

While distinct, CPS, IoT, cloud computing, and big data are merely a few examples of why designing intrusion detection and prevention systems remains highly elastic in modern computational architectures. As the information technology landscape changes, information security bends to meet the evolving needs of the complete environment. To conclude the literature review, the authors will outline several relevant studies introducing potential solutions to design stronger information security controls for big data systems.

### C. Encryption

An ongoing challenge in distributed big data systems is securing communication between multiple systems operating across various computer networks. Apache Hadoop and Apache Spark are examples of big data frameworks that present several opportunities for attackers to access the data they facilitate. Central to big data frameworks is the ability to use parallel processing to analyze massive amounts of data. MapReduce is one of many programming paradigms that leverages Hadoop to extract valuable knowledge from large volumes of data. However, like most application or service modules within big data frameworks, MapReduce highlights the vast attack vectors that exist in distributed big data systems. MapReduce examples in literature include side channel attacks [19], job composition attacks [20], and malicious worker compromises in the form of distributed denial-of-service (DDoS) or replay attacks [21], Eaves dropping and data tampering [22]. Encryption is a primary countermeasure to secure transmissions and prevent data leaks between big data servers [19].

A primary objective in addressing cybersecurity attacks on parallel processing services is identifying and preventing leaks that often occur during data transmission between distributed worker nodes, also referred to as DataNodes in Apache Hadoop. These unique yet integrated servers work in parallel to complete MapReduce jobs. Often in Hadoop, data is stored and retrieved from the Hadoop Distributed File System (HDFS). In [19] side-channel attacks are addressed that can occur between MapReduce workers that utilize HDFS for data storage. These types of cybersecurity attacks can target worker nodes to extract valuable information pertaining to MapReduce jobs such as the amount of packet bandwidth. This further contributes to successful pattern attacks. The authors proposed a solution to this vulnerability labeled Strong Shuffle that enforces strong data hiding between workers [19]. In contrast to alternative countermeasures such as correlation hiding in [20], Strong Shuffle avoids leaking the number of records accepted by each reducer during MapReduce runtime. Secure plaintext communications is a function of semantically secure encryption in the Strong Shuffle solution [19].

In [19] data communicated between Hadoop DataNodes and stored in HDFS is encrypted with semantically secure AES-128-GCM encryption. Although the latter helps prevent clear text leakage between MapReduce jobs in Hadoop, encryption in big data environments has limitations. For example, encrypted databases can still reveal certain information during operations that include table queries. Deterministic encryption and order-preserving encryption can leak the equality relationship and the order between records. One proposed solution is semantically secure encryption. In

[23] the authors propose a semantically secure database system named Arx. Alternative to order-preserving encryption, semantic security within Arx only allows an attacker to extract order relationships and frequency of the direct database query in use in contrast to the entire database. The authors note that worst-case attackers would gain as much information from a data leak as deterministic or order-preserving encryption over time [23]. While methods such as encryption and authentication help with cross-node data leaks, they do not prevent other attacks, such as DDoS and passive network eavesdropping [21]. A subsequent countermeasure is the effective design and implementation of intrusion detection and prevention systems [14].

### D. Next-Generation Security and Big Data Systems

Next-generation security at a high level can detect and prevent malicious cybersecurity attacks. Much of the literature focuses on identifying malicious network packets in real-time. The comprehensive survey in [24] reviews how modern data mining techniques are evolving to meet real-time detection needs. The review classifies intrusion detection systems by architecture, implementation, and detection methods. Detection methods are categorized as anomaly-based, signature based, and hybrids. Signature based methods or misuse often rely upon a database that defines patterns or existing malicious attack signatures. Anomaly detection can detect non-normal network traffic behavior that has yet to be defined in a signature database. Data mining methods including supervised, unsupervised, and hybrid learning are being used to improve anomaly-based intrusion detection systems [24].

While supervised, unsupervised, and hybrid learning IDS research continues to progress [24], the ongoing need to improve existing big data implementations remains. In several systematic literature reviews [1, 2, 3, 24], IDSs are known to have limitations that contradict the performance benefits of parallel processing and distributed computing. For example, large signature based systems drain CPU and memory resources [24]. While researchers continue to advance areas of intrusion detection such as packet anomalies and encryption, only a few studies are advancing security by design and its effects on varying big data architectures [1]. To address this need, the authors of this study designed a distributed big data system over a wide area network to explore the performance of distributed nodes under different network traffic loads.

## III. METHODS

This research methodology follows the design science approach in [25] and [26]. Design science is based on a scientific framework for IT research. As March and Smith [25] outline, IT research should consider natural and design science as a method to build and evaluate tangible objects. Within this philosophy, objects often have outputs in the form of models or instantiations. Instantiations associate with new artifacts in the design science methodology and the understanding of the artifact in its environment [25]. IT artifacts can be realized in many forms such as through the design of an object that helps solve business problems [26].

### A. Organizational Problem

Central to the organizational problem in this study is the need to architect a real-world or simulated big data environment that generates important inputs and outputs. In the case of this study, several architectural layers require design, configuration, benchmarking, and evaluation that accurately represent industry big data system implementations. These research activities could establish a more mature model for IDPS placement in evolving network architectures. Design science methods guide the latter activities [26].

Big data clusters can have thousands of nodes. Attempting to secure individual servers poses several issues ranging from significant costs to lost computational resources. Important to the artifact design process is the creation of an IDS and IPS testing environment that results in minimal disruption to existing big data infrastructures. Additionally, the authors constructed an experimental setup similar to several local small business environments that are readily available, relatively inexpensive, and relevant to a broad audience. Therefore, the testing environment is limited to several small commodity virtual machines (VMs) operating in physically distanced data centers. The authors will briefly outline the network architecture, hardware, software used in the experimental environment.

### B. Network Architecture

Fig. 1 depicts the baseline network architecture used in this study. The experimental network emulates a small to medium-sized business with a 200 Mbps dedicated lease line between four distinct physical locations. Connections are 1 Gbps copper from the demarcation point to the LAN nodes. Each server is connected to layer 2 switches followed by a layer 3 Cisco Systems enterprise class router.

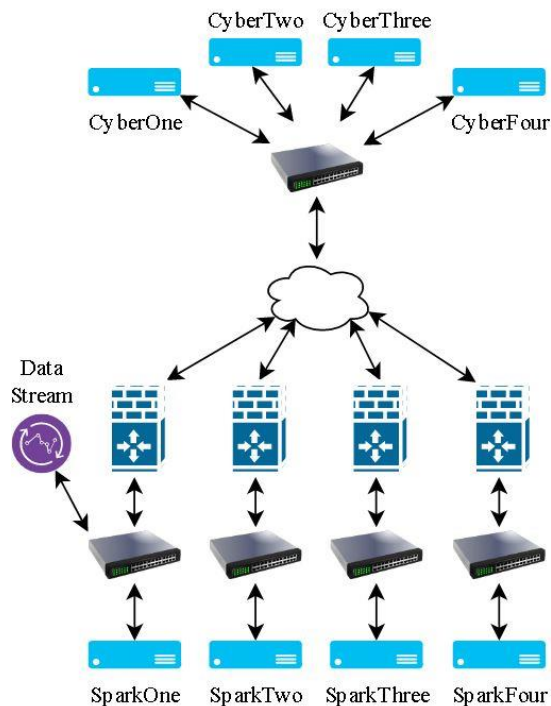

Fig. 1. Perimeter-based security network architecture.

The cybersecurity servers labeled “CyberOne” to “CyberFour” illustrate the systems used to attack the big data cluster. The big data cluster includes four servers labeled “SparkOne” to “SparkFour.” One streaming server is depicted as the data stream located in the same local area network (LAN) as SparkOne. Four intrusion detection and prevention systems are situated between each big data server and its extrinsic networks.

### C. Hardware

The big data servers run on parallel Dell hardware [27]. The hardware is manufactured on the same date and shipped in the same container. The testing server used the same single Intel CPU with 16 logical cores and 32 GBs of physical random-access memory. The baseline Intel CPU benchmark average results from the PassMark version 10 performance test [29] are 2,799 MOps per second for a single thread and 5,443 megabytes per second for data encryption.

Cisco RV series routers with integrated firewalls exist between each Apache Spark node and the external network. Cisco Firmware 1.0.3.55 is in use with the default firewall ruleset. The authors added customized rules that allow the internal LAN IP addresses to communicate on the necessary Apache HDFS and Spark ports. Subsequent ports are blocked [28].

### D. Big Data Systems

Each big data server and streaming server used equivalent software and versions. Systems ran on the Ubuntu server 20.04.3 LTS operating system. Installed software included Java 11, Python 3.8, Apache Hadoop 3.2, and Apache Spark 3.2. The big data environment is comprised of five servers. This includes one primary cluster manager labeled *SparkOne* and three secondary work nodes labeled *SparkTwo*, *SparkThree*, and *SparkFour*. Apache Spark is tuned using optimal parameters such as those specified in [30] and [31]. HDFS disks are balanced between nodes with DFS replicating three blocks. The data stream denotes the independent Spark streaming instance.

SparkOne is the primary node in the testing environment used in this study. It is comprised of the driver program. The driver program executes the big data application’s main() class and generates the SparkContext [32]. SparkContext is capable of using various big data resource managers. Tests in this study use Yet Another Resource Negotiator (YARN) as the distributed cluster manager [33].

SparkContext helps communicate application jobs containing code in various forms such as Python and JAR files to the executors on the worker or secondary nodes in the cluster. YARN has two primary high-level components labeled the NodeManager and ResourceManager. Secondary nodes in a big data cluster managed by YARN each have a NodeManager. Its function is to manage containers on each server. Containers encompass resources such as network, disk, CPU, and memory. These are allocated properly to facilitate task execution. The YARN ResourceManager consists of the ApplicationsManager and the Scheduler. While the Scheduler determines the necessary resources for each application the

ApplicationsManager identifies which container the application will use and subsequently monitors their task execution [33].

Apache Spark and HDFS replicate between three secondary big data servers. The secondary or worker nodes labeled SparkTwo, SparkThree, and SparkFour contain executor processes. An executor process remains throughout the runtime of tasks that each worker is allocated by the cluster manager. Every application receives its own executor process and/or processes as necessary. The driver program on SparkOne is configured to listen for executor process communications from the secondary nodes until the job is completed. Per Apache Spark documentation in [32], when possible, the driver program should be on the same local area network as the worker nodes due to the latter communication. In the experimental network design, the worker nodes are physically distanced. Therefore, Spark is optimized to open local remote procedure calls on the worker LANs [32].

#### E. Attack Systems

Although the cybersecurity servers ran on the same hardware as the big data servers, they used different software. CyberOne, CyberTwo, CyberThree, and CyberFour each delineate a server used to carry out cyber-attacks on the big data cluster. The software includes the Kali Linux operating system running the 5.14 kernel. Kali Linux is an open-source operating system based on Debian Linux. It is designed for numerous information security objectives such as reverse engineering, forensics, pen testing, and research [34].

#### F. Intrusion Detection and Prevention Systems

Consistent with Fig. 1, the baseline IDS and IPS systems are located between the cyber-attack and big data systems. Regardless, the authors manipulate the placement of these systems throughout each experimentation. As a simulated construct in the research methodology, the authors propose that IDS and IPS architecture placement predicts data streaming performance between worker nodes. Performance evaluation of this potential construct is an important step toward advancing a future IDPS placement framework for physically distanced big data systems.

The authors implemented Snort and Suricata, two popular open-source IDS and IPS systems. Snort is developed by Cisco Systems. It serves as a leading intrusion detection engine and rule set for Cisco next-generation firewalls and IPSs. Its mechanisms for detecting and preventing security threats continue to evolve. However, a fundamental capability during this writing is the formation of rules. In contrast to traditional methods such as signature-based detection, rules focus on vulnerability detection [35]. Suricata is developed by the Open Information Security Foundation (OISF). Similar to Snort, Suricata can use rules to detect and block cyber-attacks [36].

Version 2.9.7 of Snort ran with libpcap version 1.9.1 and version 8.39 of the payload detection rules. Suricata testing uses version 6.0.6 with the emerging threats open ruleset. The authors customized the latter default Snort and Suricata rulesets to secure the distributed nodes. The rulesets are parallel in count and type (e.g. alert, drop) to control significant variations in resource contention. Suricata and Snort use the same rules in the tests, except for minor incompatibilities. Where

incompatible, the rules are adjusted to perform the same action in both IDSs at parallel throughput rates.

Snort and Suricata run on the same server hardware and operating systems as the big data servers. A second NIC allows the servers to act as gateways between trusted and untrusted networks. The servers communicate between the local area networks using Transport Layer Security (TLS) and Secure Shell (SSH) Protocols. Ubuntu server 20.04.3 LTS is configured using OpenSSH version 8.2 and OpenSSL version 1.1.1.

#### G. Benchmarks

The authors developed custom benchmarks to identify how big data clusters perform under various IDS physically distanced network architectures. The benchmarks perform two significant network load functions, 1) streaming unstructured data to the Spark big data cluster and 2) flooding the Spark nodes via DDoS attacks. Network and system benchmarking uses version 16m of the nmon source code to measure network performance. Originally developed by IBM, nmon is an open-source Linux project that monitors system resource utilization. Performance metrics include CPU, disk, memory, and networking [37].

The authors follow the design science methodology [25] to design and implement an IDS placement experiment for physically distanced big data systems. Next, the authors construct a series of tests to determine how IDS locations influence real-world distributed worker nodes.

## IV. RESULTS

Each of the tests followed an eight-step process, 1) network architecture is determined and implemented, 2) IDPS locations are identified and configured, 3) IDPS customized rulesets are implemented, 4) the big data system cluster is started and tested as operational, 5) data streams to the cluster are invoked, 6) DDoS attacks are executed, 7) the benchmarks are run, and 8) the researchers maintain and monitor the testing environment for anomalies. Each of the tests was repeated three times to ensure saturation existed in the results.

#### A. Test 1 Perimeter-Based Security Results

Fig. 1 illustrates the IDPS placement location for the first test. The cloud represents the leased line between the geographical sites. Below the cloud icon is the selected IDPS solution followed by the Apache Spark cluster. Network architecture in the first test follows Cisco Systems' best practices for a collapsed data center and LAN core [38]. Within this design, a hardware-based IDPS is situated between the public untrusted and private trusted networks. Test one includes a traditional perimeter Cisco Systems IDPS. Individual Spark nodes are networked in a single VLAN connected through the collapsed core.

In contrast to the network architecture in Fig. 1, CyberOne through CyberFour servers are not deployed for tests 1-3. In each of these tests, typical network traffic is present void of any DDoS attacks.

Benchmark metrics are specific to the big data systems unless otherwise specified. During the data stream, HDFS is

writing 128 MB blocks to disk on all three Spark worker nodes at a constant rate. Inconsequential wait time exists on disk reads and writes. Average CPU utilization per thread or “CPU%” on the big data worker nodes is 4.3% during the first test. The average time a process waits for an input-output (I/O) to complete or “wait%” is 0.3. The average number of processor context switches per second is 1,728, identified as “PWps” hereafter.

The authors measured network performance between each of the Spark nodes using four metrics. Metrics are captured on the worker node network interface cards. The first performance variable measures the average number of all network packet reads per second (APRps). The second variable captures the average number of all network packet writes per second (APWps). The measure “APIORkBs” refers to the amount of network I/O read traffic in kB per second sent between the servers. The fourth metric, “APIOWkBs,” indicates the amount of network I/O write traffic in kB per second sent between the servers.

Fig. 3 illustrates the average network I/O (KB/s) on each Apache Spark node in tests 1-3 while Fig. 4 demonstrate the average network I/O (KB/s) on each Apache Spark node in tests 3-6.

In the perimeter-based network architecture, the average APRps reads per second are 637 across all Spark worker nodes. The average APWps writes per second are 620. The average APIORkBs read traffic between all Spark worker nodes is 80 while APIOWkBs is 78. The authors reconfigured the network architecture in the subsequent test to provide further insight into IDPS placement impact on distributed big data systems.

Fig. 2. Perimeter-less security network architecture.

### B. Tests 2-3 Perimeter-less Security Results

Fig. 2 demonstrates the big data network designed for tests two and three. Network architecture uses a modified perimeter-less design proposed by Kotantoulas [39]. In contrast to the traditional perimeter IDPS location in Fig. 1, every big data worker node is in a zero trust network. The authors designed an SD-WAN trust boundary to secure each big data node. The boundary consists of Snort and Suricata intrusion

detection and prevention security gateways. Similar to the virtual software defined perimeter (vEPC) proposed by Bello et al. [40], this study’s zero trust software-based system acts as a security gateway for all distributed servers. Sparkone through Sparkfour are designed to operate securely in most cloud architectures in this model by integrating an SDN security stack on each physically distanced server. The integrated IDPS gateways control and authorize incoming and outgoing network communication. The design emulates the trust boundary surrounding the cloud edge in [39] using the SSH and TLS protocols. Gateways authenticate and connect the distributed systems using a 3072-bit key generated by the Rivest–Shamir–Adleman (RSA) algorithm.

Benchmark results for test 2 with Snort SDN gateways show the wait% is 0.413% and CPU% is 12.54%. Results from this study show that CPU resource consumption is over two times greater in the zero trust architecture than the perimeter network design. Test 3 with Suricata SDN gateways results in 11.05% CPU% and 0.342% wait%. Similar to the perimeter-less design in test 2, test 3 used considerably more CPU resources than test 1. Despite similar rulesets, Suricata SDN gateways used slightly less CPU than Snort.

In the test 2 perimeter-less network architecture the average APRps reads per second are 2,198 across all Spark worker nodes. The average APWps writes per second are 653. The average APIORkBs read traffic between all Spark worker nodes is 298 in test 2, APIOWkBs is 82.

Fig. 3. Tests 1-3 spark per node network I/O in KB/s.

The test 3 network architecture had similar results to test 2. The average APRps reads per second are 2,120 across the distributed Spark systems. The average APWps is 611. APIORkBs between the big data servers is 289 and APIOWkBs is 77. Fig. 3 illustrates the average network I/O (KB/s) on each Apache Spark node in tests 1-3. These results indicate that network traffic and network I/O are nominal when writing to HDFS in all network architectures within this study. In contrast, the number of packets the systems have to read is higher in the perimeter-less network architectures. APRps is over three times higher in tests 2 and 3 than in test 1.

### C. Test 4 Perimeter-Based DDoS Attack Results

Test 4 uses the network architecture (Fig. 1), parallel to test 1. Perimeter-based intrusion detection and prevention systems protect the internal LANs of the Spark nodes. CyberOne through CyberFour are active in test 4. The cyber servers are configured to flood the big data cluster with unlimited TCP SYN handshakes.

Benchmark results for the big data servers during the DDoS attacks parallel test 1 in test 4. In test 4, the IDPSs prevented additional CPU load and network load on the big data servers. In the test case, the hardware IPSs successfully blocked the DDoS attacks.

### D. Tests 5-6 Perimeter-less DDoS Attack Results

Tests 5 and 6 are similar to tests 3 and 4. However, DDoS attacks are administered on the big data cluster. Tests 5-6 use the (Fig. 2) perimeter-less security network architecture. Test 5 uses the Snort-based SDN security boundary, while test 6 uses Suricata. CyberOne through CyberFour are active in tests 5 and 6. The cyber servers execute DDoS attacks on the big data cluster by flooding the servers with unlimited TCP SYN handshakes.

Snort and Suricata security gateways successfully protect the big data systems from DDoS attacks in a zero trust network in tests 5 and 6; however, at the expense of local computational resource increases. Results for test 5 with Snort SDN gateways show the wait% is 0.308% and CPU% is 13.8%. CPU resource consumption increases on average over 1% on the big data servers during the DDoS attacks. Test 6 with Suricata SDN gateways results in 11.95% CPU% and 0.337% wait%. DDoS attacks increased average CPU% by 0.9% across big data systems. Suricata SDN gateways used slightly less CPU than Snort SDN gateways during the DDoS attacks.

Within the test 5 perimeter-less network architecture the average APRps reads per second are 4,762 across all distributed by data secondary nodes. The average APWps writes per second are 626. The average APIORkBs traffic between the distributed systems is 425. APIOWkBs is 79.

Fig. 4. Tests 4-6 spark per node network I/O in KB/s.

The Suricata gateways in test 6 have average APRps reads per second of 4,311 across the distributed Spark systems. Average APWps is 661. APIORkBs between the big data servers is 416 and APIOWkBs is 81. Fig. 4 demonstrates the average network I/O (KB/s) on each Apache Spark node in tests 3-6.

### E. Test 7 Perimeter-Based DDoS Attack Results

Test 7 shares the same network architecture as test 1 and test 4, illustrated in Fig. 1. To decipher how the DDoS attacks affect the big data servers in the perimeter-based network architecture without IDPS protection, test 7 repeats test 4 but allow all network traffic from CyberOne through CyberFour to the big data cluster. When the DDoS attacks are allowed through the perimeter IPSs in the Fig. 1 network architecture, results show an average CPU% of 17.9% across all distributed big data systems. Predictably, network packets increase in test 7 compared to tests 1 and 4. APRps is 2,895 while APIORkBs is 518. Test 7 has the highest APIORkBs of all network benchmarks performed in this study.

### F. Discussion of the Results

The results illustrate that network traffic and network I/O have marginal differences when writing to HDFS in the network architectures studied. CPU resources and network traffic read by the operating systems increased in zero trust network architectures. The most substantial differences were between tests 4 and 5. During the DDoS attacks, the big data servers required more CPU resources in the perimeter-less security network architecture. In test 5, APIORkBs are considerably higher at 425 than test 4 at 80. This additional traffic is partly due to the SDN security boundaries necessary to protect the systems in a zero trust network environment.

Shifting compute resources closer to individual devices may be necessary as network security perimeters dissipate. However, zero trust architectures in the experimental environment reduced cluster performance. Therefore, additional research is beneficial to optimize the design of perimeter-less network environments.

### G. Limitations

Several environmental factors limit the results. Site-to-site networks were on leased 200 Mbps connections. Future studies might consider leased lines capable of establishing more robust data streams to the distributed nodes. A subsequent restriction is the number of architectures and communication technologies tested. Similar to the architecture in [40], gateways allow for IP Security (IPsec) or Transport Layer Security (TLS) protocols. Future IDPS SDN gateways could add this layer of encryption in a software-defined security boundary between geodistributed big data systems. The outlined limitations emphasize the need for future research to investigate more extensive network architectures and IDPS technologies for big data system security.

## V. CONCLUSION

As the volume of data expands, organizations require big data systems to perform large-scale data analytics. One of several needs for these systems is effective intrusion detection and prevention strategies. This paper builds a review of the

literature on methods used to reduce cybersecurity threats in a range of network architectures that big data systems operate. Findings from literature suggest intrusion detection and prevention systems can respond to certain security attacks. However, a potential disadvantage of capable security systems is the impact on big data system cluster performance. Using a design science approach, the authors develop an eight-step process to benchmark big data systems in varying network architectural environments. The new benchmark process is tested on real-time big data systems running in perimeter-based and perimeter-less network environments. During DDoS cyber-attacks, perimeter-based network architectures outperformed perimeter-less network architectures. This underlines the importance of optimizing the design of zero trust architectures for distributed big data systems.

**Abstract**—The smart city concept originated a few years ago as a combination of ideas about how information and communication technologies can improve urban life. With the advent of the digital revolution, many cities globally are investing heavily in designing and implementing smart city solutions and projects. Machine Learning (ML) has evolved into a powerful tool within the smart city sector, enabling efficient resource management, improved infrastructure, and enhanced urban services. This paper discusses the diverse ML algorithms and their potential applications in smart cities, including Artificial Intelligence (AI) and Intelligent Transportation Systems (ITS). The key challenges, opportunities, and directions for adopting ML to make cities smarter and more sustainable are outlined.

**Keywords**—Smart city; machine learning; artificial intelligence; intelligent transportation system; smart grids

## I. INTRODUCTION

### A. Background

According to the reports [1], by 2050, the global urban population is expected to reach 70%. This surge in urbanization will drastically impact cities' environment, management, and security. To efficiently handle the meteoric growth in urbanization, many countries have proposed the concept of smart cities to manage resources and optimize energy consumption effectively [2]. Smart city projects can precisely ensure a green environment by developing and adopting low-carbon emission technologies. Urbanization has witnessed unprecedented growth in recent decades, with an increasing number of people migrating to cities for better opportunities and improved quality of life [3]. This rapid urban expansion brings numerous challenges, such as increased energy consumption, traffic congestion, inadequate infrastructure, and environmental degradation [4]. In response, smart cities have emerged as a transformative approach to incorporate advanced Information and Communication Technology (ICT) based hardware and software in urban planning [5]. The smart city utilizes ICT to enhance 'citizens' quality of life, foster the economy, facilitate a process to resolve transport and traffic problems through proper management, encourage a clean and sustainable environment, and provide accessible interaction with the relevant authority of the government [6]. The increased urban expansion and innovations in urban planning and ICT have encouraged planners to focus on promoting the smart city's concept, which considers the well-being of the urban population by focusing on a combination of human, environmental, social, cultural,

energy, information access and usage, and other technological advances [7]. Moreover, as urbanization continues to surge, efficient and sustainable urban public transportation becomes increasingly vital. Association rule mining, a key data analysis technique, plays a crucial role in optimizing public transportation systems by uncovering valuable insights from large datasets. These insights enable cities to enhance transportation efficiency, reduce congestion, and improve overall mobility. The quality of urban public transportation directly impacts the daily lives of millions, affecting everything from commute times to air quality. By harnessing the power of data analytics, cities can provide residents with reliable, accessible, and eco-friendly transportation options, ultimately contributing to improved urban well-being and reduced environmental impact [8].

The proliferation of digital sensors, Internet of Things (IoT) devices, and the availability of vast amounts of data has created new possibilities for harnessing information to optimize urban systems and services [9, 10]. Machine Learning (ML), a branch of Artificial Intelligence (AI), has emerged as a key technology within the smart city context. It enables cities to analyze and extract valuable insights from the vast amounts of data generated by various sources, including sensors, social media, and municipal databases [11]. ML techniques can uncover patterns, correlations, and trends that may go unnoticed, enabling more informed decision-making and proactive interventions [12]. By applying ML algorithms to urban data, cities can gain actionable insights and predictive capabilities in energy management, transportation planning, waste management, public safety, and citizen engagement. These ML-driven applications have the potential to transform traditional urban systems into intelligent, adaptive networks that optimize resource utilization, improve service delivery, and enhance the overall quality of life for residents [13, 14]. However, deploying ML in the complex and dynamic urban environment comes with challenges, ranging from data privacy and security to ensuring ethical and fair AI practices. Addressing these challenges is crucial to realizing the full potential of ML for smart cities and creating sustainable urban ecosystems that meet the evolving needs of residents [15-17].

### B. Literature Review

The emergence of smart cities represents a pivotal response to the challenges posed by rapid urbanization and the increasing demand for improved urban infrastructure and services. As cities grow and evolve, the need to optimize resource management, enhance citizen well-being, and ensure

environmental sustainability has become paramount. This paradigm shift towards smart urbanization is deeply intertwined with the advancements in Information and Communication Technology (ICT) and, more notably, the integration of ML and Artificial Intelligence (AI) into urban planning and governance. In the realm of ML and AI, an extensive body of research has explored their applications across diverse domains, from healthcare to finance and beyond. Within the context of smart cities, these technologies offer unparalleled opportunities for data-driven decision-making, predictive analytics, and automation of urban processes. Studies have demonstrated the potential of ML algorithms in optimizing energy consumption, streamlining transportation systems, enhancing public safety, and promoting sustainable environmental practices. Moreover, ML-driven citizen engagement strategies have shown promise in fostering community collaboration and tailoring services to individual needs [18].

In addition to these technological advancements, the rise of ML in smart cities aligns with broader societal trends, such as the increasing importance of sustainability and the demand for efficient public services. Policymakers, urban planners, and researchers recognize the potential of ML to address the complex and interconnected challenges of modern urban environments [19]. However, the adoption of ML in the urban context is not without its hurdles. Privacy concerns, data quality, ethical considerations, and the need for scalable and interpretable ML models are among the critical issues that warrant careful consideration. This literature review establishes the significance of the research question by highlighting the transformative potential of ML in smart cities, drawing upon existing research and the broader context of urban development. It underscores the need for comprehensive exploration of ML applications, challenges, and opportunities within the smart city framework, which serves as the core focus of this paper.

### C. Objectives

This review paper aims to provide a comprehensive overview of the applications of ML in the context of smart cities. We aim to explore the various ML techniques employed, their impact on urban life, and the challenges and opportunities associated with their implementation. By examining the current state of ML applications in smart cities, we can identify key trends, gaps, and potential future directions for research and development.

### D. Structure of the Review

This paper is organized into several sections to provide a structured analysis of ML applications for smart cities. Section II introduces the foundations of smart cities and ML, highlighting their integration and the potential benefits they offer when combined. Section III explores a range of applications where ML has been successfully applied in smart cities, such as smart energy management, intelligent transportation systems, urban planning and development, public safety and security, waste management and environmental monitoring, healthcare and well-being, and citizen engagement and participation. Section IV highlights future directions and research trends in ML for smart cities,

such as explainable AI, edge computing and distributed ML, federated learning for privacy preservation, IoT integration, and the emergence of urban data marketplaces and governance. Finally, Section V concludes the review by summarizing the key findings, implications, and recommendations for adopting ML in building smarter and more sustainable cities.

## II. FOUNDATIONS OF ML IN SMART CITIES

This section provides a solid foundation by introducing the key concepts and principles underlying smart cities and ML. It offers an overview of the fundamental elements of smart cities, including their objectives, characteristics, and the integration of technology and data-driven approaches. Furthermore, this section explores the core principles and techniques of ML, emphasizing their relevance and applicability within the context of smart cities.

### A. Overview of Smart Cities

Smart cities represent a paradigm shift in urban development, driven by the rapid advancement of technology and the need to address the complex challenges faced by growing urban populations. At its core, a smart city leverages innovative technologies, data analytics, and connectivity to transform urban environments into intelligent, efficient, and sustainable ecosystems. The objectives of smart cities are centered around improving the quality of life for citizens and enhancing the overall efficiency of urban systems [20]. By integrating technology and data, smart cities aim to optimize resource allocation, enhance infrastructure and services, and enable effective decision-making. These objectives are achieved through various domains and initiatives, such as smart governance, smart mobility, smart energy management, smart buildings, and smart healthcare [21, 22].

Smart cities rely on a robust digital infrastructure that supports collecting, storing, and analyzing data from diverse sources [23]. This includes sensors, IoT devices, and communication networks that enable the seamless integration of urban systems. The proliferation of connected devices and the availability of real-time data empower city administrators and residents to make informed decisions and respond quickly to changing circumstances [24]. Moreover, smart cities emphasize citizen-centric approaches, prioritizing the needs and preferences of residents. Through digital platforms and services, citizens can actively participate in decision-making processes, provide feedback and access information about urban services. This promotes community engagement and collaboration, creating more inclusive and responsive urban environments [25]. Smart cities' sustainability is a key pillar as they strive to minimize environmental impact and optimize resource management. This includes initiatives such as smart energy grids, waste management systems, and promoting green and eco-friendly practices. Smart cities aim to reduce carbon emissions, conserve resources, and create a more sustainable future by integrating renewable energy sources, optimizing transportation systems, and implementing efficient waste management strategies [26].

### B. ML Fundamentals

ML is a powerful branch of AI that enables systems to automatically learn from data and make predictions or

decisions without explicit programming. Understanding the fundamentals of ML is essential for comprehending its integration and impact within the context of smart cities [27]. ML algorithms can be categorized into three main types: supervised, unsupervised, and reinforcement learning [28]. In supervised learning, models are trained using labeled data, where the algorithm learns to map input features to corresponding output labels. This approach is commonly used for tasks such as classification and regression [29].

On the other hand, unsupervised learning involves exploring unlabeled data to discover hidden patterns and structures. Clustering and dimensionality reduction are typical applications of unsupervised learning. Reinforcement learning focuses on training an agent to interact with an environment and learn optimal actions based on rewards and feedback. This technique is employed in scenarios where the agent must make sequential decisions [30].

As shown in Fig. 1, the general process of machine learning involves the following key stages. During training, the model learns from a portion of the data by optimizing its internal parameters to minimize prediction errors. The trained model is then evaluated using the testing data to assess its performance and generalization capabilities. Model evaluation metrics, such as accuracy, precision, recall, and F1 score, quantify the model's performance [31]. Feature engineering is a critical aspect of ML, where relevant input features are selected and transformed to improve model performance. This process involves understanding the data, identifying informative features, handling missing values, scaling features, and encoding categorical variables. Ensemble learning techniques, such as bagging and boosting, combine multiple models to make predictions. Transfer learning is another important technique that leverages knowledge gained from one task or domain to improve performance on another related task or domain, reducing the need for extensive training data [32].

Fig. 1. The general process of ML.

### C. Integration of ML in Smart Cities

Integrating ML techniques within the context of smart cities can revolutionize urban development and enhance

residents' efficiency, sustainability, and quality of life. This subsection explores how ML can be applied in smart cities and the benefits it offers [33]. One key application of ML in smart cities is urban planning and infrastructure management. ML algorithms can analyze vast amounts of data from diverse sources, such as sensor networks, social media, and municipal databases, to gain insights into urban patterns, land use, and transportation flows. These insights enable urban planners to make informed decisions regarding infrastructure development, zoning regulations, and transportation optimization, leading to more efficient and well-designed cities. ML also plays a crucial role in energy management and sustainability within smart cities. By leveraging data from smart grids, energy consumption patterns, and weather forecasts, ML algorithms can optimize energy distribution, predict energy demands, and identify opportunities for energy conservation. This enables cities to reduce energy waste, lower carbon emissions, and promote the integration of renewable energy sources, ultimately contributing to a greener and more sustainable urban environment.

Another important application is in the realm of smart mobility and transportation. ML techniques can analyze real-time data from various sources, including GPS data, traffic cameras, and transportation networks, to predict traffic congestion, optimize route planning, and improve public transportation systems. This leads to reduced congestion, shorter travel times, and enhanced mobility options for citizens. ML also contributes to public safety and security in smart cities. By analyzing data from surveillance systems, social media, and emergency calls, ML algorithms can detect patterns and anomalies, aiding in identifying potential security threats, crime hotspots, and emergency response optimization. This improves the safety and well-being of citizens and enables law enforcement agencies to address security challenges proactively.

Moreover, ML enhances citizen engagement and participation in smart cities. ML algorithms can capture public sentiment, identify community needs, and provide personalized services by analyzing data from social media platforms and citizen feedback. This promotes a sense of inclusion and empowerment among citizens, enabling them to participate in decision-making processes and co-create the urban environment actively. Integrating ML in smart cities brings numerous benefits, including improved urban planning, optimized energy management, enhanced mobility, increased safety, and citizen-centric services. However, challenges such as data privacy, security, ethical considerations, and ensuring fairness in AI algorithms must be addressed to harness the potential of ML in smart cities fully. By overcoming these challenges, cities can leverage the power of ML to create smarter, more sustainable, and livable urban environments.

### III. ML APPLICATIONS IN SMART CITIES

This section presents a clear and comprehensible trend of ML applications in smart cities. As specified in Fig. 2, the potential applications are categorized into seven main categories, including smart city, home automation, and smart healthcare. Tables I to VII summarize the obtained results from reviewing the models.

Fig. 2. ML applications in smart cities.

### A. Smart Energy Management

Smart energy management is critical to creating sustainable and efficient smart cities. ML techniques have been successfully applied in various energy management aspects, revolutionizing how energy is generated, distributed, and consumed. In this subsection, we discuss the applications of ML in smart energy management and their impact on creating greener and more efficient urban environments.

- Energy demand prediction: ML algorithms, such as regression models and artificial neural networks, are employed to predict energy demand accurately. By analyzing historical energy consumption data, weather patterns, and other relevant factors, these models can accurately forecast future energy demand. This information enables utility providers to optimize energy production and distribution, ensuring a reliable and efficient energy supply while minimizing waste.
- Energy load forecasting: ML techniques are used to forecast energy load patterns in real-time. By analyzing data from smart meters, weather conditions, and historical load profiles, algorithms can predict future load patterns. This information aids in managing peak demand, optimizing energy distribution, and facilitating the integrating of renewable energy sources into the grid. Load forecasting helps utilities balance supply and demand, reduce costs, and improve the overall reliability and stability of the energy grid.
- Energy optimization and control: ML algorithms optimize energy consumption within smart buildings and homes. By leveraging data from sensors, occupancy

patterns, and weather conditions, algorithms can learn and adapt to energy usage patterns. They can automatically adjust heating, cooling, and lighting systems to optimize energy efficiency while maintaining occupant comfort. Energy optimization algorithms help reduce energy waste, lower utility bills, and promote sustainable energy consumption practices.

- Energy theft detection: The ML techniques aid in detecting energy theft and unauthorized usage within the energy grid. By analyzing consumption patterns and identifying anomalies, algorithms can flag suspicious activities that indicate potential theft or tampering. This helps utility companies prevent revenue loss and ensure fair distribution of energy resources.
- Renewable energy integration: ML is crucial in integrating renewable energy sources into the energy grid. Algorithms can analyze weather data, historical renewable energy generation, and demand patterns to optimize the utilization and management of renewable energy resources. This enables effective grid integration, reduces reliance on fossil fuels, and promotes the transition to a greener, more sustainable energy infrastructure.

ML applications in smart energy management offer significant benefits such as improved energy efficiency, cost savings, reduced carbon emissions, and enhanced grid reliability. However, data quality, privacy, and algorithmic transparency challenges need to be addressed to ensure the responsible and effective deployment of ML techniques in smart cities' energy systems.

TABLE I. ML APPLICATIONS IN SMART ENERGY MANAGEMENT

Approach	ML type	Objective	Achievement	Challenges	References
Energy demand prediction	Supervised	Predict future energy demand accurately using ML algorithms	Accurate forecasting enables the optimization of energy distribution, cost reduction, and efficient load balancing	Relies on historical data and assumptions and may not account for sudden changes or events that deviate from historical patterns Requires continuous updating and validation to account for evolving energy consumption patterns	[34-40]
Energy load forecasting	Supervised	Forecast real-time energy load patterns based on data from smart meters and weather conditions	Enables efficient energy distribution, demand management, and integration of renewable energy sources Helps balance supply and demand, improve grid stability, and optimize resource allocation	Relies on accurate and timely data from smart meters and weather sensors Uncertainty in weather conditions and unforeseen events can impact the accuracy of load forecasts Requires robust data management and monitoring systems to ensure data quality and reliability	[41-48]
Energy optimization and control	Supervised	Optimize energy consumption in smart buildings and homes through ML algorithms.	Maximizes energy efficiency, reduces waste, and lowers utility bills Improves occupant comfort by dynamically adjusting heating, cooling, and lighting systems Enables demand response strategies and load balancing	Requires integration with smart devices and sensors for real-time data collection Dependency on accurate data and system feedback Potential privacy concerns related to the collection and usage of personal data Optimization algorithms may face challenges in highly dynamic environments and require continuous adaptation to changing conditions.	[49-53]
Energy theft detection	Supervised	Detect and flag potential energy theft or unauthorized usage within the energy grid using ML.	Helps prevent revenue loss and ensure fair energy distribution Improves the financial sustainability of utility providers Identifies anomalies and patterns indicative of energy theft or tampering	Relies on data quality and availability. False positives or false negatives may occur, requiring human intervention for verification May face challenges in identifying sophisticated or evolving techniques used for energy theft	[54-60]
Renewable energy integration	Supervised	Optimize the integration of renewable energy sources into the energy grid through ML algorithms.	Enables efficient utilization of renewable energy, reduces reliance on fossil fuels, and lowers carbon emissions Optimizes resource allocation based on weather patterns, demand, and grid conditions	Relies on accurate weather data and renewable energy generation forecasts. Uncertainty in weather patterns The intermittent nature of renewable sources can pose challenges in balancing supply and demand. Integrating diverse renewable sources and their variability may require advanced modeling and management strategies.	[61-64]

### B. Intelligent Transportation Systems

Intelligent Transportation System (ITS) plays a crucial role in enhancing urban transportation's efficiency, safety, and sustainability. ML techniques have been widely applied in various aspects of ITS to optimize traffic management, improve transportation infrastructure, and provide intelligent decision-making capabilities. In this subsection, we discuss the applications of ML in ITS and their impact on creating smarter and more efficient urban mobility.

- Traffic prediction and management: ML algorithms predict and manage traffic flow in real-time. These algorithms can forecast traffic patterns and congestion levels by analyzing historical traffic data, weather, and other relevant factors. This information aids in proactive traffic management, optimizing signal

timings, rerouting strategies, and providing real-time traffic updates to drivers and traffic management authorities. ML-based traffic prediction and management systems improve traffic flow, reduce congestion, and enhance overall transportation efficiency.

- Intelligent routing and navigation: ML techniques enable intelligent routing and navigation systems considering real-time traffic conditions, road incidents, and user preferences. These systems use ML algorithms to analyze historical and real-time data, such as traffic flow, accidents, and road closures, to provide optimal routes to drivers. By considering dynamic factors, ML-based routing and navigation systems help reduce travel time, fuel consumption, and environmental impact, improving overall transportation efficiency.

- **Vehicle and pedestrian safety:** ML algorithms contribute to improving vehicle and pedestrian safety in smart cities. Combined with ML, computer vision techniques enable intelligent video surveillance systems to detect and analyze traffic violations, identify potential safety risks, and provide early warning alerts. ML algorithms can also analyze vehicle sensor data to predict and prevent accidents by detecting anomalies, identifying aggressive driving behavior, and supporting advanced driver assistance systems (ADAS). These applications enhance road safety, reduce accidents, and improve transportation security.
- **Public transportation optimization:** ML techniques optimize public transportation systems, including bus and train schedules, route planning, and fleet management. ML algorithms can optimize public transportation services, improve reliability, reduce waiting times, and enhance passenger satisfaction by analyzing historical ridership data, weather conditions, and other factors. ML algorithms can also support demand-responsive transportation systems, enabling adaptive routing and scheduling based on real-time demand and passenger preferences.
- **Smart parking management:** ML algorithms are used to optimize parking management in smart cities. By analyzing data from sensors, historical occupancy patterns, and real-time information, ML-based parking

systems can provide accurate parking availability predictions, guide drivers to available parking spaces, and optimize parking space utilization. These applications reduce traffic congestion, lower vehicle emissions, and improve the overall efficiency of parking operations.

- ML applications in ITS offer significant benefits, including improved traffic flow, enhanced transportation efficiency, increased safety, and reduced environmental impact. However, data privacy, scalability, and algorithmic transparency must be addressed to ensure the responsible and effective deployment of ML techniques in smart city transportation systems. Ongoing research and development efforts aim to overcome these challenges and unlock the full potential of ML in shaping the future of urban mobility.

### C. Urban Planning and Development

Urban planning and development play a vital role in shaping cities' physical and social infrastructure. ML techniques have emerged as powerful tools for analyzing vast data and extracting valuable insights to support urban planning and development decisions [86]. In this subsection, we discuss the applications of ML in smart cities' urban planning and development and how they contribute to creating sustainable, livable, and efficient urban environments.

TABLE II. ML APPLICATIONS IN ITS

Approach	ML type	Objective	Achievement	Challenges	References
Traffic prediction and management	Supervised	ML algorithms predict and manage traffic flow in real-time, optimizing signal timings and providing updates.	Improved traffic flow Reduced congestion Proactive management.	Relies on accurate and up-to-date data, challenges in data integration and availability Limited control over external factors like accidents or road works	[65-71]
Intelligent routing and navigation	Supervised	ML enables intelligent routing systems to consider real-time traffic conditions, incidents, and user preferences.	Reduced travel time, fuel consumption, and environmental impact Improved navigation and route optimization	Dependency on accurate and real-time data, challenges in integrating multiple data sources Potential biases in data can lead to suboptimal route recommendations	[72-75]
Vehicle and pedestrian safety	Supervised	ML-based surveillance systems detect traffic violations, identify risks, and support driver assistance systems	Improved road safety Early warning alerts Accident prevention	Challenges in real-time detection accuracy Potential privacy concerns related to surveillance systems limitations in detecting complex traffic scenarios or unpredictable pedestrian behavior	[76-78]
Public transportation optimization	Supervised	ML optimizes public transportation systems, schedules, and route planning based on demand and historical data.	Enhanced public transportation services Improved reliability and passenger satisfaction	Data integration challenges Limited effectiveness during unexpected events or disruptions, dependency on accurate and up-to-date ridership data	[79-81]
Smart parking management	Supervised	ML algorithms optimize parking space utilization and guide drivers to available parking spaces.	Reduced traffic congestion Improved parking efficiency Lower vehicle emissions.	Dependence on accurate and real-time parking occupancy data Challenges in sensor deployment and maintenance Limited effectiveness in highly congested areas.	[82-85]

- Land use and zoning optimization: ML algorithms analyze various data sources, such as satellite imagery, demographic data, and economic indicators, to optimize land use and zoning regulations. By identifying patterns and relationships in data, ML can assist urban planners in determining the most suitable locations for residential, commercial, and industrial zones. These insights enable more efficient land use planning, balanced development, and the promotion of mixed-use neighborhoods.
  - Transportation infrastructure planning: ML techniques aid in transportation infrastructure planning by analyzing data on population distribution, commuting patterns, and transportation demand. These algorithms can identify optimal locations for transportation hubs, such as bus stops, metro stations, or bike-sharing stations, based on demand and accessibility factors. ML-based transportation planning improves connectivity, reduces travel time, and enhances transportation efficiency.
  - Environmental impact assessment: ML algorithms are employed to assess the environmental impact of urban development projects. These algorithms can predict the potential impact of proposed projects by analyzing air quality, noise levels, water resources, and biodiversity. This information assists in making informed decisions, ensuring sustainable development practices, and minimizing negative environmental effects.
  - Urban mobility and traffic management: ML techniques optimize urban mobility and traffic management by analyzing data from various sources, including sensors, GPS devices, and social media feeds. These algorithms can identify traffic patterns, predict congestion, and optimize transportation routes and signals. ML-based traffic management systems enhance traffic flow, reduce congestion, and improve the overall efficiency of urban transportation.
  - Infrastructure maintenance and management: ML algorithms contribute to maintaining and managing urban infrastructure, such as roads, bridges, and utilities. These algorithms analyze sensor data, maintenance records, and historical patterns to predict infrastructure deterioration and schedule maintenance activities. ML-based systems help ensure urban infrastructure reliability, safety, and longevity by optimizing maintenance efforts.
- ML applications in urban planning and development provide significant benefits, including optimized land use, improved transportation infrastructure, sustainable development practices, and efficient management of urban assets. However, challenges such as data quality, data integration, and interpretability of ML models must be addressed to ensure the effective and responsible application of ML techniques in urban planning processes. Ongoing research and collaboration between urban planners and data scientists aim to overcome these challenges and leverage the full potential of ML in shaping smarter and more sustainable cities.

TABLE III. ML APPLICATIONS IN URBAN PLANNING AND DEVELOPMENT

Approach	ML type	Objective	Achievement	Challenges	References
Land use and zoning optimization	Supervised	Data is analyzed to optimize land use and zoning regulations for sustainable development.	Efficient land use planning Promotion of mixed-use neighborhoods Optimized resource allocation	Relies on accurate and comprehensive data Challenges in integrating various data sources Potential biases in data affecting zoning decisions	[87, 88]
Transportation infrastructure planning	Supervised	Transportation infrastructure is optimized by identifying optimal locations for hubs and facilities.	Enhanced connectivity Reduced travel time Improved transportation efficiency	Dependency on accurate and up-to-date data Challenges in integrating different transportation modes Potential biases in data affecting planning decisions	[89, 90]
Environmental impact assessment	Supervised	The environmental impact of development projects is assessed based on various data sources.	Informed decision-making Promotion of sustainable development practices Reduced environmental impact	Relies on accurate and comprehensive environmental data Challenges in quantifying long-term environmental impacts Potential biases in data affecting assessments	[91-93]
Urban mobility and traffic management	Supervised	Urban mobility and traffic management are optimized by analyzing data from various sources.	Improved traffic flow Reduced congestion Enhanced transportation efficiency	Dependency on accurate and real-time data Challenges in data integration and processing Potential biases in data affecting traffic management decisions	[94-96]
Infrastructure maintenance and management	Supervised	Infrastructure deterioration and maintenance activities are predicted	Enhanced infrastructure reliability Optimized maintenance scheduling Improved asset management	Relies on accurate infrastructure data Challenges in integrating maintenance records Potential biases in data affecting maintenance decisions	[97-99]

#### D. Public Safety and Security

Ensuring public safety and security is a critical aspect of smart city initiatives. ML techniques have emerged as powerful tools in analyzing large volumes of data and extracting meaningful insights to enhance public safety measures and security systems. In this subsection, we discuss the applications of ML in smart cities' public safety and security domains and how they contribute to creating safer and more secure urban environments.

- **Video surveillance and monitoring:** ML algorithms enable intelligent video surveillance systems that can analyze real-time video feeds from cameras across the city. These algorithms can automatically detect and track suspicious activities, identify objects of interest, and raise alerts for potential security threats. ML-based video surveillance enhances situational awareness, improves incident response, and aids in crime prevention and detection.
- **Predictive policing:** ML techniques are employed to predict and prevent crime by analyzing historical crime data, socio-economic indicators, and other relevant factors. These algorithms can identify patterns, hotspots, and trends, enabling law enforcement agencies to deploy resources strategically and proactively. ML-based predictive policing helps reduce crime rates, improve resource allocation, and enhance public safety.
- **Emergency response optimization:** ML algorithms optimize emergency response systems by analyzing emergency call records, traffic conditions, and geographical information. These algorithms can identify the optimal deployment of emergency vehicles, predict response times, and dynamically allocate resources based on real-time incidents. ML-based emergency response systems improve response efficiency, minimize response times, and save lives in critical situations.
- **Cybersecurity and threat detection:** ML techniques aid in cybersecurity and threat detection by analyzing network traffic, user behavior, and system logs to detect anomalies and potential security breaches. These algorithms can identify patterns of malicious activity, classify threats, and provide early warnings to prevent cyber-attacks. ML-based cybersecurity systems protect critical infrastructure, sensitive data, and digital services.
- **Disaster management and resilience:** ML algorithms contribute to disaster management and resilience by analyzing data from various sources, such as weather forecasts, sensor networks, and social media feeds. These algorithms can predict and model the impact of natural disasters, aid in evacuation planning, and assist in resource allocation during emergencies. ML-based disaster management systems enhance preparedness, response, and recovery capabilities.

TABLE IV. ML APPLICATIONS IN PUBLIC SAFETY AND SECURITY

Approach	ML type	Objective	Achievement	Challenges	References
Video surveillance and monitoring	Supervised	Real-time video feeds are analyzed to detect and track suspicious activities and objects.	Enhanced situational awareness Improved incident response Crime prevention and detection	Dependency on accurate and high-quality video feeds Potential biases in the algorithmic analysis Privacy concerns related to extensive video surveillance	[100-102]
Predictive policing	Supervised	Crime is predicted and prevented by analyzing historical data and relevant socio-economic factors.	Proactive resource allocation Reduced crime rates Improved law enforcement strategies	Relies on accurate and comprehensive data Potential biases in data affecting predictions Ethical concerns related to algorithmic profiling	[103, 104]
Emergency response optimization	Supervised	Emergency response systems are optimized by predicting response times and resource allocation.	Efficient resource allocation Reduced response times Improved emergency management	Dependency on accurate and real-time data Challenges integrating multiple data sources Potential biases in algorithmic predictions	[105-107]
Cybersecurity and threat detection	Supervised	Network traffic and user behavior are analyzed to detect and prevent cyber threats and breaches.	Early detection of anomalies Improved threat prevention Enhanced critical infrastructure protection	Evolving nature of cyber threats Challenges in identifying new and sophisticated attack patterns Potential biases in algorithmic analysis	[108-110]
Disaster management and resilience	Supervised	Data is analyzed to predict and manage the impact of natural disasters and aid in recovery efforts.	Improved preparedness and response Enhanced resource allocation Efficient evacuation planning	Dependency on accurate and comprehensive data Challenges integrating various data sources Potential biases in algorithmic predictions related to complex disaster scenarios	[111-113]

ML applications in smart cities' public safety and security domains offer significant benefits, including improved situational awareness, proactive crime prevention, efficient emergency response, enhanced cybersecurity, and better disaster management. However, challenges such as data privacy, algorithmic biases, and ethical considerations need to be addressed to ensure the responsible and effective deployment of ML techniques in public safety and security systems. Ongoing research and collaboration between law enforcement agencies, security experts, and data scientists aim to overcome these challenges and leverage the full potential of ML in creating safer and more secure smart cities.

*E. Waste Management and Environmental Monitoring*

Effective waste management and environmental monitoring are essential for smart city initiatives to create sustainable, eco-friendly urban environments. ML techniques have revolutionized these areas by enabling the analysis of large-scale data sets and extracting valuable insights for optimizing waste management processes and monitoring environmental conditions. In this subsection, we discuss the applications of ML in smart cities' waste management and environmental monitoring and how they contribute to achieving efficient resource utilization and environmental sustainability.

- **Waste sorting and recycling:** ML algorithms play a crucial role in waste sorting and recycling by automating the identification and segregation of different waste materials. Using computer vision and image recognition techniques, these algorithms can analyze images of waste and classify them into specific categories, such as plastic, paper, glass, or organic

waste. ML-based waste sorting systems enhance recycling efforts, reduce landfill waste, and promote a circular economy.

- **Predictive waste collection:** ML techniques optimize waste collection routes and schedules based on predictive analysis. By analyzing historical data on waste generation patterns, population density, and other relevant factors, these algorithms can predict the optimal time and location for waste collection. ML-based waste collection systems reduce operational costs, minimize environmental impact, and improve efficiency.
- **Environmental quality monitoring:** ML algorithms analyze data from environmental sensors and monitoring devices to assess air quality, water quality, noise levels, and other environmental parameters. These algorithms can detect patterns, identify pollution sources, and predict environmental risks. ML-based environmental monitoring systems facilitate early detection of pollution events, enable targeted interventions, and promote healthier and cleaner urban environments.
- **Energy optimization and conservation:** ML techniques optimize energy consumption and promote energy conservation in smart cities. These algorithms analyze data on energy usage patterns, weather conditions, and building characteristics to identify opportunities for energy savings. ML-based energy management systems can dynamically adjust energy usage, optimize building operations, and promote sustainable energy practices.

TABLE V. ML APPLICATIONS IN WASTE MANAGEMENT AND ENVIRONMENTAL MONITORING

Approach	ML type	Objective	Achievement	Challenges	References
Waste sorting and recycling	Supervised	The identification and sorting of waste materials are automated for recycling.	Improved recycling efforts Reduced landfill waste Promoting a circular economy	Dependency on accurate and comprehensive waste data Challenges in integrating waste sorting systems Potential biases in algorithmic classification	[114-117]
Predictive waste collection	Supervised	Waste collection routes and schedules are optimized based on predictive analysis.	Reduced operational costs Minimized environmental impact Improved waste management efficiency	Dependency on accurate waste generation data Challenges in integrating real-time data Potential biases in algorithmic predictions	[118]
Environmental quality monitoring	Supervised	Data is analyzed from environmental sensors to assess air quality, water quality, and noise levels.	Early detection of pollution events Targeted interventions Promotion of healthier urban environments	Relies on accurate and comprehensive environmental data, sensor deployment, maintenance challenges Potential biases in algorithmic analysis.	[119]
Energy optimization and conservation	Supervised	Energy consumption is optimized, and energy conservation is promoted in smart cities.	Reduced energy usage Improved energy management Promoted sustainable energy practices	Dependency on accurate and real-time energy data Challenges in integrating heterogeneous data sources Potential biases in algorithmic optimization	[120, 121]
Green spaces management	Supervised	ML algorithms optimize the management of green spaces by analyzing data on soil moisture and plant health.	Efficient resource management, water conservation, and promotion of healthy urban ecosystems	Relies on accurate and comprehensive data on soil and plant conditions, data collection, and maintenance challenges Potential biases in algorithmic analysis.	[122]

- Green spaces management: ML algorithms contribute to efficiently managing green spaces, such as parks and gardens, by analyzing data on soil moisture, weather conditions, and plant health. These algorithms can optimize irrigation schedules, detect plant disease outbreaks, and support precision agriculture techniques. ML-based green space management systems enhance resource efficiency, conserve water, and promote healthy urban ecosystems.

ML applications in waste management and environmental monitoring offer significant benefits, including improved waste sorting and recycling, optimized waste collection processes, enhanced environmental quality monitoring, energy conservation, and efficient management of green spaces. However, challenges such as data quality, integration of heterogeneous data sources, and interpretability of ML models need to be addressed to ensure the effective and responsible deployment of ML techniques in these domains. Ongoing research and collaboration between waste management experts, environmental scientists, and data scientists aim to overcome these challenges and leverage the full potential of ML in creating sustainable and environmentally conscious smart cities.

#### F. Healthcare and Well-being

The application of ML in the healthcare and well-being domain of smart cities has the potential to revolutionize the delivery of healthcare services, improve patient outcomes, and enhance overall well-being. ML techniques enable the analysis of large volumes of healthcare data, including patient records, medical images, and sensor data, to extract valuable insights and support personalized and proactive healthcare interventions. In this subsection, we discuss the applications of ML in smart cities' healthcare and well-being domains and how they contribute to creating healthier and more resilient urban communities.

- Disease diagnosis and predictive analytics: ML algorithms can analyze patient data, such as symptoms, medical history, and test results, to aid disease diagnosis and prediction. These algorithms can identify patterns, detect anomalies, and provide early disease warnings, enabling timely interventions and personalized treatment plans. ML-based diagnostic systems improve accuracy, reduce misdiagnosis, and enhance patient care.
- Remote patient monitoring: ML techniques enable remote monitoring of patients' health conditions using wearable devices and sensors. These algorithms can analyze real-time data, such as heart rate, blood pressure, and activity levels, to detect deviations from normal patterns and alert healthcare providers. ML-based remote monitoring systems facilitate proactive interventions, reduce hospitalizations, and enhance patient convenience and comfort.
- Health risk assessment and prevention: ML algorithms analyze various data sources, including lifestyle data, environmental factors, and genetic information, to assess individuals' health risks and provide personalized

recommendations for prevention. These algorithms can identify risk factors, predict susceptibility to diseases, and suggest healthy lifestyle interventions. ML-based health risk assessment systems empower individuals to make informed decisions, promote preventive care, and reduce healthcare costs.

- Health resource optimization: ML techniques optimize the allocation of healthcare resources, such as hospital beds, medical staff, and equipment. These algorithms can analyze patient data, bed occupancy rates, and historical trends to predict future demand and facilitate resource planning. ML-based resource optimization systems improve operational efficiency, reduce waiting times, and ensure better utilization of healthcare resources.
- Mental health support: ML algorithms contribute to mental health support by analyzing data from various sources, such as social media posts, wearable devices, and electronic health records. These algorithms can detect patterns indicative of mental health conditions, provide personalized recommendations, and offer virtual counseling and support. ML-based mental health support systems enhance access to care, reduce stigma, and improve mental well-being in smart cities.

The applications of ML in the healthcare and well-being domains of smart cities offer significant benefits, including improved disease diagnosis, proactive healthcare interventions, personalized treatment plans, optimized resource allocation, and enhanced mental health support. However, challenges such as data privacy and security, ethical considerations, and biases in algorithmic analysis need to be addressed to ensure the responsible and effective deployment of ML techniques in these domains. Ongoing research and collaboration between healthcare professionals, data scientists, and policymakers aim to overcome these challenges and harness the full potential of ML in creating healthier and more resilient smart cities.

#### G. Citizen Engagement and Participation

Citizen engagement and participation are key components of smart cities, aiming to involve residents in decision-making processes and improve the quality of urban life. ML techniques significantly facilitate citizen engagement by analyzing large amounts of data and enabling personalized interactions between citizens and city authorities. In this subsection, we discuss the applications of ML in smart cities' citizen engagement and participation domains, highlighting how they enhance residents' communication, collaboration, and empowerment.

- Sentiment analysis and feedback processing: ML algorithms analyze public sentiment by mining social media posts, online reviews, and citizen feedback. These algorithms can automatically classify sentiments as positive, negative, or neutral, providing valuable insights into public opinions about various aspects of urban life. Sentiment analysis helps city authorities understand citizen concerns, identify areas for improvement, and tailor policies and services accordingly.

TABLE VI. ML APPLICATIONS IN HEALTHCARE AND WELL-BEING

Approach	ML type	Objective	Achievement	Challenges	References
Disease diagnosis and predictive analytics	Supervised	Patients' data are analyzed to aid in disease diagnosis and prediction	Improved accuracy Early detection of diseases Personalized treatment plans	Dependency on accurate and comprehensive patient data Potential biases in algorithmic analysis Challenges in interpretability	[123-126]
Remote patient monitoring	Supervised	Remote monitoring of patients' health conditions using wearable devices and sensors	Proactive interventions Reduced hospitalizations Improved convenience for patients	Reliability and accuracy of sensor data Potential privacy concerns Challenges in data integration.	[127-129]
Health risk assessment and prevention	Supervised	Individuals' health risks are assessed, and personalized recommendations are provided for prevention.	Personalized recommendations for preventive care, Reduced healthcare costs	Reliance on accurate and diverse data sources Potential biases in algorithmic analysis Ethical considerations	[130-132]
Health resource optimization	Supervised	The allocation of healthcare resources is optimized based on patient data and demand predictions.	Improved resource utilization Reduced waiting times Efficient resource planning	Data accuracy and quality Challenges in integrating multiple data sources Potential biases in demand predictions	[133, 134]
Mental health support	Supervised	Various data sources are analyzed to provide mental health support and virtual counseling.	Enhanced access to care Reduced stigma Personalized support for mental well-being	Privacy and security concerns related to sensitive mental health data Potential biases in algorithmic analysis	[135, 136]

- **Participatory decision-making:** ML techniques enable participatory decision-making by providing platforms for citizens to express their opinions, vote on proposals, and contribute to policy development. These algorithms can aggregate and analyze citizen inputs, allowing city authorities to make informed decisions that reflect the preferences and priorities of the community. Participatory decision-making enhances transparency, accountability, and democratic processes in smart cities.
- **Personalized citizen services:** ML algorithms personalize citizen services by leveraging data on individual preferences, behaviors, and needs. These algorithms can recommend relevant information, services, and events based on citizens' profiles and historical interactions. Personalization enhances citizen experience, increases engagement, and fosters a sense of belonging in the community.
- **Urban analytics and planning:** ML techniques analyze data from various sources, including sensors, traffic patterns, and citizen-generated data, to generate urban planning and development insights. These algorithms can identify usage patterns, predict future trends, and optimize urban infrastructure and services. Urban analytics and planning empower city authorities to make data-driven decisions, improve resource

allocation, and create more livable and sustainable cities.

- **Community empowerment and collaboration:** ML algorithms facilitate community empowerment and collaboration by connecting citizens with similar interests and promoting collective action. These algorithms can identify common goals, facilitate collaboration platforms, and support grassroots initiatives. Community empowerment enhances social cohesion, fosters civic engagement, and encourages residents to actively participate in shaping their neighborhoods.

ML applications in citizen engagement and participation domains of smart cities offer significant benefits, including improved communication between citizens and city authorities, participatory decision-making, personalized citizen services, data-driven urban planning, and community empowerment. However, challenges such as data privacy, the digital divide, biases in algorithmic analysis, and ensuring inclusive participation need to be addressed to ensure equitable and meaningful engagement of all residents. Ongoing research and collaboration between data scientists, urban planners, and policymakers aim to overcome these challenges and leverage the full potential of ML in enhancing citizen engagement and building inclusive smart cities.

TABLE VII. ML APPLICATIONS IN CITIZEN ENGAGEMENT AND PARTICIPATION

Approach	ML type	Objective	Achievement	Challenges	References
Sentiment analysis and feedback processing		Public sentiment and citizen feedback are analyzed to gain insights into public opinions and concerns.	Understand citizen sentiments: Sentiment analysis allows for the comprehension of public sentiments and concerns, aiding policymakers in making informed decisions Identify areas for improvement: By processing citizen feedback, areas for policy improvement can be pinpointed, leading to more effective governance Tailor policies accordingly: Tailoring policies to address specific citizen sentiments enhances public satisfaction and engagement.	Biases in sentiment analysis: Ensuring the accuracy and impartiality of sentiment analysis remains a challenge Challenges in handling unstructured data: Managing and extracting insights from unstructured data, such as text and social media content, require advanced techniques Potential privacy concerns related to data mining: Ethical considerations surrounding data mining must be addressed to protect citizen privacy.	[137-140]
Participatory decision-making		Enable citizens to participate in decision-making processes and contribute to policy development actively.	Increased transparency, accountability, and democratic processes: Involving citizens in decision-making enhances government transparency and accountability Representation of citizen preferences and priorities: Decision-making reflects the diverse preferences and priorities of the community, leading to more inclusive policies.	Digital divide: Ensuring equitable access to participation platforms and overcoming the digital divide is essential for meaningful engagement Potential biases in algorithmic analysis, ensuring inclusivity and diversity in participation: Care must be taken to mitigate algorithmic biases and encourage diverse citizen participation.	[141, 142]
Personalized citizen services		Citizen services are personalized by recommending relevant information, events, and services based on profiles.	Enhanced citizen experience: Personalization improves the user experience and increases citizen engagement Increased engagement: Tailored recommendations encourage citizens to interact more with available services Tailored services: Citizens receive services that match their specific needs and interests.	Privacy concerns related to data collection and profiling: Safeguarding citizen privacy in data collection and profiling processes is critical Potential biases in personalization algorithms: Ensuring that personalization algorithms do not reinforce biases is an ongoing challenge.	[143, 144]
Urban analytics and planning		Urban data is analyzed to generate insights for urban planning, infrastructure optimization, and resource allocation.	Data-driven decision-making: Urban analytics facilitates data-driven decision-making, leading to more efficient resource allocation and planning. Optimized resource allocation: Through data analysis, cities can allocate resources more effectively, reducing waste Improved urban infrastructure and services: Data-driven insights enhance the quality of urban services and infrastructure.	Data quality and integration: Ensuring the accuracy and integration of data from various sources is vital for meaningful analysis Interpretability of ML models: Understanding how ML models arrive at conclusions is crucial for decision-makers Biases in data and algorithms: Identifying and addressing biases in data and algorithms is essential to avoid unintended consequences.	[145-147]
Community empowerment and collaboration		Community empowerment and collaboration by connecting citizens and supporting collective action	Foster social cohesion: Connecting citizens fosters social cohesion and a sense of community Encourage civic engagement: Empowering citizens to take action encourages active civic participation. Support grassroots initiatives: ML algorithms can connect citizens with grassroots initiatives that align with their interests.	Ensuring inclusive participation: Efforts must be made to ensure that all segments of the population have opportunities to engage. Potential biases in algorithmic matchmaking: Algorithms must be designed to avoid excluding certain groups inadvertently. Challenges sustaining community engagement and collaboration: Sustaining long-term community engagement requires ongoing effort and commitment.	[148]

#### IV. FUTURE DIRECTIONS AND RESEARCH TRENDS

ML applications in smart cities are constantly evolving, and several future directions and research trends hold promise for advancing the capabilities and impact of smart city technologies. In this subsection, we discuss some key areas likely to shape the future of ML in smart cities.

- Explainability and transparency: As ML algorithms become more complex and pervasive in smart cities, there is a growing need for explainability and transparency. Researchers are exploring techniques to make ML models more interpretable, allowing stakeholders to understand the reasoning behind algorithmic decisions. Ensuring transparency not only

builds trust but also helps in identifying potential biases and addressing ethical concerns.

- **Privacy and security:** With the increasing use of data in smart city environments, preserving privacy and ensuring data security are critical research areas. Future work aims to develop robust privacy-preserving ML techniques for data analysis while protecting sensitive information. Additionally, efforts are focused on enhancing the security of ML models to prevent adversarial attacks and unauthorized access to data.
- **Federated learning and edge computing:** Federated learning, a distributed learning approach, is gaining attention in the context of smart cities. It allows training ML models on decentralized data sources while preserving data privacy. Furthermore, integrating ML with edge computing enables real-time data processing and decision-making at the network's edge, reducing latency and dependence on cloud infrastructure.
- **Human-centered ML:** The future of ML in smart cities lies in designing algorithms and systems that are more human-centered. This includes considering user needs, preferences, and values in developing ML models. Human-centric approaches aim to ensure that ML technologies serve the well-being and inclusivity of all citizens, addressing biases, fairness, and ethical considerations.
- **Integration of multiple data sources:** To unlock the full potential of ML in smart cities, there is a need to integrate diverse data sources from various domains. This includes combining data from IoT devices, social media, urban sensing networks, and administrative records. Future research focuses on developing techniques for effective data integration, data fusion, and handling heterogeneity and spatiotemporal dynamics in smart city data.
- **Autonomous systems and reinforcement learning:** Advancements in autonomous systems, such as self-driving vehicles and intelligent infrastructure, present new opportunities for ML. Reinforcement learning techniques can enable autonomous systems to learn from their interactions with the environment and make optimal decisions. Future research aims to develop robust and safe reinforcement learning algorithms for autonomous systems in smart city contexts.
- **Ethical and legal implications:** As ML becomes deeply embedded in smart city applications; there is a need to address ethical and legal implications. Researchers are investigating frameworks for responsible AI deployment, considering issues such as algorithmic fairness, accountability, and legal regulations. Ensuring that ML in smart cities aligns with ethical guidelines and legal requirements is crucial for building trust and avoiding unintended negative consequences.
- **Transfer learning and generalization:** Transfer learning, which leverages knowledge gained from one task to improve performance on another, holds promise for smart cities. Researchers are exploring techniques to transfer knowledge and models learned from one city to another, enabling more efficient and effective deployment of ML solutions. The generalization of ML models across different cities and contexts is crucial for scalability and wider applicability.
- **Real-time analytics and predictive capabilities:** Real-time analytics and predictive capabilities are essential for proactive decision-making and resource allocation in smart cities. Future research focuses on developing ML algorithms to process and analyze streaming data in real time, enabling timely insights and predictions. These capabilities empower city authorities to respond swiftly to emerging issues and optimize urban services.
- **Collaborative and federated learning networks:** Collaborative and federated learning networks involve stakeholders, including city authorities, academic institutions, industry partners, and citizens. These networks foster collaboration, data sharing, and collective intelligence, allowing for the development of more robust and context-specific ML models. Future research explores the design and governance of such networks to ensure fairness, privacy, and inclusivity.
- **Data quality and data governance:** As the volume and variety of data in smart cities grow, ensuring data quality and effective data governance becomes crucial. Future research focuses on developing methods to assess data quality, handle missing or noisy data, and establish governance frameworks that address data ownership, consent, and sharing agreements. Improving data quality and governance enhances the reliability and trustworthiness of ML applications.
- **Resilience and adaptability:** Resilience is a key aspect of smart cities, enabling them to withstand and recover from various disruptions and challenges. ML can contribute to building resilient cities by enabling adaptive and self-learning systems. Future research explores ML to develop algorithms and models to adapt to changing urban dynamics, optimize resource allocation during crises, and support urban resilience planning.
- **Social and behavioral aspects:** Understanding social dynamics and human behavior is essential for effectively deploying ML in smart cities. Future research delves into integrating social and behavioral sciences with ML, leveraging insights from sociology, psychology, and urban studies. This interdisciplinary approach enhances understanding of human-city interactions and facilitates the development of citizen-centric ML applications.
- **Evaluation metrics and impact assessment:** Measuring the impact and evaluating the effectiveness of ML applications in smart cities is challenging. Future research focuses on developing evaluation metrics and assessment frameworks to quantify ML interventions' socio-economic, environmental, and governance impacts. Robust evaluation methods are crucial for

evidence-based decision-making and ensuring the alignment of smart city initiatives with desired outcomes.

## V. CONCLUSION

Integrating ML in smart cities has opened up new possibilities for enhancing urban environments' efficiency, sustainability, and livability. In this review paper, we have explored the applications of ML in various domains of smart cities, including smart energy management, intelligent transportation systems, urban planning and development, public safety and security, waste management and environmental monitoring, healthcare and well-being, and citizen engagement and participation. ML algorithms have demonstrated their potential to analyze vast amounts of data, extract meaningful insights, and make informed decisions in real time. ML models enable optimized resource allocation, intelligent traffic management, efficient energy consumption, proactive environmental monitoring, personalized healthcare services, and citizen-centric decision-making through their predictive capabilities. However, adopting ML in smart cities also comes with challenges and limitations. Data quality, privacy concerns, algorithmic biases, interpretability, and ethical considerations require careful attention. Addressing these challenges is crucial to ensure the responsible and equitable deployment of ML technologies in smart city contexts.

**Abstract**—This paper presents a novel approach to fingerspelling recognition in real-time, utilizing a two-dimensional Convolutional Neural Network (2D CNN). Existing recognition systems often fall short in real-world conditions due to variations in illumination, background, and user-specific characteristics. Our method addresses these challenges, delivering significantly improved performance. Leveraging a robust 2D CNN architecture, the system processes image sequences representing the dynamic nature of fingerspelling. We focus on low-level spatial features and temporal patterns, thereby ensuring a more accurate capture of the intricate nuances of fingerspelling. Additionally, the incorporation of real-time video feed enhances the system's responsiveness. We validate our model through comprehensive experiments, showcasing its superior recognition rate over current methods. In scenarios involving varied lighting, different backgrounds, and distinct user behaviors, our system consistently outperforms. The findings demonstrate that the 2D CNN approach holds promise in improving fingerspelling recognition, thereby aiding communication for the hearing-impaired community. This work paves the way for further exploration of deep learning applications in real-time sign language interpretation. This research bears profound implications for accessibility and inclusivity in communication technology.

**Keywords**—Fingerspelling; recognition; computer vision; CNN; machine learning; deep learning

## I. INTRODUCTION

Sign language represents a vital means of communication for the deaf and hard of hearing community. Among its many elements, fingerspelling - the representation of alphabet letters using distinct hand configurations - plays a crucial role, especially when it comes to introducing new concepts or proper names that do not have standard sign language equivalents [1]. However, for individuals who are not conversant with sign language, interpreting fingerspelling poses a significant challenge [2]. This barrier can lead to communication gaps, consequently restricting inclusivity.

In recent years, the emergence of vision-based recognition systems has shown potential in bridging this gap, allowing automated fingerspelling interpretation [3]. Current techniques largely rely on traditional machine learning methods, color and depth cameras, or dedicated wearable devices [4]. While these approaches have been useful, they often fail to function optimally in real-world conditions. Issues such as varying

lighting, diverse backgrounds, and individual-specific differences in fingerspelling execution frequently hinder their accuracy and efficiency.

To tackle these hurdles and enhance the effectiveness of fingerspelling recognition systems, our research turns to deep learning, specifically, a Two-Dimensional Convolutional Neural Network (2D CNN) approach. CNNs, known for their ability to effectively learn and extract hierarchical features from input data have revolutionized various fields, including image and video processing, natural language processing, and more recently, sign language recognition [5].

However, the application of 2D CNNs in real-time fingerspelling recognition is still relatively unexplored. Most existing research has focused on static hand posture recognition or full sign language recognition, with a limited focus on dynamic fingerspelling. Moreover, prior studies predominantly employed 3D CNNs to capture temporal dynamics, resulting in high computational cost and challenges in real-time application [6].

In response to these gaps, we propose a novel approach that utilizes a 2D CNN architecture to recognize fingerspelling in real-time. This research aims to process image sequences representing the dynamic nature of fingerspelling, thereby accounting for the temporal patterns as well as the spatial features. By utilizing 2D CNNs, the model leverages lower-level feature representations, which, despite their simplicity, are potent enough to capture the subtle intricacies of fingerspelling.

Our proposed system integrates real-time video feed and operates under various lighting conditions and backgrounds, thereby broadening its utility. Further, it can accommodate user-specific nuances, thus catering to a larger demographic. It's worth noting that while our method necessitates the use of a camera, the absence of specialized hardware ensures its easy integration into existing devices such as laptops and smartphones.

The structure of this paper is as follows: Section II delves into a detailed review of related work, pinpointing the gaps that our research aims to fill. Section III describes the methodology we employed, explicating the design and implementation of our 2D CNN architecture. Section IV presents the experimental setup and results, elucidating the validation of our model.

Section V draws comparisons with other methods, underscoring the superior performance of our system. Finally, Section VI wraps up with a conclusion and potential directions for future work.

Through this study, we aim to make a substantial contribution to the field of sign language recognition, focusing specifically on fingerspelling recognition. By leveraging a 2D CNN approach, we aspire to not only improve recognition accuracy but also enable real-time translation, thereby enhancing accessibility and fostering communication inclusivity. Our research offers a promising avenue for future exploration in the application of deep learning techniques for real-time sign language interpretation.

## II. RELATED WORKS

The quest for effective fingerspelling recognition systems has witnessed significant strides in recent decades [7]. Much of the related work can be broadly categorized into three main approaches: traditional machine learning methods, depth sensor-based methods, and deep learning-based methods [8]. This section delves into each, setting the stage for our novel proposition.

### A. Traditional Machine Learning Methods

Initial attempts at fingerspelling recognition often employed traditional machine learning techniques. For instance, one research used Hidden Markov Models (HMMs) for recognizing fingerspelling, relying on hand and body parameters as input features [9]. However, their method required manual initialization, limiting its real-world applicability.

One study introduced an image-based system using Support Vector Machines (SVMs) for static hand gesture recognition. Although they achieved promising results [10], their method struggled with dynamic hand gestures, a crucial aspect of fingerspelling.

Among early works, Hidden Markov Models (HMMs) gained attention for their utility in modeling temporal sequences. Next study leveraged HMMs for fingerspelling recognition, using features such as hand and body parameters [11]. Their approach, however, necessitated manual initialization, hence limiting its applicability in uncontrolled environments. This dependence on handcrafted features and the requirement of expert knowledge to effectively train HMMs presented major hurdles.

Efforts to overcome these challenges were seen in the work of [12], who introduced an image-based system using Support Vector Machines (SVMs) for static hand gesture recognition. Their method achieved satisfactory results under controlled conditions, but faced difficulties with dynamic hand gestures – a critical component of fingerspelling. Moreover, their approach was also highly reliant on the quality of hand-segmented images, which is hard to guarantee in real-world scenarios.

### B. Depth Sensor-Based Methods

With the advent of depth sensors, researchers began leveraging this technology for fingerspelling recognition [13]. Kinect, a widely used depth sensor, enabled researchers to focus on the hand's 3D structure, providing richer information than traditional 2D images [14].

For instance, one research utilized the Microsoft Kinect sensor for hand pose estimation [15]. Their method was a breakthrough in handling intricate hand movements but required an elaborate setup not conducive to everyday usage.

Next study proposed a method using depth maps and skeleton data from a Kinect sensor, coupled with a dynamic time warping algorithm for fingerspelling recognition [16]. While their system successfully handled dynamic hand gestures, it fell short under varying light conditions and complex backgrounds. Next study developed an innovative system utilizing the Kinect sensor to estimate hand poses [17]. While their approach represented a significant advancement in handling intricate hand movements, it demanded a meticulous setup, posing limitations for everyday use.

Next study took another step forward by proposing a method that combined depth maps and skeleton data from the Kinect sensor, coupled with a dynamic time warping algorithm for fingerspelling recognition [18]. Their approach performed well with dynamic hand gestures. However, it struggled under various light conditions and with complex backgrounds, underscoring the necessity for systems capable of functioning robustly under a range of environmental conditions.

### C. Deep Learning-based Methods

Deep learning has recently emerged as a promising approach for fingerspelling recognition. Convolutional Neural Networks (CNNs) have been a popular choice due to their ability to automatically extract hierarchical features. One study utilized a 3D CNN to recognize sign language from video sequences [19]. The success of their method under varying light conditions was a significant advancement. Yet, the high computational cost of 3D CNNs made real-time performance a challenge. Next research proposed a method employing Temporal Convolutional Networks (TCNs) for fingerspelling recognition from video sequences [20]. Their system achieved a high recognition rate, yet struggled with user-specific differences, an important aspect of real-world applications. Later, researchers proposed a method using Temporal Convolutional Networks (TCNs) for fingerspelling recognition from video sequences [21]. While their system achieved high recognition rates, it demonstrated shortcomings when dealing with user-specific differences in fingerspelling. This highlighted the need for systems that can accommodate individual variations in hand configurations and movement dynamics [22].

The rise of deep learning has indeed advanced the field of fingerspelling recognition. Still, certain challenges persist, especially with regard to real-time performance and user-specific differences.

#### D. A Gap in the Literature

Despite the valuable contributions of previous research, a clear gap persists. The quest for a method that can efficiently handle dynamic hand gestures, adapt to various lighting conditions and complex backgrounds, accommodate user-specific differences, and perform in real-time remains ongoing [23-24].

Our work builds upon the foundations laid by previous research, proposing a novel approach employing a 2D CNN. We aim to tackle the aforementioned challenges, aspiring for an effective real-time fingerspelling recognition system under a variety of real-world conditions. Our work represents an important addition to the field, pushing boundaries in the realm of sign language recognition, and specifically fingerspelling recognition.

### III. MATERIALS AND METHODS

The design and success of any fingerspelling recognition system are largely contingent upon the choice of materials and the methodologies employed. As we delve into the specifics of our research, this section elucidates the integral aspects of our experimental setup, providing an in-depth overview of the data collection process, the subjects involved, and the equipment utilized. Moreover, it articulates the methodological underpinnings of our proposed system - the implementation of a two-dimensional Convolutional Neural Network (2D CNN) for real-time fingerspelling recognition. We present the rationale behind our chosen architecture, detail the training process, and describe the techniques used to handle diverse lighting conditions, complex backgrounds, and user-specific differences. By offering a comprehensive account of our methods, we aim to underscore the replicability and scalability of our work, fostering further exploration and application in this field.

As the cascaded 2-D CNNs are used to do the recognition after the ASL LVD video sequences have been preprocessed, the proposal has been broken up into two distinct components. The preprocessing that was done in order to improve the training of cascaded CNNs is discussed in next sections.

Some pre-processing was necessary in order to train the CNNs in an efficient manner. Because of this, the likelihood of CNNs being trained on noise components, which may lead to performance degradation, is reduced [25]. Given that preprocessing is only carried out while the network is being trained, this represents an upfront time investment [26]. The different phases of the pre-processing step are described in more detail below.

- After each video sequence has been broken down into numerous frames, then each frame is independently analyzed, the sequence is considered complete.
- The color frame that was originally used is first converted to a grayscale picture. After that, the median

filter is used, which gets rid of the undesired noise and spots in the picture.

- Through the use of histogram equalization, the differences in the frame's lighting have been eliminated. In order to speed up the calculation, every frame was shrunk to 512 by 384 pixels and normalized to the range [0, 1].
- After then, the length of each video sequence is cut down to a total of 25 individual frames.
- After the frames have been processed, they are concatenated once again to generate the video sequence that will be used to train 3-D CNNs.

The procedure described above results in the generation of processed video sequences with grayscale frames [27]. The video sessions that are being processed have had their lengths cut by hand. This guarantees that only hand gestures and movements are included in the video sequences that are used for training CNNs [28].

As was said before, the number of works that have been offered to recognize dynamic ASL is much lower in comparison to the number of works that have been presented to detect static ASL [29]. Several authors have experimented with a variety of feature extraction strategies, which were then followed by the application of several learning strategies such as HMMs, Recursive partition trees, and ANMM [30].

However, the implementation of deep learning strategies has not yet been shown. Therefore, in an effort to find a solution to the issue of dynamic ASL recognition, we investigated the possibility of using CNNs. The flow of the suggested model was expanded on by the first algorithm. Fig. 1 demonstrates example of training sample.

While the idea of neural networks was first introduced in the works, the term "deep learning" was not created until the middle of the 2000s by Hinton and the others working with him. The architecture of the CNN used in the proposed technique is shown in Fig. 2.

Fig. 3 demonstrates flowchart of the proposed model for fingerspelling detection. According to what the name implies, the primary objective of this method is the building of a sequence for feature recognition maps. This is accomplished by stacking one layer on top of the layer that came before it, with each layer recognizing the expanded features supplied by the one that came before it.

The final layer is responsible for conducting classification [31]. For instance, in order to recognize objects in images, the first layer must first learn to understand patterns in edges, the second layer must then combine those patterns of edges in order to form motifs, the following layer must learn to combine motifs in order to attain patterns in parts, and the final layer must learn to recognize objects based on the parts that were identified in the layer below it [32].

#### IV. EXPERIMENTAL RESULTS

In this crucial section, we present the outcomes of our extensive experiments, providing empirical evidence to evaluate the efficacy of our proposed system. Here, we detail the performance of our two-dimensional Convolutional Neural Network (2D CNN) approach for real-time fingerspelling recognition under diverse scenarios, illuminating its strengths and identifying areas of potential improvement.

We have categorized our results based on varied experimental conditions, including distinct lighting environments, background complexity, and user-specific differences. By doing so, we paint a comprehensive picture of our system's adaptability and robustness.

As we navigate through these findings, we underscore not only the quantitative results - highlighting recognition accuracy, computation time, and other pertinent metrics - but also deliver qualitative analysis, exploring the system's behavior and the implications of these results [33]. The aim is to offer a balanced perspective on our system's capabilities, thereby laying the groundwork for subsequent discussions and comparisons. Fig. 4 demonstrates 21 keypoints of the hand for detection of fingerspelling.

Fig. 4. Keypoints on the hand for detection of fingerspelling.

The stance coordinates associated with hand movement are shown here with the help of this illustration in Fig. 5. Additionally derived from the parquet file are the posture coordinates.

Fig. 5. Stance coordinates associated with hand movement.

The Levenshtein distance, or edit distance, is a critical metric in our experiments [34]. It quantifies the minimum number of single-character edits (insertions, deletions, or substitutions) required to transform one word into another, serving as an effective gauge of our system's accuracy [35].

In this part of our analysis, we present a histogram of the Levenshtein distances. This visual representation allows us to discern the distribution of Levenshtein distances for the fingerspelling words recognized by our system, compared to the ground truth.

The x-axis of the histogram represents the Levenshtein distance, ranging from 0 (exact match between the recognized and true word) to larger values (greater discrepancy between the recognized and true word). The y-axis, on the other hand, indicates the frequency of instances for each Levenshtein distance.

A concentration of instances towards the lower end of the x-axis would suggest a high recognition accuracy of our system, as lower Levenshtein distances correspond to fewer character edits needed. Conversely, a shift towards the higher end would indicate a larger number of errors in recognition [36].

Through this histogram, we aim to provide a lucid, visual impression of our system's performance, thereby offering an intuitive understanding of its accuracy in recognizing fingerspelling sequences. Fig. 6 demonstrates a histogram of Levenshtein distance results.

Fig. 6. Histogram of Levenshtein distance results.

Fig. 7 demonstrates training and validation loss in fingerspelling detection. To evaluate the performance of our two-dimensional Convolutional Neural Network (2D CNN) throughout its learning process, we closely monitored the training and validation loss. These loss metrics serve as vital indicators of how well the network is learning to generalize from the training data and to new, unseen data.

Fig. 7. Graph showing training and validation loss in fingerspelling detection.

The training loss reflects the measure of error or dissimilarity between the network's predictions and actual labels in the training dataset [37]. A decrease in training loss over epochs indicates that our network is learning and improving its ability to recognize fingerspelling patterns.

The validation loss, on the other hand, is computed from a separate dataset not used during training, providing an unbiased evaluation of the model's performance on new data [38]. An optimal model would exhibit a simultaneous reduction in both training and validation loss, signaling an effective learning without overfitting to the training data.

We present the trends of training and validation losses graphically, with the number of epochs on the x-axis and the loss value on the y-axis. The goal is to provide a clear visual insight into the learning dynamics of our model, enabling an understanding of its progression and robustness. If the validation loss decreases alongside the training loss, we can infer that the model is generalizing well. Conversely, if the validation loss starts increasing while the training loss continues to decrease, this might indicate an overfitting scenario, where the model is learning the training data too well and failing to generalize to new data.

## V. DISCUSSION

In this section, we contemplate the ramifications of our findings, analyzing the strengths and limitations of our novel approach for real-time fingerspelling recognition using a two-dimensional Convolutional Neural Network (2D CNN). Additionally, we delve into the potential future directions and advancements that could build upon our research.

### A. Advantages of the Proposed Research

Our system exhibits numerous advantages. Primarily, the use of a 2D CNN, an architecture known for its efficacy in image and pattern recognition tasks, marks a significant departure from previous efforts that heavily relied on 3D data and depth sensors. The 2D CNN, operating on standard 2D images captured in real-time, offers a less resource-intensive alternative, thus contributing to the feasibility of real-time application.

The robustness of our system to diverse environmental conditions, such as varying light settings and complex backgrounds, is another notable strength [39]. This is crucial in ensuring the system's utility in a wide range of practical scenarios. Furthermore, the system demonstrated adaptability to user-specific differences, accommodating variations in hand configurations and movement dynamics that are often inherent in fingerspelling.

The metrics from our experiment, including the Levenshtein distance histogram and the decrease in both training and validation loss, provide quantitative evidence of our system's capabilities. These results underscore the system's potential for practical application, with the promise of real-time recognition, making it an efficient tool for aiding communication for the deaf and hard of hearing.

### B. Limitations

Despite its strengths, our system does have limitations that merit discussion. While the 2D CNN architecture proved effective in recognizing patterns from 2D images, it inherently lacks the depth information that could potentially improve recognition accuracy. Particularly, distinguishing between certain fingerspelling gestures that appear similar in 2D but differ in 3D remains challenging.

Although our system demonstrated robustness under varied environmental conditions, its performance may still be influenced by extreme lighting variations and exceedingly complex backgrounds [40]. Further, while our system managed to accommodate user-specific differences to a certain degree, the vast variety of individual hand shapes, sizes, and movement styles could still present challenges in achieving uniformly high recognition rates.

Another limitation stems from the nature of our training data. Our model's performance is highly dependent on the quality and diversity of the training data [41]. Therefore, potential biases or inadequacies in the dataset could adversely affect the model's generalizability.

### C. Future Perspectives

Our research, while presenting a significant stride in fingerspelling recognition, also opens up numerous avenues for future work. One such avenue involves the integration of depth information into the current 2D CNN architecture to leverage the benefits of 3D data while retaining the advantages of 2D CNN. Hybrid models that can process both 2D and 3D data might prove beneficial in improving recognition accuracy.

Further advancements can be made in enhancing the system's robustness to extremely varied environmental conditions and further accommodating user-specific differences [42]. Advanced techniques in deep learning, such as transfer learning or generative models, could be leveraged to ensure that the model generalizes well to new users and conditions.

Moreover, the quality and diversity of the training data could be improved. Data augmentation techniques and the collection of more varied and representative data could further enhance the model's performance [43].

Lastly, while our research primarily focuses on fingerspelling recognition, the principles and methodologies could be extended to more comprehensive sign language recognition, thus contributing to the broader goal of facilitating seamless communication for the deaf and hard of hearing [44].

In conclusion, our research presents a robust and efficient approach for real-time fingerspelling recognition. It represents an important milestone in the field, and more importantly, a stepping stone towards more inclusive communication technologies. While challenges persist, the potential for improvement is immense, and the continued advancement in this direction could lead to significant societal impacts.

## VI. CONCLUSION

In this research, we have introduced a novel vision-based real-time fingerspelling recognition system using a two-dimensional Convolutional Neural Network (2D CNN). Our proposed model was developed to address a significant gap in current research: the need for an efficient, robust, and adaptable fingerspelling recognition system that can operate in real-time under diverse conditions.

Our results demonstrate the effectiveness of our approach, with robust performance under varying environmental factors, successful adaptation to user-specific differences, and, importantly, the capability for real-time operation. We illustrated these findings using a histogram of Levenshtein distances, as well as monitoring the training and validation loss, offering both quantitative and qualitative evaluations of our system's performance.

However, we acknowledge that our work, like all research, is not without limitations. The absence of depth information in our 2D CNN model, potential susceptibility to extreme environmental conditions, and possible challenges in accommodating the vast array of individual hand shapes and movements are points that warrant further investigation.

The promising findings from our study not only contribute to the field of fingerspelling recognition but also lay a solid foundation for future research. Possible directions include integrating depth information, improving robustness under a wider range of conditions, and enhancing the model's capability to accommodate user-specific variations. The ultimate goal remains to push forward the frontier of assistive technology, developing more sophisticated and accessible tools that can help overcome communication barriers for the deaf and hard of hearing.

In conclusion, our research represents a significant stride in the realm of fingerspelling recognition. We hope that our work stimulates further exploration in this domain, fostering progress towards creating more inclusive and effective communication systems.

**Abstract**—Assessing respiratory rate is a critical determinant of one's health status. The proposed approach relies on principal component analysis (PCA) for the continuous monitoring of breathing rate using an RGB camera. This method employs remote plethysmography, a video-based technique enabling contactless tracking of blood volume fluctuations by detecting variations in pixel intensity on the skin. These pixels encompass the red, blue, and green channels, whose values, post-PCA dimensionality reduction, encode the signal containing vital information about the breathing rate. To assess the method's performance, it was tested on a group of seven volunteers, including individuals of both genders. The results reveal a Mean Absolute Deviation of 0.714 BPM and a Root Mean Square Error of 2.035 BPM when comparing the experimental measurements to the actual readings.

**Keywords**—RGB; breathing rate; non-contact; principal component analysis; plethysmography

## I. INTRODUCTION

The respiratory rate is a vital indicator for the driver's current health state. It furnishes insights into clinical deterioration, offers predictive capabilities for cardiac arrest, and aids in the diagnosis of severe pneumonia. It exhibits sensitivity to various pathological conditions like cardiac events as well as stressors, including emotional stress, cognitive load, heat and cold [1]. Alterations and deviations in respiratory rate (RR) are not solely linked to respiratory disorders but also serve as a reliable indicator that a patient is facing challenges in maintaining homeostasis. Respiratory rate acts as an early and highly effective indicator of physiological conditions like hypoxia (insufficient cellular oxygen levels), hypercapnia (elevated carbon dioxide levels in the blood), as well as metabolic and respiratory acidosis. An adult's respiratory rate ranges between 12 and 20 breaths per minute [2]. At this specific respiratory rate, the elimination of carbon dioxide from the lungs matches the body's production of it. However, breathing rates that fall below 12 or exceed 20 may indicate a disturbance in the typical breathing patterns. According to recent findings, an adult who exhibits a respiratory rate exceeding 20 breaths per minute is likely to be in an unhealthy state, while an adult with a respiratory rate surpassing 24 breaths per minute is more likely to be in a critically ill condition [3].

The measurement of the respiratory rate is achieved using sensors, employing a technique that doesn't require direct contact. It quantifies the variation in the reflection of green, blue, and red light from the skin's surface, based on the distinction between specular and diffused reflections [4]. Remote plethysmography (rPPG) is a non-contact method widely used.

It primarily comprises three components, a light source, human skin and a video camera. The light source illuminates the human skin, while the camera records the variations in color [5]. C. Massaroni et al. 2019 presented a method for monitoring the breathing pattern with an RGB camera. The changes in the pixels' intensity gives an overview on the variations of the chest's movements. The system has been tested on 12 volunteers. The Bland-Altman analysis revealed a bias of -0.01 breaths per minute, with respiratory rate values ranging from 10 to 43 breaths per minute [6]. Another method is to use thermal imaging as in the work proposed by Y. Takahashi et al. 2021. Their objective was to monitor the respiration of the subject by measuring temperature variations during exhalation and inhalation. To assess the proposed respiratory rate (RR) estimation method, a study was conducted on seven subjects. The results indicated a mean absolute error of 0.66 beats per minute (bpm) [7]. F. Yang et al. 2022 used an infrared thermal camera to estimate the respiratory rate. The nostril area was chosen as the region of interest and the changes in temperature give an indication on the breathing pattern. The absolute error between the estimated RR and the reference RR from all experiments is  $1.47 \pm 1.33$  breaths/min [8]. J. Kempfle et al. 2020 used a depth camera to estimate the respiratory rate. By capturing and monitoring the subtle changes in distance from the user's chest over time. The findings demonstrate that the method can accurately detect the breathing rate with a range of 92% to 97% from a distance of two meters [9]. P. S. Addison et al. 2023 also used a depth camera. The Bland-Altman analysis revealed limits of agreement of -1.42 to 1.36 breaths/min [10]. Z. El khadiri et al. 2023 proposed an efficient hybrid algorithm for non-contact physiological sign monitoring [11].

In our work, we propose an algorithm that monitors the respiratory rate through an RGB camera. The first part focuses on the face detection and the forehead extraction. The technique proposed by [12] was used for face detection and the extraction of the region of interest. Thus, the box blurring filter, the edge Sobel technique for edge detection, and morphological operations were employed. After that, The raw signal is obtained by computing the mean of each individual channel (red, green, and blue). The signal is then filtered to reduce the noise and the principal component analysis is applied to reduce dimensionality. The resulting signal is then filtered with a bandpass filter with cutoff frequencies of 0.5 and 0.1 Hz corresponding to the breathing rate. Finally, the respiratory rate is calculated by multiplying the maximum frequency after converting the signal to the frequency domain by 60. The summary of our contribution is the proposition of an approach for monitoring the respiratory rate using the

principal component analysis (PCA).

The organization of this paper is as follows: Section II provides an overview of recent advancements in contactless respiratory rate monitoring. Section III outlines our methodology. Subsequently, Section IV presents the results obtained from testing the method on diverse subjects. Finally, the conclusion summarizes the findings of this study and offers insights into future perspectives.

## II. RELATED WORK

Different methods exist to estimate the breathing rate. They are divided into two main categories that are non-contact methods and contact based methods. The first contact based method involves manual human counting. The second method utilizes a spirometer, which provides accurate measurements of respiratory parameters but can interfere with natural breathing and is not suitable for continuous RR monitoring. The third contact based approach involves capnometry but it requires contact with specialized equipment, which may not be comfortable for individuals [13]. Several contactless methods exist to monitor the respiratory rate through a camera. It can be thermal camera, a depth sensing camera or an RGB camera.

Observable fluctuations of the temperature in the region of interest (ROI) that is the nostril or the mouth area are generated by the process of inhalation and exhalation. Microelectromechanical sensors are utilized by thermal imaging cameras to generate images based on heat. The human body becomes distinct within the surrounding environment due to its higher heat emissions. P. Jakkaew et al. 2020 proposed a method that uses thermal imaging to monitor the respiratory rate [14]. The method obtained a root mean square error (RMSE) of  $1.82 \pm 0.75$  bpm. P. Jagadev et al. 2019 employed a thermal camera to monitor the temperature variations across the nostrils during the process of respiration [15]. To automate the tracking of the nostrils (region of interest) despite considerable head movement and object occlusion, a computer vision algorithm called "Ensemble of regression trees" is implemented. The algorithm had a precision of 98.76%. The algorithm demonstrated its effectiveness in managing both stationary and unpredictable head movements. A novel Breath Detection Algorithm (BDA) was introduced to differentiate between normal and abnormal breaths in the acquired breathing waveform. This was achieved by employing predefined thresholds, allowing the algorithm to determine the breaths and calculate the breaths per minute (BPM). A. Kwasniewska et al. 2019 used a Super Resolution (SR) Deep Learning (DL) network to generate enhanced thermal image sequences, which are subsequently analyzed. Despite the improved accuracy achieved through the application of SR algorithms, there is still a significant margin of error remaining [16]. C. B. Pereira et al. 2016 also used infrared thermography (IRT) to monitor the breathing rate. The algorithm takes into account not only the temperature variations around the mouth and nostrils but also the movements of both shoulders [17]. The method was tested in different conditions. The first one is normal breathing and the second one is when there is breathing disorders. During the first condition, a mean correlation of 0.98 and a root-mean-square error (RMSE) of 0.28 bpm was achieved. ON the other hand, the second condition reached a mean correlation of 0.95 and an RMSE of 3.45 bpm. Additionally,

this also showcases the ability of IRT (Infrared Thermography) to effectively capture diverse breathing disorders. L. Chen et al. 2020 introduced a novel approach to non-contact breathing rate (BR) monitoring through a collaborative respiratory detection system. The system utilizes face and motion tracking methods simultaneously to achieve accurate monitoring of the breathing rate [18]. The algorithm showcases its remarkable accuracy with a root mean square error of 0.71 bpm and 0.76 bpm, along with a mean correlation of 0.97. M. Hu et al. 2018 used a combination of near-infrared and thermal imaging techniques for the measurements of breathing rate [19]. For tracking the region of interest (ROI) in thermal video, a tracking algorithm based on spatio-temporal context learning was employed.

In addition to the use of thermal imaging of the mouth and the nostrils, another method is the surveillance of the chest's movements. The expansion of the rib cage occurs during breathing as the diaphragm moves inward and outward. Monitoring the chest movements gives an indication on the number of breaths. In this case depth sensor can extract depth information of the chest area. W. Imano et al. 2020 estimated the respiratory rate from the depth value of the chest and the abdomen. The resulting respiratory rate was compared with the respiratory rate acquired using a spirometer. The experimental results demonstrated that the algorithm achieved a maximum error rate of 1.5% in estimating the respiratory rate [20]. A depth-sensing camera system was also assessed for its performance in continuously monitoring respiratory rate without the need for physical contact in the work of M. Mateumateus et al. 2019. The proposed algorithm involves detecting subject movements using optical flow algorithms on an infrared image. It then calculates the most appropriate region of interest (ROI) that can be utilized by the depth camera to capture the respiratory signal. The algorithm's validity was established by comparing it with a thorax plethysmography system, which served as a reference system [21]. M. Martinez et al. 2017 also used a depth camera to monitor the respiratory rate. The method demonstrates accuracy in 85.9% of the segments, which is comparable to the performance obtained from a chest sensor 88.7%. These results indicate that their use of computer vision is sufficiently precise for the given task.

The third type of cameras that can be used to monitor the breathing rate is RGB cameras. C. Romani et al. 2021 used an RGB camera. Their system enables automated tracking of chest movements associated with breathing, extracting the breathing signal through optical flow and RGB analysis methods. It eliminates events unrelated to breathing from the signal and identifies potential apneas. Additionally, it calculates the respiratory rate value every second [23]. H-S. Hwang et al. 2021 proposed a method for respiration measurement utilizing a region-of-interest detector based on machine learning, in addition to a clustering-based technique to estimate respiration pixels. The proposed approach comprises a model for classifying pixels based on their variance to determine if they convey respiration information. Additionally, a method is employed to classify pixels with distinct breathing components by analyzing the symmetry of the respiration signals [24]. It was established that the average error remained within approximately 0.1 breaths per minute (bpm). H. Ernst et al. 2022 used different combinations of RGB color channels using a hemispherical surface grid search method [25]. The grid search process led to the convergence towards the green channel in the baseline

modulation approach. M. Van Gastel et al. 2016 introduced a non-contact camera-based method for respiratory detection that is capable of operating in both visible and dark lighting conditions. The method relies on detecting the color variations of the skin induced by respiration [26].

### III. METHODOLOGY

The pulsation of the heart generates fluctuations in arterial pressure as blood is pumped through the resistance of the vascular system. Due to the elasticity of arteries, their diameter changes in synchrony with these pressure variations. These alterations in blood volume lead to varying light absorption. Photoplethysmography (PPG) leverages this principle to optically measure blood volume changes by capturing reflected or transmitted light from illuminated skin, resulting in a PPG waveform [27]. When the face is captured, each frame consists of an image composed of three channels: red (R), green (G), and blue (B). The results obtained from Photoplethysmography (PPG) indicate that not only can pulsatility be determined, but also phase information regarding the cardiovascular waveform can be deduced from these three channels [28].

#### A. Region of Interest (ROI) Recognition

Fig. 1 Face detection and ROI extraction. represents the face detection and the extraction of the region of interest algorithm proposed by H. El boussaki et al. 2023 [12].

Fig. 1. Face detection and ROI extraction.

The process begins by converting the RGB image to grayscale and then applying a box blurring filter before using the Sobel filter. In the next step, the resulting image is transformed into a binary image, enabling contour detection. Once

the contours are identified, the third step involves filling the interior of the contours with white and applying morphological operations. Finally, the last step involves locating new contours to determine the top extreme point, representing the top of the head. Fig. 1 Face detection and ROI extraction. represented the diagram of the method proposed by [12]. After the top extreme point is detected a value is subtracted from the x coordinate of the top point, and another value is added to the y coordinate. This adjustment enables us to obtain a Region of Interest that starts slightly below the top of the head, precisely where the forehead is located.

#### B. Signal Extraction

The raw signal is obtained from the image by employing a function that computes the average of the pixels in each channel (red, green, and blue). The averages of these channels are then combined to form the signal. The RGB components within the region of interest (ROI) are spatially averaged across all pixels, resulting in an RGB component for each frame. These averaged RGB components form the raw signals. As new frames are processed, their values are added to the signal. At this point, the signal reflects the variations in pixel values from one frame to another.

#### C. Signal Filtering

The signal underwent additional denoising using a band-pass filter. This filter had a lower cutoff frequency of 0.1 Hz and a higher cutoff frequency of 0.5 Hz. When multiple channels are employed, the signal's dimensionality is commonly decreased by combining the channels in a linear manner. The Principal Component Analysis (PCA) is a well-known for its ability to reduce dimensionality. The PCA is applied on the filtered signal. It generates three linearly uncorrelated components, which are obtained by combining the three RGB signals in a linear fashion. The PCA is then a linear technique for reducing dimensionality, transforming a set of correlated features from a high-dimensional space into a sequence of uncorrelated features in a lower-dimensional space [29]. These uncorrelated features, known as principal components, are produced as a result [30]. It is a linear transformation that is orthogonal, indicating that all the principal components are perpendicular to one another. It reshapes the data in a manner where the first component endeavors to account for the highest amount of variance present in the original data. PCA aids in identifying the most prominent feature within a dataset, simplifies the representation of data in 2D and 3D plots, and facilitates the discovery of a sequence of linear combinations of variables [31]. The central aspect of PCA is dimensionality reduction, which involves reducing the number of dimensions within a given dataset. When the data exhibits a clear linear trend and directed points, applying PCA allows for straightforward reduction of the dimensional data into a lower-dimensional representation. The objective of PCA is to identify a new matrix that represents the principal components. This matrix captures the essential information and structure of the original data represented by X, an  $m \times n$  matrix. Y is an  $m \times n$  matrix that is connected through a linear transformation represented by P and is a re-representation of X as shown in Eq. (1) [32].

$$Y = PX \quad (1)$$

Where P represents the matrix that transforms Y into X.

Then the covariance of X is computed. The covariance quantifies the strength of the linear relationship between two variables. A high value indicates a strong positive relationship, while a low value suggests a weak or no relationship. It is represented in Eq. (2) [33].

$$C_x = \frac{1}{n-1}XX^T \quad (2)$$

Where  $C_x$  is the square symmetric matrix, the diagonal terms of  $C_x$  are the variance of particular measurement types and the off-diagonal terms of  $C_x$  are the covariance between measurement types.

$C_x$  encompasses the correlations among all potential pairs of measurements, with the correlation values indicating the presence of noise and redundancy in our measurements. The objective is to acquire a matrix Y in such a way that the covariance matrix exhibits the highest variance. PCA operates under the assumption that P is an orthonormal matrix. Additionally, it assumes that the directions with the highest variances correspond to the most significant signals, making them the principal directions.  $C_y$  in terms of our variable P is represented in Eq. (3).

$$C_y = \frac{1}{n-1}YY^T = \frac{1}{n-1}PAP^T = \frac{1}{n-1}PXX^TP^T \quad (3)$$

$C_y$  is a symmetric matrix, whose eigenvalues are arranged on the principal diagonal of the matrix A in descendent order, and the eigenvectors constitute the columns of the matrix P. The principal components of X are the eigenvectors of  $XX^T$  or the rows of P. Performing PCA on a dataset X involves subtracting the mean of each measurement type and then computing the eigenvectors of the matrix  $XX^T$  [33].

Fig. 2Signal filtering. represents the filtering algorithm and summarizes the previous steps. The signal goes through a denoising filter and a normalization, then a bandpass filter and the principal component analysis and a moving average filter.

Fig. 2. Signal filtering.

Typically, the PCA technique uses tabular information and data, the rows stand in for the observations you want to incorporate and embed in a place with less dimensional space, while the columns correspond to the features for which you are looking for a reduced approximation. The principal components are

generated by performing the singular value decomposition after the algorithm has calculated the covariance matrix in minute detail. Since smaller data sets are easier to examine, explore, visualize, and make analyzing data much easier and faster for machine learning algorithms without extraneous variables to process, the trick in dimensionality reduction is to trade a little accuracy for simplicity. For more convenience, the following pseudo-code illustrates the prominent steps for the Principal Component Analysis (PCA) technique:

---

**Algorithm 1** Principal Component Analysis - PCA

---

Consider Z to be a data array of size nxm  
Center and standardize the data array  
 $Y \leftarrow \frac{Z - \mu}{\sigma}$  while  $\mu$  is the mean, and  $\sigma$  is the standard deviation  
Calculate the covariance matrix of Y  
 $Y \leftarrow Y^TY$   
Calculate the eigenvectors and eigenvalues of  $Y^TY$   
Sort the eigenvalues from largest to smallest  
 $\lambda_1 > \lambda_2 > \dots > \lambda_p$   
Sort the eigenvectors in the matrix P accordingly  
 $Y^* \leftarrow YP$   
Calculate the proportion of variance explained for each feature  
Add features with the highest explained proportion of variation until it reaches a certain threshold

---

**D. Respiratory Rate Estimation**

A discrete Fourier transform is used to convert the resulting signal to the frequency domain [34]. The maximum of the frequency index is extracted as the frequency corresponding to the breathing. The respiratory rate is calculated with Eq. (4) [35]. The algorithm takes a sequence of images as input and identifies a Region of Interest (RoI). For each pixel within the region of interest, it constructs a trajectory in the time domain. This trajectory represents the pixel values across the entire sequence.

$$BPM = Max * 60 \quad (4)$$

Where Max is the maximum frequency  
Fig. 3Respiratory rate estimation. represents the respiratory rate calculation algorithm. The discrete Fourier transform is applied to the signal. Then, if there is enough data and that means that the signal is large enough, the power spectrum with the highest magnitude is extracted. The value is used in Eq. (4) to calculate the respiratory rate.

Fig. 3. Respiratory rate estimation.

#### IV. EXPERIMENTAL RESULTS

A dataset was gathered, comprising seven volunteers, including four females and three males with a mean age of 37.8 years and an age range of 18 to 58 years. All participants provided informed consent for the test experiment. The volunteers was positioned at a distance of approximately 1 meter from the camera and instructed to blink and breathe naturally. This work was implemented on an Intel i7-1165G7 desktop using its camera. The respiratory rate was calculated through the proposed algorithm and compared with the values obtained by counting the number of breaths for one minute. In this paper, the performance of the respiratory rate measurement method is evaluated using the following indicators: the Mean Absolute Deviation (MAD) [36] and Root Mean Square Error (RMSE) [37]. The first metric represents the average absolute error between the estimated respiratory rate and the reference estimation. It provides insights into the accuracy of the measured respiratory rate compared to the desired respiratory rate and is calculated with Eq. (5) [38].

$$MAD = \frac{1}{n} \sum |RR_{rppg}^i - RR^i| \quad (5)$$

Where  $RR_{rppg}$  is the respiratory rate estimated through an RGB camera and  $RR$  is the respiratory rate calculated manually. The second metric is calculated with equation 6 [38].

$$RMSE = \sqrt{\frac{\sum (RR_{rppg}^i - RR^i)^2}{n}} \quad (6)$$

Table I Respiratory Rate Obtained in Different Subjects represents the breathing rate obtained from seven volunteers that consists of three males and four females. The respiratory rate obtained using the method proposed was than compared with the respiratory rate acquired by counting the number of breaths per minute.

TABLE I. RESPIRATORY RATE OBTAINED IN DIFFERENT SUBJECTS

Subjects	Gender	Respiratory rate estimated (BPM)	Reference (BPM)
Subject 1	M	15	16
Subject 2	F	17	18
Subject 3	F	20	20
Subject 4	F	21	20
Subject 5	M	17	17
Subject 6	M	22	17
Subject 7	F	23	22

The evaluation metrics to assess the deviation of the measurement results from the reference breathing rate were employed to verify the accuracy of the measurement results. The calculated Mean Absolute Deviation (MAD) is 0.714 bpm and the calculated Root Mean Square Error is 2.035 bpm. Y. Takahashi et al. 2021 used a thermal camera and their method was tested on seven subjects with a mean absolute error of 0.66 beats per minute. Yang et al. 2022 used an infrared thermal camera and the absolute error is  $1.47 \pm 1.33$  breaths per minute. P. Jakkaew et al. 2020 proposed a method that uses a thermal camera and obtained a root mean square error of  $1.82 \pm 0.75$  bpm. C. B. Pereira et al. 2016 also used infrared thermography and achieved a root-mean-square error (RMSE) of 3.45 breaths per minute. C. Romano et al. 2021 used an RGB camera and obtained a bias of  $-0.03 \pm 1.38$  bpm and  $-0.02 \pm 1.92$  bpm in the Bland Altman analysis. H-S. Hwang and E. C. Lee 2021 proposed a method that was tested and evaluated using data from 14 men and women in a real-world environment using convolutional neural networks. During this evaluation, it was found that the correlation coefficient between the contactless signal and the reference signal being 0.93 on average indicates a strong positive linear relationship between the two signals. This suggests that our method's performance was quite accurate compared to others cited before. Our method gives a nearly same or an even higher performance compared to the use of other methods. However, the use of convolutional neural networks gives better performances.

#### V. CONCLUSION

This paper introduces a non-contact heart rate monitoring algorithm designed to measure the respiratory rate of the driver. The proposed method shows a Mean Absolute Deviation of 0.714 BPM and a Root Mean Square Error of 2.035 BPM. The approach consists of detecting the top extreme point of the head through image filtering, contour finding and morphological operations. When the top extreme point is detected, it is easy to determine the region of interest as it is located under the top extreme point. The signal is extracted from the changes in the pixels' intensity. Then, the signal is filtered and the principal component analysis is applied. Future works consist of evaluating the algorithm's processing time, improving it through parallel programming and implementing it in various embedded architectures.

#### ACKNOWLEDGMENT

We owe a debt of gratitude to the Ministry of National Education, Vocational Training, Higher Education and Scientific Research (MENF-PERSRS) and the National Center for Scientific and Technical Research of Morocco (CNRST) for their financial support (grant number: 27UIZ2022) and for the project Cov/2020/109.

# An Improved Genetic Algorithm with Chromosome Replacement and Rescheduling for Task Offloading

Hui Fu, Guangyuan Li, Fang Han\*, Bo Wang

Faculty of Engineering, Huanghe Science and Technology College, Zhengzhou, China 450006

**Abstract**—End-Edge-Cloud Computing (EECC) has been applied in many fields, due to the increased popularity of smart devices. But the cooperation of end devices, edge and cloud resources is still challenge for improving service quality and resource efficiency in EECC. In this paper, we focus on the task offloading to address the challenge. We formulate the offloading problem as mixed integer nonlinear programming, and solve it by Genetic Algorithm (GA). In the GA-based offloading algorithm, each chromosome is the code of a offloading solution, and the evolution is to iteratively search the global best solution. To improve the performance of GA-based task offloading, we integrate two improvement schemes into the algorithm, which are the chromosome replacement and the task rescheduling, respectively. The chromosome replacement is to replace the chromosome of every individual by its better offspring after every crossing, which substitutes the selection operator for population evolution. The task rescheduling is rescheduling each rejected task to available resources, given offloading solution from every chromosome. Extensive experiments are conducted, and results show that our proposed algorithm can improve upto 32% user satisfaction, upto 12% resource efficiency, and upto 35.3% processing efficiency, compared with nine classical and up-to-date algorithms.

**Keywords**—Genetic algorithm; task offloading; task scheduling; edge computing; cloud computing

## I. INTRODUCTION

Smart devices, such as smartphones, Internet of Things (IoT) devices, drones, and so on, have become ubiquitous in our life and their number continues to grow rapidly [1], as communications and information technology advance and our quality of life improves. Unfortunately, due to their small physical space, most devices have limited resource capacity and battery life. As a result, devices frequently lack the processing power required by user requests, especially for complex applications like facial recognition and intelligent driving, which become more and more common.

To address the above issue, several works make use of cloud computing, which provides “infinite” computing resources, to extend the processing capacity of devices [2], [3]. However, cloud computing has poor network performance because it typically provides services via a Wide Area Network (WAN), such as the Internet. To address this issue, edge computing brings a few computing resources (edge servers) close to devices to provide low latency services [4], [5], [6]. Combining advantages of end devices, edge servers and cloud, end-edge-cloud computing (EECC) has attracted much attention from both academia and industry, as it can effectively and efficiently provide various services to end users [7], [8], [9].

In EECC environments, it is challenge to efficiently utilize the collaboration of devices, edge servers and cloud. To address the challenge, several works have designed task offloading or scheduling algorithms for EECC, to improve service performance or/and resource efficiency. The task offloading is to decide the computing node for each task’s processing. Existing works have made some assumptions to simplify the offloading problem for EECC, which limits their application scope. For example, some works ignored the heterogeneity between edge and cloud resources, which can lead to resource inefficiency [10], [11]. Some works didn’t exploit the resource capacity of end devices, even though many modern devices are equipped with a wealth of hardware resources, and thus wasted zero-delay local resources for task processing.

There are mainly two categories algorithms used for task offloading, heuristics and meta-heuristics. Heuristics exploit some local optimum search strategies tailored to the specific problem. Heuristics generally have rapid solving processes but limited performances. In contrast, meta-heuristics are general problem solvers. Meta-heuristics apply both local searches and global searches, inspired by natural and social rules. Usually, compared with heuristics, meta-heuristics can achieve better performance, but cost more time.

Therefore, in this paper, we exploit hybridization of heuristics and meta-heuristics, to exploit their complementary strengths for the task offloading in EECC, considering the resource heterogeneity. Even though some works have proposed hybrid heuristic offloading algorithms, most of them simply perform two or more algorithms sequentially, leading to a poor performance of hybridization. Specifically, we use genetic algorithm (GA) due to its representativeness and extensive application. GA has powerful global search ability, but slow convergence sometimes. To make up for this shortcoming, we propose to use chromosome replacement instead of selection operator for GA. To improve the performance of offloading solutions decoded from chromosomes, we reschedule failed tasks by a heuristic algorithm. The contributions of this paper can be summarized as follows:

- The task offloading problem of EECC is formulated into a mixed integer nonlinear programming problem (MINLP), with deadline constraints. The optimization objectives are maximizing the finished task number and the overall resource utilization, which are commonly used for quantifying user satisfaction and resource efficiency, respectively.
- A task offloading algorithm is proposed based on GA and first fit heuristic scheduling (FF). The proposed algorithm uses an integer coding approach for mapping

\*Corresponding authors.

between task offloading solutions and chromosomes. GA is employed for searching the global best solution. To improve the quality of task offloading solutions, FF is used to reschedule failed tasks to available resources in EECC, for every offloading solution. To speed up the convergence of GA, the selection operator is replaced by a replacement operator that replaces every chromosome with its better offspring produced by crossover.

- Extensive simulated experiments are conducted for evaluating the performance of our proposed algorithm. Simulation parameters are set referring to related works. Experiment results verify that our proposed algorithm can finish more tasks than nine of classical and up-to-date offloading algorithms. The efficiencies of the replacement and the task rescheduling are also verified by the results.

The content below is organised as follows. Section II formulates the task offloading problem in EECC. Section III illustrates our proposed offloading algorithm. Section IV evaluates the performance of the proposed algorithm. Section V presents the works related to task offloading for EECC. Section VI concludes this paper.

## II. PROBLEM STATEMENT

### A. Resource and Task Model

In this paper, we consider the EECC system consisting of  $D$  end devices,  $E$  edge servers (ES), and  $V$  cloud servers (CS). We use  $s_i, 1 \leq i \leq D + E + V$  to represent these computing nodes, where devices include  $s_i, 1 \leq i \leq D$ , ES are  $s_i, D+1 \leq i \leq D + E$ , and CS are  $s_i, D + E + 1 \leq i \leq D + E + V$ . For computing node  $s_i$ , there are  $n_i$  computing cores each with  $g_i$  capacity. The network connection between two computing nodes, say  $s_i$  and  $s_j$ , is represented by constants  $b_{i,j}$  which is its data transfer rate. If there is no connection between  $s_i$  and  $s_j$ ,  $b_{i,j} = 0$ . For each computing node, there is no data transmission delay within it, i.e.,  $b_{i,i} = +\infty, 1 \leq i \leq D + E + V$ .

$T$  tasks ( $t_k, 1 \leq k \leq T$ ) are launched by  $D$  devices. Binary constants  $o_{i,k}, 1 \leq i \leq D, 1 \leq k \leq T$  are used to indicate the ownerships of these tasks, where  $o_{i,k} = 1$  means  $t_k$  is launched by  $s_i$ , and  $o_{i,k} = 0$  means not. Task  $t_k$  has  $c_k$  computing size, i.e., it requires  $c_k$  computing resource for its processing. The input data amount of  $t_k$  is  $a_k$ . In this paper, we ignore the transmission delay of the output data, because the output data amount usually is very small [12]. The deadline of  $t_k$  is  $d_k$ , which means  $t_k$  must be finished before  $d_k$ . For every task, if its deadline constraint cannot be satisfied, it will be rejected, because there will be no profit for processing the task.

A task offloading solution is the mapping/assignments of tasks to computing cores for their processing, which can be represented by a set of binary variables  $x_{i,j,k}$ , as shown in Eq. 1.  $x_{i,j,k}$  is 1 if  $t_k$  is assigned to  $j$ th core in computing node  $s_i$ , and 0 otherwise. In this paper, we consider the resource granularity as computing core instead of computing node, because considering fine granularity of resources helps to improve the resource efficiency [13].

$$x_{i,j,k} = \begin{cases} 1, & \text{if } t_k \text{ is assigned to } j\text{th core in } s_i \\ 0, & \text{else} \end{cases}, \quad (1)$$

$$1 \leq i \leq D + E + V, 1 \leq j \leq n_i, 1 \leq k \leq T.$$

For each task, it can be only assigned to one core for its processing. In this paper, we don't consider to use the redundant execution for the performance improvement due to its huge resource costs. Thus, Eq. 2 holds.

$$\sum_{i=1}^{D+E+V} \sum_{j=1}^{n_i} x_{i,j,k} \leq 1, 1 \leq k \leq T. \quad (2)$$

And when  $t_k$  is accepted and processed by a computing core,  $\sum_{i=1}^{D+E+V} \sum_{j=1}^{n_i} x_{i,j,k} = 1$ . When  $t_k$  is rejected,  $\sum_{i=1}^{D+E+V} \sum_{j=1}^{n_i} x_{i,j,k} = 0$ . Then, the number of accepted tasks can be achieved by Eq. 3.

$$N = \sum_{k=1}^T \sum_{i=1}^{D+E+V} \sum_{j=1}^{n_i} x_{i,j,k}. \quad (3)$$

### B. Task Processing Model

For a task assigned to a core, its computing can be started only when its input data transfer finishes and the core is available. Then Eq. (4) must be satisfied, where  $ft_k^A$  and  $st_k$  are respectively the completion time of data transfer and the start time of computing for  $t_k$ .

$$ft_k^A \leq st_k, 1 \leq k \leq T. \quad (4)$$

When  $t_k$  is assigned to  $j$ th core in the computing node  $s_i$ , its computing consumes  $c_k/g_i$  time. Its input data is transferred from its device ( $s_{i'}$  where  $o_{i',k} = 1$ ) to  $s_i$ . Then the data transfer rate is  $\sum_{i'}^D (o_{i',k} \cdot b_{i',i})$ , and the transfer time is  $a_k / \sum_{i'}^D (o_{i',k} \cdot b_{i',i})$ . Therefore, for each task, the start time and the finish time of data transfer and computing satisfy constraints is Eq. (5) and (6), where  $st_k^A$  and  $ft_k$  represent the start time of  $t_k$ 's input data transfer and the finish time of its computing, respectively. Noticing that Eq. (5)–(6) also hold for rejected tasks, as both sides of inequality operators are 0 for these tasks. Then, the deadline constraints can be formulated as Eq. (7).

$$st_k^A + \frac{a_k}{\sum_{i=1}^{D+E+V} \sum_{j=1}^{n_i} (x_{i,j,k} \cdot \sum_{i'}^D (o_{i',k} \cdot b_{i',i}))} \leq ft_k^A, \quad (5)$$

$$1 \leq k \leq T.$$

$$st_k + \frac{c_k}{\sum_{i=1}^{D+E+V} \sum_{j=1}^{n_i} (x_{i,j,k} \cdot g_i)} \leq ft_k, 1 \leq k \leq T. \quad (6)$$

$$ft_k \leq d_k, 1 \leq k \leq T. \quad (7)$$

When multiple tasks are assigned to one computing core, they cannot be computed simultaneously. There are two cases

for the computing order of two tasks ( $t_k$  and  $t_{k'}$ ) in every computing core. If  $t_k$  is computing before  $t_{k'}$ ,  $ft_k \leq st_{k'}$ , and otherwise,  $ft_{k'} \leq st_k$ . Therefore, Eq. (8) formulates the exclusiveness of tasks' computing in every computing node.

$$x_{i,j,k} \cdot x_{i,j,k'} \cdot (st_{k'} - ft_k) \cdot (st_k - ft_{k'}) \leq 0, \quad (8)$$

$$1 \leq k, k' \leq T.$$

For each computing core, its occupied time is the latest finish time of tasks assigned to it, which is  $\tau_{i,j} = \max_{k=1}^T (x_{i,j,k} \cdot ft_k)$  for  $j$ th core of  $s_i$ . The occupied time of a computing node is the maximal occupied time of its cores, which is  $\tau_i = \max_{j=1}^{n_i} \max_{k=1}^T (x_{i,j,k} \cdot ft_k)$  for  $s_i$ . Thus, the amount of occupied computing resources is  $\tau_i \cdot n_i \cdot g_i$  on  $s_i$ . While, the resources effectively use for computing tasks are  $R = \sum_{k=1}^T \sum_{i=1}^{D+E+V} \sum_{j=1}^{n_i} (x_{i,j,k} \cdot c_k)$  in overall system. Then, the overall computing resource can be calculated by Eq. (9).

$$U = \frac{R}{\sum_{i=1}^{D+E+V} (\tau_i \cdot n_i \cdot g_i)}. \quad (9)$$

### C. Task Offloading Problem Model

Now, based on above formulations, the task offloading problem can be modelled as follows:

$$\text{Maximizing } N + U, \quad (10)$$

subject to,

$$\text{Eq. (1)–(9)}. \quad (11)$$

The objective is to maximize the number of accepted tasks plus the overall computing resource utilization. Because the total number of tasks is fixed in EECC system, the maximization of accepted task number is identical to maximizing the accepted ratio which is one commonly used metric for quantifying user satisfaction, service level agreement, and quality of service. As resource utilization is not greater than one, user satisfaction maximization is the major optimization objective in the model. Noticing that  $U$  is nonlinear and non-convex, and decision variables including binary ( $x_{i,j,k}$ ) and continuous variables ( $st_k^A$ ,  $ft_k^A$ ,  $st_k$ , and  $ft_k$ ), the task offloading problem belongs to mixed integer non-linear programming (MINLP), which is hard to be solved exactly. In fact, the task offloading problem has been proved NP-hard [14]. Therefore, in the next section, we propose a hybrid heuristic algorithm for efficiently solving the offloading problem with polynomial time.

### III. IMPROVED GENETIC ALGORITHM FOR OFFLOADING

In this section, we design an improved genetic algorithm with chromosome replacement and task rescheduling method, GRRS, to solve the task offloading problem presented in the previous section, which is outlined in Algorithm 1.

At first, we design a solution representation method (or encoding/decoding approach) to create the map between task offloading solutions and chromosomes used for search in GA-based algorithms. For GA inspired by Charles Darwin's theory of evolution, the population consists of multiple individuals and is evolved by changing these individuals' chromosomes each with multiple genes. In the solution representation

---

**Algorithm 1** GRRS: The genetic offloading algorithm with replacement and rescheduling

---

**Input:** The information of tasks, and EECC resources;

**Output:** A task offloading strategy;

- 1: Initializing chromosomes of individuals randomly;
  - 2: Evaluating fitness of every individual using Algorithm 2;
  - 3: Initializing the best chromosome ( $bc$ ) as one with the best fitness in all individuals;
  - 4: **while** the terminal condition is not reached **do**
  - 5:   **for** each individual ( $Y$ ) **do**
  - 6:     Crossing  $Y$  with another individual which is randomly selected, with a certain probability, and producing two offspring, i.e., new chromosomes;
  - 7:     Evaluating the fitnesses of two offspring;
  - 8:     Replacing  $Y$ 's chromosome with the better offspring;
  - 9:     **if**  $Y$ 's chromosome has better fitness than  $bc$  **then**
  - 10:       Updating  $bc$  as  $Y$ 's chromosome;
  - 11:     **end if**
  - 12:     mutating  $Y$  with a certain probability;
  - 13:     Evaluating fitness of  $Y$ ;
  - 14:     Updating  $bc$  as done in lines 9–11.
  - 15:   **end for**
  - 16: **end while**
  - 17: **return** the offloading strategy decoded from  $bc$  by Algorithm 2;
- 

method, there is a one-to-one relationship between genes and tasks in EECC. The value of each gene is integer, which identifies the computing core where the corresponding task is assigned. Thus, the possible value of a gene is 1 to the number of cores which can be used for processing the corresponding task. Then, we get the assignments of all tasks from a chromosome or an individual.

For example, considering an EECC system consisting two devices, two ES, and two CS, where each node has one computing core and each device launches one task. Then, the number of genes is 2, corresponding to these two tasks. The possible value in each dimension is 1 to 5, respectively representing the cores of the device, two ES, and two CS for the corresponding task.

A fitness function is needed to evaluate how goodness of every chromosome/individual. We use the optimization objective (10),  $N + U$ , as the fitness function of GRRS. The fitness evaluation of every chromosome is given in Algorithm 2. Given a chromosome, it can be easily to achieve a task assignment solution by the solution representation (lines 3–5 in Algorithm 2). To achieve a complete offloading solution, the computing order of tasks assigned to every core needs to be decided. In this paper, we use the most simple algorithm, First Fit (FF), for order decisions, and will study more efficient algorithms to improve the performance of GRRS. With FF order, we can calculate the finish time of each task one-by-one (line 7 in Algorithm 2). If the finish time fits deadline constraint for a task, it is accepted, and otherwise, rejected (lines 8–12 in Algorithm 2). After all tasks are decided to be accepted or rejected, GRRS tries to reschedule every rejected task using FF, to improve the overall user satisfaction (lines 14–22 in Algorithm 2). Now, we achieve a task offloading solution from a chromosome. The accepted task number and the overall resource utilization can be easily calculated based on the offloading solution, and the fitness is achieved for the chromosome.

---

**Algorithm 2** Decoding a chromosome into a task offloading with rescheduling

---

**Input:** A chromosome;

**Output:** A task offloading solution,  $\Omega$ , and the fitness;

```
1:  $\Omega \leftarrow \phi$ ; /*the set including assignments of accepted tasks to
   computing cores*/
2:  $\Phi \leftarrow \phi$ ; /*the set including rejected tasks*/
3: for each gene of the chromosome do
4:   Per-assigning the corresponding task into the computing core
   identified by the gene value;
5: end for
6: for each task  $t$  do
7:   Calculating its finish time in the scheme of first fit scheduling
   on the core ( $c$ ) to which it is per-assigned;
8:   if the finish time is earlier than the deadline then
9:      $\Omega \leftarrow \Omega \cup \{< t, c >\}$ ; /*deciding to assign the task to the
   core*/
10:  else
11:     $\Phi \leftarrow \Phi \cup \{t\}$ ; /*the deadline being violated*/
12:  end if
13: end for
14: for each task  $t \in \Phi$  /*rescheduling rejected tasks*/ do
15:   for each core  $c$  do
16:     Calculating its finish time as line 7;
17:     if the finish time is earlier than the deadline then
18:        $\Omega \leftarrow \Omega \cup \{< t, c >\}$ ; /*rescheduling  $t$  to  $c$ */
19:       break; /*rescheduling another rejected task*/
20:     end if
21:   end for
22: end for
23: Calculating overall resource utilization  $U$  by Eq. 9;
24: return  $\Omega$  and  $|\Omega| + U$ ; /*the accepted task number  $N = |\Omega|$ */
```

---

Based on the solution representation and the fitness evaluation, GRRS exploits the main idea of GA to iteratively search for the optimal solution for task offloading, as shown in Algorithm 1. First, GRRS initializes the population, i.e., randomly sets the value of every gene for every individual's chromosome, as done by standard GA. Then, GRRS evaluates the fitness for every initialized chromosome, and sets the best chromosome as the chromosome with the best fitness. After these initialization steps, GRRS uses some operators to evolve individuals by updating their chromosomes (lines 4–16 in Algorithm 1). The evolution procedure is as follows.

First, for every individual, GRRS uses crossover operator to create new chromosomes/offspring. GRRS randomly selects another individual, and performs the crossover operator on them, with a certain possibility (the crossover possibility). To ensure the individual diversity for large-scale offloading problems, GRRS exploits the uniform crossover operator, which swaps values of two chromosomes in every gene location with a certain probability. After crossing an individual, two new chromosomes are produced. For the individual, GRRS evaluates the fitness of its two offspring, and replaces its chromosome by the offspring with better fitness than another one. By such replacement, GRRS can increase the diversity by retaining new produced chromosomes, and speed the convergence rate by transmitting good genes of the better offspring to the next generation. If a new offspring has better fitness than the best chromosome, the best one is updated as the offspring.

To further enhance exploration ability, GRRS applies the uniform mutation operator on each individual, to increase

the diversity by creating new genes. The uniform mutation operator is to change each gene with the mutation possibility for an individual. After mutating an individual, if the new chromosome has better fitness than the best one, the best one is updated as the new one.

GRRS repeats the above evolution procedure until the terminal condition is reached. There are two approaches for the set of terminal condition. One is setting the maximal number of iterations, and another is setting the most times that the fitness of the best chromosome has no (significant) change. After the evolution procedure, GRRS decodes the best chromosome into the task offloading solution, and return it as the global best solution.

In this paper, we focus on the improvement of GA by chromosome replacement and task rescheduling. Undoubtedly, the crossover and mutation operators as well as the parameters have impact on the performance of GA. These opportunities will be studied on our future works.

#### IV. PERFORMANCE EVALUATION

In this section, we conduct extensive simulated experiments to verify the efficiency of GRRS by comparing with several classical and up-to-date offloading algorithms. The experiment environment is illustrated in Section IV-A, and the results are discussed in Section IV-B.

##### A. Experiment Environment

In simulated EECC systems, where the simulation parameters are set referring to [18], [21], [23], [15] and reality, there are ten devices, five ES, and ten types of CS. The core number of devices, ES, and CS are set randomly in ranges of [2,8], [4,32], and [1,8], respectively. The computing capacities of each core in every device, ES, and CS are respectively set as [1.8,2.5]GHz, [1.8,3.0]GHz, and [1.8,3.0]GHz, randomly. The network transfer rate between a device and an ES/CS is in the range of [80,120]/[10,20] Mbps. There are 1000 tasks generated, and the device for lunching each task is randomly allocated. The computing resource required by a task is in the range of [0.5, 1.2]GHz, and the input data amount is [1.5, 6]MB. The deadline of every task is set between one and five seconds.

The algorithms used for the performance comparison with GRRS to confirm the performance include FF, FFD, EDF, RAND, GA, GAR, PSO, PSOM, and GAPSO.

- First Fit (FF) iteratively schedules the first task to the first computing node meeting its requirements.
- First Fit Decreasing (FFD) iteratively schedules the task requiring maximal amount of computing resources to the first computing node meeting its requirements.
- Earliest Deadline First (EDF) iteratively schedules the task with the earliest deadline to the first computing node meeting its requirements.
- Random method (RAND) randomly generates a population as done by GRRS, and provides the solution corresponding to the best individual.

- GA [15], [16] uses the uniform crossover, the uniform mutation, and the roulette wheel selection operators for the population evolution.
- GA with replacement (GAR) [17] is same to GRRS without the rescheduling.
- Particle Swarm Optimization (PSO) [18] uses the idea of particle movement. PSO initializes a population with multiple particle (individual), and iteratively moves each particle toward its personal best position and the global best position for the particle position updates (the population evolution).
- PSO with mutation operator (PSOM) [19] added a mutation operator on each particle at the end of each iteration.
- GAPSO [20] first initializes a population, and then sequentially performs GA and PSO on the population evolution.

The performance of above algorithms are evaluated as following, and all performance metrics are better when their values are greater.

- User satisfaction is the experience of users, which has great influence on the profit and the reputation of service providers. In this paper, we use the number of tasks with deadline met, i.e., the accepted task number ( $N$ ), for the quantification.
- Resource efficiency is the workload processed by a unit of resources, which determines the cost-performance of service provision. The metrics used for measuring the resource efficiency are the computing resource utilization ( $U$ , the completed computing size per unit of computing resource) and the data processing efficiency (the processed data amount per unit of computing resource,  $\sum_{k=1}^T \sum_{i=1}^{D+E+V} \sum_{j=1}^{n_i} (x_{i,j,k} \cdot a_k) / \sum_{i=1}^{D+E+V} (\tau_i \cdot n_i \cdot g_i)$ ).
- Processing efficiency is the processing speed of a computing system, which is quantified by the completed computing size and the processed data amount by a time unit ( $R / \max_i \{\tau_i\}$  and  $\sum_{k=1}^T \sum_{i=1}^{D+E+V} \sum_{j=1}^{n_i} (x_{i,j,k} \cdot a_k) / \max_i \{\tau_i\}$ ).

The experiment process are as follows. We first generate a EECC system, and then sequentially measure various performance metrics for all of comparison algorithms and GRRS. For each measured value for every algorithm and every metric, we normalize it by dividing it into that of FF, to focus on the relative performance between different algorithms. These previous experiment steps are repeated more than 100 times, and we report the average value for each metric in the follows. Noticing that, in each measurement, there is a new EECC system generated randomly. Thus, the statistical information of every algorithm in each metric is meaningless without the normalization. GRRS has statistically significant difference with other algorithms in every performance metric.

Besides comparing the performance of GRRS with other offloading algorithms, we verify the efficiency of the task rescheduling, by comparing the performance between

GA/PSO/GAPSO/GAR with and without task rescheduling. The results are presented and discussed in section IV-B4.

## B. Experiment Results

1) *User Satisfaction*: Fig. 1 gives the relative number of accepted tasks when applying different task offloading methods, on average. As shown in the figure, GRRS achieves the most accepted tasks, which completes 7.98%–32% more tasks than other algorithms. This verifies that GRRS performs good on the optimization of the user satisfaction. The main reasons are as follows.

For heuristics, FF, FFD, and EDF, the priority order of resources used for task processing is devices, ES, and CS. This can complete more task in low network latency but scarce resources of devices and ES. As shown in experiment results, GRRS accepts 12%–29.4% and 32%–33.7% less tasks than these heuristic algorithms at devices and ES, respectively, as shown in Fig. 2 and Fig. 3. But this can result in some tasks with loose deadline assigned to devices or ES at first. This leads to insufficient resources for processing subsequent tasks with tight deadline, and thus can drastically decrease the number of tasks processed by CS and reduce the overall user satisfaction. As shown in Fig. 4, meta-heuristics process more than 100% more tasks than heuristics by the cloud. As shown in Fig. 2 - 4, GRRS processes not the most tasks in one tier of devices, edges, and cloud. But GRRS has the best overall satisfaction, as shown in Fig. 1. This phenomenon verifies the powerful global search ability of GRRS.

Compared with other meta-heuristic algorithms (GA, GAR, PSO, PSOM, GAPSO), GRRS achieve better performance in optimizing the user satisfaction, as shown in Fig. 1. The main advantages of GRRS is the replacement replacing the selection operator for GA and the rescheduling for improving the quality of the solution corresponded to an individual. GAR can complete more tasks than GA, which verifies that the replacement improves the evolution effectiveness by substituting the selection operator. The improvement of the rescheduling strategy on the task offloading will be illustrated in Section IV-B4.

In addition, we can see that some meta-heuristics (GA, PSO, PSOM, and GAPSO) has poorer performance than heuristics, even though they are designed for pursuing the global best and heuristics are aiming at the local best, in such a large-scale offloading problem. This inspires us that meta-heuristics should be carefully designed for a good performance.

2) *Resource Efficiency*: Fig. 5 and Fig. 6 show resource utilization and data processing efficiency achieved by different offloading algorithms. From the figure, we can see that heuristics achieve higher resource utilization and higher data processing efficiency than meta-heuristics. This is mainly because that heuristics process tasks using scarce local and edge resources at first. This can provide a good performance for accepted tasks, and a high computing resource efficiency, because there is no or a low latency for data transfer. But with prioritization of device and edge resources, much less tasks can be completed by the cloud resources, leading to a low user satisfaction as illustrated above. Contrary to heuristics, meta-heuristics try to find the global best solution, which can schedule every task to

Fig. 1. The relative accepted task number achieved by various task offloading methods in overall.

Fig. 2. The relative accepted task number achieved by various task offloading methods in device tier.

Fig. 5. The relative resource utilization achieved by various task offloading methods.

Fig. 3. The relative accepted task number achieved by various task offloading methods in edge tier.

Fig. 6. The relative processed data amount per unit of computing resources achieved by various task offloading methods.

any resource at first. This provides opportunities for processing more tasks in overall. Therefore, GRRS improves the user satisfaction by sacrificing the resource efficiency, compared with heuristics. It is worth it because the user satisfaction usually decides the income and reputation of service providers.

In all of these meta-heuristics, GRRS has the highest resource utilization and data processing efficiency, which are 6.74%–12% and 9.5%–14.1% higher than that of other meta-heuristics, respectively, as shown in Fig. 5 and 6. This demonstrates that GRRS performs good at the optimization of both the user satisfaction and the resource efficiency, and further confirms the high effectiveness of GRRS.

3) *Processing Efficiency*: Fig. 7 and Fig. 8 present the processing rates or efficiencies in computing and data processing in EECC when applying various task offloading methods. In a distributed system, the processing rate reflects the parallelism, and thus the throughput, which is one of the most used metrics quantifying overall performance. As shown in these two figures, we can see that GRRS has the highest processing rates, which are 7.6%–31.5% and 11.4%–35.3% higher than other methods in the computing and data processing, respectively. This illustrates that GRRS achieves good processing efficiency for EECC systems.

Fig. 7. The relative computing efficiency by various task offloading methods.

Fig. 8. The relative data processing efficiency achieved by various task offloading methods.

4) *Performance of Improvements*: One of our improvement schemes for meta-heuristics is task rescheduling, which can be applied by any meta-heuristic. In this section, we test the performance of rescheduling in the improvement of user satisfaction, resource efficiency, and processing efficiency. The experiment results are shown in Fig. 9-13, where  $x_{RS}$  means  $x$  improved with the rescheduling. From these figures, we can see that rescheduling can improve above 11% performance in every metric for meta-heuristic algorithms on task offloading. This verifies the high efficiency of rescheduling in improving the performance of meta-heuristic-based offloading algorithms. The main reason why rescheduling can improve the performance of meta-heuristics is that meta-heuristics make decision of task assignment without considering the load balance between computing cores. This leads to some cores are overloaded while some others are underloaded, giving a opportunity for performance improvement by rescheduling.

## V. RELATED WORKS

As the development of IoT, EECC has been applied to various fields for improving the performance of various data processing applications. To improve service quality and resource efficiency in EECC environments, several works focused on addressing the task offloading problem.

Sang et al. [21] proposed a heuristic offloading algorithm to improve the cooperativeness of EECC resources. They used cloud resources for processing offloaded tasks at first, and rescheduled some tasks from the cloud to ES and devices to

Fig. 9. The accepted task number improved by rescheduling.

Fig. 10. The resource utilization improved by rescheduling.

Fig. 11. The data processing efficiency improved by rescheduling.

Fig. 12. The overall computing rate improved by rescheduling.

improve overall performance. This can improve overall user satisfaction, but negatively affect the overall performance of task processing. Wang et al. [22] presented two offloading al-

Fig. 13. The overall data processing rate improved by rescheduling.

gorithms, named as FRFOA and LBOA, respectively. FRFOA was to offload a task to an ES such that the response time is minimum every time. LBOA iteratively assigned a task to an ES which can satisfy requirements of the most tasks. These heuristic-based algorithms generally consume few resources but have limited performance, because they only exploit local search strategies.

Therefore, some works used meta-heuristics to pursue the global best offloading solution. Both Wang et al. [18] and Gao et al. [23] applied PSO with same solution representation method to this paper. In addition, to improve exploration ability, Gao et al. [23] used Lévy Flight movement pattern for updating particle positions. Wang et al. [15] used GA for optimizing user satisfaction and resource efficiency. Chakraborty and Mazumdar [16] employed GA to reduce energy consumption with latency constraints. Bali et al. [24] used NSGA-II to optimize energy and queue delay for offloading data to ES and CS.

To further improve performance, some works considered to exploit complementary advantage of different algorithms, proposed hybrid heuristic algorithms. Hussain and Al-Turjman [17] replaced the chromosome by its better offspring generated by the crossover operator for each individual, which is similar to population evolution behavior of PSO. Nwogbaga et al. [19] performed mutation operator for every individual at the end of each evolutionary iteration for PSO to improve diversity for avoiding premature convergence. Farsi et al. [20] sequentially performed GA and PSO for the population evolution. Zhang et al. [25] presented a dynamic selection mechanism to combine multiple meta-heuristics, which selected offspring generated by these meta-heuristics to be passed on to next generation. All of above works just performed two or more meta-heuristics separately, which leads to a poor performance of combination.

Therefore, in this paper, we exploit a combination approach to integrate the swarm intelligent into the evolutionary algorithm for a better offloading solution on EECC. In addition, we propose to use heuristic rescheduling approach to further improve the solution quality.

## VI. CONCLUSION

In this section, we focus on the task offloading problem for EECC systems. We first formulate the problem into MINLP, which has been proofed as NP-hard. Then, to solve the problem with reasonable time complexity, we design a task offloading algorithm, GRRS, based on GA which is one of the most

representative meta-heuristics and performs well on solving various optimization problems in many fields. To enhance exploration and exploitation of GA, we integrate two improvement scheme into it. One is replacing each individual with its better offspring during the population evolution, to pass on good genes. Another is rescheduling rejected tasks to take full advantage of available EECC resources. Extensive experiments are conducted, and results verify efficiency and effectiveness of GRRS.

# An Efficient Convolutional Neural Network Classification Model for Several Sign Language Alphabets

Ahmed Osman Mahmoud, Ibrahim Ziedan, Amr Ahmed Zamel  
Computer and Systems Department, Faculty of Engineering, Zagazig Uni., Zagazig, Egypt

**Abstract**—Although deaf people represent over 5% of the world’s population, according to what the World Health Organization stated in May 2022, they suffer from social and economic marginalization. One way to improve the lives of deaf people is to try to make communication between them and others easier. Sign language, the means through which deaf people can communicate with other people, can benefit from modern techniques in machine learning. In this study, several convolutional neural networks (CNN) models are designed to develop an efficient model, in terms of accuracy and computational time, for the classification of different signs. This research presents a methodology for developing an efficient CNN architecture from scratch to classify multiple sign language alphabets, which has numerous advantages over other contemporary CNN models in terms of prediction time and accuracy. This framework analyses the effect of varying CNN hyper-parameters, such as kernel size, number of layers, and number of filters in each layer, and picks the ideal parameters for CNN model construction. In addition, the suggested CNN architecture operates directly on unprocessed data without the need for preprocessing to generalize it across other datasets. In addition, the capacity of the model to generalize to diverse sign languages is rigorously evaluated using three distinct sign language alphabets and five datasets, namely, Arabic (ArSL), two American English (ASL), Korean (KSL), and the combination of Arabic and American datasets. The proposed CNN architecture (SL-CNN) outperforms state-of-the-art CNN models and traditional machine learning models achieving an accuracy of 100%, 98.47%, 100%, and 99.5% for English, Arabic, Korean, and combined Arabic-English alphabets, respectively. The prediction or inference time of the model is about three milliseconds on average, making it suitable for real-time applications. So, in the future, it is easy to turn this model into a mobile application.

**Keywords**—Convolutional neural network (CNN); sign language; Arabic sign language (ArSL); American sign language (ASL); Korean sign language (KSL); Complexity time

## I. INTRODUCTION

The World Health Organization (WHO) stated in May 2022 that there are more than 360 million deaf people around the world. 80% of those who are deaf live in developing countries and use more than 300 sign languages [1]. Deaf people who suffer from hearing problems have trouble in their daily lives communicating with each other and with other people. Also, they have lower chances of having an adequate level of education.

Sign language is the means of communication between deaf people and other people and consists of hand signs and gestures for spelling letters and words. In the last two decades, many researchers have investigated several machine learning models

for developing several sign language recognition models, e.g., Arabic [2], American [3], Korean [4], Indian, Chinese, and others [5]. The approaches for sign language recognition can be classified into two main categories: sensor-based and vision-based [6]. In a sensor-based, the speaker wears gloves or sensors, and the movement and body orientation are translated into a time series of sensor readings depending on the word or letter sign. Within the same category, several researchers use Microsoft Kinect [7], developed by Microsoft, for sign classification without wearing gloves or sensors. Microsoft Kinect has three optical sensors. It provides three outputs: an RGB image, an infrared (IR) image, or a depth image, and defines up to 25 skeleton joints. Generally, the other hand, in the vision-based approach [8], images are taken by a camera and analyzed to determine the shape of signs intended by the speaker. In this approach, a researchers use depth images and skeleton joints to analyze the kinematic movement of the body or hand to determine the word or alphabet character. In this way, sign classification became easier. On sufficient number of image examples for each sign should be collected to improve classification performance.

Several methods for sign language recognition, utilizing both traditional and deep learning techniques, have been proposed in the literature [5]. Traditional techniques such as Support Vector Machine (SVM) [9], Hidden Markov Model (HMM) [10], and Random Forest (RF) [11] have all been tried by many researchers for classifying sign language alphabet recognition, but they have all yielded unsatisfactory results. On the other hand, recent studies have shown that the CNN model is one of the most commonly used models in sign language recognition [6]. Surveys such as those conducted by Rastgou et al. have shown that many models have been suggested by various researchers for sign language recognition with the help of deep learning techniques [5].

### A. Motivation

Many researchers have tried traditional machine learning methods for classifying sign language alphabet recognition models [12], but they have not provided satisfactory results. Recently, the CNN model has been widely utilized in sign language recognition, but it has not offered an efficient CNN architecture, which is considerably more challenging due to CNN’s numerous hyper-parameters. Moreover, the prediction time, which is the time to predict a single sign and a critical factor in practice, is usually ignored. In addition, although CNN model hyper-parameters have a large effect on performance and accuracy [13], they are not fully investigated. All

these issues may affect model generalization for newly unseen data. These are the primary motivations for us to study the effect of selecting hyper-parameters in CNN and how we can generalize the CNN architecture across several datasets. The primary objective of this study is to provide a realistic, straightforward, and efficient CNN architecture. In addition, it can work on several sign language alphabets.

## B. Contribution

In this paper, several CNN models are designed and analyzed to develop an optimal model for sign language recognition without any preprocessing.

- This research provided a method for selecting an optimal CNN model by analyzing the results of various hyper-parameters such as kernel size, number of layers, and number of filters in each layer.
- In the beginning, this approach investigated how changing the layer and filter numbers impacted accuracy.
- Then, the model with the highest accuracy and the fastest prediction time is chosen.
- In the end, we incorporate the impact of kernel size and the number of hidden layers to pick the best candidate.
- This approach operates directly on unprocessed data to generalize it across several datasets.
- The proposed model is examined on four different datasets, Arabic, American 2018, American 2012, and Korean alphabets, to investigate its robustness against data variation.
- In addition, the model is also tested on a combined dataset of Arabic and American alphabets.

This paper is organized as follows: Section II provides a literature review on Arabic, English, and Korean sign language detection. In Section III, a detailed design of the proposed CNN model is presented, including the selection of optimal hyper-parameters for Arabic and English sign languages. The proposed model is presented in Section IV. Several experiments are then conducted in Section V to evaluate and compare the proposed model to other state-of-the-art classification models for three sign language alphabets. Finally, conclusions and ideas for extending the current work are drawn in Section VI.

## II. LITERATURE REVIEW

Sign language differs from country to country. For example, there are Arabic, American, and Korean alphabets. In the past decade, several research efforts have been made to automate sign language processing. Some researchers used traditional classifiers, while others used convolutional neural networks or recurrent neural networks (RNNs).

Concerning Arabic sign language (ArSL) recognition, Al-zohairi, Alghonaim, et al. [9], for example, presented an SVM model to classify ArSL images. The authors, using a smartphone camera, collected a dataset of 900 images for 30 alphabet characters and extracted features from images

using the histogram of oriented gradient (HOG) descriptor. The model achieved a low accuracy of 63.5%. In addition, Hasasneh and Taqatqa [14] proposed a model based on a restricted Boltzmann machine and tiny images for 39 Arabic alphabetic sign language groups.

Convolutional neural networks have also been applied for ArSL recognition. For example, Alani and Cosma [15] proposed two CNN models consisting of seven convolutional layers and four pooling layers for the ArSL 2018 dataset. The first one achieved an accuracy of 96.59%, while the second one used some sampling techniques to improve the accuracy to 97.29%. Also, Elsayed and Fathy [16] also implemented a CNN containing five convolutional layers and three pooling models for the Arabic alphabet and word recognition. They used a premade dataset consisting of 54049 samples to evaluate their model and produced a low accuracy of 88.87% for alphabet pattern recognition.

On the other hand, several techniques for American Sign Language (ASL) classification have been extensively studied. This usually consists of a two-stage feature extraction and a classifier. For instance, Aly, Aly, et al. [17] developed an SVM model to classify the ASL alphabet using a dataset collected by Microsoft Kinect from several users. The collected data is preprocessed for segmentation and feature extraction by the principal component analysis network (PCANet). This model achieves an accuracy of 88.7%. Shin, Matsuoka, et al. [12] proposed a model using SVM and light gradient boosting machine (GBM) to classify the ASL alphabets using the Massey alphabets dataset and the Kaggle alphabets dataset. The results were 99.39% for Massey and 87.60% for Kaggle.

The CNN technique is also used for ASL classification. For example, Fierro and Perez [8] built two CNN models for sharing parameters and achieved 96% accuracy. This model was fed by samples taken from the Kaggle dataset, which contains 29 subclasses. In addition, Abdulhussein and Raheem [13] also built a CNN model for classifying 24 ASL characters after preprocessing input images using image resizing, converting images to grayscale, and edge detection. Their model achieved an accuracy of 99.3%, and the training time was shorter compared to its peers. Furthermore, Wardana, Rachmawati, et al. [18] proposed a CNN model for the Kaggle ASL dataset, achieving an accuracy of 99.81%. The data is divided 70% for training, and the remainder of the dataset is equally divided between validation and testing. Also, Can, Kaya, et al. [19] suggested a CNN model for colored natural ASL pictures and compared their accuracy with five well-known transfer learning models, including VGG16, VGG19, ResNet50, and DenseNet121, to obtain 99.91% superior to his peers.

Finally, for Korean alphabets (KSL), Na, Yang, et al. [20] presented an SVM model for classifying 31 signs consisting of 14, 10, and 7 consonants, vowels, and double vowels, respectively. This dataset was collected from 15 participants who wore gloves while taking images. The tri-axial accelerometer signals were used to segment the sign gesture while the user was performing it. This model achieves a segmentation accuracy of 98.9%, which is superior to its peers, which used multiple sensors for segmentation. This model achieved a mean recognition accuracy of 92.2% for the Korean alphabet. Multiclass SVM was designed with six different kernels (e.g., linear, quadratic, and cubic) and optimized through

accuracy comparison. The quadratic kernel produced the best classification rate among the others. In contrast, Yeo and Shin [21] proposed a model for 12 classes of consonant and vowel letters. The model was designed by combining electromyography (EMG), accelerometers, and gyro sensors to build a multi-variate Gaussian model and maximum likelihood estimation through Bayesian theory for classification. As a result, accuracy rates of 99.13% and 99.97% were achieved for consonants and vowels, respectively.

Most researchers aimed to improve the performance of the CNN by studying the influence of preprocessing techniques such as filters [22] or other techniques (e.g., cropping, adding noise, and data normalization) [23]. Despite the preprocessing success in some cases, there is no way to generalize it for all datasets. Therefore, in the proposed model, preprocessing is not utilized to examine the power of the CNN, test the effect of its parameter in the original data, and test the model against dataset variation.

All the aforementioned traditional or modern techniques for sign language recognition models were trained and tested on a single dataset and ignored the diversity of various sign languages. In addition, some researchers used a small, collected dataset to train their models, so they could not be generalized. They also neglect prediction time, although it is a critical factor in real-time applications. Finally, even though the CNN technique was used, the CNN parameters were not studied sufficiently to achieve optimal accuracy and a reasonable prediction time. The main contribution of this paper can be summarized as follows: First, an efficient CNN sign language recognition is developed by studying the effect of CNN hyper-parameters to achieve higher accuracy compared with its peers using original data without any preprocessing. Second, the proposed model is trained on three sign language alphabets, namely, English, Arabic, and Korean, to evaluate its robustness against data variation. Third, the model is trained and tested to classify numerous sign languages by combining two different sign language datasets, namely Arabic and English. Finally, the prediction time is carefully considered during the design of the proposed model.

### III. METHODOLOGY OF CNN HYPER-PARAMETERS SELECTION

A CNN is one of the most popular techniques in deep learning (DL) that is successfully used in classification problems [24] and has high success rates in several problems such as hand gestures and object detection [25]. CNN consists of convolution, pooling, and fully connected layers. The convolution layers are the main layers in CNN, as they are responsible for creating a feature map using a set of filters whose number is a design parameter, or hyper-parameter [26]. Convolution is a linear multiplication operation between the input image and a filter whose size (the kernel size is another hyper-parameter) is smaller than the input image [27]. This results in an activation map (feature map) whose size is less than the input image and whose count is the same as the number of filters used in this operation. The size of the feature map is calculated according to Eq. 1.

$$output\ size = \frac{N - N_f}{stride} + 1 \quad (1)$$

Fig. 1. Flow diagram of the methodology framework for the selection of CNN hyper-parameters.

where  $N$  is the width or height of the input image,  $N_f$  is the filter's width or height, and the stride is the pixel size between each convolution [28]. The size of the feature map in Eq. 1 must be an integer number; otherwise, padding is employed. Padding is the process of increasing the image's size without changing its content. The input image, after being convolved repeatedly with filters, shrinks in volume spatially. Shrinking too fast is not good; it does not work well. Pooling combines the nearby units to reduce the input size for the next layer. It includes maximum pooling and average pooling. Using the pooling layer directly after the convolution layer is not necessary, but its type and location are also a hyper-parameter whose settings are set empirically using expertise. The result of repeated convolution and pooling is that the list of features (a vector of features) is the input for the last layer of CNN (the number of convolutional layers is a hyper-parameter). The fully connected layer classifies the input to the best class [29].

The multiple hyper-parameters that CNN uses to make the process of picking an architecture much more challenging [30]. In this section, a detailed study is conducted for the optimal selection of CNN model hyper-parameters, namely kernel size ( $K_s$ ), the number of filters ( $N_f$ ), the number of convolution layers ( $L$ ), and the number of fully connected hidden layers, to achieve optimal accuracy in a reasonably short time for ArSL. The steps of the methodology are summarized in Fig. 1. Initially, this method looked at the effect of varying the layer and filter numbers on precision. Secondly, a model is selected based on its speed and accuracy of prediction. Finally, the influence of kernel size and the number of hidden layers is considered to select the optimal CNN architecture. The methodology is discussed in detail in the following subsections.

#### A. Selecting the Number of Layers and Filters Per Layer

The number of filters  $N_f$  in each convolution layer affects the test time because the more filters used, the more computational time is required. This occurs because the output of a convolution layer, i.e., the number of activations maps, equals the number of filters used in that layer [31]. The number of filters to be used in each layer is chosen according to Eq. 2.

$$N_f = 2^k; \quad k = 2, 3, 4, 5, \dots \quad (2)$$

to achieve the best accuracy within a reasonable prediction time. Also, the number of convolution layers has a vital role in the classification time in the ArSL problem. Because the image size was 64 by 64, the maximum number of convolutions with stride 2 would be 6. So, the number of layers is varied between 1 to 6, and tests are repeated 50 times to determine the best number of layers that gives the best average test time.

Fig. 2. Test time as a function of the number of layers and number of filters per layer.

TABLE I. ACCURACY AND TEST TIME FOR ARSL USING DIFFERENT NUMBERS OF LAYERS AND FILTERS PER LAYER

L	$N_f=4$		$N_f=16$		$N_f=128$	
	Acc(%)	$T_S$ (ms)	Acc (%)	$T_S$ (ms)	Acc (%)	$T_S$ (ms)
L = 2	95.4770	0.3793	96.8450	0.8819	96.586	8.9003
L = 4	95.2921	0.3606	97.6707	0.7986	98.52	8.8196
L = 6	56.6182	0.3598	96.1794	0.7969	98.5827	8.9013

Acc is the accuracy and  $T_S$  is the Test time in milliseconds //

In this study, several CNN models are built with different combinations of layers and filters per layer. The test time is estimated without training, as shown in Fig. 2. It can be realized that the test time increases with the number of filters per layer but decreases as the number of layers increases. This is because the number of extracted features from CNN (the last layer of CNN) decreases.

On the other hand, to take accuracy into account and decide the optimal number of layers and filters per layer, the CNN models with all combinations of layer numbers 2, 4, and 6 and filter numbers 4, 16, and 128 were trained. Table I shows the test time and accuracy in classifying the ArSL dataset. As can be seen from Table I, although a CNN with 4 filters per layer has the least amount of time, its accuracy is inferior compared to that obtained using 16 or 128 filters. Therefore, it is clear that the number of filters per layer should be at least 16. Considering the number of layers, it is noted that accuracy obtained using more than 4 layers either drops ( $N_f = 4$  or 16) or is not significantly improved ( $N_f = 128$ ). Based on these observations, the number of layers in the proposed model is set to 4. For this number of layers, the accuracy improved with the increase in the number of filters. Unfortunately, this comes at the expense of a significantly longer prediction time. Therefore, in the proposed model, instead of using 128 filters in all layers, the number of filters in the four layers is set respectively to 32, 64, 128, and 128. This reduces the total prediction time while maintaining acceptable accuracy at the last two layers.

### B. Selecting the Kernel Size

Kernel size, which is usually taken as an odd number less than 10, also affects the features produced by the convolution [32]. Therefore, kernel sizes of 3, 5, 7, and 9 are trained for the ArSL classification problem. During this experiment, 10

TABLE II. TRAINING, TEST ACCURACY, TRAINING, AND TESTING TIME VS. CNN KERNEL SIZE

$K_s$	$T_r$ Acc (%)	$T_s$ Acc (%)	$T_r$ time (h)	$T_S$ time (ms)	Std ( $T_s$ )
3x3	100	98.55	3.39	2.6621	$4.4920 \times 10^{-5}$
5x5	100	98.71	5.02	3.5870	$1.1804 \times 10^{-4}$
7x7	100	98.87	6.62	8.0030	$1.0546 \times 10^{-4}$
9x9	100	98.77	9.27	11.8441	$1.5197 \times 10^{-4}$

$T_r$  is training,  $T_s$  is test and std is the Standard deviation.

TABLE III. TEST ACCURACY, TRAINING AND TESTING TIME VS. CNN FULLY CONNECTED HIDDEN LAYER

Hidden No.	$T_r$ Acc(%)	$T_s$ Acc(%)	$T_r$ time(h)	$T_s$ time(ms)	std( $T_s$ )
0	100	98.3362	4.155	2.8157	$3.0857 \times 10^{-5}$
1	100	98.5457	4.385	2.8760	$3.3840 \times 10^{-5}$
2	100	98.7183	4.360	2.8893	$3.4234 \times 10^{-5}$
3	100	98.5580	4.455	2.9107	$1.7433 \times 10^{-5}$

$T_r$  is training,  $T_s$  is test and std is the Standard deviation.

runs are performed, and the average results are reported in Table II. As it can be seen, kernel size has a slight effect on the accuracy of training and testing. In contrast, the training time and test time increase nonlinearly with kernel size. Based on these observations, the optimal kernel size would be 3x3, as it achieves the minimum training and testing times while maintaining the same accuracy.

### C. Selecting the Number of Fully Connected Hidden Layers

CNN always ends with a fully connected network that contains hidden layers whose number is considered a hyper-parameter [33]. The network with 0, 1, 2, and 3 hidden layers is trained in ArSL to investigate the best number of hidden layers. Each model is trained and tested ten times, and the average results are reported in Table III. As can be noted, fully connected two hidden layers achieve the best test accuracy with slightly higher test and training times. By adding the last output layer to the two hidden layers, three fully connected layers are considered in the proposed CNN model.

### D. Study the Time Complexity of CNN's Prediction Time

In this section, the time complexity of CNN's prediction time is derived. The number of operations in a single convolution layer depends on the size of the image ( $N \times N$ ), the kernel size and the number of filters per layer. The number of convolutions is performed for each pixel in the image, so the time complexity is proportional to the total number of pixels in the image ( $N^2$ ). Each pixel is multiplied by a window of size  $K_s \times K_s$ . This is done for each filter; so, the time complexity for a single convolution layer is given by Eq. 3.

$$T_{conv} = O(N^2 K_s^2 N_f) \quad (3)$$

The feature map output from a single convolution layer is equal to the image multiplied by the number of filters in this layer. To reduce the dimension of the feature map, a Max-pooling layer is applied with a 2x2 window in the feature map of size  $N \times N \times N_f$ , whose time complexity can be expressed as Eq. 4.

$$T_{mp} = O(4N^2 N_f) \quad (4)$$

For L layers, the time complexity in Eq. 4 can therefore be written as Eq. 5.

$$T_L = O((N^2 K_s^2 N_f + 4N^2 N_f)L) \quad (5)$$

where time complexity is linear in L. For fully connected layers, the feature maps are generated from the final convolution layer and the size of the input layer. The max-pooling layer decreases the size of the image by one-fourth (for a stride of 2). So, the final feature map size is  $N^2/4^L$ , and the time complexity of the first fully connected layer would be Eq. 6.

$$T_{FC} = O\left(\frac{N^2 N_f}{4^L}\right) \quad (6)$$

So, the total time complexity would be calculated as shown in Eq. 7.

$$O((N^2 K_s^2 N_f + 4N^2 N_f)L + \frac{N^2 N_f}{4^L} + TimeofOtherFC) \quad (7)$$

The time for other fully connected layers is dropped in big-O notation from Eq. 7 as they are constant terms. Therefore, the time of fully contented dropped and all constants are dropped as shown in Eq. 8.

$$T = O(K_s^2 N^2 N_f L + \frac{N^2 N_f}{4^L}) \quad (8)$$

From Eq. 8, it can be concluded that the time complexity of the CNN model is linearly proportional to Nf, the square of Ks, and nonlinear with L. Furthermore, to investigate the validity of Eq. 8, three examinations are made by building several CNN models, changing one parameter at a time, and averaging the test time over 50 runs. The procedure can be stated as follows:

- Varying the  $K_s$  from 1 to 19, while fixing the layer number at 4 and the number of filters at 16. Fig. 3 shows the measured test time as a function of the  $K_s$ . As it can be seen, the relationship can be fitted using a quadratic polynomial, which means that the time complexity of the CNN model is proportional to the square of  $K_s$ .
- Investigating the effect of the number of layers L on test time (at  $K_s = 3, N_f = 16$ ). Fig. 4 shows that the time decreases as the number of layers increases up to 4 layers. Above 4 layers, the time starts to increase slightly. This experiment shows that the test time is inversely proportional to the number of layers, and a good fit can be obtained using a fifth-degree polynomial.
- Examining the effect of the number of filters Nf on test time (at  $K_s = 3, L=4$ ). Fig. 5 shows that the test time is linearly proportional to the number of filters and can be fitted using a linear equation.

From Eq. 8 and the previous experiments of CNN, it is noted that the time complexity of the CNN model increases as the kernel size and number of filters increase. Moreover, the  $K_s$  significantly affects the test time because it is in proportion to the square of the  $K_s$ . On the other hand, the test time decreases as the number of layers increases.

#### IV. THE PROPOSED SL-CNN MODEL

In this section, the architecture of the proposed model is designed to achieve high performance and less prediction time. Also, to make the model operate directly on raw data to generalize it across several datasets and data robustness. The architecture of the proposed SL-CNN model is presented next and summarized as shown in Fig. 6. Based on the analysis of the experimental results in Section III, the proposed SL-CNN model is designed using four layers with a kernel size of 3 x 3. In addition, filter numbers ranging from 32 to 128 were also tested to achieve optimal accuracy and prediction times. The proposed SL-CNN model consists of four convolutional (Conv) layers, four max pooling (MP) layers, three fully connected layers, and two dropout layers, as shown in Fig. 7. The pooling layer has a Relu activation function. Additionally, 7 batch normalization (BN) layers are used to achieve a stable distribution of the activation values through training and normalizing the input layers [34]. Also, each convolution layer is followed by a Relu function layer.

Fig. 8. Sample signs from the ArSL 2018 Arabic sign language dataset.

Fig. 9. Number of images in each class in ArSL dataset.

a) *Kaggle dataset (ASL 2018)*: The 2018 update of the American Sign Language (ASL) alphabet dataset, available on Kaggle’s data science repository, contains 29 classes for alphabet characters. Each class contains 3000 images captured with the intent to make a dataset for each character [37]. The dataset is divided into 70% for training, and the remainder is divided equally between validation and testing. Table IV shows the number of images for each partition. The data is rearranged randomly for each experiment.

b) *Massey dataset (ASL 2012)*: The last version of the Massey dataset, introduced in January 2012, contains 1815 images of 26 ASL alphabet gestures [38]. Each class contains 70 images, so the data is balanced. The dataset is divided into 85% for training, and the remainder is divided equally between validation and testing, as shown in Table IV. The data is rearranged randomly for each experiment.

3) *Arabic-English dataset*: The Arabic-English dataset combines the ArSL 2018 and ASL 2018 datasets, and the model deals with them as one dataset. The dataset contains 61 classes; each class has a different number of images, dimensions, and colors. Fig. 10 shows the number of images in each class. The combined dataset is divided into 70% for training, and the remainder is divided equally between validation and testing, as shown in Table IV.

4) *KSL consonant letters*: Korean consonant letters are also available on Kaggle and were last updated in June 2021. It contains 14 classes for consonant Korean alphabet characters [39]. The data is supported by 21962 images for training and validation and 3790 for the test. The images in the

Korean dataset are imbalanced distributed, as shown in Fig. 11. Training data is divided into 85% for training and 15% for validation, as shown in Table IV. Data is randomly fed to the network at each iteration.

### B. Experimental Setup

The experiment was conducted using MATLAB® 2020 Deep Learning Toolbox running on a 2.60 GHz Intel i5 CPU with 8 GB RAM, Intel 4 K graphics, and AMD Radeon 7500M/7600M series.

To evaluate the robustness of the model against randomization and avoid bias towards certain parameters, the experiment was conducted ten times; in each trial, the dataset was randomly divided into training and testing, and the results were averaged [15]. Also, the dropout layer is added to avoid the overfitting problems [40]. The effectiveness of the proposed model is evaluated on five datasets: (1) the ArSL 2018 dataset; (2) the ASL 2018 dataset; (3) the ASL 2012 dataset; (4) the ArSL-ASL combination; and (5) the KSL 2021 dataset. The accuracy defined as Eq. 9 is used to evaluate the classification performance, where FC and TC denote the total number of

false and correct instances of the test. Also, the sensitivity for each class is expressed as Eq. 10 and is used to express the evaluation of the performance for each class individually, where  $TC_c$  and  $TF_c$  are the numbers of correct and false instances in each class.

$$Accuracy = \frac{TC}{FC + TC} * 100 \quad (9)$$

$$TC_c = \frac{TC_c}{FC_c + TC_c} * 100 \quad (10)$$

### C. Performance Evaluation of the Proposed SL-CNN Model

The proposed model was trained for 15 or 20 epochs, and the proposed algorithm achieves high accuracy at epoch number 15. Table V summarizes the training accuracy, test accuracy, training time, test time, and standard deviation for test time with 15 epochs for the proposed SL-CNN model on ArSL 2018, ASL 2018, ASL 2012, the combination between them (ArSL-ASL) datasets, and 20 epochs for KSL 2021. Fig. 12 to 16 show the training and test accuracies and the start of the loss function to converge for ArSL 2018, ASL 2018, ASL 2012, ArSL-ASL, and KSL, respectively. It is noted from the table that the training accuracy for all datasets is 100%, and the test accuracy is 100% for ASL 2018, ASL 2012, and KSL, as well as 98.8% and 99.5% for ArSL and the combined dataset. In addition, the training and test times are different from one dataset to another. Figs. 17, 18, 19, and 20 show the confusion matrices for ArSL, ASL 2018, ASL 2012, and KSL. The diagonal of the confusion matrix refers to the number of the correct element obtained by the model, while off-diagonal predictions are false.

### D. Comparison with Other Models

In this section, we make a comparison between the SL-CNN model and other models published in other articles. The

TABLE VI. COMPARISON OF THE RESULTS BETWEEN THE PROPOSED MODEL AND OTHER PREVIOUS ARTICLES FOR ARSL

Author	Method	Dataset	Samples	Acc(%)
Latif, et al. [41]	CNN	ArSL 2018	54049	97.6
Elsayed, et al. [16]	CNN	ArSL 2018	54049	88.89
Alani, et al. [15]	CNN	ArSL 2018	54049	97.29
proposed SL-CNN	CNN	ArSL 2018	54049	98.47
M. Zakariah, et al. [42]	EfficientNetB4	ArSL 2018	54049	95.0
Rehab, et al. [43]	VGGNet	ArSL 2018	54049	97.0

comparison is divided into three parts ArSL, ASL, and KSL. It is noted that the proposed SL-CNN model outperforms its peers because each parameter of the CNN model structure has been carefully selected, as mentioned in Section III, and doesn't depend on preprocessing techniques to improve the accuracy of the application like others; but it works on raw data. For the ArSL 2018 dataset, the proposed SL-CNN model achieves 98.47% accuracy, outperforming other CNN models proposed in the literature, e.g. [16], [41] and [15] as shown in Table VI. It should be noted that the proposed model uses raw data without any preprocessing. It should be highlighted that the models by [42] and [43] employed modern classification approaches (Transfer learning) but obtained poor accuracy when compared to the proposed SL-CNN model.

For the ASL, the proposed model is compared to the models proposed in Kaggle datasets [8], [12], [18]] and [[12], [44], [45]] on the Massey dataset, which is shown in Table VII. The result of other state-of-the-art in literature [17] and [13] on collected but not publicly available datasets are also reported in Table VII. The CNN models proposed in [[46], [19]] achieved higher accuracy on selected images from the MNIST dataset. However, the proposed SL-CNN model is applied to all images in the recent Kaggle dataset, and the two versions of Massey beat all the previously suggested CNN models. Interestingly, the proposed model not only outperforms published models on ASL 2018 and ASL 2012 but also achieves 100% accuracy, in accordance with the recent results published on Kaggle [37]. It should be noted that the model by [47] achieved also 100% accuracy, however, on the Massey dataset 2011. Also, the model proposed in [13] got 99.3 % accuracy for ASL classification, but they used a collected dataset consisting of 240 images only.

Finally, for the Korean sign language, state-of-the-art methods in the literature are performed on collected but not publicly available datasets, as reported in VIII. The proposed model achieved 100% test accuracy for consonant characters, compared to the models by [20] who achieved 92.2% for vowel and consonant characters, and [21] who achieved 99.31% and 99.97% for vowel and consonant characters, respectively.

## VI. CONCLUSION AND FUTURE WORK

This paper proposes an approach to designing and analyzing an efficient CNN model for sign language recognition named SL-CNN based on a detailed study of CNN hyper-parameters, i.e., kernel size, number of layers, and filtering number in each layer. The performance of the proposed model was investigated for four sign language datasets (ArSL 2018, ASL 2018, ASL 2012, and KSL 2021), and one dataset was

obtained as a merge of the first two datasets (ArSL and ASL 2018). Table VIII shows the comparison of the results between the proposed model and other previous articles for KSL. The results show that the proposed SL-CNN model outperforms the other models in terms of classification accuracy for all datasets. In summary, the proposed model achieved accuracy for 98.8%, 100%, 99.5%, 100% and 100% for ArSL2018, ASL 2018, combining both, ASL 2012 and KSL 2021, respectively without resorting to any data preprocessing. As suggestions for future work, it is interesting to investigate the performance of the proposed model on sign language datasets consisting of words and sentences. Another possibility is to implement the proposed model in, e.g., an educational system for people who suffer from hearing problems.

ACKNOWLEDGMENT

Special thanks to Dr. Ahmed Mahmoud Alenany and Dr. Mohamed L. Elsayed for the English review of this manuscript.

**Abstract**—Visual impairment indicates any kind of vision loss including blindness. Individuals with visual impairments face significant challenges when trying to perceive their surroundings from a global perspective and navigating unfamiliar environments. Existing assistive technologies predominantly focus on obstacle avoidance, neglecting to provide comprehensive information about the overall environment. To address this gap, the proposed system employs a customized Convolutional Neural Network (CNN) model tailored to accurately predict the type of outdoor ground terrain the user is traversing. This information is then conveyed to the user audibly. It can also detect the presence of puddles on the road and let the user know whether the outside floor is wet (slippery). The proposed deep-learning architecture is trained on images collected from sources including the Stagnant Water dataset, the GTOS-Mobile dataset and a custom dataset. The trained model is then integrated into an Android app, providing visually impaired (VI) people with effective surrounding perception capabilities, leading to better travel and, ultimately, better living.

**Keywords**—Visually impaired; terrain identification; puddle detection; deep learning

## I. INTRODUCTION

Visual impairment encompasses a range of conditions that can result in partial or complete loss of vision, including color blindness, affecting over 250 million people worldwide. Such individuals encounter difficulties while comprehending and interacting with their environment due to their limited visual contact with their surroundings. Physically moving around can be particularly challenging for them as they struggle to identify their location and navigate to different places.

For navigation, individuals with visual impairments often utilize white canes or guide dogs, although the latter option can be costly. However, despite the assistance provided by white canes, the task of maneuvering through unfamiliar environments continues to pose a significant challenge. Conventional navigation techniques primarily focus on obstacle avoidance [1], which curtails the capacity of visually impaired (VI) individuals to engage with novel surroundings fully. Consequently, many still face obstacles in gaining a holistic perception of their environment.

Recent advancements in technology have paved the way for the development of intelligent or augmented white canes

that utilize image processing and deep learning techniques to aid individuals with low vision in obstacle avoidance, object detection [2], and indoor/outdoor navigation [3]. However, these systems have a limitation in that they do not provide a comprehensive perception of the surrounding environment. For instance, while these canes assist in identifying objects and navigating outdoors, they cannot provide information on the terrain, which is crucial for individuals with visual impairments to determine the floor they are walking on. By incorporating terrain information into these systems, VI individuals can benefit from a more comprehensive and seamless travel experience, ultimately leading to an improved quality of life. This is particularly important for elderly individuals with low vision.

The proposed method makes significant contributions to assistive technology for VI individuals, with a strong focus on human needs and safety. The main contributions are:

- Proposed a novel custom CNN for Comprehensive Terrain Identification: An innovative lightweight CNN has been created to recognize diverse terrains. Through the integration of this CNN, an Android application is developed for identifying different types of terrain. This pioneering functionality effectively addresses a significant deficiency in current systems, delivering vital insights to VI users regarding the specific characteristics of the ground they are traversing.
- Hazard Detection: The system's ability to detect road puddles or wet floors is a key contribution that sets it apart from conventional intelligent white cane systems. By proactively alerting users to potential hazards, the approach reduces the risk of slips, falls, and accidents, ensuring a safer travel experience for individuals with low vision, especially the elderly.
- Developed a dataset to train and test the proposed model: A dataset is made by combining standard datasets like the Stagnant water dataset, and the GTOS-Mobile dataset, collecting images from Google and images captured using a mobile phone.
- Real-time Audio Feedback: To promote effective communication between the system and the user, the integration of audio feedback proves invaluable. By conveying information through auditory cues, the system ensures that VI individuals receive timely updates

\*Corresponding authors.

about the terrain and detected hazards, allowing them to make informed decisions promptly.

In summary, our approach introduces a novel lightweight CNN with the ability to identify different terrains. We curate a specialized dataset for training and model development. Employing this innovative CNN, an Android application is developed that offers terrain insights and alerts users through audio feedback, particularly notifying them about possible hazards such as slippery floors or puddles. This approach prioritizes human needs, safety, and independence, with the potential to revolutionize assistive technology and significantly enhance the lives of individuals with limited vision, particularly elderly users, leading to an overall improved quality of life.

The structure of the paper is as follows: In Section II, we delve into the most recent advancements in intelligent tools designed [9] proposed a system explicitly for individuals with visual impairments. Section III provides a comprehensive explanation of our proposed methodology. We outline the datasets utilized in this study in Section IV. The experimental validation and outcomes of our proposed system are detailed in Section V. Finally, Section VI [9] proposed a system serves as the conclusion of this paper.

## II. RELATED WORKS

Vision forms one of the most important sense organs, which gives vital information about surroundings. Our sense of sight is responsible for 80 percent of what we perceive. Vision enables humans to interact with their surroundings. One of the side effects of vision loss is a lack of confidence in one's ability to travel safely. The placement of tactile ground surface indicators, unsafe sidewalks, and the presence of barriers on sidewalks are key challenges in comprehending the outdoor difficulties experienced by VI individuals [4]. This section reviews some of the critical works in the field of guiding aids for VI people. This analysis is split into related works regarding existing smart white canes and terrain recognition.

### A. Robotic White Cane

The white cane is the most frequently used aid by individuals with visual impairments. Its main function is to help users assess their environment for possible dangers. Additionally, it aids in signaling to others that the user is blind, ensuring they receive appropriate assistance. In recent years, numerous enhanced versions of the white cane have emerged, offering a range of capabilities. Many of these innovations concentrate on tasks such as avoiding obstacles, identifying objects, and facilitating outdoor navigation.

Anwar et al. [1], introduces a smart cane equipped with an alarm to aid individuals with visual impairments when navigating challenging paths. An RF remote transmitter and receiver make it a unique electronic stick. It is equipped with an ultrasonic sensor and a buzzer. The VI person's walking path is detected using an ultrasonic sensor. At the same time, a global positioning system (GPS) paired with a voice stick for navigation, allows users to learn their present location and distance from their destination via voice commands. However, this system is constrained to the local vicinity only. [5] proposed a smart walker navigation system that assists

VI individuals with difficulty walking. It is utilized for two purposes: local obstacle detection in the spatial information setting, and guided navigation for achieving the desired goal. Vibrotactile signals provide obstacle information or navigation commands to the user.

A voice-activated electronic stick whose goal is to give users the confidence to move around in new situations was introduced by [6]. This enhanced model comprises global system for mobile communications (GSM), GPS, and Ultrasonic technology. It also employs biological authentication and incorporates an emergency trigger in the alarm system. [7] proposed an enhanced white cane that aids the blind community in guiding by providing results for all 270 degrees from the smart security walking stick's position. Ultrasonic sensors with a wide beam angle assist in a variety of obstacle detection applications. It performs well at identifying obstructions in the user's path within a three-meter range. This technology is low-cost, lightweight, and energy-efficient, with a noticeable quick response time.

The traditional VI aiding technologies addressed the obstacle avoidance problem alone. Information about the terrain is also vital for safe and smooth navigation for the VI person. A generative adversarial network (GAN) model named DiscoGAN is created by [8] to effectively translate ground images into a tactile signal that can be presented by an off-the-shelf vibration device. In this way, it can provide a global perception of the surroundings. The research [9] proposed a system based on DeepLabv3+ that is an improved semantic segmentation network. The technology can be used on a mobile phone to assist VI people in both indoor and outdoor settings. The training dataset is preprocessed with an illumination-invariant transformation to reduce the impact of variations in light. Bashiri et al. introduced a novel framework in their study [10], employing deep neural networks to facilitate indoor navigation for visually impaired individuals.

Existing literature for puddle detection mainly uses object detection models. Some of the existing smart white canes include puddle or water detection using a moisture sensor. But if the battery is not charged, this will not work which is the main disadvantage faced by these augmented canes [11].

### B. Ground Terrain Recognition

The quality of the terrain dataset, the feature extraction method, and the classification algorithm for terrain features are the key factors that affect the performance of a terrain image recognition system [12]. These aspects are complementary, necessitating optimization and control throughout, to improve the terrain classification and generalization capacity of a new algorithm. Moreover, there exists a lack of publicly available terrain classification datasets for research purposes. The literature related to terrain recognition explained here used proprietary datasets in their study.

Terrain identification is critical for outdoor mobile robot gait planning, speed control, and observation of the surroundings, among other things. The study [13] opted for a system in which an outdoor mobile robot is built that runs on a terrain dataset and extracts the high-level elements of the terrain image from MobileNet and DenseNet using the migrating learning approach. Extent-of-Texture information proposed by

[14] is another unique way to ground-terrain recognition, which employs a CNN backbone feature extractor network to extract relevant information from ground terrain images and to model the extent of texture and shape information locally. The research [15] proposed a differential angular imaging Network (DAIN), where small angular variations in image capture provide an enhanced appearance representation that significantly improves recognition. The features of materials recorded in the angular and spatial dimensions are encoded in this innovative network architecture. A Deep Encoding Pooling network [16] is another method for ground terrain categorization. Semantic scene comprehension is critical for gaining a better grasp of the surroundings. The study [17] proposed a system based on a combination of the efficient residual factorized network (ERFNet) and the 3D point cloud with a pyramid scene parsing network (PSPNet). The above-mentioned models are complex models for which accuracy can be further improved. Furthermore, most of them have not been implemented in real time. Recently, Intelligent Vehicles (IV) methodologies have been applied to the development of navigation assistive systems for VI people.

The analysis of existing literature highlights significant research gaps in the field. Most robotic white canes prioritize addressing obstacles, overlooking the potential of offering a comprehensive understanding of the environment, especially in unfamiliar routes. Presently, there's a lack of systems that can effectively notify users about hazards like puddles, wet and slippery floors. Additionally, the accuracy of current ground floor classification systems could be enhanced. The primary objective of our proposed system is to furnish users with real-time information about outdoor ground conditions, particularly alerting them to road puddles and wet floors, through a custom CNN model that accurately predicts terrain. This crucial information is conveyed audibly to enhance user safety and experience.

### III. METHODOLOGY

The prevailing terrain recognition models predominantly feature intricate deep-learning architectures. Nonetheless, for individuals with visual impairments, conveying terrain details through an Android app holds more promise. This research strives to forge a path towards a simplified and computationally streamlined deep-learning model tailored for terrain recognition systems. To realize this vision, a direct approach is adopted, entailing the deployment of a specialized CNN model. Additionally, an Android application is meticulously crafted to enhance accessibility for VI individuals, facilitating seamless access to crucial terrain information.

A custom dataset consisting of five image classes, namely cement, grass, road, wet floor, and puddles has been created to help VI people better understand their terrain and be alerted of any potential hindrances. This dataset is a combination of GTOS-Mobile (Ground Terrain Outdoor Services) [18] data, Google images, IEEE Stagnant Water dataset, and ground terrain images captured using a mobile phone. An Android app has been developed which uses a custom-built CNN to detect ground terrain and provides audio feedback to the user with directions based on the detected features in real-time.

The proposed pipeline consists of three main steps, namely data pre-processing, CNN model design, and Android app

development. The images obtained from various data sets are resized to the same dimension in the pre-processing phase and are then augmented before feeding to the custom CNN. The pre-processing steps used were resizing, and gray scaling. The data augmentation involves random flip, random zoom, and random rotation. After model training, test data prediction and evaluation are done using the trained deep learning model. Fig. 1 shows the flow diagram of the proposed system for ground terrain detection. It represents the schematic of the proposed system.

#### A. Custom CNN

The Custom CNN architecture is comprised of five convolutional layers as depicted in Fig. 2. Detailed insights into the layer structure and parameter specifics can be found in Table I. The initial convolution layer block consists of two sets of convolution layers, each comprising 16 filters. The subsequent block contains two sets of convolution layers with 32 filters each, followed by a third block with a convolution layer featuring 64 filters. These layers employ the same padding scheme, along with ReLU activation and Max pooling. The filter size utilized in each of these convolutional layers is 3x3.

After these convolutional layers, a flattening layer is introduced, followed by a fully connected layer consisting of 128 filters, employing ReLU activation. Ultimately, a dense layer is incorporated, with the number of classes serving as a parameter. In summary, the Custom CNN model includes 560,000 trainable parameters, featuring five convolutional layers with associated Maxpooling layers and ReLU activation. It further incorporates a fully connected layer utilizing a dropout rate of 50%, followed by an output dense layer with the number of classes as a parameter. The model employs the sparse categorical cross-entropy loss function, particularly useful for multi-class image classification tasks. This loss function quantifies the cross-entropy loss between predictions and labels. Importantly, its utilization of integer representations for labels instead of vector representations contributes to efficiency in memory and computation. The mathematical formulation of this entropy function is:

$$L_{CE} = - \sum_{i=1}^n t_i \log(p_i)$$

where  $t_i$  is the truth label and  $p_i$  is the Softmax probability for the  $i^{\text{th}}$  class and  $n$  represents the number of classes.

The architecture of the Custom CNN is depicted in Fig. 2. To make the test results more accurate, we fine-tuned the CNN model so that it could better understand the test data. By doing this, the model became better at recognizing different features in the test images. This process involves making small improvements to how the model learns from the given data. The combination of the CNN's design, how it extracts features, and the fine-tuning process all work together to create a strong model that can accurately identify and classify images. The images were resized to dimensions of  $64 \times 64$  pixels and a batch size of 15 is selected empirically. The number of filters within the fully connected Layer is fixed as 128.

### IV. DATA COLLECTION

We curated an exclusive dataset tailored to our proposed system. This dataset comprises diverse visual representations

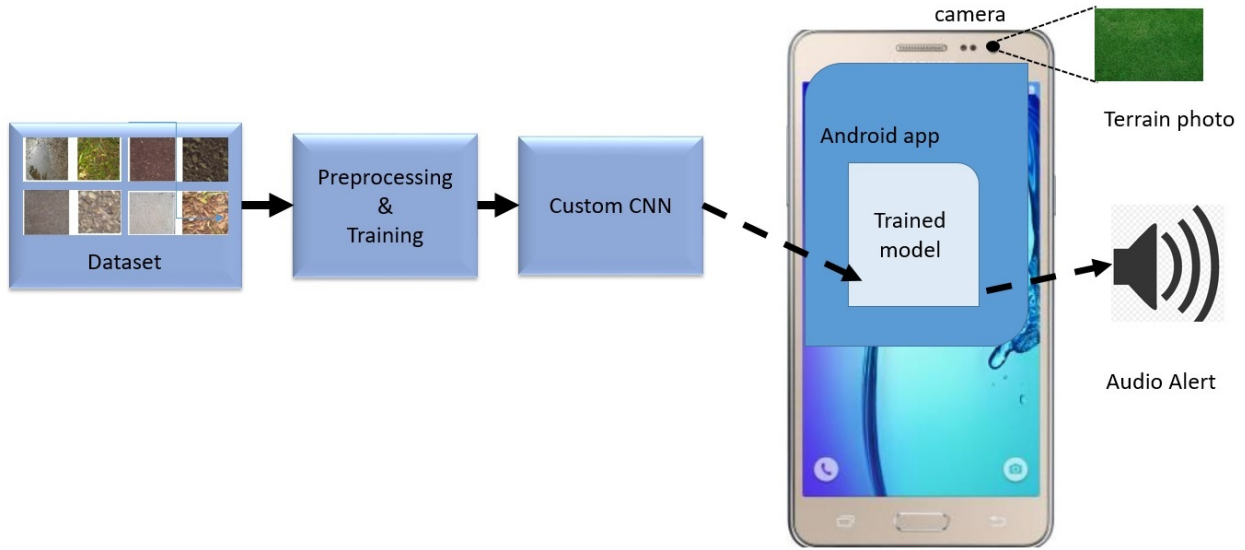

Fig. 1. Flow diagram of the proposed system for ground terrain detection.

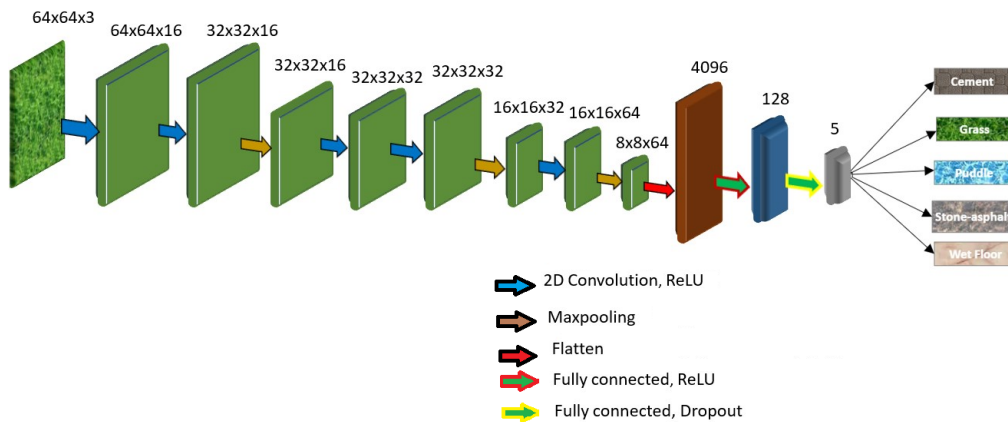

Fig. 2. Architecture of the proposed custom CNN for identifying ground terrain.

TABLE I. LAYER STRUCTURE DETAILS OF MODIFIED CUSTOM CNN

Layer	Input	Kernels	Output	Parameters
Conv1	$64 \times 64 \times 3$	16	$64 \times 64 \times 16$	448
Conv2	$64 \times 64 \times 16$	16	$64 \times 64 \times 16$	2320
Maxpool1	$64 \times 64 \times 16$	-	$32 \times 32 \times 16$	-
Conv3	$32 \times 32 \times 16$	32	$32 \times 32 \times 32$	4640

Maxpool2	$32 \times 32 \times 32$	-	$16 \times 16 \times 32$	-
Conv5	$16 \times 16 \times 32$	64	$16 \times 16 \times 64$	18496
Maxpool3	$16 \times 16 \times 64$	-	$8 \times 8 \times 64$	-
Flatten	$8 \times 8 \times 64$	-	4096	-
Dense1	4096	128	128	524416
Dense2	128	-	5	645

of outdoor ground surfaces, such as concrete, grass, and asphalt-covered stone. Additionally, it incorporates imagery depicting wet patches and puddles. Our dataset draw images from the GTOS-Mobile dataset [18] for ground terrain information, while images featuring puddles and damp floors were

sourced from the IEEE Stagnant Water dataset [19]. Furthermore, we enriched the dataset with video footage recorded using a mobile device.

#### A. GTOS-Mobile Dataset

The GTOS-Mobile dataset [18] encompasses 81 videos that showcase terrain categories similar to those found in the GTOS dataset. These videos were captured using a handheld mobile phone, introducing a variety of lighting conditions and viewpoints. The dataset comprises an extensive collection of 100,000 images distributed across 31 distinct classes. After a meticulous curation process we extracted 6066 frames by employing a temporal sampling rate of approximately 1/10th of a second. However, the emphasis is placed solely on the crucial ground terrain categories. Owing to concerns surrounding image clarity, data pertaining to sand and soil from the GTOS-Mobile dataset is deemed less dependable, prompting its exclusion from consideration. Consequently, for the purpose of outdoor terrain recognition, the analysis narrows

down to the inclusion of the cement, grass, and stone-asphalt classes extracted from this dataset. Fig. 3 shows sample images extracted from this data set.

Fig. 3. Images from GTOS-Mobile dataset.

### B. Stagnant Water Dataset

The dataset [19] comprises images with dimensions of  $256 \times 256$  pixels captured using a mobile device. This dataset comprises a total of 1976 annotated photos and encompasses two categories, namely moist surfaces and bodies of water. The dataset is further divided into distinct categories: Indoor, Outdoor, and Raw data. The raw data category comprises unprocessed images, each accompanied by a specified range of resolutions. Puddle detection presents a range of complexities due to fluctuations in lighting conditions, diverse image capture angles, and the presence of reflections on puddle surfaces. To tackle these challenges, approaches such as data augmentation and the collection of images from a diverse range of angles and lighting conditions have been implemented. Fig. 4 shows sample images from the Stagnant Water dataset.

### C. Custom Dataset

A unique dataset was compiled by capturing images using a Redmi Note 7 mobile phone with a 12-megapixel camera. This dataset encompasses 150 images for each distinct category: cement, grass, stone-asphalt, puddle, and wet floor. Images taken by VI persons using mobile phone might not exhibit flawless quality. Intentionally, the custom dataset includes both shaky and low-quality images, mimicking real-world conditions. This deliberate inclusion aims to provide the training process with a more realistic representation of the environment. The images from this custom dataset are depicted in Fig. 5.

The final dataset contains 16763 files belonging to five classes. The images are acquired from the GTOS-Mobile dataset, Stagnant water dataset and images captured using our

Fig. 4. Images from stagnant water dataset.

Fig. 5. Images from custom dataset.

own mobile device. The training data is split into train data and validation data with a validation split 20%. A total of 12973 files is used as training set, 3243 files for validation, and 759 files as test dataset. Table II shows number of images in each class of custom dataset.

## V. RESULTS AND DISCUSSION

The CNN model proposed for terrain classification underwent a comprehensive training process to realize the required customized model for accurate terrain detection. The training utilized a specialized dataset encompassing a variety of outdoor terrains, including cement, stone-asphalt, grass, as well as distinct classes for puddles and wet floors. In the

TABLE II. NUMBER OF IMAGES IN EACH CLASS OF CUSTOM DATASET

Class	Train dataset images	Test dataset images
Cement	7550	174
Grass	3100	196
Puddle	1659	114
Stone-asphalt	2370	154
Wetfloor	2084	121

initial stages of training, validation accuracy surpassed 95%, while testing accuracy remained below 70%, indicative of an overfitting scenario. To address this challenge, a combination of techniques including early stopping, dropout, and data augmentation was employed, resulting in a notable reduction of this accuracy gap.

Efforts were directed towards enhancing testing accuracy through layer-wise modifications in the CNN architecture. These refinements led to a remarkable increase in testing accuracy to 98%. The Adam optimizer, with a default learning rate of 0.001, was leveraged to optimize the modified Custom CNN model. Training the model for 300 epochs with Early Stopping set at 50 epochs based on minimum validation loss yielded promising outcomes.

The accuracy and loss curves of the Custom CNN model are visually depicted in Fig. 6, illustrating the progressive improvement achieved during the training process. Meanwhile, Fig. 7 presents the confusion matrix, offering insights into the model’s performance across various terrain classes. It is important to note that the observed oscillations in the curves can be attributed to the utilization of an imbalanced dataset in this study. Future work could involve mitigating such oscillations by considering a slightly lower learning rate or implementing exponential decay learning rate strategies. The learning rate, a pivotal parameter in optimization, requires a balanced selection that ensures a trade-off between convergence speed and overshooting tendencies. As evidenced by validation loss values ranging from 0.1 to 0.4, finding this optimal balance remains a crucial consideration.

Further advancements were achieved by enriching the puddle class with additional images sourced from the Stagnant Water dataset. This augmentation elevated the model’s validation accuracy to an impressive 98%, while testing accuracy reached 94%, as depicted in Fig. 8. The confusion matrix revealed that, post-enhancement, instances of misclassification emerged wherein puddles were sometimes classified as wet floors. It is worth noting that road puddles and wet floors both fall under the puddle category. The mispredictions of this nature do not significantly impact system functionality, as the system’s role is to provide audio feedback advising users to proceed cautiously in case of detected puddles or wet floors.

The proposed CNN model demonstrates the remarkable potential for real-time terrain classification. The results highlight avenues for further refinement, including domain transfer implementations. The integration of this model into practical applications, particularly those necessitating immediate feedback for user safety, underscores its relevance and efficacy in

real-world scenarios.

### A. Android Application Results

The central objective behind the proposed system is to enhance the capabilities of conventional robotic white canes by introducing a comprehensive understanding of the surrounding environment. This innovation aims to empower individuals with visual impairments (VIs) by seamlessly integrating global insights into their daily navigation. Rather than augmenting the white cane with additional hardware and algorithmic components, a more user-friendly approach involves encapsulating this functionality within an Android application.

To achieve this goal, a fundamental Android application was developed as a preliminary step to assess the real-time behavior of the proposed deep learning model. This undertaking laid the groundwork for subsequent domain transfer implementations. The transition from a deep learning model stored in the .h5 format to a .tflite model was a pivotal phase. The choice between a quantized or unquantized model depended on size considerations. The deep learning model, which clocked in at 2MB in its original form, maintained this size when converted into an unquantized .tflite model. Opting for a quantized eight-bit .tflite model reduced the size to 500KB. However, this reduction in size through quantization came at a trade-off with accuracy.

The development of the Android application was facilitated by the widely used Android Studio framework, which supports the Java programming language and is well-suited for mobile device applications. After a thorough simulation process, the deep learning model with the lowest validation loss was saved using model checkpointing. To ensure optimal performance on mobile devices, this selected model was converted to an unquantized .tflite model. By doing so, the .tflite model retained a manageable size of 2MB, enabling its seamless integration into the Android application.

The proposed system's core concept revolves around extending the functionality of robotic white canes through a user-friendly Android application. By encapsulating complex insights into a lightweight .tflite model, individuals with visual impairments can gain an enhanced understanding of their surroundings, thereby advancing their autonomy and safety in navigation.

The initial phase of development involved creating a basic version of the Android App, which serves as a foundation for evaluating the system's real-time performance. This App captures images and employs the deep learning model to predict the type of terrain and identify the presence of puddles or wet floors. The primary objective of this basic App version is to gain insights into the system's behavior under real-world conditions.

For testing purposes, the App's user interface includes two buttons, as illustrated in Fig. 9. One button captures an image in real time, while the other allows users to select an image from their gallery. These preliminary App results serve as a foundation for domain transfer evaluations. It is important to emphasize that the basic version of the app is not tailored for individuals with visual impairments (VIs). To address this, an advanced Android app was developed to provide continuous

Fig. 9. Android application Interface. Image shows screenshot of the android app, created for testing purposes.

video monitoring and audio feedback, ensuring its suitability and effectiveness for VI users.

## VI. CONCLUSIONS

In recent decades, advancements in technology have led to the development of robotic and augmented white canes tailored for individuals with visual impairments (VIs). These innovations primarily focus on object detection, obstacle avoidance, and navigation. The major challenge involves providing VI individuals with a comprehensive understanding of their environment to facilitate improved interaction with their surroundings during travel. The central aim of the proposed system is to furnish VI individuals with an encompassing perception of their surroundings. This is achieved through the identification of diverse ground terrains, encompassing cement, grass, and asphalt, along with the detection of road puddles and wet floors. To realize this, a Custom CNN is employed as a deep learning model for a multi-class image classification challenge. The system culminates in conveying vital information to users through audio feedback.

Following an intensive training regimen, the deep learning model achieves commendable performance, boasting a testing accuracy of 94% and an impressive validation accuracy of 98%. To facilitate domain transfer, an Android app was meticulously designed, enabling real-time testing to assess the robustness of the proposed system in various scenarios.

The future trajectory of the proposed system holds significant promise. Plans encompass the expansion of more ground terrain classes to broaden the system's scope and versatility. Additionally, there are intentions to tailor the Android app for individuals with low vision impairments, incorporating continuous video monitoring. This enhancement ensures accurate terrain and puddle identification, even under varying illumination conditions. The App's connection with users will be fortified through intuitive audio feedback, reinforcing its accessibility and usability.

**Abstract**—The widespread use of computers and smartphones has led to an increase in social media usage, where users can express their opinions freely. However, this freedom of expression can be misused for spreading abusive and bullying content online. To ensure a safe online environment, cybersecurity experts are continuously researching effective and intelligent ways to respond to such activities. In this work, we present ArCyb, a robust machine-learning model for detecting cyberbullying in social media using a manually labeled Arabic dataset. The model achieved 89% prediction accuracy, surpassing the state-of-the-art cyberbullying models. The results of this work can be utilized by social media platforms, government agencies, and internet service providers to detect and prevent the spread of bullying posts in social networks.

**Keywords**—Natural language processing; machine learning; neural network; bullying; cyberbullying

## I. INTRODUCTION

The widespread use of computers and smartphones has greatly increased the use of social media in recent years. Social media platforms allow users to express their opinions and emotions freely, either using their real identities or anonymously. Unfortunately, this freedom of expression has also led to the spread of online bullying. People can hide behind anonymity to harass and bully others, causing significant harm and distress to their victims. It's important for social media companies and individuals to take steps to prevent and address this issue and to ensure that these platforms remain safe and positive spaces for everyone.

Cyberbullying refers to any deliberate aggressive behavior via social media done by an individual or a group of individuals that post offensive or hostile messages that result in discomfort or harm to other users [1]. Dani et al. in [2] defined cyberbullying as the phenomena of intentionally harassing or abusing others through cell phones, internet, and other electronic devices. According to [3], cyberbullying is confirmed as a serious global problem that should be confronted and prevented from spreading. Cyberbullying is worse and more insidious than traditional bullying and has severe consequences since it is not restricted to a time or a place. The bullying content can be posted in a single action as a comment or a tweet by an abuser. Cyberbullying enables the perpetrator with the ability to humiliate or embarrass the victim in plain sight. Also, this content can be viewed, saved, shared, quoted, or liked by others multiple times, resulting in an ongoing cycle of the original assault creating persistent damage or distress for the victim. Cyberbullying victims suffer from depression,

anxiety, low self-esteem, anger, frustration, feelings of fear, and in tragic scenarios the victims attempt suicide [4]–[6].

Moreover, in [2], the author stated that cyberbullying is becoming more frequent due to the growth of social media platforms. A study was done by Al-Zahrani [3] investigating cyberbullying in Saudi Arabia among higher-education students, 287 students participated in the study, as 26.5% of the students admitted that they have cyberbullied others at least once, while the majority of students 57% have witnessed cyberbullying once or twice on at least one student. He concluded that cyberbullying rate in Saudi Arabia has increased by 9% during the study time period.

Twitter is a microblogging platform that allows users to express their opinions and share their thoughts. Users can follow influencers, brands, and news accounts to stay informed about current events and trends [7]. As noted by Alasem [8], the number of Twitter accounts in Saudi Arabia has been increasing, with the platform experiencing fast growth in the country. In 2012, Riyadh, the capital city of Saudi Arabia, was ranked as the tenth most active city globally in terms of statistics and tweets. Given the vast array of topics and trends that emerge on social media, cyberbullying can take on various forms and can be challenging to identify.

Detecting cyberbullying on social media requires an understanding of users' opinions, tweets, and emotions, which can then be analyzed to determine whether the content constitutes bullying or not. According to Saberi and Saad [9], sentiment analysis involves the detection, extraction, and classification of opinions or comments on a particular topic. The primary goal of sentiment analysis is to classify the opinion, comment, or blog as either positive, negative, or neutral. However, detecting cyberbullying in the Arabic language presents significant challenges due to its complex structure, diverse dialects, informal language used on social media, and wide range of synonyms. Additionally, the Arabic language in social media is often written with diacritics that aid in pronunciation, making normalization, tokenization, and stemming difficult to apply.

To ensure effective detection of Arabic cyberbullying comments on social media, a well-trained machine-learning model is essential. This is particularly important given the widespread use of the Arabic language, which is spoken by approximately 420 million people [10]. However, developing such a model is challenging due to the lack of labeled Arabic datasets and research on this topic. As of the writing of this paper, there is no well-trained model with more than 90% prediction accuracy for detecting Arabic cyberbullying

comments. Furthermore, as detailed in Dani et al. [2], detecting and combating cyberbullying in the Arabic language presents several challenges, including the nature of online comments and reviews. These comments are often unstructured, short, and obfuscated, making it difficult to identify common patterns in machine-learning models. To address these challenges, we present the following in our work:

- A comprehensive analysis on Arabic cyberbullying tweets and their growth over time.
- A novel Arabic cyberbullying dataset labeled using a rigorous methodology.
- A deep learning model that can detect Arabic cyberbullying with a prediction accuracy that is equal to or better than the state of the art.

The rest of the paper is organized as follows: Section II presents the background information and preliminaries of the cyberbullying in the Arabic language. Section III presents our proposed deep learning detection method. In Section IV, we discuss the experimental setup for our experiments. In Section V, we discuss the experimental results obtained. Section VI concludes the paper.

## II. BACKGROUND

Many studies have been published in the sentiment analysis field. Researchers have provided interesting methods and approaches contributing to this field improvement. Abdul-Mageed et al. in [11] produced an Arabic dataset that was divided into four classes, objective, subjective-positive, subjective-negative, and subjective-neutral, and was manually labeled. The authors followed classification criteria that were taken from [12] in which if a phrase is not objective, it will fall into one of the three subjective classes. Out of their strict annotation process, their dataset consists of 1281 objective, 491 subjective-positive, 689 subjective-negative, and 394 subjective-neutral news sentences. Then for the classification, they've done two stages using the SVM classifier with linear kernel. The first stage for classifying the subjectivity, train the model to differentiate the subjective and objective sentences, and the second stage is to study the sentiment, and train the model to differentiate the positive and negative subjective sentences. As a result of their work, they obtained 65% and 52% *F*-score for the subjectivity and sentiment studies respectively.

Duwairi and Qarqaz in [13] used open-source software with a graphical user interface to build their machine learning model. They have generated a dataset from Twitter and Facebook that consist of 2591 tweet and comment, 1073 positive and 1518 negative samples, and were classified using a crowdsourcing tool. The dataset addresses multiple topics such as sports, education, and political news. The Naïve Bayes, KNN, and SVM classifiers were used, the SVM achieved a higher precision rate and it equals 75.25%.

Shoukry and Rafea in [14] have used machine learning to study the Arabic sentiments. They collected more than 4000 tweets and then finally have extracted 1000 tweets consisting of 500 negative and 500 positive tweets. Their tweet extraction targeted tweets that only hold one opinion and avoided sarcastic and subjective tweets. For the feature extracting

Shoukry and Rafea method was revealed from [15] where the statistical machine-learning is implemented to highlight the most common words to act as candidate features. For the classification task, they used the Weka software to classify the tweets using Naïve Bayes and SVM with accuracy around 65% and 72%, respectively.

Al-Kabi et al in [16] developed an analysis tool that can classify the opinions and comments based on standard and slang Arabic forms. One of the tool tasks is classifying the text into positive or negative, which is indirectly related to our research. In specific, their dataset consists of reviews collected from 72 social media websites with a total of 1080 reviews, and their machine-learning method was the Naïve Bayes. Their method successfully identified the subjectivity, polarity, and intensity of the Arabic reviews with prediction accuracy around 90%, 93%, and 96%, respectively.

AL-Rubaiee et al. in [17] implemented NLP and machine learning to classify tweets according to their sentiment polarity. Their work concentrated on opinion mining in a trading strategy with Mubasher products, a stock analysis software in Saudi Arabia, which made it considered topic-specific in the field of the sentiment analysis of the Arabic language. They collected and manually labeled around 1331 tweets by two experienced Mubasher employees. Therefore as a result of their annotation process, their dataset consists of 378 positive, 755 negative, and 198 neutral tweets. The prediction accuracy of their Naïve Bayes and SVM model are around 83% and 79% respectively.

On the other hand, There are a few other topic-specific works that focus on constructing machine-learning models to detect cyberbullying behavior. In 2019 AlHarbi et al. published the first work in the Arabic cyberbullying field [18]. In specific, they built a lexicon-based model that consist of more than 100K samples. They used R language for data extraction, 50K tweets, and 50K Youtube comments. They were able to obtain 81% prediction accuracy for the trained cyberbullying model. Similarly, Almutiry and Fattah in [19] collected a dataset automatically through Twitter API and ArabiTools with a total of 17748 tweets. they followed two collecting methodologies, one is query-oriented by searching for specific keywords, and the other is random selection. The dataset was labeled by both means manual and automatic. The automatic labeling was done by considering the nature of the tweet, if a tweet contains cyberbullying words it will be labeled as cyberbullying, and otherwise non-cyberbullying. After collecting and labeling the dataset a couple of steps were performed in preprocessing such as Normalization, Tokenization, ArabicStemmerKhoja, Light Stemmer, and Term Frequency-Inverse Document Frequency(TF-IDF). Then for the classification, they used the SVM algorithm with both Python and WEKA. After performing three experiments WEKA results showed the highest efficiency with 85.49% prediction accuracy. However, we argue that relying on automatic labeling is not currently practical. Given the significance of accurate sample annotations, utilizing automatic labeling techniques would introduce a substantial risk of duplicating samples and producing inaccurate classifications. Therefore, manual labeling remains indispensable until we develop a highly accurate model capable of consistently and reliably classifying the samples.

Almutairi and Alhagry in [20] started the data collection

process using Twitter API and collected a total of 8154. The authors focused on collecting their dataset from Saudi Arabia. The data collection process spanned approximately one year and seven months, capturing tweets related to various events such as student exams, vacations, and the COVID-19 pandemic. During the preprocessing phase, they applied several cleaning steps, including the removal of URLs, mentions, emojis, hashtags, newlines, repeated letters, digits, Arabic diacritics, and unrelated tweets. For the classification task, they employed multiple machine learning algorithms and found that the SVM algorithm achieved the highest prediction accuracy of 82

As shown in the literature above and besides some works that were not mentioned [21]–[24], in the past ten years, the Arabic sentiment analysis got a lot of attention in several topics such as users reviews in the trade market, positive and negative tweets, and cyberbullying. Nevertheless, there is neither a publicly available Arabic cyberbullying dataset nor a well-trained machine learning model for cyberbullying due to the difficulty of the Arabic language and its many dialects, along with the slang language used by the majority of Arab users. Therefore, our work contributes to the research community by providing a well-trained machine learning model based on a manually labeled dataset.

### III. METHODOLOGY

This section presents the methodology used to build a machine-learning model for Arabic sentiment analysis and cyberbullying detection. The process begins with a discussion of the data collection method and labeling process. Next, the proposed preprocessing and machine learning approach are presented. Finally, the evaluation of the approach is discussed. To provide an overview of the approach and steps taken to detect cyberbullying in social platforms, Fig. 1 is presented.

#### A. Data Collection

As discussed in Section II, the lack of publicly available datasets on cyberbullying in the Arabic language posed a significant challenge for this study. Hence, the collection and labeling of a suitable dataset proved to be a time-consuming and challenging task, presenting the most significant hurdle in the project. To kickstart the project, we formed multiple teams and manually analyzed the Twitter space to familiarize ourselves with the terminologies and behaviors associated with cyberbullying on social media, as well as the techniques used by perpetrators. This led us to identify 16 keywords, including *khibel*, *Abd*, and *Marid*, which we used to collect the dataset. Table I presents some of the search keywords that we employed in this research. We hand-selected these terms based on our examination of the most prevalent Arabic bullying terms. We believe that most tweets utilizing these terms are likely to be of a bullying nature. Once the search keywords were determined, we utilized the Twitter-API, which is publicly accessible, to retrieve tweets containing the designated keywords. Each downloaded tweet was required to contain at least one of the specified keywords. During the data collection phase, we encountered various obstacles, such as the maximum number of allowed tweets to collect per day by the API, tweets written in foreign dialects and languages, and a high number of duplicate tweets. However, these obstacles are not unique to

our study and are commonly encountered in similar research. To overcome these challenges, we adopted best practices and strategies from previous studies.

TABLE I. EXAMPLES OF CYBERBULLYING KEYWORDS USED IN SOCIAL PLATFORMS AND THEIR ENGLISH TRANSLATION

Keyword	English meaning	Arabic Keyword
Khibel	Person that lacks intelligence	خبيل
Tays	Person that lacks common sense	تيس
Abd	Slave	عبد
Marid	Pervert or Sick	مريض
Nafsiyah	Refers to the person's psychological state	نفسية
Immah	Person who blindly agrees with someone regardless of their actions	امعه
Baka	Whiner	بكي
Madala	Spoiled	مدلع
Moaq	Handicapped (insult)	معاق
Bahima	Animal (insult)	بهيمه
Kalb	Dog (insult)	كلب
Maafen	Disgusting	معفن
Ghabi	Stupid	غبّي
Wajhk	Your face	وجهك
Seyah	Screaming in literal meaning but could also mean crying or whining	صياح
Yifashil	Embarrassing	يفشل

#### B. Labeling

Our dataset comprises 4140 samples, of which 2070 tweets are labeled as bullying and 2070 tweets are labeled as non-bullying. We decided to remove the user's identities to protect their privacy. For our cyberbullying tweets, manual labeling is necessary due to the absence of diacritics in written Arabic, which represent vowels. The lack of diacritics generates ambiguity, which increases the range of possible interpretations in the Arabic language [25]. Additionally, bullying can be disguised in a normal sentence that cannot be detected by automated labeling tools. Every tweet in the dataset was independently annotated by two cybersecurity specialists, all of whom are native Arabic speakers. The annotation process took place over a period of six weeks. In cases where conflicts arose among the annotators, a third specialist was involved to resolve them through discussions with the two cybersecurity specialists.

Table II lists some samples that were difficult to classify because of their confusing nature. For example, the first sample states "Finally it's my favorite time where I go to sleep and put my phone on silent while others whine while they go to work/school". One can build a case that this is indirect bullying to those who need to go to work from those with the luxury to stay home. However, you can also build a case that the user is describing their feelings without interfering with or offending anyone. In our case, we followed the later logic since the user did not use any offensive language, which is usually included based on the commonly accepted definition for bullying [1] [2]. In the second example, a user responds to a tweet announcing that schools' final exams will be held on campus, which has sparked complaints from students who have been attending

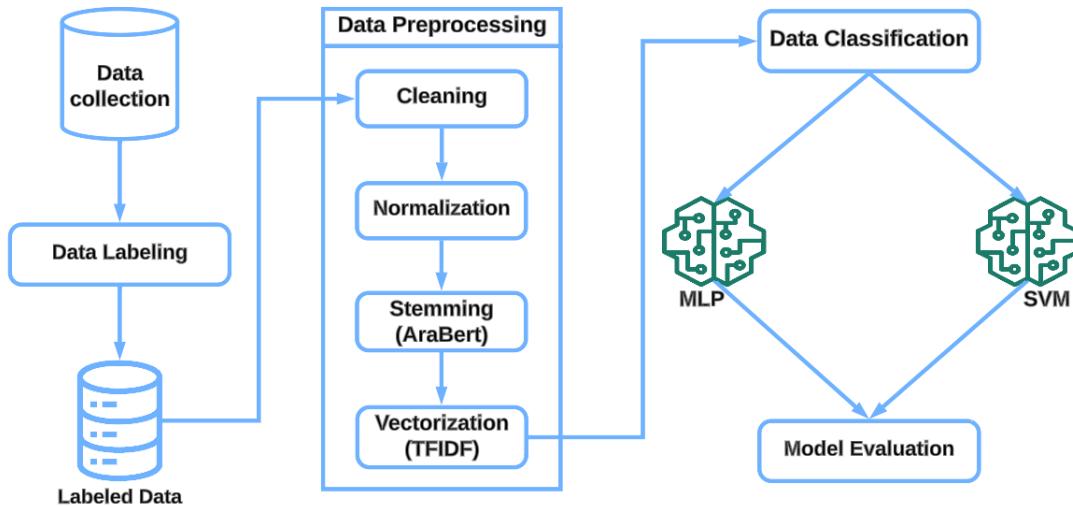

Fig. 1. The research methodology. The figure illustrates the sequential steps undertaken in this study, starting with the collection of raw data, then the labeling of the data, followed by preprocessing, modeling using AraBERT and TFIDF, and concluding with the analysis of the model’s result. The arrows indicate the flow and progression of the research process.

school online due to the COVID-19 lockdowns. The user says "They deserve it, let them test on campus. They disgust me. They want to stay at home and in bed forever. What a spoiled and useless generation". The user’s response contains offensive words and implies that the current generation is lazy, soft, and unsuccessful. You may build a case that the user is not targeting someone specifically, and you also may build a case that he is targeting a large but specific set of people. We believe the user identified the entity they are offending and bullying and used multiple offensive words in the tweet, so we classified this tweet as an instance of cyberbullying, following the definition proposed by [1], [2].

TABLE II. EXAMPLES OF TWEETS THAT ARE DIFFICULT TO CLASSIFY

Tweets	Label
اخيرا جا وقت ففرقي المفضلة تصميت الجوال والنوم على انغام صياح المداومين	0
يستاهلون نبيهم يختبرون حضوري قرفونا لين متى الدلع والتسدرح جيل مدلع و فاشل	1

Table III lists some samples from our dataset. Those examples also show that the same word can have completely different meanings depending on the context in which it is used. In our example, we focused on the keywords Nafsiyah and Khibel. Let’s first examine the samples that use the keyword Nafsiyah. The first tweet in Table III, which we labeled as non-bullying, uses the keyword in a positive manner where the user expresses relief for completing a month without going to any health clinics. However, in the second tweet, which we classified as a bullying tweet, the user replied with an accusation that the original tweet author has psychological issues. Now, let’s examine the samples that use the keyword Khibel. The third tweet in Table III, which we classified as a non-bullying tweet, uses the term to describe someone with a humorous and entertaining personality. On the other hand, in the fourth tweet, the user replies to another tweet,

criticizing the person’s actions as stupid and childish, which we labeled as a bullying tweet. As we can see, the same word can have completely different meanings depending on how it is used, which highlights the difficulty of correctly labeling a cyberbullying dataset. It requires tremendous effort.

TABLE III. SAMPLES OF MANUALLY LABELED TWEETS IN OUR DATASET WHERE THE 0 LABEL INDICATES A NON-BULLYING TWEET WHILE 1 IS FOR BULLYING

Tweets	Label
شهر بدون عيادات.. بمجرد ماتقراها تحس براحة نفسيه	0
شكله عندوا مشاكل نفسيه	1
وجود شخص خبل بحياتك يعتبر نوع من أنواع العلاج النفسي	0
الحمدلله والشكر مستحيل انه انسان عاقل فاهم وفي بخ اللي مسويها خبل ولا بزر	1

### C. Data Pre-processing

The Arabic dataset was preprocessed following standard data mining methods [16], [17], [21], which involved four key steps: cleaning, normalization, stemming, and vectorization.

The cleaning step was crucial to ensure that the dataset contained only relevant and meaningful information for further analysis. We eliminated usernames, as they do not contribute to the sentiment or content of the tweets. Additionally, numbers were removed since they often do not carry significant semantic meaning in the context of text analysis. Null samples and duplicated tweets were also eliminated to ensure data integrity and avoid skewing the analysis. URLs were removed to eliminate any bias or influence that external websites or resources may have on the dataset. Special characters, punctuation marks, and emojis were stripped from the text, as they do not provide valuable information for sentiment analysis and may introduce noise to the data. Finally, English letters were filtered out to focus exclusively on the Arabic text, as the study specifically targeted cyberbullying in the Arabic language.

Following that, we employed normalization techniques to achieve a consistent representation of words, ensuring uniformity in the dataset. We focused on converting different forms of the same word into a common base form. The tweets were normalized and standardized into a unified format. It is worth noting that the dataset consisted of tweets written in both classic Arabic and Modern Standard Arabic (MSA), with variations in dialects based on geographic regions. Furthermore, it was observed that users often substitute diacritics (Tashkeel) with letters, leading to spelling mistakes. For instance, they would write **انو** instead of **انه** and **هاذا** instead of **هذا**. To address this, we applied diacritics and letter normalization techniques to ensure consistency and accuracy in the data. Additionally, we removed stop words, which are commonly used words that carry little semantic meaning. A collection of 750 Arabic stop words compiled by Mohamed Taher Alrefaie was employed for this purpose<sup>1</sup>. Removing these stop words and normalizing the dataset served the dual purpose of reducing dimensionality and avoiding negative impacts on the training process. For a visual reference of the letters used in the samples and their corresponding replacements, please refer to Table IV.

TABLE IV. THE LETTERS USED IN THE SAMPLES AND THEIR REPLACEMENT

Original Letters	Target Letters

Finally, we performed vectorization to transform the textual data into numerical representations, enabling the application of machine learning algorithms for classification and analysis. To achieve this, we utilized the CountVectorizer module from the Scikit-Learn library [26]. This powerful tool allowed us to convert each tweet into a matrix of token counts. In simpler terms, CountVectorizer assigns a numerical value to each word in the tweet, indicating the frequency of occurrence. This process effectively creates a numeric representation of the text, which can be easily processed and analyzed by machine learning algorithms. Additionally, we employed the Term-Frequency Times Inverse Document-Frequency (TFIDF) weighting scheme, also provided by Scikit-Learn [26]. TFIDF helps determine the importance and weight of each term within the dataset. This scheme takes into account the frequency of a term within a specific tweet (term frequency) and balances it with the rarity of the term across all tweets (inverse document frequency). As stated by Scikit-Learn, TFIDF can be obtained by:

$$TFIDF(t, d) = TF(t, d) \times IDF(t), \quad (1)$$

$$IDF(t) = \log\left(\frac{n}{df(t)}\right) + 1, \quad (2)$$

where  $n$  is the total number of tweets in the dataset and  $df(t)$  is the dataset frequency of  $t$ . By applying TFIDF, we can normalize the CountVectorizer matrix, providing a more

refined representation of the tweet dataset. These vectorization techniques were essential in transforming the Arabic dataset into a suitable format for machine learning analysis and modeling. By converting the textual data into numerical representations, we enable the algorithms to understand and process the information effectively. This final preprocessing step prepared the dataset for further exploration and utilization of machine learning algorithms to extract valuable insights and classify cyberbullying patterns in the Arabic language.

#### D. Data Classification

In this paper, we utilized Support Vector Machine (SVM) and Multi-layer Perceptron (MLP) [26] as our chosen classification algorithms. SVM is a linear model that constructs a line or hyperplane to separate the data into predefined classes. It aims to find the maximum margin that separates the hyperplane between two data classes, thereby achieving optimal classification performance. One compelling aspect of using SVM in our work is its ability to effectively handle small datasets and provide accurate approximations of the underlying learning patterns. MLP is a type of fully connected feedforward neural network consisting of three layers: the input layer, hidden layer(s), and output layer. For our specific MLP configuration, we employed four hidden layers with 30, 66, 66, and 30 nodes, respectively. Since our dataset only consisted of binary classes, we utilized the logistic activation function.

$$s(x) = \frac{1}{1 + e^{-x}}. \quad (3)$$

One motivating factor for incorporating MLP into our work is its capability to learn complex patterns and relationships in data. Being a fully connected architecture, consisting of multiple layers and a large number of parameters, MLP is a suitable choice for tasks that involve complex data representations with potential non-linear relationships.

#### E. Model Evaluation

In evaluating the performance of a classification model, a range of metrics and techniques are utilized to assess its effectiveness in accurately predicting class labels.

One essential metric is the accuracy metric used to evaluate the performance of a classification model. It measures the overall correctness of the model's predictions by calculating the ratio of correctly classified instances (TP and TN) to the total number of instances (TP, TN, FP, and FN). The accuracy score is computed using the formula:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (4)$$

Additionally, we assess the model's performance using precision and recall metrics. Precision measures the model's ability to correctly identify true positives among the predicted positive instances. It is calculated by dividing the number of true positives (TP) by the sum of true positives and false positives (FP):

$$Precision = \frac{TP}{TP + FP}. \quad (5)$$

On the other hand, recall, also known as sensitivity or true positive rate, evaluates the model's capability to identify positive instances correctly. It is calculated by dividing the number

<sup>1</sup><https://github.com/mohataher/arabic-stop-words>

of true positives (TP) by the sum of true positives and false negatives (FN):

$$Recall = \frac{TP}{TP + FN}. \quad (6)$$

To provide a balanced assessment of the model's performance, particularly in scenarios with imbalanced class distributions, we employ the F1 score metric. The F1 score combines precision and recall into a single metric, taking into account both the model's ability to correctly identify positive instances and its capability to avoid false positives. It is calculated using the formula:

$$F1 = 2 \times \frac{Precision \times Recall}{Precision + Recall}. \quad (7)$$

By utilizing these evaluation metrics, including the confusion matrix, accuracy, precision, recall, and F1 score, we can comprehensively evaluate the performance and effectiveness of our classification model in accurately predicting class labels within the given dataset.

#### IV. RESULTS AND DISCUSSIONS

In this section, we present a comprehensive evaluation of our proposed approach. We begin by outlining the research questions that we aim to answer, followed by the experimental setup, and we conclude with the results and the findings.

TABLE V. MODEL PERFORMANCE

Split#	ACC	Precision	Recall	F1
MLP				
1	89	87	92	89
2	88	88	89	89
3	89	88	90	89
4	89	88	90	89
5	91	90	92	91
AVG	89	88	90	89
SVM				
1	91	87	94	91
2	93	92	94	93
3	91.7	90	95	92
4	91.8	91	93	92
5	92	89.7	94.6	92
AVG	92	90	94	92

##### RQ1. How accurately can we classify cyberbullying?

*Experimental Setup* Our machine-learning code was implemented using Python 3.7, and we utilized the Scikit-Learn library [26] for building the classification model. The experiments were conducted on a Dell Inspiron 5406 laptop equipped with a 2.8 GHz 4-Core Intel Core i7 processor and 16 GB of memory.

To ensure fairness in training the model on different samples, specifically the classes of 0's and 1's, we examined the entropy of the datasets before initiating the training process. The uniformity, as a measure of data entropy, was evaluated based on the Hamming weights of the dataset's responses. The uniformity score ( $U_s$ ) was calculated using the following formula:

$$U_s = \frac{1}{C} \sum_{i=1}^C r_i \times 100, \quad (8)$$

where  $r_i$  represents the class bit generated when the input dimensions are from the  $s$ -th tweet set or the  $s$ -th sample, and

$C$  denotes the total number of tweets in a file. By examining the uniformity scores, we ensured that both classes had a balanced representation within the training data, minimizing the potential bias towards any particular class. This step was crucial to maintain fairness and prevent the model from being biased towards the majority class during the training phase.

To address our research question, we divided the dataset into an 80% training set and a 20% testing set. We applied two classification models, namely Support Vector Machine (SVM) and Multi-Layer Perceptron (MLP) [26]. In the MLP classifier, we designed the architecture with 192 neurons in the input layer and 4 hidden layers. To optimize the model's performance, we utilized the Adam optimizer and employed the logistic activation function. These choices were made to enhance the model's ability to capture complex patterns and relationships in the data during the training process

*Results and Findings* Table V displays the model performance on five different 80/20 splits of the dataset, as well as the average performance on classifying the testing dataset, which constitutes 20% of the entire dataset. The table provides a comprehensive overview of the performance metrics for each split, allowing for a comparison of the models' consistency across different subsets of the data. The inclusion of multiple splits helps to mitigate the potential impact of dataset variability and provides a more robust evaluation of the models' performance. By averaging the results across these splits, we obtain a more reliable estimation of the models' general performance on unseen data. Overall, the results from Table V demonstrate that SVM outperformed MLP in the classification task, achieving better accuracy, F1 score, precision, and recall. These findings indicate that SVM was more effective in accurately predicting class labels in the testing dataset, making it a favorable choice for the classification task at hand.

##### RQ2. How does ArCyb compare to the state of the art?

*Experimental Setup* Arabic language sentiment analysis is a challenging task that requires significant effort to achieve high prediction rates due to the complexity of the language and the need for a well-labeled dataset. To provide a comprehensive evaluation of our model, we plan to compare it against state-of-the-art models developed. Specifically, we will evaluate our model against the models proposed by Almutiry and Fattah, Almutairi and Alhagry [19], [20], who achieved accuracies of 85% and 82%, respectively, in their cyberbullying models. To ensure a fair comparison, we will replicate their approach, including their text preprocessing and model architecture, to evaluate the effectiveness of our model in detecting cyberbullying in Arabic language texts.

*Results and Findings* Upon analyzing the work of Almutiry and Fattah [19] and Almutairi and Alhagry [20], we found that both studies have invested considerable effort in building their models and implementing preprocessing methodologies. A comparison of their approaches is presented in Table VI. We can observe that our approach outperformed all other approaches. We believe our approach performed better due to several factors, but one potential key difference lies in the stemming step during the preprocessing stage. Specifically, Almutairi and Alhagry [20] did not apply stemming to their data, whereas Almutiry and Fattah [19] employed light stemmer

and Khoja stemmer. In our approach, we utilized AraBERT [27] for stemming. The Khoja stemmer and the light stemmer are rule-based stemmers that rely on predetermined rules to remove inflectional endings from Arabic words, resulting in the base form of the word. The effectiveness and precision of these stemmers depend on the thoroughness of the rules and the complexity of the Arabic inflectional system. In contrast, AraBERT is a machine learning model trained on a large dataset of Arabic text. This enables AraBERT to perform automated and adaptable stemming by considering the context and relationships between words in both left-to-right and right-to-left directions. By understanding the surrounding words, AraBERT gains a better understanding of the meaning of the text. Through our evaluation, we aim to investigate the impact of different stemming approaches on the performance of the models.

TABLE VI. COMPARING ARCYB WITH ALMUTAIRI AND ALHAGRY [20], ALMUTIRY AND FATTAH [19]

Author	ACC	Precision	Recall	F1-score
Almutiry and Fattah [19]	90	88	92	90
Almutairi and Alhagry [20]	89	86	92	89
Our approach	92	90	94	92

TABLE VII. VALIDATING ARCYB MODEL USING AJGT DATASET

Model	Accuracy	Precision	Recall	F1
ArCyb	91	90	92	91
[28]	88.72	92	84	88.27

### RQ3. Can our ArCyb Machine-Learning approach be used on similar problems?

*Experimental Setup* For this research question, we aim to evaluate whether our approach can be applied to similar problems, such as sentiment analysis. To achieve this, we will compare the performance of our approach with an established Arabic sentiment analysis model. We will utilize the Arabic Jordanian General Tweets (AJGT) dataset obtained from Alomari et al. [28]. The AJGT dataset consists of 1800 samples, each labeled with either a positive or negative sentiment. By using the AJGT dataset, our goal is to assess and compare the predictive capabilities of our model against the state-of-the-art Arabic sentiment analysis model. This comparative analysis will allow us to evaluate the performance, accuracy, and reliability of our proposed approach. Additionally, it serves as a benchmark for determining the effectiveness of our model in capturing and understanding the sentiments expressed in Arabic language text. We will apply the same preprocessing methods to the AJGT dataset as described in III. Splitting the dataset into 80% for training and 20% for testing.

*Results and Findings* The performance evaluation results presented in Table VII demonstrate that our MLP model surpassed the performance of the original model proposed in [28], achieving an accuracy of 91% compared to the original model's accuracy of 88%. This outcome suggests that our approach has the potential to outperform existing models in various Arabic classification problems, extending beyond the domain of cyberbullying. By demonstrating superior performance in this comparative analysis, our model showcases its effectiveness in accurately classifying Arabic text across different contexts and applications. These findings highlight

the versatility and generalizability of our approach, making it a promising solution for a wide range of classification tasks in the Arabic language.

### RQ4. What insights can ArCyb tell us about Cyberbullying on Twitter?

*Experimental Setup* To validate the effectiveness and applicability of our model in classifying unlabelled data, we will utilize the same set of 16 keywords that were used in the original model. We will collect raw unlabelled data from the period of 2013 to 2022, consisting of 1000 samples for each keyword. This extensive dataset will enable us to analyze and quantify the prevalence and occurrences of bullying events over the past ten years. By applying our model to this unlabelled data, we aim to gain valuable insights into the bullying rate and trends, providing a deeper understanding of the dynamics and impact of bullying during the studied period.

*Results and Findings* Fig. 3 display the bullying rates in the last decade, which show an obvious increase in the bullying rate by 35.9% between the years 2013-2022.

We have further investigated the data to identify the most frequent words that occurs in the bullying samples. These words are not necessary bullying words but they were used in the same tweet that is classified as bullying based on it's context. The most frequent words are displayed in Fig. 2. Here are a few noteworthy examples from our findings:

In 2013, tweets related to Alittihad FC revealed dissatisfaction among fans regarding the team's performance and the management under the leadership of Mohammad Alfayez. Bullying tweets targeting the team's performance, players, and management decisions prominently featured the name "Mohammad Alfayez".

In 2014, there was a significant social media backlash against the prank show "Ramez the Sea Shark" hosted by Ramez Galal. Many viewers found the show unfunny and insulting to the guests, leading to the creation of memes that ridiculed the show. The show's name, "Ramez" and "sea", were frequently mentioned in bullying tweets.

The emergence of the Houthi movement in 2015 sparked a surge in hateful tweets and cyberbullying directed towards the group. Social media users expressed offensive and derogatory opinions, leading to an ongoing trend of bullying against the Houthi movement throughout the years, including 2022.

In 2019, Shawarmer, a popular fast food chain, posted a tweet that was deemed disrespectful to Alhilar FC, a prominent football club. This incident resulted in a hashtag campaign bullying Shawarmer's products as a form of retaliation.

In 2022, the Africa Cup of Nations (AFCON) generated significant attention on social media, particularly matches involving Algeria, Cameroon, Egypt, and Senegal. During the final match between Egypt and Senegal, an incident occurred where Senegalese fans pointed lasers at Egyptian player Mohamed Salah during penalty kicks. This incident sparked outrage on the internet and became a trending topic, leading to an influx of bullying-related hashtags.

Throughout the years 2013-2022, the top Saudi Arabian football clubs including Ittihad, Alhilar, Alahli, and Alnasser,

Fig. 2. Words mentioned in bullying samples.

Fig. 3. Cyberbullying rate in the last decade.

were consistently mentioned in the bullying samples. Additionally, the names of famous football players were frequently targeted, highlighting football as a hot topic for cyberbullying.

These examples highlight the diversity of bullying topics and events observed in the collected tweets from 2013 to 2022, providing valuable insights into the dynamics of online bullying and its association with various social, cultural, and sporting phenomena.

## V. CONCLUSION

In this research, we undertake the task of building our dataset from scratch. We start by collecting raw data, obtaining a total of 4,140 samples. To ensure a focused collection, we specify 16 bullying terminologies and use them as keywords to pull relevant data from Twitter via the Twitter API. Subsequently, we form a group consisting of three cybersecurity specialists who manually label the samples to ensure accurate annotation. After the dataset collection and labeling process, we proceed to the preprocessing phase. This involves several steps, including data cleaning, normalization, stemming, and vectorization. These steps are necessary to prepare the data for classification. Using both MLP and SVM classifiers, we conduct classification experiments on the preprocessed dataset.

The results demonstrate an accuracy of 89% for MLP and 92% for SVM. These promising performance metrics validate the effectiveness of our approach in classifying cyberbullying instances. Additionally, we seek to assess the accuracy and predictive capabilities of our model by gathering a large dataset consisting of 160,000 raw tweets spanning the years 2013 to 2022. Through analysis, we identify the most frequent words associated with bullying, which reflect specific events that occur during different periods of time. Notably, our findings indicate a significant increase in the bullying rate, with an annual growth rate of 35.9%. These findings highlight the effectiveness and relevance of our model in addressing the challenges of cyberbullying detection and classification. Furthermore, our analysis of the collected tweets provides valuable insights into the evolving landscape of online bullying, indicating the need for continued efforts to combat this issue.

## ACKNOWLEDGMENTS

This work was funded by the University of Jeddah, Jeddah, Saudi Arabia, under grant No. (UJ-21-IMT-10). The authors, therefore, acknowledge with thanks the University of Jeddah technical and financial support. The authors would like to thank

Suhail A. Segnawi, and Aws H. Aljahdli for their help in maintaining the dataset.

# Development of a Touchless Control System for a Clinical Robot with Multimodal User Interface

Julio Alegre Luna, Anthony Vasquez Rivera, Alejandra Loayza Mendoza,  
Jesús Talavera S., Andres Montoya A.  
Universidad Nacional de San Agustín de Arequipa, Perú

**Abstract**—This article introduces the development of a multimodal user interface for touchless control of a clinical robot. This system seamlessly integrates distinct control modalities: voice commands, an accelerometer-embedded gauntlet, and a virtual reality (VR) headset to display real-time robot video and system alerts. By synergizing these control approaches, a more versatile and intuitive means of commanding the robot has been established. This assertion finds support through comprehensive assessments conducted with both seasoned professionals and novices in the domain of clinical robotics, all within a controlled experimental setting. The diverse array of test results unequivocally demonstrate the system's efficacy. They substantiate the system's ability to proficiently govern a robotic arm in the clinical environment. The user interface's usability is measured at an impressive 90.2 on the system usability scale, affirming its suitability for robotic control. Notably, the interface not only offers comfort but also intuitiveness for operators of varying levels of expertise.

**Keywords**—Multimodal user interface; human-robot interaction; clinical robot

## I. INTRODUCTION

Robotic systems are progressively assuming greater significance in the development of conventional human activities, especially within the realm of healthcare, owing to their array of merits. These encompass heightened efficiency and precision, risk mitigation, and enhanced patient comfort [1]. These systems find versatile utility across a spectrum of clinical applications, spanning from surgical procedures and rehabilitation to technologies tailored for the aid of the elderly or disabled [2], [1]. Yet, the management of these systems within a clinical milieu poses intricate challenges. Conventional interfaces like buttons and joysticks, while conventionally employed, engender potential infection hazards and present difficulties for patients possessing restricted mobility or dexterity [3].

In response to these challenges, researchers have embarked upon the exploration of novel paradigms for robotic control that are imbued with heightened intuition, naturalness, and touchlessness [4], [5]. An auspicious avenue in this endeavor is the adoption of multimodal user interfaces, which amalgamate an assortment of control methodologies, thus engendering a more adaptable system [6]. Multimodal user interfaces empower users to seamlessly transition between diverse control modes contingent upon their proclivities or the specific task at hand [6]. As an illustration, a user might seamlessly oscillate between voice commands to oversee the robot's locomotion, while seamlessly transitioning to gesture-based control for tasks demanding precision in manipulation [7].

This article introduces a multimodal user interface developed for touchless control of a clinical robot. This system seamlessly integrates two distinct control methodologies: voice commands, and an accelerometer-embedded gauntlet. The voice command system empowers users to steer the robot through spoken directives, while the accelerometer-equipped gauntlet detects user-initiated gestures. Finally, the virtual reality headset allows the operator to visualize in real time the video captured by the webcam, and also allows the system to display on screen different alerts triggered by the two methods mentioned above. This system boasts a spectrum of prospective applications within varied clinical contexts. For instance, it could find utility in surgical settings, enabling surgeons to orchestrate robot movement while maintaining a sterile environment. Similarly, within rehabilitation realms, patients might exercise dominion over robotic devices using their voice or gestures. Furthermore, the system's utility is magnified for individuals with restricted mobility or dexterity, as it allows them to exert control over the robot devoid of physical interaction. To the best of current knowledge, this represents the maiden multimodal user interface tailored for touchless control of a clinical robot, concomitantly amalgamating voice commands, accelerometer-equipped gauntlet, and a VR headset that displays the developed user interface. The system's architectural blueprint prioritizes user-friendliness, safety, and reliability, buttressed by a series of meticulously devised experiments aimed at scrutinizing its efficacy in robot manipulation.

The subsequent sections of this article are structured as follows: In Section II, Related Works, prior research concerning voice-controlled systems, gesture recognition systems, and multimodal user interfaces for robot and robotic arm control is comprehensively surveyed. Section III, Experimental Development, an exhaustive account is provided regarding all employed electronic components, the clinical robotic platform, the implementation of the voice control system, the accelerometer-embedded gauntlet, and the associated software architecture conceived for this integrated system. The subsequent segment, Section IV, Results and Discussions, unveils the empirical outcomes derived from the conducted experiments, accompanied by the ensuing discussion arising from their interpretation. Ultimately, in Section V, this document culminates as conclusions are drawn and prospective avenues of research are deliberated upon.

## II. RELATED WORKS

### A. Voice-Control Systems

Sagar's article [8] reviewed the current status of speech recognition systems. In addition, the potential industrial applications of speech recognition technology, such as public safety solutions, were discussed. Furthermore, the article delves into the future scope of voice recognition, with the potential for artificial intelligence to reshape how we interact with devices [9]. In another study [10], a voice recognition control system for a robot is delineated, designed to operate effectively in noisy environments. This system employs generalized sidelobe canceller techniques resilient to outliers, noise suppression in the feature space, and reverberation mitigation. The article also delves into obstacle detection, local map design, as well as target search and avoidance behaviors using fuzzy decision-making. The system's efficacy is evaluated on a communication robot deployed within a real noisy environment. The article also contemplates the integration of robust voice recognition and navigation systems for autonomous navigation within unfamiliar surroundings.

In another study [11], a system is proposed that provides a mobile robot with the ability to separate simultaneous sound sources; an array of microphones is used along with a dedicated real-time implementation of geometric source separation and a post-filter that provides us with further reduction of interference from other sources. The work of [12] discusses the creation of target-seeking and avoidance behaviors employing fuzzy decision-making. The author in [13] introduces a method for selecting an appropriate behavior from numerous primitive behaviors using a fuzzy decision-maker. author in [14] describes an obstacle detection method and local map design utilizing an array of ultrasonic sensors. Finally, [15] introduces a novel approach to voice recognition in noisy environments, grounded in multi-condition training techniques, maximum likelihood linear regression, and missing feature theory.

### B. Gesture Recognition Systems

The article [16] introduces a human-computer interaction (HCI) model based on somatosensory interaction for robotic arm manipulation. The model utilizes a 3D SSD architecture for gesture and arm movement localization and identification, coupled with the Dynamic Time Warping (DTW) template matching algorithm for dynamic gesture recognition. Interactive scenarios and modes are designed for experimentation and implementation, with virtual experimental results demonstrating the method's efficacy. In [17], a real-time hand gesture recognition system is presented for controlling mobile robots using vision sensors. The system employs image processing techniques to extract the center of mass and features of a red glove worn by the user. These features are then used to control the robot's movements. The design of the mobile robot is uncomplicated and tailored for the system, consisting of three layers with a 4 cm separation to accommodate circuit placement. The system employs a motor control circuit and a PIC18F452 microcontroller control circuit. Additionally, the system incorporates XBee wireless transmitter and receiver modules for data transmission. The system employs color filtering to extract the red glove's shape and spot size filtering to eliminate objects below a certain size [18].

The article [19] presents a gesture recognition system for interacting with computers in dynamic environments. The system employs image processing techniques for hand gesture detection, segmentation, tracking, and recognition, transforming them into meaningful commands. The proposed interface finds applicability across diverse domains like image navigation and gaming. Real-world scenario testing exhibited effective performance in low-noise environments and balanced lighting conditions. The designed gesture vocabulary can be expanded to control different applications, enhancing adaptability in human-computer interaction. This work is aligned with research in the field of human-computer interaction and gesture recognition. The article [20] pertains to the realm of human-robot interaction, focusing on real-time hand gesture recognition to enhance human-robot interaction within dynamic environments. Enhanced classifiers are employed for hand detection and static gesture recognition, while a Bayesian classifier is utilized for dynamic gesture recognition. Additionally, the system incorporates contextual information, such as human face detection and tracking, to enhance robustness and speed. Relevant works utilizing contextual information to improve the accuracy and speed of gesture recognition systems are also referenced. The proposed system's validation is conducted on actual video sequences, achieving a recognition rate of 70% for static gestures and 75% for dynamic gestures, operating at varying speeds of 5-10 frames per second.

### C. Multimodal User Interfaces

The document [21] presents work related to human-robot collaboration (HRC) in manufacturing, specifically in assembly tasks. The challenges and limitations of existing HRC systems are discussed, including issues such as lack of adaptability and flexibility in task programming, along with the need to ensure human safety in the working environment. The article proposes a solution based on the utilization of function blocks and intuitive multimodal control to enhance flexibility and adaptability in complex assembly tasks. Concepts of multimodal control, function blocks, and their application in human-robot collaboration within manufacturing are thoroughly examined. Conversely, the article [22] delves into a usability study of three interfaces designed to present search engine results on the Internet. The study compared a text-only interface with two others that combined text, visual metaphors, and voice messages. Results indicated that the multimodal interfaces were more usable than the text-only interface. In a third work, Lunghi's article [23] details the design and software engineering process behind the development of a multimodal Human-Robot Interface (HRI) for intervention with a cooperative team of robots. The operator gains the capability to enter the control loop between the HRI and the robot, customizing control commands in accordance with the operation.

### D. Robots in the Clinical Environment

Poirier's paper [24] presents the design and preliminary evaluation of a voice command system prototype for the control of assistive robotic arms' movements; the prototype of the voice command interface developed is first presented, followed by two experiments with five able-bodied subjects in order to assess the system's performance and guide future development. In the work of Morgan et al. [25], a comprehensive literature review is presented, focusing on the utilization

of robots within the realm of healthcare. The study identifies ten primary roles that robots can undertake in clinical settings, encompassing surgery, rehabilitation and mobility, radiotherapy, social assistance, telepresence, pharmacy, disinfection, delivery and transportation, image intervention, and assistance. Furthermore, the article underscores robots' potential to adapt to the dynamic demands of healthcare, including those that arise during pandemics.

In Peter's study [26], a novel multimodal human-machine interface system is developed using combinations of electrooculography (EOG), electroencephalography (EEG), and electromyogram (EMG) to generate numerous control instructions; the results indicate that the number of system control instructions is significantly greater than achievable with any individual mode. In other paper [27], an interface centered on the deployment of the Leap Motion (LM) controller is examined. This interface facilitates the real-time tracking of a surgeon's hand position and orientation, capturing nuanced finger gestures and movements, which are subsequently relayed to a computer. Subsequently, a surgical robotic arm is manipulated using data gleaned from the LM controller, data that is systematically classified through programming. Beyond the capabilities attributed to the LM controller, attributes like its cost-effectiveness, acceptable precision, and high-speed data processing have rendered it a feasible and efficient tool for application.

### III. METHODOLOGY

The proposed system enables the user to control a contactless robotic arm through a multimodal user interface. Two control methods are integrated: voice commands, and hand gestures. The voice command system empowers users to steer the robot through spoken directives, while the accelerometer-embedded gauntlet detects user-initiated gestures. A VR headset that displays the developed user interface. Fig. 1 illustrates the block diagram of the proposed system, which is subsequently elaborated upon in each stage.

#### A. Hardware Components

The hardware components utilized in this study encompass a Raspberry Pi, an Arduino Nano with WiFi module, a microphone, an accelerometer-embedded gauntlet, and a webcam. The Raspberry Pi 4 serves as the central processing unit of the system. The Arduino is employed to manage the motor drivers of the robotic arm. The microphone, along with its associated circuitry, is employed for voice command recognition and transmission to the Raspberry Pi. The accelerometer-embedded gauntlet captures hand gestures executed by the user. Lastly, the webcam connected to the Raspberry Pi detects the user's facial features.

1) *Microphone Circuit:* The selected transducer type is a microphone, which is connected to an amplification stage (MAX4455 amplifier) to condition the signal to the desired voltage level, ranging between 0 and 5V. The microphone captures sound waves and converts them into an electrical signal, which is then transmitted to the Raspberry Pi microprocessor. Positioned between the amplification stage and the microprocessor is an analog-to-digital conversion stage (ADS1115 converter). This conversion stage is crucial as it

Fig. 1. Block diagram of the complete system.

enables the collection of analog signals and their subsequent processing in a digital-origin microprocessor.

In Fig. 2, the two pins of the microphone are connected, one to the amplification stage and the other to GND. The amplifier is configured in a non-inverting setup. The amplifier's output is connected to pin 1 of the ADC. Pin 7 of the ADC is connected to GPIO9 on the Raspberry Pi, serving as the data transmission pin. Lastly, pin 8 is connected to GPIO10 on the Raspberry Pi, serving as the clock signal pin.

2) *Glove Circuit with Accelerometer:* Accelerometers are devices that measure acceleration force in units of gravity (g) and can measure in one, two, or three planes (X, Y, and Z). The chosen module for this stage is the MPU-6050, which integrates a MEMS accelerometer and a MEMS gyroscope on a single chip. This module is installed in a glove worn by the operator of the robotic arm, capturing hand movements as well as any rotations they perform.

In Fig. 3, the GND pin of the MPU-6050 module is connected to the circuit's ground, while the VDD pin is linked to the voltage output of the Raspberry Pi 4. The SDA pin transmits accelerometer module data to the Raspberry Pi and is connected to GPIO3. The SCL pin of the MPU-6050 module transfers the clock signal to the module and is linked to GPIO5.

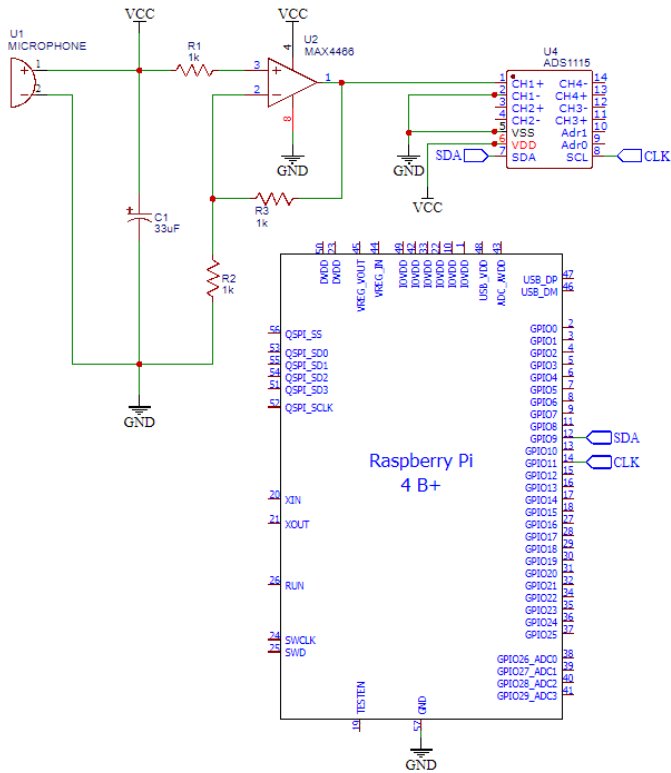

Fig. 2. Connection circuit between the microphone and the Raspberry Pi microprocessor.

Fig. 4. Connection circuit between the camera and the Raspberry Pi microprocessor.

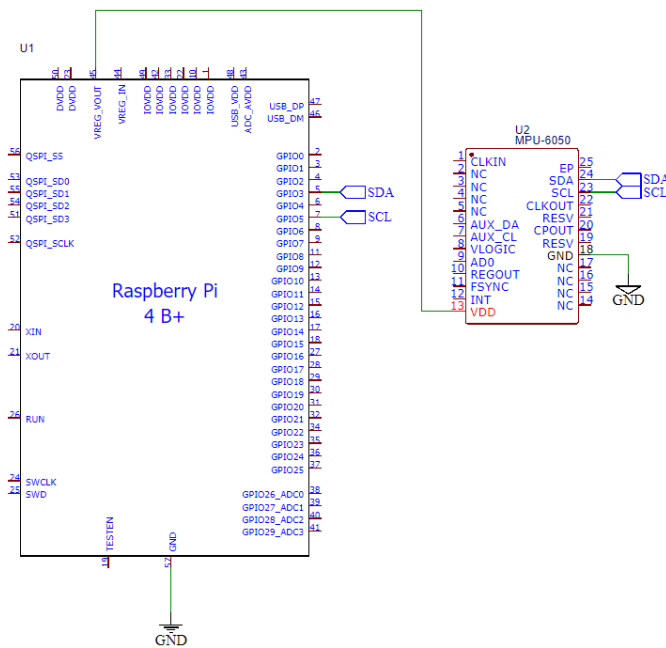

Fig. 3. Connection circuit between the accelerometer of the glove and the Raspberry Pi microprocessor.

3) *Webcam Circuit:* The operation of this stage is straightforward. A webcam is used to transmit video of the robot, which will serve as feedback to the multimodal system. In Fig. 4, the Logitech C922 camera is connected to the Raspberry Pi 4 via its USB port.

4) *Wireless Communication:* In this stage, there are two components. On one side, there's the Raspberry Pi 4, which comes equipped with integrated Wi-Fi. This Wi-Fi functionality is utilized to create a server, enabling the robotic arm to connect to it as a client. As for the robotic arm segment, an Arduino Uno is employed for control. However, since the Arduino Uno doesn't have a built-in Wi-Fi module, an external Wi-Fi module, specifically the ESP8266, is utilized for this purpose.

Fig. 5. Wireless communication connection circuit.

In Fig. 5, the Raspberry Pi 4, Arduino, and the ESP8266 module share common VCC and GND connections. The

Arduino and ESP8266 are linked through the TX and RX transmission pins.

5) *Connection of the Robotic arm:* The testing robotic arm has 3 degrees of freedom (3-DOF), which is why 3 stepper motors and 3 drivers are employed to control its movements. These components are connected to the Arduino to issue commands for their respective functions. The A4988 drivers are chosen due to their high reliability in tasks of this nature.

Fig. 6. Robotic arm connection circuit.

In Fig. 6, the Arduino and the motor drivers share the VCC and GND power supply. From the motor drivers, two pins are used to connect to the Arduino: the STEP and DIR pins. These pins determine the number of steps and the direction of rotation, respectively. The pins of the first driver are connected to Arduino pins 12 and 13, the pins of the next driver are connected to pins 10 and 11, and finally, the pins of the third driver are connected to pins 8 and 9 of the Arduino. Each driver is linked to a 4-wire stepper motor, with the 4 wires connected to A+, A-, B+, and B- pins.

**B. Software Components**

The system was developed using the Python programming language due to its extensive library support and versatility for programming innovative systems. Python was utilized to integrate the various software components of the system and to control the robot based on user inputs. Additionally, several software components were employed to make the system function effectively. On the other hand, the Arduino was programmed using its own platform and libraries for motor drivers. The following are the most significant details for this purpose.

1) *Voice Interaction:* For voice recognition, Google Speech-to-Text was employed to transcribe the voice commands issued by the user. It was implemented using the Google Cloud API and integrated into the Python code executed on the Raspberry Pi 4. Voice command language was preferred as the input to the system because it allows a more intuitive interaction to the human’s natural being [28]. The commands used and recognized by the system are displayed in Table I. An indicator provides visual information to the operator of the action being executed. During active navigation mode, the

indicator is illuminated according to the Table I. This lets the operator know which command is currently being executed, as well as whether the spoken command was successfully acknowledged.

TABLE I. DESCRIPTION OF INTEGRATED VOICE CONTROL COMMANDS

Voice Command	Indicator	Description
Start	● ●	Activates glove gesture detection
Translation	○ ●	Initiates translational navigation mode
Rotation	● ○	Initiates rotational navigation mode
Move to	● ●	Opens the options assignment display
Cancel	● ○	Closes the options assignment display
Stop	● ●	Deactivates the selected navigation mode
End	● ●	Concludes the current interaction task

2) *Glove Gesture Interaction:* Control through the glove is achieved by integrating an accelerometer which captures the degrees of inclination of the hand in its different axes (X, Y and Z). The multimodal system allows the operator to execute different commands to the robotic arm thanks to the integration of voice commands, some examples are the function of pausing the sending of accelerometer data to the Raspberry Pi, this allows the operator to rest momentarily or move the hand without worrying that the robot will recreate this movement; Other examples are the rotation and translation commands that allow the robotic arm to move according to the indication executed and the hand movement performed.

3) *User Interface Display:* The user interface collects the webcam video sent by the Raspberry Pi 4 from the server, this video is processed and the spoken command indicator is added so that the operator can realize that it worked correctly; to process the video, the OpenCv library belonging to the Python programming language was used. OpenCV is a powerful computer vision library that was used to detect hand gestures performed by the user. In Fig. 7, you can see an image of the processed video.

Fig. 7. User interface develops visualized in the virtual reality headset.

**C. Testing**

To assess the performance of the proposed multimodal system, a series of experiments were conducted involving 12 participants. Each participant was assigned a set of tasks to perform with the robot, including moving the robotic arm to a

desired position, touching specific elements in the environment with the end effector, among others. Fig. 8 depicts the testing scenario used to evaluate the system's effectiveness.

Fig. 8. Testing environment for the robotic arm.

Participants were instructed to use each of the three control methods (voice commands, glove gestures, and computer vision) individually and in combination to control the robot. The sequence of method usage was randomized to mitigate order effects. The system's performance was assessed based on task completion time, the accuracy of robot movements, and participants' subjective feedback on the ease of interface use.

#### D. Data Analysis

Task execution times and robot movement accuracy were recorded for each participant and analyzed using descriptive statistics. Subjective opinions were collected using the System Usability Scale (SUS) method and analyzed through qualitative approaches. SUS provides a "quick and dirty", reliable tool for measuring the usability, it consists of a 10 item questionnaire with five response options for respondents; from Strongly agree to Strongly disagree [29]. The multimodal user interface was implemented and tested on a clinical robot within a simulated laboratory setting. System performance was assessed in terms of accuracy, speed, and user-friendliness.

### IV. RESULTS AND DISCUSSIONS

The multimodal user interface was implemented and tested on a test clinical robot in a laboratory environment. The system's performance was evaluated in terms of accuracy, speed, and user-friendliness. The tests were carried out with a prototype of a robotic arm manufactured with three stepper

motors and an Arduino Uno microcontroller. Fig. 9 shows the system server made up of a Raspberry Pi 4, glove with accelerometer, electronic components and the Virtual Reality headset.

Fig. 9. Electronic components of the developed system.

#### A. Voice Command Control

Voice control proved effective in maneuvering the robot and executing various commands. The accuracy of the voice recognition system was evaluated using a speech recognition rate metric, which measures the percentage of correctly recognized commands out of the total number of given commands. The speech recognition rate was 92%, indicating a high level of accuracy in recognizing voice commands.

#### B. Glove Control with Accelerometer

The accelerometer-equipped glove proved to be effective in capturing hand gestures and providing a natural way to control the robot. Fig. 10, 11, 12 displays the graph obtained by comparing accelerometer values along its 3 axes (X, Y, and Z) with the angles of rotation of the robot arm's corresponding 3 axes.

Fig. 10, 11, and 12 depict each of the three accelerometer axes positioned within the operator's gauntlet. The operator executed hand movements for a duration of one minute, yielding a total of 500 samples collected per accelerometer axis. These measurements correspond to the angular velocity ( $^{\circ}/s$ ) of motion recorded during the trials. Fig. 10 showcases the data acquired from the X-axis accelerometers, encompassing both the gauntlet and the robotic arm, while Y-axis data is presented in Fig. 11, and Z-axis data is delineated in Fig. 12. On average, a variation of 3.87% was observed, attributed to the motor configurations driven by the actuators.

#### C. Multimodal Control

The three control methods were amalgamated to forge a comprehensive multimodal user interface. Users were empowered to seamlessly switch between diverse control modes, tailoring their choice based on personal preferences and the specific task at hand. Empirical evidence substantiated the

Fig. 10. Plot of accelerometer measurements and rotation of the robotic arm axes in the X-axis.

Fig. 12. Plot of accelerometer measurements and rotation of the robotic arm axes in the Z-axis.

Fig. 11. Plot of accelerometer measurements and rotation of the robotic arm axes in the Y-axis.

Fig. 13. Graph of results obtained from SUS measurement of the system.

superiority of the multimodal interface over singular control approaches, demonstrating that users adeptly transitioned between voice commands, hand gestures, and artificial vision control. This versatility imbued human-robot interaction with enhanced flexibility and intuitive fluidity. Moreover, the amalgamation of distinct modalities endowed a heightened precision of control, particularly advantageous for tasks necessitating meticulous accuracy, such as surgical procedures. Refer to Fig. 13 for a graphical representation of the values obtained through the evaluation of the user interface and the proposed system, utilizing the System Usability Scale method (SUS), a widely adopted metric for gauging the effectiveness of an interface for a given task. The color background of this graph shows three different scoring areas: light red for poor usability ( $SUS_{score} < 50$ ), light yellow for good usability ( $85 > SUS_{score} \geq 50$ ), and light green for excellent usability ( $SUS_{score} \geq 85$ ).

The obtained average value for the proposed interface was

$SUS_{score} = 90.2$  points, falling within the range indicative of commendable interfaces. These findings strongly indicate that the suggested user interface is exceptionally well-suited for orchestrating robotic arms within clinical scenarios. On the whole, the outcomes of this study strongly propose that the developed multimodal user interface holds substantial potential for enhancing the efficiency and efficacy of clinical robots within healthcare settings. The capability to govern the robot through voice commands, hand gestures, and artificial vision confers a heightened level of flexibility and intuitive interaction with the robotic system. This, in turn, stands to enhance patient outcomes and foster a higher adoption rate of the technology amongst healthcare professionals.

## V. CONCLUSIONS

In summary, a multimodal user interface has been introduced for touchless control of a clinical robot, seamlessly integrating voice commands, an accelerometer-equipped gauntlet, and display of the user interface on the virtual reality headset in real time. The outcomes derived from the conducted trials robustly suggest that the utilization of a multimodal interface holds the potential to enhance the efficiency and efficacy of clinical robots within healthcare environments, as

evidenced by the notable 90.2 point outcome on the SUS scale. The capacity to manipulate a robotic arm through the fusion of voice commands, hand gestures, and artificial vision engenders a more adaptable and intuitive means of interacting with the arm, a facet that has the potential to enhance patient outcomes and bolster the technology's embrace amongst healthcare professionals. Future endeavors will be concentrated on refining the interface and appraising its effectiveness within clinical environments, involving real patients. Additionally, the incorporation of other modalities, such as haptic feedback and augmented reality, could be explored to further heighten user experience and system performance.

School of Computer Science, Fudan University, Shanghai 200433, China<sup>5</sup>

**Abstract**—With the rapid development of virtual reality (VR) technology, a large number of omnidirectional images (OIs) with uncertain quality are flooding into the internet. As a result, Blind Omnidirectional Image Quality Assessment (BOIQA) has become increasingly urgent. The existing solutions mainly focus on manually or automatically extracting high-level features from OIs, which overlook the important guiding role of human visual perception in this immersive experience. To address this issue, a dual-level network based on human visual perception is developed in this paper for BOIQA. Firstly, a human attention branch is proposed, in which the transformer-based model can efficiently represent attentional features of the human eye within a multi-distance perception image pyramid of viewport. Then, inspired by the hierarchical perception of human visual system, a multi-scale perception branch is designed, in which hierarchical features of six orientational viewports are considered and obtained by a residual network in parallel. Additionally, the correlation features among viewports are investigated to assist the multi-viewport feature fusion, in which the feature maps extracted from different viewports are further measured for their similarity and correlation by the attention-based module. Finally, the output values from both branches are regressed by fully connected layer to derive the final predicted quality score. Comprehensive experiments on two public datasets demonstrate the significant superiority of the proposed method.

**Keywords**—Omnidirectional image quality assessment; dual-level network; human visual perception; human attention; multi-scale

## I. INTRODUCTION

Virtual reality (VR), as the most popular immersive multimedia, can offer a unique 360-degree visual experience which sets it apart from traditional two-dimensional (2D) formats. Users can explore omnidirectional images (OIs) by wearing VR devices such as head-mounted displays (HMDs). However, the qualities of OIs are degraded during the processes such as stitching, projecting, encoding, and transmitting, which further influence the user experiences, even cause motion sickness. Therefore, the quality evaluation of OIs plays a significant role in guiding OI processing and ensuring a high quality of experience.

In the past few years, many objective OIQA methods have been proposed, including full-reference (FR) type and blind/no-reference (B/NR) type. For FR type, the peak-signal-to-noise ratio (PSNR) and the structural similarity index measure (SSIM) [1] are respectively adopted for OIQA [2, 3, 4, 5, 6]. However, obtaining the undistorted OIs is challenging due to the complexity of image processing, making FR-OIQA

challenging in practical applications. Therefore, it is crucial to develop blind/no-reference omnidirectional image quality assessment (BOIQA/NR-OIQA) methods that can evaluate the quality of OIs without reference images. Regarding the NR-OIQA type, many approaches [7, 8, 9, 10] commonly involve filtering to analyze the frequency domain information or natural scene statistics (NSS) to find statistical regularities in OIs. However, the manual feature designing is challenging [11], which limits the robustness of those methods. To relieve this issue, many data-driven approaches are proposed, which are able to learn inherent relationships between the predicted values and the ground-truth labels. These methods typically consist of two steps: feature extraction and quality regression. Specifically, Convolutional Neural Networks (CNNs) are firstly used to extract high-level features from OIs. Then, fully connected layers are employed for regression to obtain the predicted quality scores. However, most data-driven solutions are directly transferred from 2D IQA methods, in which the features of OIs are extracted in EquiRectangular Projection (ERP) format. Moreover, those approaches do not consider the human visual perception during OIQA. Although several approaches [12, 13, 14, 15] try to extract the viewport (VP) images from OIs to replace the ERP as the inputs, the human visual perception is still under-explored.

Generally, people tend to pay more attention to some contents of interest rather than the entire VP with HMD. This means that the regions of interest in VP are more likely to contribute to the quality rating [15]. Furthermore, the objects in nature are usually captured by the human eyes at various scales [16], which means that the human visual perception of an OI is formed through multiple views from different directions at various viewing distances.

Based on the above analysis, we can conclude that the quality of immersive media experiences is more susceptible to subjective visual perception by humans. However, recent works on OIQA primarily analyze images and overlook the active nature of human visual perception in this process. To address this gap and further to enhance the OIQA performance, this paper proposes a dual-level BOIQA network based on human visual perception. The proposed method tries to explore the human visual perception from two aspects including the human attention and the multi-scale perception. Specifically, the proposed method is a dual-level model, which is composed of three parts: human attention branch (HAB), multiscale perception branch (MPB) and quality regression (QR). For the

HAB, to emphasize the regions of interest, an improved Vision Transformer (ViT) [17] is integrated with the residual CNNs, which enables the proposed network to capture attention-based features within the VP images without disrupting the hierarchical perception. In HAB, the CNNs are responsible for obtaining high-level feature maps of each VP image, while the ViT calculates the attention weights. Furthermore, in order to explore more information within the VP region, we also introduce an image pyramid to represent different viewing distances of each VP in HAB. Regarding the MPB, we first establish a parallel structure to extract multi-scale information from each VP in cubemap projection (CMP) format. Then, to explore the content correlations between VPs at different positions in an OI, we develop a correlation feature fusion module to establish the long-range dependencies among VPs. Finally, the obtained dual-level perception features are regressed through the QR module to predict the final quality scores. Extensive experimental results have validated the effectiveness of the proposed approach. The contributions of the proposed method are listed as follows:

- We propose a BOIQA network based on the human visual perception, in which the region of interest can better be highlighted in a VP region and the multi-scale information can be obtained from low-level to high-level based on multiple views.
- We establish the multiple viewing distances image pyramid of the front VP and obtain the attention-based features from it to explore more information within the VP region. Moreover, we fuse the multi-scale features extracted from each VP in CMP and the obtained attention-based features to explore the content correlations between VPs.
- Comparisons with the state-of-the-art metrics on two public databases demonstrate the strength of our method.

## II. RELATED WORKS

Generally, OIQA methods can be classified into two categories: subjective methods and objective methods. Subjective OIQA method involves participants directly providing subjective quality scores for the OIs they view in an HMDs. However, it is time-consuming and impractical for batch applications. By contrast, objective OIQA method is more suitable for practical production applications. The objective OIQA method can be further divided into two categories: traditional OIQA metrics and deep learning-based OIQA metrics. This section will emphatically review the objective OIQA methods.

### A. Traditional OIQA Metrics

Many works have extended the traditional common used IQA metrics to OIQA. For example, the evaluation schemes based on PSNR transfer the calculation from planar format to spherical format while still inheriting the main idea of per-pixel comparison in PSNR. Moreover, the evaluation schemes based on SSIM mainly focus on the ERP format of panoramic images and analyze metrics such as sharpness, contrast, and brightness. In [18], statistical characteristics of panoramic images were obtained using the adjacent pixels correlation (APC) features and blind quality prediction of panoramic images was then performed using support vector regression (SVR).

The methods that use the ERP as the evaluation basis are mostly borrowed directly from 2D-IQA and have made corresponding improvements for panoramic images. However, they still overlook the unique media characteristics of panoramic images and the geometric distortions present in ERP. Recent works have focused on extracting natural statistical information from other representations of panoramas. Zheng et al. [19] firstly converted the panoramic image from the ERP format to a segmented spherical projection format. They then utilized a heat map as a weighting factor to perceive features in both the two-level and equatorial regions. Zhou et al. [9] achieved panoramic image quality assessment score by analyzing multi-frequency information and statistically evaluating the local and global naturalness presented in both ERP and VP formats. Jiang et al. [8] explored the color information of each VP image unit in the rotated Cubemap Projection (CMP) format through tensor decomposition and piecewise exponential fitting. The above-mentioned works achieved satisfactory performance results by designing hand-crafted features through techniques such as machine learning. However, these manual features based approaches are evidently cumbersome and not easily comprehensive, which reduces the robustness of the proposed method.

### B. Deep Learning-based OIQA Metrics

Deep learning-based OIQA approaches benefit from powerful model architectures that can capture more quality-relevant features within the images. Thanks to the guidance of large amounts of labeled data, this kind of methods often outperforms traditional methods. In [20, 21], Kim et al. proposed an adversarial learning-based human perception guider, which improves the prediction capability of deep learning models for quality scores by enhancing the human perception guider's discriminative ability for predicted scores and subjective quality score labels.

Although the aforementioned methods have achieved satisfactory results, they have not considered the differences between immersive media experience and traditional planar images perception. This restricts the feature representation capability of deep models. To address this issue, recent VP-based end-to-end models have been developed to accurately simulate the scene content that can be perceived by the human eye while viewing panoramic images at a moment. Considering the limited field of view of the human eye in head-mounted devices, Li et al. [12] firstly proposed a VP-based assessment scheme and combined it with CNNs for feature extraction. Sun et al. [13] proposed a multi-stream network that utilized the modified ResNet-34 to extract features from each VP in the rotated CMP format. Xu et al. [14] proposed a solution with local and global branches. The local branch utilized ResNet-18 to simultaneously extract internal features from multiple VP images and established connections between them using graph convolution. The global branch extracted feature information from the panoramic ERP format using the VGG [22] network.

These deep learning-based models possess powerful feature extraction capabilities and quality score fitting abilities. However, there is still significant room for improvement in terms of their consistency with the HVS. Therefore, in this paper, we draw inspiration from human visual perception and develop an end-to-end model to investigate the impact of

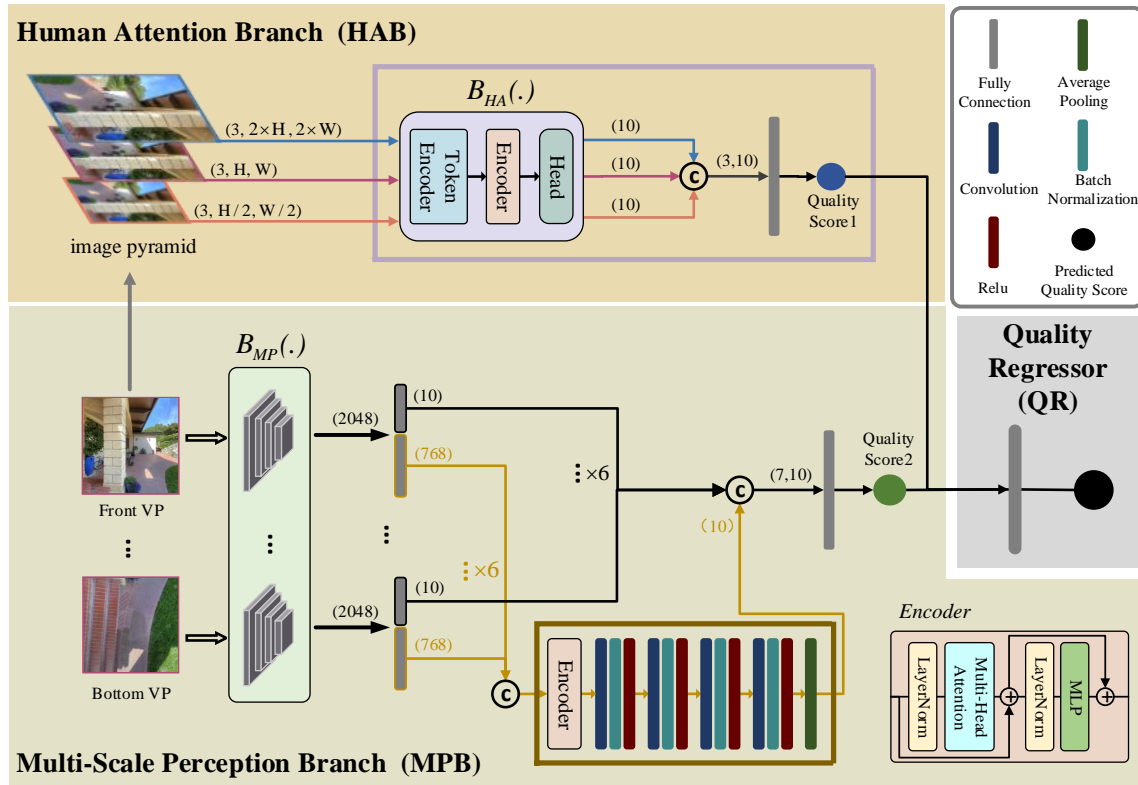

Fig. 1. The overall framework structure of our dual-level network

simulating human attention [23] and multi-scale [24] perception on panoramic quality assessment.

### III. PROPOSED METHOD

The proposed dual-level BOIQA network contains three modules, namely human attention branch (HAB), multi-scale perception branch (MPB) and quality regression (QR). The overall framework structure is illustrated in Fig. 1. The HAB focusses on extracting the high-level information from a multiple viewing distances image pyramid based on attention mechanism. The MPB aims to explore multi-scale perception features of each VP and explore the correlation information among those VPs. The QR is utilized to predict perceptual quality scores.

Fig. 2. the visualization of attention from the output features to a VP example from CVIQD database. The solid red line shows the position of the equator. (a) the simple image; (b) the learned feature maps of (a) only with ResNet-50; (c) the learned feature maps of (a) with the hybrid model of ResNet-50 and ViT.

#### A. Human Attention Network

Fig. 2 shows the visualization result of the attention weights on a VP example under different OIQA models. It is evident that the hybrid model combining CNNs and ViT pays more attention to the equatorial region and salient objects compared to a pure CNNs model. This aligns well with the attention habits of the HVS. Based on the above analysis, to obtain information that better aligns with human visual attention characteristics, the HAB branch is designed to extract internal features of VP images based on attention mechanisms. To further explore the comprehensive perception of the VP under different viewing distances, we also introduced a multiple viewing distances image pyramid of the front VP as the input of the HAB branch, which is shown in Fig. 1.

For the front VP initialized with a resolution of  $H \times W$  through the center cropping operation, we increase the center cropping resolution to  $2H \times 2W$  to represent a larger field of view with a longer distance. Similarly, we decrease the center cropping resolution to  $\frac{H}{2} \times \frac{W}{2}$  to represent a smaller field of view with a closer distance. Therefore, the input image pyramid  $V_f^l, V_f^o, V_f^s$  of the front VP can be established with a multiple distances representation. Specifically, the  $V_f^o$  represents the VP in its original resolution,  $V_f^l$  represents a version with a higher resolution, and  $V_f^s$  represents a version with a lower resolution.

To fully explore the information based on human visual attention from this VP pyramid, we integrate the ResNet-50 and an improved ViT as the backbone for feature extraction. Specifically, each layer of the pyramid is firstly fed into the ResNet-50 in parallel. The semantic features of each view can

be obtained and then being converted into token forms. In our method, the improved ViT network consists of two stages. The first stage tries to compute the attention weight among tokens within each view by multi head attention (MHA). The second stage is used to further adjust the dimensionality of the obtained feature maps based on view-content attention through the Head module which is composed of fully connected layers. Finally, we fuse the extracted high-level features of each view at different distances, and obtain the quality score of this branch with a regression operation. This process can be expressed as:

$$\begin{cases} F_f^l, F_f^o, F_f^s = B_{HA}(V_f^l, V_f^o, V_f^s), \\ Q_1 = Linear(Cat(F_f^l, F_f^o, F_f^s)), \end{cases} \quad (1)$$

where  $B_{HA}(\cdot)$  represents the feature extraction network of the HAB,  $F_f^l, F_f^o, F_f^s$  separately represent the extracted features from the image pyramid under different distances. Each extracted features of the pyramid has a dimensionality of 10.  $Cat(\cdot)$  and  $Linear(\cdot)$  respectively donate the concatenate operation and the fully connected layer.  $Q_1$  is the obtain predicted quality score of this process.

### B. Multi-Scale Perception Network

In general, the user's comprehensive quality perception of a panoramic image is influenced by multiple VPs at different positions. It is necessary to perform multi-scale quality perception across various positions in the panoramic image and explore the correlation information between these VPs in terms of both location and content.

In this work, we have established a multi-scale perceptual branch as an auxiliary branch. Firstly, a group of VP images  $V_u, V_d, V_l, V_r, V_f, V_b$  are achieved from a panoramic image at six directions (up, down, left, right, front, and back). As mentioned above, human visual perception is a hierarchical process that involves perceiving texture, contours, and high-dimensional semantics. Therefore, in this branch, ResNet-50 with residual structure is adopted as the backbone for feature extraction of each VP. The residual network is capable of capturing multi-scale perceptual features from low-level to high-level in each directional VP, which aligns well with the multi-scale perception of HVS. This process can be represented as:

$$F_i^m = B_{MP}(V_i), i \in \{u, d, l, r, f, b\}, \quad (2)$$

For each VP image  $V_i$ , multi-scale perceptual features  $F_i^m$  are simultaneously extracted through the feature extraction network.  $B_{MP}$  represents the backbone of this branch. It is worth noting that the multi-scale features obtained here have a dimensionality of 2048.

After obtaining the multi-scale features  $F_i^m$  obtained from multiple VP images, most methods propose to concatenate those high-dimensional features and perform quality regression. Conversely, in order to further capture the inter-viewpoint correlation information, we apply a fully connected layer to convert the multi-scale features corresponding to each VP into tokens with a dimensionality of 768. Subsequently, we perform element-wise multiplication operations based on attention mechanism among those tokens to obtain the correlational features. The specific formula representation is as follows.

$$\begin{cases} T_i^m = Linear(F_i^m) \\ F^c = E_{MP}(T_i^m) \end{cases}, i \in \{u, d, l, r, f, b\}, \quad (3)$$

Here,  $Linear(\cdot)$  represents the fully connected operation,  $T_i^m$  denotes the token corresponding to each VP after undergoing this fully connected operation.  $E_{MP}$  represents the Encoder network based on multi-head attention, and  $F^c$  represents the final correlation feature map among those VPs.

In order to further fuse the obtained correlation features and consider the spatial relationship between each VP, we further introduce a correlation feature fusion module. This module consists of four convolutional blocks and an average-pooling. Each convolutional block includes a convolution (Conv) layer, a batch normalization (BN) layer, and a Rectified Linear Unit (ReLU) activation. The convolutional operation calculates the internal correlations of the feature map  $F^c$  using a  $3 \times 3$  receptive field, integrating the content-based correlation information between different VPs. This locally nested convolutional structure also helps compensate for the positional correlation between VPs that may be overlooked in the previous computations. Finally, an average-pooling operation is applied to obtain the fused correlation features through regression. The specific process is illustrated by the following equation.

$$F^{c'} = C_{MP}(F^c), \quad (4)$$

where  $C_{MP}$  represents the correlation feature fusion module,  $F^{c'}$  is the achieved fused correlation features, whose dimensionality is 10.

We perform final feature regression on the multi-scale information obtained from each VP and the corresponding fusion information between them. Specifically, we first adjust each multi-scale feature map  $F_i^m$  to dimensionality 10. Then, we concatenate those adjusted feature maps with the multi-scale feature  $F^{c'}$ . Next, a fully connected operation is applied to the concatenated feature map for feature regression. This process can be described as:

$$\begin{cases} F_i^{m'} = Linear(F_i^m) \\ Q_2 = Linear(Cat(F_i^{m'}, F^{c'})) \end{cases} \quad i \in \{u, d, l, r, f, b\} \quad (5)$$

where  $F_i^{m'}$  represents the multi-scale features of each VP after dimension adjustment.  $Linear(\cdot)$  and  $Cat(\cdot)$  represent the fully connected operation and concatenation operation, respectively.  $Q_2$  denotes the quality score obtained from the final regression of this multi-scale perception branch.

### C. Quality Regressor

The quality regressor consists of two steps. Firstly, we conduct concatenation operation of HAB and MPB. Afterwards, the predicted score is obtained by the final layer of fully connected. The training loss is described as follows:

$$\begin{cases} Q = Linear(Cat(Q_1, Q_2)) \\ L = |Q - MOS|^2, \end{cases} \quad (6)$$

where  $Q$  is the final predicted quality score. The  $MOS$  is the ground-truth label of OI, which also means the subjective

quality score. The  $L$  represents the loss between  $S$  and  $MOS$ , the  $|\cdot|$  represents absolute value operation.

#### IV. EXPERIMENTAL RESULTS

Our experiment uses two popular public datasets, namely CVIQD [25] and OIQA[26]. They both include 16 original panoramic images with different types and degrees of distortion. The former includes 528 compressed images generated by JPEG, H.264/AVC and H.265/HEVC standards, and the subjective score label of it ranges from 1 to 100. The latter contains 320 distorted images generated by four distortion types: JPEG compression (JPEG), JPEG2000 compression (JP2K), Gaussian blur (GB) and Gaussian white noise (GN), and the subjective ground-truth label of it ranges from 1 to 10.

##### A. Experimental Settings

Our experiments were conducted with 11<sup>th</sup> Gen Intel(R) Core(TM) CPU i7-11700F @ 2.50GHz, 16 GB RAM, NVIDIA RTX 3060. The batch size was set to 4 and the learning strategy was RMSprop [27] whose learning rate is initialized to 0.0001. The rotation angle for the rotated CMP was fixed to 4 serving as data augmentation and the VP image resolution  $H \times W$  is set to  $256 \times 256$ . Each database is split into training and testing sets according to the standard ratio of 8:2. This means that the distorted images corresponding to 3 reference images are randomly selected as testing set and the remaining are regarded as the training set. During the training phase, we use the pretrain results of ImageNet to the HAB and the MPB's backbone. By transferring the model training parameters from a large dataset to our task-specific dataset, we can achieve significant benefits. For the Backbone of HAB, the number of the MHA is set to 8 and the number of encoder blocks is set to 11. Finally, we adopt three standard assessment methods: Pearsons linear correlation coefficient (PLCC), Spearman's rank order correlation coefficient (SROCC) and root mean squared error (RMSE) to assess the model performances. The former two respectively evaluate the prediction results based on rank correlation and linear correlation. A value closer to 1 indicates a better

prediction result. The latter measures the discrepancy between the predicted and ground-truth values, with a value closer to 0 indicating a better prediction result. We also used a five-parameter logistic function to fit the predicted quality scores and the ground-truth labels:

$$y = \beta_1 \left( \frac{1}{2} - \frac{1}{1 + \exp(\beta_2(x - \beta_3))} \right) + \beta_4 x + \beta_5, \quad (7)$$

where  $x$  refers to the predicted quality score and  $y$  represents the mapped score.  $\beta_1$  to  $\beta_5$  are five parameters.

##### B. Performance Evaluation

1) *Comparison Metrics*: In order to illustrate the effectiveness of our model, the comparison algorithms includes FR and NR OIQA metrics. The FR-OIQA metrics include PSNR, S-PSNR [2], WS-PSNR [3], CPP-PSNR [4], SSIM [1], MS-SSIM [5], FSIM [6] and DeepIQA [28]. The NR-OIQA contain BRISQUE [29], BMPRI [30], DB-CNN [31], MC360IQA [13], DDA-BOIQA [32] and VGCN [14].

The performance comparison results on the OIQA and CVIQD datasets are shown in Table I. Among these FR-OIQA methods, the PSNR-related algorithms which have weaker correlation with the HVS exhibit poorer performance compared to these state-of-the-art objective algorithms. It is a breakthrough that the SSIM takes into account the brightness, contrast, and structural features associated with the HVS. However, the evaluation results are still limited and the performances are inferior to deep learning-based FR-OIQA methods. The reason lies in that deep learning-based methods directly consider the internal relationship between images and subject scores, while other methods mainly focus on one or two features of the OI. For NR methods, these algorithms generally outperform FR-OIQA algorithms. BRISQUE, BMPRI, and DB-CNN are implemented for OIQA specifically targeting ERP format of OIs. Specifically, BRISQUE and BMPRI are implemented based on handcrafted feature designs, while DB-CNN is implemented based on a data-driven model. Furthermore, the MC360IQA and VGCN models consider the VP images into their CNN

	Ours	<u>0.9475</u>	<u>0.9133</u>	<u>0.7167</u>	<u>0.9885</u>	<u>0.9821</u>	<u>0.3390</u>	<b>0.9888</b>	0.9714	<b>0.2690</b>	0.9859	<u>0.9777</u>	0.3251

model, resulting in significant performance improvements. It is because the VP images are similar to the perception of human eyes. Our algorithm exhibits significantly higher performance compared to most deep learning based algorithms in terms of accuracy and monotonicity on those two databases. It is evident that the proposed dual-level network based on human visual perception is more consistent with the subject quality perception.

### 2) Performance Validity of Individual Distortion Types:

As illustrated in Table II and Table III, we also conducted comparative experiments of individual distortion types on OIQA and CVIQD. In general, our algorithm exhibits the best comprehensive performance for most of the distortions. The scatter plots in Fig. 3 and Fig. 4 depict the correlation between MOS and the predictions for individual distortion types on the two databases. These plots provide additional evidence to support the superiority of our approach. Specifically, our algorithm achieves top performance in both WN and AVC distortion types, and it closely follows the top-performing algorithm in JPEG and JP2K distortions. For example, as shown in Fig. 4, our algorithm exhibits an SROCC value in JPEG that is only 0.0161 lower than the top-performing VGCN, and is only 0.0062 lower than DeepQA on the OIQA. This further demonstrates the strong robustness of our algorithm in compression distortion types. Additionally, in terms of HEVC distortion, our algorithm achieves the best PLCC and RMSE values in NR-OIQA. It is noteworthy that SSIM and FSIM in FR-OIQA actually achieved the best results in this distortion type. The reason is that HEVC distortion typically includes color inaccuracies or artifacts, while FSIM primarily measures quality degradation by assessing the similarity in luminance, contrast, and structural aspects between the reference and distorted images. Therefore, FSIM is more sensitive to color changes. Additionally, FSIM benefits from having a reference image for comparison, which enhances its ability to identify

artifacts such as pseudo-imaging. This also indicates the effectiveness of these schemes for a certain type of distortion.

3) *Ablation Study:* In order to further demonstrate the effectiveness of each module, we separately removed each component of our model to conduct ablation experiments on two datasets. The experimental results are presented in Table IV. We separately adopt the human attention Branch (HAB) and the multi-scale perception branch (MPB) to predict the perceptual quality based on human visual perception in the dual-level network. In this section, we compare the performance with or without these two branches to respectively demonstrate the validity of each branch. We can conclude that both branches have strong quality prediction capabilities. However, the dual-stream network proposed in this paper, which combines features from these two branches, exhibits superior quality perception abilities, particularly in improving the SROCC values. Moreover, the influence of HAB is more pronounced on OIQA, mainly due to the diverse resolutions of OIs in this dataset, which are effectively addressed by the image pyramid utilized in the HAB. In our implementation, attentional features are obtained from an image pyramid in HAB. It is necessary to investigate how feature extraction based on attention mechanism affects overall performance. Therefore, we replace the original backbone in HAB with ResNet-50 and test the performance of the overall architecture. The results show that the performance of the CNN-based backbone is inferior to the backbone used in this paper, which further demonstrate the necessity of considering attentional features in HAB. In addition, we also conducted an ablation study for the correlation feature fusion module of VPs in MPB. As compared to the original implementation, the results on both databases showed slight improvements, which further proves that there is contextual and positional correlation information between different viewports within a panoramic image.

Fig. 3. Scatter plots of MOS values against predictions by OIQA metrics for individual distortion type on the testing set of OIQA Database.

## V. CONCLUSION

In response to the fact that the perception of immersive media quality is more susceptible to subjective visual perception by the human eye, in this paper, we propose an innovative approach that integrates two characteristics of human visual perception, namely attentional perception and multi-scale perception, into the process of acquiring panoramic image features. Specifically, we propose a dual-level network based on human visual perception for blind omnidirectional image quality assessment. By transforming the front viewport image to an image pyramid with multiple viewing distances, the human attention branch is able to capture the high-level information based on attention mechanism. To obtain the features of different viewports from different position, we further establish a module to fuse their correlation information in the multi-scale feature perception branch after parallel extraction of their multi-scale features.

Experimental on two OIQA datasets show that our approach achieves the best performance, further validating the effectiveness of the human visual perception guidance. Of course, our work needs further in-depth research. Our approach only incorporates two essential aspects of human visual perception to assist the omnidirectional image quality assessment process. However, human visual perception is diverse, and the challenge lies in quantifying it effectively in a general end-to-end model. This will be the focus of our future research endeavors.

**Abstract**—Voice pathology is a universal problem which must be addressed. Traditionally, this malady is treated by using the surgical instruments in the varied healthcare settings. In the current era, machine learning experts have paid an increasing attention towards the solution of this problem by exploiting the signal processing of the voice. For this purpose, numerous voice features have been capitalized to classify the healthy and pathological voice signals. In particular, Mel-Frequency Cepstral Coefficients (MFCC) is a widely used feature in speech and audio signal processing. It denotes spectral characteristics of a voice signal, particularly of human speech. The modus operandi of MFCC is too time-consuming, which goes against the hasty and urgent nature of the modern times. This study has developed a yet another voice feature by utilizing the average value of the amplitudes (AVA) of the voice signals. Moreover, Gaussian Naive Bayes classifier has been employed to classify the given voice signals as healthy or pathological. Apart from that, the dataset has been acquired from the SVD (Saarbrücken Voice Database) to demonstrate the workability of the proposed voice feature and its usage in the classifier. The machine experimentation rendered very promising results. Particularly, Recall, F1 and accuracy scores obtained, are 100%, 83% and 80%, respectively. These results vividly imply that the proposed classifier can be installed in various healthcare settings.

**Keywords**—Pathological voice; healthy voice; voice feature; amplitudes; machine learning

## I. INTRODUCTION

People whose professions cause them to speak louder than normal, often suffer from some kind of voice pathology. These people may include lawyers, auctioneers, motivational speakers, legislators, singers, teachers, etc. This pathology, in turn, leads to tiredness, infections of voice tissue, face soreness, muscular dystrophy and others [1]. Apart from that, this pathology casts a negative impact upon the voice functionality and vibration regularity which sometimes leads to the increment in the vocal noise. Normal voices turned to be weak, tense, and hoarse which influences quality of voice [2]. Traditionally, voice pathology detection methods are

tendentious in their character and orientation. They are based on subjective matters [3]. For instance, in the different hospital settings, an auditory-perceptual assessment is employed which includes visual laryngostroboscopy assessment [4]. In this painful process of diagnosis, a series of clinical examinations are employed for the auditory-perceptual parameters to appraise the severity of the voice malady [5]. These appraisals are subjective and are very sensitive to the sensitivity of the parameters involved. Moreover, they happen to be very much time consuming which is not in line with the current standards of quality [6]. One more disadvantage of this method is that the patients have to be present in the hospital physically which is, of course, not feasible for the patients with critical conditions.

In sharp contrast to that, there exists an objective evaluation of the voice pathology using signal processing of the voice. In particular, the signals of patients' voice are processed to conclude whether the patient concerned is suffering from the pathology or not? No surgical treatment is employed in this method. Moreover, this procedure can also work upon the inaudible sounds [1]. These methods do not depend upon the human decisions. A patient needs not be physically present in the healthcare centres since only his/her voice is required to reach to the decision. So, the voice recording can also be shared through the internet. Upon surveying the relevant literature, one will find that different voice pathology databases exist for the sake of objective evaluation of voice pathologies. Among these, the most common include Arabic Voice Pathology Database (AVPD) [7], Saarbrücken Voice Database (SVD) [8] and the Massachusetts Eye and Ear Infirmary Database (MEEI) [9]. Upon surveying the literature about the pathological voice detection, researchers have used varied voice features and diverse machine learning classifiers for discriminating between the pathological and healthy voice signals [10], [11], [12], [13], [14], [15], [16], [17], [18], [19], [20], [21]. The work [10] wrote a robust voice pathology detection algorithm using the theory of Deep Learning. In order to maximize the accuracy of classification, the pre-trained Convolutional Neural Network

(CNN) has been employed over the dataset of voice pathology. Besides, this work used SVD as a dataset for testing their work. The accuracy claimed by the reported study is 95.41%. Moreover, F1-Score and Recall scores were calculated to be 94.22% and 96.13%, respectively. In an other study [11], the voice pathology detection system was developed in the realm of smart healthcare. In this particular work, the voice data was taken through the IoT gadgetry, i.e., electroglottography (EGG) and microphones for capturing the EGG and voice signals. The voice feature spectrogram was employed in this particular study. These spectrograms were got from the reported signals and were given as an input to the pre-trained CNN. Moreover, the features obtained through the usage of CNN were mixed and later on processed through short long-term memory network (bi-directional in nature). The accuracy claimed by the said study was 95.65%. In an another research [12], the authors employed an Online Sequential Extreme Learning Machine (OSELM) as the classification algorithm in their work for detection of pathological voice signals. An other prominent feature of this study is the employment of long sentences instead of the single vowel letters for the sake of discrimination between the pathological and healthy voice signals. Three types of voice pathologies were addressed namely cyst, polyp, and paralysis. The accuracy achieved was 91.17%. Apart from that, precision and recall scores were 94% and 91%, respectively. The work is reported to give a high capability for detecting the pathological voice signals in the real-time clinical settings.

Many voice features have been discovered by the academicians and other researchers. Some of these include formant frequency [22]. Formant frequencies are a sort of resonance frequencies. These frequencies change with various vocal tract configurations [23]. Commonly, these formants denote the spectral contribution of the given resonances. Apart from that, peaks of these spectra about the local tract responses refer to the corresponding formants. The various plots of these formants depict the different peaks at the various frequencies. Spectrogram of a voice signals [24] is yet another voice feature. They are a kind of a waveform comprising of various events which change as the time goes by. Owing to the fact that they vary with the time, hence they fluctuate and exhibit the spectral properties. This is the reason that a single Fourier transform [25], [26] is humble to capture such kind of speedy time varying signals. Hence, for this purpose, a short-time Fourier transform (STFT) was used. STFT comprises of different Fourier transform for the pieces of the given waveform. The feature of linear predictive coding (LPC) is also used by machine learning experts to differentiate between the pathological and healthy voice signals [27], [28]. Initially, LPC was designed for compressing the digital signals for the efficient storage and transmission of the digital data. In current times, this feature is frequently being employed to draw a line of discrimination between the healthy and pathological voice signals. Moreover, this method models vocal tract in the form of linear all-pole infinite impulse response (IIR) filter.

Calculation of these features is mathematically intensive. Apart from that, they consume a lot of precious processing time which is not in line with the demands of the current era. So, we require simple but powerful voice features to do the job.

In this work, a novel voice feature by observing the behavior of amplitudes of the voice signals has been discovered. In particular, the average value of the amplitudes of the voice signal has been determined. This average value is potent enough to differentiate between the healthy and pathological voice signals. Moreover, this feature has been embedded in the machine learning algorithm to classify the two kinds of signals. The machine experimentation rendered very competitive results. Moreover, these results are better than many of those published in the literature.

Having said that, the following salient features characterize the contribution of this work to the exciting field of voice signal processing and machine learning:

- A novel voice feature based on the average value of amplitudes of the given voice signals has been determined.
- The voice feature found in the above bullet has been exploited in the machine learning algorithm to draw a rather clearer line of demarcation between the pathological and healthy voice signals.
- The proposed method rendered very competitive results. Moreover, it beats many results of the published works.

Rest of the paper has been fashioned like this. In Section II, the particular modus operandi employed in MFCC feature extraction has been explained. Section III describes the proposed methodology. In particular, the way novel voice feature has been determined, has been explained in detail. Afterwards, the reported feature has been embedded in the proposed framework to differentiate between the healthy and pathological voice signals. In Section IV, the results have been described and compared with the other published researches in the literature. Section V closes the paper with the concluding remarks and other possible research directions.

## II. RELATED WORK

Traditionally, MFCC has been employed by the machine learning experts to draw a line of demarcation between the healthy and pathological voice signals. MFCC is actually a feature selection method which plays a very critical role to distinguish the pathological voice signals from their healthy counterparts. Normally, three kinds of features are there for the recognition of the sound patterns. They are time domain, frequency domain and time-frequency domain [29]. Cepstral domain features are retrieved after taking their fast Fourier transform (FFT) of the amplitude's logarithm from spectrum data [30]. Since MFCCs closely resemble human auditory system, so their inherent power is normally harnessed for the speech recognition in the diverse problems [31]. MFCCs are normally got through power spectrum of sound signals with the short-term windowing after taking cosine transform of logarithmic power spectrum over Mel filter banks [32]. A standard modus operandi for extracting the MFCCs from the given audio signals have been depicted in the Fig. 1. Firstly, windowing functions, like Hanning and Hamming windows, are normally employed through some degree of overlapping for capturing local spectral characteristics. Secondly, various signals from the different frames are subjected to operation of

Fig. 1. MFCC feature extraction mechanism, given audio signals have been bifurcated into the overlapping frames along with some fixed intervals and weights have been given through hamming window.

discrete Fourier transform (DFT) for the sake of extracting information from the frequency domain. Thirdly, frequency domain data are filtered through a number of bandpass filters which are normally equal to designed number of the MFCC resolution (64,128,256,512). It is to be noted that centre frequencies of bandpass filters are spaced in uniformity on Mel scale  $M(f)$  [33].

$$M(f) = \frac{1000 \ln(1 + \frac{f}{700})}{\ln(1 + \frac{1000}{700})} \approx 1127 \ln(a + \frac{f}{700}) \quad (1)$$

In this equation,  $f$  denotes frequency term and  $M(f)$  denotes Mel scale. Moreover, this equation converts boundaries of filter bank to Mel scale. As soon as centre frequencies are distributed in a uniform fashion on Mel scale, values are converted back to frequency domain which renders the triangular filters. After that energies  $MF(t)$  of corresponding filter banks are computed by taking sum of energies in bandpass filters. Finally, MFCC coefficients are found through the application of discrete cosine transform (DCT) to the filtered energies from

the triangular bandpass filters [34].

$$MFCC_{i,j} = \frac{1}{T} \sum_{k=1}^T \log[MF(k)] \cos[\frac{2\pi}{T} (k + \frac{1}{2})j] \quad (2)$$

In this equation,  $MFCC_{i,j}$  refers to the  $j^{th}$  MFCC coefficient of  $i^{th}$  frame. Apart from that,  $1 \leq i \leq N$  and  $1 \leq j \leq M$ . They represent the indices of MFCC. Moreover,  $MF(k)$  is Mel filter bank amplitude of  $k^{th}$  filter. Apart from that, Table I sheds light on the varied studies carried out. In this table, one can examine the different studies based on the number of samples taken, phonemes, pathological condition of the patients, the classifier employed, the feature used and lastly the findings. Here will describe few studies in more details. In study [35], normal and pathological samples taken were 60 and 402, respectively. Besides, the vowels were taken as phonemes to apply the classifier. Apart from that, the voices of the patients were suffering from the pathological conditions of structure lesions and neoplasm. Additionally, the classifiers selected for this particular study were Support Vector Machine (SVM), Gaussian Mixture Modelling (GMM) and Deep Neural Network (DNN). The feature upon which the distinction was made between the healthy and pathological voice was MFCC. As far as the findings and outcomes of this study were concerned, SVM outperformed GMM. Besides, the classifier DNN rendered the highest accuracy. The study [36] took 56 normal samples of voices and 67 pathological samples. Moreover, the phonemes employed in this particular study were 'ah'. The pathological conditions of the patients concerned were that they were suffering from the Parkinson's disease, Vocal cord paralysis and cerebral demyelination. The classifier and the feature selected were SVM and MFCC. The accuracy obtained in this study was 93%. The last row of this table describes these parameters for the proposed study. It is to be noted that, we employed AVA as a voice feature for the sake of classification between the healthy and the pathological voice signals.

One can note that this traditional method of extracting the voice feature is very complicated and mathematically intensive. We require simple but powerful voice features to draw a clearer line of demarcation between the given voice signals.

### III. PROPOSED METHODOLOGY

In this work, a novel voice feature consisting of average value of the amplitudes (AVA) of the given voice signal has been determined. This voice feature has been, in turn, employed to distinguish between the given healthy and pathological voice signals. Fig. 2 draws the amplitudes of the healthy and pathological voice signals. Fig. 2a and 2b refer to the signals for the healthy and pathological voices. One can clearly observe that amplitudes in the positive and negative sides for the healthy signals are greater than their pathological counterparts. This is the very observation through which the novel voice feature has been determined. In particular, the average value of the amplitudes (both positive and negative) of the healthy and pathological voice signals has been found. Their average values have been further averaged. This average has been used while training our model. Once the model gets trained, testing phase have been employed.

TABLE I. OVERVIEW TABLE

Sr. #	Study	Samples	Phonemes	Pathological condition	Classifier	Feature	Findings
1	Ref. [35]	Normal: 60 Pathological: 402	Vowels	Structural lesions, neoplasm	SVM, GMM, DNN	MFCC	SVM outperforms GMM DNN provides the highest accuracy
2	Ref. [36]	Normal: 56 Pathological: 67	Vowel 'ah/	Parkinson's disease, Vocal cord paralysis cerebral demyelination	SVM	MFCC	Highest accuracy of 93%
3	Ref. [37]	Pathological: 60	Japanese vowel	Breathiness, Roughness, asthma and strain	Higher-Order Local Autocorrelation (HLAC)	Auto Regressive, (AR)-HMM, Feed Forward Neural Networks (FFNN)	87.75% accuracy

      $sum\_of\_amplitudes + temp$ 
10  $AvgValue \leftarrow \frac{sum\_of\_amplitudes}{P+Q}$ 

```

for loop of line 1 iterates for  $P + Q$  times. In each iteration, it loads the  $i^{th}$  file of the training data  $TD$  by using the load

function of the Python module librosa. It returns the stream of amplitudes  $data$  and the sampling rate  $sampling\_rate$ . Line 3 initializes a variable  $sum\_of\_amplitudes$  to zero. Lines 4 to 6 take the absolute value of the amplitudes of the voice signal carried by the array  $data$ . Lines 7 and 8 find the average value of the amplitudes and assigns this value to the variable  $temp$ . Line 9 accumulates the average values in the variable  $sum\_of\_amplitudes$ . Lastly, line 10 finds the grand average value of all the average values of the amplitudes of the given training data and assigns this value to the variable  $AvgValue$ . Algorithm 2 has been designed to train the data based on the average value found through the Algorithm 1. Line 1 invokes the Algorithm  $AvgValue$  with the parameters  $TD, P$  and  $Q$  and assigns the result to the variable  $AV$ . Lines 7 and 8 find the average value of the amplitudes of the given  $i^{th}$  file. If this value is less than the  $AV$  (line 9), this particular file is being labelled as pathological (line 10), otherwise, it is being labelled as healthy (line 12).

### B. Healthy and Pathological Voice Classifier Based on the Average Value of the Amplitudes

Proposed pathological voice classifier has been presented in the Fig. 4. On the left half of the figure, training procedure has been illustrated in a step by step fashion. The process gets sparked with the given training data which comprises of both healthy and pathological voice files. In the next stage, the amplitudes have been extracted from the given voice signals. It is followed by the calculation of the average value of the amplitudes (both in the positive and negative directions). Based

Fig. 3. Flowchart of extracting AVA.

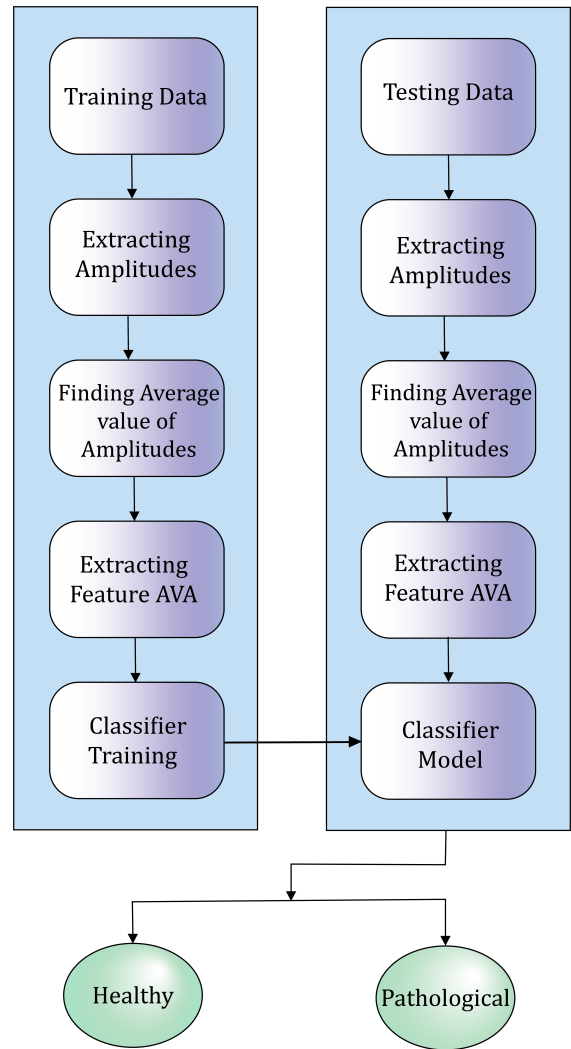

Fig. 4. AVA based pathological voice classifier.

**Algorithm 2:** Labelling voice signal as pathological or healthy based on *AvgValue*.

**Input:**  $TD, P, Q$   
**Output:** *pathological*

```

1  $AV \leftarrow AvgValue(TD, P, Q)$ 
2 for  $i \leftarrow 1$  to  $P + Q$  do
3    $[data, sampling\_rate] \leftarrow librosa.load(TD[i])$ 
4   for  $j \leftarrow 1$  to  $len(data)$  do
5     if  $data[j] < 0$  then
6        $data[j] \leftarrow -data[j]$ 
7    $temp \leftarrow sum(data)$ 
8    $temp \leftarrow \frac{temp}{len(data)}$ 
9   if  $temp < AV$  then
10     $pathological \leftarrow true$ 
11  else
12     $pathological \leftarrow false$ 

```

on this average value AVA, the GaussianNB classifier has been trained. Same process has been repeated on the right half of the figure which is pertinent to the testing data. Lastly, the classifier model outputs whether the particular voice signal is healthy or of pathological character.

#### IV. SIMULATION RESULTS

The proposed framework was simulated on the Python 3 software. We have taken 80% voice files as a training data and 20% voice files as a testing data. Additionally, these files have been taken from the SVD database. The proposed research project has used this database for the sake of experimentation. It has a collection of voice recordings of around 2000 people. To put it specifically, it contains 687 healthy voice comprising of 259 males and 428 females. Moreover, there are the recordings of 1354 pathological voices comprising of 627 males and 727 females. It is to be noted that all these recordings contain 71 different pathologies. Moreover, these recordings were sampled at 50 kHz frequency along with a 16-bit resolution. Additionally, average age of the speakers is

TABLE II. RESULTS (IN PERCENT FORM) OF DIFFERENT VALIDATION METRICS USING THE PROPOSED METHODOLOGY AND OTHER METHODS

Method	Feature	Accuracy	Precision	Recall	F1 Score	Specificity	G-mean
Ref. [10]	-	95.41	-	96.13	94.22	-	-
Ref. [11]	-	93.94	95.08	94.87	94.93	-	-
Ref. [12]	MFCC	91.17	94.0	91.0	87.0	97.67	87.55
Ref. [13]	Peak and Lag	88.70	-	88.69	-	88.71	-
Ref. [13]	Entropy	82.01	-	73.90	-	89.72	-
Ref. [14]	MPEG-7	99.994	-	73.90	-	89.72	-
Ref. [15]	LLE+CD	90.0	-	88.0	-	98.0	-
Ref. [16]	MDVP	76.0	-	45.0	-	93.0	-
Proposed	AVA	80.0	71.0	100.0	83	60.0	100.0

around 15 years. Apart from that, 1 to 3 seconds is the duration of these voice samples.

As far as the machine learning algorithm is concerned, GaussianNB algorithm was chosen to classify the healthy and pathological voice signals. Moreover, in this study, we have chosen these validation measures: accuracy, precision, recall (sensitivity), F-measures, G-mean, and specificity as shown in Eq. 3 to Eq. 7 [41], [42]. The following describes the various measures which are frequently employed in the literature.

- 1) FP (False Positive): The voice signal under consideration is of healthy character but algorithm declares it as of pathological character.
- 2) FN (False Negative): The voice signal under consideration is of pathological character but algorithm declares it as of healthy character.
- 3) TP (True Positive): The voice signal is of pathological character and algorithm declares it as of pathological character.
- 4) TN (True Negative): The voice signal is of healthy character and algorithm declares it as of healthy character.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (3)$$

$$Precision = \frac{TP}{TP + FP} \quad (4)$$

$$Sensitivity(Recall) = \frac{TP}{TP + FN} \quad (5)$$

$$F - Measure = \frac{2 \times Precision \times Recall}{Recall + Precision} \quad (6)$$

$$Specificity = \frac{TN}{TN + FP} \quad (7)$$

The Table II shows the results of the proposed study. Apart from that, this table also draws a comparison between the suggested work and other published researches found in the literature. As can be seen from the table, we got both the Recall and G-mean scores as 100% which validates and confirms the very idea of AVA, we conceived before launching this project. Apart from that, we got an accuracy of 80% which beats some of the published works in the literature. Moreover, one can see that various machine learning experts have used the voice feature of MFCC, Peak and Lag, Entropy, MPEG-7, LLE+CD and MDVP. Unfortunately, our study could only beat the study [16] as far as the metric of accuracy is concerned. However, our results of Recall, G-Mean and F1 score are very competitive.

Fig. 5. Visual demonstration of validation metrics.

Besides, the Fig. 5 depicts the results of the proposed study in a graphical form which is more intuitive.

## V. DISCUSSION

Many voice features have been investigated as the literature over the pathological and healthy voice classifiers suggests. These features are input to the machine learning classifiers in order to draw a line of separation between the given pathological and healthy voice files of the different patients. The authors of this study observed a pattern after drawing and putting side by side the graphs of the pathological and healthy voices. The amplitudes of the healthy voice signals went higher as compared to their pathological counterparts. This was the very point which was further investigated. In this way, a novel voice feature termed as Average Values of the Amplitudes was found which was further imported to the machine learning classifier in order to draw a clear line of demarcation between the healthy and pathological voice signals. This study obtained Recall and G-mean scores as 100% while the accuracy achieved reached to the tune of 80%. This outcomes vividly imply that the suggested voice feature is potent enough to predict the healthy and pathological voice

signals. Moreover, we contend that the proposed voice feature can be extracted with faster speed as compared to the other features like MFCC. MFCC has twelve parameters whereas the proposed one has only one parameter. As far as the limitations of the proposed framework are concerned, it can't differentiate all the voice pathologies.

## VI. CONCLUSION

By observing an underlying pattern in the given voice signals, a novel voice feature AVA has been developed in this study based on the varying values of the amplitudes of the healthy and pathological voice signals. Although a plethora of voice features already exist when one peruses the literature but this newly developed voice feature is very simple and robust to draw a clearer line of demarcation between the healthy and the pathological voice signals. This feature has been exploited while using the machine learning algorithm to detect the pathological voices. The simulation and the machine experimentation rendered very promising results. In particular, we got the Recall and G-mean score as 100% while the accuracy achieved by this study is 80%. We assert that the proposed voice classifier can be installed in some real world healthcare setting to reap its intrinsic benefits. As a future work, other machine learning classifiers and the voice databases would be investigated to examine the workability of the novel voice feature AVA, this study has produced.

## ACKNOWLEDGMENT

I would like to express my sincere gratitude to my supervisor and the reviewers for their invaluable support and feedback. Without their guidance and input, this paper would not have been possible. Additionally, I would like to thank my family and friends for their unwavering encouragement throughout this research journey.

**Abstract**—Smoke is often present in the early stages of a fire. Detecting low smoke concentration and small targets during these early stages can be challenging. This paper proposes an improved smoke detection algorithm that leverages the characteristics of smoke concentration using YOLOv7tiny. The improved algorithm consists of the following components: 1) utilizing the dark channel prior theory to extract smoke concentration characteristics and using the synthesized  $\alpha$ RGB image as an input feature to enhance the features of sparse smoke; 2) designing a light-BiFPN multi-scale feature fusion structure to improve the detection performance of small target smoke; 3) using depth separable convolution to replace the original standard convolution and reduce the model parameter quantity. Experimental results on a self-made dataset show that the improved algorithm performs better in detecting sparse smoke and small target smoke, with mAP@0.5 and Recall reaching 94.03% and 95.62% respectively, and the detection FPS increasing to 118.78 frames/s. Moreover, the model parameter quantity decreases to 4.97M. The improved algorithm demonstrates superior performance in the detection of sparse and small smoke in the early stages of a fire.

**Keywords**—YOLOv7tiny; smoke detection; dark channel; smoke concentration; feature fusion; depthwise separable convolution

## I. INTRODUCTION

With the rapid development of the national economy and various industries, factories are producing more production materials, but they are also facing increased safety risks. High-density residential buildings are increasingly engaging in intensive fire and electricity usage behaviors. According to statistics from the Ministry of Emergency Management as of January 20, 2022, there were a total of 748,000 recorded fires in 2021, resulting in over 4,000 casualties and direct economic losses exceeding 6.75 billion yuan [1]. Therefore, it is crucial to research fire and smoke detection methods to ensure public property safety.

Currently, smoke detection research can be categorized into methods based on hardware sensors and wireless signals, and methods based on computer vision [2]. However, methods based on hardware sensors and wireless signals have poor adaptability in certain scenarios and do not perform well [3]. To overcome these limitations, computer vision-based smoke detection methods have been widely employed in recent years. Surveillance systems have also evolved from simulation-based, networked, and high-definition systems to intelligent systems. Now, surveillance resources are not only utilized for local monitoring functions but also integrated with computer vision for intelligent monitoring. Object detection algorithms based on deep learning have rapidly developed and become

the mainstream method for smoke detection, as they possess powerful feature learning and representation capabilities, better meeting the requirements of the big data era in comparison to traditional machine learning methods [4].

He et al. [5] proposed a deep fusion convolutional neural network for smoke detection based on efficient attention, integrating spatial and channel attention mechanisms to address the issue of detecting small smoke. Sun et al. [6] presented an improved convolutional neural network for the rapid identification of forest fire smoke. However, the algorithm has poor generalization ability and weak robustness, only exhibiting high detection capability in specific scenarios. Wang et al. [7] proposed a smoke detection algorithm based on Faster R-CNN. Firstly, smoke is extracted based on its motion features, and then the Faster R-CNN network is used to extract and recognize the smoke image features, achieving high accuracy. However, the Faster R-CNN network structure is complex, and real-time detection is poor.

In recent years, the YOLO series models have garnered extensive research in the field of object detection due to their real-time performance, one-stage detection, simplicity, and good accuracy. Ren et al. [8] implemented fire detection and recognition using an improved YOLOv3 network. The algorithm improves the accuracy and detection speed of small smoke targets by modifying the predicted box sizes of the K-means clustering algorithm in YOLOv3. Cao et al. [9] proposed a precision enhancement strategy for YOLOv4 based on multi-scale feature maps and made improvements in detecting small objects by enhancing the feature extraction network. However, this significantly increased the algorithm complexity, resulting in a significant decrease in real-time detection. Xue et al. [10] proposed an improved model based on YOLOv5s. To address the issue of capturing effective information from small-sized targets in long-distance forest fire images, transfer learning methods were used to enhance the accuracy of small-target forest fire smoke detection. However, this model has a complex structure, and the detection accuracy is not sufficient [11].

The aforementioned fire smoke detection algorithms have improved the accuracy of smoke detection to some extent. However, they still face the following difficulties in the early stages of actual fire scenarios: 1) high false negative rate for thin smoke with a slow initial spread in fires; 2) difficulty in detecting small smoke targets captured from long distances; 3) high complexity of model algorithms, making real-time detection challenging.

To address these issues, this paper proposes a YOLOv7tiny lightweight improved network based on smoke concentration features, which significantly enhances the original network for complex smoke detection scenarios. The algorithm mainly includes 1) Extracting smoke concentration features based on the atmospheric transmission principle to enhance smoke characteristics and improve the detection capability for thin smoke; 2) Using a weighted bidirectional feature fusion structure to replace the original PAN+FPN feature fusion method, enhancing the algorithm’s ability to detect small smoke targets; 3) Replacing the regular convolutions in the original network with depthwise separable convolutions with fewer parameters. The main contributions of this paper are:

1) Extracting smoke image concentration features based on the dark channel prior theory and enhancing the original RGB image to an  $\alpha$ RGB image with smoke concentration features as the network input have been proven to enhance the detection capability of early-stage fires with thin smoke through experiments.

2) Proposing a lightweight feature fusion structure (light-BiFPN) to enhance the detection of small smoke targets in the YOLOv7tiny network and reduce the false negative rate of small smoke targets.

3) Replacing the standard convolutions of the original algorithm with depthwise separable convolutions, and experimental results show a significant reduction in parameters with minimal impact on accuracy.

Finally, the superiority of the proposed improvement algorithm was confirmed by analyzing the experimental results.

4) A dataset was created for detecting smoke objects in

outdoor real-world scenes. The dataset comprises 1671 smoke images with corresponding labels indicating the position of the smoke bounding boxes. This dataset holds immense significance for researching the detection of smoke in the initial phases of actual fire scenarios.

## II. BACKGROUND

The YOLOv7 algorithm is a novel object detection algorithm introduced by the original development team of YOLOv4 in July 2022. Compared to previous versions of the YOLO series, this algorithm enhances the learning capability of the network through the use of the C5 module in the aggregation network. Additionally, it introduces attention mechanisms in the backbone feature extraction network to optimize the representation of target features, thereby achieving real-time detection. However, this algorithm has a relatively lower average precision. To achieve high-precision fire smoke detection in complex outdoor environments while reducing the number of algorithm parameters and improving detection speed, this study proposes improvements to the YOLOv7tiny algorithm. The improved algorithm includes the incorporation of a smoke concentration feature extraction structure and the use of a more lightweight multi-scale feature fusion network and optimized depthwise separable convolutions. With these enhancements, the algorithm can adapt to complex scenarios and achieve good real-time detection capability.

YOLOv7tiny is a deep learning-based object detection model composed of four parts: Input, Backbone, Neck, and Head. Fig. 1 shows the diagram of the YOLOv7tiny model. The Input part applies random mosaic data augmentation and K-means clustering to optimize the model training by designing anchor boxes for preprocessing the input images.

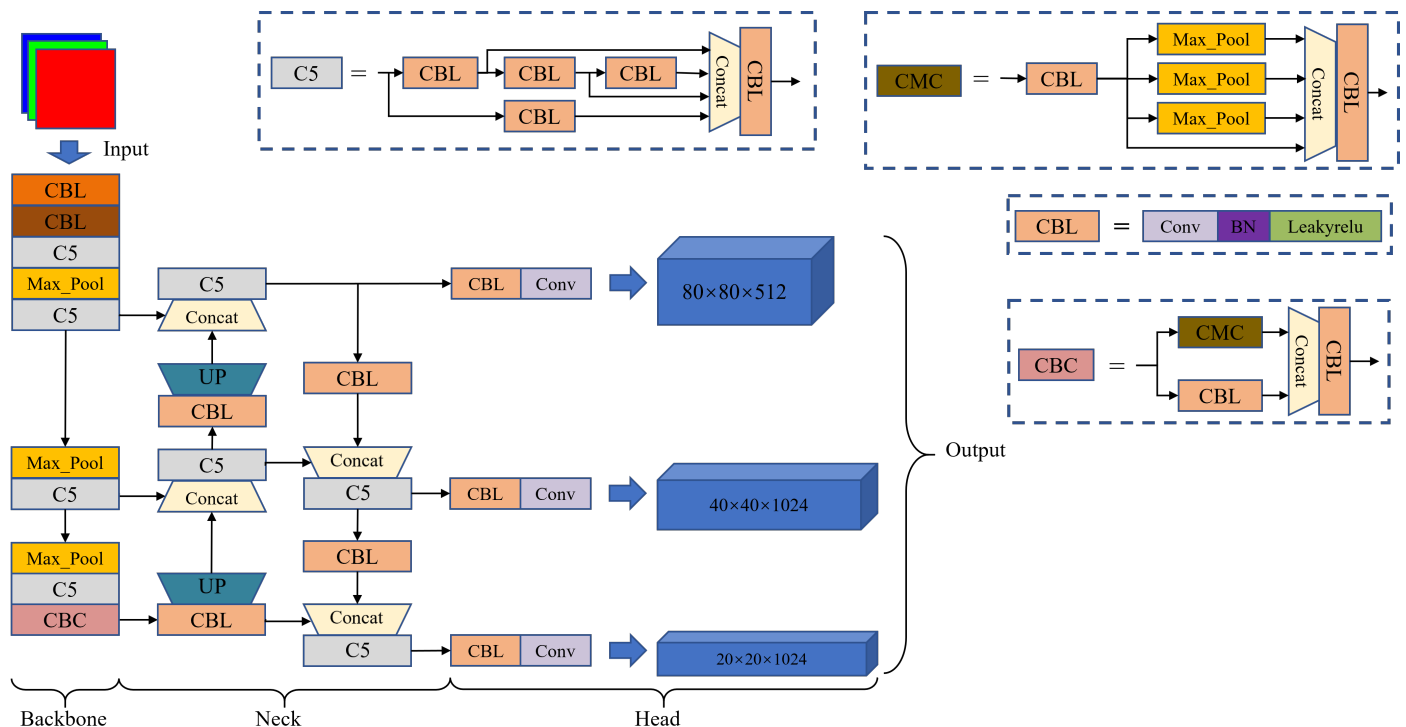

Fig. 1. The general architecture of the YOLOv7tiny network.

The Backbone part consists of multiple CBL modules, a C5 layer, and an MP layer. The CBL module is composed of a Convolution layer, a Batch Normalization layer, and a Leaky ReLU function. The C5 layer is formed by concatenating multiple CBL modules, and the MP layer includes CBL modules and Maxpool. The Neck part employs a feature fusion network, which adopts the YOLOv5 series Path Aggregation Feature Pyramid Network (PAFPN) architecture and combines Feature Pyramid Networks (FPN) [12] and Path Aggregation Networks (PAN) [13] to achieve multi-scale learning and retain small object features before downsampling. However, tensor concatenation for feature fusion lacks comprehensive integration of adjacent layer information, and nearest-neighbor interpolation for upsampling cannot effectively balance speed and accuracy in smoke detection tasks. The fusion network does not adequately focus on small object feature information, which can result in feature loss. The Head part uses a detection head similar to the YOLOR model, introducing the Implicit representation strategy [14] to refine the predictions. Based on the fused feature values, the images are classified into large, medium, and small categories, with the small image prediction branch primarily focusing on small defect objects. However, the detection head's use of IDetect to connect ordinary convolution prevents the fusion results from emphasizing the intended targets. Additionally, the detection head lacks targeted strategies to enhance small object detection performance.

### III. PROPOSED METHOD

#### A. Smoke Concentration Feature Extraction Based on Dark Channel

Smoke concentration is a characteristic of smoke that directly reflects the content of smoke in the air per unit volume. In images, smoke concentration is closely related to the transmittance of the smoke image.

$$\alpha = 1 - t \quad (1)$$

Generally, the larger the smoke concentration ( $\alpha$ ), the smaller the transmittance of the image ( $t$ ). The transmittance can be described by the smoke diffusion equation, which is a commonly used mathematical model for describing smoke concentration. Its form is as follows:

$$I = J \times t + A \times (1 - t) \quad (2)$$

Here,  $I$  represents the original foggy image,  $J$  represents the clear image after defogging,  $t$  represents the image transmission rate, and  $A$  represents the atmospheric light intensity. The dark channel prior theory [15] is a commonly used image defogging algorithm. It is based on the fog equation in Eq. (2) and analyzes the dark channel of the image to extract the transmission rate of the foggy image, thereby achieving image-defogging. The formula for the dark channel prior theory is as follows:

$$\min_{\Omega} \left( \min_C \frac{I^C}{A^C} \right) = \left\{ \min_{\Omega} \left( \min_C \frac{J^C}{A^C} \right) \right\} t + 1 - t \quad (3)$$

In the equation,  $I^C$  represents the RGB channels of the original foggy image, and  $J^C$  represents the clear and fog-free image. Through the analysis conducted by He et al. [15], it has been

revealed that the majority of images in real outdoor fog-free scenes have a significant amount of dark channels with very low pixel values, i.e.,  $\min_{\Omega} \left( \min_C \frac{J^C}{A^C} \right) \rightarrow 0$ . Therefore, after simplifying Equation (3), we can proceed with the processing:

$$t = 1 - \min_{\Omega} \left( \min_C \frac{I^C}{A^C} \right) \quad (4)$$

In the equation,  $\Omega$  represents the sliding window size. First, the brightest region is searched in the dark channel image, and then the brightness of the corresponding region in the original image is taken as the atmospheric light intensity ( $A^C$ ). As a result, the transmission rate of the foggy image ( $t$ ) can be calculated.

Fig. 2. Smoke image and corresponding transmittance grayscale image.

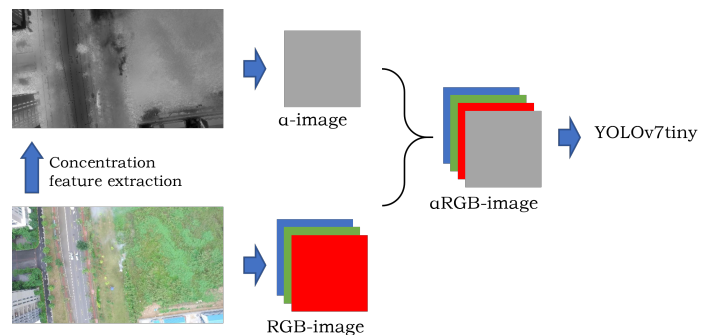

Fig. 3. Extraction of concentration features.

Mo et al. [16] extracted smoke transmittance based on the smoke aerosol equation and measured smoke concentration under different lighting conditions. The experiments demonstrated that using smoke transmittance for estimating smoke

concentration is feasible and accurate. According to Eq. (4), the transmittance of smoke images can be calculated pixel by pixel. Mapping the transmittance of smoke to a grayscale image allows for a visual representation of the transmittance map as shown in Fig. 2 (bottom).

The transmittance grayscale image exhibits dark areas that indicate low transmittance, suggesting a blockage of light, similar to smoke particles. Consequently, the smoke transmittance image is combined with the RGB image of the smoke, creating a four-dimensional vector as the input for the network model. This merged  $\alpha$ RGB image, as depicted in Fig. 3, retains the original image's shape, color, and texture, while also reflecting the inherent concentration features of the smoke.

### B. Improved Feature Fusion Network

Fig. 4 shows the PAN, BiFPN, and light-BiFPN feature fusion structures. In object detection tasks, feature fusion plays a crucial role in enhancing model accuracy. Traditional feature fusion methods focus on top-down and bottom-up feature propagation processes, with the PAN structure (Fig. 4(a)) being the most representative method [13]. By cascading, the PAN structure merges feature information from different levels and scales to expand the model's receptive field and improve detection accuracy. Its main advantage lies in effectively leveraging information from features of various scales to obtain a richer and more accurate representation.

However, the PAN structure does have some deficiencies when dealing with small objects, which can be manifested in the following two aspects:

- 1) **Feature Information Loss:** When merging feature information from different levels and scales, the PAN structure is prone to information loss, especially impacting the detection performance of small objects.
- 2) **Unstable Fusion Effects:** The cascading approach utilized in the PAN structure tends to encounter problems like gradient vanishing or explosion, leading to unstable feature fusion effects.

To address these issues, this study replaces the original PAN structure with the light-BiFPN (Bidirectional Feature Pyramid Network) [17]. The BiFPN structure [Fig. 4(b)] introduces lateral connections during the top-down and bottom-up fusion processes, effectively enhancing the exchange and transmission of feature information, particularly improving the detection performance of small targets.

The BiFPN structure is composed of multiple cascaded BiFPN modules. Each module comprises two feature propagation paths (top-down and bottom-up) and lateral connection paths. During the feature propagation process, the BiFPN module adopts a multi-level feature fusion approach to combine features from multiple sizes. These fused features are then passed to the subsequent module until the final module outputs the ultimate feature map. The lateral connection paths employ learnable weights to facilitate effective feature fusion between different layers. The weights of lateral connections are obtained through convolutional operations. Assuming the input feature map is  $x_i$ , the weights of lateral connections  $w_{ij}$  can be denoted as:

$$w_{ij} = ReLU(W_{ij}[x_i, x_j]) \quad (5)$$

Here,  $W_{ij}$  represents a learnable weight matrix, and  $[x_i, x_j]$  signifies the concatenation of feature maps  $x_i$  and  $x_j$ .

Compared to the PAN structure, the BiFPN structure better preserves detailed information of small targets, thereby improving the accuracy and robustness of object detection. Additionally, due to the scalability of the BiFPN structure, different numbers of modules and structural parameters can be chosen according to the specific scenario to achieve optimal detection performance. The light-BiFPN used in this study [Fig. 4(c)] reduces the feature layers P6 and P7 to reduce model parameters and optimize model speed.

### C. Depthwise Separable Convolution

In object detection algorithms, convolutional neural networks (CNN) are commonly employed as backbone networks to extract image features. Standard convolution serves as

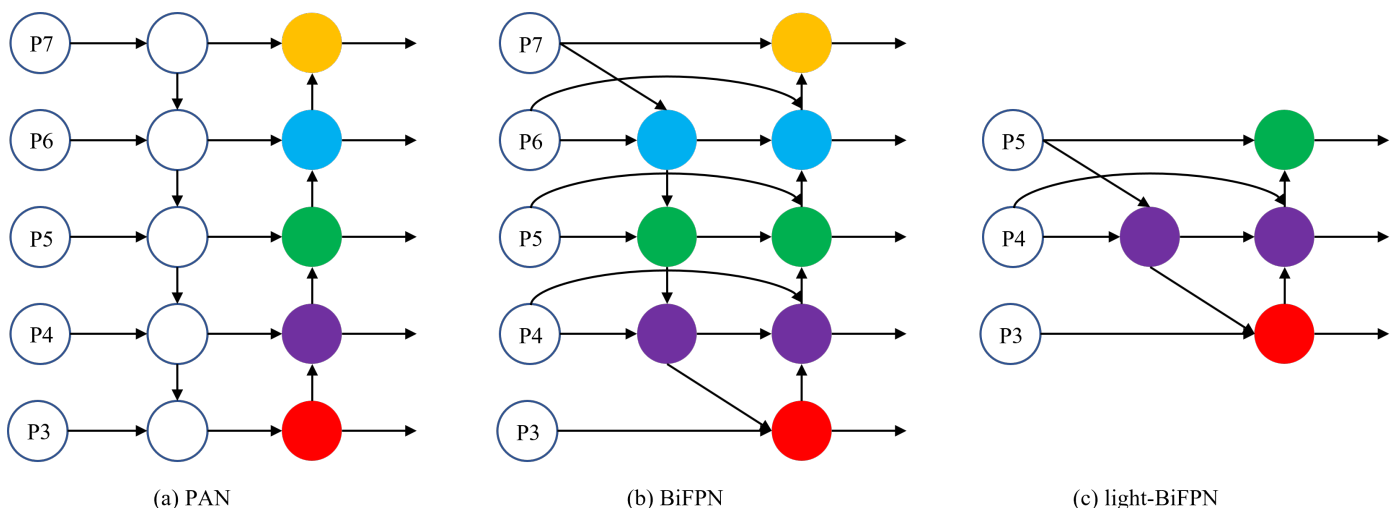

Fig. 4. PAN, BiFPN, and light-BiFPN feature fusion structures.

one of the most prevalent CNN modules, extracting features by conducting convolution operations on input feature maps and convolution kernels. However, when dealing with large-scale feature maps, standard convolution leads to significantly increased computational and memory consumption, restricting the depth and complexity of the model.

To address this issue, this paper adopts Depthwise Separable Convolution (DSC) [18] as a replacement for standard convolution in the backbone network. Depthwise Separable Convolution decomposes the standard convolution into depthwise convolution and pointwise convolution, performing convolution operations on each channel and each pixel of the input feature map, respectively. This approach considerably reduces the number of parameters and computations while ensuring the accuracy and efficiency of the model.

Depthwise Separable Convolution can be represented by the following formula:

$$Y = PW(DW(X)) \quad (6)$$

Where  $X$  represents the input feature map,  $DW$  represents the depth convolution operation,  $PW$  represents the pointwise convolution operation, and  $W$  represents the parameters of the convolutional kernel. The depth convolution operation and the pointwise convolution operation correspond to two independent convolutional layers, with parameter quantities of  $D_k$  and  $D_k \times D_o$ , respectively. Here,  $D_k$  represents the number of channels in the input feature map,  $K$  represents the size of the convolutional kernel, and  $D_o$  represents the number of channels in the output feature map. Compared to standard convolution, depthwise separable convolution reduces the parameter and computational requirements by  $K^2$  and  $D_k$  times, respectively.

#### IV. EXPERIMENTAL AND RESULT ANALYSIS

To test the effectiveness of the improved algorithm, training and testing were conducted on a self-made dataset. The optimization effects of various improvements were analyzed through horizontal comparative experiments and vertical ablation experiments.

Fig. 5. Sample images from a self-made fire smoke detection dataset.

Fig. 6. Example of image annotation.

### A. Dataset and Preprocessing

Currently, there is a limited availability of publicly accessible outdoor real fire smoke datasets. In this study, 3604 unlabeled smoke images were collected from publicly available smoke image datasets, as shown in Fig. 5. After removing low-quality images, 1671 smoke images were selected and manually annotated using the Labellmg tool to create a self-made smoke detection dataset in Pascal VOC2007 format. Fig. 6 demonstrates the smoke targets and their corresponding XML information. The dataset was split as follows:

$$(TrainingSet + ValidationSet) : TestSet = 9 : 1$$

$$TrainingSet : ValidationSet = 9 : 1$$

The training set, validation set, and test set consist of 1352, 151, and 168 images, respectively.

In the data preprocessing stage of this experiment, in addition to using traditional image processing techniques such as image flipping and HSV color space enhancement, random mosaic, and mixup image processing techniques [19] were also applied to randomly augment the dataset, aiming to enhance the robustness of the model.

The random mosaic technique combines multiple images into a new image to enhance the diversity of the dataset, while the mixup technique linearly blends two different images to generate a new image. Both data augmentation techniques effectively increase the sample size of the dataset, improving the model's generalization ability and further enhancing the accuracy of smoke object detection.

### B. Experimental Environment and Parameter Settings

#### 1) Hardware and software Environment

The experimental hardware environment of this article is shown in Table I.

TABLE I. EXPERIMENTAL ENVIRONMENT

CPU	AMD EPYC 7773X @ 3.50GHz
GPU	GeForce RTX 3090
RAM	30G
Operating System	Ubuntu
Programming Language	Python 3.8
Deep Learning Framework	PyTorch 1.8
GPU Acceleration Library	CUDA 11.1

#### 2) Training Hyperparameters Settings

The experimental hyperparameter settings of this article are shown in Table II.

TABLE II. TRAINING HYPERPARAMETERS SETTINGS

Hyperparameter	Value
Mosaic Probability	0.5
Mixup Probability	0.5
Maximum Learning Rate	0.01
Minimum Learning Rate	0.0001
Epoch	300

During the training process, the VOC pre-trained weights of YOLOv7tiny were utilized. The first 50 epochs comprised

of frozen training, where only the Neck and Head parts' parameters were trained while the backbone feature extraction network remained frozen. From epoch 51 to 300, the unfrozen training stage occurred, and the entire network was trained. The batch size was set to 64 during the frozen training stage, and it was reduced to 32 during the unfrozen training stage to accommodate the increase in training parameters. The cosine learning rate decay method was employed to progressively decrease the learning rate from 0.01 to 0.0001. The stochastic gradient descent method with a momentum of 0.937 was chosen as the parameter optimizer. Additionally, a weight decay coefficient of  $5e-4$  was implemented to prevent overfitting during the training process.

### C. Evaluation Metrics

To evaluate the performance of the improved algorithm, this study uses four metrics for algorithm assessment: Recall, mean Average Precision (mAP), Frames Per Second (FPS), and model parameter count (Params).

1) *Recall*: Recall measures the detection rate of a model for all true positive samples. In smoke object detection tasks, the calculation formula for Recall is as follows:

$$Recall = \frac{TP}{TP + FN} \quad (7)$$

Where  $TP$  represents true positive, referring to the number of positive samples correctly detected by the model, while  $FN$  represents false negative, indicating the number of positive samples that the model fails to detect. Recall is utilized in this paper as one of the evaluation metrics to assess the detection capability of the algorithm.

2) *mAP*: mAP stands for mean Average Precision, which measures the average precision of a model at different confidence thresholds. In smoke object detection tasks, the formula to calculate mAP is as follows:

$$mAP = \frac{1}{n} \sum_{i=1}^n AP_i \quad (8)$$

Where  $n$  represents the number of classes, and  $AP_i$  represents the average precision of the  $i$ th class. In this paper, since only smoke is involved as the target, mAP can be considered as AP, used to evaluate the detection accuracy of the algorithm.

3) *FPS*: FPS stands for Frames Per Second, which measures the number of frames processed by a model per unit of time. In the smoke detection task, the calculation formula for FPS is as follows:

$$FPS = \frac{1}{t} \quad (9)$$

In this case,  $t$  represents the average time for processing a frame image. This paper utilizes Frames Per Second (FPS) as one of the evaluation metrics to assess the detection speed of the algorithm.

4) *Params*: The model parameter count refers to the number of trainable parameters in the model, which is an important indicator for evaluating model complexity. In the task of smoke object detection, the calculation formula for model parameter count is given by Eq. 10.

$$N = \sum_{i=1}^n (w_i h_i c_i k_i^2 + b_i) \quad (10)$$

TABLE III. ABLATION EXPERIMENT RESULTS

Experimental Number	Improvement			Evaluation Metric			
	$\alpha$ RGB	Light-BiFPN	DSC	Recall	mAP@0.5	FPS	Params(M)
1	✗	✗	✗	88.21%	89.48%	106.65	6.23
2	✓	✗	✗	91.12%	92.33%	95.40	6.23
3	✗	✓	✗	91.99%	91.54%	94.46	6.31
4	✗	✗	✓	86.63%	87.80%	<b>124.68</b>	<b>4.82</b>
5	✓	✓	✓	<b>95.62%</b>	<b>94.03%</b>	118.78	4.97

Here,  $n$  represents the number of layers in the model.  $w_i$ ,  $h_i$ , and  $c_i$  represent the width, height, and number of channels of layer  $i$ , respectively.  $k_i$  represents the size of the convolutional kernel in layer  $i$ , and  $b_i$  represents the bias term in layer  $i$ . In this study, the model complexity is evaluated based on the number of model parameters.

#### D. Ablation Experiment

To validate the benefits of each improvement point on the network model, five ablation experiments were conducted. The experimental environment and parameter settings were kept consistent. The results of the ablation experiments are shown in Table III.

1) The first set of experiments is conducted using the YOLOv7tiny algorithm, serving as a comparative benchmark for the subsequent improvement experiments.

2) The second group of experiments is a control experiment with the inclusion of smoke concentration features. By introducing smoke concentration features, the computational burden of the model increases, resulting in a decrease in the detection frame rate. However, it achieved good performance in terms of Recall and mAP, with improvements of 2.91 and 2.85 percentage points, respectively.

3) By analyzing the experimental data of the first and third groups, it is concluded that the light-BiFPN structure increases the number of model parameters due to the addition of skip connections, which leads to a decrease in the detection frame rate. However, it demonstrates good performance in terms of accuracy and recall rate, with improvements of 3.78 and 2.06 percentage points, respectively.

4) The fourth set of experiments replaced the standard convolution in the original YOLOv7tiny network model with depthwise separable convolution (DSC). Analyzing the experimental data compared to the baseline network reveals that DSC can significantly reduce the number of parameters and improve the detection frame rate. However, the reduced number of parameters limits the expressive power of the model.

5) In the fifth experiment, the improved YOLOv7tiny network based on smoke concentration features proposed in this paper is evaluated. From the experimental data, it can be observed that compared to the baseline network, the Recall and mAP have improved by 7.41 and 4.55 percentage points, respectively. The FPS has improved by 12.13 frames/s, and the number of parameters has decreased from 6.23M to 4.97M. Therefore, it can be concluded that the algorithm proposed in this paper is lighter and more accurate.

#### E. Comparative Experiment

To investigate the performance of the improved network in detecting different targets, this study conducted three sets of comparative experiments on a self-made dataset: comprehensive comparison experiment, smoke concentration comparison experiment, and multi-scale target comparison experiment. To comprehensively assess the performance of the algorithm, mainstream object detection models were selected as the comparison models, including RetinaNet [20], CenterNet [21], EfficientDet [22], Faster R-CNN [23], SSD [24], and YOLOv5s [25].

1) *Comprehensive comparative experiment:* A comprehensive comparative experiment was conducted by training six mainstream detection algorithms on a self-made dataset for 300 epochs as comparison algorithms to the proposed algorithm in this paper. From the variations of mAP@0.5 of each algorithm during the training process (shown in Fig. 7), it can be observed that, apart from the proposed algorithm, Faster R-CNN and YOLOv5s performed remarkably well on this dataset. Both the proposed algorithm and Faster R-CNN converged quickly (basically converged at 50 epochs). The proposed algorithm achieved an mAP of 94.03% after final convergence, surpassing other algorithms.

Fig. 7. mAP@0.5 Variation Graph of Each Algorithm during Training Process.

2) *Smoke Concentration Comparison Experiment:* The concentration features are extracted from the smoke images in the dataset. Then, the mean concentration of the smoke region can be obtained by calculating the average of the con-

centrations within the smoke bounding box. The distribution of smoke concentrations in this dataset is shown in Fig. 8.

Fig. 8. Histogram of Smoke Target Concentration Distribution.

In Fig. 8, the x-axis represents the smoke concentration, and the y-axis represents the number of smoke images corresponding to each concentration. In this experiment, the smoke concentration is divided into low concentration and high concentration. The low concentration is defined as below 0.5, and the high concentration is defined as 0.5 and above. The performance of the improved model and mainstream object detection models are compared on the low-concentration and high-concentration test image sets.

TABLE IV. EXPERIMENTAL RESULTS OF SMOKE CONCENTRATION COMPARISON

Compare Models	Low Concentration mAP(%)	High Concentration mAP(%)	Params (M)
RetinaNet	84.75%	88.01%	36.33
CenterNet	83.35%	87.64%	32.67
EfficientDet	82.56%	86.51%	<b>3.83</b>
Faster R-CNN	90.45%	93.67%	136.69
SSD	82.96%	87.26%	23.61
YOLOv5s	86.75%	90.43%	46.63
Ours	<b>93.27%</b>	<b>94.64%</b>	4.97

From Table IV, it can be observed that both the mainstream algorithm models and our proposed improved algorithm model achieve similar detection accuracy for high-concentration smoke. However, our improved algorithm model achieves a significant reduction in parameter size, down to 4.97M. This reduction is particularly important for deploying the model on edge devices. Ordinary algorithms struggle to distinguish low-concentration smoke due to its semi-transparent nature. In contrast, our improved algorithm achieves good performance on low-concentration smoke, thanks to the introduced  $\alpha$ RGB concentration feature.

3) *Multi-scale Object Comparison Experiment*: In the early stage of a fire, the smoke volume is usually small. However, the detection of smoke in the early stage is particularly important for firefighting. Therefore, a small object comparison

experiment is designed to test the performance of different algorithms in detecting smoke from small objects.

Using the K-means algorithm, a cluster analysis of the size of smoke targets in the dataset was performed. The average silhouette coefficient was found to be 1.74, and the center points corresponded to large, medium, and small targets with sizes of 33×23, 80×60, and 160×142, respectively. Fig. 9 shows the distribution of width and height for the three scales of smoke targets in the self-made dataset. The horizontal axis represents the width of the smoke target, and the vertical axis represents the height of the smoke target.

The scale analysis of 168 smoke images in the test set reveals that there are 36 large objects, 47 medium-sized objects, and 85 small objects. As shown in Fig. 10, it can be observed that small smoke objects occupy a significant portion. The detection results of various algorithm models on this test set are shown in Fig. 10.

From the multi-scale object comparison experimental results in Fig. 11, it can be seen that although CenterNet, EfficientDet, SSD, and YOLOv5s have higher mAP in detecting large and medium objects, they are slightly inferior in detecting small objects. RetinaNet and Faster R-CNN perform well in detecting objects of different scales, but overall, the mAP is relatively low. By using improved algorithms, especially the optimization of light-BiFPN, the detection accuracy of small objects is significantly improved, and they have higher mAP in object detection at various scales.

Fig. 9. Distribution of smoke objects in self-made dataset.

Fig. 10. Proportion of smoke objects at various scales in the test set.

Fig. 11. Multi-scale object comparison experimental results.

Based on the multi-scale object comparison experimental results shown in Fig. 11, it can be observed that CenterNet, EfficientDet, SSD, and YOLOv5s have higher mean Average Precision (mAP) in detecting large and medium objects. However, they are slightly inferior in detecting small objects. RetinaNet and Faster R-CNN perform well in detecting objects of different scales but have relatively low overall mAP. On the other hand, our improved algorithms, especially with the optimization of light-BiFPN, achieve significantly better detection accuracy for small objects and higher mAP in object detection at various scales.

#### F. Detection Performance Analysis

The YOLOv7tiny algorithm performs poorly in detecting sparse smoke due to its low concentration in the early stages of a fire. This is because sparse smoke appears semi-transparent, often leading to false alarms [Fig. 12(a), Fig. 12(b)], missed detections [Fig. 12(d)], and low detection accuracy [Fig. 12(c)]. However, after introducing the  $\alpha$ RGB feature, our algorithm significantly improves the detection capability of sparse smoke [Fig. 13(a-d)]. Nonetheless, due to the limited proportion of low-concentration smoke in the dataset, occasional cases may arise where the detected bounding boxes do not align with the actual ones [Fig. 13(f)]. By optimizing the light-BiFPN, our algorithm achieves more accurate detection of small targets [Fig. 13(d)] and performs closer to ideal in complex environments [Fig. 13(e)].

Fig. 12 shows the detection performance of the YOLOv7tiny algorithm, while Fig. 13 depicts the detection performance of our improved algorithm.

#### V. CONCLUSION

Fire and smoke detection plays a significant role in ensuring fire safety. By combining computer vision technology to accurately locate early-stage smoke in a fire, it serves as an important tool for fire warning and prevention of fire spread. To improve the detection of small and sparse smoke in the early stages of a fire, this study extracts features related to smoke concentration, improves feature fusion structures, and optimizes algorithm complexity. By comparing with other models on a self-made dataset, the recall rate reaches 95.62%, mAP reaches 94.03%, and the detection FPS is increased

to 118.78. The algorithm complexity is reduced to 4.97M. The experimental results demonstrate the superiority of the improved algorithm in detecting sparse smoke. In future work, the algorithm will be further optimized in two aspects: firstly, by increasing the proportion of sparse smoke in the dataset to enhance algorithm robustness; secondly, by attempting to enhance algorithm expression capability through attention mechanisms, thereby further improving detection accuracy.

**Abstract**—Cloud computing has gained prominence due to its potential for computational tasks, but the associated energy consumption and carbon emissions remain significant challenges. Allocating Virtual Machines (VMs) to Physical Machines (PMs) in cloud data centers, a known NP-hard problem, offers an avenue for enhancing energy efficiency. This paper presents an energy-conscious optimization approach utilizing the Giant Trevally Optimizer (GTO) which is inspired by the hunting strategies of the giant trevally, a proficient marine predator. Our study mathematically models the trevally's hunting behavior when targeting seabirds. The trevally's approach involves strategic selection of optimal hunting locations based on food availability, including pursuing seabird prey in the air or seizing it from the water's surface. Through extensive simulations, our method demonstrates superior performance in terms of skewness, CPU utilization, memory utilization, and overall resource allocation efficiency. This research offers a promising avenue for addressing the energy consumption challenges in cloud data centers while optimizing resource utilization for sustainable and cost-effective cloud operations.

**Keywords**—Cloud computing; resource allocation; virtualization; Giant Trevally Optimizer

## I. INTRODUCTION

The flexibility of cloud computing enables the provision of infrastructure, platforms, and software services. It has gained increasing popularity in private and public institutions due to its pay-per-use pricing scheme [1]. Cloud computing offers numerous advantages, such as scalability, flexibility, and cost efficiency. However, one pressing issue associated with cloud computing is its significant energy consumption [2]. Cloud data centers, which host the infrastructure and servers powering the services, consume a substantial amount of energy to handle computing tasks and store vast amounts of data. This energy-intensive operation contributes to environmental concerns, including carbon emissions and strain on power grids [3, 4]. To mitigate this problem, efforts are underway to develop energy-efficient practices such as server consolidation, virtualization, and green data center designs. By addressing the energy consumption challenge, cloud computing can become more sustainable and cost-effective while minimizing environmental impact [5]. According to the 2020, state of the data center report, data centers exhibit rack densities of 8.2 kW, with the potential to achieve 43 kW per rack through the implementation of effective water-cooling methods [6]. In the United States alone, data centers consume an estimated 140 billion kWh of energy annually [7]. In contrast, the global energy consumption of data centers is projected to range from

200 TWh to 500 TWh [8], accounting for approximately 1% of global electricity consumption. Predictions from [9] indicate that by 2030, data centers are expected to consume 3-13% of the world's electricity [10].

The convergence of Internet of Things (IoT), smart grids, meta-heuristic algorithms, machine learning, Artificial Intelligence (AI), association rule mining, and urban public transportation plays a pivotal role in revolutionizing the landscape of cloud computing. IoT sensors and devices generate an unprecedented volume of data, which smart grids harness to optimize energy distribution [11-13]. Meta-heuristic algorithms are essential for efficiently allocating resources in cloud data centers to manage this influx of data [14, 15]. Machine learning and AI algorithms analyze this data, predicting energy demands and enabling proactive resource allocation in cloud infrastructure [16-18]. Additionally, association rule mining identifies patterns and correlations within IoT-generated data, aiding in predictive maintenance and energy optimization [19]. Urban public transportation systems leverage IoT for real-time data collection and route optimization. Cloud computing serves as the backbone for processing, analyzing, and delivering information to commuters and traffic management systems, enhancing urban mobility [20].

Inefficient utilization of computing resources in cloud data centers is a significant concern that leads to excessive energy consumption. Despite the growing demand for cloud services, many data centers operate at low resource utilization levels, with an average utilization of less than 30%. This inefficiency leads to a significant amount of energy being consumed by idle nodes, accounting for more than 70% of the peak energy consumption [21]. This wastage of energy results in increased ownership costs and reduced returns on investments in cloud infrastructure. Cloud service providers increasingly recognize the importance of enhancing energy efficiency in their data centers. They are actively seeking strategies to optimize resource utilization and minimize energy wastage in order to meet the growing demand for sustainable operations. By implementing energy-efficient practices and optimizing resource allocation, they aim to achieve a more sustainable and cost-effective operation while meeting the increasing demands of cloud services [22].

This paper introduces a novel strategy for cloud computing resource allocation based on the Giant Trevally Optimizer (GTO). By adopting a cloud-based model, data can be processed, recorded, and retrieved simultaneously, ensuring efficient resource allocation. This approach optimizes resource

allocation by considering the user's request while maintaining system performance. Task assignment to virtual machines (VMs) is primarily determined by factors such as cost, deadline, and runtime. The structure of the paper is outlined as follows: Section II offers a detailed review of existing cloud resource allocation techniques. Section III elaborates on the proposed algorithm, providing details on its methodology. Section IV presents the experimental results obtained by implementing the algorithm. Finally, Section V provides a comprehensive summary of the paper and offers suggestions for future research directions in the field of cloud resource allocation.

## II. RELATED WORK

Hanini, et al. [23] introduced a novel approach that combines a virtual machine utilization scheme with a mechanism to regulate access to the virtual machine monitor for incoming requests. The number of active virtual machines is determined based on the workload, while the access control is determined by the number of requests. A mathematical model is utilized to describe the studied process and parameter values, and a power consumption model is developed and assessed. The evaluation of the proposed mechanism includes the use of numerical data to assess the quality of service (QoS) parameters. Additionally, the impact of the method on energy consumption behavior is thoroughly analyzed. The results of this analysis indicate a positive and beneficial influence of the proposed mechanism. Cloud computing brings forth various valuable services but also introduces security concerns related to user information privacy and the optimization of virtual machine allocation to enhance resource utilization. Dubey and Sharma [24] aim to address these challenges by developing a secure VM allocation algorithm based on an extended version of the Intelligent Water Drop (IWD) algorithm, which leverages natural phenomena. The implementation of their proposed algorithm was conducted using the CloudSim simulation toolkit. To evaluate its effectiveness, a comparison was performed against established VM allocation policies in the field of cloud computing. The experimental results from the simulations demonstrated that the proposed VM allocation policy outperformed existing approaches.

Samriya, et al. [25] have introduced a novel algorithm called the multi-objective Emperor Penguin Optimization (EPO) algorithm to optimize the allocation of virtual machines in a heterogeneous cloud environment, focusing on resource utilization. The proposed approach incorporates elements from the Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), and Binary Gravity Search (BGS) algorithms to ensure its suitability for virtual machines in data centers. A comprehensive evaluation of the proposed system was conducted using a JAVA simulation platform, which demonstrated its energy efficiency and significant advantages compared to other strategies. The results revealed that the EPO-based system effectively reduces energy consumption, minimizes SLA violations, and enhances QoS requirements, thereby providing a capable cloud service.

Devi and Kumar [26] have introduced a new VM allocation approach that effectively addresses SLA violation concerns and optimally allocates VMs to the most suitable hosts using the

Improved Grey Wolf Optimization (IGWO) algorithm. It considers various host characteristics, including CPU utilization and power consumption, to determine the most appropriate hosts for VM allocation. Additionally, the host's unused CPU and RAM resources are evaluated to maximize resource utilization. The experimental evaluation involved a random dataset with different virtual machines, and the proposed method was evaluated in comparison with existing methods such as ACO and Power-Aware Best Fit Decreasing (PABFD). The results demonstrate that the approach significantly minimizes the number of VM migrations, reduces SLA violations, and improves energy consumption. Consequently, the proposed VM allocation method promotes a green computing environment by consuming less power and maintaining a higher level of SLA compliance.

Xing, et al. [27] have formulated a VM allocation problem that aims to minimize the network bandwidth resources consumed by VMs and the total amount of power consumed by Physical Machines (PMs). To tackle this challenge, they propose the energy- and traffic-aware ACO (ETA-ACO) algorithm, which incorporates three innovative strategies for improved performance. The first strategy involves a two-step PM selection process that prioritizes PMs with lower power consumption and selects PMs that consume the least bandwidth. In the second strategy, VMs are arranged in descending order according to traffic demand. The third strategy generates a new solution by distributing components of optimal solutions across multiple solutions. Simulation outcomes validate the effectiveness of these three strategies in adapting ETA-ACO to the VM allocation problem. Addressing the challenging and critical issue of VM allocation for highly reliable cloud applications, Sheeba and Uma Maheswari [28] propose an improved Firefly algorithm-based approach. A K-means clustering algorithm is used to reduce migration time. Moreover, for optimal cluster selection in VM placement, adaptive PSO with the coyote optimization algorithm is applied. The suggested method is evaluated by examining the number of VMs, packet size, execution time, and transmission overhead. Under different constraints, the proposed method achieves improved performance and an optimal virtual machine placement scheme.

We have selected GTO as the basis for our research into VM allocation within cloud computing environments due to its unique and promising attributes that set it apart from other optimization algorithms. GTO draws inspiration from the hunting tactics of the giant trevally, a natural predator known for its exceptional hunting prowess in targeting seabirds and other prey. This distinctive approach to optimization allows us to model the allocation of VMs with a fresh perspective. The key benefits of GTO lie in its ability to effectively navigate complex optimization spaces, adapt to dynamic resource allocation scenarios, and converge towards superior solutions. Unlike conventional algorithms, GTO excels in its capacity to strategically select the optimal allocation locations for VMs based on factors such as food availability, mirroring the trevally's hunting strategy. Furthermore, GTO dynamically adapts to its pursuit, seizing opportunities whether they arise in the air or near the water's surface, mirroring the trevally's agile tactics. This adaptability makes it exceptionally well-suited to

the inherently dynamic and multifaceted challenges of VM allocation in cloud data centers. Moreover, GTO offers the advantage of enhanced exploration and exploitation capabilities, striking a delicate balance between exploiting known promising solutions and exploring new allocation possibilities.

### III. ENERGY-AWARE VM ALLOCATION APPROACH

A virtualization strategy based on the GTO is discussed in this section. Resource allocation in cloud environments depends on the architecture of the system, which allows different methods of access to the resources. Datacenter infrastructure can be provisioned by using a variety of methods and schemes. Fig. 1 illustrates the suggested architecture for

energy-efficient resource allocation, comprising three fundamental elements: service providers, users, and data center resource management. Users submit their requests to the cloud service provider first, and then the broker returns a response based on the user's requirements, the date line, and the operation of the resource services. The Cloud Information System (CIS) resource manager reviews the broker's request as soon as it reaches the data center, assesses its suitability, and makes the appropriate decision. Requests are accepted by CIS based on the availability of the system and are passed on to the allocation scheme to determine the global optimal solution. GTO is responsible for the initial placement of VMs as well as monitoring the solution.

Fig. 1. Resource allocation model.

#### A. Giant Trevally Optimizer

GTO draws inspiration from nature, mimicking the behavior and strategies of giant trevallies in their pursuit of seabirds. The giant trevally belongs to the Jack family of marine predators. It is also known as the giant kingfish. The giant trevally, known as a dominant predator in its habitats, employs sophisticated hunting techniques that demonstrate its intelligence and adaptability. The giant trevally exhibits a hunting behavior that can be observed both in solitary individuals and in coordinated group efforts. It is most effective for predators to capture schooled prey when they are grouped. In a group or school, the leader, or first predator, is the most effective at capturing prey. When hunting, the giant trevally employs a remarkable strategy where it launches itself out of the water to surprise and capture its prey, often targeting seabirds.

Similarly, to other population-based meta-heuristic algorithms, GTO generates random initialization solutions termed giant trevallies. A potential or candidate solution to an optimization problem is represented by each giant trevally. These vectors, seen from a mathematical perspective as members of a population, make up the algorithm's population

matrix [29]. Eq. (1) is used to model the GTO population members.

$$X = \begin{bmatrix} X_1 \\ \vdots \\ X_i \\ \vdots \\ X_N \end{bmatrix} = \begin{bmatrix} x_{1,1} & \dots & x_{1,j} & \dots & x_{1,Dim} \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ x_{i,1} & \dots & x_{i,j} & \dots & x_{i,Dim} \\ \vdots & \ddots & \vdots & \ddots & \vdots \\ x_{N,1} & \dots & x_{N,j} & \dots & x_{N,Dim} \end{bmatrix} N \times Dim \quad (1)$$

where,  $X_i$  represents the  $i^{th}$  candidate solution of GTO,  $N$  denotes the number of GTO members,  $Dim$  denotes the number of decision parameters and  $x_{i,j}$  indicates the value of the  $j^{th}$  variable provided by the  $i^{th}$  candidate solution. When the population's size and dimensions are determined, they will not change during the experiment. Eq. (1), as originally presented, continues to serve as the foundational model for representing the GTO population members. It encapsulates the critical elements of the algorithm, wherein each giant trevally, symbolizing a potential solution, contributes to the algorithm's population matrix. Eq. (1) remains constant and integral throughout the GTO process. Every trevally in the solution space of the problem is assigned a random position prior to its operation. All feasible regions must be covered by this random assignment in the  $N \times Dim$  search space, as indicated in Eq. (2).

$$X_{i,j} = Minimum_j + (Maximum_j - Minimum_j) \times R \quad (2)$$

where,  $R$  represents a random number between 0 and 1,  $Minimum_j$  and  $Maximum_j$  indicate the limits of the described problem for the  $j^{th}$  dimension, i.e., the minimum and maximum values of population members. Each member of the GTO population is a potential solution to the VM allocation problem. Consequently, each candidate solution can be evaluated in terms of its objective function. In accordance with Eq. (3), these values are represented by a vector:

$$F = \begin{bmatrix} F_1 \\ \vdots \\ F_i \\ \vdots \\ F_N \end{bmatrix} = \begin{bmatrix} F(X_1) \\ \vdots \\ F(X_i) \\ \vdots \\ F(X_N) \end{bmatrix} N \times 1 \quad (3)$$

where,  $F_i$  refers to the  $i^{th}$  member's value of the objective function, as well as  $F$  represents the vector that contains these values.

The GTO algorithm simulates the giant trevallies' behavior while hunting for seabirds. To calculate the optimal optimization procedure of the suggested GTO algorithm, three steps are required: extensive search using Levy flight, choosing the hunting area, as well as jumping out of the water to chase and attack prey. The first and second steps represent the exploration phase of the GTO, as well as the third one represents the GTO's exploitation phase. Due to their nature, giant trevallies can travel long distances in search of food. Therefore, Eq. (4) is used in this step to simulate the foraging movements of giant trevallies.

$$X(t+1) = Best_p \times R + ((Maximum - Minimum) \times R + Minimum) \times Levy(Dim) \quad (4)$$

where  $X(t+1)$  denotes the position vector of the next-iteration giant trevally,  $Best_p$  signifies giant trevallies' current search space determined by their best position,  $R$  refers to a random number ranging from 0 to 1,  $Levy(Dim)$  stands for the Levy flight, a non-Gaussian stochastic process whose step sizes follow the Levy distribution. The algorithm is able to perform a global search due to its occasional large steps. Moreover, the levy flight increases the diversity of the population, prevents premature convergence, and enhances the ability to jump out of local optimal solutions. The recent literature has demonstrated that many animals, including marine predators, exhibit the behavior of Levy flight. Eq. (5) is used to calculate the levy (Dim).

$$Levy(Dim) = step \times \frac{u \times \sigma}{|v|^{1/\beta}} \quad (5)$$

where  $step$  refers to the step size, set to 0.01 in this case,  $\beta$  represents the Levy flight distribution index, a variable ranging from 0 to 2, set to 1.5 in this study,  $u$  as well as  $v$  correspond to random numbers normally was distributed between 0 and 1.  $\sigma$  is derived from Eq. (6).

$$\sigma = \left( \frac{\Gamma(1+\beta) \times \sin(\frac{\pi\beta}{2})}{\Gamma(\frac{1+\beta}{2}) \times \beta \times 2^{(\frac{\beta-1}{2})}} \right) \quad (6)$$

Giant trevallies determine and choose the best hunting area based on the number of food (seabirds) present in the chosen search space. This behavior is mathematically simulated by Eq. (7).

$$X(t+1) = Best_p \times A \times R + Mean_{Info} - Xi(t) \times R \quad (7)$$

where  $A$  refers to a parameter that controls position change in the range of 0.3 and 0.4,  $Xi(t)$  indicates the location of the  $i^{th}$  giant trevally in a given frame of time  $t$  (at the present iteration).  $Mean\_Info$  confirms that all of the information from the previous points has been utilized by these giant trevallies and is determined by Eq. (8).

$$Mean_{Info} = \frac{1}{N} \sum_{i=1}^N Xi(t) \quad (8)$$

Trevally starts chasing its prey during the attacking the GTO's phase. At this point, the trevally attacks the bird by jumping out of the water and catching it. During chasing and attacking prey, GTO presumed that giant trevallies experience visual distortion, which is primarily caused by the refraction of light. Refraction of light occurs as light travels from one material to another, where its direction changes at the interface. As depicted in Fig. 2, the light from point  $A$  in the first medium enters the second medium at the intersection point  $S$ . Hence refraction occurs and arrives at point  $B$  at the end of the process. The light bends toward the normal as it enters the denser medium as light travels from a rare medium, like air, to a denser medium, like water. There must be an angle between the incident and refracted rays at the point of refraction. Light rays are also affected by the medium in which they are traveling. Snell's law clarifies this connection using refractive indices, fixed values for certain media.

Fig. 2. Refraction of light principle.

Fig. 3. Visual distortion in GTO.

As shown in Fig. 3, the giant trevally acts as an observer, as well as the bird behaves as an object. Due to the refraction of light, birds appear taller than their actual height, as indicated by the dashed line.

The relationship between the angle of incidence and the angle of refraction can be predicted using Snell's law. If we know the angle of incidence, we can determine the angle of refraction and vice versa. This relationship is demonstrated by Eq. (9), which represents Snell's law.

$$\eta_1 \sin \theta_1 = \eta_2 \sin \theta_2 \quad (9)$$

where,  $\eta_1=1.0002$  and  $\eta_2=1.3$  represent air's and water's absolute refractive indices, respectively.  $\theta_1$  and  $\theta_2$  refer to angles of incidence and refraction, respectively.  $\theta_2$  denotes a random number between 0 and 360, derived from Eq. (10).

$$\sin \theta_1 = \frac{\eta_2}{\eta_1} \sin \theta_2 \quad (10)$$

Eq. (11) is used to calculate the visual distortion.

$$v = \sin(\theta_1^\circ) \times D \quad (11)$$

where,  $\sin$  stands for the sine of a variable in degrees, and  $D$  refers to prey-attacker distance, determined by Eq. (12).

$$D = |(Best_p - Xi(t))| \quad (12)$$

where,  $Best_p$  indicates the best solution gained so far, representing the prey's location. Eq. (13) is then used to simulate giant trevally behavior during jumping as well as chasing.

$$X(t+1) = \mathcal{L} + v + \mathcal{H} \quad (13)$$

where,  $\mathcal{L}$  is the launch speed for simulating the pursuit of the bird, as determined by Eq. (14), and  $\mathcal{H}$  is the jump slope

function used by the algorithm for the adaptive transition from exploration to exploitation, derived from Eq. (15).

$$\mathcal{L} = Xi(t) \times \sin(\theta_1^\circ) \times F\_obj(Xi(t)) \quad (14)$$

$$\mathcal{H} = \mathcal{R} \times (2 - t \times \frac{2}{T}) \quad (15)$$

In Eq. (15),  $R$  stands for a random number used to denote the various motion senses of the giant trevally during the exploitation step,  $t$  signifies the current iteration, and  $T$  refers to the maximum number of iterations.

### B. User Request Model

Users request resources, commonly referred to as VMs, from the data center via a broker or cloud provider. Each resource (VM) consists of a variety of components coordinated to fulfill a certain function. UR stands for users' requests. It is possible for users to submit multiple UR requests at the same time, which are executed on a First-Come-First-Served (FCFS) basis. VMs encompass three categories of resources: storage, memory, and CPU.  $i$  and  $s$  indicate the number of resources and their measuring capacities. Eq. (16) can be used to express the request mathematically.

$$A_i \subset UR \text{ and } a_s^1, \beta_s^1, \gamma_s^1 \subset A_i$$

$$a_s^1, \beta_s^1, \gamma_s^1 \subset A_i \subset UR \Rightarrow a_s^1, \beta_s^1, \gamma_s^1 \subset UR \quad (16)$$

Eq. (17) and Eq. (18) will be used to express the request for a single resource in this case.

$$UR^1 = A_i \quad (17)$$

$$A_i = (a_s^1, \beta_s^1, \gamma_s^1) \quad (18)$$

where,  $i$  represents the number of resources required, when a user submits multiple requests, they are represented by Eq. (19) and Eq. (20).

$$UR^n = \sum_{i=1}^n A_i = A_1 + A_2 + A_3 + \dots + A_n$$

$$= (a_s^1, \beta_s^1, \gamma_s^1) + (a_s^2, \beta_s^2, \gamma_s^2) + \dots + (a_s^n, \beta_s^n, \gamma_s^n) \quad (19)$$

$$UR^n = \sum_{i=1}^n (a_s^i) + \sum_{i=1}^n (\beta_s^i) + \sum_{i=1}^n (\gamma_s^i) \quad (20)$$

### C. Resource Utilization and Energy Model

CPU and memory utilization are calculated using Eq. (21) and Eq. (22), where  $i$  represents the number of tasks assigned to  $n$  VMs.  $rpu_{ijk}$  and  $rmu_{ijk}$  represent the CPU and memory utilization of  $k$  tasks running on  $j$  VMs on the  $i^{th}$  node, respectively.

$$RPU_i = \sum_{j=1}^n \sum_{k=1}^l rpu_{ijk} \quad (21)$$

$$RMU_i = \sum_{j=1}^n \sum_{k=1}^l rmu_{ijk} \quad (22)$$

The power consumption of the  $i^{th}$  PM in terms of memory and CPU utilization can be calculated using Eq. (23), where  $t$  is the unit of time and  $C$  is the number of memory units.

$$PC_i = \frac{(RPU_i)(RMU_i)}{C} \times t \quad (23)$$

Another objective of this research is to optimize the time required to assign VMS to relevant hosts. Allocation operations

are influenced by the capacity of the hosts. A numerically generated data set is generated for each source between 0.1 and 10 milliseconds. The total allocation time is calculated by adding the CPU time associated with each host using Eq. (24).

$$Time = \sum_{i=1}^n T_i \quad (24)$$

#### D. step-by-step algorithmic explanation

The proposed VM allocation approach follows the following steps:

- Initialization: Initialize the GTO algorithm by generating a population of random solutions, referred to as "giant trevallies." Each giant trevally represents a potential solution to the VM allocation problem. Define parameters: N (number of giant trevallies), Dim (number of decision parameters), and set the population size and dimensions.
- Random position assignment: Assign each giant trevally a random position within the feasible search space of the problem, ensuring coverage across the  $N \times Dim$  search space.
- Objective function evaluation: Evaluate the objective function for each giant trevally, representing the quality of their respective VM allocation solutions. This result in a vector F containing these objective function values.
- Exploration phase: Simulate the exploration behavior of giant trevallies by employing Levy flights. This phase allows for extensive search and occasional large steps. Update the position of each giant trevally using Eq. (4), where Levy flight is used to determine the next iteration's position.
- Choosing the hunting area: Giant trevallies select their hunting areas based on the number of seabirds (food) in those areas. This is simulated using Eq. (7), which determines the new position based on a combination of the best search space and previous positions.
- Chasing and attacking prey (exploitation phase): During this phase, giant trevallies pursue and attack prey, simulating their behavior when capturing seabirds. Visual distortion is considered due to the refraction of light, which affects the perceived size of prey. This is calculated using Snell's law Eq. (9) to determine the angle of refraction. The position update during the chase is determined by Eq. (13), where L represents the launch speed, v is the visual distortion, and H is the jump slope function.
- Iteration and convergence: Repeat the above steps for a specified number of iterations or until convergence criteria are met (as defined by T, the maximum number of iterations).

#### IV. EXPERIMENTAL RESULTS

In this section, we conduct a comparison between the performance of our proposed resource allocation algorithm and previous approaches. Additionally, we perform several experiments to evaluate the effectiveness of our algorithm. The

suggested algorithm is implemented and simulated using Matlab simulator 2016b. To assess the effectiveness of the optimization algorithm, we utilize key performance indicators such as skewness, CPU utilization, memory utilization, and resource utilization. These metrics allow us to quantitatively evaluate the efficiency of our algorithm and make comparisons with other algorithms.

- Skewness: Skewness measures the asymmetry or unevenness in a probability distribution. It provides an indication of the uneven utilization of multiple resources on a server. The concept of skewness is derived from the observation that if a PM runs numerous memory-intensive virtual machines with a light load, resources may be lost due to insufficient memory to accommodate an additional virtual machine. Skewness quantifies the unevenness in resource utilization across a server by applying Eq. (25). Here,  $R$  represents the resource utilization of the  $n^{th}$  virtual machine, and  $A$  represents the average resource utilization.

$$W = \left(\frac{R_n}{A} - 1\right)^2 \quad (25)$$

- CPU utilization: This metric represents the average amount of CPU consumed by all servers while handling user requests. It is computed using Eq. (26), where  $H_i$  denotes the total number of available CPU resources and  $E_i$  represents the CPU resources requested for task execution.

$$C = \sum_{i=1}^y \frac{E_i}{H_i} \quad (26)$$

- Memory utilization: Memory utilization refers to the fraction of the memory resource that is used over time for processing all submitted tasks. It is calculated using Eq. (27), where  $v_i$  represents the total available memory and  $u_i$  indicates the memory requested for task execution.

$$M = \sum_{i=1}^y \frac{u_i}{v_i} \quad (27)$$

- Resource utilization: Resource utilization is defined as the ratio of the number of allocated resources to the total number of available resources. It provides an assessment of how effectively resources are utilized and is calculated accordingly.

$$R = \frac{c}{w} \quad (28)$$

The proposed method exhibits performance enhancements compared to existing approaches when considering 15 virtual machines. Specifically, when compared to PSO [30], genetic [31], and GWO [32] algorithms, the proposed algorithm consistently outperforms them, as depicted in Fig. 4. It achieves lower skewness values faster and maintains them even with increased iterations. This superiority is attributed to the proposed algorithm's ability to adapt swiftly and accurately to different datasets, thanks to its improved learning rate and parameter tuning. As a result, it enables more efficient optimization and better overall performance.

Fig. 4. Skewness comparison.

Fig. 5. Resource utilization comparison.

Fig. 5 demonstrates that the proposed algorithm utilizes more resources than existing techniques within the same number of iterations, indicating its enhanced efficiency and ability to achieve superior results with less iteration. Furthermore, Fig. 6 illustrates that the proposed algorithm exhibits improved memory utilization efficiency, requiring significantly less memory than existing techniques for the same number of iterations. Finally, Fig. 7 presents that the proposed algorithm accomplishes tasks more efficiently than existing models like GA, GWO, and PSO, as it achieves task completion in less time with the same number of iterations.

GTO in the context of VM allocation within cloud computing environments introduces a unique set of trade-offs and benefits that distinguish it from other optimization algorithms. While it may appear that GTO consumes more computational resources within the same number of iterations compared to some existing techniques, a closer examination

reveals that the unique strengths of GTO can significantly outweigh the increased resource usage, ultimately leading to improved performance, efficiency, and sustainability in various aspects of VM allocation. GTO's use of extensive search techniques, such as Levy flights, might lead to higher resource consumption in terms of computation power and time. However, this trade-off is justified by its ability to explore a wider solution space, often resulting in superior VM allocations. The increased resource usage can be considered an investment in finding more energy-efficient and effective allocation solutions. GTO strikes a balance between exploration (discovering new allocation possibilities) and exploitation (refining promising solutions). This duality is vital in tackling the NP-hard problem of VM allocation. While some algorithms might prioritize one over the other, GTO excels in both, thereby enhancing the likelihood of finding optimal or near-optimal allocations.

Fig. 6. Memory utilization comparison

Fig. 7. CPU utilization comparison

GTO's ability to adapt its search behavior, mirroring the trevally's hunting tactics, allows it to respond effectively to changing conditions and evolving VM allocation demands. This adaptability is especially valuable in dynamic cloud environments. GTO's exploration phase, facilitated by Levy flights, enables it to perform global searches, effectively avoiding local optima. This global perspective ensures that VM allocations are not limited to suboptimal solutions, ultimately improving resource utilization and efficiency. GTO's incorporation of visual distortion due to the refraction of light is a unique feature that enhances its performance. This consideration ensures that VM allocations are not only optimal but also take into account real-world conditions, leading to more reliable and realistic allocation solutions. GTO's exploration phase increases the diversity of the population, preventing premature convergence. This diversity is crucial in avoiding stagnation and enabling the algorithm to jump out of local optima, which can be a common issue in other optimization techniques.

## V. CONCLUSION

This paper introduced an energy-conscious optimization approach based on the GTO for VM allocation. It has been compared to existing methods, including GWO, genetic, and PSO algorithms. The experimental results and performance evaluations have demonstrated the superiority of the proposed algorithm in several aspects. Firstly, the proposed algorithm consistently outperforms other algorithms in terms of skewness. It achieves lower skewness values more rapidly and maintains them even with increased iterations. This improvement is attributed to the algorithm's enhanced learning rate and parameter tuning, allowing it to adapt more effectively to different datasets. Furthermore, the proposed algorithm exhibits improved resource utilization efficiency by effectively utilizing a greater number of resources compared to existing techniques within the same number of iterations. This indicates its enhanced efficiency and ability to achieve better results with less iteration. Moreover, the algorithm demonstrates superior

memory utilization efficiency by requiring significantly less memory compared to existing techniques for the same number of iterations. This feature is valuable in resource-constrained environments where memory usage optimization is crucial. The findings highlight the promising performance and potential of the proposed GTO-based approach for VM allocation in cloud computing environments. Future research directions can explore the algorithm's applicability in different scenarios and consider additional parameters to address the complexities of diverse cloud computing environments.

While our study leverages the GTO to address VM allocation challenges in cloud computing, it is essential to acknowledge certain limitations. Firstly, GTO's resource-intensive nature, particularly in terms of computation, may pose practical constraints in real-time cloud environments where swift decision-making is crucial. Secondly, the effectiveness of the GTO algorithm may vary depending on the specific characteristics of a given cloud data center, such as size, workload, and infrastructure, which could limit its universality. Additionally, our study primarily focuses on energy efficiency and resource utilization aspects, potentially overlooking other critical performance metrics relevant to cloud service quality. Furthermore, while we account for visual distortion in VM allocation, the real-world applicability and accuracy of this consideration warrant further exploration. Despite these limitations, our research provides valuable insights into enhancing cloud sustainability and efficiency, offering a foundation for future investigations in the field.

# Corpus Generation to Develop Amharic Morphological Segmenter

Terefe Feyisa, Dr Seble Hailu

Information Network Security Administration, Addis Ababa, Ethiopia

**Abstract**—Morphological segmenter is an important component in Amharic natural language processing systems. Despite this fact, Amharic lacks large amount of morphologically segmented corpus. Large amount of corpus is often a requirement to develop neural network-based language technologies. This paper presents an alternative method to generate large amount of morph-segmented corpus for Amharic language. First, a relatively small (138,400 words) morphologically annotated Amharic seed-corpus is manually prepared. The annotation enables to identify prefixes, stem, and suffixes of a given word. Second, a supervised approach is used to create a conditional random field-based seed-model (on the seed-corpus). Applying the seed-model (an unsupervised technique on a large unsegmented raw Amharic words) for prediction, a large corpus size (3,777,283) of segmented words are automatically generated. Third, the newly generated corpus is used to train an Amharic morphological segmenter (based on a supervised neural sequence-to-sequence (seq2seq) approach using character embeddings). Using the seq2seq method, an F-score of 98.65% was measured. Results show an agreement with previous efforts for Arabic language. The work presented here has profound implications for future studies of Ethiopian language technologies and may one day help solve the problem of the digital-divide between resource-rich and under-resourced languages.

**Keywords**—Amharic; Amharic morphology; segmentation corpus; seq2seq; under-resourced languages

## I. INTRODUCTION

Language plays a significant role in achieving the sustainable development goals (SDG 2030) [1]. Regarding language technologies, the Prime Minister of Ethiopia, Dr Abiy Ahmed, recently said, “(...) teaching Somali, Tigrinya, Amharic and Oromo languages with artificial intelligence and making these languages researchable is a great achievement (...)” [2]. This Prime Minister’s quote can be interpreted as artificial intelligence (AI) in general, and natural language processing (NLP) in particular, are issues of contemporary importance in Ethiopia. This work focuses on one aspect of Amharic NLP technology.

NLP aims at enabling machines to understand human languages. Machines usually obtain “natural language” in the form of voice or text messages. Typically, textual and vocal data are not structured and therefore require advanced technologies, like deep neural networks (DNNs), to be used and understood correctly. DNNs are mainly based on large amount of corpus for automatic feature extraction [3]. Because of this (large corpus requirement), DNNs are not being fully applied by almost all under-resourced Ethiopian languages.

Despite being the working language of Ethiopia, Amharic is one of the under-resourced languages [4], [5]. Being under-

resourced, Amharic lacks digital resources, such as sizable segmentation corpus and a morphological analyzer [6].

The lack of digital resources is mainly attributed to an expensive corpus preparation by language experts. Depending on their level of expertise, a linguist may ask starting from Ethiopian Birr 10.00 per a single word segmentation. For example, in 2019 there was a joint project (between the former Information Network Security Agency and Addis Ababa University). The aim of the project was to develop core NLP tools. The biggest share of the project cost was the payment for the linguists. Even with the minimum price, Birr 10.00 per a single word segmentation, the cost gets in millions just for about 100,000 distinct word segmentation.

The problem of language corpus scarcity is a “real-life” challenge that exists when developing NLP tools and undertaking researches.

One of the primary consequences of corpus scarcity is reflected in the approaches to develop Amharic NLP technologies. The dominant approaches to develop Amharic NLP systems are mostly rule-based, such as memory-based learning [7].

Rule-based systems have their own pros and cons [8]. Rule-based systems are advantageous, as they are declarative and are easy to comprehend, to maintain, to incorporate domain knowledge, and to trace and fix the cause of errors. However, they are heuristic and require tedious manual labor as compared to machine-learning (ML) approaches.

ML-based systems too have their own pros and cons [8]. On their advantage end, they are: trainable, adaptable, and reduces manual effort. Their disadvantages includes the requirement of: labeled corpus, retraining for domain adaptation, ML expertise to use or maintain, and they are opaque.

Given the situations, it is essential to design an alternative mechanism to enrich (with corpus), and develop language processing tools for Amharic (to make it researchable). One mechanism could be the design of an algorithm that is computationally robust and less expensive.

To design such an algorithm, a possible approach would be the use of a hybrid system: a combination of rule-based and ML-based systems. The rule-based system can be applied to generate seed-corpus for a semi-supervised ML approach as suggested by [9]: “Minimally supervised approaches provide better performance compared to applying only unsupervised methods on large unlabeled datasets.”

The purpose of this work is twofold. First, to automatically generate morph-segmented Amharic corpus. Then, the newly

generated corpus is used to develop a neural network-based Amharic morphological segmenter (AMS).

To the best of our knowledge, there has not been any work that attempted neural network techniques to develop AMS by using semi-supervised learning approach to automatically generate large amount of corpus.

The main contributions are the following:

- 1) An alternative algorithm is used to construct a morphologically segmented corpus for Amharic. The corpus is annotated with boundaries that clearly mark prefix, stem, and suffix morphemes.
- 2) A sequence-to-sequence neural network approach is used to create an Amharic morphological segmenter.
- 3) The research shall motivate the understanding of (the processing challenges of) Amharic.
- 4) The research shall inspire further research (by releasing the resources – the corpus and the algorithm – of this research to the public).

The organization of this paper is as follows: Section II provides an overview of recent advancements in morphological segmentation. Section III outlines our methodology. Subsequently, Section IV presents the results obtained from testing the method on diverse subjects. Finally, the conclusion summarizes the findings of this study and offers insights into future perspectives.

## II. RELATED WORK

### A. Why Develop Amharic Corpora

Amharic corpora is useful to develop, and apply a research work for different Amharic natural language technologies. In 2005, [6] manually annotated Amharic words (in news documents) with the most appropriate parts-of-speech (POS) tags. They managed to annotate 1,065 text documents having 202,671 words [10]. Their corpora is useful to develop probabilistic POS tagger [11] and chunker [10].

In 2016, a semi-automatic approach (very similar to this work) is followed by [12] to develop a morpho-syntactically annotated Amharic Treebank to develop a text parser. They first annotated 1,000 sentences for POS tags, morphological information, and syntactic relations of words. Using these sentences as seed-corpus, they trained a machine learning system to automatically annotate 5,000 sentences.

In 2021, [13] developed a POS tagged corpus consisting of 25,199 documents using syntactic information of words. Their corpus was tagged automatically using HornMorpho analyzer [14] with manual intervention to correct erroneous results. The morphological analyzer generates the derived stems of non-verbal words rather than basic stems. For verbs, it generates only roots rather than stems producing incorrect representations. Their corpus is not directly suitable for morphological segmentation experiments. Nevertheless, one can use their corpus as part of a seed-corpus by appropriating to a desired experiments. Regardless, HornMorpho is used by most works related to Amharic morphological segmentation [15], [16]. It is a fully-fledged morphological analysis tool for Amharic, Tigrinya and Oromo languages.

The work of [17] is also worth mentioning as, they used morphological knowledge and an extension of existing annotated dataset to improve the performance of an Amharic POS tagging system.

This paper's approach is different from HornMorpho. In that it is limited to only word segmentation task (as opposed to HornMorpho, a fully-fledged morphological analysis tool).

Brief, although morphological properties have been used to create POS tagged corpora, there is no morphologically annotated large Amharic corpus to date (i.e. that can be directly consumed by a neural network model). This study aims to construct a hybrid system to generate a morphologically annotated segmented words that can be useful for sequence-to-sequence neural network models.

### B. Segmentation for Semitic Languages

Word segmentation is regarded as a first step for almost all Semitic languages [18], [19]. This work adopts most of the methods presented for Arabic word segmenter [20]. Their method involves three steps. First, they used a small manually segmented Arabic corpus (110,000 words) to create a "seed-model". Then, they used the "seed-model" to bootstrap an unsupervised algorithm. Finally, they applied the unsupervised algorithm on a large unsegmented Arabic corpus (155 million words). They claimed a 97% exact match accuracy on a test corpus (28,449 words). A significant difference between this work and theirs is the choice of an unsupervised algorithm. Theirs is a "trigram language model". This study used a conditional random field (CRF) instead. The CRF model is a relatively better algorithm (e.g., it can use language-independent features of characters, in addition to n-grams) [18].

### C. Sequence-to-Sequence Approaches

Recently, supervised sequence-to-sequence approaches have gained success [21]–[23]. The seq2seq modeling of this work is mostly inspired (and adapts most of the techniques used) by a morphological segmentation task for the Russian language [24]. The Russian work defined MS as sequence transduction using character embeddings. They used the architecture and the hyperparameters by [22].

### D. Summary

This work builds on previous works on morphological segmentation, such as by [20]. It then enriches an already existing, manually segmented seed-corpus by applying a tool – mostly used for Amharic NLP works [14]. Finally, it adapts a seq2seq model by [24].

## III. METHODOLOGY

Amharic morphological segmentation can be modeled using only hand-crafted dataset [8]. However, building a sizable hand-crafted corpus is expensive in the amount of human work. AMS can also be designed automatically using statistical models such as Hidden Markov Model (HMM) and Conditional Random Fields (CRF) [25]. Today, one can also apply deep learning methods to get a state-of-the-art performance level [26].

This work attempts to combine the best of rule-based, ML, and deep learning approaches. To that end, it follows a three-step process (see Fig. 1).

First, a supervised approach is applied to create a **seed-model** using a hand-crafted dataset (training a CRF). Then, based on the seed-model a CRF-based unsupervised method is applied on a **raw unsegmented words** to **enrich** the manually created Amharic corpus. Third, a supervised neural **sequence-to-sequence** (seq2seq) learning approach, using character embeddings, is implemented for AMS on the enriched dataset. The seq2seq is mostly inspired by the work of [20] and the soft-attention encoder-decoder research method of [27].

Fig. 1. A flowchart to highlight the three major sub-processes of the proposed method.

### A. Seed-Corpus for the Seed-Model

Two kinds of dataset are used to prepare a seed-model. The first one is a manually labeled, morphologically segmented corpus (173,000 words), prepared by [28].

The 173,000 segmented corpus is used for three purposes. First, it helped in generating an affixation table. Second, 80% of it (138,400 words) is used as a part of the training corpus. Third, 20% of it (34,600 words) is used as test corpus for the unsupervised CRF-based model.

The corpus by [28], however, has only representative *stems*. To compensate for the lack of *stem varieties*, another dataset, from Contemporary Amharic Corpus (CACO) by [4] is used.

Basically, the CACO corpus is a morphological analysis result of HornMorpho [14]. As such, it is not directly applica-

ble for the purpose of this study. So, it is filtered by applying a regular expression algorithm and the affixation table to get 906,417 words.

Finally, the two dataset (manually segmented corpus (138,400 words) and the filtered corpus (906,417 words)) are merged to get a total of 1,044,817 words (see Table I) as a seed-corpus to train a seed-model. All the 1,044,817 words are labeled using the “BMES” tagging scheme.

TABLE I. SUMMARY OF SEED-CORPUS PREPARATION

CORPUS	WORDS
MANUALLY SEGMENTED	138,400
FILTERED FROM CACO	906,417
MERGED TOTAL (SEED-CORPUS)	<b>1,044,817</b>

### B. The BMES Tagging Scheme

Training a word segmenter can be considered as an organized classification task with encoded classes [18].

An encoding is used to identify the presence of morph boundaries around a target character. Models using fine-grained tagging schemes contribute significantly for performance accuracy [29], [30]. As such, this work adopts the fine-grained “BMES” encoding scheme by [31]. This encoding scheme uses four class set {B, M, E, S} to capture information about the sequence of morphs in a given word. The labeling symbols have the following meanings:

- (B)egin: The start of a morph.
- (M)iddle: The continuity of a morph.
- (E)nd: The end of a morph.
- (S)ingle: Single morphs.

Table II depicts an instance of the “BMES” tagging scheme using an example of three Amharic words (/bet/ “house”, /betu/ “the house”, and /betunmko/ “and also the house”) with their corresponding manual segmentation (marked by a dash “-”) and labeling.

TABLE II. AN INSTANCE USAGE OF THE “BMES” TAG SCHEME

SEGMENTED WORD	LABELING
bet	[B, M, E]
bet-u	[B, M, E, S]
bet-u-n-m-ko	[B, M, E, S, S, S, B, E]

### C. Training a Seed-Model

The seed-corpus (1,044,817 words, labeled with the “BMES” tagging scheme) is used as an input for a supervised CRF training to prepare a seed-model. The linear-chain CRF model of the Wapiti toolkit [32] is used for both segmenting and labeling purposes. The CRF model takes a labeled seed-corpus, a template to mark n-grams and a text file to write the output (the seed-model). The seed-model’s accuracy is tested to be 96% exact match accuracy on a manually segmented test corpus of 34,600 words.

#### D. Corpus Generation from a Bulk Corpus

New corpus generation, from a bulk corpus, demands the seed-corpus, bulk-corpus and an affixation table. Having those prerequisites, a four step process follows. First, the seed-corpus is generated. Then, a bulk-corpus is prepared from the *most frequently used Amharic word lists* (347,039 **unsegmented** words) [33]. Third, a seed-model is **trained** using the seed-corpus. Finally, using the seed-model (iteratively) **re-training** is performed by using a block from the bulk-corpus. Fig. 2 is a flowchart to illustrate the process. (see also, Algorithm 1 on the following page, for detailed steps.)

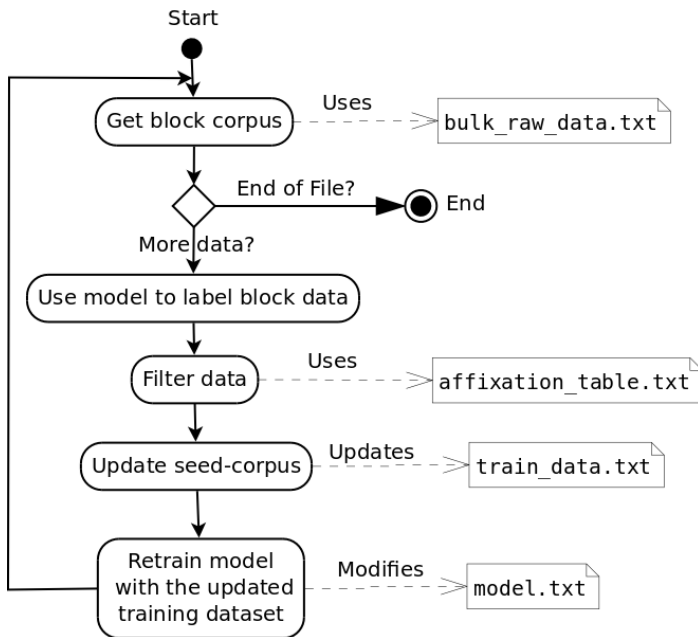

Fig. 2. Corpus preparation from a raw unsegmented corpus.

Using the algorithm, 2,732,466 segmented words are filtered from a bulk raw dataset. This corpus size (2,732,466 words) together with the seed-corpus (1,044,817) help in training the seq2seq AMS model (see Table III).

TABLE III. SUMMARY OF THE NEW CORPUS SIZE USING THE ALGORITHM

CORPUS	WORDS
SEED-CORPUS	1,044,817
CORPUS FROM BULK-CORPUS	2,732,466
MERGED DATASET FOR SEQ2SEQ	<b>3,777,283</b>

#### E. The Seq2Seq Model

The seq2seq works as transduction system [24]. That means, AMS as a seq2seq model gains an overall information from inputs and directly output a segmented sequence without using context features.

Table IV presents a sample input-output pair for a seq2seq AMS model. The input,  $\mathbf{X} = x_1, x_2, x_3, x_4$ , is the word “betu”, “the house” having 4 characters ( $x_1 = b, x_2 = e, x_3 = t, x_4 = u$ ). The output is a sequence,  $\mathbf{y}$ , having 5 characters including a boundary marker,  $\beta$ .

The final segmentation result is  $\{\text{bet}\}\beta\{\text{u}\}$ .

TABLE IV. INPUT-OUTPUT INSTANCE FOR SEQ2SEQ AMS MODEL

	Sequence	Length
<b>Input</b>	$\mathbf{X} = [b, e, t, u]$	4
<b>Output</b>	$\mathbf{y} = [b, e, t, \beta, u]$	5

The attention-based seq2seq model architecture for AMS is shown in Fig. 3. The model contains character embedding layer, an encoder layer, and an attention head and a decoder.

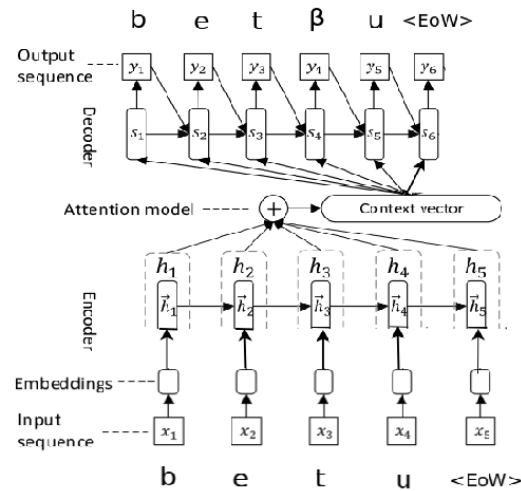

Fig. 3. Architecture of the seq2seq model (Adapted from [21]). <EoW> stands for End-of-Word.

#### F. Settings

**Dataset:** The total corpus size is 3,777,283 morphologically segmented Amharic words. This corpus is divided into two parts: 90% for training, and 10% for testing as suggested by [24]. The targets for the seq2seq model are morph-broken words (see Table V).

**Algorithm 1** Get New Corpus From Bulk Corpus

**Input:** seedCorpus, bulkCorpus, affixationTable

```

do {
    blockSize ← 1000
    begin ← 0
    end ← blockSize
    seedModel ← crfTrain(seedCorpus, 'model.txt')
    newCorpus ← seedCorpus
    while begin ≤ sizeOf(bulkCorpus)
        do {
            wordBlock ← getCorpusBlock(bulkCorpus, begin, end)
            for each word ∈ wordBlock
                do {
                    transliteratedWord ← transliterate(word)
                    writeOnFile(transliteratedWord, 'transliteratedWord.txt')
                    crfPredict('model.txt', 'transliteratedWord.txt', 'result.txt')
                    filteredSegments ← filterSegments('result.txt', affixationTable)
                    newCorpus ← merge(newCorpus, filteredSegments)
                    newCorpus ← dropDuplicates(newCorpus)
                }
            }
            newModel ← crfRetrain(newCorpus, 'model.txt')
            begin ← end+1
            end ← end + blockSize
        }
    }
return (newCorpus)

```

TABLE V. SAMPLE DATASET FOR SEQ2SEQ TRAINING AS A PAIR OF [INPUT WORD, TARGET SEGMENTED WORD]. THE EXAMPLE AMHARIC WORD HAS A ROOT **SBR**, HAVING THE SENSE OF BREAKING

INPUT WORD	SEGMENTED WORD
s babrona	s babr-o-na
s babrana	s babr-a-na
s babrwna	s babr--w-na

The Python programming language is applied for the experimentation. As for the deep learning package, Keras [34] with TensorFlow [35] as a back-end is used. For evaluating the models, the Scikit-learn [36] toolkit is used.

*G. Train the Seq2Seq Model*

The seq2seq model involves three distinct models: an encoder, an attention head and a decoder. Each of these (three) models, include a single Bidirectional Long Short Term Memory (BiLSTM) layer.

- The Long Short Term Memory (LSTM) Network  
The LSTM network architecture consists of a set of recurrently connected memory blocks, known as LSTM memory cells (dotted boxes in Fig. 4). LSTM are better at finding and exploiting long range dependencies in a data [37]. It has an input layer **X**, hidden layer **h** and output layer **y**. For example, if one inputs  $x = [b, e, t, u]$ , the house, into the LSTM, the expected prediction is a tag set as:  $y = [B, M, E, S]$  (see Fig. 4).

Fig. 4. The LSTM network.

- The Bidirectional LSTM  
As depicted in Fig. 5, BiLSTM is two hidden LSTM layers. In sequence tagging task, it enables us to have access to both past and future input features.

Fig. 5. A BiLSTM network.

- Hyperparameters
  - Inspired by previous works [22], [38], possible parameter combinations are explored in the preliminary experiments. The complete list of parameters is shown in Table VI. “Hidden layer size” stands for the number of BiLSTM layers or hidden state dimension and “Embeddings dimension” stands for dimensionality of the embedding layer.

TABLE VI. HYPERPARAMETERS OF THE SEQ2SEQ TRAINING.

HYPERPARAMETER	VALUE
<b>Encoder and decoder</b>	
Number of epochs	10
Number of units	1024
Batch size	64
Character embeddings	256
Optimizer	Adam
<b>Attention</b>	
Attention type	Bahdanau’s

- Training
  - The training involves three distinct models (an encoder, an attention head and a decoder, in that order) acting as a single end-to-end model.

#### Encoder

It takes a list of tokens. It converts those tokens into vectors by an embedding layer. Then, a BiLSTM layer processes the vectors sequentially. It outputs the processed sequence (for the attention head) and the internal state (useful to initialize the decoder).

#### Bahdanau’s additive attention [27]

It computes the attention weights and the context vectors.

#### Decoder

After accepting the output from the encoder, it converts the tokens into a vector using an embedding layer. The decoder keeps track of what has been generated so far using a similar layer as in the encoder. Finally, it produces context vectors and do “logit” predictions for the next token.

### H. Evaluation

Two morphological segmentation evaluation approaches are suggested by [39]. The first one is called “direct evaluation”, in which the results of a MS model are compared to “gold” standards. The other approach is known as “indirect evaluation”, where the MS models are used in other applications such as for speech recognition system.

As recommended by [24], this study uses the direct evaluation technique. So, boundary precision, boundary recall and boundary F1-score are reported.

$$\text{Precision} = \frac{\text{number of correct boundaries found}}{\text{total number of boundaries found}} \quad (1)$$

$$\text{Recall} = \frac{\text{number of correct boundaries found}}{\text{total number of correct boundaries}} \quad (2)$$

$$\text{F1-score} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (3)$$

Where, “boundary” means the border between morphs. For example, suppose there are two boundaries in the gold standard for the Amharic word “y-bet-u” (of-the-house). If the AMS model segments this word as “y-be-t-u”, with three boundaries, one can compute precision as 67%, recall as 100% and F1-score as 80%.

## IV. EXPERIMENTAL RESULTS

### A. Results

Overall, 3,777,283 morphologically segmented Amharic words are generated with an algorithm that involves a CRF model. The CRF model’s accuracy was 96% exact match on a manually segmented test corpus of 34,600 words.

This accuracy is slightly less than that of the Arabic word segmenter by [20], which was 97% exact match accuracy on a test corpus (28,449 words). The difference may be attributed to the use of a large unsegmented Arabic corpus (155 million words) as compared to 347,039 unsegmented Amharic corpus.

Once the morphologically segmented Amharic words are generated, the next step was to develop our seq2seq model. But, before developing the seq2seq model, the newly generated data is used for training LSTM, GRU, BiLSTM, and BiGRU models in order to choose the best performing one. The performance of the models was evaluated and contrasted (see Table VII). The results showed that BiLSTM gave the best performance compared to the other models. So, we have chosen the BiLSTM model to implement our seq2seq model.

TABLE VII. A COMPARISON: TO CHOOSE THE BEST PERFORMING MODEL

MODEL	PRECISION	RECALL	F1-SCORE
GRU	91.73%	92.56%	92.14%
LSTM	92.47%	93.36%	92.91%
BiGRU	95.58%	95.95%	95.76%
<b>BiLSTM</b>	<b>98.47%</b>	<b>98.84%</b>	<b>98.65%</b>

Fig. 6 presents the attention weights for the input characters “slvbetacnmmko”, where the sound /v/, representing //, is used for technical reason. The output is the “morph broken characters” which is found to satisfy the given “gold” standard “/slv-bet-acn-n-m-ko/”.

Fig. 6. Attention weights with inputs (Amharic characters) and outputs (morph broken characters) of the inputs.

### B. Discussion

For accurate ‘interpretation’ of the human language, machines should be equipped with effective natural language processing components [40]. But, this is not often the case for under-resourced languages.

Under-resourced languages are the majority of the world languages, which have not attracted much attention from researchers and donors due to economical and political reasons [40]. For these languages, corpus is a challenge to train deep learning models [41], as deep learning techniques demand large amounts of labeled corpus [3].

Amharic is one of the under resourced Ethiopian languages [4] that lacks necessary corpus and NLP applications.

To improve the situation, an Amharic morphological segmenter is implemented based on a supervised neural sequence-to-sequence approach using character embeddings, by carefully constructing language resources. But, there are still possible error sources that put our results questionable.

One possible source of error is the use of a segmentation corpus from an external morphological analyzer (HornMorpho). Errors may propagate from the morphological analyzer to the filtered corpus. However, it is difficult to spot out the exact source of errors, as this work lacks a proper error analysis.

Nevertheless, the obtained F1-Score (98.65%) indicates that, there is a window of opportunity to improve the accuracy of the Amharic morphological segmenter by applying deep neural networks.

The main focus of this work was on corpus preparation. As such, this work lacks testing and comparison of the implemented supervised neural sequence-to-sequence (seq2seq)

system against the stated previous works and with the resource-rich languages.

Comparing the obtained results with another similar implementation would have a much more impact to outline the achieved milestone. So, this can be considered as yet another limitation of this work.

One of the strongest suits of this research is the use of different datasets for seed-corpus preparation (as, having datasets for under-resourced languages is the main obstacle when it comes to the implementation of morphological segmentation systems).

### V. CONCLUSION

Unlike morphologically poor languages, such as English, Amharic language’s word segmentation resources aren’t sufficient for researchers to do their practices.

Addressing the most understudied corpus generation for a low-resource language is fascinating, and is a big step for further studies.

Using annotated datasets and unsupervised techniques, a relatively big dataset was generated. This enabled the implementation of a seq2seq-based morphological segmenter for Amharic language.

Rule-based approach is used alongside a supervised machine learning approach. This hybrid system is found to be cost-effective, flexible, and most importantly effective in constructing a language resource for segmentation.

To construct a language resource, three sources of dataset are used. The first set is 138,400 manually labeled, morphologically segmented corpus. The second source is a morphological analysis result from Contemporary Amharic Corpus (filtered using a regular expression algorithm and a rule-based method by using an affixation table) to get 906,417 words. The third source is the result of applying a corpus generator algorithm out of “*most frequently used Amharic word lists*”. Using the third technique, 2,732,466 segmented words are generated.

The newly generated segmentation corpus is then used to train a morphological segmenter model based on a supervised seq2seq neural network approach.

The seq2seq implementation involves three models appearing as one: an encoder, an attention head, and a decoder. For the seq2seq implementation, Python programming language is used on an Ubuntu machine having 64GB of memory.

The implemented seq2seq model is evaluated using a direct evaluation technique. Besides the 3,777,283 Amharic language corpus generated in the process, a 98.47% precision, a 98.84% recall, and a 98.65% F1-score have been achieved.

Brief, the major findings of this work are:

- An alternative algorithm that uses small seed-corpus to generate a large dataset from a raw bulk corpus.
- The generation of 3,777,283 morphologically segmented Amharic word corpus.
- An implementation of a seq2seq-based Amharic morphological segmenter model using the newly segmented word corpus.

- A state-of-the-art accuracy of the seq2seq morphological segmentation model (F1-score of 98.65%).

#### ACKNOWLEDGMENT

Our deep gratitude goes to Dr Derib Ado and Dr Demeke Asres Ayele who offered us valuable corpus and links. Our heartfelt appreciation goes to Dr Yemane Keleta Tedla, who sent us his full PhD dissertation paper on Tigrinya morphological segmentation.

**Abstract**—One of the most common biometric systems is fingerprint identification, which has been misused due to issues such as fraud. Hence, intelligent methods should be designed and used to recognize real-live fingerprints. Therefore, in the current work, we proposed a novel liveness fingerprint detection framework with low computational cost and excellent accuracy based on empirical mode decomposition and neural network to distinguish real from fake fingerprints. Our proposed scheme works based on empirical mode decomposition technique. The fingerprint images were cropped into  $200 \times 200$  images and then the two-dimensional (2D) images were converted into one-dimensional (1D) data, greatly reducing the computational process. The empirical mode decomposition (EMD) technique decomposed the data and the first five intrinsic mode functions (IMFs) were targeted for feature extraction through simple statistical features. The findings revealed that our suggested system can yield an average accuracy of 97.72% in distinguishing fake from real fingerprints through multilayer perceptron (MLP) neural network. This framework is very efficient compared to other techniques because only one piece of fingerprint image is enough to defend against spoof attacks. Therefore, such framework can reduce the cost of the fingerprint biometric systems, as no further hardware is needed. In addition, our framework method gives the best classification results in comparison to other previous techniques in real-live fingerprint recognition while being simple with lower computational cost. Therefore, this framework can be practically used in commercial biometric systems.

**Keywords**—Fingerprint; liveness; biometric; neural network; empirical mode decomposition

## I. INTRODUCTION

People's fingerprints have been used in criminology for many years, and today they are used in biometrics. The fingertip and its unique line pattern originate from the individual DNA pattern in each subject [1]. There are lines on the fingers of all people, which have been of interest to everyone for a long time. These important lines play different roles. One of them is to introduce frictions between finger and objects, by using this friction we can grab, write or touch objects [2]. Fingerprint is the oldest method of recognition and the progress in technology has increased its variety. One issue and difficulty in a biometric system is the lack of discrimination of fake fingerprints, to the extent that it leads to unauthorized entry into the system [3]. Hence, intelligent methods should be designed and used to recognize real-live

fingerprints. Liveness identification is an anti-spoofing technique that ensures that only the biometrics of a real and authorized individual are sent for recognition. Liveness detection relies on the fact that extra data can be collected from an authorization system, and that this extra data may be utilized to check the authenticity of an image [4]. Liveness detection utilizes either software- or hardware-based systems along with an authentication system to supply more protection. Hardware-related systems utilize more equipment and readers to capture biometric measures other than fingerprints to detect liveness. Such systems used additional equipment to record biological signals such as fingertip temperature, electric resistance, blood pressure, odor, or heartbeat [5-7]. Nixon and Rowe proposed a multispectral reader in which several light wavelengths and multiple polarizations provide extra data not available from a traditional system. According to several spectral pictures, they introduced a spoof recognition technique [8]. However, this technique has limitations due to additional hardware and remains vulnerable and unreliable. On the other side, software-related approaches utilize different image processing methods to directly process fingerprint image details for liveness detection. For example, Kiss et al. developed a hardware-related system for liveness detection, whereas Schukers et al. investigated software approaches for this purpose [9].

In general, despite the many efforts that have been made in this field, a comprehensive software-based system that is accepted by everyone has not yet been developed, and previous studies have emphasized the necessity of developing this work. Therefore, in this study, inspired by software-based systems and texture features extracted from different layers of fingerprint images, a novel feature calculation scheme was suggested using empirical mode decomposition (EMD) in a one-dimensional framework. One of the key benefits of EMD is its ability to extract hidden information from nonlinear data [10]. In the proposed method, the two-dimensional (2D) data is first converted into one-dimensional (1D) data, and then liveness is predicted through statistical features extracted from five layers of fingerprint images.

This paper is organized as follows. In Section II, various software-based solutions in the fingerprint anti-spoofing were described. Section III provides the procedure proposed in the present work. Section IV reports the experimental. Section V discusses the obtained results and Section VI makes a conclusion.

## II. RELATED WORKS

In the last two decades, many solutions have been proposed to address fingerprint spoofing vulnerabilities. Marasco et al. introduced a fingerprint liveness recognition system according to several textural properties and multiple classifiers (e.g., Bayesian classifier, decision tree, and multilayer perceptron) and achieved an accuracy of 87.5% [11]. The same authors published another paper two years later based on perspiration and morphological-based static features and reported an accuracy of 87.5% for fingerprint liveness detection [12]. Galbally et al. used image quality related features along with linear discriminant analysis (LDA) and quadratic discriminant analysis (QDA) classifiers and reported an accuracy of 91.8% for fingerprint liveness detection [13]. Gagnaniello et al. introduced a complex liveness detection system based on Wavelet-Markov local-based features and support vector machine (SVM) and reported a good accuracy of 97.2% [14]. Nogueira et al. utilized convolutional networks with random weight and localized binary pattern along with SVM classifier and achieved an accuracy of 96.1% for liveness detection [15]. In 2015, Jiang et al. proposed co-occurrence matrix for feature extraction from fingerprint images along with SVM classifier and reported an accuracy of 93.2% for liveness detection [16]. Gottschlich et al. achieved an accuracy of 93.3% for fingerprint liveness detection using histogram of constant gradients [17]. Zhang and his colleagues used wavelet transform and localized binary patterns and reported an excellent accuracy of 97.9% [18]. Given that fingerprints show oriented texture like paradigm, Nikam et al. used Gabor filter based features to obtain local frequency and orientation data [19]. A novel feature extraction method for detecting fingerprint liveness according to the localized phase quantization has been introduced by Ghiani and his colleagues [20]. In addition, some studies have used other features such as skin deformation and fingerprint pores to detect liveness [21, 22]. For example, Espinoza and his colleagues suggested an approach through comparing pore numbers between real live and fake fingerprints [23]. Generally, previous studies show that the use of nonlinear analysis methods can achieve better classification results due to the nonlinear nature of fingerprint data. However, none of the previous researches have used the EMD method as a robust nonlinear analysis technique to extract hidden patterns in fingerprint data. Therefore, this study aims to integrate this nonlinear analysis technique with neural network in order to distinguish real fingerprints from fake ones.

## III. METHODOLOGY

In this section, the dataset used, processing algorithms and classification methods were explained in detail.

### A. Dataset

In this study, the well-known reliable database of the Liveness Detection Competition 2011 (LivDet 2011) was used that is publicly available [24]. This dataset includes 4 different subsets of fingerprint pictures captured through the Biometrika FX2000, Sagem MSO300, ItaldData ET10 and Digital Persona 4000B sensors. 4000 fingerprint images are available for every sensor. 2000 images are real-live fingerprints and the others are fake fingerprints. The fake images are synthesized by latex, gelatin, ecoflex, wood glue

and silicone. Indeed, 400 fake fingerprint images were captured for each of these five materials. Fig. 1 displays fingerprint images from the LivDet 2011 dataset.

Fig. 1. Instances of spoof fingerprint pictures of the LivDet 2011 database, from Biometrika: (a) latex, (b) gelatin, (c) silicone; from Digital Persona: (d) latex, (e) gelatin, (f) silicone; from ItaldData: (g) latex, (h) gelatin, (i) silicone; from Sagem: (j) latex, (k) gelatin, (l) silicone.

### B. Preprocessing

Preprocessing is a crucial step in image processing. In the present work, images were prepared for further processing in terms of light intensity, color and other physical characteristics. This step provides a same condition for fake and real fingerprints. The actions performed in the preprocessing stage were image conversion to gray levels, image matching, image cropping, normalization, etc. Since the segments of the images were subjected to analysis, image equalization was performed after segmenting the image so that the effects of pixels around these segments do not appear in the image being processed [25]. In fact, since this work is only focused on fingerprint liveness and non-liveness, there is no need to process whole image. In addition, image cropping has two advantages: (1) analysis is performed on the fake and real fingerprint textures and the noise surrounding the picture is not processed,

and (2) processing only a small segment of the image reduces the computational cost and accelerates the processing speed. As a result, the processing system designed in this way will be more practical. Therefore, in the current research, a  $200 \times 200$  foursquare window was located on the fingerprint picture and subsequent analysis was performed on it (Fig. 2).

Fig. 2. Image segmentation and cropping used in this work.

1) *Conversion 2D data into 1D*: Since this work aimed to introduce a simple and effective system with minimum computational cost and maximum processing speed, an attempt was done to convert the 2D image data into 1D data in a simple way after cropping. This reduces the complexity of computations and simplifies the processing process. In this method, all the rows of the image pixel values matrix are sequentially placed in one row and form a vector of image pixel values. Therefore, the 2D matrix of image pixel values are transformed into a 1D vector similar to a time series, which is further processed on. This simple scheme is shown in Fig. 3.

### C. Empirical Mode Decomposition

In 1998, Huang developed a new decomposition algorithm based on the Hilbert transform called EMD. This algorithm decomposes a time series into some oscillatory signals called intrinsic mode functions (IMF) [26, 27]. Due to the ability of EMD to provide short time variations in frequency that are not attainable from Fourier transform, it may be utilized to analyze nonstationary and nonlinear signals [28]. EMD is developed in the Hilbert-Huang transform (HHT) under the supposition that each signal comprises of ordinary intrinsic functions of fluctuations [29, 30]. The nature of the algorithm is to

Fig. 3. A proposed scheme for converting two-dimensional data into one-dimensional data.

determine the intrinsic fluctuating functions through their characteristic temporal subscales in the signal empirically and separate it into simpler compounds correspondingly [31]. The resultant compounds obtained from the algorithm form the IMFs. IMFs are functions that satisfy two stipulates: (1) in the entire dataset, the count of extrema and the count of zero-crossings should be equal or differ not more than one; and (2) at each sample, the averaged value of the envelope determined through the local maxima and the envelope determined through the local minima approaches zero [26]. The process to produce an IMF in the EMD is known as sifting mechanism. The sifting framework to generate the IMFs of a time series  $s(t)$ , consists of the following stages:

- 1) Find all local maxima and minima of time series  $s(t)$ ;
- 2) Interpolation among the local maxima to produce lower envelope,  $s_L(t)$ , as well as interpolation among the local maxima to produce upper envelope,  $s_U(t)$ ;
- 3) For every time point  $t$ , compute the average of the lower and upper envelopes;

$$e(t) = \frac{s_L(t) + s_U(t)}{2} \quad (1)$$

- 4) Subtract the averaged resultant from the input time series;

$$d(t) = s(t) - e(t) \quad (2)$$

This is a single iteration of the sifting framework. The next stage is to verify if the time series  $d(t)$  from the previous stage is an IMF or not.

- 5) Replicate the sifting mechanism on the residue time series.

Practically, of the averaged envelop approaches zero, the sifting framework stops. This stopping condition guarantees the symmetrical property of the resultant envelop as well as the accurate relationship between the count of extremes and count of zero crossings that determine the IMFs [32].

Here, EMD was first applied to 1D data and then seven statistical features were calculated from the five first IMFs obtained from the EMD decomposition process. Previous studies on biomedical data have shown that the first five IMFs extracted from EMD contain very important details and information from the original data [33-35]. Therefore, according to previous studies and to keep the computation cost low, the first five IMFs were used in this work for feature extraction. Fig. 4 shows our proposed process according to preprocessing, EMD and feature selection approaches for fingerprint liveness identification.

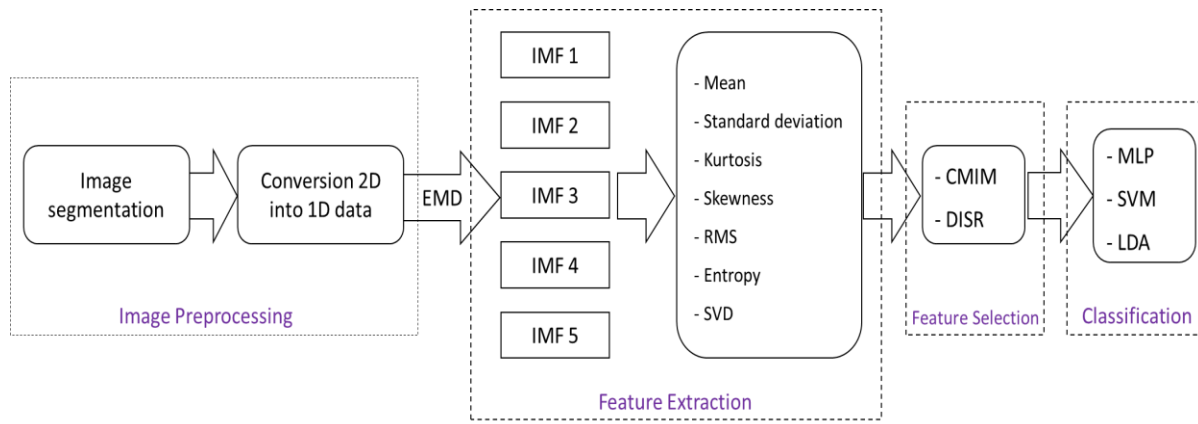

Fig. 4. The proposed process according to preprocessing, EMD and feature selection approaches for fingerprint liveness identification.

After extracting the first five IMFs for each feature vector, seven statistical features [36] (i.e., standard deviation, mean, skewness, root mean square (RMS), kurtosis, singular value decomposition (SVD), entropy) were calculated with the following mathematical definitions for each IMF:

$$\text{Mean} = \frac{1}{n} \sum_{i=1}^n (x_i) \quad (3)$$

$$\text{Standard deviation} = \left( \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2 \right)^{\frac{1}{2}} \quad (4)$$

$$\text{RMS} = \sqrt{\frac{1}{n} (x_1^2 + x_2^2 + x_3^2 + \dots + x_n^2)} \quad (5)$$

$$\text{Entropy} = \sum (P * \log_2 P) \quad (6)$$

$$\text{Skewness}(X) = \frac{E[(X-\mu)^3]}{\sigma^3} \quad (7)$$

$$\text{Kurtosis}(X) = \frac{E[(X-\mu)^4]}{\sigma^4} \quad (8)$$

$$\text{SVD} = U \Sigma V^T \quad (9)$$

where  $x$  or  $X$  denote the time series (i.e., each IMF),  $n$  represents the count of data points,  $P$  represents the count of image histograms,  $\mu$  denotes the mean of signal,  $\sigma$  denotes the standard deviation, and  $E[\cdot]$  is the mathematical expectation.

#### D. Feature Selection

In this work, all above seven features were calculated for the first five IMFs. Thus, a  $5 \times 7$  feature matrix was produced for every image. Therefore, 35 features were calculated for the entire fingerprint images. However, it should be noted that some features may be redundant or may not be informative for distinguishing real from fake fingerprints. Thus, the CMIM and DISR were utilized in our framework to select best discriminative features, improve the classification results and minimize computational cost.

1) *CMIM*: This method removes redundant features by making a trade-off between discrimination and independence to choose features that maximize mutual information with the class to anticipate. Conditional mutual information is defined by:

$$\text{CMI}(y; x_n | x_m) = H(y | x_n) - H(y | x_n, x_m) \quad (10)$$

Afterward, following relationship is utilized for selecting the  $(F+1)$ th feature while  $F$  features have been chosen.

$$f(F+1) = \arg \max_n (\min_{1 \leq l \leq F} I(y; x_n | x_{f(l)})) \quad (11)$$

2) *DISR*: This algorithm utilizes the following equation for feature selection [37, 38]:

$$F_{DISR} = \arg \max_{X_i \in X_s} \left\{ \sum_{X_j \in X_s} \frac{MI(X_i, X_j, Y)}{H(X_i, X_j, Y)} \right\} \quad (12)$$

where  $H(X_i, X_j, Y)$  is the information entropy and  $MI(X_i, X_j, Y)$  is the mutual information.

#### E. Classification

1) *Multilayer perceptron (MLP) neural network*: One of the simplest and effective structure of neural networks is MLP with back propagation learning procedure. MLP has been demonstrated to be effective in various problems, including pattern recognition, prediction, estimation and classification. The architecture of this neural network comprises of an input layer, hidden layer(s) and an output layer. The neurons of every layer are linked to the next layer with a certain weight, which is defined as follows:

$$\Delta W_{ij} = \eta \delta_j(n) y_i(n) \quad (13)$$

The above equation is known as the delta law through which weight correction is done from neuron  $i$  to neuron  $j$ .  $\eta$ ,  $\delta_j(n)$  and  $y_i(n)$  are learning rate variable, local gradients and input signal of neuron  $j$ , respectively. If  $j$  is a neuron in the hidden layer, then  $\delta_j(n)$  is obtained through:

$$\delta_j(n) = \varphi'_j(v_j(n)) \sum_k \delta_k(n) W_{kj}(n) \quad (14)$$

where  $k$  is a neuron in the output layer, and  $\varphi'_j(v_j(n))$  denotes the activation function for characterizing the input-output relationships of the non-linearity to entity  $j$  [39, 40].

2) *SVM*: In this study, SVM was used for classification because this classifier minimizes the expected risk in the test data and considers a margin around the class boundaries, which leads to increased generalizability of the results. SVM uses a kernel property to convert the nonlinear classification problem into a linear one by increasing the dimensionality of

the dataset. In this work, we used the RBF kernel. The mathematical notation of SVM is [41]:

$$a_i = [(\omega \cdot b_i) + x] - 1 \geq 0, \quad i = 1.2 \dots l \quad (15)$$

where  $a_i$  represents the identifier generated by SVM ( $a_i \in -1, +1$ ). This can be transformed into a dual problem via the Lagrange coefficient as follows:

$$\min Q(y) = \frac{1}{2} \sum_{i,j=1}^l y_i y_j a_i a_j \cdot K(b_i b_j) - \sum_{i=1}^l y_i \quad (16)$$

$y_i$  represents Lagrange coefficients.  $K$  is the kernel function with the following equation:

$$K(a, a_i) = \frac{\exp(-|a-a_i|^2)}{\sigma^2} \quad (17)$$

3) *LDA*: LDA is an expansion of Fisher's linear discriminant to find linear combinations of samples that separate two classes of events or objects. It is very associated with regression analysis and analysis of variance, which attempt to specify one dependent variable as a linear combination of other samples. LDA attempts to solve an optimal discrimination projection matrix  $W_{opt}$ :

$$W_{opt} = \operatorname{argmax}_W \left| \frac{W^T S_b W}{W^T S_t W} \right| \quad (18)$$

where,  $S_b$  and  $S_t$  are the scatter matrices with the following definitions:

$$S_b = \sum_{p=1}^q n_p (\mu_p - \mu)(\mu_p - \mu)^T \quad (19)$$

$$S_t = \sum_{p=1}^q n_p (\mu_p - \mu)(\mu_p - \mu)^T + \sum_p (x_p - \mu_{k_p})(x_p - \mu_{k_p})^T \quad (20)$$

where,  $S_b$  represents the between-class dispersion matrix and  $S_t$  represents the total dispersion matrix. The second term

in (20) represents the within-class dispersion matrix.  $\mu_p$  represents the averaged feature vector of image class  $p$ , as well as  $n_p$  denotes the count of features in image class  $p$ .  $q$  denotes the total count of the features.  $x_p$  denotes the feature vector of a data point, and  $\mu_{k_p}$  denotes the vector of the image class that  $x_p$  belongs to [42].

#### IV. RESULTS

After preprocessing and cropping the fingerprint images, the 2D data of the images were converted into 1D data, and then the EMD algorithm was applied to this 1D data, and the IMFs of each data were extracted for real and fake fingerprints. Next, all seven mentioned features were calculated for the first five IMFs. Fig. 5, 6, 7 and 8 show the box plots for the mean, standard deviation, entropy and SVD features for the five IMFs of real and fake fingerprints, respectively.

As shown in the above figures, there are obvious differences in the features extracted from different IMFs between real and fake fingerprints. However, as expected, the rate of change decreases after IMF1. This observation is due to the fact that the IMF 1 has more information and details from the original data, and in the subsequent IMFs, the amount of these details decreases accordingly.

After feature extraction, feature selection was performed with CMIM and DISR methods. Then, feature classification by three different classifiers (i.e., MLP, SVM and LDA) was performed to distinguish real from fake fingerprints. At this stage, 70% of the dataset (i.e., extracted features) was allocated for training classifiers, 10% of the dataset for validation, and the remaining 20% for testing the performance of the classifiers. To assess the classification performance, a random subsampling technique was used that replicates the hold-out cross validation  $n$  times. MLP training process was stopped if 1000 iterations executed or error reached less than 0.01%.

Mean of IMFs

Fig. 5. Mean of the first 5 IMFs computed from one-dimensional data of real and fake fingerprints.

### Standard Deviation of IMFs

Fig. 6. Standard deviation of the first 5 IMFs computed from one-dimensional data of real and fake fingerprints.

### Entropy of IMFs

Fig. 7. Entropy of the first 5 IMFs computed from one-dimensional data of real and fake fingerprints.

To evaluate the classification performance, the following error criteria were calculated and used:

False fake rate (FFR) = The number of fake fingerprints that are mistakenly recognized as real.

False real rate (FRR) = The number of real fingerprints that are mistakenly recognized as fake.

Average classification error (ACE) = (FFR + FRR)/2.

Tables I, II and III summarize the classification results obtained by MLP, SVM and LDA classifiers, respectively. All classifiers produced a lower ACE through the features chosen by the DISR feature selection approach as input. Also, all

classifiers produced a higher ACE using all features as input. This showed that feature selection is an effective approach to feed classifiers with high discriminative features. Our experiments showed that DISR is a more effective feature selection method than CMIM, which can lead to better classification results. The best results of FFR, FRR and ACE obtained by MLP were 2.48%, 2.08% and 2.28%, respectively (Table I).

Also, the best results of FFR, FRR and ACE obtained by SVM were 3.40%, 2.24% and 2.82% respectively (Table II). Finally, the best results of FFR, FRR and ACE obtained by LDA were 5.53%, 2.64% and 4.09% respectively (Table III).

## Singular Value Decomposition of IMFs

Fig. 8. SVD of the first 5 IMFs computed from one-dimensional data of real and fake fingerprints.

TABLE I. PERFORMANCE OF MLP NEURAL NETWORK IN REAL AND FAKE FINGERPRINT CLASSIFICATION

Feature set	FFR (%)	FRR (%)	ACE (%)
All features	2.55	3.30	2.93
Selected features by CMIM	2.57	2.80	2.69
Selected features by DISR	2.48	2.08	2.28

TABLE II. PERFORMANCE OF SVM CLASSIFIER WITH RBF KERNEL IN REAL AND FAKE FINGERPRINT CLASSIFICATION

Feature set	FFR (%)	FRR (%)	ACE (%)
All features	4.51	3.51	4.01
Selected features by CMIM	3.20	3.10	3.16
Selected features by DISR	3.40	2.24	2.82

TABLE III. PERFORMANCE OF LDA CLASSIFIER WITH IN REAL AND FAKE FINGERPRINT CLASSIFICATION

Feature set	FFR (%)	FRR (%)	ACE (%)
All features	6.68	5.72	6.20
Selected features by CMIM	4.95	4.45	4.70
Selected features by DISR	5.53	2.64	4.09

## V. DISCUSSION

Spoof attacks with non-real replications substantially threaten the security of different fingerprint identification systems. Thus, it is necessary to develop efficient countermeasures against these deceive attacks. In the current work, a novel liveness fingerprint detection framework with low computational cost and excellent accuracy was proposed. Our proposed scheme works based on empirical mode decomposition technique. The fingerprint images were cropped into  $200 \times 200$  images and then converted the 2D images into 1D data, greatly reducing the computational process. The EMD technique decomposed the data and the first five IMFs were targeted for feature extraction through simple statistical features. Consistent with previous studies [15, 16], our findings also demonstrated the efficacy of textural features to detect fingerprint viability. The findings revealed that our suggested

system can yield an average accuracy of 97.72% in distinguishing fake from real fingerprints through MLP neural network. This framework is very efficient compared to other techniques because only one piece of fingerprint image is enough to defend against spoof attacks. Therefore, such framework can reduce the cost of the fingerprint biometric systems, as no further hardware is needed. Image cropping, 2D to 1D data conversion and the use of nonlinear EMD analysis are the innovations of this study that distinguish our work from previous studies. As will be explained in the next paragraph, this framework led to the improvement and development of previous results and was a step forward in the development of software-based methods for fingerprint liveness detection.

In this section, our proposed framework was compared with other techniques examined on the same database (i.e., LivDet 2011 database). Table IV indicates the characteristics

and results of similar papers conducted on the LivDet 2011 database to discriminate fake from real fingerprints in terms of ACE. As indicated, seven papers have worked on this dataset with various computational algorithms to detect real-live fingerprints. Most of the previous techniques utilized texture features and all of them utilized SVM classifier. Gragnaniello et al. [43] reported the best classification results with the ACE

= 5.7%. Their system works based on local contrast phase descriptor. As shown in Table IV, our introduced technique gives the best classification results compared to other previous methods in real-live fingerprint recognition while being simple with lower computational cost. Therefore, this framework can be practically used in commercial biometric systems.

TABLE IV. CHARACTERISTICS AND RESULTS OF SIMILAR STUDIES CONDUCTED ON THE LIVDET 2011 DATASET TO DISTINGUISH REAL FROM FAKE FINGERPRINTS

Author (year)	Algorithm	Classifier	Result
Nogueira et al. (2014) [15]	Convolutional network with random weight and local binary pattern	SVM	ACE = 6.5%
Jian et al. (2015) [16]	Co-occurrence matrix	SVM	ACE = 11%
Jia et al. (2014) [44]	Multiscale local binary pattern	SVM	ACE = 7.5%
Gragnaniello et al. (2015) [43]	Local contrast phase descriptor	SVM	ACE = 5.7%
Jia et al. (2013) [45]	Multiscale local ternary patterns	SVM	ACE = 9.8%
Zhang et al. (2014) [18]	Wavelet transform and local binary patterns	SVM	ACE = 12.5%
Johnson et al. (2014) [46]	Pore characteristics	SVM	ACE = 12%
Our proposed system	Empirical mode decomposition and statistical features	MLP, SVM, LDA	ACE = 2.28%

## VI. CONCLUSION

In summary, the proposed framework includes preprocessing along with image cropping incorporation, feature extraction using nonlinear analysis, feature selection by two different information-based approach, and classification stage through neural network, improved accuracy of previous techniques for fingerprint liveness detection. The findings of the present study support the use of nonlinear analysis and texture features for liveness fingerprint detection. However, the results of this study need to be validated by additional databases. In addition, future studies should explore other advanced classification techniques, especially deep learning models, to improve our findings.

# Providing a Hybrid and Symmetric Encryption Solution to Provide Security in Cloud Data Centers

Desong Shen\*

School of Business and Trade, Anhui Wenda University of Information Engineering, Hefei, 230121, China

**Abstract**—One of the most crucial components of information technology infrastructure in the modern world is cloud data centers. Customers have access to these data centers' infrastructure and software, which enable them to store and process massive amounts of data. However, the security and protection of private data in cloud data centers is a serious problem that needs effective and c solutions. Security and privacy issues exist because cloud computing outsources the processing of sensitive data. Consumer worries about cloud infrastructure security remain, particularly those related to data privacy. A thorough analysis of research efforts in the area of cloud security is the main objective of this study. In order to do this, a variety of models were evaluated, their advantages and disadvantages were identified, and a viable security solution based on symmetric algorithms was put forth. The original text in the proposed solution (Hybrid encryption algorithm) is first encrypted using the faster symmetric key method AES, and then its key is encrypted using the faster asymmetric key scheme RSA. This increases efficiency and speed. This method will shorten the time required for data encryption while enhancing its security. The final step was implementing the desired solution in the Eclipse software environment and comparing it against the Blowfish and RSA algorithms. The evaluation's findings indicate that the solution is more advantageous, which has resulted in a nearly two-fold decrease in execution time and a marked increase in throughput when compared to the RSA algorithm. Additionally, the execution time has shrunk, and throughput has been vastly improved compared to the Blowfish method.

**Keywords**—Hybrid encryption algorithm; security; cloud computing; symmetric algorithms

## I. INTRODUCTION

In the ever-evolving IT landscape, cloud data centers stand as giants of innovation, transforming the way we store, process and access data on a scale previously unimaginable. Their ubiquitous presence in our digital lives has ushered in an era of unparalleled convenience, accessibility, and efficiency. However, in the midst of this digital utopia, a looming specter looms – the great challenge of protecting sensitive data in cloud environments. The relentless advancement of technology has brought with it increased security concerns, and data protection has become a critical battleground across the vast expanses of cloud data centers. As we unlock the enormous potential of cloud computing, we are acutely aware of the vulnerabilities it presents. The imperative to fortify data storage fortresses against malicious intrusions and data breaches has never been more prominent. Since the start of its operation, the Internet has seen several changes, some of which have altered how people live today because cloud computing offers consumers a wide range of facilities as a service, this

new technology has swiftly gained popularity [1]. Naturally, any modification and fresh idea in the technological world has its advantages, drawbacks, and issues [2]. This rule applies to using cloud computing as well [3]. We can include the absence of time and location constraints, easy resource sharing, and decreased capital and operating expenses as benefits of cloud computing [4]. Because cloud computing offers scalable resources as a service over the Internet, it has created a number of difficulties for the field's professionals, including data protection or preservation [5]. That is privacy. Early adopters still hesitate to move their businesses to the cloud despite the entire buzz [6]. The difficulties associated with data privacy and information protection continue to disrupt the cloud computing market, and security is one of the primary problems that are slowing down the expansion of cloud computing [7]. Other crucial and major elements of the current model shouldn't be threatened or jeopardized by a new model whose goal is to enhance its features [8]. Cloud architecture poses risks to the security of these technologies when they are employed in a cloud environment [9]. Users of cloud services should be cautious and knowledgeable about the risks associated with data breaches in this novel environment [10]. User data is typically safeguarded from hackers using a variety of encryption techniques in order to assure security and secrecy. This technique has also been applied in cloud computing settings. However, reliability is not ensured when numerous services are used concurrently to carry out operations like combining functions [11]. For instance, if a malicious application interferes with the service used by other customers then the numerous cloud platforms are shared by many clients. Other people's environments are also impacted by it [12]. Common security threats for cloud computing include integrity, availability, and confidentiality [13]. Attacks in this system can be split into two categories, assaults from both internal and external parties. Internal assaults are those in which the perpetrator seeks to get access to the network and its operations by obtaining virtual machine control, knowing the password or other authentication credentials, or both [14].

In contrast, attackers that use external attacks want to distribute false routing information or stop nodes from offering services. An internal intruder poses a greater threat than an outside one. A secure link between data centers and users is created concurrently using symmetric encryption as well as hybrid encryption [15]. With the aid of this technique, key structures for data encryption and decryption in cloud environments are made to be secure and dependable [16]. The benefits of utilizing hybrid and symmetric encryption in cloud data centers include boosting user privacy protection, lowering the risk of cyberattacks, strengthening protection against

intrusion, and increasing security and protection of sensitive information retrieval. Security mechanisms against hackers (attackers) including: Firewalls and intrusion detection systems (IDS), access control and authentication, encryption, security patch management, intrusion response plan, network segmentation, security information and event management (SIEM), and monitoring and logging.

Additionally, the usage of symmetric and hybrid encryption boosts the effectiveness of cloud data centers [17]. Additionally, symmetric and hybrid encryption can withstand physical assaults. Information is kept in decryption mode, and the likelihood of unwanted access to them is decreased by utilizing detection and prevention techniques. These techniques enable cloud data centers to deliver services more dependably while limiting illegal data access [18]. When using symmetric encryption algorithms such as AES, a separate MAC algorithm or an authenticated encryption mode (such as AES-GCM or AES-CCM) is used to simultaneously ensure data confidentiality and integrity/authentication. These modes incorporate MAC functions in the encryption process to achieve data integrity protection. Also, when a secure cryptographic system is implemented, a well-established MAC algorithm (such as HMAC, CMAC) or an authenticated encryption mode should be considered to protect data integrity and validity in addition to encryption. In order to guarantee security and boost efficiency in cloud data centers, a novel approach utilizing hybrid and symmetric encryption is given in this article. Combining many distinct encryption techniques at once is known as hybrid encryption. By using this technique, it is possible to increase security and defend against decoding attempts. A secure link between data centers and users is created concurrently using symmetric encryption as well as hybrid encryption. With the aid of this technique, key structures for data encryption and decryption in cloud environments are made to be secure and dependable. The author's contribution to this work can be summed up as follows:

- Offering an integrated solution based on the RSA and AES algorithms to improve security.
- Shortening the duration of encryption operations.

The remainder of the essay is structured as follows: A summary of earlier efforts is provided in the Section II. Section III goes into further detail about the suggested approach. The evaluation and effectiveness of the suggested method are described in the Section IV. Section V contains the conclusion and recommendations for further research.

## II. RELATED WORKS

One of the most talked-about subjects in the IT world is cloud computing. Due to the cloud's vast resources and low entry barrier, it is being enthusiastically embraced by many new businesses. The cloud, however, has both pros and cons, just like any other topic. Information about cloud users is saved remotely. Therefore, one of the primary concerns of any firm contemplating a move to the cloud is cloud data security. Firewalls and VPNs (virtual private networks) are two of the most popular ways for data owners to protect their information at home or the office. The company is the data owner, but it

uses uncontrolled cloud servers to store sensitive information, and its users can access this information when needed. For this reason, there is a security risk associated with storing client data elsewhere.

As a result, safeguarding data in the cloud has emerged as a key field of study [19]. Various cryptographic methods, including AES (a symmetric cryptographic method), SHA-1 (a hashing method), and ECC, are used in [20], with data first being organized into categories according to its sensitivity and significance. In the asymmetric cryptography method of elliptic curve cryptography, most existing works rely on a single key for encryption and decryption, making them vulnerable to a wide range of well-known harmful attacks. As a result, the hybrid algorithm we developed uses two independent keys applicable to any encoding/decoding process. If you wish to access data stored in the cloud, you'll need to sign up with both your cloud service provider and the cloud's owner which is required for decrypting cloud-based information. The purpose of this research [21] was to create a novel approach to cloud data security based on hybrid encryption architecture. Encrypting user data before it is sent to the cloud is an active study area because of the prevalence of malicious actors in this environment.

Since the scope of cloud computing security concerns extends to data access control, identity management, auditing, integrity control, and risk management, a hybrid cryptosystem was developed to address these concerns. Data privacy is addressed with the symmetric Blowfish algorithm rather than the asymmetric RSA scheme. Authentication is the focus of the algorithm. The Secure Hash-2 algorithm is also used in this method; therefore, the data may be trusted. Based on the current research results, it has been determined that the suggested method offers both high security for data transmission over the Internet and easy, on-demand network access to the manufacturer's shared pool of computer resources, including the latter two in particular. Due to concerns over data security, many large companies are hesitant to adopt cloud computing services. There have been numerous incidents of cloud security breaches documented over the past few years, despite the cloud service provider's claim of having a solid third-party security system. Therefore, for cloud service providers to succeed, they must have stringent safety measures. Strong security for user data is proposed in [22] via a two-layer agent-based hybrid framework that combines symmetric and asymmetric key methods. The risk of data misuse by the cloud service provider is also removed because the user alone controls the decryption process. This framework improves security without slowing down the virtual machine's processing speed since the two cryptographic algorithms utilized are optimized for low key size, low encryption time, and high speed. In [23], we examine hybrid cryptography from 2014 until the beginning of 2019. Eight are based on a tabular survey format that is easy to use, while the remaining 12 are comprehensive polls. The primary goal of this review paper is to expand the knowledge base of novice cryptography researchers, students, and practitioners. The lack of attention paid to user authentication and the improper usage of hybrid algorithms is the area where more study is needed. As a result of all this, cloud customers are beginning to worry about the

security of their data while it is being stored on these outside managed servers. Information security is necessary to prevent these data breaches and other risks. Information security relies heavily on encryption. The user employs a couple of different encryption algorithms to keep their cloud data safe. Researchers look at trust and its application in distributed computing [24]. A summary of proposed trust models for various distributed system types is provided. The proposed trust management systems for cloud computing are examined with a focus on their capabilities, realistic heterogeneous cloud applicability, and implementation viability. In actuality, data security refers to the safeguarding of information's availability, completeness, and secrecy.

Research [25] ensures that, when necessary (Availability), only authorized users have access to accurate and comprehensive information (Completeness). Information security aims to shield data and information systems from misuse, failure, disclosure, and unauthorized access. Based on the Security as a Service (SECaaS) concept, they suggested multi-layer and multi-level encryption architecture for cloud computing [26]. This article also makes the point that the implementation of this architecture is adaptable to scalable systems with various needs and can unite heterogeneous networks and different operating systems. K-anonymity, an encryption model to safeguard personal information, is provided in [27]. By employing this technique, user data can be protected from unauthorized disclosure. The term "data" in this article refers to specific, unique information that is conceptually arranged as a table with rows for reports and columns for strings. An outline of the cloud's security issues and major difficulties can be found in [28]. By the end of this piece, they have determined that a significant portion of data security may be achieved by the employment of cryptographic methods.

Additionally, it has been found that using both symmetric and asymmetric encryption at once can speed up message transmission and identity verification considerably. The employment of extensible identity recognition protocol in cloud computing is plagued by issues listed in [29]. Cloud computing authentication issues have been resolved using EAP. This technique nullifies dangers from data manipulation, DoS assaults, and identity theft. However, in this manner, a powerful algorithm and encryption are required for the cloud environment, ensuring that the client's data and the data transferred between the client and the cloud provider are encrypted. The EAP approach also has additional issues. A framework for the authentication choice was supplied by the study conducted in [30], referred to as the "Trust Cube" in this study. A high-level framework of authentication procedures is offered in this solution. The client device, the data collector, the authentication engine, and the authentication consumers are taken into account in this architecture. Each of these participants must be validated before data can be sent through the authentication engine.

### III. SUGGESTED METHOD

The suggested approach is broken up into two stages. The first stage focuses on the transfer and secure storage of data on the cloud. Data is only made available to the authorized user after passing all security mechanisms in the second step, which handles data retrieval from the cloud and data validation and integrity. A hybrid encryption technique is employed in both phases as the best option for data encryption and decryption, which is done by using the data from the user side to the server or vice versa. The proposed model and method to provide a general framework to guarantee data security and comprehensiveness are shown in the general structure in Fig. 1. You can see the overall layout and the different types of actions done on the data at each level in this structure.

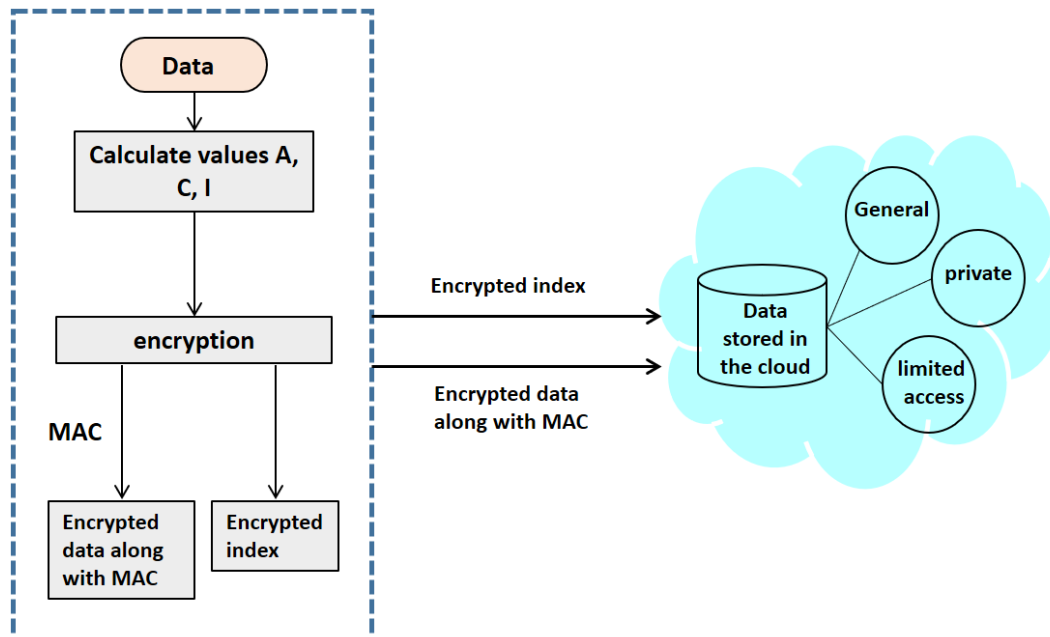

Fig. 1. General outline of the proposed model.

In actuality, this encryption method combines the strengths of AES and RSA, two symmetric encryption methods, to establish the key cryptographic parameters. There was good assurance of confidentiality, integrity, and availability. A systematic and comprehensive method was employed to explore the complexities of cloud data center security and evaluate the effectiveness of our proposed hybrid encryption solution. This method is designed to increase clarity and transparency and allow replication and validation of our research findings. The key components of our research method are as follows: Problem identification, model design, implementation, testing, security analysis, comparison with existing methods, data analysis and presentation of results.

In applying this systematic methodology, our aim was to ensure the robustness and validity of our research. The step-by-step approach brought clarity to our research process and facilitated the evaluation of the effectiveness of our proposed hybrid encryption solution in increasing security and efficiency in cloud data centers.

A. Combination of two encryption algorithms

Fig. 2 displays the overall architecture of the suggested method for integrating two techniques employing RSA asymmetric and AES symmetric encryption.

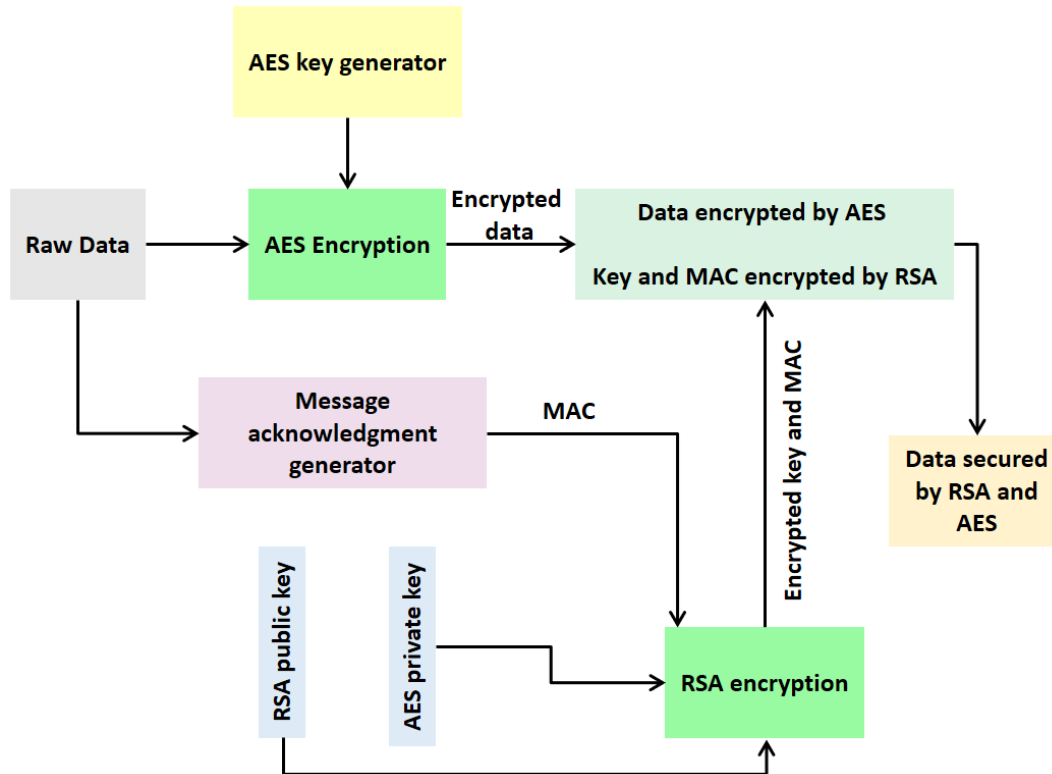

Fig. 2. The general framework of the combination of two cryptographic algorithms.

Proposed hybrid algorithm
Input: Data [] array of n integers storing data for the protection section. Where Data is an integer array containing the nonnegative integers A, C, I, AES and RSA. Output: Information sorted by category for the relevant section. For a to x C [a] = value of confidentiality. I [a]= value of integrity A [a]= value of availability Calculate AES and RSA [i] = (s [a] + (1/v[a])*10+I [a] )/2 For b= 1 to 10 For a= 1 to x If AES and RSA [a] == 1, 2, 3 then S [a] = 3 If AES and RSA [a] == 4, 5, 6 then S [i] = 2 If AES and RSA [a] == 8, 9, 10 then S [a] = 1

Since cloud storage is preferred, methods are provided for storing various types of data there (public, private, restricted access) according to three cryptographic parameters: privacy, accessibility, and security. The value of "C" (Confidentiality) is determined by how much privacy is needed at each data processing step. In contrast, the value of "I" (Integrity) is determined by how well the data is accurate, reliable, and protected against unauthorized changes. Fig. 1's A (Availability) represents how readily available the data needs to be in response to a user's request.

Users of the aforementioned algorithm are tasked with categorizing information according to the three cryptographic parameters C, I, and A. The user is responsible for providing the values for C, I, and A, where  $D_{ata} []$  is the data. Integrity is also directly tied to security and secrecy, while security is inversely related to availability. This "SR" number determines which of Fig 2's three sections the information belongs in S3 [Public], S2 [Private], or S1 [Owner's Limited Access].

In this solution, the interaction between the user and the cloud servers is considered the main step in which the user must be registered as a cloud client. If he is a registered user, the password check process is performed. Otherwise, you must first register using the service provider, and after confirming the user's authentication process, his public key will be sent to the server to encrypt the data. The scheduling unit of runtime coordination can be categorized as follows from the standpoint of runtime scheduling granularity:

- The complete application framework, which consists of all the entities that are used for execution and collaboration as well as the required external containers. Take a Hadoop, for instance.
- An instance of an application workload, comprising all the entities involved in distributed execution, is referred to as an application instance. Consider a Hadoop job.
- A single executor, which is typically a local OS process, is the internal execution entity of an application instance. Take a Hadoop task, for instance.

#### IV. EVALUATION RESULTS

These tests assess the effectiveness of data encryption at various sizes. Fig. 3 to 11 and Tables I to III exhibit the experiment's outcomes. The differences between the implementation of cryptographic operations in the combined mode and in comparison, with other methods may be readily recognized through the evaluation of the graphs. The comparison of the combined mode's execution times clearly demonstrates improved efficiency and optimal execution. In reality, the encryption procedure has been completed in half the time required by the RSA technique, making the execution time more than two times faster. The high execution time of asymmetric coding techniques is actually one of their key issues, which has a significant impact on performance. Although the throughput is somewhat less optimized when compared to the Blowfish method, the execution time is almost 30 milliseconds less, demonstrating that the combined solution is more optimal.

Fig. 3. Throughput - kilobytes per second (data size: 512 kilobytes).

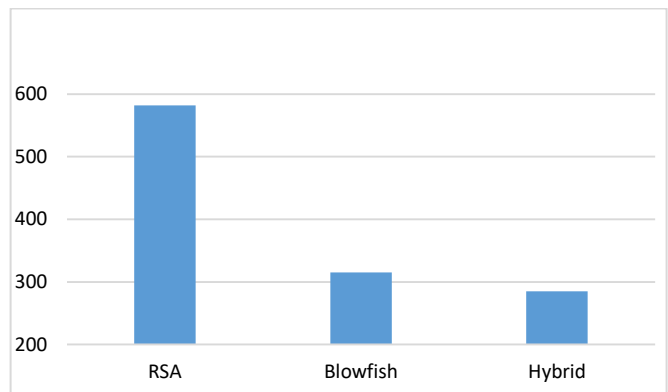

Fig. 4. Execution time - milliseconds (data size: 512 KB).

Fig. 5. Throughput - kilobytes per second (data size: 2048 kilobytes).

TABLE I. EXECUTION TIME AND THROUGHPUT (DATA SIZE: 512 KB)

	Hybrid	Blowfish	RSA
Throughput	1796	1625	880
Execution time (milliseconds)	285	315	582

Fig. 6. Execution time - milliseconds (data size: 2048 KB).

Fig. 7. Throughput - kilobytes per second (data size: 4096 kilobytes).

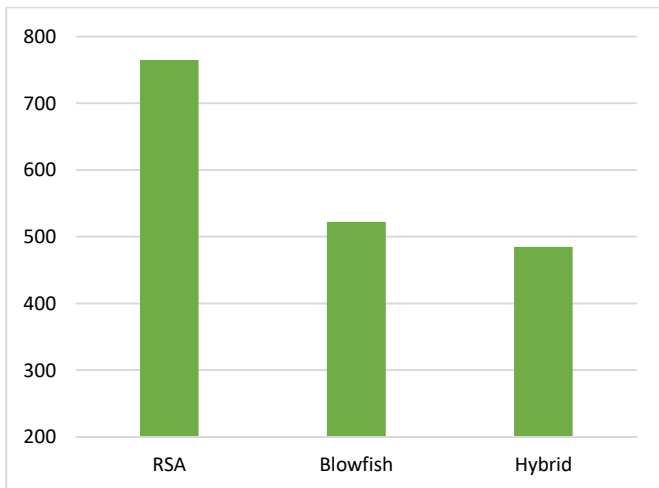

Fig. 8. Execution time - milliseconds (data size: 4096 KB).

Fig. 9. Throughput rate in different data sizes - kilobytes per second.

Fig. 10. Execution time in different data sizes - in milliseconds.

Fig. 11. The time required to decompose n into prime factors.

Due to the fact that the size of the data that can be encrypted can affect the time of the operation, in the second test, the size of the data has been increased to two megabytes (2048 kilobytes) to compare the efficiency of algorithms in this volume of data. As can be seen from Table II, the proposed solution performs much better than the RSA algorithm. In addition to the better throughput, the execution time is reduced by about 214 milliseconds. Compared to the Blowfish algorithm, the execution time has decreased by about 43 milliseconds and at the same time, the transmittance has also increased. This shows that the proposed solution works faster than these two solutions.

TABLE II. RUNNING TIME AND THROUGHPUT (DATA SIZE: 2048 KB)

	Hybrid	Blowfish	RSA
Throughput	4995	4521	3180
Execution time (milliseconds)	410	453	644

TABLE III. EXECUTION TIME AND THROUGHPUT (DATA SIZE: 4096 KB)

	Hybrid	Blowfish	RSA
Throughput	8445	7847	5354
Execution time (milliseconds)	485	522	765

Charts 9 and 10 clearly demonstrate that the proposed solution is more optimal in the last test, which compared the desired algorithms with a data amount of 4096 kilobytes. The proposed solution was able to perform the operation in less time than the other two algorithms, as shown in Table III. As the amount of data increases, the throughput likewise increases, but it impacts the encryption time and results in more time required.

The RSA technique is asymmetric, so it naturally takes a lot of time to produce the public and private keys and perform the encryption process, so its execution time is significantly higher. However, the other solution takes less time because of its symmetry. The results also demonstrate how little implementation there is.

Finally, in Fig. 9 and 10, a general comparison between execution times and throughput in different data sizes can be seen.

As can be seen, the processing action requires greater time for the initial execution than for successive executions, which indicates the necessity for warming up or preparation time. This time will be shorter for the application of larger data, yielding the desired outcome. The block size of processable threads was set at 256 for the processing resources that will be accessible for cryptographic operations, albeit this number may change depending on the resources' makeup. The greatest quantity of data that can be processed at any given time for encryption and decryption operations will be equivalent to 256 gigabytes. On the other hand, each processable thread can hold 64 bits of data (8 bytes).

### A. Time of Failure

This section evaluates the failure time of the suggested solution because, in addition to boosting efficiency, increasing security is one of the key goals of this research. Failure time is the amount of time needed to locate the algorithm's secret key and subsequently decrypt it. It is obvious that the answer is more secure the longer this period is. Although all encryption techniques can indeed be defeated, what matters is how long the information should be decrypted and what tools should be used. In relation to the suggested hybrid approach, since the RSA technique encrypts the AES encryption key, if the RSA can be decrypted, the AES key may also be retrieved, allowing for the discovery of the original content.

It should be noted that there are only a few ways to decrypt text using the RSA algorithm, the primary one being the breakdown of  $n$  into prime factors. In this instance,  $n$  and  $e$  are likewise presumed to be provided together with the RSA public key. Decomposing  $n$  into its prime factors,  $p$  and  $q$ , is the initial step at this point. Actually, the main and most challenging element of decrypting an RSA key is this step. Mathematical computations have demonstrated that it would take more than seven months to find the prime factors of a number with 155 digits, for instance, even using the fastest computers. The crucial point is that by choosing a larger key (choosing larger  $p$  and  $q$  numbers) when employing RSA, the work of analyzing  $n$  can be made much more challenging for new computers, regardless of how fast and adept they are at handling huge numbers. The outcomes of the decomposition of various values of  $n$  into prime components, along with the time needed to complete it, are presented.

According to evaluations, if the number of digits is taken to be equal to 200, four million years of time, as can be seen in the above figure, the time of decomposition might increase exponentially the greater the value of  $n$ . The ability to decode the data is required. Fig. 11 makes it evident that picking larger digits can actually make the analysis time; as a result, the RSA decryption is unfeasible in a short amount of time.

### B. Efficiency Comparison

An effective cloud data security model will solve all cloud computing's potential issues, allowing its advantages to soar to new heights while shielding its owner's data from as many threats as feasible. In Table IV, we can see how the suggested model stacks up against competing approaches to data protection.

After the security parameters for the contrasted approaches were implemented, Fig. 12 depicts the level of security. As can be seen, the security factor of the suggested method is higher compared to previous ways due to the rise in the volume of data in the horizontal axis, as well as the usage of data classification and encryption technology.

TABLE IV. FACTORS OF THE PROPOSED METHOD COMPARED TO SIMILAR WORKS

Factors	[3]	[31]	[9]	[13]	[21]	[24]	[25]	[29]	This work

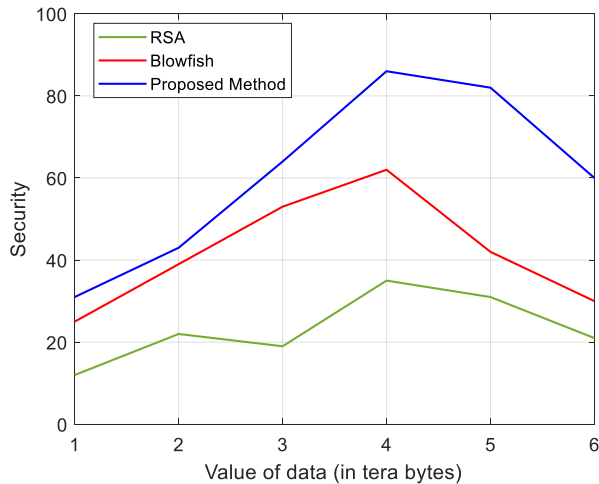

Fig. 12. Comparison of methods for security assessments.

This research includes a hybrid approach using both RSA and AES algorithms for encryption in cloud data centers, which is summarized as follows:

1) *Execution time and throughput analysis:* 512 KB data size: The proposed hybrid solution performs significantly better than the RSA algorithm when encrypting 512 KB data. In particular, it notes that the execution time is cut in half compared to RSA, which represents a significant improvement in speed. Furthermore, although the throughput is slightly lower than the Blowfish method, it is noted that the execution time is approximately 30 milliseconds shorter, indicating that the hybrid solution offers a more optimal balance between speed and security.

2048 KB data size: When the data size increases to 2048 KB (2 MB), the hybrid solution still outperforms RSA by a large margin. The execution time is reduced by approximately 214 ms compared to RSA, indicating that the hybrid approach is significantly faster. The article also mentions improvements in throughput.

4096 KB data size: In the final evaluation with a data size of 4096 KB (4 MB), the hybrid solution still shows its superiority over RSA and Blowfish. Runtimes are reported to be approximately 280ms faster than RSA and 37ms faster than Blowfish, showing consistent and significant speed benefits.

2) *Breakdown time analysis:* In this research, an analysis of the RSA algorithm's failure time is presented, which is a measure of how long it takes to decrypt RSA-encrypted data. This emphasizes the importance of choosing large key sizes to make computational decryption impossible in a reasonable amount of time. The presented results show that with a large enough key size (e.g., 200 digits), the decryption time can increase to millions of years, which highlights the security advantage of using larger key sizes in RSA encryption.

3) *Efficiency comparison:* In the following, the proposed hybrid model has been compared with other methods in terms of security evaluation. It uses a security factor as a benchmark and shows that the hybrid model consistently shows higher security levels compared to alternatives. This suggests that the hybrid approach provides a superior balance between security and efficiency.

The proposed method points out that the hybrid approach combines the strengths of AES and RSA for cryptographic parameters, which results in ensuring confidentiality, integrity, and availability. While providing runtime and throughput data, it is helpful to include specific numerical results, charts, or graphs to visually demonstrate these performance improvements.

## V. CONCLUSION

In addition to ensuring security, this article's major objective is to make encryption and decryption processes more effective. As a result, a hybrid approach based on the RSA and AES algorithms was presented to speed up encryption procedures while boosting security. As a result, the message confirmation code and the RSA method are used to secure the key after the main data has been encrypted using the AES technique. With this technique, the potential for decreasing the time required for the encryption procedure is also well established, in addition to improving security. Finally, a hybrid algorithm was constructed and tested using the Java programming language and the Eclipse programming environment, and all tests conducted on the provided solution show that it is superior to alternative approaches; there were strategies. Therefore, the encryption procedure was completed in half the time required by the RSA technique in the first test with a data volume of 512 kilobytes. Although the throughput was higher than the Blowfish method, the execution time was almost 30 milliseconds lower, demonstrating the combined solution's superiority. The proposed approach outperformed the

RSA technique in the second trial, which used a data volume of 2048 KB. Compared to the Blowfish algorithm, throughput increased more than two times, and execution time dropped by more than 214 milliseconds.

Additionally, the throughput is higher, and the execution time is decreased by 43 milliseconds, showing that the proposed method operates more quickly than the two alternatives. The proposed solution outperformed the other two algorithms in the final evaluation with a data volume of 4096 kilobytes, resulting in execution times that were about 280 milliseconds faster than those of the RSA algorithm and 37 milliseconds faster than those of the Blowfish algorithm, respectively. In comparison to these three methods, it demonstrates total optimality. The failure time of the RSA method, which is in charge of protecting the private key, was also examined to assess the solution's level of security. The findings of the experiment demonstrate that by using large keys, it can be decoded in a fair amount of time.

It is feasible to add to the described algorithm for future research and to broaden the suggested solution; it also makes use of a trusted third-party (TTP) based model because TTPs are frequently used in both commercial and cryptographic digital transactions, particularly in those involving a CA that gives a digital identity certificate to one of the two parties. Accordingly, the user is first verified using TTP-based protocols and then, after receiving the authentication certificate, can access the system and view and decode the encrypted data. At that point, the CA becomes a trusted third party for issuing certificates.

# A Single-Stage Deep Learning-based Approach for Real-Time License Plate Recognition in Smart Parking System

Lina YU<sup>1\*</sup>, Shaokun LIU

Hebei College of Industry and Technology, Hebei Shijiazhuang, 050091, China

**Abstract**—License plate recognition in smart parking systems plays a crucial role in enhancing parking management efficiency and security. Traditional methods and deep learning-based approaches have been explored for license plate recognition. Deep learning methods have gained prominence due to their ability to extract meaningful features and achieve high accuracy rates. However, existing deep learning-based fire detection methods face challenges in terms of accuracy, real-time requirement, and computation cost, as evident from previous studies. To address these challenges, we propose a single-stage deep learning approach using YOLO (You Only Look Once) algorithm. Our method involves generating a custom dataset and conducting training, validation, and testing processes to train the YOLO-based model. Experimental results and performance evaluations demonstrate that our proposed method achieves high accuracy rates and satisfies real-time requirements, validating its effectiveness for license plate recognition in smart parking systems.

**Keywords**—Smart parking; license plate recognition; deep learning; single-stage detector; Yolo

## I. INTRODUCTION

Smart parking systems have emerged as a transformative solution to address the challenges of urban parking management, aiming to optimize parking resource utilization and enhance the overall parking experience for drivers [1, 2]. These systems leverage advanced technologies to provide real-time parking information, streamline parking processes, and contribute to efficient traffic management in smart cities [3].

License plate recognition (LPR) technology plays a pivotal role in smart parking systems by enabling automated vehicle identification, entry/exit control, and payment processes [4, 5]. LPR involves the detection, extraction, and recognition of license plate information from images or videos. By accurately capturing and processing license plate data, smart parking systems can provide seamless and convenient parking experiences to drivers, optimize resource allocation, and enhance operational efficiency.

Current technologies and recent advances in license plate recognition have significantly enhanced the capabilities of smart parking systems. Various approaches, including computer vision, machine learning, and deep learning, have been employed to improve the performance of LPR systems [6]. Among these technologies, vision-based methods have garnered significant attention from researchers due to their

ability to handle variations in lighting conditions, vehicle types, and license plate designs.

Vision-based methods utilize computer vision techniques to extract and analyze license plate information from images or videos [7]. These methods have shown promising results in terms of accuracy and reliability, making them suitable for real-world deployment in smart cities. The significance of research in this area lies in developing more accurate and efficient LPR systems that can handle complex real-world scenarios and meet the real-time requirements of smart parking systems [8]. On the other hand, deep learning-based methods have emerged as state-of-the-art approaches for license plate recognition in smart parking systems. Deep learning models, particularly those utilizing convolutional neural networks (CNNs), have shown remarkable advancements in various computer vision tasks [9, 10]. However, there are still limitations and challenges in existing deep learning-based approaches for license plate recognition, particularly in achieving real-time processing and high accuracy rates.

To tackle these limitations, further research is needed to investigate alternative approaches that can achieve high accuracy rates in real-time. One such approach is the utilization of single-stage deep learning models, such as the YOLO (You Only Look Once) algorithm [11]. Single-stage models eliminate the need for time-consuming region proposal networks and achieve efficient end-to-end license plate detection and recognition [12]. By exploring single-stage and YOLO-based methods, the research aims to address the current limitations and challenges in deep learning-based license plate recognition for smart parking systems.

In this study, we propose a YOLO-based method with a custom dataset generation to tackle the identified research gap and meet the real-time requirements of license plate recognition in smart parking systems. The YOLO-based model is generated using a custom dataset, encompassing various challenging scenarios encountered in smart parking environments. The model is trained, validated, and tested to evaluate its performance in terms of accuracy, speed, and robustness.

The research contributions of this study lie in identifying the research gap in deep learning-based license plate recognition for smart parking systems and proposing a YOLO-based method to address this gap. Additionally, comprehensive experimental evaluations are conducted to validate the proposed method, assessing its performance in real-world

scenarios. The contributions of this research are significant for the development of accurate and efficient license plate recognition systems, ultimately improving the efficiency and convenience of smart parking management in urban environments.

The main research contributions in this study are listed as follows:

- The study identifies the existing limitations in real-time license plate recognition for smart parking systems and highlights the need for more efficient and accurate methods to address these challenges.
- Generating an extensive custom dataset for car license plate recognition.
- The study proposes a YOLO-based approach with a custom dataset generation to improve license plate detection and recognition in smart parking systems, offering an effective solution for real-time processing and enhanced accuracy.
- The study conducts comprehensive experimental evaluations to validate the proposed method, assessing its performance in terms of accuracy, speed, and robustness. The results demonstrate the effectiveness and superiority of the YOLO-based approach in addressing the research gap and meeting the requirements of smart parking systems.

## II. PREVIOUS STUDIES REVIEW

The authors in [4] focuses on parking entrance control using license plate detection and recognition. The method employs computer vision techniques to detect and recognize license plates of vehicles entering a parking area. The advantages of this approach include enhanced security and improved efficiency in managing parking access. By automating the entrance control process, it reduces the need for manual intervention and enables real-time monitoring. However, potential drawbacks may include challenges in accurately detecting and recognizing license plates under varying lighting conditions and vehicle speeds. Overall, this research presents a practical solution for parking entrance control, offering benefits in terms of security and efficiency while acknowledging the need for robust license plate detection and recognition algorithms.

In [13], license plate recognition algorithms are explored based on deep learning in complex environments. The proposed method utilizes deep learning techniques to address challenges such as varying lighting conditions, occlusions, and plate deformations. The advantages of this approach include achieving high accuracy rates and robustness in complex scenarios, thanks to the superior feature extraction and pattern recognition capabilities of deep learning algorithms. However, drawbacks include the need for large amounts of labeled data for training, computational complexity, and potential limitations in generalizing to different license plate formats and languages. Overall, this research highlights the effectiveness of deep learning in license plate recognition but emphasizes the importance of considering data requirements, computational complexity, and adaptability to practical implementation.

The authors in [14] proposes a license plate recognition system that utilizes YOLOv5 and CNN (Convolutional Neural Network) models. The method involves training the YOLOv5 model to detect license plates in images, followed by using a CNN model for character recognition. The advantages of this approach include the ability to accurately locate and recognize license plates in real-time, enabling efficient automation of tasks such as parking management and access control. The use of deep learning models like YOLOv5 and CNN allows for robust performance even in challenging scenarios. However, potential drawbacks may include the need for a large amount of labeled data for training the models and the computational complexity associated with deep learning algorithms. Overall, this research demonstrates the effectiveness of using YOLOv5 and CNN for license plate recognition, offering advantages in terms of accuracy and real-time processing while acknowledging the considerations related to data requirements and computational resources.

The authors in [15] developed a low-cost IoT-based Arabic license plate recognition model for smart parking systems. The method utilizes existing IoT infrastructure and image processing algorithms to automate the recognition of Arabic license plates, enhancing parking management efficiency. The advantages include its cost-effectiveness and focus on Arabic license plates, catering to regions with Arabic as the dominant language. However, limitations include reliance on IoT infrastructure and the restriction to Arabic license plates. Challenges such as connectivity issues and varying plate formats may affect accuracy.

The authors in [17] presented an all-encompassing automated license plate recognition (ALPR) system, which streamlines the entire process by employing the YOLO (You Only Look Once) algorithm for vehicle and license plate detection, coupled with vehicle classification. The proposed approach represents a comprehensive solution to license plate recognition, aiming to eliminate the need for multiple separate algorithms and enhance the automation of this crucial task in various applications. However, the study brings to light a significant concern regarding the system's low accuracy rate in certain scenarios. This limitation suggests that the system may encounter challenges in reliably recognizing license plates, particularly in complex or adverse conditions. Consequently, it underscores the necessity for further research and improvements in accuracy to ensure the system's robust performance across diverse real-world scenarios and applications.

The study [18] explored a convolutional neural network (CNN)-based approach for license plate detection. The proposed method in the study centers around the utilization of CNNs, a class of deep learning algorithms, to automatically detect license plates in images. The authors conduct a comprehensive investigation to assess the effectiveness of this approach. Their findings indicate that the CNN-based method demonstrates promise in the realm of license plate detection, providing notable advantages in terms of speed and efficiency compared to traditional methods. However, a critical limitation that emerges from their research is a relatively low accuracy rate. This limitation is particularly evident in challenging scenarios, such as low-light conditions or when license plates

exhibit variations in size, angle, or perspective. The low accuracy rate underscores the need for further refinement and optimization of the CNN-based approach to improve its robustness and reliability, ensuring accurate license plate detection across diverse real-world situations and enhancing its potential applications in fields such as automated surveillance and transportation systems.

The study [19] presented a License Plate Recognition System (LPRS) utilizing an improved YOLOv5 (You Only Look Once) architecture in conjunction with a GRU (Gated Recurrent Unit) network. The proposed method aims to enhance the accuracy and efficiency of license plate recognition, a vital task with applications in security and traffic management. Through a comprehensive exploration of the proposed approach, the study reveals that the improved YOLOv5 and GRU-based LPRS system exhibits promising potential in recognizing license plates from images and videos. However, a significant limitation is identified, notably a lower accuracy rate in challenging conditions and scenarios, such as low lighting or extreme angles. This limitation underscores the need for further refinements and enhancements to address these challenges and improve the overall accuracy and robustness of the system, as accurate license plate recognition is crucial for various real-world applications, including surveillance and automated toll collection systems.

### III. MATERIAL AND METHOD

#### A. Dataset Generation

In this study, a custom dataset is generated for license plate recognition. For this dataset, following steps are performed.

1) *Collect images*: In this study, for collecting license plate images from internet resources to generate a custom dataset, several steps are performed. Firstly, we identify reliable sources that provide license plate images, including open data repositories and publicly available datasets. Secondly, systematically search and retrieve license plate images from these sources using specific keywords or filters with image databases that contain labeled license plate images. Thirdly, verify the authenticity and quality of the collected images to ensure they are suitable for dataset creation for image resolution, clarity, and visibility of the license plates. Finally, we consider verifying the accuracy and reliability of the labeled license plate information.

2) *Image annotation*: In collected images, there are several images with no labeling which are required to label and annotate. Annotating unlabeled license plate images for our custom dataset involves manually adding annotations to identify and localize license plate regions. The annotator uses specialized software to draw bounding boxes around the license plates and assign labels representing alphanumeric characters. Accuracy and attention to detail are crucial in ensuring precise annotations. Consistent annotation guidelines and regular quality checks maintain dataset quality. Annotated license plate images enable the training and evaluation of

accurate and robust license plate recognition models for real-world applications.

3) *Data augmentation*: To cover more variations in images and extending the dataset, we performed data augmentation. Augmenting license plate images is performed to expanding the custom dataset by applying various transformations and modifications to the existing images. This augmentation technique enhances the dataset's diversity and variability, making the trained model more robust and capable of handling different scenarios. Common augmentation techniques include rotation, translation, scaling, flipping, adding noise, changing lighting conditions, and introducing occlusions. By applying these transformations, the dataset can capture variations in license plate positions, angles, sizes, and image characteristics, such as brightness and noise levels. Augmentation helps to mitigate overfitting and improve the generalization ability of the license plate recognition model. It also enables the model to better handle real-world challenges, such as variations in weather, lighting conditions, and vehicle orientations. Therefore, we generated 8642 images with above steps in our custom dataset.

#### B. One-Stage Detector

One-stage detector algorithms are a type of object detection algorithm used in computer vision tasks. Unlike two-stage detectors that involve a separate region proposal network (RPN) and object detection stage, one-stage detectors perform both object localization and classification in a single pass. One popular example of a one-stage detector algorithm is the YOLO (You Only Look Once) algorithm. This algorithm enables to process the entire image in a single pass makes it efficient and suitable for real-time applications like license plate recognition in smart parking systems. Fig. 1 [16] shows the structure of one-stage detector.

In a one-stage detector algorithm, the input to the algorithm is an image that contains objects of interest, such as vehicles with license plates in the case of license plate recognition. The algorithm processes the entire image at once and produces a set of bounding boxes along with corresponding class predictions for each detected object. This is in contrast to two-stage detectors that first propose regions of interest and then classify those regions.

The backbone network is a crucial component of the one-stage detector algorithm. It is typically a deep convolutional neural network (CNN) that extracts hierarchical features from the input image. The backbone network can be a popular CNN architecture like ResNet, VGG, or Darknet, which has been pre-trained on a large-scale image classification task. The purpose of the backbone network is to capture high-level representations and semantic information from the image.

The neck network typically consists of additional convolutional layers that fuse and combine the multi-scale features from the backbone network. This fusion helps to enhance the representation power of the features and enables the algorithm to detect objects at different scales and resolutions.

Fig. 1. Structure of one-stage detector.

The head or dense prediction part of the one-stage detector algorithm performs the final stage of object detection. It consists of convolutional layers followed by fully connected layers. The head network takes the fused features from the neck network as input and performs spatial and channel-wise convolutions to generate the final detection outputs. These outputs include the bounding box coordinates (x, y, width, height) and class probabilities for each detected object. The head network utilizes anchor boxes or default boxes to anchor the predicted bounding boxes to predefined scales and aspect ratios [16].

### C. Model Generation

Generating a YOLOv5 model for license plate recognition on a custom dataset involves several steps, including dataset preparation, training, validation, and testing. Firstly, the custom dataset is divided into training, validation, and testing sets with the typical split of 70%, 20%, and 10%, respectively. The training set, comprising 70% of the dataset, is used to train the YOLOv5 model. The validation set, consisting of 20% of the dataset, is utilized for monitoring the model's performance during training and tuning hyperparameters. Lastly, the testing set, which makes up 10% of the dataset, is used to evaluate the final model's performance.

1) *Training*: In the training module, the YOLOv5 model is trained on the training set using the labeled license plate images. This is typically achieved through an iterative process using techniques such as stochastic gradient descent (SGD) or

adaptive optimization algorithms. During training, the YOLOv5 model learns to detect and localize license plates in images and predict the corresponding alphanumeric characters. In training a YOLOv5 model for license plate recognition, several loss curves are commonly monitored during the training process: train/box\_loss, train/obj\_loss, and train/cls\_loss. Fig. 2 shows training loss curves.

As shown in Fig. 2, the train/box\_loss curve represents the loss associated with the bounding box predictions. The model aims to accurately predict the coordinates and dimensions of the bounding boxes around license plates. During training, the box loss gradually decreases as the model learns to better localize and fit the bounding boxes around the license plates. A lower box loss indicates improved precision and accuracy in the model's ability to detect and locate license plates.

The train/obj\_loss curve captures the loss related to objectness prediction. In YOLOv5, each grid cell predicts whether an object is present within it or not. The objectness loss calculates the difference between the predicted objectness scores and the ground truth labels. This loss helps the model to discriminate between objects and background regions. As the training progresses, the model learns to assign higher objectness scores to grid cells containing license plates and lower scores to empty cells, resulting in a decrease in the objectness loss. A decreasing obj\_loss curve indicates the model's improved capability to identify relevant regions for license plate recognition.

Fig. 2. Training loss curves.

The train/cls\_loss curve represents the loss associated with the classification of license plate characters. In license plate recognition, the model needs to classify the alphanumeric characters present on the license plates. The cls\_loss measures the dissimilarity between the predicted class probabilities and the ground truth character labels. The model aims to accurately recognize and classify the characters. As the training advances, the cls\_loss decreases, indicating that the model becomes more proficient at correctly identifying the characters on the license plates. A diminishing cls\_loss curve reflects the model's improved ability to perform accurate character classification.

By monitoring the train/box\_loss, train/obj\_loss, and train/cls\_loss curves during training, one can gain insights into the model's learning progress and performance in different aspects of license plate recognition. The decreasing trends in these loss curves indicate the model's improvement in bounding box prediction, objectness estimation, and character classification, respectively.

2) *Validation:* In the validation module, the YOLOv5 model is evaluated on the validation set to assess its

performance and fine-tune its hyperparameters. Based on the validation results, adjustments can be made to the model architecture, training parameters, or data augmentation techniques to improve its performance. During the validation process of a YOLOv5 model for license plate recognition, the loss curves serve as valuable metrics to assess the model's performance. Fig. 3 shows validation loss curves.

As shown in Fig. 3, the val/obj\_loss curve corresponds to the loss related to objectness prediction during validation. It evaluates the difference between the predicted objectness scores and the ground truth labels for license plates in the validation images. As the model learns to distinguish between objects and background regions, the val/obj\_loss decreases. A decreasing obj\_loss curve indicates that the model is becoming more proficient at identifying relevant regions for license plate recognition during validation. This demonstrates the model's improved capability to assign higher objectness scores to grid cells containing license plates and lower scores to empty cells, enhancing its ability to discriminate between objects and background regions.

Fig. 3. Validation loss curves.

The val/cls\_loss curve represents the loss associated with the classification of license plate characters during validation. The model aims to accurately recognize and classify the alphanumeric characters. As the model improves its ability to correctly identify characters on license plates during validation, the val/cls\_loss, decreases. A diminishing cls\_loss curve indicates that the model becomes more proficient at accurately classifying characters on license plates. This signifies the model's enhanced ability to perform accurate character recognition and classification during validation.

By monitoring the val/box\_loss, val/obj\_loss, and val/cls\_loss curves during the validation process, one can evaluate the model's performance in bounding box prediction, objectness estimation, and character classification for license plate recognition tasks. Decreasing trends in these loss curves indicate the model's improvement in accurately localizing license plates, discriminating between objects and background regions, and correctly identifying characters.

#### IV. EXPERIMENTAL RESULTS

This section presents experimental results and performance evaluation. For these results, the trained YOLOv5 model is

applied to the unseen license plate images in the testing set. The model's predictions are compared against the ground truth annotations to evaluate its performance on new and unseen data. These metrics are precision, recall and F1-score are computed to assess the model's effectiveness in license plate recognition. We use the testing sets for this evaluation. The testing module provides insights into the model's generalization ability and its performance in real-world scenarios. By following this three-module approach, the YOLOv5 model is trained on the labeled license plate images from the training set, validated on the validation set to fine-tune its performance, and then tested on the unseen license plate images from the testing set to evaluate its effectiveness in license plate recognition tasks. This process ensures the development of a robust and accurate YOLOv5 model for license plate recognition on the custom dataset.

##### A. Confusion Matrix

Confusion matrix as popular tool for evaluating the performance of deep learning-based models is utilized in this experiment. It serves as a visual representation and quantitative assessment of the license plate recognition YOLOv5 model's

predictive performance, allowing to evaluate, analyze, and improve the model's accuracy and effectiveness. Additionally, the confusion matrix enables the calculation of class-specific performance metrics, providing a more detailed understanding of the model's strengths and weaknesses across different license plate character classes.

As shown in Fig. 4, the confusion matrix is organized as a grid, with the Y-axis representing the predicted classifications and the X-axis representing the true classifications. The main diagonal of the confusion matrix corresponds to the correctly classified instances, where the predicted class matches the true class. Off-diagonal cells represent the misclassified instances, where the predicted class differs from the true class.

### B. Performance Measurement

By analyzing the confusion matrix, performance measurements can be performed. Popular metrics such as precision, recall, F1-score and mAP are calculated from the values in the confusion matrix.

1) *Precision-confidence curve*: The precision-confidence curve is a visual representation of the relationship between precision and confidence threshold in a license plate recognition YOLOv5 model. The precision-confidence curve plots the precision value at different confidence thresholds. Starting from a high confidence threshold, the precision will be relatively high because only confident predictions are considered valid. Fig. 5 demonstrates the precision-confidence curve.

Fig. 4. Results of confusion matrix.

Fig. 5. The precision-confidence curve.

As shown in Fig. 5, The X-axis represents the confidence threshold, while the Y-axis represents the precision. The curve demonstrates how precision changes as the confidence threshold is adjusted. Initially, with a high confidence threshold, the precision is high because only confident predictions are considered valid. As the confidence threshold decreases, more predictions are included, potentially leading to false positives and a decrease in precision. Higher precision implies a lower false positive rate, indicating fewer incorrect predictions. However, setting a high confidence threshold may result in missing true positive instances, reducing efficiency. By analyzing the curve, it is possible to identify the optimal confidence threshold that strikes a balance between precision

and efficiency. This information enables to assess the model's performance and adjust the confidence threshold to achieve the desired accuracy and recognition efficiency in the license plate recognition model.

2) *Recall-confidence curve*: The recall-confidence curve illustrates how the recall metric changes as the confidence threshold varies. As the confidence threshold decreases, more predictions are considered valid, including both true positives and potential false positives. Fig. 6 shows the recall-confidence curve.

Fig. 6. The recall-confidence curve.

As shown in Fig. 6, the X-axis of the curve represents the confidence threshold, which determines the minimum confidence score required for a prediction to be considered valid. The Y-axis represents the recall, also known as sensitivity or true positive rate. Recall measures the proportion of correctly predicted positive instances (true positives) out of all actual positive instances (true positives plus false negatives). Higher recall indicates that the model is better at capturing and recognizing actual positive instances, minimizing false negatives. However, a lower confidence threshold that maximizes recall may also introduce more false positives, reducing the model's efficiency. It becomes a trade-off between correctly identifying more positive instances and the potential inclusion of false positives.

3) *Precision-Recall curve*: The precision-recall curve is another visual representation that provides insights into the performance and efficiency of a license plate recognition YOLOv5 model. The curve showcases the relationship

between precision and recall, two important metrics used to evaluate the model's predictive accuracy. Fig. 7 shows the precision-recall curve.

The X-axis of the precision-recall curve represents the recall, also known as sensitivity or true positive rate. The Y-axis represents precision, which indicates the proportion of correctly predicted positive instances out of all instances predicted as positive (true positives plus false positives). The precision-recall curve illustrates how the precision metric change as the recall varies. A higher recall indicates that the model is capturing a larger number of positive instances, minimizing false negatives. As the recall increases, the model is becoming more sensitive and successfully identifying more actual positive instances. However, as the recall increases, it becomes more challenging to maintain a high precision. The inclusion of more positive instances may introduce false positives, impacting the precision of the model.

Fig. 7. The precision-recall curve.

Fig. 8. F1-score curve.

4) *F1-score*: The F1-score curve demonstrates how the F1-score change as the threshold varies. The F1-score is important for measuring the efficiency of a license plate recognition YOLOv5 model because it combines precision and recall into a single value. It provides a comprehensive assessment of the model's ability to accurately identify positive instances while avoiding false positives.

As shown in Fig. 8, the curve illustrates the relationship between the F1-score and a varying threshold used for predictions. The X-axis of the F1-score curve represents the threshold, which is the minimum confidence score required for a prediction to be considered valid. The Y-axis represents the F1-score, which is a metric that combines both precision and recall into a single value. The F1-score provides a balanced evaluation of the model's performance, taking into account both the ability to correctly identify positive instances (precision) and the ability to capture all actual positive instances (recall). As the threshold decreases, more predictions are considered valid, potentially increasing the recall of the model.

## V. CONCLUSION

In this study, we introduce a YOLO-based method complemented by a custom dataset tailored for license plate recognition within smart parking systems. Our research effectively addresses the primary research gap, delivering real-time processing capabilities and enhanced accuracy. The extensive custom dataset empowers the model to handle even the most challenging scenarios frequently encountered in smart parking environments. Our comprehensive experimental evaluations underscore the method's superior performance across accuracy, processing speed, and robustness. The significant contributions of this research encompass the identification of limitations, the creation of a specialized dataset, the proposal of the YOLO-based approach, and the thoroughness of our evaluations. These findings collectively advance the development of precise and efficient license plate recognition systems, thereby augmenting the management of smart parking in urban areas. It's worth noting that our custom dataset specifically targets the license plate types prevalent in the studied region or environment. Nevertheless, variations in license plate designs, formats, fonts, sizes, colors, and layouts exist across different countries, regions, or vehicle types. Future endeavors can prioritize the development of methods capable of generalizing and adapting to this diversity, potentially incorporating transfer learning, data augmentation techniques, or domain adaptation strategies to enhance the model's proficiency in accurately recognizing and interpreting various license plate variations.

**Abstract**—The Internet of Things (IoT) has emerged as a transformative technology, enabling various devices to interconnect and generate vast amounts of data. The insights contained within this data can revolutionize industries and improve decision-making processes. The heterogeneity, scale, and complexity of IoT data pose challenges for efficient analysis and utilization. In this paper, the field of data science is explored in the IoT context, focusing on critical techniques, applications, and challenges vital to realizing the full potential of IoT data. This paper explores the field of data science in the IoT context, focusing on critical techniques, applications, and challenges vital to realizing the full potential of IoT data. The distinctive qualities of IoT data, including its volume, velocity, variety, and veracity, are examined, and their impact on data science approaches is analyzed. Additionally, cutting-edge data science approaches and methodologies designed for IoT data, such as data preprocessing, data fusion, machine learning, and anomaly detection, are discussed. The importance of scalable and distributed data processing frameworks to handle IoT data's large-scale and real-time nature is highlighted. Furthermore, the application of data science in various IoT fields, such as smart cities, healthcare, agriculture, and industrial IoT, is explored. Finally, areas for future research and development are identified, such as privacy and security issues, understanding machine learning models, and ethical aspects of data science in IoT.

**Keywords**—Internet of Things; IoT data; data science; data preprocessing; machine learning; real-time analytics

## I. INTRODUCTION

### A. Background and Motivation

The Internet of Things (IoT) creates a world where the objects around people can sense and gather information about the environment [1]. With the proliferation of IoT devices in diverse domains such as smart homes, healthcare, transportation, and industrial systems, an enormous amount of data is continuously generated. This data presents immense potential for extracting valuable insights and driving informed decision-making [2]. However, harnessing the full potential of IoT data requires effective data science techniques and approaches [3]. This is where the significance of meta-heuristic algorithms, Machine Learning (ML), deep learning, Artificial Intelligence (AI), and urban public transportation becomes apparent in the context of data science in IoT environments.

Meta-heuristic algorithms are vital tools within the data science toolkit, as they provide intelligent, heuristic-based optimization techniques for solving complex problems. In the realm of IoT, these algorithms can be employed to optimize resource allocation, enhance data processing efficiency, and address challenges related to data routing, sensor placement, and energy management [4]. ML, a subset of AI, is at the forefront of IoT data analysis. ML algorithms empower IoT applications to learn from historical data, recognize patterns, and make predictions or decisions autonomously. They are instrumental in understanding the behavior of connected devices, detecting anomalies, and predicting future trends within IoT ecosystems [5, 6]. Deep learning, a subfield of ML, has gained substantial importance in IoT data analysis due to its ability to handle large-scale, unstructured data [7]. Deep neural networks excel in feature extraction and abstraction, making them invaluable for image and speech recognition in IoT applications such as surveillance and voice-controlled devices [8-10]. AI, encompassing ML and deep learning, extends the capabilities of IoT by enabling devices to exhibit human-like intelligence. This manifests in autonomous decision-making, natural language processing, and adaptive behavior, empowering IoT systems to become more responsive, efficient, and user-friendly [11]. Urban public transportation systems are a crucial domain within the IoT landscape. IoT sensors and data science techniques are instrumental in optimizing public transportation networks, reducing congestion, improving routing efficiency, and enhancing the overall commuter experience. Real-time data analytics, enabled by IoT and data science, can transform urban mobility and contribute to sustainability efforts [12].

The motivation behind this paper is twofold. Firstly, the rapid growth of IoT devices and the resulting data deluge present unique challenges in data management, processing, and analysis. The sheer volume, velocity, and variety of IoT data require advanced data science techniques capable of handling and extracting meaningful information from this data. Therefore, there is a need to explore and develop specialized data science techniques tailored to the unique characteristics of IoT data. Secondly, the application of data science in the IoT domain holds significant potential for driving innovation and creating value. Organizations can uncover hidden patterns, detect anomalies, optimize operations, and enhance decision-

making in IoT-based systems by leveraging data science techniques. This has implications for various sectors, including healthcare, energy management, environmental monitoring, and smart cities, where data-driven insights can improve efficiency, sustainability, and quality of life.

### B. Objectives and Scope

This paper aims to examine the application of data science techniques in the context of IoT and assess the potential benefits and challenges involved. The paper aims to achieve the following specific objectives:

- Examining the current state of data science techniques and methodologies and their relevance to IoT data analysis.
- Identifying the challenges and limitations of applying data science in the IoT domain, such as data heterogeneity, scalability, real-time processing, and privacy concerns.
- Exploring using ML algorithms, statistical analysis, and data mining techniques for extracting meaningful insights from IoT data.
- Investigating the integration of IoT data with other data sources, such as social media, weather data, and sensor networks.
- Evaluating the performance and effectiveness of data science techniques in real-world IoT applications through case studies and experiments.
- Discussing the ethical and privacy implications associated with collecting, storing, and analyzing IoT data.

The scope of this review paper encompasses a comprehensive analysis of data science techniques and their application in the IoT domain. It covers various topics, including data preprocessing and cleaning, feature engineering, anomaly detection, predictive modeling, and visualization techniques tailored for IoT data. The paper considers supervised and unsupervised learning algorithms and advanced techniques like deep learning and ensemble methods. Additionally, it explores the challenges of handling high-dimensional, streaming, and heterogeneous IoT data and proposes solutions to address these challenges. The paper focuses on the practical implications of using data science for the IoT. It examines real-world case studies and applications to highlight data science techniques' potential benefits and limitations in diverse IoT domains such as smart cities, healthcare monitoring, industrial automation, and environmental sensing. Furthermore, the paper acknowledges the ethical considerations and privacy concerns associated with IoT data collection and analysis, providing insights into responsible data practices and regulatory frameworks.

### C. Organization of the paper

The paper is organized as follows: Section II discusses the challenges and considerations of analyzing IoT data using data science methods. Section III delves into the various data science techniques that can be utilized for IoT data analysis.

Scalable data processing for IoT data is discussed in Section IV. This section also explores real-world data science applications in the IoT domain, showcasing successful case studies and their outcomes. In Section V, we present open research challenges and future directions. Finally, in Section VI, the conclusion of the paper is provided.

## II. BACKGROUNDS

This section delves into the unique challenges posed by IoT data that impact the application of data science techniques. It explores the specific characteristics of IoT data, including its sheer volume, velocity, and variety. The section discusses the inherent complexity of IoT data, such as its unstructured nature, real-time streaming nature, and potential for high dimensionality. Furthermore, it highlights the issues related to data quality, including missing values, noise, and inconsistencies, which can pose significant challenges for data science practitioners. The section also addresses the security and privacy concerns associated with IoT data, emphasizing the need for robust data protection mechanisms. Additionally, it explores the issue of data interoperability, as IoT devices often use different data formats and protocols, making data integration and analysis more challenging.

### A. IoT Data Characteristics

As shown in Fig. 1, the field of data science faces specific challenges when dealing with IoT data, mainly related to volume, velocity, variety, veracity, value, and variability. The sheer volume of data generated by IoT devices is immense. With billions of interconnected devices, the amount of data produced exponentially increases. This massive volume of data poses storage, processing, and analysis challenges [13]. IoT data is generated in real-time or near real-time, often streaming continuously from various sources. This high velocity of data requires data scientists to implement real-time analytics solutions that can process and analyze data on the fly [14]. IoT data comes in diverse formats and types. It includes structured data from sensors, unstructured data such as images and videos, and text data from social media. The variety of IoT data poses integration, quality, and interoperability challenges [15]. The veracity of IoT data refers to its reliability, accuracy, and trustworthiness. IoT data is often prone to errors, noise, and inconsistencies due to device malfunctions, network issues, or data transmission errors [16]. The data generated by IoT objects holds immense value in optimizing applications and uncovering novel insights and knowledge [17]. The speed of data collection from IoT devices can vary depending on the events triggering data collection, such as shopping data. Furthermore, data format changes may occur when devices are replaced or updated [18].

### B. IoT data properties

IoT data can be categorized based on spatial, temporal, and sensing properties. Each property plays a significant role in understanding and analyzing IoT data. A summary of these properties is presented in Table I. In the analysis of IoT data, the spatial properties of the data are diverse and have significant implications for selecting appropriate systems and techniques. One important consideration is whether the IoT devices are fixed or mobile [19]. For instance, environmental sensors in street lamps have fixed spatial information, while

vehicles possess mobile spatial information. This distinction is crucial as it impacts the analysis methods and the interpretation of the collected data. Another aspect to consider is the shape of the IoT data. Spatial data can be points, areas, line strings, or multiple disconnected points and areas. For example, weather information may be represented by polygons, whereas road networks are typically depicted using line strings.

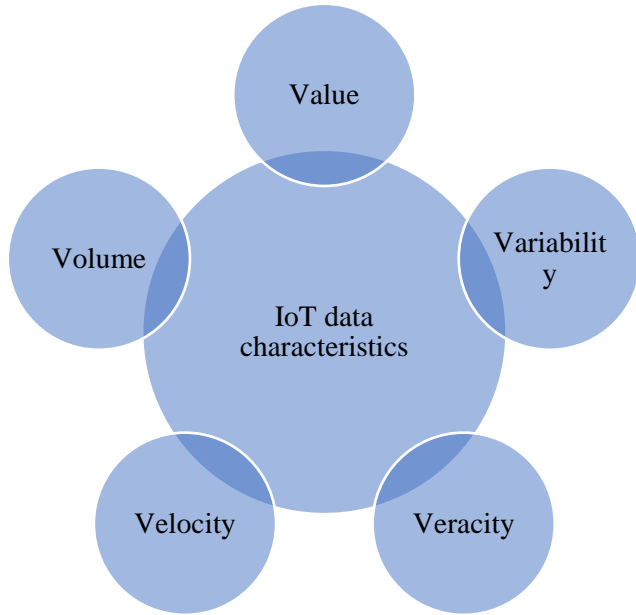

Fig. 1. IoT data characteristics.

Furthermore, it is crucial to consider any constraints imposed on the spatial information. For example, specific IoT applications involve restrictions on movement, such as cars being restricted to roads. Dealing with these constraints often requires preprocessing techniques to ensure accurate analytical results and avoid misinterpretations. Temporal information is another critical aspect of IoT data that needs to be considered. One key consideration is the nature of data updates. It is essential to determine whether data updates occur periodically or sporadically [20]. If data updates are periodic, it indicates that there are efficient methods for storing and load-balancing IoT data for stream processing. The data can be easily partitioned without any temporal skew in such cases.

On the other hand, if data updates are irregular and do not follow a specific pattern, additional techniques are required to partition the IoT data effectively and avoid temporal skew. Temporal skew can lead to imbalances in data processing and analysis, impacting the accuracy and timeliness of results.

Another temporal property to consider is the update frequency of the data. This frequency can vary significantly, ranging from frequent updates to less frequent ones. Data compaction techniques can be employed effectively when data updates occur periodically and frequently. Data compaction involves reducing the volume of data by storing only the same or similar data, as they are likely to be obtained in subsequent updates. This approach can help optimize storage and processing efficiency.

Sensing values play a significant role in IoT data, providing crucial information about the physical world. These values exhibit various types, including numerical values, text, labels, and images [21]. However, due to the independent deployment of IoT devices by different organizations, the names and units assigned to attributes can vary, even when sensed by the same type of data. For instance, one device may measure temperature and label it as "temperature," while another may use "temp" as the attribute name. Similarly, units of measurement can differ, such as Celsius or Fahrenheit. In addition to variations in attribute names and units, sensing quality is another essential characteristic of sensing values. Some sensors are highly accurate, providing reliable and precise measurements. On the other hand, specific sensors may be less accurate, leading to potential noise, errors, or invalid data in the collected values. IoT systems must have mechanisms in place to handle such incorrect values appropriately. These mechanisms may involve data cleansing, filtering, or error detection techniques to ensure the integrity and reliability of the analyzed IoT data.

### C. IoT Data Examples

In the smart city data analysis field, various data sources are utilized. These examples highlight some of the common types of IoT data analyzed in the context of smart cities [22]. Drone (UAV) data is increasingly used in smart city applications for various purposes, including environmental monitoring and surveillance [23]. The spatial representation of drone data is typically in the form of 3-D trajectories, capturing the movement of drones in the airspace [24]. Temporally, updates are periodic but occur at a low frequency. Sensing values in this context include air quality indicators such as PM2.5 and CO2 levels [25]. Shopping data provides insights into consumer behavior and trends within a smart city. Spatially, shopping data is often represented as fixed 2-D points, such as locations of retail stores or shopping centers. Temporally, updates are non-periodic and occur at a low frequency. Sensing values associated with shopping data include sales and user data, which can be used for market analysis and personalized marketing strategies [26].

TABLE I. IoT DATA PROPERTIES

Sensing	Temporal	Spatial
Quantity Unit Schema Data type	Update frequency Periodic or non-periodic	Constraint Relative or absolute Dimension Spatial shape Mobile or fixed

Public vehicle data is another key source of information in smart city analysis. This type of data captures the movements and behaviors of vehicles within a city [27]. The spatial aspect of public vehicle data is typically represented as 2-D trajectories along roads. Temporally updates are often periodic and occur at a high frequency. Sensing values in this context can include WiFi signals, environmental data, and vehicle-specific information such as speed and wheel speed. Weather data is an essential aspect of smart city analysis, providing insights into spatial patterns of temperature, humidity, and weather conditions. The spatial representation of weather data is typically in the form of fixed 2-D areas, while periodic updates at a low frequency characterize the temporal aspect. Sensing values associated with weather data include temperature, humidity, and weather labels. These examples illustrate the diverse nature of IoT data that can be collected and analyzed in the context of smart cities. The data can be obtained from various IoT devices or retrieved from the web, contributing valuable insights for urban planning, resource optimization, and decision-making processes.

#### D. Data Acquisition and Preprocessing

The challenges of IoT data for data science extend beyond volume, velocity, variety, and veracity to include specific data acquisition and preprocessing issues. These challenges are critical as they directly impact the quality and reliability of the data used for analysis and decision-making.

1) *Data acquisition*: IoT devices generate massive amounts of data, but acquiring that data can be challenging. IoT devices are distributed across various locations and environments, making data collection complex and heterogeneous [28]. Data scientists must consider data access, compatibility, and synchronization factors when acquiring IoT data. They must establish reliable data acquisition mechanisms, such as data streams or APIs, to capture and collect data in real-time or at regular intervals.

2) *Data preprocessing*: IoT data often requires extensive preprocessing before analysis. The raw data obtained from IoT devices may contain missing values, outliers, noise, and inconsistencies [29]. Preprocessing techniques are essential to clean, transform, and prepare the data for analysis. Data scientists need to address data quality issues, handle missing values through imputation methods, detect and handle outliers, and perform data normalization or scaling to ensure the data is in a suitable format for analysis.

3) *Data fusion*: IoT data is typically generated from multiple sources, such as sensors, wearables, social media, etc [30]. Integrating and fusing data from diverse sources is a significant challenge. Data fusion techniques need to be applied to combine and integrate data from different sensors or devices, ensuring that the resulting dataset provides a comprehensive and accurate representation of the phenomenon under study. Data scientists must consider the data's semantic, temporal, and spatial aspects to fuse and integrate the information effectively.

4) *Data privacy and security*: IoT data often contain sensitive and personal information, raising concerns about

privacy and security [31]. Data scientists must adhere to privacy regulations and implement robust security measures to protect the confidentiality, integrity, and availability of IoT data. Anonymization techniques, encryption methods, and access control mechanisms are crucial to ensuring data privacy and preventing unauthorized access or data breaches.

By effectively addressing the challenges of data acquisition and preprocessing, data scientists can enhance the reliability and usability of IoT data. This, in turn, enables more accurate and insightful analysis, leading to informed decision-making and the development of innovative applications in various domains, including smart cities, healthcare, transportation, and more. Continued research and advancements in data acquisition and preprocessing techniques are vital to overcoming these challenges and leveraging the full potential of IoT data for data science applications.

#### E. Scalability and Real-Time Processing

Scalability and real-time processing are two critical challenges that arise due to the massive influx of data from IoT devices. IoT data is generated at an unprecedented scale [32]. As the number of connected devices continues to grow, the volume of data generated increases exponentially. Handling and analyzing such massive amounts of data poses scalability challenges for data scientists [33]. Traditional data processing approaches may not be sufficient to handle the scale of IoT data. Data scientists need to design and implement scalable architectures and algorithms that can efficiently process and analyze large-scale IoT datasets. This involves distributed computing techniques, parallel processing, and using cloud-based infrastructures to handle the computational and storage demands of IoT data analysis. IoT data is time-sensitive, and real-time processing is essential to extract timely insights and enable immediate actions. Many IoT applications, such as smart cities, industrial monitoring, and healthcare, require real-time analytics to detect anomalies, make predictions, and trigger automated responses. Real-time processing of IoT data involves handling high-velocity data streams and making rapid decisions based on the analyzed data. Data scientists must develop streaming data processing frameworks and real-time analytics models to address the continuous flow of IoT data and generate insights in near real-time. This requires efficient algorithms, event-processing techniques, and low-latency systems to process and analyze data as it arrives.

Addressing the scalability and real-time processing challenges of IoT data requires advanced technologies and techniques. Data scientists need to leverage distributed computing frameworks such as Apache Hadoop or Apache Spark for parallel processing and handling large-scale IoT datasets [34]. They must also adopt real-time streaming platforms like Apache Kafka or Apache Flink to take high-velocity data streams and perform real-time analytics. Additionally, ML and AI algorithms can be applied to develop predictive models and anomaly detection systems that operate in real-time. By addressing the challenges of scalability and real-time processing, data scientists can unlock the full potential of IoT data for timely and informed decision-making. Processing and analyzing IoT data at scale and in real-time enables proactive monitoring, predictive maintenance, and

rapid response to emerging events and trends. However, ongoing research and innovation are required to develop more efficient and scalable data processing frameworks, algorithms, and architectures to keep pace with the ever-growing influx of IoT data.

#### F. Privacy and Security Considerations

The challenges of IoT data for data science encompass the technical aspects and the critical concerns of privacy and security. The vast amount of data generated by IoT devices poses significant challenges in ensuring the privacy and security of sensitive information.

1) *Privacy*: IoT devices collect a wide range of personal and sensitive data, including location information, health data, and behavioral patterns. Preserving the privacy of individuals becomes a crucial challenge as this data is transmitted, stored, and processed [35]. Data scientists must implement privacy-preserving techniques such as data anonymization, encryption, and access controls to safeguard personal information. Additionally, they must comply with privacy regulations and frameworks, such as the General Data Protection Regulation (GDPR), to ensure IoT data's lawful and ethical handling.

2) *Security*: IoT devices are vulnerable to security threats due to their heterogeneous nature, limited resources, and broad deployment [36]. They can be susceptible to attacks such as unauthorized access, data breaches, and tampering. Data scientists must address the security challenges by implementing robust security mechanisms. This includes ensuring secure communication protocols, device authentication, data encryption, and intrusion detection systems. Continuous monitoring and threat intelligence are essential to identify and mitigate potential security risks.

3) *Data governance*: The diverse nature of IoT data, collected from various sources and devices, poses challenges regarding data quality, integrity, and reliability [37]. Data scientists need to establish effective data governance frameworks to address these challenges. This involves data validation, data cleansing, and verifying data quality standards to ensure the accuracy and reliability of IoT data. Additionally, data scientists must establish data access controls and implement data lifecycle management practices to manage data throughout its lifecycle, including data retention and secure data disposal.

4) *Ethical considerations*: Data scientists need to be aware of the ethical implications of collecting and analyzing massive amounts of IoT data [38]. They must ethically handle data, ensure the informed consent of individuals, avoid bias in data analysis, and maintain transparency in data processing practices. Adhering to ethical guidelines and frameworks helps build trust among users and promotes responsible and accountable use of IoT data.

Addressing privacy and security challenges requires a comprehensive approach involving technical measures, regulatory compliance, and ethical considerations. Data scientists should collaborate with experts in privacy and security to design and implement robust security architectures,

privacy-enhancing techniques, and privacy impact assessments. Additionally, raising awareness among users about the privacy implications of IoT data and providing transparent data handling practices can help build trust and confidence in using IoT technologies.

### III. DATA SCIENCE TECHNIQUES FOR IOT DATA

Data science techniques are crucial in extracting meaningful insights and knowledge from the vast amounts of data generated by IoT devices. These techniques enable organizations to leverage the potential of IoT data for making informed decisions, optimizing processes, and gaining a competitive edge. Tables II to V provides additional details on data science techniques used in IoT.

#### A. Data Preprocessing and Cleaning

Data preprocessing and cleaning are crucial steps in the data science pipeline when dealing with IoT data. Due to the nature of IoT data, which is often generated from diverse sources and in real-time, it is essential to preprocess and clean the data to ensure its quality and usability for further analysis. This involves several techniques to address common challenges associated with IoT data, such as noise, missing values, and inconsistencies.

1) *Noise removal*: IoT data can be susceptible to noise due to various factors, including sensor inaccuracies, communication errors, or environmental interference [39]. Data scientists employ techniques such as smoothing algorithms, filtering, and outlier detection methods to eliminate noise and ensure the accuracy of the data.

2) *Missing data handling*: IoT data streams may encounter missing values due to device failures, network interruptions, or sensor malfunctions [40]. Data scientists utilize imputation methods (e.g., mean imputation, interpolation) or advanced ML techniques to fill in missing data points based on patterns and relationships within the dataset.

3) *Data integration*: IoT applications often involve multiple sensors or devices that generate data in different formats or structures. Data integration techniques combine and merge data from various sources, ensuring consistency and enabling comprehensive analysis [41].

4) *Data transformation*: IoT data may require modification to align with specific analysis requirements or to normalize data across different sensors or devices. Scaling, normalization, and feature engineering are applied to transform the data into a suitable format for subsequent analysis [42].

5) *Data validation and quality assurance*: Data scientists validate IoT data to identify any inconsistencies, errors, or anomalies that may impact the analysis. This involves conducting data quality checks, verifying data integrity, and performing statistical tests to ensure the reliability of the dataset [43].

6) *Time-series analysis*: IoT data often exhibit temporal dependencies and trends. Data scientists leverage time-series analysis techniques to extract meaningful insights from time-

stamped IoT data, such as detecting patterns, forecasting future trends, or identifying anomalies [44].

By applying these data preprocessing and cleaning techniques, data scientists can ensure the quality, reliability, and integrity of IoT data, enabling more accurate and meaningful analysis. These steps lay the foundation for subsequent data science tasks, such as feature selection, model building, and predictive analytics, to derive valuable insights and make informed decisions based on IoT data. Table II summarizes various data preprocessing approaches used in IoT data analysis. Each technique has strengths and shortcomings that researchers and practitioners should consider when preparing IoT data for analysis.

### B. Data Fusion and Integration

Data Fusion and Integration are essential aspects of Data Science Techniques for IoT Data. They involve combining data from various sources and integrating them into a unified dataset for further analysis. Here, we will discuss some commonly used techniques in Data Fusion and Integration for IoT Data:

1) *Sensor data integration*: In IoT systems, data is collected from multiple sensors deployed in different locations. Sensor data integration techniques combine data from various sensors to comprehensively view the environment or system being monitored [45].

2) *Data alignment and synchronization*: IoT devices often have different sampling rates and formats. Data alignment techniques ensure that data from various sources are synchronized and aligned in terms of time and format. This enables accurate analysis and interpretation of the integrated dataset [46].

3) *Data fusion*: Data fusion techniques combine data from multiple sources to derive more accurate and comprehensive insights. This can include techniques like statistical averaging, weighted aggregation, or model-based fusion. Data fusion helps to improve the reliability and accuracy of the integrated dataset [47].

4) *Contextual data integration*: IoT data often includes contextual information such as location, time, and environmental conditions. Contextual data integration techniques aim to incorporate this additional information into the dataset, enabling more profound analysis and correlation with other variables [48].

5) *Semantic data integration*: Semantic data integration techniques focus on incorporating domain-specific knowledge and ontologies to enhance the understanding and interpretation of the integrated dataset. This helps to establish meaningful relationships between different data sources and enables more advanced analytics [49].

By applying these Data Science Techniques for IoT Data Fusion and Integration, organizations can leverage combined data from diverse sources to gain deeper insights, make informed decisions, and derive maximum value from their IoT deployments. Table III provides an overview of data fusion and integration approaches used in IoT data analysis. Each

technique offers unique strengths and may have specific challenges that should be considered when integrating data from multiple sources.

### C. Machine Learning

ML techniques are crucial in analyzing and extracting valuable insights from IoT data. Here, we will discuss some fundamental data science techniques for IoT data that utilize ML:

1) *Anomaly detection*: ML algorithms can detect anomalies in IoT data, which can indicate unusual behavior, faults, or security breaches. By training models on standard data patterns, any deviations from the norm can be identified and flagged for further investigation [50].

2) *Predictive maintenance*: ML models can be employed to predict the maintenance needs of IoT devices and systems. By analyzing historical data, sensor readings, and environmental conditions, predictive maintenance models can anticipate when maintenance or repairs are required, minimizing downtime and optimizing maintenance schedules [51].

3) *Classification and regression*: ML algorithms can be used for classification and regression tasks on IoT data. For example, classification models can classify sensor readings into categories or identify specific events or conditions. Regression models can predict numerical values based on input variables, such as predicting energy consumption based on environmental factors [52].

4) *Clustering and segmentation*: ML clustering algorithms can group similar IoT data instances based on their characteristics or behavior. This can help identify patterns, segment data for targeted analysis, or detect clusters of devices with similar usage patterns [53].

5) *Feature selection and dimensionality reduction*: IoT data can be high-dimensional and contain numerous features. ML techniques like feature selection and dimensionality reduction can identify the most relevant features or transform the data into a lower-dimensional space, improving computational efficiency and model performance [54].

By applying these ML techniques to IoT data, organizations can uncover hidden patterns, make accurate predictions, optimize resource allocation, and gain valuable insights to support decision-making processes. However, it is important to carefully select and train ML models, considering IoT data's specific characteristics and challenges, such as data volume, velocity, variety, and veracity. Table IV provides insights into the various machine learning approaches employed in IoT data analysis. A particular technique for an IoT application should be chosen based on its strengths and limitations.

### D. Anomaly Detection and Outlier Analysis

Anomaly detection and outlier analysis are essential data science techniques used in IoT data to identify unusual patterns, deviations, or outliers that may indicate potential anomalies or anomalies [55]. These techniques are valuable for detecting anomalies in real-time IoT data streams and

addressing security threats, system failures, or abnormal behavior. Anomaly detection involves identifying data instances that deviate significantly from the expected or normal behavior. This can be achieved through various approaches, including statistical methods, ML algorithms, and pattern recognition techniques. The goal is to automatically distinguish between normal and abnormal data instances without prior knowledge of the specific anomalies. In the case of IoT data, anomaly detection can be particularly challenging due to the high volume, velocity, and variety of data generated by IoT devices. Traditional statistical methods, such as mean-based or standard deviation-based approaches, may not be suitable for handling the complexity and dynamics of IoT data. Instead, ML algorithms such as clustering, density-based methods, or ensemble techniques are often employed.

On the other hand, Outlier analysis focuses on identifying data points significantly different from the rest of the dataset. Outliers can arise due to measurement errors, system failures,

or malicious activities [56]. By detecting and analyzing outliers, organizations can gain insights into system vulnerabilities, identify potential risks, and take appropriate actions to mitigate them. Data science techniques for anomaly detection and outlier analysis in IoT data involve several steps. These include data preprocessing, feature engineering, model selection, training, and evaluation. The choice of techniques and algorithms depends on the specific characteristics of the IoT data and the desired level of accuracy and interpretability. Overall, anomaly detection and outlier analysis techniques are essential for ensuring the integrity, security, and reliability of IoT systems. By effectively identifying and responding to anomalies in real-time, organizations can mitigate risks, optimize operations, and enhance the overall performance of their IoT deployments. Table V presents an overview of different anomaly detection and outlier analysis approaches applied to IoT data. Each technique offers distinct strengths and potential challenges, providing researchers with insights into their suitability for specific IoT data scenarios.

TABLE II. DATA PREPROCESSING APPROACHES FOR IOT DATA

Technique	Strengths	Shortcomings
Data cleaning	Improves data quality and accuracy for analysis Removes noise, outliers, and inconsistencies	It may result in data loss if too many data points are removed Manual data cleaning can be time-consuming for large datasets
Missing data handling	Allows for analysis with incomplete data Preserves data integrity and prevents bias	Imputation methods may introduce additional uncertainty Imputed values may not accurately represent the missing data
Data normalization	Enhances data comparability and compatibility Reduces the impact of varying scales and units	Different normalization methods may yield different results Extreme values may distort the normalization process
Feature engineering	Creates informative and relevant features for analysis Capture complex relationships and patterns in the data.	Requires domain expertise to identify meaningful features It may introduce biases if features are not carefully engineered

TABLE III. DATA FUSION AND INTEGRATION APPROACHES FOR IOT DATA

Technique	Strengths	Shortcomings
Data fusion	Integrates data from multiple sources to provide a comprehensive view Enhances data quality and completeness Enables more accurate and holistic analysis	Requires careful handling of data heterogeneity and compatibility Complex integration processes may introduce errors
Data integration	Merges data from different formats, systems, or platforms Enable unified analysis and insights.	Data integration may encounter challenges due to varying data schemas and structures. Requires robust integration mechanisms for real-time or large-scale data
Data synchronization	Ensures consistency and timeliness of data across multiple sources Enables real-time analysis and decision-making	Synchronization mechanisms may introduce latency or data inconsistency Complex synchronization processes may impact system performance

TABLE IV. MACHINE LEARNING APPROACHES FOR IOT DATA

Technique	Strengths	Shortcomings
Supervised learning	Enables accurate predictions and classifications Handles well-labeled and structured IoT data	Requires labeled training data, which can be expensive or time-consuming to obtain Performance may degrade if the model encounters unseen or different data patterns.
Unsupervised learning	Discovers hidden patterns and relationships in IoT data Useful for exploratory analysis and anomaly detection	Interpretation of unsupervised learning results can be challenging Difficult to evaluate the performance objectively without ground truth labels
Reinforcement learning	Learns optimal actions and decision-making strategies based on feedback Suitable for dynamic and interactive IoT systems	It may require significant computational resources and time for training Proper reward design and environment modeling are crucial for effective reinforcement learning in IoT settings

TABLE V. ANOMALY DETECTION AND OUTLIER ANALYSIS APPROACHES FOR IOT DATA

Technique	Strengths	Shortcomings
Statistical methods	Detects deviations from normal patterns in IoT data Relatively interpretable and straightforward	It may not capture complex anomalies or patterns Assumes data distributions and assumptions, which may not hold in all IoT scenarios
Machine learning	Identifies anomalies using advanced pattern recognition algorithms Handles high-dimensional and complex IoT data	Requires labeled or anomalous training data for supervised anomaly detection It may be computationally expensive for real-time or large-scale IoT data analysis.
Time series analysis	Captures temporal dependencies and trends in IoT data Enables forecasting and anomaly detection over time	May struggle with irregular or missing time series data Proper modeling and selection of time series techniques require expertise.

#### IV. DISCUSSION

##### A. Smart Cities and Urban Analytics

Data science plays a crucial role in developing smart cities and urban analytics by harnessing the power of IoT data. Through data science techniques, cities can gather and analyze data from various sources, such as sensors, cameras, and social media, to gain valuable insights and make informed urban planning and management decisions. Data science is applied in smart cities and urban analytics in many ways, including:

1) *Traffic management*: Data science algorithms can process real-time data from traffic sensors and cameras to optimize traffic flow, identify hotspots, and suggest alternative routes to reduce traffic congestion and improve transportation efficiency.

2) *Energy optimization*: By analyzing data from smart meters, energy consumption patterns can be identified, allowing for effective energy management strategies. Data science can help optimize energy distribution, monitor power usage, and identify energy-saving opportunities in buildings and infrastructure.

3) *Waste management*: Data science techniques can analyze data from IoT-enabled waste bins and sensors to optimize waste collection routes, predict bin fill levels, and minimize operational costs. This ensures efficient waste management and contributes to environmental sustainability.

4) *Public safety*: Data science can analyze data from various sources, such as surveillance cameras, social media, and emergency service calls, to detect patterns and trends related to crime, accidents, and emergencies. This enables proactive measures for public safety and emergency response planning.

5) *Urban planning*: By integrating data from multiple sources, including transportation, infrastructure, and social demographics, data science can support urban planners in making informed decisions regarding land use, zoning, and resource allocation. This facilitates the development of sustainable and livable cities.

##### B. Healthcare and Remote Monitoring

Data science has revolutionized the healthcare industry by enabling advanced analytics and insights from IoT data, leading to enhanced healthcare delivery and remote monitoring capabilities. The application of data science in healthcare and remote monitoring offers various benefits, including improved

patient outcomes, personalized treatments, and efficient resource allocation. Data science has various critical applications in healthcare and remote monitoring, which include:

1) *Remote patient monitoring*: Data science techniques analyze data from IoT devices such as wearables, sensors, and mobile apps to monitor patients' vital signs, activity levels, and medication adherence remotely. This enables healthcare providers to detect anomalies, track patient progress, and intervene promptly if necessary.

2) *Predictive analytics for disease prevention*: By analyzing large volumes of healthcare data, including patient records, genetic information, and environmental factors, data science can identify patterns and risk factors for diseases. This helps in early detection, prevention, and personalized treatment planning.

3) *Real-time health monitoring*: Data science algorithms process real-time sensor data to continuously monitor patients' health conditions. This enables early detection of critical events, such as cardiac abnormalities or falls, and alerts healthcare providers for immediate intervention.

4) *Healthcare resource optimization*: Data science techniques optimize healthcare resource allocation by analyzing patient flow, resource utilization, and demand forecasting data. This helps healthcare organizations streamline operations, reduce waiting times, and allocate resources efficiently.

5) *Personalized medicine*: Data science enables the analysis of large-scale genomic and patient data to develop customized treatment plans based on individual characteristics, genetic markers, and treatment response patterns. This promotes precision medicine and improves patient outcomes.

##### C. Agriculture and Precision Farming

Data science has emerged as a valuable tool in agriculture and precision farming, enabling farmers to optimize crop production, improve resource management, and make data-driven decisions. The application of data science in agriculture leverages IoT devices, sensors, and data analytics to monitor and analyze various parameters related to soil, weather, crops, and farm operations. Agriculture and precision farming benefit from data science in multiple ways, including:

1) *Crop yield prediction*: Data science techniques analyze historical and real-time data on soil conditions, weather

patterns, crop health, and farming practices to predict crop yields. This helps farmers make informed decisions regarding planting schedules, irrigation, fertilization, and pest management.

2) *Precision irrigation*: Data science algorithms process data from soil moisture sensors, weather forecasts, and crop water requirements to optimize irrigation practices. This ensures that crops receive the right amount of water at the right time, minimizing water wastage and reducing the risk of water stress.

3) *Disease and pest management*: Data science models analyze data from IoT devices, such as insect traps, disease sensors, and satellite imagery, to detect and monitor pests, diseases, and weed infestations. This enables early intervention and targeted treatment, reducing the use of pesticides and minimizing crop losses.

4) *Nutrient management*: Data science techniques analyze soil composition data, crop nutrient requirements, and historical yield data to optimize fertilization practices. This ensures crops receive the necessary nutrients correctly, promoting healthy growth and maximizing yield.

5) *Farm equipment optimization*: Data science algorithms analyze data from IoT-enabled farm equipment, such as tractors and harvesters, to optimize their usage, fuel consumption, and maintenance schedules. This helps farmers improve operational efficiency, reduce costs, and prolong the lifespan of equipment.

#### D. Industrial IoT and Predictive Maintenance

Data science plays a crucial role in Industrial IoT (IIoT) by enabling predictive maintenance, optimizing operations, and improving overall efficiency in industrial settings. Applying data science techniques in IIoT allows for real-time monitoring, analysis, and prediction of equipment health and performance. IIoT and predictive maintenance are two areas where data science finds crucial applications, such as:

1) *Predictive maintenance*: Data science models analyze data from IoT sensors, equipment logs, and historical maintenance records to proactively predict equipment failures and schedule maintenance activities. By identifying potential issues before they occur, companies can avoid costly unplanned downtime and optimize maintenance schedules, leading to increased productivity and reduced maintenance costs.

2) *Asset performance optimization*: Data science techniques analyze sensor data and operational parameters to optimize asset performance and efficiency. By monitoring key performance indicators and analyzing historical data, companies can identify areas for improvement, optimize energy consumption, and enhance overall equipment effectiveness (OEE).

3) *Quality control and defect detection*: Data science algorithms analyze sensor data and production metrics to detect anomalies, identify patterns, and ensure product quality. By monitoring and analyzing real-time data, companies can

identify quality issues early, reduce defects, and improve overall product quality and customer satisfaction.

4) *Supply chain optimization*: Data science techniques can analyze data from IoT devices, inventory records, and transportation systems to optimize supply chain operations. By predicting demand, optimizing inventory levels, and improving logistics, companies can streamline their supply chain processes, reduce costs, and improve customer service.

5) *Process optimization*: To optimize industrial processes, data science models analyze sensor data, production parameters, and historical data. By identifying inefficiencies, bottlenecks, and areas for improvement, companies can optimize process parameters, reduce waste, and improve overall productivity.

#### V. OPEN RESEARCH CHALLENGES AND FUTURE DIRECTIONS

- **Privacy and security in IoT data analytics**: As the IoT expands, ensuring privacy and security becomes a paramount concern. Researchers must address the challenges of securing IoT data throughout its lifecycle, including data collection, storage, transmission, and analysis. Developing robust encryption techniques, access control mechanisms, and secure data-sharing protocols will be crucial. Additionally, exploring privacy-preserving data analytics methods, such as federated learning or differential privacy, can help protect sensitive IoT data while extracting meaningful insights.
- **Interpretable and explainable ML models**: As ML algorithms play a crucial role in IoT data analytics, it is essential to develop interpretable and explainable models. The transparency of models becomes increasingly important in critical domains such as healthcare, where trust and accountability are paramount. Researchers should develop techniques to enhance model interpretability, including feature importance analysis, rule-based models, and model-agnostic explanation methods. This will enable users to understand the reasoning behind the predictions and decisions made by the models.
- **Ethical considerations in data science for IoT**: Integrating data science and IoT raises ethical concerns that must be addressed. Researchers must explore ethical frameworks and guidelines for IoT data collection, usage, and governance. Ensuring informed consent, anonymization, and fair and unbiased data analysis are vital challenges. Ethical decision-making frameworks, transparency in data handling practices, and guidelines for responsible data usage can help address these concerns and promote ethical practices in data science for IoT.
- **Trust and reliability in IoT data analysis**: Building trust in IoT data analysis is crucial for its adoption. Researchers must focus on data quality assurance, integrity verification, and algorithmic fairness in IoT data analytics. Exploring methods for data validation,

anomaly detection, and bias mitigation will help improve the reliability and trustworthiness of IoT data analysis results. Additionally, developing mechanisms to assess and quantify the trustworthiness of IoT data sources and algorithms will contribute to more reliable and robust decision-making processes.

- Scalability and efficiency: As the scale and complexity of IoT systems continue to grow, there is a need for scalable and efficient data science techniques. Researchers should focus on developing algorithms and frameworks that can handle the massive volume of data generated by IoT devices and efficiently process it in real-time. Techniques such as distributed computing, edge computing, and stream processing can be vital in addressing scalability challenges.
- Real-time and stream analytics: The time-sensitive nature of IoT data requires real-time and stream analytics capabilities. Researchers must focus on developing algorithms and frameworks to process streaming data in real-time and extract meaningful insights. Complex event processing, predictive analytics, and online learning can enable real-time decision-making and proactive responses based on IoT data.
- Edge and fog computing: The advent of edge and fog computing brings new opportunities and challenges to data science for IoT. Researchers should explore how data science techniques can be integrated with edge and fog computing architectures to enable real-time analytics and decision-making at the network edge. Developing efficient data processing and analytics algorithms tailored explicitly for edge and fog environments will be crucial.
- Federated learning: As IoT devices are distributed across various networks and locations, federated learning presents an opportunity to train ML models directly on edge devices while preserving data privacy. Researchers should explore efficient and secure federated learning techniques in IoT environments, considering limited computational resources, heterogeneous data sources, and communication constraints.
- Context-aware analytics: IoT data is inherently contextual, capturing information about the physical environment, user behavior, and situational context. Incorporating context awareness into data science models and algorithms can lead to more accurate and personalized insights. Researchers should investigate methods for context-aware analytics, including techniques for context acquisition, context representation, and context-aware modeling and prediction.
- Integration of domain knowledge: IoT data often carries domain-specific characteristics and semantics. Incorporating domain knowledge into data science models can enhance their performance and interpretability. Researchers should focus on developing

techniques for integrating domain knowledge into IoT data analytics, leveraging ontologies, expert systems, and domain-specific feature engineering approaches.

- Adaptive and self-learning systems: IoT environments are dynamic and evolve over time. Developing adaptive and self-learning systems for IoT data science can enable models to continuously learn and adapt to changing conditions. Researchers should explore online, reinforcement, and transfer learning to build intelligent systems that adapt to evolving IoT data streams and environments.

## VI. CONCLUSION

The field of data science for the IoT holds immense potential in unlocking valuable insights and enabling transformative applications. This paper has provided a comprehensive overview of the key concepts, challenges, and techniques in this emerging field. We have explored the diverse applications of Data Science in IoT across various domains, including smart cities, healthcare, agriculture, and industrial IoT. These applications have showcased the ability of Data Science to revolutionize industries, optimize processes, and improve decision-making. Throughout the discussion, we have highlighted the significant challenges associated with IoT data, such as volume, velocity, variety, and veracity. We have examined the techniques and methodologies to address these challenges, including data preprocessing and cleaning, data fusion and integration, ML, anomaly detection, and outlier analysis. These techniques provide valuable insights from the vast and heterogeneous IoT data, enabling organizations to make data-driven decisions and derive actionable intelligence.

Furthermore, we have delved into the importance of scalable data processing, distributed computing frameworks, and edge computing for handling massive amounts of IoT data and facilitating real-time analytics. We have discussed stream processing and real-time analytics as essential components for processing data streams and extracting immediate insights from dynamic IoT environments. While Data Science for IoT presents numerous opportunities, open research challenges, and future directions still need to be addressed. These include privacy and security considerations in IoT data analytics, developing interpretable and explainable ML models, ethical considerations in data science for IoT, and ensuring trust and reliability in IoT data analysis. These areas require further exploration and innovation to fully harness the potential of IoT data while ensuring responsible and ethical practices.

# A Fruit Ripeness Detection Method using Adapted Deep Learning-based Approach

Weiwei Zhang\*

Henan Polytechnic Institute, Nanyang, Henan 473000, China

**Abstract**—Fruit ripeness detection plays a crucial role in precise agriculture, enabling optimal harvesting and post-harvest handling. Various methods have been investigated in the literature for fruit ripeness detection in vision-based systems, with deep learning approaches demonstrating superior accuracy compared to other approaches. However, the current research challenge lies in achieving high accuracy rates in deep learning-based fruit ripeness detection. In this study proposes a method based on the YOLOv8 algorithm to address this challenge. The proposed method involves generating a model using a custom dataset and conducting training, validation, and testing processes. Experimental results and performance evaluation demonstrate the effectiveness of the proposed method in achieving accurate fruit ripeness detection. The proposed method surpasses existing approaches through extensive experiments and performance analysis, providing a reliable solution for fruit ripeness detection in precise agriculture.

**Keywords**—Fruit ripeness detection; precise agriculture; deep learning; vision system; YOLOv8

## I. INTRODUCTION

Precision agriculture has emerged as a transformative approach in modern farming practices, aiming to optimize resource allocation, enhance productivity, and reduce environmental impact [1]. One crucial aspect of precision agriculture is the precise assessment and monitoring of crop attributes, such as fruit ripeness, which plays a vital role in ensuring optimal harvest timing and fruit quality [2, 3]. Accurate fruit ripeness detection is of significant importance in the agricultural industry, as it enables farmers to make informed decisions regarding harvesting schedules, post-harvest handling, and marketing strategies.

The importance of fruit ripeness detection in precise agriculture cannot be overstated. Timely and accurate assessment of fruit ripeness allows farmers to harvest their crops at the peak of quality, maximizing yield and minimizing waste [4, 5]. Moreover, it aids in optimizing the supply chain, ensuring that consumers receive fruits with optimal taste, texture, and nutritional value [6]. Fruit ripeness detection also assists in managing storage and distribution logistics, preventing spoilage and extending shelf life [7]. Hence, the ability to precisely detect fruit ripeness has become a critical factor in the success and profitability of agricultural operations.

Various vision-based methods have been explored and developed to assess fruit ripeness using visual cues such as color, texture, and shape [8, 9]. These methods leverage image processing algorithms and machine learning models to extract meaningful features and classify fruits based on their ripeness

levels [10, 20]. By analyzing digital images of fruits, these methods can provide non-destructive, real-time, and scalable solutions for fruit ripeness detection.

Previous studies have shown a growing interest in deep learning-based methods for fruit ripeness detection due to their ability to automatically learn and extract complex features from large-scale datasets [10]. Deep learning models, such as Convolutional Neural Networks (CNNs), have demonstrated remarkable performance in various computer vision tasks, including object recognition and image classification and other related applications [11, 12, 19]. Researchers have adopted deep learning approaches to develop robust and accurate models for fruit ripeness detection, overcoming some of the limitations of traditional image processing techniques.

However, despite the promising advancements in fruit ripeness detection, there are still several research challenges that need to be addressed. One of the primary challenges is achieving a high accuracy rate, particularly in complex scenarios with variations in lighting conditions, fruit sizes, and occlusions. Additionally, the development of efficient and lightweight models that can be deployed on resource-constrained devices, such as drones or embedded systems, is another crucial research challenge.

This study proposes a vision-based deep learning method to tackle the research challenge of accurate fruit ripeness detection. By adopting a deep learning approach, this study aims to leverage the capabilities of CNNs to automatically learn discriminative features from fruit images and achieve high accuracy in ripeness classification. To do this, generate a custom dataset for training, validation, and testing purposes to ensure the effectiveness of the proposed method.

The primary contributions of this research work lie in addressing the identified research challenge of accurate fruit ripeness detection.

- Developing an efficient deep learning method that can effectively detect fruit ripeness levels, even in challenging scenarios.
- Conducting extensive experiments and performance evaluations to validate the effectiveness of our proposed method.
- Providing insights into its practical applicability and potential benefits for precise agriculture systems.

## II. REVIEW OF PREVIOUS STUDIES

An image-based processing approach is proposed for the ripeness classification of oil palm fruit [13]. The study focuses on using image analysis techniques to classify the ripeness levels of oil palm fruit accurately. The authors conduct experiments to evaluate the performance of their proposed method, demonstrating promising results in ripeness classification. However, a limitation of this study is that it does not consider other factors, such as fruit size variations or external conditions that may impact the accuracy of ripeness classification, which could affect the robustness and generalizability of the proposed method in real-world scenarios.

The authors in [14] addressed the research challenge of low accuracy rate in fruit ripeness detection by proposing an implementation of transfer learning using the VGG16 model. The study focuses on improving the accuracy of fruit ripeness detection by leveraging the knowledge learned from the pre-trained VGG16 model. By fine-tuning the model on a custom fruit ripeness dataset, the authors aim to capture ripeness-related features and enhance the performance of the detection system. Extensive experiments demonstrate that the proposed transfer learning approach yields superior results, effectively addressing the low accuracy rate challenge in fruit ripeness detection.

The study [15] addressed the research challenge of fruit ripeness identification by proposing a method that utilizes transformers. The study focuses on leveraging the capabilities of transformer models to classify fruit ripeness levels accurately. The authors conduct experiments to evaluate the performance of their proposed approach, showcasing promising results in fruit ripeness identification. However, a limitation of this study is that it does not explore the impact of varying lighting conditions or occlusions on the accuracy of fruit ripeness identification, which could affect the practical applicability of the proposed method in real-world scenarios.

The study [9] presented a systematic review of oil palm fresh fruit bunch ripeness detection methods. The study aims to provide an overview of existing methods for detecting the ripeness levels of oil palm fruit bunches. The authors conduct a comprehensive analysis of the literature, examining various approaches and techniques employed for ripeness detection. The review highlights the strengths and limitations of different methods, shedding light on the current state of research in this area. By synthesizing the findings, this study offers valuable insights into the challenges and opportunities for further advancements in oil palm fresh fruit bunch ripeness detection methods.

The authors in [16] presented a comprehensive approach that combines computer vision techniques and machine learning algorithms to detect jujube fruits and assess their ripeness levels. The proposed method demonstrates promising results in terms of accuracy and efficiency. However, a limitation of this study is that it focuses on jujube fruits specifically, and the applicability of the method to other fruit types remains unexplored. Further research is needed to

evaluate its effectiveness across different fruit varieties, addressing the generalizability of the proposed method.

## III. MATERIAL AND METHODS

### A. COCO Dataset

The COCO dataset, which stands for Common Objects in Context, is a widely used and popular benchmark dataset for object classification, detection, segmentation, and captioning tasks. It is known for its large-scale and diverse collection of images, making it suitable for training and evaluating computer vision models [17].

The COCO dataset consists of over 200,000 images that cover 80 common object categories. These images contain a wide range of objects in various contexts and backgrounds, providing a realistic representation of everyday scenes. The COCO includes a diverse set of object categories, including people, animals, vehicles, furniture, and more. It captures a broad range of object appearances, poses, and scales. Fig. 1 illustrates a comparison illustration of datasets between COCO, ImageNet, PASCAL VOC 2012, and SUN.

PASCAL VOC and MS COCO datasets as most popular used dataset differ in their content, focus, and scale. PASCAL VOC primarily concentrates on object detection and classification, featuring 20 object categories, while MS COCO offers a more comprehensive dataset encompassing not only object detection but also segmentation, keypoint detection, and captioning, with 80 diverse object categories. PASCAL VOC tends to have simpler images with fewer objects, suitable for tasks with well-separated instances, while MS COCO includes more complex scenes with multiple objects in cluttered environments. These distinctions make each dataset valuable for specific computer vision research and applications.

Fig. 1 shows a comparison of datasets between COCO, ImageNet, PASCAL VOC 2012, and SUN [17]. Fig. 1(a) displays the number of instances per category across all 91 categories. Additionally, Fig. 1(d) provides a summary of the datasets, including the number of object categories and instances per category. Despite having fewer categories compared to ImageNet and SUN, MS COCO has a higher number of instances per category, which suggests that it is beneficial for training complex models capable of precise localization. Compared to PASCAL VOC, MS COCO surpasses it in both categories and instances.

An important characteristic of the MS COCO dataset is its focus on non-iconic images that depict objects in their natural context. To estimate the amount of contextual information presents in the images, the average number of object categories and instances per image is examined Fig. 1(b) and Fig.1(c). In MS COCO, each image average contains 3.5 categories and 7.7 instances. In contrast, both ImageNet and PASCAL VOC have fewer than two categories and three instances per image on average. Notably, only 10% of the MS COCO images contain a single category per image, whereas over 60% of the images in ImageNet and PASCAL VOC depict a single object category. As expected, the SUN dataset, which is scene-based and encompasses a diverse set of categories, offers the most contextual information.

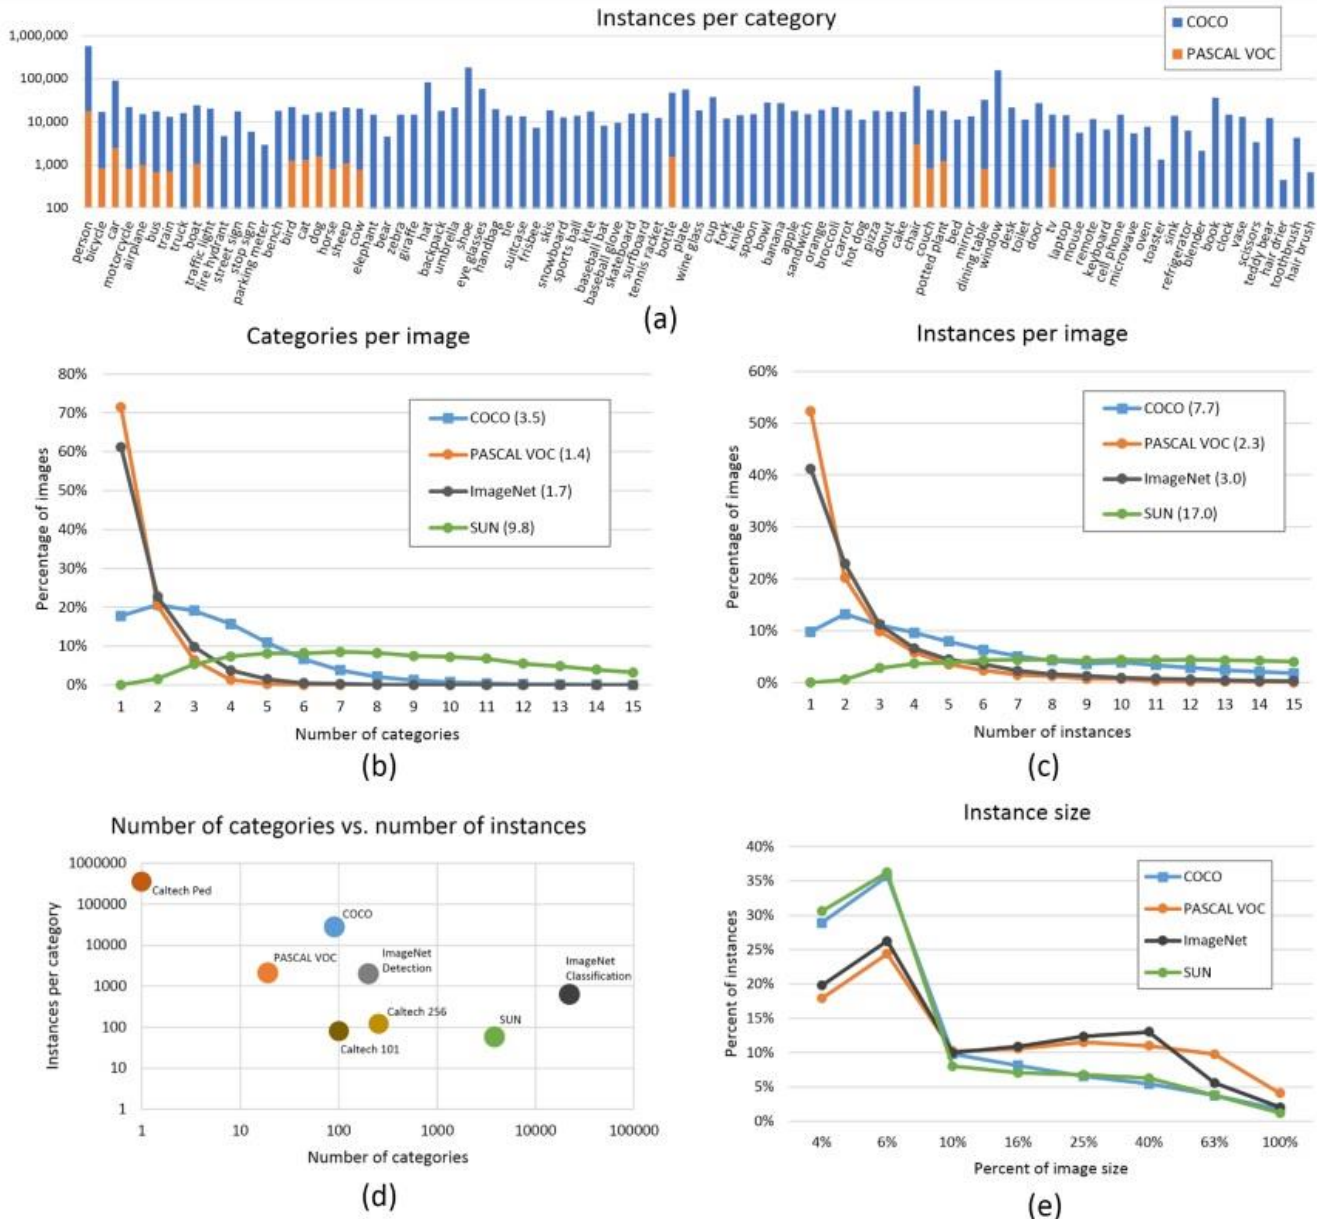

Fig. 1. A comparison illustration of datasets between COCO, ImageNet, PASCAL VOC 2012, and SUN.

### B. YOLOv8 Model

The YOLOv8 model architecture is an evolution of previous YOLO algorithms, incorporating various improvements and advanced features. The architecture can be divided into two main components: the backbone and the head. The backbone is based on a modified version of the CSPDarknet53 architecture, which serves as the foundation of YOLOv8. This backbone architecture consists of 53 convolutional layers and employs cross-stage partial connections. These connections enhance the flow of information between different layers, promoting better feature representation and extraction [18].

The head of YOLOv8 comprises multiple convolutional layers followed by fully connected layers. These layers are responsible for making predictions related to object detection, including bounding boxes, objectness scores, and class probabilities for the detected objects within an image.

The YOLOv8 introduces multi-scaled object detection capabilities. To achieve this, the model utilizes a feature pyramid network. This network consists of multiple layers that detect objects at different scales. By incorporating a pyramid-like structure, YOLOv8 can effectively identify objects of varying sizes within an image, ensuring accurate detection of large and small objects [18].

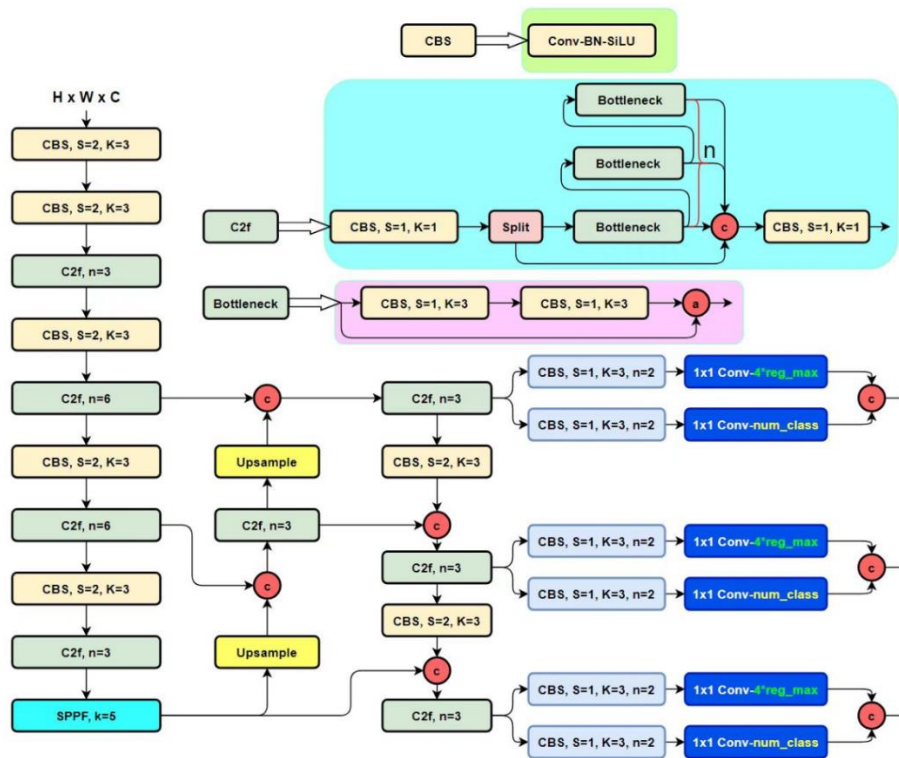

Fig. 2. YOLOv8 architecture [18].

As shown in Fig. 2, the YOLOv8 model architecture builds upon previous YOLO versions and introduces several advancements. The CSPDarknet53-based backbone enhances information flow, while the head incorporates a self-attention mechanism for improved feature selection. Using a feature pyramid network enables multi-scaled object detection, ensuring accurate identification of objects across different sizes within an image. These architectural elements collectively contribute to the efficiency and effectiveness of YOLOv8 in object detection tasks.

### C. Fruit Ripeness Detection Model

This study adopted a YOLOv8 model for fruit ripeness detection. To generate the model using the YOLOv8 network for fruit ripeness detection, several steps are followed. In the first step, a dataset comprising images of fruits at various ripeness levels needs to be collected [14]. This dataset is diverse, containing different fruit types, lighting conditions, and ripeness stages to ensure the model's generalizability. Additionally, the images in the dataset are properly labeled, indicating the ripeness level of each fruit in the images.

Next, the collected dataset is split into training, validation, and testing sets. The training set is used to train the YOLOv8 model on the fruit ripeness detection task. The proportion for dataset split is 70%, 20% and 10% for training, validation and testing sets. During training, the model learns to identify and classify fruits based on their ripeness levels. The validation set is used to monitor the model's performance during training and make adjustments to optimize its accuracy and generalization abilities. Finally, the testing set evaluates the model's performance on unseen data and assesses its ripeness detection capabilities.

Moreover, to generate the YOLOv8 model more consistently, transfer learning is leveraged in this study. Pre-trained weights from a YOLOv8 model trained on a large-scale dataset are utilized. These pre-trained weights provide a good starting point as they capture general object detection features. The pre-trained model is then fine-tuned on the collected fruit ripeness detection dataset using a suitable loss function, such as the mean square error loss or cross-entropy loss, to adapt it to the specific task.

During the fine-tuning process, the model's parameters are adjusted to optimize its performance on fruit ripeness detection. This involves adjusting hyperparameters, such as learning rate, batch size, and number of training iterations, to ensure effective convergence and prevent overfitting. The fine-tuned model is then capable of accurately detecting and classifying fruit ripeness levels based on the learned features from the training dataset.

## IV. RESULTS AND DISCUSSION

### A. Comparison of YOLO Models

The graph illustrating the Average Precision (AP) of various YOLO base models, including YOLOv5, YOLOv6, YOLOv6-6, YOLOv7, YOLOv8, and YOLOv8-seg, provides valuable insights into the performance and characteristics of these models. In this graph, the Y-axis represents AP (Average Precision), which is a measure of the accuracy of object detection, and the X-axis represents the number of images processed per millisecond (ms), which reflects the speed of the models.

Fig. 3. Performance comparison of Yolo-based models [19].

As illustrated in Fig. 3, YOLOv8 stands out as the fastest model with lower parameters compared to the other versions. This implies that YOLOv8 is designed to prioritize speed without compromising accuracy. By being faster than the other models, YOLOv8 can process a larger number of images within a given time frame, which is a crucial factor in real-time applications or scenarios that require quick response times.

Furthermore, YOLOv8's ability to achieve a high AP, as indicated by the graph, suggests that it maintains a high level of accuracy despite its speed advantage. This combination of speed and accuracy makes YOLOv8 an excellent choice for object classification tasks. Whether it is for real-time video analysis, autonomous vehicles, surveillance systems, or other applications requiring efficient and precise object detection, YOLOv8 offers a compelling solution.

Additionally, the graph shows that YOLOv8 has lower parameters compared to the other models. Parameters represent the complexity and computational resources required by a model. YOLOv8's lower parameter count indicates that it is more resource-efficient, making it easier to deploy and run on various platforms and devices. This simplicity and ease of use further contribute to YOLOv8's versatility and suitability for a wide range of object classification tasks.

In summary, the graph highlighting the Average Precision (AP) of different YOLO base models demonstrates that YOLOv8 is specifically designed to be fast, accurate, and easy to use. Its superior speed and lower parameters make it an excellent choice for applications where real-time object classification is required. YOLOv8's ability to deliver high

accuracy ensures reliable results, and its resource efficiency enhances its usability across various platforms.

### B. Experimental Results

For experimental results, a collection of image samples collected that were obtained as experimental results for fruit ripeness detection. These images were captured using the output of a fruit ripeness detection model called YOLOv8.

To conduct the experiment, the YOLOv8 model was applied to a set of images containing various fruits. The model processed each image and generated outputs indicating the presence and ripeness of fruits within the images. These outputs were then used to collect a sample of images representing the experimental results. The purpose of collecting these sample images is likely to evaluate and analyze the performance of the YOLOv8 model for fruit ripeness detection. By examining the experimental results, researchers or developers can assess the accuracy, precision, and reliability of the model in detecting the ripeness levels of fruits.

Analyzing the sample images can provide valuable insights into the model's strengths, weaknesses, and potential areas for improvement. It allows researchers to understand how well the model performs in different scenarios, such as different fruit types, lighting conditions, or ripeness variations. Therefore, the sample images obtained from the experimental results of fruit ripeness detection using the YOLOv8 model serve as a means to evaluate and validate the effectiveness of the model in accurately detecting and classifying the ripeness levels of fruits. Fig. 4 shows ripeness detection results.

Fig. 4. Fruit ripeness detection results.

### C. Performance Evaluation

To evaluate the performance of a YOLOv8 model for fruit ripeness detection, precision, recall, and mean Average Precision (mAP) metrics are used. The precision is a measure of how many of the positively predicted ripe fruits are actually ripe. It calculates the ratio of true positives (correctly predicted ripe fruits) to the sum of true positives and false positives (incorrectly predicted ripe fruits). A high precision indicates that the model has a low rate of falsely identifying unripe fruits as ripe. Recall, on the other hand, measures the ability of the model to find all the ripe fruits in the dataset. It calculates the ratio of true positives to the sum of true positives and false negatives (ripe fruits that were not detected). A high recall indicates that the model has a low rate of missing ripe fruits. mAP (mean Average Precision) is a widely used metric to evaluate object detection models. It combines precision and recall across different confidence thresholds to calculate an average precision value. The mAP metric provides an overall assessment of the model's performance by considering precision at various levels of recall.

In the given scenario, the precision of 98.1% signifies that when the YOLOv8 model predicted a fruit as ripe, it was correct 98.1% of the time. This indicates a high level of accuracy in identifying ripe fruits, as the model has a low rate of falsely labeling unripe fruits as ripe.

The recall value of 98.0% implies that the model successfully detected 98.0% of the ripe fruits present in the dataset. In other words, it only missed 2.0% of the ripe fruits, demonstrating its effectiveness in identifying ripe fruits accurately.

The mAP (mean Average Precision) score of 99.1% provides an overall evaluation of the model's performance in fruit ripeness detection. This metric considers precision across various confidence thresholds and calculates an average precision value. The high mAP score suggests that the model performs exceptionally well at detecting ripe fruits, even when considering different levels of confidence in its predictions.

Fig. 5. Results of precision, recall and mAP metrics.

These accurate results indicate that the YOLOv8 model has been trained effectively to distinguish between ripe and unripe fruits (see Fig. 5). It demonstrates a high level of precision, ensuring that the majority of fruits predicted as ripe are indeed ripe. Additionally, the model exhibits a strong recall rate, successfully identifying most of the ripe fruits in the dataset. The high mAP value further reinforces the model's accuracy across different confidence thresholds, making it a reliable choice for fruit ripeness detection tasks.

## V. CONCLUSION

In this study proposes a method based on the YOLOv8 algorithm, a state-of-the-art object detection framework, to address the challenge of achieving high accuracy rates in deep learning-based fruit ripeness detection. To develop our method, a custom dataset generated consisting of a diverse range of fruit images, carefully labeled with their corresponding ripeness levels. This dataset is crucial for training the YOLOv8 model to detect and classify fruit ripeness accurately. Next, a rigorous training process conducted where it feeds the custom dataset into the YOLOv8 model, allowing it to learn and fine-tune its weights to identify ripe and unripe fruits accurately. Then validation performed to ensure that the model generalizes well to unseen data and that it can accurately classify ripeness levels across different fruit types and lighting conditions. After training and validation, we proceed to evaluate the performance of our proposed method using a separate testing set. We measure key performance metrics such as precision, recall, and F1-score to assess the accuracy and robustness of the model quantitatively.

Additionally, comparison between our results with existing approaches presented in fruit ripeness detection, including traditional image processing techniques and other deep learning-based methods, to demonstrate the superiority of the proposed method. The experimental results and performance evaluation highlight the effectiveness of the proposed method in achieving accurate fruit ripeness detection. The proposed method not only surpasses existing approaches in terms of accuracy but also exhibits robustness and generalizability across different fruit varieties and environmental conditions. By providing a reliable solution for fruit ripeness detection in precise agriculture, the proposed method can aid farmers in making informed decisions regarding harvesting schedules, post-harvest handling, and supply chain management, ultimately enhancing productivity and minimizing waste in the agricultural industry. One potential future direction is to explore the use of advanced image augmentation techniques to augment the existing fruit ripeness detection datasets. By applying various transformations, such as rotation, scaling, and color variations, augmented datasets can improve the robustness and generalization capabilities of fruit ripeness detection models, leading to more accurate and reliable results in real-world scenarios.

# A New Method for Intrusion Detection in Computer Networks using Computational Intelligence Algorithms

Yanrong HAO, Shaohui YAN\*

Department of Software Engineering, Hebei Software Institute  
Baoding 071000, China

**Abstract**—This paper introduces a novel and integrated approach to intrusion detection in computer networks that makes use of the benefits of both abuse detection and anomaly detection techniques. The proposed method combines anomaly detection and abuse detection technologies to enhance intrusion detection functionality. The intrusion detection system is implemented using a set of algorithms and models in the proposed approach. The frog jump algorithm has been utilized to choose the system's ideal input attributes. The decision tree is utilized in this system's abuse detection portion. Support vector machines or basic-radial neural network models have been utilized to find anomalies in this system. In the process of training neural networks, other techniques like particle swarm or genetic optimization are also utilized. The NSL-KDD dataset was used the experiment, and the findings were published. These findings demonstrate that, in comparison to using only anomaly or abuse detection, the proposed approach can increase the effectiveness of intrusion detection in the network. Additionally, a model that uses the frog leap algorithm for feature selection and classification and combines decision tree and support vector machine techniques with ten chosen input features has a detection rate of 98.2%. This is true despite the fact that the detection rates of the systems trained using comparable data in prior studies with 33 and 14 selected input features to the trainer have been 83.2% and 84.2%, respectively. Additionally, the algorithm execution performance increases up to 29 times faster than the aforementioned approaches when the intrusion detection rate is maintained at the level of other competing methods that were simulated in this work.

**Keywords**—Decision tree; network intrusion detection; particle swarm algorithm; basic-radial neural network; frog jump algorithm

## I. INTRODUCTION

Computers connected to the Internet are threatened by a variety of things, including unauthorized access to user systems and the execution of unpleasant behaviors [1]. Typically, network penetration is viewed as an attack [2]. Intrusion detection systems are already a commonplace component of the security architecture. The following is a list of the intrusion detection system's objectives: Preventing behavioral issues that attack or abuse the system, recognizing attacks and coping with them, documenting current attacks, quality control, and giving security managers meaningful penetration information are just a few of the objectives [3].

According to the "CSI/FBI Computer Security and Crimes Survey" report, intrusion detection system usage increased from 42% in 1999 to 62% in 2010 and will reach 62% by 2022 has retained. These numbers demonstrate the critical role that these systems play in security technologies [4].

Network intrusion detection systems monitor network activity to find assaults. Exploit detection and anomaly detection are the two primary techniques for intrusion detection [5]. Using patterns and signatures that signal assaults, you can find exploits and intrusions. Detects assaults but is unable to identify them [6]. Due to the use of less complex identification algorithms, the abuse detection technique has the advantage of extremely rapid identification [7]. Activities that depart from regular functioning are identified as infiltration in the anomaly detection approach by the construction of normal usage profiles. Because of this, the exploit detection approach is unable to identify unexpected intrusions that the anomaly detection system can [8]. The high prevalence of false alarms in the anomaly detection approach is one of its shortcomings [9].

Intrusion detection systems that integrate both strategies have been developed to address the issues with these two approaches [10]. These systems do it in three different ways. The following approaches are used: a. abnormality is first identified, followed by abuse; b. parallel approach; and c. abuse is first identified, then abnormality [11].

The detection rate of all sorts of assaults (known and unknown) increases because under the parallel approach, incoming traffic is evaluated independently by each method (identification of abuse and identification of anomalies) [12]. The anomaly detection approach still has a high risk of false positive notifications, but if the detection model qualifies the communication as an attack, this method likewise treats the incoming communication as an assault [13, 42]. The computational cost of detection is another concern, as each communication must be examined using both anomaly detection and abuse detection models, which raises this cost [14].

In the combined strategy employed in this article, we have attempted to produce an ideal plan by combining already-existing algorithms and models [15]. In this regard, it has been managed to minimize the number of input features to the system from 41 to 10 thanks to the deployment of the optimization technique based on frog jump. Comparing this

strategy to several studies in this subject, the combined system is also one of the drawbacks. In this manner, the abuse detection system receives the inbound traffic first (Fig. 1). The exploit detection phase's outputs that do not fit the intrusion patterns are fed into the anomaly detection system as input in order to find unidentified intrusions [16, 43]. The effectiveness of anomaly detection declines as the volume of attacks rises. Hence exploit detection has been used first to address this issue. Known attacks can be found using exploit detection. The quantity of attacks required to find anomalies is drastically decreased by eliminating known attacks. Another benefit is that the suggested hybrid system can identify known intrusions in real-time due to the high speed of exploit detection techniques such as decision tree algorithms [17].

In this situation, the plan's anomaly detection component uses well-established, successful models (such as artificial neural networks) that can recognize novel attacks [6]. Instead of employing conventional methods for neural network training, computational intelligence algorithms have been adopted since they have proven to be more effective [18].

The main motivation of this research is to improve the effectiveness of intrusion detection systems (IDS). By combining abuse detection and anomaly detection methods, this approach aims to increase the system's ability to detect and mitigate various types of network intrusions. Traditional IDSs may struggle to effectively identify both known and unknown threats. Another motivation is to optimize the use of computing resources and reduce processing time. The choice of algorithms such as frog jumping algorithm, decision trees and support vector machines (SVM) shows the desire to achieve efficient and accurate intrusion detection without computational overhead. In summary, the proposed approach in this research

is motivated by the need for more effective intrusion detection systems; more efficient and adaptable in the face of evolving cyber threats. Potential benefits include improved detection rates, resource optimization, reduced false positives, and increased consistency, all of which contribute to a stronger and more comprehensive network security solution. In this regard, the suggested method's usage of radial basis neural network (RBF) in the anomaly detection phase has also led to a notable increase in the algorithm's execution speed when compared to other hybrid techniques. A comparison of the proposed hybrid system's performance with other similar schemes that have been tried on the same field with related events reveals that the suggested scheme has attained the desired detection rate (see Table VII in Section V). The main contributions of this research and their possible consequences are as follows:

- Hybrid intrusion detection system: This research introduces a new hybrid intrusion detection system that combines abuse detection and anomaly detection techniques. This hybrid approach can lead to more effective and robust intrusion detection because of its strengths. Both methods are used. The result is improved network security and a greater likelihood of detecting a wide range of intrusions.
- Feature selection and data preprocessing: This research emphasizes the importance of feature selection and data preprocessing techniques to improve the quality of input data. Choosing the right feature and normalizing the data can lead to a more reliable and accurate intrusion detection system. The consequences are higher accuracy in detecting intrusions and reduction of noise in the data.

Fig. 1. Hybrid intrusion detection system with abuse detection priority.

- **Efficiency and scalability:** This research deals with the efficiency and scalability of the intrusion detection system, especially by comparing SVM and radial basis neural networks. Understanding the trade-offs between different algorithms and their impact on performance and scalability can help deploy intrusion detection systems in different network environments. The result is consistent and resource-efficient intrusion detection.

The remainder of the essay is structured as follows. Studying earlier works is the subject of Section II. Section III offers suggestions for spotting abuse and abnormalities. Section IV discusses evaluation and simulation results, and Section V concludes with recommendations for future research.

## II. BACKGROUND RESEARCH

This section will first cover some earlier research on hybrid systems before introducing the fundamental models and techniques employed in this study.

### A. Related Work

Some of the studies on hybrid systems have been covered in this subsection. The three-layer architecture of the intrusion detection system, which was created and developed by [19], is an illustration of a hybrid system. Based on the KDD Cup'99 standard data, the system featured a blocklist, an allowlist, and a multiclass support vector machine bundle. Blocklists are used to filter out known threats from network traffic, whereas allowlists are used to identify legitimate traffic.

A method for audit data mining and analysis (ADAM) was presented by [20] in which abuse detection is used after anomaly detection. In order to identify attacks, ADAM combined an association mining rule with a classification mechanism. The suspect traffic is first identified by the association mining rule-based anomaly detection model, which then sends it to the abuse detection model. After then, the suspicious communications are classified by the abuse detection model as "normal," "known attacks," and "unknown attacks" (false alert of the anomaly detection model). Its usage is uncommon. Communications that cannot be categorized as typical patterns or known attacks under the ADAM technique are categorized as unknown attacks. If anomaly detection is used first, then abuse detection, the anomaly detection model should have a high detection rate, and the abuse detection model should eliminate the false alarms generated by the anomaly detection model by differentiating between known and unknown attacks. The majority of abuse detection systems, however, are ineffective at lowering false alerts. An anomaly detection model, an abuse detection model, and a decision support system were all incorporated in the [21] proposal for an intelligent hybrid intrusion detection system. They used a decision tree to model the abuse detection model and a self-organizing map (SOM) neural network to model anomaly detection. Following independent training of each model, the decision support system pooled the categorization outcomes of the two models.

A hybrid intrusion detection system was designed in [22] using the abuse detection approach first, then the anomaly detection method. The exploit detection model is quicker than

the anomaly detection model and can identify known attacks with a low probability of false positives. In order to identify known attacks, the Al-Teda detection and exploitation model was employed. Only non-deterministic connections were then detected using the anomaly detection model. A technique for detecting anomalies identifies outliers that deviate from typical data patterns and classifies them as well-known assaults. The anomaly detection and abuse detection models, however, are trained independently, just like the parallel hybrid technique, which causes a high risk of false positive notifications in the outcomes.

With a hybrid methodology, researchers in [23] initially used the C4.5 decision tree algorithm to evaluate the traffic during the abuse detection phase. After the exploit detection phase, in the anomaly detection phase, distinct support vector machines (SVM) were employed to discover unexpected incursions for each subset of data classified as normal by the intrusion detection model. Each subset will be more effective at generating typical profiles and finding anomalies because it has more concentrated data.

Computational intelligence techniques have been utilized for feature selection and decision trees for classification in numerous studies in the area of computer network security. For instance, researchers in [24] utilized the decision tree with the C4.5 training method to identify garbage items and the binary version of the particle swarm optimization technique (BPSO) for feature selection. The ideal collection of features was likewise chosen by the source [25] using CFA-based optimization, and the chosen features were assessed using a decision tree-based classifier. The estimation and selection of acceptable and chosen features for data classification during the tree training process is one of the decision tree's beneficial properties. On the other hand, adding a feature selection phase before training the decision tree has been shown in experiments to significantly improve the classification accuracy of the decision tree [26]. As a result, the frog jump method incorporated a feature selection step before training the decision tree in the article's suggested solution. The techniques and models used in this article are briefly introduced in the sections that follow so that the next sections can explore how to combine them and express the simulation results.

### B. Frog's Leap Algorithm

The combined optimization method based on frog jumping (SFLO) is one of many evolutionary algorithms that have been created in recent decades to decrease processing time and increase the quality of results [24]. This program uses a technique called imitative discovery [27] and aims to use a heuristic search to identify the overall best answer. In order to discover effective general solutions, this technique has been tested on a number of combinatorial problems. The population of potential solutions for the frog leaping algorithm is defined as a set of subsets of frogs (solutions). Distinctive subgroups are viewed as distinct frog species, each of which conducts a distinctive local search. Each frog in the subgroups has ideas that are shaped by those of other frogs and changed by the process of imitational evolution. Ideas spread through the subsets through the process of interweaving and interweaving after going through the evolutionary phases of imitation. Until

the convergence rule is satisfied, local search and nesting operations are carried out [28].

### C. Decision Tree

One of the most well-known techniques for creating a classification model is the decision tree. The result information of decision tree-based classification algorithms is displayed as a tree of several feature value states. Always dividing records based on a candidate feature that maximizes a particular criterion is a greedy approach to decision tree construction. The most deserving feature will be the one that improves the tree the most in accordance with this criterion. Depending on how the features of the data set are chosen to be included in the decision tree and when to cease growing the tree, there are various types of decision trees. Better than other failures are one where the distribution of bundles in the resulting nodes is homogeneous. The node is homogeneous if all of its records are suspended in the same category. Since, in this situation, that node turns into a leaf. In actuality, the node with the least number of impurities is the homogeneous node. They are placed in the interest relationship, and the amount of interest resulting from each failure is calculated after the amount of impurity arising from each failure has been determined. The failure-related impurity is removed from the parent node's impurity in the gain relation. Any failure that generates a greater profit is preferable, and that failure will ultimately be chosen [26]. The C4.5 tree, which is the decision tree employed in this article, is utilized to determine its impurity using the entropy approach based on Eq. (1):

$$\text{Entropy}(t) = - \sum_i p(j|t) \log p(j|t) \quad (1)$$

In relation (1),  $p(j|t)$  denotes the proportion of records belonging to the  $j$ th category to all other records in node  $t$ . The

fracture gain is calculated after the entropy for each node has been determined, followed by the entropy for the entire fracture. A failure is better if it has a greater interest rate. The gain of a failure is calculated using Eq. (2):

$$\text{GAIN}_{\text{split}} = \text{Entropy}(p) - \sum_{i=1}^k \frac{n_i}{n} \text{Entropy}(i) \quad (2)$$

Regarding this,  $n$  represents the overall number of records in the parent node,  $n_i$  represents the number of records in the  $i_{\text{th}}$  child,  $\text{entropy}(p)$  represents the entropy of the parent node, and  $\text{entropy}(i)$  also represents the entropy of the  $i_{\text{th}}$  node [29]. The test data set can then be used to test the classification model that was created using the decision tree. The goal of using the model is to predict, using the model, the category attribute value for the test record.

### D. Basic-Radial Neural Network (RBF)

The artificial neural network has the benefit of generalization, which sets it apart from other classifiers. With a small amount of training data, radial basis function networks are frequently used to estimate multidimensional functions nonparametrically. The RBF network is highly helpful since it trains quickly and thoroughly. With enough neurons in the hidden layer, it can estimate any continuous function with any level of accuracy. Fig. 2 depicts the three-layer network that makes up RBF's main design.

The basic-radial functions are shared by the neurons in the intermediate (hidden) layer [30]. According to Eq. (3), the third layer approximates the middle layer neurons' output by summing their weighted output:

$$F(x) = \sum_{i=1}^p w_j \phi(||x - u_j||) \quad (3)$$

Fig. 2. The architecture of an RBF network [30].

If RBF is used to approximate the function, its output will be helpful. However, a hard limiter can be applied to the output neurons to ensure output values of 0 or 1 for pattern classification purposes. The base-radial function  $p$  with centers  $u_j$  is utilized for the approximation of the F function based on Eq. (3). Sign  $\|\cdot\|$  the exponent, which is typically set to represent the Euclidean distance, is the distance function of  $R_n$  space. The most well-known basic-radial function, which has been proposed, is the Gaussian function in RBF networks. The Gaussian function, an exponential function from the category of functions with the best approximation qualities, was chosen as the response function of neurons in RBF networks. This ensures that there is a set of weights that more accurately approximates the relationship between the input and target vectors than any other set. The sigmoid function utilized in the creation of error backpropagation networks makes use of this assurance that it has no existence.

### E. Particle Swarm Optimization Algorithm

The social behavior of a group of birds is described by the population-based stochastic optimization algorithm known as the PSO algorithm. In space, a flock of birds looks for food randomly. Following the bird that is closest to the food can be one of the greatest tactics. The PSO algorithm's core concept is this tactic [31]. The search space for the PSO algorithm is analogous to the search space for the bird movement pattern. In the PSO algorithm, each solution, also known as a particle, is analogous to a bird, and there are exactly as many particles (solutions) as there are birds. Each particle has a merit value, which is determined by a merit function. The more merit a particle has, the closer it is to the target in the search space, which in the bird movement model is food. Additionally, every particle has a displacement that controls its direction of motion and is used to predict its next location. Until it ultimately reaches the ideal solution, each particle moves forward in the search space by adhering to the best particles in the current state [32]. The particle velocity vector ( $V_i$ ) and particle ( $X_i$ ) in the  $(t+1)$ th iteration are computed from relations (4) and (5) in each step of the particle swarm algorithm iteration:

$$\begin{aligned} V_i(t+1) &= w \times V_i(t) + \\ &C_1 \times \text{rand}_1 \times [p\text{best}_i(t) - X_i(t)] + \\ &C_2 \times \text{rand}_2 \times [g\text{best}_i(t) - X_i(t)] \quad (4) \\ X_i(t+1) &= X_i(t) + V_i(t+1) \quad (5) \end{aligned}$$

### F. Hereditary Algorithm

Hand first proposed the genetic algorithm in 1965. From among the chromosomes in a population, the selection operator chooses the number of chromosomes for reproduction. Fitter chromosomes are more likely to be chosen for reproduction. Chromosome segments are randomly switched between during crossing over. Because of this, the children don't exactly resemble one of their parents but instead exhibit traits from both. A single-point, two-point, or even intersection could exist [33].

All chromosomal points have an identical chance of merging during the uniform crossover. In this case, any valley can be used to pick the child's chromosome genes. It is possible to perform uniform intersection using relations (6) and (7):

$$y_{1i} = a_i x_{1i} + (1 - a_i) x_{2i} \quad (6)$$

$$y_{2i} = a_i x_{2i} + (1 - a_i) x_{1i} \quad (7)$$

In these relationships,  $x_1$  and  $x_2$  are the parents, while  $y_1$  and  $y_2$  are the first and second children, respectively. Additionally, the values of  $a_i$  in continuous issues are in the range  $[0,1]$ , while those in binary problems are equal to zero or one. The letter  $i$  stands for the input dimensions (solution space dimensions).

The chromosomes are subjected to the mutation operator after crossing over. This operator chooses a gene at random from a chromosome and modifies the information within that gene. If the gene is a binary number, it is inverted; if it is a member of a set, another value or component of that set is substituted for the gene. The created chromosomes are known as the new generation and are sent to the following round of algorithm execution after the mutation operation is finished.

## III. SUGGESTED METHOD

Fig. 1 shows the suggested method's operating principles. The specifics of spotting abuse and abnormalities will be covered in this section. Prior to applying the data to the model in the proposed combined method, the data was first preprocessed using the leapfrog computational intelligence algorithm to extract its key features, which improved the system's overall performance and, in particular, the effectiveness of the decision tree. The regular training data is then separated into subgroups during the misuse detection stage whose connection patterns have less variation than the entire normal data. Then, in the anomaly detection stage, a different anomaly detection model is applied for each subset. As a result, each subset's efficiency will be higher in producing more normal profiles and rejecting the result in anomaly detection since each subset has more concentrated data [9, 34]. The quality of the input data to the anomaly detection stage is not good enough and has a significant impact on the accuracy of the SVM network if the decision tree is unable to appropriately partition the data into subsets while retraining the model in the operational environment. This lowers the effectiveness of the SVM network; however, the RBF neural network is not constrained by this issue. Since model training is a linear process and neural network training is slower, the effectiveness of the models is unaffected [34].

The RBF neural network was employed in the anomaly detection phase, and the effectiveness of SVM and RBF was compared in the anomaly detection phase, in accordance with the foregoing and to prevent the reduction of the accuracy of the SVM network, in cases where the output of the decision tree is not effective. It is important to note that switching from SVM training to RBF training and performing feature selection prior to the abuse detection stage in order to condense the problem's dimensions were the adjustments that significantly increased the effectiveness of the newly proposed method. The simulations were conducted using Matlab software version 2022a as well. The steps for intrusion detection in the suggested approach are as follows:

- Data preprocessing includes the following steps:

a) Data homogenization (training and test data) by replacing the letter characters of the data set with numerical values

b) Data normalization (training and test data): In this step, the values of the continuous features are normalized to the interval [-1,1] according to Eq. (8).

$$X = 2 \times \frac{x - \min(x)}{\max(x) - \min(x)} - 1 \quad (8)$$

c) Reducing the dimensions of the problem by feature selection by the leapfrog computational intelligence algorithm

It should be noted that normalization (or rescaling of features) removes the imbalance between the data [36-34]. In the dataset used in this paper (NSL-KDD), some features have large numerical values that can dominate other features. For example, the *dst\_bytes* attribute can have values from zero to about  $1.3 \times 10^9$ , while the *same\_srv\_rate* attribute has values between zero and one [35].

- Applying various methods in the combined model of penetration detection:

(First the abuse detection phase and then the abnormality detection phase) including the C4.5 decision tree in order to detect abuse and then apply separate RBFs in the abnormality detection phase for the categories that are detected as normal. It is reminded that the training parameters in the RBF neural network are determined with the help of the genetic algorithm or the particle swarm algorithm. The block diagram presented in Fig. 3 shows the working steps in the proposed intrusion detection method in more detail.

### A. The Stage of Identifying Abuse

In the data mining process, the data are ready to be applied to the model learning stage after feature selection and data pretreatment. The C4.5 decision tree is utilized for this. The data exploration strategy that is chosen will determine the sequence guiding the preprocessed data during the learning stage, and the created model will then be sent to the evaluation stage (i.e., evaluation and interpretation of the model) for evaluation. It was time to cut the decision tree after training and preserving it, leaving only 12 leaves with conventional labels. Too small sets make this operation excessively slow because it takes time to split training data into distinct subsets based on various rules. The tree was pruned for these reasons because, on the other hand, the restriction and lack of overdispersion of neural network inputs during the training phase will reduce the generalization capacity of the network.

### B. Anomaly Identification Stage

At this point, distinct RBFs were utilized for each of the remaining leaves with the conventional label, and the data input for each of them was identical to the information classified by the decision-making process. The neural network's leaves had come. The conditions of their development were determined for all the leaves with the normal label in order to obtain the data in each leaf. Based on these conditions, the training data set was then segmented into several input subsets, and for each of them, different neural networks were employed. The usage of a more homogeneous data set boosts the network's accuracy, and the anomaly detection system is better prepared to deal with anomalies that do not follow the typical pattern since it is more accustomed to normal patterns with lower dispersion [36].

Fig. 3. Process block diagram of the proposed intrusion detection method.

#### IV. EVALUATION RESULTS OF THE PROPOSED SOLUTION

##### A. NSL-KDD Dataset

The NSL-KDD dataset has been utilized to evaluate and contrast the performance of the suggested method [37]. The NSL-KDD dataset is an edited version of the KDD'99 dataset that was made available as a result of KDD'99's issues with the presence of numerous duplicate samples in the training and test data, as well as the resolution of these issues. The 41 characteristics in this dataset span a wide range of numerical values and are of continuous, discrete, and symbolic types. As previously stated, data preprocessing is required to correct the imbalance in the entire dataset and eliminate the impact of scale differences in such a database [38]. In other words, normalization in such data on all data (in the following, some of them as training data and others as training data) tests are selected) [39] in order to prevent features with high numerical values from overpowering other features.

##### B. Overall Evaluation Results

The frog jump algorithm was used to intelligently choose ten attributes from among them in order to decrease the problem's dimension. Feature selection (variable reduction) aids in data comprehension, lower processing demands, lessens the impact of the dimensionality problem and enhances prediction performance. The goal of feature selection is to choose a subset of input variables that can accurately characterize the input data while minimizing the impact of extraneous factors and producing accurate prediction results [40].

In this step, the trained decision tree was first given all the input data from the abuse detection phase (signature detection) in order to evaluate the model. Assuming they are unidentified

attacks whose signatures or data packet characteristics could not be recognized by the exploit detection model; the identification component will once more detect the data that the decision tree classified as regular packets. In this phase, anomalies (trained RBF) were examined to determine their class. The way the anomaly detection phase operates is that the inputs are first reviewed again in accordance with the requirements of the decision tree's leaves to choose which of the RBFs should be provided as input. The selective RBF then determines the data packet's final class.

The time needed to run the model is significantly reduced if RBF is used in place of SVM, according to the results, so that the time needed for the test is decreased by an average of 26 times (if PSO is employed), a 24 times improvement, and if we employ GA, we will see an improvement in execution time of more than 28 times); however, the model error had a modest decline.

It should be noted that the ideal number of kernels for each RBF was found independently during the RBF training procedure. If PSO and inheritance algorithms are applied, the number of optimal cores for every RBF may be deduced from Fig. 4 and 5, respectively. According to the number of various kernels, each line in the graphs depicts the MSE error trend for one of the RBFs, and the number of optimal kernels for each RBF is the same as the number of kernels that minimize the MSE error.

As previously indicated, PSO and genetic algorithms (GA) were used to train the RBF neural network individually, and the outcomes of both were compared. The results were nearly identical, and no discernible difference was found regarding the effectiveness of applying PSO or GA in RBF training.

Fig. 4. Training error of all RBFs using PSO algorithm for different numbers of kernels.

Fig. 5. Training error of all RBFs using GA for different numbers of kernels.

In accordance with relations (9) to (12), the following metrics were employed to assess the models: mean square error (MSE), root mean square error (RMSE), mean absolute error (MAE), and set of square error (SSE).

$$MSE = \sum_{i=1}^n \frac{(t_i - y_i)^2}{n} \quad (9)$$

$$RMSE = \sqrt{\sum_{i=1}^n \frac{(t_i - y_i)^2}{n}} \quad (10)$$

$$MAE = \sum_{i=1}^n \frac{|t_i - y_i|}{n} \quad (11)$$

$$SSE = \sum_{i=1}^n (t_i - y_i)^2 \quad (12)$$

In the relationships mentioned above, n denotes the number of samples, t<sub>i</sub> is the goal output value, and u<sub>i</sub> denotes the output value of the class that the model predicted [41]. An Intel Core i7 machine with a clock speed of 2.1 GHz and 6 GB of random-access memory was used for the models' training and testing phases. Sixty-two thousand eight hundred sixty-four data points were used to train the models, while 85347 data points were used to test the models. The outcomes of using the models are shown in the paragraphs that follow.

### C. Decision Tree Training Results

Table I shows the results of errors in detecting abuse. The time required to train the tree was equal to 0.18 seconds.

### D. The Results of the Combined Model of Decision Tree and RBF with Training by PSO Algorithm

In Table II, the results of using the combined intrusion detection model are presented in the condition that the RBF model is trained with the PSO algorithm. The errors presented in Table II were obtained for this setting of values for the PSO algorithm parameters: number of population members: 60, personal learning coefficient (C1): 1.4962, collective learning coefficient (C2): 1.4962, W coefficient: 1 and Reduction factor W: 0.9.

### E. The Results of the Combined Model of Decision Tree and RBF with Training by GA

Table III also shows the results of using the combined intrusion detection model in the conditions where the RBF model is trained with the genetic algorithm. The errors presented in Table III were obtained for this setting of values for the parameters of the genetic algorithm: number of population members: 20, crossover probability: 0.9, mutation probability: 0.3, and mutation rate: 0.6.

Additionally, Table IV provides the amount of time needed to train the simulated models. Because PSO and GA have different populations with different numbers of population members, RBF training and PSO and GA differ in innovative ways. Each model with the least population members that leads to the lowest error rate has been taught since increasing the number of population members in population-based optimization algorithms increases training time because more iterations are required for more population members. As can be seen, using SVM rather than RBF cuts down on training time during the anomaly detection stage. This is because RBF training involves using the aforementioned smart optimization algorithms to find the ideal network weights, and finding these ideal values requires a significant amount of repetition. However, because the training process takes place offline, it is

acceptable to extend it in order to enhance the performance of the model's online execution.

#### F. The Results of Testing the Models with Test Data

The experimental results demonstrate that the model performs poorly when used in the anomaly detection phase with a significant amount of input data, which eventually results in the model's inefficiency in online applications (Table V). As can be shown, using a decision tree and an RBF neural network together (with training via the PSO algorithm) is the optimum option in terms of the model's online execution time. The aforementioned alternative offers competitive values and comes quite near to the combined decision tree and RBF neural network model (with GA training) in terms of the number of various error criteria (Table VI).

TABLE IV. THE TRAINING TIME OF THE MODELS

proposed model	Anomaly detection model training time (sec)	Time required to provide data for anomaly detection model (sec)	Training time of the misuse detection model (sec)	total time (sec)

With a false positive rate of 1.3%, DT has a detection rate of 99.2% for known threats and 31.06 percent for unknown attacks. DT turns out to be unsuitable for detecting new assaults but has strong detection performance for known attacks. The proposed method's detection performance was carefully examined in terms of anomaly detection since its goal is to enhance the detection performance of the anomaly detection model. Fig. 6 compares the suggested method's receiver operating characteristic (ROC) curves for unknown attacks with those for increases in parameter  $\gamma$  from 0.01 to 1. The proposed method has a greater detection rate than traditional ones. The rate of false positives in the decision boundaries of the anomaly detection model in the proposed method can depict normal behavior better than existing methods since each class 1 SVM model can concentrate on its corresponding decomposed region.

The proposed method's detection rate is roughly 11% greater than that of traditional approaches when the false positive rate is below 11%, which is ideal. It was found that the conventional method's detection rate improves when the false positive rate is about 51%. This outcome is believed to be the consequence of the suggested technique, which calls for building a class 1 SVM model for each deconstructed region. Instead of concentrating on each deconstructed zone when the false positive is very significant (like 51%), it is preferable to concentrate on the highly concentrated regions. It can be deduced that the detection performance of the suggested method is superior to traditional methods for unknown assaults because an IDS operator should have a very low false positive rate.

(a) Unknown assaults with parameter  $\gamma=0.01$  on ROC Curve.

(b) Unknown assaults with parameter  $\gamma=0.1$  on ROC Curve

(c) Unknown assaults with parameter  $\gamma=1$  on ROC Curve

Fig. 6. Investigation and comparison of detection efficiency for unknown attacks using ROC curves.

G. The Class 1 SVM Model's Detection Rate Approaches that of the Traditional Hybrid Method as

The parameter  $\gamma$  rises. This demonstrates that DT cannot influence the identification of unknown threats by enhancing Class 1 SVM performance. However, it has a major impact on hybrid intrusion detection models' ability to identify known attacks. Fig. 7, which varies the parameter  $c$  from 0.01 to 1, displays the ROC curves of the known attacks for the proposed technique and its comparisons. The figure shows that

regardless of performance, both combined detection approaches from the SVM class 1 model have a detection rate of more than 99.1%. When  $\gamma$  is set to 1, the hybrid intrusion detection model's detection rate is somewhat greater than DT's, but its effectiveness is minimal. The class 1 SVM model's detection rate rises as  $c$  rises, as in the event of an unknown attack. However, in this instance, the class 1 SVM model-based anomaly detection approach is outperformed by the abuse detection method employing DT.

(a) Known assaults with parameter  $\gamma=0.01$  on ROC Curve

(b) Known assaults with parameter  $\gamma=0.1$  on ROC Curve

(c) known assaults with parameter  $\gamma=1$  on ROC Curve

Fig. 7. Investigation and comparison of detection efficiency for known attacks using ROC curves.

This paper introduces an innovative approach to intrusion detection in computer networks by combining abuse detection and anomaly detection techniques. This hybrid approach looks promising because it leverages the strengths of both methods and potentially leads to more effective network security. To select the algorithm, it is also attractive to use computational intelligence algorithms such as frog jumping algorithm, decision trees, support vector machines (SVM) and radial-based neural networks. These algorithms offer a variety of ways to handle intrusion detection, and it makes sense to choose them based on the specific needs of the system. It is also instructive about the execution speed and comparison between SVM and radial neural networks. It is noteworthy to observe that the use of RBF can significantly reduce model training time, as real-time intrusion detection often requires efficient algorithms. Overall, the paper provides a comprehensive overview of the proposed intrusion detection system, its methodology and performance metrics. It provides valuable insights into the potential benefits of combining exploit and anomaly detection techniques and provides a structured approach for future research in network security.

This paper presents a detailed evaluation of the proposed intrusion detection system, including results obtained from experiments using the NSL-KDD dataset. The evaluation includes various performance metrics and comparisons with other intrusion detection systems. Performance measures, detection rate, comparative analysis, training and test results, execution speed and ROC curves are among the evaluations discussed in this research. This paper concludes that the proposed hybrid intrusion detection system provides competitive detection rates and feature selection capabilities compared to other systems. This shows that the system performance can be improved by using RBF models instead of SVM in certain scenarios.

In general, the results and evaluations presented in the paper show the effectiveness of the proposed intrusion detection system in detecting known and unknown attacks. Using various performance metrics, comparative analysis and visual displays (such as ROC curves) provide a comprehensive assessment of system capabilities and tradeoffs. These results help to understand how computational intelligence algorithms can enhance network security.

## V. CONCLUSION

This paper provided a hybrid approach to network intrusion detection. This section will contrast the proposed mixing system's performance with that of comparable systems that employ feature selection algorithms and classification tools from various models, such as decision trees. The proposed mixing system utilizes multiple methods and models in its various components. SVM, Natural Bayes, and artificial neural networks have all been utilized for intrusion detection. The system test with KDD'99 or NSL-KDD data produced the findings that are shown in Table VII. The NSL-KDD dataset, which has the same number of characteristics as the original KDD'99 dataset, should be noted. Classifiers do not favor data with more repetitions since the extension records in the training set are destroyed during the compression process. The majority of detection rates, though, are higher on KDD'99 than NSL-KDD.

The hybrid approach suggested in this work has the best detection rate compared to other models tested on NSL-KDD data in prosperous years, as shown in Table VII. Meanwhile, the proposed models use fewer features than other models, which is a smaller number of features overall. As a result, it can be said that the suggested system offers a good mix of feature selection and classification techniques and that its

performance results are comparable to those of other systems that have been shown effective using KDD'99 and NSL-KDD data.

Additionally, the findings of the experiment demonstrated that while employing parallel SVMs, whose inputs are the leaves of a tree from smaller and more coherent data, resulting in a reduction in model training time, the model execution time relative to using RBF is increased. Instead of SVM, it is significantly longer (roughly 28 times the execution time of the model using RBF), which results in the model's inefficiency, particularly in high-speed networks; In the scenario where the execution errors and false alarm rates of the system are comparable in both models. It can be stated that using RBF instead of SVM has considerably increased the efficiency of the combined model because model training is an offline process, whereas testing and implementation are online processes.

This article examines the performance of the system in detecting known and unknown attacks. However, the system's effectiveness in detecting brand new and zero-day attacks has not been addressed. Future research can focus on developing methods to enhance the detection of previously unseen threats. We also pointed out in this research that using SVM instead of RBF can lead to a significant increase in execution time. Scalability is a critical concern for intrusion detection systems, especially in high-speed networks. Future research can explore ways to optimize the computational efficiency of the system without compromising the detection accuracy. In summary, future research in intrusion detection should focus on addressing these limitations and advancing the field by developing more robust systems. A more consistent and efficient focus can effectively detect a wide range of network intrusions while taking into account ethical and privacy considerations.

For those people who are eager for more research and new work in this field, it is suggested that in order to reduce false alarms in the anomaly detection stage, they should look for a solution to reduce the rate of false negative alarms in the abuse detection stage, because the outputs of the abuse detection stage which were categorized under the title of normal, are used as the input of the anomaly detection stage, and the anomaly detection model needs normal data as its input for better training and detection of violations from the normal pattern, and by reducing the negative rate of error in the detection stage abuse can achieve this.

**Abstract**—The prevalence of autism has increased dramatically in recent years and many people around the world are facing this difficult condition. There is a need to develop an objective method to diagnose autism. Various analysis methods have been used to classify the EEG signals of people with autism, from linear methods in the time and frequency domain to nonlinear methods based on chaos theory. However, there is still no consensus on which method of EEG signal analysis can provide us with the best diagnostic accuracy and valid biomarkers for autism diagnosis. Therefore, in this study, we evaluate different feature extraction methods from EEG signals to diagnose autism from healthy individuals. For this purpose, EEG analysis was performed in time, time-frequency, frequency and nonlinear domains. Furthermore, the self-organizing map (SOM) method was used to classify features extracted from autistic and normal EEG. The data used in this study were recorded by the research team from 24 children with autism and 24 normal children. The accuracies of 92.31, 93.57, 95.63 and 97.10% were achieved through time and morphological, frequency, time-frequency and nonlinear analyzes, respectively. Indeed, the findings showed that nonlinear analysis could yield the best classification results (accuracy = 97.10%, sensitivity = 98.80% and specificity = 97.02%) in the EEG discrimination of autistic children from typical children through the SOM neural network.

**Keywords**—Autism; EEG; linear analysis; nonlinear analysis; neural network

## I. INTRODUCTION

Autism is a severe psychiatric disease in which patients have serious problems in executive functions, social relations, cognition, normal behaviors and daily activities [1]. Its prevalence has grown in recent years drastically, and many people around the world are facing this difficult condition [2-4]. However, psychiatrists and psychologists do not deal with the definitive state of this disorder, but they have to deal with autism spectrum disorder with different biological and behavioral symptoms [5, 6]. This causes doctors to choose different screening tools to diagnose patients with autism and therapists to choose different treatment approaches for each patient [7]. But most of the existing screening and diagnostic tools are subjective, and various types of research suggest the need to develop an objective method to diagnose autism [8]. For example, a review article highlighted various biomarkers, such as hormones, to develop reliable, objective methods for diagnosing autism [9]. A systematic review focused on the

application of artificial intelligence in autism screening and diagnosis through validated questionnaire-based data such as the Autism Diagnostic Interview-Revised (ADI-R) and the Autism Diagnostic Observation Schedule (ADOS) [10]. Another systematic review showed that a combination of eye-tracking technology and machine learning could be taken into account as a suitable approach for objective and early diagnosis of autism [11]. Lai et al. proposed an objective method for autism diagnosis based on automatic retinal image analysis and machine learning and reported a good accuracy of 97.4% for this purpose [12]. Zhao et al. proposed an automatic objective system based on the analysis of the movements of patients during a motor task and machine learning algorithms. They reported an accuracy of 88.37% for autism diagnosis [13]. Therefore, as we can see from the literature, many researchers around the world have tried to develop objective methods of autism diagnosis through various psychological, biological and physiological data.

In the meantime, electroencephalogram (EEG) is one of the electrophysiological data that has received much attention from researchers and has been analyzed in various ways to develop objective methods for diagnosing autism [14]. EEG indicates the pattern of neural electrical activity in different areas of the brain, providing brilliant information about brain function in various healthy and unhealthy conditions [15, 16]. Therefore, EEG signals have been targeted by computational neuroscientists and biomedical engineers for various biomedical applications [17-23]. So far, various EEG biomarkers have been introduced to diagnose psychiatric and neurological disorders [24, 25]. Bosl et al. used a combination of nonlinear EEG analysis and different machine learning techniques, achieving a 95% accuracy in screening pediatric populations at risk for autism [26]. Haputhanthri et al. extracted statistical features from wavelet analysis applied to EEG signals of children with autism, achieving a diagnostic accuracy of 93% [27]. Ahmadlou et al. proposed a fuzzy synchronization likelihood wavelet approach, achieving an EEG classification accuracy of 95.5% for autism diagnosis [28]. Pham et al. applied the higher-order spectra bispectrum method to EEG signals and achieved a high accuracy of 98.7% using a probabilistic neural network for autism diagnosis [29]. Baygin et al. utilized a combined deep lightweight feature extraction method based on one-dimensional local binary patterns and deep features of the spectrogram images generated by the short-time Fourier transform. The 10-fold cross-

validation algorithm showed an ability to identify children with autism with a support vector machine with 96.44% accuracy [30]. Alotaibi and Maharatna proposed an EEG classification system based on functional connectivity features conceptualized by graph theory and cubic support vector machine, achieving an accuracy of 95.8% for autism diagnosis [31]. Radhakrishnan et al. evaluated deep learning models for the diagnosis of autism from EEG signals, reporting an average accuracy of 81% using their methodology [32].

As can be seen in the literature, various analysis methods have been used to classify the EEG signals of people with autism, from linear methods in the time and frequency domain to nonlinear methods based on chaos theory. However, there is still no consensus on which method of EEG signal analysis can provide us with the best diagnostic accuracy and provide valid biomarkers for autism diagnosis. Therefore, in this study, we are going to evaluate different feature extraction methods from EEG signals in order to diagnose autism from healthy individuals. For this purpose, EEG analysis in time, time-frequency, frequency, and nonlinear domains were performed through various analysis techniques. This paper is organized as follows. Section II provides the procedure proposed in the current study. Section III reports the experimental results. Section IV discusses the obtained results and makes a conclusion.

## II. METHODS

In this section, various analysis methods applied to EEG signals for autism diagnosis were described. Fig. 1 shows the framework adopted in this study.

### A. Time and Morphological Analysis

EEG signals have specific temporal characteristics that may be affected by different neuropathologies. As a result, according to these temporal characteristics, it is possible to

extract features based on the signal waveform over time, which can be used to distinguish between the two classes of autism and normal. These features are simple and require very little computation. The advantage of such features is increasing the speed of the designed system and the possibility of using it in real-time [33-35]. The following features in this category were calculated from EEG signals.

$$\text{Absolute amplitude} = \max|s(t)| \quad (1)$$

$$\text{Peak-to-Peak} = S_{max} - S_{min} \quad (2)$$

$$\text{Negative Area} = \sum_t 0.5(s(t) - |s(t)|) \quad (3)$$

$$\text{Positive Area} = \sum_t 0.5(s(t) + |s(t)|) \quad (4)$$

$$\text{Total Absolute Area} = |\text{Negative Area}| + \text{Positive Area} \quad (5)$$

$$\text{Zero Crossing} = \sum_t \delta_s(t) \cdot \delta_s(t) = \begin{cases} 1 & s(t) \times s(t-1) < 0 \\ 0 & \text{otherwise} \end{cases} \quad (6)$$

$$\text{Mean} = \frac{1}{n} \sum_{t=1}^n s_t \quad (7)$$

$$\text{Standard deviation} = \left( \frac{1}{n} \sum_{t=1}^n (s_t - \bar{s})^2 \right)^{\frac{1}{2}} \quad (8)$$

$$\text{Energy} = \sum_t |s(t)|^2 \quad (9)$$

$$\text{Skewness} = \frac{E[(s-\mu)^3]}{\sigma^3} \quad (10)$$

$$\text{Kurtosis} = \frac{E[(s-\mu)^4]}{\sigma^4} \quad (11)$$

where  $s(t)$  is the time series under analysis,  $n$  is the number of data points,  $\mu$  is the mean of the time series,  $\sigma$  is the standard deviation, and  $E$  denotes the expectation operator.

Fig. 1. Adopted framework in this study for EEG classification of autistic children and typically children.

### B. Frequency Analysis

Frequency features actually represent the rate of change in the signal. Methods such as the Fourier transform are used to convert the signal from the time domain to the frequency domain. Here, the Welch method was utilized to extract EEG sub-bands, including delta (1-4 Hz), theta (4-8 Hz), alpha (8-12 Hz), sigma (12-16 Hz), beta (16-30 Hz) and gamma (30-45 Hz). This method is Fourier transform-based algorithm to estimate the power spectral density. After signal sub-bands extraction and power spectrum density estimation, we calculated mean, standard deviation, skewness, kurtosis, absolute power and relative power from each sub-band as frequency features.

### C. Time-Frequency Analysis

We utilized this type of analysis to assess signals in the time and frequency domains concurrently. For this purpose, wavelet transform was used, which provides a time-frequency representation of EEG signals with good frequency and time localization. This technique decomposes time series into shifted and scaled versions of the basic wavelet function. The wavelet function can be written as:

$$\psi_{a,b}(t) = 2^{a/2}\psi(2^{a/2}(t - b)) \quad (12)$$

where  $\psi(t)$  denotes the wavelet function,  $a$  is the scale parameter, and  $b$  is the shift parameter. The discrete version of this algorithm decomposes EEG signals into high- and low-frequency components at each level, known as detail and approximation coefficients [19]. In the current work, the Haar wavelet was employed to represent the time-frequency sub-components of the signals. After calculating the detail and approximation coefficients, we calculated the mean, standard deviation, variance and entropy as time-frequency features.

### D. Nonlinear Analysis

Due to the nonlinear characteristics of EEG, nonlinear analyzes may reveal more details about the neuropathological mechanisms involved in autism. In the current study, we tried to calculate various nonlinear features for the signals, including large Lyapunov exponent, Lempel-Ziv measure, approximate entropy, sample entropy, Higuchi fractal dimension, and detrended fluctuation analysis. In this subsection, the mathematical notation of these nonlinear features was explained.

1) *Large lyapunov exponent*: This feature is a chaotic concept to assess the trajectory divergence in dynamical systems. Lyapunov exponent determines the exponential divergence rate between the two adjacent trajectories. The mathematical notation of this exponent can be written as:

$$\lambda = \frac{1}{n} \ln \left( \frac{d_n}{d_0} \right) \quad (13)$$

where  $d_n$  and  $d_0$  denote the divergence/distance between sequential data points in the  $n^{\text{th}}$  and initial times, respectively.

2) *Lempel-Ziv measure*: It is a complex feature to estimate new paradigms in EEG signals. This method converts a signal to a binary one by median thresholding and scans the binary signal for new subsequences in sequential symbols [36].

$$LZ = \frac{\log_2(n) \cdot c(n)}{n} \quad (14)$$

where  $n$  is the number of data points and  $c(n)$  denotes the number of new subsequences.

3) *Approximate entropy*: It is a measure to estimate the randomness of EEG fluctuations over time.

$$ApEn(m, r, N) = \ln \left[ \frac{C_m(r)}{C_{m+1}(r)} \right] \quad (15)$$

where  $C_m(r)$  denotes the repeating paradigms of length  $m$  in a signal of  $N$  data points according to the similarity index  $r$ . In this work, we set  $m = 2$  and  $r = 0.2$  standard deviation of EEG signals [37].

4) *Sample entropy*: Sample entropy: It is a modified algorithm of approximate entropy that reduces the self-matching bias in the entropy calculation [38]. This algorithm depends on the length of the data and yields relatively consistent results in various conditions.

$$SampEn(m, r, N) = -\ln \left( \frac{A^m(r)}{B^m(r)} \right) \quad (16)$$

where  $r$ ,  $m$  and  $N$  indicate tolerance, embedding dimension and the number of samples, respectively.  $B^m(r)$  represents the probability that two series of data samples of length  $m$  have a distance smaller than the tolerance  $r$ , and  $A^m(r)$  indicates a similar probability for two series of data samples of length  $m+1$ .

5) *Higuchi fractal dimension*: Consider a time series  $S(N) = S(1), S(2), \dots, S(N)$  as an input. Higuchi algorithm builds a new time series based on  $S(N)$  as follows:

$$S_m^k = \left\{ S(m), S(m+k), S(m+2k) \dots S \left( m + \left\lfloor \frac{N-m}{k} \right\rfloor k \right) \right\}. \text{ for } m = 1, 2, 3 \dots k \quad (17)$$

where  $m$  is the first sample of the time series and  $\left\lfloor \frac{N-m}{k} \right\rfloor$  represents the integer part of the series. Length  $L_m(k)$  for  $S_m^k$  is obtained by:

$$L_m(k) = \frac{\sum_{i=1}^k |S(m+ik) - S(m+(i-1)k)| (N-1)}{\left\lfloor \frac{N-m}{k} \right\rfloor k} \quad (18)$$

where  $N$  represents the number of total samples in the time series and  $\frac{(N-1)}{\left\lfloor \frac{N-m}{k} \right\rfloor k}$  represents the normalization coefficient. The total mean length,  $L(k)$ , is calculated for  $k_1$  to  $k_{\max}$  for all  $k$ .

6) *Detrended fluctuation analysis*: The DFA criterion is used to reveal the correlation of the time series with itself in the long-term time range [39]. To calculate the DFA in the time series, it must first be aggregated according to the following relationship.

$$y(k) = \sum_{i=1}^k [x(i) - x_{\text{average}}] \quad (19)$$

Then  $y(k)$  is divided into equal segments of length  $n$ . One line fits each segment. This line is denoted by  $y_n(k)$ , and  $y_n(k)$  is subtracted from  $y(k)$ .

$$F(n) = \sqrt{\frac{1}{N} \sum_{k=1}^N [y(k) - y_n(k)]^2} \quad (20)$$

To obtain the DFA, one must obtain the equivalent of  $F(n)$  for a suitable number of  $n$ . Then its graph is drawn in a logarithmic scale, and the slope of the scaling area is introduced as DFA.

### E. Classification

In the current work, the self-organizing map (SOM) method was used to classify features extracted from autistic and normal EEG. This method is a popular unsupervised neural network with many applications in prediction, classification and clustering problems [40]. In this algorithm, a vector of weights is defined for every neuron  $i$ . The dimension of this vector is equal to the dimension of the input data. Firstly, a winner neuron is specified by the following equation:

$$i^*(t) = \operatorname{argmin}\{g_i(x(t))\} \quad . \quad g_i(x(t)) = \|x(t) - w_i(t)\| \quad (21)$$

where  $w_i(t)$  is the weight vector that must be updated based on the following equation:

$$\Delta w_i(t) = \alpha(t)h(i^*.i;t)[x(t) - w_i(t)] \quad (22)$$

where  $h(\cdot)$  denotes the neighborhood function with the following definition:

$$h(i^*.i;t) = \exp(-\|r_i(t) - r_{i^*}(t)\|^2 / \sigma^2(t)) \quad (23)$$

$\|r_i(t) - r_{i^*}(t)\|$  defines the distance between  $i$  and  $i^*$ ,  $\sigma(t)$  is the neighborhood radius, and  $\alpha(t)$  is the learning rate parameter.

To be classified by SOM, the output neurons must be labeled. After training the SOM, a winner neuron is devoted to each training vector. Then, the label of each training vector is determined. Eventually, the label of the winner neuron is defined based on the most frequent class labels of the training vectors. In this work, the initial neighborhood parameter was defined as 3, which was reduced to 1 after 100 iterations. Moreover,  $\alpha(t)$  was set at 0.8.

### F. EEG Data

The data used in this study were recorded by the research team from 24 children with autism and 24 normal children. Participants ranged in age from 4-9 years, and all patients received a diagnosis of autism based on DSM-5 diagnostic criteria by experienced clinicians. The patient enrollment was administered in a psychiatric clinic. The research project was done in accordance with the principles of the Declaration of Helsinki (1996) and the current Good Clinical Practice guidelines. The goal and an overview of the project were characterized by the participants and their parents during the initial contact. For those who agreed to participate, all the necessary information was provided prior to signing written informed consent. Information about the subjects was utilized anonymously and for the purpose of the study.

EEG was recorded for 10-18 minutes for each participant in one session. Given the difficulties of working with autistic patients and the difficulties of recording EEG from these patients in the awake state, the Emotiv Epoch headset device

was employed in this research. Since the Emotiv Epoch headset is a wireless EEG device, the signal recording was conducted in autistic patients more easily. This EEG device uses a Bluetooth module for wireless communication. The Emotiv Epoch headset and Software Development Kit include 14 electrodes (AF3, AF4, F7, F8, F3, F4, FC5, FC6, T7, T8, P7, P8, O1, O2 based on 10-20 international system) along with DRL/CMS references at P4/P3 locations. The sampling rate in this device is 128 Hz. The impedance of the electrode is reduced through saline liquid and alcohol pads. Emotive software was utilized to record EEGs and convert their format to MATLAB format.

After signal recording, in the signal pre-processing step, a band-pass Hanning window with a finite duration and frequency range of 1-45 Hz was applied to the EEGs through MATLAB software. Furthermore, electrode interpolation was done through adjacent channels for low-quality electrodes. EEGs were re-referenced to the common average and then were decomposed via independent component analysis. Components with motion and muscle artifacts were identified and were then eliminated according to time courses and frequency scalp maps. The cleaned components were reconstructed, and a 50-second cleaned EEG signal was prepared for each participant.

## III. EXPERIMENTAL RESULTS

After data conditioning, all mentioned analyzes were applied to EEG signals and different described features were extracted in both typically and autism groups. Fig. 2 shows an example of an EEG signal recorded from a child with autism before pre-processing. Fig. 3 shows the time-frequency representation of two channels, P7 and P8, for normal and autistic children obtained from wavelet analysis. As shown in this figure, there are clear differences in the frequency content of the EEG signals of normal and autistic children over time. In addition, Fig. 4 to 6 show the nonlinear features (i.e., sample entropy, DFA and Lempel-Ziv measure) extracted from EEG signals of normal and autistic children in the O1 channel. These graphs show that there is a clear difference between the nonlinear dynamics of the EEG signals of the two groups. The noteworthy point is that the values of nonlinear features in the normal group were generally higher than in the autism group.

In the next step, we tried to classify different features extracted from EEGs through various analyzes. In this step, the leave-one-subject-out cross-validation method was utilized to validate the efficiency of every analysis method as well as the performance of the SOM classifier for autism diagnosis. In this cross-validation method, a subject was left out to test, and the rest of the subjects were utilized to train the SOM. As a result, after implementing the 48 tests, the average accuracy was calculated over all the obtained accuracies. Specificities, sensitivities and averaged classification accuracies for each type of analysis are depicted in Table I. Accuracies of 92.31, 93.57, 95.63 and 97.10% were achieved through time and morphological, frequency, time-frequency and nonlinear analyzes, respectively. Indeed, the findings showed that nonlinear analysis could yield the best classification results (accuracy = 97.10%, sensitivity = 98.80% and specificity =

97.02%) in the EEG discrimination of autistic children from typical children through the SOM neural network.

Fig. 3. Time-frequency representation of two channels, P7 and P8, for normal and autistic children.

Fig. 4. Calculated sample entropy at the O1 channel for typical and autistic children.

Fig. 5. Detrended fluctuation analysis at O1 channel for typically and autistic children.

Fig. 6. Calculated Lempel-Ziv measure at O1 channel for typically and autistic children.

TABLE I. ACCURACY, SENSITIVITY AND SPECIFICITY FOR DIFFERENT ANALYZES USING SOM CLASSIFIER

Type of analysis	Accuracy (train) (%)	Accuracy (test) (%)	Sensitivity (%)	Specificity (%)
Time and morphological analysis	94.78 ± 4.25	92.31 ± 3.59	90.36	93.39
Frequency analysis	96.13 ± 3.36	93.57 ± 4.61	93.00	94.69
Time-frequency analysis	97.71 ± 2.06	95.63 ± 2.48	95.89	94.26
Nonlinear analysis	99.54 ± 2.14	97.10 ± 1.95	98.80	97.02

#### IV. DISCUSSION AND CONCLUSION

Autism is a neurodevelopmental condition that is related to different neural and neurotransmission impairments in various brain areas. These functional abnormalities of the brain are supposed to play a critical role in the neuropathology of autism [41, 42]. Therefore, the search for a reliable biomarker through EEG analysis is a hot topic in autism research. In the present study, we aimed to explore the different types of EEG analysis for feature extraction for autism diagnosis. For this purpose, time and morphological, time-frequency, frequency and nonlinear features were extracted from EEG signals of typical and autistic children at resting-state. The obtained findings revealed that nonlinear features achieved the best classification results for autism diagnosis. Indeed, the proposed nonlinear features integrated with the SOM classifier yielded an average accuracy of 97.10% in detecting autism cases, which is a good result for improving research achievements in this field. This type of quantitative analysis is more consistent with the nonlinear and chaotic properties of brain signals. This finding is in line with previous studies [43-47]. In other words, based on the findings of the present study, it is recommended that future studies focus more on various nonlinear EEG analysis methods and their optimization in order to diagnose autism. Since none of the previous EEG studies on autism have conducted a comparative study between different linear and nonlinear analysis methods, the findings of the present study as the first example in this field can be a roadmap for future research. However, this study, like many other studies, has limitations. The limited sample size is one of the important

limitations of the current research, which reduces the generalizability of the obtained findings. In this study, only five nonlinear analysis methods were investigated, while there are many more nonlinear methods and future studies should investigate different methods. In addition, we only analyzed resting-state EEG, while other recording protocols may have helped to improve the results.

Table II summarizes the characteristics of the studies on autism diagnosis using EEG analysis and machine learning. As shown in this table, previous studies used different methods for feature extraction from EEG signals, from linear frequency analysis to various nonlinear approaches such as recurrence quantification analysis and fractal dimension. The obtained results showed that future studies should work on the nonlinear dynamics of EEG signals and the combination and optimization of nonlinear features for autism diagnosis. Support vector machine (SVM) is the most frequently used classifier in these works to classify EEG features. Moreover, some studies used neural networks such as radial basis function and probabilistic neural networks for this purpose. Most studies have achieved an autism classification accuracy of 90% or higher, which shows the high potential of this approach for the objective diagnosis of autism. However, most of these studies suffer from important limitations that reduce their generalizability. Small datasets, complex implementation processes and low accuracy are some of these limitations. In addition, the results obtained in the present study compared to previous works show that the nonlinear approach adopted along with the SOM classification has a very good ability to diagnose autism.

TABLE II. CHARACTERISTICS OF THE STUDIES ON AUTISM DIAGNOSIS USING EEG ANALYSIS AND MACHINE LEARNING

Study	Population	Feature Extraction	Classifier	Results
Ahmadlou et al. (2010) [48]	Nine autistic and eight non-autistic children	Higuchi and Katz fractal dimension, wavelet-chaos neural network	Radial basis function (RBF)	Accuracy = 90%
Bosl et al. (2011) [49]	46 infants at high risk for autism and 33 healthy controls	Modified multiscale entropy	Support vector machine (SVM)	Accuracy = 90%
Ahmadlou et al. (2012) [28]	Nine autistic and nine healthy children	Fuzzy synchronization likelihood	Enhanced probabilistic neural network	Accuracy = 95.5%
Sheikhani et al. (2012) [50]	17 autistic children and 11 healthy children	Short-time Fourier transform	KNN	Accuracy = 96.4%
Jamal et al. (2014) [51]	12 subjects in each autism and normal group	Brain connectivity	Linear discriminant analysis (LDA) and SVM	Accuracy = 94.7%
Eldridge et al. (2014) [52]	19 autistic children and 30 healthy children	Modified multiscale entropy	SVM, Logistic regression, Naïve Bayes	Accuracy = 79%
Bosl et al. (2018) [26]	99 infants with an older sibling diagnosed with autism	Wavelet analysis, Sample entropy, DFA, Recurrence quantitative analysis	SVM	Accuracy = 95%
Heunis et al. (2018) [45]	Seven autistic children and seven non-autistic children	Recurrence quantitative analysis	SVM	Accuracy = 92.9%
Kang et al. (2018) [53]	52 autistic children and 52 non-autistic children	Fast Fourier transform	SVM	Accuracy = 91.38%

Haputhanthri et al. (2019) [27]	Ten autistic children and five non-autistic children	Wavelet analysis	Logistic regression, SVM, Naïve Bayes, Random forest	Accuracy = 93%
Pham et al. (2020) [29]	40 autistic children and 37 healthy children	higher-order spectra (HOS) bispectrum	LDA, SVM, k-nearest neighbor (KNN), probabilistic neural network (PNN)	Accuracy = 98.7%
Baygin et al. (2021) [30]	61 autistic subjects and 61 healthy subjects	one-dimensional local binary pattern and deep features of the spectrogram images	SVM	Accuracy = 96.44%
Alotaibi et al. (2021) [31]	12 autistic children and 12 healthy children	Brain connectivity	SVM	Accuracy = 95.8%
Our proposed approach	24 autistic children and 24 healthy children	Time, time-frequency, frequency, and nonlinear analysis	Self-organizing map (SOM)	Accuracy = 97.1%

**Abstract**—Addressing the limitation of conventional single-scene image denoising algorithms in filtering mixed environmental disturbances, and recognizing the drawbacks of cascaded image enhancement algorithms, which have poor real-time performance and high computational demands, The composite weather adaptive denoising network (CWADN) is proposed. A Cascade Hourglass Feature Extraction Network is constructed with a visual attention mechanism to extract characteristics of rain, fog, and low-light noise from authentic natural images. These features are then transferred from their original real distribution domain to a synthetic distribution domain using a deep residual convolutional neural network. The generator and style encoder of the adversarial network work together to adaptively remove the transferred noise through a combination of supervised and unsupervised training, this approach achieves adaptive denoising capabilities tailored to complex natural environmental noise. Experimental results demonstrate that the proposed denoising network yields a high signal-to-noise ratio while maintaining excellent image fidelity. It effectively prevents image distortion, particularly in critical target areas. Additionally, it adapts to various types of mixed noise, making it a valuable tool for preprocessing images in advanced machine vision algorithms such as target recognition and tracking.

**Keywords**—Image denoising; domain adaptation; generative adversarial network; autoencoder

## I. INTRODUCTION

Haze, rain, and low illumination are the three types of natural noises that have the greatest impact on the detection accuracy of machine vision. These noises will destroy the optical information in the original image through global blurring, superimposed noise, and information desalination, bringing a great challenge to all-weather target detection tasks.[1], [2]. Therefore, the denoising methods for the above three natural noises have become the key research directions of domestic and foreign scholars in the field of image denoising. Among them, the study [3] directly learns and estimates the mapping function between the noisy image and its noise-free counterpart and cooperates with the bilateral rectified linear unit (BReLU) to reduce the search space and improve the convergence, to realize the end-to-end training and interference process of the dehazing network. Based on the transmittance parameters and atmospheric light of the scattering model, the research in [4] directly learned the residual information between the haze image and the haze-free image by using

smooth dilated convolution and threshold fusion sub-networks to realize image dehazing. The study in [5] pass a binary rain mask to the multi-task network for learning, and the negative rain layer generated by iteration is compared with the input, which reduces the effect of rain noise on the original image. Based on the reverse stacking denoising strategy, the study in [6] use a dataset marked with the rain size to train a multi-task network and realizes image denoising through the obtained rain noise features, [7] use Retinex theory, the reflectance image under ideal illumination is multiplied by the noisy low-illumination image, and the low-illumination noise is directly removed by guided filtering, which solves the problem that the traditional low-illumination denoising algorithm over-enhances or under-enhances some areas. Enhanced question in study [8] constructed an unsupervised network EnlightenGAN, which can be trained in a large number of imprecisely matched images to establish a mapping relationship, which overcomes the problem of low-illumination noise denoising accuracy when the dataset is insufficient. The study in [9] designed a dual-branch unit endowed with physics-aware, complemented by a course learning contrast regularization approach. This research underscores the significance of fine-tuning various negative samples within the contrast regularization process. These insights offer valuable concepts for leveraging multimodal contrastive regularization techniques to enhance image quality.

However, because the environmental noise in nature appears in the form of mixed accompaniment, that is the three kinds of noises of haze, rain and low illumination may be generated at the same time in different weather and will be mapped on the original image in the form of mixing in any proportion. The interference of noise on image information will become more complicated. The above algorithms all adopt the directional denoising strategy, and it is difficult to achieve an optical result when it comes to mixed noise in real scenes. Therefore, researchers gradually focus their research on the field of adaptive denoising that is more in line with actual needs and can integrate various physical models of weather noise. The research in [10] applied the strategy of Neural Architecture Search in reinforcement learning to image restoration to generate the most suitable denoising network structure, and at the vector level, Denoising the output results of Encoders), giving the algorithm the ability of adaptive filtering of compound noise; The study [11] introduced an attention mechanism (Spatial Attention Mechanism, SAM) and

cross-multi-stage feature fusion in the encoding and decoding process of the network. The mechanism (Cross-stage Feature Fusion, CSFF) avoids the loss of target feature information before and after denoising. It takes into account the functions of efficient denoising and target information transfer. Although these composite noise-denoising deep neural networks have good image processing capabilities, their overly complex structures lead to high demands on computing resources. The training difficulty and convergence speed are not ideal. At the same time, a large number of supervised learning links make this kind of network must be supported by abundant real noise datasets to obtain better training results. When the real noisy images of the actual scene are difficult to obtain, the noise reduction accuracy of this kind of network will be greatly improved. These problems will limit the versatility of denoising algorithms in real environments. Providing all-weather adaptive denoising capabilities for platforms such as space vehicles and ground-based photodetectors is difficult.

In order to solve the problems of the above algorithms and improve the adaptability and all-weather computing efficiency of the image denoising algorithm in the denoising task for complex natural environments, this paper proposes a denoising method for the free mixed environment noise of rain, haze and low illumination. Noise neural network, the innovations of this network are: (1) An end-to-end image denoising network based on domain transfer is proposed, which realizes rain, haze, low illumination and three kinds of mixed noise images under a single structure. (2) Integrate multi-stage autoencoder structure and multi-domain transfer strategy to achieve directional separation and targeted denoising of an unknown proportion of mixed noise. (3) Based on domain adaptive generative confrontation module, effectively reduce the difference between noisy synthetic data and real noisy data is eliminated, and the traditional denoising algorithm training process is free

from the dependence on a large number of real noisy data sets. Based on the above methods and characteristics, the denoising network proposed in this paper achieves a high signal-to-noise ratio and image structure consistency in multi-type mixed noise filtering tasks and achieves high-quality denoising and information restoration for complex natural environment noise.

## II. PROPOSED METHODS

This paper draws extensive inspiration from the multi-level architecture of MPRNet [12], which strikes a balance between preserving local and global information. It introduces the concept of projecting any natural environmental image into multiple modes, followed by individual processing and subsequent integration. The composite weather adaptive denoising network (CWADN) designed in this paper is composed of a separation module, a denoising module and a conversion module, and its network structure is shown in Fig. 1.

CWADN comprises three integral components: the Multi-stage Progressive Separation Network (MPSN), the Multi-domain Translation Noise Network (MTDN), and the Domain Adaptation Translation Network (DATN). In the denoising process, CWADN initially takes images containing complex real-world composite noise as input into the multi-level autoencoder of MPSN. Subsequently, MTDN leverages the noise distribution within the image space as a feature and transfers the three distinct noise images to the synthetic domain for generation. Finally, DATN restores these three transformed images, consolidates the acquired results, and accomplishes the denoising task. Through these methodologies, CWADN achieves adaptive and precise denoising, as well as the restoration of target image information for original images captured in real-world scenarios featuring natural compound noise.

Fig. 1. The framework of our proposed network.

### III. NETWORK DETAILS

#### A. Multi-Stage Progressive Separation Network

For any noisy image shot in a natural environment, it can be regarded as the result of the original noise-free image.  $I_{ori}$  is affected by three kinds of noise: rain, haze and low illumination, and different types of noise have different effects on  $I_{ori}$ . The image quality degradation process can be expressed as:

$$I_n = \lambda_{rain} N_{rain}(I_{ori}) \odot \lambda_{haze} N_{haze}(I_{ori}) \odot \lambda_{dark} N_{dark}(I_{ori}) \quad (1)$$

Where  $\odot$  is the mixing operation of noise,  $N_i$  and  $\lambda_i$  are the noise degradation sub-function and the noise component weight coefficient under the conditions of rain, haze, and low illumination ( $i = \{rain, haze, dark\}$ ), respectively. When there is no certain kind of noise, the trade-off  $\lambda_i$  equals to 0, and when the image is an ideal noise-free image, all  $\lambda$  are 0.

Due to the diversity and unpredictability of the combination of each proportional coefficient  $\lambda_i$  of the composite noise in the natural environment, it is difficult for the conventional denoising network to fit the image quality degradation function with a certain coefficient, and it is impossible to learn the mapping relationship between  $I_n$  and  $I_{ori}$  or complete image restoration. To solve this problem, we design a multi-stage progressive separation network (MPSN) to separate the composite noise and sequentially extract the low-illumination noise component  $N_{dark}$ , the haze noise component  $N_{haze}$  and the rain noise component  $N_{rain}$ , and the different noise components

are limited to their own domain according to their characteristics. MPSN is composed of three cascaded Channel Attention Autoencoder Module (CAAM), and its network structure is shown in Fig. 2.

In the autoencoder network based on the full convolution layer, although the continuous convolution operation can enrich the semantic information of the feature map, it also causes the gradual loss of the texture information in the original image, which makes the deconvolution operation unable to correct the decoding process and accurately restored details of the image. Therefore, we add a Channel Attention Block (CAB) [13] to all convolution and deconvolution operations in all CAAM to reduce information loss in key areas of interest. The input feature map group of CAB is denoted as  $X = [x_1, x_2, \dots, x_n]$ , where  $x_n$  is the feature map of the  $n$  channel with size  $H \times W$ . The frequency information of features is included in  $x_n$ , and its high-frequency features can better represent the edge and detail information in the image. Therefore, the global average pooling obtains the global feature frequency  $z_n$  by scaling the size of  $x_n$  to  $1 \times 1$ . Then, in order to extract the channel feature of  $z_n$  and obtain the weight coefficient through the activation operation, CAB will adjust the weight of  $x_n$  to obtain the final feature  $x_n^*$  with the attention mechanism. This process can be expressed as:

$$\begin{cases} z_n = \frac{1}{H \times W} \sum_{i=1}^H \sum_{j=1}^W x_n(i, j) \\ x_n^* = x_n \otimes \sigma(\phi(z_n)) \end{cases} \quad (2)$$

Fig. 2. Channel attention autoencoder Module for our network.

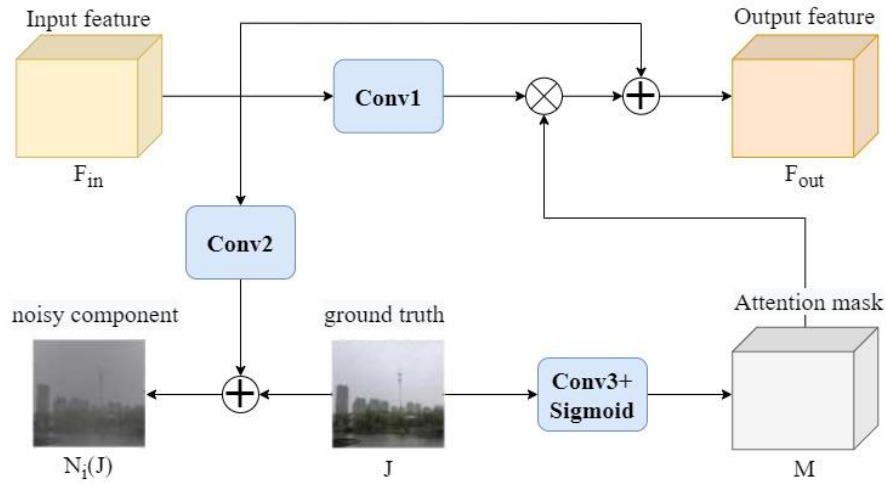

Fig. 3. Spatial attention module for our network.

Where  $i$  and  $j$  represent a pixel's horizontal and vertical position coordinates in the current image, respectively;  $\sigma$  and  $\phi$  represent the sigmoid activation function and the channel feature extraction process, respectively, and  $\otimes$  is the corresponding multiplication on pixel-wise. Through the above attention mechanism, MPSN can assign higher weights to feature channels with high-frequency information in the reconstruction process so as to preserve the texture details of the region of interest.

In addition, we introduce a Spatial Attention Module [14] between each two CAMM to enhance the transfer and fusion of information between different stages. As shown in Fig. 3, SAM obtains the noise component  $N_i$  by performing channel dimension reduction on the input feature map  $F_{in}$  and adding it pixel-by-pixel with the noise-free image  $I_{ori}$ . At the same time, SAM extracts features from  $I_{ori}$  and activates it to obtain the attention mask  $M$  and then linearly changes  $F_{in}$  to obtain the output feature map  $F_{out}$  as the input of the next stage. The process is expressed as:

$$\begin{cases} N_i(I_{ori}) = W_2(F_{in}) + I_{ori} \\ M = \text{sigmoid}(W_3(I_{ori})) \\ F_{out} = F_{in} + W_1(F_{in}) \times M \end{cases} \quad (3)$$

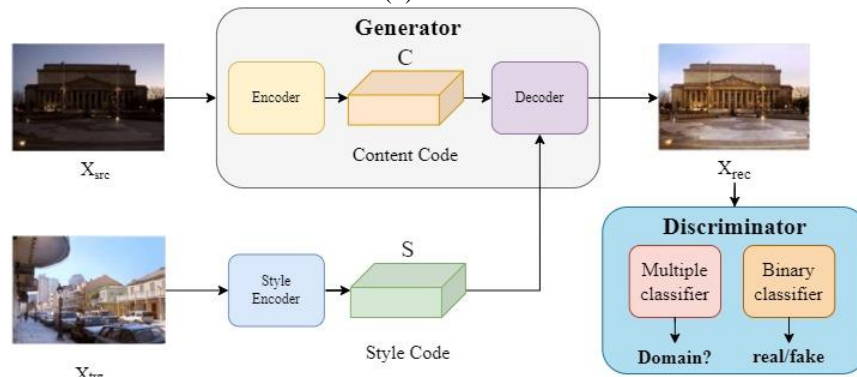

Fig. 4. The framework of multi-domain translation network.

where, the  $W_1$ ,  $W_2$ , and  $W_3$  represent three convolution operations, respectively. After passing through the SAM module,  $F_{out}$  contains ground truth information, which can improve the texture feature representation ability of the subsequent separated images. Due to the constraint of the attention mask, the transmission of invalid information to the next stage is suppressed. After the original noisy image is separated by MPSN, three images containing only a single type of independent noise can be obtained, which effectively solves the problem that the composite noise image quality degradation function is difficult to fit and limits the scope of the solution space, and facilitates the subsequent denoising network.

### B. Multi-Domain Translation Denoise Network

At present, the image restoration methods using image translation mainly regard the noisy image and the noise-free image as two independent domains and use the generator to learn the mapping relationship between them to realize image denoising. Still, this method can only remove a single type of noise. In order to realize the adaptive removal of multiple types of composite noise under a single model, inspired by StarGANv2 [15], we construct a multi-domain translation network (MTDN), including generator  $G$ , style encoder  $E$  and discriminator  $D$ , three main parts which are shown in Fig. 4.

We take the samples of noisy images, which include rain, haze and low illumination as the source domain  $X_{src}$ , that is,  $X_{src} = \{N_{haze}, N_{rain}, N_{dark}\}$ , and the noise-free images as the target domain  $X_{trg} = I_{org}$ , by learning the mapping function between  $X_{src}$  and  $X_{trg}$  to realize the removal of many different types of noises. E extracts features from the target domain image  $x_{trg}$  ( $x_{trg} \in X_{trg}$ ), and obtains the style code  $s$  containing the high-dimensional feature information of the noise-free image. G extracts the high-dimensional semantic information  $c$  of the original noise image  $x_{src}$  ( $x_{src} \in X_{src}$ ) through internal coding, integrates  $c$  and  $s$  in the decoder, and decodes the reconstructed image of  $x_{rec}$ . As a multi-task discriminator,  $D$  is composed of a binary classifier and a multi-classifier. The multi-classifier is used to determine whether the  $x_{rec}$  has the characteristics of a noise-free image, that is, whether the denoising process is complete; the binary classifier evaluates the image quality of

the  $x_{rec}$ , that is, whether the reconstructed image has higher restoration. Through the above process, MTDN can achieve directional denoising for various types of noises and effectively retain the original image's texture, details and other information.

### C. Domain adaptation translation network

Due to the inability to obtain a large number of real noisy-clean paired datasets, both MPSN and MTDN can only be trained on synthetic datasets. However, the spatial distribution and texture features of environmental noise in the synthetic dataset are different from those in the real dataset. This makes the model trained on the synthetic dataset generalize well to the real-world samples and reduces the denoising performance. In order to solve the above problems, we use DATN to improve the adaptability of the model in different datasets.

Fig. 5. The framework of domain adaptation translation network.

The structure of DATN is shown in Fig. 5, which is composed of three translation modules with the same structure, corresponding to three different types of noise, respectively. DATN takes CycleGAN [16] as the core framework, which contains two generators,  $G_{S2R}$ ,  $G_{R2S}$  and two discriminators,  $D_R$  and  $D_S$ . The generator  $G_{S2R}$  takes the synthetic noise  $N_{syn}$  as input and uses the spatial distribution characteristics of noise in the real noise image  $N_{rea}$  as the learning object to reconstruct  $N_{syn}$ . The discriminator  $D_R$  compares the difference between the reconstructed image and  $N_{rea}$  and uses it as an indicator to constrain  $G_{S2R}$ . During training,  $G_{S2R}$  improves its domain adaptation ability by continuously increasing the similarity between the generated image and  $N_{rea}$ . Similarly, the same process will be used for training and calculation for  $G_{R2S}$  and  $D_S$ . Therefore, DATN can realize the mutual translation between real and synthetic noise images through a large number of unpaired datasets, thereby improving the generalization performance of CWADN in real noise samples.

### D. Loss function

In order to obtain the best training effect of each functional module and improve the convergence ability and subsequent calculation accuracy of network denoising learning, this paper analyzes the loss of each sub-network in the proposed CWADN according to the task types and structural characteristics of different functional modules. The function has been specially designed.

### Image separation Losses

We expect MPSN to separate three different kinds of noise  $N_i$  from composite noise. We train the MPSN in a supervised manner due to the synthetic training samples. Firstly, we calculate the mean square loss between MPSN result  $N_i^{out}$  and ground truth  $N_i^{gt}$

$$L_{mse}^{MPSN} = \left\| N_i^{out} - N_i^{gt} \right\|_2^2 \quad (4)$$

Where  $i = \{haze, rain, dark\}$  represents the three noise conditions under haze, rain and low illumination, respectively. In order to prevent the noise separation process from destroying the information of non-noise areas in the original image, we use structural loss  $L_{ssim}^{MPSN}$  to constrain the distortion between  $N_i^{out}$  and  $N_i^{gt}$ , and judge the image quality after noise separation.

$$L_{ssim}^{MPSN} = 1 - SSIM(N_i^{out}, N_i^{gt}) \quad (5)$$

Where SSIM is the image similarity calculation rule, which is based on the distribution of image data in the mean, variance and covariance, compared the difference between  $N_i^{out}$  and

$N_i^{gt}$  in lighting, contrast, and image structure, the computing process can be defined as:

$$SSIM(N_i^{out}, N_i^{gt}) = \frac{(2\mu_{out}\mu_{gt} + c_1)}{(\mu_{out}^2 + \mu_{gt}^2 + c_1)} \cdot \frac{(2\sigma_{out,gt} + c_2)}{(\sigma_{out}^2 + \sigma_{gt}^2 + c_2)} \quad (6)$$

Where  $\mu_{out}$  and  $\mu_{gt}$  represent the mean of  $N_i^{out}$  and  $N_i^{gt}$ ,  $\sigma_{out}^2$  and  $\sigma_{gt}^2$  represent the variance of  $N_i^{out}$  and  $N_i^{gt}$ ,  $\sigma_{out,gt}$  is the covariance of  $N_i^{out}$  and  $N_i^{gt}$ .  $c_1$  and  $c_2$  are tiny decimals,  $L$  is the dynamic range of pixel values. When the SSIM value equals to 1, it represents that the MPSN has strong image noise separation and quality restoration capabilities. Therefore, the total loss of MPSN can be expressed as follows:

$$L^{MSPN} = \lambda_{mse} L_{mse}^{MSPN} + \lambda_{ssim} L_{ssim}^{MSPN} \quad (7)$$

Where  $\lambda_{mse}$  and  $\lambda_{ssim}$  represent the trade-off of  $L_{mse}^{MSPN}$  and  $L_{ssim}^{MSPN}$  respectively.

#### Image denoising Losses

For MTDN, unsupervised training can enable the network to achieve denoising by reconstructing images. Still, the reconstructed images lose texture details, affecting the accuracy of subsequent target recognition, tracking and other advanced machine vision [17]. To solve this problem, we combine supervised and unsupervised learning, adopting a semi-supervised learning method to train MTDN. The unsupervised training process uses a generative adversarial loss. The style encoder  $E_{dn}$  maps the target domain image  $x_{trg}$  to the corresponding style code  $s = E_{dn}(x_{trg})$ , and the generator  $G_{dn}$  integrates the original domain images  $x_{src}$  and  $s$ . After reconstruction and denoising, the image  $G_{dn}(x_{src}, s)$  is combined with the discriminator  $G_{dn}$  to get the adversarial loss of the denoising network, which is defined as:

$$L_{adv}^{MTDN} = \mathbb{E}_{x_{src}} [\log(D_{dn}(x_{src}))] + \mathbb{E}_{x_{src}, x_{trg}} [\log(1 - D_{dn}(G_{dn}(x_{src}, s)))] \quad (8)$$

MTDN realizes the adaptive removal of various types of noise by learning the mapping function between  $x_{src}$  and  $x_{trg}$ . However, when only introduce an adversarial loss in the training process; it will cause the generator to confuse the discriminator to get a higher score, which will reduce the problem of the diversity of generated images, called mode collapse. In order to solve this problem, we add the cycle consistency loss; after translating image  $G_{dn}$  to the source domain again, the result should be consistent with source

domain image  $x_{src}$ , that is  $x_{src} = G_{dn}(G_{dn}(x_{src}, s), s^*)$ , the above process can be expressed as:

$$L_{cyc}^{MTDN} = \mathbb{E}_{x_{src}, x_{trg}} [\|x_{src} - G_{dn}(G_{dn}(x_{src}, s), s^*)\|_1] \quad (9)$$

Where  $s^*$  is the style code of the source domain image, that is,  $s^* = E_{dn}(x_{src})$ . In addition, in order to make the style code  $s$  better guide the image reconstruction process, we introduce the style reconstruction loss on the basis of the above, which is similar to the cycle consistency loss. The style code  $s$  of the noise-free image is obtained after  $G_{dn}$ ; when it is encoded by  $E_{dn}$  again, the output result should be less different from  $s$ , that is,  $s^* = E_{dn}(G_{dn}(x_{src}, s))$ , the style reconstruction loss is defined as follows:

$$L_{sty}^{MTDN} = \mathbb{E}_{x,z} [\|s - E_{dn}(G_{dn}(x_{src}, s))\|_1] \quad (10)$$

Through the above unsupervised loss, MTDN can recover images affected by three different noises of rain, haze and low illumination, respectively, and can effectively preserve the content information of the images. In order to further retain the details of the denoised image, we introduce a supervised loss based on the unsupervised loss to calculate the mean square error between the denoised image and its noise-free counterpart Iori and preserve the underlying texture information of the image by minimizing the pixel-by-pixel difference between the two.

$$L_{mse}^{MTDN} = \|G_{dn}(x_{src}, E_{dn}(x_{trg})) - I_{ori}\|_2^2 \quad (11)$$

In summary, the overall loss function of MTDN Loss can be expressed as follows:

$$L^{MTDN} = L_{adv}^{MTDN} + \lambda_{sty} L_{sty}^{MTDN} + \lambda_{cyc} L_{cyc}^{MTDN} + \lambda_{mse} L_{mse}^{MTDN} \quad (12)$$

Where,  $\lambda_{sty}$ ,  $\lambda_{cyc}$ , and  $\lambda_{mse}$  are trade-off weights. During the training process, MTDN minimizes loss to realize the targeted removal of rain, haze and low illumination on the basis of retaining the target texture information.

#### E. Image translation Losses

Noise  $N_i$  can be divided into real noise  $N_{rea}^i$  and synthetic noise  $N_{syn}^i$  that is  $N_i = \{N_{rea}^i, N_{syn}^i\}$ . The training datasets of MPSN and MTDN are all synthetic samples, due to the problem of domain shift between different datasets; the removal effect of the model for real noise has decreased, so the loss function of DATN mainly solves the difference between the real noise domain and the synthetic noise domain. DATN contains three parallel transformation sub-networks, each of which is composed of generators GS2R, GR2S and discriminators DS, DR. For the real noise image  $x_{rea}$  ( $x_{rea} \in N_{rea}^i$ ), the  $GR2S(x_{rea})$  transformed by the generator can be closer to the synthetic noise image  $x_{syn}$  ( $x_{syn} \in N_{syn}^i$ ). The adversarial loss can be expressed as:

$$L^{MTDN} = L_{adv}^{MTDN} + \lambda_{sty} L_{sty}^{MTDN} + \lambda_{cyc} L_{cyc}^{MTDN} + \lambda_{mse} L_{mse}^{MTDN} \quad (13)$$

Similarly, the adversarial loss function of  $x_{syn}$  to  $x_{rea}$  translation can be expressed as:

$$L_{adv}^{DATN}(G_{S2R}, D_R) = \mathbb{E}_{x_{rea}} \|\log D_R(x_{rea})\|_1 + \mathbb{E}_{x_{syn}} \|\log(1 - D_R(G_{S2R}(x_{syn})))\|_1 \quad (14)$$

In addition to the same principle as the denoising module, DATN adopts cycle consistency loss to alleviate the mode collapse problem. For the real noisy image  $x_{rea}$ , after sequentially passing through GR2S and GS2R, the result should be close to the input image, that is,  $x_{rea} \approx \text{GR2S}(\text{GS2R}(x_{rea}))$ , then the cycle consistency loss of DATN can be defined as:

$$L_{adv}^{DATN}(G_{S2R}, D_R) = \mathbb{E}_{x_{rea}} \|\log D_R(x_{rea})\|_1 + \mathbb{E}_{x_{syn}} \|\log(1 - D_R(G_{S2R}(x_{syn})))\|_1 \quad (15)$$

In order to further improve the details of the generated image and enhance the texture feature information of the image, we introduce the perceptual loss to measure the distance of the image before and after transformation in the perceptual feature space; it will not only be limited to the pixel space and the feature extraction will be carried out on the two through the convolutional neural network, but the transformed image will be constrained from the high-dimensional space to make it more stylistically the target domain image.

$$L_{pect}^{DATN} = \mathbb{E}_{x_{rea}, x_{syn}} \frac{1}{CHW} [\|\phi(G_{R2S}(x_{rea})) - \phi(x_{syn})\|_1 + \|\phi(G_{S2R}(x_{syn})) - \phi(x_{rea})\|_1] \quad (16)$$

Where, C, H, and W represent the feature map's channel number, height and width, respectively;  $\phi$  is the feature extraction network. In this paper, VGG16 is used as the network basis, and the high-dimensional perceptual information provided by perceptual loss is used to enhance the high-frequency information of the converted image so as to improve the reconstruction effect of image details.

In addition, the dark channel  $D_c$  (In) of the image with noise can represent the approximate location of the noise distribution in space [16], so this paper proposes the dark channel consistency loss, which limits the dark channel of the image before and after transformation. The L1 loss is used to ensure the consistency of the dark channels of the two so as to strengthen the network's ability to learn the law of noise distribution. Dark channel consistency loss is defined as:

$$L_{dc}^{DATN} = \mathbb{E}_{x_{rea}, x_{syn}} [\|D_c(G_{R2S}(x_{rea})) - D_c(x_{syn})\|_1 + \|D_c(G_{S2R}(x_{syn})) - D_c(x_{rea})\|_1] \quad (17)$$

Where  $D_c$  is the dark channel computing process that can be defined as:

$$D_c(I) = \min_{y \in W(x)} [\min_{c \in \{r, g, b\}} I^c(y)] \quad (18)$$

Where  $x, y$  represents the coordinates of the pixel point;  $I^c(y)$  represents the colour channel of the image  $I$ ;  $W(x)$  represents the sliding window where the pixel point  $x$  is located. Therefore, the overall loss of DATN is defined as:

$$L^{DATN} = L_{adv}^{DATN}(G_{R2S}, D_S) + L_{adv}^{DATN}(G_{S2R}, D_R) + L_{cyc}^{DATN}(G_{R2S}, G_{S2R}) + L_{pect}^{DATN} + L_{dc}^{DATN} \quad (19)$$

In summary, DATN can alleviate the domain shift problem and improve the generalization of models trained on synthetic samples in real scenarios. So far, the design of all loss functions of CWADN has been completed. By training the network to achieve the best convergence of the loss function, the adaptive denoising and information restoration of composite noise in images captured in real scenes can be realized.

#### IV. IMPLEMENTATION

In order to verify the adaptive denoising and image information restoration capabilities of the designed CWADN, this paper uses the noisy dataset to train and test the network. It compares its computing performance with the current state-of-the-art denoising algorithms to prove the feasibility, accuracy and practicality of CWADN.

##### A. Dataset

Due to the lack of various types of natural weather noise image datasets so far, and it is impossible to get a real paired dataset, we design and build a synthetic natural noise dataset, namely Campus. The dataset contains 1009 images taken on Campus as noise-free samples. It augments the data through random cropping, inversion, etc., and according to the atmospheric physical model, by applying rain, haze and lower brightness on the noise-free samples. The method completes the construction of synthetic noise datasets. At the same time, in order to verify the self-adaptive denoising capability of CWADN for composite noise, we randomly generate three decimals with a sum of 1 as the proportional weight in the Campus dataset and mix the three noises of rain, haze and low illumination to generate different noises like Synthetic noise datasets with different types of noise and matching different natural environments. Finally, the obtained 2500 images are paired with the set noise type labels {clean, haze, rain, dark, compound}. Part of the paired data is shown in Fig. 6. In addition, we also randomly selected 1000 samples from the real datasets RESIDE, LOL, and SPA to further verify the computing power of the CWADN conversion module.

##### B. Training Details

The verification platform of this paper is a computer equipped with an NVIDIA GeForce RTX 3080 GPU. The algorithm is written in the Tensorflow framework and uses ADAM as the training optimizer. The batch size is set to 1, and the size of the input image is set to 256×256. The training process adopts two-stage training. In the first stage, MPSN, MTDN and DATN are trained, respectively. We train MPSN firstly, the epoch is set to 100,  $\lambda_{mse}=1.0$ ,  $\lambda_{ssim}=0.5$ , and the learning rate is set to  $2 \times 10^{-4}$ ; Then train the denoising network MTDN, with a total of 20k iterations,  $\lambda_{sty}$ ,  $\lambda_{cyc}$ ,  $\lambda_{mse}$  are 1.0, 1.0, 0.8, respectively, and the learning rate decays linearly from 10

<sup>4</sup> to  $10^{-6}$ ; Finally, the conversion module DATN is trained, and the epoch is set to 150, The learning rate is set to  $2 \times 10^{-4}$ . The second stage uses a small amount of real data sets to fine-tune the network and supervises the results of the current mainstream denoising algorithms as paired real data. In this process, all the models trained in the first stage are imported,

and then the transformation and denoising network parameters are frozen. Only the parameters of the MPSN are updated for 50 epochs. In the second training process, the real paired dataset we used is the results from the mainstream denoise algorithms.

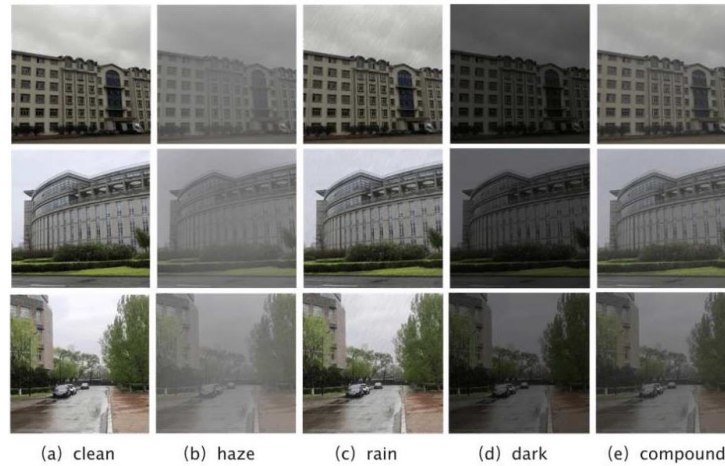

Fig. 6. Samples of the Campus dataset.

## V. RESULTS ANALYSIS

### A. Qualitative Experiment

In this paper, in the real rain, fog, and low illumination scenarios, CWADN and mainstream algorithms in various fields (refer to DCP [18], Cycle GAN, AOD-Net[19] for dehazing capability; reference RESCAN [20] for dehazing capability, PReNet[21], CycleGAN for deraining capability; low illumination enhancement capability is compared with CycleGAN, EnlightenGAN, and Zero-DCE[22]), and the algorithm designed in this paper will be compared from the perspectives of intuitive visual qualitative and image data quantification respectively. The denoising results and computing power are analyzed and judged.

Fig. 7, 8, and 9, respectively, show each algorithm's intuitive visual solution effects in processing images that are degenerated by real haze, rain, and low illumination. Fig. 7 shows the result of the haze removal test of the real sample, from which it can be seen that after DCP calculates the area where the pixel value is close to the atmospheric light value

and the sky area with low contrast, the image after the haze removal will have colour spots and colour shift problems; The image processed by CycleGAN loses more detailed information, and the restored image has low clarity; the image after AOD-Net dehazing is dark as a whole, and the fog noise in some areas is not completely removed; compared with the above algorithm, the saturation and brightness of the image after denoising by CWADN designed in this paper are more natural, and the details of the image are better restored.

Fig. 8 shows the real sample's comparison test of the rain removal effect map. The test image will have rain noise, haze noise and mixed rain and haze noise at the same time. It can be seen from the test results that CycleGAN can filter rain noise and has a certain ability to remove fog noise, but the reconstruction of image texture information is relatively vague; Compared with RESCAN, the rain removal effect of PReNet is significantly improved, but it does not have the ability to remove rain and fog; compared with other algorithms, CWADN has the ability to remove composite noise, it also has a suppressive effect on haze while removing the rain.

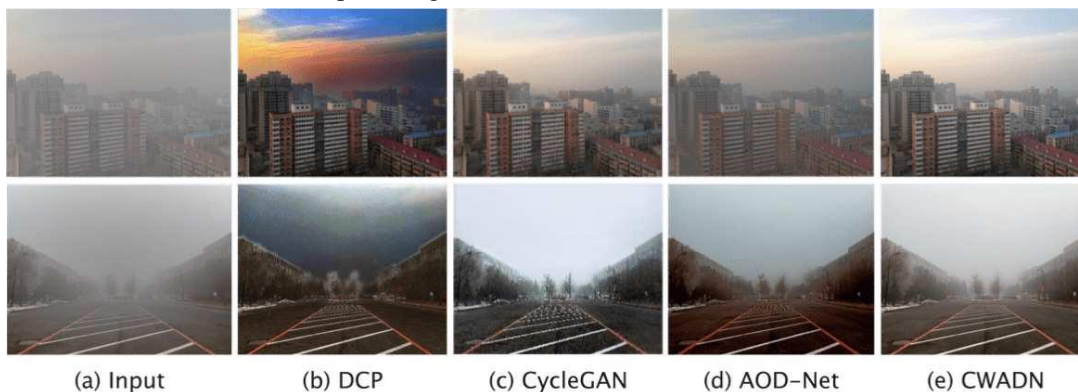

Fig. 7. Comparison of dehazing results on the real-world samples.

Fig. 8. Comparison of deraining results on real-world rain samples.

Fig. 9. Comparison of low-light enhancement results on real-world low-light samples.

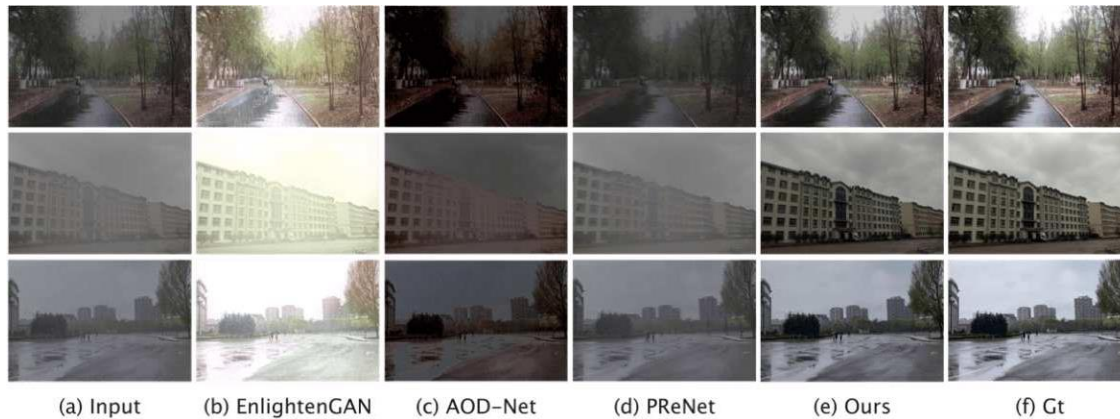

Fig. 10. Comparison of composite noise removal results on Campus dataset.

Fig. 9 shows the low-light enhancement test results under the real sample. It can be seen that the brightness improvement of CycleGAN in some areas is not obvious enough; the saturation of the image enhanced by Zero-DCE is improved, but the overall brightness is low; after EnlightenGAN and CWADN are enhanced. The image achieves good results in both saturation and brightness.

In addition, to further verify the composite noise removal capability of CWADN, we also use the composite noise images in the Campus dataset for testing. In this test, EnlightenGAN, AOD-Net and PReNet were selected for comparison, and the test results are shown in Fig. 10. It can be seen that the image restored by EnligtenGAN is overexposed; the overall brightness of the denoising result of AOD-Net is low, and the

removal effect of dense haze is not ideal; PReNet can effectively remove the rain noise in the image, but there is still a lot of haze noise residual. The above three algorithms cannot effectively remove the image's compound noise. We propose that CWADN is closer to the labelled data image regarding overall visual effect and texture detail retention, which verifies CWADN's denoising ability on composite natural environment noise.

To sum up, through testing on real and synthetic natural noise samples, it can be seen that the CWADN proposed in this paper can remove various types of natural environment noise and various types of mixed noise in any proportion, and its noise adaptive denoising ability can reach even exceeding the effect of some mainstream algorithms, the total subjective

image performance verifies the mixed noise adaptive denoising capability of CWADN.

Intuitive visual qualitative analysis can only judge the denoising and image restoration capabilities of the algorithm from the perspective of macroscopic morphology, and this process is only for the denoising task with the human eye as the observation terminal. For advanced machine vision algorithms such as target recognition and tracking, subsequent calculations need to be performed from the pixel-level data direction after image denoising is completed. In order to further verify the denoising and information restoration capabilities of CWADN at the digital image level, we will further carry out quantitative analysis and evaluation of denoised image data on the basis of the above denoising results.

### B. Quantitative Test

We use Peak Singal to Noise Ratio (PSNR) and Structural Similarity (SSIM) as evaluation indicators to quantitatively verify CWADN and comparison algorithms on three public datasets of SOTS, Rain100H and LOL. The results are shown in Table I, Table II and Table III, respectively. In addition, this paper also tested the effect of each algorithm in removing composite noise on the Campus dataset, and the results are shown in Table IV.

TABLE I. QUANTITATIVE COMPARISON OF DEHAZING RESULTS ON SOTS

Method	PSNR	SSIM
DCP	15.49	0.64
CycleGAN	14.65	0.48
AOD-Net	19.06	0.85
Our method	19.21	0.84

TABLE II. QUANTITATIVE COMPARISON OF DERAINING RESULTS ON RAIN100H

Method	PSNR	SSIM
CycleGAN	24.22	0.77
RESCAN	26.36	0.79
PReNet	26.77	0.86
Our method	26.72	0.86

TABLE III. QUANTITATIVE COMPARISON OF LOW-LIGHT ENHANCEMENT RESULTS ON LOL

Method	PSNR	SSIM
CycleGAN	7.83	0.15
Zero-DCE	14.86	0.59
EnlightenGAN	17.48	0.68
Our method	16.51	0.63

It can be seen from the results in the table that in the dehazing results on the SOTS dataset, the PSNR of CWADN is 19.21dB, which is the best, and the SSIM index is slightly lower than that of AOD-Net; in the rain removal experiment of Rain100H, CWADN and PReNet. The SSIM achieved the best value of 0.86 among all comparison algorithms; in the low-light enhancement comparison results of LOL, the two indicators of EnlightenGAN achieved the best results, and the two indicators of CWADN were slightly lower than those of EnlightenGAN. In the noise-free results, CWADN achieves the

best results in both PSNR and SSIM, with 25.48dB and 0.88, respectively. In Table I, Table II, and Table III, although some indicators of the CWADN designed in this paper are slightly lower than the current mainstream algorithms, the gap between the indicators of CWADN and the mainstream optimal algorithms is small, and the intuitive visual performance and image data calculation are not consistent. No impact. At the same time, Table IV verifies that CWADN has achieved the best performance in the complex noise denoising task, which proves that the algorithm has the ability of all-weather adaptive denoising and is more practical, generalization and denoising than other mainstream algorithms, adaptability.

To sum up, the CWADN proposed in this paper shows good denoising and image restoration capabilities in quantitative experiments, some quantitative detection indicators of denoising exceed the current mainstream algorithms, and the rest performance is on par with the mainstream algorithms. In addition, the experiments on the Campus dataset show that the ability of CWADN to remove mixed noise breaks through the limitation that traditional algorithms are difficult to remove composite noise. Combined with the intuitive visual qualitative analysis results, it is proved that the algorithm in this paper has good noise adaptive filtering and information restoration capabilities in single-type noise directional denoising, multi-type noise denoising and mixed noise denoising tasks, which verifies the performance of the algorithm that is feasibility, practicality and efficiency.

### C. Ablation Study

In order to verify the effectiveness of the components added in MPSN and the loss function added in DATN, a series of ablation experiments are established in this paper. Therefore, a series of ablation experiments are established to test different feature extraction strategies and loss function convergence methods. The effects on MPSN and DATN are, respectively, to verify network performance improvement by the method introduced in this paper.

The effectiveness of the components added in the separation network versus the loss function added in the transformation module.

For MPSN, this paper uses UNet as the basis and gradually increases CAB, SAM and multi-stage strategies. The performance impact of different feature extraction strategies on MPSN is shown in Table IV.

It can be seen from Table IV that after the introduction of CAB, SAM and multi-stage strategies in MPSN, the network performance in PSNR and SSIM is increased by 5.5% (1.555) and 0.43% (0.004), respectively, compared with the standard UNet, which proves that the effectiveness of the feature extraction enhancement strategy introduced in this paper.

TABLE IV. ABLATION RESULTS FOR SEPARATION NETWORK

Method	Multi-stage	SAM	PSNR	SSIM
UNet	-	-	28.649	0.936
UNet+CAB	-	-	28.661	0.821
UNet+CAB	√	-	28.685	0.852
UNet+CAB	√	√	30.206	0.94

TABLE V. ABLATION RESULTS FOR TRANSLATION NETWORK DATN

Loss	PSNR	SSIM
Ladv	13.012	0.463
Ladv +Ldc	13.961	0.496
Ladv +Lpect	23.389	0.923
Ladv +Ldc +Lpect	25.632	0.943

For DATN, based on the unsupervised adversarial loss Ladv, this paper adds the perceptual loss Ldc and the dark channel consistency loss Lpect designed in this paper. The test results are shown in Table V.

It can be seen from Table V that the two added loss functions are helpful to the improvement of network performance, and when the two loss functions of Ldc and Lpect are added at the same time, PSNR and SSIM are nearly doubled compared with the original network. To sum up, by introducing different feature extraction strategies and loss functions into MPSN and DATN, this paper effectively enhances the network denoising performance and convergence state and has a significant improvement effect.

Schemes follow another format (see Fig. 2). If there are multiple panels, they should be listed as (a) a Description of what is contained in the first panel; (b) a Description of what is contained in the second panel. Figures should be placed in the main text near the first time they are cited. A caption on a single line should be centered.

## VI. CONCLUSIONS

In this paper, the composite weather adaptive denoising network (CWADN) is introduced to address the challenge posed by complex mixed weather interference on natural imaging. CWADN leverages cascaded autoencoders with an attention mechanism to effectively separate distinct noise components within mixed noise. Through the adoption of an image translation strategy, a multi-domain denoising network is constructed, enabling adaptive denoising across various noise types. The adaptive domain network structure narrows the gap between real and synthetic noise, thereby enhancing the model's generalization capability in real-world scenarios. This approach combines both supervised and unsupervised techniques during training, yielding excellent results. Experimental findings demonstrate the algorithm's effectiveness in removing single-type and multi-type random mixed noises in real shooting environments while preserving detailed information in key areas of interest. In comparison to traditional algorithms, CWADN exhibits significant improvements in both PSNR and SSIM metrics, highlighting its robust adaptive denoising and image information restoration capabilities.

## VII. LIMITATIONS AND PROSPECTS

While the white-light image enhancement under complex weather conditions is explored in this paper, however, it has been hampered by the limited availability of diverse white-light images captured in varying weather conditions within the same scene. The constrained data volume and scene uniformity have resulted in limited generalization of the training outcomes. Future work aims to address these challenges through extensive data collection efforts, particularly during

nighttime, to curate datasets essential for algorithms in this domain.

Furthermore, considering the difficulties associated with training GAN networks and the inherent blurriness and uncertainties in generated images, the intention is to replace them with state-of-the-art diffusion models in subsequent research. Additionally, the introduction of LLM and video comprehension models into the framework is expected to yield superior image generation results, potentially enhancing the quality of generated images and overall performance.
