ISSN 2158-107X(Print)

# Editorial Preface

## *From the Desk of Managing Editor...*

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

**Thank you for Sharing Wisdom!**

# Editorial Board

## Editor-in-Chief

**Dr. Kohei Arai - Saga University**

*Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation*

---

## Associate Editors

**Alaa Sheta**

**Southern Connecticut State University**

*Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems*

**Domenico Ciuonzo**

**University of Naples, Federico II, Italy**

*Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things*

**Doroła Kaminska**

**Lodz University of Technology**

*Domain of Research: Artificial Intelligence, Virtual Reality*

**Elena Scutelnicu**

**"Dunarea de Jos" University of Galati**

*Domain of Research: e-Learning, e-Learning Tools, Simulation*

**In Soo Lee**

**Kyungpook National University**

*Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning*

**Krassen Stefanov**

**Professor at Sofia University St. Kliment Ohridski**

*Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design*

**Renato De Leone**

**Università di Camerino**

*Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming*

**Xiao-Zhi Gao**

**University of Eastern Finland**

*Domain of Research: Artificial Intelligence, Genetic Algorithms*

# CONTENTS

Paper 1: Data Anomaly Detection in the Internet of Things: A Review of Current Trends and Research Challenges

*Authors: Min Yang, Jiajie Zhang*

**PAGE 1 – 10**

Paper 2: Segmentation of Motion Objects in Video Frames using Deep Learning

*Authors: Feng JIANG, Jiao LIU, Jiya TIAN*

**PAGE 11 – 20**

Paper 3: Classification of Coherence Indices Extracted from EEG Signals of Mild and Severe Autism

*Authors: Lingyun Wu*

**PAGE 21 – 29**

Paper 4: Enhancing Breast Cancer Diagnosis using a Modified Elman Neural Network with Optimized Algorithm Integration

*Authors: Linkai Chen, CongZhe You, Honghui Fan, Hongjin Zhu*

**PAGE 30 – 38**

Paper 5: Stacked LSTM and Kernel-PCA-based Ensemble Learning for Cardiac Arrhythmia Classification

*Authors: Azween Abdullah, S. Nithya, M.Mary Shanthi Rani, S. Vijayalakshmi, Balamurugan Balusamy*

**PAGE 39 – 48**

Paper 6: A Versatile Shuffle Resource Units Recomputation Algorithm for Uplink OFDMA Random Access

*Authors: Azyyati Adiah Zazali, Shamala Subramaniam, Zuriati Ahmad Zukarnain, Abdullah Muhammed*

**PAGE 49 – 56**

Paper 7: The Promise of Self-Supervised Learning for Dental Caries

*Authors: Tran Quang Vinh, Haewon Byeon*

**PAGE 57 – 61**

Paper 8: Optimization Method for Trajectory Data Based on Satellite Doppler Velocimetry

*Authors: Junzhuo Li, Wenyong Li, Guan Lian*

**PAGE 62 – 69**

Paper 9: Optimized YOLOv7 for Small Target Detection in Aerial Images Captured by Drone

*Authors: Yanxin Liu, Shuai Chen, Lin Luo*

**PAGE 70 – 79**

Paper 10: DevOps Implementation Challenges in the Indonesian Public Health Organization

*Authors: Muhammad Yazid Al Qahar, Teguh Raharjo*

**PAGE 80 – 93**

Paper 11: A Bibliometric Analysis of Smart Home Acceptance by the Elderly (2004-2023)

*Authors: Bo Yuan, Norazlynn Kamal Basha*

**PAGE 94 – 104**

Paper 12: Automatic Generation of Image Caption Based on Semantic Relation using Deep Visual Attention Prediction

*Authors: M. M. EL-GAYAR*

**PAGE 105 – 114**

Paper 13: Enhancing Oil Price Forecasting Through an Intelligent Hybridized Approach

Authors: Hicham BOUSSATTA, Marouane CHIHAB, Younes CHIHAB, Mohammed CHINY

PAGE 115 – 125

Paper 14: Compression Analysis of Hybrid Model Based on Scalable WDR Method and CNN for ROI-based Medical Image Transmission

Authors: Bindulal T.S

PAGE 126 – 135

Paper 15: A Proposed Intelligent Model with Optimization Algorithm for Clustering Energy Consumption in Public Buildings

Authors: Ahmed Abdelaziz, Vitor Santos, Miguel Sales Dias

PAGE 136 – 152

Paper 16: A Survey of Evolving Performance Analysis Technologies, Algorithms and Models for Sports

Authors: Shamala Subramaniam, Manoj Ravi Shankar, Azyyati Adiah Zazali, Hong Siaw Swin, Zarina Muhamed, Sivakumar Rajagopal, Mohamad Zamri Napiah, Faisal Embung

PAGE 153 – 161

Paper 17: An Improvement for Spatial-Temporal Queries of ATMGRAPH

Authors: ZHANG Zhiyuan, HAN Boyang

PAGE 162 – 168

Paper 18: Comparison of Machine Learning Algorithms for Crime Prediction in Dubai

Authors: Shaikha Khamis AlAbdouli, Ahmad Falah Alomosh, Ali Bou Nassif, Qassim Nasir

PAGE 169 – 173

Paper 19: Preserving Cultural Heritage Through AI: Developing LeNet Architecture for Wayang Image Classification

Authors: Muhathir, Nurul Khairina, Rehia Karenina Isabella Barus, Mutammimul Ula, Ilham Sahputra

PAGE 174 – 181

Paper 20: A Comprehensive Review of Modern Methods to Improve Diabetes Self-Care Management Systems

Authors: Alhuseen Omar Alsayed, Nor Azman Ismail, Layla Hasan, Farhat Embarak

PAGE 182 – 203

Paper 21: An Improved Convolutional Neural Network for Churn Analysis

Authors: Priya Gopal, Nazri Bin MohdNawi

PAGE 204 – 210

Paper 22: A New Method for Classifying Intracerebral Hemorrhage (ICH) Based on Diffusion Weighted –Magnetic Resonance Imaging (DW-MRI)

Authors: Andi Kurniawan Nugroho, Jajang Edi Priyanto, Dinar Mutiara Kusumo Nugraheni

PAGE 211 – 217

Paper 23: Application Prototype for Inclusive Literacy for People with Reading Disabilities

Authors: Laberiano Andrade-Arenas, Roberto Santiago Bellido-García, Pedro Molina-Velarde, Cesar Yactayo-Arias

PAGE 218 – 225

Paper 24: LAD-YOLO: A Lightweight YOLOv5 Network for Surface Defect Detection on Aluminum Profiles

Authors: Dongxue Zhao, Shenbo Liu, Yuanhang Chen, Da Chen, Zhelun Hu, Lijun Tang

PAGE 226 – 234

**Paper 25: Improved YOLO-X Model for Tomato Disease Severity Detection using Field Dataset**

*Authors: Rajasree R, C Beulah Christalin Latha*

**PAGE 235 – 242**

**Paper 26: He and She in Video Games: Impact of Gender on Video Game Participation and Perspectives**

*Authors: Deena Alghamdi*

**PAGE 243 – 249**

**Paper 27: Hyperparameter Tuning of Semi-Supervised Learning for Indonesian Text Annotation**

*Authors: Siti Khomsah, Nur Heri Cahyana, Agus Sasmito Aribowo*

**PAGE 250 – 256**

**Paper 28: Usability Testing of Memorable Word in Security Enhancing in e-Government and e-Financial Systems**

*Authors: Hanan Alotaibi, Dania Aljeaid, Amal Alharbi*

**PAGE 257 – 265**

**Paper 29: Enhanced Brain Tumor Detection and Classification in MRI Scans using Convolutional Neural Networks**

*Authors: Ruqsar Zaitoon, Hussain Syed*

**PAGE 266 – 275**

**Paper 30: Method for Hyperparameter Tuning of Image Classification with PyCaret**

*Authors: Kohei Arai, Jin Shimazoe, Mariko Oda*

**PAGE 276 – 282**

**Paper 31: A Novel Artifact Removal Strategy and Spatial Attention-based Multiscale CNN for MI Recognition**

*Authors: Duan Li, Peisen Liu, Yongquan Xia*

**PAGE 283 – 293**

**Paper 32: SFFT-CapsNet: Stacked Fast Fourier Transform for Retina Optical Coherence Tomography Image Classification using Capsule Network**

*Authors: Michael Opoku, Benjamin Asubam Weyori, Adebayo Felix Adekoya, Kwabena Adu*

**PAGE 294 – 306**

**Paper 33: Deep Neural Network-based Detection of Road Traffic Objects from Drone-Captured Imagery Focusing on Road Regions**

*Authors: Hoanh Nguyen*

**PAGE 307 – 314**

**Paper 34: Strengthening Network Security: Evaluation of Intrusion Detection and Prevention Systems Tools in Networking Systems**

*Authors: Wahyu Adi Prabowo, Khusnul Fauziah, Aufa Salsabila Nahrowi, Muhammad Nur Faiz, Arif Wirawan Muhammad*

**PAGE 315 – 324**

**Paper 35: Hybrid Local Search Algorithm for Optimization Route of Travelling Salesman Problem**

*Authors: Muhammad Khahfi Zuhanda, Noriszura Ismail, Rezzy Eko Caraka, Rahmad Syah, Prana Ugiana Gio*

**PAGE 325 – 332**

**Paper 36: A Systematic Literature Review of Computational Studies in Aquaponic System**

*Authors: Khaoula Taji, Ali Sohail, Yassine Taleb Ahmad, Ilyas Ghanimi, Sheeba Ilyas, Fadoua Ghanimi*

**PAGE 333 – 343**

**Paper 37: Cocoa Pods Diseases Detection by MobileNet Confluence and Classification Algorithms**

*Authors: Diarra MAMADOU, Kacoutchy Jean AYIKPA, Abou Bakary BALLO, Brou Médard KOUASSI*

**PAGE 344 – 352**

**Paper 38: Wireless Capsule Endoscopy Video Summarization using Transfer Learning and Random Forests**

*Authors: Parminder Kaur, Rakesh Kumar*

**PAGE 353 – 358**

**Paper 39: Contributed Factors in Predicting Market Values of Loaned Out Players of English Premier League Clubs**

*Authors: Muhammad Daffa Arviano Putra, Deshinta Arrova Dewi, Wahyuningdiah Trisari Putri, Refno Hendrowati, Tri Basuki Kurniawan*

**PAGE 359 – 365**

**Paper 40: Exploring the Challenges and Impacts of Artificial Intelligence Implementation in Project Management: A Systematic Literature Review**

*Authors: Muhammad Irfan Hashfi, Teguh Raharjo*

**PAGE 366 – 376**

**Paper 41: Deep Residual Convolutional Long Short-term Memory Network for Option Price Prediction Problem**

*Authors: Artur Dossatayev, Ainur Manapova, Batyrkhan Omarov*

**PAGE 377 – 387**

**Paper 42: Factors and Models Influencing Value Co-Creation in the Supply Chain of Collection Resources for Library Distribution Providers Under Data Ecology**

*Authors: Xiaoyun Lin*

**PAGE 388 – 397**

**Paper 43: A Flexible Manufacturing System based on Virtual Simulation Technology for Building Flexible Platforms**

*Authors: Zhangchi Sun*

**PAGE 398 – 407**

**Paper 44: Enhanced Plagiarism Detection Through Advanced Natural Language Processing and E-BERT Framework of the Smith-Waterman Algorithm**

*Authors: Franciskus Antonius, Myagmarsuren Orosoo, Aanandha Saravanan K, Indrajit Patra, Prema S*

**PAGE 408 – 416**

**Paper 45: Comparative Study of Machine Learning Algorithms for Phishing Website Detection**

*Authors: Kamal Omari*

**PAGE 417 – 425**

**Paper 46: Study of the Impact of the Internet of Things Integration on Competition Among 3PLs**

*Authors: Kenza Izikki, Mustapha Hlyal, Aziz Ait Bassou, Jamila El Alami*

**PAGE 426 – 434**

**Paper 47: A Framework for Predicting Academic Success using Classification Method through Filter-Based Feature Selection**

*Authors: Dafid, Ermatita, Samsuryadi*

**PAGE 435 – 444**

**Paper 48: A Performance Analysis of Point CNN and Mask R-CNN for Building Extraction from Multispectral LiDAR Data**  
*Authors: Asmaa A. Mandouh, Mahmoud El Nokrashy O. Ali, Mostafa H.A. Mohamed, Lamyaa Gamal EL-Deen Taha, Sayed A. Mohamed*

**PAGE 445 – 452**

**Paper 49: Securing IoT Devices in e-Health using Machine Learning Techniques**

*Authors: Haifa Khaled Alanazi, A. A. Abd El-Aziz, Hedi Hamdi*

**PAGE 453 – 464**

**Paper 50: A Multispectral Ariel Image Stitching using Decorrelation and EEG Signal Extraction Technique**

*Authors: Mukul Manohar S, K N Muralidhara*

**PAGE 465 – 472**

**Paper 51: Texton Tri-alley Separable Feature Merging (TTSFM) Capsule Network for Brain Tumor Detection**

*Authors: Vivian Akoto-Adjepong, Obed Appiah, Peter Appiahene, Patrick Kwabena Mensah*

**PAGE 473 – 483**

**Paper 52: Unraveling Ransomware: Detecting Threats with Advanced Machine Learning Algorithms**

*Authors: Karam Hammadeh, M. Kavitha*

**PAGE 484 – 491**

**Paper 53: K-Means Extensions for Clustering Categorical Data on Concept Lattice**

*Authors: Mohammed Alwersh, László Kovács*

**PAGE 492 – 507**

**Paper 54: Intelligent Heart Disease Prediction System with Applications in Jordanian Hospitals**

*Authors: Mohammad Subhi Al-Batah, Mowafaq Salem Alzboon, Raed Alazaidah*

**PAGE 508 – 517**

**Paper 55: A Novel Approach for Content-based Image Retrieval System using Logical AND and OR Operations**

*Authors: Ranjana Battur, Jagadisha Narayana*

**PAGE 518 – 528**

**Paper 56: Imperative Role of Digital Twin in the Management of Hospitality Services**

*Authors: Ramnarayan, Rajesh Singh, Anita Gehlot, Kapil Joshi, Ashraf Osman Ibrahim, Anas W. Abulfaraj, Faisal Binzagr, Salil Bharany*

**PAGE 529 – 537**

**Paper 57: Design of a Hypermodel using Transfer Learning to Detect DDoS Attacks in the Cloud Security**

*Authors: Marram Amitha, Muktevi Srivenkatesh*

**PAGE 538 – 544**

**Paper 58: Cyberbullying Detection Based on Hybrid Ensemble Method using Deep Learning Technique in Bangla Dataset**

*Authors: Md. Tofael Ahmed, Afroza Sharmin Urmi, Maqsdur Rahman, Abu Zafor Muhammad Touhidul Islam, Dipankar Das, Md. Golam Rashed*

**PAGE 545 – 551**

**Paper 59: SE-RESNET: Monkeypox Detection Model**

*Authors: Krishnan Thiruppathi, Selvakumar K, Vairachilai Shenbagavel*

**PAGE 552 – 558**

**Paper 60: Enhancing Skin Cancer Detection Through an AI-Powered Framework by Integrating African Vulture Optimization with GAN-based Bi-LSTM Architecture**

*Authors: N. V. Rajasekhar Reddy, Araddhana Arvind Deshmukh, Vuda Sreenivasa Rao, Sanjiv Rao Godla, Yousef A. Baker El-Ebiary, Liz Maribel Robladillo Bravo, R. Manikandan*

**PAGE 559 – 572**

**Paper 61: Enhancing Diabetic Retinopathy Detection Through Machine Learning with Restricted Boltzmann Machines**

*Authors: Venkateswara Rao Naramala, B. Anjanee Kumar, Vuda Sreenivasa Rao, Annapurna Mishra, Shaikh Abdul Hannan, Yousef A. Baker El-Ebiary, R. Manikandan*

**PAGE 573 – 585**

**Paper 62: Feline Wolf Net: A Hybrid Lion-Grey Wolf Optimization Deep Learning Model for Ovarian Cancer Detection**

*Authors: Moresh Mukhedkar, Divya Rohatgi, Veera Ankalu Vuyyuru, K V S S Ramakrishna, Yousef A. Baker El-Ebiary, V. Antony Asir Daniel*

**PAGE 586 – 596**

**Paper 63: Utilizing Deep Convolutional Neural Networks and Non-Negative Matrix Factorization for Multi-Modal Image Fusion**

*Authors: Nripendra Narayan Das, Santhakumar Govindasamy, Sanjiv Rao Godla, Yousef A. Baker El-Ebiary, E. Thenmozhi*

**PAGE 597 – 606**

**Paper 64: Hybrid Image Encryption using Non-Adjacent Bits Dynamic Encoding DNA with RSA and Chaotic Systems**

*Authors: Marwa A. Elmenyawy, Nada M. Abdel Aziem*

**PAGE 607 – 620**

**Paper 65: Object Detection and Recognition in Remote Sensing Images by Employing a Hybrid Generative Adversarial Networks and Convolutional Neural Networks**

*Authors: Araddhana Arvind Deshmukh, Mamta Kumari, V.V. Jaya Rama Krishnaiah, Suraj Bandhekar, R. Dharani*

**PAGE 621 – 632**

**Paper 66: AIRA-ML: Auto Insurance Risk Assessment-Machine Learning Model using Resampling Methods**

*Authors: Ahmed Shawky Elbhrawy, Mohamed A. Belal, Mohamed Sameh Hassanein*

**PAGE 633 – 641**

**Paper 67: An MILP-based Lexicographic Approach for Robust Selective Full Truckload Vehicle Routing Problem**

*Authors: Karim EL Bouyahyiouy, Anouar Annouch, Adil Bellabdaoui*

**PAGE 642 – 650**

**Paper 68: Design of Personalized Recommendation and Sharing Management System for Science and Technology Achievements based on WEBSOCKET Technology**

*Authors: Shan Zuo, Kai Xiao, Taitian Mao*

**PAGE 651 – 660**

**Paper 69: Mechatronics Design and Development of T-EVA: Bio-Sensorized Space System for Astronaut's Upper Body Temperature Monitoring During Extravehicular Activities on the Moon and Mars**

*Authors: Paul Palacios, Jose Cornejo, Juan C. Chavez, Carlos Cornejo, Jorge Cornejo, Mariela Vargas, Natalia I. Vargas-Cuentas, Avid Roman-Gonzalez, Julio Valdivia-Silva*

**PAGE 661 – 672**

**Paper 70: Artificial Intelligence-based Volleyball Target Detection and Behavior Recognition Method**

*Authors: Jieli Huang, Wenjun Zou*

**PAGE 673 – 680**

**Paper 71: Deep Learning-based Multiple Bleeding Detection in Wireless Capsule Endoscopy**

*Authors: Ouiem Bchir, Ghaida Ali Alkhudhair, Lena Saleh Alotaibi, Noura Abdulhakeem Almhizea, Sara Mohammed Almuhanha, Shouq Fahad Alzeer*

**PAGE 681 – 687**

**Paper 72: A Novel Feature Fusion for the Classification of Histopathological Carcinoma Images**

*Authors: Salini S Nair, M. Subaji*

**PAGE 688 – 697**

**Paper 73: Deep Conv-LSTM Network for Arrhythmia Detection using ECG Data**

*Authors: Alisher Mukhamefkaly, Zeinel Momyunkulov, Nurgul Kurmanbekkyzy, Batyrkhan Omarov*

**PAGE 698 – 707**

**Paper 74: DetBERT: Enhancing Detection of Policy Violations for Voice Assistant Applications using BERT**

*Authors: Rawan Baalous, Joud Alzahrani, Mariam Ali, Rana Asiri, Eman Nooli*

**PAGE 708 – 715**

**Paper 75: Digital Stethoscope for Early Detection of Heart Disease on Phonocardiography Data**

*Authors: Batyrkhan Omarov, Assyl Tuimebayev, Rustam Abdrakhmanov, Bakytgul Yeskarayeva, Daniyar Sultan, Kanat Aidarov*

**PAGE 716 – 724**

**Paper 76: Predicting the Level of Safety Feeling of Bangladeshi Internet users using Data Mining and Machine Learning**

*Authors: Md. Safiul Alam, Anirban Roy, Partha Protim Majumder, Sharun Akter Khushbu*

**PAGE 725 – 739**

**Paper 77: A Novel Deep Neural Network to Analyze and Monitoring the Physical Training Relation to Sports Activities**

*Authors: Bakhytzhhan Omarov, Nurlan Nurmash, Bauyrzhan Doskarayev, Nagashbek Zhilisbaev, Maxat Dairabayev, Shamurat Orazov, Nurlan Omarov*

**PAGE 740 – 747**

**Paper 78: Hybrid CNN-LSTM Network for Cyberbullying Detection on Social Networks using Textual Contents**

*Authors: Daniyar Sultan, Mateus Mendes, Aray Kassenkhan, Olzhas Akyzbekov*

**PAGE 748 – 756**

**Paper 79: Real-Time Road Surface Damage Detection Framework based on Mask R-CNN Model**

*Authors: Bakhytzhhan Kulambayev, Magzat Nurlybek, Gulnar Astaubayeva, Gulnara Tleuberdiyeva, Serik Zholdasbayev, Abdimukhan Tolep*

**PAGE 757 – 765**

**Paper 80: Osteoporosis Detection and Classification of Femur X-ray Images Through Spectral Domain Analysis using Texture Features**

*Authors: Dhanyavathi A, Veena M B*

**PAGE 766 – 773**

**Paper 81: A Systematic Review on Blockchain Scalability**

*Authors: Asmaa Aldoubaee, Noor Hafizah Hassan, Fiza Abdul Rahim*

**PAGE 774 – 784**

**Paper 82: Machine Learning Techniques for Diabetes Classification: A Comparative Study**

*Authors: Hiri Mustafa, Chrayah Mohamed, Ourdani Nabil, Aknin Noura*

**PAGE 785 – 790**

**Paper 83: An Optimized Survival Prediction Method for Kidney Transplant Recipients**

*Authors: Benita Jose Chalissery, V. Asha*

**PAGE 791 – 797**

**Paper 84: Analyzing RNA-Seq Gene Expression Data for Cancer Classification Through ML Approach**

*Authors: Abdul Wahid, M Tariq Banday*

**PAGE 798 – 810**

**Paper 85: Historical Building 3D Reconstruction for a Virtual Reality-based Documentation**

*Authors: Ahmad Zainul Fanani, Arry Maulana Syarif*

**PAGE 811 – 818**

**Paper 86: Identifying and Prioritizing Digital Transformation Elements Using Fuzzy Analytic Hierarchy Process**

*Authors: Mohammed Hitham M.H, Hatem Elkadi, Neamat El Tazi*

**PAGE 819 – 831**

**Paper 87: Machine Learning based Predictive Modelling of Cybersecurity Threats Utilising Behavioural Data**

*Authors: Ting Tin Tin, Khiew Jie Xin, Ali Aitizaz, Lee Kuok Tiung, Teoh Chong Keat, Hasan Sarwar*

**PAGE 832 – 840**

**Paper 88: Enterprise Marketing Decision: Advertising Click Through Rate Prediction Based on Deep Neural Networks**

*Authors: Luyao Zhan*

**PAGE 841 – 849**

**Paper 89: Design and Development of an Intelligent Rendering System for New Year's Paintings Color Based on B/S Architecture**

*Authors: Zaozao Guo*

**PAGE 850 – 861**

**Paper 90: Using EEG Effective Connectivity Based on Granger Causality and Directed Transfer Function for Emotion Recognition**

*Authors: Weisong Wang, Wenjing Sun*

**PAGE 862 – 868**

**Paper 91: Development of an Image Encryption Algorithm using Latin Square Matrix and Logistics Map**

*Authors: Emmanuel Oluwatobi Asani, Godsfavour Biety-Nwanju, Abidemi Emmanuel Adeniyi, Salil Bharany, Ashraf Osman Ibrahim, Anas W. Abulfaraj, Wamda Nagmeldin*

**PAGE 869 – 877**

**Paper 92: Tampering Detection and Segmentation Model for Multimedia Forensic**

*Authors: Manjunatha S, Malini M Patil, Swetha M D, Prabhu Vijay S S*

**PAGE 878 – 887**

**Paper 93: PRESSNet: Assessment of Building Damage Caused by the Earthquake**

*Authors: Dewa Ayu Defina Audrey Nathania, Alexander Agung Santoso Gunawan, Edy Irwansyah*

**PAGE 888 – 894**

**Paper 94: Group Intelligence Recommendation System based on Knowledge Graph and Fusion Recommendation Model**

*Authors: Chengning Huang, Bo Jing, Lili Jiang, Yuquan Zhu*

**PAGE 895 – 904**

**Paper 95: Statistical Language Model-based Analysis of English Corpora and Literature**

*Authors: Wenwen Chai*

**PAGE 905 – 913**

**Paper 96: Marginal Distribution Algorithm for Feature Model Test Configuration Generation**

*Authors: Mohd Zanes Sahid, Mohd Zainuri Saringat, Mohd Hamdi Irwan Hamzah, Nurezayana Zainal*

**PAGE 914 – 924**

**Paper 97: A QoS-Aware Resource Allocation Method for Internet of Things using Ant Colony Optimization Algorithm and Tabu Search**

*Authors: Shuling YIN, Renping YU*

**PAGE 925 – 934**

**Paper 98: Artificial Rabbits Optimizer with Deep Learning Model for Blockchain-Assisted Secure Smart Healthcare System**

*Authors: Mousa Mohammed Khubrani*

**PAGE 935 – 945**

**Paper 99: A QoS-aware Mechanism for Reducing TCP Retransmission Timeouts using Network Tomography**

*Authors: Jingfu Li*

**PAGE 946 – 954**

**Paper 100: Routing Strategies and Protocols for Efficient Data Transmission in the Internet of Vehicles: A Comprehensive Review**

*Authors: Yijun Xu*

**PAGE 955 – 965**

**Paper 101: Design and Implementation Submarine Cable Object Detection YOLOv4 based with Graphical User Interface (GUI) for Remotely Operated Vehicle (ROV)**

*Authors: Fikri Arif Wicaksana, Eueung Mulyana, Syarif Hidayat, Rahadian Yusuf*

**PAGE 966 – 981**

**Paper 102: Research on Clothing Color Classification Method based on Improved FCM Clustering Algorithm**

*Authors: Jinliang Liu*

**PAGE 982 – 989**

**Paper 103: Next-Generation Intrusion Detection and Prevention System Performance in Distributed Big Data Network Security Architectures**

*Authors: Michael Hart, Rushit Dave, Eric Richardson*

**PAGE 990 – 998**

**Paper 104: Machine Learning for Smart Cities: A Comprehensive Review of Applications and Opportunities**

*Authors: Xiaoning Dou, Weijing Chen, Lei Zhu, Yingmei Bai, Yan Li, Xiaoxiao Wu*

**PAGE 999 – 1016**

**Paper 105: Two Dimensional Deep CNN Model for Vision-based Fingerspelling Recognition System**

*Authors: Zhadra Kozhamkulova, Elmira Nurlybaeva, Leilya Kuntunova, Shirin Amanzholova, Marina Vorogushina, Mukhit Maikotov, Kaden Kenzhekhan*

**PAGE 1017 – 1024**

**Paper 106: Non-contact Respiratory Rate Monitoring Based on the Principal Component Analysis**

*Authors: Hoda El Boussaki, Rachid Latif, Amine Saddik, Zakaria El Khadiri, Hicham El Boujaoui*

**PAGE 1025 – 1030**

**Paper 107: An Improved Genetic Algorithm with Chromosome Replacement and Rescheduling for Task Offloading**

*Authors: Hui Fu, Guangyuan Li, Fang Han, Bo Wang*

**PAGE 1031 – 1039**

**Paper 108: An Efficient Convolutional Neural Network Classification Model for Several Sign Language Alphabets**

*Authors: Ahmed Osman Mahmoud, Ibrahim Ziedan, Amr Ahmed Zamel*

**PAGE 1040 – 1050**

**Paper 109: Enhancing Outdoor Mobility and Environment Perception for Visually Impaired Individuals Through a Customized CNN-based System**

*Authors: Athulya N K, Sivakumar Ramachandran, Neetha George, Ambily N, Linu Shine*

**PAGE 1051 – 1058**

**Paper 110: ArCyb: A Robust Machine-Learning Model for Arabic Cyberbullying Tweets in Saudi Arabia**

*Authors: Khalid T. Mursi, Abdulrahman Y. Almalki, Moayad M. Alshangiti, Faisal S. Alsubaei, Ahmed A. Alghamdi*

**PAGE 1059 – 1067**

**Paper 111: Development of a Touchless Control System for a Clinical Robot with Multimodal User Interface**

*Authors: Julio Alegre Luna, Anthony Vasquez Rivera, Alejandra Loayza Mendoza, Jes´us Talavera S., Andres Montoya A*

**PAGE 1068 – 1075**

**Paper 112: Dual-Level Blind Omnidirectional Image Quality Assessment Network Based on Human Visual Perception**

*Authors: Deyang Liu, Lu Zhang, Lifei Wan, Wei Yao, Jian Ma, Youzhi Zhang*

**PAGE 1076 – 1084**

**Paper 113: A Novel Voice Feature AVA and its Application to the Pathological Voice Detection Through Machine Learning**

*Authors: Abdulrehman Altaf, Hairulnizam Mahdin, Ruhaila Maskat, Shazlyn Milleana Shaharudin, Abdullah Altaf, Awais Mahmood*

**PAGE 1085 – 1092**

**Paper 114: Improved Model for Smoke Detection Based on Concentration Features using YOLOv7tiny**

*Authors: Yuanpan ZHENG, Liwei Niu, Xinxin GAN, Hui WANG, Boyang XU, Zhenyu WANG*

**PAGE 1093 – 1103**

**Paper 115: Virtual Machine Allocation in Cloud Computing Environments using Giant Trevally Optimizer**

*Authors: Hai-yu Zhang*

**PAGE 1104 – 1113**

**Paper 116: Corpus Generation to Develop Amharic Morphological Segmenter**

*Authors: Terefe Feyisa, Seble Hailu*

**PAGE 1114 – 1122**

# Data Anomaly Detection in the Internet of Things: A Review of Current Trends and Research Challenges

Min Yang<sup>1\*</sup>, Jiajie Zhang<sup>2</sup>

Department of Information Engineering, Shandong Communication & Media College, Jinan 250200, Shandong, China<sup>1</sup>  
School of Intelligent Transportation, Shandong Technician Institute, Jinan 250200, Shandong, China<sup>2</sup>

**Abstract**—The Internet of Things (IoT) has revolutionized how we interact with the physical world, bringing a new era of connectivity. Billions of interconnected devices seamlessly communicate, generating an unprecedented volume of data. However, the dramatic growth of IoT applications also raises an important issue: the reliability and security of IoT data. Data anomaly detection plays a pivotal role in addressing this critical issue, allowing for identifying abnormal patterns, deviations, and malicious activities within IoT data. This paper discusses the current trends, methodologies, and challenges in data anomaly detection within the IoT domain. In this paper, we discuss the strengths and limitations of various anomaly detection techniques, such as statistical methods, machine learning algorithms, and deep learning methods. IoT data anomaly detection carries unique characteristics and challenges that must be carefully considered. We explore these intricacies, such as data heterogeneity, scalability, real-time processing, and privacy concerns. By delving into these challenges, we provide a holistic understanding of the complexity associated with IoT data anomaly detection, paving the way for more targeted and effective solutions.

**Keywords**—Internet of things; anomaly detection; security; machine learning

## I. INTRODUCTION

The Internet of Things (IoT) is a network of connected objects, systems, and devices that gather, share, and react to data. It facilitates device-to-human communication utilizing sensors, software, and internet connectivity [1]. IoT facilitates diverse applications and services, spanning from intelligent residences and urban environments to industrial automation and healthcare surveillance [2]. By seamlessly integrating physical objects into the digital realm, IoT enhances operational effectiveness, refines decision-making processes, and enables unprecedented levels of automation and connectivity across various facets of our everyday experiences [3]. The IoT structure typically consists of three main layers: perception, network, and application. The perception layer, also known as the sensing layer or physical layer, is the lowest layer of the IoT architecture. It comprises physical devices and sensors that capture data from the physical world. The network layer, also known as the communication layer, facilitates the connection and transmission of data between IoT devices and systems employing Wi-Fi, Bluetooth, Zigbee, cellular networks, or even IoT-specific protocols such as MQTT and CoAP. The application layer is the topmost layer in the IoT-layered structure. This layer utilizes data from IoT devices to provide valuable insights and services. It processes and

analyzes the data for various purposes, including data visualization, decision-making, automation, and control [4, 5].

Smart cities, healthcare, industrial automation, and transportation are among the sectors that have benefited greatly from IoT's rapid growth. Since IoT devices generate huge amounts of data, ensuring the integrity and reliability of this data is crucial [6]. There is a significant threat to security and efficiency in IoT systems due to anomalous data patterns, deviations, and outliers [7]. Detecting data anomalies in the IoT is crucial for several reasons. Firstly, anomalies can indicate system malfunctions, faults, or cyberattacks that may disrupt normal operations or compromise the safety and privacy of individuals and organizations [8]. Early detection of anomalies enables proactive measures and timely responses to mitigate potential risks. Secondly, anomaly detection is crucial in optimizing system performance, enhancing decision-making processes, and ensuring data quality. Organizations can improve operational efficiency, optimize resource allocation, and gain valuable insights from the collected data by identifying unusual patterns or outliers in the data [9, 10].

The significance of data anomaly detection in the IoT lies in its potential to enhance system reliability, security, and overall performance. Through traditional monitoring approaches it identifies critical events, anomalies, or irregularities that may go unnoticed [11]. Machine learning and advanced analytics can identify data anomalies in IoT systems to enable real-time insights and preventive maintenance [12]. This not only boosts operational efficiency within the IoT landscape but also ensures the safety, security, and sustainability of the infrastructure. Given the dynamic nature of IoT deployments and the diverse range of IoT devices and applications, effective data anomaly detection techniques are required. These techniques must be scalable, adaptable, and capable of handling high volumes of data [13].

The detection of abnormal patterns or behaviors within data flows generated by IoT sensors is of utmost importance, especially in fields that largely rely on IoT technology, such as education and agriculture. Within these industries, the seamless integration of devices results in a substantial amount of data that facilitates improvements in operational effectiveness and fosters innovation. Nevertheless, the increase in data volume also exposes these fields to possible vulnerabilities, hence emphasizing the significance of identifying atypical or unsuitable patterns to uphold integrity and ensure security. Through the utilization of sophisticated anomaly detection methods, educators and agricultural practitioners have the ability to protect against malevolent behaviors, deviations, and

anomalies that have the potential to disrupt systems or jeopardize confidential data. This process not only guarantees the dependability of IoT-driven processes but also emphasizes the crucial significance of anomaly detection in strengthening the fundamental aspects of Education and Agriculture. This enables these sectors to effectively utilize the advantages offered by IoT technology while maintaining the integrity of data and achieving operational excellence.

Consequently, there is a growing interest in anomaly detection algorithms, innovative data preprocessing techniques, and integrating anomaly detection with real-time analytics and decision-making systems. In order to deploy IoT systems across various domains reliably and securely, advanced data anomaly detection techniques are needed [14]. This study makes the following major contributions:

- To conduct a comprehensive review of the current trends and techniques used for data anomaly detection in the context of the IoT.
- To identify and analyze the major research challenges and limitations associated with data anomaly detection in IoT environments.
- To explore and evaluate existing anomaly detection methods and algorithms, including statistical approaches, machine learning techniques, and anomaly-scoring mechanisms.
- To investigate the impact of different IoT data characteristics, such as high dimensionality, heterogeneity, and dynamic nature, on the performance of anomaly detection methods.
- To propose potential solutions and strategies for enhancing the accuracy, efficiency, and scalability of data anomaly detection in IoT applications.
- To highlight the open research issues and future directions in the field of data anomaly detection in IoT, providing insights for researchers and practitioners.

The remainder of the paper is organized in the following manner. Data anomaly detection strategies are reviewed in Section II. Challenging problems in IoT data anomaly detection are outlined in Section III. Discussion in Section IV and future research directions are highlighted in Section V. Finally, Section VI concludes the paper.

## II. DATA ANOMALY DETECTION STRATEGIES IN IOT

Anomaly detection in the context of IoT involves identifying unusual or abnormal behavior in the data generated by IoT devices. Statistical methods support IoT anomaly detection by leveraging various statistical techniques to detect deviations from expected patterns [15]. These methods analyze the data collected from IoT devices and apply statistical models to identify anomalies that could indicate potential security breaches, system failures, or other abnormal events [16]. One widely used statistical method for IoT anomaly detection is the use of probability distributions [17]. This approach assumes that the data generated by IoT devices follow a specific probability distribution, such as Gaussian or Poisson distribution. By fitting the observed data to these distributions,

statistical parameters can be estimated, allowing for the identification of anomalies based on deviations from the expected distribution [18]. For example, if the data deviate significantly from the mean or exhibit unusually high or low values, it could indicate the presence of anomalies. Time series analysis is another statistical method commonly employed in IoT anomaly detection [19]. IoT data often exhibit temporal dependencies, where the measurements captured by devices are collected over time. Time series analysis techniques, such as Autoregressive Integrated Moving Average (ARIMA) or exponential smoothing models, can be used to model and forecast the expected behavior of the data. Anomalies are then detected by comparing the observed and predicted values, and any significant deviations from the expected pattern are flagged as anomalies [20].

An anomaly can be described as a data point that exhibits a substantial deviation from the expected behavior within a modeled system. Anomalies are generally regarded as infrequent events or observations that significantly deviate from known patterns of behavior. These aberrations have the potential to occur in a single data point, a particular context or temporal segment, or even over the whole dataset. Anomalies, at their core, are frequently ascribed to extraneous variables, such as sensor faults or external assaults [21]. The main goal of a detection algorithm is to accurately identify occurrences of abnormalities, while also classifying or deducing their root causes. The careful selection of an approximation model that closely matches with the expected behavior of the data is crucial in the domain of binary classification for anomalies. Furthermore, the complexities inherent in various situations frequently require customized detection approaches that are specifically designed for each specific application. Fig. 1 illustrates a visual representation of several abnormalities as examples. The categorization of an IoT anomaly detection approach is derived by integrating the classifications presented in prior scholarly works, including [22]. The categorization of algorithms is determined by their problem-solving technique, application, method type, and algorithmic delay. Fig. 2 provides a visual representation of the four categories, offering a comprehensive and explanatory perspective.

A prevalent categorization of anomalies comprises three primary types: point, contextual, and collective anomalies. Point anomaly pertains to situations where a single data point diverges significantly from the anticipated behavior. An illustrative example involves the detection of credit card fraud [23]. In contextual anomaly, an instance could be regarded as anomalous within a particular context. Comparing multiple perspectives of the same data point might not consistently reveal anomalous behavior. Detection of contextual anomalies hinges upon considering both contextual and behavioral attributes together. For instance, anomalies related to traffic violations differ based on geo-location information [24]. Unlike point or contextual anomalies, the collective anomaly examines the entire dataset. A prime example of this type involves the use of electrocardiograms to monitor and identify anomalies or irregularities in the human heart's functioning [25].

Fig. 1. Visual representations of anomalous occurrences.

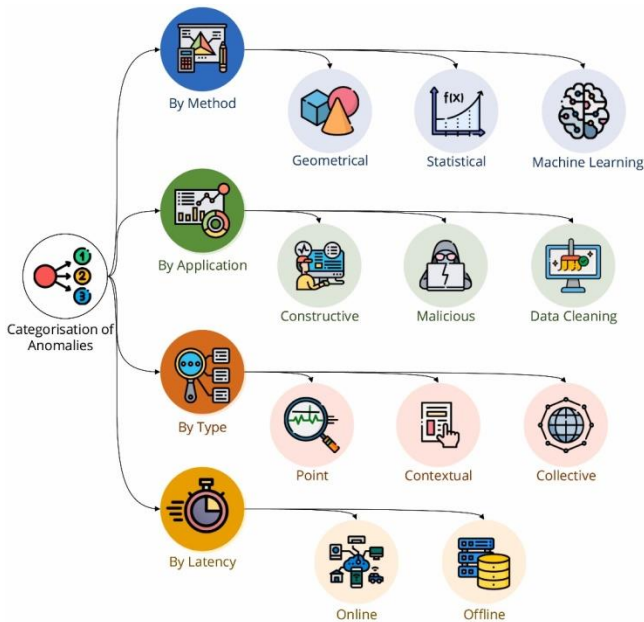

Fig. 2. An overview of anomaly classification.

Anomaly categorization by application can be classified into three distinct routes: constructive, destructive, and data cleaning. Constructive applications are inherently productive and contribute value to various domains. Examples include monitoring the daily activities of the elderly to prevent falls using image descriptors [26]. These applications encompass evaluating the performance of classifiers like multilayer

perceptron (MLP), k-nearest neighbors (k-NN), and support vector machines (SVM). Another instance involves the utilization of reinforcement learning by Lu, et al. [27] for diverse unmanned aerial vehicle (UAV) applications, such as smart farming. Additionally, Nguyen, et al. [28] employ a federated learning approach for smart home applications. Destructive applications are devised to disrupt regular operations, often for dubious financial gains or with intentions to inflict harm upon networks, application data flowing through IoT networks, or critical business practices. These applications have a detrimental impact on society. For instance, Alsheikh, et al. [29] conducted a survey on IoT cyberattacks, shedding light on the latest advancements in IoT security. Solutions to counter such applications, such as RAPPER [30] and NBaIoT [31] employing autoencoders (AEs), focus on prevention or preemptive measures taken before an illicit incident, as well as detection or actions executed after an incident. Data cleaning or data cleansing applications, like DeepAnT [32], employ deep convolutional neural networks (CNNs) to eliminate unwanted data spikes and sensor noise from input signals. These applications play a pivotal role in enhancing the quality of data used in various contexts.

The latency and scalability characteristics of a detection algorithm play a pivotal role in determining its execution timeline, whether it operates on the fly during data collection or at a later storage stage. Online algorithms operate in a serial manner, processing information either one data point at a time or within a window. These algorithms function without requiring access to the entire input dataset. Traditional online methods encompass geometrical and statistical approaches, including distance-based, density-based, and deviation-based techniques. Illustrative examples of online methods are the IoT-Keeper by Hafeez, et al. [33], employing fuzzy C-means, and Bosman, et al. [34] adopt an ensemble approach. Offline algorithms, in contrast, have access to the complete dataset. These algorithms tend to be computationally intensive and sophisticated, aimed at solving complex problems within a reasonable timeframe. It is important to highlight that recent advancements have blurred the distinction between online and offline methods. For instance, [35] utilizes LSTM and Gaussian Naive Bayes, along with other aforementioned models, to perform model training offline and subsequently deploy the model online. This integration allows for more flexibility in the deployment process.

The methods employed can be categorized into geometrical, statistical, or machine learning approaches. Geometrical methods operate under the premise that when employing distance-based or density-based strategies to depict a dataset, the anticipated and anomalous data points become distinguishable. Within a dataset, the underlying principle of isolation or density-based techniques revolves around the notion that anomalies tend to manifest within sparse regions. These techniques utilize a threshold, denoted as 't', either statically or dynamically on the calculated distance 'd' to classify anomalies. This threshold-driven classification is represented by the following equation:

$$d = \begin{cases} < t, & \text{Normal (under threshold)} \\ > t, & \text{Anomaly (above threshold)} \end{cases}$$

Statistical methods, exemplified by the minimal volume technique in [36], aim to model normal data patterns through mathematical models and distributions. The minimal volume approach constructs an n-dimensional simplex around the provided data cloud (considered as ground truth). The objective is to minimize the volume enclosed by the simplex while maximizing the inclusion of ground truth data points. Any data point that does not conform to the simplex is classified as an anomaly. Another example is the forecasting technique known as exponential smoothing [37], which predicts future data points using previous data and a smoothing parameter. Anomalous data detected via statistical methods are those that significantly diverge from the established model.

The third subcategory encompasses machine learning and deep learning models, which have seen an uptick in publication frequency in recent years. The choice of model is contingent on the inherent characteristics of the supplied data [38]. For instance, when dealing with sequential data inputs like audio, video, and time series, models like long short-term memory (LSTM) and transformer models tend to be preferred [39]. Conversely, non-sequential data types, such as image inputs, align well with convolutional neural networks (CNN) and autoencoders (AE) [40, 41]. These algorithms endeavor to discern between normal and anomalous behaviors by establishing a decision boundary. Examples include the utilization of SVM classifiers [42] to delineate such boundaries or employing LSTM networks [35] for future value forecasting in streaming data [43]. The nature of the task dictates whether these approaches fall under the categories of supervised, semi-supervised, self-supervised, or completely unsupervised learning [22, 44], depending on the availability of training labels.

Machine learning algorithms also are crucial to statistical methods for IoT anomaly detection. These algorithms learn patterns and relationships from the data and use them to classify normal and abnormal events. Supervised learning techniques, such as SVM or random forests, excel in scenarios where labeled data is available. By training on labeled data, where anomalies are specifically identified, these techniques generate models capable of automatically detecting anomalies in new, unlabeled data. On the other hand, unsupervised learning techniques, including clustering or outlier detection algorithms, prove valuable in identifying abnormal data points without the need for labeled training data.

Furthermore, statistical methods for IoT anomaly detection often involve thresholds or rule-based approaches. These methods establish predefined thresholds or rules based on the statistical properties of the data. Any data point that exceeds these thresholds or violates the predefined rules is considered an anomaly. For example, if the temperature readings from a temperature sensor exceed a certain predefined range, it could indicate a malfunction or abnormal condition. Statistical methods for IoT anomaly detection encompass a range of techniques, including probability distributions, time series analysis, machine learning algorithms, and threshold-based approaches. By leveraging statistical models and algorithms, these methods can effectively detect anomalies in the data generated by IoT devices, enabling proactive monitoring, early

detection of abnormal events, and mitigation of potential risks in various IoT applications [45].

#### A. Machine Learning Algorithms for Anomaly Detection

Machine learning algorithms enable the automated and efficient detection of abnormal events in the vast amount of data generated by IoT devices [46, 47]. As IoT systems become increasingly complex and interconnected, traditional rule-based or threshold-based approaches may not be sufficient to capture anomalies' diverse and evolving patterns. Machine learning algorithms can learn from historical data, identify hidden patterns, and adapt to changing conditions, making them well-suited for IoT anomaly detection. One key advantage of machine learning algorithms in IoT anomaly detection is their ability to handle large-scale and heterogeneous data [48]. IoT environments generate various data types, including sensor readings, network traffic data, and system logs. Machine learning algorithms can process and analyze this data to identify abnormal patterns that may indicate security breaches, system failures, or other abnormal behavior. These algorithms can handle the high volume, velocity, and variety of IoT data, making them scalable and applicable to real-time monitoring and analysis [49].

Machine learning algorithms are also capable of detecting anomalies that may not be recognized explicitly or anticipated in advance [50]. The capabilities of machine learning algorithms differ from those of rule-based approaches because they can learn from historical data and detect anomalies that may not be apparent to humans. This allows for proactive anomaly detection and early warning of potential issues, reducing the risk of system downtime or security breaches. Machine learning algorithms also offer the advantage of adaptability to changing IoT environments. As IoT systems evolve and new anomalies emerge, machine learning algorithms can continuously learn and update their models to capture these changes. This adaptability is crucial in dynamic IoT environments where anomalies manifest in various forms and evolve over time. By continuously analyzing and updating their models, machine learning algorithms can effectively detect and respond to emerging anomalies, ensuring the reliability and security of IoT systems.

Automated anomaly detection in the realm of IoT is made possible through the utilization of machine learning algorithms. This approach significantly reduces the need for manual inspections and analysis [51]. Manual analysis of IoT data is known to be a time-consuming, error-prone, and inefficient process, particularly in large-scale deployments. By employing machine learning algorithms, data streams from IoT devices can be continuously and efficiently monitored in real time. This empowers human operators to focus their attention on more critical tasks, such as investigating anomalies, taking appropriate actions, or fine-tuning the anomaly detection system. In IoT anomaly detection, machine learning algorithms are indispensable for handling large-scale, heterogeneous data, detecting previously unseen anomalies, adjusting to changing environments, and automating the process. By leveraging machine learning, IoT systems become more secure, reliable, and efficient by proactively detecting and mitigating abnormal events.

### B. Deep Learning Algorithms for Anomaly Detection

The power of neural networks allows deep learning algorithms to detect IoT anomalies by analyzing the data generated by IoT devices and learning complex patterns and representations [52]. Deep learning algorithms, specifically deep neural networks (DNNs), have shown impressive performance in a variety of domains, such as computer vision, natural language processing, and speech recognition. Their ability to automatically extract hierarchical features and model intricate relationships makes them well-suited for detecting anomalies in IoT data. One key advantage of deep learning algorithms in IoT anomaly detection is their ability to handle high-dimensional and unstructured data. IoT environments generate vast amounts of data, often in the form of images, sensor readings, or textual information. Deep learning algorithms can effectively process and analyze this data, capturing subtle and nuanced patterns that may indicate anomalies. Convolutional neural networks (CNNs) excel at analyzing images or sensor data, while recurrent neural networks (RNNs) can handle sequential or time series data. These architectures enable deep learning algorithms to learn highly relevant representations for anomaly detection.

Another crucial aspect of deep learning algorithms is their ability to automatically learn from data without relying on explicit feature engineering. Traditional machine learning algorithms often require manual extraction of relevant features, which can be time-consuming and challenging, especially in the context of IoT data. Deep learning algorithms can autonomously learn and extract relevant features directly from raw data, alleviating the need for extensive domain knowledge and manual feature engineering. This enables them to uncover intricate and non-linear relationships in the data, improving the accuracy and robustness of anomaly detection. Furthermore, deep learning algorithms offer the advantage of transfer learning and knowledge sharing across different IoT domains. Pretrained deep neural networks, trained on large-scale datasets from other domains, can be fine-tuned and adapted to specific IoT anomaly detection tasks. This knowledge transfer allows deep learning algorithms to leverage the learned representations and patterns from other domains, even when

labeled training data is limited or unavailable in the IoT domain. Transfer learning facilitates faster model convergence, improves generalization, and enhances anomaly detection performance in IoT environments.

Deep learning algorithms also exhibit the potential for anomaly detection in real-time or streaming IoT data. Recurrent neural networks, such as LSTM or gated recurrent units (GRU), are well-suited for modeling sequential dependencies in time series data. This makes them effective for detecting anomalies in streaming IoT data, where anomalies can occur in real-time. By analyzing the temporal patterns and dependencies in the data, deep learning algorithms can provide timely detection and response to abnormal events, enabling proactive monitoring and mitigation. Deep learning algorithms, with their ability to handle high-dimensional data, automatically learn relevant features, facilitate transfer learning, and analyze sequential dependencies, are instrumental in IoT anomaly detection. By leveraging deep neural networks, IoT systems can effectively detect anomalies in complex and diverse data generated by IoT devices. The role of deep learning algorithms extends to enhancing the security, reliability, and operational efficiency of IoT systems by enabling proactive anomaly detection and timely mitigation of abnormal events.

### C. Comparative Analysis of the Different Techniques

Table I presents a side-by-side comparison of the machine and deep learning algorithms for IoT data anomaly detection. SVM is known for its high accuracy and effectiveness in handling linearly separable data. It is robust against overfitting and can handle high-dimensional data. However, SVMs can be computationally intensive for large datasets, and selecting appropriate kernel functions requires careful consideration. Random Forests offer high accuracy and are robust against overfitting. They handle high-dimensional data well and provide feature importance rankings. However, they are less interpretable compared to individual decision trees. k-NN is a simple and intuitive algorithm that detects local anomalies. It is non-parametric and adaptive, making it suitable for handling noisy data. However, k-NN is sensitive to the choice of distance metric and requires careful selection of the value for k.

TABLE I. AN OVERVIEW OF THE MACHINE AND DEEP LEARNING ALGORITHMS FOR IOT DATA ANOMALY DETECTION

Algorithm	Performance	Strengths	Limitations	References
Support Vector Machines (SVM)	High accuracy Effective for linearly separable data	Robust against overfitting Can handle high-dimensional data	Computationally intensive for large datasets Requires careful selection of kernel functions	[42, 53-59]
Random Forests (RF)	High accuracy Robust against overfitting	Handles high-dimensional data Provides feature importance rankings	Less interpretable compared to individual decision trees	[8, 60-62]
k-Nearest Neighbors (k-NN)	Simple and intuitive Effective for local anomalies	Non-parametric and adaptive Handles noisy data	Sensitive to the choice of distance metric Requires careful selection of k value	[7, 63-66]
Recurrent Neural Networks (RNN)	Captures sequential dependencies in time series data	Handles variable-length sequences Suitable for streaming data	Can suffer from vanishing/exploding gradients Computationally intensive training	[67-74]
Long Short-Term Memory (LSTM)	Captures long-term dependencies in sequential data	Robust against vanishing gradients Suitable for modeling time series data	Requires more training time compared to traditional RNNs	[75-77]
Convolutional Neural Networks (CNN)	Effective for image or sensor data analysis	Automatically learns hierarchical features Robust to spatial variations	It may require large amounts of labeled training data Computationally intensive for large images	[78-81]

Recurrent Neural Networks (RNNs) capture sequential dependencies in time series data, making them suitable for IoT anomaly detection. They can handle variable-length sequences and are well-suited for streaming data. However, RNNs can suffer from vanishing or exploding gradients during training and can be computationally intensive. LSTM networks are a type of RNN that can capture long-term dependencies in sequential data. They are robust against vanishing gradients and are suitable for modeling time series data. However, LSTM networks generally require more training time compared to traditional RNNs. Convolutional Neural Networks (CNNs) are particularly effective for analyzing image or sensor data in IoT applications. They automatically learn hierarchical features from the data and are robust to spatial variations. CNNs can capture local patterns and spatial dependencies, making them suitable for anomaly detection in image-based IoT data. However, CNNs often require large amounts of labeled training data to achieve optimal performance. Training large CNN models can also be computationally intensive, especially when dealing with high-resolution images or large-scale datasets.

### III. CHALLENGES IN DATA ANOMALY DETECTION FOR IOT

Data anomaly detection in IoT is challenging due to the unique characteristics of IoT data and the constraints imposed by IoT environments. Some of the key challenges are as follows:

- **High dimensionality:** IoT data is often high-dimensional, consisting of multiple sensors, devices, and data sources. This high dimensionality increases the complexity of anomaly detection, as the algorithms need to handle a large number of features and capture complex relationships between them. Dimensionality reduction techniques may be required to mitigate this challenge.
- **Scalability:** IoT systems generate massive amounts of data in real-time. Anomaly detection algorithms must scale to handle the high data volume and velocity. Processing such large-scale data in real-time requires efficient algorithms and infrastructure capable of handling the computational and storage demands.
- **Imbalanced data:** IoT datasets often suffer from imbalanced class distributions, where the number of normal instances significantly outweighs the number of anomalies. This imbalance can lead to biased models that favor the majority class and fail to detect anomalies accurately. Specialized techniques, such as oversampling or undersampling, must address this challenge and improve the detection of rare anomalies.
- **Concept drift:** IoT environments are dynamic and subject to concept drift, where the statistical properties of the data change over time. Anomaly detection models trained on historical data may become less effective when faced with new data patterns. Continuous model updating and adaptation are necessary to cope with concept drift and ensure the detection of evolving anomalies.

- **Lack of labeled data:** Anomaly detection typically requires labeled data for training supervised learning algorithms. However, acquiring labeled data for anomalies can be challenging in IoT settings, as anomalies are rare and may not be explicitly labeled. Obtaining a sufficient amount of accurately labeled data for training can be a significant obstacle, necessitating the exploration of unsupervised or semi-supervised techniques.
- **Privacy and security:** IoT data often contains sensitive information, making privacy and security crucial concerns. Anomaly detection algorithms must operate in a privacy-preserving manner, ensuring that sensitive data is not exposed or compromised during the detection process. This requires carefully designing algorithms and techniques to balance anomaly detection accuracy with privacy protection.
- **Real-time detection:** Many IoT applications require real-time anomaly detection for timely response and mitigation. Achieving real-time detection poses challenges due to the computational complexity of certain algorithms and the need to process and analyze data in near real-time. Efficient algorithms and scalable infrastructure are necessary to enable real-time anomaly detection in IoT environments.
- **Interpretability:** Understanding why a certain instance is flagged as an anomaly is important for effective anomaly management and decision-making. However, some advanced machine learning and deep learning algorithms, while powerful in detecting anomalies, may lack interpretability. Balancing accuracy and interpretability becomes crucial, especially in applications requiring explainability.

Addressing the mentioned challenges in data anomaly detection for IoT requires the development of innovative algorithms, techniques, and frameworks for detecting high-dimensional, streaming data effectively, adjusting to dynamic environments, maintaining privacy, and enabling detection in real-time. Such solutions should also be energy efficient and easily scalable to accommodate large-scale networks. Finally, they should be able to detect anomalies caused by malicious activities, natural phenomena, and human errors.

### IV. DISCUSSION

Various case studies demonstrate the diverse applications of IoT data anomaly detection across industries, ranging from manufacturing and home security to healthcare. Organizations can achieve improved operational efficiency, enhanced security, and proactive decision-making in various IoT-enabled environments by leveraging anomaly detection algorithms. Table II shows an overview of case studies of IoT data anomaly detection. IoT sensors are deployed across machinery and equipment in a manufacturing plant to collect data on parameters such as temperature, vibration, and energy consumption. Anomaly detection algorithms are applied to this data to identify deviations from normal behavior that may indicate potential failures or malfunctions. By detecting anomalies in real-time, maintenance teams can proactively

schedule repairs or replacement of components before costly breakdowns occur. This approach is employed by companies like General Electric (GE) for their industrial IoT applications, resulting in shorter downtime, longer equipment lifetime, and reduced costs.

TABLE II. CASE STUDIES OF IoT DATA ANOMALY DETECTION

Industry	Case study	Key benefits	References
Manufacturing	Predictive maintenance	Reduced downtime Increased equipment lifespan Cost savings	[82-85]
Smart home	Security	Improved home security Real-time anomaly detection Mitigation of potential security risks	[86-89]
Healthcare	Patient monitoring	Early detection of health issues Personalized healthcare monitoring Timely intervention	[90-93]

Smart homes use IoT devices, such as cameras, motion sensors, doors, and windows, to generate data on activities and events within the home. Anomaly detection algorithms are applied to this data to identify abnormal behaviors or potential intrusions. This allows homeowners to receive real-time alerts and take appropriate actions to mitigate security risks. Companies like Ring and Nest have implemented IoT data anomaly detection techniques in their smart home security systems, providing homeowners with improved security and peace of mind. IoT devices and wearables in healthcare generate vast amounts of patient data, including vital signs, activity levels, and medication adherence. Anomaly detection algorithms are applied to this data to identify deviations from normal patterns, indicating potential health issues or abnormal behavior. Healthcare providers can receive alerts and take timely interventions, leading to early detection of health issues and personalized patient care. Companies like Philips and Medtronic utilize IoT data anomaly detection in their healthcare monitoring solutions to improve patient outcomes and enhance healthcare delivery.

## V. FUTURE RESEARCH DIRECTIONS

Future research in IoT data anomaly detection is expected to address several key challenges and explore novel techniques to improve the effectiveness and efficiency of anomaly detection in IoT systems. Here are some potential research directions:

- **Real-time and edge-based anomaly detection:** As the IoT ecosystem continues to grow, there is a need for more real-time and edge-based anomaly detection methods. Research efforts will aim to develop lightweight algorithms and models to efficiently process and analyze IoT data at the edge, reducing latency and enabling timely anomaly detection and response.
- **Robustness to evolving IoT environments:** IoT environments are dynamic, with device changes, data distributions, and system configurations. Future

research will focus on developing anomaly detection techniques that adapt to evolving IoT environments. This includes techniques for transfer learning, online learning, and incremental learning, allowing anomaly detection models to learn and adapt to new patterns and anomalies continuously.

- **Multi-modal anomaly detection:** IoT systems generate data from diverse sources, including sensors, images, audio, and video streams. Future research will explore multi-modal anomaly detection techniques that can effectively integrate and analyze data from different modalities to detect complex anomalies that may not be apparent when analyzing each modality individually.
- **Explainable AI for anomaly detection:** Explainability and interpretability are critical for building trust and understanding in anomaly detection systems. Future research will focus on developing explainable AI techniques for anomaly detection in IoT data. This includes methods to provide interpretable explanations for detected anomalies, visualizations of anomaly patterns, and feature importance analysis to enhance the transparency and usability of anomaly detection models.
- **Privacy-preserving anomaly detection:** IoT data often contain sensitive and personal information. Future research will explore privacy-preserving anomaly detection techniques that can detect anomalies without compromising the privacy of individuals or revealing sensitive data. This includes techniques such as federated learning, secure multi-party computation, and differential privacy to ensure data privacy and security in anomaly detection processes.
- **Adversarial anomaly detection:** As IoT systems become more interconnected and susceptible to attacks; future research will investigate adversarial anomaly detection techniques. These techniques aim to detect anomalies caused by malicious activities, such as data poisoning or evasion attacks. Research efforts will focus on developing robust anomaly detection models to detect and mitigate adversarial attacks on IoT data.

By addressing these research directions, IoT data anomaly detection can advance to effectively handle the complexities and challenges of large-scale IoT systems, leading to more reliable anomaly detection, enhanced security, and improved operational efficiency.

## VI. CONCLUSION

Data anomaly detection plays a crucial role in the IoT ecosystem, enabling the detection of abnormal behavior, potential failures, and security breaches in IoT systems. This paper comprehensively reviews current trends and research challenges in IoT data anomaly detection. We have discussed utilizing machine learning and deep learning algorithms, such as ensemble methods, RNNs, and CNNs, in IoT anomaly detection. These algorithms offer advanced capabilities in

handling IoT data's complexity and high dimensionality, leading to more accurate and efficient anomaly detection. Additionally, unsupervised learning approaches and real-time processing have emerged as prominent trends, enabling the detection of anomalies without the need for labeled data and facilitating timely responses to detected anomalies.

Furthermore, integrating multiple data sources and pursuing explainable AI techniques have been identified as important trends in IoT data anomaly detection. By leveraging diverse sources of IoT data and providing interpretable explanations for detected anomalies, organizations can enhance anomaly detection systems' reliability, usability, and trustworthiness. However, several research challenges remain in the field. These include the development of real-time and edge-based anomaly detection methods, addressing the robustness of anomaly detection models in evolving IoT environments, and exploring multi-modal anomaly detection techniques. Privacy-preserving and adversarial anomaly detection are crucial areas requiring further research to ensure data privacy, security, and resilience against malicious activities.

**Abstract**—The segmentation of the moving objects in the video sequences is one of the most usable series in the machine vision field, which has absorbed the consideration of researchers in the latter decades. It is a challenging task, especially when there are several motion objects in the video, and then the system needs to discover the objects that should be segmented among the trail. Therefore, in this article, we present a new method to segment several motion objects at the same time. In this work, the propagation of the credence of the confidently-estimated frames by fine-tuning the DCNN model with the other frames is the main idea. We exert a DCNN model (which is pre-trained) for the frames to estimate the class of the object; then, we gather the frames where the approximation is locally or globally reliable. In the following, we apply a collection of the frames of CE as the training set to fine-tune the pre-trained network with the existing examples in a video. Our proposed model provides acceptable results, which are better than the results of similar models. These comparisons are made in the dataset of YouTube-VOS. Also, our presented approach is applied in the dataset of DAVIS-2017 and the obtained results are better than the results of the similar works.

**Keywords**—Segmentation; video processing; motion objects; deep convolutional neural network (DCNN)

## I. INTRODUCTION

With the growth of technology and the presence of machines in human life, the various applications of this technology have increased daily. Currently, with the increase in computing capabilities along with the low price of the cameras, image perception is an important part of many applications. One of these applications in image processing is the segmentation of motion objects. The segmentation of the object is the separation of the background and the objects in a trail of video images with a specific purpose [1]. The discovery and segmentation of the moving objects on the trail of videos is a prerequisite step for the high-level systems of machine vision, such as stewardship systems, robotics, and so on. The accuracy of the mentioned systems depends on the segmentation method used. For example, in a surveillance system that uses the information of the movement model for the recognition of people, it should be possible to continuously segment and track the moving objects with high accuracy through the installed cameras in the desired location. Then, by analyzing the received information about the movement and the location of these people, in case of unfortunate events such as falling down which occur, the system can be notified automatically to the relevant centers such as the emergency [2].

With the consideration of the important mentioned applications in the above and many other applications of object segmentation, in the current article, we propose a novel approach for the segmentation of the object in video trials.

Therefore, the main purpose of the segmentation of the video is to separate the foreground from the background with respect to a video trail [3]. Recently, new approaches have been proposed to segment all motion objects in a video and produce larger datasets. This work leads to more challenging tasks [4]. Most of the presented methods in this field evaluate the frames separately [5], and they do not remark on the dimension of the temporal to obtain the affiliation among the successive frames. Recently, an encoder-decoder architecture has been presented based on RNN [6] and is similar to our proposed method.

Therefore, in this paper, the key idea is the propagation of the CE frame credence into another frame using the fine-tuning of the model of DCNN. So, we exert the DCNN model (which is pre-trained) for the frames to estimate the class of the object, and then, we gather the frames where the estimation as globally or locally is reliable. In the following, we exert a collection of the frames of CE as the training set to fine-tune the used pre-trained model with the examples in the videos. Also, we confine the used model of DCNN [7] to only the video. For example, we perform the model centralization in the particular examples in the input video. We, in this procedure, only use the CE region labels and permit the CE frames to determine the un-estimated regions. In addition, we use the feeble labels to prevent the degradation of the model by a few incorrect labels. Our procedures for the generation of the self-consistent datasets and the use of the CE frames for the updation of the system can retrieve the unspecified parts or the classified sections from the frames of UE, which contain several objects.

The article continuation is as the below: Section II characterizes the related works and their overview. Section III characterizes the details of our presented method. The evaluation details and the details of the performed tests are provided in Section IV. In this section also, we provide the visual outcomes and the numerical outcomes of the done tests. In Section V, we provide the suggestions and conclusions.

## II. RELATED WORKS

Due to the wide applications of the segmentation of motion objects in the arena of machine vision, researchers have studied and have presented different methods for this task in recent

years. Among the comprehensive performed works in this field is the presented work in [8], which has reviewed and classified the proposed segmentation methods. In [9]–[12], the different methods for the segmentation and the tracking of the motion objects have been investigated. Usually, the segmentation is done based on the obtained information for a series of special characteristics from the objects. These characteristics include the below cases: the edge, the texture, the color of the objects, the movement information, the corner points, the appearance of the objects, etc. Any segmentation algorithm based on the application can use any of these characteristics or a combination of these characteristics. For example, in the algorithms that segment and track the objects based on the object contour, the edge feature [13] is used. In [14], the motion objects were segmented based on the difference between the existing edges between two consecutive frames. The detectors of the corner points in the literature on object segmentation are Moravec [15], Harris [16], KLT [17], and SIFT [18].

In addition, the segmentation of moving objects based on deep learning techniques has received regard in the association of the research in the latter years. It can be due to the emergence of novel segmentation datasets and new challenges: Berkeley (2011), SegTrack (2013) [19], Berkeley Freiburg (2014) [20], DAVIS (2016-2017) [21], and YouTubeVOS (2018) [22]. These datasets provide the biggest content of the tagged videos.

The later works, such as [15], use the optical flow for the temporal adaptation after the use of the fields of Markov random, which is the basis on the taken specifications of a CNN model. The other suggestion for the obtention of the coherence of the temporal is the use of the boded masks on prior frames as a guide for the subsequent frames [7]. The proposed method in [23] disseminates the information using spatiotemporal features. Finally, the proposed method in [24] uses an architecture of the encoder-decoder RNN that employs the LSTM for the learning of the trail.

In the segmentation of the objects in the video, the learning with the single-shot is found as the use from an alone tagged frame for the estimation of the residual frame's segmentation in a sequence. Also, the learning with the zero-shot is found as the construction models, which do not require the initialization for the generation of the masks of the segmentation of the object in the trail of the video. There are multiple articles in the literature which is emphasized the first mask for the input to can propagate via the trail [3], [7], [10], [25], and [26]. Generally, the approaches with the single-shot outperform in comparison to the approaches with the zero-shot because the first segmentation is formerly taken, so there is no need for the estimation of the mask of the first segmentation of the

abrasion. Most of the proposed systems emphasize online learning, which is the adaption of the weights with the first frame and associated masks. Usually, the methods of online learning achieve better outcomes, but they need more computing time. On the learning with the zero-shot, for the estimation of the segmentation of the object on a video, multiple papers have used the object saliency [8], [27], [28] or they have used the object suggestion methods outputs [12], or they have used network with two-stream. The exploitation of the motion templates on the videos is perused at [29], but the article of [14] formulates the 3D representation conclusion of a planar object and the motion segmentation. In addition, foreground segmentation which is the basis of the sample embedding is presented in [16].

Also, optical flow computation is one of the fundamental tasks in computer vision. Deep learning methods allow efficient computation of optical flow, both in supervised learning on synthetic data [42], and in the self-supervised [39] setting. Additionally, in [40], the authors propose to highlight the independently moving object by compensating for the background motion, either by registering consecutive frames, or explicitly estimating camera motion. Another line of work has tackled the problem by explicitly leveraging the independence, in the flow field, between the moving object and its background. For instance, [41] proposes an adversarial setting, where a generator is trained to produce masks, altering the input flow, such that the inpainter fails to estimate the missing information.

Finally, in [43-45], two protocols have attracted increasing interest from the vision community, namely, semi-supervised video object segmentation (semi-supervised VOS), and unsupervised video object segmentation (unsupervised VOS). The former aims to re-localize one or multiple targets that are specified in the first frame of a video with pixel-wise masks, and the latter considers automatically separating the object of interest (usually the most salient one) from the background in a video sequence.

### III. PROPOSED METHOD

To present our method, we consider an important hypothesis. We presume that the video contains at least some frames of CE such that it is useful for the improvement of the uncertainly-estimated frame outcomes. In the presented method, the main idea is the propagation of the credence of the frames of CE using the fine-tuning of DCNN. Therefore, our method includes the below stages: the election of the CE frames, the production of the label mapping, and the matching of a model with the input video. In the following subsections, we characterize the desired algorithm of these stages. Fig. 1 displays the general format of our presented approach.

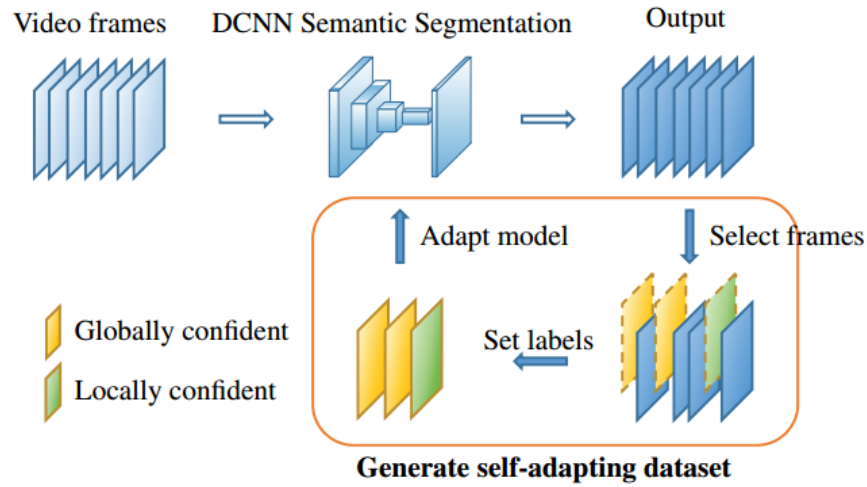

Fig. 1. The general format of our presented approach.

### A. Steps of Our Presented Method

Fig. 1 displays the general steps of our presented method. In this sub-section, we will characterize the presented approach details to segment the motion objects in the video frames.  $F$  shows the collection of the indices of the frames; also  $W$  displays the collection of the desired poor labels from the input video. The presented method starts using the DCNN model  $\theta$  which is pre-trained (for the frame  $f \in F$ ), then we apply *Softmax* for the computation of the probability  $P(x_i|\theta)$  where  $i$ -th pixel is the organ of the class  $x_i \in O$  which in it,  $O$  represents a collection of the classes of the object and the classes of the background. The mapping of the semantic label  $S$  can be measured by the use of the *argmax* for each pixel  $i$ :

$$S(i) = \arg \max_{x_i} P(x_i|\theta) \quad (1)$$

We gather the self-adaptive dataset  $G$  for adaption of the model of DCNN with the input video, which  $G$  includes the frames of CE and the related tag mappings. We gather the global CE frames and the local CE frames. Then we calculate corresponding label mappings  $G^g$  and  $G^l$  for the make of a self-consistent collection. Algorithm 1 summarizes the processes of the frame selection and the label calculation. First, we apply the analysis of the connected part in each mapping from the class  $S$  for the generation of the collection of the candidate object zones. For  $k$ -th mapping of  $R_k \in R$ , the confidence of  $\mathcal{C}(R_k)$  measures the evaluated zones, which in it, the operator  $\mathcal{C}(\cdot)$  catches the label mapping as the input. Then, it calculates the mean probability of which pixels are labeled as objects. The label mapping has the labels of the related class.

In the following, we construct the mapping of the label  $G_f^g$  with the setting of the zone label when the confidence value

trespasses an upper threshold  $t_0$ . Also, we adjust the label of the background for each pixel where  $P(x_i = bg|\theta)$  (for being the background) is the greater than the threshold of  $t_b$ .

For the completion of  $G_f^g$ , the residual undefined zones must be processed. We, for this goal, let the residual pixels be labeled as "ignored." The pixels of the unspecified "ignored" are not attended to in the calculation of the loss value for the updation of the model. Also, we relinquish all pixels which have tags that are not on the collection of  $W$ . We surcharge the global frames of CE with  $G_f^g$  which have one safe zone for self-consistent dataset  $G$ .

Since the elected frames may be distributed temporally, our model can be overcome by the frames which are elected in a short time. For the reduction of the obtained error and for the regularization of the model, it is recommended to select the local frames of CE which have the best confidence of the object in each interval  $\tau b$ . We determine the local CE frames and their label mapping  $G^l$  as follows: For each frame  $f$ , we create a label mapping  $G_f^l$  using label keeping of total pixels if and only if  $S(i)$  to be consisted on  $W$ , when we set the background as the prior. In the following, we compute the frame confidence by the computation of  $\mathcal{C}(G_f^l)$  and then we consider the frame with the highest confidence during each part of the frame  $\tau b$  as the local CE. Let the local frame of CE formerly not elected as the global frame of CE; then we surcharge it into the self-adaptive dataset  $G$ .

With the consideration of the self-adaptive dataset  $G$  which is computed by the mentioned processes, finally, we reconcile the model  $\theta$  with the video. This task is done using the fine-tuning of the model into  $\theta'$ . In the following, we calculate the novel label mapping using  $\theta'$  for each frame.

<b>Algorithm 1. Procedures for Selecting the Frames and Calculating the Labels</b>	
Input: DCNN model $\theta$ , a set of weak labels $W$	
Local best confidence $d = 0$	
<b>for</b> $f \in F$ <b>do</b>	
Initialize $G_f^g, G_f^l$ to ignored label	
Compute $P(x \theta)$ and $S = \mathit{arg\ max}_x P(x \theta)$	
Compute set $R$ of connected components in $S$	
<b>for</b> $R_k \in R$ <b>do</b>	
<b>if</b> $S(i) \notin W, i \in R_k$ <b>then continue</b>	
<b>if</b> $C(R_k) > t_0$ <b>then</b>	
Set $G_f^g(i) = S(i), \forall i \in R_k$	
Set $G_f^l(i) = S(i), \forall i \in R_k$	
Set $G_f^g(i) = G_f^l(i) = 0, \forall i \text{ st. } P(x_i = \mathit{bg} \theta) > t_b$	
<b>if</b> $C(G_f^g) > 0$ <b>then</b> $G \leftarrow G \cup \{G_f^g\}$	
<b>if</b> $C(G_f^l) > d$ <b>then</b>	
Update $t = f$ and $d = C(G_f^l)$	
<b>if</b> $f \bmod \tau b = 0$ <b>then</b>	
<b>if</b> $G_f^g \notin G$ <b>then</b>	
	$G \leftarrow G \cup \{G_f^l\}$
Initialize $d = 0$	
Fine-tune DCNN model $\theta$ to $\theta'$ using the set $G$	

### B. Development of Proposed Method for Un-Supervised Video

Our presented approach can be used for the processing of unsupervised video. This task can easily be applied to unsupervised videos using the limitation of line eight in Algorithm 1. This omission means that the model doesn't manage whether the class emerges really on the video. So, we adjust all tags of the CE zones even if the tags are wrong. The experiments show that most processed videos have the same outcomes as the weakly-supervised videos is so much that the pixel tags specified by a great probability typically match the true tags. However, exceptions occur, which these exceptions are related to incorrect labels. They can degrade the model, and they can reduce the accuracy compared to the settings of weakly supervised.

### C. Implement the Post-Processing for the Correction

Since the DCNN output is not sufficient to accurately characterize the object therefore, we apply the fully-connected CRF [30]. We apply the DCNN output for the single expression. Also, we apply the pixel's positions and the pixels' colors for the calculation of the even expressions (similar to [31]). We, finally, modify the label mapping via the practices of morphology (such as erosion and dilation).

## IV. TESTS AND THE OUTCOMES EVALUATION

In this sub-section, first, we will present the implementation details and the performed tests. Also, we will introduce the used dataset. In the following, the tests' results are presented, and an analytical evaluation is done.

### A. Details of Implementation

The tests in this article are performed as the single-shot and the zero-shot. Also, the designed tests are done using two datasets: YouTube-VOS [32] and DAVIS-2017 [33]. The first dataset, YouTube-VOS, contains 474 films on the set of the validation and 3471 films on the set of the training. It is the biggest dataset in the field of the segmentation of the video object. In addition, the training dataset contains 65 unique

groups of the object, which are considered as the observed groups. Also, in the dataset of the validation, there are 91 groups of the object that consist of 26 unseen groups and all seen groups.

On the other hand, the dataset of DAVIS-2017 includes 60 films for the training dataset, 30 films for the validation dataset, and 30 films for the test dataset. In both datasets, the videos contain several objects, and their duration is between three to six seconds. The Python programming language has been used for the implementation of these tests. The presented method is implemented in a machine with Core (TM) i7 CPU 3.0 GHz Intel(R) and 8G RAM. The convolutional network is implemented on GPU, and the used graphic card in this method is NVIDIA GEFORCE 840M. The tests are analyzed by the use of the normal analysis criteria: (1) the accuracy of the contour  $F$  and (2) the similarity of the region  $J$ . On the YouTube-VOS dataset, these criteria are divided into two sub-criteria, depending on whether groups already have been seen with a network ( $F_{seen}$  and  $J_{seen}$ ) or have not been seen by the model ( $J_{unseen}$  and  $F_{unseen}$ ). The concept of the seen (or the unseen) means that, these categories are included in the set of training (or are not included).

### B. Experiments and Results for the YouTube-VOS Dataset

As mentioned, the tests and the results are presented in two modes: the single-shot and the zero-shot. The single-shot mode consists of the object segmentation of a video according to the mask of the objects on the initial frame. But zero-shot mode involves the video objects segmentation without the previous data about that which of the objects must be segmented. It means that no object mask is obtained. This work is more complicated than the single-shot mode because the network must identify and then segment the objects that appeared in the film.

Table I shows the obtained results on the validation dataset of YouTube-VOS for the single-shot mode. All presented models in this study were trained using an 80-20 split for the training dataset. Fig. 2 shows some qualitative results, which in it, we can view, which our proposed method better maintains

the segmentation of the objects over time. The proposed network can learn how the fixing the faults that may arise in the deduction. Table I can view which this approach is strong and has a suitable performance. Fig. 3 displays some qualitative outcomes which compare our trained approach over the mask of the ground truth and our trained approach over the concluded mask.

Table II displays the comparison of our presented model and similar approaches using the entire training dataset of YouTube-VOS. As it is clear, our proposed model has analogous outcomes with the mentioned model in [32]. The proposed method has an awhile worse turnover for the similarity of the region  $J$ . However, it has an awhile better turnover for the accuracy of the contour  $F$ . The proposed network performs better than the remaining advanced methods [25], [34]–[36] for the observed categories. Also, depending on the number of examples in the videos, Table III displays the related outcomes to the similarity of the region  $J$  and the accuracy of the contour  $F$ . We can view which objects for segmentation be fewer, then the work is easier, and we get better outcomes for the trails with only one or two annotated objects. Fig. 4 displays the qualitative outcomes for our presented approach for different trials from the validation set of YouTube-VOS. It contains the samples by the different samples number. Note that which samples are segmented correctly. However, there are different samples of a similar group on the video trail (the leopard, the sheep, the bird, the fish, or the person), or there are cases that vanish from the trail (a sheep on third row and a dog in fourth row).

So far, we have presented the test outcomes for our presented approach in the single-shot mode for the YouTube-VOS dataset. Also, we provide the outcomes for the mentioned dataset on the zero-shot mode. It should be noted that today, there is no designed special dataset for zero-shot segmentation. Although the YouTubeVOS dataset and the DAVIS-2017 dataset can be used to train and evaluate the models without the use of the provided annotations in initial frame, these datasets have this restriction in which the total appeared objects on the film are not annotated. In the YouTube-VOS dataset, specifically, a maximum of five object instances in each video are annotated. This makes sense when the objects are given for the segmentation but may be problematic for the zero-shot segmentation because the model can correctly segment the objects which are not annotated on the dataset. Fig. 5 displays some samples in it and some annotations of the missing object. Notwithstanding the stated quandary on the annotations of the missing object, for this mode, we have trained our network using the existing object annotations in this dataset.

Table IV displays the obtained outcomes for the validation dataset of YouTube-VOS on the segmentation with the zero-shot. Similar to the segmentation problem in single-shot mode, the proposed model has a good performance for object segmentation in the video. Fig. 6 displays some outcomes for segmentation in the zero-shot mode on the validation dataset of YouTube-VOS. Note that the masks are not obtained, so the system must detect the objects that must be segmented.

### C. Experiments and Outcomes for the DAVIS-2017 Dataset

We test our pre-trained model (which is trained using the YouTube-VOS dataset) on a different dataset: DAVIS-2017. As shown in Table V, if the pre-trained network is done directly for the DAVIS-2017 dataset, our presented approach performs better than the rest of the approaches that do not use online learning. In addition, when the proposed model is adjusted for the training dataset of DAVIS-2017, the proposed method outperforms some methods (for example, OSVOS [3]). Fig. 7 displays the obtained visual outcomes on the dataset of DAVIS-2017 in the single-shot mode.

But in the zero-shot mode, by reviewing the articles and the research literature, it was found that there are no formal outcomes for the zero-shot mode on the DAVIS-2017 dataset so that we can compare our proposed method with it. The segmentation with zero-shot mode only is remarked for the DAVIS-2016 dataset, which in the unsupervised approaches have been made for it. Using the YouTube-VOS dataset on the zero-shot mode, if our model is directly done on the DAVIS-2017 dataset, our pre-trained model yields an average region similarity equal to  $J = 22.4$  and an average contour accuracy equal to  $F = 28.0$ . If this pre-trained network is fine-tuned using the validation dataset of DAVIS-2017, then it results in a while better efficiency:  $F = 30.6$  and  $J = 24.7$ . This poor efficiency of the zero-shot segmentation on the DAVIS-2017 dataset can be illustrated by the poor efficiency of the YouTube-VOS dataset in the unseen groups. Fig. 8 displays the visual outcomes of the test dataset of DAVIS-2017, which in it the mask of the object is not obtained.

### D. Discussion

The results obtained from the qualitative experiments showed that our proposed method maintains the segmentation of the objects as better over time. This is because the proposed network can learn how to fix the errors that may occur in the deduction. Also, the results showed that when we test our pre-trained model on a different dataset, our proposed approach outperforms other approaches that do not use the online learning. Furthermore, when the proposed model is adjusted to DAVIS-2017 training dataset, the proposed method outperforms other approaches. Also, the various tests on YouTube-VOS showed that if our model is run directly on the DAVIS-2017 dataset, our pre-trained model yields an average regional similarity of  $J=22.4$  and an average contour accuracy of  $F= 28.0$ . If this pre-trained network is fine-tuned by using the DAVIS-2017 validation dataset, it gives the better performance for some time:  $F=30.6$  and  $J=24.7$ . This poor performance of the zero-shot segmentation on the DAVIS-2017 dataset can be illustrated by the poor performance of the YouTube-VOS dataset on the unseen groups. Finally, the presented method in this article has a specific limitation that occurs sometimes. This limitation occurs when a video does not match the hypothesis that we stated at the beginning (at least one zone of the object collates with the classes of the pre-trained object, or at least one frame has the true tag). Mostly, these samples happen due to the size of very small the objects on a video. The lack of a frame for improvement of other frames gives similar outcomes to the base model. The researchers can remark on this limitation in their subsequent works.

TABLE I. OBTAINED RESULTS FOR VALIDATION DATASET OF YOUTUBE-VOS IN THE SINGLE-SHOT MODE

YouTube-VOS Dataset in the Single-Shot Mode

## V. CONCLUSIONS AND SUGGESTIONS

In our article, we propose a novel method for the segmentation of the motion objects which exist in the video. This method reconciles the model of the pre-trained DCNN with the input film. For the fine-tuning of the model, which is trained as vastly to be special for the video, we created a self-adaptive set that includes multiple frames, which helps to the improvement of the results of the frames of UE. This model is designed for segmentation in the single-shot mode and the zero-shot mode. Also, this model is applied in the YouTube-VOS dataset and the DAVIS-2017 dataset. The tests display that our trained model has a better performance than similar methods. In addition, our model improves the performance of similar methods. For future research, it is suggested to develop a semi-supervised film framework for the accuracy increase. It can also be expected that this efficient self-adaptive method can generate video datasets with accurate labels.

# Classification of Coherence Indices Extracted from EEG Signals of Mild and Severe Autism

Lingyun Wu

School of Culture Communication, Henan Vocational Institute of Arts, Zhengzhou 451464, Henan, China

**Abstract**—Autism spectrum disorder is a debilitating neurodevelopmental illness characterized by serious impairments in communication and social skills. Due to the increasing prevalence of autism worldwide, the development of a new diagnostic approach for autism spectrum disorder is of great importance. Also, diagnosing the severity of autism is very important for clinicians in the treatment process. Therefore, in this study, we intend to classify the electroencephalogram (EEG) signals of mild and severe autism patients. Twelve patients with mild autism and twelve patients with severe autism with the age range of 10-30 years participated in the present research. Due to the difficulties of working with autism patients and recording EEG signals from these patients in the awake state, the Emotiv Epoch headset device was utilized in this work. After signal preprocessing, we calculated short-range and long-range coherence values in the frequency range of 1-45 Hz, including short- and long-range intra- and inter-hemispheric coherence features. Then, statistical analysis was conducted to select coherence features with statistical differences between the two groups. Multilayer perceptron (MLP) neural network and support vector machine (SVM) with radial basis function (RBF) kernel were used in the classification stage. Our results showed that the best MLP classification performance was obtained by selected inter-hemispheric coherence features with accuracy, sensitivity and specificity of 96.82%, 97.82% and 96.92%, respectively. Also, the best SVM classification performance was obtained by selected inter-hemispheric coherence features with accuracy, sensitivity and specificity of 94.70%, 93.85% and 95.55%, respectively. However, it should be noted that the MLP neural network imposes a much higher computational cost than the SVM classifier. Considering that our simple system gives promising results in diagnosing autistic patients with mild and severe severities from EEG, there is scope for further work with a larger sample size and different ages and genders.

**Keywords**—Autism spectrum disorder; electroencephalography (EEG); classification; neural network; support vector machine; coherence feature

## I. INTRODUCTION

Autism spectrum disorder is a debilitating neurodevelopmental illness characterized by serious impairments in communication and social skills. Patients with autism manifest repetitive and restricted behavior [1-3]. The prevalence of autism has increased considerably from 0.67% in 2000 to 2.58% in 2016 in the United States [4-6]. Therefore, in recent years, researchers emphasized different approaches to early diagnosis of this disorder to provide timely intervention and achieve better treatment outcomes [7, 8]. In this regard, it is also very important to determine the severity of the disease in autism spectrum disorder because it leads to changing

treatment approaches due to the level of brain disorders [9]. Brain images have shown abnormalities in brain and head size and limbic and cerebellar structure in autistic patients [10]. Magnetic resonance imaging (MRI) studies have shown that autistic patients have serious disturbances in the functional connectivity between different brain regions [11, 12]. fMRI and diffusion tensor imaging (DTI) studies also showed that patients with autism had reduced long-range functional connectivity at rest and during different executive cognitive tasks [13]. However, due to its high availability, cheapness, and ease of use, many researchers have analyzed the electroencephalogram (EEG) signals of autism patients to study their brain function [14-18]. For instance, in a recent study, Hadoush et al. [19] analyzed and compared the brain complexity of children with mild and severe autism through multiscale entropy analysis of EEG signals. They found that the brain complexity of children with mild autism is higher than that of children with severe autism in the right parietal, right frontal, left parietal and central cortices. Finally, they concluded that EEG multiscale entropy could serve as a sensitive index to detect the level of autism severity. In a review study, Wang et al. suggested excessive power in low- and high-frequency EEG bands and impaired functional connectivity as common EEG abnormalities in autism spectrum disorders [20]. The organization of this article is as follows. In Section II, we briefly review some related work in autism diagnosis through EEG analysis. In Section III, the proposed system for preprocessing the EEG signal and extracting and classifying the EEG features of autism patients is presented. Then the obtained results are presented in Section IV. Section V discussed the obtained results. Finally, in the last section, the conclusion of this work is presented.

## II. RELATED WORK

As mentioned, due to the increasing prevalence of autism worldwide, the development of a new diagnostic approach for autism spectrum disorder is of great importance. Several studies have shown significant differences between various EEG features of individuals with autism and normal individuals [21-23]. These studies mainly focused on the spectral power of EEG frequency bands, connectivity and coherence between cortical areas, and hemispheric activity asymmetry [24, 25]. For instance, Jamal et al. obtained an accuracy, sensitivity and specificity of 94.7%, 85.7% and 100%, respectively, in autism diagnosis using connectivity features and a support vector machine (SVM) with the polynomial kernel [26]. Sheikhan et al. used spectral power features and K-nearest neighbours and reported a classification accuracy of 82.4% for autism diagnosis [27]. Fan et al.

proposed a similar framework for EEG classification of autism and non-autism subjects and reported an accuracy of 85% for this purpose [28].

On the other hand, several recent studies have investigated the nonlinear features of EEG for autism diagnosis. Bosl et al. reported good EEG classification results for autism diagnosis using multiscale entropy and SVM [29]. Ahmadlou et al. used the fractal dimension of EEGs and radial basis function neural network and achieved a classification accuracy of 90% for autism diagnosis [30]. Djemal et al. proposed an EEG-based computer-aided diagnosis of autism through entropy and wavelet-based features as well as an artificial neural network and achieved a classification accuracy of 99.71% [31]. Abdulhay et al. proposed a computer-aided autism diagnosis system through second-order plot area and empirical mode decomposition and achieved a classification accuracy of 94.4% for autism diagnosis [24].

Although several studies have been published in the field of computer-aided diagnosis of autism using EEG signals, very few studies have paid attention to the fact that in autism, we are dealing with a relatively wide range of patients with different behavioral and cognitive symptoms. Meanwhile, diagnosing the severity of autism is very important for clinicians in the treatment process. Therefore, in this study, we intend to classify the EEG signals of mild and severe autism patients using coherence indices and machine learning approaches (i.e., SVM and artificial neural networks).

### III. MATERIALS AND METHODS

#### A. Patients

Twelve patients with mild autism and twelve patients with severe autism were participated in the present research. All participants with autism were diagnosed by psychiatry experts according to the diagnostic criteria of DSM-5 [32]. Also, the severity of autism was determined through psychiatric interviews with specialists. The age range of the selected patients was 10-30 years. During the selection stage, patients with autism who had other neurological conditions, such as epilepsy or head trauma, were excluded. The patient enrollment was administered in a psychiatric clinic. The research project was done in accordance with the principles of the Declaration of Helsinki (1996) and the current Good Clinical Practice guidelines. The goal and an overview of the project were characterized by the participants and their parents during the initial contact. For those who agreed to participate, all the necessary information was provided prior to signing written informed consent. Information about the subjects was utilized anonymously and for the purpose of the study.

#### B. Data Acquisition and Cleaning

Previous studies have shown that resting with eyes open is the best EEG recording condition for EEG classification of autism from healthy subjects. Hence, in the current work, EEG recordings were performed while the patients were awake with their eyes open and sitting comfortably in an armchair without any stimuli. Depending on the subject's cooperation, EEG was recorded for 12-20 minutes for each patient in one session. Due to the difficulties of working with autism patients and recording EEG signals from these patients in the awake state,

the Emotiv Epoch headset device was utilized in this work. Since the Emotiv Epoch headset is a wireless EEG device, the signal recording was conducted in autistic patients more easily. This EEG device uses a Bluetooth module for wireless communication. The Emotiv Epoch headset and Software Development Kit include 14 electrodes (AF3, AF4, F7, F8, F3, F4, FC5, FC6, T7, T8, P7, P8, O1, O2 based on 10-20 international system) along with DRL/CMS references at P4/P3 locations. As depicted in Fig. 1, the EEG headset is wireless and has a large lithium-based battery for 12 hours. The sampling rate in this device is 128 Hz. The electrode impedance is reduced through the saline liquid and alcohol pads until the circles shown in Fig. 1 turn green. Emotive software was utilized to record EEGs and convert their format to MATLAB format.

Fig. 1. Emotiv Epoch device and sensors organization. (a) headset and sensors, (b) 10-20 EEG international protocol.

Emotiv Epoch utilizes a 50 Hz notch filter to eliminate the main power line component. After EEG recording, in the signal preprocessing and conditioning stage, a band-pass Hanning window with a finite duration and frequency range of 1-45 Hz was applied to the signals via MATLAB software [33-35]. In addition, we performed electrode interpolation using adjacent channels for low-quality electrodes. EEGs were re-referenced to the common average and then were decomposed via independent component analysis (ICA). Components with motion and muscle artifacts were recognized by ICA and were then removed based on time courses and frequency scalp maps. The cleaned components were reconstructed, and a 50-second cleaned EEG signal was prepared for each patient.

### C. Coherence Features

EEG coherences measure the level of synchronization between two channels (i.e., two brain regions) in terms of EEGs recorded at different regions of the scalp. The coherence function gives information about the functional connectivity of the brain [36]. The value of the coherence function is in the range of zero to one, which shows the correlation of two signals in terms of frequency. If the value of the coherence function is zero, it means that the two channels are independent of each other, and the value of one indicates a high correlation between the two channels. The coherence function of two signals,  $i$  and  $j$ , at frequency  $f$ , is calculated as follows:

$$COH_{i,j}(f) = \frac{|S_{i,j}(f)|^2}{S_{i,i}(f) \cdot S_{j,j}(f)} \quad (1)$$

Where,  $S_{i,j}(f)$  is the cross-spectrum of the two signals, and  $S_{i,i}(f)$  and  $S_{j,j}(f)$  are auto-spectrum of the two signals. Fig. 2 shows the EEG coherence visualization method through matrix representation and node-link diagram.

In this work, we calculated short-range and long-range coherence values in the frequency range of 1-45 Hz, including short- and long-range intra- and inter-hemispheric coherence features. Totally, 89 coherence features were calculated.

### D. Feature Selection and Classification

To avoid the curse of dimensionality, statistical analysis was applied to the calculated coherence features to select features with significant differences between the two groups of patients with autism. Statistical analysis was also performed in MATLAB software. After performing the Shapiro-Wilk test to confirm the normality of the data, repeated measures analysis of variance (ANOVA) was used to handle the multiple comparison problems and the independent t-test was used as a post hoc analysis to compare the mean of the extracted features between the two groups [37-40].  $P < 0.05$  was considered as the threshold of significance.

### E. Multilayer Perceptron (MLP) Neural Network

The selected coherence features through a statistical analysis were applied to suitable classifiers to classify the feature set into mild and severe autism. SVM and artificial neural networks are common classifiers in biomedical applications. Neural networks have been utilized in classification and pattern recognition for different research projects because of their unique properties, such as self-organizing, adaptability, and robustness [41]. There are three layers in a feed-forward neural network like MLP: an input layer, a hidden layer, and an output layer. In the current research, the supervised learning network was utilized to classify mild and severe autism. The architecture of the network is depicted in Fig. 3.

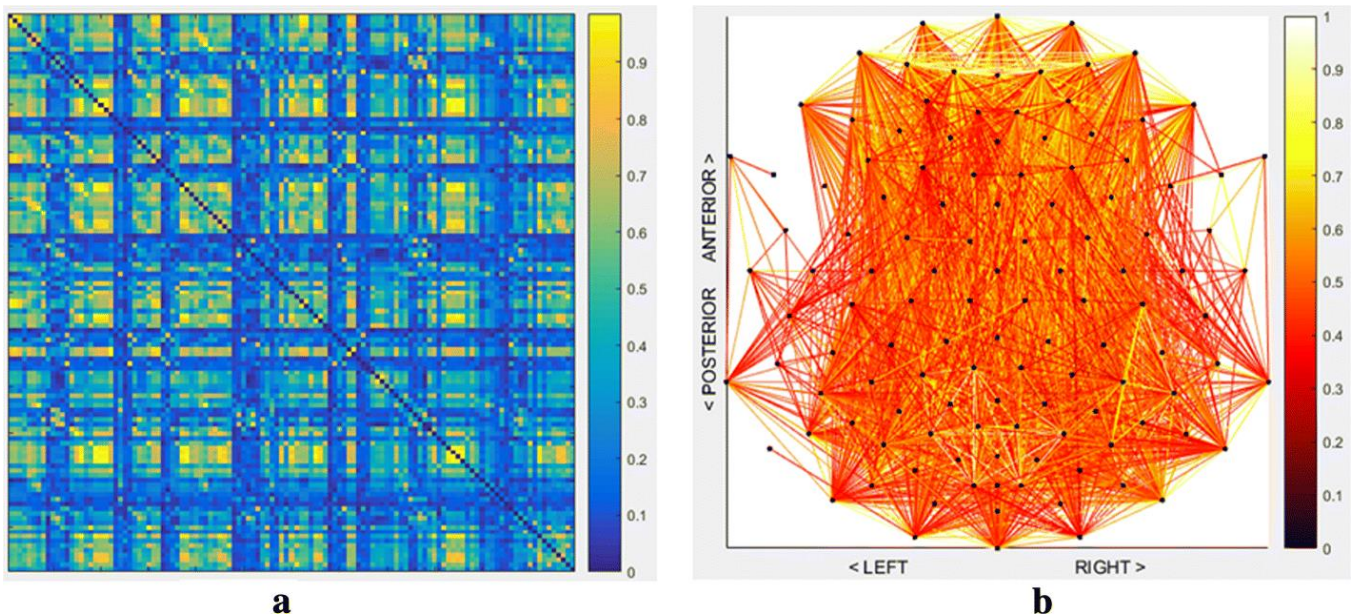

Fig. 2. EEG coherence visualization method. (a) matrix representation, (b) node-link diagram [43].

Fig. 3. Artificial neural network architecture.

The neural network was configured with  $n$  neurons (based on the number of selected features) in the input layer, five neurons in the hidden layer, hyperbolic tangent hidden transfer function, softmax output transfer function, and backward propagation training algorithm. The bias and weights for the network were initialized through the Nguyen-Widrow method. The neurons of each layer are connected to the next layer with a certain weight, which is defined as follows:

$$\Delta W_{ij} = \eta \delta_j(n) y_i(n) \quad (2)$$

The above equation is known as the delta law, through which weight correction is done from neuron  $i$  to neuron  $j$ .  $\eta$ ,  $\delta_j(n)$  and  $y_i(n)$  are the learning rate parameter, local gradient and input signal of neuron  $j$ , respectively. If  $j$  is a neuron in the hidden layer, then  $\delta_j(n)$  is obtained by:

$$\delta_j(n) = \varphi'_j(v_j(n)) \sum_k \delta_k(n) W_{kj}(n) \quad (3)$$

Where,  $k$  is a neuron in the output layer, and  $\varphi'_j(v_j(n))$  denotes the activation function to characterize the input-output relationships of the non-linearity to neuron  $j$ .

#### F. SVM with Radial Basis Function (RBF) Kernel

SVM has been widely utilized by researchers to solve various nonlinear problems and classification tasks with small data samples [42]. We used SVM in this study because this classifier minimizes the expected risk in the test data and considers a margin around the class boundaries, which leads to increased generalizability of the results. SVM uses a kernel function to transform the nonlinear classification problem into a linear one by increasing the dimensionality of the dataset. In this work, we used the RBF kernel. The RBF kernel is the most widely utilized kernel in SVMs. The RBF kernel has good performance in various classification problems. It is expressed as:

$$(x_i \cdot x_j) = \exp(-\gamma \|x_i - x_j\|^2) \cdot \gamma > 0 \quad (4)$$

Where,  $\gamma$  is the free parameter to scale the extent of influence, two samples have on each other.

#### IV. RESULTS AND EVALUATION

The coherence features were calculated from every 14 channels of EEG signals. Fig. 4 shows an example of recorded EEG signals of mild autistic and severe autistic patients for the right and left hemispheres after preprocessing. After feature extraction, the feature selection process was done through statistical analysis. Fig. 5 shows box plots for short-range and long-range intra-hemispheric coherence features with significant differences ( $P < 0.05$ ) between mild and severe autism groups. As shown, there were significant differences in both the left and right hemispheres. In addition, Fig. 6 shows box plots for short-range and long-range inter-hemispheric coherence features with significant differences ( $P < 0.05$ ) between mild and severe autism groups. These 10 coherence features with significant differences between the two groups were considered as selected features for the classification step. In the classification step, based on the results obtained from the statistical analysis, we considered four feature sets as input to the classifiers: all coherence features, all selected features, selected intra-hemispheric features, and selected inter-hemispheric features. It should be noted that the training and testing processes of the classifier were carried out with the four-fold cross-validation method.

Accuracy, sensitivity and specificity were calculated in this study to measure classification performance. These metrics were calculated based on the concepts of false negative (FN), false positive (FP), true negative (TN), and true positive (TP), which represent cases that were incorrectly or correctly identified as negative or positive cases.

$$\begin{aligned} \text{Accuracy} &= \frac{TP+TN}{N+P} \\ \text{Sensitivity} &= \frac{TP}{TP+FN} \\ \text{Spesificity} &= \frac{TN}{TN+FP} \end{aligned} \quad (5)$$

Fig. 4. Sample EEG signals of mild autistic (top) and severe autistic (bottom) patients for right and left hemispheres.

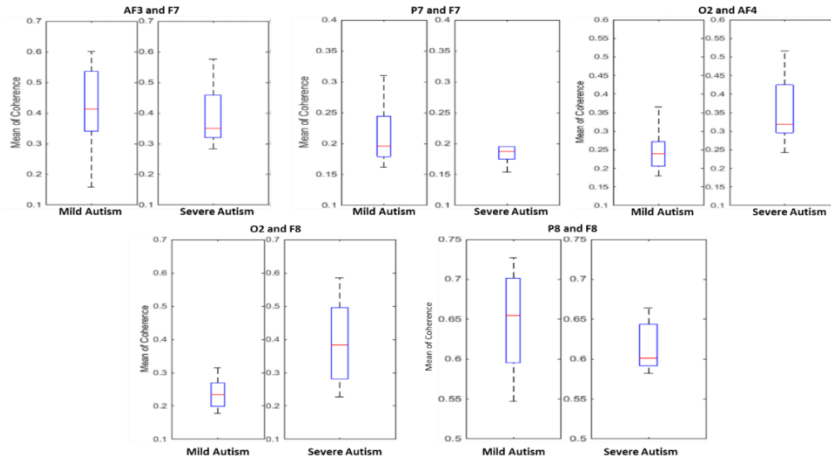

Fig. 5. Box plots for short- and long-range intra-hemispheric coherence features with significant differences ( $P < 0.05$ ) between mild and severe autism groups.

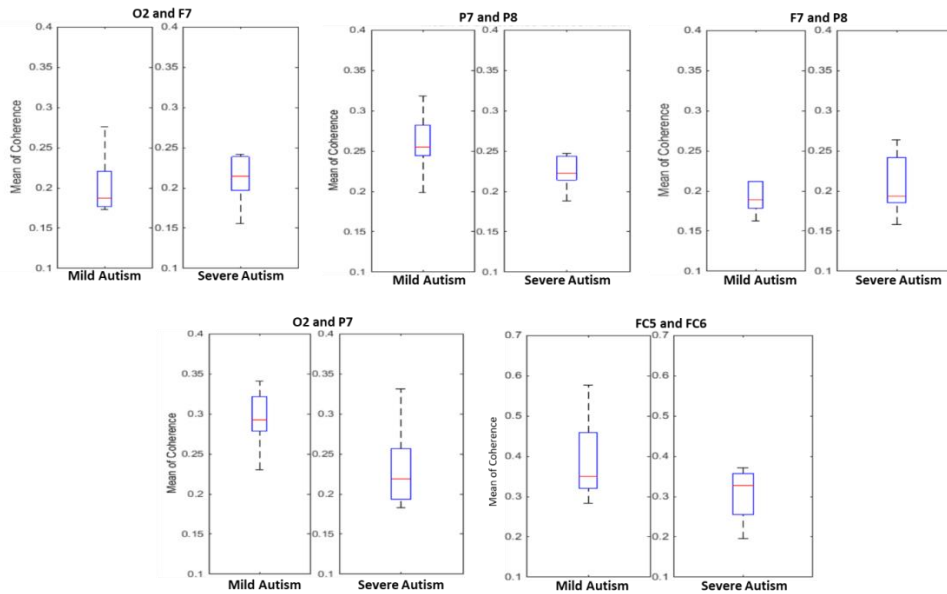

Fig. 6. Box plots for short- and long-range inter-hemispheric coherence features with significant differences ( $P < 0.05$ ) between mild and severe autism groups.

The performance of the MLP and SVM classifiers is evaluated based on the above indices, as depicted in Tables I and II.

Table I shows the performance of the MLP neural network in the classification of coherence features using the four mentioned feature sets. According to this table, the best classification performance was obtained by selected inter-hemispheric coherence features with accuracy, sensitivity and specificity of 96.82%, 97.82% and 96.92%, respectively. Furthermore, Table II shows the performance of the SVM classifier with RBF kernel in the classification of coherence features using the four mentioned feature sets. Again, the best classification performance was obtained by selected inter-

hemispheric coherence features with accuracy, sensitivity and specificity of 94.70%, 93.85% and 95.55%, respectively.

Fig. 7 compares the accuracy rates obtained by MLP and SVM for coherence features extracted from EEG signals for mild and severe autism classification. As shown, the MLP neural network has performed better in classifying coherence features and distinguishing mild autism from severe autism compared to the SVM classifier with the RBF kernel. However, it should be noted that the MLP neural network imposes a much higher computational cost than the SVM classifier. Table III shows the average time of classification operations (in terms of seconds) using MLP and SVM classifiers with and without feature selection.

TABLE I. PERFORMANCE OF MLP NEURAL NETWORK IN THE CLASSIFICATION OF COHERENCE FEATURES

Feature set	Accuracy (%)	Sensitivity (%)	Specificity (%)
All coherence features	88.94	85.90	89.36
All selected features	92.25	91.45	92.99
Selected intra-hemispheric features	93.68	93.70	92.51
Selected inter-hemispheric features	96.82	97.82	96.92

TABLE II. PERFORMANCE OF SVM CLASSIFIER WITH RBF KERNEL IN THE CLASSIFICATION OF COHERENCE FEATURES

Feature set	Accuracy (%)	Sensitivity (%)	Specificity (%)
All coherence features	86.39	84.10	87.91
All selected features	91.12	90.34	92.02
Selected intra-hemispheric features	91.97	89.63	92.69
Selected inter-hemispheric features	94.70	93.85	95.55

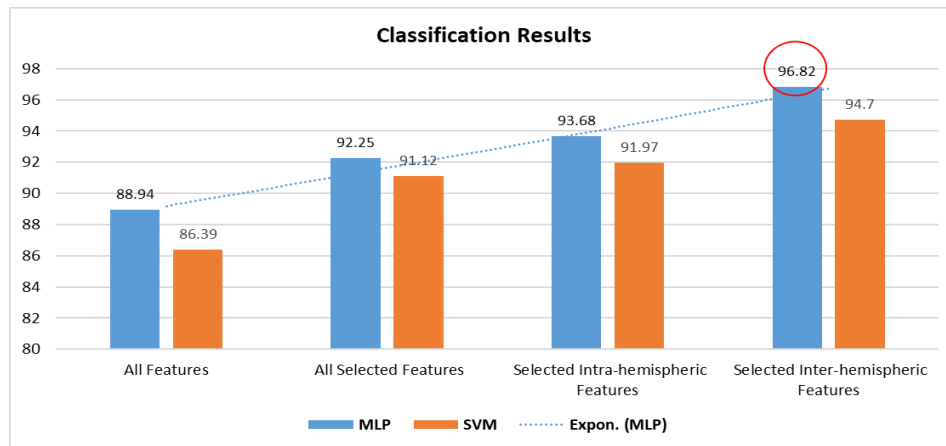

Fig. 7. Average accuracies obtained by MLP and SVM for coherence features extracted from EEG signals for mild and severe autism classification.

TABLE III. AVERAGE TIME OF CLASSIFICATION OPERATIONS USING MLP AND SVM CLASSIFIERS WITH AND WITHOUT FEATURE SELECTION

Operation	Time (s)
MLP classification without feature selection	40.82
MLP classification with feature selection	5.16
SVM classification without feature selection	0.62
MLP classification with feature selection	0.28

## V. DISCUSSION

In the present work, we attempted to investigate the potential of EEG coherence features in the classification of mild from severe autism and compare the ability of the MLP neural network and SVM classifier with RBF kernel to classify these features. Our findings showed that the MLP neural network has a better classification performance than the SVM classifier in the task of classifying the coherence features extracted from the EEG signals of two patient groups (96.82% versus 94.70%) at the cost of a more complicated computational process. The computation time of MLP classifier implementation was much longer than that of SVM. Very few similar studies have been published to date to classify mild from severe autism through brain signal analysis. For this reason, it is very challenging to compare the results of this research with other methods based on engineering algorithms. Cheong et al. applied wavelet transform to feature extraction from EEG signals and MLP classifier and reported an accuracy of 92.3% for classifying mild autistic patients from severe autistic patients [44]. In a three-class problem, Howell et al. [45] proposed a general linear model for feature extraction, a recursive feature elimination method for feature selection, and a random forest classifier to classify fMRI data into mild, moderate, and severe autism. They reported 72% accuracy on this three-class problem. Therefore, compared to the previous limited works in this field, our neural network-based system performs better. This can be due to the use of coherence features in the present work. Many electrophysiology and neuroimaging studies on autism spectrum disorders have shown that abnormality and impairment in brain connectivity are one of the most reported neuropathological mechanisms of autism [46-48]. Therefore, the coherence feature, which expresses the degree of coupling of different brain regions with each other, can be one of the strengths of our proposed system for classifying different severities of autism. In addition, it should be noted that most coherence impairments are located in the frontal region, consistent with previous neurophysiological works [49, 50].

Although SVM is a powerful classifier for two-class classification problems, MLP neural network was able to show better performance in the present work. However, the high computational cost of neural networks can limit their practical application in clinical systems [51-54]. Therefore, it is recommended to optimize the MLP neural network in order to reduce the calculation cost and improve the classification performance in future research. In addition, the investigation of other SVM kernels (such as linear, polynomial or sigmoid kernels) can also be done in future research. Furthermore, our results showed that feature selection through statistical analysis is a suitable approach to optimize the two-class classification problem of autism spectrum disorders. In fact, the feature selection approach adopted in this study led to improved classification performance and a significant reduction in computational cost. Therefore, future studies should do more research on the feature selection stage extracted from the EEG signals.

The strength of our study is to propose a simple semi-automatic system based on coherence features and a neural network for classifying mild autistic patients from severe

autistic patients from EEG signals. However, limitations such as the small sample size could reduce the generalizability of the results of the current research. Furthermore, in this work, the resting state EEG was analyzed, while previous neurophysiological studies have demonstrated that patients with autism spectrum disorders exhibit important neuropathological mechanisms in different states of arousal. Therefore, different EEG recording protocols should be considered in future studies.

## VI. CONCLUSION

In this paper, the classification of mild and severe autism from EEG signals was investigated by coherence features with MLP neural network and SVM classifier with RBF kernel. The effectiveness of these features was investigated via statistical analysis, and it was seen that coherence features with significant differences between the two groups have more discrimination in diagnosing autistic patients with different severities. In addition, the effectiveness of MLP and SVM was compared, and the MLP neural network yielded the maximum classification accuracy, sensitivity, and specificity. Considering that our simple system gives promising results in diagnosing autistic patients with mild and severe severities from EEG, there is scope for further work with a larger sample size and different ages and genders.

# Enhancing Breast Cancer Diagnosis using a Modified Elman Neural Network with Optimized Algorithm Integration

Linkai Chen\*, CongZhe You, Honghui Fan, Hongjin Zhu

Jiangsu University of Technology, School of Computer and Engineering, Zhongwu Road No.1801, Changzhou, China, 2130011

**Abstract**—Breast cancer is a class of cancer that starts in the cells of the breast. It happens once the cells of the breast divide and amplify abnormally and uncontrollably. Other parts of the body, including lymph nodes, bones, lungs, and liver, can be affected by breast cancer. Early diagnosis and treatment are critical in helping to lessen the risk of death from breast cancer. Machine learning is a type of artificial intelligence that can be used to diagnose breast cancer. It uses algorithms to analyze data and assess patterns associated with breast cancer. Machine learning models can help improve diagnostic accuracy, reduce false-positive results, and improve the efficiency of diagnosis. Elman Neural Networks (ENNs) are machine learning algorithms that can be used to diagnose breast cancer. ENNs use medical data to detect patterns that are associated with the presence of cancer. The accuracy of ENNs in diagnosing breast cancer is still being researched, but they have the potential to help improve diagnostic accuracy and reduce false-positive results. In the existing study, a new modified version of ENN founded on a combination of an upgraded version of the imperialist competitive algorithm is proposed for this objective. Likewise, the results of the model compared with some other methods illustrated the proposed method's higher efficiency.

**Keywords**—Breast cancer model; Elman Neural Network; upgraded imperialist competitive algorithm

## I. INTRODUCTION

A class of cancer that begins in the cells of the breast is called breast cancer. It occurs once the cells in the breast start to expand abnormally and uncontrolled. It can affect both men and women, although women are more likely to be diagnosed with it than men [1]. The advantage of recognizing breast cancer in the initial steps is that it can significantly increase a person's chances of survival and decrease the risk of complications from surgery and other treatments [2]. Early treatment is also more likely to be successful, as tumors are generally smaller when detected in their earliest stages. Furthermore, early detection can reduce the risk of cancer spreading to other organs in the body.

The use of AI, machine learning, and computer-aided detection (CAD) technologies can help with early breast cancer diagnosis [3]. The CAD utilizes algorithms to pinpoint potentially harmful areas in mammography images and compare them with existing patterns [4]. Moreover, AI-based automatic identification of tumors is becoming more precise and is allowing doctors to detect smaller, possibly more aggressive cancers sooner. Additionally, AI is the wing of

computer science focused on developing machines able to execute duties that usually demand human wit. ML (Machine learning) is a type of AI which involves algorithms and models that can “learn” from data to make decisions on their own [5].

An ANN (artificial neural network) is a type of ML algorithm inspired by how neurons work in the human brain to process information. It uses a large number of connected “neurons” to form an interconnected web of nodes [6]. Each node can take in data, process it, and pass it along to another node, eventually forming a prediction or classification.

Vijayakumar et al. suggested a technique based on DNN (deep Feed-forward Neural Network) with four Activation Functions (AFs) for the category of breast cancer [7]. Its purpose was twofold: increase understanding of how different AFs can be used in different layers of a DNN and develop a predictive model with improved accuracy. The model performance was evaluated using a 10-fold Cross Validation (CV) method and various metrics. Results showed that the proposed solution performed better than other AFs-based DNNs, making it a viable expert-level system for breast cancer dataset classification [6]. Also, the method provided better results than the other validated techniques.

Al-Haija et al. introduced a precise and comprehensive computational model for diagnosing breast cancer with the help of ResNet-50 CNN [8]. The given framework used the ResNet-50 CNN as a pre-trained neural network on ImageNet for the purpose of transferring learning to classify the BreakHis dataset into benign or malignant. The evaluation results demonstrated that their method attained outstanding classification accuracy, exceeding the performance of other models trained on a similar dataset.

Ahila et al. presented a bio-inspired algorithm to optimize variables of a neural network for computer-aided diagnosis of breast ultrasound images [9]. The preprocessing of the images involves sigmoid filtering, despeckling, and anisotropic diffusion, followed by extraction of the location of concern from which weave and morphological features are tallied. The classification task is achieved using a wavelet neural network tuned with grey wolf optimization, culminating in evaluating the model's performance against 346 images via the receiver operating and confusion matrix characteristic. Analysis shows this method produces higher accuracy than existing methods, thus proving its application in accurate tumor detection and classification. Among different kinds of artificial neural

networks, Elman Neural Network (ENN) is an artificial Recurrent Neural Network (RNN) type of Artificial Intelligence (AI) that can be used to analyze and identify patterns in data. It has a recurrent connection between its input and output layers, allowing it to remember the previous output when computing its current output. This memory enables the algorithm to learn from past experiences and apply them to future decisions. In this study, a modified form of ENN (Elman Neural Network) founded on a modified metaheuristic has been used in order to Model Breast Cancer. The method is a variation of the Elman Neural Network specifically adapted for breast cancer modelling. The modifications are designed to enable the algorithm to analyze hundreds of different features of the breast tissue in order to identify cancerous cells accurately. In this process, the modified Elman Neural Network can model the data.

In summary, this paper delves into the pivotal role of AI, machine learning, and neural networks in revolutionizing the early detection and accurate classification of breast cancer. Through an exploration of various models, including Elman Neural Networks, ResNet-50 CNNs, and optimized algorithms, we aim to illuminate the strides being made towards enhancing diagnostic accuracy and ultimately improving patient outcomes. The subsequent sections delve deeper into these methodologies, their applications, and the promising results they yield. By harnessing the power of technology and innovative approaches, we aim to contribute to the ongoing efforts in combating breast cancer and transforming the landscape of medical diagnosis.

## II. ELMAN NEURAL NETWORKS

ENNs are a Recurrent Neural Network developed by Ronald J. Elman in the late 1980s [10]. Unlike traditional feed-forward neural networks, Elman Neural Networks can retain and use information from previous inputs, allowing them to understand context and patterns over time better. This makes them particularly well-suited for processing time series data [11]. They have been used in various applications, such as predicting stock market prices and recognizing speech patterns.

The core components of the network are analogous to those in a feed-forward neural network [12]; the junctions between the input layer ( $W_h^i$ ), the hidden layer ( $W_h^h$ ), and the output layer ( $W_h^o$ ) are similar to what's found in a multi-layer neural network. As seen in Fig. 1, this is an overall representation of an Elman Neural Network.

Furthermore, Elman Neural Networks includes an extra layer known as the context layer ( $W_h^c$ ), which takes input from the hidden layer's outputs in order to store the values of the hidden layer from the prior step [11]. This is visible in Fig. 1.

It is assumed that the dimensions of both the output and input layers are  $n$ , such that:

$$x^1(t) = [x_1^1(t), x_2^1(t), \dots, x_n^1(t)]^T \quad (1)$$

$$y(t) = [y_1(t), y_2(t), \dots, y_n(t)]^T \quad (2)$$

While the context layer dimension is  $m$ .

The  $l^{th}$  input layer and the  $k^{th}$  hidden layers are undeniably essential for optimal functionality.

$$u_i(l) = e_i(l), \quad (3)$$

$$v_k(l) = \sum_{j=1}^N \omega_{kj}^1(l)x_j^c(l) + \sum_{i=1}^n \omega_{ki}^2(l)u_i(l) \quad (4)$$

where,  $i = 1, 2, \dots, n$  and  $k = 1, 2, \dots, N$ .

The  $\omega_{kj}^l(l)$  describes the hidden layers' weights from the  $o^{th}$  node and  $x_j^c(l)$  signals converted from the  $k^{th}$  the node of the context layer powerfully demonstrates that there should be. Therefore, the weight of the hidden layer  $k$  for the input layer  $i$  can be determined by  $\omega_{kj}^2(l)$ .

Therefore, the following approach can determine the last output of the hidden layer presented to the context layer.

$$W_k(l) = f_o(\bar{v}_k(l)) \quad (5)$$

where,

$$\bar{v}_k(l) = \frac{1}{\max(v_k(l))} \times v_k(l) \quad (6)$$

where,  $\bar{v}_k(l)$  specifies the hidden layer's normal value.

As a result, the context layer produces its output in the following way.

$$C_k(l) = \beta \times C_k(l-1) + W_k(l-1), \quad (7)$$

Such that  $W_k|_{k=1,2,\dots,N}$  defines the self-connected feedback between  $[0, 1]$ .

As a result, the Elman Neural Network's output layer has been gained as follows:

$$y_o(l) = \sum_{k=1}^N \omega_{ok}^3(l)W_k(l), \quad (8)$$

Such that,  $\omega_{zk}^3(l)$  specifies the connection weight from the  $k^{th}$  layer into the  $z^{th}$  layer, where,  $z = 1, 2, \dots, n$ .

Utilizing Ren et al.'s method [13], the structure of the ENN has been enhanced. This approach is executed according to the pseudocode provided in Table I.

Such that  $c$  is a constant,  $t$  specifies the recent iteration,  $\mu$  signifies the learning rate.

To maximize the effectiveness of the upgraded Elman Neural Network, it is essential to incorporate it with a metaheuristic algorithm. In this study, an upgraded version of the imperialist competitive algorithm has been utilized for this purpose.

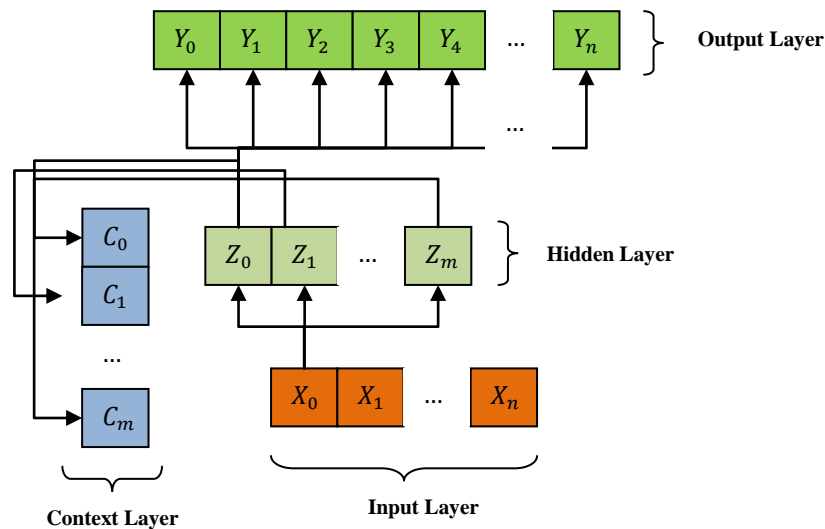

Fig. 1. Configuration of the Elman Neural Networks.

TABLE I. PSEUDOCODE OF THE IMPROVED ENN ON THE BASIS OF REN ET AL.'S METHOD [13]

Learning rate value initialization $\mu = \varepsilon$
<pre> In the lth iteration: if <math>l \leq 2</math> : <math>\mu = defaultvalue</math>; end if <math>t \geq 3 \&amp;\&amp; e(l) &lt; 1.02e(1 - 1)</math>: <math>\mu = \frac{c(1 + \frac{1}{l})^l}{exp(1)}</math> else <math>\mu = defaultvalue</math> end end Improve weights; compute <math>e(t)</math>; If stop criteria have been earned: stop; else carry on                     </pre>

### III. UPGADED IMPERIALIST COMPETITIVE ALGORITHM

#### A. The Conception of the Imperialist Competition Algorithm

As a population-based optimization approach, the Imperialist competition algorithm is introduced to solve optimization problems that take inspiration from human societal and cultural processes [14]. It begins with an initial population of random values and progresses toward an optimal solution by exploring the problem space, much like other population-based optimization methods.

This algorithm uses principles of assimilation, imperialistic competition, and revolution to solve complex optimization issues [15]. It takes the form of countries and gradually optimizes the solutions through an iterative process until it finds the best solution. As with other heuristic-based algorithms, it initiates with a haphazard initial population named "countries". A few of the highest-performing elements, akin to the GA elites, are then picked as "imperialists," while

the remainder is considered colonies [16]. These colonies were drawn to the imperialist based on their strength via a specific process. Any empire's power is determined by its imperialist country (as the central core) and its colonies.

The initial stage of the algorithm includes setting up the conditions for displaying the solution, generating the first group of entities, and forming the original colonies. The response will be shown as a vector with  $n$  components, where  $n$  is the quantity of orders and  $g$  is the number of pieces per order. Any piece must be manufactured  $n$  times, meaning it is repeated in each part number of the string [17]. Assembling begins by taking all parts that were created in the preliminary phase of production. The starting population of the ICA (the quantity of countries) is randomly generated. The algorithm stops when the set processing time elapses.

In order to ensure that a solution is always possible in the permutation display method for this problem, it is essential to observe the entire permutation and keep any operators from disrupting its completion [18]. To figure out the costs of each

country, their cost function is measured. From the number of empires, the participants in the candidates with the less cost function value are chosen as the remaining colonizers. The "Roulette wheel selection" technique is employed to split the colonies among the colonizers. This entails taking the cost of all colonists and computing their normalized cost with Eq. (9).

$$C_n = \exp(-c_n / \max c_i) \quad (9)$$

where,  $c_i$  describes the  $n^{th}$  imperialist cost value, and  $C_n$  signifies the  $n^{th}$  colonizer and  $n$  specify the normalized cost  $i$  of the maximum cost among all colonizers.  $n_E$  describes the number of empires. With  $\max c_i$  having a normalized cost, the normalized relative power of any colonizer is computed according to Eq. (10) and is the basis for dividing the colonized countries among the colonizers.

$$p_n = \left| \frac{c_n}{\sum_{i=1}^{n_E} c_i} \right| \quad (10)$$

And

$$\sum_{i=1}^{n_E} P_i = 1 \quad (11)$$

The roulette cycle technique is one of the most well-known selection approaches. Initially, the selection chance figures are organized nearby one another, and afterwards, a haphazard number in the scope of zero to one is made. This scope is chosen on the grounds that the aggregate of the determinations in likelihood will dependably be equivalent to one. The random number is compared to the roulette wheel interval to determine the colonizer that corresponds to it. Since the probability of each colonizer taking up a section of the roulette wheel, higher quality colonizers (with lower cost functions) are more likely to be picked. After assigning all countries to their respective colonizers, the process moves into a loop with the colonial competition algorithm, continuing until a set stopping condition is reached.

In every empire, the colonizing country tries to increase the number of its colonies in order to increase its influence; therefore, in each empire, the colonized countries move towards the respective colonizer. In the presented algorithm, the attraction policy is defined as follows: to change the colony based on the emperor, two points in the colony are selected and before and after these two points are removed; then the removed components are added to the solution based on their relative order in the colonizer.

The revolution brings about an abrupt alteration to a nation's social and political qualities. In the imperialist competition algorithm, revolution is simulated by moving an imperial country to a separate random position. From a computational standpoint, the revolution halts the evolutionary moves from getting stuck in a nearby optimum snare, potentially enhancing the spot of a nation and carrying it towards areas with a more desirable situation. In the presented algorithm, each colony within a respective empire may revolt with a designated likelihood.

In this Algorithm, 2 positions are randomly chosen and swapped. As a result of the migration to a colonizing nation and the implementation of policies of revolution, some of these countries might potentially move up in comparison to the

colonizer. This means that the colonizer and the colonized will exchange places with one another, and the algorithm will continue with the newly appointed ruling nation. This country can then begin to enforce assimilation policies on its colonies.

The might of the colonizing country as well as a ratio of the entire might of its colonies, is the entire power of an empire; Hence, the whole cost of an empire is calculated through Eq. (12):

$$TC_n = c_n + \zeta[\text{mean}(c_n^i)] \quad (12)$$

where,  $TC_n$  describes the whole cost of the  $n^{th}$  empire and  $\text{mean}(c_n^i)$  signifies the mean amount of the cost of the colonizer  $n$ ,  $\zeta$  is a positive integer. Any empire that cannot improve its power and lose its competitive power during the colonizer's competition will be eliminated. For modelling this fact, it is supposed that the empire being deleted is the feeble-existent empire. Therefore, in each iteration of the algorithm, one or a number of the weakest colonies are removed from the weakest empire, and a rivalry is created among every empire to take over these colonies. Noteworthy colonies will not necessarily be taken over by the strongest emperor. Rather, stronger empires are more likely to take over. For simulating the rivalry between empires to take over this colony, first of all, its normalized total cost is determined from the entire cost of the empire via Eq. (13):

$$NTC_n = \exp(-TC_n / \max TC_i) \quad (13)$$

$NTC_n$  describes the normalized total cost of the  $n^{th}$  empire,  $TC_n$  is the  $n^{th}$  empire, and  $\max TC_i$  is the total cost of the weakest empire.

With the normalized total cost, the probability of taking over the competing colony by each empire is calculated through Eq. (14):

$$P_{emp_n} = \frac{NTC_n}{\sum_{i=1}^{n_E} NTC_i} \quad (14)$$

With the possibility of taking over any empire, the said colony belongs to the empire that wins the Roulette wheel. In the proposed algorithm, when an empire having no colonies is added as a colony to another empire. Selection Empire is made through the roulette cycle.

This research introduces a modified version of the imperialist competitive algorithm (ICA) called the upgraded imperialist competition (UIC) algorithm that hopes to address the issues of being prone to local minima and slow convergence speeds. Despite its successes, the original algorithm still poses a challenge.

### B. Upgraded Imperialist Competition Algorithm

To avoid becoming stuck in a local optimum, population-based evolutionary algorithms can apply the concept of revolution (colonial competition) or mutation (genetic algorithm). This research specifically investigates the use of the Quad Countries Algorithm and its "rejection policy" in order to help populations escape from such traps.

The algorithm of the Quad Countries Algorithm is based on the ICA, and in addition to colonial and colonizing countries, two new types of countries with the names of independent

countries and countries seeking independence have been added to its set of countries [19]. Independent countries search the solution space randomly, and countries seeking independence distance themselves from colonizing countries according to a targeted policy called exclusionary policy.

In the basic Imperialist competitive algorithm, when the revolution operator is applied, firstly, the position of a number of colonial countries changes randomly, and secondly, it changes in the form of divergence (moving away from the colonizer).

While in the ICA, inspired by the policy of repelling the algorithm of the Quad Countries Algorithm, at the time of the revolution, firstly, the position of some colonial countries changed in a purposeful way, and secondly, it changes in the form of convergence (getting closer to the colonizer).

The purposeful calculation of the new position of the colonial countries when the revolution is applied is that the total distance between the colonizer and the target country is first calculated in all dimensions.

Then by multiplying the current position of the desired colony country by the resulting vector (Center), the desired country moves to a new position. This causes when the revolution operator is applied, the position of a percentage of the population elements is purposefully moved in the direction of the best element (the colonizer) to change.

$$Center = \sum(Col_i - Imp_j) \quad (15)$$

Eq. (15) shows how to calculate the Center vector. In this regard, first, the sum of the distances of all colony countries ( $Col$ ) with the colonizing empires ( $Imp$ ) is calculated. Then the product of this vector with a coefficient of 0.1 in the vector of the current position of the colony gives the new position of the colony country.

$$Col_i^{new} = Col_i^{old} \times (0.01 \times Center) \quad (16)$$

In the basic colonial competition algorithm, when a revolution occurs, the colonies move randomly in space and away from the colonizer, the best element of the empire, hoping to gain a better position in the problem space. While the colonies in the improved colonial competition algorithm avoid random movements while analyzing the movement of the best element of the group, they follow its movement and in order to reach a better position, not only do they not move away from the colonizer, but also according to their distance from the emperor. The leader's movement is inspired, and they step in that direction. This method makes all the colonies participating in the revolution process guess the optimal global location in the same number of algorithm iterations and converge around the global optimal point.

#### IV. OPTIMAL MODIFIED ENN USING UIC ALGORITHM

In the given section, the procedure for refining the ENN has been outlined. To refine the suggested ENN, the aim is to determine its best possible weights. This study implements a two-layered neural network for modelling purposes, as shown below:

$$\sum_{i=1}^H w_i \sigma(\sum_{j=1}^d w_j \times x_j + b) \quad (17)$$

Where  $H$  describes the hidden layer neurons' quantity,  $w$  signifies the network's weightings, the bias is defined by  $b$ , and the activation function for the neurons is defined by  $\sigma$ . The main steps for the developed ENN optimization can be outlined as follows:

- 1) Set the starting positions of the population.
- 2) Compute the error function value for all of the locations. The error function is achieved as follows:

$$Error = 0.5 \times \sum_{k=1}^g \sum_{j=1}^m (Y_j(k) - E_j(k))^2 \quad (18)$$

Where  $m$  is the output nodes quantity,  $g$  stands for the training set quantity, and the output of the real and the expected output value are defined, In turn, by  $Y_j(k)$  and  $E_j(k)$ .

- 3) Save the finest place of the population.
- 4) Adjust the locations of the population by moving closer (or away from) the neighbors founded on local attractive and repulsive forces.
- 5) Introduce the random solutions movement.
- 6) Analyze the termination criteria to determine if the network has achieved the desired error rate.
- 7) Should the termination criteria be met, proceed to step 9. Otherwise:
- 8) Utilize chaos dynamics to develop chaotic positions and go to phase 2.
- 9) Stop the process

#### V. SIMULATION RESULTS

This insightful study utilizes input variables to ascertain whether breast cancer is benign or malignant accurately.

##### A. Dataset Description

The objective of this study is to leverage input variables for predicting the classification of breast cancer as either malignant or benign. To achieve this, the researchers analyzed a dataset sourced from a Wisconsin Hospital's breast cancer patient records, which was accessible via the UCI machine learning repository [20]. This dataset comprises a total of 699 examples, each characterized by nine distinct features. It's noteworthy that among these samples, sixteen instances lack complete attribute information. Collectively, these data points are represented in the form of a 683x9 matrix, where each row corresponds to a patient's data entry.

Within the dataset, a fundamental division exists between two primary categories of breast tumors: benign and malignant. The analysis reveals that out of the entire dataset, 444 patients (approximately 65%) are diagnosed with benign tumors, while the remaining 239 patients (about 35%) are diagnosed with malignant tumors. This distribution of tumor types forms a critical foundation for the subsequent analysis and model development.

The essence of the dataset lies in its nine features, which play a pivotal role in determining the classification of breast cancer. These features encompass a diverse range of parameters, including clump thickness, uniformity of cell size, and uniformity of cell shape, marginal adhesion, single epithelial cell size, bare nuclei, bland chromatin, normal

nucleoli, and mitoses. Each of these attributes holds significance in differentiating between benign and malignant tumors.

By delving into these specifics, the study provides a more comprehensive context regarding the dataset's origin, its composition, the distribution of tumor types, and the significance of the individual features that contribute to the accurate classification of breast cancer.

Table II provides the descriptive statistics of the disease and its varying range [21]. The number of network inputs is nine parameters, as in similar studies in Table II. A confusion matrix is generally used to check the success and efficiency of disease classification and diagnosis systems. The analysis of this matrix in the classification and diagnosis of patients leads to four classes of TP, TN, FN, and FP (True Positive, True Negative, False Negative, and False Positive).

From the results of the confusion matrix, three indicators of sensitivity (accuracy of the system in detecting the malignant type), specificity (accuracy of the system in detecting the benign type) and precision (the proportion of all cases that were correctly classified) are obtained, which are used to analyse the performance of the classification systems. The algorithm used in this research is presented in Fig. 2.

As the algorithm shows, in this research, after separating the test and test samples and dividing them into two benign and malignant, cancer was modelled with the help of two different types of neural networks, including the Bayesian network [22] and the standard improved ENN to demonstrate its efficiency and the outcomes were compared with each other. During the simulations, 80% of the data are employed for training, and 20% are used for testing the dataset.

### B. Results and Discussions

This research examined 685 patients with breast cancer whose data was derived from the Wisconsin hospital in the

UCI machine learning database. The number of clinical variables in each patient equalled nine risk factors. In order to train the network, 80% of the patients (548 samples) were used. The remained 10% (137) were used to test the system. As the range for each of the nine disease risk factors ranged from one to ten, Tables III to IV illustrate their frequency distributions.

Several strategies have been presented in various studies to discover the relationships between breast cancer factors. The use of artificial neural networks to diagnose the type of cancer has been investigated in various studies. In this research, we tried to use the proposed modified ENN/UIC network to improve disease diagnosis.

The confusion matrix of the proposed modified ENN/UIC network compared with the Bayesian network (BN) [22] and the standard improved ENN is shown in Fig. 3.

Fig. 3 makes it abundantly evident that, as shown by the numerous metric indicators, the proposed modified ENN/UIC model beats the modified ENN model and BN model with regard to predictive ability. Remarkably, the improved ENN/UIC model offers a breast cancer model that is more accurate. Figure 4 indicates the comparison between the three types of networks used in this research [22].

In Fig. 4, using the suggested modified ENN/UIC model with 98.54% accuracy yield the best results when compared to the other approaches, including the ENN/UIC model with 96.78% and BN model with 97.95% accuracy. The simulation results show that applying the proposed strategy yields superior outcomes when compared. The results indicated that all three types of neural networks have the ability to predict breast cancer disease with high ability.

TABLE II. INPUT VARIABLES AS MATRIX COLUMNS INCLUDING NINE FEATURES TO DETERMINE THE TYPE OF CANCER [21]

Attribute	Domain
Clump Thickness	1-10
Uniformity of Cell Size	1-10

## VI. CONCLUSION

Among different cancers, one cancer that starts from breast cells is breast cancer. Both men and women are affected by this disease, but this cancer is more prevalent among women. Symptoms of breast cancer can consist of a mass in the breast, a change in the form or measure of the breast, variations to the skin over the breast, like puckering or dimpling, and a discharge from the tit. Breast cancer treatment can be various, contingent on the sort and phase of the disease, but may comprise chemotherapy, radiation therapy, surgery, hormone therapy, and aimed therapy. Many deep neural networks show excellent results in accurately classifying tumor cells. Therefore, a deep artificial neural network can be used along with other non-invasive diagnostic methods that are usually used (such as mammography and radiography), as a diagnostic support system with high sensitivity and specificity to identify benign and malignant breast tumors. The existing study aimed to diagnose benign and malignant breast cancer using a new method based on deep neural networks and an improved meta-heuristic algorithm. Since artificial neural networks based on

deep calculations in the diagnosis of diseases have attracted the attention of many researchers in recent years, therefore, in this research, a novel optimized and improved process was used for classifying the type of breast cancer into two categories, malignant and benign. First, a modified version of the Elman Neural Network was trained with samples. Then, it was optimized on the basis of an upgraded version of the imperialist competitive algorithm.

At last, the model was evaluated with test samples. The model validation was performed based on a breast cancer dataset of the Wisconsin hospital. For a failed comparison, the outcomes of the proposed technique were validated by two other methods, including the Bayesian network and the standard improved ENN without optimization. Outcomes showed that all three methods provide good accuracy for a cancer diagnosis; using the proposed method for this aim achieved higher accuracy.

Looking forward, advancements in nanotechnology hold the potential to revolutionize early detection and monitoring of

breast cancer. Researchers are exploring the development of highly sensitive and specific nanosensors that can detect subtle molecular changes associated with cancer cells. These nanosensors could be integrated into wearable devices, providing continuous monitoring of biomarkers in bodily fluids. This real-time data could offer clinicians valuable insights into disease progression and treatment response, enabling more precise and timely interventions. Moreover, the combination of nanotechnology with AI could enhance the accuracy of data interpretation, leading to earlier and more accurate diagnoses. While this field is still in its infancy, the convergence of nanotechnology and AI could pave the way for groundbreaking advancements in breast cancer management, ultimately improving patient outcomes and quality of life.

**Abstract**—Cardiovascular diseases (CVD) are the most prevalent causes of death and disability worldwide. Cardiac arrhythmia is one of the chronic cardiovascular diseases that create panic in human life. Early diagnosis aids physicians in securing life. ECG is a non-stationary physiological signal representing the heart's electrical activity. Automated tools to detect arrhythmia from ECG signals are possible with Machine Learning (ML). The ensemble learning technique combines the power of two or more classifiers to solve a computational intelligence problem. It enhances the performance of the models by fusing two or more models, which extremely increases its strength. The proposed ensemble Machine learning amalgamates the potency of Long Short-Term Memory (LSTM) and ensemble learning, opening up a new direction for research. In this research work, two novel ensemble methods of Extreme Gradient Boosting-LSTM (EXGB-LSTM) are developed, which use LSTM as a base learner and are transformed into an ensemble learner by coalescing with Extreme Gradient Boosting. Kernel Principal Component Analysis (K-PCA) is a significant non-linear dimensionality reduction technique. It can manage high-dimensional datasets with various features by lowering the dimensionality of the data while retaining the most crucial details. It has been applied as a preprocessing step for feature reduction in the dataset, and the performance of EXGB-LSTM is tested with and without K-PCA. Experimental results showed that the first method, fusion of EXG-LSTM, has reached an accuracy of 92.1%, Precision of 90.6%, F1-score of 94%, and Recall of 92.7%. The second proposed method, KPCA with EXGB-LSTM, attained the highest accuracy of 94.3%, with a precision of 92%, F1-score of 98%, and Recall of 94.9% for multi-class cardiac arrhythmia classification.

**Keywords**—Arrhythmia classification; ensemble learning; extreme gradient boosting; kernel PCA; LSTM; machine learning

## I. INTRODUCTION

Cardiovascular diseases have become a significant public health problem globally, accounting for an average of 30% of all deaths worldwide in 2008. With the rapid increase in the world population, cardiovascular disease prevalence has been on a steady rise, increasing related mortality and morbidity. Recent statistical data indicate that CVD caused 17 million fatalities in 2015 [1].

This rising trend in cardiovascular diseases presents a challenge to both developed and developing countries.

Moreover, they cause a major economic burden on nations due to the significant costs associated with treatment and management [2].

Each patient's clinical examinations and medical histories provide the basis of the conventional CVD diagnosis paradigm. These results are evaluated under a set of quantitative medical indicators to categorize the patients based on the taxonomy of medical disorders [3].

One of the most dangerous symptoms of heart disease is cardiac arrhythmia. Early arrhythmia prognosis is becoming more significant in heart failure research since it can support clinical patient treatment. Diagnosing potentially fatal cardiac arrhythmias now requires the competence of cardiologists [4].

Cardiac Arrhythmia is an abnormal phenomenon observed in the electrical activity of the human heart. The irregular heart rhythm indicates numerous complications in the heart chamber. This condition is due to an unhealthy lifestyle and various medical conditions [5]. Bradycardia and tachycardia are the two main categories of arrhythmias. Bradycardia is an arrhythmia in which the heartbeat is less than 60 beats per minute (bpm), while tachycardia is an arrhythmia in which the heartbeat can increase to 100 bpm [6]. A sudden onset of a cardiac problem, such as inadequate heart blood flow, shortness of breath, chest pain, fatigue, or unconsciousness, is how arrhythmia often occurs. Abnormal ECG indicates the symptoms. As a result, it's critical to recognize and address arrhythmia as soon as possible [7]. Cardiologists typically spend a lot of time classifying arrhythmias with great precision. Automatic arrhythmia classifiers based on AI algorithms can assist cardiologists in getting higher precision and spending less time diagnosing patients [8].

The Electrocardiogram (ECG) is a painless method to register the electrical impulse generated by the heart in a human being. It is a time-varying signal that reflects ionic current flow resulting from the contraction and subsequent relaxation of the heart [9]. ECG is composed of the P wave that corresponds to the electrical activity of the atria, the Q, R, and S waves composing the QRS complex that corresponds to depolarization of the ventricles, and the T wave that registers the repolarization of the ventricles [10]. Furthermore, the R-R intervals, the time difference between two R waves, can be

obtained from the QRS complex. The different components of the ECG signal have specific shapes in the time and frequency domains, which allow specialists to detect possible anomalies by analyzing the ECG signal in these two domains. Moreover, the ECG signal is stochastic and can include abnormal components such as narrower or wider QRS complexes. The abnormal ECG signal can provide important information about cardiac abnormalities and may aid in diagnosing various heart conditions. However, there is still much to learn about the ECG signal and its uses in clinical settings. In recent years, researchers have made significant progress in enhancing the accuracy and efficacy of ECG signals [11].

The ECG signal is a crucial diagnostic tool for identifying heart diseases and assessing cardiac health, so understanding its properties and analysis techniques is paramount. The abnormal heart rhythms are recorded through ECG to help the physicians identify the abnormal rhythm. Earlier diagnosis of irregular beats can avoid various cardiac complications. Prediction of cardiovascular disease is a tedious process for the cardiologist. Hence, the automated arrhythmia diagnosis will assist clinicians in diagnosing and providing timely patient treatment, averting fatalities [12].

The situation will worsen in areas with inadequate medical professionals and clinical equipment, particularly in emerging nations. This drives the need for a trustworthy, automated, affordable monitoring and diagnosing system. The need for this is growing among healthcare professionals so that using computer-aided diagnosis (CADS) systems can be linked to doing the necessary medical assessments [13].

ML is a powerful tool playing a pivotal role in every field, such as Healthcare, Text classification, Plant disease classification, Robotics, Compression, Banking, etc., [14 - 20].

With advancements in technology and signal processing techniques, the accuracy of ECG signal analysis has significantly improved. Furthermore, using ML algorithms has shown promising results in enhancing accuracy in diagnosing arrhythmia.

The significance of effective and precise arrhythmia categorization and detection is becoming more evident with the advent of remotely controlled healthcare systems for heart disease patients. Over the past several years, various ML techniques have been built into diagnostic systems to help with the difficult challenge of accurately classifying arrhythmias from recorded ECG data. Selecting the best methods for identifying and categorizing cardiac disease might be challenging. It entails considering context, analyzing data, and the needs of particular patients' details [21].

Effective ML techniques enable implicit programming-free ML. The goal is to create an algorithm that can take a set of patterns and automatically generalize from preliminary data with or without human intervention. Cluster analysis, or clustering, is a component of unsupervised ML techniques [22-26].

Recently, boosting algorithms have been applied to accelerate the performance of ML algorithms. The concrete objective of this research work is to develop ensemble learning for predicting cardiac arrhythmia challenges.

The novelty of the article includes the following significant contributions:

- Development of Ensemble Model for effective Arrhythmia classification.
- Implementation of fusion of Stacked LSTM and XGBoost algorithms in the classification.
- Application of K-PCA for Feature Reduction.
- Identification of 16 types of arrhythmias with enhanced accuracy by hyper-parameter tuning.
- Validation and comparison of the performance of the proposed models with state-of-the-art methods.

The organization of the paper is outlined as follows. Section I presents the introduction. Section II elaborates on the literature survey in related fields and datasets. Section III presents a brief note on the dataset used for experimentation, followed by the methods used for classification. Section IV depicts the experiments and results obtained, followed by a discussion. Finally, the work is concluded in Section V.

## II. LITERATURE REVIEW

Numerous methods are currently available for classifying heart arrhythmias. Some techniques use ML techniques, including support vector machines, neural networks, decision trees, and K Means. This section presents a brief survey of ML and DL-based methods for arrhythmia classification.

Ozcift et al. focused on the following two strategies: i) To choose pertinent characteristics from the cardiac arrhythmia dataset, using a correlation-based feature selection algorithm. ii) The effectiveness of the suggested training method is assessed using the performance of selected features with and without simple random sampling using the Random Forest (RF) ML algorithm. This method achieved an accuracy of 90% [27].

Namsrai et al. developed a new ensemble method using feature selection schema to derive several feature subsets from the original dataset. The feature subsets are then used to train classification models, and the classification performance of each feature set is combined with a voting approach. The ensemble classifier reportedly beats the classifiers learned on the original dataset by 7.28 % for Naive Bayes (NB), 2.27 % for the Support Vector Machine (SVM), 17.84 % for the Decision Tree (DT), and 13.43 % for the Bayes Network of F-score [28].

Guvendir et al. presented a Voting Feature Intervals (VFI), a supervised ML algorithm for detecting arrhythmia classification. A majority vote among the class predictions produced by each characteristic individually is the basis for how it operates. The VFI algorithm performs better than other standard algorithms like Naive Bayesian and K-Nearest Neighbour (KNN), according to comparisons [29].

Freund et al. proposed a novel Adaptive Boosting (AdaBoost) algorithm and the ensemble technique based on the Adaptive Boosting algorithm by engrafting the decision tree into a framework. They created the new boosting algorithm by

using the multiplicative weight update technique. This boosting approach doesn't need any prior understanding of how well the weak learning algorithm performs. Additionally, they investigated how the novel boosting approach can be applied to problems involving learning functions whose domain, rather than being binary, is an arbitrarily finite set or a bounded segment of the real line [30].

Friedman et al. developed a general gradient descent boosting paradigm for additive expansions based on any fitting criterion. Tools for analyzing Tree Boost models are described, and special enhancements are built for the particular case where the individual additive components are regression trees. Gradient boosting of regression trees generates highly competitive, dependable, and comprehensible regression and classification algorithms that are particularly suitable for mining imperfect data [31].

Khemchandani et al. developed Twin SVM (TSVM) since conventional SVM has computational complexity. The developed twin SVM is faster in computation and has good generalization for binary classification [32].

Dhyani et al. employed SVM and the 3D Discrete Wavelet Transform (DWT) to characterize and analyze ECG signals. SVM is used to classify the ECG using the nine types of heartbeats identified by the different classifiers. In comparison to the complex support vector machine (CSVM) 98.5% and weighted support vector machine (WSVM) 99%, the SVM classifier has a normal precision of 99.02% [33].

Mohanty et al. experimented with the Cubic Support Vector Machine (CSVM) and the C4.5 classifiers for the classification of Ventricular Fibrillation (VF), ventricular tachycardia (VT), and normal sinus rhythm (NSR). Early detection and prevention of ventricular arrhythmias require the ability to predict VT and ventricular fibrillation VF. By combining temporal, spectral, and statistical data, the researchers described a method for identifying and categorizing VT and VF arrhythmias. The results of this study indicate that the suggested approach outperformed cubic SVM, which had an accuracy of 92.23%, with a sensitivity of 90.97%, specificity of 97.86%, and accuracy of 97.02% in the C4.5 classifier [34].

Yadav et al. determined the significance of particular elements pertinent to diagnosing cardiac arrhythmia. They employed a random forest classifier model, measuring the significance of many features like blood pressure, sodium, potassium, calcium, and respiratory rate, among other features. Hyperparameter optimization methods like grid search and genetic algorithms are compared to find the maximum number and depth of trees in the forest. Area Under the Receiver Operator Curve (AUC) score of 0.9787 was the model's highest performance [35].

Kumari et al. researched classifying arrhythmias more accurately and quickly than before. The research uses an SVM classifier using Discrete Wavelet Transform (DWT). DWT was used to extract 190 features from the prepared data. The SVM classifier, which is the best for classification, was given the retrieved features. The testing set was used to assess the results,

and a confusion matrix was used to plot the final results. The model's performance accuracy is 95.92 % [36].

Taher et al. tested with a fusion-based model, which is used to choose the highest-ranked features most effectively. The fusion's output is subsequently subjected to an ensemble of classifiers. High-ranked features acquired from several heuristic feature-selection algorithms are fused using a fuzzy-based feature-selection fusion method. The three primary sections of the work are sensing data and preprocessing, feature queuing, selection and extraction from features, and the predictive model. The method performs classification tasks with higher accuracy, F1 measure, recall, and precision. For binary and categorized class modes, respectively, it obtains an accuracy of 98.5% and 98.9% [37].

Ayar et al. suggested a model for binary and multi-class classification, and the model used genetic algorithms for feature selection and the C4.5 algorithm with DT for classification. The average accuracy for binary classification was 86.96%, and for multi-class classification, it was 78.76% [38].

Jadhav et al. proposed an approach based on feature elimination to diagnose arrhythmia in binary classification. With ensemble sizes of 15 and 20, the random subspace ensemble classifier can identify arrhythmias with an accuracy of 91.11% [39].

Khan et al. (2018) depicted a two-stage cascade structure technique for categorizing cardiac arrhythmia. The first stage used logistic regression (LR), DT, and RF to classify arrhythmias. In contrast, the second stage used Multi-Layer Perceptron's (MLP) and then LSTM to classify arrhythmias into many classes and binary classes. The accuracy obtained by the first experiment for the LR, DT, and RF was 83.0%, 85.4%, and 87.5%, respectively. The accuracy obtained for the MLP and LSTM experiments was 89.0% and 94.8%, respectively [40].

Itzhak et al. proposed a study on detecting three forms of arrhythmia: Atrial fibrillation, bradycardia, and tachycardia. The authors used random forest, SVM, and logistic regression as classifiers. Their best result was a multiclass random forest classifier that performed with a sensitivity and specificity of 0.92 and 0.86, respectively [41].

Chang et al. found 12 different cardiac rhythm classes using an LSTM model. The LSTM model had an accuracy of 0.982 and an AUC of 0.987 for classifying each of the 12 cardiac rhythms. The F1 score was 0.777, and the precision and recall were 0.692 and 0.625, respectively [42].

Xu et al. developed an innovative ML approach called the Twin Support Vector Machine (TSVM), which seeks to identify two nonparallel planes for each class. The binary classification issue can be solved using traditional TSVM. The multi-class categorization problem can be solved with the Twin-KSVC multi-class classification technique. It combines the benefits of the Support Vector Classification Regression Machine for K-class classification (K-SVCR) with both TSVM and K-SVCR [43].

Mustaqeem et al. selected the wrapper feature selection method in conjunction with SVM-based methods like one-against-one (OAO), one-against-all (OAA), and an error-correction code (ECC) for determining whether an arrhythmia is present or absent. Kappa statistics, accuracy, and Root Mean Square Error (RMSE) measures are used to measure the performance. OAO outperformed all others by scoring 92.07% [44].

Khan et al. tested with Principal Component Analysis (PCA) for feature reduction technique in classifying arrhythmia. The Deep Learning (DL) architecture LSTM is used for classification. An accuracy of 93.5% was attained using PCA and LSTM together [45].

Chen G et al. suggested a wrapper method called Cosine Similarity Measure Support Vector Machines (CSMSVM) by introducing the cosine distance into SVM to reduce features. Traditionally, feature selection methods have extracted features and learned SVM parameters separately or in the attribute space. This may have led to a loss of information about the classification process or increased classification error when the kernel SVM was included. The suggested CSMSVM framework combines feature selection, SVM parameter learning, and removing low-relevance features to achieve better performance [46].

Chandrashekar et al. experimented with several feature selection methods since each underlying algorithm will respond differently to different data types. Using feature selection approaches demonstrates that more information may not be better in ML applications. The feature selection technique for the application is chosen based on the following factors: simplicity, stability, number of reduced features, classification accuracy, storage needs, and computing requirements. It will have advantages like stronger classifier models, improved generalization, and identification of irrelevant variables [47].

Celin et al. used filtering techniques such as low pass, high pass, and Butterworth filter to eliminate the high-frequency noises. The peak detection algorithm is used to locate the peaks, and statistical parameters extract the signal's features. The ML classifiers SVM, Adaboost, ANN, and NB were implemented. The accuracy of the SVM, Adaboost, ANN, and NB classifiers is 87.5%, 93%, 94, and 99.7%, respectively, according to experimental results [48].

Park. J et al. suggested a novel heartbeat classification model that combines an adaptive feature extraction approach and cascade classifiers. The cascade classifiers are constructed from two different random forest classifiers. This can be used with normalized beat morphology features in an environment with limited resources. This model's accuracy was 97.34 %. The random forest classifier was chosen to reduce computational costs and memory even though the k-NN classifier performed better on the initial feature set [49].

Amorim et al. implemented Contourlet, and Shearlet transforms to separate ECG signals into different frequency bands and then extracted features from time-frequency coefficients. They evaluated the performance of KNN, SVM, and Random Forest classifiers on these collected features to

categorize seven different forms of beat arrhythmia. With an accuracy of 91.32% and a sensitivity of 90.23%, they used features based on contourlet transforms to get the greatest performance for random forests [50].

Romdhane et al. presented a CNN model to design an algorithm for heartbeat segmentation. This approach is straightforward and efficient because it doesn't need any signal processing that depends on prior knowledge of the signal's morphology or spectrum. The work focused on imbalanced datasets and designed a deep CNN model using a novel focal loss function. The evaluation's findings showed that the targeted loss function increased the overall metrics and the classification accuracy for imbalanced classes. Our suggested strategy achieved 98.41% accuracy, 98.38% F1-score, 98.37% precision, and 98.41% recall [51].

Sharma et al. employed both noisy and denoised (clean) ECG signals. The ECG signals were wavelet decomposed using a dyadic orthogonal filter bank with stop-band energy (SBE) minimization. Characteristics based on fuzzy entropy, Renyi entropy, and fractal dimension were then extracted for a quicker and more precise classification into the five classes. These features were then fed into classifiers, with the KNN classifier attaining maximum accuracy (MAAC) of 98.1%, maximum sensitivity (MASE) of 85.63%, and maximum specificity (MASP) of 98.27% for clean data and MAAC of 98.1%, maximum sensitivity (MASE) of 85.33% for noisy data. This technology can be utilized in intensive care units to help clinicians make fast diagnoses [52].

Chen et al. developed a novel methodology of piecewise linear splines for feature selection and a gradient-boosting algorithm to classify atrial fibrillation and other cardiac dysrhythmias. A piecewise linear spline is used to fit the ECG waveform, and morphological properties associated with the coefficients of the piecewise linear spline are retrieved. The morphological coefficients and heart rate variability features are categorized using XGBoost. The algorithm received an average F1 score on the independent testing set of 81% and an F1 score on a 10-fold cross-validation of 81%. With certain morphological features, the system performs well on multi-label short ECG classification [53].

Assodiky et al. employed LSTM to categorize the types of arrhythmias, using AdaDelta as the adaptive learning rate method and improved performance. It was contrasted with LSTM, which lacked an adaptive learning rate. The best outcome that demonstrated great accuracy was produced by combining LSTM and AdaDelta. The accurate classification rate for train and test data was 98% and 97%, respectively [54].

Although the aforementioned techniques have shown some reasonable accuracy in classifying arrhythmias, more work has to be done, such as increasing accuracy. Most arrhythmia classification techniques currently in use are based on traditional ML techniques, which emphasize careful feature selection and classification less. DL techniques have found widespread usage due to the quick development of tools for working with high-dimensional data and advancements in computing power. Despite several research works reported in the literature, there is still a pressing need for novel strategies

to improve the accuracy and effectiveness of classification models for Arrhythmia.

### III. MATERIALS AND METHODS

#### A. Experimented Dataset

The proposed research work has been experimented with the Arrhythmia dataset available in the UCI Irvine ML repository. The dataset contains data on 452 patients in total, and each record has 279 features that describe the traits of an arrhythmia. Age, sex, height, and weight are the first four characteristics that best describe the subject. The remaining 274 features are taken from recordings of typical 12-lead ECGs. The heart muscle depolarizes during each heartbeat, causing small electrical changes on the skin that are detected and amplified by the ECG. A 12-lead ECG captures 12 distinct electrical heart impulses at approximately the same time. Arrhythmia data has an extensive feature size, which may need a feature reduction approach. It has numerous missing values. Some columns with missing values are eliminated, and the experiments are carried out. The goal is to categorize cardiac arrhythmia into one of the three categories and to distinguish between its presence and absence. Class 01 denotes regular ECG classes, Class 02 through Class 15 denotes various arrhythmia classes, and Class 16 denotes the remaining unclassified ones [63].

#### B. Methods

The proposed work reports on two methodologies EXGB-LSTM and KPCA-EXG-LSTM. The proposed methods classify arrhythmia through a pipeline that includes extreme boosting and stacked LSTM together and implemented in the preprocessed dataset. The flow diagram of the proposed work is shown in Fig.1.

Fig. 1. A flow diagram of EXG-LSTM with K-PCA.

The implementation of the proposed model EXGB-LSTM is shown in the Algorithm 1.

<b>Algorithm 1 EXGB-LSTM</b>
<b>Input:</b> UCI Arrhythmia Machine Learning Dataset
<b>Output:</b> Classification of 16 classes of Arrhythmia
<b>Begin</b>
<b>Phase I : Data Cleaning</b>
Eliminating columns with more number of missing values.
<b>Phase II : Applying Stacked LSTM with XGBoost</b>
Fusion of Stacked LSTM with XGBoost in the Processed dataset.
<b>Phase III: Multi-Class Classification of Arrhythmia</b>
<b>End</b>

In the second method, the dataset is dimensionally reduced by K-PCA, followed by ensemble learning using LSTM and extreme boosting and classification. The steps of the proposed K-PCA with the EXGB-LSTM model are outlined below in the Algorithm 2.

<b>Algorithm 2 K-PCA + EXGB-LSTM</b>
<b>Input:</b> UCI Arrhythmia Machine Learning Dataset
<b>Output:</b> Classification of 16 classes of Arrhythmia
<b>Begin</b>
<b>Phase I : Data Cleaning</b>
Eliminating columns with more missing values.
<b>Phase II : Dimensionality Reduction using Kernel-PCA</b>
<b>Phase III: Applying Stacked LSTM with XGBoost</b>
Fusion of Stacked LSTM with XGBoost in the Processed dataset.
<b>Phase IV : Multi-Class Classification of Arrhythmia</b>
<b>End</b>

#### C. Kernel Methods

Dimensionality reduction plays a significant role in effectively handling massive dimensional data. The motive of dimensionality reduction may be noise reduction, pre-processing, compression, etc. PCA is a mathematical approach to converting several correlated variables into uncorrelated variables known as Principal components (PC). This PC represents the maximum variance in the dataset. PCA works only for linear structures, and K-PCA has been developed as a non-linear extension of standard PCA. The primary notion of K-PCA is to map the original data into a huge dimensional space through a specific function and then implement the PCA algorithm to it. The linear PCA of the vast dimensional feature

space represents a non-linear. Most interesting directions can be found in the original input space by the PCA [64]. It is mainly applied in complex non-linear data such as 3D reconstruction, handwritten digits, bioinformatics face images, natural signals, and geostatistics kriging. Various kernel methods include polynomial, Gaussian, Laplace Radial Basis Function, Sigmoid, and hyperbolic tangent. One of the merits of K-PCA is that original data can be regenerated from its principal components [65] in the following three steps.

- Computing Covariance Matrix

The Covariance Matrix(C) is used to represent the relationship between two random variables and is defined in Eq. (1):

$$C = \frac{1}{n} \sum_{i=1}^n \phi x^i \phi x_i^T \quad (1)$$

where  $\phi x^i$  represents the input feature space,  $x^T$  represents the Transpose and  $x^i$ , is one of the 'n' multivariate observations. Also, the mean of the data in the feature space is assumed to be zero.

- Decomposition of Eigenvalues

Eigen decomposition of an input data distribution results in the generation of eigenvectors, which form the principal components of the data as given in Eq. (2):

$$\lambda v = Cv \quad (2)$$

where 'λ' is the eigenvalue and 'v' is the eigenvector which is a linear combination of samples.

- Selection of Eigenvectors and transform data

A function that holds the vectors in the original input space and when the dot product of the vectors in the feature space is returned then it is known as a kernel function as is shown in Eq.(3):

$$K(x_i, x_k) = \phi x_i^T \phi x_k \quad (3)$$

Kernel extracts up to 'n' samples in non-linear PCs without expensive computations [65].

#### D. LSTM

A conventional Recurrent Neural Network (RNN) is an extension of a feedforward neural network that can handle variable lengths of sequential input, also called an Auto Associative or Feedback Network. The neural network model is structured to preserve previously hidden neurons' output, and it is fed as input to the next cell [66]. LSTM was first proposed in 1997 by Sepp Hochreiter and Jurgen Schmidhuber. A modified version of RNN makes each recurrent unit adaptively capture dependencies of different time scales. It has a forget cell to modulate the flow of information. RNN suffers from complex training time for longer sequences and vanishing gradient problems. LSTM was structured to eliminate gradient problems with three gates namely, an input gate  $i_t$ , an output gate  $o_t$ , and forget gate. . The design of the LSTM cell is represented in Fig. 2.

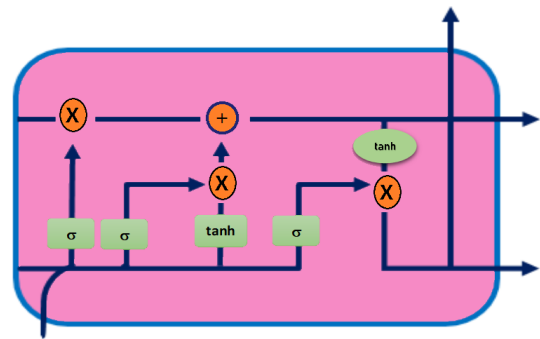

Fig. 2. LSTM cell.

The Model of LSTM is working in principle by representing the input sequences as  $\{x_1, x_2, x_3, \dots, x_t\}$ ,  $\{y_1, y_2, y_3, \dots, y_t\}$  as an output sequence and  $\{S_1, S_2, S_3, \dots, S_t\}$  as an internal sequence of cell states.

In the LSTM cell, the three gates are computed with Eq.(4-5):

$$i_t = \sigma (W_i \cdot [y_{t-1}, x_t] + b_i) \quad (4)$$

$$f_t = \sigma (W_f \cdot [y_{t-1}, x_t] + b_f) \quad (5)$$

$$O_t = \sigma (W_o \cdot [y_{t-1}, x_t] + b_o) \quad (6)$$

where  $W_i$ ,  $W_f$ , and  $W_o$  denote the weight of the corresponding input, and  $b_i$ ,  $b_f$ , and  $b_o$  are the respective bias in the cell. The activation function sigmoid is represented as 'σ' in the equation.

The candidate state  $\hat{S}_t$  is computed with the Eq. (7):

$$\hat{S}_t = \tanh (W_s \cdot [y_{t-1}, x_t] + b_s) \quad (7)$$

The current cell state value  $S_t$  is calculated from the previous cell state value  $S_{t-1}$  using Eq. (8):

$$S_t = f_t * S_{t-1} + i_t * \hat{S}_t \quad (8)$$

The output of the cell  $y_t$  is determined by Eq. (9):

$$y_t = o_t * \tanh(S_t) \quad (9)$$

The input gate in the LSTM model chose what to store in the current cell. The output gate determines what is to be passed over. The forget gate determines how to forget the current state [65].

#### E. Stacked LSTM

Multiple hidden layers in stacked LSTM architectures can be used to increase the amount of abstraction gradually. They operate better because they give a more accurate representation of sequence data. In the stacked LSTM architecture, the input from the previous LSTM hidden layer is passed into the current LSTM hidden layer. This has the potential to improve neural network performance significantly. Including enough layers in the model improves the LSTM model's accuracy and dependability. Fewer neurons are needed in each layer, which cuts down on training time. In this study, a stacked LSTM network is suggested with the fusion of XGBoost [67, 68]

F. Extreme Gradient Boosting

The eXtreme Gradient Boost (XGBoost) is a decision tree-based algorithm that transforms weak learners into strong learners. Boosting is an iterative algorithm compared to bagging, a parallel algorithm. The computational procedure for constructing a decision tree in gradient boosting is very time-consuming. XGBoost is an optimized version of the gradient boosting algorithm, which improves the training time. Many models were trained on different subsets of data, and the best-performing model was chosen. It is best suited for non-linearity problems [69, 70]. Combining the models is part of ensemble learning, where different models are combined to optimize the algorithm's performance. Stacking is one of the usual processes in combining models and training an ensemble model on the classification, enabling convenient experimentation and model comparisons. Even though Light Gradient Boosting is faster when compared with the performance it is equivalent [71-73]. The framework of the developed method is presented in Fig. 3.

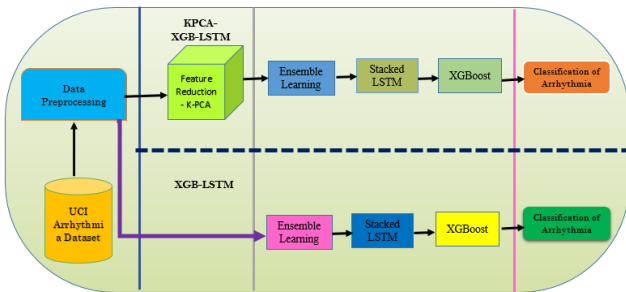

Fig. 3. A framework of EXG-LSTM with K-PCA.

IV. EXPERIMENTATION AND ANALYSIS

A. Experimental Setup

The proposed model uses an Intel Core(R) i5-9300H CPU running at 2.40 GHz, an NVIDIA GeForce® GTX 1050 graphics card, a 64-bit operating system, and 8GB of RAM.

The experiment on ensemble LSTM was carried out with the Arrhythmia dataset. The medical dataset consists of 206 linear valued features and a few categorical features among the 279 features. 452 instances are present in the dataset. It has been distinguished into 16 groups to indicate the existence and non-existence of arrhythmia. Class 1 shows healthy or normal samples. The total number of healthy samples is 245. Classes 2-15 are categorized as different types of arrhythmias. Class 16 indicates the other unclassified arrhythmia. As the dataset may have null values for certain features. Those features having more missing values are removed during the pre-processing stage. The remaining features with fewer missing values are treated by the statistical mean method. The proposed work was tried in two different ways. The dataset was chosen directly after applying data cleaning and data normalization methods to implement LSTM in the first experiment. To improve the performance of LSTM, XGBoost was added, and it showed a better performance. In the second method, the dataset was further subjected to feature reduction by K-PCA sequentially followed by the stacking LSTM with XGBoost. The parameters used for K-PCA is listed in the Table I.

TABLE I. EXPERIMENTAL PARAMETERS

Experimental Parameters for K-PCA		Values
n_components		94.3
Kernel		rbf
Gamma		0.04
Alpha		0.03
fit_inverse_transform		True
eigen_solver		Auto
n_jobs		-1

The dataset is split into 80/20 for training and testing. The results obtained by both proposed methods are shown in Table II.

TABLE II. PERFORMANCE OF PROPOSED METHODS

Classifier	Accuracy	Precision	F1-score	Recall	No. of Features
EXG-LSTM	92.1	90.6	94.0	92.7	252
KPCA+EXG-LSTM	94.3	92.0	98.0	94.9	135

The proposed model EXG-LSTM reached an accuracy of 92.1%, a precision of 90.6%, a recall of 92.7%, and an F1-score of 94 % with the features 252. The second method performed exceptionally well when applying K-PCA compared with the result of EXG-LSTM by accomplishing an accuracy of 94.3%, a precision of 92 %, a recall of 94.9%, and with an F1-score of 98% by reducing the feature into 135. The proposed methods' results are compared with the state-of-the-art techniques presented in Table II. Using the cardiologist as the gold standard, the attempt is made to lessen this difference by utilizing ML methods.

TABLE III. PERFORMANCE OF THE PROPOSED METHODS WITH STATE-OF-THE-ART METHODS

Authors	Classifier	Accuracy	Class
Zuo et al. [55] (2008)	KDF-WKNN	70.66	2

<b>Proposed Method 1</b>	<b>EXG-LSTM</b>	<b>92.10</b>	<b>16</b>
<b>Proposed Method 2</b>	<b>KPCA+EXG-LSTM</b>	<b>94.30</b>	<b>16</b>

Table III clearly reveals the superior performance of our proposed methods. It is worth noting that our proposed methods are capable of classifying 16 classes of arrhythmia with the highest accuracy of 94.30 when compared with state-of-the-art methods as depicted in Fig. 4.

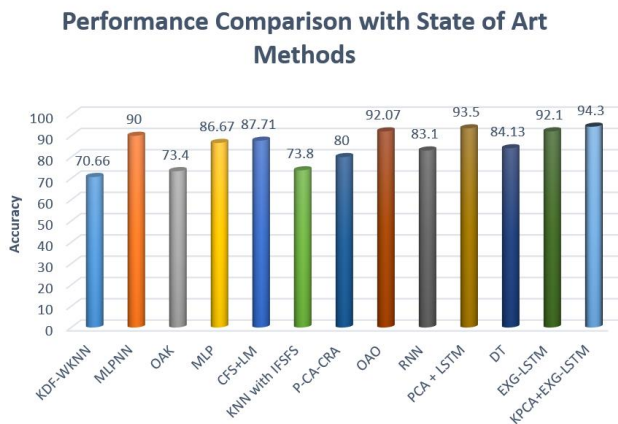

Fig. 4. Proposed models with state-of-the-art methods.

Arrhythmias are potentially fatal. Hence, it is imperative that prediction and analysis be employed in the medical profession with the greatest possible accuracy. The proposed approach highlights these issues by selecting a few notable features using a feature selection mechanism, which enhances classification efficiency.

#### V. CONCLUSION

A novel hybrid DL pipeline for multi-class Arrhythmia classification has been proposed. This approach involves selecting maximally distinct features using the feature selection technique and helps improve the performance of the classification of arrhythmia data. The work implied Kernel-PCA and a Stacked LSTM DL technique with the fusion of XGBoost for classification to determine whether an arrhythmia was present or absent. This research work aims to upgrade the performance of LSTM through the novel pipeline with XGBoost. It was good in its execution and recorded a high accuracy of 92.1%. Concurrently, feature reduction was done, and the performance of the ensemble of LSTM is monitored. Both the proposed models performed well. Among them, EXG-LSTM with K-PCA has reached the highest accuracy of 94.3%. This research works on stacking LSTM shows that the strength of LSTM was boosted by ensembling, and showed better results in classifying the classes of arrhythmia efficiently. Arrhythmias are deadly disorders. Hence prediction and analysis must be exceedingly accurate before being applied in the medical field. The suggested method draws attention to these problems by choosing several standout features with an improved feature selection mechanism, which enhances classification efficiency with reduced number of features of 135. The future direction of the research would be to construct an interpretable ML classifier to augment the classifier's accuracy that will serve as an effective handy diagnostic tool for physicians.

# A Versatile Shuffle Resource Units Recomputation Algorithm for Uplink OFDMA Random Access

Azyyati Adiah Zazali, Shamala Subramaniam, Zuriati Ahmad Zukarnain, Abdullah Muhammed  
Department of Communication Technology and Network, Faculty of Computer Science and Information Technology,  
Universiti Putra, Malaysia, Serdang, 43400, Selangor Darul Ehsan, Malaysia

**Abstract**—IEEE 802.11ax introduces Uplink Orthogonal Frequency Division Multiple Access (OFDMA)-based Random Access (UORA), a novel feature for facilitating random channel access in Wireless Local Area Networks (WLANs). Similar to the conventional random access scheme in WLANs, UORA employs the OFDMA backoff (OBO) procedure to access the channel's Resource Units (RUs) and selects a random OBO counter within the OFDMA contention window (OCW) range. The Access Point (AP) can determine and communicate this OCW range to each station (STA). Multiple STAs accessing RUs result in transmission failure due to RU collisions, which occur when specific RUs remain unassessed by any STA, leading to wastage. Efforts to optimize channel efficiency require minimizing both collisions and idle RU despite the challenges arising from UORA's distributed and random nature. The Fisher-Yates shuffle algorithm introduces a random uniform distribution strategy for managing RU allocations among STAs. The results demonstrate that this approach enables STAs to access RUs in a distributed manner, effectively reducing idle and wasted RUs, especially in scenarios involving a limited number of STAs. Furthermore, this approach effectively mitigates collisions among STAs, even in scenarios with a more significant number of STAs.

**Keywords**—IEEE 802.11ax; OFDMA; UORA; random access; backoff; resource units allocation; multi-user

## I. INTRODUCTION

Developing MAC (Medium Access Control) protocols that can support large-scale networks with low-power devices elevate the growing number of Internet of Things (IoT) devices; hence, secure communication is essential. OFDMA is a wireless communication technique that allows multiple users to transmit data simultaneously over the same frequency band [1, 2]. Utilizing OFDMA allows sending (e.g., power) to utilize only a fraction of the bandwidth, facilitating simultaneous transmissions, minimizing MAC congestion and reducing overhead, enhancing data transmission efficiency over dense networks, and reducing time wastage.

OFDMA functions in two distinct modes: scheduled access (SA) and random access (RA) [3]. While random access methods like Distributed Coordination Function (DCF) or Enhanced Distributed Channel Access (EDCA) were employed to manage or distribute radio resources in previous WLAN standards, they do not apply to the OFDMA system [1]. UORA is a new feature for random channel access introduced in IEEE 802.11ax.

The channel split into sub-carrier groups known as Resource Units (RUs) in the UORA process. These comprise the minimum OFDMA RUs that STAs need to reach the channel and transmit a frame. With various RUs, multiple STAs can send data packets simultaneously. Each STA chooses a random OBO counter from the OCW value and reduces it by the number of RUs available for UORA to send a particular control frame called a trigger frame (TF). The TF carries information such as the identity information of each STA that may take part in the UL multi-user transmission, the transmission duration, the RUs allocation for each STA, and other helpful information. If the decreased OBO counter drops to zero or less, the STA can send the TF with any available RU. UORA can flexibly control the OCW range based on the number of contending STAs, unlike DCF and EDCA, where the range of contention window (CW) is predetermined.

OCW range is crucial to the UORA performance and primarily depends on the number of contending STAs, but it is challenging for the AP to accurately and quickly estimate or keep track of the number of contending STAs without a specific signaling mechanism.

The Wi-Fi standard random access protocol seldom enables the advantages of reducing network congestion and channel access delay because of the severe frame collision brought by the crowded network conditions to initiate the OFDMA uplink broadcasts. Most studies consider saturation network throughput, but 802.11ax nodes' access delay needs careful examination due to their dependency on AP schedules. In short, the operation of UORA is based on the OCW range and OBO counter values, showing that the random modes of operation make the STAs compete to access the RUs in order to send their UL request during the random selection of one of the 26-RU [4, 5].

The organization of the remaining sections of this article is as follows. Section II delves into the discussion of related open issues concerning UORA. Section III presents the problem formulation. The proposed algorithm is presented in Section IV. The performance evaluation and discussion are in Section V. The conclusion is provided in Section VI.

## II. RELATED OPEN ISSUES IN UORA

Numerous strategies have been put forth in the literature to enhance UORA effectiveness, such as grouping, joint, and clustering [6-12]. By aiming to give high channel efficiency, [6, 7] developed an adaptive grouping scheme on UORA. The study [6] consider a target wake time (TWT) to reduce

transmission collision. At the same time, [7] proposed a Buffer State Report (BSR)-based Two-stage Mechanism-based adaptive STA grouping scheme (BTM) that analyses the relationship between group size and the RU efficiency in an ultra-dense wireless network, mainly when RUs properties are not identical. The proposed spatial clustering group division-based OFDMA (SCGD-OFDMA) by [8] allows the head STA and multiple STAs to compete for the channel resource where the number of STAs is up to 200 when used for random access. The AP in the Grouping-based UORA (G-UORA) method by [9] divides users based on the utility and distributes resources accordingly using the utility prediction model and matching the utility-based resource allocation algorithm. (OFDMA)-based joint reservation and cooperation MAC (OJRC-MAC) protocol proposed in [10] combines channel reservation and cooperation to reduce access collisions and increase transmission dependability, outperforming the basic UORA. Another protocol outperforms the basic UORA by [11] splitting network STAs into spatial groups based on neighbor channel sensing capacity. Designing an information collection system utilizes a probability-based two-level buffer state report, where intra-group STAs transmit data with minimal power consumption. Simultaneously, the AP strategically organizes two spatial groups to prevent interference. The modification by [12] from the 2019 IEEE 802.11be Wi-Fi standard combined with a novel resource allocation algorithm provides effective real-time communications for the uplink OFDMA feature.

UORA introduces the OBO counter for the operation of multi-user transmission. An important observation is that the backoff procedure for UORA differs from that of DCF or EDCA. While DCF and EDCA perform backoff in the time domain to decide when to transmit, UORA's backoff procedure is two-dimensional, which simultaneously determines both the RUs to occupy in the frequency domain and the transmission time to produce high-efficiency results [1, 13, 14, 15, 16]. The research in [1] demonstrates a noteworthy increase in throughput through a straightforward modification to the OBO counter. However, implementing this suggested mechanism in real-world WLANs with practical settings becomes impractical due to the complexities associated with the OBO control rule. The CRUI (Collision Reduction and Utilization Improvement) method, introduced in [13], improves UORA performance by reducing transmission collisions. This enhancement involves increasing backoff times and utilizing opportunistic sub-channel hopping. Notably, the CRUI scheme ensures that it does not degrade the performance of UL transmissions and prioritizes distributed real-time STA transmissions. Retransmission number aware channel access (RNACA) increases throughput when there are more random access RUs than STAs and lowers packet latency [14]. By optimizing parameters like  $CW_{min}$  and  $CW_{max}$ , RNACA significantly increases the throughput of the maximum number of transmission trials (MNTTSTAs can conduct complementary transmission without backoff using the probability complementary transmission scheme (PCTS) described in [15]. However, it is essential to note that this scheme is applicable only in WLANs with lower mobile station numbers than random access RUs, as STAs must choose RUs based on OFDMA-based backoff counters, causing retransmission delays. In [16], developing a new uplink hybrid UORA (H-

UORA) OFDMA access mechanism introduces an RU-sensing slot, enabling additional channel sensing to minimize transmission collisions further. However, H-UORA needs a much finer carrier sensing circuit for the current 802.11ax amendment.

The 802.11ax network throughput can be optimized through RU allocation strategies, as demonstrated in [17, 18, 19, 20, 21]. The research in [17] examined the effects of various RA RU and SA RU distributions on the MAC layer performance, while [18] created a new RU distribution scheduler for managing access that features a closed-loop feedback controller with proportional gain. In [19], the research algorithm achieves a delay of less than one millisecond with a remarkably high level of reliability. On the other hand, in [20], OFDMA transmissions ensure reliable and dependable communication, especially in the presence of interference. Both studies demonstrate the ability to support real-time applications. The study in [21] proposed a channel access scheme for next-generation vehicle-to-everything (V2X) systems that expands backward compatibility with IEEE 802.11-based extension.

Fair Allocation and Effective Utilisation of RUs (FAEU-RUs) protocol in [5] handles the OFDMA MU communications based on the two factors. First is the fairness criterion of ensuring that all STAs in UL reasonably access the RUs, and second is the practical criterion of ensuring that the RUs are optimally allocated and used. The suggested solution in [3] guarantees fairness in RU access and requires minimal overhead, producing results close to optimal. However, it does not effectively adapt to traffic needs.

UORA and RU allocation are a big area to discover because of the drawback of this access mode, which is the high rate of collisions due to competition. Researchers continuously refine advancements in RU allocation for OFDMA as indicated by ongoing research on related open issues. This research focuses on the RU allocation for UORA.

### III. PROBLEM FORMULATION

The IEEE 802.11ax standard [22] defines scheduled and random access as two distinct kinds of uplink multi-user (MU) OFDMA operations. In scheduled access, each STA uses BSR signaling to ask the AP for authorization to transmit while the STAs share the OFDMA RUs without causing any contention. The AP then transmits a TF carrying the scheduling data to allot a dedicated RU to a particular STA. On the other hand, in a random access mode, the STA acquires the RU by the UORA mechanism in a contention-based way.

Fig. 1 illustrates a multi-user wireless communication network model with a single AP and a plurality of STAs based on [4] invention. Table I presents device attributes, which are in Fig. 1. The AP represents the access points, while STA1, STA2, STA3, STA4, STA5, STA6, and STA7 represent various wireless communication devices or STAs.

The UORA method operated by the AP shows that every  $n^{\text{th}}$  TF for random access transmitted by the AP includes at least one RU for random access available to 20 MHz operating STAs, where N is a positive integer. In other words, every Nth TF for random access contains at least one RU for random

access in the primary 20 MHz channel and is unrestricted from being used for 20 MHz operating STAs. A 20 MHz operating STA is allowed to reach the AP with the UORA mechanism when receiving TF for random access.

Fig. 1. Network model of a multi-user wireless communication network.

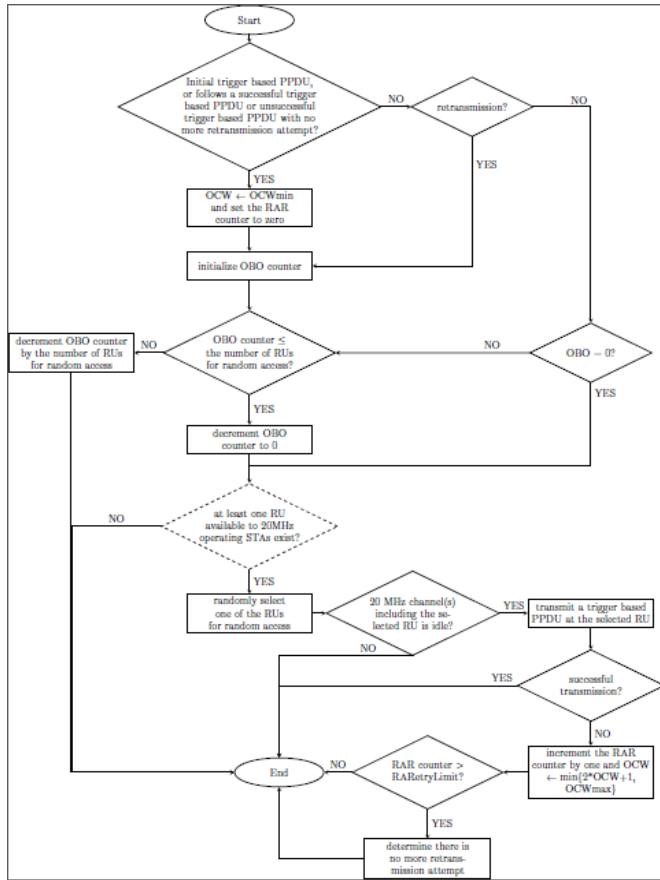

Fig. 2. UORA method operated by a 20MHz station.

The flow chart in Fig. 2 shows an example UORA method operated by a 20 MHz operating station with a detailed explanation in Table II. We assume this scenario occurs between the AP and any available STA capable of operating with a 20 MHz channel width, particularly STA3, STA6, and STA7, as indicated in Table I, since these STAs can only operate using this channel width.

TABLE I. DEVICES ATTRIBUTES

	STA1	STA5	STA2	STA4	STA3	STA6	STA7
Device type	laptop	CCTV	smartphone	smartwatch	Door lock	Thermostat	
QoS requirement	high			low			
Power	Low power	Concern about		Compassionate power			

management	saving	power consumption	consumption
Channel width (MHz)	20, 40, 80, 80+80, 160	20, 40, 80	20

TABLE II. DETAILING ON STEPS ACCORDING TO THE FLOW CHART IN FIG. 2

Step	Event
1	20 MHz operating STA receives a TF for random access from the AP.
2	20 MHz operating STA determines its UL transmission as an initial trigger-based PPDU transmission, follows a successful trigger-based PPDU transmission, or follows an unsuccessful trigger-based PPDU transmission for which there is no more retransmission attempt.
2.1	If 20 MHz operating STA UL transmission fulfils Step 2, the STA sets OCW value to OCWmin value and the Random Access Retry (RAR) counter to zero.
2.2	If 20 MHz operating STA UL transmission is unfit, Step 2, 20 MHz operating STA, continues to check if its UL transmission is a retransmission of an unsuccessful trigger-based PPDU transmission.
2.2.1	If 20 MHz operating STA UL transmission is retransmission, the UORA method proceeds to Step 3
2.2.2	If 20 MHz operating STA UL transmission is not retransmission, 20 MHz operating STA determines if the OBO counter is equal to value zero.
2.2.2.1	If the 20 MHz operating STA OBO counter equals zero, the UORA method proceeds to Step 5, implying that the 20 MHz operating STA won the contention but did not transmit a trigger-based PPDU in the previously selected RU in Step 1 since one or more 20 MHz channels containing the previously selected RU are considered busy.
2.2.2.2	If the 20 MHz operating STA OBO counter is not equal to zero, the UORA method proceeds to Step 4. This situation implies that the 20 MHz operating STA did not win the contention to access the RUs for random access in the previous TF in Step 1.
3	20 MHz operating STA initializes its OBO counter to a random value in the range of zero and OCW.
4	20 MHz operating STA checks that its OBO counter is smaller or equal to the number of RUs for random access in the previous TF in Step 1.
4.1	If the OBO counter is smaller or equal, 20 MHz operating STA decreases its OBO counter to zero. This situation implies that 20 MHz operating STA wins the random access contention, which proceeds to Step 5.
4.2	If the OBO counter is higher than 0, 20 MHz operating STA decrement its OBO counter by the number of RUs for random access in the received TF in Step 1, which proceeds in Step 11.
5	20 MHz operating STA determines if at least one RU for random access available to 20 MHz operating STA exists in the received TF.
5.1	If 20 MHz operating STA fulfils Step 5, the UORA method proceeds to Step 6.
5.2	If 20 MHz operating STA is unfit in Step 5, proceed to Step 11.
6	20 MHz operating STA randomly selects one of the RUs for random access in the previous TF in Step 1.
7	20 MHz operating STA checks if each of one or more 20 MHz channels, including the selected RU, is idle due to physical and virtual carrier sensing.
7.1	If the selected RU is idle, 20 MHz operating STA transmits a trigger-based PPDU at the selected RU.
7.2	If the selected RU is not idle, proceed with Step 11.
8	The STA operating at 20 MHz determines the successful transmission of the trigger-based PPDU on the selected RU.
8.1	In the event of a successful transmission, proceed to Step 11.
8.2	If an immediate response is not received as solicited by Step 8, consider the transmission unsuccessful and proceed to Step 9.
9	20 MHz operating STA increments the RAR counter by one and sets the OCW value to the minimum of a sum of double the current OCW value plus one and a value of OCWmax.
10	20 MHz operating STA determines if the RAR counter is more significant than a RARRetryLimit threshold, indicating the maximum

	number of random access retransmission attempts.
10.1	If the RAR counter is lesser than RARetryLimit, proceed to Step 11.
10.2	If the RAR counter is enormous than RARetryLimit, 20 MHz operating STA determines there is no more retransmission attempt and then proceeds to Step 11
11	UORA method comes to an end or stops.

Fig. 3. An example of UORA operation in time and the OBO decrementation after TF reception based on [23].

The usage of the UORA mechanism in a contention-based manner, the STA acquires the RU, as shown in Fig. 3. The AP sends a TF to start the UORA process in the UORA mechanism. The TF includes various data bits, including the associated association identifiers and the eligible random access RUs (RA-RUs) (AIDs). The associated STAs can utilize RA-RUs with the AID number 0, while unassociated STAs can occupy RA-RUs with the AID number 2045 following the 802.11ax standard. The AP may assign some RUs to planned access and others to random access.

However, to concentrate on the efficiency of UORA, the assumption was made that all RUs are qualified for random access without taking scheduled access into account. To be more precise, one RU is assigned to have an AID of 2045 and the rest to have an AID of 0. According to the IEEE 802.11ax standard, the overall number of RUs depends on the channel bandwidth and the number of sub-carriers used for each RU.

Fig. 3 represents an example of the UORA operation. STA 1 is unassociated, and STAs 2-7 are associated. The channel bandwidth is 20 MHz, and 9 RA-RUs consist of eight RUs with AID 0 and one with AID 2045. On receiving the TF, STA 1 decreases its OBO counter by 1, and STAs 2-7 decrease the OBO counter by 8. In this example, the OBO counter for STAs 2-7 becomes ≤ 0, which means the OBO counter is not greater than the number of eligible RUs, and then the STAs sets its OBO counter to 0. Each time OBO = 0, the STAs select a random RA-RU among RU 1-8 to transmit a frame. If there are cases between the STAs where the OBO counter is > 0, the STA cannot access the channel and decreases its OBO counter, waiting for the next contention round upon receiving the next TF. This example also shows that RU can collide and remain idle. STA 3 and STA 6 access the same RU 2, so their transmission can fail due to collisions. Instead, STAs do not

access specific RUs (1, 3, and 8), causing these RUs to become wasted. In case of an unsuccessful transmission, the STAs follow the retransmission procedure shown in Algorithm 1 as in the standard UORA. To ensure channel efficiency, one must minimize the number of collisions and wasted RUs. However, achieving this goal is challenging, given the distributed and random nature of UORA. The backoff procedure in UORA is two-dimensional because it determines which RU to occupy in the frequency domain and simultaneously establishes the transmission time, unlike DCF or EDCA, which performs the backoff procedure in the time domain to determine when to transmit.

### Algorithm 1 Standard UORA

```

OCWmin = 7
OCWmax = 31
if first transmission, then
    OCW = OCWmin;
    OBO = random integer(0, OCW);
else if retransmission, then
    OCW = 2 × OCWold + 1;
    if OCW ≥ OCWmax then
        OCW = OCWmax;
    end if
    OBO = random integer(0, OCW);
end if
Station decrements OBO by number of RU and selects a random
RU for transmission if OBO = 0
    
```

More examples are provided by [4] for different types of STA channel widths to perform the frequency scheduling for OFDMA multi-user transmission in 802.11ax. Frequency scheduling is generally performed based on RU that comprises a plurality of consecutive subcarriers. According to frequency scheduling, a radio communication AP adaptively assigns RUs to a plurality of STA based on the reception qualities of frequency bands of the STAs. The situation makes it possible to obtain a maximum multi-user diversity effect and efficiently perform communication.

While the techniques outlined in this disclosure apply to various wireless communication systems, it is essential to note that, for illustrative purposes, the subsequent descriptions in this disclosure pertain to an IEEE 802.11 WLAN system and its associated terminologies. However, this choice of example should not restrict the scope of this disclosure concerning alternative wireless communication systems. In IEEE 802.11-based WLANs, most networks operate in infrastructure mode, i.e., all or most of the traffic in the network must go through the AP. As such, any STA wishing to join the WLAN must first negotiate the network membership with the AP through association and authentication.

### IV. PROPOSED VERSATILE SHUFFLE RECOMPUTATION RU ALGORITHM

We proposed to change the operation of standard UORA behaviors as in Algorithm 1 to improve its efficiency. To ensure the adaptability of STAs allocation based on the

available RUs, we introduce the versatile shuffle recomputation RU (VSR-RUs) algorithm.

In VSR-RUs, The Fisher-Yates shuffle algorithm [24] shown in Algorithm 2, also known as the Knuth shuffle or the Durstenfeld shuffle, was applied for the RUs recomputation. The Fisher-Yates shuffle algorithm is employed to efficiently generate a random permutation of an array of elements by randomly shuffling them. This shuffle algorithm iterates the array in reverse order and swaps the current element at each step with a randomly chosen element that comes before it (including itself). This process ensures that every element in the original array has an equal chance of being placed in any position within the shuffled array, which means that when applied to UORA, it is the RUs allocation. Introducing randomness at each process step establishes a uniform likelihood of interchanging with any previous element. The algorithm has a time complexity of  $O(n)$ , where  $n$  is the number of elements in the array. It is considered a highly efficient and unbiased method for shuffling arrays.

**Algorithm 2** The Fisher-Yates shuffle algorithm

```

function fisherYatesShuffle(array)
    n = length(array);

    for i from n - 1 down to 1:
        j = random integer(0, i);
        swap(array[i], array[j]);
        OBO = random integer(0, OCW);

function randomInteger(min, max):
    return random(min, max);

function swap(a, b):
    temp = a;
    a = b;
    b = temp;
    
```

Table III shows the STAs RA-RUs allocation in standard OURA in Fig. 3 after applying the Fisher-Yates shuffle algorithm. Recomputing the allocation of RUs prevents collisions within RU 2 while distributing the available RUs among STAs ensures that each STA is guaranteed its allocation without sharing. However, RU 3 and RU 4 remain idle as the number of STAs is < the number of RUs. If an STA OBO counter is greater than 0 and cannot access the channel, it could be due to the STA not being allocated in any available RUs. In such cases, the STA must wait for the next contention round upon receiving the next TF.

Fig. 4 is an example of the Fisher-Yates shuffle mechanism using the RUs array [1, 2, 3, 4, 5, 6, 7, 8, 9]. The mechanism is performed in the following order;

- 1) Randomly select a number  $k$  from 1 to 9, and then swap the  $k^{\text{th}}$  and 9<sup>th</sup> STA. So, if the random number is 4, swap the 4<sup>th</sup> and 9<sup>th</sup> STA in the list.
- 2) Select the following random number from 1 to 8 and swap the chosen STA with the 8th STA. If it is 6, for example, swap the 6<sup>th</sup> and 8<sup>th</sup> STA.

- 3) If the array contains multiple STAs, a random selection will determine which STAs are placed on the list.
- 4) The iteration continues until the permutation is completed, as illustrated in Fig. 4.

After shuffling, the last row of the shuffle displays the output on RUs. This process ensures that the original order of the array is completely randomized while maintaining a uniform distribution of possible outcomes.

TABLE III. THE STAs RUS SELECTION ON STANDARD UORA BEFORE AND AFTER APPLYING ALGORITHM 2

RU #	STAs allocation on RU #	
	Before	After

V. PERFORMANCE EVALUATION AND DISCUSSION

This section concentrates on the implementation and evaluation of the performance of the proposed VSR-RUs algorithm. A comparison is made against the standard UORA [22]. These evaluations are used to assess the effectiveness of the VSR-RUs algorithm. The Java programming language develops the DES simulation using Eclipse IDE for Java Developers with Indigo Service Release 2 software.

**Algorithm 3** Standard OURA pseudocode structure

```

for a := 1 to NumberofExperiment do
  initialization()
  for i := 1 to maxNoOfStation do
    event[i][j] = time assign; //rand()%(OCW-1)
  end for
  while simulation run do
    if (simulationTime < 60) then
      scheduler()
      update simulationClock()
      if eventType = 1 then
        intendtoTransmit()
      else if eventType = 2 then
        packetGeneration()
      else if eventType = 3 then
        triggerFrame()
      else if eventType = 4 then
        acknowledgment()
      end if
    end if
  end while
  result()
end for

```

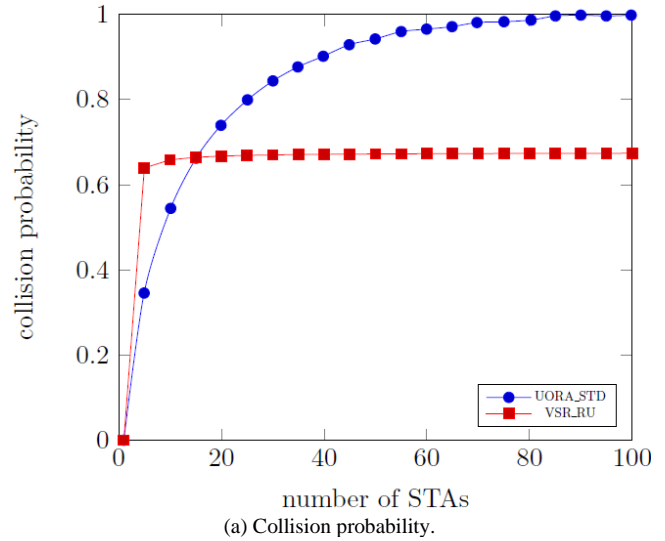

Algorithm 3 shows the pseudocode structure for the novel UORA. The pseudocode begins with the initialization of all the parameters involved. Table IV displays the parameters. Each STA has an event defined, and Table V illustrates these defined events. The Random() function from the mathematical Java library generates the random number, adhering to a uniform distribution. The larger the number generated, the smaller the access probability. During the simulation, as long as the simulation time remains under a minute, the scheduler function will execute, leading to an update of the simulation clock. Subsequently, the event will be chosen based on its type, and the simulation present the outcome afterwards.

TABLE IV. SIMULATION PARAMETERS

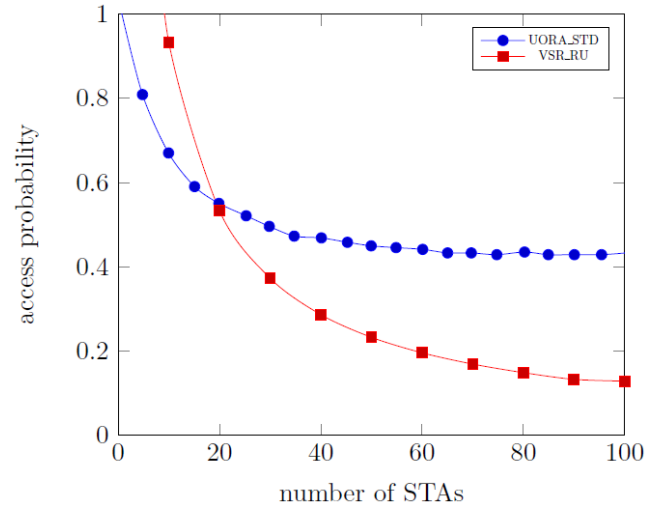

Parameter	Value
Simulation time	60 s
Channel bandwidth	20 MHz
Number of subcarriers RU	26
Number of RU AID = 0	8
Number of RU AID = 2045	1
Number of contending STAs	1~100
Data rate per RU	6.67 Mb/s
Trigger frame length	100µs

TABLE V. UPLINK OFDMA EVENT DEFINE

No	Event	STA	Time Assign
1	Frame transmission intention	1	ev[1][1]
2	Generate random number	1	ev[1][2] = rand();
3	Trigger frame	1	ev[1][3] = transmit TF
4	Acknowledgment	1	ev[1][4] = transmit ACK
No	Event	AP	Time Assign
1	Frame transmission intention	1	evAP[1]
2	Trigger frame	1	evAP[2] = transmit TF
3	Acknowledgment	1	evAP[3] = transmit ACK

(a) Collision probability.

(b) Channel access probability.

Fig. 5. Performance comparison of collision probability and channel access probability between standard UORA and the proposed VSR\_RU.

Fig. 5 compares the collision probability and channel access probability between the standard UORA and VSR\_RU proposed algorithm. Fig. 5(a) shows that the number of collision probabilities for VSR-RUs is at steady state once the number of STAs approaches ten and increases. As the number of STAs increases, the RUs allocation is more uniformly distributed, thus contributing to the decrease in collision.

When examining Fig. 5(b), it becomes evident that with fewer STAs (1-20), the increased access probability of VSR\_RUs has reduced the probability of having idle RUs. This reduction in idle RUs has the potential to enhance overall throughput. Conversely, employing lower access probabilities from VSR\_RU could be a strategic choice for distributing resources among STAs or processes demanding a higher quality of service or performance. This approach would prioritize critical tasks appropriately.

The proposed VSR\_RU algorithm improved the random distribution for allocating STAs to RUs, resulting in lower collisions among STAs. This strategy enables STAs to access RUs in a distributed fashion, which may cause fewer idle and wasted RUs, especially in scenarios with limited STAs. Besides, STA collisions are less when the number of STAs is higher.

## VI. CONCLUSION

The VSR\_RU algorithm, as proposed, employs a random uniform distribution approach using the Fisher-Yates shuffle algorithm for each STA to manage allocations in available RUs. This algorithm operates without requiring any prior information about the number of STAs. The key innovation lies in introducing a shuffled random distribution for assigning STAs to RUs, effectively minimizing collisions among STAs. This approach enables STAs to access RUs in a distributed manner, thereby reducing the occurrence of idle and wasted RUs, particularly in scenarios with a small number of STAs. Moreover, it also mitigates STA collisions in scenarios with many STAs. The adaptability incorporated into the proposed algorithm improves the standard IEEE 802.11ax UORA mechanism.

Further development could involve refining the OBO control rule through a more efficient UORA mechanism within the proposed algorithm. The limitation of the research is that shuffling can take a significant amount of time for massive arrays by applying the Fisher-Yates algorithms. Additionally, reinforcement learning technology can enhance UORA performance in real-world WLAN environments.

# The Promise of Self-Supervised Learning for Dental Caries

Tran Quang Vinh, Haewon Byeon\*

Department of Digital Anti-Aging Healthcare (BK21), Inje University, Gimhae 50834, South Korea

**Abstract**—Self-supervised learning (SSL) is a type of machine learning that does not require labeled data. Instead, SSL algorithms learn from unlabeled data by predicting the order of image patches, predicting the missing pixels in an image, or predicting the rotation of an image. SSL has been shown to be effective for a variety of tasks, including image classification, object detection, and segmentation. Dental image processing is a rapidly growing field with a wide range of applications, such as caries detection, periodontal disease progression prediction, and oral cancer detection. However, the manual annotation of dental images is time-consuming and expensive, which limits the development of dental image processing algorithms. In recent years, there has been growing interest in using SSL for dental image processing. SSL algorithms have the potential to overcome the challenges of manual annotation and to improve the accuracy of dental image analysis. This paper conducts a comparative examination between studies that have used SSL for dental caries processing and others that use machine learning methods. We also discuss the challenges and opportunities for using SSL in dental image processing. We conclude that SSL is a promising approach for dental image processing. SSL has the potential to improve the accuracy and efficiency of dental image analysis, and it can be used to overcome the challenges of manual annotation. We believe that SSL will play an increasingly important role in dental image processing in the years to come.

## I. INTRODUCTION

Artificial intelligence (AI) represents a domain within computer science that focuses on crafting intelligent entities, these being systems endowed with the capacities of logical deduction, knowledge acquisition, and independent decision-making. The field of AI has witnessed remarkable achievements in formulating potent methodologies to address a diverse spectrum of challenges, spanning from strategic game playing to intricate medical diagnostics [1]. Interest in the medical application of AI has lately surged due to the impact of this technology on the outcome and caliber of clinical practice during and after the 1980s [2]. Precision medicine, population health, and natural language processing are just a few of the areas of healthcare and medical practice where AI has been researched [3].

Machine learning (ML), a type of AI that allows computers to learn without being programmed. ML algorithms are trained on large datasets of data, and they can then be used to make predictions or decisions. ML is being used in a variety of medical applications, including diagnosis, treatment planning, drug discovery, personalized medicine, and

healthcare management. ML algorithms have been shown to be effective in a variety of tasks, such as detecting cancer, planning radiation therapy, and identifying potential new treatments for diseases [4].

Annotation in medical imaging is the process of labeling or describing medical images with relevant information. This information can be used to train machine learning algorithms to diagnose diseases, plan treatments, or conduct research. There are a variety of ways to annotate medical images, including: Manual annotation, Semi-automated annotation, and Automated annotation [5]. Nonetheless, the substantial expenses tied to acquiring essential specialized annotations often impede endeavors to employ machine learning algorithms for aiding clinical applications. Even partially automated software tools might fall short of significantly alleviating the financial burden associated with annotations. [5]. Self-supervised representation learning [6] is a type of machine learning that learns to represent data without being explicitly labeled. This is in contrast to supervised learning, where the data is labeled with the desired output. Recently, interest in these techniques has increased [7, 8]. In particular, self-supervised representation learning may enhance label effectiveness and performance in scenarios involving the classification of dental caries. In the area of dental caries, this article reviews self-supervised algorithm and compare it to other learning techniques.

## II. MATERIALS AND METHODS

### A. Artificial Intelligence and Machine Learning in Dental Caries

Dental caries, commonly known as tooth decay, is a disease that causes tooth decay by bacteria in the mouth producing lactic acids, which directly harm the tooth surface layer known as the enamel layer. This can progressively lead to a small hole or cavity in the teeth; if not treated, this can cause discomfort, infection, and finally tooth loss [9]. Early detection of carious lesions is necessary for the management of dental caries.

The discipline of dentistry saw the emergence of AI, just like other industries. In a dental clinic, it can carry out simple and difficult tasks with higher precision, accuracy, sensitivity, and—most importantly—in less time [10]. In recent years, Machine Learning algorithms have the potential to be used to develop automated caries detection systems that are more accurate and efficient than traditional methods. Adaptive neural network architecture [11], deep learning [12], an artificial multilayer perceptron neural network [13], convolutional neural network [14], backpropagation neural network [15], and

\*Corresponding Author.

k-means clustering [16] are some of the different methods used in dentistry, specifically for the detection of caries. A large, difficult assignment has been seen to disappear utilizing these strategies. Therefore, this review aims to provide an overview of the diverse artificial techniques used to identify dental cavities in this systematic review, as follows:

**B. Artificial Neural Networks**

Artificial Neural Networks (ANNs) are computational systems profoundly influenced by the functioning of biological nervous systems, such as the human brain. ANNs consist predominantly of numerous interconnected computational units, commonly known as neurons. These neurons collaboratively operate in a distributed manner to assimilate knowledge from input data, with the objective of refining their ultimate output.

O’Shea [17] represented the fundamental architecture of an ANN as depicted in Fig. 1.

Fig. 1. The basis of a number of common ANN architectures.

The input, often organized as a multidimensional vector, is introduced to the initial layer, known as the input layer. Subsequently, this input is propagated through intermediary layers called hidden layers. In these hidden layers, decisions are made based on the preceding layer’s information. The hidden layers then assess how alterations within themselves positively or negatively impact the final output. This iterative process of evaluating and adjusting is termed learning. The stacking of multiple hidden layers, creating a tiered arrangement, is commonly referred to as deep learning.

**C. Adaptive Neural Network Architecture**

An adaptive neural network architecture refers to a type of artificial neural network that can dynamically adjust its structure and parameters based on the characteristics of the input data. In the context of images, an adaptive neural network architecture is designed to intelligently adapt its layers, nodes, or connections to better capture the features present in the input image. This concept aims to enhance the network’s performance by tailoring its architecture to the specific complexities and patterns within the image data.

The adaptive nature of such architectures allows the neural network to optimize its internal representation as it learns from the data. Traditional neural network architectures have fixed structures, making them less flexible in handling variations in data characteristics. In contrast, an adaptive neural network architecture has the ability to modify itself during training, potentially leading to improved accuracy, efficiency, and

generalization. Haykin [18] presents a conceptual framework outlining a singular stage of neural processing intended for adaptable behavior in Fig. 2.

Fig. 2. Schematic diagram of an adaptive system.

The model centers on the retention of past experiences to predict likely future occurrences. Specifically, for a given input vector  $x(n-1)$  at time  $n-1$ , the model estimates the expected value  $x^*(n)$  at time  $n$ . By comparing this prediction to the actual value  $x(n)$ , the difference, termed the correction or innovation signal, is computed. A non-zero correction signifies an unfamiliar condition, necessitating model updates to better anticipate similar situations. This dynamic adjustment enables the model to learn and adapt to its environment, as it continually operates in real-world scenarios.

**D. Convolutional Neural Network**

A convolutional neural network (CNN) represents an evolved variant of artificial neural networks, meticulously designed to handle the intricate analysis of visual data like images and videos. Fig. 3 shows the concept model of convolutional neural network. Drawing inspiration from the intricate visual processing mechanism observed in the human brain, CNNs demonstrate exceptional proficiency in tasks that encompass image recognition, classification, and the domain of computer vision. The quintessential prowess of CNNs originates from their innate ability to independently glean intricate features from visual content, thereby accentuating their utility in intricate data interpretation. This is achieved through several distinctive architectural components:

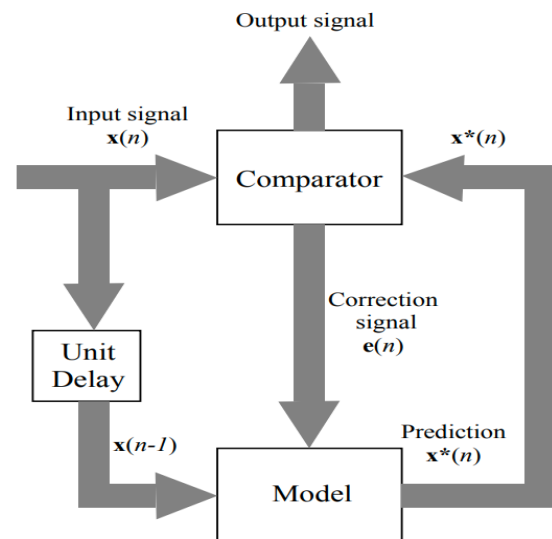

Fig. 3. The concept model of convolutional neural network [19].

- **Convolutional Layers:** These layers employ adaptable filters for performing convolution operations on input images. This hierarchical feature extraction encompasses both rudimentary features, such as edges, and more intricate features, like object contours.
- **Pooling Layers:** Subsequent to convolution, pooling layers downsize the spatial dimensions of features while retaining vital information. Employing methods like max-pooling, these layers preserve the maximum value within localized regions, distilling key features. This pooling process bolsters resilience against minor input variations and concurrently reduces computational requirements.
- **Fully Connected Layers:** Features extracted from prior layers are flattened and channeled through fully connected layers. These layers mirror conventional neural network structures and undertake roles as classifiers or regressors, relying on the features they have learned.

**E. Backpropagation Neural Network**

The backpropagation algorithm, integral to neural network training [20], operates as a pivotal mechanism in optimizing model parameters for improved performance in tasks such as classification, regression, and pattern recognition. This process empowers neural networks to glean insights from labeled training data, effectuating adjustments in weights and biases to minimize the disparity between projected outputs and actual target values. Backpropagation fosters neural networks to refine parameters, facilitating an enhanced fit to training data. By iteratively adjusting weights and biases using gradients, networks learn to identify pertinent features and relationships within data. This systematic learning process enables neural networks, encompassing deep learning architectures like CNNs and Recurrent Neural Networks (RNNs), to achieve elevated levels of performance across various tasks.

**F. K-Means Clustering**

K-means clustering is a widely utilized unsupervised machine learning technique employed to partition a dataset into distinct groups, or clusters, based on inherent patterns in the data. This technique is particularly effective in uncovering underlying structures and relationships within unlabeled datasets. The K in K-means represents the user-defined number of clusters. The choice of K significantly impacts the quality of the clustering results.

**G. Studies of Predicting Depression based on Self-Supervised Learning Method**

Self-Supervised Learning is an emerging machine learning paradigm that leverages unlabeled data to train models in a semi-supervised manner [21]. A two-phase learning scheme in self-supervised learning is illustrated by Taleb et al. [22]. Fig. 4 shows the flowchart of self-supervised learning stages.

Unlike traditional supervised learning, where labeled data is used to directly predict specific targets, self-supervised learning formulates tasks that allow the model to learn meaningful representations from the data itself. In self-supervised learning, the learning signal comes from the data

itself, generating surrogate tasks that help the model capture underlying patterns and structures. For a more comprehensive perspective on self-supervised learning, we shall conduct a comparative examination juxtaposed against alternative machine learning techniques. Several studies are illustrated in Table I.

Fig. 4. Flowchart of self-supervised learning stages.

TABLE I. SUMMARY OF DENTAL CARIES DETECTING STUDIES

Article	Data	Models /Algorithms	Results
Patil et al. (2019)[11]	Small size of dataset (45 dental images)	K-nearest neighbor, ANN	Accuracy=95%, Precision=90%
Casalegno et al. (2019)[12]	217 X-dental images	Convolutional Neural Network (CNN) algorithm	Accuracy of 85.6% and 83.6%
Devito et al. (2008)[14]	160 radiographic images	Backpropagation algorithm	Accuracy= 88.4%
Zanella-Calzada et al. (2018)[23]	9812 subjects were in an age range of 0 to 80 years old; 4830 belonged to the masculine gender and 4982 to the feminine gender	ANN by classifying subjects	Accuracy= 88%
Lee et al. (2018)[24]	2417 images (853 healthy tooth surfaces/1,086 non-cavitated carious lesions/431 cavitations/47 automatically excluded images during preprocessing).	Convolutional Neural Networks	Accuracy= 93%
Taleb et al. (2022)[22]	38,094 bitewing radiographs	Self-Supervised Learning Algorithms	ROC-AUC= 71.50 Sensitivity=51.80 Specificity of 91.30

### III. RESULTS AND DISCUSSION

Patil et al. (2019) [11] embarked on a comprehensive exploration to discern the optimal algorithm for diagnosing tooth caries. This endeavor entailed a thorough assessment of multiple algorithms, including support vector machines (SVM), k-nearest neighbors (KNN), Naïve Bayes (NB), and the adaptive dragonfly algorithm (ADA-NN). Their dataset encompassed 120 dental images, forming the foundation for a series of three distinct tests, each centered around 40 dental images. Notably, the ADA-neural network emerged as a consistent frontrunner across these evaluations, showcasing superior performance vis-à-vis the aforementioned algorithms. Impressively, the ADA-neural network surpassed its counterparts by margins of 5.5%, 11.76%, and 6.5%, respectively. However, it's crucial to acknowledge that Patil and collaborators operated within a notably constrained dataset, comprising a mere 45 images, thereby raising legitimate queries regarding the reliability of their findings. The utilization of such a limited dataset, consisting of merely 45 images, inevitably instills doubts concerning the robustness of their outcomes. Within this subset, 30 images were earmarked for training, while the remaining 16 were allocated for testing.

In parallel, the studies orchestrated by Devito et al. [14] harnessed the potent backpropagation algorithm within deep learning for dental caries prognosis. In the realm of Devito et al.'s investigation, the training dataset encompassed 80 dental images, with the remaining 80 images partitioned into two distinct subsets: 40 images for validation purposes and an additional 40 images designated for comprehensive testing [14]. Expanding the scope of inquiry, Devito and associates directed their efforts toward forecasting the proximal category of dental caries through the prism of X-ray dental radiographs, culminating in a commendable accuracy level of 88.4%.

Likewise, Casalegno et al. (2019) [12] pursued a separate avenue of exploration, deploying a dataset brimming with 217 X-ray dental images. Embracing the CNN algorithm, their study undertook the ambitious task of caries prediction, encompassing the nuanced realms of proximal and occlusal caries. Impressively, the outcomes bore witness to a level of accuracy amounting to 85.6% for proximal caries and 83.6% for occlusal caries.

The expedition orchestrated by Lee et al. (2018) [24] unfolded within the realm of CNNs, their dataset comprising 2,417 images. This comprehensive assemblage featured 853 images depicting healthy tooth surfaces, 1,086 images of non-cavitated carious lesions, 431 images capturing cavitations, and a subset of 47 images that underwent automatic exclusion during the preprocessing phase. It's noteworthy; however, Lee and co-authors deviated from the conventional dataset division percentages of 25%, 50%, 75%, and 100% for training. Rather, their dataset was bifurcated into a training set (comprising 1,891/673/870/348 images for each respective category) and a test set (consisting of 479/180/216/83 images for the corresponding categories). This unconventional distribution, though divergent, did not deter them from achieving an impressive diagnostic precision through CNNs, boasting an accuracy rate approximating 93.3%.

Taleb et al. (2022) [22] utilized a Self-Supervised Learning Algorithms on dental caries detection. The dataset was obtained by three specialized dental clinics in Brazil, focusing on radiographic and tomographic examinations [22] and consisted of 38,094 BWRs taken between 2018 and 2021. The study's strengths included its pioneering demonstration of self-supervised techniques in dentistry, with the potential to address the immense volume of X-ray images generated globally. Additionally, it employed a dataset of over 30,000 Bitewing Radiographs (BWRs) with EHR-based labels, overcoming the challenge of diagnostic inconsistency by incorporating a refined ground truth. Nonetheless, limitations included the use of EHR-based labels, which may be biased and incomplete, and the focus on tooth-level classification rather than finer assessments. This discrepancy might account for the relatively minor decrement in study results compared to those reported by Lee et al. [24].

In summary, the amalgamation of Self-Supervised Learning Algorithms has shown effectiveness in enhance performance and optimize label utilization in scenarios involving dental caries classification. Nevertheless, the predictive efficacy of machine learning approaches differs between studies due to disparities in data distribution, the characteristics of features integrated into the model, and the manner in which the outcome variable is gauged. Consequently, while certain investigations have indicated proficient performance of ML algorithms, a persistent requirement remains for further research to authenticate the predictive capabilities of each algorithm. This necessity arises from the inability to universally extend the results to encompass all forms of data.

### IV. CONCLUSION

In conclusion, the potential of self-supervised learning for advancing dental caries detection is substantial. By pretraining models on large datasets derived from routine care, self-supervised learning provides a practical solution for scenarios where labeled data is limited. The presented studies underscore the positive impact of self-supervised learning algorithms on the predictive performance of dental caries classification models. However, it's important to acknowledge that the success of self-supervised learning is not uniform across all scenarios. Variability in data distribution, feature characteristics, and outcome measurement can lead to differing predictive performances. While some studies have demonstrated impressive results, the applicability of these findings to all types of data requires careful consideration.

Despite these challenges, the prospect of self-supervised learning remains promising. It offers a pathway to leverage the vast amounts of unannotated data generated in routine clinical practice, potentially revolutionizing dental diagnostics. As this field continues to evolve, further research is imperative to refine methodologies, validate findings, and establish the generalizability of self-supervised learning techniques in dental caries detection. The integration of self-supervised learning into clinical practice could mark a significant advancement in early caries diagnosis, ultimately leading to improved patient care and oral health outcomes.

**Abstract**—Due to cost and energy consumption limitations, there are significant differences in the positioning capabilities of mobile terminals, resulting in unsatisfactory quality of trajectory data. In this paper, satellite Doppler data is used to optimize trajectory data. First, the system state equation is established by the kinematic relationship between the measured velocity and position, and the static linear Kalman filter estimates the optimal system state. Then a dynamic Kalman filter system is established by correlating the measurement error matrix parameters of the Kalman filter with the vertical dilution of precision of satellite positioning. Finally, the whole-day trajectory of a taxi in Shenzhen was visualized, and the deviation between the trajectory points and the urban road was calculated to compare the optimized and non-optimized taxi trajectories. The results show that the proposed optimization method can effectively reduce the deviation between trajectory points and urban roads, and this method can be used to process vehicle trajectory data in urban traffic research.

**Keywords**—Urban transportation; Kalman Filter; information fusion; trajectory data

## I. INTRODUCTION

The rise of mobile Internet and location-based services (LBS) has generated a large amount of trajectory data. These data provide abundant materials for analyzing and researching social behavior and economic activities and have significant scientific research value. In the study of social phenomena, trajectory data have many advantages [1, 2], such as: 1) Trajectory data is an objective record and description of the position changes of mobile terminals and users, which is not affected by subjective feelings and has objectivity. 2) Mobile Internet has the characteristics of timeliness, which makes trajectory data update very fast and can provide timely feedback on social phenomenon and behavior changes. 3) With the popularity of mobile terminals such as mobile phones, location-based services have been widely applied, generating a massive amount of trajectory data. 4) Mobile terminals with positioning functions, such as mobile phones, tablets, taxis, and shared bicycles, can generate various trajectory data through various methods such as GPS, cellular network positioning, WI-FI positioning, etc.

During the collection process of trajectory data, there are inevitably systematic errors due to positioning technology. For example, the positioning accuracy of GSP is related to factors such as the signal reception ability of the receiver, calculation methods, local shading conditions, atmospheric conditions, and the number of observable satellites, and the positioning accuracy of cellular networks is closely related to network

format, solution methods, and the density of signal base stations. Due to cost, energy consumption, safety, and other reasons, mobile terminals such as mobile phones can usually only receive L1 carrier signals and C/A codes and cannot use differential positioning based on carrier phase. Therefore, optimizing their trajectories is very crucial [3].

Improving positioning and information communication technology is a direct way to improve positioning accuracy. For example, the third-generation GPS satellite launched in 2018 can launch a new civilian signal L1C in the 1575.42MHz band, making GPS more compatible with other GNSS systems and enabling receivers to receive more satellite signals [4]. In addition, the third-generation GPS satellite is equipped with a better accurate rubidium atomic clock and has higher signal transmission power [5,6]. With the upgrading of communication technology, the accuracy of positioning technology based on cellular networks is also unceasingly improving [7]. In 3GPP Release 16, a new Down Link-Position Reference (DL-PRS) is brought in, and various positioning technologies with better performance, such as DL-TDOA, UL-TDOA, DL-AOD, UL-AOA, E-CID, could be used in the fifth-generation communication network [8]. In the fifth-generation communication network, the dense network makes TDOA and DOA positioning more reliable, Massive Multiple Input Multiple Output (Massive MIMO) technology provides an Infrastructure for AOA positioning, and lower network latency improves the accuracy of time-based positioning methods [9-11].

In addition to improvements in positioning and communication technology, data processing and fusion can also improve the quality of trajectory data. Using spatial clustering and filtering algorithms can make trajectory data smoother, avoiding deviations or anomalies in trajectory data [12-15]. By integrating information beyond positioning data, such as electronic maps, Doppler velocimetry, and vehicle inertial measurement units, the quality of trajectory data can also be improved [16-18].

In this study, the trajectory data is optimized using the velocity measured by GPS satellites based on the Doppler effect. The structure of this article is as follows: In Section II, the system state equation is established according to the kinematics principle, and then the acquisition of the measurement value of the system state equation is introduced, that is, the pseudo-range positioning method and the Doppler velocity measurement method of the satellite. In Section III, the static Kalman filter is used to estimate the optimal system state. Then the dynamic Kalman filter is used to estimate the

optimal system state by correlating the system measurement matrix with the satellite positioning Dilution of Precision (DOP). In Section IV, the daily trajectory of a taxi in Shenzhen was visualized, and the deviation between the trajectory and the urban road network was calculated to compare the optimized and non-optimized taxi trajectories.

## II. ESTABLISH SYSTEM STATE EQUATION

The state equation of the Kalman filter system mainly includes two prediction and measurement processes. According to the laws of kinematics, the system state equation can be obtained as Formula (1). In this formula,  $o_k$  is the system state at time  $k$ , which includes  $(x^k, y^k)$  meaning the position of the object and  $(v_x^k, v_y^k)$  meaning the speed of the object.  $A_k$  is the system state transition matrix,  $w_k$  is the system noise, which conforms to the Gaussian distribution with the mean value of 0, and the variance of  $Q$ ,  $v_k$  is the measured noise, which conforms to the normal distribution with the mean value of 0 and the variance of  $R$ .

$$\begin{cases} o_k = A_k x_{k-1} + w_k \\ z_k = o_k + v_k \end{cases} = \begin{bmatrix} x^k \\ y^k \\ v_x^k \\ v_y^k \\ z_k = o_k + N \sim (0, R) \end{bmatrix} = \begin{bmatrix} 1 & \Delta t & & & \\ & 1 & \Delta t & & \\ & & 1 & & \\ & & & 1 & \\ & & & & 1 \end{bmatrix} \begin{bmatrix} x^{k-1} \\ y^{k-1} \\ v_x^{k-1} \\ v_y^{k-1} \end{bmatrix} + N \sim (0, Q) \quad (1)$$

### A. System Measurement: GPS Pseudo-Range Positioning

GPS has the advantages of fast positioning speed, accurate positioning, low cost, and wide coverage. The positioning results can be obtained by solving Formula (2) with four unknown variables  $x$ ,  $y$ ,  $z$ ,  $\delta$ . When the receiver can receive four satellite signals, the equation has a unique solution; when the received signal is less than 4, the GPS satellite cannot independently calculate the receiver position; When the received signals are more than 4, the least square method is usually used to solve the overdetermined equations. When many satellite signals can be received, the more the number of equations, the more stable the solution result, and the more minor effect of one satellite measurement deviation on the positioning result, making the positioning result more accurate and stable [19, 20]. The positioning accuracy of GPS is closely related to the number of satellite signals received. Due to cost and energy consumption limitations, mobile terminals' satellite signal reception capacity is commonly insufficient, and high-rise buildings could block GPS signal transmission in urban areas. Many reasons will affect the reception of satellite signals, resulting in inaccurate positioning, so improving the accuracy of trajectory data is crucial [21].

$$(x^s - x)^2 + (y^s - y)^2 + (z^s - z)^2 = (\rho^s - \delta c)^2 \quad (2)$$

In Formula (2),  $[x^s, y^s, z^s]$  is the coordinates of the received satellite;  $[x, y, z]$  is the coordinates of the receiver;  $\delta$  is the receiver's clock error;  $c$  is the speed of light;  $\rho^s$  is the pseudo-range of the received satellite, which can be calculated by Formula (3).

$$\rho^s = (r^s + \delta - \delta^s + I + T)c + \varepsilon^s \quad (3)$$

In Formula (3),  $r^s$  is the time required for the signal to be transmission between the receiver and the satellite under vacuum conditions,  $\delta^s$  is the clock error of the satellite,  $I$  is the ionospheric delay,  $T$  is the tropospheric delay, and  $\varepsilon^s$  is the error of the pseudo-range.

### B. System Measurement: Satellite Doppler Velocimetry

Formula (3) calculates the derivative of time to obtain Formula (4).

$$\dot{\rho}^s = (\dot{r}^s + \dot{\delta} - \dot{\delta}^s + \dot{I} + \dot{T})c + \dot{\varepsilon}^s \quad (4)$$

In Formula (4),  $\dot{\rho}^s$  is the rate of change of pseudo-range, which can be calculated by Doppler frequency shift [22], as in Formula (5);  $\dot{r}^s c$  is the change rate of the geometric distance between the receiver and satellite, as shown in Formula (6);  $\dot{\delta}$  and  $\dot{\delta}^s$  are frequency drift of receiver and satellite;  $\dot{I}$  and  $\dot{T}$  are the change rate of ionospheric delay and tropospheric delay, which are small enough to be ignored [23].

$$\dot{\rho}^s = -\lambda(f - f^s) \quad (5)$$

In Formula (5),  $\lambda$  is the wavelength of the transmitted signal,  $f$  and  $f^s$  are the frequency of the signal received by the receiver and the frequency of the signal transmitted by satellite, respectively.

$$\dot{r}^s c = (v^s - v)I^s \quad (6)$$

In Formula (6),  $v^s = [v_x^s, v_y^s, v_z^s]^T$  is the travel speed of the satellite;  $v = [v_x, v_y, v_z]^T$  is the travel speed of the terminal device or user, which is an unknown variable to be solved;  $I^s$  is the directional unit vector of the receiver, which can be calculated according to Formula (7).

$$I^s = \frac{1}{\sqrt{\Delta x^2 + \Delta y^2 + \Delta z^2}} \begin{bmatrix} \Delta x \\ \Delta y \\ \Delta z \end{bmatrix} \quad (7)$$

Substitute Formula (5-6) into Formula (4) to get Formula (8), and then sort out all unknown variables into the left side to get Formula (9) with four unknown variables  $v_x$ ,  $v_y$ ,  $v_z$ ,  $\dot{\delta}$ . When the number of satellite signals that can be received is greater than or equal to four, the travel speed of the mobile terminal or user can be obtained by solving Formula (9).

$$-\lambda(f - f^s) = (v^s - v)I^s + \dot{\delta} - \dot{\delta}^s + \dot{\varepsilon}^s \quad (8)$$

$$vI^s - \dot{\delta} = \lambda f - \lambda f^s + v^s I - \delta^s + \varepsilon^s \quad (9)$$

### III. KALMAN FILTERING SYSTEM

Kalman filter is an optimal estimation method using the system state equation. When the measurement variance is known, the Kalman filter can estimate the optimal state of the system from a series of measurements containing noise [24, 25]. This Section introduces the basic calculation process of the Kalman filter, and the static Kalman filter method is used to calculate the changing trend of system Kalman gain and system state uncertainty. Then, the random error of the measured value of the system is correlated with the DOP of satellite positioning to establish a dynamic Kalman filter system.

#### C. Static Kalman Filter System

The linear Kalman filter method calculation includes two stages of prediction and update involving five formulas.

In the prediction stage, the calculation of the linear Kalman filter includes:

- System state prediction equation. It uses the previous state  $\hat{\sigma}_{k-1}$  to infer the current state  $\hat{\sigma}_k$ , such as Formula (10). In Formula (10),  $A$  is the state transition matrix, which establishes the relationship between the current system state and the system state at the previous moment through kinematics laws.

$$-\lambda(f - f^s) = (v^s - v)I^s + \dot{\delta} - \delta^s + \varepsilon^s \quad (10)$$

- Prediction equation of system uncertainty. It calculates the prior estimate  $P_k$  of the current system state uncertainty according to the uncertainty  $P_{k-1}$  of the previous moment and the system's random error  $Q$  of the observation value, as shown in Formula (11).

$$-\lambda(f - f^s) = (v^s - v)I^s + \dot{\delta} - \delta^s + \varepsilon^s \quad (11)$$

- In the update stage, the calculation of the linear Kalman filter includes:

$$K_k = \frac{P_k}{P_k + R} \quad (12)$$

- System state update equation. It calculates the current system optimal state  $\hat{\sigma}_k$  according to the prior estimate  $\hat{\sigma}_k$  of the system state, the current measured value  $z_k$ , and the Kalman gain  $K_k$ , such as Formula (13).

$$\hat{\sigma}_k = \hat{\sigma}_k + K_k(z_k - \hat{\sigma}_k) \quad (13)$$

- Update equation of system uncertainty. It calculates the optimal uncertainty  $P_k$  of the current system state according to the prior estimated uncertainty  $P_k$  and Kalman gain  $K_k$ , such as Formula (14). In Formula (14),  $E$  is an identity matrix.

$$P_k = (E - K_k)P_k \quad (14)$$

The calculation flow of the whole Kalman filter is shown in Fig. 1. The upper level of Fig. 1 includes two initial and measurement modules responsible for data input. The initialization module inputs the iterative initial values of  $\hat{\sigma}_0$  and  $P_0$ , and the parameters needed for random error  $R$ , systematic error  $Q$ , and transition matrix  $A_k$  to establish the system equation. The measurement module continuously inputs the measured values  $z_k$  in the iterative calculation process of the system. The middle level of Fig. 1 is the core of the calculation in the Kallman filter, which uses Formula (10-14) to iterate the system's state, including the prediction and update modules. The lower level of Fig. 1 is responsible for the output of the system's optimal state and uncertainty.

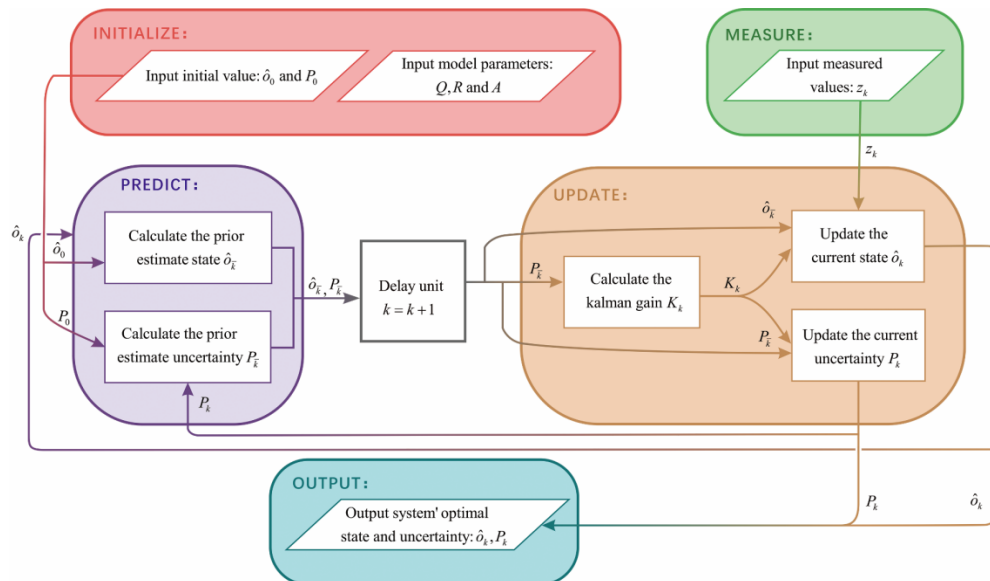

Fig. 1. The calculation flow of the linear kallman filter.

This study uses the Doppler velocity measurement and pseudo-range positioning results of GPS to establish the system state, with a calculation step of  $\Delta t=10$ , and the settings of the system error and random error of measurement are shown in Formula (15-16).

$$Q = \begin{bmatrix} \varepsilon_x & \varepsilon_y & \varepsilon_{vx} & \varepsilon_{vy} \\ 0.5 & & & \\ & 0.5 & & \\ & & 0.1 & 0.1 \\ & & 0.1 & 0.1 \end{bmatrix} \begin{matrix} \varepsilon_x \\ \varepsilon_y \\ \varepsilon_{vx} \\ \varepsilon_{vy} \end{matrix} \quad (15)$$

$$R = \begin{bmatrix} \partial_x & \partial_y & \partial_{vx} & \partial_{vy} \\ 2.5 & & & \\ & 2.5 & & \\ & & 0.5 & 0.5 \\ & & 0.5 & 0.5 \end{bmatrix} \begin{matrix} \partial_x \\ \partial_y \\ \partial_{vx} \\ \partial_{vy} \end{matrix} \quad (16)$$

According to the established system state equation, the variation trend of the Kalman gain and uncertainty with iteration is calculated and plotting Fig. 2. This Kalman filter system is static because the parameters  $A$ ,  $Q$ , and  $R$  of the system are constant. According to Fig. 2, the Kalman gain and uncertainty gradually decrease and converge with the calculation iteration in the static system.

#### D. Dynamic Kalman Filtering System

The transition matrix  $A$  is invariant, determined by the kinematic relationship between position and speed in the system state equation, as well as the system error matrix  $Q$  will not be easily changed in specific equipment. However, the number and geometric distribution of received satellites in space change over time according to the ephemeris and can affect the measurement random error  $R$ . When  $R(t)$  is added to the system instead of  $R$ , a dynamic Kalman filter system can be obtained [26]. Generally, GPS measurement random error can be indicated by the DOP. Fig. 3

shows the DOP and the number of received satellites in the study area on the day of the experiment.

Fig. 3 shows five different DOPs, geometric DOP, time DOP, position DOP, horizontal DOP, and vertical DOP, among which the horizontal DOP is the most suitable for establishing a functional relationship with  $R(t)$ . At 9:50, the maximum value of horizontal DOP was 1.66, and at 00:00, the minimum value of horizontal DOP was 0.73. Therefore, the variation trend of the Kalman gain and system state uncertainty with iteration was calculated when  $R(t)=1.66$  and  $R(t)=0.73$ , as shown in Fig. 4. In the dynamic Kalman filter system, the Kalman gain and the system state uncertainty will vary within the values of the filling area in Fig. 4. With the iterative calculation of the system, the Kalman gain and the system state uncertainty will gradually stabilize and fluctuate in a small range.

Fig. 2. The variation trend of the kalman gain and uncertainty in the iterative calculation.

Fig. 3. The DOP and the number of received satellites in the study area on the day of the experiment.

Fig. 4. The variation range of the kalman gain and the uncertainty in the dynamic kalman filtering system.

#### IV. EXPERIMENT

##### A. Study Region

In this study, the performance of the proposed method is verified by using the taxi travel trajectory data in Shenzhen.

The longitude range of the study area is 113.8 to 114.25, and the latitude range is 22.5 to 22.75. The study date is October 22, 2013. Fig. 5 shows the study area's administrative divisions, natural resources, land use, and urban road conditions.

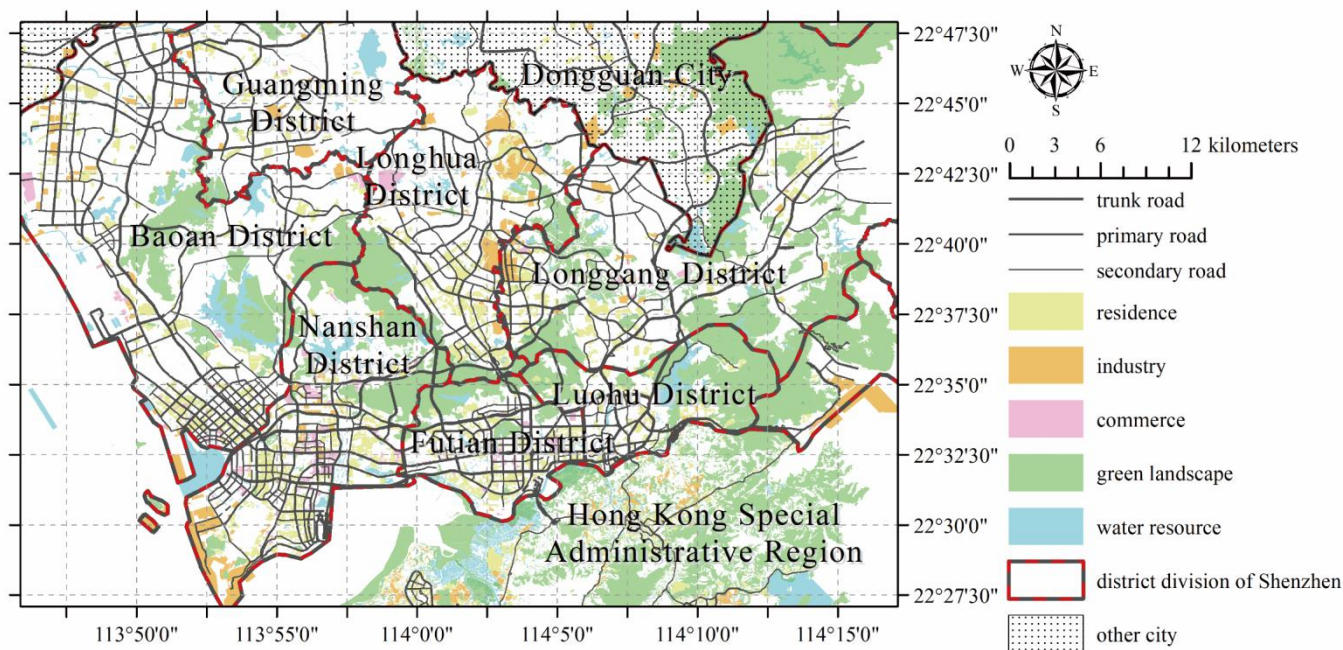

Fig. 5. The geographic information of the study region.

### B. Data Description

The data set records the taxi ID, current time, longitude, latitude, speed, and occupancy status. Table I shows some data.

TABLE I. EXAMPLES OF SOME RECORDS IN THE DATA SET

taxi ID	time	longitude	latitude	speed (m/s)	occupancy status
22223	00:03:39	114.167732	22.562550	2.56	1
22223	00:03:54	114.168999	22.562550	11.94	1
22223	00:04:09	114.170998	22.562550	13.06	1
22223	00:04:23	114.172897	22.562599	15.11	1
22223	00:04:39	114.175232	22.561701	18.33	1

The field taxi ID is used to distinguish between different taxis and has no practical meaning. The time, longitude, latitude, and speed fields record an equipment's current time, position, and speed. The field occupancy status records whether the taxi has an ongoing order, with 1 meaning a passenger and 0 meaning no passenger. The data set contains 46927855 records of 14728 taxis. To display the spatial distribution of trajectory points in the study area, evenly divide the study area into 100 by 100 grids, count the number of records in each grid, and draw Fig. 6.

### C. Data Analysis and Visualization

The entire dataset contains a large number of trajectories, which cannot be displayed in one picture, so just one taxi's trajectories are drawn. Fig. 7 shows 21 orders' trajectories for one taxi in a whole day. Due to trajectories having different lengths and too many trajectories are easy to overlap, it is unsuitable to be displayed in a figure with a constant scale. So, Fig. 7 is divided into four subfigures with different view ranges and scales. In Fig. 7, the solid line represents the trajectory that has not been optimized, and the dotted line represents the trajectory that the Kalman filter has optimized. Fig. 7(a), with the largest scale, shows some orders with long travel trajectories and long service duration, most of which occur late at night. Fig. 7(d), with the smallest scale, can more clearly compare the trajectories before and after optimization, which shows some orders in the city center.

### D. Results

In order to more intuitively compare the accuracy of the trajectory before and after optimization, the deviation between the trajectory point and the nearest road is calculated, and accumulate the deviations by each order. The results show that the average deviation between trajectory points and urban roads is reduced by 33.6%, which indicates that the trajectory data optimization method based on Doppler velocimetry proposed in this study can reduce the deviation between trajectories and urban road networks and improve the quality of trajectory data. Notably, the deviation between trajectory points and urban roads is related to the error level but cannot directly represent it. For example, in the trajectory of the 19th order in Fig. 7(d), there is a section of the trajectory with a significant deviation. Still, the deviation value of the entire order is insignificant due to the lack of positioning points in this trajectory section. Sometimes the optimized trajectory cannot reduce the deviation, such as the 7th order in Fig. 7(c). At the overall level, the proposed optimization method can be considered efficient.

Fig. 6. The spatial distribution of trajectory points in the study area.

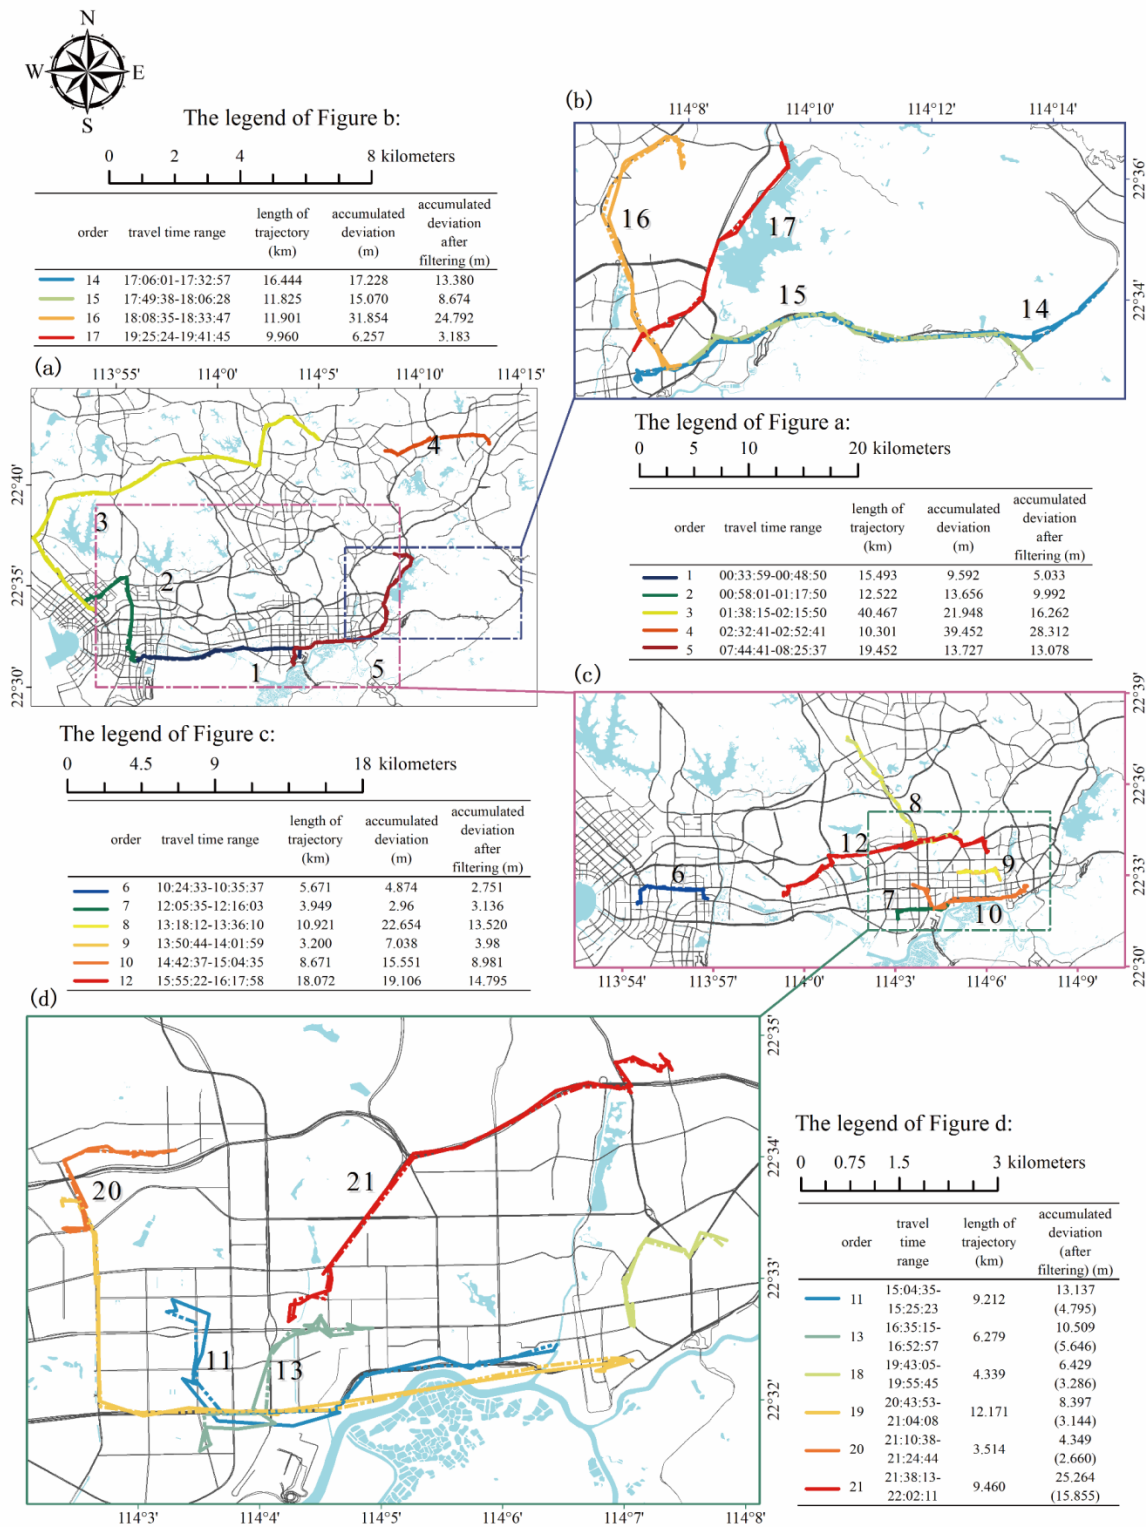

Fig. 7. Visualization of travel trajectories of a taxi before and after optimization.

### V. CONCLUSIONS

With the development of the mobile Internet, the number of terminal devices with positioning capability has increased rapidly. However, due to cost and energy consumption, the positioning capabilities of these devices have significant

differences. This paper establishes the system state equation of travel trajectory using Doppler velocity measurement and pseudo-range positioning data. By correlating the measured random error in the system state with the DOP of satellite positioning, a dynamic Kalman filter system is established to

optimize the trajectory data. The results show that the optimized trajectory data can better fit the urban road and can be applied to data analysis in transportation studies.

# Optimized YOLOv7 for Small Target Detection in Aerial Images Captured by Drone

Yanxin Liu, Shuai Chen\*, Lin Luo

School of Information and Control Engineering, Liaoning Petrochemical University, Fushun, China

**Abstract**—It is challenging to detect small targets in aerial images captured by drones due to variations in target sizes and occlusions arising from the surrounding environment. This study proposes an optimized object detection algorithm based on YOLOv7 to address the above-mentioned challenges. The proposed method comprises the design of a Genetic Kmeans (1-IoU) clustering algorithm to obtain customized anchor boxes that more significantly apply to the dataset. Moreover, the SPPFCSPC\_group structure is optimized using group convolutions to reduce model parameters. The fusion of Spatial Pyramid Pooling-Fast (SPPF) and Cross Stage Partial (CSP) structures leads to increased detection accuracy and enhanced multi-scale feature fusion network. Furthermore, a Detect Head is incorporated into the classification phase for more accurate position and class predictions. According to experimental findings, the optimized YOLOv7 algorithm performs quite well on the VisDrone2019 dataset in terms of detection accuracy. Compared with the original YOLOv7 algorithm, the optimized version shows a 0.18% increase in the Average Precision (AP), a reduction of 5.7 M model parameters, and a 1.12 Frames Per Second (FPS) improvement in the frame rate. With the above-described enhancements in AP and parameter reduction, the precision of small target detection and the real-time detection speed are increased notably. In general, the optimized YOLOv7 algorithm offers superior accuracy and real-time capability, thus making it well-suited for small target detection tasks in real-time drone aerial photography.

**Keywords**—Small target detection; drone aerial photography; YOLOv7; clustering algorithm; spatial pyramid pooling

## I. INTRODUCTION

Modern urban areas are characterized by dense city blocks, tall buildings, high population density, and heavy traffic, and they are capable of creating complex and dynamic environments. Satellite remote sensing is subjected to limitations in capturing high-resolution and high-dynamic range information for small targets for its revisit cycles, spatial resolution, and urban canyon effects. As sensor technology has been leaping forward, Unmanned Aerial Vehicles (UAVs) equipped with various sensors have emerged as effective tools for dynamically acquiring target images. UAV aerial imaging offers several advantages (e.g., a wide field of view, strong target detection capability, high real-time performance, as well as comprehensive information acquisition). Accurate detection and recognition of small targets through UAV aerial imaging enable fine-grained monitoring and provide valuable data for data-driven decision-making. However, conventional object detection algorithms struggle to effectively localize and accurately recognize small targets due to their low resolution and high noise interference.

Deep learning-based object detection algorithms have become the mainstream method due to their optimized efficiency and accuracy. The above-mentioned algorithms typically employ two-stage or one-stage detection strategies. Two-stage detection methods generate a series of candidate object boxes, which are subsequently filtered and refined by classifiers. Examples of two-stage algorithms include Faster Region-based Convolutional Neural Network (Faster R-CNN) [1] and Region-based Fully Convolutional Network (R-FCN) [2]. One-stage detection methods utilize convolutional neural networks [3] to extract image features and perform object classification and localization based on the above-described features. Algorithms such as You Only Look Once (YOLO) [4]–[11] and Single Shot MultiBox detector (SSD) [12] offer higher accuracy and generalization capability. To be specific, YOLOv7 has been confirmed as an advanced detection algorithm in the YOLO series, surpassing previous versions for inference speed and detection accuracy. Besides, it exhibits enhanced performance in detecting targets at different scales. However, challenges remain when YOLOv7 is employed for small target detection in UAV aerial imaging. First, small targets exhibit weak feature representation, such that they turn out to be susceptible to background interference and result in issues (e.g., false positives and false negatives). Second, deep learning models require significant computational resources for training and inference, whereas UAV aerial systems are subjected to limited computing resources and storage capacity. Accordingly, improving model size and computational efficiency becomes necessary. Lastly, deep learning algorithms are dependent on large-scale, high-quality annotated datasets to enhance their generalization capability, which is challenging to obtain specifically tailored for small target detection in UAV aerial imaging.

In this study, an enhanced YOLOv7 algorithm is presented for detecting small targets in UAV aerial imaging, to tackle the above challenges and fulfill the improvement requirements. The VisDrone2019 dataset is employed as the benchmark for detection. The proposed algorithm incorporates several significant enhancements, which comprise the redesign of anchor box sizes using an optimized clustering algorithm, the reduction of unnecessary candidate boxes, the reconstruction of the Spatial Pyramid Pooling (SPP) module, the integration of group convolutions and improved pooling connections, the reduction of model parameters, and the increased detection efficiency. Furthermore, a more accurate detection head, termed Detect, is introduced for target classification and position regression. The specific contributions of this study are elucidated below:

- The design of a high-precision anchor box clustering algorithm, termed Genetic Kmeans (1-IoU), employs genetic algorithms to optimize Kmeans clustering and adopts Intersection over Union (IoU) distance as a novel distance metric. The above-described algorithm leads to higher detection accuracy while reducing the likelihood of missing small targets.
- The optimization of the SPP module, SPPFCSPC\_group, by integrating group convolutions and combining the SPPF module and the CSP structures. This enhancement improves the ability exhibited by the algorithm to detect multi-scale targets and reduces model complexity while increasing object detection accuracy.
- The adoption of a more precise detection head, termed Detect, achieves higher precision and recall in target classification and localization. Accordingly, false positives are reduced significantly, and the model is endowed with the enhanced ability to distinguish between targets and the background.

The optimized YOLOv7 algorithm is assessed on 10 target categories. Comparative analysis with the baseline YOLOv7 model demonstrates a 0.18% increase in Average Precision (AP), a reduction of 5.7% in model parameters, and a 1.12 times improvement in Frames Per Second (FPS). As revealed by the experimental results, the optimized YOLOv7 algorithm achieves high precision and speed in the recognition of tiny objects during UAV aerial imagery.

## II. RELATED WORK

In object detection, small targets are commonly defined in accordance with the relative scale, with a bounding box area to image area ratio less than the square root of 0.33, or following the absolute scale, with a resolution less than 32 by 32 pixels. In UAV aerial imaging, tiny target detection requires adjustments in data format, algorithm structure, and parameter settings to tackle several challenges (e.g., small target size, weak feature representation, occlusion, deformation, high noise interference, and real-time requirements). In general, researchers address the above-mentioned challenges by implementing multi-scale detection strategies to cope with small targets of different sizes, incorporating contextual information and spatial constraints to increase the target localization accuracy, and introducing attention mechanisms to handle complex scenarios with occlusions and deformations involved.

For algorithm optimization, Zhang et al. [13] proposed YOLOv7-RAR algorithm for urban vehicle recognition. To be specific, these researchers reconstructed the backbone network using the Res3Unit structure, with the aim of enhancing the model's capability to capture more nonlinear features. Moreover, they introduced an ACmix attention mechanism to address weak target localization arising from background interference. Zhu et al. [14] developed TPH-YOLOv5 algorithm for target detection in UAV captured scenes. In the above-described method, YOLOv5 serves as the baseline model, a Transformer prediction head is employed, and a Convolutional Block Attention Module (CBAM) attention

mechanism is incorporated to enhance detection performance in dense aerial target scenarios. The enhanced algorithm achieves a 7% increase in accuracy compared with the baseline YOLOv5 model. However, the above-described methods often introduced additional network layers and parameters, resulting in increased computational complexity and limiting practical applications.

For data preprocessing, augmenting the training dataset can lead to the enhanced diversity and quantity of small targets, such that the model can be endowed with the enhanced generalization capability. Optimizing anchor box strategies can reduce computational costs and improve the matching between anchor boxes and real targets, enhancing detection accuracy. For instance, Liu and Wang [15] developed a YOLO-based detection network for corn detection and used a technique for data synthesis to create simulated images of broken maize from genuine corn photographs, such that the challenge of acquiring training data for damaged corn can be addressed. In the task of insulator defect detection, Zheng et al. [16] optimized YOLOv7 algorithm using the Kmeans++ clustering algorithm to cluster insulator targets and generate anchor boxes that more significantly apply to the detection of insulator defects. In the video surveillance vehicle detection task, Pan et al. [17] designed the improved YOLOv5s algorithm using Kmeans algorithm to correct the anchor frames and coordinated the CA attention mechanism for image recognition, which provided more accurate vehicle detection results and higher efficiency in terms of processing speed. The proposed method achieved high detection accuracy and speed on NVIDIA TX2 platform. However, optimized anchor boxes may struggle to accurately differentiate targets when they are occluded or overlapped, such that the detection accuracy can be reduced.

To conform to real-time requirements, algorithm optimization techniques (e.g., network pruning and quantization) are capable of reducing model computation and memory usage, such that the inference process can be expedited. Moreover, computational complexity can be reduced using lightweight model structures. Wu et al. [18] employed pruning techniques to lightweight the YOLOv4 network for concrete crack detection, where the EvoNorm-S0 algorithm was adopted to increase the detection accuracy. The resulting model achieved a high mAP value of 92.54% and a 15.9% reduction in the inference time, such that a real-time and high-precision detection algorithm was yielded. With the aim of detecting rice diseases and pests, Jia et al. [19] improved the YOLOv7 method and used the lightweight MobileNetV3 network for feature extraction, such that the model parameters were reduced, while an accuracy of 92.3% was generated. However, lightweight structures or network pruning may reduce model capacity while adversely affecting its representation capability, particularly in complex scene tasks, such that the accuracy and generalization capability can be decreased.

Despite the advancements achieved by regulating network structures, existing network architectures still struggle to reconcile detection speed and accuracy, particularly in highly overlapping small target areas. Thus, in-depth improvements should be made to increase the speed and precision of small target recognition algorithms based on UAV aerial imagery,

ultimately elevating the capabilities of small target recognition and fine-grained monitoring in UAV aerial photography.

### III. OPTIMIZED YOLOV7 ALGORITHM

#### A. Overview of YOLOv7

YOLOv7 refers to a single-stage deep learning-based object detection framework that achieves efficient object detection by detecting all objects in a single forward pass [11]. Compared with previous versions of the YOLO series, YOLOv7 offers faster convolution operations and higher detection accuracy, enabling it to detect more fine-grained objects while maintaining high detection speed. The YOLOv7 network structure comprises three components, i.e., a backbone network, a feature pyramid pooling layer, and a Head. Fig. 1 presents the simplified diagram of the YOLOv7 network structure. Backbone utilizes multiple convolutional layers to extract rich feature information, which is employed for subsequent object detection. The neck structure introduces the Path Aggregation-FPN (PAFPN) structure, combining feature maps at different scales to endow the algorithm with the enhanced capability to recognize various-sized things. The head layer employs the RepConv structure in conjunction with the IDetect Head to predict the target class and bounding boxes from the feature maps. The YOLOv7 algorithm exhibits high speed and real-time object detection capabilities while finding wide applications in areas (e.g., real-time video surveillance, UAV aerial imaging, and autonomous driving). It is capable of expediting the realization of intelligent and automated applications in a wide variety of scenarios.

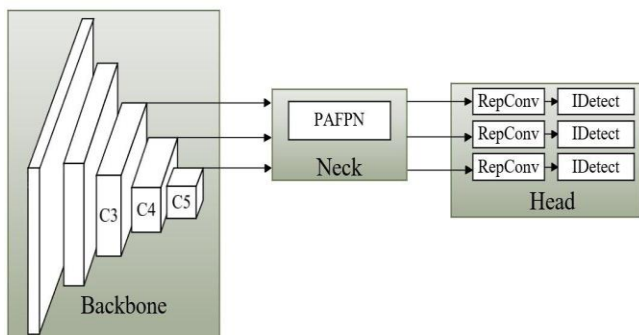

Fig. 1. Simplified diagram of YOLOv7 network structure.

However, YOLOv7 has high memory usage and may not be advantageous for mobile devices or resource-constrained systems. Additionally, the default anchor boxes of YOLOv7 are clustered based on the entire Common Objects in Context (COCO) training set, which may result in significant differences in target sizes and aspect ratios compared with the targets in specific detection scenarios. Accordingly, it is necessary to optimize and improve the YOLOv7 algorithm to better adapt to practical detection tasks and achieve superior detection performance.

#### B. Overall Structure of the Optimized YOLOv7 Network

In the optimized YOLOv7 object detection algorithm, YOLOv7 serves as the baseline model, and optimizations and improvements are introduced in three aspects (i.e., clustering anchor box sizes, SPP structure, and detection head). Fig. 2 presents the overall structure of the optimized YOLOv7. At the

preprocessing stage, the Genetic Kmeans (1-IoU) clustering algorithm is proposed in this study to redefine the shape of anchor boxes. The above-described algorithm adopts genetic algorithms to optimize Kmeans clustering while employing IoU distance as a distance metric. Based on this method, the redefined anchor box shapes are more significantly consistent with the custom sample data, such that the detection accuracy can be improved, and the false positives can be reduced. The spatial pyramid structure in the feature fusion network divides the feature map into various groups via group convolution, and each group is then subjected to convolution processes independently. Moreover, the SPPF module with a serial structure is combined with the CSP structure to decrease computational costs and increase the effectiveness of the receptive field. This combination forms the SPPFCSPC\_group module, which reduces the number of parameters, accelerates inference speed, and enhances the generalization ability of the model. The head layer incorporates RepConv module and Detect Head. By stacking multiple convolutional layers and sharing weights, the model can enhance its capacity to represent features and better comprehend the target's finer nuances. Moreover, RepConv module can adapt to targets of different scales and shapes. When combined with the Detect Head, it can be applied to feature maps at a wide range of levels, enhancing the model's capacity to recognize targets of all sizes and forms.

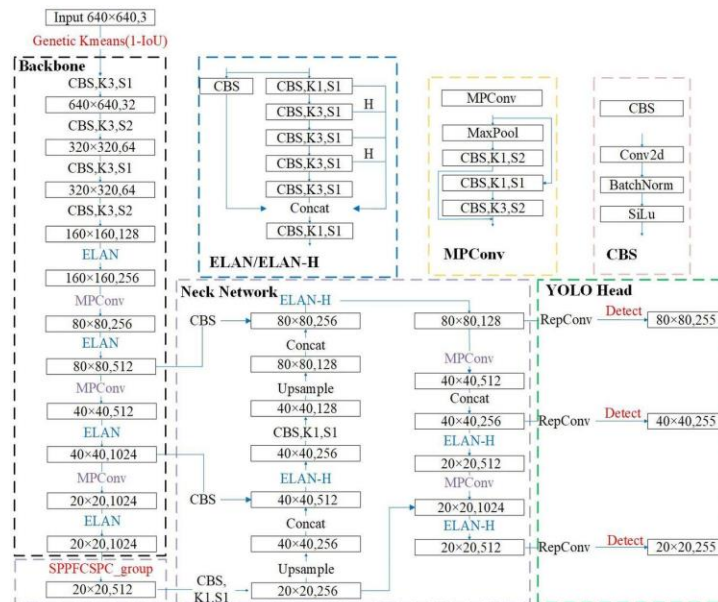

Fig. 2. Overall structure of optimized YOLOv7 network.

#### C. Genetic Kmeans (1-IoU) Anchor Box Clustering Algorithms

At the preprocessing stage of the object detection algorithm, this study proposes Genetic Kmeans (1-IoU) algorithm to recluster the anchor box shapes. Genetic Kmeans (1-IoU) algorithm utilizes genetic algorithms to optimize Kmeans clustering [20]. Following the random initialization of the population and iterative optimization through genetic operations, the problem of local optima is addressed, and clustering quality is improved [21]. Furthermore, under the presence of significant overlap between different scales and

categories in the dataset employed in this study, the conventional Kmeans algorithm employs Euclidean distance as the distance measure between sample points without considering the size and overlap of the object bounding boxes. This increases the uncertainty of the model regarding the object bounding boxes. Thus, Genetic Kmeans (1-IoU) algorithm introduces IoU distance, taking into account the separation between the center points and the overlap of the two bounding boxes. To be specific, this algorithm measures the similarity between different categories by calculating the IoU distance between the cluster centers and sample points.

The specific steps of Genetic Kmeans (1-IoU) algorithm are elucidated below:

1) Randomly select  $k$  samples as the initial centers of the clusters and randomly initialize the cluster centers. Determine the IoU distance between each sample's location and the center of each cluster, then place the sample in the cluster to which it is closest. The calculation equations are written in Eq. (1) and Eq. (2).

$$d(box, centroid) = 1 - IoU(box, centroid) \quad (1)$$

$$\mathcal{L}_{IoU} = 1 - IoU = 1 - \frac{B \cap B^{gt}}{B \cup B^{gt}} \quad (2)$$

2) Transform the clustering problem into an optimization problem of assessing the objective function, which can be written as:

$$\min J_E = \sum_{j=1}^c \sum_{k=1}^{n_j} \|x_k^j - m_j\| \quad (3)$$

$$\max J_B = \sum_{j=1}^c (m_j - m)^T (m_j - m) \quad (4)$$

where  $x_k^j$  represents the  $k$ -th sample that falls into the class;  $n_j$  denotes the number of samples in class  $j$ ;  $m_j$  expresses the center of class  $c_j$ , which is determined by Eq. (5);  $m$  represents the center of all samples, which is written in Eq. (6).

$$m_j = \frac{1}{n_j} \sum_{k=1}^{n_j} x_k^j \quad (5)$$

$$m = \frac{1}{n} \sum_{i=1}^n x_i \quad (6)$$

3) The clustering performance of the genetic algorithm is assessed using the *fitness* value, as shown in Eq. (7). A higher fitness value indicates a greater likelihood for the individual's genes to be selected for the next generation.

$$fitness = \frac{J_B}{J_E} = \frac{\sum_{j=1}^c (m_j - m)^T (m_j - m)}{\sum_{j=1}^c \sum_{k=1}^{n_j} \|x_k^j - m_j\|} \quad (7)$$

#### D. SPPFCSPC\_Group Structure

Based on the SPPCSPC module (as shown in Fig. 3(a)), the SPPFCSPC\_group module is designed to perform feature fusion and dimensionality reduction at different scales in the Neck network structure of the improved YOLOv7 algorithm. Fig. 3(b) presents the structure of the SPPFCSPC\_group module, comprising a series of group convolutions, SPPF module, and CSP structure. By partially connecting at different stages of the network and cross-linking the features of the earlier stage with the later stage, the SPPFCSPC\_group module

increases the performance of target recognition and the network's capacity to represent features.

Fig. 3. Space pyramid pooling module (a) Structure of SPPCSPC module (b) Structure of SPPFCSPC\_group module.

To be specific, the input image undergoes feature extraction through a series of group convolution layers. After feature extraction, the SPPF module uses group convolutions to execute multi-scale pooling operations to capture broad and specific information at various scales. The input feature map is divided into various scales by the SPPF module, and each scale undergoes a group convolution operation to obtain scale-specific feature representations [22]. The group convolutions concatenate the feature maps from multiple scales, resulting in a feature representation that contains global and local information at different scales. After feature fusion, The CSP module separates the feature map into two parts after feature fusion: one portion directly conducts the subsequent convolution operation; the other half is preprocessed before being fused with the previous component, such that the feature representation capability can be enhanced.

Fig. 4 depicts the structure of group convolution. Eq (8) and (9), respectively, indicate the number of parameters in a single convolution kernel and the total number of parameters in the convolution layer.

$$P_1 = \begin{cases} C_{in} \times K_1 \times K_2, bias = False \\ C_{in} \times K_1 \times K_2 + 1, bias = True \end{cases} \quad (8)$$

$$Parameters = C_{out} \times P_1 \quad (9)$$

where the input is expressed as  $C_{in}$ ,  $H_{in}$ ,  $W_{in}$ , and  $D_{in}$ ; the output is denoted as  $C_{out}$ ,  $H_{out}$ ,  $W_{out}$ , and  $D_{out}$ .

Group convolution divides the input feature map into  $g$  groups following the channel dimension while applying a regular convolution to the respective group. The number of parameters for group convolution is represented by Eq. (10).

$$Parameters_{Group} = \begin{cases} C_{out} \times (\frac{C_{in}}{g} \times K_1 \times K_2), bias = False \\ C_{out} \times (\frac{C_{in}}{g} \times K_1 \times K_2 + 1), bias = True \end{cases} \quad (10)$$

where  $\frac{C_{in}}{g}$  denotes the number of channels in each group of the input feature map, i.e., the number of channels in the respective convolutional kernel. After group convolution is

completed, a regular convolution is applied to the respective group. Since the respective group requires at least one convolutional kernel, the output channel number  $C_{out}$  for group convolution is at least  $g$ . If the respective group covers  $n$  convolutional kernels, the output channel number  $C_{out}$  is given by  $n \times g$  ( $n > 1$ ), here  $y$  expresses the number of groups. In other words, the output channel number  $C_{out}$  is a multiple of the number of groups. Accordingly, group convolution requires that the input and output channel numbers be evenly divided by the number of groups  $g$ . The reduction in the number of parameters is the fundamental reason behind the decrease in the channel number of the respective convolutional kernel to  $1/g$  after group convolution is completed.

Fig. 4. Structure of group convolution.

### E. Optimized YOLOv7 Detection Head

The optimized YOLOv7 algorithm utilizes the Detect Head in the Head layer to obtain prediction results. The feature map transfers the Detect Head by the optimized YOLOv7 model. Fig. 5 depicts the Detect module's flowchart. The Detect Head utilizes a series of convolutional layers and fully connected layers to predict the position and class of the target. The above-described layers extract features through convolution operations and nonlinear activation functions and map them to the spatial coordinates and class of the target. The optimized YOLOv7 algorithm outputs the prediction results through the Detect Head, along with labels and confidence scores for the target classes. Since no extra classifiers or regressors are necessary because the Detect Head can anticipate the bounding boxes and classes of the targets directly, the model structure can be simplified, computational and memory overhead can be reduced, and the inference speed can be increased. Furthermore, the Detect Head is not dependent on feature vectors to predict the position and size of the targets, such that the bounding boxes and classes can be directly predicted. Consequently, the Detect Head enhances the precision of target localization to a certain extent.

Fig. 5. Flowchart of detection head.

## IV. EXPERIMENTAL VALIDATION AND ANALYSIS

### A. Dataset Preparation

In this study, the performance of the optimized YOLOv7 model for small object detection is assessed using the VisDrone2019 dataset. A total of 2158 samples are randomly selected to generate a custom dataset, with the aim of investigating the detection capabilities of the optimized YOLOv7 algorithm on small objects. A training set and a test set are divided into the custom dataset in 7:3 ratio. The original detection categories are further assigned to 10 classes. For simplicity, new names are assigned to the above-mentioned 10 classes in the experiment. The names and distribution of the target categories are listed in Table I. In the custom dataset, based on the definition of small objects for relative scale, small objects account for approximately 70% of the dataset. Likewise, small objects take up approximately 54% of the dataset, following the definition of small objects for absolute scale.

TABLE I. CORRESPONDING NAMES AND QUANTITY DISTRIBUTION OF TARGET CATEGORIES

Category	Models	Accuracy (%)
pedestrian	C1	79339
people	C2	27059
bicycle	C3	10480
car	C4	144867
van	C5	24956
truck	C6	12875
tricycle	C7	4812
awning-tricycle	C8	3246
bus	C9	5926
motor	C10	29647

### B. Experimental Condition and Assessment Metrics

The experiments are performed on an Alienware X15 R1 laptop with the following hardware specifications: 11th Gen Intel (R) Core (TM) i7-11800H CPU (2.3GHz), 32GB RAM, NVIDIA GeForce RTX 3070 GPU with 8GB VRAM. The experiments are performed using the PyTorch deep learning framework on Windows 11 operating system. The program code is implemented in Python, utilizing libraries (e.g., CUDA, Cudnn, and OpenCV). The above-mentioned setup contributes to the training and testing of tiny item detection on the VisDrone2019 dataset. In the comparative experiments and fusion studies, the input image is configured to be 640 by 640 pixels. 50 total epochs of training are completed, with a batch size of 2. Weight decay is set to 0.0005, momentum is set to 0.937, and the initial learning rate is set to 0.01.

Common assessment metrics in object detection algorithms are employed to objectively evaluate the effectiveness of the detection models. The above-described metrics comprise AP, mean Average Precision (mAP), Number of Parameters (Params), Giga Floating-point Operations Per Second (GFLOPS), as well as FPS.

C. Comparative Analysis of Experimental Results

1) Comparison and analysis of clustering algorithm loss curves: During the training of the YOLOv7 model, the Best Possible Recall (BPR) between the default anchor boxes and each target in the custom dataset is automatically determined by the network. If the BPR falls below 0.98, the detection model uses a combination of genetic algorithm and Kmeans to recluster and generate new anchor boxes, known as Autoanchor. Autoanchor combines genetic algorithm with Kmeans clustering and utilizes Euclidean distance for mutation on the clustering results. The experiment tested three different clustering algorithms: Autoanchor using Euclidean distance, Kmeans using 1-IoU distance, and Genetic Kmeans. Table II displays the predicted anchor box forms for each clustering algorithm at various scales.

TABLE II. ANCHOR BOX SHAPES FOR THREE CLUSTERING ALGORITHMS AT PREDICTED SCALES

Branch	P3	P4	P5
Dimension	80 × 80	40 × 40	20 × 20
Autoanchor	(2,3,3,8,6,5)	(7,14,12,8,21,12)	(13,21,30,23,48,45)
Kmeans (1-IoU)	(2,3,3,7,6,5)	(6,12,11,9,11,20)	(22,12,25,25,47,39)
Genetic Kmeans (1-IoU)	(2,4,3,8,6,6)	(6,12,12,9,11,18)	(25,14,23,28,47,36)

Table III presents a comparison of assessment metrics for a variety of clustering algorithms. The models with optimized anchor box sizes achieve overall improved detection accuracy compared with the baseline network. mAP achieved by the model using Genetic Kmeans (1-IoU) as the clustering algorithm reaches 31.8%, marking improvements of 0.4% and 0.4% compared with Autoanchor and Kmeans (1-IoU), respectively. To be specific, mAP is raised by 0.9% in comparison to the original YOLOv7 algorithm. Furthermore, AP obtained by training the network with Genetic Kmeans (1-IoU) reaches 17.04%, marking improvements of 1.41% and 0.61% over the original YOLOv7 algorithm and Autoanchor, respectively. As revealed by the above-mentioned results, the detection model achieves higher detection accuracy by using 1-IoU distance and improving Kmeans clustering method with genetic algorithms to generate anchor boxes that more effectively match the sizes of detection targets in the sample dataset. In general, compared with the original YOLOv7 model, Genetic Kmeans (1-IoU) achieves the optimal performance.

TABLE III. COMPARISON OF ASSESSMENT METRICS FOR DIFFERENT CLUSTERING ALGORITHMS

Anchor	YOLOv7	Autoanchor	Kmeans (1-IoU)	Genetic Kmeans (1-IoU)
AP (%)	15.63	16.43	17.05	17.04
mAP (%)	30.9	31.4	31.4	31.8
GFLOPS	103.5	103.5	103.5	103.5
FPS	60.61	65.79	65.79	64.93
Params (M)	36.54	36.54	36.54	36.54

The trained models are further validated for loss. Fig. 6 presents the comparison of loss curves for different clustering algorithms. As depicted in Fig. 6, Autoanchor and Kmeans (1-IoU) have slightly higher losses compared with Genetic Kmeans (1-IoU), with average losses of 0.13, 0.1309, and 0.1288, respectively. In contrast, YOLOv7 has the slowest decrease in loss, with a final average loss of 0.1316. The above result suggests that the Genetic Kmeans (1-IoU) algorithm reduces the loss of the original YOLOv7 algorithm by 0.28%.

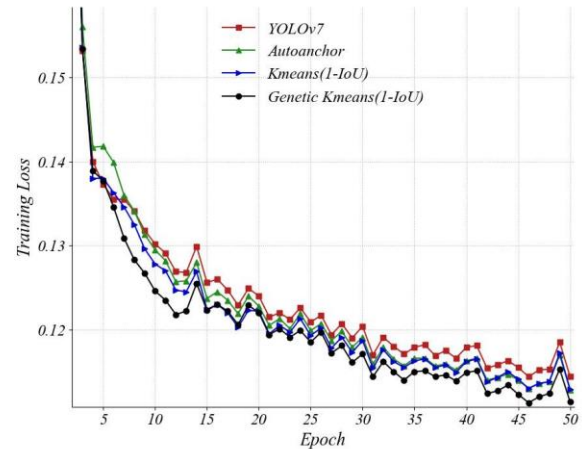

Fig. 6. Comparison of loss curves for different clustering algorithms.

2) Comparison and analysis of assessment metrics for pyramid pooling structure: A fusion experiment is performed on the pyramid pooling module to validate the effectiveness of the SPPFCSPC\_group module, which utilizes grouped convolution and the SPPF structure, in small object detection from aerial images captured by drones. Starting with the SPPCSPC module, improvements are made sequentially with grouped convolution and the SPPF structure. Table IV presents the comparison of assessment metrics for the fusion study of the pyramid pooling module. As seen in Table IV, using grouped convolution decreases the module’s parameter size by 5.7 M. The SPPFCSPC\_group structure achieves an AP value of 15.82%, marking an improvement of 0.19% compared with the SPPCSPC structure. Moreover, FPS is increased by 3.91, validating the performance of the optimized structure for accuracy and speed.

TABLE IV. PERFORMANCE COMPARISON OF ASSESSMENT METRICS IN FUSION STUDY ON PYRAMID POOLING MODULE

Neck	SPPCSPC	SPPCSPC_group	SPPFCSPC_group
AP (%)	15.63	15.26	15.82
mAP (%)	30.9	30.8	30.8
GFLOPS	103.5	99.0	99.0
FPS	60.61	60.98	64.52
Params (M)	36.54	30.84	30.84

To further verify the effect of the SPPFCSPC\_group module on the detection accuracy of small object samples in the YOLOv7 model for aerial drone images, experiments are performed to compare five different pyramid pooling structures, i.e., SPP [23], SPPF, Atrous Spatial Pyramid Pooling (ASPP) [24], Receptive Field Block (RFB) [25], and SPPFCSPC\_group. Table V presents the comparison of assessment metrics for the comparative study of the pyramid pooling module.

As depicted in Table V, the YOLOv7 baseline network achieves the maximum AP value and mAP value when using the SPPFCSPC\_group structure, which is 15.82% and 30.8% respectively. The adoption of group convolution reduces the model parameters to only 30.84 M, resulting in a reduction of 14.61 and 2.44 M compared with the ASPP module and the RFB module that utilize dilated convolution, respectively. As revealed by the above result, while reducing the model parameters, the model maintains a high detection accuracy and avoids weakening the information interaction between different layers by using group convolution. The above-described findings validate the effectiveness of SPPFCSPC\_group module.

TABLE V. PERFORMANCE COMPARISON OF ASSESSMENT METRICS IN COMPARATIVE STUDY ON PYRAMID POOLING MODULE

Neck	SPP	SPPF	ASPP	RFB	SPPFCSPC_group
AP (%)	15.26	15.50	15.73	15.78	15.82
mAP (%)	30.6	30.7	30.6	30.5	30.8
GFLOPS	98.7	98.7	110.6	100.9	99.0
FPS	65.79	68.49	64.51	64.94	64.52
Params (M)	30.51	30.51	45.45	33.28	30.84

3) Comparison and analysis of different detection heads:

The positive and negative sample allocation strategy of YOLOv7 is designed around the Lead head and the Auxiliary head, combining the positive and negative sample allocation strategies of YOLOv5 and YOLOX. To assess the impact of different detection heads on the model’s detection accuracy, a comparative analysis was conducted among YOLOv5, YOLOX, the default Detect Head used in YOLOv7, Decoupled Head, and IDetect Head.

TABLE VI. PERFORMANCE COMPARISON OF DIFFERENT DETECTION HEADS IN DETECTORS

Head	IDetect	Decoupled Head	Detect Head
AP (%)	15.63	16.80	15.73
mAP (%)	30.9	24.7	30.4
GFLOPS	103.5	144.6	103.5
FPS	60.61	54.05	62.50
Params (M)	36.54	44.03	36.54

As depicted in Table VI, the Decoupled Head achieves the minimum overall precision, with a mAP value of only 24.7%, which is significantly lower than the IDetect Head (6.2%) and

the Detect Head (5.7%). Besides, the Decoupled Head also has the largest parameter count, exceeding that of IDetect by 7.49 M and Detect by 7.49 M. Furthermore, when using the Detect Head, the overall AP value reaches the maximum point at 15.73%, representing a 0.1% increase compared with IDetect Head, while keeping the model size unchanged.

In order to further observe the effect of different detection heads on the model detection accuracy, the experiments are shown in Fig. 7 as scatter plots of the P-R curves on the VisDrone dataset for detectors using different detection heads. The precision P is represented by the vertical axis, while the recall rate R is represented by the horizontal axis. The area enclosed by the curve and the coordinate axes represents the AP value, where a curve closer to the top right corner indicates a better detection model. As seen in Fig. 7, the recall rate steadily raises but the accuracy declines as the number of epochs rises. Decoupled Head shows a rapid decline in precision when the recall rate reaches 20%, suggesting a lower performance of the detector. The P-R curve of Detect largely envelops the curve of IDetect, demonstrating higher precision and recall. This indicates that Detect has stronger adaptability to different scenes, lighting conditions, and variations in target morphology. Thus, through experimental analysis and comparison, Detect achieves optimal classification performance, making it the preferred detection head for the detection model.

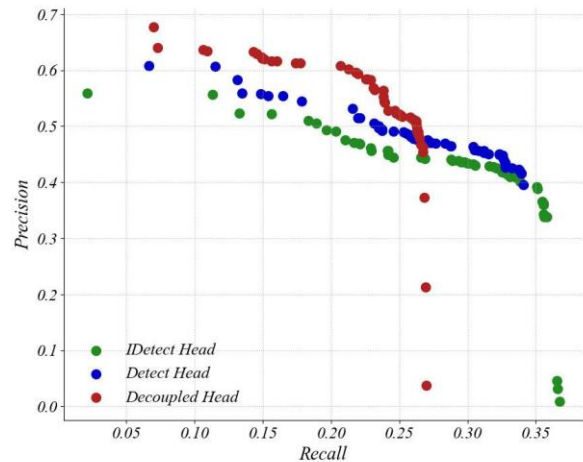

Fig. 7. P-R scatter plot of detectors with different detection heads on the VisDrone dataset.

4) Comparative analysis of fusion studies: To validate the effect of the suggested improvements on the detection model, fusion studies were conducted by testing the components of the improvement method. Table VII compares the results of the fusion studies. The fusion experiments were performed based on the YOLOv7 baseline model, and the improvements were incrementally added to observe their effects on the research objectives and assess their importance. First, IDetect Head was replaced with the Detect Head. Then, Genetic Kmeans (1-IoU) clustering algorithm was added. Finally, the

SPPFCSPC\_group module was added on top of the previous modifications.

TABLE VII. COMPARATIVE RESULTS OF FUSION STUDIES

Method	Baseline	+Detect Head	+Genetic Kmeans (1-IoU)	+SPPFCSPC_group
AP (%)	15.63	15.73	15.13	15.81
mAP (%)	30.9	30.4	30.0	30.3
GFLOPS	103.5	103.5	103.5	99.0
FPS	60.61	62.50	59.52	61.73
Params (M)	36.54	36.54	36.54	30.84

Table VII shows that the proposed improvements have achieved performance gains in small object detection from aerial images. First, replacing the Detect Head resulted in higher detection accuracy with a 0.1% increase in AP and a 2.4 FPS improvement in detection speed, suggesting the good performance of the Detect Head in the context of this study. Second, when the Genetic Kmeans (1-IoU) algorithm and SPPFCSPC\_group module were added on top of the Detect-based model, AP reached its maximum value at 15.81%, which is an improvement of 0.8% compared with YOLOv7. Additionally, the model's parameter count decreased to 30.84 M, which is a reduction of 5.7 M compared with YOLOv7, while achieving an FPS of 61.73, which is a 1.12 improvement over YOLOv7. The above-mentioned results demonstrate that the model may concentrate on positive anchor boxes of high quality by upgrading the original anchor boxes leading to increased detection accuracy. Moreover, the improvements in the form of group convolution and the SPPF module effectively reduce the model's parameter count while increasing the inference speed, thus conforming to the requirements for real-time detection.

5) Comparison and analysis of different models: Table VIII lists the comparative experimental results of a variety of algorithms. Two lightweight models (i.e., YOLOv5s and YOLOv7-Tiny) are tested and compared through the experiments. As depicted in Table VIII, YOLOv5s achieves a higher AP value than YOLOv7-Tiny by 1.45%, whereas its mAP value is 70.7% lower than that of YOLOv7-Tiny. As indicated by the above results, YOLOv5s exhibits high performance in certain categories, while YOLOv7-Tiny exhibits overall higher performance. Among other larger models, the YOLOR-P6 algorithm achieves the minimum detection accuracy, with an AP value of only 10.21% and an mAP value of 20.9%. Optimized YOLOv7 achieves the maximum AP value, with improvements of 0.89%, 3.63%, 5.6%, and 0.18% compared with YOLOv3-SPP, YOLOv51, YOLOR-P6, and YOLOv7, respectively. mAP value of Optimized YOLOv7 is 30.3%, with improvements of 1.0%, 4.8%, and 9.4% compared with YOLOv3-SPP, YOLOv51, and YOLOR-P6, respectively.

TABLE VIII. COMPARATIVE EXPERIMENTAL RESULTS OF DIFFERENT ALGORITHMS

Models	AP (%)	mAP (%)	GFLOPS	FPS	Params (M)
YOLOv3-SPP	14.92	29.3	155.7	54.05	62.61
YOLOv51	12.18	25.5	114.3	59.52	44.66
YOLOv5s	10.20	16.6	16.4	100.00	7.08
YOLOR-P6	10.21	20.9	80.4	63.29	36.87
YOLOv7-Tiny	8.75	17.3	13.2	70.42	6.04
YOLOv7	15.63	30.9	103.5	60.61	36.54
Optimized YOLOv7	15.81	30.3	99.0	61.73	30.84

To provide a more intuitive comparison of different models in detecting the same samples, the comparison of AP values for the respective category is presented in Fig. 8. For some categories with fewer samples, difficult discrimination, and occlusion, such as 'people', 'truck', and 'bicycle', the improvement in accuracy and speed of the models is limited. However, in general, there is a balance between the reduction in model parameters and the improvement in accuracy.

Fig. 8. Comparison of AP values for the respective category.

The detection results of YOLOv3-SPP, YOLOv51, YOLOR-P6, and the optimized YOLOv7 algorithm are compared for three different scenarios: slight category differences, dense object distribution, and low-light conditions at night. As depicted in Fig. 9, detection algorithms are more prone to false positives and false negatives when there exists slight category differences and dense object distribution. Under low-light conditions at night, the visibility of small objects declines significantly, such that the blurred details and edges are generated, adversely affecting the effective feature extraction of the detection network. In contrast to other algorithms, the optimized YOLOv7 algorithm is effective in mitigating the above described interference factors and demonstrates outstanding detection performance in various scenarios.

Fig. 9. Comparison of test outcomes among various algorithms.

6) *GradCAM heatmap visualization analysis*: In this study, the heatmaps of the 102nd layer of the detection network are visualized using GradCAM. The highlighted regions in the heatmaps represent the areas that the network considers relevant to the target categories. The 102nd layer represents the P3 branch of the model, i.e., the feature layer specifically developed for small object detection. This visualization presents a more intuitive insight into the network’s attention and decision-making process in detecting small objects. In the VisDrone dataset, categories (e.g., ‘pedestrian’, ‘people’, and ‘motor’) are considered small objects for their relatively small sizes. Moreover, ‘car’ can still be considered a small object category in scenarios with long distances and significant occlusions even it exhibits a larger relative size. During the experiment, feature visualization is performed for the above-mentioned four small object categories, and Fig. 10 presents the visualization of the detection image heatmaps.

As depicted in Fig. 10, the highlighted regions in the heatmaps represent the detected object positions, suggesting that the network can clearly concentrate on small targets. Furthermore, the intensity of colors in the heatmaps represents the degree of network attention. Compared with the YOLOv7 algorithm, the optimized YOLOv7 algorithm exhibits stronger intensity in the highlighted regions (① and ②) when detecting ‘pedestrian’ and ‘people’, suggesting that the optimized YOLOv7 algorithm accurately focuses on the target objects while exhibiting a higher level of attention towards small targets. In the visualization image for the ‘motor’ category, as indicated by the label (③), when a significant overlap exists between ‘people’ and ‘motor’, the YOLOv7 algorithm tends to produce false positives. However, the optimized YOLOv7 algorithm displays a more distinctive and accurate highlighting in the area representing the ‘motor’ target, suggesting improved attention towards the detection targets. For the ‘car’

category, under a long distance or tree occlusion, the attention intensity of YOLOv7 turns out to be weaker, such that potentially missed detections are conducted. In contrast, the optimized YOLOv7 algorithm achieves the notably enhanced color intensity in the heatmap, marked as (④), suggesting an improvement in detecting small objects that are previously missed.

Fig. 10. Visualization of detection image heatmaps.

As revealed by the experimental analysis, the optimized YOLOv7 algorithm demonstrates significant advantages in accuracy and speed for locating tiny objects in aerial photographs taken by UAVs. In the comparative experiments, the proposed Genetic Kmeans (1-IoU) clustering algorithm allows the model to more effectively cluster the anchor box sizes for small targets. Moreover, the optimized SPPFCSPC\_group module, utilizing group convolution, effectively reduces the model parameters. The integration of the SPPF module with the CSP structure enhances both the speed of inference and the precision of detection. Lastly, the use of the Detect Head improves the model’s confidence in target detection. The optimized YOLOv7 algorithm is capable of recognizing small-sized objects in UAV aerial images more significantly, even in sophisticated backgrounds. Furthermore, fusion experiments are used to confirm the effectiveness of the proposed methods.

## V. CONCLUSION

In this study, an optimized YOLOv7 algorithm is proposed to address the challenges of detecting small-sized and heavily occluded objects in aerial images captured by UAVs. The proposed method comprises three key steps. At the preprocessing stage, an anchor box clustering algorithm is designed to achieve anchor boxes that better suit the dataset,

increasing the accuracy of object detection and reducing the rate of missed detections for small targets. In the feature fusion network, SPP structure based on group convolution is introduced to reduce model parameters and computational complexity. The inference speed of the model is enhanced by adopting a serial pyramid pooling method. Lastly, a detection head that is more tailored to the custom dataset is employed to refine the detection layers. With this method, more accurate detection of small-sized and low-count categories of objects can be achieved. Experimental findings show that compared with the standard YOLOv7, the suggested approach achieves an AP improvement of 0.18%, reduces the model size by 4.5 GFLOPS, decreases the network parameter size by 5.7 million, and increases FPS by 1.12. Accordingly, the proposed method enhances the applicability of the YOLO algorithm for locating tiny targets in aerial photographs that UAVs have recorded.

# DevOps Implementation Challenges in the Indonesian Public Health Organization

Muhammad Yazid Al Qahar, Teguh Raharjo

Faculty of Computer Science, University of Indonesia, Jakarta, Indonesia

**Abstract**—The importance of accelerating software development to meet rapidly changing business needs has driven the Indonesian Public Health Organization (IPHO) to adopt DevOps. But after three years, the expected benefits have not been achieved. This research aims to identify the main challenges and obstacles in implementing DevOps at IPHO. A comprehensive examination of existing literature is employed to recognize prevalent difficulties encountered by organizations when implementing DevOps. The main factors are ranked using the Fuzzy Analytic Hierarchy Process (FAHP) based on survey data from DevOps practitioners at IPHO. This study helps fill in some gaps left by empirical studies on the challenges in applying DevOps, especially in the public healthcare sector. It also streamlines the data collection and analysis process by utilizing FAHP, simplifying the survey process, and reducing the number of questions compared to previous approaches. According to the research findings, the primary hurdle that requires attention is the mindset to transform from a traditional approach to continuous delivery. In addition, the lack of understanding about the benefits of implementing DevOps and the lack of cross-functional leadership are also identified as challenges that need to be considered. However, IPHO does not view the use of legacy tools and technologies as a significant impediment to adopting DevOps.

**Keywords**—DevOps; challenges; fuzzy AHP; software development

## I. INTRODUCTION

Organizations are currently competing to speed up the conversion of business requirements and business concepts into software applications. The rapidity of software application development plays a critical role in addressing the swiftly shifting business needs of customers and accommodating the ever-changing demands of the business landscape [1]. Software organizations must release effective and sustainable products in a volatile market to compete and maintain a competitive advantage [2]. Therefore, companies that focus on software development must continuously improve their project management practices to achieve higher product quality and enter the market faster [3].

The new approach known as DevOps is often described as a way to deliver software faster and with higher quality through collaboration between development (Dev) and operations (Ops) teams [3]. DevOps is still considered a relatively new approach in software engineering but has garnered significant attention from organizations seeking to improve their software delivery processes [1]. DevOps encompasses various aspects such as tools, organizational culture, practices, and collaboration and can help the software

industry achieve better performance and development processes [2].

As Indonesia's largest social insurance company, appointed by the Indonesian government to execute a social health insurance program [4], the Indonesian Public Health Organization (IPHO) is currently attempting to implement DevOps technology in its information system development process. However, the expected benefits have not been realized after running this program for three years. Although IPHO obtained DevOps software licenses and technical support in 2020 [5], no software has yet to utilize DevOps technology in intensive production successfully.

This research aims to identify the key factors that pose challenges and barriers to implementing DevOps at IPHO. The study begins with a literature review to identify challenges and obstacles commonly encountered by companies implementing DevOps technology and culture. A survey is then conducted among the teams at IPHO who have been directly involved in the DevOps implementation process over the past three years. From the survey, the factors posing the main challenges and barriers at IPHO are ranked using the Fuzzy Analytical Hierarchy Process (FAHP) approach.

Comprehensive empirical research on the analysis of challenges in implementing DevOps is currently scarce, especially in sectors such as Public Health Organizations. Hence, this research has the potential to contribute novelty to the domain of DevOps adoption. Furthermore, it will streamline the data collection and analysis of survey data by employing FAHP (Fuzzy Analytic Hierarchy Process). Previous research conducted by M. A. Akbar et al. [6] and A. A. Khan et al. [7] involved two stages of the survey: sentiment assessment of the categories for ranking and pairwise comparison survey. These previous approaches took a long time and required many questions of survey. In this study, the researcher attempts to conduct only one survey stage: a sentiment survey regarding the suitability of categories to real-life events. The researcher will then use the technique of geometric means to translate the scores provided by the survey respondents into Triangular Fuzzy Numbers (TFN) for the computation of pairwise comparisons. The study poses the following research issues regarding this:

RQ1: What are the common challenges and barriers in a company during the implementation of DevOps?

RQ2: What are the main challenges and barriers in implementing DevOps at IPHO?

In this research, the author proposes several sections to provide a clear and comprehensive understanding. Section II provides an in-depth discussion of the research's theoretical foundation, while Section III explains the research methodology used to collect and analyze data. Section IV presents the study results and discussion. Finally, Section V summarizes the study and provides limitations on this research and recommendations for future research directions.

## II. BACKGROUND OF DEVOPS

Evolution tools and methodologies have undergone considerable modifications as a result of the quick development of information technology. Businesses are driven to switch from manual to digital processes because automation can increase efficiency and ensure consistent product quality. The demand for software systems has dramatically expanded [8].

Software organizations continue to seek active development approaches to meet market demands by developing and delivering high-quality software on time and within budget [8]. Dörnenburg [9] suggests that software organizations must adopt new and efficient software development approaches to respond to market demands and effectively address technological changes.

Agile paradigms like Scrum and Kanban have superseded traditional software development methodologies like Waterfall and Spiral to keep up with technological changes and market trends. Because manual processing is prone to mistakes and can cause delays in feedback, production and operational processes have grown more complex [10]. Therefore, a new and more effective software development model known as DevOps has arisen to stay up with the current trend in the software business.

DevOps offers supplemental agile methods based on agile concepts and operational considerations. This strategy facilitates the rapid and continual delivery of developed features over shorter life cycles. DevOps initially had conflicting meanings in the software industry since some communities saw it as a career path requiring expertise in development and operations [11]. Research that defines DevOps as a development environment where growth and operational teams collaborate closely has resolved this issue [11]–[13].

Although there is still a division between developers and operations in DevOps, the operations team oversees changes made to service levels and production [10]. In contrast, the development team consistently creates new features to meet established business objectives. The two teams' tools, procedures, and knowledge bases are distinct. With the help of this system, the development team can continually add new features. In contrast, the operational team works to run the most recent version and control modifications to uphold project quality standards and other non-functional needs [10].

An automated pipeline is needed to address the information flow between the development and operations teams [14]. According to Humble and Farley's [10] automated deployment pipeline, each software version committed to the repository must be prepared for production. To provide a route that

enables automated development, testing, and the quick delivery of tested software features to production, Sten [15] highlights the significance of automation procedures. Callanan and Spillane [16] refer to the deployment pipeline as the DevOps platform and emphasize the need for continuous delivery.

## III. RESEARCH METHODOLOGY

The process depicted in Fig. 1 encompasses several stages. To identify the optimal strategies pertaining to DevOps initiatives, a systematic literature review (SLR) was conducted initially. Subsequently, a survey with a questionnaire was carried out to gather feedback and viewpoints from business experts regarding the selected DevOps concepts. The identified challenges were then prioritized using the fuzzy Analytic Hierarchy Process (fuzzy-AHP) method.

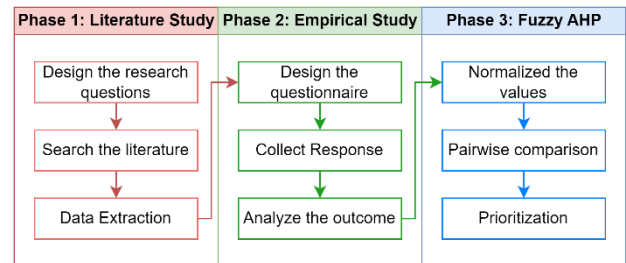

Fig. 1. The utilized research methodology.

- Phase 1: It entailed performing a comprehensive review of the literature to determine the difficulties with DevOps as stated in previous studies.
- Phase 2: It comprised a questionnaire survey aimed at validating the identified challenges empirically, specifically from an industrial perspective.
- Phase 3: Applied the fuzzy AHP methodology to determine the relative importance of the identified challenges in DevOps.

### A. Conducting a Systematic Literature Review (SLR)

The systematic literature review (SLR) used in this study was conducted following the standards set out by Kitchenham and Charter [16]. The SLR process was divided into three stages: planning, conducting, and reporting.

1) *Planning the review*: Making the protocols for data collection and analysis is part of planning. The procedures in the review methodology listed below are employed to obtain and evaluate the available literature to respond to the research question.

a) *Data Collection Source*: Finding literature pertinent to the study's purpose requires carefully selecting data sources. We followed the recommendations of Zhang [17] and Chen [18] in this investigation. The following digital archives found the primary studies relevant to the search:

- Science Direct at <https://www.sciencedirect.com>
- ACM Digital Library at <https://dl.acm.org>
- ProQuest at <https://www.proquest.com>

- Scopus at <https://www.scopus.com>
- IEEE Xplore at <https://ieeexplore.ieee.org>

b) *Search String*: We used the recommendations in the pertinent literature to create the search string for this investigation. First, essential phrases from the relevant papers were determined. Then, the search string was created by combining the "AND" and "OR" operators with the following key phrases and their synonyms: ("DevOps" OR "Development and Operation") AND ("challenge" OR "barriers" OR "obstacles" OR "hurdles" OR "difficulties" OR "impediments" OR "hindrance")

c) *Inclusion And Exclusion Criteria*: The protocols' primary function is to apply the exclusion and inclusion standards to literature found using search terms. Other information technology research, such as those by Niazi and colleagues [19] and the work of Akbar [20], have also used this strategy. The requirements for inclusion are specified in the procedures below:

- Inclusion Criteria:
  - The publication must be from a credible journal, conference, or book.
  - The publication ought to go into the difficulties of putting DevOps into practice.
  - The report must clearly explain how DevOps is implemented.
  - English must be used in the writing of the chosen article.
- Exclusion Criteria:
  - Only the most comprehensive one will be considered when two studies are relevant to the same project.
  - The paper lacks specific information regarding the implementation of DevOps.
  - Studies unrelated to DevOps will be disregarded.
  - Literature studies will not be considered.

d) *Conducting Quality Assessment (QA)*: The efficacy of the chosen literature in answering the study aim was evaluated using the quality assessment (QA) procedure. The QA procedure adhered to the recommendations made in [16]. The Likert scale is depicted in Table I and was used to evaluate the five questions created. Appendix B (Table XIV) has the full QA scores.

TABLE I. CHECKLIST FOR QA OF THE CHOSEN STUDIES

No	Checklist Questions	Likert scale
QA1	Does the analysis strategy use to answer the questions posed?	"Yes=1, Partial=0.5, NO=0"
QA2	Does the analysis look at the difficulties that come with DevOps?	"Yes=1, Partial=0.5, NO=0"
QA3	Does the report offer a convincing justification for putting DevOps into practice?	"Yes=1, Partial=0.5, NO=0"
QA4	Are the data gathered pertinent for using DevOps techniques?	"Yes=1, Partial=0.5, NO=0"
QA5	Do the outcomes that have been discovered support the research issues?	"Yes=1, Partial=0.5, NO=0"

2) *Conducting the Review*: In the initial response of the search string on the chosen databases, 906 studies were recovered. The gathered literature was further improved using the tollgate technique created by Afzal [21]. The tollgate technique involves five steps, and each meticulously carried out with the ultimate goal of selecting the studies for data extraction. As indicated in Fig. 2, 24 studies were chosen for the last data extraction procedure (see Table XIII in Appendix A).

Fig. 2. Filtering formal literature.

a) *Assessment of Selected Study Quality*: The quality evaluation aims to analyze how well the chosen literature addresses the study's research topic. The selected studies are sufficiently relevant in addressing the research topic since 65% of the papers evaluated had a score of or higher than 60% (see Table XIV in Appendix B). During the quality evaluation procedure, a cutoff point of 50% was selected.

b) *Years of Publication of Chosen Articles*: During the data extraction stage, we gathered the studies' publication years to investigate the prevalence of DevOps literature. According to the frequency evaluation, the chosen studies cover 2018 through 2023, demonstrating a developing trend in DevOps research. The result indicates that the field of software engineering research is actively interested in DevOps.

### B. Conducting an Empirical Study

The questionnaire was created using the Google Forms platform, specifically the docs.google.com/forms platform. The questionnaire was broken up into three different sections for clarity and organization.

The first section's primary goal is to collect bibliographic data from survey respondents to give their comments some context. A set of closed-ended questions aimed at addressing the DevOps difficulties discovered via a thorough and systematic literature review (SLR) research was added in the second part. These closed-ended questions provide respondents with a predetermined range of response alternatives, enabling a complete examination of the problems that have been highlighted.

Finally, the questionnaire's third section includes open-ended questions meant to elicit participants' responses on any additional DevOps security problems that the SLR research might not have covered. Therefore, contributors are encouraged to offer thorough justifications, viewpoints, and proposed solutions in this part to contribute to a thorough knowledge of the topic.

The survey's target population includes all IPHO personnel actively working on the DevOps implementation project, which began in 2020 at the early stages of DevOps adoption and will continue until this research is finished in 2023. The main goal is to have a more profound knowledge of the limitations and difficulties encountered while IPHO embraced DevOps.

### C. Utilizing The Fuzzy Analytic Hierarchy Process (Fuzzy AHP)

The fuzzy AHP presents a practical approach for addressing multicriteria decision-making problems. One of the key advantages of utilizing fuzzy AHP is its ease of application and comprehensibility, making it accessible to users. Moreover, it can handle both quantitative and qualitative data effectively. The primary steps employed in implementing the fuzzy AHP methodology are as follows:

- Step 1: Organize the complex decision-making problem into a hierarchy.
- Step 2: Determine the highest and lowest values for each hierarchy element.
- Step 3: Check each pairwise comparison matrix's consistency to confirm correctness.

- Step 4: Establish final ranks for each factor and its corresponding categories.

When assessing the relative importance of various criteria, the traditional Analytic Hierarchy Process (AHP) cannot deal with the ambiguity and vagueness of decision-makers. The AHP approach has been combined with fuzzy theory to solve this issue, creating a fuzzy AHP. As mentioned in the reference [22], this method permits the determination of more precise and dependable judgments in real-time and unforeseen issue scenarios.

In multicriteria decision-making (MCDM) situations, fuzzy AHP is applicable to both qualitative as well as quantitative inputs. The extent analysis approach is used in this method to estimate the priority weight of certain criteria and express preference ratings for the criteria utilizing triangular fuzzy numbers. For this investigation, we used Chang's fuzzy AHP method, which produces more accurate and reliable findings than the traditional AHP method [23].

## IV. RESULT AND DISCUSSION

### A. Findings of SLR Study

The SLR technique was carefully used to pinpoint DevOps operations' challenging and essential elements. Table II lists the 34 tasks that were examined in total. The five categories of "Culture," "Management," "Process," "Teams," and "Tools," which are seen to be crucial elements for the effective use of DevOps principles in the software industry, were then used to map these challenges. This procedure led to the creation of the structure shown in Fig. 3. This mapping exercise's primary goal is to run a fuzzy AHP analysis.

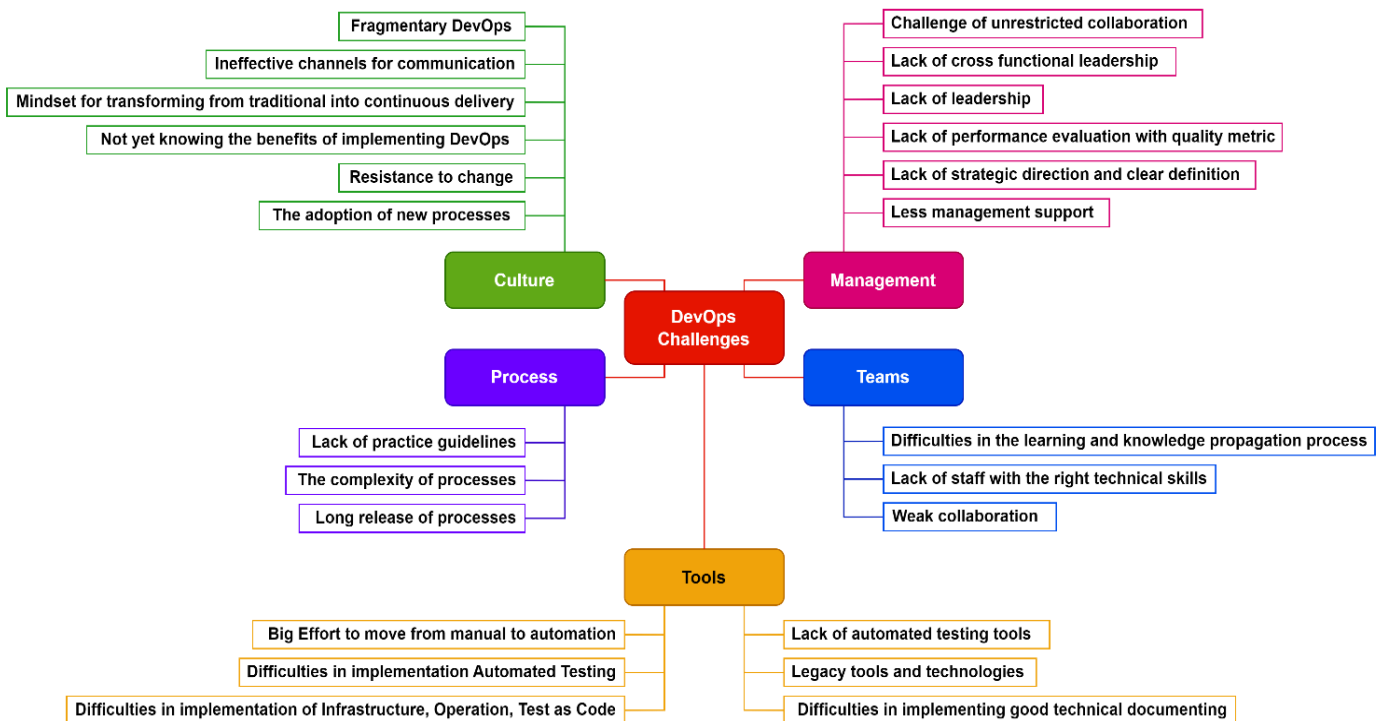

Fig. 3. Mapping of investigated challenges into categories.

TABLE II. LIST OF DEVOPS CHALLENGES

No	Factors	Source
C1	Fragmentary DevOps	[24]–[26]
C2	Ineffective channels for communication	[27]
C3	Mindset for transforming from traditional into continuous delivery	[28]–[30]
C4	Not yet knowing the benefits of implementing DevOps	[28], [31]
C5	Resistance to change	[3], [32]
C6	The adoption of new processes	[3]
C7	Difficulties in allocating resources	[33]–[36]
C8	Lack of cross-functional leadership	[25]
C9	Lack of leadership	[25], [37]
C10	Lack of performance evaluation with a quality metric	[31], [37]–[40]
C11	Lack of a clear concept and strategic direction	[24], [37], [41]
C12	Less management support	[25], [27]
C13	Lack of practice guidelines	[24]
C14	The complexity of processes	[26], [29]
C15	Long release of processes	[29], [42]
C16	Difficulties in the learning and knowledge propagation process	[32]
C17	Lack of technical expertise staff	[25], [27], [29], [41]
C18	Weak collaboration	[24], [25], [27], [41]
C19	Big effort to move from manual to automation	[29], [33], [43]
C20	Difficulties in the implementation of Automated Testing	[34]
C21	Difficulties in implementation of Infrastructure, Operation, Test as Code	[29], [34], [35], [44]
C22	Difficulties in implementing good technical documenting	[35]
C23	Lack of automated testing tools	[34], [45]
C24	Legacy tools and technologies	[26], [29], [37]

**B. Empirical Study Results**

1) *Analysis of survey participants' demographic data:* Detailed demographic data on the survey respondents was gathered while the data was being collected. According to Patten [46], demographic information is critical for understanding survey respondents and assessing if the participants in a given research are a representative sample of the target population to generalize the findings. According to Finstad [47], bibliographic information on survey respondents might provide insight into the maturity of the gathered dataset. Furthermore, Altman [48] underlined that knowing more about survey respondents aids in comprehending the target population's viewpoints. This study acknowledged the significance of the respondents' bibliographic information, and an analysis of many factors, including respondents'

designation and organization size, was done. The following sections explain the findings of this analysis.

a) *Designation of the respondent:* The importance of the influencing elements, which differ depending on the characteristics of the respondents, were stressed by Finstad [47]. Niazi [19] adds that the practitioner's position affects how a factor has an effect, adding that the influence of a component may be appropriately rated if the responder regularly works with that specific issue. The analysis of respondents based on their titles is shown in Fig. 4, which demonstrates that project managers make up most survey respondents. According to the results, "Junior Programmer (Staff)", "Senior Programmer (Assistant Manager)", and "Senior Programmer (Manager)" are the most often used response designations.

Fig. 4. Job title evaluation in survey.

b) *Respondent's Experience:* An analysis was conducted on the experience of the survey participants. The median and mean values were computed, resulting in scores of 3 and 2.4, respectively, indicating a relatively young group of participants. Additionally, notable variations in the respondents' experience were briefly observed. Fig. 5 shows a visual depiction of the survey respondents' information.

Fig. 5. Survey respondents' experiences.

TABLE III. AN EMPIRICAL INVESTIGATION OF CHALLENGES FACTORS

ID	Challenges List	Number of Responses (P=25)							
		Positive			Negative			Neutral	
		S-A	A	%	D	S-D	%	N	%
<b>P1</b>	<b>Culture</b>	<b>5</b>	<b>15</b>	<b>74%</b>	<b>0</b>	<b>0</b>	<b>0%</b>	<b>7</b>	<b>26%</b>
C1	Fragmentary DevOps	12	7	70%	7	0	28%	1	2%

C22	Difficulties in implementing good technical documenting	9	13	81%	1	0	4%	4	15%
C23	Lack of automated testing tools	9	9	67%	3	0	11%	6	22%
C24	Legacy tools and technologies	6	11	63%	5	2	27%	3	10%
<b>Average</b>				<b>73%</b>			<b>10%</b>		<b>17%</b>

2) *Analysis of responses to DevOps challenges:* The empirical study's primary objective was to learn more from business experts about the difficulties faced by DevOps, as determined by a systematic literature review (SLR). Three categories—positive (“agree, strongly agree”), negative (“disagree, strongly disagree”), and “neutral”—were used to classify the replies given by practitioners. The positive category represents the proportion of survey participants who acknowledged the difficulties that might negatively influence DevOps techniques. The opposing group comprises respondents who frequently disagreed with the challenges noted in the SLR research. The neutral type represents the participants who often expressed uncertainty about how the specified factors will affect DevOps operations. Please see Table III for more specific data.

The study's findings are shown in Table III, which shows that most survey respondents concur that DevOps has a bad relationship with the issues in actual operations. According to the frequency analysis, over 50% of survey respondents considered each challenging element. C4, or “Not yet knowing the benefits of implementing DevOps,” was cited as the most challenging problem by survey respondents (94%).

The poll respondents named P2 (Management, 81%) as the most critical categories among the researched complex variables, with P1 (Culture, 74%) placing second. The third most important types of problems are P3 (Process, 63%) and P4 (Team, 73%).

Among the challenges categorized as negative factors, C1(Fragmentary DevOps) emerged as the highest-ranking challenge, with 28% of the respondents disagreeing with its classification as a significant factor in DevOps practices. Following closely behind, and C24 (Legacy tools and

technologies, 27%) received the second highest level of disagreement among the respondents.

Additionally, challenges were sorted based on respondents' limited understanding of their impact on both DevOps implementation with neutral response options. The top-ranked challenge, labeled as C6 (The adoption of new processes), received a 24% response rate. It was closely followed by C10 (Lack of performance evaluation with quality metric), C17 (Lack of staff with the right technical skills), and C23 (Lack of automated testing tools), all of which received a 22% response rate and were ranked as the second-highest challenges.

C. Implementing Fuzzy AHP

The fuzzy-AHP used to investigate the rank of challenges and the categories they fall into is presented in this part. The issues were prioritized using the fuzzy AHP step-by-step procedures mentioned in the preceding section.

Step 1 (Hierarchical Categorization of Complex Problems): The complicated problem is separated into linked decision-making components using the method described in [49] and [50] to do the fuzzy AHP analysis. The top level of the problem reflects the primary goal, whereas Stages 2 and 3 show the types of issues and their accompanying challenges. Fig. 6 depicts the suggested hierarchical structure.

Step 2 (The process of pairwise comparisons): On the basis of professional judgments, the pairwise comparison was undertaken. The author continued using the first questionnaire's data (see Table XV in Appendix C) to gather reference values for the paired comparison data process utilizing the geometric mean calculation approach to provide sufficient and quicker pairwise comparison data. Triangular fuzzy numbers (TFNs) can be generated using the geometric mean from survey respondents' judgments. The following geometric mean formula was applied in this study:

$$\text{Geometric mean} = \sqrt[n]{j_1 \times j_2 \times j_3 \dots j_n} \tag{1}$$

$j$  = Individual judgment weights  
 $n$  = Count of judgments

Step 3 (Verifying the Pairwise Matrix's Consistency): The method for determining if the pairwise comparison matrices are consistent is laid out sequentially in this section. The matrices must show consistency in fuzzy AHP. Consideration is given to the categories on the Likert scale (Table IV). To create the matching Fuzzy Crisp Matrix (FCM) displayed in Table V, the primary categories triangular fuzzy numbers in the pairwise comparison matrix are defuzzification into crisp numbers.

The fuzzy Analytic Hierarchy Process (AHP) can use a comparison matrix that is adequate and trustworthy for many issue categories. The consistency ratio for each category of challenge elements was computed using the same approach, and the results are shown according to Tables VI to X in the appropriate order.

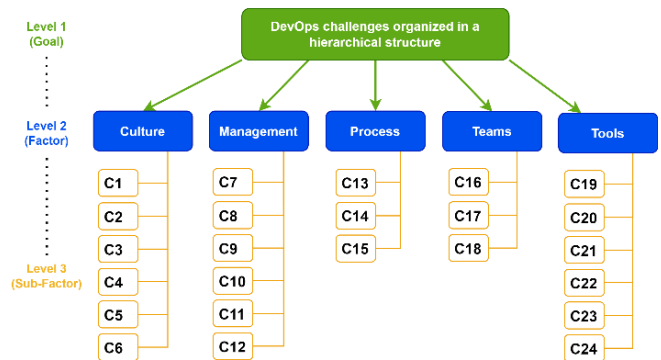

Fig. 6. The hierarchy of the problem structure.

TABLE IV. CONVERSION SCALE OF A FUZZY [51]

Grade	Linguistic scale	Triangular fuzzy scale	Triangular fuzzy reciprocal scale
1	Element j holds the same level of importance as element i.	(1, 1, 1)	(1, 1, 1)
2	Slightly of lower importance.	(1, 2, 3)	(0.33, 0.50, 1.00)
3	Somewhat important, falling within the range of slightly important.	(2, 3, 4)	(0.25, 0.33, 0.50)
4	Moderately important, ranging from slightly important to more important.	(3, 4, 5)	(0.20, 0.25, 0.33)
5	Significantly more important.	(4, 5, 6)	(0.17, 0.20, 0.25)
6	Between a more important and highly important.	(5, 6, 7)	(0.14, 0.17, 0.20)
7	Highly important.	(6, 7, 8)	(0.13, 0.14, 0.17)
8	Between highly important and most important	(7, 8, 9)	(0.11, 0.13, 0.14)
9	Most significance.	(9, 9, 9)	(0.11, 0.11, 0.11)

Tables VI to X indicate that the consistency ratio (CR) is below 0.1, allowing the questionnaire data to be used for the subsequent step, calculating local and global ranking weights.

Step 4 (Weights are determined locally and globally): The weights of the challenges and their associated categories, both locally and globally, were computed. Table XI displays the findings and compares each task's importance to all other challenges (global weight), showing how each problem ranks within its category.

TABLE XI. CALCULATE THE CUMULATIVE WEIGHT OF THE CHALLENGES

Category Weight	Challenges	Local		Global	
		Weight	Rank	Weight	Rank
Culture (0.49952)	C1	0.09543	4	0.04767	7
	C2	0.13911	3	0.06949	6
	C3	0.39976	1	0.19968	1
	C4	0.28827	2	0.14400	2
	C5	0.03210	6	0.01603	15
	C6	0.04534	5	0.02265	14

Category Weight	Challenges	Local		Global	
		Weight	Rank	Weight	Rank
Management (0.25854)	C7	0.13911	3	0.03597	8
	C8	0.39976	1	0.10335	3
	C9	0.28827	2	0.07453	5
	C10	0.03210	6	0.00830	20
	C11	0.09543	4	0.02467	12
	C12	0.04534	5	0.01172	16
Process (0.03880)	C13	0.69183	1	0.02685	11
	C14	0.07648	3	0.00297	23
	C15	0.23169	2	0.00899	19
Teams (0.08156)	C16	0.69183	1	0.08411	4
	C17	0.23169	2	0.02817	10
	C18	0.07648	3	0.00930	18
Tools (0.12158)	C19	0.04534	5	0.00370	22
	C20	0.28827	2	0.02351	13
	C21	0.13911	3	0.01134	17
	C22	0.39976	1	0.03260	9
	C23	0.09543	4	0.00778	21
	C24	0.03210	6	0.00262	24

Step 5 (Challenges Prioritization): The fuzzy AHP analysis's primary goal is to rank the researched challenges according to their importance to the DevOps paradigm. Table XII lists the final standings for each challenge.

TABLE XII. PRIORITY ORDER FOR THE DIFFICULTIES

ID	Challenges List	Rank
C3	Mindset for transforming from traditional into continuous delivery	1
C4	Not yet knowing the benefits of implementing DevOps	2
C8	Lack of cross-functional leadership	3
C16	Difficulties in the learning and knowledge propagation process	4
C9	Lack of leadership	5
C2	Ineffective channels for communication	6
C1	Fragmentary DevOps	7
C7	Difficulties in allocating resources	8
C22	Difficulties in implementing good technical documenting	9
C17	Lack of staff with the right technical skills	10
C13	Lack of practice guidelines	11
C11	Lack of strategic direction and clear definition	12
C20	Difficulties in the implementation of Automated Testing	13
C6	The adoption of new processes	14
C5	Resistance to change	15
C12	Less management support	16
C21	Difficulties in implementation of Infrastructure, Operation, Test as Code	17
C18	Weak collaboration	18
C15	Long release of processes	19
C10	Lack of performance evaluation with quality metric	20
C23	Lack of automated testing tools	21
C19	Big effort to move from manual to automation	22
C14	The complexity of processes	23
C24	Legacy tools and technologies	24

Based on the global weights, it is decided that C3 (Mindset for changing from conventional into continuous delivery) is the most critical challenge that must be solved to implement DevOps methods at IPHO effectively. Additionally, C4 (Not understanding the advantages of applying DevOps) and C8 (Lack of cross-functional leadership) are listed as the second and third most significant priority difficulties for implementing DevOps methods. It is also important to note that C24 (Legacy tools and technologies) is listed as the least major issue for the DevOps paradigm in IPHO.

## V. CONCLUSION

IPHO has adopted DevOps principles due to the significance of expediting software application development to satisfy quickly changing business demands and preserve a competitive edge. The anticipated advantages have not materialized despite this program being in place for three years. This study tries to pinpoint the key variables that IPHO must overcome to use DevOps technology successfully.

The research utilizes a systematic literature review to identify common challenges companies face when implementing DevOps technology and culture. Furthermore, over the past three years, a survey has been conducted among teams directly involved in the DevOps implementation process at IPHO. Using the Fuzzy Analytical Hierarchy Process

(FAHP) method, the detected elements that provide significant problems and impediments are rated.

The limits of empirical studies concerning difficulties in DevOps adoption, particularly in the public healthcare sector, are addressed in this study. It also makes data gathering and analysis easier by employing FAHP, which streamlines the survey process and uses fewer questions than earlier methods.

The most critical challenge that has to be resolved for IPHO to apply DevOps methods effectively is C3 (Mindset for transitioning from conventional to continuous delivery), according to the global weights used in the analysis. In addition, C4 (Lack of knowledge about the advantages of applying DevOps) and C8 (Lack of cross-functional leadership) are noted as the second and third priority hurdles in implementing DevOps methods. It is important to note that at IPHO, C24 (Legacy tools and technologies) is rated as the least important issue for the DevOps concept.

## A. Limitations

Although this study has implemented a comprehensive research methodology, the authors acknowledge the presence of limitations. One of these limitations is the constraint of using only one public health institution as a case study, resulting in a study with a limited scope and more relevant to that specific institution. Additionally, the number of respondents involved in this research is considered inadequate for achieving a more robust analysis.

## B. Future Work

In the future, researchers can still conduct multivocal literature studies to examine the factors influencing DevOps practices but expand the research scope to investigate the success and challenges of adopting DevOps in organizations and involve multiple companies for more comprehensive results. Additionally, utilizing multiple case studies within the same sector can provide a larger sample size and generate more comprehensive analyses.

## ACKNOWLEDGMENT

This research was carried out with the support of a fully funded scholarship program by IPHO, which the first author obtained for study at the University of Indonesia.

TABLE XV. SAMPLE SURVEY QUESTIONNAIRE WAS USED TO CONFIRM THE SECURITY ISSUES WITH DEVOPS

Survey questions to determine the challenges with DevOps adoption in IPHO						
Section A: Personal information of respondents.						
Name						
EmployeeID						
Email address						
How long have you been familiar with or using DevOps?	< 1 year <input type="radio"/>	1 year <input type="radio"/>	2 years <input type="radio"/>	3 years <input type="radio"/>	4 years <input type="radio"/>	5 years <input type="radio"/>
Section B: Challenges related to security in DevOps and their categorization.						
The purpose of this section is to identify Challenges that can have a negative impact on the adoption of DevOps in IPHO. Please provide a rating for each challenge based on your understanding and experience.						
Strongly Agree = 'S-A', Agree = 'A', Neutral = 'N', Disagree = 'D', Strongly Disagree = 'S-D'						
ID	Factors and Categories Identified	S-A	A	N	D	S-D
C1	Does the separation of Developer and Operational teams pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C2	Does ineffective communication channel pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C3	Does the mindset shift from traditional to automated deployment processes pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C4	Does lack of awareness of the benefits of DevOps implementation pose a barrier to its implementation?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C5	Does resistance to change pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C6	Does adoption of new processes pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C7	Does difficulty in resource allocation pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>

C8	Does lack of cross-functional leadership pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C9	Does lack of a key leader pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C10	Does lack of performance evaluation with quality metrics pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C11	Does lack of strategic direction and clear definition pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C12	Does lack of management support pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C13	Does lack of examples/guidelines in practice pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C14	Does process complexity pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C15	Does long release cycles pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C16	Does difficulty in learning and disseminating knowledge pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C17	Does lack of staff with good technical skills pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C18	Does weak collaboration pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C19	Does significant effort to transition from manual to automation pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C20	Does difficulty in implementing Automated Testing pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C21	Does difficulty in automating code generation for Infrastructure, Operation, and Test functions pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C22	Does difficulty in implementing good technical documentation pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C23	Does lack of automated testing tools pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
C24	Does the use of legacy tools and technologies pose a barrier to implementing DevOps?	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Please give other factors that hinder the implementation of DevOps in IPHO (optional): -----						

# A Bibliometric Analysis of Smart Home Acceptance by the Elderly (2004-2023)

Bo Yuan<sup>1</sup>, Norazlyn Kamal Basha<sup>2</sup>

School of Business and Economics, Universiti Putra Malaysia (UPM), Kuala Lumpur, Malaysia<sup>1,2</sup>

**Abstract**—Both academia and business firmly endorse the notion that a smart home would be the solution to easing the excessive social burden associated with demographic ageing and improving older adults' quality of life by enhancing living independence while encouraging their desire to age in place. This study uses bibliometric analysis to examine the research trends on elderly people's acceptance of smart home. The results are derived from analysis using the VOSviewer software on 257 documents in the Scopus database. The results reveal that: there is an accelerating growth rate for the smart home literature focusing on the elderly's acceptance since 2004; the majority of these studies are journal articles filed in the research area of computer science; the most commonly mentioned keywords include "smart home(s)" and "older adults"; the US has produced the highest number of related works; and the most cited articles are composed by authors across nations with tight collaborations.

**Keywords**—Smart home; acceptance; elderly people; ageing-in-place; bibliometric analysis; VOSviewer

## I. INTRODUCTION

A report from the United Nations [1] revealed a global ageing trend by stating that the worldwide population of people aged 65 and above has grown to 771 million by 2022, and is estimated to reach 1.6 billion by 2050 with an increased proportion of 16 percent from 10 percent (in 2022) of the overall population. Demographic ageing may incur serious social problems, such as overburdened health care systems due to the increased demand for nursing facilities and care services [2],[3]. In addition, elderly people are showing significant willingness to continue living in their own homes [4], [5] for the strong desires of independent living, healthcare and social connection [6]. Meanwhile, the elderly care industry has been driven towards intelligence by the Internet technology sector's quick expansion, so the smart home-based elderly care model has come into being for the reason that smart homes would considerably ease the strain of social health care systems by integrating limited elderly care resources in the market and society to provide elderly care services with wisdom, precision and efficiency [7], and on the other hand, would satisfy the need for ageing-in-place (AIP) by the elderly [2]. Therefore, smart home research from the elderly perspective is of great significance to comprehensively learn how their intentions to accept and utilize smart home technologies are formed.

Smart homes are commonly considered as residences in which devices and appliances equipped with interconnected sensors are placed for the purpose of improving inhabitants' comfort, convenience, safety, security and quality of life [5], [8]. The increasingly expanding consumer interest has led to a

rapid growth in the smart home industry. Tech giants like Google, Amazon, Apple, Huawei, Xiaomi and Samsung are racing to meet the demands for their smart home products and services by competing in this emerging market [9]. As Statista [10] estimated, from US\$115.7 billion in 2022, the global smart home market's revenue is projected to soar to US\$222.9 billion in 2027, a CAGR of 22%. Users can benefit from personalized smart home services through either automation or remote control [11] since data and information are automatically interchanged between devices to make corresponding responses according to changes in surrounding environment or users' customization [12]. With the aid of assistive technologies, the elderly may enjoy a higher quality of life in a "smart home" as evidence has shown that the utilization of nursing homes or care-givers leads to negative impacts on older people, such as feelings of stress, depression and change of habit [3]. In this case, the academia around the world all considered AIP through the adoption of smart home as the optimal solution for ageing societies [13], [14].

The term "smart home" is used in this study to describe homes that provide their residents with superior levels of convenience, security, and comfort, which is actualized by networked devices and appliances with processors and sensors [15]. Elderly people, following the extant research, particularly include people who are aged 60 years old and above [16], [17]. Thus, this study's overarching goal is to identify the current state of research on the topic of elderly citizens' adoption of smart homes, including its driving forces and key players, with the expectation of potentially providing suggestions for future studies in this domain.

The remainder of the study is organized as follows. Based on different research focuses on smart homes, Section II overview the recent literature mainly from the perspective of older adults. Section III describes the employed methodology. The results and findings are presented in Section IV, followed by a detailed discussion on the findings. Section V makes conclusions of the whole study.

## II. LITERATURE REVIEW

### A. From Technology Perspective

There has been a lot of research on many aspects of the smart home for the elderly. One group of researchers looked at how and whether smart home technologies helped the elderly. For example, with the use of Ambient Assisted Living technology, Blackman et al. [18] demonstrated that older individuals' autonomy and quality of life could be improved. Aramendi et al. [19] tried to detect functional health decline in the elderly using in-home behavior data collected by smart

homes, and they concluded that functional health issues are predictable from smart home data, which is important for early intervention in ageing societies. Fritz et al. [20] explored a potentially prominent use of health-monitoring smart homes to provide assistance to older adults with chronic conditions by remotely detecting a range of physical status. Results showed that smart homes helped recognize clinical changes in seniors' health and treatment and medication management. To foresee the likelihood of falls among the elderly, Kulurkar et al. [21] developed a low-cost fall detection system using wearable sensors in a smart home setting, and they ended up with a considerably high accuracy rate of 95.87%.

### B. From User Perspective

Another group of researchers has been looking into smart homes from the viewpoint of the elderly since there is a dearth of literature on the attitudes of older individuals about embracing such technology [22]. According to research by Pignini et al. [23], elderly people value health monitoring systems that employ smart technology for their own protection. Yu et al. [24] clustered Korean seniors based on their residential lifestyles to examine whether or not there are distinct requirements for smart home features, and they found that there was some variation. In a focus-group-based study, Ghorayeb et al. [5] revealed that both users and non-users of smart home monitoring technology considered feasibility, customization and data security of great importance to accept the technology; while users concerned more about utility, and less about privacy intrusion and trust.

### C. Bibliometric and Scientometric Work

Benefit from the rapid growth of information technology and statistics tools, scholars have recently made effort to systematically analyze extant smart home literature through bibliometric data. Choi et al. [25] used a bibliometric approach and analyzed 2339 articles published between 2015 and 2019 from the Scopus database in smart home and Internet of Things (IoT) domain in order to indicate key research trends and knowledge mapping for future studies. Li et al. [26] applied a scientometric analysis with smart home research published from 2000-2021 in the Scopus database to illustrate historical changes, emerging trends, and research clusters. Ohlan and Ohlan [27] comprehensively analyzed bibliometric data published in the Web of Science from 2001 to 2021, and suggested indispensable trends and patterns of smart home research. Another study by Hong et al. [28] applied bibliometric and scientometric analyses with 1408 related articles acquired from the Web of Science database to thoroughly overview smart home features for the elderly.

However, in the existing review studies on smart homes, bibliographic approach was seldom applied, and none of the authors made older adults the central focus of their work. Besides, taking the competence of smart homes in helping ease social stress into consideration in the context of demographic ageing, there is a need for systematic research to comprehensively analyze the research trends on the smart home acceptance literature particularly for the elderly. As far as the authors are aware, no research has been done in the area of Smart Home Acceptance by the Elderly (SHAE). Given that it contributes to substantial insights via bibliometric analysis on

a specific subject, structurally reviewing earlier studies to tease out key research trends becomes crucial for scholars. Therefore, this study aims to investigate current research trends of smart home studies, especially those related to the acceptance by the elderly, applying a bibliometric approach to summarize current directions in this field, prominent venues and authors, research clusters, as well as to identify and suggest prospective research directions. Findings of this study will present relevant stakeholders, such as academics, policymakers, and businesses, with research and working directions for the near future.

## III. METHODOLOGY

### A. Bibliometric Analysis

In the study, published articles in the Scopus database on the global trend of SHAE from 2004 through 2023 (by 25 July) are analyzed using bibliometric analysis. Bibliometric analysis was firstly introduced by Pritchard [29], and has been commonly described as a technique using mathematics to statistically analyze published books, articles, and other communication media so as to provide a broad overview of certain knowledge field [25], [30]. By conducting this technique, academics will gain insight into selected research domains in terms of research trends, significant authors, institutions, publishers, nations, as well as potential research gaps [31].

### B. Data Collection

The Elsevier Scopus database was utilized to collect bibliographic data for this study, which has been recognized as a leading multidisciplinary repository of influential peer-reviewed research in social science fields [25], [32] for the reason that it contains a considerable number of high-quality materials, e.g., 75.5 million files, 24.6 thousand titles, and 194 thousand books [26]. Compared to other commonly used databases for bibliometric analyses (i.e., PubMed and Web of Science), Scopus is advantageous for the reasons that it is the largest database containing multidisciplinary publications, and publications are classified into multiple research areas accordingly [33], which makes it more suitable for mapping based on research areas. And the appropriateness of adopting Scopus database has been particularly acknowledged by scholars in the smart home domain [25], [26]. Thus, from the time the first publication on SHAE appeared in the Scopus database until this study was composed, all publications on the subject of the smart home acceptance by the elderly were included (25 July, 2023).

The objective of this research is to examine, from a user's point of view, the relationships between and clusters of related studies on smart homes. Therefore, the query (TITLE-ABS-KEY (smart AND home) AND (adoption OR acceptance)) was set as the search task, which produced a number of 1421 documents. Based on the search results, the query was then refined as (TITLE-ABS-KEY (smart AND home) AND (adoption OR acceptance) AND (elderly OR older)) to focus on the predetermined target age-group, and this resulted in a reduced number of 257 documents. All of the generated documents from the refined searching are retained for a thorough analysis and understanding of the research trends.

The data was collected on 25 July, 2023. The search result includes conference papers, articles, book chapters, reviews, conference reviews, books, notes, letters, and short survey. Data were exported in “CSV” format to be compatible with VOSviewer, the software employed for data analysis.

IV. RESULTS

A. Publication Trend

Table I summarized the publication trend by year since the first article on the elderly acceptance in smart home industry published in 2004. It is clear that not all research articles have been cited. Except for the first six years (2004 – 2009), the proportions of cited publications over total yearly publications never reached 100% for the following years onwards. Overall, the average proportion was 77.14% with a standard deviation of 13.10 from 2010 to 2023. The number of citations received also varied a lot. Documents published in 2018 seem to be most influential since they gained the highest number of citations of 855. Besides, publications in the years of 2008, 2014, 2016 and 2019 also had significant impact for the academia with citations over 460, respectively.

TABLE I. PUBLICATION TREND

Year	Number of Publications	Cited Publications	Proportion	Total Citations
2004	2	2	100%	67
2005	0	0	-	0
2006	1	1	100%	1
2007	2	2	100%	50
2008	5	5	100%	503
2009	3	3	100%	40
2010	6	5	83%	69
2011	10	8	80%	256
2012	13	11	85%	204
2013	9	6	67%	339
2014	13	10	77%	520
2015	10	9	90%	202
2016	13	12	92%	505
2017	17	13	76%	341
2018	22	15	68%	874
2019	20	16	80%	480
2020	23	21	91%	285
2021	30	26	87%	359
2022	41	26	63%	92
2023	17	6	35%	17
<b>Total</b>	<b>257</b>	<b>197</b>		<b>5204</b>

The publication trend can be seen in three stages in terms of research productivity, which is shown in Fig. 1. The first publication appeared in 2004, and was composed by Barlow and Venables [34], entitled “Will technological innovation create the true lifetime home”. For the first stage (2004-2009), no more than five documents were published each year. With an average of 2.2 publications per year, 13 publications (5.06%) in total were produced throughout this time period. In the second stage (2010-2017), a steady growth emerged, and yearly publications ranged from 6 to 17. Overall, 91 publications (35.41%) were produced with an annual average of 11.4. Starting from 2011, a threshold of minimum ten articles (except for 2013, 9 articles) were achieved every year. The third stage extends throughout the most recent six years (2018-2023). Productivity increased considerably as

researchers shifted their focus to the positive or negative effects of smart homes on the elderly. The lower bound for annual publications in this phase increased to 20 from the previous level of 6 with an exception of 17 publications in 2023, which is just the middle of the year. Notably, scholars made the most publications of 41 solely in 2022, and the total publications since 2020 (111) has way exceeded the sum of the entire second stage (91).

Fig. 1. Publication trend.

B. Types of Documents & Sources

By analyzing the data obtained from the Scopus database, seven types of documents were identified, i.e., article, conference paper, conference review, review, book chapter, book, and note. As displayed in Table II, the proportion of “article” (43.58%) is the highest, followed by “conference paper” (34.24%). While other document types account for less than 10% respectively, and there are only one “book” and one “note” published only within the investigated time range.

TABLE II. SUMMARY OF DOCUMENT TYPES

Document Types	Number of Publications	Proportion
Article	112	43.58%
Conference Paper	88	34.24%
Conference Review	22	8.56%
Review	20	7.78%
Book Chapter	13	5.06%
Book	1	0.39%
Note	1	0.39%
<b>Total</b>	<b>257</b>	<b>100%</b>

From Table III, all publications related to the elderly people's openness to smart homes fall into four source types. More than half of the total documents were published in “journal” (52.14%). Not much differences were found between “conference proceeding” (24.12%) and “book series” (19.07%), while “book” seems to be the least interested by researchers since only 12 have been published throughout 19 years since 2004.

TABLE III. SUMMARY OF SOURCE TYPES

Source Types	Number of Publications	Proportion
Journal	134	52.14%
Conference Proceeding	62	24.12%
Book Series	49	19.07%
Book	12	4.67%
<b>Total</b>	<b>257</b>	<b>100%</b>

C. Subject Areas

In all, 21 research areas were addressed by the 257 documents. The distribution of the top ten subject areas related to older adults' adoption of smart homes over a five-year period is shown in Table IV. The density of publications is shown by the red backdrop. The more papers that emerged within a certain year period, the deeper is the shade of red. "Computer Science" (140 publications) has the highest number of articles that are relevant; it is followed in relevance by "Medicine" (80 publications), "Engineering" (70 publications), "Mathematics" (46 publications), and "Social Sciences" (40 publications). It seems that the majority of the studies examining the benefits of smart homes for the elderly focus on their technical and medical applications. In contrast to recent increase in "Biochemistry", "Genetics", and "Molecular Biology", subject areas such as "Engineering", "Social Sciences", and "Physics and Astronomy" exhibit constant growth. "Health Professions" shows a brief decline followed by a minor recent rise.

TABLE IV. DISTRIBUTION OF TOP TEN SUBJECT AREAS IN FIVE-YEAR PERIOD

Table with 6 columns: Research Area, 2004-2008, 2009-2013, 2014-2018, 2019-2023, Total. Rows include Computer Science, Medicine, Engineering, Mathematics, Social Sciences, Nursing, Biochemistry, Genetics and Molecular Biology, Health Professions, Physics and Astronomy, Business, Management and Accounting.

D. Source Title

Research on the SHAE is covered by 160 publication sources. With a minimum of three publications, Table V lists the publications sources with the most activity. The greatest numbers of studies relating to computer science fields are presented in the form of conference proceedings, which are included in the source of "Lecture Notes in Computer Science" (31, 12.1%). When it comes to producing high-quality conference materials, "ACM International Conference Proceeding Series" is another top pick, coming in at number four on the list of all source titles. "Gerontechnology", "Communications In Computer And Information Science" and "Jmir Aging" are the three most prolific journals, with 7, 6, and 5 publications, respectively. Each of the remaining sources contributes less than 2%.

E. Author Keywords

Understanding the distribution and links between the primary research themes on the SHAE was facilitated by the use of co-occurrence analysis, which may probe the internal relationships of a given academic subject [35]. Based on

"keywords" of bibliographic data, a map is produced using the VOSviewer software co-occurrence analysis. Setting the minimum occurrence number to five resulted in a clear keyword network visualization after a number of optimization processes that varied the minimum number of keyword occurrences. The results created a graph with 32 keywords based on five clusters, each with a different focus (see Fig. 2). Cluster 1 (red) focuses on assistive technology for older adults, Cluster 2 (green) emphasizes smart home functionality, Cluster 3 (blue) highlights the Internet of Things and healthcare, Cluster 4 (olive) emphasizes the acceptance of smart home technology, and Cluster 5 (purple) focuses on older people and gerontechnology. Generally, the most common keywords related to older adults and smart homes are included in Cluster 1, while Cluster 4 is mainly about aging and disease.

TABLE V. PRODUCTIVE PUBLICATION SOURCES

Table with 3 columns: Source Title, Publications, Proportion. Rows include Lecture Notes In Computer Science, Gerontechnology, Communications In Computer And Information Science, ACM International Conference Proceeding Series, IEEE Access, Jmir Aging, International Journal Of Environmental Research And Public Health, Gerontology, Handbook Of Smart Homes Health Care And Well Being, International Journal Of Medical Informatics, Journal Of Medical Internet Research, Personal And Ubiquitous Computing, Procedia Computer Science, Proceedings Of The ACM On Human Computer Interaction, Sensors, Universal Access In The Information Society, Others.

In particular, regarding the topic of ageing-in-place and the use of smart technology by the elderly, the most often occurring terms are concentrated in Cluster 1, which has a total link strength of 168. The keyword "smart home" dominates Cluster 2 and has the greatest frequency of occurrence and total link strength of any other term generated. Cluster 3 is somewhat related to Cluster 2 and focuses on the application of IoT technology in the field of geriatric care due to the tight relationship between the technical features of smart homes and IoT. Ageing and the acceptance of smart home technologies are the two topics majorly covered under Cluster 4. With the lowest total link strength of 84 among all five clusters, Cluster 5 focuses primarily on investigating elderly-oriented technologies.

Fig. 2. Co-occurrence network by author keywords.

Table VI lists all keywords generated from related publications in a cluster view. All clusters contain keywords relating to both the elderly (e.g., “older adults”, “elderly people”, “elderly”, “ageing”, “older people”) and technological concepts (e.g., “assistive technology”, “ambient intelligence”, “internet of things”, “ambient assisted living”, “gerontechnology”). However, only the fourth cluster specifically concerns about individuals’ willingness to accept or adopt smart home technology. This is consistent with the viewpoint that there is a lack of studies regarding smart homes from the perspective of users’ perceptions of embracing smart home technologies [12], especially for the elderly people [5].

TABLE VI. KEYWORDS BY CLUSTERS

Cluster	Keyword	Occurrence	Total Link Strength
Cluster 1 (red)	older adults	26	39
	aging in place	14	37
	assistive technology	14	29
	smart home technology	12	16
	privacy	6	17
	telehealth	6	10
	telemedicine	6	8
	security	5	12
Cluster 2 (green)	smart home	58	86
	independent living	8	17
	ambient intelligence	6	13
	elderly people	6	5
	smart technologies	5	10
	sensors	5	9
	usability	5	7
Cluster 3	elderly	21	35

Cluster	Keyword	Occurrence	Total Link Strength
(blue)	internet of things	15	24
	healthcare	10	13
	iot	8	10
	smart technology	5	8
	elderly care	5	7
Cluster 4 (olive)	smart homes	24	33
	technology acceptance	21	33
	ambient assisted living	16	33
	technology adoption	8	18
	ageing	5	12
Cluster 5 (purple)	user-centered design	5	5
	gerontechnology	12	34
	older people	13	15
	home automation	7	14
	technology	6	10
	artificial intelligence	5	11

#### F. Citation Analysis

The top ten most influential papers in the field of SHAE as determined by citation analysis are listed in Table VII of the findings. The article with the highest total citations addressed elderly people’s adoption of voice-activated smart homes and proposed corresponding benefits and concerns [36]. After this article appeared in 2013, it has attracted 305 citations. The second-highest cited work developed a conceptual model to describe the influencing elements of older individuals’ usage of technology that support ageing-in-place [37]. A total of 276 citations have been made to this article since its publication in 2016. Even though over 42% of the publications were merely from the top five most prolific countries, it is worth noting that

leading studies in the field of SHAE were authored by researchers from a variety of nations.

TABLE VII. TOP TEN CITED ARTICLES

Author(s)	Article Title	Year	Source Title	Citations
Portet, F., Vacher, M., Golanski, C., Roux, C., Meillon, B.	Design and evaluation of a smart home voice interface for the elderly: acceptability and objection aspects [36]	2013	Personal and Ubiquitous Computing	305
Peek, S. T. M., Luijckx, K. G., Rijnaard, M. D., Nieboer, M. E., van der Voort, C. S., Aarts, S., van Hoof, J., Vrijhoef, H. J. M., Wouters, E. J. M.	Older Adults' Reasons for Using Technology while Aging in Place [37]	2016	Gerontology	276

### G. Co-Authorship Analysis by Countries

The analysis of international co-authorship networks covered only nations with at least five total publications. Only 18 of the 43 countries satisfied the criteria. There are six European countries, two American, one Asian, and one Oceanian among the top ten most productive countries listed in Table VIII. The US, Germany, and the UK are the top three nations. In terms of publications, the US is well ahead of any other country in the SHAE field. C/P value, which measures the average citation count in a single publication, places the Netherlands, France, and Austria among the leaders in this field despite their relatively low total number of publications.

TABLE VIII. TOP TEN PRODUCTIVE COUNTRIES

Country	Number of Publications (P)	Citations (C)	C/P	Total Link Strength
US	46	1308	28.43	7
Germany	27	434	16.07	11
UK	27	538	19.93	9
Italy	22	555	25.23	12
Canada	19	213	11.21	7
China	15	198	13.20	7
Netherlands	15	680	45.33	11
Australia	13	158	12.15	3
France	11	418	38.00	6
Austria	8	300	37.50	7

Fig. 3 show the national network. The size of the node expands as more articles are published in a single country, and the connecting lines between nodes represent the closeness of the collaboration between the two nations; a thicker line indicates greater cooperation. This network consists of 35 links and 4 clusters. Within each of their different clusters, the US, Germany, UK, and China all contribute significantly to publications, and with the exception of Germany, they are all tightly connected. Since Italy, Germany, and Netherlands have the top three total link strengths (12 for Italy, 11 for Germany, and 11 for Netherlands) among the 18 countries, there are strong lines connecting them, showing tight collaborations. And, in terms of publications, they also ranked highly.

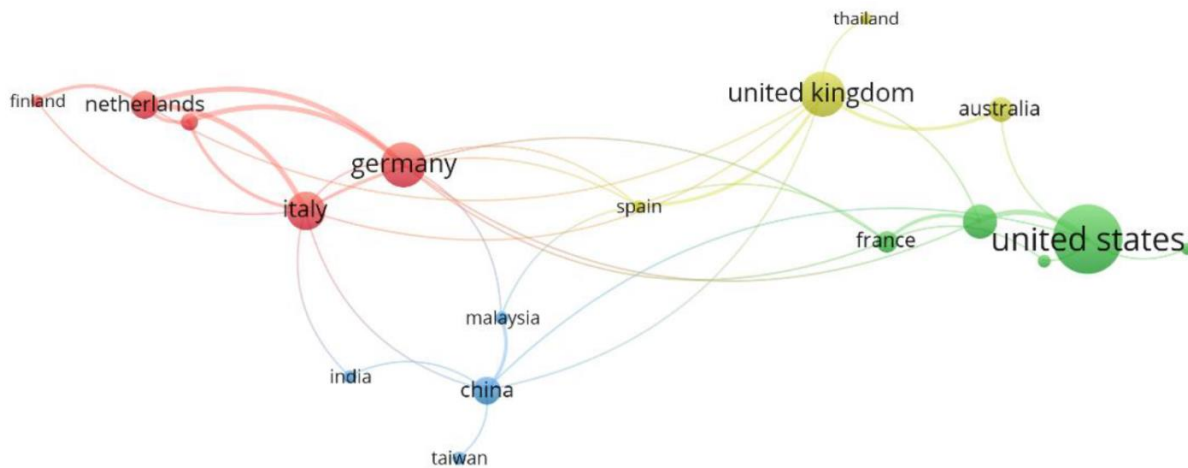

Fig. 3. Co-authorship network by countries.

#### H. Co-Authorship Analysis by Authors

Modern research has entered the age of big science, which emphasizes the need of scientific cooperation due to increased comprehensiveness and complexity [45], [46]. As a result of the complementarity in knowledge and intelligence, academics tend to form solid connections and network blocks [47], and sustain persistent collaborations [48]. Table IX provides a summary of the top ten prolific writers on the SHAE by concentrating on writers who have coauthored at least two papers and been referenced in no less than four other works. Demiris, G. has published the most articles with the highest citations collected; however, his C/P figure only ranked the 8th. Aarts, S., Peek, S.T.M. and Wouters, E.J.M. are closely collaborating with the same publications of 3, and citations of 325. The same pattern has been detected between Portet, F. and Vacher, M.

The scholars who have co-authored with the most other authors is analyzed by the co-authorship network analysis. Co-authorship relationships revealed in research on seniors' acceptance of smart homes are shown in Fig. 4. The constructed network has 63 authors that satisfy the aforementioned criteria with 109 links and a total link strength of 197. The authors are divided into 21 groups, each of which is indicated by a distinct color. The size of each node in the network, which represents an individual author, reflects its relative importance in the network. The findings reveal that Aarts S., Peek S.T.M., and Wouters E.J.M. are top three biggest author nodes and that they are all members of the same cluster (green), which has the greatest total link strength of

134. And academics from the Netherlands predominate, with many members having ties to the same institution, such as Maastricht University and Tilburg University. The interest areas of this group include older adults' technology acceptance, ageing-in-place and healthcare. For example, Peek S.T.M. "Older Adults' Reasons for Using Technology while Aging in Place" [37] in 2016, the most highly collaborative article (9 authors), and "Factors influencing acceptance of technology for aging in place: a systematic review" [49] in 2014, the most cited article (1044 times). In another group (red), scholars are from various countries (e.g., Austria, UK, Netherlands and US), and this group specializes in social applications of intelligent technology.

TABLE IX. TOP TEN PROLIFIC AUTHORS

Author	Publications (P)	Citations (C)	C/P	Total Link Strength
Demiris, G.	9	489	54.33	15
Ziefle, M.	9	174	19.33	10
Brauner, P.	4	42	10.5	7
Funilkul, S.	4	310	77.5	8
Pal, D.	4	310	77.5	8
Aarts, S.	3	325	108.33	17
Peek, S.T.M.	3	325	108.33	17
Portet, F.	3	324	108	9
Vacher, M.	3	324	108	9
Wouters, E.J.M.	3	325	108.33	17

Fig. 4. Co-authorship network by authors.

### I. Bibliographic Coupling

Bibliographic coupling happens when a third source is often cited in two distinct research publications. A visualized bibliographic coupling map at the country level (except for Taiwan) is shown in Fig. 5 with five clusters denoted by different colors, 100 linkages, and a total link strength of 3188. Totally, 18 countries and district that contributed at least five documents are covered.

In terms of published documents, the US, UK, Germany, and Italy are the most substantial nodes. The linking lines indicate the coupling relationship between countries/district

and suggest that nations from various parts of the world are linked by similar patterns of citing reference in their research articles. There are a number of thick lines between countries/district from the same or different clusters, for example, China and Malaysia (the highest link strength of 265), UK and Netherlands (link strength of 199), Germany and Malaysia (link strength of 168), which reveal that there exist collaborations between these connected countries/district. In sum, the investigated data set shows a significant bibliographic connection between the countries and district in different parts of the world.

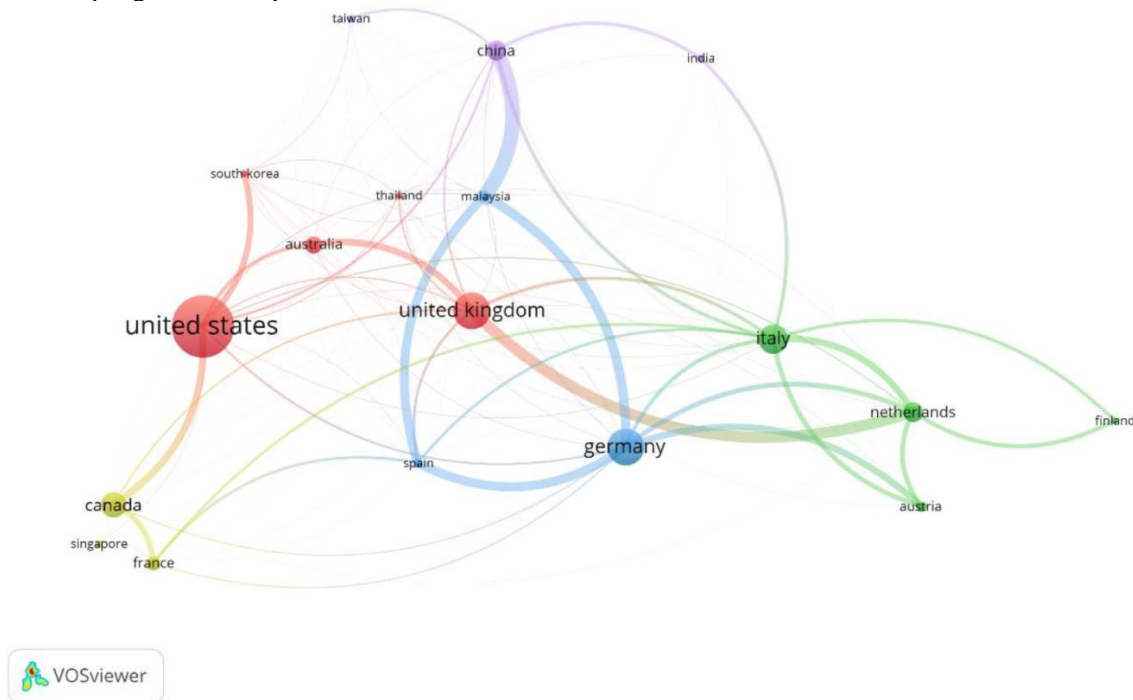

Fig. 5. Bibliographic coupling of countries/district.

## V. DISCUSSION

Due to the worldwide increasingly growing number of ageing population and the associated social issues, research about smart home focusing on the elderly population has been rapidly expanding. However, it has become challenging for academics and practitioners to have a thorough understanding of SHAE due to the enormous rise in the number of related publications. Thus, based on a number of research facets, this study offers a bibliometric analysis of studies on SHAE. The results are discussed in this section regarding each of these facets.

### A. Growing Publication Trend

Since its first presentation, SHAE literature has seen a rising tide of publications, indicating growing interest in the field. Rapid development of the Internet of Things (IoT) has spawned growing practical applications across a wide range of industries, which may account for the uptick in research activity [50]. Additionally, in response to the worldwide challenges (e.g., ageing progress, resources shortage, COVID-19 pandemic), many in academia, business, and government see smart homes as a way to help solve these societal problems [26].

### B. Lack of Interdisciplinary Collaboration

Over half of the current SHAE research may be categorized within the domains of "Computer Science," "Medicine," and "Engineering," according to a breakdown of the most important research topics based on the categories offered by Scopus. Moreover, the majority (13) of the 15 cited published sources focused on either computer-related topics or medically-related applications. Even though knowledge from some cross-disciplinary domains (e.g., psychology, arts and humanities, biology) were referred to, the frequencies were fairly low. Thus, researchers commonly made suggestions and appeal for more attempt at conducting interdisciplinary work [26], [51],[52]. Possible reasons for the currently less convergent research pattern might be a consequence of the competition between tech giants and with other industries [53], which limits the access of specialized knowledge, labor and services [54], then in turn hindered the interdisciplinary collaborations.

### C. Little Emphasis on Elderly Users

As the rising proportion of the ageing population and the trend of AIP while applying smart home technologies [2], More studies on how well smart homes are accepted by the elderly are urgently needed. The results of keywords analysis show that technology-related terms appeared in all keyword clusters, such as "assistive technology", "ambient intelligence", "internet of things", "ambient assisted living", and "gerontechnology". This indicates that the main topics covered in SHAE research are centered on technology attributes and advances, which has been presented in extant research [26].

Conversely, user-oriented keywords such as "technology acceptance", "technology adoption" and "user-centered design" appeared 19, 8 and 5 times respectively, accounting for only 9 percent totally, which agrees with the argument that few research has considered the special needs and using experience of older people in the development and utilization of smart home technologies [55], [56]. Concerns about home and

personal network security have been heightened as a consequence of the intensive adoption of work-from-home strategies due to the COVID-19 pandemic [57], and thus, smart home research extensively put focus on enhancing technological features to ease the concerns relating to possible risks [58]. So, technological advance is currently dominating the research interest and prevalence of existing smart home studies with little emphasis on users' perceptions of the challenges and benefits while using smart home technologies [12], [28]. Furthermore, the ways in which technology is changing the life of the elderly has been surprisingly neglected in research on AIP in smart home settings [59]. Therefore, more elderly user-oriented research on SHAE is needed in order to offer more precise insights into this industry from the demand perspective.

## VI. CONCLUSION

In order to comprehend research publishing trends, document and source types, subject areas, popular source titles, research keyword clusters, notable authors, co-authorship networks, and bibliographic coupling patterns, this study performed bibliometric analyses on the SHAE research since 2004 till 25 July, 2023. By scanning the Scopus database for keywords related to the smart home acceptance by the elderly, the study conducted all analyses with a dataset including 249 documents using the VOSviewer software. Based on the results, this study draws conclusions that the elderly-friendly smart home has dramatically gained academic interest on a global scale in terms of the rapid rise in publications during the last five years; collaborations across disciplines is needed for further research progress in SHAE; the "Lecture Notes In Computer Science" appears to be the most common research venue; technology and health related keywords are all crucial terms other than "smart home(s)" and "older adults"; there exists some global scientific collaboration; and the coincidence of citing preferences at the country level is proved; while the co-authorship network between individual authors is not yet well-established. Thus, researchers should put more attention on learning elderly users' acceptance toward smart homes that are considered promising solution to ageing issues.

Implications of the study are as followed. Firstly, this is the first study, to the authors' knowledge, that employs a comprehensive bibliometric approach to analyze the global trends in research on the acceptance of smart homes by the elderly population. Quantitative information on essential knowledge is provided by the results of the study, which may be utilized to identify research gaps and to plan for future research. Secondly, for policymakers relating to smart homes, more evidence-driven decisions on resource allocation and investment priority could be made according to the findings of this study. Thirdly, insights gained from this study will help develop both national and international strategies for the smart home market.

The results should not be taken as definitive because of the study's limitations. Firstly, the scope of the study could be expanded by including more research databases (e.g., Web of Science) that index additional significant research publications. Secondly, clusters presented in the study are not absolute since the numbers are specified by the criteria determined by the

authors. Thirdly, the VOSviewer software may incur imprecise and complex results due to the issue of regarding single and plural forms of the same term as different words (e.g., “smart home” and “smart homes”).

Therefore, future research would benefit greatly from either an improved version of the VOSviewer software or the inclusion of additional tools for network analysis and visualization. Moreover, as a consequence of the COVID-19 pandemic and the accompanying restrictions on working and living at homes, people have been forced to engage in substantial and mandatory technological learning behaviors [60]. Thus, possible future study directions include accounting for the pandemic's impact on the adoption of smart home technologies among the elderly.

#### ACKNOWLEDGMENT

The authors of this study are appreciative to the reviewers for their insightful feedback and valuable recommendations that will help make this article even better.

# Automatic Generation of Image Caption Based on Semantic Relation using Deep Visual Attention Prediction

M. M. EL-GAYAR 

Department of Information Technology-Faculty of Computers and Information, Mansoura University  
Mansoura 35516, Egypt

Faculty of Computer Science and Engineering, New Mansoura University, New Mansoura, Egypt

**Abstract**—While modern systems for managing, retrieving, and analyzing images heavily rely on deriving semantic captions to categorize images, this task presents a considerable challenge due to the extensive capabilities required for manual processing, particularly with large images. Despite significant advancements in automatic image caption generation and human attention prediction through convolutional neural networks, there remains a need to enhance attention models in these networks through efficient multi-scale features utilization. Addressing this need, our study presents a novel image decoding model that integrates a wavelet-driven convolutional neural network with a dual-stage discrete wavelet transform, enabling the extraction of salient features within images. We utilize a wavelet-driven convolutional neural network as the encoder, coupled with a deep visual prediction model and Long Short-Term Memory as the decoder. The deep Visual Prediction Model calculates channel and location attention for visual attention features, with local features assessed by considering the spatial-contextual relationship among objects. Our primary contribution is to propose an encoder and decoder model to automatically create a semantic caption on the image based on the semantic contextual information and spatial features present in the image. Also, we improved the performance of this model, demonstrated through experiments conducted on three widely used datasets: Flickr8K, Flickr30K, and MSCOCO. The proposed approach outperformed current methods, achieving superior results in BLEU, METEOR, and GLEU scores. This research offers a significant advancement in image captioning and attention prediction models, presenting a promising direction for future work in this field.

**Keywords**—*Semantic image captioning; deep visual attention model; long short-term memory; wavelet driven convolutional neural network*

## I. INTRODUCTION

One of the active research topics in the field of computer vision is the creation of captions for images automatically. Image captioning refers to generate a text-based description or caption for a given image. This task unites computer vision and natural language processing methodologies to produce an easily understandable narrative that concisely conveys the image's content. The primary objective is to offer a brief and precise depiction of the elements, settings, actions, and occurrences depicted in the image [1-3]. There is an increasing daily demand for image retrieval and analysis systems because they are used in many fields and on a large scale via the

Internet, social media, and various search engines [4] [5]. Some ways in which image captioning benefits daily life include the following:

- For individuals with visual impairments: Image captions offer crucial details about an image's content, allowing them to gain a better understanding of the context surrounding the image.
- Cross-lingual communication: By translating image captions into various languages, individuals from different language backgrounds can better grasp the content of an image, promoting intercultural communication and appreciation.
- Search Engine Optimization (SEO): By offering pertinent textual data connected to an image, image captions can enhance SEO. This allows search engines to index and rank the content more precisely, improving online visibility and discoverability.
- User engagement on social media: Image captions contribute to a better user experience on social media platforms by supplying contextual information and additional details about images. This results in increased interaction and improved communication among users.
- Educational and e-learning contexts: Image captions play a supportive role in learning environments by making visual content more explicit and accessible for students, especially those facing learning disabilities or language challenges. This assistance leads to enhanced learning outcomes and better understanding of diverse topics.
- Data management and retrieval: Image captioning assists in organizing and locating visual information within extensive databases, simplifying the process of searching for particular images or content based on their descriptions.

In summary, image captioning serves as a crucial tool that enhances accessibility, comprehension, and distribution of visual content, providing advantages to a broad spectrum of users and applications in everyday life. This type of research is a vital topic that researchers are attracted to because it

combines three main areas: machine learning, natural language processing, and computer vision. It also serves a wide range of practical applications. Fusing these components result in sophisticated systems capable of autonomously interpreting the situation depicted in the image and generating coherent sentences to describe it.

The conventional method for image captioning consists of two key components: feature extraction and language modeling. In the feature extraction stage, an input image is processed by a pre-trained Convolutional Neural Network (CNN) model, such as VGG, Inception, or ResNet, to derive high-level visual features. Subsequently, during the language modeling phase, these extracted features are input into a language model, typically a Recurrent Neural Network (RNN) or a Long Short-Term Memory (LSTM) network, which produces a word sequence that forms the caption. By training the language model on a vast dataset of images and their associated captions, it learns to associate visual features with right words and phrases. Automatic image caption creation can be used in many practical systems and applications such as image retrieval through search engines, video labels, answering visual questions, assisting visually impaired people, biomedical imaging, robotics, etc. Recently, multiple approaches have been developed to automatically generate image captions, reducing many computer vision challenges [6].

The first method used in the image retrieval process relies on comparing the input image with a similar template to create a caption for the image through the matching or comparison process. However, the effectiveness of this method remains unproven, and it yields imprecise outcomes when dealing with intricate images containing multiple targets. Consequently, an alternative strategy relies on the development of a deep neural network, where the image is encoded, and captions are produced using a language model. In this process, the visual content of the image is analyzed in depth, and then this information is translated into natural language text descriptions. Nevertheless, there is a need to enhance CNN-based attention models by effectively utilizing multi-scale features in this model.

This paper introduces an automatic image captioning framework that generates semantically meaningful captions. The approach uses a deep neural network architecture, comprising a CNN that encodes the visual features and RNN that decodes and generates the text [7], [8]. It then employs LSTM [9], [10] and gated recurrent units (GRU) [11] to derive

significant insights. The key contributions of this article can be summarized as follows:

- Propose an encoder and decoder framework to automatically create a semantic caption on the image based on the semantic contextual information and spatial features present in the image.
- A Deep Visual Prediction Model (DVPM) is proposed by enabling the extraction of further semantic information from the image to utilize the convolutions on the feature maps generated using the Wavelet-driven Convolutional Neural Network (WCNN). Both channel and spatial attention are calculated using this approach, which are derived from the resulting feature maps.
- A semantic spatial contextual connection derived from the WCNN model is established to predict area proposals between distinct objects within the image.
- The feature maps produced by the WCNN model are leveraged by a Semantic Relation Extractor (SRE) to predict region proposals to determine the spatial relationships among diverse objects in the image.

The effectiveness of the suggested framework is assessed by employing three widely recognized benchmark datasets: Flickr8K, Flickr30K, and MS-COCO. Furthermore, a comparison with existing studies is conducted using various evaluation metrics, including Bilingual Evaluation Understudy (BLEU), Metric for Evaluation of Translation with Explicit Ordering (METEOR), and Consensus-based Image Description Evaluation (CIDEr).

This manuscript is organized into five sections. Section II reviews relevant previous work. Section III describes the proposed approach in detail. Experiments and results are presented in Section IV. Section V concludes the paper.

## II. RELATED WORKS

This section will review related studies regarding recent modalities in image captioning using attention mechanisms. A previously trained CNN (Encoder) would generate a hidden state (HS) in classic image captioning. Next, decoding this hidden state utilizes an LSTM (as the decoder) to frequently generate each word from the state. However, when the model attempts to produce the next word of the caption, there is an issue that this word typically only describes part of the image.

Fig. 1. A traditional image captioning model.

It is also unable to capture the essence of the entire input image. The model cannot efficiently generate different words for different parts of the image. Therefore, the attention mechanism is useful for representing the image [12]–[14]. Thus, generating an appropriate textual description requires a deeper understanding of the image's spatial and semantic content. As previously mentioned, initial efforts to create image translations involve extracting visible features using RAM (CRF) and converting these features into text through holistic or consensus-based improvements. Later recovery methods generate translations of single or multiple sentences from predefined phrases based on visual similarities. Developing a deep neural network architecture aids in achieving more advanced visual and natural language modeling by producing more insightful descriptions of the image.

Karpathy et al. [15] proposed a multimodal RNN for producing better descriptions using an alignment of replacement between the segments of the image and the sentence. Deng et al. [16] proposed an adaptive attention model with a visual sentinel. This model is presented to extract the global image characteristics of the encoding phase.

Zha et al. [17] proposed a context-aware visual policy network for better caption generation, reducing the dependency on previously predicted words using fine-grained image sentence captioning. Yu et al. [18] proposed a model that used dual attention (P and D) feature maps in the hierarchical image to explore the visual semantic connections and improve the quality of the sentences created.

Yang et al. [19] proposed a CaptionNet model for improved caption generation, which decreased the reliance on previously predicted words. This model only allows attended image features to be input into the memory of CaptionNet through input gates. Cornia et al. [20] proposed an innovative image captioning technique utilizing memory vectors and connecting the encoder and decoder sections of the transformer model.

Li X et al. [21] proposed an innovative technique for aligning the image and language modalities to gain more reasonable semantic extraction from images using anchor points. Jiang et al. [22] introduced a Multi-Gate Attention model to enhance caption generation, expanding upon the conventional self-attention mechanism by integrating an extra Attention Weight Gate. Wang et al. [30] proposes an automatic architecture search method for neural networks focused on cross-modality tasks like image captioning. The method approximates the associative connection between visual and language models through the internal structure of RNN cells. Over 100 generated RNN variants exceed performance of 100 on CIDEr and 31 on BLEU4, with the top model achieving 101.4 and 32.6, respectively. Wu et al. [31] introduced a novel global-local discriminative objective built on a reference model to generate more detailed descriptive captions. Evaluated on MS-COCO, the method outperforms baselines significantly and competes well with top approaches. Self-retrieval experiments demonstrate its ability to generate discriminative captions. Wang et al. [32] introduced a visual attention layer for low-level visual information and a semantic

attention layer for high-level semantic attributes. The margin-based loss encourages more discriminative captions. Extensive experiments on COCO and Flickr30K datasets validate the approach, demonstrating superior performance in captioning. The method achieves state-of-the-art 70.6 CIDEr-D on Flickr30K and competitive 123.5 CIDEr-D on COCO.

Although these methods effectively generate image captions, they fail to incorporate refined semantic components and the contextual spatial connections between various objects within the image. Therefore, expansions in network structure are essential to remedy these deficiencies. Furthermore, when several objects exist in the image, it is critical to properly consider the optical contextual connection between them to produce a more detailed and representative caption. This problem can be resolved by integrating attention mechanisms and assessing the spatial relations among elements within the instance. Table I shows the summary of recent related works.

### III. PROPOSED FRAMEWORK

As illustrated in Fig. 1, a typical image captioning model would use a pre-trained convolutional neural network (CNN), such as VGG-16, to encode the input image and generate image features (HS) [23], [24]. Then, it would decode this HS using a Long Short-Term Memory (LSTM) and recursively render each caption word. The downside of this approach is that when the model tries to generate the following word in the caption, it fails to fully comprehend the overall meaning or essence of the entire input image. Therefore, a semantic deep visual attention mechanism can be helpful. With a semantic deep attention mechanism, the image is separated into  $n$  regions, and we calculate with CNN representations of each region  $HS(1), \dots, HS(n)$ . When the RNN-decoder generates a further word, the attention procedure concentrates on the appropriate region of the image, so the decoder only uses exact areas. Attention could be considerably distinguished into two types [25]–[29]:

- Global Attention is positioned on all origin positions, as shown in Fig. 2.
- Local Attention is positioned just on a few sources' places, as shown in Fig. 3.

Fig. 2. Global attention model.

Fig. 3. Local attention model.

The global attention considers each HS coding for the excitation of the context vector. However, focusing global attention on all the main collateral terms of all destiny words is computationally expensive. In addition, it is not valid to use long phrases. To address this limitation, we can employ local attention to focus only on a small, relevant subset of the image features (HS) for generating each word in the caption. The proposed framework consists of an encoder- decoder model with a Deep Visual Prediction Model (DVPM), that transforms an input image (IMG) into a series of encoded expressions and words,  $T = [T_1, T_2, \dots, T_L]$ , with  $T_i \in \mathbb{R}^M$ , depicting the image, where  $L$  is the rendered caption's size, and  $M$  is the terminology size. The architecture of the proposed framework is illustrated in Fig. 6. The proposed framework is divided into four main phases. The first phase is the encoder using WCNN. The second phase is DVPM. The third phase is the semantic relation extractor. The final phase is the decoder using the LSTM model.

#### A. Encoder Phase

Comprising the WCNN model, the encoder merges two tiers of different wavelet decomposition alongside

convolutional neural network layers to extract the image's visual characteristics, as illustrated in Fig. 4. The Level 1 and Level 2 features obtained from the CNN layers are bilinearly downsampled and fused into a  $32 \times 32 \times 960$  feature map. In the first phase, the input image (I) is first resized to  $256 \times 256$  dimensions. The image is then separated into RGB color components. Each color component is decomposed into specifics and approximations using low-pass (LP) and high-pass (HP) discrete wavelet filters. The implementation of dual-phase discrete wavelet decomposition generates  $\{LP, LF\}$ ,  $\{HP, LF\}$ ,  $\{LP, HF\}$ , and  $\{HP, HF\}$  sub-bands, where LF and HF represent the low-frequency and high-frequency sections of the input image, respectively. In the second phase, only the  $\{LP, LF\}$  sub-band encounters further disassembly for each of the three elements. These components are combined and fused at every tier with the initial dual CNN stage outputs, encompassing four layers featuring numerous convolutional and pooling layers with a  $2 \times 2$  kernel dimension, as shown in Fig. 5.

Table II offers detailed information on the different convolutional layers. By incorporating the DWT stage alongside CNN, we aim to improve the visual modeling of the input image and extract some unique spectral characteristics. This method assists in capturing finer details of objects, including spatial orientation and color information, which allows for the identification of visually salient features or regions within the image. These features draw more attention, much like the human visual system, due to their distinct characteristics compared to other areas.

#### B. DVPM Phase

Extracting semantic attributes from input image feature maps, including aspects like an object's scale, shape, and texture features, is crucial. Differences in these characteristics within an image can create obstacles to accurate identification or recognition. To generate a semantic feature map of dimensions  $32 \times 32 \times 256$ , four multi-receptive filters are employed: one consisting of 64 filters with a  $1 \times 1$  kernel size and the other three featuring  $3 \times 3$  kernel sizes, each containing 64 filters with dilation rates of 3, 5, and 7, respectively. An example of attention changes to reflect the relevant parts of the image is shown in Fig. 7.

Fig. 4. Proposed encoder using WCNN.

### C. Semantic Relation Extractor Phase

Generating rich image translations requires leveraging the contextual spatial relationships between multiple objects in the image and their semantic details. In the WCNN model, the ultimate tier's feature map serves as input for the Semantic Relation Extractor (SRE) to identify object regions in the image. Subsequently, objects are paired, and numerous uniformly sized 32x32 sub-images are created through resizing. Each sub-image is fed into the CNN layers that contain 64 filters, with each filter having a receptive field of 3x3. This process generates features that represent the spatial relationships between pairs of objects. The feature maps of individual objects are combined to form a 32x32x64-dimensional contextual spatial relation feature map. This feature map is then merged with the output from a feed-forward neural network of local attention (fa) and supplied to the LSTM to produce the next word in the caption.

### D. Decoder Phase

To generate more precise image captions, the channel attention weights  $W_c$  and spatial attention weights  $W_s$  are computed based on  $H_{t-1} \in R^n$ .  $D$  is the dimension of the hidden state. By using this method, additional contextual data is integrated into the image while generating captions. The feature map, denoted as  $F_{map}$  has dimensions  $F_{map} \in R^{h \times w \times c}$  where  $h$ ,  $w$ , and  $c$  represent the height, width, and a total number of channels of the feature map, respectively. The initial step involves average pooling on a per-channel basis, resulting in a channel feature vector,  $F_v \in R^c$ .

Since global attention focuses on all the words of the secondary origin of all objective words, This process becomes expensive and impractical for translating lengthy sentences. So instead, local attention concentrates on a small subset of the encoder's hidden states for each target word to address this limitation. So, we do softmax to get the input probability distribution of the channel attention weights ( $W_c$ ).  $W_c$  can be calculated as follows:

$$W_c = \text{Softmax}(E_{it}) \quad (1)$$

$$E_{it} = X_c(P_{t-1}, H_i) \quad (2)$$

$$X_c = V_{att}^T * \tanh(U_{att} * H_i + W'_c * P_t) \quad (3)$$

Where:

- $E_{it}$  means at every  $t^{th}$  time steps of decoder, how important  $i^{th}$  is the pixel location in the input image.
- $P_{t-1}$  is the pervious state of decoder.
- $H_i$  is the state of encoder.
- $X_c$  is simple feed forward neural network which is a linear transformation of input ( $U_{att} * H_i + W'_c * P_t$ ) and then a non-linearity (tanh) on the top of that.
- $V_{att}^T \in R^D$ ,  $U_{att} \in R^{K \times D}$ ,  $W'_c \in R^{K \times D}$ ,  $H_i \in R^D$  and  $P_t \in R^D$ .

Now, we need to feed weighted sum combination to decoder. So, the weighted sum of input (context vector  $C_t$ ) is calculated from Eq. (4).

$$C_t = \sum_{i=1}^T W_c H_i \text{ such that } \sum_{i=1}^T W_c = 1 \quad (4)$$

### E. Summary

In this part, we summarize the steps of the proposed system and link them to the proposed algorithms.

- 1) *Clean* data (as discussed in algorithm-I), i.e., clearing punctuations and numeric values from the text.
- 2) *Preprocessing* the images and captions (as discussed in algorithm-II and algorithm-III, respectively, by appending '<start>' and '<end>' labels to every caption) so that the proposed model understands the starting and stopping of each caption.
- 3) *We* have to reshape every image before feeding it to the WCNN model.
- 4) *The* captions will be tokenized, and a vocabulary of words in our data corpus will be established.
- 5) *Producing* Encoder Hidden States — The encoder employs a WCNN model that integrates dual-level discrete wavelet decomposition with CNN layers, efficiently extracting an image's visual features.
- 6) *Applying* DVMP to output the semantic feature map of size 32x32x256, we use four multi-receptive filters.
- 7) *Applying* SRE to find the object regions in the image by entering the feature map from the last level of the WCNN model.
- 8) *As* described in Algorithm 4, the RNN Local Decoder utilizes the hidden state (HS) from the previous decoder and the current decoder output.

The Decoder RNN processes these inputs to generate a new hidden state.

- 9) *The* alignment scores are calculated as in algorithm IV.
- 10) *Softmaxing* the previous scores.
- 11) *A* context vector is calculated.
- 12) *The* context vector is merged with the decoder's hidden state (HS), produced in Step 8, resulting in a new output.
- 13) *Steps* 6 through 13 are iteratively executed for each time step in the decoder until a token is generated.

<b>Algorithm I - Data Cleaning</b>

#### IV. EXPERIMENTAL RESULTS ANALYSIS AND DISCUSSION

This section will discuss and compare the outcomes of our diverse experiments with pertinent prior studies. We implemented the proposed framework using TensorFlow 2.3 and executed it on Google Cloud with the help of Google Colab.

##### A. Description of Datasets

Numerous open-source datasets, including Flickr 8k, Flickr 30k, and MS COCO, are accessible for this research. The experiments are carried out on the following three benchmark datasets:

- Flickr 8k — 6400 images (training set), 700 images (validation set), and 700 images (testing set).
- Flickr 30k— 24k images (training set), 3k images (validation set), and 3k images (testing set).

- MS-COCO — 128k images (training set), 16k images (validation set), and 16k images (testing set).

##### B. Hyperparameters

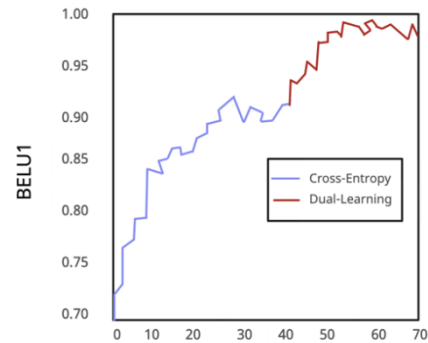

During the model's training stage, we used hyperparameter settings such as batch size, dropout, etc. The values of a few hyperparameters include the exponential decay rates for ADAM optimizer, learning rate, batch size, and dropout. The number of iterations used is 50. These hyperparameters are changed on a trial-and-error. Finally, the hyperparameters are tuned into our method to improve the results.

- For Flickr8k, Flickr30k, and MSCOCO datasets, *the batch sizes* employed are 16, 32, and 64, respectively.
- *Dropout*: To prevent overfitting, a dropout rate of 0.2 is applied, L2 regularization, and a weight decay value of 0.001.
- *Epochs*: The model begins with 40 epochs of training based on cross-entropy loss. Afterward, an extra 80 epochs of fine-tuning are conducted via dual learning to reach the highest CD score within the validation set.

##### C. Evaluation Metrics

Our experiments use the performance evaluation metrics – BLEU as B score from 1 to 4, METEOR as MR score, and CIDEr as CD score. The BLEU metric is employed to assess the generated captions for the test set. Recognized as a reliable metric, BLEU quantifies the similarity between a single predicted sentence and multiple reference sentences. Table III provides a summary of the metrics featured in this paper. Additionally, the Beam search technique was utilized to evaluate the captions.

### F. Discussion

As shown in Fig. 8 and Fig. 9, after about 40 epochs, all the evaluation metrics converge, and the performance of the proposed model evolves better when we fine-tune the model on the unpaired data by employing the dual learning mechanism. The results comparing the proposed model on the Flickr8K and Flickr30K datasets are presented in Table III and Table IV. As seen in Table III, the proposed model shows notable improvements of 2.3%, 2.8%, and 2.1% in B-1, B-4, and MR scores for the Flickr8K dataset. Likewise, the model achieves increases of 2.4% and 0.9% in B-4 and MR scores for the Flickr30K dataset in Table IV. The model also attains a respectable CD value of approximately 66.8. Table V displays the evaluation outcomes for the comparative analysis on the MSCOCO test partition. As indicated in Table IV, the proposed model yields a strong CD score of 123.9 and exhibits relative enhancements of around 0.9%, 0.5%, and 0.7% in B-4, MR, and CD scores, respectively. We can use the proposed model in IoT systems in [33],[34] to ensure controllability, safety and effectiveness as a future work. Unlike other methods, this improvement stems from the proposed model's image feature maps incorporating spectral information alongside spatial and semantic details. The model

can obtain detailed data during object identification by integrating discrete wavelet decomposition into the CNN model. Additionally, the model considers the contextual spatial relationships between objects in the image and employs spatial and channel-specific attention to enhance feature maps resulting from convolution. Using multi-receptive field filters facilitates the detection of visually prominent objects with diverse shapes, scales, and sizes.

## V. CONCLUSION

This manuscript introduces a deep visual attention framework for image caption generation, utilizing an encoder-decoder architecture based on semantic relationships. The encoder comprises a WCNN, while the decoder comprises a DVPM and LSTM. The DVPM calculates channel and location attention for visual features, taking into account the spatial-contextual relationship between various objects. Merging wavelet decomposition with the convolutional neural network allows the model to extract spatial, semantic, and spectral data from the input images. In-depth image captions are produced by applying spatial and channel-wise attention to the feature maps generated by DVPM and considering the contextual spatial relationships among objects via the CSE network. Assessments are conducted on three standard datasets—Flickr8K, Flickr16K, and MS-COCO—utilizing evaluation metrics such as BLEU, METEOR, and CIDEr. With the MS-COCO dataset, the model achieves remarkable B-4, MR, and CD scores of 39.2, 28.8, and 123.9, respectively. We believe there are several promising directions for future work. First, the proposed model could be refined and tested with various other attention mechanisms, potentially improving the model's performance even further. Second, the application of this model to other vision-and-language tasks, such as visual question answering and image-based storytelling, IoT systems could be explored. Additionally, the integration of other types of contextual information, such as object-object interaction or more explicit spatial information may enhance the model's ability to generate even more detailed and accurate captions. Finally, while the model has been tested on standard datasets, it would be worthwhile to evaluate its performance on a diverse array of real-world images and scenarios. These future research directions will help to further reinforce and extend the significant contributions of our study.

**Abstract**—The oil market has long experienced price fluctuations driven by diverse factors. These shifts in crude oil prices wield substantial influence over the costs of various goods and services. Moreover, the price per barrel is intricately intertwined with global economic activities, themselves influenced by the trajectory of oil prices. Analyzing oil behavior stands as a pivotal means for tracking the evolution of barrel prices and predicting future oil costs. This analytical approach significantly contributes to the field of crude oil price forecasting. Researchers and scientists alike prioritize accurate crude oil price forecasting. Yet, such endeavors are often challenged by the intricate nature of oil price behavior. Recent times have witnessed the effective employment of various approaches, including Hybrid and Machine Learning techniques to address similarly complex tasks, though they often yield elevated error rates, as observed in financial markets. In this study, the goal is to enhance the predictive precision of several weak supervised learning predictors by harnessing hybridization, particularly within the context of the crude oil market's multifaceted variations. The focus extends to a vast dataset encompassing CPSE Stock ETF prices over a period of 23 years. Ten distinct models, namely SVM, XGBoost, Random Forest, KNN, Gradient Boosting, Decision Tree, Ridge, Lasso, Elastic Net, and Neural Network, were employed to derive elemental predictions. These predictions were subsequently amalgamated via Linear Regression, yielding heightened performance. The investigation underscores the efficacy of hybridization as a strategy. Ultimately, the proposed approach's performance is juxtaposed against its individual weak predictors, with experiment results validating the findings.

**Keywords**—Oil market; prediction; crude oil; hybrid approach; CPSE stock ETF price; machine learning; stock markets

## I. INTRODUCTION

Hybridization approach refers to the combination of two different approaches or models to improve the accuracy of exchange rate forecasting in time series analysis. [1], given the significance of time-series prediction in many real-world situations, it is important to carefully select an appropriate model. For this reason, numerous performance measures have been proposed in the literature [1-7] to assess forecast accuracy and compare different models. These are known as performance metrics [6]. The goal of time series models is to gain an understanding of the underlying factors and structure that shaped the observed data, fit a model, and uses it for forecasting. These models have a wide range of applications in the daily operations of electric utilities, such as energy generation planning, energy purchasing, load switching, and contract evaluation [8], The purpose of forecasting is to make

and improve decisions, increase profits, and in the case of forecasting oil prices, better decisions largely depend on the accurate prediction of trends, actual prices, and expected prices  $x(t)$  and  $x'(t)$ . The ability to predict movement can be measured statistically (R2) [9]. Similarly, the significance of forecasting lies in reducing the risk or uncertainty involved in short-term decision making and planning for long-term growth. Forecasting the demand and sales of a company's products usually begins with a macroeconomic forecast of the overall level of economic activity, such as Gross National Product (GNP). Companies use macroeconomic forecasts of general economic activity as inputs for their microeconomic estimates of the demand and sales for the industry and the firm. The demand and sales for a business are typically estimated based on its historical market share and planned marketing strategy (e.g, forecasting by product line and region). Companies use long-term forecasts for the industry and the economy to determine the necessary investment in plant and equipment to achieve their long-term growth objective. The focus of this study is on multi-step ahead prediction of crude oil prices. This involves extrapolating the crude oil price series by predicting multiple time-steps into the future without access to future outputs. Despite the influence of many complex factors, oil prices exhibit highly non-linear behavior, making it challenging to predict future oil prices, especially when looking several steps ahead (Fan et al., 2008) [10]. The unpredictability of crude oil prices is due to their sensitivity to fluctuations in both global demand and supply. The world economy was destabilized for a decade when oil supplies were disrupted 40 years ago. The formation of the OPEC cartel and the nationalization of the oil industries in the Middle East led to a quadrupling of world oil prices and caused steep recessions in the mid-1970s. The 1979 overthrow of the Shah of Iran by Muslim clerics disrupted Iran's oil supplies, leading to another round of even deeper recessions. The productivity of the future oil market and the expected accuracy of future prices are evaluated. The precision of forecasts using futures prices is compared to that of other methods, including time series and econometric models, as well as key forecasts. The predictive power of futures prices is further investigated by comparing the forecasting accuracy of end-of-month prices with weekly and monthly averages, using different weighting systems [11] Previous studies have shown that the behavior of oil prices is non-linear and traditional econometric and statistical methods struggle to provide accurate predictions in these cases. To address this issue, newer techniques like genetic algorithms, artificial neural networks, and support vector machines have emerged [13]. Alizadeh and Mafinezhad [13] used a General

Regression Neural Network (GRNN) model to forecast Brent oil prices by incorporating seven types of variables as inputs. The authors claimed that this model performed well under various conditions and provided a high level of accuracy. Previous studies have shown that oil price behavior is non-linear, and traditional econometric and statistical models may not be sufficient for analyzing this behavior [12]. To address this, new techniques such as genetic algorithms, artificial neural networks, and support vector machine have emerged [13]. Alizadeh and Mafinezhad [13] used a General Regression Neural Network (GRNN) model to forecast Brent oil price, incorporating seven types of structures as inputs. They found that their model provided a high level of accuracy under challenging conditions. Predicting oil prices is a challenging task due to its significant impact on various economic and non-economic aspects. There is currently a lack of consensus among experts on the most effective methods and models for forecasting oil prices. To address this issue, a hybridization approach that combines multiple models can be used to increase forecasting accuracy [14]. In this study, the aim is to enhance the accuracy of crude oil price predictions by combining weak predictors through hybridization. The dataset comprises daily CPSE Stock ETF prices spanning 23 years. Ten different machine learning models are utilized. (SVM, Random Forest, Gradient Boosting, Neural Network, XGBoost, Decision Tree, Ridge, Lasso, Elastic Net and KNN) to make individual predictions, and then combine these predictions using a Linear Regression model to achieve enhanced performance. The results clearly illustrate the advantages of employing the hybridization approach. After testing the 10 models, The SMRM approach yielded the most accurate results, as it converges towards the minimum of the empirical response and minimizes information loss, outperforming the other models. The study's findings suggest that the Hybrid Proposed System (SMRM) stands out as the most efficient option, outperforming all other individual models. The SMRM achieved an average negative MAPE of -0.023, which was the highest among all models and sets. The proposed SMRM hybrid system offers a promising solution for predicting crude oil prices, leveraging the power of machine learning, and combining multiple models to better capture the complex relationships between different factors. The experiments reveal that SMRM excels over existing models in both accuracy and stability, making it a valuable tool for investors, traders, and other stakeholders in the energy sector. The system can also be continually refined and improved by incorporating irregular factors like political risks and extreme weather events, which can help to better predict changes in crude oil prices. With further development, this approach could have important implications for supporting decision-making and risk management in the energy sector, enabling stakeholders to make more informed and effective decisions in the dynamic and complex world of stock market trading. By providing more accurate and reliable predictions of crude oil prices, the SMRM hybrid system has the potential to revolutionize how we approach predicting crude oil prices, providing valuable insights that can help optimize decision-making and drive greater value in the energy sector. This passage highlights that the main research contribution is the development of the SMRM hybrid system, which combines

machine learning models to improve the accuracy and stability of crude oil price predictions. It also emphasizes the system's potential to enhance decision-making and risk management in the energy sector.

The rest of the paper is organized as follows: Section II reviews the current literature on forecasting crude oil prices. Following that, Section III details methodology, and Section IV covers the proposed approach. The empirical results are presented in section V.

## II. RELATED WORK

Crude oil prices are difficult to predict due to a complex pricing system with insufficient information, numerous variables, and inaccurate elements [15]. Despite this challenge, researchers are actively exploring methods to accurately forecast crude oil prices and manage related risks. While traditional methods like Arima and Arma have been used, they often fall short in the face of complex data and asymmetric effects. The growth of AI and text mining technologies provide new opportunities to predict crude oil prices and measure investment risk. One such successful machine learning model [16] uses artificial intelligence to predict crude oil prices, including the use of Decision Trees (DTs), a commonly used technique in crude oil modeling. To further improve accuracy, [17] incorporates technical trading indicators like RSI and Stochastic Oscillator into the Random Forest model for minimizing investment risk. These advances in AI technology have the potential to significantly improve the accuracy of crude oil price forecasts. Two PCA-KNN models, which combined PCA for information reduction and KNN for oil price forecasting, were tested on historical EUR/USD exchange rate data sets over a 10-year period. These models achieved the highest success rate of 77.58%. To improve the success rate, [18] presents a novel approach to financial time series prediction by combining K-Nearest Neighbor (KNN) Regression with Principal Component Analysis (PCA). The authors aim to enhance the accuracy of financial time series forecasting, a critical task in the finance domain, [19] proposed a PANK model, which involves three components: (1) Principal Component Analysis to minimize redundant information, (2) Affinity Propagation Clustering for feature extraction through example generation and corresponding cluster formation, and (3) nearest k-neighbour regression reformulated through nested regression for prediction modeling. The PANK model was tested on a 15-year historical data set of the Chinese stock market index, yielding a success rate of 80%. Previous studies have defined the behavior of oil prices as a statistical system, but these methods only provide logical results for linear behavior. The study in [20] used the SVM model to estimate oil prices, but these methods are inadequate for highly complex and non-linear data. The study in [21] recently compared different forecasting models, including ARIMA, FNN, ARFIMA, MS-ARFIMA, and the RW model, and found that the SVM model performed best and is a strong candidate for crude oil price forecasting in one or more stages. Machine learning models often require hand-crafted features, which can make them challenging to implement in real-world situations, especially with large amounts of data. A recent and successful approach comes from the subfield of machine learning, deep learning [22]. The

accuracy of forecasting can be improved through hybridization by combining simple forecasts from multiple weaker predictors [23]. A hybrid system combining Artificial Neural Networks (ANN) and Recurrent Neural Networks (RES) based on text mining was proposed to improve prediction performance [24]. Another study proposed a Multi-Intelligent Bat-Neural Network Multi-Agent System (BNNMAS) for predicting the price of oil-linked stocks, comparing it to genetic algorithm neural network (GANN) and generalized neural network regression (GRNN) [24]. However, both systems are subject to performance problems due to the identification of tuning parameters. A recent study [25] developed an intelligent system for forecasting oil prices using time series models, but the system is not suitable for predicting long-term trends. In reference to the study of oil prices, various methods have been used to make predictions and analyze the factors affecting its fluctuation. The research in [26] utilized the Complementary Empirical Ensemble Mode Decomposition (CEEMD) to break down the barrel price into its components and identify the impact of extreme events on crude oil prices. The researcher combined the Iterative Cumulative Sum of Squares (ICSS) test and Chow's test to detect structural breaks, then used ARIMA and SVM models to forecast oil prices. The results showed that the SVM-CEEMD-ARIMA model with structural breaks was the best performing model compared to SVM and ARIMA models alone. During the COVID-19 pandemic, [27] attempted to predict oil price movements using ANN and SVM models. The results showed that his model outperformed other ANN and SVM models, with an RMSE value of 0.6018 and a MAE value of 0.5295. The study in [28] used a Convolutional Neural Network (CNN) to extract features from online news texts, divided into categories such as oil price, oil production, overall oil consumption, and oil stocks. Other models such as MLR, BPNM, SVM, RNN, and LSTM were used for prediction and the results showed that social media factors play a role in oil price prediction. During the Russian-Ukrainian conflict, [29] forecasted oil prices by using exotic options such as Asian Options, Barrier Options, and Gap Options. The GARCH model and Monte Carlo simulation were used to study the options and the results showed that considering the overall performance of all exotic options was better. In [30], the authors analyzed the relationship between oil prices and various wars, including the first and second Gulf Wars and the Russian-Ukrainian War. The results showed that the relationship between real GDP growth and oil prices differed between periods and that it was possible to predict oil prices during the Russian-Ukrainian War. The ongoing conflict between Russia and Ukraine continues to have a significant impact on the financial market and oil prices. The research in [31] used the TVP-VAR technique to identify the sources of oil market volatility and the interconnections between gold, crude oil, and the stock market on February 24, 2022. The results showed that the conflict between Ukraine and Russia affects the interdependence of the markets analysed, both in stable and war situations. In [32], the authors compared the performance of support vector machines (SVM), K-nearest neighbors (KNN), and random forest (RF) models in predicting crude oil prices. The authors found that the SVM model outperformed the KNN and RF models in terms of both in-sample and out-of-sample prediction accuracy. Guliyev and Mustafayev in [33] to

compare their predictive accuracy and identify the most effective model for crude oil price forecasting. The three machine learning models used in the study are Linear Regression, Support Vector Regression (SVR), and Random Forest Regression. These models are trained using a range of explanatory variables, such as supply and demand factors, macroeconomic indicators, geopolitical risks, and oil market-specific variables, such as oil inventories. The study found that all three models can effectively predict the WTI crude oil price changes with reasonable accuracy. However, the Random Forest model produced the most accurate forecasts compared to the other two models. In addition, the study found that geopolitical risks, such as tensions between OPEC members and potential supply disruptions, have the most significant impact on WTI crude oil prices. The study's results suggest that machine learning models can be a useful tool for crude oil price forecasting. The findings could be useful for traders, investors, and policymakers who need to make informed decisions based on the expected future price dynamics of crude oil. The study in [34] is to evaluate the effectiveness of different machine learning models in predicting the closing prices of stocks. The study employs three machine learning algorithms: Random Forest (RF), Support Vector Regression (SVR), and Multilayer Perceptron (MLP) for predicting the closing prices of stocks using a range of input features such as volume, moving averages, and technical indicators. The study finds that all three machine learning models are effective in predicting the closing prices of stocks, with Random Forest performing the best, followed by Support Vector Regression and Multilayer Perceptron. The study also found that technical indicators, such as Relative Strength Index (RSI) and Moving Average Convergence Divergence (MACD), were the most effective input features for the prediction models. Overall, the study suggests that machine learning models can be useful for predicting the closing prices of stocks and can help traders and investors make informed decisions based on expected future prices. [35] is to develop a hybrid artificial intelligence model to predict the uniaxial compressive strength of oil palm shell concrete. The study uses a combination of machine learning algorithms, including Artificial Neural Networks (ANN), Genetic Programming (GP), and Support Vector Regression (SVR), to develop a hybrid model for predicting the uniaxial compressive strength of oil palm shell concrete. The model uses input features such as the water-binder ratio, curing time, and oil palm shell content. The study finds that the hybrid model outperforms individual machine learning models in predicting the uniaxial compressive strength of oil palm shell concrete. The hybrid model also achieves a high prediction accuracy with a coefficient of determination (R-squared) value of 0.965. The results of the study suggest that the hybrid model can be a useful tool for predicting the uniaxial compressive strength of oil palm shell concrete, which is important for the design and construction of sustainable building materials. The hybrid model can also be extended to predict the properties of other types of concrete by modifying the input features. The research in [36] is to propose a novel hybrid model for forecasting crude oil prices based on time series decomposition. The study combines two machine learning algorithms, Support Vector Regression (SVR) and Artificial Neural Networks (ANN), with a time series decomposition

method called Seasonal and Trend decomposition using Loess (STL), to create a hybrid model for crude oil price forecasting. The study finds that the proposed hybrid model outperforms individual machine learning models and traditional time series models in forecasting crude oil prices. The hybrid model achieves a high prediction accuracy with a Mean Absolute Percentage Error (MAPE) value of 3.22%. The results of the study suggest that the proposed hybrid model can be a useful tool for predicting crude oil prices, which is important for making informed decisions in the oil and gas industry. The study also highlights the importance of combining different machine learning algorithms and time series decomposition methods for improving the accuracy of crude oil price forecasting. The study in [37] is to propose a novel approach for predicting crude oil prices by combining complex network analysis and deep learning algorithms. The study uses a complex network analysis to identify the relationships and dependencies between different economic variables, such as exchange rates and stock prices, and crude oil prices. The identified network is then used as input for deep learning algorithms, specifically a Convolutional Neural Network (CNN) and a Recurrent Neural Network (RNN), to predict crude oil prices. The study finds that the proposed approach outperforms traditional machine learning models and time series models in predicting crude oil prices. The CNN and RNN models achieve high prediction accuracy with a Mean Absolute Error (MAE) value of 0.55 and 0.51, respectively. The results of the study suggest that the proposed approach can be a useful tool for predicting crude oil prices, which is important for making informed decisions in the oil and gas industry. The study also highlights the importance of considering the complex relationships and dependencies between different economic variables in crude oil price prediction. In [38], Abdollahi and Ebrahimi propose a new hybrid model for predicting the Brent crude oil price. The proposed model combines two different techniques: an ensemble of Extreme Learning Machines (ELMs) and a wavelet transform. The study first applies a wavelet transform to decompose the time series data into different frequency bands, which allows the model to capture different patterns and trends in the data. The decomposed signals are then used as input for the ELM ensemble, which is a machine learning technique that combines multiple ELM models to improve prediction accuracy. The study finds that the proposed hybrid model outperforms several benchmark models, including traditional statistical models, machine learning models, and other hybrid models. The proposed model achieves a high prediction accuracy, with a Mean Absolute Percentage Error (MAPE) value of 1.76% for one-day ahead forecasting and 3.31% for five-day ahead forecasting. The results of the study suggest that the proposed hybrid model can be an effective tool for predicting the Brent crude oil price, which is important for making informed decisions in the oil and gas industry. The study also highlights the importance of combining different techniques to improve prediction accuracy and to capture different patterns and trends in the data. The research in [39] is to propose a weighted hybrid data-driven model for forecasting daily natural gas prices. The proposed model combines two different techniques: an Empirical Mode Decomposition (EMD) method and a Support Vector Machine (SVM) method.

The study first applies the EMD method to decompose the original time series data into several Intrinsic Mode Functions (IMFs). These IMFs capture the different temporal scales of the natural gas prices and are used as input variables for the SVM method. The SVM method is a popular machine learning algorithm that can be used for regression and classification tasks. To further improve the performance of the model, the study introduces a weight-based approach that assigns different weights to the historical data based on their importance. The weights are calculated using a genetic algorithm that searches for the optimal weight values. The study finds that the proposed weighted hybrid data-driven model outperforms several benchmark models, including traditional statistical models, machine learning models, and other hybrid models. The proposed model achieves a high prediction accuracy, with a Mean Absolute Percentage Error (MAPE) value of 1.87% for one-day ahead forecasting and 2.55% for five-day ahead forecasting. The results of the study suggest that the proposed weighted hybrid data-driven model can be an effective tool for forecasting daily natural gas prices, which is important for making informed decisions in the energy industry. The study also highlights the importance of combining different techniques and introducing a weight-based approach to improve prediction accuracy.

Prediction accuracy, with a Mean Absolute Percentage Error (MAPE) value of 1.87% is for one-day ahead forecasting and 2.55% is for five-day ahead forecasting. The results of the study suggest that the proposed weighted hybrid data-driven model can be an effective tool for forecasting daily natural gas prices, which is important for making informed decisions in the energy industry. The study also highlights the importance of combining different techniques to improve prediction accuracy.

In this article, the aim is to enhance prediction accuracy by combining several weak predictors through hybridization to address the varying degrees of variability in the oil market. Ten models are used (SVM, XGBoost, Random Forest, KNN, Gradient Boosting, Decision Tree, Ridge, Lasso, Elastic Net and Neural Network) to obtain basic predictions and then integrate them in a Linear Regression for a better outcome. The previous section discussed different types of algorithms including Text Mining algorithms, genetic algorithms, and deep learning algorithms. Although advancements have been made in dynamic system modeling and analysis over the past 23 years to minimize prediction error, the uncertainty of learning models remains limited. However, combining diverse predictive models can prove to be effective in improving prediction accuracy. The study centers on the integration of various regression methods (SVM, Random Forest, Gradient Boosting, Neural Network, XGBoost, Decision Tree, Ridge, Lasso, Elastic Net and KNN) to make predictions and produce a final prediction through stacking. The idea is to construct a predictive model by combining various models, as shown in the diagram:

#### A. Units

The original training dataset, (X), consists of m observations and n features, resulting in an (m×n) matrix. Multiple models M are trained on X using a training method, such as cross-validation. These models make predictions for the result, (y), which are then consolidated into a second

training dataset,  $(X^{(2)})$ , with a shape of  $(m \times M)$ . These  $(M)$  predictions serve as features for this second-level dataset. The goal of creating a second-level model is to produce the final prediction by utilizing the combination of these different models.

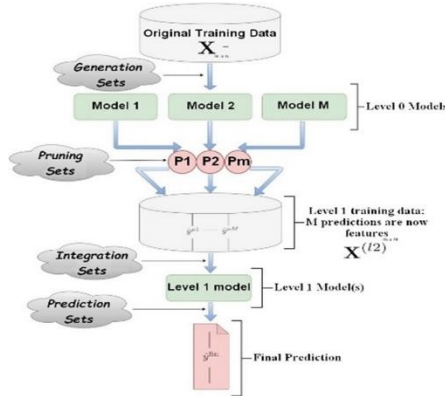

Fig. 1. Stacking Multi-Regression Models (SMRM).

### B. Pruning Sets

Evaluation criteria such as MAPE, MAE, RMSE and R-Squared  $R^2$  play a crucial role in selecting the best models based on ranking. These criteria are presented in Table I.

TABLE I. META-FEATURES USED

Features	Description
MAPE	Mean Absolute Percentage Error
MAE	Mean Absolute Error
RMSE	Root Mean Square Error
$R^2$	R-Squared

### C. Integration Sets

This section explains the behavior of the selected models as shown in Table II in their combinations for predicting barrel price. Stacking models is a technique used to create a secondary dataset for cross-validation using k-fold to address two key issues:

To make off-sample predictions, the stacking process uses predictions  $f_1, \dots, f_m$  to determine the generator biases for the learning set in different regions, where each model is most effective. The right linear combination with the weights vector is then learned by the meta-learner  $a_1, \dots, (i=1, \dots, m)$ :

$$f_{stacking}^{(x)} = \sum_{i=1}^m a_i f_i(x) \quad (1)$$

### D. Prediction Sets

The final predictions are generated from the training data  $X$  or from the second-level learner's model(s). The stacking model is used to select various sub-learners and to study how to collect and combine sub-models and their predictions. A meta-model is employed to merge the best predictions from all models. Each model provides predictions for the outcome  $(y)$ , which are integrated into a second training dataset  $(X^{(2)})$ , resulting in  $(m \times M)$  predictions. These second-level data possess  $M$  new characteristics. A second-level model is created to generate the results used for the final prediction. Fig. 1

illustrates the overall design of the results after applying this approach. Three models were generated and the basic model type at level 0, as well as the differences between the ten models, is explained as follows:

- 1) The first model used in the base layer is Random Forest
- 2) The second model used in the base layer is KNN
- 3) The third model used in the base layer is SVM
- 4) The fourth model used in the base layer is Gradient Boosting
- 5) The fifth model used in the base layer is Decision Tree
- 6) The sixth model used in the base layer is Ridge.
- 7) The seventh model used in the base layer is Lasso
- 8) The eighth model used in the base layer is Elastic Net
- 9) The ninth model used in the base layer is XGBoost
- 10) The tenth model used in the base layer is Neural Network

## III. STUDY OF THE PROPOSED APPROACH

The prediction capacity is tested against some reference models. First, the data description will be presented in Section (A). Second, all measures for evaluating prediction performance and the statistical tests that compare and adjust predictive accuracy will be discussed in Section (B). Finally, the stacking learning sets algorithm will be explained in Section (C).

### A. Dataset

The ETF Prices data was used as a reference point and was uploaded to the ETF prices website [40]. This data represents the global oil price and is daily in nature, covering the period from 2000 to 2023 with 5751 observations. The data consists of important factors that impact supply and demand and the dependent variable of oil consumption. These variables were selected to model the barrel price series for the following reasons: Firstly, they are closely linked to oil prices and represent various drivers of the end price. Secondly, the relationship between these factors and the oil price series is noisy, non-linear, and volatile, but one of them is likely to provide valuable information on oil price schedules at any given time. Thirdly, more insights can be gained by including as many variables as possible. Finally, the system that contains

all these models, namely (SVM, Random Forest, Gradient Boosting, XGBoost, Neural Network, Decision Tree, Ridge, Lasso, Elastic Net and KNN) is mainly powerful in modeling high-dimensional data using all these variables. The data is divided into two parts, with the training samples consisting of the first 80% of observations of all series and the rest used as test data, as shown in Fig. 2. All data is obtained from websites, including the Energy Information Administration (EIA), Exchange Traded Funds (ETF), and Yahoo Finance (36). The visualization of the entire actual time series (annual and monthly) is shown in Fig. 3 and Fig. 4. For model formation, oil prices and exogenous variables are pre-processed using first differences helps remove zero values, and the use of standardized variables avoids estimation problems such as an explosion of parameters. The methods are designed to model price series rather than oil performance series. The proposed system SMRM is developed with the aim of identifying and validating the factors that contribute to oil price variations. To achieve this objective, a hybrid system SMRM is implemented and utilized to understand the fluctuation of the barrel price while utilizing information from Yahoo Finance. Table IV demonstrates the storage and testing of the data based on its quantitative characteristics. The system reveals 12 key performance indicators which were used as explanatory variables in the model with the expected next-day oil price as the dependent and output variable. These key performance indicators are listed in Table III.

TABLE III. KEY PERFORMANCE INDICATORS AFFECTING CRUDE OIL PRICES

Algorithm	Description
S_3	Moving average for past 3 days
S_9	Moving average for past 9 days
RSI_3	Moving average of Relative Strength Index for past 3 days
RSI_9	Moving average of Relative Strength Index for past 9 days
MME_26	Exponential Moving Average for past 26 days
MME_12	Exponential Moving Average for past 12 days
%K	Stochastic Oscillator
RVI	Relative Vigo Index
MOM	Momentum
MACD	Mobile Average Convergence Divergence
%D_3	Moving Average of %L for past 3 days
%D_9	Moving Average of %L for past 9 days

TABLE IV. OIL MARKET EXPLANATORY VALUES

Features	Description
Close	Reference to the end of a trading
Open	Reference to the starting period of trading
Hight	Reference to the involving large amounts of price
Low	Reference to the reaching of the price

Fig. 2. Splitting the dataset.

Fig. 3. Annual crude oil price.

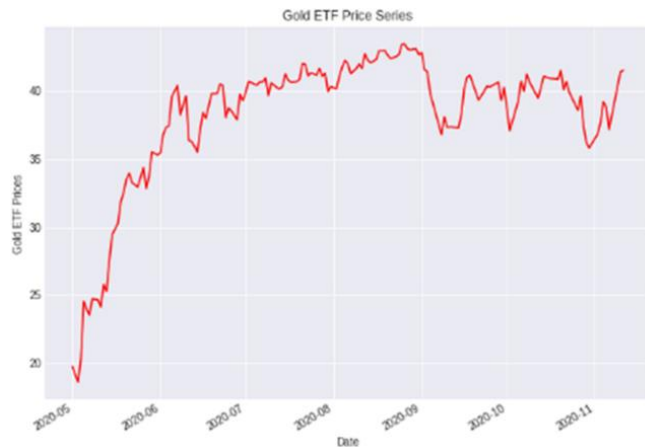

Fig. 4. Monthly crude oil price.

**B. Performance evaluation criteria and statistical test**

In evaluating the performance of the prediction models, four important indicators were used. These include the Mean Absolute Percentage Error MAPE calculated using Eq. (2), Mean Absolute Error MAE calculated using Eq. (3), Root Mean Squared Error (RMSE) calculated using Eq. (4) and R-Squared R2 calculated using Eq. (5). These indicators play a

crucial role in estimating the performance of prediction models across various aspects.

$$MAPE = \frac{1}{N} \sum_{t=1}^N \frac{y(t) - \hat{y}(t)}{\hat{y}(t)} \quad (2)$$

$$MAE = \frac{1}{N} \sum_{t=1}^N (y - \hat{y})^2 \quad (3)$$

$$RMSE = \sqrt{\frac{1}{N} \sum_{t=1}^N (y(t) - \hat{y}(t))^2} \quad (4)$$

$$R2 = 1 - \frac{\sum_{t=1}^N (y - \hat{y})^2}{\sum_{t=1}^N (y - \bar{y})^2} \quad (5)$$

Or  $y(t)$  and  $\hat{y}(t)$  represent, respectively, the actual value and the predicted value,  $a(t)=1$  if  $(y(t+1) - y(t))(\hat{y}(t+1) - y(t)) \geq 0$  or  $a(t)=0$ , and  $N$  is the size of the predictions.

### C. The Algorithm for Staking Learning Sets

This section outlines the process of the proposed system, which is based on a typical sequence of the dataset for improved prediction. The general design of the method is expressed using pseudo code.

Input: Dataset  $\{D=(x_1,y_1),(x_2,y_2),\dots,(x_m,y_m)\}$

First-level learning algorithms  $L_1,L_2,\dots,L_n$

Second-level learning algorithm  $L$

Process:

% Have a training of first-level individual learner  $h_t$  by applying the first-level learning algorithm  $L_t$  to the original dataset  $D$

for  $t = 1, \dots, T$ :

$h_t=L_t(D)$

end

% Generation of a new dataset

$D^{\wedge}=\emptyset$

for  $t = 1, \dots, m$

for  $t = 1, \dots, T$

$z_{it}=h_{it}(x_i)$  % Used  $h_t$  to predict training

dataset  $x_i$

end

$D^{\wedge}=D^{\wedge} \cup \{(z_{i1}, z_{i2}, \dots, z_{iT}), y_i\}$

end

% Have a training of the second  $h^{\wedge}$  learner by applying the second level, learning the  $L$  algorithm to the new dataset set  $D^{\wedge}$

## IV. RESULTS

### A. Benchmarking and Comparison of the Predictive Modelling

The results of testing 10 models (SVM, XGBoost, Random Forest, KNN, Gradient Boosting, Decision Tree, Ridge, Lasso,

Elastic Net and Neural Network) show that the use of the Random Forest algorithm is more effective and closer to reality. This is because the Random Forest algorithm minimizes information loss and converges towards the minimum of empirical response, as shown in Fig. 6. On the other hand, the other models appear to be less effective and less modulable, with more variability present in the data, as seen in Fig. 5 and 7 in which, the case of the two SVM and KNN models is considered.

Fig. 5. Predicted and actual ETF Price via the KNN model.

Fig. 6. Predicted and actual ETF price via the Random Forest regressor model.

### B. Examination of Algorithms

First, the ETF Price data was utilized as a reference dataset, and various machine learning models were examined on the dataset. The assessment will include the following 10 algorithms.

- 1) KNN
- 2) Random Forest
- 3) SVM
- 4) XGBoost
- 5) Gradient Boosting
- 6) Neural Network
- 7) Decision Tree
- 8) Ridge
- 9) Lasso
- 10) Elastic Net

Fig. 7. Predicted and actual ETF Price via the SVM model.

All the algorithms will be evaluated, and their average performance will be compared by describing the distribution of accuracy scores for each. The models will undergo evaluation based on the MAPE. Due to the stochastic nature of the algorithm and numerical accuracy differences, the results may vary. In this context, it was found that the Random Forest algorithm gave the best result with a negative MAPE of approximately -0.021, as shown in Table VI, and with a best R2 of 95.40% as shown in Fig. 8.

### C. The Combination of Models

The approach defines the Stacking Multi-Regression Models (SMRM) by initially presenting a list of tuples for the 10 basic models and subsequently defining the Linear Regression, which acts as a meta-model, to combine the predictions of the basic models and learn how to best combine the outputs of each of the 10 separate models (see Fig. 1). This implementation allows us to assess the performance of each model and the findings indicate that SMRM is the most efficient when compared to the other models, with a negative MAPE of approximately -0.023. The average and median scores for the SMRM are the highest in comparison to the other individual models, as seen in Table V. However, A stacking set can be chosen as the final model, fine-tune it, and use it to make predictions on novel datasets using the linear model created from all the training data. The prediction method estimates the ETF Price (y) for the explanatory variable X as shown in Fig. 10. The results show that the R2 has a score of 97% as shown in Fig. 9. A score close to 100% indicates that the model effectively explains the ETF prices for crude oil. The cumulative returns, represented as a purchase signal, are shown in Fig. 11, where a "1" value indicates that the expected price for the next day is higher than the current day's price, while no position is taken otherwise.

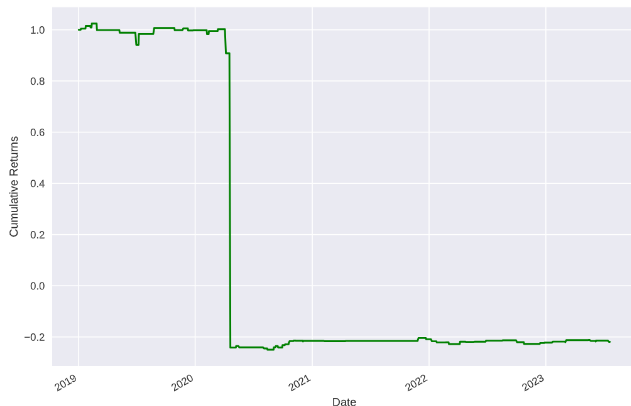

Fig. 11. Cumulative returns signals crude oil price.

## V. DISCUSSION

In this section, a stacking set can be chosen as the final model. Both individual and overall predictors have been applied to address the problem of estimating the expected price of the next day, providing a more comprehensive evaluation of the stability of the SMRM hybrid system. All models were examined in their predictions. It is evident that the proposed SMRM hybrid system was the best for forecasting oil prices, as shown in Fig 10, compared to the other models studied. In all models, the Random Forest Regressor model based on the SMRM hybrid system not only achieved the highest accuracy in estimation, as measured by MAPE, but also achieved the highest success rate in R2, as measured by R2. Additionally, among the models studied, the KNN performed the worst in growth forecasts. This model not only had the lowest MAPE, but also achieved the worst score in terms of R-Squared, as measured by R2. This could be since SVM was a linear regressor, which couldn't capture non-linear models. In addition to the Random Forest, KNN, and the other models based on the SMRM hybrid system, which produced the best and worst results, respectively, all models studied produced encouraging mixed results, which were analyzed using four evaluation criteria (i.e., MAPE, MAE, RMSE, and R2). First, in terms of level accuracy, the results of the MAPE measurement showed that the Random Forest based on SMRM achieved the best results, followed by the other models that are based on SMRM was the weakest, as shown in Table VI. Second, high

accuracy does not necessarily imply a high success rate in predicting the R2. It is crucial that the R2 is correct for the policy maker to make an investment plan in oil-related processes (production, price, and demand). Thus, comparison of the R2 is essential. Similar conclusions can be drawn from Table VII regarding the R2. The SMRM hybrid system achieved significantly higher results and closer to 100 than all others, followed by the other 10 overall models (i.e., SVM, XGBoost, Random Forest, KNN, Gradient Boosting, Decision Tree, Ridge, Lasso, Elastic Net and Neural Network). The 10 overall methods typically outperformed individual forecasting models, and among the overall methods, the Random Forest model based on the SMRM hybrid system produced the best results, while the other models based on SMRM, The Ridge model exhibited the lowest R-Squared at 74%, as shown in Table VII. The Random Forest Regressor model within the SMRM hybrid system demonstrated the ability to adapt to the data, meaning that the difference between the predicted and observed values is important (RMSE and MAE), as shown in Tables VIII and IX.

## VI. CONCLUSION AND FUTURE WORK

Predicting crude oil prices is a difficult task that requires a nuanced understanding of a wide range of economic and political factors. The SMRM hybrid system proposed in this

paper is an innovative approach that leverages machine learning to better capture the complex relationships between these factors and crude oil prices. By combining multiple models, SMRM can generate more accurate and reliable predictions, which can help investors and traders make more informed decisions. The experiment results illustrate that SMRM surpasses existing prediction models in terms of both accuracy and stability, making it a valuable tool for anyone interested in predicting crude oil prices. While there is still much work to be done to fully understand and predict stock market trends, SMRM represents a major step forward in this field, and holds the potential to revolutionize the approach to crude oil price prediction in the coming years. Predicting crude oil prices is a complex and challenging task, requiring a nuanced understanding of economic and political factors. The proposed SMRM hybrid system represents a significant improvement over existing approaches, as it can leverage both quantitative and qualitative factors to generate more accurate predictions. By learning from past data, the system can continually improve its forecasts, making it a robust and flexible forecasting tool that can support decision-making for a range of stakeholders, including investors and policymakers. Experiments demonstrate that SMRM outperforms existing models in terms of accuracy and stability, highlighting its potential as a powerful tool for predicting crude oil prices in the years to come. However, the proposed SMRM hybrid system offers a robust tool for predicting crude oil prices with heightened accuracy and reliability. However, there are still challenges to address, such as quantifying the impact of irregular factors like political risks and extreme weather events on crude oil prices. To address these challenges, future research will aim to incorporate these factors into the SMRM hybrid system and quantify their impact, leading to even more accurate predictions. With continued research and development, SMRM has the potential to revolutionize crude oil price prediction and help stakeholders make more informed decisions in the dynamic and complex world of stock market trading. In conclusion, the proposed SMRM hybrid system offers a promising solution for predicting crude oil prices, leveraging the power of machine learning, and combining multiple models to better capture the complex relationships between different factors. The experiments reveal that SMRM excels over existing models in both accuracy and stability, making it a valuable tool for investors, traders, and other stakeholders in the energy sector. The system can also be continually refined and improved by incorporating irregular factors like political risks and extreme weather events, which can help to better predict changes in crude oil prices. With further development, this approach could have important implications for supporting decision-making and risk management in the energy sector, enabling stakeholders to make more informed and effective decisions in the dynamic and complex world of stock market trading. By providing more accurate and reliable predictions of crude oil prices, the SMRM hybrid system has the potential to revolutionize how approach to predicting crude oil prices, providing valuable insights that can help to optimize decision-making and drive greater value in the energy sector.

# Compression Analysis of Hybrid Model Based on Scalable WDR Method and CNN for ROI-based Medical Image Transmission

Dr. Bindulal T.S.

Assistant Professor, Dept. of Computer Science, Govt. College, Nedumangad, University of Kerala, India

**Abstract**—The image compression techniques are the fast-growing methods and have developed on large scale. Among them, wavelet-based compression methods are most promising and efficient techniques widely used in the field of medical image processing and transmission. The compression techniques are treated as lossy or lossless models and these can be applied on the medical images considering different situations. The medical image parts are separated into two regions. The central part of the image is treated as core region called region of interest (ROI) and others are treated as non-ROI. ROI based coding techniques are considered as most important in the medical field for efficient transmission of clinical data. The proposed method focuses on these concepts. The ROI parts considered are either smooth or textured regions. These are extracted using a segmentation method called singular value decomposition (SVD) method. An efficient run length coding method called wavelet difference reduction method (WDR) with region growing approach is used to code the extracted ROI part after applying 5/3 based integer wavelet transform. The remaining parts called non-ROI part or background artifacts are coded using Convolution Neural network (CNN) method. The proposed method is also restructured as layered structure to achieve adaptive scalable property and named as scalable WDR-CNN (SWDR-CNN) method. The proposed SWDR-CNN method has been evaluated using rate distortion metrics such as Peak Signal to Noise Ratio (PSNR) and Structural Similarity Index (SSIM). The coding gains in terms of PSNR values of SWDR-CNN method has been analysed and compared to popular scalable algorithm like S-SPIHT. The SWDR-CNN method has achieved better coding gain from 0.2 dB to 6 dB in terms of PSNR values. Hence, it is proved that proposed model can be used to code the ROI of images and has applications in the field of medical image data coding and transmission.

## I. INTRODUCTION

Design and development of efficient image processing methods is a subject of intense research for the last several decades. The demand of properly designed algorithm is much more in image coding [1] and transmission scenario. Advanced development in the networking technologies [2] with high processing power and transmission capacity, make it possible to implement modern signal processing [3] techniques in data computing scenarios. Hence, new technologies are developed, combining more than one method called hybrid model [4] to address specific user requirements. Moreover, tremendous

growth of the Internet and data sharing facilities, the developed hybrid model addresses the situations to achieve better computing capabilities in different network access bandwidths.

The image coding algorithms are developed and widely accepted with multiresolution features which are based on the JPEG2000 image compression standard. For Human Visual Systems, multi-resolution based coding algorithms are developed by using [5] wavelet transform. Thus, wavelet transform is used as supportive framework for decomposing images with different time-scale resolution form. The data analysis in wavelet domain has significant impact on the medical image computing scenario like in disease diagnosis and visualization. Due to the powerful multiscale/multiresolution representation of data in wavelet domain, many wavelet-based coding algorithm are developed for magnetic resonance Imaging (MRI) technologies.

Considering the inter scale/intra scale properties of wavelet transform, different approaches were developed in the late 1990s and 2000s. Among them, Shapiro's [6] Embedded Zero-tree Wavelet (EZW) coding scheme, Set Partitioning in Hierarchical Trees (SPIHT) [7] introduced by Said and Pearlman are most important. Due to the spatial orientation tree (SOT) based algorithm, the computational complexity of these algorithms remained very high. Hence, alternate methods that avoid the heavy use of SOTs, without sacrificing the desired properties of embedded coding, progressive transmission and scalability were also required to be developed.

Considering the time complexity, a new method called Wavelet Difference Reduction (WDR) method [9, 10] was developed by Tian and Well. The spatial orientation tree-based data structure was precluded in this method, but preserves the embedded principles, lossless bit plane coding and set partitioning concepts. The wavelet coefficients are linearly arranged using a fixed scan path by mapping the 2-D transform coefficients to 1-D index array which are present in the multiresolution pyramidal structure of wavelet transform. The WDR performs the run between two neighbouring significant coefficients and takes the difference between their indices and then these indices are coded efficiently. The WDR also maintains the simplicity while keeping the coding performance advantages of spatial orientation tree-based methods like EZW and SPIHT. Further, WDR methods were improved by incorporating many other desired features [24, 25] like coding regions of interest, scalability [26, 27, 28], object-based shape coding etc. Among them, Adaptive Scanned WDR (ASWDR)

of Walker and Ngan [11] considers one level of parent-child relationship, embedded progressive coding method developed by Wilhelm Berghorn [22, 23] with context conditioning and Context Modelling with ASWDR method (CMWDR) developed by Yuan and Mandal [12] considered much better method with coding gain than standard SPIHT algorithm even if the absence of entropy coding.

Significant development of coding methods is progressed to incorporate scalability concepts to decode the data by different resolution capacity devices on particular bit rate. David Taubman proposed a method called EBCOT, originally based on JPEG2000 standard [31] which supports SNR scalability. These types of algorithms are suitable for applications like remote browsing of large compressed images. The scalable image transmission is possible by using the layered approach and Hwang and Chine [43] proposed a medical image compression and transmission called Layered SPIHT. In LSPHIT, the bit streams are generated from different layers of subbands. According to time scale property of wavelet sub-bands, subbands are arranged on the basis of the priority and the bit streams are produced progressively with scalable property. Astri Handayani [44] proposed a medical image transfer method considering the ROI over heterogenous network, where good image quality and data compactness are both of crucial concern. The method follows wavelet-based coding techniques with layered approach as used in JPEG2000.

In ROI based image compression scenario, the new technique called object coding was developed by using shape adaptive wavelet transform, proposed [18] by Shipeng Li in 2000. In 2005, Ping Xu [19] and Shan'an Zhu proposed a method for arbitrary shaped ROI coding based on integer wavelet transform. Using this arbitrary shaped adaptive wavelet transform, Danyali [8] proposed the flexible scalable object coding using SPIHT method. Mehrotra, Srikanth and Ramakrishnan [30] proposed their coding method for MR images using shape adaptive integer wavelet transforms.

Generally, the medical images are coded using lossless image compression techniques and that can be done using integer wavelet transform. Many of the methods with progressive transmission facility have poor rate distortion performance in low bit rates. In medical images, the central portion of the image is considered as most important part. These central parts are either smooth or textured regions and can be extracted using some segmentation techniques. These segments are coded with maximum priority in lossless manner. The background can be repeatedly coded with lossy/lossless algorithm. In this paper, the objects are identified as ROI using singular value decomposition method and are coded using scalable WDR method [13, 14, 15, 16, 17]. The scalable WDR method is a layered architecture of wavelet different reduction method with embedded region growing method (WDR-SRG). The lossless coding is performed by using arbitrary shaped integer wavelet transform and SWDR. The remaining parts are coded using lossy coding techniques. Here, we use convolution neural network (CNN) model to code non-ROI area of the image. In 2020, Chung K. J. et al. proposed [34] a cross-domain cascade of U-nets that was the W-net compression technique and operated over the discrete cosine transform (DCT). In 2020, Guo P. et al. [41] had introduced the CNN-

based compression technique. The model focuses on retina optical coherence tomography (OCT) images. The model was trained and tested on OCT images with pathological details.

Here, the paper presents a hybrid model which includes SVD based image segmentation and DWT based object coding. The layered region-growing approach [15] based WDR method is used in DWT Coding algorithm. Also, CNN-based medical image compression [35] technique with minimum information loss is used for non-ROI. The coding performance of proposed model is analysed in terms of PSNR values and SSIM [41] metric. The analysis shows that the coding gain is much better in terms of PSNR values from 0.2 dB to 6 dB in various bit rates than the traditional coding schemes like SPIHT and its scalable version.

## II. SEGMENTATION USING SVD METHOD

Segmentation is a process to identify important portion of an image as per the user requirements. Most probably, the central portion of the medical images is considered as ROI which consists of important information. Hence, ROI part should be extracted for lossless data coding and can be done very efficiently by using the SVD method. SVD method [15] is based on eigen value and eigen vector analysis and it is observed that a small Eigen values in the non-ROI part will be generated. Therefore, applying some optimum threshold value on Eigen value, we can extract the ROI part of the image. The eigen value analysis applied on image to get textured region is explained below.

Consider the image,  $I(x, y)$ . Before starting the SVD analysis, windowing method is applied on the image  $I(x, y)$  and collected fixed sized windows which are used for labelling content feature. The textured regions are identified in terms of corners and edges. These can be easily separated by doing the gradient calculation. Let  $L_i$  is the linearly arranged signal values in window 'w'.  $\nabla L_i$  is the gradient in w.

$$\nabla L(i) = \left( L_x(i), L_y(i) \right)^T \quad (1)$$

where  $L_x(i) = \partial L / \partial x$  and  $L_y(i) = \partial L / \partial y$

The autocorrelation matrix is calculated as follows:

$$C = \begin{bmatrix} \sum L_x^2(i) & \sum L_x(i)L_y(i) \\ \sum L_x(i)L_y(i) & \sum L_y^2(i) \end{bmatrix} \quad (2)$$

The generated 2x2 matrix C is as symmetric autocorrelation matrix and eigen value analysis is applied on this matrix. After analysis, we can write symmetric matrix C as,

$$C = UDU^T \quad (3)$$

where, U is the ortho-normal column vector and D is the diagonal matrix. The diagonal matrix consists of two eigen values. The matrix values satisfy the following condition such that  $diag(e_1, e_2)$ ,  $e_1 \geq e_2$ , where  $e_i$  are the eigen values of the autocorrelation matrix C. Considering the values of  $e$ 's, the segmentation can be done according to the following conditions.

1) Let the window w contains a smooth region, then corresponding eigen values  $e_1$  and  $e_2$  are small.

- 2) Let the window  $w$  contains edges or corners, then first eigen value  $e_1$  is of principal component and the second eigen value  $e_2$  is of extremely small magnitude.
- 3) Let the content in window  $w$  consists of textures and patterns, then eigen value  $e_2$  is significant one.

Fig. 1. Segmentation using SVD (i) Original MRI image (512x512) (ii) binary representation (iii) identified ROI (T = 1000 for eigen value) (iv) identified ROI (T = 10 for eigen value).

Fig. 2. Segmentation using SVD (i) Original MRI image (256x256) (ii) identified ROI.

The texture extraction is done by applying threshold value on eigen values ( $e_1, e_2$ ) satisfying the above three conditions. Segmentation using SVD analysis of *MRI* medical image is shown in Fig. 1 and Fig. 2. The eigen values are calculated on each block with window size  $2 \times 2$ . The obtained eigen values are from 0 to a value of power of 10. A threshold value  $T$  can be applied to remove negligible correlation of values and it may be in noise part or smooth region of the image. The obtained eigen values from 100 window blocks are shown in the Fig. 3.

Fig. 3. Eigen values of first 100 blocks (window -  $2 \times 2$ ).

### III. LAYERED SCALABLE WDR METHOD WITH SELECTED REGION GROWING APPROACH (SWDR-SRG)

The ROI based coding is important in many applications in telemedicine so that important medical data needs to be coded without loss. The balance between coding of ROI and BG of the medical images is maintained by using object coding. Moreover, Integer Wavelet Transform is used to improve the quality of the reconstructed ROI. The Shape Adaptive DWT is used in object coding and also maintains spatial correlation between the actual data and its transformed data. Moreover, it keeps count of the coefficients obtained from SA-DWT [18, 19] is same to the count of pixels in the region.

The shape adaptive DWT [20, 29, 30] is done based on the procedure as follows. The process begins by identifying arbitrary shaped objects using a segmentation method. The first segment of the object is applied by length adaptive 1-D DWT with proper subsampling. The calculated wavelet coefficients are categorized into low pass and high pass bands. After the completion of row wise operation, each column of the low pass and high pass objects are applied by the same operations. The same operation is repeatedly applied on object in low pass band to get desired level of wavelet decomposition. Thus, 2D SA-DWT provides multi-resolution pyramid of arbitrary shaped objects. The subband structure of arbitrary shaped object is shown in the Fig. 4.

The segmentation process is carried out as a preprocessing in image compression model. The main aim is not only object identification, but classifying spatially connected homogeneous pixels present in a small region with similar gray levels. In this situation, region growing approach is better for ROI based image coding. The Selected Region Growing starts with a seed pixel and connected with four neighbouring pixels with similar features. The process progresses until last seed pixel reaches and terminated when condition fails. Here, the SRG process is done on the transform values which are present in the wavelet domain. The significant coefficients are identified in the extracted region. WDR method is used here to perform SRG operation. Index coding with differential coding method is used

in WDR method where it codes the index positions of significant transform values very efficiently. The 2D wavelet transform coefficients are linearly arranged in increasing order of the index positions using a predefined scan path [21]. The general structure of algorithm WDR-Selected Region Growing (WDR-SRG) [15] is depicted below:

Fig. 4. Subband structure of objects using shape adaptive DWT.

#### A. Wavelet Difference Reduction with Selected Region Growing (WDR-SRG)

Algorithm starts with two-dimensional shape adaptive DWT which is applied on the arbitrary shaped objects. The decomposition of the medical ROI is done using a 5/3-tap wavelet filter with symmetric extension. Wavelet coefficient at pixel location  $(i, j)$  is represented as  $w_{ij}$ . The iterative operation is progressed within the limit of a threshold value and initialised as,  $t_{n-1} = 2^{n+1}$  and  $t_n = t_{n-1}/2$ , where  $n = \left\lfloor \log_2 \left( \max_{(i,j) \in I} |w_{ij}| \right) \right\rfloor$ . The algorithm is progressed through sorting pass and refinement pass. These are narrated as below.

1) *Sorting pass*: The sorting pass uses different data structures or lists to store the positions of coefficients which are collected during the process. The collection of coefficients during region growing process is stored in the list R, significant coefficients are stored in the list C and its neighbouring pixels are stored in the list N. The parent child connection pixels are stored in the list P. The list T is used to store temporary set of significant coefficients. Also, the list I is used to store set of remaining insignificant coefficients. The significant coefficients are identified by using  $\sigma(w, t_n)$  such as,

$$\sigma(w, t_n) = \begin{cases} 1 & : |w| \geq t_n \\ 0 & : |w| < t_n \end{cases} \quad (4)$$

The sign of coefficient 'w' is identified by using function  $Sign(w)$  such as,

$$Sign(w) = \begin{cases} + & : w \geq 0 \\ - & : w < 0 \end{cases} \quad (5)$$

The  $cluster(w_{ij}, t_n)$  function is to collect the neighbouring coefficients of the significant coefficients. The sorting pass procedure is depicted below:

```

If I ≠ ∅ {
    If σ(wij, tn-1) = 0 {
        If σ(wij, tn) = 1 {
            Coding (wij);
            R = cluster(wij, tn);
        }
        Do {
            If R ≠ ∅ {
                If σ(R(wij, tn)) = 1 {
                    Coding ( wij )
                    R = cluster(wij, tn)}
            } While (End (R) ≠ True);
        }
    }
}
    
```

The encoding process is done by differential coding using a function Coding ( $w_{ij}$ ). The function procedure is depicted below:

#### Function Coding ( $w_{ij}$ )

```

{
    Binary representation of value obtained as distance between
    two significant coefficients avoiding MSB '1'. The sign
    information generated using the function Sign(wij). Append
    wij into temporary list T.
}
    
```

The next step of sorting pass is progressed only after the updation of list and that is depicted in the Index updating pass as shown below:

```

If T ≠ ∅ {
    N = cluster(wij, tn) ; ∀(i, j) ∈ T
    P = child(wij, tn) ; ∀(i, j) ∈ T
}
    
```

List of insignificant coefficients, I is reset after removing these coefficients

$$I = R + N + P + I.$$

2) *Refinement pass*: After the sorting pass, the collected significant coefficients are coded as bit plane coding manner using the refinement pass as shown below:

```

If C ≠ ∅ {
    If C(σ(wij, tn-1) = 1) {
        Add nth MSB of C(wij).
    }
    C = C + T.
    T = ∅
}
    
```

Next iteration starts after the threshold update process. i.e.,  $t_{n-1} = t_n$ ,  $t_n = t_n/2$ . The encoding procedure generates four symbols like +, -, 1 and 0. The entropy coding like arithmetic coding is avoided by replacing the symbols by using two bits like 11 for +, 10 for -, 01 for 1 and 00 for 0.

### B. Scalable Wavelet Difference Reduction Method

The developed coding scheme WDR-SRG is quite useful in the field of communication over heterogeneous networks if it supports the concepts of adaptive scalability. For that, wavelet difference reduction method with selected region growing (WDR-SRG) is applied on ROI after the SA-DWT. Thus, the base algorithm is restructured in layered manner so that the algorithm can generate different scalable images. Hence, we renamed the method as scalable WDR (SWDR) [13, 14, 16] method. Thus, the coding procedure is following the adaptive scalable concepts. The coding procedure is depicted in Fig. 5. The scalable image generation from the layered bit stream is depicted in Fig. 6.

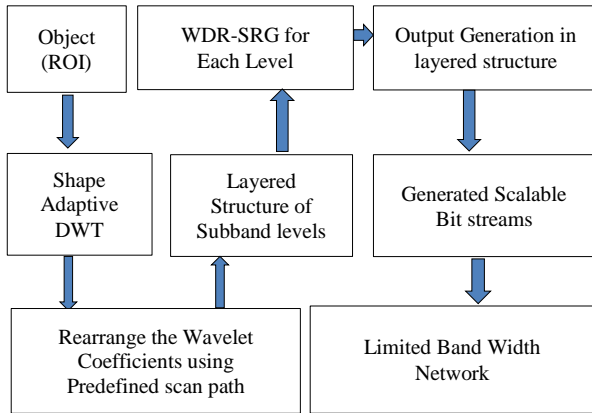

Fig. 5. Scalable WDR model (SWDR).

### C. Algorithm: ROI coding using Scalable Wavelet Difference Reduction Method

Step 1: The MRI Medical Image is inputted in the procedure,  $I(x, y)$

Step 2: The SVD is applied on MRI medical image to identify the ROI

- $I(x, y) \rightarrow O(x, y) + N(x, y)$
- Input Image = Object Image + Noise
- Input Image = ROI + nonROI

Step 3: The ROI is treated as object and applied SA-DWT

- $O(x, y) \rightarrow SA(x, y)$

Step 4: The Layered Structure of Scalable WDR is applied.

- $SA(x, y) \rightarrow SWDR(x, y)$

Step 5: The bit stream is generated for transmission

- $SWDR(x, y) \rightarrow E(Binary)$

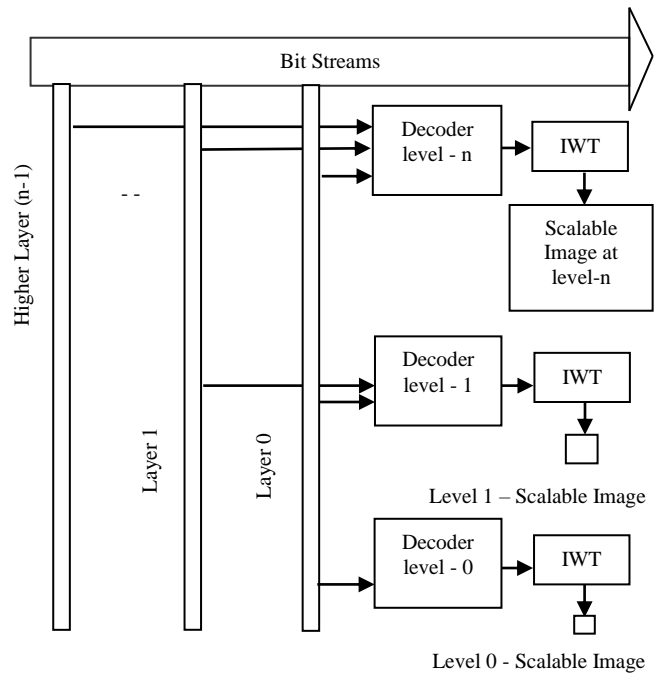

Fig. 6. Scalable image generation (layered architecture).

### IV. NON-ROI CODING USING CNN MODEL

During the image compression process, the artifacts are identified with several features. These artifacts may be suppressed efficiently by using CNN model. In this field, many of the scientists [32, 33, 34] have developed efficient CNN models which can be used in data coding situations. Fully convolutional model is also used to obtain a compact representation of an image. The general idea of CNN model is shown in Fig. 7. The image features are identified and represent as parameters to train the data how it can be represented in compact form. Here, a series of convolutional layers are fixed in such a way that features of [35, 36, 37] images are captured. Thus, structural configuration of an image is maintained as well. The model shown in Fig. 7 describes the CNN Forward as a well-designed network [38, 39, 40] which is used to represent the image in identified properties. Thus, CNN forward is used to compress in such a way that original data can be reproduced by reconstruction network. The model consists of three convolutional layers in which the second layer followed by batch normalization layer. After the operation of first convolutional layer, the image size is reduced by half. The data in the form of grid is used in Convolutional Neural Networks. In CNNs, each kernel produces in a new convoluted layer. These layers are also called activation maps. In CNN model, the convolution operation is used such that a kernel or a mask moves over an image and a convoluted representation of output is generated [40, 41]. The identified dependencies in an image are captured by CNN.

CNN Model [45] with different layers is used to perform convolution operation on matrix data. The image is inputted as matrix with two dimensional or three-dimensional form. The other matrix called filter matrix or kernel matrix is inputted with features like height, width and dimension. Let inputted image is  $I(x, y)$ , then filter matrix is  $F(h, w, d)$ , where  $h$  is

height,  $w$  is width and  $d$  is dimension. After convolution operation, generated output matrix is  $C(x-h, y-w)$  for gray scale image. The basic architecture of CNN is shown in Fig. 8.

A. Algorithm: Non-ROI Coding using CNN Model

- Step 1. Input nonROI image  $\leftarrow N(x, y)$
- Step 2. Read  $N(x, y)$  and transform to CNN forward
- Step 3. ReLU based Two-dimensional convolution with Layer 1 and Layer 2  
Optimum Value  $\leftarrow$  Padding and striding is used in Max pooling two-dimensional layer 1
- Step 4. ReLU based Two-dimensional convolution with Layer 3 and Layer 4  
Optimum Value  $\leftarrow$  Padding and striding is used in Max pooling two-dimensional layer 2
- Step 5. ReLU based Two-dimensional convolution with Layer 5
- Step 6. NE(Binary)  $\leftarrow$  Compressed nonROI MRI medical image

Fig. 8. Basic architecture of convolutional neural network.

The CNN model consists of three layers: convolution layers, pooling layers or subsampling, and fully connected layers. The model uses specific filters for image compression and decompression. The filter helps to represent the image in definite manner so that it removes the unnecessary features. The size of Kernel can be adjusted to increase the performance of data coding which is used in convolution operation at every point. The padding process is applied on all sides of image matrix to reduce the loss of data. The pooling layer is one layer used to reduce the feature map's dimension. But it is possible to recall necessary information. The optimum value is taken as maximum value which is done by Max pooling operation. Famous method called ReLU (Rectified Linear Unit) [32, 36, 37, 38] activation function is used in CNN for a non-linear operation. This method activates neurons in which the gradient provides all times the optimum value.

V. PROPOSED METHOD: HYBRID SCHEME WITH SCALABLE WDR AND CNN

The paper proposes a hybrid scheme with two coding techniques, one for the ROI and another for unimportant parts nonROI of the medical image. ROI parts are identified as object and coded using DWT based coding method (suitable for lossless image compression). The remaining nonROI parts called BG part is coded using CNN (useful for lossy image compression scheme). Medical image is inputted and SVD analysis is done for object identification. The shape adaptive DWT is applied on arbitrary shaped object and Scalable WDR is used to perform the lossless coding. The remaining BG part is coded using a lossy compression with CNN model. The outline of proposed method is shown in Fig. 9.

VI. EXPERIMENTAL RESULTS

This paper presents the compression analysis of a new fast hybrid method SWDR-CNN for medical image transmission. The MRI medical images are used for the simulation and analysis. The proposed scheme SWDR-CNN model is analysed in terms of the basic parameters like PSNR and SSIM. The hybrid model is useful for both lossy and lossless image coding. The quality of images at any bit rates is calculated as the peak signal to noise ratio (PSNR). It is defined as,

$$PSNR = 10 \log_{10} \left( \frac{max^2}{MSE} \right) \text{ dB} \quad (6)$$

where, MSE is mean squared error obtained by comparing the inputted image and the recreated image;  $max$  is the extreme value of a pixel inside the image.

Fig. 7. CNN model for image compression.

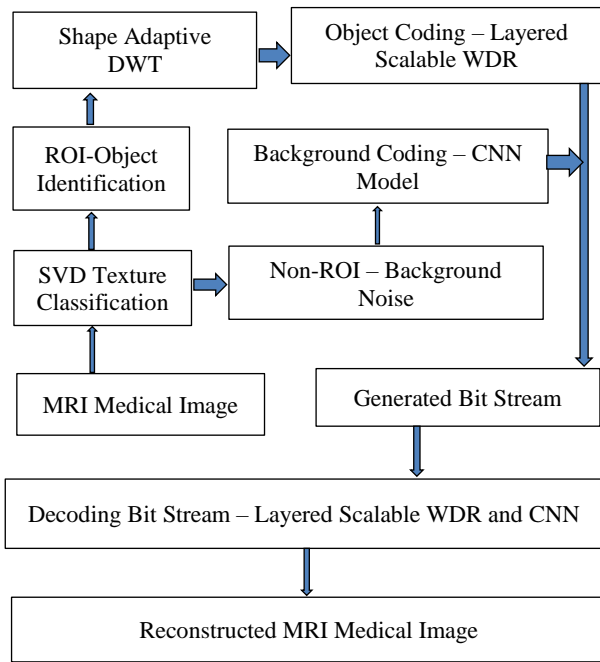

Fig. 9. Proposed compression method – SWDR-CNN.

Structural similarity index (SSIM) [42] is also used to analyse the performance used as rate distortion metric and can be defined in following equations. The SSIM between signals  $x$  and  $y$  is calculated as:

$$SSIM(x, y) = \frac{(2\mu_x\mu_y + C_1)(2\sigma_{xy} + C_2)}{(\mu_x^2 + \mu_y^2 + C_1)(\sigma_x^2 + \sigma_y^2 + C_2)} \quad (7)$$

where  $\mu_x$  is mean of  $x$ ,  $\mu_y$  is mean of  $y$ ,  $\sigma_x^2$  is variance of  $x$ ,  $\sigma_y^2$  is variance of  $y$  and  $\sigma_{xy}$  is the covariance of  $x$  and  $y$ ,  $C_1$  and  $C_2$  are constants, i.e.,  $C_1 = (K_1L)^2$  and  $C_2 = (K_2L)^2$  where  $L$  is the dynamic range of the pixel values, and  $K_1$  and  $K_2$  are two constants. The overall quality value called the average of the quality map or the Mean SSIM (MSSIM) index is defined as,

$$MSSIM(X, Y) = \frac{1}{M} \sum_{j=1}^M SSIM(x_j, y_j) \quad (8)$$

where  $X$  is reference image and  $Y$  is the distorted image.  $x_j$  and  $y_j$  are the image contents at the  $j^{th}$  local window and  $M$  is the number of local windows of the image.

The rate distortion metric PSNR is calculated and coding gain of SWDR-CNN method is compared with the traditional methods like SPIHT and CMWDR without any entropy coding. Coding results for MRI test image with size 256x256 are shown in Table I and Fig. 10. Reconstructed images with size 256x256 are shown in Fig. 11. Coding results for MRI test image with size 512x512 are shown in Table II and Fig. 12. Reconstructed images with size 512x512 are shown in Fig. 13. The wavelet transform with 6-level is done for 512x512 images and 5-level is done for 256x256 images.

Structural Similarity Index (SSIM) of MRI image is shown in Table III. The proposed method is also simulated by incorporating with the scalability concept. Here, the comparison of the proposed model SWDR-CNN is done with layered form SPIHT method. Simulation results obtained are given in Table IV. For MRI with Full resolution, the coding is from 0.3 dB to 0.7 dB for different bpp. During the analysis, we identified one important point is that the coding gain in PSNR values (in dB) tremendously changes when the resolution scale decreases. At level 2 resolution 256 x 256, the coding gain is from 0.80 dB to 5.50 dB compared to SPIHT and from 0.7 dB to 1.5 dB compared to its scalable version at different bpp.

MATLAB tool in Windows OS is used to implement all the algorithm modules. The convolution-based DWT is developed using Bi-orthogonal 5/3 tap filter coefficients.

## VII. CONCLUSION

The paper presents a hybrid scheme based on wavelet based scalable encoder with convolution neural network for image transmission. The scheme has high encoding performance with scalability property and can be used in medical image transmission field. The paper focused on efficient transmission of important parts present in medical images where quality is effectively preserved. It is required to review large images which are often required in the field of medical image computing. Moreover, data transfer is required over limited bandwidth channel in very low bit rate. Hence, object coding is essential for data transfer and here a modified

WDR called SWDR is used. These are implemented by using the arbitrary shaped DWT. Thus, new method has interesting perceptions for numerous medical data computing and transmitting applications. The medical data is classified into ROI and non-ROI with the help of SVD method. ROI parts are compressed using the SWDR and non-ROI parts are compressed using CNN model. The Shape Adaptive DWT in association with scalable WDR method is used as lossless compression technique and it is applied on an ROI portion of medical image data. Then, CNN model is applied on non-ROI as lossy coding scheme which is used to reduce the losses using weight and learning rate. After analysis, the projected method is good one with better coding speed with 12% gain than that of traditional methods. Moreover, better coding gain is obtained in terms of PSNR value from 0.2 dB to 6 dB in all situations. Thus, proposed coding scheme called SWDR-CNN model have better results than the existing coding models.

**Abstract**—Recently, intelligent applications gained a significant role in the energy management of public buildings due to their ability to enhance energy consumption performance. Energy management of these buildings represents a big challenge due to their unexpected energy consumption characteristics and the deficiency of design guidelines for energy efficiency and sustainability solutions. Therefore, an analysis of energy consumption patterns in public buildings becomes necessary. This reveals the significance of understanding and classifying energy consumption patterns in these buildings. This study seeks to find the optimal intelligent technique for classifying energy consumption of public buildings into levels (e.g., low, medium, and high), find the critical factors that influence energy consumption, and finally, find the scientific rules (If-Then rules) to help decision-makers for determining the energy consumption level in each building. To achieve the objectives of this study, correlation coefficient analysis was used to determine critical factors that influence on energy consumption of public buildings; two intelligent models were used to determine the number of clusters of energy consumption patterns which are Self Organizing Map (SOM) and Batch-SOM based on Principal Component Analysis (PCA). SOM outperforms Batch-SOM in terms of quantization error. The quantization error of SOM and Batch-SOM is 8.97 and 9.24, respectively. K-means with a genetic algorithm were used to predict cluster levels in each building. By analyzing cluster levels, If-Then rules have been extracted, so needs that decision-makers determine the most energy-consuming buildings. In addition, this study helps decision-makers in the energy field to rationalize the consumption of occupants of public buildings in the times that consume the most energy and change energy suppliers to those buildings.

**Keywords**—Energy consumption in public buildings; self-organizing map; K-means; genetic algorithm; principal component analysis

## I. INTRODUCTION

The growing construction sector is struggling to cope with the increasing demand for energy despite efforts to develop sustainable buildings [1]. Therefore, improved energy efficiency and analysis of energy consumption patterns in buildings become necessary. This unveils the importance of understanding and classifying energy consumption patterns in buildings. For example, the more precise and pragmatic energy consumption profiles are computed, the better building energy quality evaluation becomes [2]. Energy consumption depends

on various factors such as building characteristics, energy prices, and climate conditions, amongst others [3]. Therefore, aiming to classify the energy consumption of buildings requires advanced computational intelligent approaches, particularly adopting the latest trends in machine learning, such as deep learning techniques, which exploit familiarity from historical data and can support decision-makers in the energy domain, creating a basis for styling new power allocation dispositions, particularly for public buildings areas [4].

Energy consumption in public buildings merits particular attention since it accounts for a large share of final energy consumption if we look at 2019 figures from the OECD (Organization for Economic Cooperation and Development) countries, which reached 27% in the European Union [5]. For example, public buildings consume nearly one-third of all electricity in Portugal, increasing by 35% from 1995 to 2019 [6]. Understanding this consumption means solving a complex problem involving physical, technological, and performance characteristics of the dwelling, the status of the demography, socio-economic factors, climate and weather conditions, and the behavior of the building's occupants [7]. Therefore, academic research in European countries, notably Portugal, needs help understanding the energy consumption patterns of public buildings.

In the past, we can find several data mining and machine learning techniques that have been used for energy consumption classification. Among those, clustering is considered one of the most applied techniques [8]. Clustering comprises splitting objects with similar styles into various groups [9]. Researchers have provided many manuscripts on classifying energy consumption into discrete levels. For instance, Gouveia [10] discovered electricity consumption profiles in households through clusters by combining smart meters and door-to-door surveys. His study used hierarchical clustering to divide household profiles and obtained three clusters. Hernandez et al. [11] presented a study to classify daily load curves in industrial parks by using a self-organizing map and k-means to determine the number of clusters. Ford and Siraj [12] presented a fuzzy c-means clustering to classify smart meter electricity consumption data to similar groups. Hodes et al. [13] presented a study to classify residential houses with similar hourly electricity using the k-means algorithm. Azaza [14] presented a method to find the most responsible energy consumers in the peak hour by using

hierarchical clustering and a self-organizing map. Al-Jarrah et al. [15] presented a method to discover power consumption in buildings using multi-layered clustering. K-mean has been utilized to partition power consumption profiles. Then, the authors discover different patterns of power consumption profiles. Furthermore, Cai et al. [16] presented a hybrid method to divide the electricity consumption of an entire region into various levels by using k-means with particle swarm optimization. To extract behavior in daily electricity consumption in households, Nordahl et al. [17] utilized the centroids of the generated clusters.

Most research focuses on the total energy consumption in different buildings by reviewing the analyzed literature. However, other factors that affect energy consumption, such as the consumption behavior of the occupants of these buildings at peak time or during empty hours (00h00-02h00; 06h00-08h00; 22h00-00h00), were neglected. In this paper, we follow this literature trend, and we propose an intelligent computing model capable of automatically classifying energy consumption into discrete levels, such as low, medium, and high. In this model, we can discover the different consumption patterns of public buildings across the country and visualize such patterns at different levels of the geographical organization and during the year, showing the different districts, municipalities, and parishes in which, the energy consumption is low, medium or high, in a certain period, helping to direct the occupant's behavior in such public buildings. The contribution of our paper has four dimensions:

1) Development of a novel hybrid model for classifying energy consumption in buildings (with an application to public buildings): the SOM, PCA, K-means (KM), and Genetic algorithm (GA), referred to as the SPKG model.

2) Evaluation of the performance and precision of the proposed model is trained and tested with real big data of energy consumption of public buildings in Portugal, collected in the years 2018 and 2019 (81 260 public buildings of 238 Portuguese cities).

3) Correlation coefficient analysis, to understand the relationship between the factors influencing energy consumption in buildings and determine the optimal factors amongst them.

4) A clustering and classification model of energy consumption levels in buildings, featuring a comparison between SOM and Batch-SOM based on PCA, in terms of quantization error, to select the optimal model between them and determine the optimal number of clusters in energy consumption in buildings. In our approach, we use the PCA algorithm to optimize SOM's weights, which helps to enhance the SOM model's fitting ability. Moreover, GA was used to find the optimal initial centroids in KM. This last technique predicts the cluster label in each building.

The paper is organized as follows. Section II presents our related work. In Section III, we present research questions and methodology: intelligent computing model. Section IV presents experimental results and discussion. Finally, in Section V, we conclude and suggest lines for further work.

## II. RELATED WORK

Putting public buildings that use the same amount of energy into similar groups is a key part of figuring out how much better or worse one building performs compared to similar buildings, like peers in the same group. Therefore, it is imperative to correctly identify these divisions to help the decision-maker in energy on three essential points: rationalizing the occupants of public buildings that consume much energy, determining the required amount of energy expected in the coming years, and changing energy providers in public buildings.

The most common methods for analyzing energy consumption in buildings are the different types of clustering methods [17]. Previous research analyzed raw meter data and used that data to represent energy consumption patterns using traditional statistical methods such as regression analysis and others [18,19]. The two most used clustering methods are K-means and Hierarchical clustering, which provide the most energy for occupancy and load forecasting [20 - 22]. Other machine learning methods are used to predict power consumption and loads, such as Artificial Neural Networks (ANN), Support Vector Machines (SVM), and K-Shape and other clustering methods [21 - 25].

Some important studies focused on finding an optimal way to understand occupancy schedules and user demand in different buildings, using anomaly detection and clustering methods [8, 26, 27, 28]. In anomaly detection, occupancy behavior is often used to design strategies that fit dynamic needs, user conditions, and interior space [9]. In addition, it helps design future buildings with a strategy that conserves wasted energy [29].

Other studies focus on measuring electricity consumption in buildings with their various activities using different methods of machine learning (i.e., decision trees [30] and stochastic frontier analysis [31]). These studies used intelligent methods to determine the different forms of electrical loads. In addition, it has been applied to more than 3000 residential and non-residential buildings.

Literature efforts are being conducted to find an intelligent computing model for clustering energy consumption in buildings using different factors that depend on the state of those buildings at different times and discovering the energy consumption patterns of occupants in such buildings [6]. Identifying and clustering the energy load patterns of occupants in public buildings based on such consumption profiles can be beneficial to stakeholders who aim to improve the energy efficiency of buildings effectively. K-means clustering is one of the methods used in the analyzed literature. However, it shows several issues. For example, K-means cannot group data where the groups are of varying volume and density [32]. Secondly, centroids can be pulled by outliers [33]. Finally, K-mean assumes that all variables have the same variance [34]. Consequently, our work tries to find a more accurate clustering method to overcome the limitations of the K-means clustering approach.

By analyzing previous works, we noticed the inability of these studies to find data that represents the occupants'

behavior of buildings at different times. Also, some papers use traditional statistical models like regression analysis and common clustering methods without paying attention to how well these models divide energy use into similar groups. The inaccurate classification of energy consumption leads to several ways to mislead the decision-maker: (1) the inability to find buildings that have high energy consumption; (2) the lack of anticipation of the energy required to cover the needs of public buildings adequately, and finally, the inability to identify the best energy providers. An energy consumption dataset was collected from Portuguese public buildings in 2018 and 2019 to remedy these shortcomings. This dataset was used to train and test a hybrid intelligent computing model to cluster energy consumption in public buildings. We believe that the decision-maker in the energy field can rely on this model to make sound decisions regarding energy consumption in public buildings and energy providers. In addition, there is a clear difference between the data used in this study and the data used in previous studies in terms of data quality and size, as the quality of detailed data on electricity consumption at various times of the day and the large size of data compared to previous studies. Moreover, in the preprocessing section, recent hybrid intelligent techniques such as isolation forest and interpolation methods were used that were not used in the same form and accuracy in previous studies. Furthermore, public buildings with high energy consumption have been determined in detail compared to previous works. Finally, recent hybrid intelligent techniques such as KM with GA were used to predict cluster labels. All these features make this study distinct from the rest of the previous studies.

### III. RESEARCH QUESTIONS AND METHODOLOGY

To properly frame our research, we raised the following research question:

- RQ1: What types of data sources and critical factors can be adopted to profile the energy consumption of buildings?
- RQ2: Which intelligent computing technique(s) can be adapted to identify the number of clusters in the given energy consumption dataset?
- RQ3: What general rules can be extracted to help the decision-maker rationalize energy consumption for public buildings?
- RQ4: What are the different and essential patterns discovered in the given energy consumption dataset?

To tackle the raised research question, we propose a hybrid approach (see Fig. 1), with a mixture of machine learning and optimization techniques, namely, (SOM [9]), (PCA [4]), KM, and GA [4], referred to as the SPKG model, able to discover different energy consumption patterns in buildings, with a proof of concept of its application to public buildings in Portugal.

In this section, we describe in detail our proposed model, which is composed of four main phases, as depicted in Fig. 1, namely:

- **Data Collection:** Our collected data includes energy consumption and building characteristics, such as (but not limited to): unique energy point of delivery ID, address of such a point of delivery, contracted electrical power, electricity consumption, and billing data with the month of consumption. The objective of this phase is to ensure that the units of measurement are consistent, that the sampling rates are adequate, that the time series is the same and synchronized over time, and that there were no structural changes during the data collection period.
- **Data Analysis and Pre-Processing:** In this phase, we analyze the data in detail and, if needed, transform it to expose its information content better. We adopt different mathematical techniques, namely, outlier removal with Isolation Forest (ISF) [35] and polynomial interpolation [31].
- **Feature Engineering:** In this phase, we find the optimal variables used to discover energy consumption patterns in (public) buildings, adopting a coefficients analysis approach [35].
- **Clustering Analysis:** In this phase, we fine-tune, apply, and evaluate our SPKG hybrid machine learning model, which can find clusters (each cluster corresponds to an energy consumption profile of buildings), and cluster the energy consumption profile in a particular building. Intelligent computing techniques, such as SOM and KM, are assessed and compared for automatic cluster discovery and the definition and classification of energy consumption behavior in (public) buildings.
- **Clustering Results:** In this phase, we tried to find three important results: generate energy consumption rules, determine the final number of clusters, and determine municipalities and Portuguese building activities that consume high, medium, and low energy consumption.

#### A. Data Collection

The data used in this study consists of the energy consumed in public buildings in Portugal, with the following characteristics: monthly data collected during the years of 2018 and 2019 in 77 996 buildings of various public sectors and 238 cities, reaching 2 775 082 records. After removing the records related to public lighting (since it is outside the scope of our study) and removing buildings that do not contain consumption data for the full observed period of 24 months, the number of records used in this study reached 1 222 695, corresponding to 26 624 public buildings.

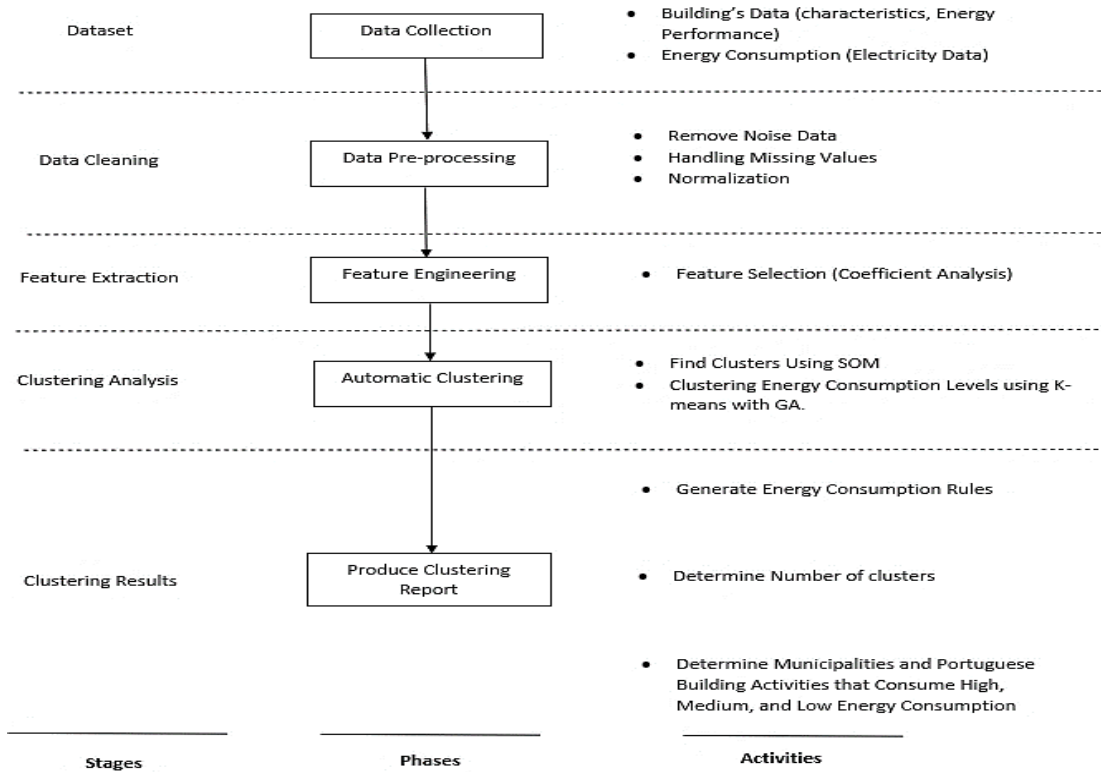

Fig. 1. Our proposed SPKG model for discovering energy consumption in public buildings

As mentioned, the dataset used in this study consists of two parts: the building characteristics and the actual energy consumption in these buildings (see Table I). Building characteristics include several attributes, namely:

- Unique energy is the point of the delivery ID of each building.
- Details of each building.

Energy consumption data, in our data set, includes:

- Actual active energy consumption in public buildings.
- Super empty: Active energy in the period 02h00-06h00 AM.
- Empty: Active Energy in the periods 00h00-02h00, 06h00-08h00, and 22h00-00h00.
- Outside empty: Lighting and plug loads that cannot be turned off.
- Peak: Active Energy in the periods 09h00-10h30 and 18h00-20h30.
- Full: Active Energy in the periods 08h00-09h00, 10h30-18h00, and 20h30-22h00.
- Total energy consumption: Active and Reactive Energy, where reactive energy is electrical energy that is stocked rather than transformed to some other form of energy and thus not "used" or "consumed."

TABLE I. DATASET DIMENSIONS OF ENERGY CONSUMPTION IN PUBLIC BUILDINGS

Dataset Dimensions	Attribute Name	Description
Characteristics of buildings	Unique Energy Point Delivery ID	The ID of each public building
	Business Partner	Identification of the institution that owns or rents the building.
	Building Address	Address of each building
	Municipality	City Location of each building
	Installation Type	Details of the electrical installation of each building
	Contracted Power	Power in MW has been agreed upon with the operator for each building.
	Year/Month	Consumption date
Energy consumption (Active Energy (KWh))	Simple	Total of active energy
	Super Empty	Active Energy (02h00-06h00)
	Empty	Active Energy (00h00-02h00; 06h00-08h00; 22h00-00h00)
	Outside Empty	Lighting and plug loads that cannot be turned off
	Peak	Active Energy (09h00-10h30; 18h00-20h30)
	Full	Active Energy (08h00-09h00; 10h30-18h00; 20h30-22h00)
	Total	Total of energy consumption (Active plus Reactive Energy)

## B. Data Preprocessing

Outlier detection and missing value imputation are the two primary processes in the data preprocessing for missing data utilizing the isolation forest and interpolation method. Here is a general description of the procedure [36 - 42]:

### Step 1: Outlier Detection using Isolation Forest

- Determine which features (columns) are missing data.
- For each characteristic, distinguish between the entire data (rows without missing values) and the partial data (rows with missing values).
- Using the whole data for each feature, isolate outliers using the isolation forest algorithm. A well-liked approach for anomaly identification called isolation forest isolates outliers by building random forests and calculating the typical number of splits required to isolate a data point.
- Establish a threshold to help you spot outliers. This may depend on the number of splits or a predetermined cutoff point.

### Step 2: Missing Value Imputation

- Use interpolation techniques to impute the missing values for the features that have missing data. Interpolation is a method that calculates the missing values from the data points already there.
- There are numerous interpolation techniques, including linear interpolation, polynomial interpolation, and methods tailored to time series, including forward-fill and backward-fill.

### Step 3: Combine Outlier Detection and Imputation

- We chose to keep outliers in the data after identifying them with the isolation forest.
- Use the selected polynomial interpolation technique to fill in the data gaps for the missing values.

## C. Feature Selection

This section aims to find the critical variables or factors in our energy consumption dataset. To overcome this problem, we used the T-test correlation coefficient. This statistical technique is used in literature to detect if two factors/variables are significant [43]. It can be helpful in our study. In our dataset, looking at pairwise correlations between the various variables (or factors) may propose a causal relation between two factors that we can investigate further. Eq. (1) computes the T-test value by assuming no correlation with  $\rho = 0$ , where, P refers to that; there is no relationship between variables [44].

$$t = r \sqrt{\frac{n-2}{1-r^2}} \quad (1)$$

In (1),  $n$  refers to the instances, and  $r$  represents the correlation coefficient of the energy consumption dataset. The importance of relevance is expressed in probability levels:  $p$  (e.g., significant at  $p = 0.05$ ). The degree of freedom for entering the t-distribution is  $n - 2$ . If the  $t$  value is less than the

critical value (CV) at a 0.05 significant level, the factor is not essential and is avoided [44].

In Algorithm 1, we build the correlation coefficients using the training dataset. In Steps 1 to 4, we calculate the correlation coefficients between the proposed factors. Step 6 to step 7 computes significant values by using the T-test. Finally, step 8 to step 10 finds the final list of energy consumption factors.

---

### Algorithm 1: Feature Selection Algorithm

---

Input:  $S(F_1, F_2, \dots, F_k, F_c)$  // a training data set

Output:  $S_{best}$  // the selected feature set

```
1. begin.
2. For I to k do
3. r = compute correlation coefficient ( $F_i, F_c$ )
4. End
   // let P = 0.05 significant level
   let P = 0 // assuming there is no significant correlation
5. For I to k do
6. t = compute significant values (r,p) for  $F_i$  // Eq.4
7. If t > CV // critical value
8.  $S_{list} = CV$ 
9.  $S_{best} = S_{list}$ 
10. End
11. End
12. Return  $S_{best}$ 
```

---

## D. Finding the Number of Clusters

To determine the optimal number of clusters in energy consumption data, we used three literature methods: Self-Organizing Map (SOM), the Elbow method, and the Bouldin & Davis method [14, 15]. These methods have been used in prior studies to find the optimal number of clusters, notably in energy consumption in buildings.

1) *Self-Organizing Map*: SOM is a specific class of neural networks utilized broadly as a clustering and visualization instrument in exploratory information analysis [45]. The main objective of SOM is to convert a complex high-dimensional discrete input space into a less low-dimensional discrete yield space by keeping the topology within the information but not the real separations [46, 47]. An unsupervised learning calculation employs a basic heuristic strategy for finding covered-up non-linear structures in high dimensional information [46].

The SOM method is adopted because it deals with big data accurately and effectively [45]. Contrary to the other methods mentioned, it better deals with small and medium-sized data [46]. Therefore, the SOM method determined the number of clusters in the energy consumption dataset. SOM is composed of three main processes: competition, cooperation, and adaptation [45].

The SOM network is composed of two layers, the input, and the output layer, as shown in Fig. 2. Each input variable is shown using an m-dimensional input vector [48]. In the output layer, the number of nodes indicates the most extreme number of clusters and impacts the precision and generalization capability of the SOM [45]. The arrangement of the SOM

begins with the initialization of the weight vectors [46]. Then, weights are joined that interface the input nodes to the output nodes and are overhauled through learning. Finally, to discover the best match unit (BMU), the spaces between an input ( $x$ ) and the weight vectors ( $w_i$ ) of the SOM are calculated by using various measurement methods, such as [47,49]:

- Manhattan distance.
- Chebyshev distance.
- Euclidean distance.
- Mahala Nobis distance
- Vector product, among other methods.

Euclidean distance is an approved measure in most scientific papers [47], as shown in Eq. (2):

$$d_i(t) = \|x(t) - w_i(t)\| \quad (2)$$

At the finish of the propinquity matching method (Determine the similarity between points in the dataset), the most excellent matching unit  $c$  at repetition  $t$  is identified by the minimum distance [45].

$$c(t) = \arg \min_i \|d_i(t)\| \quad (3)$$

By analyzing the weight vector  $w_i(t)$  of the winning neuron,  $i$  at iteration  $t$ , the overhauled weight vector  $w_i(t+1)$  at iteration  $(t+1)$  is determined by Using a discrete-time formalism in Eq. (4) [47].

$$w_i(t+1) = w_i(t) + \alpha(t) [x(t) - w_i(t)] \quad (4)$$

The weights ( $\alpha$ ) adjustment rate diminishes away from the winning node regarding the Spatio-temporal decay function [46].

$$h_{ci}(t) = \exp(-(d^*d)^{ci} / 2\sigma^2(t)) \quad (5)$$

where,

- $d$  is the lateral distance between the winning neuron  $c$  and the excited neuron  $i$ .
- $\sigma$  is the effective width or radius of the neighborhood at iteration  $i$ .

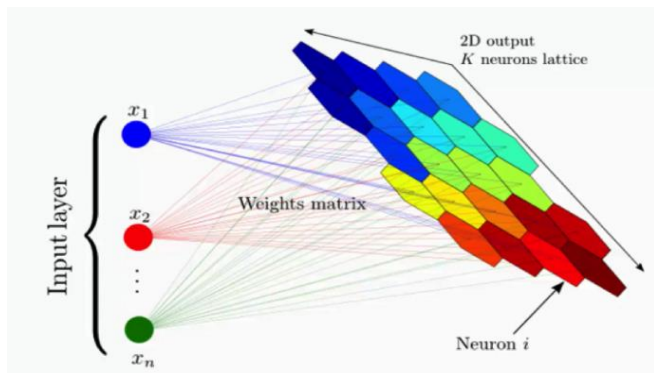

Fig. 2. Structure of SOM [45]

In Algorithm 2, we implemented a SOM network based on energy consumption data to determine the optimal number of clusters. Firstly, we have identified the lattice space of the  $10 \times$

$10$ , set weights based on random weights and PCA weights, set iterations from 100 to 1000. Secondly, pick the random points in energy consumption data, then find the best match point based on Eq. (5), set learning rate = 0.5, set neighborhood function = triangle, compute neighborhood distance weight matrix and modify SOM weight matrix, and finally, repeat from the step of picking random point ( $z$ ) until the maximum number of iterations is reached.

---

Algorithm 2: Main Idea of the SOM Network Training

---

**Input:** ECD  $\leftarrow$  the energy consumption data.

**Output:** USOM  $\leftarrow$  U-matrix of SOM network.

1.  $\beta \leftarrow$  initialize lattice nodes.
2.  $\Omega \leftarrow$  initialize weight vectors.
3.  $N \leftarrow$  Iteration count.
4. **For**  $i \leftarrow 1$  to  $N$  do
5.  $z \leftarrow$  picks a random point in ECD.
6.  $c \leftarrow \beta$  closest to  $z$ .
7. move the weight vector of  $c$  closer to  $z$ .
8. move the weight vectors of the neighbors of  $c$  slightly closer to  $z$ .
9. **End**

**Return** USOM

---

2) *Elbow method:* We can plot the curve indicating the average inner per cluster sum of squared error (SSE) distance vs the number of clusters to discover a visual "elbow", the ideal number of clusters. The average inner whole of squares is the average distance between focuses interior of a cluster [11], as shown in Eq. (6).

$$k = \sum_{r=1}^k \left( \frac{1}{n_r} + D_r \right) \quad (6)$$

Where:

- $k$  is the number of clusters,
- $n_r$  is the number of points in cluster  $r$ .
- $D_r$  is the sum of distances between all points in a cluster.

3) *Bouldin and davis method:* In Davis and Bouldin (DB), the score is characterized as the average similitude degree of each cluster with its most identical cluster. The similitude is the proportion of within-cluster separations to between-cluster separations. In this way, clusters that are more distant separated, and less scattered will result in a distant better score. The least score is zero, with lower values indicating superior clustering [13], as shown in Eq. (7) and (8) [16].

$$DB(c) = \frac{1}{k} \sum_{i=1}^k (\max_{j \leq k, j \neq i} D_{ij}), \quad k = |c| \quad (7)$$

$D_{ij}$  is the "within-to-between cluster distance ratio" for the  $i$ th and  $j$ th clusters.

$$D_{ij} = \frac{d_i^- + d_j^-}{d_{ij}} \quad (8)$$

where,  $d_i^-$  is the average distance between every data point in cluster  $i$  and its centroid, similar for  $d_j^-$ .  $d_{ij}$  is the Euclidean distance between the centroids of the two clusters.

E. K-Means with GA

GA is a research process inspired by Charles Darwin's theory of naturalist evolution. It is a process to select the fittest individuals to reproduce to create offspring of the next generation. GA is good at dealing with multiple points and is good in noisy environments; therefore, it quickly helps implement any fitness function such as Euclidean distance in the energy consumption dataset. GA was used to find the optimal centroids in KM to speed up convergence between energy consumption points through three fitness functions which are Euclidean distance (ED), Manhattan distance (MD), and Cosine distance (CD), as shown in formulas (2, 9, 10) [47]. Moreover, it helps to improve the accuracy of KM in our study.

MD indicates the sum of the absolute values of the differences of the coordinates. For example, if  $X = (E, M)$  and  $Y = (B, K)$ , the MD between  $X$  and  $Y$  is:

$$MD = |E - B| + |M - K| \tag{9}$$

CD calculates the cosine of the angle between vectors  $X$  and  $Y$  as shown below:

$$CD = \frac{X \cdot Y}{\|X\| \|Y\|} \tag{10}$$

Where:

- $\|X\|$  = Euclidean norm of vector,  $X = (X_1, X_2, \dots, X_n)$ .
- $\|Y\|$  = Euclidean norm of a vector,  $Y = (Y_1, Y_2, \dots, Y_n)$ .

KM aims to group identical data points as one cluster and detect underlying patterns. It has many challenges. First, determine the optimal number of previously determined clusters utilizing SOM. Second, determine the optimal centroid placement in each cluster utilizing GA. Thus, KM has been used to predict cluster labels in each building in ECD. In Algorithm 3, we constructed the improved KM using SOM and GA as inputs. From step 1 to step 4, improved KM tries to find the new centroid positions in each cluster for enhancing the accuracy of predicting the cluster label in each building in ECD.

Algorithm 3: Improved KM to predict cluster label in each building

---

```

Input: K = 3, // Specify the number of clusters using SOM
Initialize  $\sigma$  of centroids using GA.
Output:  $\beta \leftarrow$  predicting cluster label in each building in ECD
1. Repeat
2. Assign each point to its closest centroid.
3. Compute the new centroid of each cluster.
4. Until the centroid positions do not change.
Return  $\beta$ 
    
```

---

IV. EXPERIMENTAL RESULTS AND DISCUSSION

This section comprises four sections: data pre-processing, feature selection, finding the number of clusters, and finally, k-means with GA to produce energy consumption rules. We have used Python programming and the Scikit-learn library to implement the proposed algorithms.

Fig. 3. Sample of data preprocessing.

A. Results of Data Preprocessing

Intelligent machine learning techniques always depend on the quality and efficiency of the dataset proposed in the study. Therefore, if the dataset provided is high quality and accurate, which helps to build and train an intelligent model with high efficiency. Furthermore, the energy consumption data is collected from a real-world environment. Therefore, it is

unstructured and incomplete. Thus, we always need the pre-processing data stage to remove noise and outliers. Data pre-processing has two stages. Fig. 3 shows the steps for pre-processing the energy consumption dataset in the first stage. Initially, (a) the sample of the raw dataset was displayed in terms of contracted power ( $X_i$ ) and total energy consumption ( $Y_i$ ); secondly, (b) Public buildings have been removed that

have several months less or more than 24 months, and public lighting buildings also have been removed because it is outside the scope of the study. Thirdly, (c) there are still public buildings that contain harmful and zero values. Fourthly, (d) outlier values have been removed using ISF, but harmful and zero values have also been removed.

After pre-processing, the final dataset was reached, which was relied upon to find the different patterns in energy consumption in public buildings. Fig. 4 shows the sample of the final data set between contracted power and total energy consumption.

Fig. 4. Sample of Final Dataset

### B. Results of Feature Selection

The aim of this section is to show the results of the T-test correlation coefficient and find the critical factors in the energy

consumption dataset. Fig. 5 shows the relationships between energy consumption factors. We observed a relationship between contracted power with Full, Peak, Empty, outside empty, and total consumption, and there is also a relationship between Full and Peak. Moreover, there is a relationship between Empty and Outside Empty. Moreover, we can avoid the Super Empty factor because it contains null values in all the columns, and there is no relationship between it and all the other factors. Finally, there is a negative relationship between the Simple factor with Full, Peak, and Empty consumption.

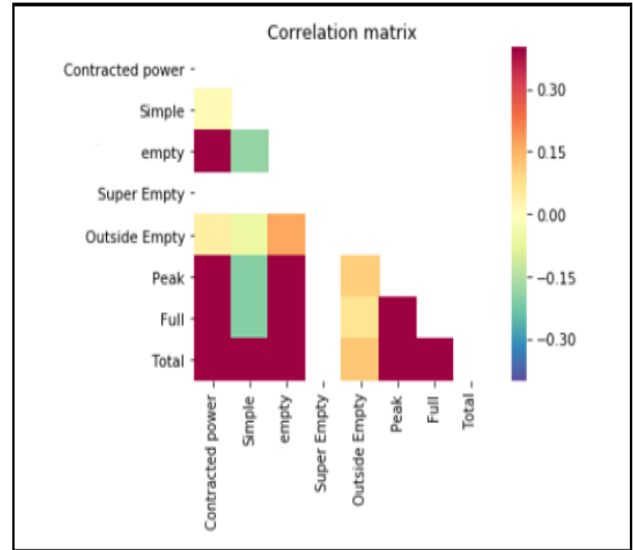

Fig. 5. The applied correlation coefficient in the energy consumption dataset.

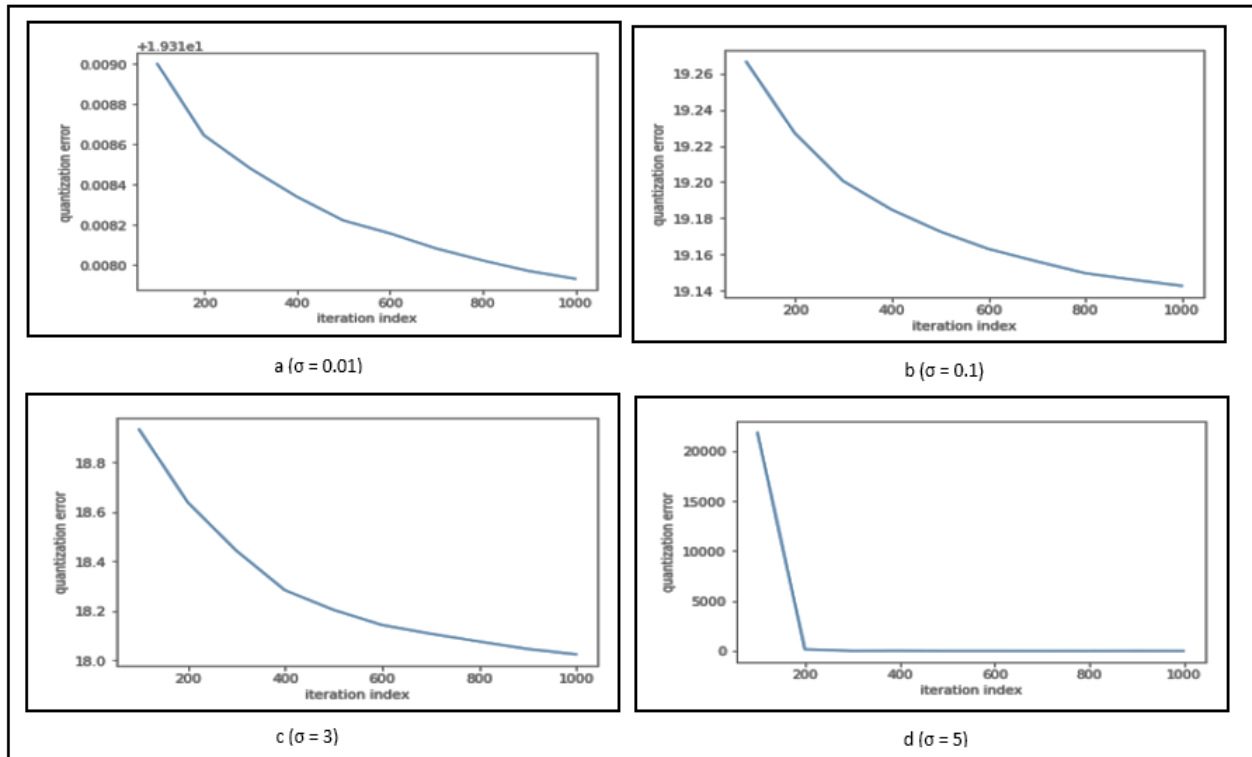

Fig. 6. q- error in random weights. Set iteration = 1000, (a)  $\sigma = 0.01$ , (b)  $\sigma = 0.1$ , (c)  $\sigma = 3$  and (d)  $\sigma = 5$ .

C. Results of Finding Number of Clusters

This section shows the results of three methods to find an optimal number of clusters: self-organizing map, Elbow method, and Bouldin and Davis method. A comparison was made on the weights of the SOM network in two different ways, the first utilizing random weights and the second through PCA weights. We set the iterations = 1000 and, we set sigma = 0.01, 0.1, 3 and 5. By comparing random weights and PCA weights, PCA weights are better than random weights in terms of quantization error (q- error), especially in iteration = 1000 and sigma = 3, as shown in Table II and Fig. 6 and 7.

The q- error expresses the squared distance (usually the average Euclidean distance) between input data x and their corresponding so-called BMU. Thus, the QE reflects the average distance between each data vector (X) and its BMU, as shown in Eq. (11):

$$q - error = 1/N \sum_{i=1}^N \|X_i - (BMU_{(i)})\| \quad (11) \quad [47]$$

The q- error appeared within Table II and Fig. 6 and 7 are midpoints for all data patterns. A comparative assessment of how this quantization is changed permits us to recognize distinctive clusters, which is one of the primary purposes of utilizing these techniques.

The SOM network was trained in two different ways based on PCA weights: random training SOM (RTSOM) and batch SOM (BSOM). The batch overhaul does not require a learning rate function. Typically, profitable since it reduces the number of required parameters. PCA weights with RTSOM (PCAW-RTSOM) are better than PCA weights with BSOM (PCAW-

BSOM) in terms of q- error. Q- error in PCAW-RTSOM and PCAW-BSOM is 8.97 and 9.24, respectively, as shown in Table III and Fig. 8.

TABLE II. A COMPARISON BETWEEN RANDOM WEIGHTS AND PCA WEIGHTS

<b>1000</b>	<b>8.97</b>	<b>9.24</b>

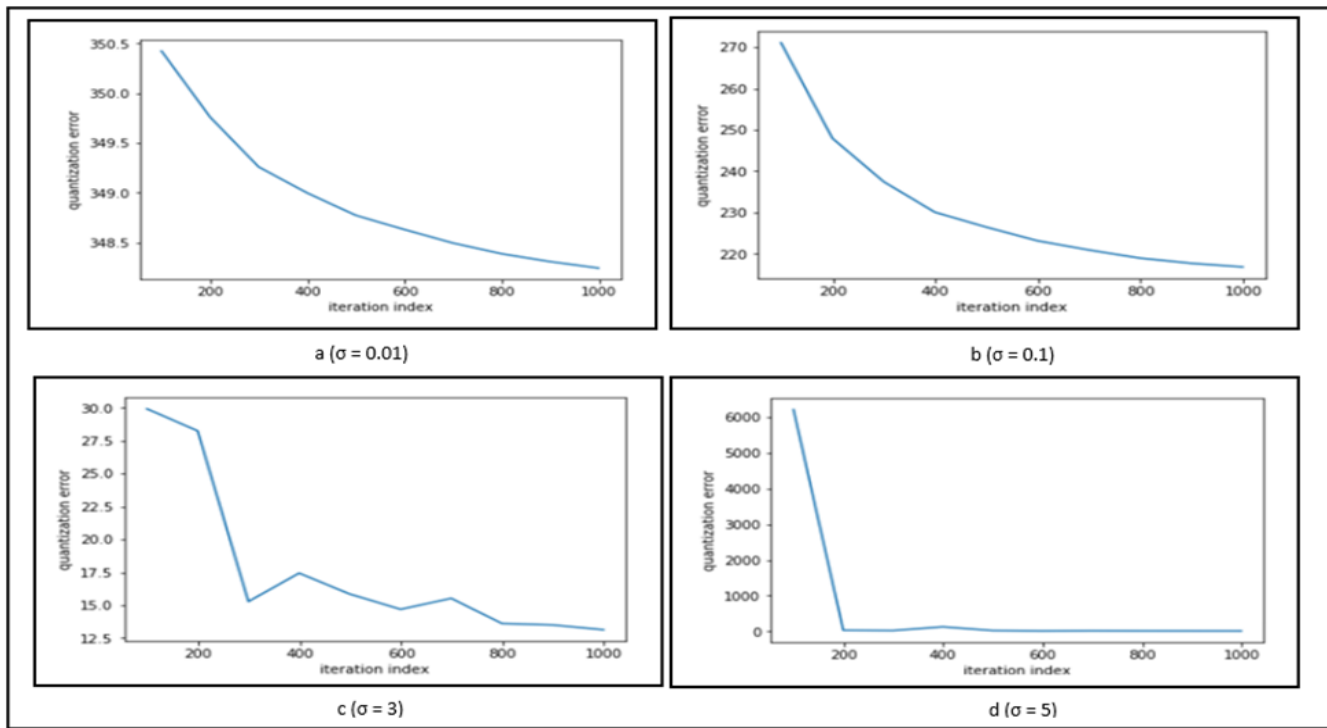

Fig. 7. q- error in PCA weights. Set iteration = 1000, (a)  $\sigma = 0.01$ , (b)  $\sigma = 0.1$ , (c)  $\sigma = 3$  and (d)  $\sigma = 5$ .

Fig. 8. A Comparison between PCAW-RTSOM and PCAW-BSOM.

Fig. 9 shows the visualization of U-matrix in PCAW-RTSOM and PCAW-BSOM. In that U-matrix, we may determine three light color areas (white color) that match the minimum values in the U-matrix and indicate three clusters in the energy consumption dataset. These areas are detached by dark blue, which matches the segregation between the clusters.

We have obtained three clusters by implementing Elbow and Bouldin & Davis method in our energy consumption dataset, as shown in Fig. 10 and 11.

The U-matrix in SOM shows the distances between the points (points represent the energy consumption dataset) on the SOM. The dark areas in that U-matrix show the areas of the map where the points are far away from each other so, which represents the segregation between the clusters, and the lighter areas show fewer distances between the points so, which means the number of clusters. The Elbow method is computed as the intermediate of the squared distances from the cluster centers of the clusters. Typically, the Euclidean formula is utilized. In Bouldin & Davis method, to obtain the intra-cluster scuttle, we compute the average distance between each vector within the cluster and its centroid, which computes the Euclidean method between the centroid of the cluster. Finally, we could determine three clusters (low, medium, high consumption) in the energy consumption dataset by analyzing the SOM network, Elbow method, and Davis-Bouldin method.

D. K-Means with GA to Produce Energy Consumption Rules

In this section, we computed the distance between each cluster by two methods: The first method is K-means clustering with K-means++ initialization (KMCKI) and the second method is SPKG. GA has been implemented through the main parameters, as shown in Table IV. There are three methods to compute distances between clusters: ED, MD, and CD. We compared the performance between KMCKI and SPKG in terms of standard error (SE), as shown in formula 12, and standard deviation. CD with SPKG is better than all methods, as shown in Table V. Thus, this study relied on CD with SPKG to predict cluster labels in each building in ECD and detect underlying patterns.

$$SE = \frac{STDEV(\Omega)}{\sqrt{COUNT(\Omega)}} \quad (12) \quad [11]$$

Where:

STDEV = Standard deviation

$\Omega$  = Distances between each center of clusters.

It is an important step to visualize big data analytics. The clustering outputs have been shown in different methods to facilitate decision-makers and stakeholders in the energy field in Portugal to take suitable decisions in energy consumption in public buildings. In addition, ECD has the significant factor of contracted power, which is very useful in understanding how much energy is consumed during different times in the day in each public building. Fig. 12 shows a sample analysis of the various visualizations that show the dimensions used in the ECD through CD with SPKG.

By analyzing the clustering results, several essential rules have been extracted to assist stakeholders in the energy sector in Portugal in identifying the different styles of public buildings, as shown in Table VI. Energy consumption rules help the decision-maker identify public buildings that need guidance for their occupants and change the energy suppliers for those buildings.

Fig. 12. Sample of clustering results.

TABLE IV. GA PARAMETERS

No	Parameters	Value
1	Population Size	ECD

21	Total>=993 AND Full>=484 AND Peak>=341 AND Outside empty>=878 AND Empty>=386 Then cluster 3 (high energy consumption)

Fig. 12 was better for detecting energy consumption levels; however, it could not determine the months in which energy consumption increases, as well as the months in which energy consumption decreases. Monthly consumption patterns show broader details of energy consumption by an occupant in public buildings. For ECD, the energy consumption levels were

determined based on cluster label predictions, as shown in Fig. 13. Fig. 13 shows a noticeable increase in electricity consumption in January, February, November, and December. In addition, energy consumption levels decreased in June and July. It also helps the decision-maker identify the months of increased energy consumption for public buildings. Thus, the occupants of these buildings are guided promptly.

Fig. 13. Monthly energy consumption patterns captured in different clusters for the ECD.

Fig. 14 and Table VII show municipalities and Portuguese public buildings activities that contain the number of buildings that consume low energy at different times. Three municipalities contain public buildings that consume little energy in Fig. 14, such as 'LOULE', 'SANTA MARIA DA FEIRA', and 'LISBON'. In addition, Table VII shows Portuguese public buildings activities that consume little energy such as: 'INFRAESTRUTURAS PORTUGAL SA', 'GUARDA NACIONAL REPUBLICANA', and 'INSTITUTO SEGURANCA SOCIAL'.

Fig. 15 and Table VIII show the municipalities and Portuguese public buildings activities that contain the number of public buildings that consume energy on average between low and high consumption at different times. In Fig. 15, three municipalities contain public buildings that consume energy reasonably, such as 'PORTO', 'LISBOA', and 'OEIRAS'. In addition, Table VIII shows Portuguese public buildings

activities that consume energy reasonably, such as: 'IHRU INSTIT DA HABIT E REABILITACAO URBANA IP', 'INFRAESTRUTURAS PORTUGAL SA', and 'MUNICIPIO PORTO'.

Fig. 16 and Table IX show the activities of municipalities and Portuguese public buildings containing the number of public buildings that consume high energy at different times. In

Fig. 16, four municipalities contain public buildings that consume high energy, such as: 'LOULE', 'SANTA MARIA DA FEIRA', 'VILA NOVA DE GAIA', and 'LISBOA'. In addition, Table IX shows Portuguese public buildings activities that consume high energy such as: 'GUARDA NACIONAL REPUBLICANA', 'ADMINISTRACAO REGIONAL SAUDE CENTRO IP', 'ADMINISTRACAO REGIONAL SAUDE NORTE', and 'AUTORIDADE TRIBUTARIA E ADUANEIRA'.

Fig. 15. Sample of Municipalities that Consume Medium Energy Consumption

Fig. 16. Sample of Municipalities that Consume High Energy Consumption

This accurate analysis helps the decision-maker identify the municipalities and Portuguese public buildings activities that need to guide their consumers and change their energy providers.

By analyzing Fig. 14 to 16 and Tables VII to IX, municipalities such as 'LISBOA' and 'LOULE' contain public buildings with low, medium, and high energy consumption. In addition, there are Portuguese public buildings activities such

as 'INFRAESTRUTURAS PORTUGAL SA' that consume low and medium energy. Therefore, we seek to find the distribution of the number of public buildings with different activities with low, medium, and high energy consumption over the different municipalities.

Tables VII, VIII, and IX show a sample of the public buildings located within each municipality. Knowing that each building has more than one location appears 24 times, distributed over 24 months over two years, 2018 and 2019.

By analyzing Fig. 17, the number of public buildings in these Municipalities increased in certain months in 2018 and 2019 as follows:

- LOULE: Aug-18, Oct-18, Jan-19, Feb-19, Mar-19, and Oct-19.
- SANTA MARIA DA FEIRA: Feb-18, Mar-18, Apr-18, May-18, Jun-18, Nov-18, Jan-19, and Feb-19.
- BRAGA: May-18, Aug-18, Oct-18, Jan-19, Mar-19, Apr-19, and May-19.
- VILA NOVA DE GAIA: Aug-18, Sep-18, Oct-18, Nov-18, and Jan-19 to Oct-19.
- LISBOA: Feb-18 to Nov-18, and Jan-19 to Dec-19

Regarding answering our research questions, and starting from RQ1, which aimed to collect public buildings energy consumption data in Portugal, and to find which where the critical factors in such dataset that could helped us in profiling such consumption, we were able to obtain aggregated monthly data for the years 2018 and 2019, regarding 77 996 buildings of various public sectors in 238 cities in Portugal, reaching 2 775 082 records. We concluded that all factors (variables) of the collected data are critical for the mentioned profiling, except for the super empty variable. Our RQ2 aimed to find the more appropriate intelligent computing techniques, for the preparation of the energy consumption dataset to proceed with further clustering analysis. Answering to this question, we adopted different mathematical techniques to that aim, namely, outlier removal with Isolation Forest and polynomial interpolation. With a dataset ready for clustering analysis, we raised RQ3, seeking first, to identify the number of clusters in the given energy consumption dataset, where we adopted literature techniques such as Self Organizing Map (SOM), the Elbow method, and the Davis – Bouldin method, and then to propose a novel and optimized hybrid model for classifying (labelling) energy consumption in buildings. This model includes a mix of different techniques, namely, SOM, Principal Component Analysis (PCA), K-means (KM), and Genetic algorithm (GA), is referred to as the SPKG model, and was applied successfully to our dataset, predicting the cluster label (low, medium, or high consumption) of each building. With a set of labelled buildings at hand, we turned our attention to RQ4, targeting to discover essential patterns and general rules in such labelled dataset, that could help the decision-maker to rationalize energy consumption. Therefore, we analysed the clustering results and came up with a set of rules that can help the characterization of energy consumption of a given public building in Portugal.

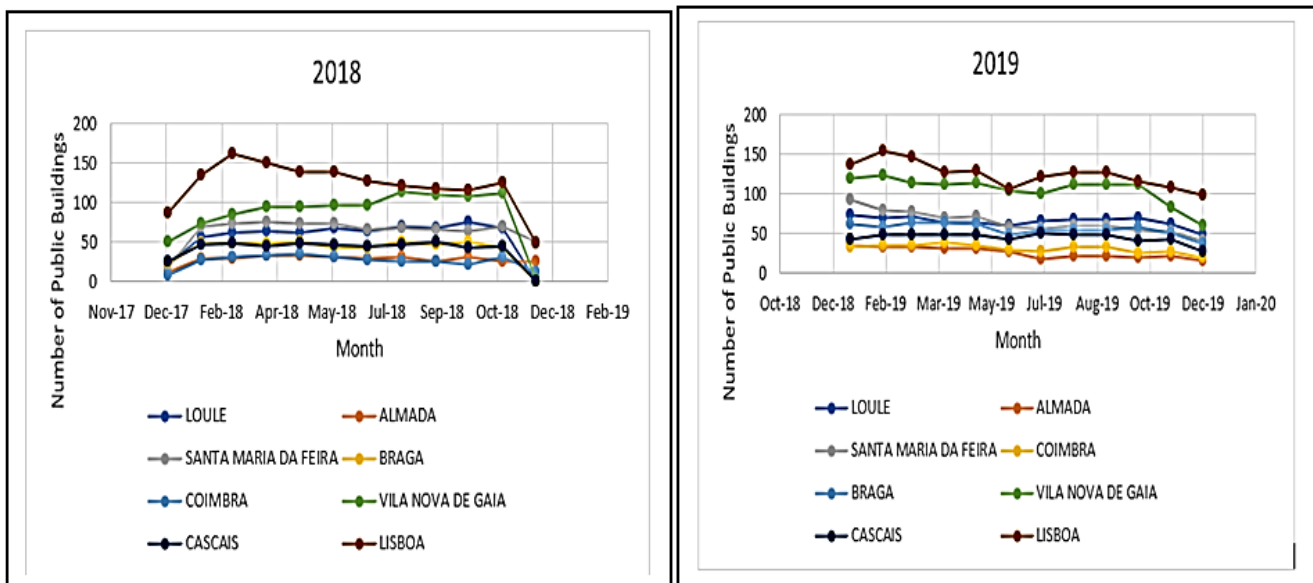

Fig. 17. Sample of Public Buildings in Different Municipalities that Consume High Energy in 2018 and 2019.

We have compared our results with state-of-the-art methods in the literature related to our work, in terms of using the K-means algorithm. M. Azaza study [14] and Al-Jarrah study [15]. The Standard Error (SE) of clustering in M. Azaza [14] and Al-Jarrah [15] is 28.3 and 22.5, respectively. However, SE in our study is 0.002. Therefore, our study outperforms state-of-the-art methods in previous work, in terms of SE of the K-means algorithm.

## V. CONCLUSION AND FUTURE WORK

This paper presented a novel hybrid intelligent model for classifying the energy consumption level (low, medium, high) of buildings that was tested in a dataset of energy consumption of Portuguese public buildings. To frame our research, we raised four research questions that were properly answered. To understand our data, a correlation coefficient analysis was used to find the critical factors (variables) that influence energy consumption of public buildings and understand the relationship between those factors. In a data preparation step, an isolation forest was used to remove outliers in the dataset. Additionally, an interpolation method was used to find compensation values or estimate unknown values using related known values. As for our modelling approach, aiming at labelling the energy consumption level of each building, we first computed the number of clusters of energy consumption in the dataset, and SOM, the Elbow method, and Davis-Bouldin method all agreed in 3 as the figure for the found number of clusters (corresponding to low, medium, high consumption).

Then we used K-means with a Genetic Algorithm to predict the energy consumption cluster level of each building. This study provides contributions in four aspects. The first one considers factors that influence the energy consumption of buildings. The second one provides a novel model for classifying energy consumption of public buildings into levels (e.g., low, medium, and high). The third one provides analysis on real big data of the energy consumption of public buildings in Portugal, in the years of 2018 and 2019 (77 996 public

buildings in 238 Portuguese cities). As an example, we were able to identify the municipalities that consume high energy levels. We have also identified monthly energy consumption patterns of buildings of the years of 2018 and 2019. The last aspect extracts proper scientific If-Then rules to help decision-makers rationalize the energy-consuming and determine the most energy-consuming public buildings, from a set of 3 values (low, medium, or high consumption).

Together, all these results may help the decision-maker to evaluate the public building's future energy requirements, and rationalize the occupants of those buildings, with the correct energy consumption behaviours.

As a recommendation for future work, we can think of using other techniques, such as statistical methods like multiple linear regression or logistic regression to find critical factors that influence energy consumption of public buildings. We could combine SOM and other optimization techniques (grey wolf, lion, and whale optimization), aiming find the optimal number of clusters of the energy consumption data of buildings. In addition, combining clustering and optimization techniques (grey wolf, lion, and whale optimization) could yield better prediction of cluster labels as for predicting the amount of energy consumption of buildings, this study follows the recent literature trend and suggests adopting machine learning approaches from the family of deep learning techniques, such as long short-term memory, convolutional neural networks, or deep forest.

## ACKNOWLEDGMENT

This work has been supported by Portuguese funds through FCT-Fundação para a Ciência e Tecnologia, Instituto Público (IP), under the project FCT UIDB/04466/2020 by Information Sciences and Technologies and Architecture Research Center (ISTAR-IUL), and this work has also been supported by Information Management Research Center (MagIC)-Information Management School of NOVA University Lisbon.

**Abstract**—The emergence and extensive development and deployment of Industrial Revolution 4.0 have distinctly transformed the methodologies of sports performance monitoring. Consequently, there has been an increase in the emergence of new and adapted technologies in various areas of sports, such as competition analysis, player performance analysis and many others. There are rich and heterogeneous sports performance analysis technologies, algorithms and frameworks which provide constant basis for elevating new horizons of sports technologies. Thus, this paper aims to encompass significant findings that will provide a comprehensive survey in this area. Previous surveys have extensively focused on various methodologies of sports performance analysis, sport-specific analysis and other technology revolving around sports performance analysis. However, most of the focus is largely on training and competition performances and not off-field. The objective of this paper is to understand the current research trends, challenges and future directions of dynamically evolving technology embedded in the world of sports. This survey aims at contributing to this rich repository but with a new focus element of off-field that researches the connection between the athlete, the sports aspect of their life, the non-sport aspect and the methodologies of sports performance analysis. In addition, the exponential growth of Artificial Intelligence (AI) as a base for sports performance analysis systems and platforms is analysed extensively. This paper also presents a comprehensive classification of athlete performance analysis using algorithm tools and sports performance platforms and systems. Subsequently, the detailed analysis of this taxonomy has enabled the identification and detailed analysis of open issues and future directions.

**Keywords**—*Sports performance analysis technology; on-field analysis; IoT; real-time monitoring; off-field analysis*

## I. INTRODUCTION

The Industry Revolution 4.0 (IR 4.0) has seen the extensive harnessing of multitudes of technologies in wide and rich spectrum of areas [1]. This encompasses the domain of sports and is a significant element in positioning itself as a national and global agenda. Since the inception of technological advances, the sporting world and its entities have been strengthened in multiple aspects [2], such as the usage of wearable Global Positioning System (GPS), sensor technology, virtual imaging, Hawk-Eye Line-Calling System, and time tracking systems. These contributions to sports have increased the accuracy of measuring equipment and instruments. Among the reference success cases of sportsmen partnering with

technologist are like athletes Kell Brook have worked with Sheffield Hallam University in the lead-up to his International Boxing Federation (IBF) world welterweight title fight. The scientists collected Heart Rate (HR) and lactate data. Like Brook, multiple-time National Basketball Association Most Valuable Player (NBA MVP) Stephen Curry has overcome his physical shortcomings by incorporating technology into his training regime. The All-Star basketball player has used strobe goggles and on-court light discs that force a sensory overload and demand quick decisions. Team sports athletes constantly strive to improve their international and league rankings. Football athletes in the second division of England, Germany, and France have been monitored with over 11,000 team-matches observations to monitor the factors influencing the chance of promotion to the elite leagues [3]. The researchers executed a series of logistical regression analyses and made observations, proving that teams will do anything and everything to evolve and improve their status in the sporting world constantly. The athletes and coaching staff of the modern generation have resourced technology tremendously to enhance their athletic ability [1]. The cases presented above serves as a basis to justify the need to articulate the rich repository of sports technology to enable the trend analysis and determination of open issues especially with the rise of Artificial Intelligence (AI). The analysis of off-field and on-field correlations from a distinct perspective of existing work has high constraints. Thus, creating problem in identifying pertinent open issues in this domain of analysis. Thus, this survey paper is objectives are to address the solutions for this problem. The goal of this survey paper is to show the state-of-the-art sports performance analysis technologies. It encompasses a comprehensive review of papers. In the papers we reviewed, each algorithm, architecture or system is reviewed in detail from the implementation, their advantages and respective disadvantages. The developed taxonomy of comparison has provided a detail basis of the identification of the open issues.

This paper is organized as follows. Section I is the Introduction. Section II discusses in detail the various Surveys that have been published in this area and highlights the uniqueness of our Survey. Section III presents the Proposed Classification Model based on the research from three subsections: Competitive and Training Performance Monitoring or On-Field, Non-competitive Performance Monitoring or Off-Field, and Systems and Platform. Open

issues collectively analysed throughout this paper, recorded and arranged in relevance discussed in Section IV with six subsections: Relating the Monitored Research of Athletes on Competitive and Training and the Non-Competitive States, Adapting to Sports Performance Monitoring Systems, Combating Athletes' Stress, Rise of Extensive research in Machine Learning (ML) and AI Will Enable the Dominance of Demographics, Sport-Specific, and Data-Handling Ethics. Finally, the paper concluded in Section V.

## II. ANALYSIS OF RELATED SURVEYS AND TAXANOMIES

Reiterating the important fact that the recent acceleration in sports technology has motivated researchers towards the inclination to publish research based on sports performance analysis. This section discusses and reviews extensively the previous surveys conducted on sports performance analysis and the critical issues surrounding them. Research in [4] surveys elite and pre-elite athletes, evaluating unseen factors contributing to their success. 135 Australian Olympic, Paralympic, National, and state-level athletes from 25 Olympic sports were surveyed. Our research has also improved and elaborated that there are more factors than those included in athlete development programs such as lifestyle, social and support factors. In [4] it has been found that international athletes perceived psychological skills and attributes, along with strong interpersonal relationships, as vital to their success, and they also rated 'Recovery practices' as very important and made extensive use of available support services. However, the athletes have indicated the necessity for access to these services at the grassroots level. The study has concluded that athlete development systems need a complete environment that allows athletes to succeed, perform consistently, have longer careers, and gracefully transition into retired athletes.

In [5] the research done on analysis methods in sport for intelligent data has been reviewed in detail. More than 100 studies on intelligent data and its analysis methods use Smart Sport Training (SST). Some of the methods among others surveyed included Computational Intelligence (CI) methods like fuzzy systems and simulated annealing, data mining methods like Support Vector Machines (SVM), and Random Forests (RF), Deep Learning (DL) methods like Recurrent Neural Networks (RNN) and Conventional Neural Networks (CNN), and other methods like Naive Bayes (NB) and Bayesian Networks (BN). The research also classified the research surveyed by sport type; individual, mixed, and team. Researchers have focused their attention on soccer, running, and weight lifting. The relation to participation levels, over half of the research study focused on individual sports, with team and mixed sports accounting for a third of the total. The research elaborated on the study type done on a particular sport and the focus of the research and results. This research may improve by adding more validation-level research publicly available with the datasets for replicating research, which improves methods.

In team sports, numerous variables influence the outcome and performance of the teams. The research in [6] surveys team sports and the usage, challenges, and techniques of implementing AI and ML with computation, including forecasting match results, tactical decision making, player

investments, fantasy sports, and injury prediction. The work evaluation on match outcome prediction found that, due to the unpredictability of sports, models still fail to forecast outcomes much better than bookmakers and appear to have hit a barrier, but there are several feasible solutions. This article also demonstrated the possibility of developing a one-of-a-kind real-world live testbed for AI and ML approaches to be validated in the future. According to a literature survey in the fantasy sports area, there are some AI approaches in the Fantasy Premier League (FPL) football competition to beat most human players dramatically. Overall, this study illustrates the impact of AI and ML approaches on the team sports domain, highlighting some processes with open areas and research issues. The survey focuses the research on six sports where only a finite amount of literature has been done. The narrow scope has allowed the team to be fortunate in finding research that contains the highest accuracy, cricket, with 75% in the prediction model. A broader scope would have seen sports with far more uncertainties and lower levels of accuracy in their research.

In [7] the role of ML in predicting and avoiding sports injuries has been discovered. The article uses Tree-based ensemble methods, SVM, and Artificial Neural Networks (ANN) ML methods. Pre-processing steps aided the classification algorithms, enhanced over and under sampling methods, hyper parameter tuning, feature selection, and dimensionality reduction. The comprehensive study found that ML technologies forecast sports injuries in 11 researches. The study closes by requiring ML to identify high injury risk athletes and essential injury risk indicators. AI offers a fascinating new viewpoint on injury risk and team sports performance prediction. Another literature study [8] covers AI in sports medicine, data processing, injury diagnosis, and prevention in competitive sports. Models and approaches in the literature study include fuzzy sets, ANN, Markov process, and other models such as Bayesian theory and multi-dimensional models groups. The review needs to be more systematic, a weakness of the research. In [9] the implementation of GPS units to collect data on a full-time basis has been done. The athletes, 52 players, enrolled into the Korean National Team, provided data to calculate the optimal ratio of Acute to Chronic Workloads (ACWR). The observational study reviewed other injury related research to deduce the calculation behind workload and the probability of an injury occurring to an athlete. Unlike the previous studies, which focused on pre-collected data, the research quantifies the workload of 52 athletes using GPS units collected during game-based training and matches. The research has filled the need for a standalone study, which has also conclusively suggested that hockey athletes and their ACWR should stay within the moderate low, especially for strikers and midfield playing positions, to manage non-contact and soft tissue injury.

In [10] the functional usage of ML and CI in sports prediction has been surveyed. ML, ANNs, BN and Logistic Regression Methods, SVM, and Fuzzy Logic and fuzzy systems are some models discussed in sports-related works. Many elements influence the outcome of a sporting event, including a teams' (or a players') morale, talents, and coaching plan. This review paper examines past research on data mining

methods for predicting sports outcomes and weighs the benefits and drawbacks of each approach. However, some sports, such as most track and field sports, are simply too easy to justify the complicated framework to the point where it is no longer necessary. There is a use of deep NN approaches in team sports analytics. Sports analytics using a DL approach is now possible thanks to tracking and visual data in sports and recent technological advancements. In [11] the use of modern DL techniques in team sports analytics has been reviewed. The survey researches two sports among the team sports that have benefitted from sports analytics, basketball, and football. The survey has tracked the advances in DL techniques in the two sports. The researchers aim to provide a study that provides insight to team sports analysts in sports and the ML aspect.

As discussed in the performance analysis subsection, [12] surveys the journal databases, reviewing the literature on Smart Wearables. The research classifies health, sports, daily activity, tracking and localization, and safety into four major clusters. However, data resolution of wearable sensors, power consumption, wearability, safety, security, regulation, and privacy became the primary obstacles of wearable Internet of Things (IoT) devices. In [13] the need for performance analysts within the coaching process within elite football coaches has been evaluated. The research dissects the differences in the necessity of PA's at the professional and football academy levels. The purpose of this study was to fill a gap in the literature on the function of match analysts in providing feedback via match and notational analysis techniques and systems. The exploratory study uses an online questionnaire based on information from current match analysts in elite football, academic practitioners in performance analysis, and current literature. 48 match analyst practitioners from significant football clubs completed the survey. The majority of 32 analysts worked in a professional team setting, while 16 worked in an educational setting. Educators and coaches can use the data gathered from training sessions and games analysis to understand better the challenges faced by a trainee, a player, or even an entire team and develop appropriate training and strategy plans. The research done by [14] has heavily influenced the structure and taxonomy due to emphasis on deliberating the finding of current surveys, current techniques, and trends of performance monitoring. This paper then proposes a classification scheme for these systems, separating them into invasive and non-intrusive categories. Researchers prefer nonintrusive systems since they do not interfere with the game. Each system's unique traits and strengths and weaknesses are listed. However, the system is still early and cannot extract high-level metrics such as game circumstances, team formations, or psychological characteristics.

The discussion in [15] is an in-depth understanding of content-aware systems for sports video analysis by examining the insight offered by research into the content structure under different scenarios. Themes relevant to the research on context-aware systems for broadcast sports were analysed. Analysis can benefit significantly from the use of ML. After evaluating coaches' responses, the study found that the system is valuable to daily work. The research summarizes the future trends and challenges for sports video analysis and sets the tone for the rest of this study in the section on video analysis. On the other

hand, developing a unified framework that enables processing data from diverse sports is still challenging. The trade-off between commonality and robustness must prevail because the future goal of action recognition in sports is to develop a machine that can read, write, listen to, and speak a voice over to broadcast sports videos directly.

The uniqueness of creation is that no two human beings are the same. Similarly, the conditions of individuals are different based on their fitness level and training consistency [16]. The researcher must determine a standard or baseline for every athlete individually to evaluate the athlete's performance. This way, it is considered that all humans are unique and may react differently to the stimulus applied, thus increasing the accuracy of studies and making surveys more accurate for the reader's comprehension in mapping them to specific domains. In contrast, more requiring research on Tai Chi and Qigong effects has only a few studies. Future research could also use shorter time intervals between RHR measurements to understand the underlying processes, potentially contributing to RHR decreases. The research done by [17] gave an in-depth method of monitoring an athlete's sports performance or a team of athletes, and this includes looking at several potential moderator variables' effects, and the cohesion-performance relationship revealed in research utilizing the Group Environment Questionnaire (GEQ). Standard literature searches turned in 46 studies with 164 effect sizes in total. This analysis breaks down the cohesiveness and performance in the sport. The GEQ had a moderate effect in studies that employed it. Refereed publications (as opposed to unpublished sources) and female teams had a more substantial cohesion performance effect. The research further breaks down the methods of measuring splitting variables like gender, type of sport, level of skill or experience of the athlete, and data source.

Face video-based Photoplethysmographic (PPG) signals acquired with professional or consumer-level cameras to obtain HR remotely. In [18] the latest advances in video-based HR management were surveyed. The research focused on the technological updates that overcame the existing and overwhelming challenges caused by illumination variations and motion artifacts. The majority of available remote Photoplethysmographic (rPPG) methods currently work with uncompressed video data. Conversely, the uncompressed videos will take up a lot of disc space, making internet data exchange impossible. The background of imaging Photoplethysmographic (iPPG) and rPPG, which is an estimation method for HR, was discussed, and debating the prospects of this technique and potential research direction in [19]. PPG and noise reduction using wavelet transforms to measure people's HR, which proposed recreation of the method for obtaining HR from the rPPG. rPPG is a technology that uses current or previously recorded video from a simple web camera to estimate HR, oxygen saturation, and other parameters. The heartbeat is usually highly regular over a short time; these physiological characteristics estimate that arteries blood flow shows some periodic flow. As a result, slight fluctuations in the amount of light reflected from the face are visible in the arteries and blood vessels of the face, which can be caught by the camera and processed as a Blind Source Separation (BSS) problem. The research successfully created a

real-time system that detects an individual's face and facial tracking and displays the HR with maximum noise reduction. The work could be improved by incorporating the ML technique into the PPG signal identification and increasing face detection accuracy.

HRV is a promising and essential research technique for cardiovascular disease diagnosis. The Parasympathetic Nervous System (PNS) and Sympathetic Nervous System (SNS) of the Autonomic Modulate System (AMS) regulate and control the HRV. HRV analysis can evaluate a variety of cardiological and non-cardiological illnesses. The research done by [20] surveyed HRV and the linear methods involved in the methodological evaluation. The two linear domains are the time domain and frequency domain. The researchers also discussed nonlinear methods of HRV like Poincare Plot Analysis, Approximate Entropy (APEN), Sample Entropy (Sampentropy), Detrended Fluctuation Analysis, and Correlation Dimensions. The parasympathetic and sympathetic controls, on the other hand, may have an impact on the alpha value in the study and fail to discriminate between them ultimately. As a result, a separate examination of both the short-term and long-term scales is necessary to determine the actual range of the scale as it withdraws the reciprocal effect.

In [21] the focus is on football as the ML applications in sports analytics relate to player injury prediction and prevention, potential skill, or market value evaluation. CI has shown to be a valuable tool in various fields. This study looks into the possibility of predicting long-term team and player performance. By surveying 31 categories of study and deriving the methodologies, information, and applications, large amounts of data turn into meaningful knowledge through data mining. Historical data and advanced statistics offer a reliable projection of the final league table and whether a team will have a more robust season. The findings taken from different leagues show a significant disparity. As a result, essential differences across leagues should apply universally. Player exhaustion and severe long-term injuries are problems that can harm players or teams, but if addressing the intricacy of the situation, such data could be valuable study tools. Many sports organizations have begun to understand that the data previously retrieved has a treasure of undiscovered knowledge, as data mining techniques capture the attention of the information industry and society due to a significant volume of data and the impending need to turn it into valuable knowledge. The research in [22] classified the 31 articles into nine thematic types with a systematic review of sports data mining from 2010 to 2018. The researchers also located possible areas to be explored, such as swimming, athletics, hockey, boxing, fencing, and tennis. The review concluded the survey by encouraging new research in this field.

The work in [23] surveyed multiple online databases for articles using AI techniques applied to the team sports athletes. The team applies AI to predict injury risk and team sports performance possibly. The most used methods surveyed are ANN, decision tree classifier, SVM, and Markov process, including good performance metrics. Soccer or football, basketball, handball, and volleyball were researched as the traditional team sports. The research concluded with the assurance of a promising AI and team sports future. There are

some differences in sample sizes in the manuscripts, with some samples being lesser than others.

The review done by [24] analyzed the literature on sports predictions that have utilized the application of ML. The research categorizes the method of ML into unsupervised learning and reinforced learning. Location, player health, player performance, weather, and ground conditions are all factors that influence whether a game is won or lost. Plenty of data is available for long-seasoned and high-scoring games like basketball, making prediction considerably more manageable, but guessing the outcome for games that are only played once a year and are low-scoring becomes a problematic endeavor. The team then attempts to show the comparison using a table, displaying the approach, game, technique, and review of the research surveyed. The research concludes by highlighting the study's limitations and prospects.

In [25] the microsensors usage and the monitoring approach implemented in basketball and did an online survey, and applied multiple responses, Likert-scale level of agreement, and open-ended questions on basketball practitioners were researched. Questions for the basketball practitioners included how player monitoring was performed, highlighting the barriers and facilitators with microsensors. Nearly two-thirds of respondents implement player monitoring, and almost one-third of basketball practitioners use microsensors. The survey concludes that basketball has low uptake of microsensors in sports performance monitoring. Because of this study's small sample size, it was impossible to analyse results based on criteria such as the playing skill of respondents.

The study in [26] did a survey on recovery strategies among basketball practitioners. The majority agreed that recovery strategies are very vital in their routine. The best strategies were active recovery, massage, foam rolling and stretching. The biggest challenges for the basketball athletes surveyed would be the lack of devices and facilities, high cost and lack of time. The research does find that there is a disassociation between scientific evidence and perceived evidence. The survey also noticed the inclination of athletes to prefer easily implemented strategies rather than evidence-supported strategies.

The work in [27] has given a comprehensive explanation about wearable monitoring systems. There are highlights of the usage of sensors, specifically commercial wearable systems for sports applications. The book overviews the psychological parameters measured by wearable systems. The HR and oxygen consumption parameters are analyzed in the respective sections. The following sections discuss the practitioners and the sports utilizing these wearable systems. The book concludes by evaluating the immense value of wearable systems to multiple sectors, including sports. The authors express their opinion on the current business expansion of wearables, which is currently small, and market forecasting has yet to produce an accurate and generally disseminated insight. Wearables technology can collect rich contextual data from the device itself and use it to provide a truly tailored experience.

In [28] the work surveys wearable technology, the progression in the development of wearable devices, and the

latest advances in the wearable devices market. They also classified the wearable devices based on factors and analysed in-depth information on the technology, highlighting the adverse challenges and prospects of wearable devices. Due to the lack of good practices in interoperability and proper standardization in the new Internet of Wearable Things (IoWT) niche, the close connection of various systems provided by different suppliers remains one of the most critical issues of wearables. AI in Sports Performance, ML and Sports monitoring, and RTM are the primary demographics and focus searched for throughout the research.

### III. PROPOSED CLASSIFICATION MODELS

In this paper, we proposed two classification models as a basis to address the importance of the term “off-field” performance analysis tool. This proposed classification being given a distinction is based on the extensive survey conducted in the previous section and the analysis has inspired that there is a need to give the analysis of athletes beyond the training and competition venue. Thus, creating the need to empirically analyse their off-field activities and their impact on the on-field. In this section we will review pertinent research done in off-field and subsequently the next section will present the open issues we have identified based on our extensive survey.

The ecosystem of an athlete consists of a broad spectrum of activities with multiple interactions with varying groups of people. This research surveyed 50 athletes, from national to state, and added the most common results.

Different athletes may have different timetables or schedules. Top-tier athletes train at least one or more times a day. Before stepping on the pitch, many athletes have Pregame Rituals (PGR) to complete [29]. In Ghana and other Sub-Saharan African countries, unorthodox PGR is common in sports, mainly soccer. Based on scientific descriptions, empirical investigations, and specific field observations, the paper also underlines the conceptual contrasts between PGR and pre-performance routines. The study in [30] put these superstitions to the test among track and field athletes, where there is more to the athlete’s preparation than mere superstition. The positive correlation between athletic identity and superstitious behaviour shows that student-athletes with strong athletic identities used more superstition in sports events. Individuals with a high athletic identity utilize superstition as a coping mechanism to minimize anxiety during the competition [31] and protect their egos. Precompetitive Mood States (POMS) have been reviewed by [32] and give us the ideology behind the Mental Health Model of the athlete before a competition as well as the more suitable Hanin Individual Zone of Optimal Function (IZOF) model. An athlete must consider all facets of the preparation time allocated before the tournaments. Whether on the pitch or off the pitch, every move imprints the athletes. There are multiple studies targeted at the effects of the actions carried out by athletes when the athletes are in a non-competitive state. The research surveys the studies devoted to uncovering the truth behind the effects of non-competitive actions on the athlete’s performance.

The proposed patent Prest and Hoellwarth is looking to monitor the vital signs of an athlete using headphones, earbuds, or headsets. While managing the electronic device, the

monitoring system monitors user activity during exercise or sporting activities. Other user characteristics such as biometric data, temperature, sweat, and HR are attributable to the monitoring system’s placement. The usage of headphones or earphones is rising during training sessions, despite having multiple side effects such as perforated eardrums [33]. There has been a study relating the effects of music on exercise [34]. It is also viable for a non-competitive approach. The athlete might want to calm his nerves before and after the game, and during that period, a reading of the HR, perspiration level, and steps taken should be recorded. Music can have a considerable positive impact on exercisers and athletes, especially in terms of increased effective reactions and physical performance, reduced perceived exertion, and more efficient oxygen consumption. The duration an athlete takes to reach a state of physical readiness for the next activity allows coaches to plan out substitutions of athletes for the games. Other alternatives like monitoring the step counter through the shoes have lost some avenues to monitor vital signs like HR and perspiration levels as effectively as this patent. The research in [35] measures an athlete’s performance without measuring their physical performance, but instead taking a psychological measurement, Sports Performance Inventory (SPI). A principal components’ analysis with Varimax Rotation performed on the original survey items resulted in an 83-item survey with six interpretable factors: competitiveness, team orientation, mental toughness, emotional control, positive attitude, and safety consciousness. Compared to novice athletes, college athletes had a higher SPI composite, a more positive attitude, and were more competitive. Females were more team-oriented than men, and novice males were more competitive than novice females, with college females outperforming college males. However, there is no direct proof that the SPI’s dimensions will predict an athlete’s performance, and sex differences discovered between athletes may be premature due to the small sample size.

The health industry has a huge responsibility. Discharged patients are still under the monitoring eye of the hospitals. The common issues for missing monthly check-ups are distance and transportation. The analysis in [36] has multiple uses and currently monitors the patients’ vital signs. The developed VJ is a microelectronics and textiles based vital signs monitoring system. The VJ has multiple readings for the usual ECG, respiration, perspiration, and oxygen saturation percentage. One unique feature that a clothing-based sensor can detect is posture. The VJ can detect the posture reading of the test subject. The posture reading can be beneficial in a sports-based environment because sports require posture perfection, which could be one of the solutions for these sports. Moreover, games that find an external wearable sensor disrupt the gameplay’s efficiency. Not to mention the question of safety, some sensors are waist-mounted, and even watch-based can quickly disrupt a play of games like rugby, whereas a shirt or vest used under the players’ uniform will form minimal resistance for the gameplay.

Other studies have touched on the negative behaviours among athletes and how that affects training to gather evidence that no matter to what extent the athlete puts the body through gruelling training sessions, the effects from non-competitive

activities leave a lasting impression on the performance. Drugs are categorized by [37] into usage and abuse [38]. The usage of allowed substances for an athlete's recovery has long been a part of the life and diet of performance athletes, but there is a fine line between usage and abuse. The overall harm of drug misuse comprised the substance's direct physical harm to the individual user, the drug's ability to create dependence, and the impact of drug abuse on families, communities, and society [39] [40]. Marijuana addicts are more likely to develop a persistent cough, bronchitis, and lung and upper airway cancers. Regular marijuana usage has sadness, anxiety, and schizophreniform illness in some people with a pre-existing predisposition [41]. Many drugs are outside the Health Ministry and International Sports governing bodies such as the World Anti-Doping Agency (WADA) [42]. The study in [43] highlights drugs like cocaine, meth/amphetamine, ketamine, and other drugs among "full-time" athletes and discusses the effects on the population of "full-time" athletes. The monitoring happens on a self-reporting basis and drug tests. The survey has also clarified that drugs harm current performing athletes and affect them when they stop competing and retire. It is common knowledge to note that drugs are harmful to any class of humans, but as the study has thematically targeted athletes, the survey discovers that athletes are no exception.

The athlete must recognize the body's biological signs and capabilities and sense what the body is going through. The research in [44] monitors the point at which the subject has reached the level of fatigue. This analysis documents a self-reporting, and the athlete notes the point at which he or she reaches fatigue while playing a sport of the choice. The test subjects needed to complete three surveys daily, and some relied solely on these surveys to convey what the test subjects were experiencing. The test subject saw that as the weeks progressed, there was more and more load that test subjects could handle, and this showed that progressively overloading the body meant that the body was less likely to feel fatigued at an earlier stage. The body muscles get accustomed to the athletes' load, and as the documentation proved, the athletes can withstand more the next time the test subjects are under the tests.

In [45] the manner in which an athlete's training affects their competitive performance is examined. The researchers analyze the link between competitive disc throwing performance and maximum lifting weights in female disc throwers. Maximum lift weights were recorded for the bench press, full squat, deadlift, high clean, and snatch. They use Pearson's R Accumulated Correlation Coefficient to determine the relationship between competition performance and 1-RM. Weights show a substantial positive link between female disc throwers' performance and their maximal lifting weight in the bench press, high clean, and snatch as female disc throwers weigh less than male disc throwers; hence they need to throw faster to convey the same amount of force. The high clean and snatch actions may contribute to power output during the delivery phase.

The COVID-19 pandemic is an example of an extended period forcing the athlete to be away from training. Almost all nations enforced nationwide lockdowns. The research in [46]

observes the usage of Virtual Reality (VR), which has already proven to be a step forward compared to video playback training. VR was used to separate the visual data of player movements from the visual data of the ball trajectory. The three conditions described are the player's throwing action, ball trajectory, and final location. The immersive environment emulates the field of play, the players, and the game methodologies, allowing for a comprehensive game mode to be tapped and trained in the athlete.

#### IV. OPEN ISSUES

The extensive discussion and review of the wide spectrum of research conducted in off-field and on-field has distinctly and empirically illustrated the depth and spectrum of research in sports performance analysis. Our analysis has derived the following open issues which will further enhance the spectrum of harnessing resources *to elevate sports*.

##### A. *Relating the Monitored Research of Athletes on Competitive and Training and Non-Competitive States*

In summary, when writing this survey, there is no predefined research between the stress applied to the athletes from the non-competitive daily routines and the performance displayed during competitive and training states. Studies performed on monitoring an athlete in competitive and training states, creating baseline readings, and through training and practice comparing the athlete's current state and performance over a while. Despite having studies done to relate pre-competition state using POMS, and the athlete's performance during competition, no specific correlation has been derived between what happens when the athlete leaves training or competition. An athlete spends an average of 20 to 30 hours a week in training and doing on-field activities, and there is an average of 140 hours that an athlete is away from the field. Therefore, 80% of the athlete's schedule is bound to affect the 20% spent on the field.

##### B. *Adapting to Sport Performance Monitoring Systems*

As sporting fraternities continue to evolve, all avenues must ensure excellence. An avenue like a stress monitoring system to access the athlete's current state will be extremely valuable and open to being tapped. There has been a void in this sector that has limitless potential in the case of pursuit. The sports world must accept the digitalization of performance analysis. Newer and more advanced systems than video monitoring have emerged in the sports fraternity. A recent survey researched the perception of rink-hockey head coaches and the usage of performance analysis as a tool to assist training, match preparation, observation, and interventions. The research has further cemented the importance of performance analysis by including seven experienced First Division Portuguese rink-hockey head coaches and conducting semi-structured questions, and the data analyses through inductive and deductive content analyses. Rink-hockey head coaches prefer to analyse the opponents themselves to plan training, assist with tactical preparation, and implement within-match strategies. They considered video analysis a vital tool to analyse opponents' strengths and weaknesses, focusing on the opponent's goalkeeper. Rink hockey has adopted performance analysis to prepare for tournaments and world sporting events in their armoury, like many other sports. Like rink hockey,

many other sports and coaching staff must be open to working with researchers, providing data on their athletes, and taking part in performance analysis of the individual athlete or team. The grassroots federations have less to worry about introducing new technology because the severity of the contracts and agreements, if present, is less than that of the professional leagues. The athletes are younger and will be more open to accepting and working with new technology introduced by the researchers. Also, wearable devices in grassroots level training sessions and games will not hinder high-profile games, unlike the professional games played by star athletes.

### C. Combating Athletes' Stress

An athlete is the face of the country in international multi-sport events, and there should be no unnecessary stimuli that bother the athlete. Research on the lifestyle of an athlete analysis the action that may induce stress recorded through HRV and isolates the athletes from such actions. An athlete should be able to allow competing without stress, which in turn is known to cause performance anxiety. Research that proves the importance of athletes' surroundings and the effects on performance will encourage national sports bodies to shape the surroundings of athletes according to their needs and remove stress triggers to ensure more potential tapped out of the athlete and more glory brought to the nation.

### D. Rise of Extensive Research in ML and AI will Enable the Dominance of Demographics

The modern sport of hockey boasts a fast-paced, physically grueling sporting event. One such sport is field hockey; with over two billion viewers annually and the top five most watched sports globally, minimal documented studies have been done on the sport or its athletes. Athletes of the top calibre require very high levels of stamina. Elite athletes need to maintain a high fitness level and constantly train their skills. The skills of hockey are displayed in the accuracy of shots and passes, the ability to run with the ball, and take power shots. The athletes in the sport need to monitor their performance during the competition and training and non-competitive states if the aim is to reach the top level of hockey play. The National Level hockey players could benefit from the study and the knowledge that many activities knowingly or unknowingly cause the dip in sports performance during athletes' competition and training. It will be another tool in the arsenal for the coaches and athletes to exploit and further improve.

### E. Sport-specific

The study has surveyed an array of different sports and the method of monitoring athletes and monitoring the performance of the athletes. The difference from one sport to the other changes drastically the more profound the research goes into the details and skills of a sport. Every sport has a unique skill set and abilities that the athletes must complete, and sports monitoring has been very sports-specific. Some sports have a huge reception globally, but very little documented research. Sport-specific research proposed directing towards that is focused on the uniqueness of the sports and the respective demographics. The research should cover an existential issue of the effects of the athletes' non-competitive practices and how top-level athletes are affected by it. The study should cover the area of wearable sensors as their go-to research

method. Using the current systems in the market, like Suunto, boast a repertoire of precision and accuracy in measuring the physiological changes in the body. Unfortunately, mega-corporations like Suunto do not divulge the readings and information recorded on their watches to the public or is search team. They expect users to use their hardware and readings taken at face value. Another option is the Samsung Watch due to their operating system running on Tizen. Tizen allows developers and researchers to develop their applications to be tested in the Samsung Watch hardware, applying using the sensors optimally. The Tizen software also allows for the readings to be taken, recorded, and analysed by researchers.

### F. Data-Handling Ethics

Bio-metric data has been a repeating element in most of the research discussed in the survey. The power and accessibility of the technology behind bio-metrics have made it very susceptible to monetization or the user's identity being stolen. In the professional sporting sector, some laws involve data sharing policies. The agreements and contracts for athletes allow their documents and data to be protected from being misused, which is not the case for lower levels of the sport. There is a gray area in the confidentiality of athlete data collected by researchers. There has to be a standard protocol for all athletes and researchers, allowing for more ethical practice in sports research. The current trend leaves a gap that hackers can exploit.

## V. CONCLUSIONS AND FUTURE WORK

This paper presents a survey on the sports performance analysis of athletes' competitive and training states in various sports. We also surveyed the athletes and monitored their non-competitive activities or away from training. Then taxonomy of comparison was done on the research based on metrics like using the wearable sensors. The most common method in the modern age is to use mobile wearable sensors on the athletes while monitored during competition and training. However, there is also an avenue to use the same concept of wearable sensors to monitor athletes that leave the pitch. As mentioned above, an athlete's job is continuous and not only during competition and training. Therefore, we have presented the option of a bridge where non-competitive monitoring is the void many researchers may need to exploit in the open issues. On the topic of open issues, we have also found that:

- Stress monitoring among athletes is done extensively during competitive and training activities, but not once the athlete leaves training. The stress subjected to the athletes could be why the player's progress and performance are stunted.
- The national sporting bodies in nations need to pay heed to the lifestyle of athletes and foster an environment conducive to the athlete, besides the vigorous and state-of-the-art training facilities.

Sports with a fan following and stadium ambience creation by these fans need more research on their players and the sporting environment. The future direction of this research will be to encourage more researchers to create holistic and complete performance monitoring systems. The performance monitoring system or architecture must contain a registration

module for the national-level database of athletes, which acts as a recommend system for national-level athlete selection. The athlete selection must be based on collective performance data and not only a single qualifying event win. Single event qualifying win has been the method of qualifying for state to national level athletes. The lack of a complete database of athletes requires sports federations to select athletes through events, not merit or potential performance. Thus, performance analysis tools will constantly need to be enhanced and to be designed to furnish the specific and demographics in precise.

The future work will be focused on the analysis of sports performance analysis based on sports specifications. The harnessing of intelligence in its wide spectrum will be further covered. The detailed review and analysis of hardware development such as biomedical sensors is also being pursued.

#### ACKNOWLEDGMENT

This project has been supported by the Contract Research Grant of University Putra Malaysia – National Sports Council for the iGames (Vot Number - 6300375) and the UPM Innohub Market Validation Grant for IoSRocks – Mobile Device Application (Copyright (CRLY2022W04194 )) (Vot Number - 9005003).

# An Improvement for Spatial-Temporal Queries of ATMGRAPH

ZHANG Zhiyuan<sup>1</sup>, HAN Boyang<sup>2</sup>

School of Computer Science and Technology, Civil Aviation University of China, Tianjin, China, 300300

**Abstract**—As a knowledge graph for the field of ATM (Air Traffic Management), ATMGRAPH integrates aviation information from various sources, and provides a new way to comprehensively analyze ATM data, but the storage schema of ATMGRAPH is inefficient for trajectory-related queries which have typical spatial-temporal characteristics, thus cannot meet the application requirements. This paper presents an improved storage model of ATMGRAPH, specifically, we design a cluster structure to connect trajectory points and spatial-temporal information to speed up trajectory-related queries, and we link flights, airports, and weather information in an effective way to speed up weather-related queries. We create a dataset of about 10,000 real domestic flights, and build a knowledge graph of it which contains about 11.66 million triplets. Experimental results show that ATM knowledge graph constructed by this storage model can significantly improve the efficiency of spatial-temporal related queries.

**Keywords**—Air traffic management; knowledge graph; storage model; spatial-temporal query; ontology

## I. INTRODUCTION

With the rapid development of the economy, people are willing to travel by air due to its efficiency and convenience. The civil aviation industry generates a large amount of data every day, coming from multiple departments such as airports, airlines, Air Traffic Managements (ATMs) and meteorological bureaus, with varying data forms and coding rules, make it a great challenge for semantic data query and analysis. As Aviation data are scattered in different systems, integrating them into a big semantic database seems to be a good idea. The most representative work is ATMGRAPH (Air Traffic Management Knowledge Graph) constructed by NASA. This KG (Knowledge Graph) integrates multiple aviation information and is benefit for semantic data analysis. Flight trajectory information accounts for the vast majority in ATMGRAPH, it has obvious spatial-temporal characteristics, and data analysis on trajectory is often about spatial and temporal. However, in practical applications, ATMGRAPH encounters great scale problems, especially when facing spatial-temporal related data queries, i.e. its performance decreases dramatically for huge data volumes.

There are few works to address this problem, in order to fill this research gap, this paper conducts on spatial-temporal query optimization of ATMGRAPH. A knowledge graph can be logically divided into two layers: the data layer and the schema layer. The data layer stores knowledge facts, and the schema layer defines ontology to standardize a series of fact expressions in the data layer [7]. This paper designs an improved storage model for ATMGRAPH to solve the

problem of slow and inefficient processing of spatial-temporal related queries. Specifically, we design a cluster structure to connect trajectory points and spatial-temporal information to speed up trajectory-related queries, and we link flights, airports, and weather information in an effective way to speed up weather-related queries. Experimental results on real aviation data show that the query efficiency using our model is significantly improved in typical application scenarios.

The rest of this paper is organized as follows. Section II is the related work. Section III is the problem definition, which introduces NASA's original ATMGRAPH model and analyzes its shortcomings in spatial-temporal related queries. In Section IV, we introduce our improved ATMGRAPH model in detail. Section V is the experimental results and discussion, and we conclude our work in the final section.

## II. RELATED WORK

With the rapid development of the global transportation industry, air traffic flow has significantly increased. There were lots of research works on air traffic management such as airspace saturation, flight accidents, flight delays, and air control difficulties. The Federal Aviation Administration (FAA) used big data analysis to identify operational patterns, which can support the identification and prediction of airport data [2]. Rezo [3] introduced a paradox in aviation data processing and proposed a probable solution. Dorota [4] discussed the requirements of aviation data in Polish regulations and gave a practical proposal. Keller et al. [5] introduced a system for combining heterogeneous air traffic management with semantic integration techniques, which transforms data from disparate source formats into a unified semantic representation of ontology-based triplets. Liu et al. [6] implemented seamless communication and mutual cooperation between civil aviation systems through information sharing, which could support collaborative decision-making of air traffic management and improve the capacity of airspace systems. Lu et al. [7] proposed an integration architecture of cloud computing and blockchain for ATM systems, in which it pointed out the advantages of the new technology architecture over the traditional architecture of existing ATM systems. Europe and the United States are trying to use ontology technology to integrate and fuse aviation data from multiple sources, so as to provide a unified data exchange mechanism with semantic information for all participants in the aviation industry. For example, the Single European Sky Program launched the BEST project (<http://www.project-best.eu>), which designed AIRM (ATM Information Reference Model) and constructed an ontology

model for aeronautical and meteorological information [8]. At the same time, NASA constructed ATMONGO (ATM Ontology), involving ATM core data such as aircraft, flight, airport, airline, route, and navigation facility [9]. It includes over 150 classes, over 150 datatype properties, and over 100 object properties. Based on ATMONGO, NASA also built ATMGRAPH, a knowledge graph containing 260 million triplets [10]. Many information of ATM has temporal and spatial characteristics, e.g. when an airport is temporarily closed due to snow conditions, the airport operation status in KG should be changed to CLOSED, and the start and end time should also be indicated. Therefore, Schuetz et al. [11] proposed the concept of Contextualized Knowledge Graphs by adding semantic dimensions such as time, space, and data source in KG to solve the problem of information distribution and acquisition for all participants in the aviation industry.

### III. PROBLEM DEFINITION

As the latest achievement of symbolism, knowledge graph is an important milestone of artificial intelligence. Knowledge graph can provide valuable structured information by data integration and standardization, and it has been widely used in information retrieval, automatic question answering, decision making and other fields, and it is also an important basic technology to promote data mining and intelligent information services [12]. With the growing scale of the knowledge graph, data management issues become increasingly prominent [13]. KG is generally divided into general knowledge graph and domain knowledge graph, and the latter usually needs to carefully design the storage model according to the industry data's characteristics in order to meet the retrieval requirements under large-scale data.

Consider the following two representative queries in ATM:

- Find all flights passing through the ZBAAAR20 sector of Beijing on July 20, 2022 and landing at Beijing Capital International Airport under strong wind conditions.
- Find which sector controlled the most flights between 9am and 10am on July 16, 2022.

ATMGRAPH consists of one month's flights (approximately 100,000 flights) and weather data in the New York metropolitan area, which includes eight classes: airspace structure and facilities, flight routes and procedures about takeoff and landing, traffic management measures, flight carriers and aircrafts related, airport and ground operations, weather, sequence related, and spatial-temporal related. Fig. 1 is a segment of ATMGRAPH, with a specific flight instance at its center: UAL535, which took off at 00:19:00 on July 15, 2014. Connected to it includes the departure and arrival airport of the flight, the carrier airline, the aircraft model, the planned route and the actual route. The lower part of the figure represents the track points of the flight, each contains information such as time, longitude, latitude, altitude, speed etc. (not listed in the figure for brevity). Although there are classes about weather and sectors in ATMGRAPH, getting the results of the two representative queries above is very inefficient, cause it must check all points

one by one whether it matches the corresponding constraint. For example, when querying the workload of a sector during a certain period of time (i.e. the number of flights flying within the sector during this time), at first we must find all track points within that period of time, then for all of them we need to check whether their positions are within that sector, and finally output the corresponding flight information. Obviously, these kinds of operations are quite inefficient.

Fig. 1. Flight information storage segment.

This paper designs an improved storage model, which not only considers the strongly correlated characteristics between flight and weather information, flight and spatial-temporal information, but also links the trajectory points with spatial-temporal entities, so as to speed up spatial-temporal related queries. Experimental results on real flight data show that our proposed model greatly improves the query speed for representative queries and for some queries which the original model may take hours, our model can finish them in just a few seconds.

### IV. IMPROVED STORAGE MODEL

Although there are already eight major classes in ATMGRAPH to represent various knowledge in ATM field, some of them are relatively independent, making it difficult to obtain results using a single query statement involving multiple classes. The nodes of flight trajectories in ATMGRAPH account for nearly 70% of the entire graph, and each track point is only connected in chronological order using the hasNextTrackPoint relationship. This kind of storage model not only occupies a large amount of storage space but also reduces query efficiency. On the premise of being consistent with the original structure of the ATMGRAPH, this paper extends it to express more spatial-temporal information without taking up more storage space.

Fig. 2 illustrates our improved storage model, where ellipses represent the newly added classes and dashed edges represent the newly added relationships. TimeInterval is a new class for standard time segment, which connects the Trackpoint class through belongToTimeInterval relationship to express track points with the standard time segment information. The relationship belongToSector connects the Trackpoint class with the Sector class representing which sector the track point is located in. The new class WeatherInterval represents weather conditions of each airport in different time periods, and it also connects to the Flight class through two new edges: hasArriveWeather and hasDepartureWeather. The class ActualRoute represents the actual flight route, which contains the first and last track points of the trajectory through the edge of hasFirstTrackpoint and hasLastTrackpoint.

Fig. 2. Improved storage model of ATMGRAPH.

Through this storage model, track points has a direct connection to time and sector information, thus alleviates the problem of inefficient spatial-temporal related queries in the original ATMGRAPH. At the same time, weather information also has a direct connection to flights, which can solve the problem of slow query speed for weather and flight related queries.

#### A. Standard Time Interval

In the real world, many facts have time attributes, which play an important role in knowledge graph [14]. For example, the fact represented by a triplet (Steve Jobs, diedIn, California) is that Steve Jobs died in California, which occurred on October 5, 2011; The fact (Ronaldo, playing for A.C. Milan) was only valid between 2007 and 2008. In air transportation, when an aircraft performs a complete flight mission, time

information cannot be ignored. In our experiment, the flight data comes from ADS-B, which broadcasts real-time information including aircraft position, speed, identification code, flight number, and air-ground status to ATC (Air Traffic Control system) or other aircrafts through the air-to-air and air-to-ground data links [15]. Table I shows an ADS-B data fragment that contains three track points of flight EPA6206 during its mission on July 27, 2020. The specific information includes the flight number, aircraft number, and the current position (longitude, latitude, altitude), speed, heading, and data transmission time expressed in UTC (Universal Time Coordinated).

In ATM data analysis, usually we do not care much about the instantaneous state of an aircraft at a specific time point, and the time unit in queries is mostly hours or days. For example, finding the number of flights flying at altitudes above 6000m from 8:00 to 10:00 on July 10, 2022. To quickly retrieve the flight status of many flights within a same time segment, creating standard time intervals seems to be a feasible and effective method. This paper takes ten minutes as a standard time interval. If it is too long, it will lead to too many track points within a time interval, which will affect the query performance. If it is too short, it will cause too many TimeInterval nodes in the graph, and waste the storage space. Track points belonging to a same time interval are all linked to the TimeInterval entity representing that time segment, forming a cluster structure. Fig. 3 shows some track points of flight KNA8202 and flight CSZ9106 during the time interval from 7:00 to 7:10 on July 18, 2022. It can be seen that this cluster structure can gather all track points within the standard time interval without damaging the original relationships in the graph. Due to the fact that each track point is connected to its corresponding standard time interval node, related track points can be directly retrieved, without checking all track points one by one to judge whether they meet time constraints. This provides a more efficient way for time related query tasks.

The process of adding standard time intervals is as follows: Create all standard time intervals in the graph, and then calculate the corresponding TimeInterval for each track point according to UTC Time, and connect it with the relationship belongToTimeInterval. After that, the above query can be solved through a single Cypher query statement:

```

match(n:Trackpoint)-[r:belongToTimeInterval]-
(m:TimeInterval)
where n.height >= 6000
and m.startTime >= 2022/07/10 08:00:00
and m.endTime <= 2022/07/10 10:00:00
    
```

TABLE I. ADS-B DATA SEGMENT

Fnum	UTC Time	Latitude	Anum	Angle	Speed	Height	Longitude
EPA6206	2022/7/27 11:59:16	30.5709	B204N	21	361.14	1013.46	103.94346
EPA6206	2022/7/27 11:59:31	30.61871	B204N	22	355.584	1226.82	103.96566
EPA6206	2022/7/27 11:59:46	30.63263	B204N	22	357.436	1325.88	103.97208

Fig. 3. Temporal cluster structure based on TimeInterval.

### B. Spatial Sector Clusters

Spatial is an essential attribute of geographic data, which is mainly used to describe the spatial features of geographical entities, including position, shape, and spatial relationships [16]. Sector is a major geospatial entity in ATMGRAPH, usually formed as a polygon with height range, and the polygon is consisted of multiple points with longitude and latitude coordinates connected from head to tail. Sector is a fundamental unit of air traffic management services and is an important component for airspace planning and allocation [17]. In the field of ATM, many typical queries focus on the workload of a sector over a period of time (i.e. the number of flights in that sector within a specific time period). For example, finding the workload of sector ZBAAAR18 from 8:00 to 10:00 on July 10, 2022.

Traditional way to answer this kind of question in ATMGRAPH is to check trajectory points one by one if it is located in the given sector, which is very time consuming. To address this, this paper takes the sector as a central node and connects all track points within the sector to it, thus forming a cluster structure. When executing above queries, we only need to search the corresponding sector first, and find all track points connected to it. After filtering out duplicate flight numbers, the query results can be obtained immediately. Due to the fact that adjacent trajectory points may belong to two different sectors, how to determine whether a track point is within a sector? The ray crossing number method is generally used to determine whether a point falls inside a polygon. Specifically, firstly we draw a ray emitted from that point, and then we calculate the number of intersections between the ray and the polygon boundary: if the number of intersections is odd, then the point is inside the polygon, otherwise it is outside the polygon. In Fig. 4, a ray passes through an irregular polygon, and if the starting point of the ray is located in the thin line section, it has an even number of intersections with the polygon, and if it is located in the thick line section, it has an odd number. According to the above method, the points in the thick line section are inside the polygon, and the points in the thin line section are outside.

Fig. 5 shows a cluster structure fragment centered on sector ZBAAAR18 in the Beijing flight control area, with surrounding nodes of trajectory points. The names displayed in the nodes are the flight numbers and instantaneous times.

Similar to the temporal cluster, this structure also does not disrupt the original track point connection relationship in the graph. When conducting a query about workload of an air traffic control sector, it is possible to directly find the Sector node and use the belongToSector relationship to reversely find its connected track points, and it is not necessary to calculate the position of each track point any more, thus greatly reducing the query time.

Fig. 4. Ray crossing number method to determine whether a point is inside the polygon.

Fig. 5. Spatial cluster structure based on sector.

The process of adding spatial sector nodes is as follows: First, import the information of all sectors into the knowledge graph, then use ray crossing number method to calculate each track point to judge its relationship to the sectors, and finally connect each track point with its sector through the belongToSector relationship. With the spatial cluster structure, it is very easy to answer sector related queries. For example, when solving the query mentioned in this section, we can obtain the results in Neo4j by a single Cypher query statement:

```
match(n:Trackpoint) -[r1:belongToTimeInterval]-
(m:TimeInterval)
```

where  $m.startTime \geq 2022/07/10\ 08:00:00$

and  $m.endTime \leq 2022/07/10\ 10:00:00$

```
with n match(n)-[r2:belongsToSector]-
(o:sector{name:'ZBAAAR18'})
return count(distinct(n.fnum))
```

After adding temporal and spatial clusters to ATMGRAPH, all track points are connected with their corresponding temporal and spatial information. Fig. 6 shows a segment about the connection relationship between TimeInterval, sector and Trackpoint of our improved knowledge graph. At this point, when considering a query like 'Which sector controlled the most flights between 9:00 am and 10:00 am on July 16, 2022', we can simply find the six TimeIntervals that represent this period of time, filter out all the track points within them, and then count the number of flights included in each sector to obtain the final results.

### C. Airport Nodes with WeatherIntervals

Weather conditions are very important for aircraft takeoff and landing. For the first representative query mentioned in Section II about finding all flights that pass through the ZBAAAR20 sector and land at Beijing Capital International Airport (BCIA) under strong wind conditions on July 20, 2022, the usual processing method requires two query operations (querying the time span of strong wind conditions at BCIA that day, and querying all flights that land at BCIA that day) and one comparison operation (check those flights one by one if its landing time is in the time period of strong wind). If the weather information when an aircraft arrives at or departs from an airport is directly stored in the knowledge graph, then the speed of answering such questions will be significantly improved.

This paper adds weather information to each airport based on the class WeatherInterval, and each flight is also directly connected to its weather information during departure and arrival. Considering that weather generally does not change frequently in a short period of time, unlike TimeInterval, the span of the WeatherInterval is set to 12 hours. As shown in Fig. 7, flight CHH7810 landed at Beijing Capital International Airport on July 18, 2022, and the weather when landing was rainy. Airports may have different weather conditions at different time periods and are connected to WeatherInterval by the relationship of hasWeather. Flights are also connected to WeatherInterval by relationships of hasArriveWeather and hasDepartureWeather. Using the new schema, when processing queries related to weather conditions, there is no need to match the landing time and corresponding weather information of flights one by one anymore, and it can be obtained directly through WeatherInterval. For the typical query mentioned in this section, we can obtain the results in Neo4j by a single Cypher query statement:

```
match(n:flight)-[r:arriveAirport]-(m:Airport{code:'PEK'})
where n.endtime >= 2022/07/20 00:00:00
and n.endtime < 2022/07/21 00:00:00
with n match(n)-
[:hasArriveWeather]- (:weatherInterval{weather: 'strong
wind'})
```

Fig. 6. A fragment of our improved ATMGRAPH.

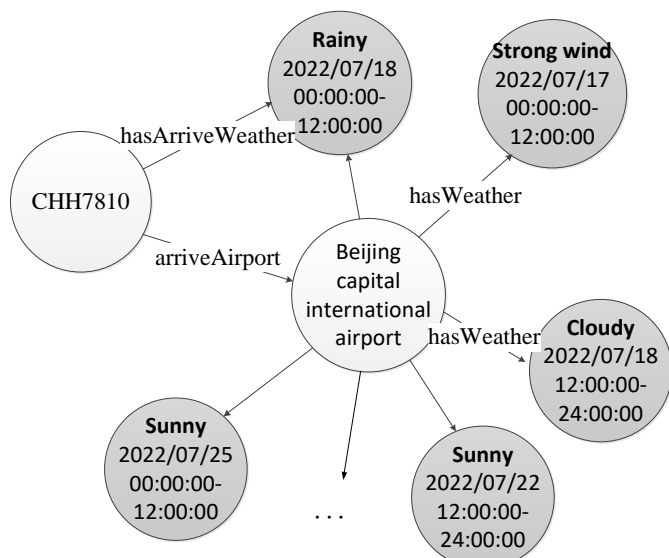

Fig. 7. A fragment of flights, airports and WeatherIntervals.

### V. EXPERIMENTAL RESULTS AND DISCUSSION

The experimental environment is a 64bit Windows system (Intel i7-7700HQ CPU, 16GB memory), 4.2.2 community version Neo4j, implemented using Python language.

We crawled ADS-B data from varflight website (<https://www.variflight.com>) about 10,000 flights from July 16 to 27, 2020. The data of airports, flight information regions, and sectors are from AIP (Aeronautical Information Publication), and weather data is randomly set. Using these data, we built ATMGRAPH of two versions: NASA's original version and our improved version, with the latter containing 5.5 million nodes and 11.66 million relationship edges. We then evaluate their performance using three typical query cases, and the results are shown in Table II. The evaluation metric is query time. The first query case is only temporal related, the second query case is spatial-temporal related, and the third query case is about time, airport, and weather condition.

Table II shows the comparison results between NASA's original ATMGRAPH and our improved version on commonly used spatial-temporal related queries. The first is a common time related query in ATM data analysis. Using our storage model, due to the existence of standard time segment clusters, it is very easy to find all track points belonging to the TimeInterval from 9:00 to 12:00 on July 27, 2020. On the contrary, for the original ATMGRAPH we must compare the UTC value in each track point. From the results in Table II, we can see that our model is about eight times faster than ATMGRAPH. The second query adds spatial constraint to the first one. For ATMGRAPH, because there is no direct connection between track points and flight information regions, to get the query results, we must calculate all track points in the graph and judge the topological relationship between each track point and each flight sector. Because the number of track points is very huge and grows lineally with flight numbers, plus the position calculation is also very complex, thus it takes hours to obtain the query result. After adding a spatial cluster structure in our improved model, track points in the specified region can be directly found through the relationship belongToSector, and then the corresponding number of flights can be quickly obtained. The third query is related to the weather conditions at landing time. For this query, our model can directly get the flights that meet the conditions through a simple Cypher statement, while the original ATMGRAPH can be very complex: it should first identify the flights that land at the airport, and then find weather information of the airport during the landing time of the flights. Due to the fact that weather and flights in the original ATMGRAPH are not connected, the analyzer must manually check these flights one by one which is very time consuming, or develop a program to handle it which is very inconvenient. The result of ATMGRAPH for the 3rd query in Table II is gotten in a program way, which is about two seconds, while our model only uses five milliseconds, more than 400 times faster.

The above experimental results and discussion indicate that adding the spatial-temporal cluster structure proposed in this paper to ATMGRAPH can quickly process queries related to spatial-temporal features and improve data analysis speed.

TABLE II. PERFORMANCE COMPARISON OF TYPICAL QUERIES

Query cases	ATMGRAPH Version	Query Time
Find the number of flights from 9:00 to 12:00 on July 27, 2022	ORIGINAL	3748ms
	IMPROVED	421ms
Find the number of flights passing over Beijing on July 25, 2022	ORIGINAL	2.5h
	IMPROVED	1346ms
Find the number of flights landed at Beijing Capital International Airport from July 16 to 27, 2022	ORIGINAL	2160ms
	IMPROVED	5ms

## VI. CONCLUSION

In order to solve the problem of low efficiency of spatial-temporal related queries in ATMGRAPH, this paper proposes an improved storage model, which uses spatial-temporal clusters to represent flight information regarding time and location. In our improved model, trajectory points are connected to standard time intervals and sectors, and flight and airport entities are connected to weather intervals. Experimental results show that after adding the spatial-temporal cluster structure to the knowledge graph, the speed of relevant queries is greatly improved.

Due to the fact that the track data in ATMGRAPH accounts for approximately 70% of the total data volume, this article only focuses on improving the mode layer and cannot solve the redundancy problem of a large amount of track data. Aircraft trajectory points are stored as an unidirectional chain structure in Neo4j, and we can study a new storage structure for this typical kind of data in the future to save storage space and to optimize data query speed.

Dept. of Computing and Informatics, University of Sharjah, Sharjah, UAE<sup>4</sup>

**Abstract**—This study aims to find the most accurate algorithm that is capable of predicting crimes in Dubai. It compares models on a dataset of sample crimes in the Emirate of Dubai, United Arab Emirates using the open-source data mining software WEKA, which enabled us to use Random Forest, KNN, SVM, ANN, Naïve Bayes and Decision Tree. We chose those algorithms as former studies that were effective used them. We have applied the algorithms on a dataset containing 13440 Major Crime in four categories occurred between 2014 and 2018. After comparing the models and analyzing their success rates, we identified the ideal algorithms and evaluated the effectiveness of variables in making predictions by measuring the correlation coefficients. One of the study's most crucial recommendations is to increase the variables and data, also adding more details about the crime, the criminal, and the victim. These variables make an impact on the analysis and the ultimate prediction.

**Keywords**—Machine learning; crime analysis; crime patterns; KNN; random forest; SVM; ANN; Naïve Bayes; Decision Tree; major crime

## I. INTRODUCTION

The modern society in Dubai has gathered people from around all the world, more than 170 nationalities, estimated at 3,478,300 people in 2021 [1], Dubai is well known for the low crime rate [2], in Q3 of 2022, Dubai Police has reported 65% drop in the number of criminal reports at the General Department of Criminal Investigations (CID) quarterly appraisal meeting, which was presided over by Lieutenant General Abdullah Khalifa Al Marri, Commander-in-Chief of Dubai Police [3].

The rise in urban crime statistics has become a major concern for law enforcement agencies across the world. Machine learning algorithms have been progressively used to predict and prevent crime in recent years. We intend to compare the performance of various machine learning algorithms for crime prediction in Dubai in this applied scientific research. Crime is a pervasive, global social problem that lowers people's quality of life and slows economic growth [4]. As it affects people's security, crime reduction remains one of the most important social issues in large metropolitan areas [5].

In order to reduce crime by predicting and preventing it, we must have a clear understanding of the current crime situation, which requires a crime data set that enables the use of machine learning. Predicting the future occurrence of crime is more possible today than ever before with digitalization and e-

governance generating data that allows for effective analysis [6].

We hope to gain insights into the most effective methods for predicting and preventing crime in this city by analyzing and comparing the accuracy, precision, and recall of these algorithms. Some research claims that crime cannot be predicted, as predictions are never 100% accurate [7]. Indeed, data is not always helpful in solving real world problems, but some scholars have succeeded in building models that helped to prevent crime [8]. This suggests that the issue with prediction may sometimes be caused by using the wrong model. Predictive policing aims to identify areas that may be subject to crimes. This is supported by routine activity theory and rational choice theory. According to both theories, a crime occurs when a person who is willing to commit it has the chance to do so and these opportunities follow patterns in both location and time rather than being distributed randomly [9].

This paper is structured as follows: Section II presents the main problem and motivation for the work. Section III presents work related to this research. Section IV describes the methodology. Section V presents the prediction models we use to analyze the data. Section VI presents our results, and Section VII summarizes our conclusions and related work.

## II. PROBLEM AND MOTIVATION

There are no applied, academic studies open to students based on Dubai Crime Data as they due to the restrictions which keeps access to crime data internal and confidential.

With the unprecedented support of the Dubai Police, this applied study gave us access to real crime data in Emirates of Dubai.

By this research, we are trying to find the most accurate algorithm that is capable of predicting crimes in Dubai.

## III. RELATED WORK

There are very few similar studies in the Arab Region so far. Scholars tend to conduct theoretical research and surveys, and not real crime data-based studies, On the other hand, we have found countless examples of work from other regions.

- Crime Rate Prediction Using Machine Learning and Data Mining by Sattar, Abdus and others [10] uses different clustering approaches of data mining to analyze the crime rate of Bangladesh. The authors use the KNN algorithm, and identify geographical areas that

have higher crime rates, making recommendations for individuals to be cautious in those areas.

- Crime Analysis and Prediction Using Machine Learning by Olta Llaha [11] identifies the most appropriate data mining methods for analysing data collected from crime prevention sources by theoretically and practically comparing them. The authors use gender, age, employment status, and crime location as attributes. They find that data mining methods help to predict the incidence of a crime occurring and, as a result, contribute to avoiding it.
- An Experimental Study of Crime Prediction Using Machine Learning Algorithms by Sikhnam Nagamani and others [12] uses open data from Kaggle, a mix of crime types, description, time and date, and latitude and longitude to find patterns in crimes.
- Comparison of Machine Learning Algorithms for Predicting Crime Hotspots by XU ZHANG and others [13] uses an open data source from China (2015 to 2018). It suggests the use of historical crime data as well as covariates associated with criminological theories in order to evaluate the merit of machine learning algorithms.
- Crime Prediction through Urban Metrics and Statistical Learning by Luiz G. A. Alves and others [14] uses random forest regressor to predict crime and quantify the influence of urban indicators on homicides. This study finds that random forest algorithm is an excellent model for predicting crime.
- Using Machine Learning Algorithms to Analyze Crime Data by Lawrence McClendon and Natarajan Meghanathan [15] uses WEKA, open-source data mining, to conduct a comparative study between the violent crime patterns from the Communities and Crime Unnormalized Dataset provided by the University of California-Irvine repository, and actual crime statistical data for the state of Mississippi that has been provided by neighborhoodscout.com. This study finds the linear regression algorithm to be very effective and accurate in predicting crime data based on the training set input for the three algorithms.

The current study makes significant contributions by attempting to fill multiple research gaps.

First, the study adds to the relatively limited research on crime prediction in the Arab world. Our study is one of the first to use prediction models on real data from a reliable source in the Arab region.

Second, ours is one of the few research projects that has used six prediction models to determine which provides the best outcome with greater understanding and insight into the data used.

Third, to the best of the author's knowledge (based on a search of peer-reviewed databases), no previous study has compared machine learning algorithms on crime prediction in Dubai in an applied academic setting.

## IV. METHODOLOGY

### A. Dataset

The crime data used in this study is confidential data individually supplied to the research team by the Dubai Police. The only publicly available crime data in Dubai are the total published by the Dubai Police, which would be insufficient for the completion of the present study [16]. This restricted and non-georeferenced dataset consists of a spread sheet that contains data compiled by the police, as shown in Table I, containing the date, the hour, the typology, used tool, the technique used, and the area of the crime, as well as the age, nationality, status and education level of the criminal for all reported crimes occurring inside the city limits between January 2014 and December 2018, amounting to approximately 52 thousand entries.

TABLE I. DATA SET USED

Name	Description	Data Type
Date	Date of crime	Date
Time	Time of crime	Nominal T1: 12:00 am to 5:59am T2: 6:00am to 11:59 am T3: 12:00pm to 5:59pm T4: 6:00pm to 11:59pm
Police	Police Station responded to the crime, which refers to the area as well	String
Age	Age of criminal	Numerical
Sex	Sex of criminal	String
Nationality	Nationality of Criminal	String
Education	Educations of Criminal	String
Status	Status of Criminal	String

### B. Pearson Correlation Coefficient

Pearson correlation coefficient; descriptive statistic; indicates relationship (extent of linear correlation) between two continuous variables; the better comparable the data resulting from two different methods are (i.e. the closer the correlation is) the more the r value approaches the value 1, whereby 0 represents no correlation, -1 a perfect inverse correlation (negatively sloping line) and +1 a perfect positive correlation [34].

We calculated the correlation coefficient value in order to determine how strong the association between the factors.

The correlation coefficient can be understood as follows:

- There is absolutely no association when the correlation coefficient is 0. It implies that the variables have a fully unfavorable connection. There is no association if the correlation coefficient is zero.
- If the correlation coefficient is 1, a significant positive correlation is demonstrated. It implies that the variables have their optimal positive correlation.
- A correlation coefficient with a larger absolute value denotes a stronger link between the variables.

We applied Pearson correlation in the crime dataset using Weka by selecting the attribute ranking using correlation Attribute Eval. Here are the outcomes we obtained:

TABLE II. RANKED ATTRIBUTES

Ranked Attributes	
0.1055	Nationality
0.0999	Time
0.076	Date
0.0621	Status
0.0508	Sex
0.0495	Police
0.031	Education
0.025	Age

In the Table II, we notice the most significant attribute affect for crime type is nationality with a weight = 0.105. The second largest attribute is time with a weight = 0.099. The third largest attribute is date with a weight = 0.076. The fourth largest attribute is status with weight 0.062. Next is sex, with a weight of = 0.050. Then police, with a weight of = 0.049. Finally, the last two attributes are education with a weight of = 0.031, and age with a weight of = 0.025.

### C. Preprocessing

First, we selected four major crime typologies out of 10. The Major Crimes are categorized as: (Willful Murder, Aggravated Assault, Rape, Robbery, Theft, Abduction, Grand Auto Theft, Burglary, Drugs, Human Trafficking) due to the Non-disclosure Agreement we cannot declare which four categories we have chosen. We removed any crimes that had missing values due to missing data or compiling errors. This reduced the number of entries to 13,440.

Instead of using exact times, we categorized hours into four periods, 6am to 12pm, 12pm to 6pm, 6pm to 12am, and 12am to 6am. We categorized nationalities into three groups: Gulf Countries (Saudi Arabia, United Arab Emirates, Oman, Kuwait, Bahrain, Qatar), Arab countries (Algeria, Comoros, Djibouti, Egypt, Iraq, Jordan, Lebanon, Libya, Mauritania, Morocco, Palestine, Somalia, Sudan, Syria, Tunisia and Yemen), and rest of world.

To train and validate the data, the dataset is divided into various subsets with 10 folds in cross-validation, the training was on 70% and test was on 30%.

### D. Evaluation Metrics

1) *Accuracy*: The percentage of overall predictions that were correct.

2) *Accuracy*:  $((TP + TN) / (TP + FP + TN + FN)) * 100$

3) *Precision*: Precision reveals the proportion of genuinely positive forecasts among all positive ones. The ratio of accurately positive predictions to all positive predictions is how it is defined.

4) *Precision* = Predictions accurately positive / Total predicted.

5) *Precision* =  $TP / (TP + FP)$

6) *Recall*: Shows how many truly positive values were predicted out of all positive values. It measures the proportion of accurate positive predictions to all the positive examples found in the dataset.

7) *Recall*: It is the ratio of predicted values that came true to actual values in the dataset.

8) *Recall* =  $TP / (TP + FN)$

9) *F1 Score*: It is the harmonic mean for precision and recall values as depicted in Fig. 1. [17]

$$F_1 = \left( \frac{\text{recall}^{-1} + \text{precision}^{-1}}{2} \right)^{-1} = 2 \cdot \frac{\text{precision} \cdot \text{recall}}{\text{precision} + \text{recall}}$$

Fig. 1. F1 equation.

## V. PREDICTION MODELS

### A. Random Forest

During the training phase of the random forests or random decision forests ensemble learning approach (which is used for classification, regression, and other tasks), a large number of Decision Trees are built. For classification problems, the random forest output is the class that the majority of the trees choose. For regression tasks, the mean or average prediction of each individual tree is returned. Random decision forests correct Decision Trees' proclivity for overfitting their training dataset [18] [19] [20] [21].

The classifier used is Random Forest.

### B. (The K-Nearest Neighbor's Algorithm) KNN

The K-Nearest-Neighbours (KNN) is a non-parametric classification method, which is simple but effective in many cases [22]. KNN is a non-parametric classification algorithm, it works as a supervised learning algorithm. A labeled training dataset is provided where the data points are categorized into various classes, so that class of the unlabeled data can be predicted [23].

The classifier used in KNN is IBk.

### C. Support-Vector Machines (SVM)

Support vector machines (SVMs) can be used to handle classification, regression, and outlier problems that are frequently encountered in supervised learning [24].

The mathematical pedigree of SVMs is the best of any statistical learning procedure. It was created as a classifier that maximizes a slightly different definition of a margin, resulting in a novel "hinge" loss function [25]. Weka can classify objects using the support vector machines algorithm [26].

### D. Artificial Neural Networks (ANNs)

Artificial Neural Networks can be defined as systems designed to model functions that simulate the human brain [27]. They are increasingly being used to model complex, nonlinear phenomena [28]. ANNs are nonlinear, adaptive information processing systems that are made up of many interconnected processing units. ANNs have functions such as associative memory, nonlinear mapping, classification

recognition, and optimization computation as an effective empirical modelling tool [29].

The classifier used in ANN is Multilayer Perception.

### E. Naive Bayes

The naive Bayes classifier significantly simplify mastering through assuming that capabilities are impartial given class [30]. Naive Bayes is a probability classification model that makes machine learning easier by performing calculations on datasets with the goal of predicting probabilities in a class under the assumption of strong independence. Classification is a type of directed learning [31].

The classifier used in Naive Bayes is Naive Bayes

### F. Decision Tree

Decision tree is one of the popular predictive modelling approaches used in many areas including statistics, data mining and machine learning [32]. Decision tree classifiers are regarded to be a standout of the most well-known methods to data classification representation of classifiers [33].

The classifier used in Decision Tree is J48 which is a Decision Tree classification algorithm based on Iterative Dichotomiser 3.

## VI. RESULTS

We can summarize the results in Table III:

TABLE III. ALGORITHMS RESULTS

Algorithm	Accuracy	Recall	Precision	F1
Random forest	76.986%	0.77	0.77	0.769
KNN	78.474%	0.785	0.789	0.784
SVM	54.575%	0.546	0.524	0.520
ANN	51.093%	0.511	0.511	0.509
Naïve Bayes	53.526%	0.535	0.516	0.511
Decision Tree (J48)	67.976%	0.680	0.678	0.678

Fig. 2. Accuracy and F1 results.

In the preceding Table III and Fig. 2, we observe that Random Forest and KNN achieve the best results. KNN achieves the best results where accuracy = 78.474%, and F1 = 0.784. Next comes Random Forest with accuracy = 76.986%, and F1= 0.769. Decision Tree achieves good results with accuracy = 67.976%, and F1 = 0.678. SVM, Naïve Bayes, and ANN achieve low performance. SVM achieves accuracy = 54.58%, and F1 = 0.520. Then comes Naïve Bayes with low results of accuracy = 53.526%, and F1 = 0.511. Last comes ANN with the lowest results: accuracy = 51.093%, and F1 = 0.509. For time complexity, Random Forest, KNN, Naïve Bayes, and Decision Tree take seconds while SVM takes minutes. ANN takes more than two hours.

## VII. CONCLUSIONS AND FUTURE WORK

This study compared several popular machine learning algorithms for use in crime prediction, including KNN, Random Forest, SVM, ANN, Nave Bayes, and Decision Tree.

Our findings show that these algorithms can provide useful insights into predicting crime patterns, with KNN having the highest overall accuracy (78.474%) and F1 scores. The performance of each algorithm, however, varied depending on the dataset and crime type being analyzed.

According to our findings, using machine learning for crime prediction has the potential to improve public safety and law enforcement efforts. However, it is critical to recognize the limitations and ethical concerns associated with the use of predictive algorithms in criminal justice systems. Because machine learning models are only as good as the data on which they are trained, it is critical to ensure that crime prediction datasets are diverse and representative of the population. Furthermore, it is critical to address potential biases and avoid discrimination when deploying these models.

Also, by using the correlation, we discovered that adding more attributes, and detaching and elaborating the current data rather than grouping it into periods, may yield better results in the future.

Overall, our research highlights the potential and challenges of using machine learning to predict crime in Dubai. As the field develops, it will be critical to carefully evaluate and refine these algorithms to ensure their accuracy, fairness, and ethical implementation.

We suggest that future work in this area include more variables, such as: data about buildings, street names, exact locations containing longitude and latitude, data about the victims, income, and the relationship between the criminal and victim.

**Abstract**—Wayang, an ancient cultural tradition in Java, has been an integral part of Indonesian culture for 1500 years. Rooted in Hindu cultural influences, wayang has evolved into a highly esteemed and beloved performance art. In the form of wayang kulit, this tradition conveys profound philosophical messages and implicit meanings that resonate with Javanese society. This research aims to develop an artificial intelligence (AI) model using deep learning with the LeNet architecture to accurately classify wayang images. The model was tested with 2515 Punakawan wayang images, showing excellent performance with an accuracy of 80% to 85%. Although the model successfully recognizes and distinguishes wayang classes, it faces some challenges in classifying specific classes, particularly in scenarios 2 and 4. Nevertheless, this research has a positive impact on cultural preservation, as the developed AI model can be used for automatic wayang image recognition. These implications open opportunities to better understand and preserve this rich cultural heritage through AI technology. With further improvements, this model has the potential to become a valuable tool in the efforts to preserve and introduce wayang culture to future generations.

**Keywords**—Wayang; LeNet; artificial intelligence; deep learning; cultural tradition

## I. INTRODUCTION

Wayang, a cultural tradition in Java, has been cherished and recognized by the Javanese people for around 1500 years. Its origins can be traced back to the influences of Hindu culture, particularly in the form of shadow puppetry, which eventually evolved into the renowned wayang performances [1], [2]. Indonesia is rich in folktales inherited from our ancestors, and among them, wayang kulit holds a special place as one of the most beloved and influential stories. Wayang kulit art is highly esteemed, primarily due to its profound philosophical values deeply rooted in the history of wayang kulit [3]. Wayang can be classified into two main types: wayang orang, performed live by human actors, and wayang boneka, controlled by a puppeteer called a dalang. Wayang kulit, a form of puppetry, features intricately crafted wooden puppets dressed in leather attire [4]–[8].

In Indonesia, the term "wayang" generally refers to puppetry [9]. The Javanese language defines "wayang" as shadow, while in Malay it denotes shadow, vagueness, or even transcendence [10], [11]. Wayang represents the embodiment of human qualities, encompassing virtues, greed, and more [12]–[15]. For over a thousand years, wayang has been cherished and embraced by the Javanese community, carrying

implicit meanings that resonate with their local languages. It showcases classical stories and narratives, often derived from the Ramayana and Mahabharata, which have been adapted to Javanese culture while maintaining their Hindu-Indian origins [13], [16]. Wayang performances hold significant value as they go beyond mere entertainment, serving as a form of cultural art that imparts life lessons, education, and guiding principles for living [17].

Wayang holds a versatile nature that allows its application in various contexts [18], [19]. A wayang performance carries numerous valuable lessons and life principles. Notably, it serves as an educational and moral medium, particularly benefiting the younger generation [17]. Wayang encompasses a wide range of types and forms, each possessing its distinct characteristics, influenced by specific regions. In Javanese cultural traditions, wayang exhibits diverse variations and styles, including wayang Gareng, Batara Wisnu, Yudishtira, Werkudara, Arjuna, and others, exemplifying the richness of its cultural significance.

The rapid advancement of technology in Indonesia has had a detrimental impact on the preservation of cultural heritage [20]. Wayang, one of Indonesia's invaluable cultural treasures, has historically played a vital role in shaping character through its insightful advice and captivating stories. However, the visibility of wayang performances has significantly declined, primarily due to a waning interest among the audience [21], [22]. Consequently, younger generations are becoming increasingly unfamiliar with the names and significance of wayang characters.

This diminishing awareness of wayang and other cultural aspects poses a significant challenge in contemporary society. To address this issue, it is essential to explore innovative approaches and leverage technological advancements. Computerization emerges as a potential solution to educate and engage the community effectively. Utilizing techniques such as LeNet classification, computer-based methods can be employed to enhance the understanding and appreciation of various wayang types and other cultural elements. By leveraging technology, we can revive interest, foster cultural appreciation, and ensure the preservation of Indonesia's rich cultural heritage for future generations.

The study introduces a CNN-based approach for recognizing artificial tire-side pressure printing characters on tire surfaces. The method employs image pre-processing with an enhanced SSR algorithm, character localization and

segmentation using template matching, and character recognition utilizing an improved LeNet-5 network structure. Experimental results showcase impressive recognition accuracy, with 95.9% accuracy on the training set, 99.5% accuracy on the validation set, and 95.6% accuracy on the testing set [23].

We propose a novel fault diagnosis model for rotating machinery that overcomes the limitation of directly feeding one-dimensional data into convolutional neural networks. Our model employs a rainbow recursive plot (RRP) to convert vibration signals into two-dimensional color images, allowing for the capture of important fault information. By utilizing a LeNet-5-based CNN, we extract features from the converted images, enabling accurate fault diagnosis recognition. Experimental results on public datasets show a significant improvement in recognition accuracy, reaching 97.86% [24].

Motivated by the strengths and uniqueness of the LeNet method in object classification, this research aims to create a new classification model applied to the case of wayang identification. The selection of wayang as the research case is based on its intricate shapes and the similarities among different types of wayang, posing a challenge in accurately detecting objects with high accuracy.

The explicit objectives of this research are as follows:

- Classify wayang types based on images using the LeNet architecture.
- Evaluate the performance of the classification approach based on the LeNet architecture with depthwise separable method.

## II. EXPERIMENT

### A. Research Architecture

The research architecture built in this study is presented in Fig. 1.

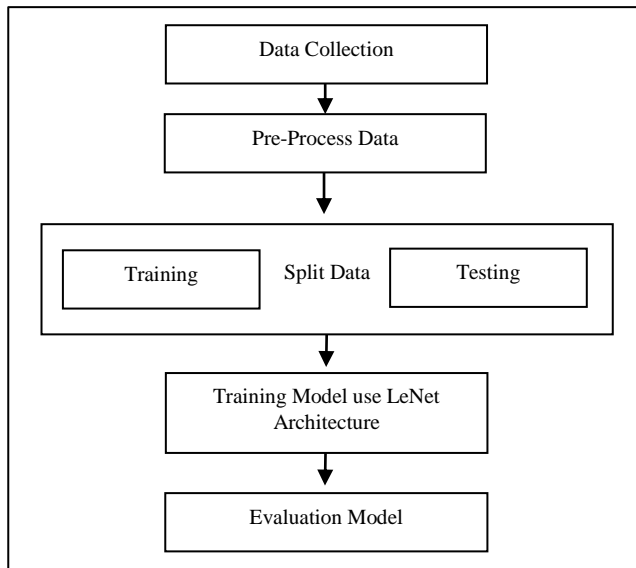

Fig. 1. Research architectural model utilized in this study for wayang classification.

Fig. 1 depicts the research architectural model utilized in this study for Wayang classification. The process begins with data collection, followed by pre-processing, where the dataset is curated to include suitable and unsuitable images as samples. Subsequently, the dataset is divided into three subsets: training, validation, and testing. The LeNet architecture is then employed to construct a deep learning model, utilizing the training set for model training. After the training phase, the model's performance and accuracy are evaluated using the validation set. The evaluation process involves the application of Eq. (1) to (4) to calculate relevant metrics such as accuracy, precision, recall, and F1-score. Finally, the model's effectiveness is assessed by testing it on the independent testing set. This comprehensive approach ensures the robustness and reliability of the developed Wayang classification model.

### B. Data Collection and Pre-Processing Data

In this study, the technique of collecting wayang data was conducted using a smartphone camera at a distance of approximately 30cm. The data collection procedure began by preparing the necessary equipment, which included a high-quality smartphone with a camera. The lighting conditions around the wayang object were then adjusted to ensure adequate lighting. Next, the distance between the smartphone camera and the wayang object was set at around 30cm to ensure optimal focus and capture detailed images. The position of the smartphone camera was also considered to align with the wayang object, avoiding perspective distortion. The camera settings on the smartphone were adjusted according to the needs, including image resolution and appropriate modes. During the photo capture process, the smartphone camera was directed directly at the wayang object without obstructing the light or object with hands or fingers. The captured photos were then examined to ensure clarity and detailed depiction of the wayang images. If necessary, the photo capture process could be repeated to obtain the best results. Thus, the technique of collecting wayang data using a smartphone camera at a distance of 30cm can provide adequate data for further analysis.

After collecting the wayang image data using a smartphone camera, the next step is to preprocess the data to prepare it for further analysis. Wayang data preprocessing involves several important stages. Firstly, the image format and resolution are adjusted to meet the analysis requirements. This includes resizing the images, adjusting the file format, and enhancing image clarity. In this preprocessing stage, efforts are made to remove noise or disturbances that may appear in the images. If necessary, disruptive elements such as shadows or other artifacts are also removed. By carefully following the preprocessing steps, the wayang image data is ready to be used in the next stage of analysis, such as pattern recognition and character classification of wayang. Thorough and meticulous preprocessing ensures the reliability and quality of the data that will be used in this research.

### C. Split Data

In the data analysis of this research, we used a sample of 2515 Punakawan wayang images, consisting of four different types of wayang. The sample was divided proportionally for

training and testing purposes. The training data, which accounts for 80% or approximately 2000 images, was used to train the model for analysis. The testing data, comprising 20% or about 515 images, was used to assess the model's performance and evaluate its ability to classify wayang images. This division is crucial to ensure a good representation of various types of wayang in the dataset and minimize bias in the analysis. Therefore, this data analysis provides a strong foundation for this research and ensures the validity of the results obtained from the developed model.

**D. LeNet Architecture**

LeNet-5 is a convolutional neural network (CNN) architecture designed for image recognition tasks. It was developed by Yann LeCun et al. in 1998 and has become a foundational model in deep learning [25]–[27]. The architecture consists of convolutional layers, pooling layers, and fully connected layers. For LeNet-5, the input is typically a grayscale or color image with a size of 32x32 pixels. The convolutional layers apply learnable filters to extract features from the input image, generating feature maps that capture different aspects of the image. Pooling layers reduce the spatial dimensions of the feature maps, aiding in feature extraction and computational efficiency. Max pooling is commonly used, selecting the maximum value within a specified window. The resulting feature maps are then flattened and fed into fully connected layers for classification. The final fully connected layer produces the output, representing the predicted class probabilities. LeNet-5 has played a significant role in advancing CNNs and remains a widely studied architecture in image recognition. Fig. 2 illustrate the architectural design of LeNet, which was developed for the purpose of classifying wayang.

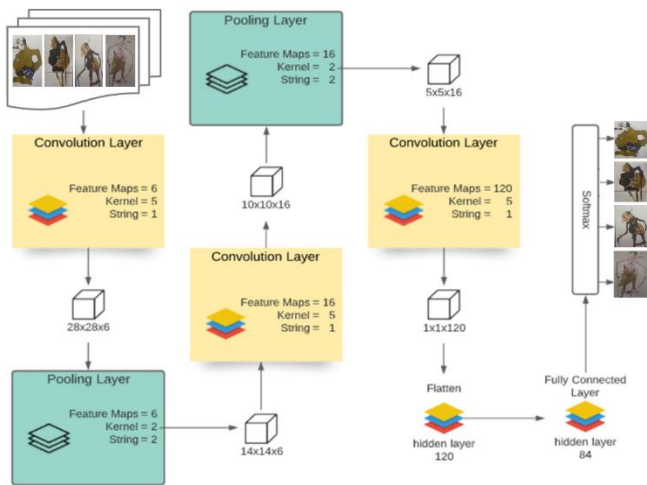

Fig. 2. LeNet architecture.

**E. Hyperparameter Initialization**

Learning parameters play a crucial role in the accuracy and performance of a model during training. This study explores several important learning parameters, namely Epoch, Batch size, Optimizer, and activation functions. Epoch determines the number of times the entire dataset is used during training. A higher epoch value increases the number of iterations but may lead to overfitting. Batch size refers to the number of data

samples used in each iteration. A larger batch size enhances training speed but may impact generalization. Optimizer algorithms like SGD, Adam, and RMSprop optimize the model during training, each with its strengths and weaknesses. Activation functions introduce non-linearity, such as ReLU, Sigmoid, and Tanh, influencing convergence speed and feature representation. Selecting appropriate learning parameters is crucial for achieving optimal model performance. Careful experimentation and parameter tuning are necessary to find the most suitable combination for each specific task and dataset. The candidate hyperparameters utilized in this study are outlined in Table I.

TABLE I. HYPERPARAMETER MODEL

Parameter	Candidate
Epoch	(10, 50, and 100)
Batch Size	(10,20,40,60,80,and 100)
Optimizer	(SGD, RMSprop, Adagrad, Adam and Nadam )
Activation function	(Tanh, Relu, Linear, Sigmoid, Softmax)

**F. Performa Measure**

The confusion matrix is a valuable method for evaluating the accuracy of an object estimation model. It compares the predicted classification results with the actual classes and provides a detailed view of the model's performance [28]–[30]. The accuracy of the method reflects how well the predicted values align with the actual values. Precision, on the other hand, measures the repeatability of the measurements or the proportion of accurate predictions. Recall represents the number of correct positive responses identified by the model. Combining precision and recall yields the f1-score, which gives a balanced average assessment of the model's performance. These metrics can be calculated using the following formulas, where TP, TN, FP, and FN represent true positive, true negative, false positive, and false negative, respectively [31]–[33].

Description

TP = True Positive

FP = False Positive

FN = False Negative

TN = True Negative

$$Accuracy = \frac{TN+TP}{TN+FP+TP+FN} \tag{1}$$

$$Precision = \frac{TP}{TP+FP} \tag{2}$$

$$Recall = \frac{TP}{TP+FN} \tag{3}$$

$$F1 = \frac{2*Presicion*Recall}{Presicion+Recall} \tag{4}$$

**III. RESULT AND DISCUSSION**

In this session, we present the research results on wayang classification using the deep learning architecture LeNet. Two scenarios were built to extract information from object images, namely using the default LeNet and implementing the

depthwise separable method. Depthwise separable is a data processing technique in neural networks that combines two convolution stages: depthwise convolution and pointwise convolution. Depthwise convolution applies filters to each input channel separately to reduce the number of parameters [34], [35]. Furthermore, we conducted a search for the best hyperparameters to improve model performance using Grid search. This approach aims to achieve optimal model performance by selecting the right combination of hyperparameters, enabling the model to provide accurate and efficient results in the wayang classification training and testing process.

### A. Samplel Wayang

Fig. 3 illustrate the unique characteristics of each wayang character. In this image, Bagong is seen with a cheerful face full of wit, while Gareng appears loyal and friendly with a heartwarming smile. Additionally, Petruk's image portrays a funny yet clumsy figure, bringing joy with his comical expressions. On the other hand, the image of Semar presents a wise and gentle character with a gaze full of understanding. Through these images, the distinctiveness and roles of each character in wayang performances can be clearly explained, enhancing the charm and allure of Indonesia's wayang art. The beauty and profound meaning depicted in Fig. 3 enables the audience to appreciate and understand the local wisdom and cultural richness of Indonesia that emanate from this traditional wayang art.

Fig. 3. Indonesian wayang characters (a) Bagong, (b) Gareng, (c) Petruk, and (d) Semar.

### B. Training LeNet

The deep learning architecture based on LeNet is designed for image classification, as depicted in Fig. 2. The input is a 32x32x1 image, with the last dimension representing the color channel. The network includes two convolutional layers with 28 and 10 filters, followed by 2x2 max pooling layers to reduce feature map size. Rectified Linear Unit (ReLU) activation functions are used in the convolutional layers. After the second pooling layer, the output feature maps are flattened into a 120-dimensional vector. Dropout is applied to prevent overfitting by randomly zeroing input units during training. The dropout output then goes through a fully connected layer with 84 neurons using the dense activation function. Batch normalization is employed to normalize activations and improve model stability. ReLU is a popular activation function for its efficiency and performance improvement. Max pooling down samples feature maps to extract essential characteristics and enhance the network's effectiveness. A flatten layer transforms the output of the last convolutional layer into a 1D vector, followed by a fully connected dense layer. The final classification is determined by this layer, using the softmax

activation function to generate probability scores for each class. The output layer produces the final classification predictions.

Based on the results of training the LeNet model on the wayang classification task, as presented in Fig. 4, a total of 61,496 parameters were obtained. These parameters encompass all the weights and biases that are fine-tuned and optimized throughout the training process. The overall count of parameters serves as an indicator of the model's complexity and capacity to discern patterns and features from the data. A greater number of parameters empowers the model to acquire intricate data representations. However, this must be carefully balanced against the potential for overfitting and the increased computational demands.

Fig. 4. Training model LeNet (scenario 1).

The evaluation of deep learning models during training is primarily based on two key metrics: training loss and validation loss. Training loss measures the discrepancy between the predicted and actual values on the training data, while validation loss measures the discrepancy on the validation data. It is crucial to analyze both training and validation loss to obtain a comprehensive understanding of the model's performance. For visualizing the performance of the proposed algorithm, Fig. 5 presents the performance visualization, which incorporates both training and validation loss.

Fig. 5. Training and validation model LeNet (Scenario 1).

C. Training LeNet with Depthwise Separable

In this scenario, the deep learning model was constructed with the same architecture as the previous model, but with the integration of the depthwise separable approach to effectively diminish the total number of parameters. Following the application of the depthwise separable approach, the entire model comprises a total of 58,985 parameters. This represents a notable reduction in the parameter count compared to the previous model, all while maintaining the quality of the classification performance, as illustrated in Fig. 6.

Fig. 7. Training and validation model LeNet with depthwise separable (Scenario 2).

D. Hyperparameter tuning

In this scenario, we used grid search to tune the hyperparameters of the LeNet model for both Scenario 1 and Scenario 2. Grid search is a systematic technique that allows us to explore various combinations of hyperparameter values. By experimenting with different combinations, we can find the best hyperparameter settings in terms of model performance and generalization for the wayang classification task. The results of tuning the hyperparameters for each scenario are presented in Table II. Additionally, to visualize the training and validation performance of the model, the training and

validation curves for each scenario are shown in Fig. 8 and Fig. 9, respectively. These graphs provide a visual representation of how the model learns and adapts during the training process.

E. Evaluation

The findings of four scenarios utilizing the confusion matrix are depicted in Fig. 10, providing a valuable tool for evaluating model performance in classification tasks. The study employed the confusion matrix to assess four distinct scenarios' outcomes in data classification. By utilizing this matrix, we gauge the model's accuracy in classifying data accurately. Information from the confusion matrix aids in calculating essential performance evaluation metrics like precision, recall, accuracy, and F1-Score.

Furthermore, the performance metrics for the four scenarios are presented in Tables III-VI, offering a comprehensive evaluation of the model's classification performance. These tables present precision, recall, accuracy, and F1-Score for each scenario, crucial for assessing the model's effectiveness. Table III corresponds to Scenario 1, Table IV to Scenario 2, Table V to Scenario 3, and Table VI to Scenario 4. Analyzing these metrics allows us to determine the model's performance in various scenarios, facilitating comparisons to identify the most suitable approach for the classification task at hand. These tables play a pivotal role in comprehending the strengths

and weaknesses of each scenario, guiding data-driven decisions to optimize and enhance the model's classification performance. The confusion matrix analysis and performance metrics' results provide valuable insights into the model's capabilities, enabling us to refine and fine-tune it for improved classification results.

Fig. 10. Confusion Matrix Results (a) Scenario 1, (b) Scenario 2, (c) Scenario 3, and (d) Scenario 4.

TABLE III. LEnET PERFORMANCE IN SCENARIO 1

	Precision	Recall	F1_score
<b>Bagong</b>	0.81	0.79	0.80
<b>Gareng</b>	0.87	0.76	0.81
<b>Petruk</b>	0.78	0.96	0.86
<b>Semar</b>	0.90	0.81	0.85
<b>Accuracy</b>	0.83		

TABLE IV. LEnET PERFORMANCE IN SCENARIO 2

	Precision	Recall	F1_score
<b>Bagong</b>	0.80	0.85	0.83
<b>Gareng</b>	0.89	0.67	0.76
<b>Petruk</b>	0.75	0.93	0.83
<b>Semar</b>	0.78	0.74	0.76
<b>Accuracy</b>	0.80		

TABLE V. LEnET PERFORMANCE IN SCENARIO 3

	Precision	Recall	F1_score
<b>Bagong</b>	0.83	0.87	0.85
<b>Gareng</b>	0.90	0.76	0.82
<b>Petruk</b>	0.90	0.93	0.92
<b>Semar</b>	0.81	0.87	0.84
<b>Accuracy</b>	0.85		

TABLE VI. LEnET PERFORMANCE IN SCENARIO 4

	Precision	Recall	F1_score
<b>Bagong</b>	0.73	0.84	0.78
<b>Gareng</b>	0.77	0.74	0.76
<b>Petruk</b>	0.88	0.84	0.86
<b>Semar</b>	0.82	0.78	0.80
<b>Accuracy</b>	0.80		

In Scenario 1, the model achieved an accuracy of 83%. The evaluation results showed good performance in classifying all wayang classes. Petruk had the highest precision and recall values, indicating its excellent ability to identify the Petruk class. Bagong and Semar also had good F1\_score values, indicating a balance between precision and recall. However, it should be noted that the precision for Petruk and Semar classes was slightly lower than recall, possibly due to some difficulty in classifying complex samples.

In Scenario 2, the model achieved an accuracy of 80%. There was variation in performance among the wayang classes. Gareng had a lower recall value, indicating some difficulty in accurately recognizing the Gareng class. Bagong and Petruk had good F1\_score values, but the precision for the Petruk class was lower than recall. Semar had low F1-score values, suggesting challenges in classifying the Semar class accurately.

In Scenario 3, the model achieved an accuracy of 85%. The model showed consistent performance for all wayang classes with high F1\_score values. The Petruk class had the highest precision and recall values, indicating an excellent ability to classify this class. The Gareng class also had a good F1\_score. These results indicate that the model has a strong ability to recognize and distinguish between different wayang classes.

In Scenario 4, the model achieved an accuracy of 80%. Precision and recall for all wayang classes were relatively balanced, but the F1\_score for the Gareng and Semar classes was slightly lower than other classes. It is important to note that the model showed some difficulty in accurately classifying the Gareng and Semar classes.

Overall, the evaluation results indicate that the model has good performance in classifying the wayang classes. However, there is some variation in performance among specific classes, which could be the focus of further model improvements. Careful evaluation of all performance metrics can help identify areas where the model can be enhanced to achieve better results in wayang classification tasks.

F. Discussion

The evaluation results of the four wayang classification scenarios show good performance in classifying wayang images. All scenarios achieve relatively high accuracy, ranging from 80% to 85%. Additionally, the precision, recall, and F1-Score values are balanced, indicating the model's ability to classify wayang images accurately and consistently. The best scenario is Scenario 3, which achieves an accuracy of 85% with a high precision of 86%, recall, and F1-Score of 85.75%. This demonstrates that the model in this scenario excels in classifying wayang images with great accuracy. On the other hand, the worst scenario is Scenario 2, with an accuracy of 80% and slightly lower precision, recall, and F1-Score compared to the other scenarios. Although it still performs well, this scenario can be improved to achieve higher accuracy and consistency. Overall, the evaluation results indicate that the developed model performs well in the wayang classification task and is reliable for further analysis. The best and worst scenarios can serve as a basis for further improvements and the development of more optimal models in wayang image recognition.

The AI models developed using the deep learning approach with LeNet (Scenarios 1, 2, 3, and 4) exhibited better performance compared to AI models using other methods such as KNN + GLCM [5] and MLP + GLCM [36]. The LeNet-based AI models achieved higher accuracy and more balanced precision, recall, and F1-Score, as shown in Table VII.

The results of this study provide insight into the effectiveness of using depthwise separable LeNet models in image-based puppet classification. This contributes to the development of better classification techniques in the domain of puppet recognition. Moreover, the use of depthwise separable is able to reduce the total number of model parameters, which indicates efficiency in the use of computational resources, although the addition of depthwise separable affects the level of accuracy gain.

In future research, there are several recommendations that can be considered. First, increasing the amount of puppet image data can help improve the performance of the model. Second, further exploration of hyperparameters and optimization techniques can be an important step in improving classification accuracy such as random search and Bayesian optimization. In addition, future research can consider the use of attention modules to improve the model's ability to deal with a larger variety of wayang images.

TABLE VII. COMPARISON WITH PREVIOUS STUDIES

Study (Ref)	AI Model	Accuracy	Precision	Recall	F1-Score
Sandy et al [5]	KNN + GLCM	0.775	-	-	-
Muhathir et al [30]	SVM + GLCM	0.834	-	-	-
Santoso et al [36]	MLP + GLCM	0.734	-	-	-
Scenario 1	Lenet	0.83	0.84	0.83	0.83
Scenario 2	Lenet	0.8	0.805	0.7975	0.795
Scenario 3	Lenet	0.85	0.86	0.8575	0.8575
Scenario 4	Lenet	0.8	0.8	0.8	0.8

#### IV. CONCLUSION

This research contributes to the development of AI models for wayang image classification using deep learning with the LeNet architecture. The AI models developed show superior performance in classifying wayang images compared to models using other methods such as KNN + GLCM and MLP + GLCM.

The evaluation results indicate that all wayang classification scenarios achieve relatively high accuracy, ranging from 80% to 85%. The precision, recall, and F1-Score values are well-balanced, demonstrating the model's ability to classify wayang images accurately and consistently. However, there is variation in performance among specific wayang classes, suggesting potential areas for further model improvements. Careful evaluation of all performance metrics

can help identify these areas and enhance the model's performance in wayang classification tasks.

The research has the potential to benefit cultural recognition and preservation, as the developed AI model can be used for further analysis and automated recognition of wayang images. However, the study has some limitations, such as the size of the dataset and the complexity of wayang images, which may affect model performance. Therefore, future research should consider augmenting the data and exploring alternative deep learning approaches or combining different methods to further enhance the model's accuracy and robustness in wayang image recognition.

King Abdulaziz University, Jeddah 21589, Saudi Arabia<sup>1</sup>

**Abstract**—Diabetes mellitus has become a global epidemic, with an increasing number of individuals affected by this chronic metabolic disorder. Effective management of diabetes requires a comprehensive self-care approach, which encompasses various aspects like monitoring blood glucose levels, adherence to medication, modifications in lifestyle, and regular healthcare monitoring. Innovative techniques for bettering diabetic self-care management have been developed recently as a result of developments in technology and healthcare systems. This comprehensive review examines the modern methods that have emerged to enhance diabetes self-care management systems. The review focuses on the integration of technology, Behavioural Change Techniques (BCTs), behavioural health theories such as Transtheoretical Model (TTM), the Health Belief Model (HBM), Theory of Reasoned Action/Planned Behaviour (TPB), Social Cognitive Theory (SCT) techniques to promote optimal diabetes care outcomes. The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 standards were followed in this research's documentation. The Systematic Literature Review (SLR) period, which covered 2009 to 2020, was used to acquire the most recent complete review. Overall, the SLR results show that self-care interventions have a favourable impact on behaviours modification, the encouragement of good lifestyle habits, the lowering of blood glucose scales, and the accomplishment of significant weight loss. According to the review's findings, treatments for diabetic self-management that included behavioural health theories and BCTs in their creation tended to be more successful. In order to assist academics and practitioners with the creation of future applications, the restriction and future direction were finally defined. After recognising the potential for combining BCT methodologies and theories, it creates self-management interventions. Depending on these recognised cutting-edge mechanisms, the current SLR can assist application developers create a model to construct efficient self-care interventions for diabetes.

**Keywords**—Diabetes self-care; diabetes management; systematic literature review; BCT theories

## I. INTRODUCTION

Diabetes is a serious condition caused due to high blood sugar levels. High blood pressure, renal disease, and heart failure may all occur as a result of this chronic illness [1]–[4]. Type 1 diabetes and Type 2 diabetes represent two different types of diabetes. While Type 2 diabetes, which accounts for roughly 90% of all cases, is the most common type, Type 1 diabetes, which can't be prevented, is characterised by inadequate insulin in youngsters. A major issue faced by the health system is the rising incidence of diabetes, which has

turned into a global crisis. For example, according to the National Diabetes Statistics Report, 13% of Americans have diabetes. Global estimates indicate that 9% of people worldwide have diabetes, and that number is expected to rise to 12% by 2030 [5]. Ageing, obesity, and people's dietary habits are thought to be contributing factors to the rising number of diabetes [3]. These troubling trends highlight the critical requirement for researchers and technologists to develop practical diabetes treatment strategies. Several applications have been created for managing diabetes self-care as a result of the rise of diabetes cases in the world. Applications for managing diabetes are believed to be among the most popular ones from the Google Play store [4]. Numerous studies have demonstrated that diabetes self-care practises can considerably enhance a range of clinical outcomes for diabetics [5], [6]. In earlier studies, the effectiveness of diabetes self-care tools was qualitatively investigated [7], [8]. Additionally, a number of meta-analyses [9]–[11] have examined the usefulness of self-care tools for managing diabetes using quantitative data. The majority of previous investigations, nevertheless, ought to have uncovered the impact of BCTs on self-care management [11], [12]. Besides self-monitoring, the major problem with the existing system models is that the majority of the current mHealth apps make limited usage of BCTs and have few features [13], [14]. Moreover, the absence of customized feedback, poor user interface design, and accessibility concerns with current medical monitoring programmes are further problems (e.g. limited data entry options) [7], [15]–[17]. Additionally, diabetes patients think that e-self-management health applications should be interesting and provide a variety of functions that cover an extensive amount of information encompassing emotional and psychological support [18]. The impact of individual BCTs on diabetes management cannot be discounted because managing diabetes is strongly related to behaviour that requires appropriate modification [19]–[22]. Therefore, it seems like there is a lot of uncertainty if these mobile and web-based healthcare applications are an affordable means to give diabetes self-management education and whether they improve health outcomes and provide support in the real world [19], [20], [23].

The study aims to comprehensively review and analyze modern methods designed to enhance diabetes self-care management systems. The formulation of research questions (RQs) is crucial for determining the overarching goals and anticipated results of a study. The study mainly focuses on the research question “How can we use technology and

behaviour-based techniques to make diabetes self-care better and healthier for people with diabetes?" To find a solution for this question, following research questions are framed.

- 1) How well do diabetes management applications support and facilitate diabetic self-care practices?
- 2) What are the prevailing methodologies and techniques commonly utilized in the realm of diabetic self-care management to facilitate behavior modification?
- 3) Which theoretical frameworks and models can be effectively employed to underpin and guide the progress and application of diabetes self-care management applications?
- 4) What common aspects do diabetic self-care management programmes use today to effectively and completely treat the disease and empower patients?
- 5) What are the intricate challenges encountered in the current landscape of diabetes self-care applications, and what are the anticipated future directions and potential advancements?

In order to answer this question, the research builds following research objectives: i) to evaluate the extent to which existing diabetes management applications effectively support and facilitate self-care practices among individuals with diabetes. ii) to identify and analyze the methodologies and techniques commonly employed within the domain of diabetic self-care management. This includes an examination of strategies for behaviour modification and lifestyle improvement, iii) to explore and assess the theoretical frameworks and models that can be leveraged to underpin and guide the development and implementation of diabetes self-care management applications. iv) to identify the common elements and best practices employed by successful diabetic self-care management programs to comprehensively address the disease and empower patients in their self-care journey, v) to investigate the intricate challenges and limitations present in the current landscape of diabetes self-care applications. It will also explore anticipated future directions and potential advancements in the field to enhance the efficacy and usability of these applications.

The key significance of this study is that it underscores the importance of addressing various facets of diabetes management beyond medication, including lifestyle modifications and monitoring. It also offers valuable insights into how psychological and behavioral principles can improve diabetes self-management. It serves as a roadmap for future researchers and application developers to develop a more effective tools and interventions for diabetes self-care.

The rest of the sections are given as follows: Section II provides the detailed investigation of literature works on diabetes self-management and healthcare behavioral models, diabetes management interventions. Section III briefs the review methodology that comprises of the selection of articles for the review process. Section IV details the search results and analysis, and Section V briefs the outcomes and findings of the research questions. Section VI provides the overall discussion and Section VII finally concludes the study.

## II. RELATED WORKS

### A. Diabetes Mellitus

A major wellness concern and pandemic disease with a high incidence in both emerging and industrialized nations, diabetes impacts people all over the globe [24], [25]. As per the World Health Organization, diabetes is a chronic disorder with a variety of causes. The characteristic of this illness is prolonged hyperglycemia with abnormalities in carbohydrate, lipid, and protein metabolism induced by impairments in insulin action, insulin synthesis, or both. Additionally, diabetes-related complications and mortality could cause serious economic and social consequences for people, families, enterprises, and society overall [26]. People and medical institutions all across the world are being plagued by this epidemic [27], [28]. Diabetes presents a variety of dangerous side effects, involving dysfunction or long-term damage, and also organ failure [29]. There are numerous causes that might lead to a chronic illness like diabetes, but the following are the most typical ones: the pancreas' insulin is not generated properly or the pancreas has been unable to produce enough insulin. Additionally, if left untreated, increased blood glucose levels, also known as hyperglycemia, raise the risk of long-term harm to a range of organs, including blood vessels and neurons. Some of the diabetes-related symptoms include increased urine and weight loss, weariness, and increased appetite and thirst [30], [31].

Type 1 diabetes affects 10-15% of all diabetics and can appear at any age, with the majority of cases occurring in those under 40. It can be triggered by a range of critical variables such as infections, diet, and toxins in those who are genetically predisposed. An investigation [32] found that people with diabetes who have Type 1 have life expectancies that are around twelve decades lower than those of the entire community. The second type of diabetes, often called non-diabetes, has become the most frequent. It is responsible for 85-90 per cent of all diabetic patients [33]. Diabetes that occurs later in life is referred to as "late-onset diabetes." Dietary changes, a regular fitness routine, and medications could be treated Type-2 diabetes effectively. The third type of diabetes is gestational diabetes. Diabetes develops during pregnancy, unless the pregnant women already have been diagnosed, as a result of enhanced glucose levels or insulin levels. According to the International Diabetes Foundation, around 16% of women giving birth in 2019 have DM during pregnancy, with GD accounting for 85.1% of the total [34].

### B. Self-Management of Related Activities

The expression "self-management" denotes the routine tasks or activities that an individual needs to carry out for managing or lessening the effects of disease on their wealth and wellness in order to avoid further illness [35]. Medication adherence, physical exercise, healthy diet, monitoring, good coping, risk reduction, and problem-solving all seem to be examples of diabetes self-management practises that are important for better preventive measures [36]. Patients' adherence to diabetes self-management differed, showing that a number of factors will influence self-management decision-making mechanisms, either as enablers or as obstacles [37]. The care of diabetes mellitus is crucial for reducing long-term

effects and enhancing the T2D patients' quality of life. As per the American Diabetes Association, diabetes self-management-based education has been a pillar for optimum diabetes care. One viewpoint is that the complexity of T2D management necessitates the usage of DSME. Patients are assigned a variety of responsibilities, including a keeping regular doctor's appointments, confirming prescription schedules, and concentrating on self-care measures like online glucose tracking, healthy food modifications, and enhanced physical exercise [38]. However, people frequently struggle to maintain the many behavioral factors necessary for optimum glycemic control. Struggling to meet daily obligations, irritation, various types of mental discomfort, and an absence of self-commitment are all frequent problems [39]. Moreover, patients' levels of commitment to diabetic self-management varied, implying that many factors can affect self-management decision-making processes that could function as facilitators or barriers. DM management is critical for minimising long-term consequences and enhancing T2D patients' quality of life [36]. Therefore, consistent diabetic self-management was already linked to improve fewer complications [40], [41], blood glucose control, better quality of life, and a less peril of diabetes-related mortality [35]. Family members were able to offer both emotional and physical support. Instrument assistance could involve assisting patients with various chores, such as making appointments with healthcare providers or aiding with insulin treatment, and also assisting patients through self-management care. Providing delight and motivation to patients who've been frustrated or unhappy as a consequence of their therapeutic intervention is a common form of emotional support [8], [42]. Additional behavior change treatments are necessary because conventional techniques are ineffective at modifying behaviours [43]. In order to communicate with patients as well as give them the tools they need to manage their individual health; a web-based system is a suitable choice [13]. It has been demonstrated that diabetics' glucose levels could be improved through the implementation of mobile and internet-based diabetes care strategies [44].

### C. Concepts and Paradigms of Health Behavior's Impact on Diabetes Management Interventions

Theories of behavioural change aid in understanding human behaviour and change. They provide justification for why particular acts occur. These ideas are crucial for altering behaviour to improve health consequences [45]. Current years have seen the application of these theories to the management of persistent adherence to prescribed drugs and lifestyle changes [46]. Interventions for changing behaviour related to health may be more successful if they are based on the right hypothesis [47]. Through the identification of specific mediators—behaviour-causing variables, change-causing factors, and the mechanisms by which they operate during an intervention—theoretical models shed insight on basic concepts [48]. The following theoretical models are frequently used for strategizing and assessing public health behavioural change interventions: Health Belief Model (HBM), Transtheoretical Model, Social Cognitive Theory, Social Ecological Model, and Theory of Reasoned Action/Planned Behaviour [49], and Information-Motivation-Behavioural Skills models [50].

The Trans theoretical Model, also called as the Phases of Transformation Model [51], is one of the most well-known theories or models for health behaviour change that places a strong emphasis on the person's capacity for decision-making. Prochaska and DiClemente [52] created this model in the late 1970s based on research comparing the experiences of people who modify their conduct on their own to those who get therapy and how capable they are of doing so. This study's framework is based on this model. TTM underlines that people don't alter their behaviours right away but rather gradually, consistently, and through a cyclical process. There are five stages of change that individuals can go via in accordance with TTM: contemplation, planning, action, servicing, and relapsing [53]. When changing their lifestyle, everyone, even those with diabetes and prediabetes, typically goes through these stages. TTM provides comprehensive instructions on how to assist diabetics and prediabetics in making lifestyle and dietary changes that will promote healthy behaviour. The Theory of Reasoned Action (TRA) is expanded upon by the Theory of Planned Behaviour (TPB). Icek Ajzen put out this notion in 1985. According to TPB, an individual's willingness and degree of control over an activity impact how vigorously that behaviour will be carried out. An individual's behavioural intents and behaviour are influenced by their attitude towards a conduct, subjective standards, and perceived behavioural control [48], [54]. According to this principle, the concept of Personality is indirectly affected by beliefs that are influenced by background and demographic information like education, income, personality characteristics, prior behavior's, and aspects of the social and cultural environment [55].

The attitude towards behaviour, the importance others place on the behaviour, and the degree of perceived behavioural control all affect how strong an intention is. This applies to people with diabetes and prediabetes because in order to modify their conduct, they must also alter their mindset. They must also identify the triggers that encourage change [54]. The main significant factor influencing people's behaviour is their want to modify [54]. When patients want to change, they might alter their food and way of life. To forecast human social conduct, this theory is frequently applied and quoted [56]. Self-determination theory (SDT) encourages individuals to act in productive and beneficial ways. SDT emphasises a person's level of self-motivation and self-determination. Objectives and the pursuit of objectives are stressed in SDT. It suggests that what we are working for and why we are working towards it are both crucial for our wellbeing [57], [58]. According to the belief, if someone may pursue their objectives in their own way rather than being forced to adhere to rigorous rules, they would be happier and more successful. When someone pursues their goals for their own reasons and through their own ways, they would be happy and self-actualized [59]. By focusing on health-related advantages, patients will be more likely to accept personal responsibility for their health. The objectives for this must be independent and intrinsic. They should let to choose their own realistic goals. According to studies, SDT therapies for diabetes resulted in successful treatment outcomes [60]. It also encourages individuals by allowing them to identify the driving force behind transformation. Additionally, it is

observed that goal-setting is effective when supported by encouraging and compassionate individuals as opposed to dominating or directive people [61].

The Health Belief Model [62], [63], was created in the 1950s to address why certain individuals do not utilise the available health treatments. According to HBM, perceived vulnerability, severity, advantages, and obstacles all have an impact on conduct. The model describes and forecasts behaviour connected to health, including attitudes about one's health issues, the perceived advantages of taking action, obstacles, and self-efficacy in engaging in health-promoting activity. The health-promoting conduct should be triggered by cues to action. This approach was initially developed by social psychologists at the United States Department of Health and Human Services [64]. The concept of "perceived vulnerability" describes the probability that a person believes to be susceptible to get the illness if they continue with their current behaviors. On the contrary, perceived severity describes how serious the ailment is and how it affects people [65]. The perceived threat changes as a consequence of these behaviors. When people alter their behaviour, there could be apparent benefits or shortcomings of putting the unique activity into practise, among them perceived difficulties which could prevent the successful effectiveness, as well as both. For example, there might be perceived reduction in their chances of getting sick. The four factors mentioned above work together to affect the likelihood of participating in the behaviour. Information on the dangers and consequences of diabetes should be given to patients. Individuals must be made aware of the seriousness of the condition in order for them to change their bad behaviours and adopt healthy ones. Additionally, the advantages and drawbacks of their new outlook and behaviour ought to be explained to them. This should encourage individuals to adopt new habits and maintain their commitment to an improved diet and way of life [66].

Self-Regulation Theory describes the steps and elements involved in making decisions about one's thoughts, feelings, words, and actions. Self-regulation is concerned with the mechanisms that convert beliefs into intentions and intentions into actions, which ultimately results in the accomplishment of the connected objective. This idea focuses on a person's capacity to control their behaviours and their lives [67], [68]. SRT is made up of four components: requirements for desired behaviour, the drive to sustain standards, awareness of the conditions and thoughts that proceed standards-breaching, and willpower. SRT is centred on the idea of people setting the goals and monitoring their development in respect to those goals [69]. When there is a difference between their present situation and their aim during the comparison, individuals adjust their activities and behaviour in order to reach the goal. Diabetics should have the internal fortitude to alter their conduct in order to adjust their food and lifestyle. They should be self-motivated and devoted, with the purpose of transforming coming from inside. Self-control is crucial for developing new habits and viewpoints [70]. It aids patients in committing to their new conduct. In addition, students become more driven to accomplish their goals when they may define their own objectives and assess their progress in relation to

those objectives [71]. The Relapse Prevention Model seeks to impart knowledge on how to anticipate and address the issue of recurrence to persons wanting to change their behaviour's. Relapse occurs when a person fails to alter their conduct to match the desired behaviours. This approach proposes two methods for preventing relapses, which may be used either as a targeted maintenance plan or as a more comprehensive programme of lifestyle modification. The major goal of this paradigm is to change compulsive or addictive behavioural patterns.

One of the most well-liked theoretical paradigms for comprehending and altering health-related behavior's targeted at controlling persistent diseases is social cognitive theory (SCT). The SCT has proven significant behavioural changes leading to better health outcomes as the cornerstone of efficient illness self-management strategies [72], [73]. It began as the Social Learning Theory, which was referred to be the convergence of the cognitive and behaviourist approaches. Contrary to many other hypotheses of behavioral modification in health promotion, the concept of the SCT takes into consideration the unique ways that individuals develop and sustain a habit. In the most recent version of social cognitive theory, a complex causal structure is proposed in which beliefs about self-efficacy interact with knowledge of health hazards and advantages, targets, standards for the results, structural and social obstacles to modification, and the perceived facilitators of behavioral growth. In the temporal framework of the Social Comparative Theory self-efficacy plays a crucial regulatory function and is a fundamental belief that significantly impacts behaviour [74]. As per the Social-Cognitive Theory (SCT), interactions between the environment, a person's characteristics, and their behaviour affect behaviour change. The most significant influence on the acceptance of physical activity as a lifestyle change has come from the Social-Cognitive Theory [75]. It uses both cognitive and behavioural elements to encourage behaviour modification, comparable to the TTM [76]. Self-efficacy is the central construct of the social cognitive theory, but it also includes the concepts of social support, outcome expectancies, and self-regulation [77]. According to recent studies, while boosting a person's self-efficacy is vital for enhancing physical activity and exercise adherence, doing so is most successful when combined with using the other SCT elements. For the specialized maintenance approach, attention should be focused on strengthening the maintenance of behavior change, once a person has successfully predicted a behaviour change. The maintenance of behavioral change might take the shape of ongoing meetings, treatments, and other techniques that can make it last longer. Regarding the general one, the emphasis should be on facilitating variations in a person's habits and way of life. This general program's objectives are to instruct the client on how to live a balanced lifestyle and to stop the development of negative habit patterns [78].

The Information-Motivation-Behavioral Skills (IMBS) paradigm promotes the user-centered and evidence-based application of information in health-related situations [79], [79], [80]. It was first created to anticipate HIV preventive behaviour in response to the HIV epidemic. It was effectively used in the design of treatments that enhanced and predicted

adherence to medication among diabetic patients [81]. The IMBS offers a framework for comprehending and supporting disease prevention practises across populations, and it has a wide range of possible applications in health promotion practise [82]. The model focuses on a collection of components (factors) linked with illness management in terms of information, motivation, and behavioural skill. The model claims that behavioural changes are primarily brought about by changes in behaviour that occur as a consequence of informational and motivational interventions [80]. The third part of the model shows how knowledge, motivation, and the behavioural abilities needed to carry out self-management behaviours independently and to a substantial amount indirectly influence actions. When they regularly found a strong correlation among behavioural outcomes and IMBS and in cases of diabetes, academics and educators in diabetes health promotion have used IMBS. Information and motivation affect the behavioural skills of diabetes patients, ensuring that they have the resources necessary to engage in the desired actions. Finally, this boosts a patient's self-efficacy, or belief in their ability to carry out self-management actions [83]–[85].

#### D. Diabetes Prevention and Management Interventions

Diabetes is a chronic illness with a high incidence in many countries. It is marked by raised blood glucose levels and the possibility of both acute and chronic complications. It is generally recognized that treating diabetes is a difficult procedure that necessitates both a specific pharmacologic treatment plan and a change in lifestyle [86]. Effective behavioural change, thorough education, and self-management are some of the most important ways to prevent complications from diabetes. However, this procedure is time-consuming and costly. Recent research on the use of smartphone technology for managing diabetes has shown to be a useful tool for lowering haemoglobin levels, particularly in Type-2 diabetic (T2D) patients. The effectiveness of this approach among Saudi patients has not, however, been the subject of any recognised studies [87]. Diabetes management is a difficult procedure that needs a wide-ranging strategy. Pharmacologic therapy is crucial, but it must be supplemented with lifestyle changes such a nutritious diet, frequent exercise, and careful blood glucose monitoring. People with diabetes can effectively manage their illness lower their risk of complications, and lead satisfying lives by using these techniques. In order to support diabetic self-management (DSM), mobile phone applications are frequently utilised. Numerous apps have been created to improve diabetic self-management [87]–[120].

Numerous studies have found compelling proof that employing apps motivates individuals to stick to management medical care, enhances glycemic control, and delays or avoids the onset of diabetic complications while also improving their standard of life [10], [121]. Additionally, studies revealed that applications for diabetes self-care can dramatically enhance a number of clinical outcomes related to diabetes [5], [6]. Earlier research examined the effectiveness of self-care applications for diabetes qualitatively [7], [8]. Users' desires and requirements for self-empowerment applications, however, have changed over time. For example, prior to this,

the emphasis was primarily on the consumers administering their treatment alone with little help from the healthcare professionals and user preferences [15], [90], a large number of users, however, seem to anticipate that the applications would involve their healthcare providers in their regimens and routines, according to recent research [16], [122], [123]. The absence of customized feedback, poor user interface design, and accessibility concerns with current medical monitoring programmes are further problems (e.g. limited data entry options) [7], [15]–[17]. In addition, very few programmes have been created taking the needs of consumers into account [16], [85], [124]. As an outcome, many currently available programmes lack certain functionality [122]. It has been suggested that not enough thought has been given to end users' preferences as a cause of the low acceptance and utilisation of applications. Investigations are beginning in this area, and it is crucial to incorporate theories of health behaviour modification in the creation of diabetes management. Current research by Block et al. [125] stresses the benefits of the fully automated Alive-PD Diabetes Prevention Programme, which offers six to twelve months of weekly, step-by-step counselling on improving exercise, modifying eating habits, and losing weight . Although it is claimed that several applications have been created employing health behavioural change ideas, these theories have not yet been the subject of any study [126]. Additionally, there is additionally no appropriate outline for preventing diabetes that incorporates behavioral change theories and all other essential components [127].

### III. REVIEW METHODOLOGY

A PRISMA-based technique is used in the SLR approach. PRISMA provides a reliable and repeatable strategy for identifying literature. It also offers a manual for identifying, evaluating, and choosing research papers. In Fig. 1, the PRISMA procedure used in this SLR is depicted. The following subsections provide details on the SLR procedure:

#### A. Selection of Resources

The search process was carried out using nine digital online libraries to gather pertinent articles. In this study, Scopus, Google Scholar, ScienceDirect, Web of Science, SAGE, and Taylor & Francis Online were among the online databases that were investigated. These online databases were selected because they were thought to be the most ideal for offering comprehensive information in the area of older persons' social communities. While Scopus is a collection of peer-reviewed literature with approximately 22,000 articles from 5000 publishers worldwide, WoS is a powerful database with around 33,000 journals encompassing more than 250 subjects. In the area of diabetes treatment interventions, other digital libraries including Google Scholar, ScienceDirect, SAGE, and Taylor & Francis Online also have a sizable number of pertinent records available.

The articles from 2010 to 2022 were chosen for the SLR study in order to gain the most recent and complete review: (1) Appropriate resources pertaining to diabetes, mHealth apps (web-based and mobile apps), BCTs, and behavioural change theories make up the search phrase. Terms like "Mobile App" AND "Internet based Application" OR "diabetes" AND

"mHealth" OR ("behaviour change techniques" AND "diabetes" AND "mHealth" AND "Internet based application") are utilized to find more pertinent papers for this review. Moreover, the references of earlier literature were thoroughly examined in accordance with the comparable studies published in [9]–[11], [128], [129].

proceedings. Only conferences and journals are considered as types of literature; review articles, books, book series, and individual book chapters are not included. In order to clear up any ambiguity regarding translated literature, non-English publications were also expelled.

The chosen 36 articles were then imported into Zotero, a reference manager, for synthesis. The retrieved information includes information about the studies' and interventions' characteristics, such as the regions where the research studies took place, the platforms employed for the interventions, the percentage of baseline weight loss, and glycemic level. It should be pointed out that only the publicly accessible materials (such as the primary text, development procedures, supplementary materials, etc.) are taken into account for the extracting the data, identifying the application features, and BCTs coding processes because obtaining detailed information from authors remains challenging in many instances.

### C. Coding Scheme

To identify the existence or absence of every method from the evaluated articles, the list of BCTs taxonomy published in reference [130] was given special consideration. To more accurately evaluate the chosen research, the coding process was carried out individually and separately based on the primary publications, protocols, and related investigations. The initial research methods described in reference [131] and the BCT training materials were employed to create an accurate and suitable coding process for the BCT's taxonomy application. It was noted that equivalent research activities could have described the same standardised therapies based on earlier investigations in [132], [133]. But it was also noted that the interventions are described in a different way in the literature for every research, but with some BCTs having been identified in one study yet absent in another and vice versa. The present research uses an imputation approach to tackle these problems and recover the missing BCTs.

Based on the three phases of all intervention data, an analysis was done to find the characteristics in [134]. In order to accomplish this, every application component's description, coding, as well as the platform itself, must initially specified. The imputation process was also used in a scenario where numerous studies evaluated a similar standardised intervention. Furthermore, the characteristics were divided into two categories based on the degree of engagement between the user and the application: interactive (two-way interaction) and passive (one-way interaction). A random sample of all application descriptions was used for these first two steps in order to assess their dependability. Third, each interactive and passive component was collected, examined, and discussed as a whole. These findings led to the identification of common themes between the interactive and passive components. After being divided into interactive and passive elements, the themes or clusters were given individual labels.

### D. Quality Evaluation

To avoid the risk of biases in propagating a study, it is also essential to analyse the SLR data and assess its quality. Basically, an inadequately done study's outcomes could be

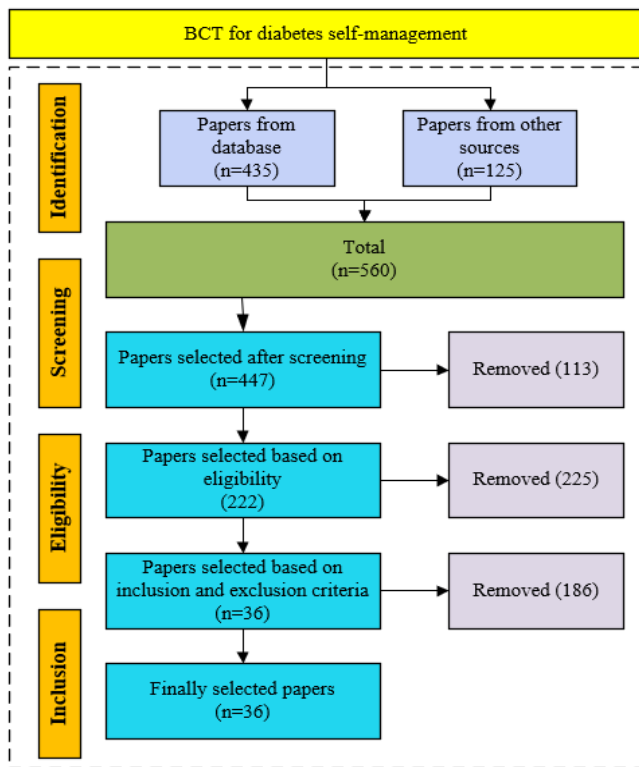

Fig. 1. The flow diagram of the review process based on PRISMA adopted in this study.

### B. Selection of Papers

A manual search was taken into account in addition to the search phrases used in the automatic search in order to completely recognize the pertinent research. The 500 research papers were found using keywords during the identification step, comprising 435 records found automatically when searching digital databases and 125 publications found manually by searching citations. After eliminating duplicates, inappropriate, and irrelevant publications, 447 published papers were chosen for the screening stage. 113 papers were ultimately eliminated after the remaining documents underwent additional screening based on titles and abstracts. After that, 222 more entries were subjected to the full-text evaluation. Following the removal of 186 articles based on the inclusion and exclusion criteria as well as the quality rating criteria, 36 articles remained. Regarding literature types, the effectiveness of self-care applications for adults 18 years and older at risk for getting diabetes was only investigated in article journals that concentrate on either research or design. For the current SLR, in particular, experimental, quasi-, and design investigations were taken into consideration. Many eligibility requirements and exclusion criteria are chosen. The studies that were chosen were those that have been peer-reviewed and published in English in journals or conference

greatly influenced by a considerable bias from the research process, necessitating careful interpretation. Consequently, in order to produce an objective result in the SLR, these studies must be disregarded or at the very least acknowledged as such. It is also crucial to evaluate the strength of the evidence and any inherent bias in every research investigation using the correct standards. For the quantitative intervention analysis, the National Institute of Health and Care Excellence (NICE) quality evaluation checklist is employed to validate the quality of the chosen studies in [135]. It includes 27 items that allow for the evaluation of external and internal validity when each criterion was met, with "++" denoting the lowest bias risk or greatest level of quality.

#### IV. SEARCH RESULTS AND ANALYSIS

##### A. Scholarly Publications over Time

Diabetes patients' self-management system seems to be a research study that will be crucial for society development in the future. In this part, the number of publications discovered over a fourteen-year period from 2010-2022 was selected. In Fig. 2, it shows how the quantity of papers has decreased during the last three years. The number of articles published starts from one in 2010, gradually increased to 4 in 2013, 5 in 2016, peaked to 7 in 2019 and afterwards rapidly declined to 1 in 2020 and increased to 3 in 2022.

##### B. Research Methods and Methodologies

Researchers employed a number of methodologies, including mixed method analysis, non-randomized controlled observational study, randomized controlled observational study, single arm prospective study and quasi-experimental methods to analyse the data connected to online supporting systems for diabetes self-management. The majority of these researches were predicated based on randomized control study. Both qualitative and quantitative methodologies were used in combination to support each other in a certain study. The distribution of included papers across research approaches is shown in Fig. 3.

As shown in Fig. 3, one study employed a quasi-experimental single arm technique. Furthermore, 4 employed

both observational study and non-randomized controlled observational study, 3 used single-arm prospective study, 6 employed mixed method design study, 2 employed prospective quasi-experimental study, and majority of the study, 15 articles employed randomized controlled trial-based study.

##### C. Publication Regions

The articles in this review came from all over the world, namely US, China, Australia, India, Saudi Arabia, Norway, Netherlands, Malaysia, Germany, Finland, Iran, Indonesia, Switzerland, Denmark, Italy and Sweden. In Fig. 4, it shows that the majority of the selected articles, 13 articles (36%) met our criteria from the US followed by China with 4% and Australia with 3%, India, Saudi Arabia and Norway with 2% each, and Netherlands, Malaysia, Germany, Finland, Iran, Indonesia, Switzerland, Denmark, Italy and Sweden with 1% each respectively.

The finding indicated that a large number of publications have been done for countries in the USA. The investigation was carried out in the Middle East, with a focus on Saudi Arabia. Furthermore, according to a WHO report, numerous individuals in Saudi Arabia have DM.

Fig. 2. Total amount of publications based on year.

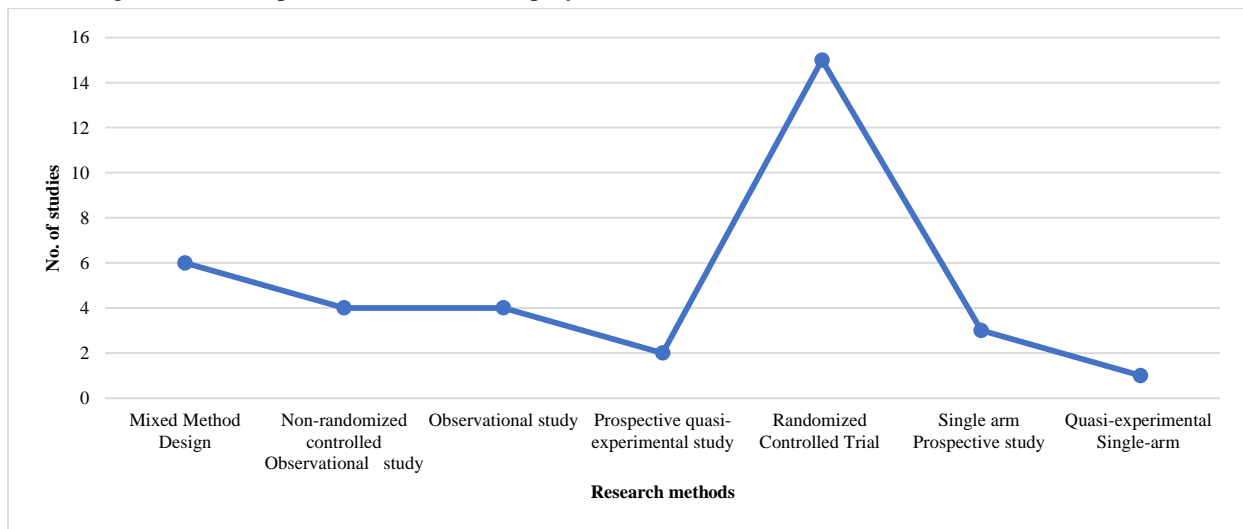

Fig. 3. Studies included over research approaches.

Fig. 4. Publication region/country.

#### D. Intervention Durations

Intervention duration in the reviewed articles ranged between 3 months and 24 months is showed in Fig. 5. More number of studies, 12 articles took approximately 3 months intervention duration, 10 articles took appropriately 6 months intervention duration, 6 articles took appropriately 12 months intervention duration, while rest of the 7 articles took more than 12 months of intervention duration.

#### E. Scholarly Articles Based on Theories

Fig. 6 shows the number of studies that have employed theory or model, ranging from Social Cognitive Theory (SCT) and Transtheoretical Model of Behavior (TTM) to Theory of Planned Behavior (TPB) and Health Belief Model (HBM). Other theories and models such as Self-Regulation Theory (SRT), Fogg Behavior Model, Cognitive Behavioral Therapy, COM-B model, IMB (Information-Motivation-Behavioral Skills Model), SDT (Self-Determination Theory), Just-in-time Adaptive intervention design, and Socio-material perspective have also been included.

From the Fig. 6, it is observed that the Social Cognitive Theory (SCT), Transtheoretical Model of Behavior (TTM), and Theory of Planned Behavior (TPB) are the most frequently used theories/models among the studies, whereas some theories/models like Fogg Behavior Model, Cognitive Behavioral Therapy, SDT (Self-Determination Theory), Just-in-time Adaptive intervention design, Socio-material and self-efficacy model have been utilized in a limited number of studies.

#### F. Scholarly Publications Based on Different Platform

Fig. 7 shows the various platforms used in various studies, showcasing the diverse approaches in delivering interventions or conducting research. Mobile apps emerged as the most frequently utilized platform, accounting for 56% of the studies. The combination of mobile app and web app platforms was employed in 19% of the studies, highlighting the recognition of multiple platforms' advantages. A smaller proportion of studies relied on websites (14%), DVDs (5%), and a combination of Short Message Service (SMS) and Email and a combination of website and mobile app (3%).

Fig. 7. Number of articles based on different platforms.

## V. RESEARCH QUESTION OUTCOME

*RQ1- How well does diabetes management applications support and facilitate diabetic self-care practices?*

In general, mobile diabetes interventions have shown promise in improving short-term outcomes for individuals with diabetes [87], [88], [90]–[92], [96], [98], [99], [101], [114], [115], [124], [136]–[138]. These interventions typically involve the use of mobile applications (apps) or other digital tools to help individuals manage their condition, track their blood glucose levels, monitor physical activity, and provide educational resources. Several studies have evaluated the effectiveness of mobile diabetes interventions over short-term periods (e.g., a few months to a year), and many have reported positive results that is short-term effectiveness [87], [88], [90]–[92], [96]–[98], [100], [101], [109], [114], [115], [124], [131], [136]–[138]. These interventions have been shown to improve glycemic control, increase self-management behaviors, enhance medication adherence, and promote healthy lifestyle choices, however, twelve interventions were short-term ineffective [91], [94], [98], [104], [105], [111], [113], [117], [139], [140]. Six interventions were long-term effective [92], [98], [110], [111], [136], [137]. Finally, ten interventions were long-term ineffective [101]–[106], [113], [114], [118], [139]. For example, some studies have found that mobile apps with features like glucose monitoring, medication reminders, and dietary guidance can lead to improvements in HbA1c levels (a measure of long-term blood glucose control) in the short term. Additionally, mobile interventions that include real-time feedback, coaching, and personalized recommendations have shown effectiveness in motivating individuals to adopt healthier behaviors. However, it's worth noting that the long-term effectiveness of these mobile interventions may vary. Some studies have reported challenges in maintaining the positive effects over a longer duration. Factors such as user engagement, adherence to the intervention, and sustainability of behavior change can influence the long-term effectiveness of these interventions. As technology advances and more research are conducted, it's

possible that newer mobile diabetes interventions may have improved long-term outcomes. It's essential for researchers and developers to continue evaluating the effectiveness and sustainability of these interventions to ensure their long-term benefits for individuals with diabetes.

*RQ2- What are the prevailing methodologies and techniques commonly utilized in the realm of diabetic self-care management to facilitate behavior modification?*

The term "behavioural change techniques" (BCTs) refers to discrete, observable, and repeatable elements of interventions intended to influence behaviour [131]. BCTs are a part of an intervention meant to change or restructure the causal mechanisms that control behaviour. The BCT Taxonomy, developed by Michie et al. in 2013, is a classification system for 93 hierarchically clustered approaches. Behavior change techniques are specific strategies or methods used to facilitate behavior change in individuals. These techniques are often employed in various fields, including healthcare, psychology, and public health, to promote positive behavior changes and support individuals in achieving their goals. BCTs can be used to modify a wide range of behaviors, including health behaviors like smoking cessation, physical activity, medication adherence, and dietary changes. They can be applied in individual counseling sessions, group interventions, digital health programs, or self-help materials. Behavior change techniques are designed to target specific determinants of behavior, such as motivation, self-efficacy, knowledge, and environmental factors. They are evidence-based and grounded in theories of behavior change, such as the Transtheoretical Model, Social Cognitive Theory, and the Theory of Planned Behavior.

Over the course of all the interventions examined, a total of thirty separate behaviour change methods (BCTs) were discovered, average 11.6 BCTs per intervention. Ten of these behaviour modification strategies were used in at least 55 per cent of both short and long-term interventions. In particular, behavioural goal-setting was used in 58.33% of interventions and was acknowledged in 75% of cases for both the short- and long-term categories. In 61.11% of the therapies that were considered, problem-solving was present, and its success was rated as being 75% short-term and 100% long-term. Defining outcome-related goals was another method that was used in 61.11% of all interventions, with recognition rates of 85% and 68.75% for short-term and long-term efficacy, respectively. Feedback on behaviours was noted in 61.11% of all interventions, with the rate of recognition for short and long-term interventions being 85% and 68.75%, correspondingly. In 80.56% of interventions overall, 100% of short-term treatments and 81.25% of long-term interventions showed evidence of the self-monitoring of behaviour technique. In line with this, the method of self-monitoring behavioural outcomes was recognised in 100% of short-term interventions and 75% of long-term interventions, or 77.7% of all interventions. Additionally, the undefined type of social support was recognised in 61.11% of all interventions, 95% of short-term interventions, and 62% of long-term interventions. Also noted in 50%, 55.56%, and 58.33% of all treatments, respectively, were strategies including informing participants about the potential health effects of their actions, citing reliable sources,

and modifying environmental signals. As mentioned in (see Fig. 8), for short-term and long-term interventions, respectively, the recognition rates for these approaches were 65%, 80%, and 90%.

Fig. 8. BCT interventions (a) Goal and planning cluster, (b) Feedback and monitoring cluster, (c) Shaping knowledge, (d) Social support cluster.

Fig. 9. Ten identified BCTs.

Fig. 9 depicts that the Goal setting (behavior) and problem-solving techniques are consistently employed in both short-term and long-term interventions, with percentages ranging from 75% to 100%. This suggests their recognized effectiveness in promoting behavior change. Goal setting (outcome) is more frequently utilized in the short term (85%), while its usage decreases slightly in the long term (68.75%), indicating a potential shift in focus over time. Feedback on behavior and self-monitoring of behavior are consistently utilized BCTs, highlighting their importance in promoting awareness and accountability. For both short-term and long-term therapies, the percentages range from 75% to 100%. Self-monitoring of behavior's result(s) is heavily used in the short term (100%) but less so in the long term (75%), suggesting a possible change in focus across various stages of behaviour change. Short-term (95%) but long-term (62.50%) use of social support (unspecified) declines, implying a potential shift to more focused types of social support with time. There are differences in percentages between short-term and long-term treatments when it comes to the use of information on health effects, reliable sources, and adding things to the environment. This implies that according to the particular environment and intervention goals, their efficacy and significance may change.

1) *Effectiveness in short term:* In comparison to long-term therapies, which used an average of 7.8 BCTs per intervention (range from 1 to 16), short-term interventions used an overall of 19 BCTs each intervention (range from 0 to 20). Self-monitoring of behaviours and self-monitoring of the results of behaviours were two behavioural change theories that were identified significantly more frequently in short-term therapies.

Fig. 10. Effectiveness in short-term.

As depicted in Fig. 10, the effectiveness of this BCT in the short term in self-monitoring of behavior is reported to be 81%. This suggests that when individuals actively monitor and track their behaviors, they are more likely to engage in positive self-care practices. While, the effectiveness of this BCT in the short-term self-monitoring outcome of behaviour is reported to be 75%, which implies that when individuals regularly track and observe the outcomes of their self-care behaviors, they can better understand the impact of their actions and make adjustments as needed.

2) *Effectiveness in long term:* In contrast to the 19 BCTs per intervention (range from 0 to 20) needed to achieve short-term efficacy, interventions that were long-term effective employed an average of 7.8 BCTs (ranging from 1 to 16). Two BCT found with noticeable higher frequency include action planning with 93.75%, and information about antecedents with 87.5%. As depicted in Fig. 11, the 87.50% effectiveness suggests that providing information about antecedents can be beneficial in promoting sustained behavior change and long-term self-care management. While, the 93.75% effectiveness indicates that when individuals engage in detailed action planning, they are more likely to maintain consistent self-care behaviors over an extended period.

Fig. 11. Effectiveness in long-term.

*RQ3: Which theoretical frameworks and models can be effectively employed to underpin and guide the progress and application of diabetes self-care management applications?*

Multiple theoretical frameworks are frequently used to develop and assess public health interventions that aim to modify behaviors. The Health Behaviour Model examines a person's impression of a health problem's severity and vulnerability, in addition to the perceived advantages and challenges of implementing preventative behaviors. The TTM suggests that when changing behaviours, people go through phases of transformation. It emphasizes how crucial it is to adjust therapies depending to a person's level of progress. The Theory of Reasoning asserts Action/Planned Behaviors (TPB), a person's attitudes, personal standards, and perceived behavioral control all have an impact on their decision to engage in a behavior. It places a strong emphasis on how societal pressures and a person's beliefs might affect their behaviour. According to the Social Cognitive Theory (SCT), a person's behaviour, personal characteristics, and external factors all interact in a reciprocal manner. It emphasizes the significance of self-regulation and observational learning in behavior change. It also recognises that varieties of variables

such as those at the individual, interpersonal, communal, and societal levels, have an impact on behaviors. It highlights how these levels interact and the necessity of therapies that focus on several levels at once.

An overall of 29 interventions made reference to a theoretical underpinning for their design, whereas the other seven interventions made no such mention. Different behavioural change theories were used in the reviewed articles, which include Social Cognitive Theory (SCT) [141], [142], Theory of Planned Behaviour [143], [144], Transtheoretical Model (TTM) [145], [146] [147], Self-determination Theory [148], Information-Motivation-Behavioral Skills Model [142], Health Belief Model [144], [149]. Furthermore, COM-B model [150], Just-in-time Adaptive intervention design [151], Fogg Behavior Model [146], Self-efficacy [152] have been used in diabetes related interventions design. Twenty-nine interventions were supported (informed) by one theory or more theories. Some studies used several theories [142]–[144], [146], [148], [150], [153]–[166], while other interventions used a single behaviour theory [141], [151], [152], [165], [167]–[171].

Based on the reviewed articles, the most popular theories used in the studies were: Social Cognitive Theory (SCT) [141], [142], [153]–[157], [159]–[162], [164], [166], [172], [173] and the Transtheoretical Model of Behaviour Change (TTM) [144], [146], [154]–[157], [159], [160], [162], [163], [166], [169], [172]–[175]. SCT, which theorises knowledge gaining through social awareness and considers self-efficacy as one of the main channels of goal actualization, was used in 16 articles. TTM, which emphasizes changes as the progressive venture through pre-contemplating of behaviour change to behaviour maintenance [144], was informed in 17 articles. The Fig. 6 illustrate the distribution of the health behavioural theories in the reviewed articles.

According to Webb et al. [176] and Van Rhoon et al. [177], the Social Cognitive Theory and the TTM were among the most frequently utilised conceptual bases. On the other hand, the Theory of Planned Behaviour (TPB) represented one of the more often cited frameworks of theory in Webb et al.'s study [176]. Chao, Lin, and Ma [178] and Kusananto et al. [179] utilised concept only as an evaluation metric, while those that used concept as a component of the research design provided just a cursory description of how treatments were incorporated into the relevant theory.

Future study should focus on this issue, perhaps highlighting the importance of building a theoretical knowledge of the probable procedure for eliciting behaviour change at the outset of the conceptualization of an approach in [180] and, using Michie and Prestwish's description of the 'standardized' contribution of concept in [181]. Researchers in the future ought to be able to assess the efficiency of the role of concept in these kinds of interventions as well as possibly the relationship among the amount of theory utilised and the changes in behaviour and corresponding health outcomes. This could be possible with an explicit, systematic, and relatively consistent overview of the part of concept in the planning and creation of the intervention.

The management of sicknesses and overall well-being is clearly aided by self-care applications created utilizing health behavioural change techniques. These programmes are effective at encouraging patients to better adhere to their prescription regimens, encourage self-care, enhance their health, and lessen their despair. A number of investigations were undertaken to assess the accessibility of the programmes, and it was determined that these self-care apps were mainly simple to comprehend and utilize since the patients felt comfortable utilizing them and completing the necessary chores. Additionally, self-care behaviours and prevalent concepts employed in their creation have been identified. These concepts encompass the following: the Theory of Planned Behaviour, the model of health beliefs, Cognitive Behaviour Therapy, Self-Care Behaviour, Motivational Interviewing, and behaviour changes. Finding the health behaviour change paradigm that has been employed in previous research more frequently would be fascinating. According to the results of the investigations, every theory has been applied continually, whether solely or in conjunction with other approaches.

*RQ4- What common aspects do diabetic self-care management programmes use today to effectively and completely treat the disease and empower patients?*

Thematic analysis [182], was executed across three phases to uncover patterns within all interpolated data points. Initially, comprehensive explanations and codes were provided for every application components and its corresponding platform. Additionally, in cases where multiple studies evaluated identical standardized interventions, the imputation process was carried out. Subsequently, characteristics were classified according to the degree of engagement between the user and the application, categorized as either interactive (involving two-way interaction) or passive (involving one-way interaction). To test for dependability, we finished the initial two phases on an instance of randomly selected app specifications. Furthermore, all both active and passive characteristics were gathered, analyzed, and debated jointly. These findings led to the identification of common themes between the interactive and passive components. The interactive or passive characteristics of the themes or clusters were afterwards classified and labelled in accordance with each theme. In particular, several kinds of mobile and web-based therapies have tools for monitoring blood sugar, diet calories, and body weight, as well as alerts for remembering to take medications or schedule medical appointments. Consider dividing the characteristics into interactive and passive ones.

3) Digital feature descriptions: The different digital passive features are utilized in health interventions. Health and lifestyle information and advice provide educational materials on topics like healthy eating, physical activity, and stress reduction. Activity tracking involves tools like pedometers and accelerometers to record physical activity, while reminders and prompts send notifications to remind participants of specific tasks. Diet tracking allows participants

to record their dietary behaviors, including calorie counting and food diaries. Weight and bio-measure tracking involve tools like digital scales and blood glucose monitors to track body weight and biological measures. These features offer one-way interaction without active feedback.

Previous assessments of self-care apps have examined how the effectiveness of these applications is linked to their attributes in managing diabetes. Applications that demonstrated substantial effectiveness incorporated both passive and interactive features, while those with less pronounced effects tended to rely solely on passive attributes [183]. Passive attributes don't require user interaction, whereas interactive attributes involve real-time user engagement. In another investigation [184], diverse attributes in self-care apps were explored. This study revealed that interactive attributes were notably more successful than passive ones in enhancing medication adherence among individuals with type 2 diabetes. Nonetheless, this study exclusively concentrated on type 2 diabetes management, leaving uncertain the most efficacious features across various applications. Interactive elements encourage engagement and active involvement in programmes for a healthy lifestyle. The data shows that gamification, automatic feedback, social media and support, online medical coaching, and educating about healthy living all incorporate interactive components. Passive features include tracking nutrition, weight and measurements, suggestions and alerts, information on wellness and lifestyle, and activity monitoring. These elements are essential for providing people with information and insights so they may choose their lifestyle and health with knowledge. For instance, the majority of interventions incorporate health and lifestyle information, demonstrating the value of this information in educating people about several facets of their well-being [183].

The passive features include activity tracking, weight, biometric measurements, diet tracking, reminders and prompts and health and style information. From Fig. 12(a), it is observed that Health and lifestyle information is a commonly included passive feature in both short-term and long-term interventions. It is present in 58.33% of all interventions, 65% of short-term interventions, and 81.25% of long-term interventions. Activity tracking is another frequently incorporated passive feature, with 52.78% of all interventions including it. In the short term, all short-term interventions (100%) utilize activity tracking, while it decreases to 43.75% in the long term. Reminders and prompts are included in 47.22% of all interventions. They are used in 70% of short-term interventions and 56.25% of long-term interventions. Diet tracking is present in 41.67% of all interventions. It is used in 80% of short-term interventions but decreases significantly to 12.5% in the long term. Weight and measure tracking is utilized in 44.44% of all interventions. In the short term, 75% of interventions include this feature, but it drops to 6.25% in the long term. On average, short-term interventions have a higher number of passive features per intervention (3.81) compared to long-term interventions (2).

Fig. 12. (a) Passive features intervention and (b) Interactive features intervention.

The capabilities that are interactive include social media and support, automated feedback, lifestyle lessons, gamification, interactive wellness and online health instruction, and social networking sites. From Fig. 12(b), it is observed that Interactive health and lifestyle lessons are a commonly included interactive feature, present in 55.56% of all interventions. In the short term, 60% of interventions incorporate this feature, while in the long term, it decreases to 37.5%. Social media and support is another frequently included interactive feature, with 52.78% of all interventions including it. In the short term, 70% of interventions utilize social media and support, and in the long term, it remains high at 56.25%. Online health coaching is present in 50% of all interventions. It is used in 80% of short-term interventions but decreases significantly to 6.25% in the long term. Automated feedback is utilized in 36.11% of all interventions. In the short term, 40% of interventions include automated feedback, but it is not present in any of the long-term interventions. Gamification is the least frequently incorporated interactive feature, present in only 5.56% of all interventions. It is used in 15% of short-term interventions and 18.75% of long-term interventions. On average, short-term interventions have a

higher number of interactive features per intervention (2.52) compared to long-term interventions (1).

*RQ5: What are the intricate challenges encountered in the current landscape of diabetes self-care applications, and what are the anticipated future directions and potential advancements?*

While many diabetic self-management software programmes offer features like tracking diet and exercise, it's noteworthy that type 2 diabetes is frequently associated with insufficient dietary intake and insufficient physical activity. The features of machine learning (ML) or AI-powered dietary recommendation and planning, clinical support, fitness tracking, visualizing blood pressure, calorie expenditure estimation, and behavioural intervention (BI) techniques, still clearly have shortcomings. Additionally, most of these apps lacked well-recognized research underpinnings and ideas, including the nudge theory, which would add credibility. As a result, some diabetic self-management software programmes may not successfully help patients manage their condition on their own. It's interesting to note that none of these applications includes a food monitoring system powered by ML or AI, a system for providing individualised nutrition

advice, or a platform for meal recording (micronutrient detection) powered by AI using picture analysis. For diabetics to avoid hypo- or hyperglycemic episodes, improved nutrition management systems can significantly improve glycemic control [128]. These programmes, however, lack thorough feedback systems, such as organised behavioural agreements, consistent self-monitoring tracking, and goal setting. Based on the system's learned insights from recent data and preprogrammed guidelines, this input is customised for patients. Additionally, the majority of applications do not have AI-driven tools like insulin dose calculators that are intended to help patients make informed decisions by offering advice on activities, diets, and medications.

In future, a comprehensive self-care application for diabetes could be envisioned, encompassing both basic and advanced functionalities. This application would encompass elements like nutrition, blood glucose monitoring, clinical support, physical activity tracking, medication management, and tailored features. Moreover, this proposed diabetes self-care app would adopt an extensive feedback mechanism, fostering effective communication with all involved parties. Additionally, it would integrate behavioral intervention techniques guided by theories and artificial intelligence, promoting prolonged adherence to patients' self-care regimens.

## VI. DISCUSSION

A total of 36 therapies from multiple investigations were analysed and evaluated for this research. The SLR seeks to compile and evaluate the literature on diabetic self-care apps in order to assess the effectiveness of treatments for diabetes management. The Systematic Literature Review also looks for the best behavior change methods (BCTs) and application features that are frequently employed in the research investigations that are already out there. This study showed that, in the short term, a substantial number of diabetic self-care strategies resulted in noticeable weight loss, as evidenced by an average weight reduction of at least 3% from the original level, based on the evaluations that were chosen. However, after taking into account the longer time, the majority of therapies did not meet the clinically significant threshold of 5% weight loss. Previous reports [9]–[11], [128], [129] on the effectiveness of diabetes self-care applications found similar results and heterogeneity among studies. According to earlier research [121], applications that used more behaviour change methods (BCTs) typically had higher efficacy. Within the interventions, seven typical behaviour modification strategies were found, including goal formulation, self-monitoring, feedback on behaviour, problem-solving outcome, self-monitoring, and social support. The suggested behavior modification elements listed in the IMAGE toolkit for diabetes prevention are in line with these identified BCTs, which is significant [185]. The most successful behavior change method involves participants in problem-solving activities that encourage them to come up with potential behavioural modification methods, choose the best one, and implement it. According to the research, applications that included more behavior change methods were generally more likely to be more successful. Furthermore, consistent patterns of Behavior Change

Techniques (BCTs) were identified in both long-term and short-term therapeutic interventions. Notably, interventions with a higher number of distinctive attributes exhibited greater effectiveness, aligning with behavior change strategies. Similar findings were documented in studies [186] and [187], illustrating that self-care applications yielded enhanced efficacy in diabetes management through the incorporation of interactive features. Three elements have been frequently mentioned as useful interventions, indicating that they may make up an efficient core collection that would serve as the foundation for all subsequent applications.

In order to overcome the constraints to face-to-face interventions' connectivity, self-care applications have been developed. According to the present research, interventions that use more BCTs and characteristics are more effective, and because of their enhancing capabilities and adoption rates, websites and smartphones might serve as the best platforms for these strategies. Given that these behaviors are similarly comparable to the evidence-based treatment, that mostly depends on how the concepts are applied in the intervention layout, health behavioral theories have been shown to be an essential strategy for promoting behavioural modifications such as physical activity and nutritious eating [188]–[190]. While technology has the potential to positively impact self-care in diseases like diabetes, it alone is not enough. Effective outcomes rely on tailoring information appropriately and ensuring patients are highly motivated [191]. According to research, the broad implementation of BCTs, features, and theories into mobile and web-based therapies increases their effectiveness [188], [189]. Because there has been less prior research in this field, the creation of self-care interventions is an essential and developing direction in information science. However, current studies in the sector have shown that programmes created with the integration of BCTs and behavioural change theories produce better clinical results in [188], [189]. It may be concluded that in order to attain long-term effectiveness and help users reach their therapeutic goals, an ideal self-management intervention should incorporate BCTs and behavioural health theories during the design process.

Theoretical frameworks for influencing behaviors to improve medical results are crucial. Due to their ability to provide light on human behaviour and change, these theories are crucial components of successful intervention. By incorporating methods for behavioral change, these theories could be utilised in the creation of fresh apps. Researchers offer encouraging recommendations for developing, putting into practice, and assessing health promotion programmes that might be incorporated into the creation of self-care interventions dealing with health-related behaviours [187]. BCT-based therapies may be employed to encourage users to improve their health-related behaviours [131].

Any health support programmes that include more behavioral change theories are thought to be more successful at achieving the intended behavioral change. Many research investigations have looked into how health behavioral change theories could be included into the creation of medical assistance apps. However, few researches have focused on such incorporation in prediabetes self-care strategies.

According to the findings of the prediabetes research, it would be achieved to avoid diabetes and manage prediabetes—but only when prediabetics are inspired to take charge of their well-being by altering their attitudes through self-care behaviors. In the present research, examine the efficacy of existing theories of health behavior change as they are applied to prediabetes therapies worldwide and assess the efficacy of self-care apps that combine these concepts. The development of self-care strategies that target behaviours associated with health could be influenced by behavioural change concepts and approaches, which offer promising principles for creating, carrying out, and evaluating health promotion programmes [192]. Understandings how individuals act and modification could assist us achieve better health effects, according to behavioural change concepts [64]. Incorporating ideas of wellness behavior modification into the creation of healthcare applications has been the subject of several research. However, few researchers have focused on this inclusion in diabetic self-care programs [91], [93]. According to the findings of the mellitus research, managing and preventing diabetic is only feasible if individuals are inspired to take control of their well-being by altering their attitudes through self-care behaviors. As a result, researchers advise the investigators to create diabetes self-management software that includes both simple and sophisticated features, including dietary advice, fitness advice, calorie prediction, and insulin bolus calculations. The software should also facilitate stakeholder communication, incorporate theory based on artificial intelligence that improves the programme's effectiveness in managing diabetes, and allow diabetic patients to commit to their self-management regimens progressively over time.

As previously mentioned, this study's investigation of the effectiveness of self-care applications for managing diabetes and the effects of the BCTs and application features is one of its contributions. As a result, the information obtained from the examined papers was presented and organized using a narrative synthesis technique, with tables that summarised the descriptive analysis and statistical data. The data are more than adequate to perform a complete meta-analysis, but, the majority of the examined articles included in the primary efficiency analysis of the therapies did not present a percentage of weight loss and other essential requirements.

Furthermore, it was believed that body weight and glycemic status (A1c) were the main outcomes of importance. Due to its relationship to diabetic issues and the fact that diabetic self-care research commented on it more often than publications in other fields, body weight was seen as the major measure of success [193]–[195]. Since this value is considered to be clinically important [196] and usually complies with standards of weight loss for twelve-month diabetes self-care therapy [195], [197]. and the effectiveness of the intervention was assessed in terms of an average weight loss of fewer than five per cent from the starting weight.

In essence, interventions lasting less than six months were deemed successful if an average weight loss of over 3% occurred within this timeframe. For interventions extending beyond twelve months, success was determined if an average weight reduction of 5% or more was achieved within a twelve-

month follow-up period. Based on these criteria, the applications in the studies under review were categorized as either short-term effective, short-term ineffective, long-term effective, or long-term ineffective. Specifically, interventions exceeding twelve months were grouped into short-term (ST) and long-term (LT) follow-ups. The study investigated relationships between types of Behavior Change Techniques (BCTs) and intervention attributes identified in long-term compared to short-term interventions. Similar to pertinent findings in reference [196], effective BCTs and features were identified for each respective time (ST or LT) if present in a minimum of 55% of effective interventions.

## VII. CONCLUSION

This study focused on assessing the impact of self-care apps, particularly those integrating Behavioral Change Techniques (BCTs) and related concepts, in managing diabetes compared to standard treatment. The findings from the analysis of various studies suggest that the use of self-care apps can lead to improvements in A1c levels and weight loss for individuals with diabetes when compared to standard care. These results align with previous research, reinforcing the potential benefits of self-care apps in diabetes management. It also demonstrated that previous studies that utilised behavioral health concepts and BCTs in the creation of diabetic self-management treatments tended to be more successful. Importantly, the analysis highlights that the incorporation of BCTs and related concepts into interventions is associated with a reduction in A1c levels. This underscores the significance of integrating these strategies into self-care applications, even though the precise influence on application features can sometimes be unclear.

### A. Limitations and Future Directions

After determining the possibility for incorporating BCT theories and practises into the creation of self-management interventions, it is vital to build a paradigm for creating successful self-care programmes based on particular BCT. As a foundation for developing future applications, it is also necessary to explicitly elaborate on the use of BCTs and concept. While this systematic literature review (SLR) provides valuable insights, it's important to acknowledge its limitations. The studies included in this review varied in terms of methodology, participant characteristics, and intervention design, which may introduce heterogeneity into the findings. To build on these findings, future research should consider more standardized methodologies and explore the long-term effects of self-care apps. Furthermore, research should focus on elucidating the specific mechanisms through which BCTs and related concepts influence the efficacy of self-care interventions for diabetes management. Such efforts could provide a clearer foundation for the development of more effective self-care programs and applications in the future.

## ACKNOWLEDGMENT

The authors would like to express gratitude to Universiti Teknologi, Malaysia for the financial sponsorship of the research through the UTM Encouragement Research Grant (UTMER), grant reference number/no: PY/2022/03968; cost center: Q.J130000.3828.31J51

# An Improved Convolutional Neural Network for Churn Analysis

Priya Gopal, Dr. Nazri Bin MohdNawi

Faculty of Computer Science and Information Technology, University Tun Hussein Onn Malaysia

**Abstract**—The significance of customer churn analysis has escalated due to the increasing availability of relevant data and intensifying competition. Researchers and practitioners are focused on enhancing prediction accuracy in modeling approaches, with deep neural networks emerging as appealing due to their robust performance across domains. However, the computational demands surge due to the challenges posed by dimensionality and inherent characteristics of the data. To address these issues, this research proposes a novel hybrid model that strategically integrates Convolutional Neural Networks (CNN) and a modified Variational Autoencoder (VAE). By carefully adjusting the parameters of the VAE to capture the central tendency and range of variation, the study aims to enhance the effectiveness of classifying high-dimensional churn data. The proposed framework's efficacy is evaluated using six benchmark datasets from various domains, with performance metrics encompassing accuracy, f1-score, precision, recall, and response time. Experimental results underscore the prowess of the hybrid technique in effectively handling high-dimensional and imbalanced time series data, thus offering a robust pathway for enhanced churn analysis.

**Keywords**—Customer churn analysis; deep learning; variational autoencoder; convolutional neural networks; dimensionality reduction

## I. INTRODUCTION

In today's rapidly evolving business landscape, driven by the surge of online technological advancements, companies are compelled to navigate a competitive arena characterized by the influx of new business models and market entrants [1]. This has intensified the significance of customer churn analysis, as businesses seek to attract new customers and retain their existing clientele [2]. Retaining customers has been proven to yield higher returns on investment, as the costs associated with retaining an existing customer are considerably lower than acquiring a new one [3]. Amidst this context, the retention strategy gains paramount importance, requiring companies to mitigate the risk of customer churn – the phenomenon where customers switch providers swiftly [4-5].

To address this challenge, the utilization of machine learning has emerged as a potent tool, leveraging historical data to predict potential churn events and enable informed decision-making [6, 7]. However, there are hurdles to overcome in this endeavor. Issues such as inaccurate customer information, intricate datasets with numerous variables, imbalanced class distributions, and a lack of industry expertise create formidable hurdles [8]. Despite the strides made by advanced techniques like Convolutional Neural Networks (CNNs), which uncover hidden relationships within data, accurately predicting real-

world churn scenarios remains intricate [9-11]. In light of these challenges, this paper introduces a hybrid model named the Space Vector Variational Autoencoder (SV-VAE), a fusion of CNN, and an optimized Variational Autoencoder (VAE) [12, 13].

By addressing these challenges, this study contributes to the enhancement of churn prediction in the dynamic landscape of modern business. It brings together cutting-edge technologies in a concerted effort to improve retention rates and elevate the strategic decision-making process for businesses across diverse industries.

The core objective of this paper is to enhance both the accuracy of predictions and the efficiency of model learning. This enhancement is achieved through the integration of a Convolutional Neural Network (CNN) with a modified Variational Autoencoder (SV-VAE). By combining these techniques, we aim to achieve superior performance in terms of predictive precision and reduced model training time.

To validate the effectiveness of the proposed hybrid model, a comprehensive evaluation is conducted. This evaluation encompasses various critical performance metrics, including precision, recall, accuracy, and learning time. To establish a robust baseline for comparison, the proposed SV-VAE hybrid model is benchmarked against other popular autoencoder architectures such as Vanilla, Stacked, Sparse, Denoising, and Variational Autoencoders. These comparisons are conducted across diverse industry-standard benchmark datasets, which provide a real-world context for assessing model performance.

The validation process primarily centers around the scrutiny of the proposed model's predictive capabilities. The study meticulously assesses the accuracy of predictions, the ability to accurately classify positive instances (precision), and the model's effectiveness in capturing actual positive instances (recall). This thorough evaluation ensures that the proposed hybrid SV-VAE model's performance improvements are statistically significant and practically relevant in the context of churn analysis and prediction tasks. The following section contains a comprehensive review of the existing literature in the field of churn prediction, machine learning techniques, and autoencoder architectures relevant to this study.

## II. LITERATURE REVIEW

Many methods have been explored in the quest to predict churn in service industries, often rooted in machine learning and data mining techniques. A significant portion of the prior research has been concentrated on individual data mining

techniques or has involved comparative analyses of different methodologies for predicting attrition.

In a study conducted by Brandusoiu et al. [11], the focus was on predicting prepaid customer turnover rates using a contemporary data mining approach. The study utilized a dataset comprising more than 3000 call details, encompassing 21 attributes, and a predictive churn variable categorized with Yes/No labels. These attributes encompassed details about the volume of voice and video usage for each subscriber, alongside the count of inbound and outbound texts. The researcher employed the principal component analysis algorithm to streamline the data's complexity for dimensionality reduction. Three machine learning algorithms, namely Support Vector Machine (SVM), Naive Bayes (NB), and Neural Networks (NN), were employed to forecast churn rates. Model reliability was assessed using the Area under the Curve metric, and the results highlighted the superior performance of SVM over the other two algorithms. Notably, the dataset used in this study didn't contain any missing values. However, when dealing with time-series features, the model's ability to leverage information over time might be limited, necessitating various sampling techniques to incorporate temporal information effectively [12-13].

Artificial neural network approaches designed for sequential data have gained popularity, and this trend is evident in their increased adoption for churn modeling, as evident from the overview provided in Table I.

Martins [14] conducted a study revealing that the accuracy of Long Short-Term Memory (LSTM) models equipped with time series attributes is comparable to an approach that integrates this pertinent data using the mean and a random forest technique. This research outcome contributes to synthesizing insights from various studies.

Numerous research endeavors have underscored the efficacy of combining Convolutional Neural Networks (CNN) with Long Short-Term Memory (LSTM) models to enhance performance across diverse tasks. For example, in a study by Tan et al., [15], a fusion of CNN and LSTM was employed to forecast user-intended actions, demonstrating that this integration surpasses the individual performance of the two models and traditional machine learning methods. Furthermore, another investigation employed encoded sequential data, such as images and videos, wherein the utilization of CNN yielded superior outcomes compared to gradient boosting and random forest techniques [16].

These discoveries accentuate the potential advantages of harnessing the strengths of distinct models, leading to heightened performance across a spectrum of applications.

In summary, previous studies indicate that the exploration of time-varying data to enhance the effectiveness of churn algorithms is still in its nascent stages. While CNN and LSTM models exhibit improved performance, they encounter challenges when confronted with high-dimensional data. Moreover, the diverse characteristics inherent to various industry sectors make it challenging to definitively determine the performance boost resulting from the inclusion of such varied information. Introducing these diverse features into the training phase can inadvertently amplify model complexity, potentially leading to overfitting against the training data. A potential solution to this lies in the preprocessing stage, where a dimensionality reduction step is undertaken. This step strives to curtail the number of features while retaining as much meaningful information as possible within the dataset [25]. Autoencoders prove adept at handling high-dimensional data, a domain where CNNs might face limitations. Notably, the Variational Autoencoder (VAE) is of special significance, given its ability to generate more probabilistic latent outputs [18]. The VAE emerges as a robust choice, particularly well-suited for churn analysis due to its capability to generate novel data instances and its compatibility with the time series nature of churn data. Additionally, dimensionality reduction plays a vital role in effectively mitigating noise from the data. This process facilitates the discovery of latent variables that arise from intricate relationships among different variables in the dataset. This approach provides a more comprehensive understanding that goes beyond analyzing individual variables in isolation. In conclusion, this study makes a valuable contribution to the services industry by meticulously assessing the efficacy of deep learning classification techniques and exploring alternative strategies to effectively manage high-dimensional data challenges.

### III. RESEARCH METHODOLOGY

In scenarios involving time-varying features, various aggregation methods [23-24] have been explored alongside machine-learning classification techniques [26-27]. However,

these methods often fall short due to the requirement of having one observation per client in most classification techniques. This limitation becomes problematic when tracking the behavior of the same customer over time with time-varying features. Consequently, conventional classification methods struggle to effectively utilize this type of information.

In order to address our problem effectively, we have devised a structured approach that leverages a modified Variational Autoencoder (VAE). This method aims to uncover latent space attributes, overcome challenges in traditional autoencoders, and generate new features from complex datasets.

#### Step 1: Variational Autoencoder (VAE) Setup

We begin by setting up a Variational Autoencoder (VAE), a powerful tool known for its ability to uncover latent space attributes in data. The VAE comprises two essential components: an encoder and a decoder.

#### Step 2: Encoder and Decoder Functions

The encoder processes input data samples and maps them to latent variables. This encoder is instrumental in generating meaningful latent features. On the other hand, the decoder strives to replicate the input data using the learned latent variable distribution.

#### Step 3: Leveraging Latent Space

Latent variables are relatively low-dimensional representations of the input data, which contrasts with the high-dimensional input and reconstructed data. This approach is built on the idea that data is generated by the model  $P(x|z)$ .

#### Step 4: SV-VAE Architecture

Our proposed methodology incorporates four major blocks within the Space Vector Variational Autoencoder (SV-VAE): Encoder, Latent Distribution, KL Divergence, and Decoder. The SV-VAE leverages posterior distribution for data sampling and applies an empirical rule to reduce noise and approximate data points.

#### Step 5: Training the Model

Training involves optimizing two key loss functions: The KL divergence loss, which regularizes the learned latent distribution against a prior distribution, and the reconstruction loss, which ensures fidelity between decoded samples and original inputs.

#### Step 6: Deep Neural Network

Compressed features obtained from the SV-VAE are fed into a deep neural network with layers like pooling, dropout, ReLU, and a sigmoid layer. The output of this CNN flows into the decoder for data reconstruction.

#### Step 7: Evaluation

Model evaluation is performed through the assessment of SV-VAE loss, including the KL divergence loss function. Model predictions are evaluated for accuracy, F1-score, and precision. Hyperparameter tuning is carried out to enhance model accuracy.

#### Step 8: Dual Loss Optimization

Our SV-VAE model optimizes two crucial loss functions: The reconstruction loss, ensuring alignment with original dataset images, and the KL-divergence loss, quantifying the divergence from a standard normal distribution. This dual loss optimization ensures the model's effectiveness in capturing latent features.

The proposed model incorporates a modified Variational Autoencoder to uncover latent space attributes. VAE's ability to generate data across the entire space addresses the challenge of non-regularized latent space in traditional autoencoders. Within the VAE framework, an encoder module transforms the input sample  $x$  into a latent space representation  $x'$ . Variational autoencoders are particularly well-suited for generating new features from complex datasets [28].

The VAE consists of two core components: The encoder and the decoder. The encoder is a separate network that accepts samples from the data  $\{x_i\}_{i=1}^N$  and attempts to map them to the latent variables  $z$ . The decoder, on the other hand, attempts to replicate the input  $\{\hat{x}_i\}_{i=1}^N$  using the learned distribution  $z$ . Input  $x$  and reconstructed data samples  $\hat{x}$  are in high dimensional space, however, latent variable  $z$  is relatively low dimensional. The foundation of the variational autoencoder rests on the notion that data is generated by the model  $P(x|z)$ .

As illustrated in Fig. 1, the proposed methodology comprises four major blocks within the SV-VAE: Encoder, Latent Distribution, KL Divergence, and Decoder. The space vector variational autoencoder samples the data based on the posterior distribution. To remove noise and approximate data points, an empirical rule is applied. The encoder block plays a crucial role in generating latent features from the normal distribution data, emphasizing mean and standard deviation.

Training the model involves optimizing two loss functions: the KL divergence between the learned latent distribution and the prior distribution, which acts as a regularization term, and the reconstruction loss, which enforces fidelity between the decoded samples and the original inputs.

The compressed features from the SV-VAE are fed into a deep neural network that includes layers like pooling, dropout, ReLU, and a sigmoid layer. The output from the CNN flows to the decoder for data reconstruction. The evaluation of SV-VAE loss is accomplished through the KL divergence loss function. Similarly, the model's predictions are assessed for accuracy, f1-score, and precision. Hyperparameter tuning is conducted to enhance model accuracy.

The proposed SV-VAE model optimizes two key loss functions: reconstruction loss, which ensures that the decoder's output aligns with the original dataset images, and KL-divergence loss, which quantifies the divergence between the latent vector and a unit normal distribution. This divergence measurement ensures that the latent variables closely adhere to a standard normal distribution.

Martins [14] conducted a study revealing that the accuracy of Long Short-Term Memory (LSTM) models equipped with time series attributes is comparable to an approach that integrates this pertinent data using the mean and a random forest technique. This research outcome contributes to synthesizing insights from various studies.

Numerous research endeavors have underscored the efficacy of combining Convolutional Neural Networks (CNN) with Long Short-Term Memory (LSTM) models to enhance performance across diverse tasks. For example, in a study by Tan et al., [15], a fusion of CNN and LSTM was employed to forecast user-intended actions, demonstrating that this integration surpasses the individual performance of the two models and traditional machine learning methods. Furthermore, another investigation employed encoded sequential data, such as images and videos, wherein the utilization of CNN yielded superior outcomes compared to gradient boosting and random forest techniques [16].

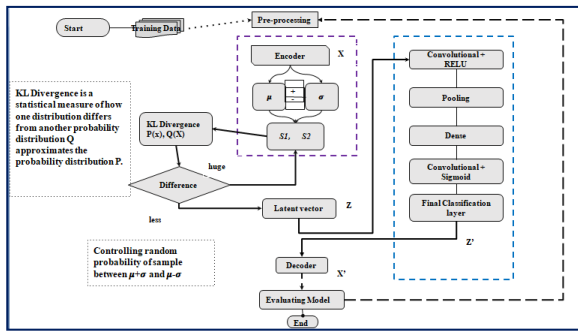

Fig. 1. Proposed SV-VAE model.

The sampling scenarios in VAE are to map the input to a distribution instead of mapping the input to a fixed vector.

$$x = \text{sample}(N(\mu, \sigma^2))$$

The modified approach uses mean and standard deviations to approximate the distribution of data,

$$x = (\mu + 2\sigma) + (-2\sigma) \text{sample}(N(0,1))$$

#### IV. EXPERIMENTAL SETUP

##### A. Dataset

This study utilizes six distinct publicly available datasets from diverse domains, sourced from repositories like Kaggle and UCI. The datasets encompass a range of data types, including discrete, continuous, and categorical values. The dataset sizes vary, with a minimum of 954 records from the Tour & Travels domain to a maximum of 15,000 records from the Music streaming subscriptions domain. Additional insights regarding the dataset characteristics and the specifics of the training-test split are provided in Table II.

TABLE II. DETAILED CHURN DATASET

Domain	Number of records			No of attributes	Train Set	Test Set
	Churn	Non Churn	Total			
Bank	32000	68000	10000	14	80000	20000
Telecom – fixed line	2000	5000	70000	19	5600	1400
Employee churn	270	1200	1470	35	1176	294
Online subscription	15000	135000	150000	30	120000	30000
Tour & Travels	109	845	954	7	763	191
Telecom – mobile	869	2281	3150	13	2520	630

##### B. Hardware and Software

The study was conducted on an Ubuntu 20.04 LTS operating system, employing an i9 12th-generation processor coupled with 16GB RAM and a 1TB HDD. The implementation process was carried out using a Jupiter Notebook in Python v3.10.0. For the implementation, a suite of Python libraries was utilized, encompassing NumPy, Pandas, Seaborn, Sklearn, Keras, TensorFlow v2.0, and Matplotlib. These libraries played pivotal roles in both data pre-processing and modeling stages, contributing to the overall analysis.

##### C. Pre-Processing

Data pre-processing is a fundamental phase in the workflow of every machine learning engineer. This stage encompasses a range of essential steps aimed at refining the dataset for optimal analysis. Imputation of missing values, type conversion, duplicate removal, cleansing, normalization, and transformation are key procedures frequently applied in this phase. For addressing missing values, diverse strategies can be employed, such as statistical methods like mean, median, or even leveraging regression models to predict and fill in the absent values. Data cleansing, on the other hand, entails eliminating noisy data through techniques like binning, regression, and clustering. Once the crucial pre-processing steps are completed, a thorough analysis of the attributes follows, often leading to the creation of new features. The process of attribute selection involves assessing the correlation between variables and selecting the appropriate number of attributes that contribute most effectively to the analysis. To prepare the data for subsequent modeling, it is transformed into a structured format, typically in the form of two-dimensional arrays. These arrays are then divided into training and testing sets. The training data, which constitutes the input for model training, is carefully configured to enable accurate analysis and prediction.

##### D. Hyperparameter

The model is fine-tuned through the manipulation of hyperparameters, which play a crucial role in enhancing the algorithm's performance. These hyperparameters encompass attributes such as batch size, optimizer, number of epochs, learning rate, dropout rate, and random initialization. By carefully adjusting these parameters, the algorithm can be optimized to yield a more generalized and accurate model. Batch size, a vital hyperparameter in gradient descent, determines the number of training data instances utilized in

each iteration. It governs the update of internal model parameters before proceeding to the subsequent iteration. The epoch parameter controls the iteration count for data feeding into the model. The learning rate hyperparameter adjusts the step size of weight adjustments during each epoch, critically influencing the optimization process. To guard against overfitting, a common challenge in model training, the dropout hyperparameter is introduced. This mechanism randomly omits a portion of neurons during training, preventing the model from becoming overly tailored to the training data. This practice enhances the model's capacity to generalize to unseen data.

In the context of this study, these hyperparameters are strategically manipulated to regulate the network's behavior during the training phase, ultimately contributing to the development of a more robust and efficient model.

### V. RESULT AND DISCUSSION

The model's performance was assessed using essential metrics such as precision, recall, accuracy, and F1-score. Depending on the specific business context, the choice between prioritizing precision or recall was determined to gauge the effectiveness of the churn model. Each of these metrics is mathematically derived to provide a comprehensive understanding of the model's classification capabilities. These quantitative assessments serve as valuable tools for objectively evaluating the model's performance, catering to different business needs and objectives. Mathematically each of these measurements is derived by,

$$\text{Precision} = \frac{TP}{TP + FP}$$

$$\text{Sensitivity} = \frac{TP}{TP + FN}$$

$$\text{Accuracy} = \frac{TP + TN}{\text{Total}}$$

$$F1 - \text{Score} = 2 * \left( \frac{\text{Sensitivity} * \text{Specificity}}{\text{Sensitivity} + \text{Specificity}} \right)$$

TP = True Positive                      FP = False Positive

FN = False Negative                    TN = True Negative

TABLE III. SV-VAE WITH IMPACT DROPOUT OVER ACCURACY

Dropout rate	0.1	0.25	0.5	0.75	0.9
Accuracy					
Telecom - fixed line	94	94.25	91.0	89.45	81.6
Telecom	96.2	96.15	90.4	85.6	78.0
Tour and travel	97.8	98.1	88.3	80.2	72.6
Banking	93.1	90.5	85.26	79.36	72.0
Music online subscription model	95.8	96.3	87.1	80.1	74.0
Employee retention	98.1	98.2	90.0	85.0	74.5

To investigate the behavior of the proposed model, a range of dropout values was experimented with (see Table III). It was observed that dropout values between 0.1 and 0.25 yielded

optimal results, striking a balance between preventing overfitting and retaining useful information and Table IV shows the effect of different learning rates and average accuracy.

TABLE IV. EFFECT OF DIFFERENT LEARNING RATES AND AVG. ACCURACY

Learning rate	1	0.5	0.1	0.01	0.001	0.0001
Avg. Accuracy %	68.3	72.7	83.1	85.6	93.25	90.2

Table V displays the confusion matrix, offering a detailed breakdown of instances in which non-churn data is correctly classified as such (True Positives - TP) and churn data is accurately identified as churn (True Negatives - TN). In the context of a churn predictive model, the primary goal is the precise identification of churn users. This matrix provides a comprehensive assessment of the model's performance, shedding light on both accurate and erroneous classifications. Consequently, it informs the calculation of various evaluation metrics utilized in the analysis. In Fig. 2, a recall comparison between the proposed model and standard autoencoders is presented, highlighting the superior recall performance of the proposed model.

TABLE V. MODEL EVALUATION WITH CONFUSION MATRIX - ONLINE MUSIC STREAMING SUBSCRIPTION DATASET

	Actual Churn	Actual Not Churn
Predicted Churn	<b>4300</b>	<b>300</b>
Predicted Not Churn	<b>200</b>	<b>145000</b>
Total Records	<b>150000</b>	
Total Not Churn	<b>148000</b>	
Total Churn	<b>4500</b>	
Precision	<b>0.9712</b>	
Recall	<b>0.9966</b>	
Accuracy	<b>0.9680</b>	

The evaluation of recall enhancement not only underscores the technical progress achieved with the SV-VAE model but also carries profound implications for churn analysis. The notable uptick in the average recall, approximately 4.38%, signifies a substantial boost in the model's capability to accurately detect instances of churn. Within the realm of churn analysis, recall serves as a pivotal metric, quantifying the model's proficiency in capturing genuine churn occurrences among the overall churn cases. This enhancement directly translates into a more potent identification of customers at risk of churning, thereby equipping businesses with the proactive means to intervene and retain these valuable customers.

Table VI presents a comparative analysis of churn prediction accuracy using different types of autoencoders across various domains. Notably, the SV-VAE model consistently stands out, demonstrating superior accuracy across multiple sectors. The remarkable improvement of 5.01% in average accuracy underscores the model's enhanced ability to make precise classifications, distinguishing between churn and non-churn instances with greater accuracy. In churn analysis, accuracy is a vital metric that quantifies the overall correctness of the model's predictions. The improved accuracy ensures that the decisions based on the model's predictions are more

reliable, leading to optimized resource allocation for customer retention efforts and yielding better business outcomes. In both instances, these improvements in recall and accuracy substantiate the efficacy of the SV-VAE model in the realm of churn analysis. By accurately identifying potential churners and enhancing overall classification precision, the SV-VAE model enables businesses to devise more targeted and effective strategies to mitigate customer churn. This not only contributes to retaining valuable customers but also optimizes resource allocation and strategic decision-making, ultimately bolstering the competitive edge of businesses in the market.

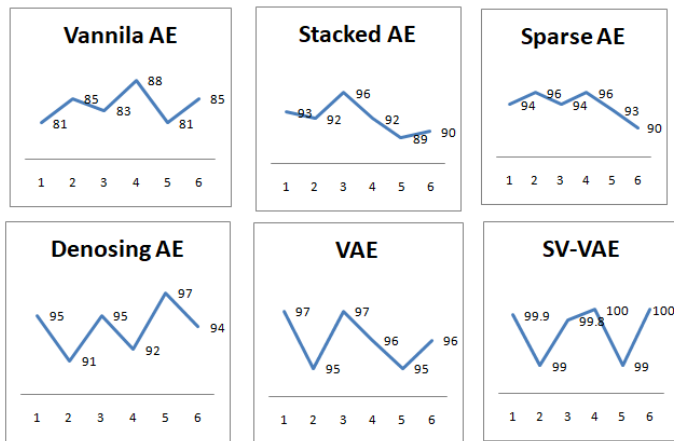

Fig. 2. Recall of the different types of autoencoders with proposed SV-VAE.

TABLE VI. CHURN PREDICTION ACCURACY OVER VARIOUS DOMAINS COMPARED AGAINST DIFFERENT TYPES OF AUTOENCODERS

Model/Dataset	Vanilla AE	Stacked AE	Sparse AE	Denoising AE	VAE	SV-VAE
Telecom Mobile	81	93	94	95	97	99.9
Bank	85	92	96	91	95	99
Music streaming	83	96	94	95	97	99.8
Employee	88	92	96	92	96	100
Telecom – Fixed line	81	89	93	97	95	99
Tour & Travels	85	90	90	94	96	100

Fig. 3. ROC Curve of the proposed SV-VAE.

A ROC (Receiver Operating Characteristic) curve is a graphical tool that shows how the True Positive Rate (TPR) and False Positive Rate (FPR) change when we adjust the threshold for classifying data points as either positive or negative.

$$FPR = \frac{\text{False Positives}}{\text{False Positives} + \text{True Negatives}}$$

$$TPR = \frac{\text{True Positives}}{\text{False Positives} + \text{True Negatives}}$$

By adjusting this threshold, one can observe the variation in TPR (True Positive Rate) and FPR (False Positive Rate) values. Typically, as the threshold decreases, TPR increases, but FPR also rises. The ROC (Receiver Operating Characteristic) curve provides a visual representation of this trade-off and serves as a valuable tool for assessing a model's performance across various thresholds. The AUC (Area Under the Curve) is a quantitative metric that summarizes the model's overall performance over all conceivable thresholds. It quantifies the model's capacity to differentiate between positive and negative instances. In the case of the proposed model, the AUC value stands at 92.45. A greater AUC score denotes enhanced discriminatory power, with a value of 1 denoting a model that operates perfectly, and 0.5 indicating a model that merely makes random guesses. Fig. 3 graphically presents the ROC curve of the proposed model, offering a clear visual representation of its discriminatory power.

## VI. CONCLUSION AND FUTURE WORK

The proposed hybrid model, known as the Space Vector Variational Autoencoder with Convolutional Neural Networks (SV-VAE with CNN), represents a powerful solution for churn prediction tailored to the unique characteristics of churn data. The proposed approach represents a significant departure from prevailing systems in several key aspects. While contemporary systems often rely on traditional machine learning techniques and struggle to effectively utilize time-varying features, this method harnesses the power of a modified Variational Autoencoder (VAE) to unlock latent data attributes. This approach offers several distinctive advantages. It excels in the effective handling of time-varying features. Unlike conventional systems that face limitations when tracking the behavior of the same customer over time with time-varying features, this approach excels in this regard. By leveraging a VAE, it can capture the dynamic nature of features and generate latent representations that encapsulate temporal patterns. Additionally, it effectively reduces data dimensionality through the VAE's latent space, enabling more efficient analysis and modeling. In comparison to standard autoencoders, this approach incorporates Space Vector Variational Autoencoder (SV-VAE) architecture, enabling better discrimination and noise reduction, contributing to more accurate predictions. Moreover, while some systems focus solely on reconstruction loss, this approach optimizes two critical loss functions: reconstruction loss and KL-divergence loss, ensuring the effective capture of latent features while adhering to a standard normal distribution.

This research also opens avenues for generalization to more intricate scenarios and challenges.

**Multi-Modal Data Integration:** The approach, rooted in the VAE framework, can readily adapt to scenarios involving multi-modal data sources. By extending the encoder and decoder components, it can incorporate various data types and establish a more comprehensive understanding of complex cases.

**Temporal Sequence Modeling:** While addressing time-varying features, there is potential to explore more advanced temporal sequence modeling techniques, such as incorporating recurrent neural networks (RNNs) or attention mechanisms to capture intricate temporal dependencies.

**Transfer Learning and Scalability:** As the foundation of this approach lies in feature extraction and latent space representation, it is well-suited for transfer learning, allowing for the application of knowledge gained from one domain to another. Additionally, this methodology can be scaled to accommodate larger datasets and more extensive feature sets by leveraging distributed computing and parallel processing, extending its applicability to handle big data scenarios.

In conclusion, the proposed approach not only distinguishes itself from existing systems but also paves the way for broader applications in complex cases. These differences and potential generalization pathways are discussed here to provide a more comprehensive view of the research's contributions and future possibilities.

Informatic Department-Faculty of Science and Mathematics, Universitas Diponegoro, Semarang, Indonesia

**Abstract**—Stroke is a condition where the blood supply to the brain is cut off. This occurs due to the rupture of blood vessels in the intracerebral area or Intracerebral Hemorrhage (ICH). Examination by health workers is generally carried out to get an overview of the part of the brain of a patient who has had a stroke. The weakness in diagnosing this disease is that deeper knowledge is needed to classify the type of stroke, especially ICH. This study aims to use the Modified Layers Convolutional Neural Network (ML-CNN) method to classify ICH stroke images based on Diffusion-Weighted (DW) MRI. The data used in this study is a DWI stroke MRI image dataset of 3,484 images. The data consists of 1,742 normal and ICH images validated by a radiologist. Because the data used is relatively small and takes into account the computational time, Stochastic Gradient Descent (SGD) is used. This study compares the basic CNN model scenario with the addition of layers to the original CNN model to produce the highest accuracy value. Furthermore, each model is cross-validated with a different k to produce performance in each model as well as changes to batch size and epoch and comparison with machine learning models such as SVM, Random Forest, Extra Trees, and kNN. The results showed that the smaller the number of batch sizes, the higher the accuracy value and the number of epochs, the higher the accuracy value of 99.86%. Then, four machine learning methods with accuracy, sensitivity, and specificity below 90% are all compared to CNN2. As a summary of this research, the proposed CNN modification works better than the four machine learning models in classifying stroke images.

**Keywords**—Batch size; Epoch; ML-CNN; SGD; Stroke

## I. INTRODUCTION

There are more than 3.4 million new intracerebral hemorrhages each year. Globally, more than 28% of all stroke events are intracerebral hemorrhage. Annually, more than 23% of all intracerebral hemorrhages occur in persons aged 15-49 years [1]. Stroke is a fairly serious problem because stroke is a medical emergency that can threaten disability and death in patients if it is not handled quickly and appropriately. In the diagnosis of stroke, neurological imaging always plays an important role. Most stroke patients carry out examinations using Computerized Tomography Scanning (CT scan) radiology modalities. However, the CT scan image results for each patient vary according to the time interval that has passed since the stroke. Therefore, a radiologist plays a major role in

determining the management of stroke patients whether further imaging is carried out using Magnetic Resonance Imaging (MRI) to find out how severe the cell damage is in the brain, so that knowledge of the patient's radiological image will determine the treatment to be undertaken by the patient [2].

Stroke causes a reduction or stoppage of blood flow carrying oxygen which results in the death of brain cells. Based on the cause, stroke is divided into two, namely ischemic stroke where the blood supply stops flowing to the brain due to a blockage and hemorrhagic stroke where bleeding occurs in the brain tissue [3]. It is important to receive the correct diagnosis before stroke treatment begins, because treatment for stroke differs according to the type of stroke. If the patient fails to receive prompt and appropriate treatment, a stroke will have serious consequences and cause permanent damage to the brain and even death to the patient. Treatment and diagnosis of stroke is carried out by clinical examination, and then followed by examining radiologist modalities such as CT scan and MRI [4].

Fig. 1. DWI lesions in the acute and nonacute time periods.

Fig. 1 shown A visible parietal DWI lesion one day after a contralateral basal ganglia hemorrhage in a 66-year-old man (A) and a frontal DWI lesion two years after a contralateral parietal bleeding in a 69-year-old man (B). DWI = diffusion weighted imaging. Computational analysis of MRI images often aids physicians in diagnosis and helps reduce the subjectivity of diagnosis, and also provides higher accuracy for intensive care. Modern applications of artificial intelligence are designed to help humans solve various problems. CNN is a subcategory of deep learning development that is now widely used in neuroimaging [5]. Deep learning techniques and the use of CNN are often used to diagnose acute ischemic stroke. A popular topic in automated diagnostics is end-to-end system architecture. In this study, several CNN modifications are

proposed to find the best performance value in classifying ICH stroke and normal conditions so that doctors can quickly make the quickest diagnosis to determine the therapy given. This paper consists of five sections: the Section I contains an introduction; Section II contains related work; Section III contains the methodology used in the research; Section IV contains performance results from three CNN models, hyperparameters, and comparisons with machine learning models; and Section V contains conclusions and future research work.

## II. RELATED WORK

Recently, several important publications have presented implemented algorithms classifying brain stroke. In addition, the ischemic stroke lesion segmentation method and risk prediction are also applicable to stroke diagnosis [6]. Several studies have used common deep learning models such as Inception-V3 and EfficientNet-b0 to detect acute stroke using DW-MRI with an accuracy value of 86.3% [7]. A study related to the diagnosis and prediction of stroke by developing a detection system for only one type of stroke have detected early ischemia automatically using the Convolutional Neural Network (CNN) algorithm with 256 original images and augmented images, with the classification results obtaining an accuracy value of 90% [8]. Another study used the CNN algorithm with an open stroke dataset from [www.radiopaedia.org](http://www.radiopaedia.org) to classify patient data into three classes, namely normal, ischemic stroke, and hemorrhagic stroke through CT scan images.

Meanwhile, other researchers using the same dataset performed hyperparameter optimization in the Deep Learning algorithm to improve the accuracy of stroke diagnosis using CT scan image segmentation with the thresholding method and the binarization process. The implementation of the threshold method uses global binary thresholding and Otsu thresholding [9].

I.P. Kerta et al. [10] have segmented patient data to produce patient class labels and classify the results of grouping data to test the performance of the classification algorithm used. A total of 4,906 patient data used in this study were grouped using the K-Means method into several clusters, including two clusters, three clusters, four clusters, and five clusters, and the findings of these data groupings will be classified. The classification results produce the best accuracy value on the number of clusters tested, namely two clusters of 99.71%.

Jenna and Kumar [11] have performed a stroke classification using International Stroke trial data. The database includes patient information, patient history, hospital details, risk factors, and symptoms. Preprocessing is done to eliminate missing and inconsistent data. After preprocessing, 350 samples were taken in this work, with parameters sensitivity, specificity, accuracy, precision and F1 scores calculated to evaluate the performance of various kernel functions of the SVM classifier. The experimental results obtained the best precision in the kernel linear function with an accuracy value of 91%.

P. Govindarajan et al [12] presented a prototype for classifying strokes that combines text mining and machine

learning algorithms. At the data collection stage, patient data from 507 patients were collected from Sugam Multispecialty Hospital, Kumbakonam, Tamil Nadu, India. Processed data is fed into various machine learning algorithms such as artificial neural networks, Support Vector Machine (SVM), and random forest. Among these algorithms, the neural network trained with the Stochastic Gradient Descent algorithm outperforms other algorithms with a higher classification accuracy of 95%.

Y. Q. Zhang et al investigated the ability of a machine learning model based on MRI radiomic features (ML) to classify time since stroke onset (TSS), which could aid in stroke assessment and treatment options. This study involved 84 patients with acute ischemic stroke. Segmentation of the infarct area is made manually with 3D-slicer software. A total of 4312 radiomic features from each image sequence were captured and used in six machine learning models to estimate stroke onset time for binary classification ( $\leq 4.5$  hours). Receiver-Operating Characteristic (ROC) curves and other parameters are calculated to evaluate the performance of the model in the training and test groups. Twelve radiomic results and six clinical features were selected to construct the ML model for TSS classification. The deep learning model-based DWI/ADC radiomic feature showed the best for binary TSS classification in the independent test group, with AUC 0.754, accuracy 0.788, sensitivity 0.952, specificity 0.500, positive predictive value 0.769, and negative predictive value 0.857, respectively [13].

Our contributions to this study are as follows:

1) We propose a classification of stroke intracerebral hemorrhage (ICH) using MRI images with modifications to the addition of a convolution layer to the simple CNN model with hyperparameter tuning, such as changes in epoch, batch size, and the use of k- fold validation in knowing performance values from a limited number of datasets.

2) We have compared the performance of Modified Layer CNN (ML-CNN) with machine learning models to produce a good method for classifying DW- MRI ICH stroke images with normal images.

Several CNN models were analyzed using several optimal methods to compare the performance of various machine learning algorithm approaches using four parameters, namely accuracy, precision, recall, f1- measure, and k-fold cross-validation to optimize performance, resulting in high prediction accuracy.

## III. METHODOLOGY

### A. Data Collection

The stages of data collection in this study were to collect image data from DW-MRI of the patient's brain consisting of Intracerebral Hemorrhage (ICH) stroke image data and normal image data. DW-MRI image data comes from Gatot Subroto Hospital Jakarta which was taken during the January-May 2019 period and came from 430 patients with ICH stroke indications. The image taken has a slice thickness of 5.0 mm, the distance between slices is 6.5 mm, the pixel spacing is 0.7 mm and the original image size is 320 pixels x 320 pixels.

The data that has been collected is labeled to distinguish between ICH stroke data and normal data by radiologists. To eliminate noise, a filter is performed and to add data to prevent overfitting, augmentation is carried out in real time. Images were entered for each CNN model and the values for accuracy, precision, recall, f1-score, and specificity were calculated. Next, the collected data is compared with machine learning models to find out how high the performance of each of these models is. The research method is shown in Fig. 2.

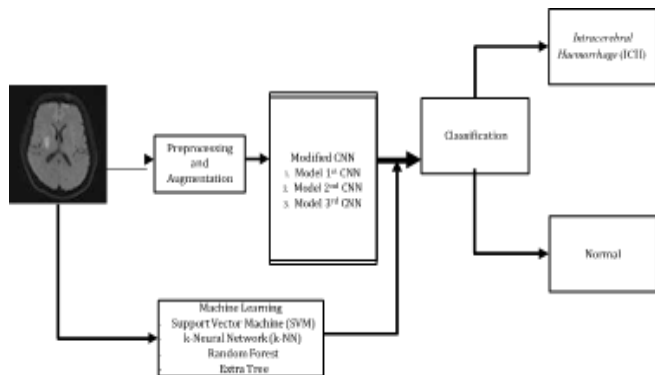

Fig. 2. Research method.

**B. CNN Models**

This research was conducted using three variations of the CNN architecture to obtain the most appropriate architecture in detecting and differentiating the presence of intracerebral hemorrhage (ICH) stroke and normal brain images. Computations are performed using NVIDIA GeForce GTX 1650 GPU RAM 16 GB 2600 MHz DDR4 to shorten the compilation time of the CNN program.

The architectural design is presented in Table I. Fig. 3 shows the basic architecture of the CNN method (CNN1). Fig. 4 (CNN2) shows an additional development of the convolution layer from CNN1. Fig. 5 (CNN3) is the development of the CNN2 model by adding each layer and its activation function to get the classification accuracy value. Comparisons can be made between these designs individually (CNN1, CNN2, CNN3) or between design groups to obtain the most appropriate type of design in classifying DW-MRI image data.

**C. Augmentation Data**

Data Augmentation is a technique to increase the diversity of image data by performing basic transformations such as rotation, shared, horizontal flip, and zoom. According to Luis Perez et al. [14] by using this technique, the model can overcome the problem of overfitting and improve the accuracy of the CNN model. In this study, each class (ICH and Normal) used 430 data with 4 (four) geometric transformations, and generated data for each class of 1720 datasets per class. In each epoch, the model receives images with different transformations. This study applies real time data augmentation [15].

Configuration of data augmentation in this study is in the form of:

- 1) *Shared range* = 20 skews the image to a maximum angle of 20 degrees. The value used should not be too large because it will make the image flat.
- 2) *Rotation range* = 20 randomly rotates the image up to a maximum angle of 20 degrees.
- 3) *Horizontal flip* = True flips the image horizontally.
- 4) *Zoom range* = [0.75-1.0] randomly enlarges the image. A value of 0.75 means that the image is enlarged to 75%, while 1.0 is a normal image size.

Fig. 6 shows the real time augmentation results that are generated after running the CNN model training.

Fig. 6. DW-MRI image augmentation results.

#### D. K-Fold cross-validation

Evaluating machine learning models is very difficult. Usually, to divide the dataset into training and test sets it is necessary to use a training set to train the model and a test set to test the model. The next step is to evaluate the performance of the model based on the error matrix to determine the accuracy of the model. However, this method is not very reliable because the accuracy obtained for one test set can be very different from the accuracy obtained for different test sets. K-fold Cross-validation (CV) provides a solution to this problem by dividing the data into folds and ensuring that each fold is used as a test set at multiple CV points [16] [17].

This study uses 3,484 data. If using five-fold cross-validation, the data is divided into five folds of the same size where four folds will be used as training data and one fold is used as validation data. From a total of 3,484 ICH and normal image data, 2,787 data will be used at the training stage and 697 at the testing stage as test data. A total of 2,787 data used at the training stage will be divided into five (Each fold consists of 557 data), so that the amount of training data used is 2,230 data and validation data used is 557.

#### E. Performance Matrix for Classification

Three CNN models and machine learning algorithms were trained and evaluated by comparing four performance matrices such as: accuracy, precision, recall, and F1-score [16]:

$$Accuracy = \frac{TP+TN}{TP+FN+FP+TN} \quad (1)$$

$$Recall = \frac{TP}{TP+FN} \quad (2)$$

$$Precision = \frac{TP}{TP+FP} \quad (3)$$

$$F\ Score = 2x \frac{Precision \times Recall}{Precision + Recall} \quad (4)$$

FN, FP, TN and TP are False Negative, False Positive, True Negative, and True Positive.

## IV. RESULTS AND ANALYSIS

### A. CNN Model Performance Test

Comparisons are made by means of one parameter being a variable and the other parameters being assigned the same value for the three types of CNN architectures. Parameters compared were epoch, batch, and classification accuracy. Meanwhile, the other parameters are set to the same value, namely the number of filters is 32.64 and 128, with Stride 1 x 1, kernel 3 x 3, kernel pooling size 3 x 3, and using the SGD optimization function because it is stochastic. This means sampling random training data at each step, and then calculating gradients making it much faster because there is less data to manipulate at any one time. The image used as input from CNN is a rescaled grayscale image so that the size is 90 x 90 pixels.

Fig. 7. Confusion matrix for classification of Intracerebral Hemorrhage (ICH) stroke and normal brain images using 3 modified CNN models.

Based on the results of the tests that have been carried out, a confusion matrix for Intracerebral Hemorrhage (ICH) and normal brain images can be made using three modified CNN models as presented in Fig. 7. The test results show that the confusion matrix classification of the CNN\_1 model and the CNN\_2 model with 343 ICH image values is correctly predicted and 17 ICH images were not correctly predicted. Likewise, 315 normal images were correctly predicted as normal images and two normal images were predicted incorrectly as normal images. On the other hand, model\_3 shows that 330 ICH images are correctly predicted as ICH images and 28 ICH images are predicted incorrectly as ICH images. Meanwhile, there are 319 normal images that can be predicted as ICH images, and only 20 ICH images that are predicted as ICH images.

Based on the performance results of the three CNN models shown in Table II, it can be seen that the accuracy values for

CNN model\_1 and CNN model\_2 have better performance than CNN\_3. This is because the more convolution layers are generated, the more map features will also be. Therefore, the system experiences overfitting in classifying the image dataset.

TABLE II. CNN PERFORMANCE ANALYSIS

CNN MODELS	Precision (%)	Recall (%)	Specificity (%)	F1_score (%)	Acc (%)
CNN1	95%	93%	95%	94%	94.40 %
CNN2	95%	93%	95%	94%	94.40 %
CNN3	92%	94%	92%	93%	94.11 %

The algorithm used to test the validity of the accuracy results is k = 3, 5, 7 and 10 Cross-validation. The dataset is divided according to the number of k-folds into five folds in which there are 1,720 datasets, and at each iteration one fold is taken as a testing dataset and the other is used as a training dataset. The selection of the dataset for testing is adjusted according to the iteration order and the fold order, namely the 1st iteration folds 1, the 2nd iteration folds 2, and so on. After each training is finished, testing is immediately carried out to find the predicted value, and then the level of accuracy is calculated on average. The test results are shown in Table III.

TABLE III. EFFECT OF CROSS-VALIDATION

CNN Models	Precision (%)	Recall (%)	Specificity (%)	F1_score (%)	Acc (%)
CV (n=3)					
CNN1	66%	79%	59%	72%	68.95%
CNN2	70%	93%	61%	80%	76.81%
CNN3	58%	61%	56%	60%	58.48%
CV (n=5)					
CNN1	86%	84%	86%	85%	85.20%
CNN2	89%	85%	89%	87%	87.00%
CNN3	72%	86%	67%	87%	76%
CV (n=7)					
CNN1	93%	76%	94%	83%	84.84%
CNN2	86%	91%	85%	89%	88.09%
CNN3	73%	90%	66%	80%	77.98%
CV (n=10)					
CNN1	86%	84%	86%	85%	84.84%
CNN2	86%	87%	85%	87%	86.28%
CNN3	70%	76%	68%	73%	71.74%

Table III shows that for each k-fold tested, the CNN2 model has the best performance value compared to the CNN1 and CNN3 models.

B. Effect of Batch Size

In this test, the epoch value is set at 30 with SGD optimization and a dropout value of 0.5. Usually, large batch sizes are used because they allow computational acceleration. If you use a small batch size, it will take a very long time. However, there is a price to pay behind the speed of computing. Batch sizes that are too large will produce less than optimal results. The larger the batch size, the less accurate the results will be [18].

The test results are shown in Table IV, V, and VI. It can be seen that batch size 8 has the best performance with the highest accuracy of the several variations in batch size values for the three models tested. The larger the batch size value, the lower the accuracy value of each CNN model.

TABLE IV. EFFECT OF BATCH SIZE MODEL CNN\_1

Number of Batch Size	Precision (%)	Recall (%)	Specificity (%)	F1_score (%)	Acc (%)
8	100%	100%	100%	100%	100.00 %
16	99%	96%	99%	98%	97.70%
32	94%	72%	95%	81%	83.00%
64	72%	78%	73%	75%	75.40%
128	69%	80%	64%	75%	72.02%
256	51%	56%	40%	54%	48.78%

TABLE V. EFFECT OF THE BATCH SIZE MODEL CNN\_2

Number of Batch Size	Precision (%)	Recall (%)	Specificity (%)	F1_score (%)	Acc (%)
8	100%	100%	100%	100%	99.86%
16	99%	97%	99%	98%	98.13%
32	72%	95%	61%	82%	78.48%
64	75%	85%	74%	77%	77.04%
128	69%	88%	60%	77%	74.03%
256	50%	63%	35%	56%	49.21%

TABLE VI. EFFECT OF BATCH SIZE MODEL CNN\_3

Number of Batch Size	Precision (%)	Recall (%)	Specificity (%)	F1_score (%)	Acc (%)
8	100%	98%	100%	99%	98.71%
16	100%	60%	100%	75%	80.06%
32	79%	53%	85%	64%	68.58%
64	71%	68%	72%	70%	70.16%
128	58%	99%	17%	73%	60.98%
256	51%	99%	5%	68%	52.65%

### C. Effect of Number of Epoch

The next design trial was carried out with a batch size of 32 with SGD optimization and a dropout value of 0.5, and the number of epochs varied. The test results are shown in Table VII. The greater the epoch, the higher the accuracy acquired, namely 99.86% accuracy at epoch 90, which is the greatest accuracy value in the ICH stroke dataset.

TABLE VII. DEGREE OF ACCURACY WHEN THE NUMBER OF EPOCHS VARIES

Number of Epochs	Precision (%)	Recall (%)	Specificity (%)	F1_score (%)	Acc (%)
30	73%	98%	63%	84%	80.77%
50	77%	100%	71%	87%	85.51%
70	99%	98%	99%	98%	98.13%
90	100%	100%	100%	100%	99.86%

### D. Comparison with Other Classification Methods

The following trials were conducted to compare the performance of the CNN2 Model design (as the best proven CNN design) with other classification methods, namely, SVM, Random Forest, Extra Trees, K Neighbors. For k-NN, the DW-MRI image dataset was tested using the k parameter of 3.

Meanwhile, for the SVM method, the dataset was tested using a linear kernel. Tests were carried out to classify the DW-MRI image dataset in the ICH or normal stroke class. The input data for the k-NN and SVM classifiers are the grayscale intensity values of each image pixel in the dataset.

The dataset used with all machine learning models uses 1720 normal images and 1720 ICH images with a training data and testing data ratio of 70:30. From the test results presented in Table VIII, it was found that the four machine learning methods (SVM, Random Forest, kNN, and Extra Trees) had poor performance, with levels of accuracy, sensitivity, and specificity all below 90%.

The CNN 2 model method produces the highest performance. This shows that the CNN 2 method can be implemented to classify DW-MRI images of stroke Intracerebral Hemorrhage (ICH) and normal brain images with good performance.

TABLE VIII. PERFORMANCE COMPARISON OF THE CNN2-SVM-KNN-RANDOM FOREST-EXTRA TREES METHODS ON ICH STROKE CLASSIFICATION

Method	Precision (%)	Recall (%)	Specificity (%)	F1_score (%)	Acc (%)
CNN2	95%	93%	9500%	94%	94.40%
SVM	70%	70%	6900%	70%	70%
Random Forest	62%	79%	2500%	56%	62%
Extra Tress	57%	77%	14%	47%	57%
K Neighbors (k=3)	36%	36%	41%	36%	36%

## V. CONCLUSIONS

From the results of the tests and analyzes that have been carried out, it can be concluded that the CNN algorithm can be used properly in the classification of DW-MRI images to distinguish stroke ICH images from normal DW-MRI images. In the first trial related to the CNN model performance test, the highest accuracy value was 94.40% for CNN1 and CNN2 compared to CNN3 because the more layers, the lower the accuracy value. To produce further performance on the CNN1 and CNN2 models, it was tested using the cross-validation method, the highest accuracy value was generated in the CNN 2 model for several variations of the number of k folds. Each CNN model was tested by changing the number of batch sizes. From the test results, the smaller the number of batch sizes (8), the higher the accuracy value and the number of epochs, the higher the number of epochs (90) the higher the accuracy value of 99.86%.

This study compares the basic CNN model scenario with the addition of layers to the original CNN model to produce the highest accuracy value. The dataset used is 1720 images for each class. Furthermore, each model is cross-validated with a different k to produce performance in each model as well as changes to batch size and epoch and comparison with machine learning models such as SVM, Random Forest, Extra Trees, and kNN. The results showed that the smaller the number of batch sizes, the higher the accuracy value and the number of epochs, the higher the number of epochs, the higher the accuracy value of 99.86%. Then, four machine learning methods with accuracy, sensitivity, and specificity below 90% are all compared to CNN2. The proposed CNN modification works better than the four machine learning models in classifying stroke images.

In the future, this study will be developed in terms of using CNN to classify 3D images so that classification classes can be multiplied. An example is not only to find out DW-MRI images of brain hemorrhage (ICH) or normal DW-MRI images, but can also find out blockages in several locations in the brain vessels with DW-MRI images.

Departamento de Estudios Generales, Universidad Continental, Lima, Perú<sup>4</sup>

**Abstract**—This article details the process of creating a prototype mobile application that aims to promote inclusive literacy for people with reading disabilities. The goal of this application is to help people with reading difficulties to become more independent so that they can participate in society and take advantage of educational and employment opportunities that were previously unavailable to them. The methodology used in this work is Design Thinking as it is a user-centered creative approach to solving difficult challenges and addresses creativity, design and problem solving. The results obtained from the expert judgment based on Atlas TI 22 provide a valuable perspective on the viability and potential of these technological tools. The analysis of the results of the application prototype designs gives an encouraging picture of 85%. Similarly, 75% confirm that the app effectively complements inclusive literacy efforts, a significant achievement in line with the objective, and 70% appreciate the app's interaction with people with reading disabilities. Finally, a staggering 87% would gladly recommend the app, underscoring its valuable impact. In conclusion, the article discusses how mobile applications can help people with reading difficulties become more literate. The good reception of the prototype confirms the importance of technology in inclusive education and the value of this approach to improving the lives and education of this demographic.

**Keywords**—Atlas TI 22; inclusive literacy; mobile applications; reading disability; design thinking

## I. INTRODUCTION

The aim of this study was to report on the design of specialized reading materials, such as books with altered fonts and simplified text [1]. According to the findings, this type of content helped people with reading difficulties to read and comprehend what they read. The authors also discuss the advantages of cooperative and group learning for language acquisition [2]. The researchers found that when people with reading difficulties worked together in small groups, they were able to encourage and support each other as they learned.

However, despite advances in technology and education, considerable impediments remain in the way of literacy for people with reading difficulties [3]. Many potential elements come into play here, including cognitive, sensory, financial, and lack of specialized educational resources [4]. Symptoms can range from having trouble interpreting words to having trouble understanding what they read [5]. The impact has far-reaching effects, limiting social, employment and educational opportunities and prolonging marginalization.

Promoting inclusion and empowering people with reading difficulties requires action [6]. The study and creation of mobile applications tailored to inclusive literacy not only have the capacity to remove conventional barriers but also to reinvigorate learners [7]. With the results of this study, we hope to develop effective strategies to respond to the educational challenges faced by this population and give them access to resources that take into account their particular strengths and preferences [8]. The positive effects of promoting diversity and inclusion in the community are not limited to the individuals directly involved [9].

The importance of this article is to report on the creation of a prototype mobile application for inclusive literacy, aimed at users with reading difficulties. In the same way provide a welcoming and individualized classroom environment in which students can work on their reading comprehension problems [10]. The goal of this application is to help people with reading difficulties to become more independent so that they can participate in society and take advantage of educational and employment opportunities that were previously unavailable to them.

An innovative and potentially fruitful solution to the pedagogical difficulties faced by people with reading disabilities is presented: the development of mobile applications for inclusive literacy. This article delves into the global context, explains the problem, explains why this study is important, and sets the goal of creating a prototype mobile application that will help create a more just and egalitarian world.

The structure of the research is based on the following: Section II will present the literature review, Section III will present the methodology used in the research, Section IV will present the results, Section V will present the discussions and finally Section VI will present the conclusions and future work.

## II. LITERATURE REVIEW

For students with reading difficulties, inclusive literacy is a rapidly expanding area of study. The purpose of this literature review is to examine the various methods and techniques employed in inclusive literacy for individuals with reading difficulties. The education and literacy of this population will be examined along with research, programs, and practices that aim to improve their accessibility.

The authors [11] studied how mobile apps and screen readers, two examples of accessible technologies, can help people with reading difficulties become more literate. The results showed that text comprehension improved by using read-aloud features and by modifying the material. This group's reading comprehension and access to information were greatly enhanced by the use of technology.

The results of this study focus on the effectiveness of using flexible methods of teaching and reading. The authors [12] emphasize that students' reading comprehension and engagement increased when individualized tactics such as guided reading and the use of pictograms were introduced. These results underscore the need for personalized approaches to reading and writing instruction. The research also focused on the production of accessible literature for people with reading difficulties, such as simplified texts and audiobooks [13]. The results showed that the use of these modified materials increased interest in reading and improved comprehension. There is a broad consensus that the availability of literature in accessible formats is crucial to enable and encourage reading autonomy.

They discuss individuals with reading problems and the effects of teacher training in inclusive practices on their literacy. Also, the authors [14], teachers who received professional training were more adept at modifying lessons and providing students with individualized attention. As a result, the children's reading ability improved significantly, demonstrating the value of inclusive education. The study also analyzed the effectiveness of collaboration between teachers, speech-language pathologists and assistive technology specialists. Using a combination of methods from different fields, specialists were better able to meet the specific needs of individuals. The results underscored the need for inclusive literacy strategies.

Similarly, the authors [15] studied people with reading problems to see how increasing their literacy levels affected their ability to relate to others and feel self-confident. Those who made efforts to improve their skills felt more ownership of their lives and had easier access to resources. Because of its good effects on quality of life, universal literacy is important. The authors also detail how they have included artificial intelligence (AI) and augmented reality (AR) in their teaching of reading [16]. Mobile apps and devices equipped with these features facilitated interaction with written content and provided a more immersive learning environment. The findings point to the potential of technology to increase literacy opportunities for all.

According to the authors [17], they aim to demonstrate a comprehensive strategy to promote digital literacy among India's most marginalized rural population as part of the government's ambitious Digital India initiative. For low literacy learners in resource-poor environments with poor Internet bandwidth, lack of ICT facilities and inconsistent power, tackling multiple literacies at once poses a major challenge. The educational concept is an effective way to bring tablet-based digital literacy directly to communities, thus overcoming long-standing obstacles [18]. In order to improve both digital and life skills, it draws on a variety of actors,

including pre-existing civil society, schools, and government agencies, to deliver digital literacy and awareness. It demonstrates the benefits of a holistic approach to digital literacy as a tool to promote digital equity.

On the other hand, the authors [19] do a study to report on the design of specialized reading materials, such as books with altered fonts and simplified text. According to the findings, this type of content helped people with reading difficulties to read and understand what they read. The authors also discuss the benefits of cooperative and group learning for language acquisition. The researchers found that when people with reading difficulties worked together in small groups, they were able to encourage and support each other as they learned.

As more and more students with disabilities enroll in mainstream universities, the question of how best to accommodate them has become more pressing. The authors [20], define the support provided to these students remains a crucial task, despite the emphasis on inclusion and engagement in policy and practice. This collective case study used interviews and focus groups to gather information from 125 secondary school staff members from seven different schools about their experiences with students with disabilities [21]. Using the results of this research as a basis, a series of professional development initiatives were designed with the goal of improving the inclusion of older students with disabilities.

In this literature review, we analyzed the effectiveness and applicability of various techniques and a comprehensive synthesis of the most important findings. While it is true that the authors have expanded knowledge about intelligence, they have not offered any concrete plans on how to implement it using mobile applications.

### III. METHODOLOGY

Design Thinking is a method for identifying problems and proposing novel user-centered solutions. In this approach, priority is given to the requirements, desires, and feelings of the people for whom a product, service or experience is developed [22]. Product and service creation, as well as business innovation and complicated problem solving, are some of the areas in which this approach has been successful. Its human-centered approach and its ability to inspire innovation have led to its widespread adoption beyond the design world. The Design Thinking process is based on a series of five phases, the exact number of which will vary depending on the model or source used as shown in Fig. 1.

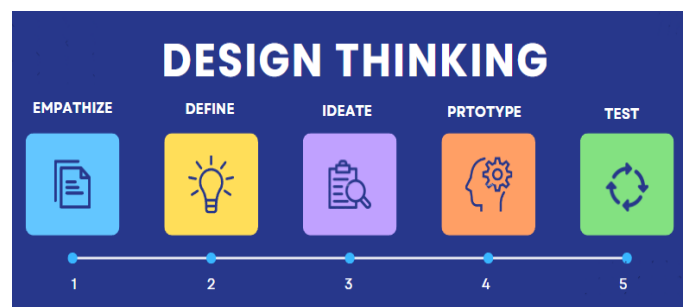

Fig. 1. Phases of design thinking.

A. Empathize

In this phase, the group investigates the target audience to learn more about their desires, needs, feelings and routines [23]. In doing so, it hopes to better understand the difficulties encountered by users. To do so, it can resort to interviews, participant observations and other ethnographic research methods. Table I shows the four questions posed for the interview with parents of people with reading disabilities.

TABLE I. INCLUSIVE LITERACY QUESTIONS

N°	Questions
1	Tell me about the learning and literacy experience of your child with a reading disability?
2	What kind of support or assistance has your child received to improve his/her reading skills?
3	Have you currently used any mobile apps or technology to support your child's literacy?
4	What specific content do you think would be most useful for your child in an inclusive literacy application?

B. Define

The "Define" phase of Design Thinking is the second step of the process and attempts to properly identify and characterize the problem or challenge that the design will address. A well-defined objective in this phase ensures that the rest of the design process moves in the right direction. Table II shows four questions posed for the survey to experts in special education using ICTs taking into account the interview report made in the previous step.

TABLE II. MOBILE APPLICATION QUESTIONS ON INCLUSIVE LITERACY

Dimensions	Questions
Support	Does the mobile application currently support you in developing your reading and comprehension skills more effectively?
Accessibility	Is the mobile application currently accessible for use by children with reading disabilities?
Monitoring	Are children frequently monitored by their teachers for academic progress in literacy in the proper use of the mobile application?
Motivation	Are special children motivated through appropriate strategies in the teaching and learning process by their teacher?

Table III shows the current status and prototype status of mobile applications for inclusive literacy for each of the dimensions such as support, accessibility, monitoring and motivation.

C. Ideas

The third step of Design Thinking, "Ideate" is about coming up with a wide range of original ideas and possible solutions to the problem or challenge identified in "Conceive" [24]. The goal at this point is to develop as many ideas as possible without worrying about their feasibility, thus encouraging diverse thinking, for the design of prototypes, about inclusive literacy. Table IV shows four consensual activities for the design of the mobile application for inclusive literacy in people with reading disabilities.

TABLE III. CURRENT AND PROPOSED SITUATION

Dimension	Current status	Proposed Situation
Support	We currently do not have a mobile support application.	To create a prototype of a mobile application to support learning.
Accessibility	Generally, there is no App available for its use.	Create a user-friendly App.
Monitoring	There is no frequent monitoring of your teacher.	There must be a monitoring and control plan
Motivation	No adequate motivation strategies	Strategies must be implemented in order to motivate

TABLE IV. CONSENSUAL ACTIVITIES FOR THE DESIGN OF THE MOBILE APPLICATION

N°	Consensual activities
Support	Design registration and Login to enter the inclusive literacy application for people with disabilities.
Accessibility	Conduct intuitive language and cognitive therapy inclusive literacy design for people with disabilities.
Monitoring	Design a mobile application of inclusive literacy educational games for people with disabilities.
	Design a mobile cognitive therapy application
Motivation	Design a mobile application for teaching reading for people with basic level disabilities
	Design a mobile application for teaching reading for people with intermediate level disabilities

D. Prototyping

The fourth step of Design Thinking is called "Prototyping" and its objective is to build rapid, low-cost prototypes of the solutions chosen in the "Ideate" phase [25]. Before settling on a final solution, ideas can be visualized and evaluated using these prototypes. At this point, the most important thing is to get feedback quickly and collect user feedback to help shape future iterations of the solutions.

Fig. 2 shows the Registration and Login of the inclusive literacy application. Users can access their own accounts and their own material by registering and logging into a mobile application. This function is essential to create a personalized and secure environment for all users.

Additionally, the registration and login process plays a pivotal role in enhancing user engagement and tracking individual progress within the app. By offering a personalized experience, users can easily pick up where they left off, track their achievements, and tailor their learning journey to meet their unique needs. This not only fosters a sense of ownership but also reinforces the commitment to fostering inclusive literacy, making the application a valuable tool for learners of all backgrounds and abilities.

Intuition-based cognitive and linguistic processing Designing for literacy inclusion requires a deep understanding of the strengths and weaknesses of people with cognitive or reading disabilities. Successful, accessible learning environments are the result of the combined efforts of educators, speech-language pathologists, and developers of

mobile apps and educational platforms. It helps people with disabilities improve their language and literacy skills by providing them with accessible information and tools. Images, visual elements and visual symbols are used extensively throughout the design to reinforce main points and improve readability. How to assemble vowels, combine by size and color (see Fig. 3).

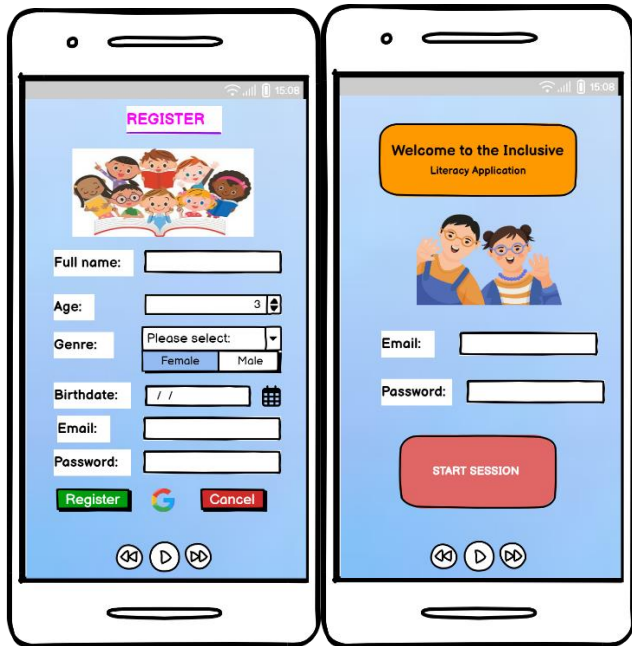

Fig. 2. Application registration and login.

Fig. 4. Basic level educational games.

Fig. 3. Cognitive therapy.

Accessible, intelligible, and engaging learning experiences are the goal of the intuitive design of disability-inclusive literacy games. These video games take into account the specific needs of players to ensure that everyone has an equal opportunity to master the language, phonetic, letter recognition, and writing skills they offer. As shown in Fig. 4.

These inclusive educational games are modifiable to meet the needs of children with reading disabilities, giving them a voice in the learning process. These games provide a stimulating environment for children to learn to read and write using visual, auditory and tactile elements (see Fig. 5).

These inclusive educational games not only offer customization to cater to the specific requirements of children with reading disabilities but also play a crucial role in fostering inclusivity in the broader educational landscape. By accommodating diverse learning needs, they empower children with reading disabilities to actively participate in the learning process, promoting a sense of inclusion and equity. Additionally, these games serve as a dynamic and engaging platform for children to develop their literacy skills. Through a combination of visual, auditory, and tactile elements, they create a multisensory learning experience that appeals to various learning styles and strengths, further enhancing the accessibility and effectiveness of literacy instruction. Moreover, by embracing technology in education, these games align with the evolving digital era, preparing students with valuable digital literacy skills that are essential for their future success in a technology-driven world. In essence, these inclusive educational games not only bridge educational gaps but also nurture a more inclusive, adaptable, and tech-savvy generation of learners.

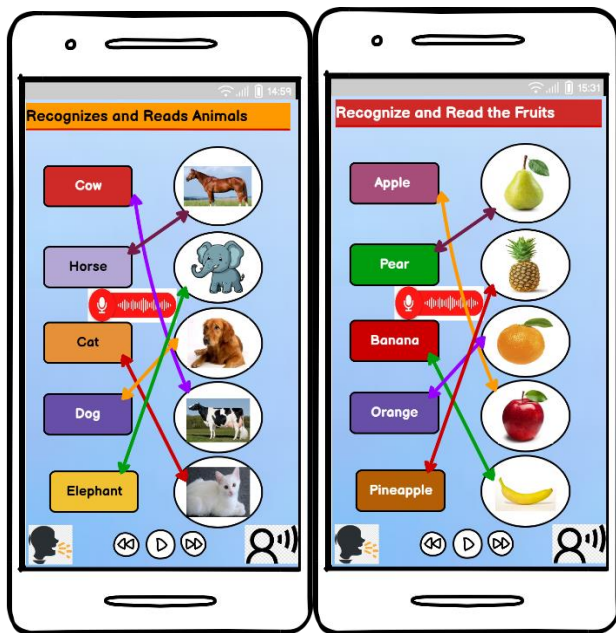

Fig. 5. Intermediate level educational games.

#### IV. RESULTS

##### A. About the Interview

Parents of people with reading disabilities were interviewed about inclusive literacy, especially in children, analyzing through Atlas TI 22 (See Fig. 6).

The utilization of Atlas.ti software in interviews holds significant importance as it empowers researchers to efficiently analyze and interpret qualitative data. This powerful tool facilitates the systematic organization of large volumes of textual, audio, or visual data, enabling researchers to uncover patterns, themes, and insights that might otherwise remain concealed. Its robust coding and data visualization capabilities not only streamline the research process but also enhance the rigor and credibility of qualitative studies, ultimately contributing to a deeper understanding of complex phenomena and more informed decision-making in various academic and professional domains.

- Experience:

It has been observed that all parents mention challenges in their children's learning experience, highlighting moments of frustration due to reading difficulties. However, a positive attitude toward each child's individual progress and their unique capacity to learn is also evident. This suggests that adaptability and a focus on individual achievements are essential aspects of the learning experience for these children.

- Support:

The analysis reveals that all parents have sought support and assistance both within the school environment and therapeutic settings. Speech and language therapy sessions emerge as a common intervention to enhance pronunciation

and auditory comprehension. Furthermore, collaboration with specialized tutors and the adaptation of learning environments are mentioned as effective strategies to address the unique needs of these children. This suggests that a combination of school-based and therapeutic approaches is crucial for the development of reading skills in children with reading disabilities.

- Use of Mobile Applications:

While all parents have experimented with mobile apps to support their children's literacy, there is a consistent search for a solution that perfectly aligns with the children's needs. Apps offering interactive exercises and voice narration have proven effective in maintaining interest and engagement. However, the lack of options perfectly tailored to the specific needs of the children underscores the importance of adaptability and customization in literacy apps.

- Content:

The analysis of parents' responses regarding useful content in an inclusive literacy app demonstrates a consensus on the significance of multimodality. The combination of text, images, and audio is essential to cater to diverse learning styles. Furthermore, interactive activities that reinforce vocabulary, sentence formation, and comprehension are considered valuable for enhancing reading skills. This highlights the need for tailored content addressing multiple aspects of literacy.

##### B. Expert Testing

Fifth, in the testing phase of Design Thinking, prototyped solutions are subjected to more rigorous testing with experts. In this phase, the solution is tested to gauge its interaction, usability, interface and quality before it is fully implemented. Expert validation of the design of the inclusive literacy prototypes was performed through evaluation with eight experts (E).

The solution undergoes testing to fine-tune its interaction, usability, interface, and quality before full implementation. The validation of the inclusive literacy prototype designs involved assessment by eight experts. The resulting average scores are as follows: For interaction, the mean was 81.25, indicating generally positive expert perceptions. Usability averaged 82.5, implying good overall usability. Interface garnered a high average of 91.25, reflecting strong approval of the design. The quality received an average of 82.5, denoting consistent good quality. Collectively, experts' evaluations suggest promising potential, yet addressing specific improvement areas noted by individual experts will further amplify their effectiveness and user experience (see Table V).

TABLE V. EXPERT VALIDATION

Criteria	E1	E2	E3	E4	E5	E6	E7	E8	Media
Interaction	80	90	80	90	70	80	80	80	81.25
Usability	70	80	90	80	80	90	80	90	82.50
Interface	80	90	90	100	100	90	90	90	91.25
Quality	80	80	80	90	80	80	80	90	82.50

Fig. 6. Network analysis with the use of ATLAS ti22.

C. About the Survey

Table VI shows the four questions posed for the survey to parents about the use of the mobile application for inclusive literacy in people with reading disabilities.

TABLE VI. PARENT SURVEYS ON THE USE OF THE MOBILE APPLICATION

N°	Questions
1	Is the design of the mobile application user friendly?
2	Did the use of the mobile application serve as a complement for inclusive literacy?
3	Does the mobile application interact with people with reading disabilities?
4	Would you recommend the mobile application for inclusive literacy?

The analysis of the results from our prototype of a mobile application for inclusive literacy in individuals with reading

disabilities paints an encouraging picture. With an impressive 85%, the majority find the application design to be user-friendly, a vital aspect for creating a comfortable user experience. Furthermore, 75% confirm that the application effectively complements inclusive literacy efforts, a significant achievement in line with our goal. While 70% appreciate the application's interaction with individuals with reading disabilities, delving into the reasons behind the 30% who didn't share the same perception would be valuable. Lastly, an astounding 87% would gladly recommend the application, underscoring its valuable impact. While we're on the right track, it's crucial to address the feedback from those who didn't respond positively to continue refining and meeting their needs (see Fig. 7).

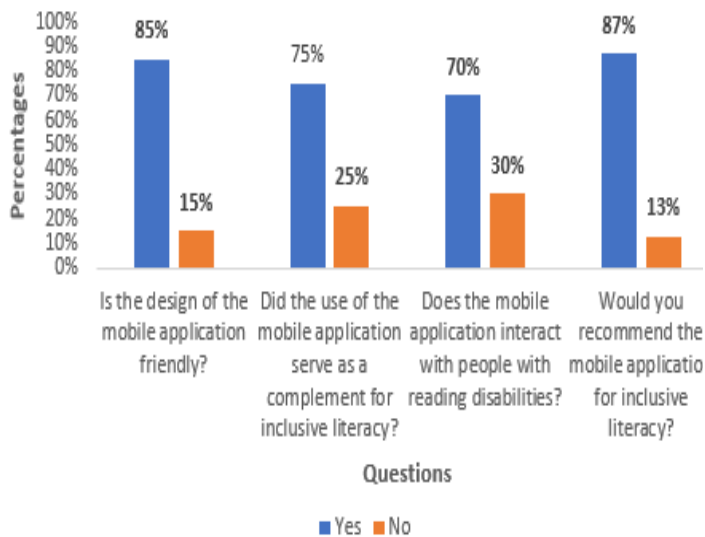

Fig. 7. Questions on the use of the mobile application.

## V. DISCUSSIONS

The authors [12] emphasize that reading comprehension and student engagement increased when individualized tactics such as guided reading and the use of pictograms were introduced. In the present research work, prototypes of didactic mobile applications specifically designed to enrich cognitive-behavioral therapy skills in people with reading disabilities were developed.

This study builds on previous research highlighting the importance of mobile applications and screen readers in promoting literacy among people with print disabilities [11]. Also, by adapting mobile applications for inclusive literacy to the needs of people with reading disabilities, the scope of these opportunities can be increased. Thus, in the present work, the contribution to the development of reading and writing skills, as well as to the full integration and participation of this population in society was realized.

This work was carried out based on interviews with parents and surveys of experts in special education with the use of ICTs. In the same way, the results were based on the inclusion of expert judgments and AtlasTI22 of the use of prototype mobile applications for inclusive literacy in people with reading disabilities. In contrast, the authors [15] did not conduct surveys and interviews, only studied people with reading disabilities to see how increasing their literacy levels affected their ability to relate to others and feel confident.

## VI. CONCLUSIONS AND FUTURE WORK

In conclusion, this study has investigated and developed the prototypes of mobile applications, with the aim of promoting inclusive literacy among people with reading difficulties. In order to evaluate the effectiveness and value of the proposed applications, interviews and surveys were conducted to collect the opinions of experts in the field to assess the effectiveness and usefulness of the proposed applications. The results obtained from expert judgment provide valuable insight into the feasibility and potential of these technological tools.

Analysis of the results of the prototype application designs yields an encouraging 85%. Similarly, 75% confirmed that the app effectively complements inclusive literacy efforts, a significant achievement in line with the objective, and 70% appreciated the app's interaction with people with reading disabilities. Finally, a staggering 87% would gladly recommend the app, underscoring its valuable impact. As for the methodology, design thinking was used as it is based on the human being approach, which addresses creativity, design and problem solving. A limitation of the research work is that it was not possible to contact directly the institutions of inclusive education to conduct interviews and make a qualitative analysis. As future work, it is recommended to implement the prototypes of mobile applications of inclusive education for people with reading disabilities complemented with augmented reality.

# LAD-YOLO: A Lightweight YOLOv5 Network for Surface Defect Detection on Aluminum Profiles

Dongxue Zhao, Shenbo Liu, Yuanhang Chen, Da Chen, Zhelun Hu, Lijun Tang

School of Physics and Electronic Science, Changsha University of Science & Technology, Changsha 410114, China

**Abstract**—In this paper, we leverage the advantages of YOLOv5 in target detection to propose a highly accurate and lightweight network, called LAD-YOLO, for surface defect detection on aluminum profiles. The LAD-YOLO addresses the issues of computational complexity, low precision, and a large number of model parameters encountered in YOLOv5 when applied to aluminum profiles defect detection. LAD-YOLO reduces the model parameters and computation while also decreasing the model size by utilizing the ShuffleNetV2 module and depthwise separable convolution in the backbone and neck networks, respectively. Meanwhile, a lightweight structure called "Ghost\_SPPFCSPC\_group", which combines Cross Stage Partial Network Connection Operation, Ghost Convolution, Group Convolution and Spatial Pyramid Pooling-Fast structure, is designed. This structure is incorporated into the backbone along with the Convolutional Block Attention Module (CBAM) to achieve lightweight. Simultaneously, it enhances the model's ability to extract features of weak and small targets and improves its capability to learn information at different scales. The experimental results show that the mean Average Precision (mAP) of LAD-YOLO on aluminum profiles defect datasets reaches 96.9%, model size is 6.64MB, and Giga Floating Point Operations (GFLOPs) is 5.5. Compared with YOLOv5, YOLOv5s-MobileNetv3, and other networks, LAD-YOLO proposed in this paper has higher accuracy, fewer parameters, and lower floating-point computation.

**Keywords**—YOLOv5; ShuffleNetv2; lightweight and fast spatial pyramid pooling structure; convolutional block attention module; aluminum profiles surface defect detection

## I. INTRODUCTION

Aluminum profiles are one of the important raw materials for the manufacturing industry, widely used in industry, construction, medicine, and other industries. However, due to its complex production process and more transportation links, aluminum profiles are prone to surface defects such as scratch, dirt, pinhole, and wrinkle. These defects will directly affect the quality of aluminum profiles and even lead to distortion and deformation of aluminum profiles, which is more obvious for high-end aluminum profiles. Therefore, it is of great significance to improve the detection efficiency and accuracy of aluminum profiles surface defects to ensure the production and application of aluminum profiles.

At present, most enterprises still use traditional manual detection methods to detect defects on the surface of aluminum profiles. However, this manual inspection method is slow, subject to the influence of subjective consciousness, not only low efficiency but also poor stability, prone to misdetection, and leakage detection. Ultrasonic flaw detection, eddy current

flaw detection, and other traditional non-destructive testing are also used for the detection of surface defects in aluminum profiles, but due to its slow detection speed, high cost, complex equipment operation, etc., which limits its popularity in practical applications. In 2014, Girshick et al. proposed a Regional Convolutional Neural Network (R-CNN), which broke the deadlock of slow progress in the field of target detection [1], and subsequently gave birth to Fast R-CNN [2], Faster R-CNN [3], Mask R-CNN [4], Single Shot MultiBox Detector (SSD) [5], You Only Look Once (YOLO) series [6-11], and other generalized deep learning-based target detection algorithms. As a result, deep learning-based surface defect detection is starting to develop rapidly.

For metal surface defect detection, references [12-14] combined neural networks with traditional detection algorithms to realize the detection and classification of surface defects of aluminum and other metal materials. Duan et al. [15] built a dual-stream Convolutional Neural Network (CNN) for the detection of aluminum profiles image features and gradient features, effectively realizing the classification of defect-free and multi-type defect samples. Cheng et al. [16] proposed a network DEA-RetinaNet with differential channel attention and adaptive spatial feature fusion for steel surface defect detection. The mean Average Precision (mAP) of the network on the steel surface defect dataset (NEU-DET) was 78.25%. The detection accuracy of the above methods is lower than 85%, which cannot meet the requirements of practical industrial applications.

Zeng [17] et al. proposed a data augmentation method and a migration learning technique for solving defective parts detection in steel plates. References [18-20] used Faster R-CNN to detect metal surface defects such as steel and railroad fasteners with an accuracy of more than 95%, but the detection speed is slow. Chen [21] et al. applied Convolutional Neural Networks (DCNNs) to the defect detection of fasteners and carried out experiments on high-speed railroad scenarios. ZHAO et al. [22] innovated based on YOLOv4 architecture to improve the detection accuracy of surface defects of metal materials. Wang et al. [23] proposed a structure called PE-Neck, which replaces the Neck part of the YOLOv5 network structure with a combination of scaled convolutional kernels and efficient channel attention to enhance the model's ability to extract and localize defects at different scales. However, the accuracy is only 87.4% and the strategy for generating candidate regions suffers from many flaws. Although the above methods enhance the detection accuracy by improved means, it is unable to realize the real-time detection of surface defects on

industrial aluminum profiles due to their complex network structure and large computation, and slow detection speed.

Conventional CNN inference is computationally intensive and difficult to apply in resource-constrained scenarios such as mobile and Internet of Things (IoT). Starting from SqueezeNet [24] and MobileNetV1 [25], the design of CNNs has begun to focus on efficiency in resource-constrained scenarios. The more mature lightweight networks include the MobileNet series [26-27], ShuffleNet series [28-29], GhostNet [30], etc. Li [31] et al. proposed a YOLOv3-Lite detection method, which combines a deep convolutional neural network and a feature pyramid in YOLOv3, to improve the defect detection accuracy. Xiao [32] et al. added a residual network structure to YOLOv3-Tiny, which was applied to detect obstacles in a mine, with improved accuracy compared to the original YOLOv3-Tiny, but with decreased speed. Zhang [33] et al. proposed a multi-model rail surface defect detection system based on a convolutional neural network (MRSDI-CNN). The system network uses SDD combined with YOLOv3 to improve the system's accuracy. Wang et al [34] proposed a lightweight YOLO-ACG detection algorithm that balances accuracy and speed while improving the defect detection classification error and leakage rate. Ma [35] et al improved the YOLOv4 network by replacing the backbone network with a lightweight Ghost module. At the same time, a joint attention mechanism is added to the stacked Ghost modules to ensure accuracy, so that the network is compressed and lightweight is achieved while achieving an accuracy of 94.68%. These methods have improved in detection accuracy and detection speed, but the model size is still large and memory consumption is high, which is not conducive to real-time detection on mobile, especially in devices with tight computing resources.

The YOLOv5 algorithm is an end-to-end target detection algorithm known for its fast detection speed and high accuracy. It has found wide application in the field of surface defect detection. However, the large number of parameters in the YOLOv5 model can hinder improvements in detection speed. Additionally, its backbone layer, consisting of CSPDarknet53, faces challenges in effectively extracting features of small

targets. In this paper, a lightweight aluminum profiles surface defect detection network is designed to solve this problem, which significantly improves the accuracy and detection speed. The algorithm is evaluated for its performance on aluminum profiles surface defect dataset and compared with other algorithms. The experimental results show that the LAD-YOLO proposed in this study can accurately identify aluminum profiles surface defects with excellent detection speed.

The Section I is the research purpose and significance of aluminum profiles surface defects detection and the current status of domestic and international research on target detection algorithms for metal surface defects detection. The Section II is the research on the improvement method of lightweight aluminum profiles surface defect detection model based on YOLOv5. The Section III is the experimental results and analysis of the model application. The Section IV summarizes the research in this paper and the outlook for future research.

## II. METHODOLOGY

LAD-YOLO follows the network structure of YOLOv5, which consists of four main parts: Input Layer, Backbone, Neck, and Head. The overall structure of LAD-YOLO is depicted in Fig. 1. The Input Layer takes a  $640 \times 640 \times 3$  aluminum profiles defect image as input. The Backbone network contains six ShuffleNetv2 modules, three Convolutional Block Attention Modules (CBAM), and the Spatial Pyramid Pooling Cross Stage Partial Concat structure based on ghost convolution and group convolution (Ghost\_SPPFCSPC\_group) for extracting surface defect features of aluminum profiles. In the neck network, depthwise separable convolution is used to extract depth features of aluminum profiles surface defects, reducing computational overhead. Simultaneously, the feature image size is doubled by using the nearest neighbor interpolation upsampling method, and the feature maps with the same size in the aluminum profiles surface defect map are connected. In the prediction layer, three different sizes of detection heads are generated to detect the aluminum profiles' surface defect image.

Fig. 1. LAD-YOLO network structure.

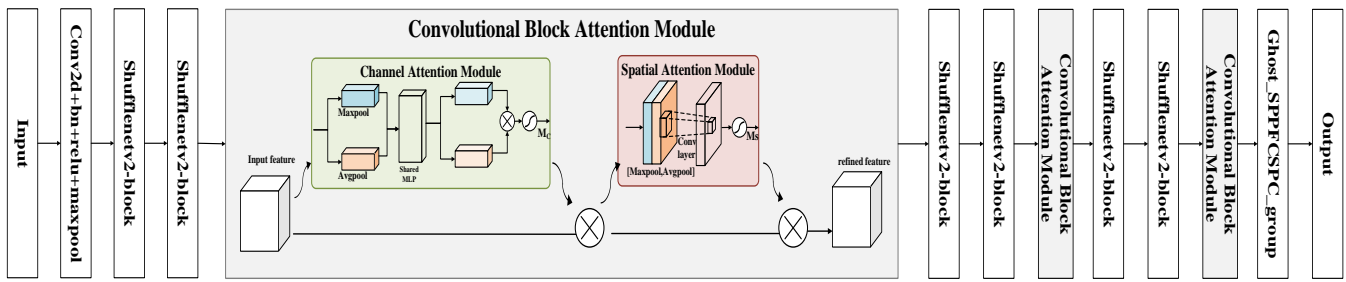

Fig. 2. CBAM and LAD-YOLO backbone layer network structure.

A. Backbone Structure

The Backbone Structure shown in Fig. 2 consists of three parts: ShuffleNetv2, Convolutional Block Attention Module (CBAM), and the Spatial Pyramid Pooling-Fast Cross Stage Partial Concat structure combining Ghost Convolution and Group Convolution (Ghost\_SPPFCSPC\_group). ShuffleNetv2 uses Channel Split, 1\*1 convolution, depthwise separable convolution, and mixing and washing of channels to accomplish the detection of input aluminum profiles defect information, which reduces the memory access time, reduces the number of model parameters, and improves the detection speed. The adoption of the ShuffleNetv2 structure drastically reduces the number of parameters of the model, but also brings a certain loss of accuracy. To compensate for the loss of accuracy, CBAM is used to embed into the backbone, as shown in Fig. 2.

CBAM mainly consists of two key modules: the Channel Attention Module and the Spatial Attention Module. The Channel Attention Module captures the importance of each feature channel by calculating global statistics and applies attention weights to each channel. The Spatial Attention Module highlights important spatial regions in the feature map by computing global statistics and applying attention weights to different spatial positions. Combining the above two modules, CBAM enables the network to adaptively focus on significant channels and spatial areas, improving feature representation for aluminum profiles surface defect detection tasks.

B. Ghost\_SPPFCSPC\_Group Structure

The Spatial Pyramid Pooling (SPP) structure can effectively capture target features at different scales by stacking pyramid layers of different sizes together, improving the model's detection ability for targets of different sizes. The Spatial Pyramid Pooling-Fast (SPPF) structure is a faster structure proposed based on the SPP structure. The Cross Stage Partial structure consists of two parts, the convolution, and the complex structure, in parallel to increase the speed of the network.

In 2023, wang et al. [11] first proposed the Spatial Pyramid Pooling Cross Stage Partial Concat (SPPCSPC) structure in YOLOv7, as shown in Fig. 3, which uses the SPP and CSP modules for better handling of multi-scale targets.

The use of the SPPCSPC structure can effectively improve the model detection accuracy, but it will increase the amount of computation and the number of model parameters. To improve the speed, this paper replaces the SPP in the SPPCSPC

structure with the SPPF structure to obtain the Spatial Pyramid Pooling-Fast Cross Stage Partial Concat (SPPFCSPC) structure. To reduce the amount of computation and parameters, Ghost convolution and group convolution are used to replace standard convolution in the SPPFCSPC structure.

Fig. 3. Spatial pyramid pooling cross stage partial concat structure.

The standard convolution, Ghost convolution, and group convolution are compared and analyzed below. Fig. 4 shows the operation process of standard convolution, Eq. (1) is the standard convolution parameters, where  $c$  is the number of input channels,  $n$  is the number of output channels, and the size of the convolution kernel is  $k*k$ .

$$P_{std} = c \cdot n \cdot k \cdot k \tag{1}$$

Fig. 4. Standard convolution operation.

Fig. 5 shows the group convolution operation process, which divides the input channels and output channels into the same number of groups, and then allows the input channels and output channels in the same group number to be fully

connected. Eq. (2) is the parameters of the group convolution. Where  $g$  is the number of groups divided into output channels.

$$P_{Group} = \frac{c}{g} \cdot \frac{n}{g} \cdot g \cdot k \cdot k \quad (2)$$

Fig. 5. Group convolution operation.

Fig. 6. Ghost convolution operation.

Fig. 6 shows the Ghost convolution operation process. First, a standard convolution operation with  $m$  ( $m \leq n$ ) output channels (where  $n$  is the number of final output channels) is performed on the feature map with input channel  $c$  to obtain a feature map with  $m$  channels. Second, a new feature map is obtained by  $s-1$

linear operations. Finally, the two feature maps are connected to obtain an output feature map with  $n$  channels ( $n=m*s$ ). Eq. (3) is the parameters of Ghost convolution. Where the convolution kernel size of linear operations in Ghost Module is  $d \times d$ .

$$P_{Ghost} = \frac{n}{s} \cdot c \cdot k \cdot k + (s-1) \cdot \frac{n}{s} \cdot d \cdot d \quad (3)$$

By comparing the above three convolution parameters, Eq. (4) shows the parameters compression ratio ( $R_1$ ) for standard and Ghost convolution, and Eq. (5) shows the parameters compression ratio ( $R_2$ ) for standard and group convolution. Where let  $k=d$ .

$$R_1 = \frac{n \cdot c \cdot k \cdot k}{\frac{n}{s} \cdot c \cdot k \cdot k + (s-1) \cdot \frac{n}{s} \cdot d \cdot d} \approx \frac{s \cdot c}{s+c-1} \approx s \quad (4)$$

$$R_2 = \frac{n \cdot c \cdot k \cdot k}{\frac{c \cdot n}{g} \cdot g \cdot k \cdot k} = g \quad (5)$$

From the above computation results, it is shown that the number of parameters of standard convolution is  $g$  times more than that of group convolution and  $s$  times more than that of Ghost convolution, so the number of parameters can be drastically reduced by choosing group convolution and Ghost convolution compared to standard convolution.

Therefore, in this paper, a lightweight SPPFCSPC structure (Ghost\_SPPFCSPC\_group) is designed by combining SPPFCSPC, Ghost convolution, and group convolution, as shown in Fig. 7. The structure utilizes the smaller number of parameters of Ghost convolution and group convolution to achieve lightweight. The Ghost\_SPPFCSPC\_group structure uses a smaller computational cost to enable the fusion of multi-scale features and improve feature representation.

Fig. 7. Ghost\_SPPFCSPC\_group structure.

### C. Depthwise Separable Convolution

Depthwise Separable Convolution (DSCConv) contains two parts, Depthwise Convolution and Pointwise Convolution. As shown in Fig. 8, Depthwise Convolution computes the convolution of each channel separately to extract the features of each channel; Pointwise Convolution computes the feature map generated by Depthwise Convolution and adopts a convolution kernel with the size of  $1 \times 1 \times M$  convolution kernel, weighted combination in the depth direction, to realize the fusion of features between the channels, to generate a new feature map.

Fig. 8. Depthwise separable convolution module structure.

Eq. (6) is the FLOPs for standard convolution. Eq. (7) is the FLOPs Operations for Depthwise Separable Convolution. Eq. (8) is the ratio  $R$  of Depthwise Separable Convolution to the standard convolutional computation. The input feature map size is  $H \times W \times C_i$ , the output feature map size is  $H \times W \times C_o$ ,  $H$ ,  $W$ ,  $C_i$  and  $C_o$  denote the height, width, number of input channels, and number of output channels of the feature map respectively, and the size of the convolution kernel in the standard convolution is  $K_1 \times K_2$ .

$$C_{std} = K_1 \cdot K_2 \cdot H \cdot W \cdot C_i \quad (6)$$

$$\begin{aligned} C_{separable} &= C_{depthwise} + C_{pointwise} \\ &= K_1 \cdot K_2 \cdot H \cdot W \cdot C_i + H \cdot W \cdot C_i \cdot C_o \end{aligned} \quad (7)$$

$$\begin{aligned} R &= \frac{C_{separable}}{C_{std}} = \frac{K_1 \cdot K_2 \cdot H \cdot W \cdot C_i + H \cdot W \cdot C_i \cdot C_o}{K_1 \cdot K_2 \cdot H \cdot W \cdot C_i \cdot C_o} \\ &= \frac{1}{C_o} + \frac{1}{K_1 \cdot K_2} \end{aligned} \quad (8)$$

From Eq. (8), it can be seen that the floating-point computation of Depthwise Separable Convolution is only  $\frac{1}{C_o} + \frac{1}{K_1 \cdot K_2}$  of the standard convolution. Assuming the convolution kernel size of  $3 \times 3$  for Depthwise Convolution, the computation of the standard convolution is about eight to nine times that of Depthwise Separable Convolution. Replacing the standard convolution with the Depthwise Separable Convolution reduces the floating-point computation.

## III. RESULTS AND DISCUSSION

### A. Datasets Introduction

In this paper, for aluminum profiles defect detection, the Hikvision high-definition industrial camera model MV-CS050-10GC-PRO is used to collect the sample images of aluminum profiles and make the aluminum profiles defect datasets, and some of the data in the datasets are shown in Fig. 9.

The labeling categories are pinhole, scratch, dirt, and wrinkle. Since the original image samples are too few, panning, rotating, changing brightness, shearing, mirroring, and other means of expanding the datasets are chosen to expand the original aluminum profiles surface defect datasets. After the expansion, the total number of defect images is 5013, including 6325 pinholes, 3042 dirt, 5863 scratches, and 2415 wrinkles. The datasets are categorized into 60% training set, 20% validation set, and 20% test set containing 3008, 1002, and 1003 images, respectively.

Fig. 9. Part of the datasets.

### B. Evaluation Metrics

Precision (P), Recall (R), Average Precision (AP), and Mean Average Precision (mAP) are used as the evaluation metrics of detection effectiveness. The mAP is the average value of AP for all defect categories, which is used as a comprehensive index for evaluating precision. The higher the values of AP and mAP, the better the algorithm is for detecting the target defects. P, R, AP, and mAP are calculated as follows: (9), (10), (11), (12).  $TP$  is the number of defects in the positive samples that were detected as correct,  $FP$  is the number of defects in the negative samples that were incorrectly detected as correct,  $FN$  is the number of defects in the positive samples that were not detected, and  $m$  is the number of defect categories. In addition, Floating Point Operations (FLOPs), parameters, and Model Size are used to evaluate the lightness of the model.

$$P = \frac{TP}{TP+FP} \quad (9)$$

$$R = \frac{TP}{TP+FN} \quad (10)$$

$$AP_i = \int_0^1 PRdr \quad (11)$$

$$mAP = \frac{1}{m} \sum_{i=1}^m AP_i \quad (12)$$

### C. Experimental Process

The GPU used for defect detection training and testing is NVIDIA TITAN RTX, and the specific configuration of the experimental platform is shown in Table I. During the training

experiments, the optimizer chooses the stochastic gradient descent with momentum (SGD) with a momentum factor of 0.937. The weight attenuation coefficient is set to  $5 \times 10^{-4}$ . The learning rate is initially set to  $10^{-3}$ , while the Cosine Annealing is used to reduce the learning rate to  $10^{-5}$ . The batch size is set to 64, and the epochs are set to 500.

TABLE I. THE SPECIFIC CONFIGURATIONS OF THE EXPERIMENTAL PLATFORM

Name	Version
CPU	Intel(R) Xeon(R) Gold 5218R CPU @ 2.10GHz
Memory Bank	32GB
GPU	NVIDIA TITAN RTX
GPU Memory	24GB
Operating System	Windows10
Software environment	CUDA11.6
Python Version	Python 3.8
Deep learning framework	PyTorch 1.12

#### D. Comparative Experiment and Analysis

Comparison experiments are conducted by LAD-YOLO with SSD, YOLOv3, YOLOv3-tiny, YOLOv4-tiny, YOLOv5, and YOLOv5s-MobileNetv3, and the results are shown in Table II. As can be seen in Table II, LAD-YOLO achieved 96.9% mAP, 97.4% Precision, and 95.7% Recall on the aluminum profiles surface defects dataset, and the model size is 6.64MB. Compared with the YOLOv5s algorithm, mAP increases by 2.8% and model size decreases by 58%.

TABLE II. COMPARATIVE RESULTS OF EVALUATION METRICS FOR DIFFERENT METHODOLOGIES

Methods	Precision (%)	Recall (%)	mAP (%)	Model Size (MB)
SSD	68.4	70.2	70.6	90.13
YOLOv3	91.9	87.7	91.2	120.67
YOLOv3-tiny	87.6	84.7	86.9	33.79
YOLOv4-tiny	90.9	89.6	90.8	23.03
YOLOv5s	95.3	94.0	94.1	14.07
YOLOv5s-MobileNetv3	89.9	88.4	89.7	7.28
LAD-YOLO (OURS)	97.0	95.7	96.9	6.64

TABLE III. RESULTS OF THE ABLATION EXPERIMENT

ShuffleNetV2	CBAM	SPPFCSPC	Ghost_SPPFCSPC_group	DSCConv	mAP	Parameters (10 <sup>6</sup> )	Model Size (MB)	GFLOPs
--	--	--	--	--	94.1%	7.03	14.08	15.8
√					92.2%	3.23	6.66	5.8
√	√				95.8%	3.25	6.69	5.9
√	√	√			97.3%	9.77	19.46	11.1
√	√		√		97.0%	3.85	7.91	6.3
√	√		√	√	96.9%	3.19	6.64	5.5

Compared with YOLOv5s-MobileNetv3, the precision is improved by 7.2% and the model size is reduced by 8.8%. The experimental results show that the LAD-YOLO network improves the precision and recall rate of defect detection, and reduces the model parameters and size.

#### E. Ablation Experiment

To further verify the role of each improvement in enhancing the performance of the algorithm, ablation experiments are conducted. The results are shown in Table III.

From Table III, the mAP of the baseline model YOLOv5s is 94.1%, the model size is 14,08MB, the number of parameters is  $7.03 \times 10^6$  and the GFLOPs is 15.8. It can be seen that after using ShuffleNetV2 and CBAM, the mAP is improved by 1.7% compared to YOLOv5s, the model size is reduced from 14.08MB to 6.69MB, and the GFLOPs are reduced from 15.8 to 5.8; after using the Ghost\_SPPFCSPC\_group structure, the mAP is again improved by 1.5%, with a slight increase in Model Size and GFLOPs; with the use of deep separable convolution, the mAP is 96.9%, Model Size is again reduced to 6.64M, and GFLOPs are 5.5. compared to the original network. mAP is improved by 2.8%, Model Size is reduced by 52.8%, and GFLOPs are reduced by 65.6%. The results show that improvements to YOLOv5 are necessary everywhere.

#### F. Test Results of Defect Detection

Fig. 10 shows the schematic diagram of four kinds of defect detection in aluminum profiles. The non-maximum suppression (NMS) is used in the prediction as the post-processing method. The confidence was set to 0.5 and the IoU was set to 0.6.

Fig. 10. Partial detection images for aluminum profiles defect detection.

The obtained LAD-YOLO P-R curve for defect detection is shown in Fig. 11, and it can be seen that the AP of pinholes is 98.8%, the AP of dirt is 99.3%, the AP of scratches is 91.1%, and the AP of wrinkles is 98.2%. Except for scratches, all other types of defects have an AP of 98% or more. The poor detection of scratches is due to its high defect precision requirements and susceptibility to environmental influences.

Fig. 11. LAD-YOLO P-R curve.

The accuracy of detecting various defects under different methods is plotted in Fig. 12. It is evident from the figure that LAD-YOLO exhibits improvements in accuracy for different defect types compared to other methods. Specifically, LAD-YOLO shows an increase in accuracy of 4.6% for pinhole

detection, 2.3% for dirt detection, 3.2% for scratch detection, and 0.9% for wrinkle detection when compared to YOLOv5s.

Fig. 12. Accuracy of defects in each category under different methods.

The results demonstrate that LAD-YOLO achieves enhanced accuracy across all defect categories, with particularly notable improvements in the detection of small targets, such as pinholes and scratches.

#### IV. CONCLUSION

We propose a lightweight aluminum profiles surface defect detection network, which involves improvements to the backbone and neck layers of YOLOv5. By designing the Ghost\_SPPFCSPC\_group structure with low floating-point

operation and combining it with the ShuffleNetV2 module and the Convolutional Block Attention Module (CBAM) to construct the backbone network, we reduce the model parameters and computation amount while obtaining richer feature information, thus improving the network's ability to detect defects on small-sized targets. By using depthwise separable convolution to replace the standard convolution in the neck layer, the number and size of model parameters are further reduced to improve the network operation speed. The specific experimental results are as follows:

(1) The Model Size of LAD-YOLO is only 6.64MB, which is 52.84% less compared with YOLOv5s; its GFLOPs are only 5.5, which is 65.19% less compared with YOLOv5s. It shows that LAD-YOLO occupies fewer memory resources, which is more helpful to be applied to platforms with scarce computational resources to achieve low-cost aluminum profiles surface defect detection.

(2) The detection accuracy of LAD-YOLO is much higher than that of current detection methods, including SSD, YOLOv3, YOLOv3-tiny, YOLOv4-tiny, YOLOv5s, and YOLOv5s-MobileNetv3, etc. Compared with YOLOv5s, the mAP of LAD-YOLO is 96.9%, an improvement of 2.8%; compared with YOLOv5s-MobileNetv3, the accuracy is improved by 7.2%. The results indicate that the LAD-YOLO network not only achieves model lightweight but also shows an improvement in accuracy.

In the forthcoming phases, we intend to augment the variety of defects within our dataset, thereby enhancing its diversity. Furthermore, to bolster the model's resilience and versatility in real-world scenarios, we will acquire images portraying authentic situations characterized by uneven lighting, occlusions, and other intricacies. This approach aims to further elevate the model's overall performance.

# Improved YOLO-X Model for Tomato Disease Severity Detection using Field Dataset

Rajasree R, C Beulah Christalin Latha

Department of Digital Sciences, Karunya Institute of Technology and Sciences, Coimbatore, India

**Abstract**—In the past decade, the field of automatic plant disease detection has undergone significant complexity. Advancements in convolutional neural network in deep learning have enabled the rapid and precise detection of ailments, facilitated the development of effective treatments and ultimately led to higher crop yields. One of the most challenging scenarios in plant disease occurs when multiple diseases manifest on a single leaf, exacerbating the difficulty of diagnosis due to overlapping symptoms. This study addresses these challenges by employing an enhanced YOLO-X model for detection tomato leaf diseases. The technique presented here enhances the Spatial Pyramid Pooling layer in order to extract valuable features from training data of various sizes more efficiently. We were able to increase the model's ability to identify a broader spectrum of disease symptoms by concatenating variables from multiple layers and varying sizes. In addition, we incorporate a large number of connections to increase the generalizability of the design. The application of an IoU-based (Intersection over Union) regression loss function increases the convergence of the network and the precision of the detection. For experimentation, we created a customized dataset consisting of 1220 tomato plant leaf images from various farms in Southern part of India, encompassing overlapping diseases and varying degrees of severity. The dataset includes images of healthy leaves as well as different severity levels of tomato leaf curl and tomato leaf mold stress on a single leaf. Our suggested improved SPP-based YOLO-X model beats the original YOLO-X model, according to experimental findings, which show an improvement in test dataset accuracy and a 73.42% mean Average Precision on field-collected dataset.

**Keywords**—Convolutional neural network; deep learning; object classification; plant disease detection; spatial pyramid pooling; YOLOX

## I. INTRODUCTION

In India, tomatoes are a significant economical crop that is produced on 15% of the nation's total cultivated land. A significant portion of the global textile economy is contributed by the nation's tomato production and export, in addition to its local consumption. The crop is afflicted with several diseases during the course of its existence. A leaf might sometimes have many diseases, some of which have similar symptoms. Even an experienced pathologist may make mistakes when evaluating disease severity signs and the presence of numerous stressors. Precision farming practices have undergone a revolution with the development of artificial intelligence and computer vision technology. In plant disease detection systems, a number of machine learning and deep learning models have shown outstanding performance [1] on field-collected or publicly accessible plant disease datasets, some researchers have combined deep learning-based feature extraction and

classification tasks with transfer learning [8]. In order to propose the use of pesticides or other preventative measures and achieve near-ideal performance in recognizing diseases signs automatically, several research have been conducted. Well-known deep learning architectures such as region-based convolutional networks [2], single shot detectors [3], and region proposal networks [4] have been employed in the area of plant leaf disease detection, with major alterations happening during the preceding few years [37, 38, 41]. Almost all previous studies either used the well-known PlantVillage public dataset [3] or their own datasets collected in the field [5], [6]. But only a small number of studies have looked at the stages of disease growth and the chance that many living and nonliving things can attack a plant leaf at the same time. In these situations, it is hard for both human and automatic monitoring systems to figure out the type of infection and the exact area of sickness signs.

In this study, we describe a YOLO-X-s based detecting system that uses a modified Spatial Pyramid Block to combine fine spatial data with local features to find sickness phases and split diseases with symptoms that overlap. We made the spatial pyramid pooling block better by putting together feature maps at low-level scales. This helped us solve the problem more accurately. The original size feature vector was added to improve the quality of the features. The recognition performance got even better when the Alpha IoU regression loss function was used [36].

### A. Contributions to the Research

- A better YOLO-Xs model with a modified Pyramid pooling module (SPP) layer is given so that many diseases on a single leaf plant can be found. It collects location information at local, multi-scale levels to get the information it needs more quickly.
- To improve generalization and convergence, we used Alpha IoU (Intersection over Union) loss as the bounding box regression for multiple disease localization when multiple diseases showed up on the same plant leaf.
- With the help of enhancement, a group of unique shots from a tomato field are shown. The photos show how diseases spread and how many different diseases can be found on a single leaf.

The paper has been structured in the following manner: The Section II provides a summary of the existing literature. The Section III describes the proposed methodology. The Section IV presents research outcomes, comparisons to existing

methods and outcomes, and discussions of future research opportunities and limitations of the study. Section V provides a conclusion for this proposed research.

## II. LITERATURE REVIEW

Plant leaf diseases may be identified using computer vision-based methods for (1) detection and (2) identification. Both of the methodologies used in the area are prevalent in research literature released in the last ten years.

Highlights of various modern and cutting-edge techniques for identifying and detecting plant leaf diseases literatures are included in Table I. In this part, these methods will be thoroughly reviewed in relation to: (1) the kind of application targeted, (2) the methodology employed, (3) the contribution. The usage of deep learning in this field of study has increased during the previous several years. Transfer learning and data enrichment have made it easier to use deep learning models on a variety of devices, such as central processing units (CPUs) and graphics processing units (GPUs). In the study done by a research [10], the MobileNet v2 model was trained by adding more color space data in a few different ways. Transfer learning and data enrichment have made it easier to run deep learning models on CPUs, GPUs, and other types of computer systems. This is because these two methods have been put together. In the study done by a researcher [10], color space data addition methods were used to train the MobileNet v2 model. To compare the effectiveness of the classification, the scientists trained the model using images of cassava leaf disease of various quality levels. According to a study, low-quality images cause the classification accuracy to decrease. The diseased region has also been identified using high-quality images and a color difference, according to authors [11]. Using advanced machine learning classifiers, such as the bagging tree ensemble, it is now possible to identify sick regions based on color and textual information with an overall accuracy of 99%. Plant disease monitoring systems that use computer vision are meant to automatically find and identify the part of a plant that is sick. Because of this, these systems use customizable deep-learning meta-architectures that have been used in the related study.

The earliest deployed deep learning algorithms were region-based convolutional neural networks (RCNNs), and their purpose was to recognize objects in general [3]. In line with Fast Convolutional Neural Network [12], Faster Region based CNNs, and R-FCNNs [3]. Segmentation and noise reduction operations were carried out using the OTSU algorithm and multilayer median filters, respectively. By using a two-stage detector, the technique achieves an inference time of 0.52 s. A research study [14] employed a comparable two-stage detector, Mask RCNN, to identify sick regions after contrast stretching. CNN performs feature extraction of improved areas, which was afterwards categorized. After applying entropy to choose the best features, accuracy was improved. Another important work [15] identified various rice diseases by using a quicker R-CNN with a reinforced backbone to analyze the still pictures of the rice. In terms of recall and accuracy, the upgraded two-stage model performs better than earlier models such as YOLO-V3, while having longer detection times. The model presented in [16] significantly

improved mAP by using a superior anchor box method that was based on a more efficient RCNN model for weed detection.

With single shot detection (SSD), need to make a region proposal network in order to get the best total speed and a faster inference time. But you can get both without making a region proposal network. They use certain boxes to figure out how likely it is that a certain item will be in a picture. This improved model, which used the Inception module and Rainbow union, was used to get information about features and make it easier to find ill spots on apples [17]. Both the VGG and the origin module were added to the model so that it could diagnose diseases with a mAP of 78.8%. YOLO (You Only Look Once) [18] models, on the other hand, are single-stage detectors that can find and label objects in a picture with just one forward spread. The name of these models comes from the saying "you only look once." It initially divides a picture into a grid to begin the detection process, and for each bounding box, it then forecasts the likelihood of an item and its class. In order to identify tomato diseases in difficult background settings, Wang et al. [19] utilized a similar YOLO architecture and added the DenseNet block for feature extraction. Additional information is provided in Table I of the relevant work comparison. The YOLO-V5 model was effective in identifying bacterial leaf spots. Additionally, the outcomes were contrasted with those of YOLO-V3, YOLO-V4, Single Shot Detector algorithm, and other two-stage detectors techniques [20].

A new upgrade to the YOLO series, called YOLO-X [26], has made a considerable improvement in the field of object identification. To improve feature extraction, YOLO-X makes use of the YOLO-V3 with a Darknet architecture added with SPP Layer baseline structure. To diagnose kiwi leaf diseases, DeepLabV3 and UNet are used in conjunction with YOLO-X to separate the leaves from the complicated backdrop. The mix of Cross Stage Partial Network and sigmoid activation function in the approach of finding colon cancer has led to a better version of the YOLO v3 algorithm.

The model is strengthened for real-time polyp identification by using the CIU loss function [28]. The YOLO-V5 model was used in a research work [22] to accurately detect plant disease. Using the SE module and Involution Bottleneck, the accuracy and number of parameters were improved. The researchers must overcome difficulties with disease development and detecting many lesion areas in a single frame. Multiple diseases may be difficult to identify, both manually and when using artificial image processing algorithms [29], since their locations and symptoms tend to overlap. The EfficientNet model, which has a classification accuracy of 96%, was successfully used to address the plant disease detection problem on a single cucumber leaf [25] and other notable research [42] explains the hyper-tuned efficientdet architecture for object detection. The authors utilized a Ranger optimizer to find symptoms that seemed to be related. Although SSD algorithm with respectable object identification and detection performance have been employed in the methodologies from the literature (included in Table I).

TABLE I. SELECTED STUDIES FROM THE LITERATURE ON PLANT DISEASE DETECTION

Reference	Application Targeted	Methodology Employed	Contribution
[7]	Automatic detection of plant diseases	Classic machine learning	Utilization of various classic machine learning approaches
[13]	Rice disease identification	Faster region-based model + K-means clustering	Identification of rice diseases using a two-stage detector with clustering
[17]	Identification of apple sick patches	YOLO-V5 model with Inception module and Rainbow concatenation	Enhanced feature extraction and improved identification of apple sick patches
[19]	Tomato disease identification	YOLO architecture with DenseNet block	Utilization of YOLO architecture for identifying tomato diseases
[22]	Plant disease detection	YOLO-V5 model with SE module and Involution Bottleneck	Accurate detection of plant diseases with improved accuracy and parameters
[23]	Segmentation of sick lesions on paddy leaves	CNN and YOLO	Segmentation of sick lesions with refined model parameters
[24]	Classification of severity of strawberry leaf disease	Faster RCNN and Siamese network	Identification of leaf position and estimation of severity
[42]	Object detection	Efficientdet	Identification of hyper-tuned efficientdet architecture for object detection

The majority of these investigations have focused on classifying lesions or locating locations. The difficulties associated with accurately distinguishing distinct phases of disease severity and a multitude of stresses on a single leaf are presently the ones that have received the least amount of attention. In order to identify overlapping and overlapping plant leaf diseases, we suggest in this study an updated YOLO-X model tailored specifically for the application.

### III. METHODOLOGY

The suggested technique is fully explained in this part and will be utilized to handle the issues of (1) leaf disease progression symptoms and (2) the presence of several diseases on a single tomato leaf. The supplied data is initially pre-processed to remove extraneous background information and guarantee class balance. The suggested deep learning model's specifics are then discussed, with a focus on the two crucial instances indicated above.

#### A. Customized Dataset Creation

Tomatoes are grown in different parts of Southern India from March to May. For the purpose of this study, images were taken from various tomato fields in Tamil Nadu and Kerala. No extra pesticides or fertilizers were used to maintain the conditions that allowed the infections to flourish. The pictures were taken at various angles using a smart phone (Apple iPhone X) that was held 15 to 25 cm away from the tomato

leaf. Original image size was 1125 x 2436 pixels with 19.5:9 ratio. Images were taken in the morning, with varied lighting conditions. The smart phone's focus was changed to portrait mode and zoom mode to capture one leaf. Seven different categories of tomato curl severity and disease coexistence images were created from the data.

Fig. 1 displays a few examples of images extracted from the dataset which was collected from the fields. In India, the ailment known as "tomato curl virus" is widespread. Stage 1 of tomato leaf curl's early signs is described as leaf chlorosis. Within two to three weeks, the symptoms become worse as the leaf's veins start to thicken and darken. From the underside of the leaf, the thickening of the veins is plainly visible. The second stage of the tomato leaf disease is distinguished by the subsequent curling of the leaf margins. Three weeks later, the leaves begin to develop dark black specks that prevent the virus from spreading. The pathologists determine that it is tomato leaf mold brought on by the aphid infestation. The curl virus and leaf mold infect almost all of the nearby plants.

Fig. 1. Sample dataset images collected from the tomato field.

#### B. Pre-processing the dataset images

Since leaf photographs were taken in actual field settings, they included background details like dirt and tree branches, among other things. The work of the suggested detection system is anticipated to be made simpler by extracting just the leaf region containing one or more diseases and deleting the background noises [30]. There are many methods in place to eliminate extraneous background details from real-world situations [9]. Grab Cut technique [31] is a quick and effective machine learning-based approach that can eliminate unwanted background data with little human adjustments. On the basis of graph cuts, the backdrop is removed. According to a user-provided window, anything beyond the window is taken into account to be the clear backdrop, however within the window, both the foreground and the background may exist.

The procedure is repeated until convergence in order to fine-tune the background removal job. On the hardware utilized for testing, background removal was reported to take an average of 4.12 seconds per picture. The algorithm's ability

to eliminate background data outside of the infected leaf was determined to be effective. After the backgrounds have been removed, the images are annotated before being subjected to image augmentation methods including flipping, rotating, and brightness boosting.

### C. Annotation and Labelling

The Roboflow annotation tool was used to manually design the ground truth boxes and labeling the healthy and diseased tomato leaf images. According to Fig. 2 it shows the experiments done for the annotation and labeling, sample taken from the roboflow tool. Each box's enclosing box coordinates, height, breadth, and class name are listed in Fig. 3. When an image is included into the model for learning, testing, or assessment, an accompanying XML file is included [17].

Fig. 2. Tomato leaf image annotation with bounding box created using roboflow tool.

Images captured at different angles and sizes are included in the dataset used for the tests. In order to maintain the bounding boxes on the item of interest regardless of any augmentation step applied to it subsequently, we executed an auto-orient procedure. As often requested by YOLO, the photographs were also scaled using a normalization set at a resolution of 416X416. When working with an unbalanced dataset, we prefer to execute the augmentation techniques to minimize over-fitting. Proposed study used augmentation

techniques includes flip horizontal, rotation, and brightness (25%). The addition of these augmentations will increase the dataset's size as well as the variety of the photographs taken in various lighting situations. The dataset is augmented at random, increasing the size to 1, 112. Roboflow data services were used for each of these pre-processing phases.

### D. Hardware and Software Configuration

Every experiment was run on Windows 7 system using an Intel i3 processor. The necessary repositories and libraries were installed before configuring the experimental environment. Pre-trained weights for the YOLO-X model were downloaded when the dataset was uploaded to the drive. Experiment was performed using google collab notebook environment. With the help of the hyper-parameters using 100 epochs, our suggested model was trained. The best weights produced after training were kept and then utilized to assess the effectiveness of our suggested model on test images with a batch size of 32. In order to conduct the experiment, 640 × 640 resolution images from the dataset were used. The dataset has been split automatically with the code on the collab on the basis of 80% of the images were utilized for training and testing, while the other 20% were used for validation process.

### E. Enhanced YOLO-X Proposed Model for Tomato Leaf Disease Detection

YOLO- X deep learning model is a single stage object detection technique that differs from YOLO-v3. It derives from DarkNet53 architecture. Beginning with a 1 X 1 convolutional layer, the feature channel for each level of FPN features is reduced to 256. Then, for the classification and regression tasks, respectively, we add two parallel branches with two 3X3 convolution layers. The anchor-free detector YOLO-X [26] has shown exceptional speed and accuracy performance. To improve convergence while the system was being trained, the head of YOLO-X was cut off from the original detector [32]. Because to the implementation's anchor-free design, the overall number of trainable parameters has been significantly decreased.

SimOTA [26], which reduces the amount of time required for training and aids in the solution of the Optimal Transport (OT) issue [21], is also used to enhance the label assignment approach.

For the application that is covered in this article, we build a more sophisticated YOLO-X model. The CSP darknet serves as the foundation for feature extraction in this model. In order to accomplish better feature fusion throughout the classification and regression tasks, the feature layers are first up-sampled for feature fusion and then down-sampled for classification [27]. One of the crucial elements that must exist for good feature extraction is the focus module. The input photographs are split into four pieces, then concatenated in order to preserve information about the features of the objects. This makes it possible to observe the characteristics more clearly. The Bottleneck CSP layer, which comes after the top layer, is where the deep features are recovered with more accuracy. Convolution, related batch normalization, and activation processes are performed on the feature maps. To learn about overlapping and mild symptoms, advanced data augmentation methods like mosaic and mix-up are utilized

during training [33]. The non-maximal suppression (NMS) strategy prevents the chance of multiple detections happening at the same time.

A definition for the modeling error that arises between the anticipated class and the ground truth is Binary Cross Entropy (BCE) loss [34] with logits. A sigmoid activation function is utilized to eliminate all accurate predictions [26]. The bounding box's coordinates (x, y, w, and h) are predicted in the regression branch's output.

In order to forecast bounding box outputs, YOLO-X employs the IoU metric and compares its predictions to the actual data.

#### F. YOLO X Model Working Environment with Bounding Box

The localization of objects and their categorization are two processes that are critically important for applications based on computer vision. How precisely a machine learning model can pinpoint an object's placement inside a scene or image is determined by the loss function [35]. This is why conventional single-stage and two-stage detectors are developed using the bounding box regression approach.

Vanishing gradients provide a challenge because they cause IoU losses, which prohibit the model becoming convergent. The basis of the problem is that the predicted boxes do not precisely overlap the ground truth boxes, leading to inaccurate findings. To increase the precision with which the objects were tracked, it was chosen to give a number of enhanced bounding box losses depending on a number of parameters. The Generalized Intersection over Union, the Distance Intersection over Union, the Complete Intersection over Union, and the Efficient Intersection over Union (GIoU, DIoU, CIoU, EIoU) are acronyms for these intersections. The amount of overlap between the target and the anchor boxes is represented by these loss functions via the use of several metrics.

### IV. RESULTS

Training effectiveness was assessed based on increased convergence speed and detection performance of overlapping illness symptoms and severity classes using datasets collected from the field. For detection models, the Mean Average Accuracy (mAP) statistic is often used. This statistic indicates the accuracy for all classes when the Intersection over Union (IoU) criteria is set to 50%. The IoU threshold was held constant at 0.5 while calculating the mAP score. Similar levels of training accuracy were originally shown by the default YOLO-X model, but it was unable to converge in the last 30 epochs of training. As illustrated in Fig. 4, this resulted in the default YOLO-X model's accuracy being lower (69.90%) than the suggested enhanced YOLO-X model's accuracy (73.42%).

A SE block was added to the SPP module of the standard YOLO-X in an effort to boost detection performance. [39] To achieve this, many tests were conducted. The YOLO-X-SE model's training performance was plainly overfit in the last 20 training epochs, which decreased inference speed. Several unique classes were misclassified, despite the fact that our model's inference time is a little faster than the default YOLO-X. The model's validation and test results were assessed over a range of IOU losses in order to attain the best degree of

convergence and mAP performance. The model performed noticeably better in terms of the results of the enhanced SPP block compared to vanilla-IoU and other regression techniques. For the localisation of overlapping medical symptoms, this was crucial.

Fig. 4. YOLOX vs improved YOLOX model performance (mAP).

The best weights are chosen when the training process is finished, and the model's performance on the test dataset is assessed using these weights. The regression will come to an end once the item included by the bounding box has been located. The BCE loss may be used to assess a bounding box's capacity to hold an item. The disease's ability to exist inside the anticipated bounding box is assessed using the confidence score. We conducted a number of tests to determine the ideal threshold value in order to increase the detection mAP score. This figure shouldn't be too high or low in order to avoid false positives and genuine predictions, respectively. The degree of confidence will stay at 0.25 after an analysis of the test data. Each projected bounding box in the test photos has a corresponding confidence level, which may be used to represent the detection performance of the test dataset as determined by Improved YOLO-X. The result offers proof that strengthens confidence in the localization and classification procedures. Fig. 5 represent the loss graph of YOLOX and improved YOLOX model in each epoch.

Fig. 5. Graph depicts the YOLOX vs improved YOLOX loss vs epochs.

The YOLO-X model uses the same basic idea as its predecessor but with an SPP anchor-free system. The decoupled head lowers convergence, as shown by comparing its performance to that of the YOLO-V4 [40] and YOLO-V5 [20] models, both of which were trained and validated using our Tomato severity dataset. The findings are shown in Table II depending on the image size and processing inference time needed for inference. The accuracy of detection has reduced even though YOLO-V4 and YOLO-V5 have inference rates that are noticeably quicker than our model. Both the default

YOLO-X model and our Improved YOLO-X model demonstrate higher convergence performance compared to other models trained on our dataset because the anchor-free method decreases the possibility of complexity and obstacles emerging during training.

TABLE II. RESULT OF MODEL COMPARISON BASED ON TIME ATTRIBUTE

Experimented model	Input Size	Inference Time
YOLO-v4	416X416	20.81
YOLO-v5	416X416	16.01
YOLO-X	640X640	32.08
YOLO-X-SE	640X640	56.42
Enhanced YOLO-X	640X640	32.03

To evaluate how well our suggested YOLO-X model performs in classifying overlapping symptoms and severity phases. Because it was incorrectly categorized with the healthy and leaf curl disease stage-2 class, curl stage-1 was recognized with substantially lower average precision. The overlapping signs of leaf mold and curl stage-2 were also more accurately picked up by our upgraded YOLO-X model. As the class does not visually resemble any other classes and there are not many problematic images in our test dataset, the models successfully identify leaf stress.

#### A. Comparison with Other Existing Models

Here, we contrast the effectiveness of our upgraded YOLO-X model with that of current state-of-the-art models. The performance of our proposed model is contrasted with that of cutting-edge models in Tableau. We trained the YOLO-V4, YOLO-V5, YOLO-V7, Efficientdet, and YOLO-X models on our tomato severity dataset for 100 iterations using the default code settings. The mAP scores are noticeably lower than those anticipated by the YOLO-X model, as seen in Table III. We created the YOLO-X- lite model, a YOLO-X version that works well for edge computing. An SPP block that has been tailored for embedded device operation is included in the model. However, it did not provide the expected results for a specific dataset. The advantages of applying Spatial Pyramid Pooling findings into mAP analysis are shown in Table IV. It indicates that when SPP with 3, 5, 7, and 9 connections is taken into account, our optimized YOLO-X model performs better.

TABLE III. RESULT ANALYSIS OF THE PROPOSED MODEL IN COMPARISON WITH OTHER STATE OF HEART ALGORITHMS

Experimented model	mAP in Healthy	mAP in Leaf Curl Disease - Stage 1	mAP Leaf Curl Disease - Stage 2	mAP in leaf mold
YOLO-v4	27.87%	56.61%	40.12%	54.01%
YOLO-v5	65.91%	29.21%	47.72%	53%
YOLO-X	64.21%	49.58%	61.23%	62.31%
YOLO-X-SE	56.01%	63%	64.02%	59.82%
Enhanced YOLO-X	62.37%	62.32%	65.72%	75.02%

TABLE IV. AN ANALYSIS OF EVALUATION METRICS USING MEAN AVERAGE PRECISION WITH SPATIAL PYRAMID POOLING

Spatial Pyramid Pooling (5,9,14)	Spatial Pyramid Pooling (3,5,7,9)	Skip Connections	mAP
Yes	No	No	69.90 %
No	Yes	No	67.42%
No	Yes	Yes	71.31%
No	Yes	Yes	73.42%

#### B. Future Work and Research Opportunities

Multiple stresses on the host and multiple disease stages on the leaf are typical outdoor conditions. For these two scenarios, this research suggests a deep learning-based solution that has been put to the test on a large dataset. The scope of the proposed study is restricted to assessing the severity of diseases only on the leaves of tomato plants. Future study might potentially prioritize the study of disease severity detection in various parts of the plant. In order for our model to be applicable in real-world scenarios, its reliability is of utmost importance. To achieve this, the dataset will be continuously enhanced by incorporating new photographs depicting various ailments and harvests.

- It is strongly advised to subject the recommended model to additional training and testing, specifically using individual leaves placed against a clean background.
- To enhance its practicality and efficiency, we intend to allocate a greater financial investment towards obtaining more field samples.
- Furthermore, to expedite the training and testing processes on state-of-the-art technology, we will prioritize designing the model to be as lightweight as possible.

#### V. CONCLUSION

The suggested study offers a framework for classifying symptoms of a particular disease on tomato plants according to increasing severity. The detection of many illnesses that are present on a single leaf may also be done using this approach. We have suggested a YOLO-X-based model with an enhanced Spatial Pyramid Pooling block to achieve this. Various pooling rates were used to aggregate multi-scale characteristics. Remaining links were added to better preserve spatial information. With the use of this model, we were able to identify diseases symptoms that were similar and overlapped more accurately. The suggested model outperformed the default YOLO-X by 3.27 percent according to experimental findings, achieving mAP scores of 73.42% and 72.31% using training dataset and testing dataset respectively. Additionally, Curl stage-2 and Leaf mold yielded the greatest results, with average precisions of 65.76% and 74.02%, respectively, for overlapping and co-existing classes.

# He and She in Video Games: Impact of Gender on Video Game Participation and Perspectives

Deena Alghamdi

Department of Computer Science and Information Systems, Umm Al-Qura University, Makkah, Kingdom of Saudi Arabia

**Abstract**—Playing video games is now considered one of the day-to-day activities of many adolescents and young people. This research studies the gender impact on video game participation and perspectives among college students in the Kingdom of Saudi Arabia (KSA). The data were collected by first conducting discussions involving four focus groups with a total of 26 participants to explore the topic. An online questionnaire was then distributed, and a total of 2,756 responses were received. The analysis of the data shows a clear impact of gender on the playing practices adopted, perceptions towards the pros and cons of video games, and the most used consoles and popular games. However, the practices and perspectives of male and female players did not differ regarding bullying in video games. The findings of this study can advance the understanding of this subject, and game developers who are targeting the KSA game market can use the results as the basis for developing games that are more suitable for the players in that country.

**Keywords**—College students; gender differences; KSA; video games

## I. INTRODUCTION

The Kingdom of Saudi Arabia (KSA) is the nineteenth biggest gaming market in the world and is currently experiencing an enormous (41.1%) year-on-year growth in this sector [1], with 21.1 million gamers in KSA in 2020 [2]. Several studies have discussed the possible impact of violent video games and potential gender-related effects [3] [4] [5]. While [6] argued for the positive effects of video games on well-being greatly depend on the presence of moderation; the aspects involved, such as social aspects, violence, or physical activity; and the motivations behind playing the game. In addition, Comeran-Chueca et al. [7] emphasized on this positive effect when they used active video games (AVG) as an effective strategy to increase energy expenditure in children and adolescents with overweight and obesity when they found that energy expenditure with AVG combined with multi-component exercise was 5.68 kcal/min in boys and 4.66 kcal/min in girls with overweight and obesity.

In the present study, the author explored gender differences in video game-playing among college students in the KSA, players' perspectives of the male and female characters' roles in the video games that they played, and the potential interference of gaming with other aspects of college students' lives. This study aimed to answer the following research questions: (1) What are the main areas that identify the practices and perceptions of players in the KSA? (2) Are there differences between male and female players' perceptions towards video games in the KSA? (3) Does gaming interfere with academic preparation and interpersonal relationships?

In this paper, we illustrate related previous research, describe and discuss our methodological approach, outline the findings about the participants' participation and perspectives regarding video games, and finally discuss the implications of these practices in the KSA.

## II. LITERATURE REVIEW

Previous studies explored and discussed the impact of gender on different aspects of video games such as playing duration, the content of video games, and how this is affecting players' personal life. One study [8] reported that more boys than girls played video games at least once based on two 24-hrs activity diaries for three age groups: 3–5 year-olds, 6–8 year-olds, and 9–12 year-olds. According to the Kaiser Foundation [9], there is a gender impact on console video game playing, with boys spending an average of almost an hour a day playing (0:56) and girls just under fifteen minutes (0:14). One clear reason for the disparity in this age group is that girls lose interest in computer games as they enter their teenage years, whereas boys do not. Other studies have also reported gender differences in children's video game playing [10] [11], and the 2003 consumer survey by Interactive Digital Software Association [12] showed that approximately 72% of the most frequent players are boys or men. In arcades, video games are more often played by boys or men than by girls or women [13]; meanwhile, according to [14], approximately equal numbers of men and women in college play video games.

Gender is also a relevant issue regarding video games' content. More video games are male-oriented than female-oriented where Scharrer [15] examined 1,054 video game advertisements from video game magazines and reported that the ratio of male to female characters was greater than three to one. After their analysis of 597 characters from 47 randomly selected Nintendo 64 and PlayStation games, Beasley and Standley [16] found that only approximately 14% of those characters were women. In addition, female characters were depicted with more exposed skin than male characters. In a study of video game reviews on an Internet site, Ivory [17] similarly reported under-representation and sexualization of female video game characters. In none of these previous studies, though, were players' perspectives of gender-related content assessed.

Differential video game-playing by men and women may also be related to other aspects of individuals' lives. In [18], the author shows that brief exposure of children to a prosocial video game (PVG) increased their prosocial thoughts and prosocial behaviors. More precisely, boys reported higher accessibility of prosocial thoughts and more prosocial

behaviors than girls. The PVG effect on prosocial behaviors was mediated by prosocial thoughts. These findings suggest that increasing PVG exposure and training prosocial thoughts were effective ways to promote the positive development of prosocial behavior during early childhood. The research in [19] suggested that players' in-game motivational experiences can contribute to affective well-being, but they do not affect the degree to which play time relates to well-being. On other hand, the "displacement hypothesis" has been used previously to explain how children's television viewing may affect their other activities [20]; time spent in one activity displaces time that could have been used to do something else. Similarly, Gentile, Lynch, Linder, and Walsh [21] reported that both the amount of game playing and exposure to game violence were negatively linked to poor school grades in eighth- and ninth-grade students. Sixth- and ninth-grade boys were more likely than girls of the same age to indicate that they spent their free time playing computer/video games, and they were more likely to select "none" when asked how much time per day they spent reading for pleasure [22]. Video game playing has been linked with hostility [21], which could negatively impact interpersonal relationships in a variety of ways. Also, if men spend more time than women playing video games, romantic relationships may be negatively impacted because "couple time" could be displaced by time spent gaming, which could result in interpersonal conflict.

### III. METHODOLOGY

The study began by forming focus groups, which are effective in exploring and examining participants' perspectives and concerns by allowing them to create new questions and concepts [23]. Focus group sessions are social gatherings, usually of six to eight participants [24]. Morgan [25] reported that it can take up to 32 telephone calls or personal visits to recruit just eight participants for a group. Participants are encouraged to debate the relevant issues and to develop their opinions and thoughts, as they would in real-world situations [26]. A moderator presents the focus of the discussion and helps to elicit conflicting arguments without judging the participants' opinions [27]. The approach used to analyze the resulting data was to categorize quotations from the focus groups into types of description, i.e., concepts, and then to compare them with targeted concepts of privacy perspectives [28]. Four focus groups were formed during March 2023 with 26 participants in total: a men-only group (seven participants), a women-only group (six participants), and two groups of mixed-gender (four women and three men, and three women and three men). All the focus group participants were college students aged 18–25 years and a snowballing technique was used to recruit them. Prior to each focus group, participants' consent obtained for ethical considerations. Conducting the four focus group discussions early in the study was useful, as they provided preliminary information on which to focus on the next step of the data collection.

A questionnaire was then designed to evaluate the possible influence that gender had on college students' perspectives and participation in video games. The questionnaire was based on the outcomes of the focus groups and face-validated using exploratory interviews; some items were rephrased in order to reflect the intended meaning, while others were deleted or

added. To define the final list of statements, respondents were asked to identify whether the proposed items from the questionnaire represented their perspectives toward video games and to indicate some additional items that they considered important for investigation. The questionnaire consisted of two parts: the first gathered gender and age information, and the second included 54 five-point Likert statements ranging from "strongly disagree" to "strongly agree." The questionnaire was created using Google Forms and the random target subjects of the questionnaire were college students in the KSA aged 18–25 years. The questionnaire took 10–15 minutes to complete. After collecting the responses, the data were entered into the computer and processed using the Statistical Package for the Social Sciences (SPSS V.20), which is a widely used program for statistical analysis in the social sciences.

## IV. RESULTS

### A. Focus Group Results

Analysis of the data from the focus groups revealed four main areas related directly to the perspectives and participation of students in video games in the KSA: playing practices; bullying; the pros and cons of video games; and the most used consoles and most popular games.

Playing practices consisted of variables that relate to activities such as spending money on video games, watching professionals playing, gender issues in video games, and the effect of playing on social and academic life. Bullying in video games comprised questions related to someone being bullied and practices to avoid bullying. The third area referred to possible advantages and disadvantages of playing video games, such as isolation or engagement with others, wasting money or time, health and religious effects, and improvements in mental agility and concentration. The final area includes variables relating to the most used consoles and the most popular video games.

### B. Questionnaire Results

There were 2,756 responses to the questionnaire, of which 39.2% were from men and 60.8% were from women. However, 469 responses were excluded from the results because they were from respondents over 25 years of age; therefore, 2,287 responses were included in the study.

1) *Playing time:* Table I shows that when participants were asked about how much time they spent playing during the previous week, 26.9% did not play, and more women did not play than men. It can also be seen that 23% of participants played 1 to 2 hrs per week, and again most of them were women. However, the percentage of male players was higher for the last three categories: 2 to hrs, 6 to 10 hrs, and every day. In addition, the chi-squared test was used to determine the gender differences and playing hours in video games, and it was found that the p - value showed there was a statistically significant difference between men and women, and the number of hours of play differed according to gender. From the table below it can be seen that men prefer to spend more hours on video games than women.

TABLE I. TIME SPENT PLAYING DURING THE PREVIOUS WEEK

	Male	Female	Total (%)
None	132	610	742 (26.9%)
1–2 hrs	228	406	634 (23%)
2–5 hrs	226	182	408 (14.8%)
6–10 hrs	122	72	194 (7%)
Every day	191	118	309 (11.2%)
<b>Total (%)</b>	899 (39.3%)	1,388 (60.7%)	2,287(100%)

Chi-squared value = 21.41 *p* - value = 0.000\*

\**p* - value is statistically significant at 0.05

Respondents who did not play video games in the last week were presented with a choice of reasons why. The mean, standard deviation, and level of agreement of the responses are illustrated in Table II. The reasons chosen by respondents reflect a generally positive perspective, as the reasons for not playing were not lack of money or lack of ability to play, but rather their lack of time or enthusiasm to play.

TABLE II. REASONS FOR NOT PLAYING IN THE PREVIOUS WEEK

Reason	Mean	Standard Deviation	Level of Agreement
I don't have time	3.86	1.30	High
I don't like video games	3.90	1.29	High
I don't have enough money to play	2.39	1.37	Low
I am not good at video games	3.14	1.41	Medium

2) *Playing practices*: Table III demonstrates the respondents' answers to their playing practices, along with the mean, standard deviation, and level of agreement where the average mean was 3.28, which is medium.

The respondents' perspectives for all items varied between high and medium, where the highest mean of 3.72 was for item 1 (“For fun, I prefer to watch videos of other people playing”) followed by item 2 (“I will not pay for a video game that I never tried before; I have to try it first”) with a mean of 3.65, which indicates respondents' mindfulness of spending money on games. Items 12 and 13 have the lowest means of 2.93 and 2.70, respectively, indicating that respondents believe that video games do not have a significant effect on their academic performance or their social relationships, or that they are not sure.

3) *Bullying in video games*: Tabel IV presents the mean, standard deviation, and level of agreement regarding 13 items relating to bullying in video games. The mean was 3.46 in the high level, which indicates that respondents have high awareness regarding this topic, and as noted the mean for all the 13 items related to this topic ranged between 2.90–3.89, indicating a high to medium level. The highest mean, 3.89, is for item 1 (“I see a lot of bullying in video games”), followed by item 2 (“I play only with my friends”) where the mean was 3.84. The lowest means, 3.08 and 2.90, were for items 12 and 13, respectively (“I don't care if I witnessed someone being bullied,” and “Bullies are always female characters”); the level of perspectives was medium, indicating that respondents' are neutral about these two items.

TABLE III. PLAYING PRACTICES

	Item	Mean	Standard Deviation	Level of Agreement
1	For fun, I prefer to watch videos of other people playing	3.72	1.26	High
2	I will not pay for a video game that I never tried before; I have to try it first	3.65	1.28	High
3	I watch videos of other people playing just to learn from them	3.57	1.25	High
4	Most famous video games are masculine	3.48	1.14	High
5	In video games female characters are always sexually provocative	3.40	1.28	Medium
6	Playing affects my sleeping hours negatively	3.35	1.26	Medium
7	I might pay for a video game that I never tried before	3.24	1.38	Medium
8	I don't like to deal with people who play video games a lot	3.20	1.24	Medium
9	There are no famous video games that are feminine	3.20	1.19	Medium
10	I might pay to update a game or buy a weapon	3.13	1.39	Medium
11	I always pick a male character	3.04	1.40	Medium
12	Playing affects my academic performance negatively	2.93	1.29	Medium
13	Playing affects my relationships with others negatively	2.70	1.31	Medium
	Total	3.28	0.62	Medium

TABLE IV. BULLYING IN VIDEO GAMES

	Items	Mean	Standard Deviation	Level of Agreement
1	I see a lot of bullying in video games	3.89	1.05	High
2	I play only with my friends	3.84	1.14	High
3	Usually, if the team is all female players, they would refuse a guy playing with them	3.75	1.10	High
4	I do play with strangers picked randomly by the game.	3.71	1.08	High
5	Male characters are more professional in video games	3.69	1.23	High
6	Bullies are always men	3.57	1.14	High
7	If I witness someone being bullied, I always stand out	3.45	1.19	High
8	I do play with strangers from the opposite sex picked randomly by the game	3.41	1.25	High
9	Bullying is always against female characters	3.37	1.20	Medium
10	Women are more professional in video games	3.15	1.19	Medium
11	Usually, if the team is all male players, they would refuse a female player with them	3.11	1.31	Medium
12	I don't care if I witness someone being bullied	3.08	1.30	Medium
13	Bullies are always female characters	2.90	1.14	Medium
	Total	3.46	0.63	High

4) *Pros and cons of playing video games:* Participants in the focus groups were asked about the pros and cons of playing video games. Table V shows that the average mean was 3.88, with a high level, and this falls within the category of “agreed,” which indicates the respondents' agreement towards the pros and cons of playing video games and that they have awareness of the listed items. It is also noted that the mean of their perspectives ranged between 3.56–4.31 for the items listed and the highest mean was 4.31 for item 1 (“Spending fun time’ is an advantage of playing”). The lowest, 3.57 and 3.56, were for items 9 and 10, respectively (“Neglecting work/study’ is a disadvantage of playing,” and “Wasting money’ is a disadvantage of playing”) The perspective level was high which indicates that the respondents' approval of these cons is high, confirming that they concur on the defects of video games including their impact on work, academic achievement, and financial loss.

TABLE V. PROS AND CONS OF PLAYING VIDEO GAMES

	Items	Mean	Standard Deviation	Level of Agreement
1	Spending fun time’ is an advantage of playing	4.31	0.78	Very High
2	Living exciting moments in artificial reality’ is an advantage of playing	4.18	0.89	High
3	Evolving player's smartness and reflections’ is an advantage of playing	4.07	0.97	High
4	Affecting player's sight negatively or causing obesity’ is a disadvantage of playing	3.88	1.09	High
5	Knowing other players and get along with them’ is an advantage of playing	3.86	1.08	High
6	Neglecting prayers’ is a disadvantage of playing	3.84	1.20	High
7	Isolating players from community’ is a disadvantage of playing	3.80	1.09	High
8	Wasting time’ is a disadvantage of playing	3.74	1.17	High
9	Neglecting work/study’ is a disadvantage of playing	3.57	1.18	High
10	Wasting money’ is a disadvantage of playing	3.56	1.18	High
	Total	3.88	0.65	High

5) *Impact of gender:* In addition to the mean and standard deviations, the independent samples test was used to identify gender impact on respondents' perspectives towards playing practices, bullying, and the pros and cons of playing video games. Table IV shows that the p - value is statistically significant in both playing practices and the pros and cons of video games. This indicates that the perspectives of male respondents differ from those of female respondents towards these two areas, where the mean for men’s perspectives toward playing practices is higher than the women’s, indicating that men have a better perception of their playing

practices; however, it is the opposite case in the second area, where women’s perspectives toward pros and cons for playing video games is higher, indicating that they have a better perception of this area. However, it should be noted that there are no differences in male and female respondents' perspectives towards bullying in video games, meaning that their opinions are similar in this area. Fig. 1 below demonstrated the mean and standard deviations for males and females participants towards the three areas.

TABLE VI. IMPACT OF GENDER

Item	Gender	Sample Size	Mean	Standard Deviation	p - value
Playing practices	Male	767	3.34	0.59	0.000*
	Female	778	3.22	0.64	
Bullying	Male	767	3.46	0.62	0.911
	Female	778	3.45	0.64	
Pros and cons	Male	767	3.83	0.62	0.005*
	Female	778	3.93	0.67	

\*p - value is statistically significant at 0.05

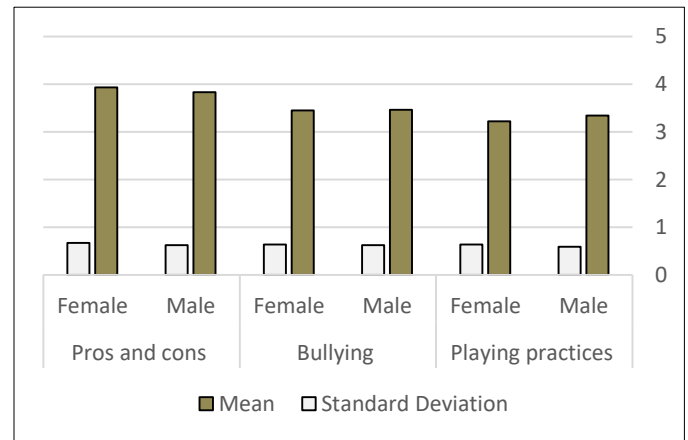

Fig. 1. Gender impact.

6) *Most used game console and most popular game:* The independent samples test was used in addition to mean and standard deviations to identify the influence of gender on the game consoles most used by male and female respondents, as presented in Table VII. The p - values in the table below indicate a statistical significance in the following consoles: Sony PlayStation, mobile phone, PC, and Xbox; this indicates that men's opinions differ from women’s towards these consoles, and it is clear from the table that the differences were in favor of males respondents, indicating that men have a higher preference than females for their use. Meanwhile, the p - value in the table is not statistically significant in the perspectives of male and female respondents towards Wii and Nintendo, indicating that the perspectives of male respondents do not differ from those of women towards these consoles. Fig. 2 demonstrated the mean and standard deviations for males and females participants towards the different game consoles.

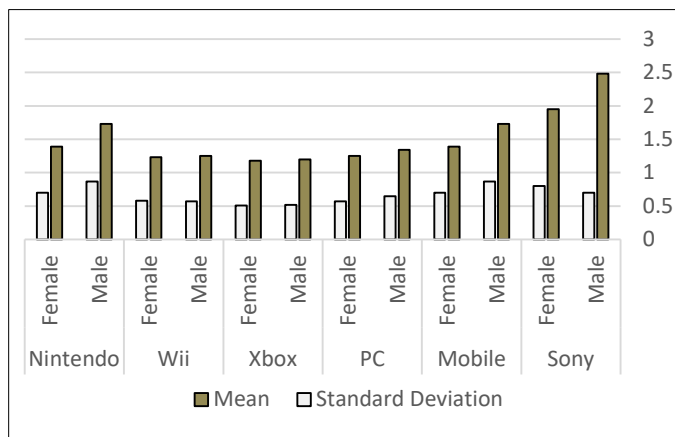

Fig. 2. Game consoles.

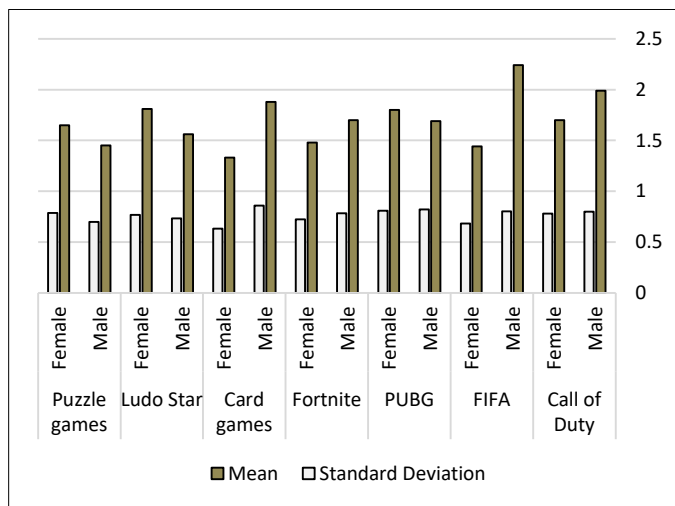

Fig. 3. Popular games.

Meanwhile, seven video games were mentioned by participants in the focus groups: Call of Duty, FIFA, PUBG, Fortnite, card games, Ludo Star, and puzzle games. Call of Duty is a video game series starting in 2003 and originally focused on the World War II setting, FIFA is a discontinued football video game, PUBG (previously known as PlayerUnknown's Battlegrounds) is a battle royal game, Fortnite is an online fighting video game released in 2017, card games are any game using playing cards as the primary device with which the game is played such as Solitaire, Spider Solitaire, Hearts, etc. Ludo Star is an online board dice video game, puzzle games are make up a broad genre of video games that emphasize puzzle solving. The types of puzzles can test problem-solving skills, including logic, pattern recognition, sequence solving, spatial recognition, and word completion. By exploring gender influence on the popularity of these games, Table VIII shows that the  $p$  - value is statistically significant in the perspectives of male and female respondents towards all the games, and this indicates that the perspectives of men differ from those of women towards playing those games. The differences were in favor of male respondents for Call of Duty, FIFA, Fortnite, and card games, and this indicates that men have a better perception than women of these games or that these games suit men better than women. On the other hand,

the differences were in favor of women for PUBG, Ludo Star, and puzzle games, and this indicates that women have a better perception than men of these games or that these games are more suitable for women than men. Fig. 3 demonstrated the mean and standard deviations for males and females participants towards popular games.

TABLE VII. MOST USED CONSOLES

Console	Gender	N	Mean	Standard Deviation	$p$ - value
Sony PlayStation	Male	767	2.48	0.70	0.000*
	Female	778	1.95	0.80	
Mobile phone	Male	767	1.73	0.87	0.000*
	Female	778	1.39	0.70	
PC	Male	767	1.34	0.65	0.000*
	Female	778	1.25	0.57	
Xbox	Male	767	1.20	0.52	0.003*
	Female	778	1.18	0.51	
Wii	Male	767	1.25	0.57	0.367
	Female	778	1.23	0.58	
Nintendo	Male	767	1.73	0.87	0.383
	Female	778	1.39	0.70	

\* $p$  - value is statistically significant at 0.05

TABLE VIII. MOST POPULAR VIDEO GAME

Video game	Gender	N	Mean	Standard Deviation	$p$ - value
Call of Duty	Male	767	1.99	0.798	0.000*
	Female	778	1.70	0.780	
FIFA	Male	767	2.24	0.801	0.000*
	Female	778	1.44	0.684	
PUBG	Male	767	1.69	0.822	0.000*
	Female	778	1.80	0.810	
Fortnite	Male	767	1.70	0.782	0.003*
	Female	778	1.48	0.723	
Card games	Male	767	1.88	0.859	0.000*
	Female	778	1.33	0.631	
Ludo Star	Male	767	1.56	0.732	0.000*
	Female	778	1.81	0.769	
Puzzle games	Male	767	1.45	0.700	0.000*
	Female	778	1.65	0.787	

\* $p$  - value is statistically significant at 0.05

## V. DISCUSSION

Regarding the first research question about the main areas that identify the practices and perceptions of video game players in the KSA, the analysis found four main areas: playing practices, bullying, pros and cons of video games, and most used console and most popular game.

Meanwhile to answer the second research question: Are there differences between male and female players' perceptions

towards video games in the KSA? The similarities and differences between male and female players' perceptions towards video games have been highlighted. Regarding the playing practices, the study found that approximately one-third of the participants did not play at all in the week before the questionnaire, and the majority of these were women. For participants who played video games, the study found that more men than women prefer to play, and for longer hours, which supports the original hypothesis. This is supported by [8], [9] and [29], which reported that the percentages of daily and weekly male players are higher than those of female players. In addition, men's perspectives toward playing practices mentioned in Table III are higher than women's, which indicates that men have a better perception of their playing practices and wide agreement regarding the items mentioned in the table, particularly the first four items: watching others playing for fun or to learn something, not buying a game without trying it first, and the masculinity of famous games. Also, gender difference is noticeable in the responses of participants regarding the pros and cons of playing video games where, in this case, women have a better perception of them and wide agreement regarding the items mentioned in Table V such as playing for fun, increasing thinking and response abilities, and getting friendly with strangers are the advantages of playing video games, while the disadvantages are the negative impact on academic/work performance and social relationships, and wasting time and money. According to [29], 17.7% of players in the KSA use smartphones to play, 17.6% of them use Sony PlayStations, and the rest of the consoles are used by less than 5% of players. This study found the opposite, where the Sony PlayStation is used more than smartphones, and men's usage is higher than women's. Moreover, [29] specify the order of the most popular games in playing consoles as follows: FIFA, PUBG, Fortnite, Roblox, and Call of Duty. Similarly, the most popular games on smartphones are as follows: Subway Surfers, Snake.io, Roblox, Ludo Star, Yalla Ludo, and PUBG MOBILE. This order of popular games did not consider the gender aspect. In this study, the order of popular games would be the following: FIFA, Call of Duty, PUBG, Ludo Star, Fortnite, and Card games at the same level, and then finally puzzle games. The gender impact appears in men favoring the first two along with Fortnite and card games, while women favor PUBG, Ludo Star, and puzzle games. On the other hand, gender differences did not occur in one area, namely bullying in video games. This indicates that male and female players' opinions are similar, and there is wide agreement about the items in this area. These are mentioned in Table IV particularly the first eight items about the frequency of bullying and specifically male bullies in video games and the general preference of only playing with friends if possible; if not, it is still acceptable to team up with strangers picked out randomly by the game even if they are from the opposite sex.

The third research question regarding the interference of video games with academic preparation and interpersonal relationships was answered by the analysis of the data in V, where participants highly agreed that getting friendly with strangers are one of the advantages of playing video games, while the disadvantages are the negative impact on academic/work performance and social relationships.

The current study was exploratory and the self-reported approach used were as transparent as possible to enable others to examine and build upon this work, however, moving beyond this initial exploration of players' practices and perceptions to a more confirmatory approach, further research should follow different approach relying on collecting practical practices. Following this will result in a more reliable knowledge base for game developers.

## VI. CONCLUSIONS

In the present study, the authors explored gender differences in video game playing among college students in the KSA, covering players' perspectives of the male and female characters' roles in the video games that they played, and the potential interference of gaming with other aspects of college students' lives. It found clear evidence supporting the high impact of gender on the participation and perceptions of college students in the KSA, as predicted. In addition, the four main areas identified can serve as the foundation for the development of appropriate game-marketing strategies for game vendors in the KSA. Game developers who are targeting the KSA game market can use the results of this study as the basis for developing video games by considering the impact of gender and the practices and perceptions of Saudi players detailed in this study. However, selecting college students puts a limitation on how generalizable our results are. Moreover, collecting data from participants using self-reports instead of objective measures of technology use can be other limitation to the current study. The findings in this study advance the knowledge of this subject and future research could be expanded by increasing the number of questions asked regarding students' academic performance and income or expanding the study range to include players other than college students. In addition, as this study was exploratory, we recommend other researchers to examine and build upon our work and collecting data regarding players' practices by using of more confirmatory approach.

# Hyperparameter Tuning of Semi-Supervised Learning for Indonesian Text Annotation

Siti Khomsah<sup>1</sup>, Nur Heri Cahyana<sup>2</sup>, Agus Sasmito Aribowo<sup>3</sup>

Department of Data Science, Institut Teknologi Telkom Purwokerto, Indonesia<sup>1</sup>

Department of Informatics, Universitas Pembangunan Nasional Veteran Yogyakarta, Indonesia<sup>2,3</sup>

**Abstract**—A crucial issue in sentiment analysis primarily relies on the annotation task involving data labeling. This critical step is typically performed by linguists, as the nuanced meaning of text significantly influences its contextual interpretation. If there is a large volume of data, annotation is time-consuming and financially burdensome. Addressing these challenges, a semi-supervised learning annotation (SSL) that integrates human annotator and artificial intelligence algorithms emerges as a potent solution. Building accurate SSL needs to explore the best architecture, including a combination of machine learning and mechanism. This research aims to construct semi-supervised model annotation text by tuning the parameter of the machine learning algorithm to gain the most accurate model. This study employed a Support Vector Machine and a Random Forest algorithm to build semi-supervised annotation. Grid-Search and Random-Search were employed to tune the Random Forest and Support Vector Machine parameters. The semi-supervised annotation model was applied to annotate Indonesian texts. The outcomes signify that hyperparameter-tuning enhances SSL performance, surpassing the performance achieved using default parameters. The experiment also shows that the SSL annotation using a Support Vector Machine tuned by Grid Search and Random Search is more robust than the Random Forest algorithm. Hyperparameter tuning is also robust to training data that contains many manual labeling errors by experts.

**Keywords**—Text annotation; semi-supervised; parameter-tuning; grid search; random search

## I. INTRODUCTION

The challenge in text classification-based machine learning is data labeling. Each textual instance has meaning upon the context and grammatical nuance specific to each language. Thus, human intervention is vital for data labeling, as humans are adept at assessing the contextual relevance of text. Human annotator requires expertise in understanding the language context. However, labeling numerous volumes of data requires quite an amount of time and causes tiredness for the annotator - consequently, the objectivity loss of the labeling process. Hence, automation annotation is highly needed before the dataset feeds into a machine learning classifier.

There has been a new development of an annotator-based machine built by learning knowledge of the language experts or humans. SSL uses a small sample of data annotated by language experts and then uses the sample to build a training model. Then, the training model is used for the annotation of unlabeled data. The SSL model draws expert insight from a small sample to build robust annotator unlabeled data. Here, the SSL challenge is to produce a reliable and precise model.

In previous related research, a semi-supervised learning (SSL) model was developed to classify text [1-4]. The performance of semi-supervised text annotation still needs to improve. Al-Laith et al. used LSTM and FastText for annotating Arabic text with only three classes, resulting in an accuracy of 69.4% on the SemEval 2017 dataset. In contrast, the best system achieved a 63.38% F1 score, while on the ASTD dataset, performance improved from 64.10% to 68.1% [4]. Aydin and Güngör [5] combined semi-supervised and unsupervised methods and implemented the J-48 tree, Support Vector Machine, and Naive Bayes algorithms. As a result, the accuracy is more than 90%. However, this model has not proven its performance for multi-class datasets and other language datasets. Alahmary and Al-Dossari [2] applied Naive Bayes as a semi-supervised learning classifier with high accuracy (83%). However, researchers have yet to test this model on other datasets, and we do not know its performance when utilized for SSL in other languages. So, developing a semi-supervised text annotator for Indonesian text that utilizes multiple machine learning models and various vectorizers is expected to yield improved performance. Previous related Research SSL in Indonesian by NurHeri Cahyana et al. annotates hate speech [3]. The maximum accuracy in those research employing KNN and TF-IDF is only 59.68%. SSL model in [3] has a weakness: the model has not been applied to other Indonesian text datasets and has not tried other model combinations.

Many ways are done to gain a high-performance model, such as identifying data samples with hesitant labels and removing training data with unreliable labels. Those can improve the quality of the training data and improve classifier performance [6]. Another approach to improve model performance is to overcome by trying various amounts of training data proportions when building the annotation model, then applying the ensemble method, using several machine learning to classify the same data consensus on classification decisions using confidence values [7]. Performance machine learning depends on parameter setting [8]. Some ways to leverage the performance of machine learning are tuning the parameters [9–11] and applying optimization [12-14]. The goal of tuning these parameters is to find the best combination parameter [15]. Tuning parameters can significantly impact the model performance and finding the right combination involving experimentation and iterative adjustments [16]. A tuning parameter is a parameter that is not learned directly from the data during the training process of a machine-learning algorithm. Instead, it is a value set before training to control the algorithm behavior. Unlike the default individual parameters of

a model, which are learned from the training data, tuning parameters are set by the user before training. Fine-tuning parameters can have a substantial impact on the model performance [17].

Besides tuning individual algorithm parameters, hyperparameter techniques such as Grid Search and Random Search can help find the best parameter combination. Several researchers in text labeling or other domains employ Grid Search [9], [18], [19] and Random Search [10], [11], [20], [21] to enhance the accuracy and performance of machine learning algorithm. Not all parameter tuning techniques are in tune with machine learning algorithms and the data they handle. In previous research, several algorithms that can generally be tuned include Support Vector Machine (SVM), Random Forest (RF), Logistic Regression, Naive Bayes, Neural Networks, and Gradient Boosting. It is necessary to research the best hyperparameters for each algorithm. This research aims to leverage the performance of semi-supervised text annotation through tuning parameters Support Vector Machine and Random Forest using Grid Search and Random Search. Different language corpus needs an appropriate architecture model for automated text labeling. This research uses the Indonesian dataset for the research material. Thus, SSL architecture for the Indonesian dataset becomes the focus.

Our research proposed SSL with the SVM and Random Forest as classifier. Random Search and Grid Search as hyperparameter tuning to obtain the most optimal model. The research problem boundary employs hyperparameter tuning to gain high-performing SSL models for Indonesian text annotation—the performance metric using F1-Score and accuracy. This research is limited to utilizing two machine learning algorithms, Random Forests and Support Vector Machine, and two hyperparameters technique Grid Search and Random Search. We divide the article into four sections: introduction, methods, results and discussion, and conclusions.

## II. Methods

The following section describes the research steps, including data collection, data cleaning, feature extraction, building classifier model annotation, and evaluation.

### A. Data Collection

Due to several reasons, this research has used various datasets to test the Semi-Supervised Text Annotation Model. The primary rationale behind this approach is to enhance the model's ability to generalize and effectively accommodate variations within the data. By subjecting the model to evaluation using diverse datasets, the model can objectively assess its performance across different domains. Also, this approach can examine the model's efficacy in managing linguistic heterogeneity. Additionally, testing on various datasets has comprehensively evaluated the model performance. Thus, this research endeavor involves the utilization of three publicly available datasets, as described in Table I, for the explicit purpose of rigorous testing and analysis.

TABLE I. DATASETS USED FOR MODEL ASSESSMENT

No	Dataset	Instance	Source
1.	Hate Speech	13168	<a href="https://github.com/okkyibrohim/id-multi-label-hate-speech-and-abusive-language-detection/blob/master/re_dataset.csv">https://github.com/okkyibrohim/id-multi-label-hate-speech-and-abusive-language-detection/blob/master/re_dataset.csv</a>
2	Sentiment Ridife	10805	<a href="https://github.com/ridife/dataset-idsa/blob/master/Indonesian%20Sentiment%20Twitter%20Dataset%20Labeled.csv">https://github.com/ridife/dataset-idsa/blob/master/Indonesian%20Sentiment%20Twitter%20Dataset%20Labeled.csv</a>
3	IndoNLU Sentiment	12759	<a href="https://github.com/IndoNLP/IndoNLU/tree/master/dataset/smsa_doc-sentiment-prosa">https://github.com/IndoNLP/IndoNLU/tree/master/dataset/smsa_doc-sentiment-prosa</a>

Before their utilization in the testing phase, the four datasets were processed by the same steps, including data cleaning, word embedding, and feature extraction. The subsequent section elaborates on the empirical outcomes of analyzing these four distinct datasets.

### B. Data Cleaning and Preprocessing

The datasets used in this experiment comprised comments in the Indonesian language. The cleaning purpose is to clear up the dataset from noise such as punctuation, numerical character, and stop words. The clean data was transformed into a vector through several stages, including tokenization (unigram, bigram, and trigram), stemming, and finally, turning the stem into the vector using TF-IDF. Tokenizing onto unigram is breaking down a piece of a sentence into individual units. Bigram is a pair of sequence words within a sentence, while trigram refers to three sequence words within a sentence. Unigram, bigram, and trigram are N-gram types in which  $N$  is any number. N-Gram with  $N$  is two or more, often used to capture more contextual information than a single word.

### C. Word Embedding and Feature Extraction

The Bag of Words (BoW), often mentioned as Term-Frequency (TF), constitutes an algorithm employed to determine the weight of individual words within a document. The weight of Term-Frequency is computed by quantifying the occurrence of the term  $t$  in document  $D$  and dividing it by the total count of words present in document  $D$ . The underlying objective is to identify unique words that can serve as an essential document feature. The large documents generate a big matrix. Given a number feature of  $N$  and a sum document of  $D$ , the feature matrix has dimensions of  $N \times D$ . TF is the occurrence of a word  $t$  in document  $D$ , computed as in Eq. (1).

$$TF_{t,d} = \frac{n_{t,d}}{\text{Total number of terms in document}} \quad (1)$$

The  $TF_{t,d}$  is the frequency of term  $t$  in document  $d$ , where  $t$  is a term (word within a sentence),  $f$  is the number of occurrences of term  $t$  in document  $d$ , and  $n_{t,d}$  is the number of terms  $t$  in document  $d$ .

TF-IDF (Term Frequency-Inverse Document Frequency) is the weight computed by multiplication between TF and IDF. IDF (Inverse Document Frequency) is a value that indicates how important a word is in the entire document in the dataset. A word with a lower TF-IDF value is considered less important, and vice versa. Words that appear frequently throughout the document are considered as less important words. The weight IDF of a document calculated as in Eq. (2)

$$IDF_d = \log\left(\frac{\text{Number of Document}}{\text{Number of document with term } t_i}\right) \quad (2)$$

To compute the TF-IDF (Term Frequency-Inverse Document Frequency), the TF value is multiplied by the IDF value according to the following formula, as in Eq. (3)

$$TFIDF_{t,d} = tf_{t,d} \times idf_d \quad (3)$$

#### D. Model of Semi-Supervised Text Annotation

Random Forest is a robust ensemble learning algorithm widely used in machine learning for classification. Random Forest defines the target class by combining multiple decision tree outputs to yield a single outcome. As suggested by its name, a "forest" comprises numerous trees generated through bagging or bootstrap aggregating. Each tree in the Random Forest produces class predictions, with the majority class prediction as the candidate prediction model. Increasing the number of trees leads to enhanced accuracy and mitigates overfitting concerns. Random Forest is known for its robustness and resistance to overfitting. Tuning its parameters can improve performance on specific datasets.

SVM is a robust machine learning algorithm widely used for classification tasks. It is particularly effective for tasks involving complex data distribution and when clear dividing lines are needed to differentiate between classes. SVM aims to find the optimal hyperplane that best separates different classes of data points in a high-dimensional space. The basic idea of SVM is to find a hyperplane that maximizes the margin between classes of data points. The margin is defined as the distance between the hyperplane and the nearest data points from each class. The idea is to choose the hyperplane with the largest margin, which is expected to classify well to new data with no class yet. However, SVM's effectiveness depends on properly tuning parameters to make the data separable.

#### E. Proposed Semi-Supervised Learning Architecture

This research proposes a novel architecture for the semi-supervised learning (SSL) model with tuning parameters, depicted in Fig. 1. The SSL workflow initiates by utilizing an annotated dataset encompassing training, testing, and unlabeled data, as in Fig. 1. Training and testing data are manually labeled by an Indonesian language expert.

The process begins with word embedding, transforming textual data from the training set into vectors using the TF-IDF technique. This word embedding procedure generates three distinctive vectors: unigram, bigram, and trigram. These three vector representations subsequently serve as inputs for building three separate models employing Random Forest and Support Vector Machine (SVM). The algorithm Random Forest and SVM parameters were tuned to gain the best classification model.

Following the stacking principle, these three distinct models operate independently. Each model participates in the annotation of the unlabeled data. Then, the unlabeled data is annotated by each model, resulting in pseudo-labels of three sets of datasets, each classified according to one of the three models. A pseudo-label has high confidence if the cumulative weight assigned to it divided by the cumulative weight of all models is high. This confidence value is compared to a

predefined threshold. This threshold serves as a criterion to identify annotated data (with pseudo-labels) with confidence values deserving inclusion as part of the training data. Then, documents with high-ranking confidence and existing training data are mixed. Through this innovative approach, the SSL process harnesses the strengths of multiple models to improve predictions on unlabeled data iteratively. Considering confidence values and applying the threshold optimizes integrating pseudo-labeled data into the training set, ultimately enhancing the model's performance.

Fig. 2 describes the main algorithm of SSL. The process started by reading the labeled training dataset (DT), testing dataset (DTest), and unlabeled dataset (UN). All three datasets are transformed into the vector with feature unigrams, bigrams, and trigrams. Then, the model-building process is shown in lines 9-11, the hyperparameter process is in lines 12-14, the annotation process with the best parameter model is in lines 15-17, and the line 18-21 is the voting process.

```

Fig. 2. Algorithm of proposed SSL.

### F. Tuning Techniques

Grid Search and Random Search were applied for tuning both SVM and RF. *Grid Search* is a hyperparameter tuning technique that systematically searches for a machine learning optimal combination model of hyperparameter values. It involves defining a grid of possible hyperparameter values and then evaluating the model performance using each combination of these values through cross-validation. The best parameter combination selected is the optimal set of hyperparameters [18].

Random Search does not explore all combinations like Grid Search. Instead, it tracks the combinations that provide the best performance to date. When more combinations are evaluated, the combination becomes the new best combination if the performance of a combination is better than the previous one [22]. This randomness can be more efficient in exploring the hyperparameter space, primarily when enormous search space exists.

### G. Evaluation Model

To evaluate the classification performance of the SSL model, we employ a confusion matrix, as shown in Table II. The confusion matrix will compare the predicted results with the actual class using the rules in Table II. This study uses two parameters for model validation, namely accuracy and F1-score.

TABLE II. CONFUSION MATRIX

		Actual	
		Positive	Negative
Predicted	Positive	True Positive (TP)	False Positive (FP)
	Negative	False Negative (FN)	True Negative(TN)

Accuracy is the ratio of the correctly predicted dataset to all datasets in the experiment. Accuracy, as in Eq. (4), is a good measurement, but it is only on symmetric datasets, i.e., when the number of false positives and false negatives is almost the same or balanced.

$$Accuracy = \frac{TP+TN}{TP+FP+FN+TN} \quad (4)$$

Precision measures the proportion of genuinely positive instances among all instances predicted as positive by the model. In other words, it quantifies how well the model avoids false positives. High precision indicates that when the model predicts a positive class, it is more likely to be correct. Precision is crucial where the instances of false positives are high or when we want to ensure that the positive predictions made by the model are accurate. However, it is worth noting that precision does not consider instances that were predicted as negative, which could be actual positive cases that were missed (false negatives). Eq. (5) is the precision formula.

$$Precision = \frac{TP}{TP+FP} \quad (5)$$

Recall (sensitivity) is the opposite of precision, as in Eq. (6).

$$Recall = \frac{TP}{TP+FN} \quad (6)$$

Eq. (7) is the average weight of precision and recall. F1 Score is more beneficial than accuracy, especially if the results have an unequal class distribution.

$$F1\ Score = \frac{2(Recall * Precision)}{Recall + Precision} \quad (7)$$

## III. RESULT AND DISCUSSION

### A. Data Distribution

The following Table III shows the distribution of class data for each dataset. Ridife corpus has class positive (24%), neutral (49.1%), and negative (26.9%). IndoNLU Sentiment has class positive (57.7%), neutral (10.7%), and negative (31.6%). Hate Speech only has two classes: positive (42.2%) and negative (57.8%). There are all three datasets in imbalanced class data.

TABLE III. DISTRIBUTION LABEL CLASS

Dataset	Label Class						Total
	Positive	Proportion	Neutral	Proportion	Negative	Proportion	
Ridife	2574	24.0%	5271	49.1%	2882	26.9%	10727
IndoNLU Sentiment	7359	57.7%	1367	10.7%	4034	31.6%	12760
Hate Speech	5561	42.2%	-	-	7606	57.8%	13167

The proposed SSL model employed a tuning parameter. Our experiment uses two techniques, namely Random-Search and Grid-Search. Random Forest and SVM parameters were tuned to gain the best performance of the SSL model. Before applying the SSL model, all datasets corpus are dispart into training, testing, and unlabeled data. Training and testing data are each 10% of the dataset—human labels 10% of training and testing data. The remaining 90% is unlabeled data.

### B. Performance SSL Model

Data testing was employed to assess the performance of the SSL model under both baseline and final conditions. Baseline conditions involved the SSL model being constructed solely using labeled training data. In contrast, the final condition entailed forming the SSL model by fusing labeled training data and Pseudo-Labels generated from unlabeled training data. The experiment was done in two distinct stages. The initial stage entailed evaluating the SSL model using hyperparameters Grid Search, while the subsequent stage involved testing the SSL model performance with hyperparameters using Random Search.

1) *Performance SSL using SVM*: The performance of SSL without hyperparameter is shown in Table IV, while after tuning is shown in Tables V and VI.

TABLE IV. PERFORMANCE SSL SVM

Datasets	Without Hyperparameter			
	Accuracy (%)	Precision (%)	Recall (%)	F1-Score(%)
Ridife	26.9	100	26.9	42.3
IndoNLU Sentiment	57.6	100	57.6	73.1
Hate speech	57.8	100	57.8	73.2

TABLE V. PERFORMANCE SSL SVM TUNED BY GRID SEARCH

Datasets	Grid Search			
	Accuracy (%)	Precision (%)	Recall (%)	F1-Score(%)
Ridife	50.0	97.8	50.0	65.2
IndoNLU Sentiment	78.4	85.5	78.4	81.4
Hate speech	73.7	82.6	73.7	75.6

TABLE VI. PERFORMANCE SSL SVM TUNED BY RANDOM SEARCH

Datasets	Random Search			
	Accuracy (%)	Precision (%)	Recall (%)	F1-Score(%)
Ridife	50.0	98.0	50.0	65.3
IndoNLU Sentiment	78.8	85.2	78.8	81.3
Hate Speech	73.0	83.5	73.0	75.4

Table IV shows the result of the SSL model using SVM with standard parameters having low performance. Accuracy towards all three datasets is under 60%, even though the F1-Score is high. The F1 score shows that the SSL SVM model without parameter tuning is quite good, although only for some data (IndoNLU sentiment and Hate Speech). The Ridife dataset does not reach 50% accuracy, requiring further investigation of the condition of the data, especially the validity of the sample annotation results by Indonesian language experts. With perfect precision values, it is surprising that the recall values are so much lower. With these results, an analysis can be drawn that the standard parameters used in SVM cannot optimize the performance of the SSL model.

Meanwhile, Table V shows that SVM tuning using Grid Search can increase accuracy, indicated by increased accuracy and F1 scores. Because of the differences in class distribution, the performance observations emphasize the F1 score. By comparing the performance of the models without tuning and with tuning, Grid Search increases the F1 Score in the three datasets by 22.9% in the Ridife dataset, 8.3% in the IndoNLU sentiment dataset, and 2.4% in the Hate Speech dataset. Random Search increased the F1 Score by 23.0%, 8.2%, and 2.2%, respectively, on Ridife, IndoNLU sentiment, and Hate speech.

The effect of the parameter tuning done for SVM can be seen in the F1 score performance, as shown in Fig. 3. The F1 score is a valid evaluation to represent the unequal class distribution. Fig. 3 shows that both tuning techniques (Grid and Random Search) can improve the SSL model performance.

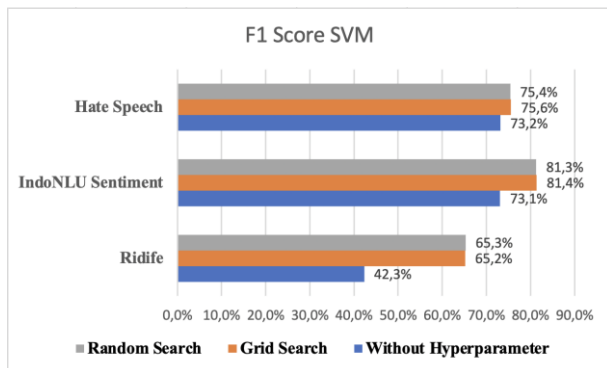

Fig. 3. Performance F1 Score SVM.

2) Performance SSL using random forest (RF): The performance of SSL RF without a hyperparameter is shown in Table VII; SSL tuned by Grid is in Table VIII, and tuned by Random Search is in Table IX. In contrast, tuning on RF does not improve the SSL model's performance like tuning on SVM.

TABLE VII. PERFORMANCE SSL RF

Datasets	Without Hyperparameter			
	Accuracy (%)	Precision (%)	Recall (%)	F1-Score(%)
Ridife	31.5	75.2	31.5	37.1
IndoNLU Sentiment	75.0	81.0	75.0	76.4
Hate Speech	72.8	85.0	72.8	75.5

TABLE VIII. PERFORMANCE SSL RF TUNED BY GRID SEARCH

Datasets	Grid Search			
	Accuracy (%)	Precision (%)	Recall (%)	F1-Score(%)
Ridife	46.0	60.0	46.0	51.0
IndoNLU Sentiment	75.4	80.9	75.4	76.7
Hate Speech	72.6	86.2	72.6	75.6

TABLE IX. PERFORMANCE SSL RF TUNED BY RANDOM SEARCH

Datasets	Random Search			
	Accuracy (%)	Precision (%)	Recall (%)	F1-Score(%)
Ridife	36.5	71.2	36.5	40.7
IndoNLU Sentiment	75.6	81.1	75.6	76.9
Hate Speech	72.0	85.7	72.0	75.0

Table VII shows that the SSL model using RF with standard parameters performs poorly for the Ridife dataset, which only reached 40.7%. However, the IndoNLU Sentiment and Hate Speech datasets are pretty good, above 75%. Meanwhile, Table VII shows that tuning parameter RF using Grid Search was unsuccessful enough to increase model performance. It can be seen that F1 Score before and after tuning in the IndoNLU Sentiment and Hate Speech datasets. By comparing the performance of the RF model without tuning and tuning with Grid Search, the improving performance in all datasets is 13.9% for the Ridife dataset: 0.3% for the IndoNLU Sentiment dataset, and 0.1% for the Hate Speech dataset. While tuning with Random Search could not improve RF performance significantly. The effect of Random Search tuning on RF is only shown by the Ridife dataset. Random Forest is a tree-based algorithm that uses an ensemble tree to increase performance. Therefore, setting up RF with Random Search did not work significantly. The graphical visualization in Fig. 4 supports this. Suppose the conditions of the initial data are observed in more detail. In that case, the Ridife dataset tends to have a lot of noise, slang words, and inaccurate labeling by experts, which may be good for examining the effect of tuning. Meanwhile, the other two datasets (IndoNLU Sentiment and Hate Speech) are relatively cleaner. Considering the condition of the dataset, tuning is suitable for models built from a lot of noise-training data.

Fig. 4. Performance F1 score RF.

We find that our SSL model for the hate speech dataset obtained higher accuracy (more than 75%) than the SSL proposed by Nur Heri Cahyana et al. [6], which has only reached an accuracy of 59.68% using KNN. Our proposed method proved that SVM and Random Forest perform better for hate speech datasets. In initial data conditions, the Ridife dataset contains more noise, slang words, and inaccurate labels from experts. In contrast, the IndoNLU Sentiment and Hate speech datasets have less noise, and expert labeling is precise. This research found that the proposed SSL using hyperparameter tuning is more suitable for noisy datasets. Hyperparameter tuning is also robust to training data that contains many manual labeling errors by experts.

#### IV. CONCLUSION

Annotation or data labeling in sentiment analysis is a substantial stage in the case of numerous large datasets. Annotation is time-consuming if humans do it. Thus, building model annotation using a computer is needed, but the accuracy model is notable. This research uses a semi-supervised model for annotating sentiment using a Support Vector Machine (SVM) and a Random Forest (RF) algorithm. SVM and RF were respectively tested as classifiers. To gain the most accurate model, RF and SVM were tuned using Random-Search and Grid-Search, respectively. The experiment used three Indonesian corpora as a dataset (Ridife, IndoNLU Sentiment, and Hate speech). Overall, Grid-Search and Random Search leverage performance only in the Ridife dataset. The result shows that tuning works significantly on SVM, but on RF, it does not work on all datasets. This research found that models with hyperparameter tuning are robust to training data containing a lot of noise and incorrect human labeling. For further experiments, employing many variation datasets and paying attention to imbalanced and noise conditions in the data are suggested.

#### ACKNOWLEDGMENT

The authors are grateful to The Ministry of Education, Culture, Research and Technology, Indonesia, for funding this research through the Fundamental Research Grant 2023, which has led to the publication of this paper.

# Usability Testing of Memorable Word in Security Enhancing in e-Government and e-Financial Systems

Hanan Alotaibi, Dania Aljeaid, Amal Alharbi  
Faculty of Computing and Information Technology  
King Abdulaziz University  
Jeddah, Saudi Arabia

**Abstract**—Most applications increase their security by adding an extra layer to the login process using two-factor authentication (2FA). In Saudi Arabia, One-Time Password (OTP), which is 2FA, is the most common method used as users log in to their accounts. However, some issues have emerged with using OTP as 2FA; these issues from previous research were investigated in the study. Also, the study proposed a new method of account authentication, which is a Memorable Word (MW). MW is the second and short password in which the user enters a certain number of characters instead of the whole password. The study conducted usability testing to compare two 2FA methods, OTP and MW. The study included 60 participants logged into a simulated website using both authentication methods. Then, all participants have to complete the questionnaire. The collected data analyses showed a favourable opinion of the MW method.

**Keywords**—Security; usability testing; two factor authentication; one time password; memorable word

## I. INTRODUCTION

The digital world is a rapidly evolving landscape, and using e-Systems is becoming increasingly commonplace. e-Systems are electronic systems that allow users to access, store, and share information and data. These systems are used in various ways, from e-government and online banking to social media, and they are becoming an integral part of our lives. e-Government has the potential to modernise the way governments interact with citizens and provide services. It can give citizens access to government services and information more efficiently and cost-effectively [1]. It can also help governments to manage their resources better and improve the delivery of services. e-Government can help reduce the administrative burden on government employees and improve the transparency and accountability of government services [2, 3, 4]. For instance, the government of Saudi Arabia has taken a proactive approach to ensure the security of its e-government systems. The Saudi e-government security policy is designed to protect data resources from a wide range of risks, including malicious attacks, unauthorised access, and data loss, by implementing aspects of the data security [5].

Similarly, e-financial services in Saudi Arabia have seen a significant shift in recent years as banks have offered more innovative services through online banking. This shift has enabled banks to maintain their market share and gain customers as online banking has become increasingly popular [6]. However, this digital transformation to systems poses several challenges and security threats. For example, it can be

difficult to ensure that systems are reliable and resilient in the face of cyber-attacks and other threats.

However, with the increased use of systems comes an increased risk of security threats. Cybercriminals are constantly looking for ways to exploit weaknesses in these systems and expose sensitive information such as social security numbers or verification numbers sent to e-mail addresses or contact numbers [7, 8]. Cybercriminals use a variety of methods to accomplish successful cyberattacks, which include phishing, malware, and ransomware attacks, as well as data breaches. To protect against these threats, it is essential to implement strong security measures in place within systems. This includes keeping software and systems up to date, which can help prevent vulnerabilities from being exploited. It is essential to be aware of the latest security threats and to take steps to protect against them. Moreover, using strong passwords, multifactor authentication, and encryption are essential fields [9]. An authentication system is deployed to ensure that both parties involved in the communication are authentic ones. The dominant form used in various authentication systems is based on username and password. Nevertheless, passwords can be easily guessed if it is weak or stolen, so it is significant to use additional security measures. One of the most common methods used to increase the security of authentication is to adopt two-factor authentication (2FA). Implementing 2FA for end users can provide organisations with several benefits, including increased security and improved user experience. Recent studies found that 2FA can help protect user accounts from unauthorised access and malicious actors and reduce the risk of data breaches [10, 11]. However, it can also pose some challenges and complications. For example, implementing 2FA can be difficult and costly, as organisations need to invest in the necessary infrastructure and technologies to support the authentication process. Additionally, users may find entering their 2FA code tedious and time-consuming [10, 12]. Thus, this research studies the implementation of Memorable Word (MW) as a 2FA and evaluates its security efficiency and usability.

The main contribution of this paper is to investigate the users' perspective when accessing Saudi systems, such as government and bank websites, using MW instead of the current authentication method, SMS One-Time Password (OTP).

The rest of the paper is organised as follows: Sections II describes the common methods used in authentication while Section III highlights recent works related to usability testing

in authentication, followed by methodology in Section IV. In Section V, exhaustive experiments are conducted to validate the MW. In Section VI, the results of the experiments are discussed. Lastly, the paper is concluded along with the limitations and future work in Sections VI and VIII, respectively.

## II. AUTHENTICATION METHODS

Due to the increasing number of cybercrimes, traditional username and password authentication methods are no longer enough to protect sensitive information from malicious actors. Businesses and individuals must take additional steps to secure their data. Multi-factor authentication (MFA) is one of the most effective methods for protecting sensitive information. MFA requires users to provide two or more pieces of evidence to prove their identity. This could include a combination of something the user knows (such as a password), something the user has (such as a physical token or smartphone), and something the user is (such as a biometric scan) [13]. 2FA is one of the most common authentication methods. It is a security measure that requires two different authentication factors to verify a user's identity. It is used to protect sensitive information from unauthorised access and is becoming increasingly popular as a way to protect against data breaches. The two factors used in 2FA are typically something the user knows (e.g., a password or PIN) and something the user has (e.g., an OTP, token, or digital certificate). This combination of factors makes it much more difficult for an attacker to gain access to a user's account, as they would need to know both the password and have access to the physical device or token. 2FA is a great way to protect against phishing, brute force attacks, keylogging, and credential theft attacks. It is also a great way to protect against data breaches, requiring two different authentication factors to verify a user's identity. There are several different types of 2FA, such as OTP-based and Biometrics-based. OTP-based 2FA requires users to enter an OTP valid for a single login session. Biometrics-based 2FA requires a user to provide a biometric factor such as a fingerprint or iris scan [6]. Several different 2FA methods exist, such as SMS, Time-Based One-Time Password, Pre-generated Codes, Push, and Universal Second Factor Security Keys. Each method has advantages and disadvantages, as discussed in the following subsections.

### A. SMS Token / SMS-based Authentication

SMS-based authentication is one of the most common methods of 2FA, and many organisations use it to protect their users' accounts and systems. In SMS-based, a one-time verification code is sent to the user via a text message to their mobile phone. This code is usually six digits long and is used to verify the user's identity. The user then enters the code into the system to gain access. This code is only valid for a short period of time, usually a few minutes, and it must be used within that time frame, or it will expire. It is easy to use and requires minimal effort from the user [6, 14]. However, SMS-based 2FA is not without its drawbacks. It is vulnerable to SIM-swapping attacks, where an attacker can access the user's phone number and intercept the verification code. It is also vulnerable to phishing attacks, where an attacker can send a fake text message with a malicious link that leads to a fake

website. SMS messages can take a long time to arrive, and they can be blocked or delayed by network congestion because they are delivered over cellular network standard SMS. This can be a problem if users need to access their accounts quickly [15, 14]

### B. Time-Based One-Time Password

Time-based one-time password (TOTP) is an alternative to SMS-based 2FA that provides an additional layer of security for online accounts. It generates a unique, valid code for a limited time, usually 30 seconds. This code then authenticates the user's identity [6, 16]. Yet, there are some drawbacks to using it. One of the main drawbacks is that it can be challenging to use. The user must have access to the device generating the code, such as a smartphone or a hardware token. This can be inconvenient for users who do not have access to the device or who do not have the time to wait for the code to be generated. Another drawback is that TOTP codes can be vulnerable to replay attacks. This is when an attacker captures the code and uses it to gain access to the account. To mitigate these attacks, it is essential to use a secure connection when generating the code and ensure that it is not stored in plain text. Finally, TOTP codes can be challenging to remember. This can be a problem for users not using 2FA [17].

### C. Pre-Generated Codes

Pre-generated tokens are an effective backup 2FA method if the user cannot access the primary 2FA method. This method is relatively straightforward to implement, as the service provider simply creates a list of verification codes and asks the user to print or write down the codes. The list length is variable; the codes are usually about eight digits long. Tokens can be used in any order and must be kept secure by both the server and the user to prevent theft. Since these codes are usually longer than codes sent via SMS or generated using TOTP, there is additional room for user error when entering codes. Moreover, the user must be careful not to lose the broker on which they registered the codes, and they will be vulnerable to an offline brute force attack [6].

### D. Push

Push authentication requires the user to receive a push notification on their smartphone to approve or deny a login attempt. This method is advantageous because it eliminates the need for users to type in numbers, as required by other 2FA methods, making it both faster and more user-friendly [18]. Additionally, push authentication requires Internet access, which is necessary to keep communication between the user's device and the server secure, such as through TLS. However, the most prominent push-based authentication methods are proprietary, making it difficult to verify the exact security measures in place and require implicitly trusting a third party [6]. Furthermore, push-based authentication has not yet been well-studied by the security community, making it difficult to assess the security of this method.

### E. Universal Second Factor Security Keys

Universal Second Factor (U2F) Security Keys are an open standard for authentication through a USB device. The user must connect the device to the computer to authenticate with a security key and activate the device when the website requests.

U2F Security Keys are designed to be more secure than traditional 2FA methods, such as SMS or email-based authentication. One of the main drawbacks of U2F security keys is that they can be challenging to set up and use. U2F security keys require users to install a particular driver on their computer or mobile device to use them. This can be a time-consuming process, and it can be difficult for users who need to be tech-savvy. Additionally, U2F security keys are incompatible with all devices and can be expensive. Besides, U2F security keys can be lost or stolen, which can be a significant inconvenience for users who need to replace them [19].

#### F. Memorable Word Technique

The Memorable Word (MW) is a short password (usually assumed to consist of one word) and is one of the layers of authentication, where the MW differs from the password in how it is used; instead of entering the whole MW, the user enters a certain number of MW's characters, usually, three letters and the letters to be entered vary each time the user is asked to enter it. Initially, the client and the server know a short password of length  $m$  characters that has been shared before. During authentication, the server sends unique numbers between 1 and  $m$  to the client. The client responds with the letter in each corresponding position in the password. If all these characters are correct, the authentication succeeds; otherwise, it fails [20]. It has been recognised that transaction systems must include authentication and data encryption. To complete these requirements, MW has been proposed to contain mutual authentication and data encryption using the symmetric algorithm that improves the security of existing transactions. Symmetric encryption is employed in transactions to prevent identity theft of clients or banks—additionally, user authentication and authorisation to protect against cyber-attacks [21, 22].

### III. RELATED WORK

Usability testing can help identify areas for improvement in the system, such as user experience and security, which can help improve the system's overall performance. Furthermore, usability testing can help to identify any areas of confusion or difficulty that users may need help with when using the 2FA system. This can help improve the user experience by making the system easier and more convenient. Usability testing is one of the preferred methods for assessing user experience with 2FA due to its ability to provide direct feedback from users [11]. Das et al. [23] suggest that usability testing can be used to evaluate the effectiveness of 2FA systems and identify potential usability issues. This type of testing often includes a series of tasks to measure user performance and satisfaction with the 2FA process. Other evaluation methods, such as surveys, interviews, and focus groups, provide additional insight into user experience with 2FA [11]. Gunson et al. [24] found that usability testing was the most effective way to evaluate 2FA due to the complexity of the task and the need to ensure that users understand and follow the authentication process correctly. However, they also identified several challenges in implementing usability testing. These include finding a representative sample of users, developing suitable test scenarios, and ensuring that the test results are valid and

reliable. According to a study by Golla et al. [24], implementing 2FA for end users can provide organisations with several benefits, including increased security and improved user experience. The study found that 2FA can help protect user accounts from unauthorised access and malicious actors and reduce the risk of data breaches. Additionally, 2FA can provide users with an improved experience when logging into their accounts, as they can be quickly and easily authenticated. However, while 2FA can provide organisations and end users many benefits, it can pose some challenges. The study found that implementing 2FA can be difficult and costly, as organisations need to invest in the necessary infrastructure and technologies to support the authentication process. Additionally, users may find entering their 2FA code tedious and time-consuming [24]. As such, organisations must be aware of these challenges and take steps to ensure that their implementations of 2FA are secure, efficient and user-friendly. Abbott and Patil [12] explored the potential for improving user experience through 2FA. They found that 2FA can enhance security, provide users with greater confidence in the service, and provide a better overall user experience. Through their study, the authors found that users are more likely to remain engaged with services that use 2FA as they feel more secure and trust the service provider. Furthermore, they noted that 2FA can be tailored to the individual user's needs, which can help to improve user experience by providing them with a more tailored experience.

The usability dimensions of ISO 9241-11 form the basis for measuring user experience based on the three usability dimensions, which are efficiency, effectiveness, and satisfaction. Efficiency focuses on the amount of time taken to complete a task, effectiveness is the ability to complete a task, and satisfaction is the user's opinion of the convenience and acceptability of the system, which is measured by the System Usability Scale (SUS) [25]. Factors impacting each usability dimension can be documented, such as the time it takes to complete a task or user demographic information. Collecting this information can help developers and designers create and improve the 2FA MW systems [26]. SUS is a tool that has become increasingly popular in the field of usability testing. Developed by John Brooke in 1986, SUS is an efficient and cost-effective way to measure the usability of a system. The tool has been used in a wide range of studies and has consistently produced reliable results. Additionally, SUS is a popular option for usability testing because it is efficient and cost-effective. It is a straightforward tool that can be administered quickly and easily.

Weir et al. [27] compared the usability of three two-factor authentications: push-button tokens, card-activated tokens, and PIN-activated tokens. The study aimed to measure the time required for authentication and user satisfaction. Their findings were that user prefers authentication methods which are easy to use rather than security; however, quality and usability decreased when additional levels of security were required.

An exploratory comparative investigation study conducted by [28] into the usability of 2FA. The study assessed and compared the usability of three widely used 2F solutions: security token-generated codes, OTP delivered through email or SMS, and dedicated smartphone apps like Google

Authenticator. Also, they investigated motivations behind users' choices and examined how these factors influence their perception of usability. The finding from the study indicates that 2FA are widely accepted and highly usable. This means that users are embracing the user of additional layer of security beyond just password. The study also highlights that user opinions of 2F usability are frequently connected with individual attributes. This suggests that different users may have varying levels of comfort or experience with using 2FA, which can influence their perception of its usability. Moreover, the study reveals that the trustworthiness of 2F is positively correlated with ease of use.

In a study conducted by Reese et al. [29] the usability of five 2FA methods was examined. The study aimed to compare the usability of Pre-generated Codes, Push, SMS, OTP, and U2F Security Keys. The sample consisted of 72 participants who logged into a simulated banking website using 2FA. The objective was to gain insights into users' perspectives on 2FA and assess their experiences with different authentication methods. The findings showed that the majority of participants expressed a desire to use 2FA as a means to enhance the security of their sensitive online accounts. However, it was noted that some participants encountered difficulties when utilizing these methods such as spending longer time at login phase, particularly with the OTP and U2F methods.

Our research is different from the previous studies as it focuses on the implementation of a new two-factor authentication (2FA) method, specifically the Memorable Word (MW), in Saudi Arabia's e-government and banking systems. The aim of our study was to examine the user perspective on utilizing MW as a 2FA method. To achieve this objective, a survey was conducted to compare the currently employed 2FA method in Saudi Arabia, which is One-Time Password (OTP), with the proposed 2FA MW method.

#### IV. METHODOLOGY

The study's first phase, as described in Sections II and III, involved conducting a literature review on authentication methods and usability. By thoroughly examining existing literature, gaps in knowledge were identified, highlighting areas that required further research. In the second phase, a website was developed to support both OTP-2FA and MW methods. To gain a deeper understanding of MW authentication, a questionnaire was conducted through a simulated webpage. Additionally, three expert reviews were obtained to ensure that the usability testing aligned with the study's objectives. The purpose of these interviews was to assist the authors in confirming the usability testing process. Afterward, a comprehensive questionnaire was constructed and administered to collect data on users' perspectives towards both OTP and MW methods. The research methodology, including the various phases and steps undertaken, is presented in Fig. 1.

The participants were assigned various tasks to perform on a simulated website and subsequently completed a survey. To ensure a smooth process, participants were initially scheduled for an appointment with a study coordinator. During this meeting, the coordinator provided necessary guidance and assistance to the participants in creating an account as the following steps:

Fig. 1. Research methodology.

1) *User registration*: This step involved user registration, where the participants were required to provide their details, such as their name, phone number, and email address. Once registered, the participants were able to create their unique username and password. In addition, they were required to set up an MW with the following considerations:

- Six to eight characters long without spaces.
- Contains only letters (A to Z), excluding any numbers or special characters.
- It cannot be the user's first and last name.
- It should not include alphabetic sequences such as "QWERT" keyboard.

The participants were informed that they would need to remember three random characters from their MW, which they would be prompted to enter after providing their login credentials. Fig. 2 shows the creation MW page.

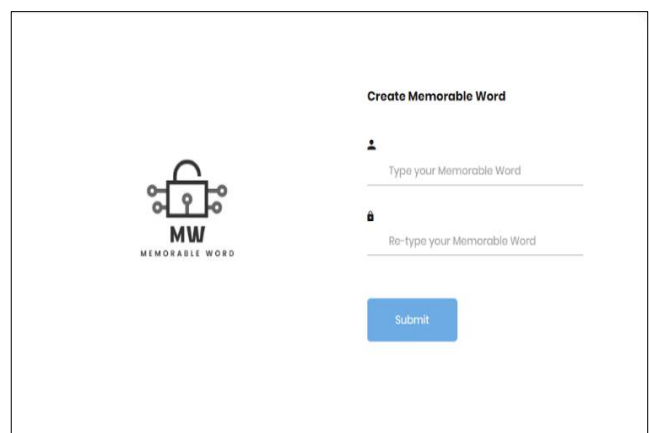

Fig. 2. Create MW page.

2) *User log-in*: The participants were prompted to log in to the website after successfully registering. To ensure that the participants were familiar with both authentication methods, they were instructed to initially select the OTP method and then log out and re-login using the MW method. This step was deemed necessary as it allowed the users to experience and become comfortable with both methods before proceeding to the next stage. Fig. 3 shows the login page, where the user can select the authentication methods. Fig. 4 shows the MW authentication page.

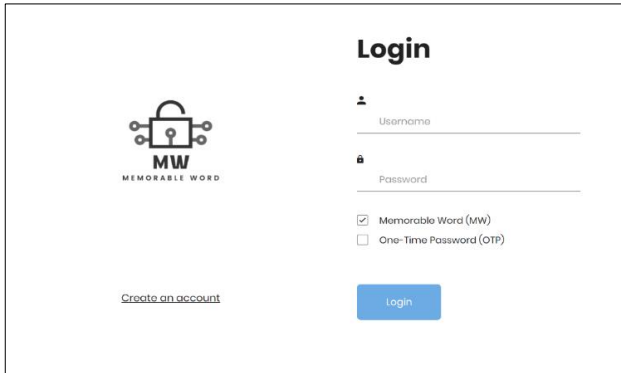

Fig. 3. Login page.

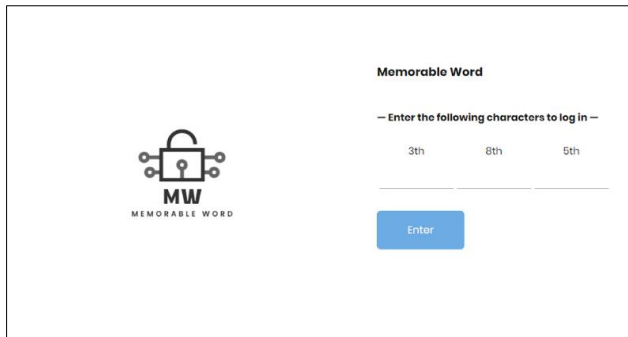

Fig. 4. The MW authentication page.

3) *Survey questionnaire*: Once the participants had completed the registration and login process, they were directed to answer a questionnaire. A total of 60 participants were recruited for this purpose, and they were randomly selected to ensure unbiased results. After two weeks, the collected data from the questionnaire was meticulously analysed, providing valuable insights and conclusions for further evaluation.

## V. RESULTS ANALYSIS

The data was collected from 60 participants in a span of two-week. In this study, participants were asked to answer eight parts of a survey, each consisting of questions with different objectives.

### A. Demographics/ Participants

The demographic data collected from the participants revealed a slightly higher number of female participants than male participants, with 62.5% and 37.5%, respectively.

Additionally, the study showed that most participants were young adults, with 65.5% being between the ages of 18-29 years, 23.6% between 30-49 years, and only 10.9% between 50-69 years. The data also indicated that most participants had a bachelor's degree, accounting for around two-thirds of the participants (63.6%). Interestingly, all participants were familiar with using e-government and online bank systems, indicating their technological proficiency. However, it was also found that 100% of the participants had no prior knowledge of the MW method. To ensure that participants clearly understood the MW method, a brief description was given to them during the registration process through the simulated website.

Table I summarises the participant's demographics. As can be seen from the table, although the sample size is small (total = 60), overall, the study showed that the participants were diverse in gender, age, and education level, but their technological proficiency was high.

TABLE I. PARTICIPANTS' DEMOGRAPHICS (TOTAL = 60)

Gender	
Male	37.5%
Female	62.5%
Age	
18-29 years	65.5%
30-49 years	23.6%
50-69 years	10.9%
Qualification	
Secondary School	20%
Diploma	7.3%
Bachelor	63.6%
Postgraduate	9.1%
Familiar with using E-government and online bank systems?	
Yes	100%
No	0%
Familiar with Memorable Word?	
Yes	0%
No	100%

### B. Timing Data

Login timing is an essential element in analysing user experience regarding systems. The study analysed the timing data of two authentication methods used for logging into a system: OTP and MW. The login time for two different methods was measured, counting the time from when the login page initially loaded to when the user submitted a password. To obtain reliable data, users were asked to repeat the login process ten times, five times for each method. Once all the data was collected and analysed, the findings revealed that users spent more time in the OTP method due to the delay in receiving the verification code. Fig. 5 presents the time spent in second to login to the system using both methods. Table II shows the mean time in seconds for both methods.

Fig. 5. The time spent to login to the system using both methods.

TABLE II. THE MEAN TIME IN SECONDS FOR THE TWO AUTHENTICATION METHODS

Method	Mean Time
MW	9.3
OTP	15.81

### C. Individual Learnability

One of the objectives of the survey was to explore individual learnability. The hypothesis in this part of the experiment was that participants would become faster at validating their accounts with specific authentication methods as they become more familiar with them. To test this hypothesis, we computed a correlation between the time an individual spent in the session and the amount of time it took to validate their account using different authentication methods. The results showed a statistically significant difference between the two authentication methods (P-value  $\leq 0.01$ ). The MW method was found to be faster than the OTP method. This suggests that individuals can learn and become faster at validating their accounts with MW authentication methods over time.

### D. System Usability Scale

The main goal of SUS is to evaluate a user's perception of a system's ease of use and overall usability. The SUS survey consists of nine tool questions with five-point Likert-scale answers. The survey is designed to gather feedback from users about how easy it is to use an MW authentication. To increase the reliability of the survey, four of the questions are phrased positively, while the other five are phrased negatively. This approach helps to reduce response bias and provides more accurate results. The results indicated that 98.18% of participants found the MW method easy to use for login, demonstrating high usability. Additionally, 94.91% of participants preferred the MW method to the OTP method. These results were all statistically significant and supported the hypothesis that the MW method was easy to use and preferred by users (P-value = 0.00  $\leq 0.05$ ). Table III and Fig. 6 show the findings from each question.

### E. Previous Experiences with Account Compromise and Worth Inconvenience

Participants were asked if they had ever faced difficulty logging in to their accounts regarding compromised online accounts. 12.7% of participants have an experience with remote attackers taking over their online accounts. Also, 52.7% know someone had an experience with remote attackers taking

over their online accounts. Participants with previous experience and who know someone with an account compromised would be more likely to feel that an MW method was worth using. For worth inconvenience, the participants were asked to use MW as a second authentication is worth an extra step of login. 87.27% of participants felt using MW is worth an additional inconvenience.

### F. Security and Inconvenience

The security and inconvenience factor was also investigated. Participants were asked if the MW authentication method made them feel more efficient and convenient to access their accounts than the OTP method. Most participants thought that the MW method was secure and convenient. The study showed that 92.36% of participants felt that MW was secure when logging into their accounts. Furthermore, 89.45% of participants found MW more convenient than OTP.

TABLE III. SYSTEM USABILITY SCALE ANALYSIS OF THE NINE STATEMENTS

Statement Number	Statement	Mean	Standard Deviation	P-value
1	I find the various functions in this MW were well integrated.	4.95	0.23	.000
2	I think the MW was easy to use.	4.91	0.55	.000
3	I would like to use this MW frequently.	4.75	0.48	.000
4	I think most users would learn to use this MW very quickly.	4.69	0.96	.000
5	I find the MW is complex.	1.51	0.84	.000
6	I find the MW is hard to use.	1.51	0.84	.000
7	I think I need support to use MW.	1.45	0.54	.000
8	I need time to learn how to use MW	1.38	0.97	.000
9	I think there is inconsistency in using MW.	1.11	0.57	.000

Fig. 6. System usability scale analysis of the nine statements.

### G. Perception of Likelihood for Account Compromise

Participants were asked how much value they placed on their online accounts, such as bank and government accounts, to investigate whether they felt the need to protect their information and data. The results showed that 92.5% of participants expressed that they needed to secure their accounts from others, while 7.5% felt that there was nothing essential to protect.

### H. MW Timeout

After a week of creating an account on the simulated website, the participants were asked to log in to their account using MW as an authentication factor to test their experience using the proposed method if they needed help entering randomly selected letters. The result is that 94.91% of participants logged into their accounts without any mistakes; before time out; also, 97.82% found MW easy to use. 96.36% of participants agreed with the statement, "I did not struggle in using MW as much as struggling in OTP".

## VI. DISCUSSION

The main contribution of this study is to investigate the users' perspective when accessing Saudi electronic systems, such as government and bank websites, using MW instead of the current authentication method, SMS OTP. The study found a favourable opinion and feedback toward MW, where the participants reported faster login times than the OTP method. An overwhelming majority of participants (97.82%) logged into their accounts without any mistakes or forgetting their memorable words, indicating that MW was convenient, learnable, and easy to use.

Comparing the study results with similar study results [29], we found that timing data in MW authentication method is the faster way for users to log in to their accounts. At the same time, U2F is the quickest method in the [29]. Moreover, our study tested MW timeout to check if participants needed help entering MW letters. The result was that 94.91% of participants logged into their accounts without any mistakes before it timed out. Another study tested OTP timeout and found that 65% of participants had problems entering the six-digit verification code before it timed out. Both studies conducted SUS to evaluate a user's perception of a system's ease of use and overall usability. Our study found that the median score of the MW method was 96.22. Regarding Reese et al. study [29], the finding of evaluating five methods was passwords had the highest median SUS score, with a median score of 95, followed by TOTP, which had a median SUS score of 88.75.

In today's fast-paced world, users have increasingly high expectations for carrying out their tasks promptly on various digital platforms. Any delay or inconvenience in the login process can lead to frustration, negative user experiences, and potential cyberattacks. Our study highlighted a critical finding regarding the OTP method, which showed a delay in receiving the verification code. Eliminating the need for users to wait for OTPs can enhance the efficiency of authentication systems and provide a seamless login experience for users. OTP can be less secure when a user's mobile device or token generator is compromised or intercepted maliciously. One of the significant vulnerabilities associated with SMS OTP is SIM swapping [30,

31]. This occurs when an attacker convinces a mobile network provider to transfer a victim's phone number to a new SIM card under their control. Once the attacker controls the victim's phone number, they can intercept any SMS OTPs sent to that number, effectively gaining access to the victim's accounts. Another common attack vector for OTP is the phishing attack [32, 33]. Phishing involves tricking and deceiving the victim into revealing their login credentials or multi-factor authentication (MFA) code by posing as a legitimate entity. In the case of OTP, the attacker could send a phishing message to the victim's phone, making it appear as if it is coming from a trusted source such as a bank or other known service providers. Once the victim falls for the scam, the attacker can use that code to authenticate themselves and gain unauthorised access to the victim's account.

On the other hand, using the MW technique can help prevent certain types of attacks, such as MITM attacks [34, 35], where malicious attackers redirect users to a fake website before forwarding them to the legitimate one. Since users are only required to type random letters from the memorable word instead of their entire secret token, it becomes more difficult for attackers to capture the complete word in one go. While the MW technique may provide some protection against MITM attacks, unfortunately, it does not entirely prevent them. In the event of a MITM attack, an attacker could still prompt the user for the same letters they are being prompted for, thereby gaining access. Thus, it is recommended that the MW be changed frequently.

It is important to consider that while MW may provide some level of security at the user's end, it may be less secure at the server or organisation's end. One potential vulnerability exists in storing memorable words as a single field within the system. This means that if there were to be a database leak or breach, the MW authentication system would be susceptible to the same risks as other forms of 2FA.

In conclusion, using MW as a security solution offers few advantages over OTP methods. It provides a better level of security than just relying on a password alone by preventing the transmission of the complete word and protecting against certain types of attacks. However, it may be less secure in specific scenarios and should ideally be implemented as an additional layer of security alongside other authentication methods.

## VII. LIMITATION

The main limitation of this research was the time needed to spend with the participants, which reduced the sample size. Thus, this may prevent generalising the findings to the general population.

## VIII. CONCLUSION AND FUTURE WORK

The study investigated and compared the usability of two authentication methods, MW and OTP, in e-government and e-bank systems in Saudi Arabia. A usability testing survey was conducted to gain insights into users' perspectives on the proposed MW method and compare it with OTP. Overall, the participants expressed a positive opinion about MW, finding it easy to use and highly convenient. In contrast, OTP presented several challenges, including delays in receiving verification

codes and ineffective authentication when the signal was interrupted. The study revealed that many users struggled with OTP and required an alternative authentication method. Through analysis and simulation, it was determined that the proposed MW method offers comparable security control to existing OTP authorisation while minimising the dynamic risk of theft and eliminating the need for additional hardware. As this method eliminates the possibility of crucial theft, it can be used on private and public computers. Notably, this method is cost-effective and poses no significant hurdles.

The proposed method holds potential for further research on security attacks, particularly in addressing replay attacks, man-in-the-middle attacks, reflection attacks, and parallel session attacks.

#### ACKNOWLEDGMENT

The authors are grateful to Afrah Almalki and Retal Mehdawi for their work during projects.

# Enhanced Brain Tumor Detection and Classification in MRI Scans using Convolutional Neural Networks

Ruqsar Zaitoon, Hussain Syed

School of Computer Science Engineering, VIT- AP, Amaravati, Near AP Secretariat, Andhra Pradesh, India

**Abstract**—Tumor detection is one of the most critical and challenging tasks in the realm of medical image processing due to the risk of incorrect prediction and diagnosis when using human-aided categorization for cancer cell identification. Data input is an intensive process, particularly when dealing with a low-quality scan image, due to the background, contrast, noise, texture, and volume of data; when there are many input images to analyze, the task becomes more onerous. It is difficult to distinguish tumor areas from raw MRI scans because tumors pose a diverse appearance and superficially resemble normal tissues, which makes it more difficult to detect tumors. Deep learning techniques are applied in medical images to a great extent to understand tumor contours and areas with high intensities in input images. For timely diagnosis and the right treatment with less human involvement, and to interpret and enhance detection and classification accuracies this automated method is proposed. This proposed work is to identify and classify tumors on 2D MRI scans of the brain. In this work, a dataset is used, inside it, there are images with and without tumors of varied sizes, locations, and forms, with different image intensities and textures. In this paper, multi-layer Convolutional Neural Network (CNN) architectures are implemented. This shows two main experiments to assess the accuracy and performance of the model. First, five-layer CNN architecture with five layers and two different split ratios. Second, six-layer CNN architecture with two different split ratios. In addition, image pre-processing and hyper-parameter tuning were performed to improve the classification accuracy. The results show that the five-layer CNN architecture outperforms the six-layer CNN architecture. When results are compared with state-of-the-art methods, the proposed model for segmentation and classification is better because this model achieved an accuracy of 99.87 percent.

**Keywords**—Multi-layer Convolutional Neural Networks (CNNs); MRI images; tumor segmentation and classification; deep learning; learning rate

## I. INTRODUCTION

Medical imaging is often used by doctors to get a better look at what's going on within a patient's body and arrive at a correct diagnosis. The classification of medical images is not only a formidable intellectual challenge but also a potentially fruitful research field in the field of image processing. Cancers in medical pictures may be difficult to detect. A difficult diagnostic problem has arisen. The importance of cancer screenings cannot be overstated. Death rates and the prevalence of brain tumors attest to the fact that cancer, whether it manifests externally or inside, is a devastating disease. Every year, doctors diagnose more than a million people with tumors. The death toll keeps climbing. In terms of

cancer-related mortality in those under the age of 34, it is second only to lung cancer [1]. In their quest to locate the tumor, doctors are now adopting cutting-edge methods that only serve to make patients more uncomfortable. Computerized tomography scans (CT scans) are used to examine the human body and look for anomalies. Medical Imagination Reasoning (MRI) and the alternatives each have their advantages. There is a rising interest in the study of brain tumors, and the field of image analysis has attracted a lot of attention as a means of analyzing the vast amounts of data available in medical databases. Tools to produce visual representations and complex computational measurements are both necessary for the study of such a wide range of image types. Because of this, MRI scans may now be used to detect malignant brain tumors. This is where the value of handwriting data really shines since it greatly reduces the quantity of paper that would otherwise need to be used. Medical imaging is mostly used for therapeutic and diagnostic purposes in the human body. Thus, it contributes significantly to the development of healthcare and to the betterment of people's lives. In order, to improve the efficiency of image processing as a whole [2], the process of segmentation is vital. This is because it enables the breakdown of the image into its individual elements. We have been diligently working to isolate the tumor in the patient's brain MRIs, providing assistance to medical professionals in pinpointing the precise location of the tumor in the brain. Help is given to medical professionals in pinpointing the specific site of the tumor in the brain. Diagnosis, therapy (including surgical planning), and research all depend on this kind of careful dissection and interpretation. Radiologists, engineers, and doctors all employ medical image processing to learn more about a patient's or a population's unique anatomy. It is possible to get insight into, say, how a patient's anatomy interacts with a medical device via the use of measurement, statistical analysis, and the development of simulation models that contain genuine anatomical geometries. Neoplasm, or tumor, is the medical term for a mass of abnormally growing cells. Cancer and tumor are very different concepts [2]. There are two main subtypes that might each make up a brain tumor. In contrast to malignant tumors, which do contain cancerous cells, benign tumors do not, and vice versa.

1) *Benign tumor*: Benign brain tumors are caused by a disruption in the normal processes of cell division and proliferation, which results in a collection of cells that, on a microscopic level, do not exhibit the classic characteristics of cancer. These traits distinguish benign tumors from malignant ones: Imaging techniques such as computed

tomography (CT) and magnetic resonance imaging (MRI) can identify the great majority of tumors, even benign ones. All these traits point to the fact that this tumor is benign since it develops at a modest rate, and seldom spreads to other parts of the body, which might ultimately result in death, the term "benign" may give the wrong impression about the nature of these injuries.

2) *Malignant tumor*: Development of Carcinoma Cancer cells is the building blocks of malignant brain tumors, which often do not have well-defined borders. The rapid development of these tumors and their ability to invade adjacent brain tissue [4] has led experts to the grim conclusion that they provide a significant risk of death. The following is a list of traits that malignant tumors have malignancy that is quickly spreading, with broad metastases in both spinal and cerebral. Malignant brain tumors are graded as either 3 or 4, whereas benign brain tumors are often categorized as 1 or 2. They usually pose a far bigger danger to human life.

Recent and reliable forecasts [5] estimate that 24,530 persons in the United States will be diagnosed with brain or spinal cord tumors in 2021. There will be 13840 men and 10690 women impacted by this. Less than one percent of the population is expected to get this kind of brain tumor at some point in their life. Roughly 85–90% of primary CNS cancers have this etiology as their root cause. This article focuses on the most common types of brain tumors in adults; however, each year 3,460 children under the age of 15 are diagnosed with a tumor in their central nervous system (CNS). Both men and women rank brain and central nervous system cancer as the ninth biggest cause of death. About 18,600 fatalities in 2021 are projected to be the result of primary brain and central nervous system tumors [6]. There were around 10,500 men and 8,100 women. Therefore, it is crucial to enhance the precision of previously proposed approaches for the advancement of medical image analysis. To summarize, several advanced methods have been introduced to address the problem associated with low image quality. Various techniques have been observed to possess durable effectiveness in improving contrast, illustrating texture intricacies, and reducing noise levels. Moreover, these techniques excessively magnify the intricate features of the images. As per the existing literature paradigms, as far as the Author's knowledge, the issue of brain tumor classification for low-quality MRI scans is yet to be set up to consider it in real-time applications. Hence, to achieve this goal in the present study, a novel technique has been proposed.

The main contribution of this research is summarized as follows:

- A robust multi-layer CNN-based system is proposed for binary-class brain tumor classification on the publicly available dataset.
- An analysis is performed on MRI data because it is one of the main sources for detecting tumors in the patient's brain to detect it.
- The repetition of this invasive method in the case of non-clear images could be avoided if the system is auto

trained with deep learning techniques. To overcome such problems in medical imaging. Hence, an MRI as a data input.

- An enhanced CNN classification model is implemented to identify and classify the brain tumor and compare the achieved accuracy and performance with the state-of-the-art approaches.

The existing framework is offered in the Section II of the paper, the background details are explained in the Section III, the suggested approach is explained in the Section IV, experimental findings and comments are presented in the Section V of the paper, and lastly, a conclusion is presented in the Section VI of the paper.

## II. LITERATURE REVIEW

Khan et al. [7] utilized contrast to lesion area compared to the background. The 2D blue channel is selected for the construction of saliency map, at the end of which threshold function produces the binary image. In addition, particle swarm optimization (PSO) based segmentation is also utilized for accurate border detection and refinement. Few selected features including shape, texture, local, and global are also extracted which are later selected based on genetic algorithm for identifying the fittest chromosome. Hussain et al. [8] devised a way to identify and measure brain tumors using MRI images. The algorithm can identify and eliminate any size, location, or form of tumor. MRI pictures are grayscale first. The blurred picture is then merged with the original. Median filters reduce noise. Dilation and erosion compute morphological gradients. A picture is improved with a morphological gradient and filter. Mean and standard deviation are used to compute the threshold. Before binarization, each pixel's threshold is checked. The image is thinned, and then dilated to reattach the destroyed tumor. Comparing original and dilated photos helps eliminate Javed et al. [9] focus will be to review the optimal features which have been used in an accurate skin cancer melanoma diagnosis computer-aided system. They addressed this problem an extensive review is performed. To perform this review, they collected quality papers based on features selection and extraction for skin lesion detection. These papers are collected by two approached: (1) search by keywords and year, (2) cross-references within the papers.

Javed et al. [10] proposed to deal with under/over segmented images is proposed a region-based active contour method and low contrast skin lesion dermoscopic images handle by implementing JSEG technique. An image fusion technique is proposed on two segmented images get by apply region-based active contour and JSEG techniques. Rashid et al. [11] used a joint design that fuses both the RBAC and JSEG method for skin lesion segmentation. Design technique improved the lesion segmentation as well as deal with the failure cases. The outcomes exhibited an incredible potential by beating state-of-the-art strategies for skin lesion segmentation from thermoscopic images. The proposed method also deals with different artifacts present in the thermoscopic images. They proposed for approach low contrast images by using histograms. Ullah et al [12] proposed early detection and classification of EXs in color fundus

images. An ensemble classification of exudates in color fundus images using an evolutionary algorithm based optimal features selection. Experiment performed on benchmark datasets and a real dataset developed at local Hospital. It has been observed that the proposed technique achieved an accuracy of 98% in the detection and classification of EXs in color fundus images. Sajjad et al. [13] proposed the data augmentation with various parameters and techniques to fill the gap of data and make the system noise invariant. Multi-grade brain tumor classification system, the tumor regions from the dataset are segmented through a CNN model, the segmented data is further augmented using parameters to increase the number of data samples, and a pre-trained VGG-19 CNN model is fine-tuned for multi-grade brain tumor classification. Rehman et al. [14] proposed skull masking method to identify issues. Unsupervised SVMs build and preserve patterns using this approach.

Ahmed et al. [15], which enhances calculation time. The suggested solution hasn't been tested yet. It has 86% classification and 92% cancer detection accuracy. Histograms were utilized by Liu et al. [16] segmenting brain tumors involves two modalities: FLAIR and T1. FLAIR aberrant areas were found using an active contour model. Edema and tumor tissues in aberrant locations were separated using k-means. The dice coefficient is 73.6% and the sensitivity is 90%. Nikam et al. [17] employed edge detection and adaptive thresholding to extract ROI. By using edge detection, the dataset included 102 pictures. First, images were preprocessed, and then two neural network sets underwent canny edge detection and adaptive thresholding. Two neural networks determine whether the brain is healthy or has tumors and the kind of tumor. Canny edge detection was more accurate based on the data and models. Ye et al. [18] enhanced texture-based tumor segmentation in longitudinal MRI using tumor growth patterns. This technique exploits tumor characteristics. Mean DSC LOO and three-Folder measured the model's performance. Sarkar et al. [19] presented a PNN-based LQ model. 18 MRI scans were used for testing and the remainders were used for training. Gaussian filter smoothed photos. Improved PNN cut processing time by 79%. Sharif et al [20] used probabilistic neural networks for segmentation. PCA identified characteristics and reduced high-dimensional data. Mehrotra et al. [[21] proposed a neural network for classifying MRI matrix data and conducted a comprehensive performance analysis with the assistance of deformable models and fuzzy clustering. Rehman et al. [22] separated tumors using Linknet. All seven training datasets were initially segmented in a single Link net network. They didn't examine the perspective of the images and instead created a way for CNN to automatically separate prevalent brain tumors.

Tufail et al. [23] different DL methods are used to solve both binary and multiclass classification problems to differentiate between different stages and deployed a ten-fold cross-validation approach to select the optimal set of hyperparameters for the binary and multiclass classification tasks. For the binary classification task, the performance of architecture trained using combined augmentation methods is the best while the performance of the model trained without

any augmentation is found to be the worst. Other retinal diseases such as retinal detachment using fundus images deploying data augmentation methods such as elastic/plastic deformations as well as other DL-based architectures such as graph convolutional networks.

Pitchai et al. [24] automated deep learning-based Fuzzy K-means clustering segmentation approach has been developed for brain tumor segmentation. This method includes four stages. Initially, the MRI images are preprocessed using a wiener filter for noise expulsion. From the filtered images, the significant features are extricated by using the CSOA algorithm. Then, the normal and abnormal images are classified through ANN. Finally, the fuzzy K-means algorithm has been utilized on the abnormal images to segment the tumor region. This can replace conventional invasive brain tumor classification and enhances the overall classification accuracy. An efficient strategy is employed to enhance the low visual quality of MRI images. Data augmentation technique is used to achieve high classification accuracy on a small dataset, and the impact of over-fitting on classification performance is studied. An efficient and simpler object (tumor) localization method is developed, which gets the initial locations by computing multiple hierarchical segmentation using superpixels and then rank the locations according to region score, which is defined as a number of contours wholly enclosed in the located region, only the top object locations are passed for the next task. Guan et al. [25] proposed a deep neural network (EfficientNet) is employed for rich features extraction. A comparison of the proposed method with existing state-of-the-art approaches for brain tumor classification is presented. The proposed method achieved classification accuracy compared to traditional methods.

Kaplan et al. [[26] proposed two different feature extraction approaches were used to classify the most common brain tumor types; Glioma, Meningiomas, and Pituitary brain tumors; nLBP and  $\alpha$ LBP. Brain tumor classification using modified local binary patterns - nLBP and  $\alpha$ LBP feature extraction methods used. This work introduces an optimized deep learning mechanism; named Dolphin-SCA based Deep CNN, to improve the accuracy and to make effective decisions in classification of brain tumor classification. Kumar et al. [27] presented mechanism of deep learning; named Dolphin-SCA based Deep CNN, to improve the accuracy and to make effective decisions in classification. The segmentation process is carried out using a fuzzy deformable fusion model with Dolphin echolocation-based Sine Cosine Algorithm (Dolphin-SCA). It looks at the posterior and anterior (PA) views of X-rays, therefore it can't tell the difference between other X-ray perspectives like anteroposterior (AP), lateral, and so on. It also needs Grad-CAM (Class Activation Mapping) visualization.

Deepak et al. [28] proposed a classification system that adopts the concept of deep transfer learning and uses a pre-trained GoogLeNet to extract features from brain MRI images. Proven classifier models are integrated to classify the extracted features. The experiment follows a patient-level five-fold cross-validation process, on an MRI dataset from Figshare. They proposed system records a mean classification accuracy of 98%, outperforming all state-of-the-art methods.

Raja et al. [29] developed a brain tumor classification using a hybrid deep autoencoder with a Bayesian fuzzy clustering-based segmentation approach. Initially, the pre-processing stage is performed using the non-local mean filter for denoising purposes. Then the BFC (Bayesian fuzzy clustering) approach is utilized for the segmentation of brain tumors.

Rammurthy et al. [30] presented a fully automated deep CNN for brain tumor detection using MR images. It also proposed a Whale Harris Hawks optimization (WHHO) is employed for training the deep CNN. The proposed WHHO algorithm is designed by combining the WOA and HHO algorithms, which can be utilized for finding the optimal weights for establishing effective brain tumor detection. Here, the segmentation is performed on each input brain MRI image using cellular automata and rough set theory. The pertinent pixel of tumor regions helps to provide improved segmentation results. Advanced optimization techniques can be explored to further compute the efficiency of existing methods.

Agarwal et al. [31] proposed a new Conv2D model for cucumber disease classification with an accuracy of 93.75%, which outperforms the state-of-the-art accuracy by 8.05%. Modified the ReLU activation function and experimentally established that it boosts the classification accuracy by 2.5% over the regular ReLU function. They proposed a segmentation algorithm to identify the diseased regions of cucumber leaf images and work out the severity of the disease. Botta et al. [32], this approach focuses only on relevant image patches from the image, making the technique fast and memory efficient. The low FPR values obtained indicate a low chance of an intact egg being classified as cracked. Thakur et al. [33] proposed to detect and classify Covid-19 disease from normal (healthy) and pneumonia patients; to check the generalizability of the method, develop a larger dataset that includes both X-rays and CTs; to achieve a higher value of performance measures for both binary as well as multiclass problems; to calculate all the performance measures and compares the different parameters of the proposed technique to those of current techniques. Despite having a great performance, it has some drawbacks. In Ullah et al. [34], a medical decision support system using malignant and benignant classes was discussed. This system is designed by median filter, CLAHE, wavelet transform, color moments and feed-forward NN. The proposed system provides results in categorizing malignant and benign MRI images.

It has been noticed from the above research that findings with the traditional machine learning (ML) techniques are not sufficient to segment and classify the brain tumor from raw MRI images. In addition, deep learning techniques outperform the accuracy of brain tumor classification effectively. However, the size of the patient's brain tumor changes periodically, which makes it hard and time-consuming to diagnose and categorize the tumor from massive imaging sets. The structural complexity of the brain makes the building of an expert system for identifying brain tumors a challenging undertaking that is plagued by several problems, including under-fitting, biased results, overfitting, and repetition of the training samples. It takes more time to complete activities like determining the infected area, segmenting, and identifying

tumors from MRIs, and it is challenging to see the abnormal brain structures using standard image processing methods. The present proposal clearly put a light on the Convolutional neural network which is the backbone of every other deep neural network. Thus, authors have tried to show the working of CNN with a slight change in layers and proportions to advance the accuracy and performance to overcome the problem of accurate detection and classification of brain tumours in MRI scans (see Table I).

### III. BACKGROUND

#### A. Convolutional Neural Network

CNN is an example of an artificial neural network, often known as a multilayered sensor. Its architecture is inspired on the structure of the visual cortex. One of the most important ideas behind deep learning is the Convolutional Neural Network or CNN. CNN consists of two basic processes, which are referred to as convolution and pooling, and is often used in applications that are related to image recognition. Additional layers of convolution and pooling are added as necessary up to the point when a high level of classification accuracy is obtained. In addition to this, certain feature maps are included in each convolutional layer, and the weights of convolutional nodes that are contained inside the same map are shared. These designs minimize the number of traceable parameters while allowing for the learning of a variety of network properties. CNN, in contrast to more traditional methods, may learn to completely extract features while simultaneously performing a reduced number of specialized duties. The whole process plan of a CNN is shown in Fig. 1.

Fig. 1. CNN process.

#### B. Background of Tumor Detection

Preprocessing: Noise may affect MR images. Picture compression and data transfer may produce noise. Nonlocal techniques and local smoothing were used to reduce noise [ ]. Some significant visual structures and features might appear as if they were made of noise; these vital details may also be deleted. Below figure shows axial, coronal, and sagittal MR images. Fig. 2(a) and 2(b) show an original and preprocessed image.

#### C. Watershed Segmentation and Morphological Process

Good cranial MRI segmentation using watershed segmentation. This method detected cancer. Geography and water supply basins determine watershed lines. It analyses grey data and determines the object's boundaries by using the topological structure of the object inside an image. It enhanced the submerge-based watershed transformation method. It's lowest and maximum values are hmin and hmax. Moving from hmin to hmax shows recursion. Xh basin clusters were comparable to dot clusters with hmin at recursion's start. The Xh basin cluster in the threshold cluster eventually grows.

$$Xh = \min_U IZTh + 1(f)(Xh), \forall h \in [hmin, hmax - 1] \quad (1)$$

Fig. 2. (a) Original image, (b) Pre-processed image, (c) Segmented skull image, (d) Brain tissue extraction, (e) Tumor detection.

First, the program collects gradient data. Subtracting the first derivative of pixel change yields this data. Next-level activation requires the signal. Image segmentation requires pointer pixels for each class. These pixels' location and quantity affect segmentation success. The watershed transformation has interesting features for mathematical morphology image segmentation. This change is intuitive. It generates closed curves quickly. Over-segmentation is a nearby one fused, and gaps were filled. Fig 2(c) shows how watershed segmentation eliminates data from MR images. Fig. 2d shows how the brain's soft tissue was created by removing the skull from the original image. Fig 2(e) shows how morphological segmentation and classification of brain tumour in MRI scans and assist the radiologist.

### IV. PROPOSED WORK

The proposed five-layer CNN model can identify a tumor in MRI images. Fig. 3 shows the five-layer CNN technique. Firstly, load the input dataset with the same-sized images. Five-layer CNN is used for early identification of tumors and a model includes seven steps (eight if you include the hidden layers), yielding the best results for tumor detection and splitting down the process into seven steps from which a brain tumor may be detected utilizing CNN. Step-by-step instructions shown below reveal the process. In Fig. 4, the proposed method for tumor detection using a five-layer Convolutional Neural Network is shown. Five discrete dimensions are also used.

#### A. Convolutional Layer

A convolutional layer is CNN's backbone. First, a convolutional layer is used to resize MRI images. This makes a 64\*64\*3 input shape. After gathering all same-orientation input images developed a convolutional kernel using 32 3\*3 convolutional filters and three channel tensors. The activation

function is ReLU. The filter size is three times the 64x64x3 input volume.

Fig. 3. Five layer CNN model workflow.

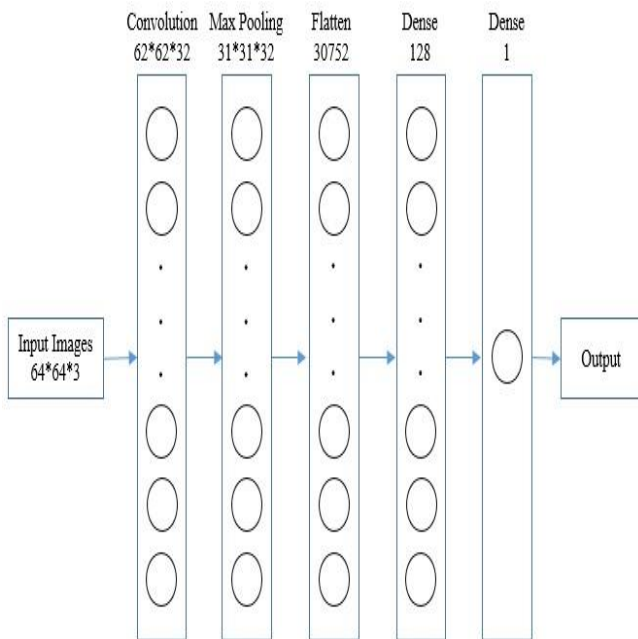

Fig. 4. Five-layer CNN for brain tumour detection.

Each neuron in the convolutional layer has  $3*3*3 = 27$  weights, plus one for the bias parameter. Assess depth, stride, and zero-padding. The model contains a  $64*64*3$  input volume and a 33 spatial filter. Since it didn't specify border padding, padding and stride are both 1. If the stride is set to 1,

only the pooling layers will down sample; the CONV layers will alter the input volume in depth. After the convolutional layer, added max pooling.

**B. Max Pooling Layer**

The fundamental objective of the pooling layer is to reduce the number of parameters and computation workloads in the network by progressively decreasing the spatial size of the representation. Over-fitting may be managed thanks to its ability to scale down the settings. The max pooling layer may be used to enlarge the input spatially, and it can do so on a per-slice basis if the input is deep enough. From another angle, the Max Pooling layer is great for preventing over-fitting, which might introduce contamination into the brain MRI image when editing it (see Fig. 5). Therefore, MaxPooling2D (see Fig. 6) check the effect of the pooling operation as a pre-processing step which was used on the input image. There are a total of 32 nodes in this convolutional layer, resulting in a  $31*31*31$  matrix.

Fig. 5. CNN operation unit.

Fig. 6. Pooling operation unit.

**C. Flatten Layer**

Pooling creates a pooled feature map that extracts necessary features only and discards unimportant features refer to Fig. 6. The flattened layer is crucial after pooling because it transforms the input's feature maps into a single-column vector for processing. The neural network processes it as Layer  $31*31*32 = 30752$  pixels.

**D. Fully Connected Layer**

The dense-1 and dense-2 (see Fig. 7) layers were linked. Keras processes the neural network using the dense function, and the output vector is fed to this layer. Each layer has 128

nodes. Due to high processing costs, the number of dimensions or nodes is 128. ReLU is employed due to its high convergence. The model's final layer was the second totally linked layer, utilizing the sigmoid function as the activation function in this layer with one node to reduce execution time. Sigmoid activation may impair deep network learning. The sigmoid function has been lowered, reducing the number of nodes in this deep network.

Fig. 7. Proposed model workflow.

## V. RESULTS AND DISCUSSION

### A. Experimental Setup

Jupyter Notebook and Python technologies like NumPy, Pandas, and OpenCV were used for image processing. For classifiers, use Scikit-Learn, Anaconda and Python 3.6.

CNN model was trained and tested using TensorFlow and Keras used Google Colab's GPU.

### B. Dataset Acquisition

Br35H-Mask-RCNN dataset [16] is used to segment brain tumors. Cancers and non-tumors are labeled. A set has two classes. Class-1 is tumors MRI while Class-2 is non-tumors (class-0). Training is 700, testing is 100 and 24 images test performance.

### C. Performance Measures

To assess how well the proposed model works, one must consider performance metrics. Below is the discussion on the proposed model's performance statistics. One must learn performance measurement lingo to understand the Confusion Matrix.

Confusion Matrix:

TP: Number of correctly identified tumor images.

TN: The number of correctly detected non-tumor images.

FP: The number of non-tumor images labeled tumor.

FN: Number of tumor images misclassify as non- tumor.

Accuracy: It's the most common way to measure how often a classifier is correct. Accuracy is the ratio of accurately predicted images to the total number of photos.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (2)$$

Precision: The model's data is retrieved. Precision is the ratio of correctly detected tumor images (TP) to misclassified

ones (TP+FP). Precision rises with FP. A more accurate model is more effective. It's the proportion of retrieved images.

$$Precision = \frac{TP+TN}{TP+FP} \quad (3)$$

Recall: Recall is the ratio of tumor photographs correctly detected to images to be projected. It's also called sensitivity, hit rate, and true positive rate. Because non-tumor images are rare, a smaller false negative increases memory.

$$Recall = \frac{TP}{TP+FN} \quad (4)$$

F-Score: The harmonic mean of recall and precision is used as a measurement of test accuracy. F-scores range from 1 (perfect accuracy and recall) to 0 (zero).

$$F - Score = \frac{2TP}{2TP+FP+FN} \quad (5)$$

Specificity: Specificity is the F-Score. The model's True Negative Rate (TNR) and binary classification test's statistical measure is specificity. Use this as a performance evaluation as it's binary (tumor or non-tumor). The ratio of correctly identified non-tumor images (TN) to wrongly categorized non-tumor images (TN + FP). The more specificity, the fewer false positives (FP).

$$Specificity = \frac{TN}{TN+FP} \quad (6)$$

### D. Experimental Results

The five-layer CNN model got the best results for splitting ratio and other parameters. Then split CNN model performance by layer count. Next, is presented the experimental results and quality and evaluation. Experiments I and II tested the five-layer model with 70:30 and 80:20 learning rates and epoch-splitting ratios. Later, it is examined as five, six, and seven-layer CNN models.

1) *Experiment-I*: The five-layer CNN model is trained using 70 by 30 ratios. Table II shows how this ratio impacts learning rate, epochs, training length, and accuracy. The highest accuracy was attained using a 0.001 learning rate, 50 epochs, and 500 seconds of training.

TABLE II. CNN TRAINING TIME ACCURACY (SPLITTING RATIO OF 80:20)

Learning Rate	Time	Time to train(sec)	Accuracy (%)
0.001	10	175	99.51
	20	233	98.87
	50	527	95.74
	100	1200	95.69
0.005	10	177	96.03
	20	203	97.62
	50	488	95.55
	100	1027	95.55
0.01	10	178	92.09
	20	200	93.04
	50	599	93.77
	100	966	92.00

2) *Experiment – II:* The five-layer CNN model is trained using 80 by 20 ratios. Table III compares training, accuracy, learning rate, and epochs. The greatest accuracy is 99.51 percent at a 0.001 learning rate and 10 epochs, and training takes 175 seconds.

TABLE III. CNN TRAINING TIME ACCURACY (SPLITTING RATIO OF 70:30)

Learning Rate	Time	Time to train(sec)	Accuracy (%)
0.001	10	180	98.66
	20	231	98.95
	50	500	99.58
	100	1227	96.01
0.005	10	198	98.18
	20	240	99.13
	50	555	97.68
	100	1133	97.22

3) *Experiment-III (Five-layer Architecture):* This analysis used several hyper-parameters and splitting ratios to test the five-layer CNN model. Table IV compares 80:20 and 70:30 five-layer CNNs. The model is most accurate for 80:20, 64, and 10 epochs. The model overfits thereafter. Five-layer CNN accuracy is 99.87%.

TABLE IV. CNN PERFORMANCE FOR FIVE LAYERS

Convolution Layer	Coalescing	Fracture Percentage	Group Measurement	Time	Accuracy (%)
62*62*32 62*62*32 (2 layer)	31*31*32	80:20	32	8	89.29
				9	92.83
				10	93.76
				11	93.62
			64	8	94.01
				9	96.08
				10	95.49
				11	94.21
		70:30	32	8	82.37
				9	83.71
				10	84.24
				11	86.17
			64	8	88.27
				9	82.23
				10	81.69
				11	80.07

4) *Experiment-IV (Six-layer Architecture):* Add 62\*62\*32 convolutional layer. Changing model dimensions may affect accuracy. Table V demonstrates 80:20 splitting, 64 batches, and 11 epochs. Model accuracy deteriorated. Convolutional layers don't improve accuracy. Two kinds of CNN models

were employed for the suggested model, and the five-layer CNN model had 99.87% accuracy. Table VI compares an CNN models from trial III and IV.

TABLE V. CNN PERFORMANCE FOR SIX LAYERS

Convolution Layer	Coalescing	Fracture Percentage	Group Measurements	Time	Accuracy (%)
62*62*32	31*31*32	80:20	32	8	99.87
				9	99.77
				10	99.51
			64	8	93.67
				9	94.98
				10	97.87
				11	94.89
				11	94.90
		70:30	32	8	81.35

				10	87.87
				11	89.13
			64	8	88.07
				9	88.76
				10	91.23
				11	94.90

TABLE VI. COMPARISON OF CNN MODELS

No. of Layers	Convolutional Layer	Coalescing	Fracture Percentage	Group Measurements	Time	Accuracy (%)
5	62*62*32	31*31*32	80:20	64	8	99.87
6				64	9	96.08

*E. Discussion*

The proposed method uses a pre-processing, data augmentation, convolutional kernel, filter, and three channel tensors added in the process to improve classification. Techniques like MaxPooling2D were used to reduce the overfitting problem and added two fully connected dense layers with ReLU as an activation function.

A detailed discussion on the effect of execution time, variation in proposed results, and comparison with different add or removal of layers in CNN are projected here. The process is implemented on two different architecture styles and measures the accuracy and system computational time, such as 80:20, and 70:30 on five-layer CNN architecture which can be viewed from Table II and Table V. In these tables, it is shown that the best-achieved accuracy is 99.87%, 99.77%, 99.51% etc. The variant performance of the proposed methodology is noticed when we add or drop the classifier layers and training proportions on the proposed model. The proposed selected features are best for five-layer CNN. Also, applied hyperparameter tuning on six-layer CNN. However, the results are not up to the scale (see Table V) when

compared with five-layer CNN, 80:20 training split ratio (see Table IV) and observed that this method improves the computational and classification accuracy.

List of Hyperparameters used in this study are Batch size, Learning Rate, number of epochs, number of filters, kernel size, pooling size. Refer to Table II and Table III to check tuning performance of proposed model. In addition, Adam optimizer is used. The above parameters can fine-tune each time we find less accuracy as per the evaluation metrics see Fig. 7. To evaluate the proposed model plotted confusion matrix (See Fig. 8)

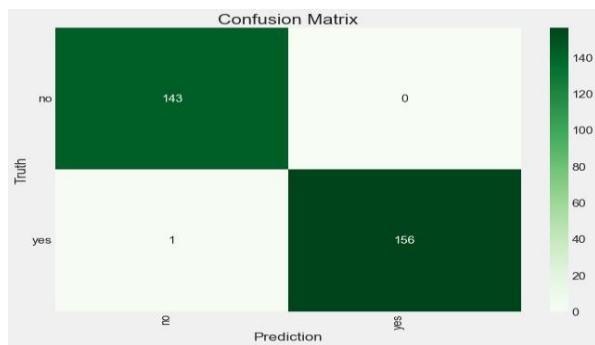

Fig. 8. Confusion matrix.

## VI. CONCLUSION AND FUTURE WORKS

In this analysis, the enhanced tumor segmentation and classification from MR images is presented. The proposed model used two techniques with CNN which works in two phases: (1) five-Layer CNN with Hyper-parameter tuning; (2) six-layer CNN with hyperparameter tuning with various data training proportions. This model performed well because of 2D Max pooling, ReLu activation function and used Adam as optimizer and fine tune with batch size, learning rate. In a proposed approach, the best features selection step not only increases the accuracy but also minimizes the classification time. However, this study has limitation for computing large datasets and complex CNN's this model may not give same accuracy to other datasets. In the future, we aim to extend our current work for fine-grained classification of multi-modal MRI images on advanced CNN architectures like R-UNet and aim to use a high-performance computational platform for the complete dataset for further improvement in segmentation feature map and classification. This soon can be deployed in real-time applications in a broader prospect.

# Method for Hyperparameter Tuning of Image Classification with PyCaret

Kohei Arai<sup>1</sup>, Jin Shimazoe<sup>2</sup>, Mariko Oda<sup>3</sup>

Information Science Dept., Saga University, Saga City, Japan<sup>1</sup>  
Applied AI Laboratory, Kurume Institute Technology, Kurume City, Fukuoka, Japan<sup>1, 2, 3</sup>

**Abstract**—A method for hyperparameter tuning of image classification with PyCaret is proposed. The application example compares 14 classification methods and confirms that Extra Trees Classifier has the best performance among them, AUC=0.978, Recall=0.879, Precision=0.969, F1=0.912, Time=0.609 bottom. The Extra Trees Classifier produces a large number of decision trees, similar to the random forest algorithm, but with random sampling of each tree and no permutation. This creates a dataset for each tree containing unique samples, and from the ensemble set of features a certain number of features are also randomly selected for each tree. The most important and unique property of the Extra Trees Classifier is that the feature split values are chosen randomly. Instead of using Gini or entropy to split the data to compute locally optimal values, the algorithm randomly selects split values. This makes the tree diverse and uncorrelated. i.e. the diversity of each tree. Therefore, it is considered that the classification performance is better than other classification methods. Parameter tuning of Extra Trees Classifier was performed, and training performance, test performance, ROC curve, accuracy rate characteristics, etc. were evaluated.

**Keywords**—PyCaret; extra trees classifier; AUC; gini; entropy; feature split; ROC curve

## I. INTRODUCTION

Most machine learning problems require many hyperparameter tunings. Unfortunately, it is not possible to provide specific tuning rules for all models but may converge very slowly for another model. Finding the best set of hyperparameters for your dataset requires experimentation. Some rules of thumb, here is the training loss, which should decrease abruptly at first, then more slowly and steadily until the slope of the curve reaches or approaches zero, and if the training loss does not converge, wait for more epochs of training.

If the training loss decreases too slowly, increase the learning rate. Note that setting the learning rate too high can prevent the training loss from converging. Decrease the learning rate if the training loss varies a lot (that is, if the training loss jumps around). Increasing the number of epochs or batch size while decreasing the learning rate is often a good combination. Setting the batch size to a very small batch number can lead to instability. First, try increasing the batch size value. Then reduce the batch size until you see a drop. For real datasets consisting of a very large number of samples, the entire dataset may not fit in memory. In such cases, the batch size should be reduced so that the batch fits in memory. For the optimization of these hyperparameters, hyperopt, gpyopt,

AutoML, PyCaret, Optuna, etc. are proposed as black-box optimization methods, automating trial-and-error on hyperparameters and automatically finding the optimal solution. Similarly, a method for training and white boxing DL, BDT, random forest and mind maps based on GNN is proposed [1]. In particular, Optuna uses an algorithm called TPE (Tree-structured Parzen Estimator), which is a new technique among Bayesian optimization, and parallel processing is possible, and by saving the results in a database, it is possible to resume in the middle. Depending on the definition of the objective function and the validity of the importance of the parameters, hyperparameters that do not necessarily match the evaluation criteria may appear. Usually, it is desirable to introduce such cases, and propose a method to intentionally change the hyperparameters of Optuna and PyCaret and select parameters with less loss by trial and error. It, however, PyCaret only uses hyperparameters obtained by random grid search, and does not intentionally change hyperparameters in this paper.

As a comparative study on classification methods with PyCaret and its application to textile fluctuations of classifications, we propose a comparative study of classification methods by PyCaret and its application to the classification evaluation of textile pattern deviations. Many classification methods have been applied to the classification evaluation of textiles, but trial and error are necessary to determine the optimum method, which requires not a little time. The method proposed in this paper finds the optimal method using PyCaret, and is a method for finding the optimal method easily in a relatively short time without repeating trial and error. As one application of this method, an example of applying it to classification of Kurume Kasuri patterns is shown. This is just one application example, and the proposed method can be widely applied to other classifications.

The application example compares 14 classification methods and confirms that Extra Trees Classifier has the best performance among them, AUC=0.978, Recall=0.879, Precision=0.969, F1=0.912, Time=0.609 bottom. The Extra Trees Classifier produces a large number of decision trees, similar to the random forest algorithm, but with random sampling of each tree and no permutation. This creates a dataset for each tree containing unique samples, and from the ensemble set of features a certain number of features are also randomly selected for each tree. The most important and unique property of the Extra Trees Classifier is that the feature split values are chosen randomly. Instead of using Gini or entropy to split the data to compute locally optimal values, the

algorithm randomly selects split values. This makes the tree diverse and uncorrelated i.e. the diversity of each tree. Therefore, it is considered that the classification performance is better than other classification methods. Parameter tuning of Extra Trees Classifier was performed, and training performance, test performance, ROC curve, accuracy rate characteristics, etc. were evaluated.

In the following section, some of the related research works are described together with a research background, followed by the comparative study conducted. Then, some of the simulation studies are described, followed by a conclusion with some discussions.

## II. RELATED RESEARCH WORKS AND RESEARCH BACKGROUND

### A. Research Background

Image classification is required for textile pattern discrimination in this concern. Patterns are boring and uninteresting because they are regular, but moderately irregular patterns feel comfortable. For instance, Kurume Kasuri textile patterns are moderately irregular so that we feel these patterns are comfortable. It is understandable that the moderately irregular patterns contain 1/f fluctuations. However, a pattern with too much irregularity gives an unpleasant feeling to the person who sees it. Therefore, it is thought that there is a boundary between pleasant irregularities and unpleasant irregularities. The purpose of this paper is to discriminate between both. In order to find the best discrimination performance of classification method, 14 of classification methods are compared these accuracies and their other performances.

### B. Examples of Pleasant and Unpleasant Irregularity of Kurume Kasuri

One of the typical Kurume Kasuri of textile patterns is shown in Fig.1 (a). Also, examples of the regular (green) and the moderately irregular patterns (red) are shown in Fig. 1 (b), respectively. As shown in Fig. 1 (b), it is obvious that the regular patterns make a good impression while the irregular patterns make a bad impression. The cause of these irregular patterns is the lack of control over the warp tension of the Kurume Kasuri automatic loom. If the pattern is too comfortable, it will exceed the allowable limit and become an unpleasant pattern. It is too difficult to control the warp tension. It is important to evaluate the quality of woven Kurume Kasuri and determine whether it is good or bad to send it to the market.

### C. Related Research Works

Method for 1/f fluctuation component extraction from images and its application to improve Kurume Kasuri quality estimation is proposed [2]. In this paper, it is shown that Kurume Kasuri textile pattern quality depends on 1/f component. On the other hand, classification by re-estimating statistical parameters based on auto-regressive model is proposed [3]. Similarly, multi-temporal texture analysis in TM classification is proposed [4] together with Maximum Likelihood (MLH) TM classification taking into account pixel-to-pixel correlation [5]. Meanwhile, a supervised TM classification with a purification of training samples is proposed [6]. Also, TM classification using local spectral variability is proposed [7]. Furthermore, a classification method with spatial spectral variability is proposed [8].

An inversion for emissivity-temperature separation with ASTER data is proposed [9]. TM classification using local spectral variability is also proposed [10]. On the other hand, application of inversion theory for image analysis and classification is proposed [11]. Meanwhile, polarimetric SAR image classification with maximum curvature of the trajectory in eigen space domain on the polarization signature is proposed [12]. Moreover, a hybrid supervised classification method for multi-dimensional images using color and textural features are proposed [13].

Human gait gender classification using 3D discrete wavelet transformation feature extraction is proposed [14]. Meanwhile, polarimetric SAR image classification with high frequency component derived from wavelet multi resolution analysis: MRA is proposed [15]. On the other hand, a comparative study of polarimetric SAR classification methods including proposed method with maximum curvature of trajectory of backscattering cross section in ellipticity and orientation angle space is proposed [16]. Human gait gender classification using 2D discrete wavelet transforms energy is proposed [17]. Also, human gait gender classification in spatial and temporal reasoning is proposed [18]. Comparative study on discrimination methods for identifying dangerous red tide species based on wavelet utilized classification methods is conducted [19].

Multi spectral image classification method with selection of independent spectral features through correlation analysis is proposed [20]. On the other hand, image retrieval and classification method based on Euclidian distance between normalized features including wavelet descriptor is also proposed [21].

Gender classification method based on gait energy motion derived from silhouettes through wavelet analysis of human gait moving pictures is proposed [22]. Similarly, human gait skeleton model acquired with single side video camera and its application and implementation for gender classification is proposed [23] together with human gait skeleton model acquired with single side video camera and its application and implementation for gender classification [24]. Gender classification method based on gait energy motion derived from silhouette through wavelet analysis of human gait moving pictures is proposed [25].

Image classification considering probability density function based on simplified beta distribution is proposed [26]. Also, Maximum Likelihood (MLH) classification based on classified result of boundary mixed pixels for high spatial resolution of satellite images is proposed [27]. Meanwhile, context classification based on mixing ratio estimation by means of inversion theory is proposed [28]. On the other hand, optimum spatial resolution of satellite-based optical sensors for maximizing classification performance is discussed [29]. Combined non-parametric and parametric classification method depending on normality of PDF of training samples is proposed [30].

### III. EXPERIMENT

#### A. Data used

180 of training samples and 30 of test samples are used. A small portion of the data used as a good data is shown in Fig. 2(a) while those for a bad data are shown in Fig. 2(b), respectively. There are 24 images in total, including two good and bad training data and two good and bad test data, including data augmentation (noise, skew).

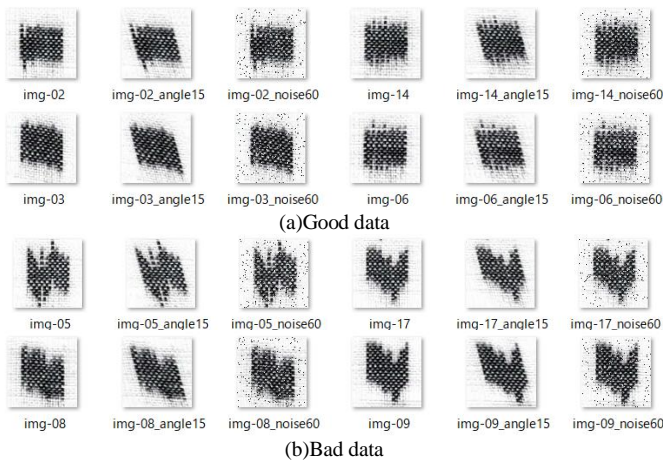

Fig. 2. A portion of good and bad data used.

#### B. Classification Methods for Comparison

There are the following methods for comparing classification performance of the good or bad categories,

- Extra Trees Classifier
- Logistic Regression
- Ridge Classifier

- Random Forest Classifier
- Light Gradient Boosting Machine
- Ada Boost Classifier
- SVM - Linear Kernel
- Gradient Boosting Classifier
- K Neighbors Classifier
- Naive Bayes
- Linear Discriminant Analysis
- Decision Tree Classifier
- Quadratic Discriminant Analysis
- Dummy Classifier

These are typical and widely used classification methods. Therefore, details of explanation of the method are not necessary.

#### C. Evaluated Performances

The following typical and widely used classification performances are evaluated for comparison,

- Accuracy
- AUC
- Recall
- Precision
- F1 score
- Kappa value
- MCC
- TT (Sec)

These are typical and widely used classification performances. Therefore, it seems that details of explanation of the performances are not necessary.

#### D. Evaluation Results

Evaluation results are summarized in Table I. Cells shaded yellow have the best performance. Almost all the classification performances of the Extra Trees Classifier show the best performance except "Recall". Total time required for learning and classification is also not so bad either. Extra Trees are similar to Random Forests. The points to construct multiple trees are the same, but one of the features (Gini coefficient, entropy) at which the node (leaf) of the tree is divided is randomly selected.

In the decision tree, when dividing the feature axis, the feature that maximizes the gain based on the feature amount (Gini coefficient, entropy), etc., and the threshold for the division are selected. Extra-Trees randomly select them. Prepare multiple random trees and bag them in the same way as Random Forest.

Fig. 3. Finalized parameters of the extra trees classifier.

Bagging is short for bootstrap aggregating. As the name suggests, the training data used for each learner is obtained by bootstrap sampling, and the learned learner is used for prediction and the final ensemble is performed.

Bootstrap sampling is a method of resampling by randomly extracting some data from the population while allowing overlaps when there is data to be used as a population.

Ensemble learning in machine learning is a method of generating a single learning model by fusing multiple models (learners). A feature of Extra-Trees learning is that each tree is trained without bootstrap sampling, that is, without resampling by randomly extracting some data from the population while allowing for duplication. Use all data. Let it learn from all the data. Table II shows the parameters for Extra Trees learning processes. After the above mentioned hyperparameter tuning, the Extra Trees Classifier is finalized as shown in Fig. 3. Accuracy was specified as an optimization metric. Accuracy improved after 100 trials, but there is no guarantee that the parameters are optimal because they are optimized by random grid search.

Because it is simple, processing speed is very high, and the classification accuracy is better than Random Forest, a representative machine learning library for Python. The Extra Trees Classifier when using scikit-learn looks like this: When you think of machine learning, you might think of using complex formulas or something that seems difficult, but with scikit-learn you can try out machine learning very easily.

The learning curve of the Extra Trees Classifier is shown in Fig. 4(a) while the validation curve is shown in Fig. 4(b), respectively.

N-fold cross validation with shuffle and stratification (for classification tasks). Different hyperparameters for each algorithm were checked during the training. For binary classification the Area Under ROC Curve (AUC) metric was used. Table III shows the results of the n-fold cross validation while Fig. 5 shows the AUC.

Also, confusion matrix of the Extra Trees Classifier is shown in Fig. 6. In the Fig. 6, the number of “Good” samples is 17 while the number of “Bad” samples is 19. Of the 180 training data, 20% are used as validation data, so there are 36 validation data. Of the 36 cards, 17 are 0: good and 19 are 1: bad. All good answers were correct (17 0), and three bad answers were incorrect (3 16). It is such a confusion matrix.

Fig. 6. Confusion matrix of the extra trees classifier.

#### IV. CONCLUSION

A method for hyperparameter tuning of image classification with PyCaret is proposed. The application example compares 14 classification methods and confirms that Extra Trees Classifier has the best performance among them, AUC=0.978, Recall=0.879, Precision=0.969, F1=0.912, Time=0.609 bottom. The Extra Trees Classifier produces a large number of decision trees, similar to the random forest algorithm, but with random sampling of each tree and no permutation.

This creates a dataset for each tree containing unique samples, and from the ensemble set of features a certain number of features are also randomly selected for each tree. The most important and unique property of the Extra Trees Classifier is that the feature split values are chosen randomly. Instead of using Gini or entropy to split the data to compute locally optimal values, the algorithm randomly selects split values.

This makes the tree diverse and uncorrelated, i.e. the diversity of each tree. Therefore, it is considered that the classification performance is better than other classification methods. Parameter tuning of Extra Trees Classifier was performed, and training performance, test performance, ROC curve, accuracy rate characteristics, etc. were evaluated.

#### FUTURE RESEARCH WORKS

Further investigations are required to identify alternative prediction methods that may lead to more accurate results.

#### ACKNOWLEDGMENT

The authors would like to thank to Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda of Saga University for their valuable discussions.

She is currently working on applied AI research in the fields of education.

# A Novel Artifact Removal Strategy and Spatial Attention-based Multiscale CNN for MI Recognition

Duan Li, Peisen Liu, Yongquan Xia

School of Computer and Communication Engineering, Zhengzhou University of Light Industry, Zhengzhou, Henan, China

**Abstract**—The brain-computer interface (BCI) based on motor imagery (MI) is a promising technology aimed at assisting individuals with motor impairments in regaining their motor abilities by capturing brain signals during specific tasks. However, non-invasive electroencephalogram (EEG) signals collected using EEG caps often contain large numbers of artifacts. Automatically and effectively removing these artifacts while preserving task-related brain components is a key issue for MI de-coding. Additionally, multi-channel EEG signals encompass temporal, frequency and spatial domain features. Although deep learning has achieved better results in extracting features and de-coding motor imagery EEG (MI-EEG) signals, obtaining a high-performance network on MI that achieves optimal matching of feature extraction, thus classification algorithms is still a challenging issue. In this study, we propose a scheme that combines a novel automatic artifact removal strategy with a spatial attention-based multiscale CNN (SA-MSCNN). This work obtained independent component analysis (ICA) weights from the first subject in the dataset and used K-means clustering to determine the best feature combination, which was then applied to other subjects for artifact removal. Additionally, this work designed an SA-MSCNN which includes multiscale convolution modules capable of extracting information from multiple frequency bands, spatial attention modules weighting spatial information, and separable convolution modules reducing feature information. This work validated the performance of the proposed model using a real-world public dataset, the BCI competition IV dataset 2a. The average accuracy of the method was 79.83%. This work conducted ablation experiments to demonstrate the effectiveness of the proposed artifact removal method and SA-MSCNN network and compared the results with outstanding models and state-of-the-art (SOTA) studies. The results confirm the effectiveness of the proposed method and provide a theoretical and experimental foundation for the development of new MI-BCI systems, which is very useful in helping people with disabilities regain their independence and improve their quality of life.

**Keywords**—Motor Imagery (MI); Brain Computer Interface (BCI); EEG signal; artifact removal; spatial attention; Convolutional Neural Network (CNN)

## I. INTRODUCTION

Brain-computer interfaces (BCIs) have the capability of translating brain activity signals into commands to control external devices or communicate with the external environment [1]. One of the most common paradigms of BCIs is motor imagery (MI), which involves mentally simulating motor commands of specific body parts. The generation of MI signals is possible even in the presence of disabilities as the

corresponding brain region is functioning properly. MI-BCIs have shown promising results in areas such as communication, control and rehabilitation [2-7]. Electroencephalography (EEG) is widely used for MI-BCI systems due to its convenience and low physical and psychological stress on the subject [8]. However, EEG signals can be affected by environmental factors, which can generate artifacts. The background noise will distort the signal of interest and consequently reduce the MI recognition accuracy. In recent years, deep learning has gradually received attention for MI recognition. However, extracting appropriate spatial and temporal information from EEG signals has always been a significant challenge, whether in deep learning or traditional studies.

Due to the fact that EEG signals are collected by electrodes in contact with the scalp, the signal-to-noise ratio of the EEG is relatively low. During the acquisition process, the EEG signals are easily contaminated by various factors, resulting in artifacts in the signal, such as eye movements, muscle movements and electric line noise [9,10]. Therefore, some studies exploring different types of artifact features and removal methods have achieved certain results. Independent component analysis (ICA) [11] is a widely used method for artifact removal in MI recognition. ICA can separate a specified number of components from the input signal. Typically, experienced researchers identify and exclude the components that are considered artifacts and then the remaining components are used to reconstruct the signal for further analysis. This approach has achieved some success in various studies [12-14]. However, classifying components extracted by ICA will require much time and effort from professionals, which is not feasible for large datasets. Therefore, the automatic classification of ICA components has been proposed in some literature. For example, Hesam et al. [15] used three features-based K-means clustering methods to automatically cluster and differentiate artifacts from brain states in ICA components, achieving a 3.95% accuracy improvement on the Physionet dataset. However, there is still a lack of effective exploration of different feature methods and the impact of different features on clustering is not yet clear. Therefore, further research in this area is necessary.

Traditional convolutional neural networks extract and learn features through convolutions. In contrast to the two-dimensional convolutions commonly used in image applications, one-dimensional convolutions are often employed in MI-related research to capture temporal information and electrode information from EEG signals. For example, well-known models such as EEGNet [16] and DeepConvNet [17], utilize one-dimensional convolutions to extract

information from the signals. Recently, the TS-SEFFNet [18] also incorporates one-dimensional convolutions with multiple scales, which has been proven to be effective. The multi-scale module can effectively concentrate on multiple dimensional information. How to improve the useful multi-dimensional features and suppress useless information is a key issue for MI recognition. Attention mechanism [19], after its proposal in 2014, which has been widely used in both the computer vision (CV) [20] and natural language processing (NLP) [21] fields, provides an efficient way for multiple channel EEG recognition. The Attention mechanism mainly focuses limited attention on important information, thereby saving resources and quickly obtaining the most relevant information. There are three main types of attention models for multi-channel EEG: spatial attention, channel attention and a combination of spatial and channel attention [22]. Spatial attention pays attention to specific regions within the spatial domain, allowing the model to prioritize important spatial information. Channel attention assigns different weights to different channels based on their attention values, facilitating the model to focus on important channel-wise features. However, in MI-BCI research, constructing a robust CNN is still a challenging problem. The utilization of various modules in the network structure still requires exploration.

In this paper, a novel features selection ICA and K-means-based automatic artifact removal method and an end-to-end CNN that includes multi-scale convolutions and spatial attention mechanism were proposed to overcome the problem of low classification accuracy and enhance the network's robustness. It is well known that the artifacts can lead to the acquisition of task-irrelevant features by subsequent classifiers, resulting in a decrease in classification accuracy. Therefore, this work proposes an automatic artifact removal method that combines ICA and clustering algorithms. For the subsequent network architecture, this work introduces a modularized network called SA-MSCNN. It utilizes multi-scale block and spatial attention modules to extract different types of information. The method takes into account the deep network's ability to learn different features from the data and offers a novel approach for classifying motor imagery. This work evaluates the performance of the proposed method using 5184 trials with 22 EEG channels from nine subjects in the BCI-IV-2a dataset.

The remainder of this paper is organized as follows. Section II introduces the method for this study which includes the proposed artifact removal method and SA-MSCNN. In Section III, this work introduces the dataset and the evaluation metrics used in this work. And also describes preprocessing steps, experimental parameter settings and the experimental results. Section IV is the discussion and Section V concludes the paper.

## II. METHOD

This section describes the method this work proposed in this paper. First, this work gives an overall framework of the proposed method and a brief introduction to the workflow. Then, this work describes in detail the proposed ICA+K-means artifact removal method and the SA-MSCNN. Finally, this work shows the training strategy for the proposed network.

### A. Overall Framework

The proposed method is shown in Fig. 1. This work first pre-processed the data for all subjects and then performed artifact removal using the proposed ICA+K-means method. For each subject, this work pre-trained the proposed Spatial Attention-based Multi Scale Convolution Neural Network (SA-MSCNN) using data from all the subjects except the specific subject, then saved the SA-MSCNN's weights. Finally, the SA-MSCNN model was trained and adjusted by the specific subject data (on the right side of Fig. 1) and the following experiments were performed to obtain the classification results for comparison.

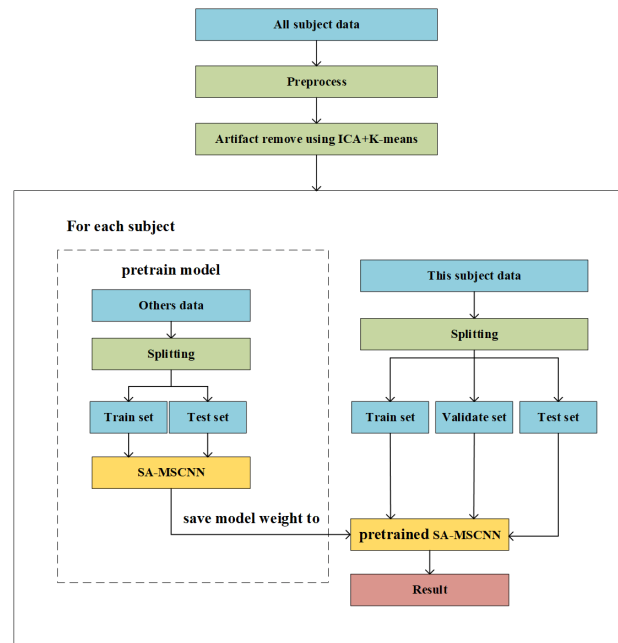

Fig. 1. Block diagram of the proposed framework.

### B. Artifact Removal using ICA+K-means

Independent Component Analysis (ICA) is a statistical method used for signal processing and data analysis. It is widely used in MI to remove artifacts from EEG signals [23]. Unlike other traditional signal analysis methods such as Principal Component Analysis (PCA), ICA emphasizes the independence rather than the correlation of the signals. ICA decomposes signals according to Eq. (1) and (2).

$$\mathbf{X}_{m \times n} = \mathbf{A}_{m \times m} \mathbf{Y}_{m \times n} \quad (1)$$

$$\mathbf{Y}_{m \times n} = \mathbf{W}_{m \times m} \mathbf{X}_{m \times n} \quad (2)$$

Where X is the input EEG signal, A represents the mixing matrix, Y represents the original signal sources and W represents the inverse matrix of A. Here, m and n represent the number of EEG channels and the number of samples, respectively. The objective of the ICA algorithm is to find the weight matrix W that will decompose the EEG signals into ICs assuming temporal and spatial independence. Most artifact ICs in MI EEG signals are caused by eye movements, muscle movements and electric line noise [9, 10]. Traditionally, manual observation of ICs are used to differentiate artifact

components from brain-related components and then remove the artifact components. This approach is feasible for datasets with a small number of subjects or a small amount of data for each subject. However, with the recent development of EEG measurement devices and experimental paradigms, large datasets like OpenBMI have emerged [24]. As the amount of data in the dataset increases, the manual selection of ICs becomes cumbersome and time-consuming. Therefore, the development of automated methods for ICs selection is necessary.

To address the above-mentioned issues, Hesam et al. [15] proposed using the K-means clustering method for component selection on extracted ICs from datasets including Physionet. They extracted three specific features from ICs and performed clustering, designating the class with the highest variance as the artifact class, and removing the components in that class. However, they only considered three specific feature selections and did not demonstrate the clustering results. Moreover, they did not explore the impact of different feature selections and multi-class datasets on K-means clustering from a broader perspective. Therefore, this study focuses on studying the impact of different feature selections on K-means clustering using representative datasets such as BCI-IV-2a. It provides recommendations for feature combinations and presents brain maps and ablation experiments after clustering. The seven selected statistical measures are variance, covariance, inverse covariance, correlation coefficient, kurtosis, skewness, and quartile range. Since the extracted ICs are vectors of certain lengths, these seven statistical measures can extract corresponding features of the ICs, as shown in Eq. (3) to (9) for their extraction method.

$$\sigma^2 = \frac{\sum (Y_i - \mu)^2}{n} \quad (3)$$

$$Cov(Y_i, Y_j) = E(Y_i, Y_j) - E(Y_i)E(Y_j) \quad (4)$$

$$invCov(Y_i, Y_j) = Cov(Y_i, Y_j)^{-1} \quad (5)$$

$$p = \frac{Cov(Y_i, Y_j)}{\sigma_{Y_i} \sigma_{Y_j}} \quad (6)$$

$$Kurt = \frac{\frac{1}{n} \sum_{i=1}^n (Y_i - \mu)^4}{\sigma^4} \quad (7)$$

$$Skew = \frac{\frac{1}{n} \sum_{i=1}^n (Y_i - \mu)^3}{\sigma^3} \quad (8)$$

$$IQR = Y_{75\%} - Y_{25\%} \quad (9)$$

Where  $\sigma^2$  represents variance,  $Cov$  represents covariance,  $E(A, B)$  represents the expected value of a function involving two random variables,  $A$  and  $B$ , with their respective probability distributions,  $invCov$  represents inverse covariance,  $p$  represents correlation coefficient,  $Kurt$  represents kurtosis,  $Skew$  represents skewness, and  $IQR$  represents interquartile range.  $Y_i$  represents the  $i$ -th sample,  $\mu$  represents the sample mean,  $n$  represents the total number of samples, and  $Y_{75\%}/Y_{25\%}$  represents the values at the 75th/25th percentile when the data is sorted in ascending order.

K-means is an unsupervised clustering algorithm where the parameter "K" in its name is set by the user to determine the number of clusters in the final result. The K-means algorithm iteratively maximizes the similarity among data points within each cluster while minimizing the similarity between clusters until the cluster centers no longer change or the predetermined number of iterations is reached. The most commonly used similarity measure is distance, such as Euclidean distance or Manhattan distance. The choice of K significantly impacts the clustering result and therefore, K-means clustering may converge to a locally optimal solution.

The different feature combinations for K-means algorithm will result in different clustering results. How to select optimal features for the automation of artifacts ICs identification is a key issue. Therefore, this study explores the different combinations of the aforementioned seven features and then adaptively achieves the best clustering results for denoising. The process is illustrated in Fig. 2. First, we extract the original ICA weights from the raw EEG signals of the first subject in the dataset.

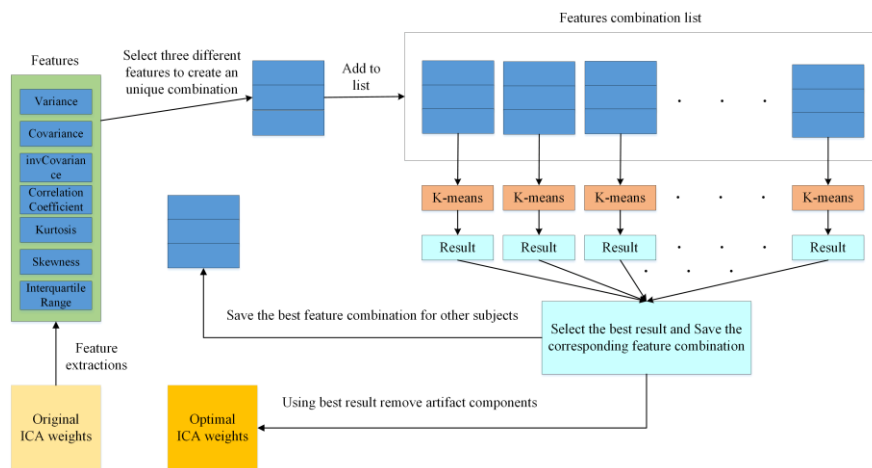

Fig. 2. Proposed ICA+K-means artifacts removal framework.

These weights are obtained by labeling the brain components and artifact components by experienced experts. Next, seven features were extracted from ICA weights. For these features, this work selects three different features to form a unique combination and then adds them to a feature's combination list. Each combination in the list is distinct from the others, resulting in a total of 35 unique feature combinations. For each combination, the K-means algorithm is used to cluster using the three combined features. Then evaluate the clustering results based on the previous labels. Finally, select the best feature combination that achieves the optimal results. This work uses the best feature combination to obtain the optimal ICA weights in the following experiments for removing artifacts from the rest subjects. The proposed method is capable of automatically removing artifacts, reducing the expenditure of time and effort.

### C. Spatial Attention-based Multi Scale Convolution Neural Network (SA-MSCNN)

The proposed SA-MSCNN is an end-to-end CNN, composed primarily of a multi scale temporal convolution block, a spatial convolution block, a spatial attention block, a separable convolution block and a classification block. The network structure is illustrated in Fig. 3.

As the 22 leads EEG data sampled at 250Hz and each sample has a length of 2.5s, the size of the sample is  $22 \times 625$ . The multi scale temporal convolution blocks and spatial convolution blocks of SA-MSCNN primarily capture the temporal and spatial features of the input EEG signals. The filters for the multi-scale temporal convolution block and spatial convolution block are set as  $[1, k]$  and  $[c, 1]$  respectively, where  $k$  and  $c$  are the lengths of the filters. Then, 2D convolution is performed accordingly. As mentioned in FBCSP [25], there may be some fluctuations in the MI frequency bands for different subjects. Therefore, to improve the classification accuracy, this work incorporates multi-scale convolutions with filters of different lengths in the temporal dimension to obtain information at different time scales. The obtained multi-scale features are then concatenated, normalized and passed through the spatial convolution blocks to extract spatial-scale information.

The subsequent Spatial Attention Block primarily utilizes the spatial attention module to obtain a refined feature map, further enhancing the model's attention and perception abilities in the spatial domain. The input feature, after undergoing max pooling and average pooling, has a shape of  $[\text{batch\_size}, \text{input\_channels}, \text{height}, \text{width}]$ . Then, a convolution operation is performed, resulting in a feature map with a shape of  $[\text{batch\_size}, 1, \text{height}, \text{width}]$ . The values of the feature map are then mapped to a range between 0 and 1 using the Sigmoid function, achieving attention weights. Finally, these weights are multiplied element-wise with the original feature map, resulting in a weighted feature map, which is referred to as the refined feature map. In traditional feature extraction networks, the features at each position in the feature map are treated equally, without considering the importance of different positions. However, in real-world scenarios, the contribution of information from different positions varies. The spatial attention module introduces different weights to each position in the feature map, allowing the network to focus more on important positions and regions. This enables the network to capture richer and more accurate feature information thus improving the overall performance. Moreover, since the spatial attention module is introduced in the middle module, it does not directly process the raw EEG signals. It only requires the intermediate weights for feature extraction, thereby almost not increasing the complexity and computational cost of the network.

The refined feature map is performed batch normalization and ELU activation. Average pooling is applied to reduce the size of the feature map, while dropout is employed to prevent overfitting of the model. Then the feature map is fed into the depthwise separable convolution block. The depthwise separable convolution consists of depthwise convolution and pointwise convolution, with filters set as  $[1, k]$  and  $[1, 1]$ , respectively. These convolutions aim to further shrink the feature map. Subsequently, batch normalization, ELU activation, average pooling and dropout are performed and the results are passed to the classification block. In the classification block of SA-MSCNN, the input features are flattened and then fed into a fully connected layer to compute the final output classification label.

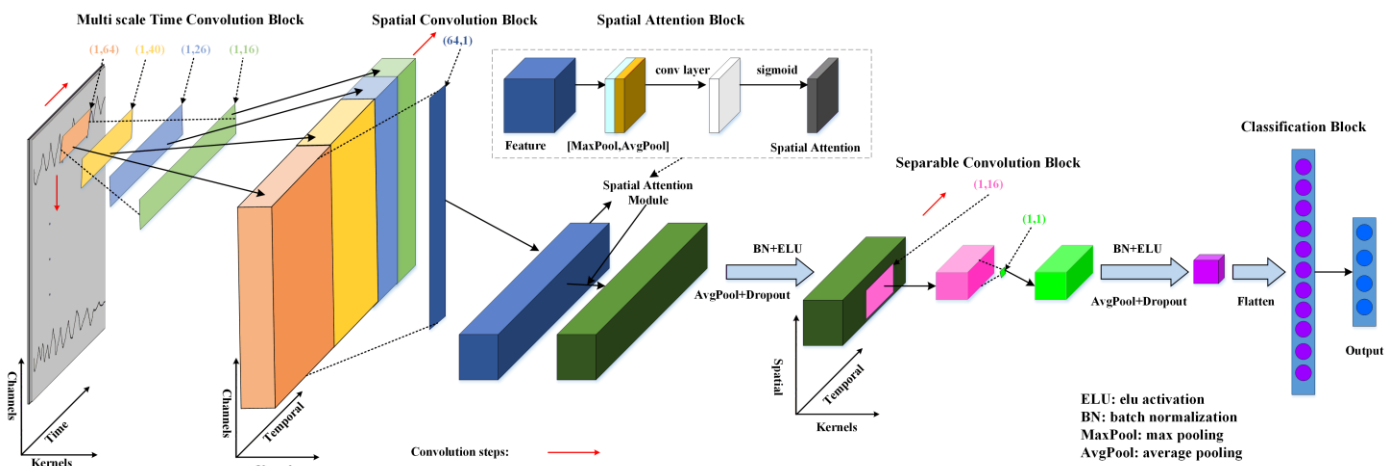

Fig. 3. Proposed SA-MSCNN architecture.

#### D. Training Strategy

For each subject, SA-MSCNN is pre-trained using data from all other subjects except the specific one and then trained, validated, and tested on the pre-trained model using the data of this specific subject. The reason for using the pre-training step is inspired by the idea of transfer learning. This training strategy aims to enable the model to learn features from the entire dataset as much as possible and increase the amount of data used for training. This allows the model parameters to converge faster when the data of the specific subject is fed into the pre-trained SA-MSCNN.

### III. EXPERIMENTS AND RESULTS

#### A. Data Sources and Evaluation Metrics

In this experiment, dataset 2a of the BCI competition IV, which contains 22 EEG channels and three monopolar EOG channels from nine subjects was used [26]. The 22 EEG electrodes were made by Ag/AgCl (with inter-electrode distances of 3.5 cm). The sampling frequency is 250Hz and bandpass filtering between 0.5Hz and 100Hz was applied when the dataset was recorded. The subjects were asked to perform four types of motor imagery tasks: left hand, right hand, tongue and both feet. Each category of the task was performed 72 times, resulting in 288 trials per session and each subject had two sessions. So, there are a total of 5184 trials in the dataset.

In this study, the performance of the proposed method was evaluated using its accuracy (represented by the symbol  $Acc$ ) and Kappa value (represented by the symbol  $Kappa$ ), defined by Eq. (10) and (11).

$$Acc = \frac{TP + TN}{TP + TN + FP + FN} \quad (10)$$

$$Kappa = 1 - \frac{1 - P_o}{1 - P_e} = \frac{P_o - P_e}{1 - P_e} \quad (11)$$

Among them, TP, FP, TN and FN are true positive, false positive, true negative and false negative respectively.  $P_o$  represents the total classification accuracy, and  $P_e$  is the sum of the product of the ground truth and predicted numbers for each category divided by the square of the total number of samples [27].

#### B. Pre-processing

In the data preprocessing stage, this work removed three EOG channels and retained 22 EEG channels to reduce their influence. MI tasks produce event-related synchronization (ERD) and event-related desynchronization (ERS) in EEG signals, corresponding to the sensorimotor rhythms of mu (8-13Hz) and beta (18-30Hz). The ERD/ERS patterns exhibit variability across subjects. Therefore, a wide-range band-pass filter of 4-40Hz was used to minimize band-pass filtering's influence on data while retaining MI-related features. For each task, the EEG data is segmented between 0 s to 2.5s after its start. Thus, each sample size is  $22 \times 625$ . No other operations are performed because this work wants to retain as much useful information as possible.

#### C. Experimental Setup

In the artifact removal stage, for the first subject, after ICA, the first two ICs were removed, and the remaining 20 components were manually classified into artifact and non-artifact categories. Then, the proposed method was used for clustering with three clusters, as the dataset consisted of four classes. The clustering results were recorded, excluding the features where artifacts and non-artifacts were clustered into the same category. The percentage of artifact ICs in the category with the most artifact ICs and the percentage of non-artifact ICs in the category with the most non-artifact ICs were recorded separately. The two percentages were added and divided by two to obtain the final clustering distinction percentage. A higher clustering distinction percentage suggests that the corresponding feature extraction method is more effective in artifact removal. For the remaining subjects, the most effective feature extraction method was applied to remove artifacts. To compare, two experiments were also conducted on all subjects: using ICA+manual artifact removal, and without using ICA for artifact removal.

ICA can be performed using the MNE package in Python [28] or the EEGLAB toolbox in MATLAB [29]. In the ICA artifact removal stage, for the first subject's ICs, the first two ICs were removed and the remaining 20 components were manually labeled as artifact and non-artifact categories. Hesam et al. [15] only used two classes of data from the Physionet dataset for their experiment and set the clustering to two classes. In this experiment, this work used a four-class dataset. Since each session for clustering involved four classes, in order to acquire more accurate clustering results, a three-class clustering approach was opted for. Then this work employed the proposed method for all the subjects using K-means clustering with three clusters. The clustering results were recorded, excluding the feature combinations where most artifacts and most non-artifacts ICs were clustered into the same category. The percentage of artifact ICs in the category with the maximum number of artifact ICs and the percentage of non-artifact ICs in the category with the maximum number of non-artifact ICs were calculated and recorded for each feature combination. The two percentages were added and divided by two to obtain the final clustering distinction. A higher clustering distinction suggests that the corresponding feature extraction method is more effective in artifact removal. For the remaining subjects, the three most effective feature extraction methods were applied to remove artifacts. To compare, the other two experiments were also conducted on all subjects: using ICA+manual artifact removal, and without artifact removal.

In SA-MSCNN, the kernel sizes for the multi-scale time convolutional blocks are set as [1,64], [1,40], [1,26], [1,16] and the kernel size for the spatial convolutional block is set as [64,1]. The depthwise separable convolution block consists of a depthwise convolution with a kernel size of [1,16] and a pointwise convolution with a kernel size of [1,1]. Each scale in the multi-scale temporal convolutional block has eight convolutional kernels, the spatial convolutional block has 16 convolutional kernels and the depthwise separable convolution block has 16 convolutional kernels. The dropout rate is set to

0.5 and the cross-entropy loss function is used. The Adam optimizer with a learning rate of 0.001 is utilized.

During the pretraining phase, for each subject, this work combined the data of the other eight subjects, totaling 4608 trials. This combined dataset was then divided into 75% for training and 25% for testing to pre-train the model parameters of SA-MSCNN. Then, the 576 trials from the current subject were divided into 50% for training, 25% for validation and 25% for testing, which were fed into the pre-trained SA-MSCNN to obtain results. Both the pre-training and training epochs are set to 200.

All the experiments were implemented on Windows 11 with an Nvidia RTX 3060 12GB GPU and the neural network was performed on the PyTorch platform.

**D. Compared Methods**

For comparison, this work also used three recent years' outstanding open-sourced models for EEG recognition including EEGNet, DeepConvNet and TS-SEFFNet.

- EEGNet [16]: EEGNet is a compact convolutional neural network specifically designed for processing EEG data. It extracts spatial and temporal features of EEG signals through one-dimensional convolutional layers and depthwise separable convolutional layers.
- DeepConvNet [17]: DeepConvNet is a model based on a deep convolutional neural network architecture used for classifying EEG signals. It employs multiple convolutional layers, pooling layers and fully connected layers to extract high-level features.
- TS-SEFFNet [18]: TS-SEFFNet is a time-frequency-based compressed and excitatory

feature fusion network used for decoding motor imagery EEG. The network utilizes a novel time-frequency compression and excitatory feature fusion method for motor imagery EEG decoding

**E. Result of Clustering**

In Table I, Feature Combination represents the selected combinations of features. NBS MaxCate corresponds to the category where most of the artifact components are clustered. NBS MaxCatePercent represents the percentage of artifact components in this category out of the total artifact components. BS MaxCate corresponds to the category where most of the brain state components are clustered. BS MaxCatePercent represents the percentage of brain state components in this category out of the total brain state components. Clustering Distinction corresponds to the clustering distinctiveness, which is equal to half the sum of NBS MaxCatePercent and BS MaxCatePercent. In Table I, kurt represents kurtosis, skew represents skewness, cov represents covariance, iqr represents interquartile range, var represents variance, inv\_cov represents inverse covariance and corr represents correlation coefficient. Three different feature extraction methods were selected from seven available methods to form a unique combination, resulting in a total of 35 combinations. Firstly, features that cluster artifact components and brain state components into the same category were excluded. Then, features with a clustering distinctiveness of less than 60% were excluded and the results are summarized in Table I. From Table I, it can be seen that the combination of kurt, skew and cov has the highest clustering distinction. Therefore, these three feature extraction methods were used in subsequent ICA+K-means automatic clustering to remove artifact components in other subjects.

TABLE I. CLUSTER RESULT OF SUBJECT 1

Feature Combination	NBS MaxCate	NBS MaxCatePercent	BS MaxCate	BS MaxCatePercent	Clustering Distinction
kurt, skew, cov	2	80%	0	86.67%	83.34%
kurt, skew, iqr	1	60%	0	86.67%	73.34%
kurt, skew, var	1	60%	0	86.67%	73.34%
inv_cov, iqr, var	0	100%	1	46.67%	73.34%
corr, kurt, cov	0	60%	1	73.33%	66.67%
corr, kurt, var	1	60%	0	73.33%	66.67%
kurt, cov, iqr	2	40%	0	86.67%	63.34%
corr, skew, inv_cov	2	80%	0	40%	60%

TABLE II. COMPARISON OF DIFFERENT EXPERIMENTS

Method	Subjects									
	A01	A02	A03	A04	A05	A06	A07	A08	A09	Avg
base model without artifacts remove	85.71%	64.86%	93.22%	69.86%	73.71%	61.33%	88.11%	81.31%	80.47%	77.62%
base model+ICA+ Manual select	89.71%	67.25%	95.9%	75.11%	77.21%	62.79%	89.25%	82.51%	83.22%	80.33%

F. Ablation Experiment of Artifact Removal Method

In this section, ablation experiments without artifacts, manual select and ICA combined K-means are performed respectively. The experimental results are summarized in Table II, the second column is the experimental results without artifact removal. The "ICA+Manual select" in the table represents the experimental results where manual observation was used to remove artifacts for all subjects. In the "ICA+K-means" experiments, the artifacts removal and optimal feature combinations for the remaining subjects were according to the first subject. The results are shown in Table II and Fig. 4.

Fig. 4. Comparison of different experiments.

In the ICA+K-means method, the first subject still required manually classifying and removing artifact components. Therefore, the experimental results for the first subject, both in terms of manual artifact removal and cluster-based artifact removal, are the same. The results for the remaining subjects are different. From Fig. 4, it can be observed that both experiments using artifact removal methods outperformed the base model, which did not include artifact removal. This result demonstrates the effectiveness of artifact removal methods. Furthermore, Table II shows that the average classification accuracy for manual identification and exclusion of artifacts is 80.33%, while the average classification accuracy for using K-means clustering to identify and exclude artifacts is 79.83%, a difference of only about 1%.

Fig. 5 illustrate the training process for the third subject using the proposed method. Train\_acc and Val\_acc represent

training and validating accuracy respectively, while Train\_loss and Val\_loss represent training and validation loss. Using the pre-training strategy, the model converges speed at a fast rate.

Fig. 5. Training process of subject 3.

G. Comparative Experiment with other Networks

EEGNet, DeepConvNet, and TS-SEFFNet are popular and excellent networks in the field of BCI decoding. From Table III, DeepConvNet achieves an average accuracy of 71.99%, EEGNet achieves 72.44% and TS-SEFFNet achieves 74.71%. By using the proposed artifact removal method and SA-MSCNN, the accuracy improves to 79.83%. Furthermore, two ablation experiments were also performed: 1) Removal of the multiscale block and the spatial attention block and 2) Removal of the artifact removal module. The results demonstrate the effectiveness of the proposed method. Fig. 6 is the confusion matrix of the four methods. The values of the matrix have been normalized by rows.

As can be seen in Table III, the proposed method outperforms these comparative methods in terms of both average classification accuracy and Kappa value. This work also conducted ablation experiments to compare and prove the effectiveness of the method, both SSA-MSCNN with multi-scale convolutional block and spatial attention block and ICA+K-means artifact removal method can improve the performance of the model. In Fig. 6, the classification accuracy of the method is improved on all four classes, especially on the left and right hands.

TABLE III. COMPARISON OF OTHER METHODS

Method	Subjects' Acc										Kappa
	A01	A02	A03	A04	A05	A06	A07	A08	A09	Avg	
DeepConvNet	80.90%	52.08%	84.72%	71.18%	70.49%	55.56%	69.10%	81.94%	81.94%	71.99%	0.627
EEGNet	81.25%	50.69%	91.67%	63.89%	70.14%	59.03%	79.17%	77.98%	78.18%	72.44%	0.632
TS-SEFFNet	82.29%	49.79%	87.57%	71.74%	70.83%	63.75%	82.92%	81.53%	81.94%	74.71%	0.663
SA-MSCNN without Multiscale Block and Spatial Attention Block	83.23%	61.07%	82.53%	65.23%	70.28%	57.47%	84.90%	78.16%	75.73%	73.18%	0.642

#### IV. DISCUSSION

From the clustering results in Fig. 7, it can be seen that the combination of features (kurtosis, skewness, and covariance) can effectively cluster brain state components and non-brain state components into different clusters. The brain states within the red box are labeled as artifacts. However, in Cluster 2, two brain state components are still clustered together with artifacts. From the characteristics of these brain states, except for the central region of activation, the other regions of these two components are relatively inactive, that is similar to other artifact components in this category. This suggests that these two components may have some similarity in their features, resulting in clustering with artifacts. In the ablation experiment in Table I, the method of clustering and artifact removal using kurtosis, skewness and covariance features still achieves good average accuracy compared to not using this method. This proves that the selected features are still applicable to the remaining subjects. Compared to manually removing artifacts from nine subjects' ICs, the ICA+K-means method eliminates the time-consuming process of manually screening and removing artifact components for all subjects while achieving a performance loss of less than 1% in average accuracy. This is crucial for large datasets with many subjects and sessions. Manual identification and removal of ICs for each subject would be time-consuming and inefficient in large datasets. On the other hand, the automated process of the ICA+K-means method can quickly and accurately remove artifacts, saving significant labor and time costs.

As shown in Fig. 8, this work also performed a feature visualization of the comparison experiment. This was done by performing parameter extraction prior to the final classification of each network and then visualizing it via the t-SNE method. Different colors represent different parts of the motor imagery being performed: green for the left hand, purple for the right hand, blue for the tongue, and red for the feet. Different colors are used to distinguish the visualization results in order to represent them more intuitively. The visualization results of the proposed method have a smaller intra-class spacing than the other methods. This is consistent with the previous experimental results in Table III.

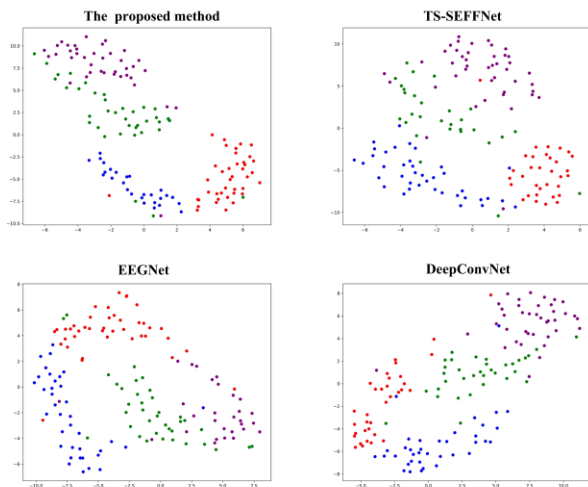

Fig. 8. Visualization results of comparison experiments.

EEG signals primarily require the extraction of temporal and spatial information. Previous studies have demonstrated that different people show specific electrical signal patterns in a certain range of frequency bands when imagining the same motor imagery task. However, the specific frequency bands may vary across individuals. Therefore, similar to the FBCSP approach, this study employs filters at multiple scales to capture temporal information, aiming to mitigate the impact of individual differences on temporal information extraction. For spatial information extraction, instead of electrode selection employed in some studies [30-34], the proposed method utilizes a spatial attention strategy after performing spatial convolution to automatically allocate weights to feature maps. The reason for this choice is that the dataset itself only has 22 EEG channels and performing electrode selection would result in the removal of some channels, which could have a negative impact on the result, especially in datasets with limited channels. To make full use of the feature maps, the proposed method utilizes spatial attention to automatically allocate weights to them. The results of the ablation experiment in Table III confirm the effectiveness of the multi-scale block and spatial block.

In addition to the above high-performance models, this work has also investigated some methods from recent MI-BCI studies that use the same dataset. Wang et al. [35] proposed an unsupervised domain adaptation framework called Iterative Self-training Multisubject Domain Adaptation (ISMDA) for the offline MI task, achieving an average classification accuracy of 69.51%. Liu et al. [36] proposed a SincNet-based hybrid neural network (SHNN) for MI-based BCIs to improve information utilization, achieving an average classification accuracy of 74.26%. She et al. [37] proposed an improved domain adaptation network based on Wasserstein distance, which utilizes existing labeled data from multiple subjects (source domain) to improve the performance of MI classification on a single subject (target domain), achieving an average classification accuracy of 77.6%. Fang et al. [38] proposed a fusion method combining Filter Banks and Riemannian Tangent Space (FBRTS) in multiple time windows to obtain more robust features, achieving an average classification accuracy of 77.7%. The comparative results are shown in Table IV.

TABLE IV. COMPARISON OF RECENT STUDIES

Method	Acc
ISMDA <sup>[35]</sup>	69.51%
SHNN <sup>[36]</sup>	74.26%
domain adaption network based on Wasserstein distance <sup>[37]</sup>	77.6%
FBRTS <sup>[38]</sup>	77.7%
Ours	79.83%

The optimal best feature combination used in this study achieved high performance on the BCI-IV-2a dataset. However, different datasets may have different parameters such as the number of electrodes, the number of subjects and the task types [39-41]. Therefore, when applying the proposed method to other publicly available datasets, parameters used in the experiment, such as the optimal feature combination, the

number of training epochs for the network and the number of clusters for clustering should be adaptively adjusted further. Since deep neural networks require a large amount of data for training, some data augmentation or other methods may be required by the experimenter to avoid model overfitting if the method is to be reproduced on a smaller dataset. Moreover, the performance of the model can be further improved if more useful features are provided and optimal parameters are searched. However, as the number of features increases, combining and selecting them self-adaptively for a specific subject will be discussed in future work.

## V. CONCLUSION

This study proposes a multi-scale CNN with a novel artifact removal strategy and spatial attention module for motor imagery recognition. By appropriately combining the selected features, it automatically removes artifacts using clustering algorithms on the components extracted by ICA, while ensuring high classification accuracy. The multi-scale convolutional blocks in SA-MSCNN, composed of different kernel sizes, extract multi-scale semantic features from the raw EEG data for classification purposes. The feature maps are then refined using a spatial attention module. The dense layer obtains the final classification results. To validate the effectiveness of this framework, the model has been applied to the BCI Competition IV-2a dataset. Compared to other existing excellent algorithms, this algorithm shows a significant improvement in classification accuracy. Experimental results demonstrate that this algorithm achieves high classification accuracy with an average accuracy of 79.83%. The current framework exhibits good classification performance and generalization. Compared to widely used EEGNet and DeepConvNet, the average classification accuracy improves by 7.39% and 7.84%, respectively. Compared to the newer state-of-the-art TS-SEFFNet, it achieves average classification accuracy improvements of 5.12%. This work also compares it with other recently published methods and the result shows the competitiveness of the proposed method. The proposed model can extract more effective features from EEG signals. This work contributes a novel method for automatic EEG artifact removal and an effective deep-learning model. It can be used to design efficient and accurate MI-based brain-computer interface frameworks to assist individuals with disabilities.

## ACKNOWLEDGMENT

The work was supported by the Science and technology key project of Henan Province (232102210017).

**Abstract**—The work of the Ophthalmologist in manually detecting specific eye related disease is challenging especially screening through large volume of dataset. Deep learning models can leverage on medical imaging like the retina Optical Coherence Tomography (OCT) image dataset to help with the classification task. As a result, many solutions have been proposed based on deep learning-based convolutional neural networks (CNNs). However, the limitations such as inability to recognize pose, the pooling operations which affect resolution of the featured maps have affected its performance in achieving the best accuracies. The study proposes a Capsule network (CapsNet) with contrast limited adaptive histogram equalization (CLAHE) and Fast Fourier transform (FFT), a method we called Stacked Fast Fourier Transform-CapsNet (SFFT-CapsNet). The SFFT was used as an enhancement layer to reduce noise in the retina OCT image. A two-block framework of three-layer convolutional capsule network each was designed. The dataset used for this study was presented by University of California San Diego (UCSD). The dataset consists of 84,495 X-Ray images categorized into four classes (NORMAL, CNV, DME, and DRUSEN). Experiment was conducted on the SFFT-CapsNet model and results were compared with baseline models for performance evaluation using accuracy, sensitivity, precision, specificity, and AUC as evaluation metrics. The evaluation results indicate that the proposed model outperformed the baseline model and state-of-the-arts models by achieving the best accuracies of 99.0%, 100%, and 99.8% on overall accuracy (OA), overall sensitivity (OS), and overall precision (OP), respectively. The result shows that the proposed method can be adopted to aid Ophthalmologist in retina disease diagnosis.

**Keywords**—Capsule network; convolution neural network; medical imaging; optical coherence tomography

## I. INTRODUCTION

The concept of identifying specific medical conditions in the human body through the analysis of medical images to establish basis for the existence and growth rate of a particular disease can be very tedious and stressful. As a radiologist, one is confronted with the burden of finding and interpreting extracted features from medical images to diagnose and monitor different kinds of diseases associated with human body [1-3]. Human beings in our nature are not only slow in processing medical images but are prone to errors especially when stressed out. Considering a sensitive area like medical field, a wrong diagnose can be quite expensive as its

implications can lead to unexpected consequence [4]. As a result, the attention of many researchers has been diverted into finding a substantive solution to assist the radiologists to deal with the complications confronted on daily bases as part of their work [1]. Computer aided models can help but the major challenge has been selecting the right method and acquiring good performance such as high prediction accuracy, achieving low runtime and low computational cost [5-12].

The introduction of deep learning (DL) brought a promising breakthrough especially in the field of medical science. The Artificial Neural Networks (ANN) [13-14] and Convolutional Neural Networks (CNN) [15] which are DL techniques became the most predominantly employed methods in identifying and diagnosing anomalies using radiological imaging technologies. However, both the ANN and the CNN have their benefits and limitations which usually affect performance of the model. They both require huge dataset for efficient training of models and increasing the image resolution adds up to number of trainable parameters which affects runtime and computational cost of the model [16]. According to Noord, and Postma, [17] ANN is not flexible and does not allow for easy customization of the model. Moreover, ANN also has deficiency with diminishing and exploding of gradient [17]. The CNNs framework gained more attention as a result of the high performance it can offer and its flexibility to use. The enormous computer-aided algorithms providing state-of-the-art early disease detection results for the medical imaging diagnosing tasks have depended on the building blocks of CNNs for most of the models produced [18].

However, the million unanswered yet important question is whether CNN models truly generalize. According to Gu, [19], a well-trained CNN model is still prone to adversarial attack as the network can easily be fooled by images that are carefully designed with imperceptible perturbations. According to Xi et al., [20], the CNNs face two major challenges which are lack of rotational invariance and failure to consider the spatial orientation hierarchies between features of the image. CNNs therefore, require huge dataset with different poses for same images, if one wants to achieve high performance for such classification model.

In an attempt to address these challenges, Hinton et al., [21] introduced novel type of neural network known as the capsule network (CapsNet). Sabour et al., [22] enhanced the CapsNet

architecture by introducing the dynamic routing by agreement between capsules. The CapsNet used the routing by agreement to resolve the problem resulting from the pooling operations of the CNNs which affects the resolution of the feature maps. Again, the CapsNet employed what is known as the reconstruction regularization to recognize the spatial hierarchical relationships among the entity parts. Moreover, since the CapsNet is equivariant in nature, it does not require huge dataset or data augmentation like rotation and scaling during training and testing also, adversaries' attacks such as the imperceptible pixel perturbation of the CNNs is also addressed by the CapsNet.

The study therefore adopts the CapsNet to classify retina optical coherence tomography (OCT) images due to the many advantages it offers over the other DL models. The study reconstructs the CapsNet architecture to include other controlled parameters to enhance its performance significantly. To ensure effective distribution of coupling coefficient which can enhance performance accuracy and convergence, the study performs normalization using the sigmoid function [23] instead of the SoftMax [22]. The study makes the following contributions:

- Proposes new capsule networks architecture named Stacked Fast Fourier Transform capsule network (SFFT-CapsNet).
- Evaluate the proposed model on retina OCT dataset.
- Compares results of proposed model with original capsule networks and state-of-the-art deep learning models performance.
- Provides visualization of internal processing results to establish better explainability of the proposed architecture.

The rest of the study is organized in the following manner;

The Section II of the study provides insight on related works. The Section III provides the methods of the study. The Section IV presents the experimental setup and results discussion. Finally, the Section V presents conclusion and recommendation for future expansion.

## II. RELATED WORKS

Every computer vision has a simple task of performing classification on given images or objects. Deep learning models have been applied to different domains like medical field for classification task. Wang et al., [24] implemented a deep learning model for automatic detection of metastatic breast cancer. The method employed enhanced the localization task. Nithya et al., [25] implemented ANN to detect kidney disease like kidney stones. Arunkumar et al. [26] implemented another algorithm based on ANN to classify the abnormal magnetic resonance (MRI) image which was used to identify brain tumor.

According to Karri et al., [27], transfer learning was easily included in CNN architecture to train on small dataset after which the results were successfully implemented on OCT image for classification of DME and dry AMD. However, due

to the limitation of the CNNs mentioned earlier, the CapsNet [22] was introduced to provide better classification which also addressed most of the failures of the CNNs.

The performance of CapsNet has always been compared to CNNs [28] in many researches to help enhance the algorithm and architecture of the CapsNet. The results of the comparison also indicate that CapsNet also has its own challenges [29]. A major challenge identified by Sabour et al., [22] indicated that the CapsNet architecture attempted to extract features on every entity part found of the image which might not be necessary for classification task. Extracted information such as background information makes CapsNet implementation more vulnerable to misclassification [21]. The explanation given to this was that the shallow structure of the CapsNet implemented with single convolutional layer is not sufficient enough to extract only required features. Liu et al., [30] demonstrated in their article that the original CapsNet performed very poor on complex data due to insufficient convolutional layers required to extract better features to enhance performance. This conclusion was made when the original CapsNet was compared with their proposed model called the DDRM-CapsNet for performance efficiency. In their study, they modified the original CapsNet architecture to include more convolutional layers to ensure better feature extraction. The study also enhanced the dynamic routing mechanism to include two stages and changed the output vector to 24 dimensions. So, in all, the network had three standard convolutional layers, a primary capsule layer, two-digit capsule layers and three fully connected layers.

To improve the architecture of the CapsNet, many researchers attempted improving the algorithm to include new features. In the CapsNet architecture, information of each capsule is sent to the next available layers at the full magnitude of its activation value but still lacks an appropriate control mechanism for selecting discriminant features from the outputs of each layer [29]. This means in the routing mechanism, encoded information from one capsule to the next capsule layer is not filtered even if it contains background information or unwanted information that is not required for classification decision. Also, CapsNet introduced an initial logit  $b_{ij}$  in the routing Softmax function to represent the log prior probability of how tight the coupling of the initial capsule  $i$  is with capsule  $j$  which depended on location and type of two capsules. Nonetheless, the function instead transformed the logits of the coupling coefficients to what is known as concentrative values. This means background information can mistakenly be sent to the next capsule layer with very high coefficient that can impact large values for summation of the predicting vectors [23]. Hence, Zhao et al., [31] concluded in their article that the SoftMax function implemented for normalization process to ensure uniform assignment of probability values between capsules prevented fair distribution of coupling coefficients which affected the performance. In another research, Yang & Wang, [29] also proposed two different methods to address the issue of capsules obtaining high activation values. Their study also introduced Cubic-Increase Squash (CI – squash) and Powered Activation (PA) which was modification to the original version of the squash function. The study demonstrated information sensitiveness was a major reason why CapsNet was not achieving high performance with color

background images. Again, the study concluded there was the need to restrict the capsules from achieving unreasonably high distribution of activation values as it also affected the performance. As a result, Mensah et al, [32] implemented the power squash function as the original squash is susceptible to generating high activation values. The activation values of the original capsules experienced faster growth at the initial stage leading to very high generated activation values. It was therefore important to include a sparsity which constrains the capsules from achieving such high activation values so that the capsules would be able to identify distinguishing features that are of greater interest to the classification process.

Many researchers have also tried to find different means to improve the performance of the CapsNet models to resolve the issue of the information sensitiveness and the high activation values. Some focused on reengineering the CapsNet architecture while others tried to improve the algorithm [32-35]. Nguyen and Ribeiro [36] reconstructed the vector CapsNet architecture to include more convolution layers and also varied the fully connected layers to leverage better filter input images for best feature extraction and image restoration. In another study, Xiang et al. [37] developed a multi-scale capsule network for classifying images which sorted to address the shortfalls of the original CapsNet architecture. The proposed multi-stage CapsNet included structural and semantic information on the first layer. Phaye et al., [38] enhanced extraction of the discriminative feature maps by introducing dense and diverse CapsNet. Their study replaced the convolutional layer with densely connected convolutional layer to improve the performance. In another studies by Huang et al., [39], to address the issue of vanishing gradient problem, the study introduced a dense connection between every layer. The results also indicated a significant improvement of the model. Other studies also tried to introduce residual connections in their attempt to address the vanishing gradient problem [40-41]. Bhamid & El-Sharkawy, [42] also implemented a CapsNet model which allowed the primary capsule to carry information at three different image scales. Their study dealt with complex data such as CIFAR10 which the model showed a significant improvement in the classification accuracy.

The capsule architecture has been applied to many different areas where image classification was a problem. Li et al. [43] implemented a capsule network model to recognize and monitor the growth rate of the rice crops through the images captured with unmanned aerial device. According to another article by Paoletti et al. [44], a CNN-Based-CapsNet was implemented in their study to classify remotely taken hyperspectral images. A similar study was also conducted by on hyperspectral image classification [45-46]. The overall performance also indicated a promising result than using the convolutional network. The implementation of CapsNet in the area of medical imaging has also shown very promising results. Adu et al, [47], implemented Dilated CapsNet in their research on Brain Tumor Classification Also, Afshar et al, [9] implement another CapsNet model for brain tumor classification. Koresh and Chacko, [48] also implemented CapsNet noiseless image classification algorithm which was used to classify corneal optical coherence tomography (OCT) dataset.

In our studies, we look at introducing two different enhancement layers to increase the information sensitivity to enhance the performance of the model. We also replace SoftMax activation function (AF) with sigmoid AF and reconstruct the original architecture to include six convolutional layers which were as a result of best performance from different modifications.

#### A. Optical Coherence Tomography Images

The Optical Coherence Tomography (OCT) is an accepted standard clinical practice diagnostic imaging technique for diagnosing retinal diseases. The results of this method provide an OCT image with possible features enough to provide sufficient visualization for detecting if there is a change in the retinal vessels from the imprint of the OCT film. The evaluation parameter is usually to identify if there is an increase or decrease in the retina layer [26]. The OCT is usually employed to acquire very high-resolution cross-sectional images from the retina. It uses low-coherence light to capture two and three-dimensional images from optical scattering media like biological tissue. The OCT can be used to capture large number of images through which the level of deterioration of the optic nerves can be determined with time.

The method is very easy to implement and does not involve any ionizing radiation [49]. This makes it possible to differentiate between the various layers of the retina so that specific diagnose can be established based on the measurement of the retina thickness to detect a retinal disease. The OCT now serve as a baseline retinal assessment and popular choice capturing retinal image for clinical practice before therapy session is initiated [50-51]. Ophthalmologist might depend on the results of the OCT image to select a choice of treatment for their patient. Therefore, emphasis on the increasing essential role of the OCT imaging cannot be overlooked. There are so many diseases that can be diagnosed using OCT imaging. Disease like diabetic retinopathy which is as a result of damage to blood vessels of retina, Macular pucker, Glaucoma, Macular hole, Age-related macular degeneration, Drusen, Central serous retinopathy, Macular edema, Vitreous traction, and Optic nerve abnormalities other macular and other related diseases are visible to OCT images. There are many eye diseases resulting from deteriorating of these retina cells. The focus of this study is centered on classification of three major Macular diseases. According to research age is a major risk factor associated with macular disease. The common diseases that may affect the healthiness of the macula are age-related macular degeneration [AMD], choroidal neovascularization (CNV) and diabetic macular edema (DME) [50] [52-53].

#### B. The CapsNet Architecture

The concept of CapsNet was first introduced in the Transforming Auto-Encoders in 2011 by Hinton et al., [21]. In their article, it was concluded that the CNN loose valuable information such as pose and spatial relationships among features maps due to the Max pool operation. As a result, the concept of the Transforming Auto-Encoders which used capsules to encode entities instead of neuron was introduced to keep the meaningful information that could influence the output of the classification task. Nonetheless, the concept did not receive any attention until the dynamic routing by

agreement using CapsNet [22] was introduced. The CapsNet uses capsules to encode entities such that each capsule is represented as activity vector to indicate an instantiation parameter (e.g. Texture, color, angle etc.) of a specific entity. The activity vector elements encode the properties that represent the entity and their activation vector indicates a probability of pose that an instantiation feature of an entity exist within its limited domain. This means the direction of the capsules indicates detailed characteristics of the features and the length of the capsule indicates its probability of existence of different features. The CapsNet architecture can be represented as an inverse computer graphic [22]. The implementation of the CapsNet in many research have always resulted in producing high accuracy [54-55].

In its operation, the CapsNet takes input vector from the lower capsule layer and multiply them by the weight matrices and a coupling coefficient. The CapsNet is seen as an equivariant in nature and therefore is able to recognize pose such as size, position and direction as well as varieties of features that have been randomly placed. In an article presented by Lenssen et al., [56], it was indicated that the CapsNet does not only represent equivariance of the characteristics of the entity type but can also signify invariance of the existence probability. The design of the CapsNet is basically meant for classification of images through feature extraction like that of CNN. This brands the CapsNet as an efficient platform when it comes to dealing with establishing spatial relationship and dealing with hierarchical data. The meaningful information is stored at different levels of capsules and the higher the levels the greater the information they can accumulate. The various levels can be seen as lower level which represent the primary capsule and the higher level which represent the digitCapsule. The capsules become activated when certain conditions are satisfied.

Through the dynamic routing process which implements routing by agreement mechanism, each active capsule must select another capsule from the next layer that the features captured can be passed to. The process ensures that the lower-level capsules agree on a feature before it is sent to the higher-level (digit Capsule). Through the training process, each capsule is able to capture certain features or characteristics of the image and the assumption is that the capsule is activated if there are properties of the image required by the higher layer for which the capsule must respond. The routing process is a major feature in the CapsNet. Fig. 1 shows the Dynamic routing process. The dynamic routing process is implemented to update weights between capsules from one layer to next which allows characteristics or properties captured by lower node capsules to be propagated to the next suitable capsule at the upper layer. If the prediction matches the higher-level capsule's output, then the coupling coefficient for these two capsules is increased. Let  $u_i$  be the output of capsule  $i$  and its prediction from parent capsule  $j$  is expressed as:

$$S_j = \sum_i c_{ij} \hat{u}_{j|i} \quad (1)$$

A nonlinear function is used to shrink long and short vectors to 1 and 0 respectively. Eq. (2) shows the non-linear squash function.

$$v_j = \frac{\|s_j\|^2 s_j}{1 + \|s_j\|^2 \|s_j\|} \quad (2)$$

where  $s_j$  in Eq. (6) is the input vector to the  $j$ th capsule and  $v_j$  is the output vector. CapsNet adopts non-linearity squashing function on output vectors ( $v_j$ ) in each iteration [11]. This shows the likelihood of the vector between 0 and 1, which means that it squashes small vectors and maintains long vectors in the unit length.

$$\{v_j \approx \|s_j\| s_j = 0 \quad v_j \approx \frac{\|s_j\|}{\|s_j\|} \quad (3)$$

The log probabilities are updated in the routing process based on the agreement between  $v_j$  for the fact that the agreement between two vectors will be increased and have a large inner product. Therefore, agreement  $a_{ij}$  for updating the log probability and coupling coefficient is defined as:

$$a_{ij} = v_j \hat{u}_{j|i} \quad (4)$$

Capsule  $k$  in the last layer is connected with a loss  $l_k$ . This puts a big loss value on capsules with long output instantiation parameters when the entity does not exist. The loss function  $l_k$  is expressed as follows:

$$l_k = T_k \max(0, m^+ - \|v_k\|)^2 + \lambda(1 - T_k) \max(0, \|v_k\| - m^-)^2 \quad (5)$$

where  $T_k$  is 1 when class  $k$  is present, and is 0 otherwise. The  $m^+$ ,  $m^-$ , and  $\lambda$  are hyperparameters that are set before the learning process.

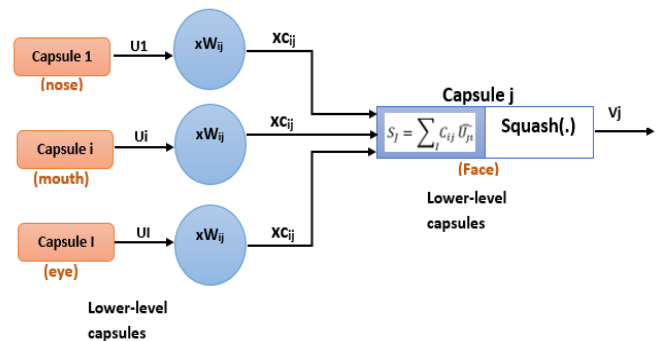

Fig. 1. Dynamic routing process.

### III. PROPOSED METHOD

The main objective of the study is to design a capsule network model that include image processing tools to ensure textural enhancement for better feature extraction to improve performance. Increasing the depth of the model too much can lead to overfitting, so the study carefully introduced two blocks of three convolutional layers through several model modifications to address the insufficiency nature of the convolutional layer in the original architecture. This was implemented while ensuring the model does not become too complex which can lead to overfitting. The study employed two different enhancement techniques. The network after reconstruction makes the model more sensitive to input image and still suppresses overfitting as we introduce a dropout technique by setting the early-stopping hyperparameter (patience) to 10 epochs if validation loss does not improve

during training to save only best models [59]. After exploring several model modifications, we arrived at the following conclusions:

- Implementation of contrast limited adaptive histogram equalization (CLAHE) technique and Fast Fourier Transform (FFT) enhancement to reduce noise in the various input images for better textural feature extraction while reducing number of trainable parameters.
- Power Squash: The study adopted the power version of the original squash function  $\|V_j\|^n \frac{V_j}{\|v_j\|}$  based on [30] [32]. The power squash is able to suppress smaller activation values (see Fig. 2).
- Sigmoid Activation: The sigmoid [23] activation function improved the distribution of the coupling coefficients leading to the overall improvement of the model performance. Even though the original CapsNet used the SoftMax function which was believed to constrain the  $C_{ij}$  within a smaller interval [31]. The goal is to acquire a coefficient that is sufficient enough to produce large values for better distribution. This way, it will be able to establish relevant features that are required by prediction vectors. Based on experimental results obtained from the different model modifications, there is a clear indicated that sigmoid activation function improved the convergence and overall accuracy of the model.
- Loss Function: The study introduced a loss function called E-swish to enhance the performance of the model instead of using existing activation function. This was an enhanced version of the original swish function. We compare the performance of our activation function with RELU and from the experimental results our function outperformed the existing baseline activation functions.

Power Squash: The study adopted the power version of the original squash function based on [29] [32]. The power squash has capability to compress short vectors to almost zero length while extending the long vectors to a value slightly below one. However, the original squash function generated high activation values for smaller  $\|s_j\|$  which intend generated very high activation values that are not sufficient to maintain high information sensitivity for the CapsNet model. Therefore, sparsity is required to constrain the capsules from achieving high activation values. Sparsity as explained by [32] is employed to differentiate and consider highly discriminant capsules that can extract required information from complex images especially ones with varied backgrounds. Fig. 2 shows the original squash function versus the suppressed small values of the power squash function. The power squash however, introduced sparsity to the model by controlling how the initial activation values are computed by the primary capsule. Therefore, for high values of  $n$ , the function experience very slow values at the initial stage and appreciated as the  $\|s_j\|$  increased. This was not the case of the original squash function which experienced a sharp increase at the initial stage as indicated in the Fig. 2.

Fig. 2. The power squash versus the original squash.

#### A. Contrast limited Histogram Equalization and Fourier Transform

The study employed Contrast Limited Adaptive Histogram Equalization and Fourier Transform techniques to enhance the contrast of textural features and spatial patterns of the various input images. The conclusion for employing the two enhancements strategy was due to the results from the best performance of many model modifications. The method ensures visibility of the features for better feature extraction. The two enhancement methods have been deployed separately in many different researches due to their flexibility in implementation with low computation work load. The contrast limited adaptive histogram equalization (CLAHE) has mostly been deployed in research to reduce noise and improve the color of the x-ray images. It works best for all biomedical images by removing noise that can lead to miss classification. Histogram equalization produces over brightness of the input image which makes it difficult for the model to identify most required patterns and hidden objects.

Therefore, the CLAHE is employed to amplify the contrast of the image and limit neighboring pixel's procedure to reduce noise on the image. On the other hand, the Fourier Transform allow for images to be represented as a sum of complex exponentials of broad range frequencies. It has been implemented successfully in image processing applications such as enhancement, restoration or compression. It's usually employed as a processing tool to decompose images into its sine and cosine components. The output can then be represented in a Fourier or frequency domain when their input images are represented in a spatial domain equivalent. The Fourier domain allows each point to represent specific frequency in the spatial domain. It is best known for proving geometric characteristics of the spatial domain image as the images are decomposed into a sinusoidal component which makes it more flexible to analyze or process.

#### B. The Dataflow Analysis of the Model

Data augmentation was done by resizing the dataset images due to varied sizes of 1024x1050, 784x950, and 800x1020. Though the amount of retina OCT dataset used in this study was small however, CapsNet does not require huge dataset for training a model compared to CNNs. Fig. 3 shows summary diagram depicting the dataflow of the model.

### C. Model Architecture

The paper proposes a capsule network named Stacked Fast Fourier Transform CapsNet (SFFT-CapsNet). Fig. 4 illustrates the proposed Stacked Fast Fourier Transform CapsNet (SFFT-CapsNet) architecture. The SFFT-CapsNet consists of two blocks of convolutional layers. The convolutional layer block 1 consists of CLAHE layers, three convolutional layers, and batch normalization whereas the convolutional block 2 consists of Fourier transform layers, three convolutional layers, and batch normalization. The model consists of a Primary Capsule layer and a classification layer (retinaCaps). The process begins with passing all the input images with the dimension of  $48 \times 48 \times 3$  through CLAHE layer and the Fourier transform layer in the two blocks. The Fourier transform and CLAHE layer are image enhancement layers and therefore does not contribute additional parameters to the model. The output feature maps are forwarded to convolutional layers followed by batch normalization layers. After the input image goes through the enhancement layers, the output feature maps from the enhancement layer will still have the same dimension of  $48 \times 48 \times 3$  as the input image.

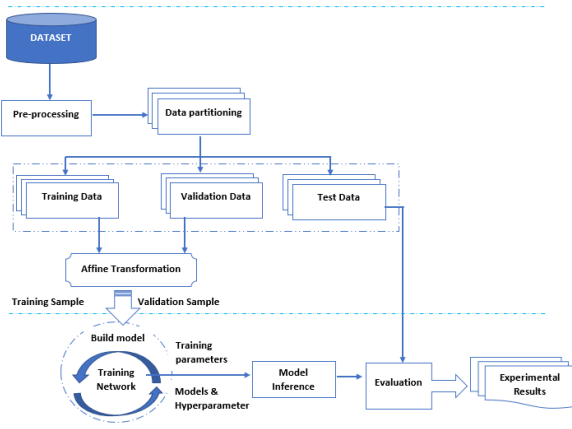

Fig. 3. Data flow diagram of the proposed model.

Fig. 4. Proposed Stacked Fast Fourier Transform CapsNet architecture.

The output  $48 \times 48 \times 3$  feature maps are sent to Block1\_Conv1 and Block2\_Conv1 with filter of 256, kernel size of  $3 \times 3$ , and stride of 2 which gives output feature map of  $24 \times 24 \times 256$ . These output feature maps are forward to the next convolutional layers which are Block1\_Conv2 and Block2\_Conv2 with the filters of 256, kernel sizes of  $3 \times 3$ , and strides of 2. This will convolve to feature maps of  $11 \times 11 \times 256$ . Again, these feature maps of  $11 \times 11 \times 256$  are sent to Block1\_Conv3 and Block2\_Conv3 with filters of 256, kernel sizes of  $1 \times 1$ , and strides of 1 to produce the feature maps of  $11 \times 11 \times 256$ . These feature maps from Block1\_conv3 and Block2\_Conv3 are concatenate to produce the feature map of  $11 \times 11 \times 512$  for the next layer. The feature maps from the feature extractions layers are forward to a PrimaryCaps with filter 256, kernel size of  $3 \times 3$ , and stride of 2 which will obtain output feature map of  $5 \times 5 \times 256$ . At the PC layer, a tensor product between  $u$  and the weights ( $W$ ) produces  $u \cdot w_j$  made up of 576 (i.e.,  $4 \times 4 \times 16$ ), 8-dimensional vectors. At the Digit Caps layer, the Recognition Caps will form  $k$ , 16D vectors, where  $k$  = number of classes. There are three fully connected (FC) layers in the decoder network consisting of 512, 1024, and 6912 neurons in the first, second, and third layers respectively.

### D. Experimental Settings

This practical aspect of the study was deployed using a Windows system with NVIDIA 394 GeForce GTX 1650 6GB GPU. The codes which used TensorFlow as the backend was implemented via Keras Libraries and python (Anaconda). Both the proposed CapsNet model (CLAHE-FT) and the original CapsNet were trained for 100 epochs respectively in order to compare their performance. The batch size of the input images was set to 32 while the learning rate was maintained at 0.0001. Through the deployment process, the study made use of the Adams algorithm with momentum as the gradient optimizer. The momentum was adjusted to 0.9 while the descent rate was set 10<sup>-6</sup>. To avoid overfitting as part of the reconstruction process, the early stopping hyperparameter thus patience was set to 10 during the training so the algorithm can only save the best model. To complement the reconstruction layer (FC) in avoiding overfitting, we set the early stopping hyperparameter; patience, to 10 during training and saved only the best model. The extracted code implemented is a modified code which is available at <https://github.com/XifengGuo/CapsNet-Keras>.

### E. Dataset

The dataset was made up of 84,495 x-ray images (jpeg) when it was downloaded from Kaggle.com. The folder contained subfolders which each contained specific category of images. In all, there were four categories of images which have been sampled into directories as Normal, CVN, DME and DRUSEN. However, the dataset had imbalance classes and since CapsNet could work with small size dataset, we decided to make it balanced for fair distribution by reducing the size of the various classes with large dataset. The images have been labeled as follows; (disease type)-(patient ID)-(image number of the patient). Again, these were OCT images that have been selected from retrospective cohorts of adult patients from institutions such as Shiley Eye Institute at University of California San Diego, California Retinal Research Foundation, Medical Center Ophthalmology Associates, Shanghai First 377

People’s Hospital, and Beijing Tongren Eye Center. It took barely four years to make such selections which were between the year 2013 and 2017. The inclusion criteria for eligible images were performed by different levels of trained and expert graders with enough experience to verify and establish correct data labels of the images into their respective classes. The first groups of graders were made up of undergraduate and medical students who had successfully passed an OCT interpretation course review.

These first graders were able to initiated quality control and excluded OCT images containing critical artifacts or significant image resolution reductions. Four ophthalmologists with a lot of experience were the second graders who independently graded the image that had passed the first grading. These second graders had a primary task of recording the present or absent of specific disease on each OCT scan. CNV, macular edema, drusen, and other pathologies which are present or absent on the OCT scan were recorded. The third group of graders consisted of two senior independent retinal specialists. Each specialist has over 20 years of clinical retinal experience, who varied the true label of the images. The Images that were imported into the database started with a label matching the recent diagnosis of the patient. The sample dataset selection is illustrated in a CONSORT-style as indicated in Fig. 5

Fig. 5. Sample retina OCT image representing different classes of images.

#### IV. EXPERIMENTAL RESULTS

This section presents the results of the proposed model used on the retina OCT image dataset. The SFFT-CapsNet model was established based on different modifications. We then compare the results to the original CapsNet by Sabour et al., [22] which has been serving as the baseline for most models in CapsNet. We evaluated the model by conducting comparative analysis on performance-accuracy with the current state-of-the-art models which have compelling efficient results on the same retina OCT dataset. This comparison is conducted to establish the best model for classification of the retina OCT images.

The study also establishes the efficiency of proposed model and its ability to generalize by comparing and visualizing the clusters formed through the routing process. An evaluation matrix such as accuracy (ACC), sensitivity (SE), precision (PR), specificity (SP), confusion matrix, receiver operating characteristic-area under ROC curve (ROC-AUC) are used to examine the performance of the models. The Precision and Recall were used to evaluate the model in order to achieve the Receiver Operating Characteristics (ROC) as well as the Precision Recall curves. The overall accuracy (OA), overall sensitivity (OS) and overall precision (OP) are also calculated. The computation of the OA for instance is by finding the average of the total accuracy scores for the four classes (CNV, DME, DRUSEN, NORMAL) from Table I as indicated in Eq.(6).

Thus,

$$OA = \frac{\text{correct classified classes}}{\text{total number of classes}} \tag{6}$$

The computation of the OS for instance is by finding the average of the total sensitivity scores for the four classes (CNV, DME, DRUSEN, NORMAL) from Table I as indicated in Eq. (7).

$$OS = \frac{\text{total sensitivity for the four classes}}{\text{total number of classes}} \tag{7}$$

The computation of the OP for instance is by finding the average of the total Precision-recall scores for the four classes (CNV, DME, DRUSEN, NORMAL) from Table I as indicated in Eq. (8).

$$OP = \frac{\text{total precision-recall for the four classes}}{\text{total number of classes}} \tag{8}$$

The results of the comparison between the original CapsNet and the SFFT-CapsNet is presented in Table I. The results indicated that the SFFT-CapsNet obtained overall accuracy of 99.0% which establishes a very high performance of the model over the original CapsNet which had an overall accuracy of 94.2% when applied to the retina OCT images. The performance of the model also indicated an overall sensitivity (OS) of 100% and overall precision of 99.8% for the SFFT as against the original CapsNet which had 94.5% and 97.0% respectively. Fig. 6 shows a histogram representing the comparison of accuracies based on the overall accuracies of OA, OS, and OP. Fig. 7 shows the validation and loss accuracy. Also, Fig 8 and 9 shows the Confusion Matrix and the ROC-AUC, respectively. Fig. 10 shows the Precision and Recall curves as applied on the dataset.

TABLE I. COMPARISON OF RESULTS OF THE SFFT-CAPSNET MODEL AND ORIGINAL CAPSNET

Method	Classes	ACC (%)	SE (%)	PR (%)	SP (%)	AUC (%)	OA (%)	OS (%)	OP (%)
Original CapsNet [22]	CNV	95.5	97.5	99.0	100	100	94.2	94.5	97.0
	DME	95.0	94.3	97.0	95.8	99			
	DRUSEN	98.8	88.2	96.0	97.6	99			
	NORMAL	87.6	98.2	96.0	98.2	97

A. Ablation Study

For every model, it is imperative to identify the various components which impacted significantly in the performance of the model. This can help to establish the robustness of our method and the various layers that contributed to improve the performance. To determine these components which impacted on the validation accuracy, an adjustment is made to the proposed architecture and its hyperparameters through several

experimental modifications to find the level of impact each component makes to the model. The results are then recorded and presented for further analysis. Table II shows the results of the ablation on retina OCT dataset. From the Table II, combination of the block-1 and the block-2 layers gave the best accuracy of 99.0% on the retina OCT dataset.

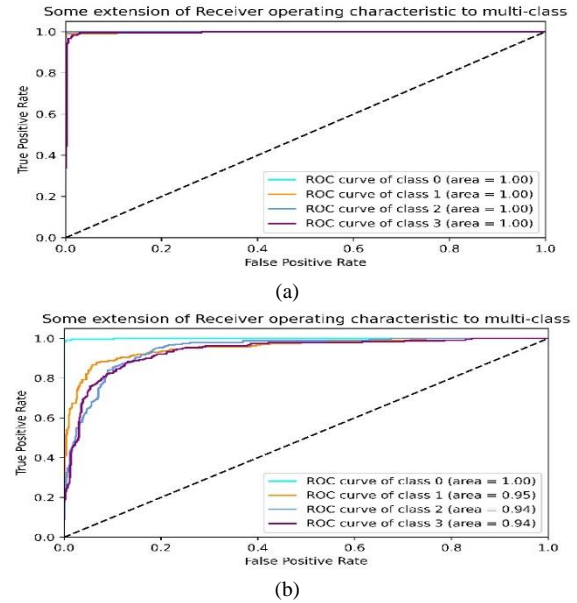

Fig. 9. Comparison of ROC-AUC on the proposed model and original CapsNet. (a) SFFT-CapsNet ROC (b) Original CapsNet ROC curve.

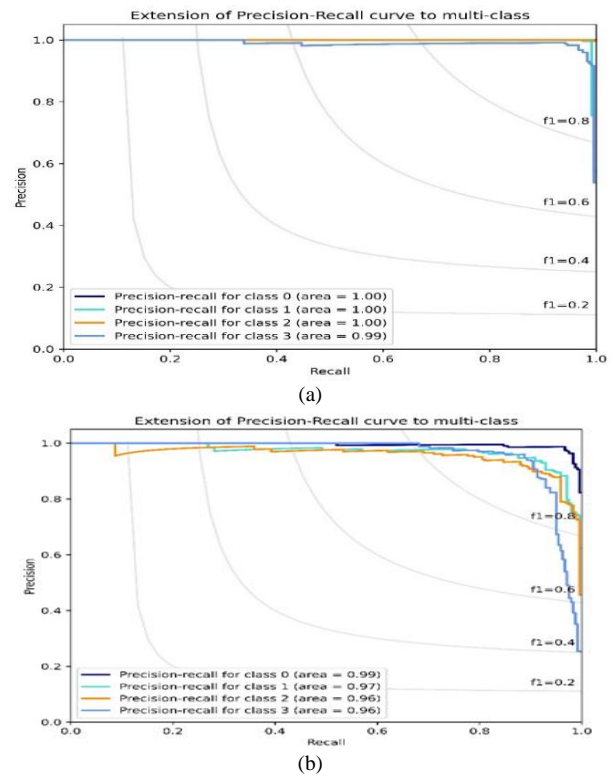

Fig. 10. Precision-recall curves comparison on the SFFT-CapsNet model and original CapsNet. (a) represents the SFFT-CapsNet Precision-Recall curve, and (b) Original CapsNet Precision-Recall curve.

TABLE II. RESULTS OF ABLATION STUDY ON SFFT-CAPSNET

No.	Layers	Number of Layers	Normalizer	Validation accuracy
1	Block-1(Conv layer)	1	SoftMax	94.22%
2	Block-1(Conv layer)	2	SoftMax	94.83%
3	Block-1(Conv layer)	3	SoftMax	95.02%
4	Block-1(Conv layer)	3	Sigmoid	95.91%
5	Block-1 (CLAHE layer, Conv layer)	1, 3	SoftMax	96.03%
6	Block-1(CLAHE layer, Conv layer)	2, 3	SoftMax	96.85%
7	Block-1(CLAHE layer, Conv layer)	2, 3	Sigmoid	97.70%
8	Block-2(FT,Conv layer)	1, 3	SoftMax	96.35%
9	Block-2(FT,Conv layer)	2, 3	SoftMax	97.52%
10	Block-2(FT, Conv layer)	2, 3	Sigmoid	98.01%
11	Block-1(CLAHE layer, Conv layer), Block-2(FT, Conv layer)	2,3, 2,3	SoftMax	98.71%
12	Block-1(CLAHE layer, Conv layer), Block-2(FT,Conv layer)	2,3, 2,3	Sigmoid	99.0%

A further analysis and evaluation were conducted by comparing our proposed SFFT-CapsNet with state-of-the-art results from other models that made use of the same retina OCT dataset. The evaluation matrix was based on accuracy, sensitivity, precision, specificity, overall accuracy, overall sensitivity, and overall precision. Table III presents the results of comparison of SFFT-CapsNet and previous works. The comparison was done considering the performance of the models on the individual classes of the retina OCT dataset. The letter “x” used in the table shows areas where the research paper failed to report the expected results for a particular evaluation metrics.

From the Table III, the best results have been highlighted in bold. The results from the Table III shows our proposed model achieved the best performance in all instances for all the classes using the ACC, SE, PR, SP, and AUC evaluation metrics. It can be observed from Table III that SFFT-CapsNet obtained OA, OS, and OP results of 99.0%, 100%, and 99.8%, respectively. This means the results from Table III concludes that the proposed model outperformed all the other state-of-the-art works compared. The second-best emanated from another work presented by Rajagopalan et al., [57] using CNN which obtained 97.0%, and 93.4%, on OA and OS. Though in their paper, the study failed to report the result for OP. The third best model with accuracies of 90.1%, 86.8% and 86.3% for OA, OS, and OP, respectively was also presented in a study known as the Lesion Attention Convolutional Neural Network (LACNN) which was proposed by Leyuan et. al. [53]. In all, the HOG-SVM model achieved the least performance with the accuracies of 78.1%, 65.3%, 460 and 71.8% on OA, OS, and OP, respectively.

Fig. 11 shows Histogram representing of the overall accuracies of OA, OS, and OP for HOG-SVM, Transfer Learning, VGG16, LACNN, IFCNN, LGCNN, CNN by Rajagopalan, and SFFT-CapsNet. Fig. 11 indicates that the

proposed model outperformed the current-state-of-art models in all the metrics tested.

TABLE III. COMPARISON OF RESULTS OF THE SFFT-CAPSNET AND THE STATE-OF-THE-ART WORKS

Method	Classes	AC C (%)	SE (%)	PR (%)	SP (%)	AUC	OA	OS	OP

Fig. 11. Histogram representing the overall accuracies of OA, OS, and OP for HOG-SVM, Transfer Learning, VGG16, LACNN, and SFFT-CapsNet.

Fig. 12 shows an evaluation of clusters generated from the raw data and the routing process. Fig. 12(a) represents the raw clustering generated from the input dataset which has no visible clusters. It can be seen that the content is scattered on one cannot observe any possible clusters. Fig. 12(b) also shows the result of the clusters acquired from using the original CapsNet and finally Fig. 12(c) also shows the clusters formed from using the SFFT-CapsNet. From the Fig. 12, it can be visualized that the Fig. 12(c) which was acquired from the proposed model produced better clustering after the routing process than the original CapsNet.

Fig. 12. Visualization of the clusters formed at the retina caps layer (a) raw dataset before routing (b) clusters formed after the routing process of the original CapsNet (c) clusters formed after the routing process of the proposed model.

This can be attributed to the fact that during the routing process, the primary capsules combine with class capsules to establish high agreement which forms better clusters at the retinaCaps layer in the SFFT-CapsNet. The various separations created by the cluster which have been indicated using different colors can be used to determine how efficient the routing process could be and hence determine the efficiency of the model.

Fig. 13. Activation maps from digit capsule and evaluation capsule of the original CapsNet and SFFT-CapsNet. (a) digit capsule activation from original CapsNet. (b) evaluation capsule activation map from original CapsNet, (c) digit capsule activation from SFFT-CapsNet, and (d) evaluation capsule activation map from SFFT-CapsNet.

Fig. 13 visualizes activation maps performance of the various layers in the original CapsNet and the proposed SFFT-CapsNet as they receive input images. From the visualization, it is observed that the activation from the SFFT-CapsNet provides enough details on how a layer extracts features from the input image to influence the final output of the model. It provides better insight on the actual operations of the CapsNet.

### B. Discussion

The study proposed SFFT-CapsNet for classification of retina OCT images. The result of the model is compared to the original CapsNet which is serving as a baseline for the study. From Table I, the results indicated that the accuracy of proposed SFFT-CapsNet outperformed the baseline model by a difference of 4.8% upon achieving accuracy of 99%. This is a very significant improvement in the field of computer vision. The outstanding performance is due to the novelty employed in the method. Increasing the convolutional layers to six was a good strategy for improving the feature extraction by the model. Secondly, the two enhancement layers introduced in the model improved visibility of hidden patterns and controlled over brightening of the images. Replacing the SoftMax with sigmoid and introducing the power squash prevented the model from generating high activating values that can prevent effective learning of features of the model. From the results of the ablation study in Table II, it can be concluded that such significant improvement was achieved because every layer we introduced strategically had significant impact on the model.

Again, the validation and loss accuracy in Fig. 7 shows that our model achieved higher performance compared to the baseline. Also, Fig. 8(a) and 8(b) show the confusion matrix of the proposed evaluated SFFT-CapsNet models against the original CapsNet. The diagonal outputs indicated in blue illustrated the correct prediction from the models (True positives and true negatives). The misclassifications generated from the model are indicated in white colors as output at the upper and bottom part of the correct predictions. Fig. 8(a) represents the confusion matrix of the SFFT-CapsNet. Fig. 8(b) on the other hand represents the confusion matrix of the original CapsNet. From the confusion matrix, the four instances of the dataset have 242 images each as test samples. The results from the confusion matrix can be concluded that the proposed model obtained the highest correct predictions thus 242, 239, 242, and 235 on CNV, DME, DRUSEN, and

NORMAL, respectively whereas the original CapsNet obtained 231, 230, 239, and 212 on CNV, DME, DRUSEN, and NORMAL, respectively. Fig. 9 presents the ROC-AUC curves and Fig. 10 illustrates the result of Precision-Recall curve. From the results, it can be deduced that the proposed SFFT-CapsNet controls misclassification better than the original CapsNet. From the output of the confusion matrix, our proposed model recorded the least misclassifications when compared to that of the baseline CapsNet. The results of the visualization in Fig. 12 are strong indication that our model is able to generalize well by learning the required features for better classification performance.

The performance of the proposed model can be associated to fact that the introduction of the two layers thus the CLAHE and Fourier transform could sufficiently reduce the noise in the input images. Also, increasing the convolution layer also enhanced the chances of the model extracting required features that could impact on the results of the model.

However, the high misclassification of the original CapsNet can be attributed to the insufficient convolutional layers to extract the required features to support the prediction and classification task. This is in line with the findings proposed by Cao et al., [63] which concluded that CapsNet is unable to perform well on complex images because the convolutional layer is not sufficient able to extract the required features which ends up including features that may not be required and can lead to misclassification.

Also, the performance of our model could compete and outperform the state-of-the-art models that have been implemented on the retina OCT dataset as indicated in Table III. The results indicate a strong confirmation that the proposed SFFT-CapsNet achieved the best performance in all scenarios of the evaluation Matrix. The performance of the CapsNet was not surprising as compared to the other methods which were implemented using CNN. This is because the CapsNet with the dynamic routing algorithm was able to recognize the pose, texture and spatial relationship which contributed to the performance of the classification model.

## V. CONCLUSION

The study proposed an efficient CapsNet architecture for classifying retina OCT images. The study reconstructed the original CapsNet to include two extra layer components thus the contrast limited adaptive histogram equalization layer and Fourier transform layer. The two layers are all image enhancement layers which presented the model with more visibility of the input images. Again, the study increased the convolutional layers to six to ensure better feature extraction and replaced the SoftMax activation function with sigmoid.

Four-class (CNV, DME, DRUSEN, and NORMAL) retina OCT image dataset presented by UCSD were used for training and testing the proposed capsule framework. Evaluations of models were conducted using evaluation metrics such ACC, SE, PR, SP, AUC on the individual Class while OA, OS, and OP to measure the overall performance of the models. The results of the proposed model were compared with that of the original CapsNet in terms of performance accuracies. A further comparative analysis was conducted using the results of the

propose model and that of the state-of-the-arts deep learning standard models that have been applied to the retina OCT image dataset.

The summary of the results has been presented in Table III. The results indicated that the proposed SFFT-CapsNet obtained OA, OS, and OP results of 99.0%, 100%, and 99.8%, respectively which were the best results in all instances compared with the other existing works. This performance indicates that the proposed technique is better in detecting eye diseases from retina OCT images. The method can be adopted to help ophthalmologists in detecting eye disease from retina OCT images. Although the proposed SFFT-CapsNet model achieved high performance compared to the state-of-the-art models, however, it was found that the model still needs improvement. As part of the future works, the study aims to propose an effective activation function that can help the convolutional layers implemented to extract better features required for the model performance. Also, the study seeks to test the final version of the model on complex images to establish the robustness of the model.

## ACKNOWLEDGMENT

The authors would like to thank the editor and the reviewers for their helpful suggestions and valuable comments.

# Deep Neural Network-based Detection of Road Traffic Objects from Drone-Captured Imagery Focusing on Road Regions

Hoanh Nguyen

Faculty of Electrical Engineering Technology, Industrial University of Ho Chi Minh City, Ho Chi Minh City, Vietnam

**Abstract**—This paper presents a novel deep learning approach for the detection of traffic objects from drone-based imagery, focusing predominantly on the rapid and accurate detection of vehicles within road sections. The proposed method consists of two primary components: a road segmentation module and a vehicle detection network. The former leverages a residual unit with skip-connections to effectively extract road areas, while the latter employs a modified version of the YOLOv3 architecture, tailored for high-accuracy and high-speed vehicle detection. To address the issue of data imbalance, which is a pervasive challenge in drone images, this paper utilizes a range of data augmentation techniques to improve the robustness of the proposed model. Experimental results on the UAVDT and UAVid datasets exhibit that the proposed model attains a substantial boost in accuracy and inference speed of vehicle detection in comparison to the existing methods. These findings underscore the potential of the proposed approach for real-world traffic monitoring applications, where rapid and reliable vehicle detection is paramount.

**Keywords**—Deep learning; drone images; vehicle detection; road segmentation; data imbalance

## I. INTRODUCTION

As drone technology has rapidly advanced in recent years, numerous practical applications based on images collected from drones have been developed. Among these, the most notable are intelligent processing applications based on images obtained from drones, such as object detection [1-2], object segmentation [3], traffic analysis [4], traffic prediction [5], and work monitoring systems [6]. Compared to ground-collected images, drone-collected images often have many more advantages, such as encompassing information from a vast area, dynamic coverage, and different altitudes and positions. Due to these benefits, processing based on drone images often faces many challenges. These challenges stem from various factors including complex backgrounds, a global perspective, and varying scales of targets. Fig. 1 describes some cases of drone images that pose many challenges for object detection and segmentation tasks. More specifically, objects in drone images are often obscured or overlap with other objects. The number of objects in drone images is usually very large, and the size of the objects in the images is often small.

Given the significant advancements in deep learning, particularly in convolutional neural networks (CNN), numerous methods have been introduced in recent years to address object detection and segmentation using drone images

and CNN. In [7], the authors propose an automatic image annotation method, analyze YOLOv3's training behavior on the natural UAVDT dataset, and demonstrate the performance that can be achieved through synthetic training, as well as how synthetic augmentation can enhance the natural training set's performance. Kyrkou et al. [8] present a comprehensive approach to developing a single-shot object detector based on CNN for UAVs, specifically focusing on vehicle detection in resource-constrained environments. The paper covers the entire development process including data collection, training, CNN architecture design, and optimizations for efficient deployment on lightweight embedded processing platforms suitable for drone images. Li et al. [9] introduced the Density-Map guided object detection Network (DMNet) as an inventive approach to tackle the complexities of object detection in high-resolution aerial photos, particularly issues related to vast differences in object size and irregular object distribution. The DMNet, which integrates a density map generation module, an image cropping module, and an object detector, uses pixel intensity to establish a subtle boundary for image cropping and to discern object scales. In [10], the authors propose a separate resampling algorithm to alter the input test images' size and subsequently extend the object's impact in deeper layers of the detection model. They utilize a pre-trained Faster R-CNN [11] object detection model with Inception-V2 [12], applying transfer learning to submeter satellite images with passenger vehicles as the target objects. In [13], the author present a novel vision-based system for vehicle detection and counting on highways, aiming to address the challenge of detecting vehicles of varying sizes. This system utilizes a novel segmentation technique to partition the highway road surface in the image into distant and near areas. Subsequently, it leverages the YOLOv3 network for vehicle detection. Recently, Feng et al. [14] suggested utilizing the mean classification score as a metric for gauging the classification accuracy of each category during training. They introduced the Equilibrium Loss (EBL) and Memory-augmented Feature Sampling (MFS) techniques to ensure balanced classification. Together, EBL and MFS notably enhance detection performance for less represented classes while either preserving or boosting performance for the more prevalent ones. In addition to the methods mentioned above, references [15-18] provide systematic reviews of object detection and segmentation methods based on drone images.

While the aforementioned methods have achieved certain successes, there remain numerous issues that need to be

addressed to construct an effective model for object detection based on drone images. This paper introduces a proficient model for detecting objects in drone images. Aiming to provide efficient data for intelligent traffic monitoring applications, the model proposed in this paper performs vehicle object detection based on regions of interests (RoIs) rather than on the entire image. Detecting objects based on RoIs helps to eliminate unrelated areas during processing, not only increasing the model's accuracy but also significantly enhancing execution speed, particularly for high-resolution images obtained from drones. To efficiently create RoIs, specifically road sections, this paper proposes applying a segmentation model for road detection. Based on extracted road sections, a method is proposed to enhance both the accuracy and inference speed of vehicle detection from road sections. Moreover, in response to the widespread issue of data imbalance often encountered in drone imagery, this paper applies an assortment of data augmentation strategies aimed at enhancing the resilience and reliability of the proposed model. Finally, this paper also proposes using suitable models and datasets that meet the requirements.

The paper is organized as follows: Section II delves into the details of the proposed methodology. Section III presents the results derived from the framework's implementation. Finally, Section IV concludes the paper and highlights potential avenues for future research.

Fig. 1. Some images illustrate the challenges of object detection and segmentation tasks with images from drones.

## II. METHODOLOGY

### A. Overview of the Proposed Method

Fig. 2 illustrates the overall structure of the model proposed for the problem of road traffic object detection from drone images. Aiming at detecting objects on the road, specifically vehicles, with high inference speed to provide real-time information for road management systems, a deep learning network is first used for road detection and segmentation. Extracting the road sections helps the model focus on detecting objects on the road, thereby not only significantly increasing the inference speed of the overall model but also improving accuracy. The input to this deep learning network is the input images, and the output is the predicted road sections. Based on the extracted road sections, a deep learning network based on the YOLOv3 architecture is designed for object detection, specifically vehicles on the road. Using a vehicle detection model based on the YOLOv3 architecture significantly

improves the model's inference time, especially with images obtained from drones where the number of objects on the road is considerable. Additionally, the paper also proposes using data augmentation strategies to address issues related to data imbalance often encountered in drone imagery. Details about each proposed network will be presented in the following sections.

### B. Road Segmentation

This paper approaches road segmentation in images as a binary segmentation task, classifying each pixel in the input image as either part of the road or the background. Several models have been proposed for segmentation, such as UNet [19], Segnet [20], DeepLabv3+ [21], or the more recent DoubleUNet [22]. These models typically combine an encoder for feature extraction with a decoder for segmentation. The encoder is critical in extracting features, capturing contextual information, reducing dimensionality, creating a hierarchical representation, and making use of transfer learning. Conversely, the decoder is responsible for upsampling, reconstructing the feature maps, refining the segmentation output with contextual information, applying non-linear mappings, and generating the final segmentation output through multi-level feature fusion and skip connections. In pursuit of high accuracy and fast inference speed, this paper proposes the use of the ResNet50 model [23] as the encoder and a combination of residual blocks and other operations [24] as the decoder, as depicted in Fig. 3. Specifically, this paper utilizes the ResNet50 model, which is pre-trained on the ImageNet dataset [25], to ensure smoother convergence and elevate the overall performance. The decoder consists of four blocks, each including upsampling, concatenation, and skip-connections operations. In detail, each block's input feature map is initially upsampled to a higher resolution using transpose convolution. Following this, a concatenation operation merges the upsampled feature map with its encoder counterpart. A residual unit with skip-connections then produces the final feature map for that block. Opting for residual blocks over standard convolutional ones streamlines network training and guarantees undegraded information propagation due to the skip connections. The decoder's final block output undergoes a  $1 \times 1$  convolution layer and a sigmoid function, resulting in the output segmentation map.

For training the road segmentation network, this paper employs Dice Loss [26] as the main loss function. Dice Loss is particularly useful in segmentation tasks where the classes are imbalanced. The goal of the road segmentation task is to categorize each image pixel as either road or background. Given that the number of pixels associated with roads is typically far less than those tied to the background, this presents a significantly imbalanced problem. Dice Loss helps mitigate this issue by maintaining a balance between the foreground and the background. Mathematically, the Dice Loss can be defined as:

$$L_d = 1 - 2 \frac{y_{pre} \cdot y_{gt} + \epsilon}{y_{pre} + y_{gt} + \epsilon} \quad (1)$$

where  $y_{pre}$  and  $y_{gt}$  represent the predicted and ground truth, respectively.  $\epsilon$  is a minute positive quantity employed to prevent a division by zero issue.

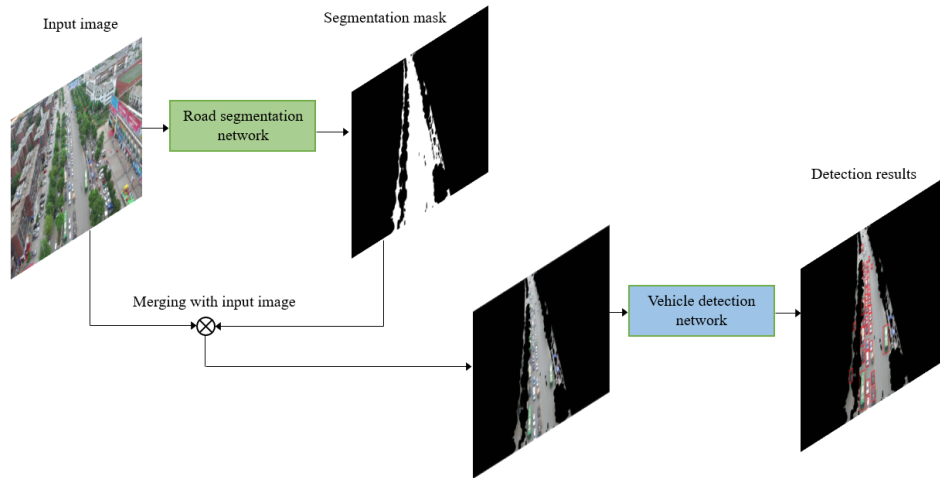

Fig. 2. The structure of the proposed approach.

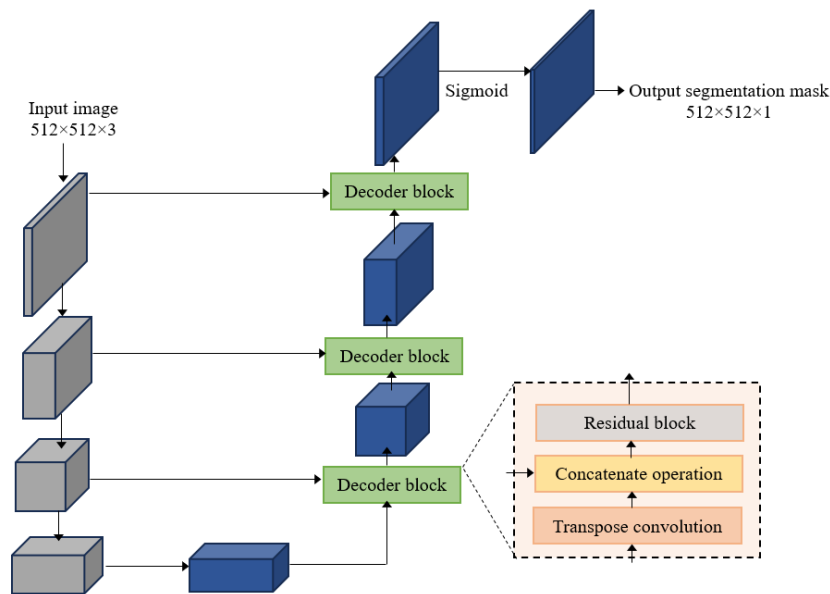

Fig. 3. Encoder-decoder structure for road segmentation.

### C. Vehicle Detection based on Road Sections

Aiming for quick and accurate vehicle detection based on road sections extracted from input images, especially for small vehicles, this paper proposes a vehicle detection model based on the YOLOv3-tiny architecture [27]. Specifically, modifications were made to the YOLOv3-tiny model based on two criteria: model size and its capability to detect small objects. In CNN architecture, deeper layers containing larger numbers of channels and smaller sizes typically store rich semantic information, beneficial for object classification. Conversely, shallower layers with fewer channels and larger sizes typically house rich spatial information, useful for preserving object structure details. Since vehicle detection task only distinguishes between vehicles and background classes, it is significantly simpler than generic object detection. As a result, the shallower network layers can be reduced in the number of channels to decrease the model's complexity without

impacting its accuracy. Based on these analyses, this paper implemented changes to the structure of the first convolutional layers of the YOLOv3-tiny architecture. Specifically, the number of filters in the first two convolutional layers was reduced to three. The rest of the convolutional layers maintained their original number of filters. Table I details the structure of the proposed model in this paper and the original YOLOv3-tiny model. The detection head makes predictions on two feature maps with scales of  $13 \times 13$  and  $26 \times 26$ . With these modifications, the proposed model can significantly reduce computation costs while maintaining network performance. Additionally, the filter size in the detection layers was changed from  $3 \times 3$  to  $1 \times 1$ , improving the model's nonlinearity and aiding the detection model in learning difficult samples. With these changes, the new model has reduced FLOPs to 2.5BFLOPs compared to the original model's 5.4BFLOPs, while the model size has shrunk to 20MB compared to the original 34MB.

TABLE I. COMPARING THE STRUCTURE OF THE ORIGINAL YOLOV3-TINY MODEL AND THE MODEL PROPOSED IN THE PAPER

D. Data Augmentation Strategy

Since data imbalance among classes presents a significant challenge for vision tasks based on drone images, this paper proposes several data augmentation techniques to address this issue. Fig. 4 displays the outcomes of the data augmentation techniques applied in this paper on a consistent input image. The strategies employed to augment drone image data in this study encompass random erasing, random rotation, random brightness, random cropping, and random zoom.

1) *Random erasing*: Random erasing [28] involves selecting a rectangular area within an image at random and replacing its pixels with arbitrary values. This region is determined using a uniform distribution, with both the area and aspect ratios chosen randomly. When parts of the input image are randomly erased during training, it compels the model to develop more adaptable and robust representations. This means the model has to identify the correct class without

depending solely on the complete image, enhancing its focus on pertinent sections of the input. This can enhance the model's generalization capabilities, potentially leading to superior performance on unfamiliar data.

2) *Random rotation*: Random rotation is achieved by rotating the image by a random degree between -90 and +90 degrees. By randomly rotating the image, the model is encouraged to learn to recognize the object in different orientations. This makes the model more robust to the orientation of objects in the input data. Let  $(x, y); (x', y')$  be the coordinates of the bounding boxes before and after implementing random rotation. In that case,

$$\begin{cases} x' = (x - M_x) \cdot \cos\alpha - (y - M_y) \cdot \sin\alpha + M_x \\ y' = (x - M_x) \cdot \sin\alpha - (y - M_y) \cdot \cos\alpha + M_y \end{cases} \quad (2)$$

where  $\alpha$  is rotation angle and  $(M_x, M_y)$  is the center coordinate of the input image.

Fig. 4. Data augmentation used in this paper. (a) Original image; (b) Random erasing; (c) Random rotation; (d) Random brightness; (e) Random crop; (f) Random zoom.

3) *Random brightness*: Random brightness involves adjusting the brightness of an image by a random factor. It's usually achieved by converting the image to the HSV color space, adding a random value to the V (Value) channel, and then converting back to the original color space. By modifying the brightness of the image, the model can be trained to be invariant to different lighting conditions. This means that the trained model can recognize an object or feature in an image regardless of whether the image is bright, normally lit, or dim.

4) *Random crop*: Random crop involves selecting a random subsection of the input image for training. The cropped region is smaller than the original image and is resized to the input dimensions of the model. By training the model on a diverse set of cropped images, it can learn to focus on different parts of an object and recognize an object even if only part of it is visible. It can also help to mitigate overfitting as the model cannot rely on the position of features in the image.

5) *Random zoom*: Random zoom involves randomly zooming into or out of an image by a certain amount. This is typically done by resizing the image (upscaling or downscaling) and then cropping or padding it to match the original dimensions. By randomly zooming in or out, the model can learn to recognize objects or features at different scales. It makes the model more scale-invariant, which is beneficial when objects in the test data may appear at different sizes than in the training data. The coordinates of the bounding boxes are updated after implementing random zoom as follows:

$$\begin{cases} x' = \frac{w}{z} + \frac{(x-\frac{w}{2})}{R} \\ y' = \frac{h}{z} + \frac{(y-\frac{h}{2})}{R} \end{cases} \quad (3)$$

where  $R$  is zoom ration and  $(w, h)$  is the width and height of the input image.

### III. RESULTS

#### A. Dataset

This paper utilizes distinct datasets for different tasks as specified in Table II. Specifically, the UAVDT dataset [29] is used to train the vehicle detection network. This dataset is tailored for vehicle detection and tracking tasks, encompassing three categories: car, truck, and bus. For the vehicle detection evaluation in this study, all classes are grouped under a singular category termed 'vehicle'. The images feature a resolution of 1080×540 pixels and capture diverse typical scenes, including squares, arterial roads, and toll stations. For training the road segmentation network, the UAVid dataset [30] is employed. UAVid consists of 300 drone images with resolutions of 4096×2160 or 3840×2160 pixels, captured at a slanted angle, enhancing the intricacy and scale variance of urban street scenes with complex foreground-background elements. Given the substantial image sizes, this paper derives 10,000 random, non-overlapping 512×512 patches from the UAVid dataset. Of these, 8,000 are designated as the training set, while the remaining 2,000 are split equally between the

validation and testing sets. For the purpose of road segmentation, only the annotations relevant to roads are used for training and evaluation in the road segmentation network. Additionally, the UAVid dataset is also used for a joint evaluation of the proposed model. In this evaluation setting, only road annotations are employed throughout the paper, and images lacking road annotations are excluded from the dataset. Furthermore, this study manually uses all vehicle annotations within road sections for object detection training and evaluation.

TABLE II. DATASETS USED IN THIS PAPER

Dataset	Road segmentation	Vehicle detection	Joint segmentation and detection
UAVDT [29]		√	
UAVid	√		√

#### B. Implementation Details

All road segmentation and vehicle detection networks are trained on a NVIDIA RTX 4080 GPU with the support of the PyTorch library. For the road segmentation network, the ResNet50 model, pretrained on the ImageNet dataset, is used as the baseline encoder. This enhances the precision of feature extraction, consequently improving segmentation performance. To boost training performance, an initial learning rate of  $1e^{-4}$  is used to update the parameters, which is then reduced to  $1e^{-7}$  after six consecutive epochs to achieve a better loss rate. The Adam optimizer [31] is utilized to fine-tune the model. The model is trained over 20 epochs with a batch size of 16. For the vehicle detection network, training is carried out using default configurations with a few minor modifications. More specifically, the DarkNet model [27] is deployed, and the SGD optimizer with momentum and weight decay factors of 0.9 and 0.001 respectively is used in the detector training process. The vehicle detection model is trained for 100 epochs with a batch size of 32. A step learning schedule is also employed to gradually reduce the learning rate.

#### C. Road Segmentation Results

This paper conducts experiments with various models to evaluate the effectiveness of the proposed model for the road segmentation task. The compared models are based on EfficientNet [32] and MobileNetv2 [33] as encoders, while the decoders are networks such as DeepLabV3, FPN [34], and Unet. Experiments are performed on the same UAVid dataset with identical training and testing sets. Fig. 5 illustrates the results of the segmentation models used in the experiments, including the model proposed in this paper. It can be seen that the proposed model achieves the best inference speed, while maintaining accuracy comparable to the other models. In terms of accuracy, the DeepLabV3 with EfficientNet model performs the best. However, this model requires 8.2ms as inference time, which is not suitable for intelligent transportation systems requiring real-time processing. Additionally, the results in Fig. 5 also show that models using complex decoder structures, with many layers like DeepLabV3, often require longer processing times due to higher computational demands. The comparison results show that designing an encoder-decoder model that leverages a residual unit with skip-connections, as

proposed in this paper, is very effective both in terms of accuracy and inference speed for the road segmentation task.

Fig. 5. Performance of different models on the UAVid dataset.

#### D. Vehicle Detection Results

To evaluate the vehicle detection network proposed in this paper, several models have been tested on the UAVDT dataset, including YOLOv3, YOLOv3-tiny, YOLOv4 [35], and SSD-MobileNet [36]. Table III presents the vehicle detection performance of various models on the UAVDT dataset, with the metrics being the Average Precision (AP) in percentage and the speed in milliseconds. From the results, it is clear that YOLOv4 exhibits the highest AP of 86.4, closely followed by YOLOv3 with 82.1. However, when it comes to speed, YOLOv4 falls short with a processing time of 10.4ms, compared to YOLOv3's 12.2ms. On the other hand, YOLOv3-tiny, known for its lightweight architecture, posts a decent AP of 69.4 but shines in speed with a processing time of 6.4ms. The proposed model, a modification of the YOLOv3-tiny architecture, was designed specifically to optimize the model size and improve detection of small objects. Despite achieving a slightly lower AP of 76.2 compared to the original YOLOv3 models, it considerably outperforms all other models in terms of speed with an impressive 4.2ms. This result reflects the efficiency of the proposed design in balancing both precision and speed. In comparison to SSD-MobileNet, which has an AP of 80.4 and speed of 10.6ms, the proposed model excels in inference speed, showing its potential for real-time applications. Therefore, the proposed model offers a promising approach for traffic monitoring, where speed and accurate vehicle detection is crucial.

TABLE III. VEHICLE DETECTION PERFORMANCE OF DIFFERENT MODELS ON THE UAVDT DATASET

Models	AP (%)	Speed (ms)
YOLOv3	82.1	12.2
YOLOv3-tiny	69.4	6.4
YOLOv4	86.4	10.4
SSD-MobileNet	80.4	10.6
Proposed model	76.2	4.2

#### E. Joint Evaluation Results

For joint evaluation, the road segmentation and vehicle detection networks have been integrated to carry out the task of vehicle detection within road sections. Based on the UAVid dataset, labels have been modified to include only vehicles in road sections to determine how accurately the combined model can detect vehicles in these areas. Table IV presents the overall results of several models, including Unet + YOLOv3 and Unet + YOLOv3-tiny. In Table IV, two parts of the comparison are introduced, which include the detection of vehicles in road sections and the detection of vehicles across the entire image. It can be seen that the detection of vehicles in road sections significantly improves the accuracy and inference speed of all models compared to vehicle detection across the entire image. This can be explained by the fact that by focusing only on the necessary parts of the image during detection, the computational cost and the number of objects that need to be predicted are substantially reduced. These findings suggest that intelligent transportation applications could leverage these results to build more efficient systems in their design, thereby facilitating easier system development.

TABLE IV. JOINT EVALUATION RESULTS ON THE UAVID DATASET

Models	AP (%)		Speed (ms)	
	Road sections	Entire image	Road sections	Entire image
Unet + YOLOv3	76.4	62.8	11.6	16.2
Unet + YOLOv3-tiny	62.1	54.4	8.4	10.3
Proposed model	74.1	60.5	6.9	8.4

#### IV. CONCLUSIONS

This paper has designed a novel deep learning method for the detection of traffic objects from drone-based imagery, specifically focusing on the rapid and accurate detection of vehicles within road sections. The proposed method consists of two key components: a road segmentation network and a vehicle detection network. The segmentation network utilizes a residual unit with skip-connections to effectively predict road areas, while the vehicle detection network leverages a modified version of the YOLOv3 architecture, fine-tuned for high-accuracy and high-speed vehicle detection. Moreover, this study addressed the challenge of data imbalance inherent in drone images by implementing various data augmentation techniques, thereby enhancing the model's robustness. The experimental results achieved on the UAVDT and UAVid datasets highlighted the effectiveness of the proposed model. It not only enhanced the accuracy of vehicle detection but also improved the inference speed as compared to existing methods. These results highlight the potential of the proposed approach for practical traffic monitoring applications, where rapid and accurate vehicle detection is of utmost importance. However, it's important to note that the proposed model's effectiveness may be limited to adverse weather conditions or low-light scenarios, as it heavily relies on visual data captured by drones, which can be adversely affected by such factors. Additionally, the model's performance might degrade when applied to highly congested traffic scenes with overlapping vehicles, posing challenges in accurate object detection. For future work, this

paper plans to extend this approach to the detection of more diverse traffic objects beyond vehicles, such as pedestrians and cyclists.

**Abstract**—This study aims to enhance network security by comprehensively evaluating various Intrusion Detection and Prevention Systems tools in networking systems. The objectives of this research were to assess the performance of different IDPS tools in terms of computer resources utilization, Quality of Service metrics namely delay, jitter, throughput, and packet loss, and their effectiveness in countering Distributed Denial of Service attacks, specifically ICMP Flood and SYN Flood. The evaluation used popular IDPS tools, including Snort, Suricata, Zeek, OSSEC, and Honeypot Cowrie. Real attack scenarios were simulated to measure the tools performance. The results indicated CPU and RAM usage variations among the tools, with Snort and Suricata showing efficient resource utilization. Regarding QoS metrics, Snort demonstrated superior performance in delay, jitter, throughput, and packet loss mitigation for both attack types. The implication for further research lies in exploring the optimal configurations and fine-tuning of IDPS tools to achieve the best possible network security against DDoS attacks. This research provides valuable insights into selecting appropriate IDPS tools for network administrators, cybersecurity professionals, and organizations to fortify their infrastructure against evolving cyber threats.

**Keywords**—IDPS; network security; computer performance; Quality of Service; DDoS attacks

## I. INTRODUCTION

In today's digital landscape, cybersecurity measures are paramount to protect and protect networks and sensitive data. Among the various cyber threats organizations and individuals face, Distributed Denial of Service (DDoS) attacks pose significant challenges. These attacks involve overwhelming a target system with excessive traffic, rendering it unavailable to legitimate users [1]. Developing effective defense mechanisms against DDoS flooding attacks requires a comprehensive understanding of the problem and the techniques used to prevent, detect, and respond to such attacks [2]. In a DDoS attack, the attacker orchestrates the assault using a network of remotely controlled and widely dispersed nodes. These nodes work collaboratively to flood the victim's network with overwhelming traffic. The primary objective of this attack is not to directly exploit the victim's data but to disrupt the normal functioning of the victim's resources, making it challenging for legitimate users to access the services.

The agent-handler model is a significant structure utilized in DDoS attacks, involving four key participants: the attacker or botmaster, handlers, agents, and the victim [3]. The attacker, also known as the botmaster, communicates indirectly with the agents through the handlers, which act as intermediaries facilitating coordination and communication [4]. The agents compromised devices or systems attack by flooding the victim's network with massive malicious traffic [5], [6].

The agent-handler model provides several advantages for attackers, enabling them to maintain anonymity and distance themselves from the attack [4]. The owners of compromised agent systems often remain unaware that their devices are being exploited to launch DDoS attacks [5]. Moreover, handlers allow the attacker to control multiple agents simultaneously, significantly amplifying the scale and impact of the attack [7]. This model proves particularly effective when targeting web servers during DDoS attacks [5]. By overwhelming the target server with a flood of HTTP requests, such as in an HTTP flood attack, the attacker can exhaust the server's resources, disrupting its availability [7]. Another technique within this model is the Slowloris attack, where partial HTTP requests are sent to the target server, causing it to open additional connections and eventually leading to resource exhaustion [7].

To counter these attacks, Intrusion Detection and Prevention Systems (IDPS) have emerged as a crucial tool in safeguarding networks [8]–[10]. These systems effectively detect and mitigate DDoS attacks to prevent service disruption and data compromise [11]. However, one of the challenges IDPS faces is the ability to effectively detect and defend against evolving and unprecedented attacks [12], [13]. IDPS have traditionally employed two approaches for attack detection: signature-based and anomaly-based [14].

Signature-based detection relies on predefined attack patterns or signatures to identify threats. Although this method can accurately identify known attacks, it becomes ineffective against new or unprecedented attacks that do not match existing signatures [14]. On the other hand, anomaly-based detection analyzes network traffic and identifies abnormal patterns or behavior that deviates from regular network activity [12], [15]. This approach is more effective in detecting unknown attacks, as it does not rely on specific attack

signatures but instead focuses on identifying anomalous behavior [16]. Intrusion detection and prevention system (IDPS) is vital to cybersecurity measures. It is crucial to safeguard computer networks and systems from unauthorized access and malicious activities. IDPS monitors network traffic and analyzes it for any signs of suspicious or malicious behavior [17]–[19]. IDPS includes detecting and preventing unauthorized access attempts, malware attacks, and other security breaches [20], [21].

An IDPS can be either network-based or host-based [22]. Network-based IDPS monitors network traffic at various points in the network infrastructure, such as routers and switches, to identify any abnormal patterns or activities. Host-based IDPS, on the other hand, focuses on monitoring an individual host or endpoint device to detect signs of intrusion or malicious activity [23]. The primary function of an IDPS is to detect and prevent unauthorized access to a network or system. It achieves this by analyzing network traffic and comparing it against predefined patterns or signatures of known attacks [24]. Suppose an IDPS identifies any suspicious activity or a match with a known attack signature. In that case, it generates an alert or takes immediate action to prevent further damage and secure the system [25]. An IDPS can also detect and prevent anomalous behavior not covered by known attack signatures [26].

In the comparative analysis of Intrusion Detection and Prevention Systems (IDPS), several popular systems are evaluated, including Snort, Suricata, Zeek, OSSEC, and the honeypot Cowrie. The existing literature on Intrusion Detection and Prevention Systems (IDPS) is extensive and diverse, with each study providing valuable insights. Based on the comprehensive test results in this study [27], the utilization of pfSense and Suricata emerges as the proposed solution to thwart attacks initiated by internal users and curtail assaults stemming from internal networks, as evidenced by the conducted attack test scenarios. With supplementary devices, the next-generation firewall pfSense and Suricata can significantly bolster network security compared to relying solely on traditional firewalls.

Previous studies have examined the use of IDPS in ensuring Quality of Service in various network environments. These studies have highlighted the importance of IDPS in maintaining network performance and protecting against potential cyber threats. One study was conducted by [28]. Focused on using IDPS in cloud environments to achieve desired security in next-generation networks. The study analyzed different intrusions that could affect cloud resources and services' availability, confidentiality, and integrity. Based on their findings, they recommended positioning IDPS in cloud environments as a crucial step towards ensuring network security. Previous studies have also emphasized the need for IDPS to protect against various attacks, such as distributed denial-of-service attacks, malware infections, and unauthorized access attempts. Another QoS study by [29], [30] also emphasized the role of IDPS in maintaining QoS. Specifically, their study focused on using IDPS in wireless sensor networks. By deploying IDPS in wireless sensor networks, they observed improved QoS metrics such as network reliability, latency, and packet delivery ratio.

Another relevant study, conducted by [31], explores the approach of integrating a Network Intrusion Detection System (NIDS) and a Host-based Intrusion Detection System (HIDS), which can yield more optimal results in addressing security threats. In this approach, Snort is employed as NIDS to detect network-based intrusions by implementing rules capable of recognizing attack patterns. On the other hand, OSSEC functions as HIDS and effectively detects threats at the host level through log analysis, integrity monitoring, and rootkit detection. Both systems complement each other, with NIDS focusing more on network traffic analysis while HIDS concentrates on device and system protection at the host level.

The study by [32] proposes an analytical queuing model for assessing the impact of IDPS performance on network QoS. It explores the trade-off between security and QoS, demonstrating how enhancing security can lead to improved performance, albeit with some trade-offs. The study by [33] employs a multi-objective Bat algorithm to optimize security and QoS in a real-time operating system. It efficiently selects optimal security policies, ensuring minimal disruptions to Quality of Service. These studies offer valuable insights into enhancing network security and QoS through innovative IDPS approaches, highlighting the importance of balancing security measures with network performance considerations.

Contributions from other research, as presented in the studies by [33]–[38], also provide valuable insights within the domain of IDPS. Researchers examine diversity analysis for open-source IDS, aiding security architects in optimizing system performance. The study in [34] proposes a comprehensive multi-cloud integration security framework incorporating honeypots, significantly enhancing attack detection accuracy. The research in [35] introduces SYNGuard, a dynamic threshold-based SYN flood attack detection and mitigation system in Software-Defined Networks (SDNs), and compares the performance of Snort and Zeek IDS. Researchers [36] and [37] present policy-based security configuration management for IDPS, demonstrating its effectiveness using real-world intrusion detection datasets. Meanwhile, [38] analyzes password attacks via honeypots using machine learning techniques to unveil valuable password attack patterns.

Despite the significant insights provided by previous studies regarding the effectiveness and performance of IDPS systems, a comprehensive analysis of Distributed Denial of Service (DDoS) attacks, particularly ICMP Flood and SYN Flood attacks, on networking systems still needs to be improved. This research aims to fill this gap by evaluating the capabilities of IDPS systems such as Snort, Suricata, Zeek, OSSEC, and Honeypot Cowrie within network traffic. Through meticulous experiments, including real attack scenarios and calculations of Quality of Service (QoS) parameters such as throughput, jitter, delay, and packet loss during ICMP Flood and SYN Flood attacks, this study aims to provide valuable insights for network administrators, cybersecurity professionals, and organizations. The ultimate goal is to assist decision-makers in selecting and implementing the most suitable IDPS tools to safeguard their infrastructure against DDoS attacks, particularly in the context of ICMP Flood and SYN Flood attacks.

In the subsequent sections of this paper, the comprehensive analysis of Intrusion Detection and Prevention Systems (IDPS) in the context of DDoS attacks is explored. Following this introduction, the research methodology is described in Section II. Section III presents the results and findings of the experiments, including an evaluation of Snort, Suricata, Zeek, OSSEC, and the honeypot Cowrie. In Section IV, conclusions are provided based on the results and discussions on potential future works to enhance network security further.

## II. METHOD

This research employs an experimental methodology to evaluate the performance of various intrusion detection tools (Snort, Suricata, Zeek, Ossec, and Honeypot Cowrie) in handling specific cyber-attacks, including ICMP Flood and SYN Flood. The research objective is to analyze how each tool responds to the attacks regarding key performance metrics. The independent variables consist of the intrusion detection tools, while the dependent variables include Delay, Jitter, Throughput, and Packet Loss measured before and after the attacks. In Fig. 1, the experimental design encompasses controlled experiments, where each tool is subjected to the same attack scenarios under consistent network conditions.

Fig. 1. Research method.

The experimental setup includes deploying the selected tools in a test network environment, and the attacks are initiated to evaluate the detection and response capabilities. The experimental setup involves deploying the selected intrusion detection tools within a controlled test network environment. Subsequently, targeted cyber-attacks are initiated to rigorously evaluate and assess each tool's detection and response capabilities. This evaluation allows for a comprehensive analysis of their performance under realistic attack scenarios, providing valuable insights into their effectiveness in safeguarding computing systems against potential threats.

Data collection involves meticulously recording each tool's performance metrics during the attack simulations. Throughout the simulations, relevant performance data, including Delay, Jitter, Throughput, and Packet Loss, is carefully documented for each detection tool. Quality of Service (QoS) is a method used to measure the quality of a network and determine the level of service it provides. QoS measures specific performance characteristics such as Delay, Jitter, Throughput, and Packet Loss, which are associated with a service [39], [40].

1) *Throughput*: Throughput refers to the actual bandwidth measured at a specific time when sending a file. Unlike bandwidth, which is measured in bits per second (bps), throughput better represents the actual bandwidth at a specific moment and under certain network conditions, particularly when downloading a particular file. It is calculated as the total number of successfully transmitted data (in bits) divided by the total time taken to transmit that data (in seconds):

$$\text{Throughput} = \frac{\text{Total amount of transmitted data}}{\text{Total time to transmit the data}} \quad (1)$$

2) *Packet loss*: Packet Loss is the percentage of packets lost during data transmission. Various factors, such as weak signals in the network, network hardware errors, or environmental interference, can cause this. Packet Loss is a critical parameter that illustrates the number of lost packets due to collisions and congestion in the network. It is calculated as follows:

$$\text{Packet Loss} = \frac{\text{Number of lost packets}}{\text{Total Number of packets sent}} \times 100\% \quad (2)$$

3) *Jitter*: Jitter is the variation in delay (time difference) between packets in the network, which is influenced by the queue length when processing data. It is affected by the traffic load and the number of packets (congestion) in the network, particularly during periods of high traffic. Jitter is calculated using the following equation:

$$\text{Jitter} = \frac{\text{Total delay variation}}{\text{Total amount of transmitted data}} \quad (3)$$

4) *Delay*: Delay or Latency is the time it takes for data to travel from the source to the destination. The delay is influenced by distance, physical media, congestion, and processing times. It is calculated as follow:

$$\text{Delay} = \frac{\text{Total delay}}{\text{Total amount of transmitted data}} \quad (4)$$

In cybersecurity, particularly in defending against Distributed Denial of Service (DDoS) attacks, IDPS plays a pivotal role. To bolster the effectiveness of IDPS in countering the ever-evolving DDoS threats, it becomes imperative to incorporate more analytical metrics. One such metric that merits heightened attention is the Detection Rate (DR) [41], calculated as follows:

$$\text{Detection Rate} = \frac{\text{True Positive}}{\text{True Positive} + \text{False Negative}} \quad (5)$$

The Detection Rate (DR) is a critical metric that gauges the system's ability to identify genuine DDoS attacks accurately among all positive instances. True Positives (TP) represent instances where the IDPS correctly identifies and labels a legitimate DDoS attack. At the same time, False Negatives (FN) indicates instances where the system fails to detect a real DDoS threat, potentially leading to a security breach. In the DDoS mitigation landscape, the significance of DR cannot be overstated. It is a cornerstone for evaluating the IDPS aptitude to identify and thwart DDoS attacks precisely. Achieving a high DR is paramount as it minimizes the risk of false negatives, ensuring that legitimate DDoS threats do not go undetected.

By adopting this approach, this research acquires comprehensive and detailed data on the performance of each detection tool under various attack scenarios. Subsequently, data analysis entails statistical comparisons to determine significant differences in performance metrics between the tools. The data analysis process encompasses conducting thorough statistical comparisons to discern notable variations in performance metrics among the different detection tools. Through the application of advanced statistical techniques, the aim is to identify any statistically significant differences in the

performance of each tool. This rigorous analysis enables us to gain valuable insights into the relative strengths and weaknesses of the detection tools, facilitating a comprehensive assessment of their capabilities in handling diverse cyber-attacks.

The rigorous experimental methodology aims to provide reliable insights into the efficiency and effectiveness of intrusion detection tools in diverse computing environments, particularly under varying attack conditions. Through comprehensive evaluations and controlled experiments, valuable data is sought to assess the capabilities and performance of these tools in safeguarding computing systems against a wide range of potential cyber threats. Doing so aims to establish a robust understanding of IDPS Tools, enhance cybersecurity practices, and ensures a more secure computing landscape.

### III. RESULT AND FINDING

#### A. Experimental Design

The experimental design employed in this study involved conducting controlled experiments to evaluate the performance of each intrusion detection tool under consistent network conditions. All selected tools were subjected to the same attack scenarios in a controlled test network environment to ensure a fair and unbiased assessment. For the attack scenario in Fig. 2, the researchers utilized a computer laboratory comprising ten computers infiltrated with DDoS bots controlled by an attacker operating the handler. This simulation was used to launch attacks on a server, from which the necessary data was obtained during the testing of IDPS (Intrusion Detection and Prevention System) tools, including Snort, Suricata, Zeek, Ossec, and Honeypot Cowrie. This simulation aimed to assess the IDPS tools' performance in detecting and responding to the DDoS attacks orchestrated by the attacker through the compromised bots. The data collected from these simulated attacks served as crucial input for evaluating and analyzing the effectiveness of each IDPS tool in defending against such cyber threats.

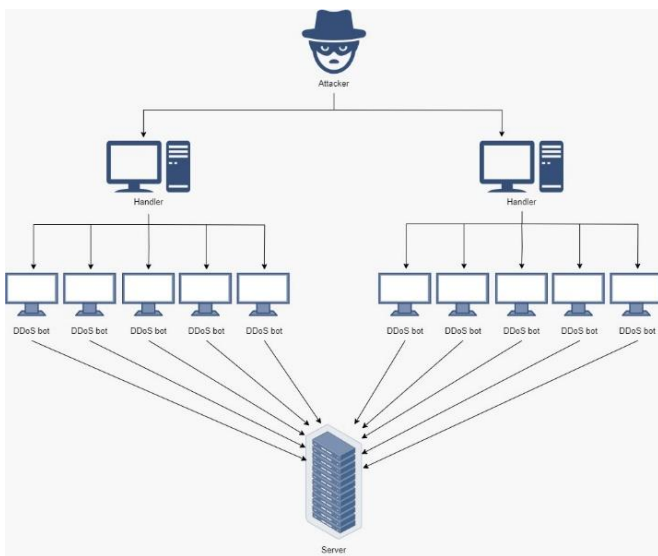

Fig. 2. Attack scenario.

Through controlled experiments, the aim was to eliminate any potential confounding variables and ensure that the observed differences in performance metrics were solely attributed to the capabilities of the intrusion detection tools. Each tool underwent testing under identical conditions, including network traffic, attack intensity, and duration. This standardized approach allowed for objectively comparing the tools' performance and drawing meaningful conclusions about their efficacy in detecting and mitigating various cyber-attacks. The performance metrics, such as RAM usage, CPU utilization, network throughput, delay, jitter, and packet loss, were carefully monitored and recorded during the attack simulations for each tool. Furthermore, to enhance the reliability of the findings, the experiments were repeated multiple times to account for any random variations and ensure the consistency of the results. The aggregated data from the repeated experiments provided a more robust basis for analysis and interpretation.

#### B. Controlled Variables

A carefully selected set of hardware specifications was strategically employed to ensure the successful acquisition of pertinent data for the research. These specifications were pivotal in establishing a robust experimental environment, enabling controlled experiments and the meticulous recording of performance metrics for the intrusion detection tools under investigation. With utmost attention to detail, specific hardware components were carefully chosen and implemented, tailored precisely to align with the research objectives. The following hardware specifications in Table I were utilized to facilitate data collection.

TABLE I. EXPERIMENTAL HARDWARE TOOLS

No	Hardware	Version	Number of Tools	Ip Number
1	switch	cisco sf95d-16 16-port 10/100	2 unit	192.168.100.150 & 192.168.100.151
2	computer server	server dell t150 xeon e-2324g	1 unit	192.168.100.154
3	computer server idps	server dell t40 xeon e-2224g	1 unit	192.168.100.153
4	computer idps console	all in one (aio) pc dell optiplex 7440	1 unit	192.168.100.152
5	computer agent	asus pc all in one v222gak wa141t - dualcore	10 unit	192.168.100.1-10
6	computer handler	asus pc all in one v222gak wa141t - dualcore	2 unit	192.168.100.11 & 192.168.100.12
7	computer attacker	hp pavilion aero 13 be2001au ryzen 5 7535u	1 unit	192.168.100.13

Meticulously designed and implemented a network topology for this research, as illustrated in Fig. 3, which comprised a carefully selected set of computers, each assigned specific roles. At the heart of the topology, the computer server served as a centralized repository for data. At the same time, the deployment of IDPS tools spanned across multiple computers, including servers, effectively safeguarding the network traffic from potential DDoS attacks. The assignment

of IP addresses was skillfully managed through the switch, distributing the network across 13 computers. Among these designated systems, ten were dedicated to functioning as agent botnets for DDoS, two served as handlers with control over the agents, and one acted as the attacker. This research opted for the Kali Linux 2023.1 operating system, facilitating the smooth integration of essential intrusion detection tools, namely Snort, Suricata, Zeek, Ossec, and Honeypot Cowrie. This research employed Wireshark 4.0 as the chosen monitoring tool to ensure efficient network traffic monitoring.

The hardware setup and carefully crafted network topology laid the foundation for the controlled experiments, enabling us to systematically assess the performance of each intrusion detection tool under varying attack scenarios. By employing a standardized approach, reliability and accuracy in research results were ensured, providing the means to make informed evaluations regarding the capabilities and effectiveness of these tools in countering diverse cyber threats.

Fig. 3. Network topology.

### C. Experimental Setup

The experimental Setup section of this research focuses on the systematic deployment and evaluation of several intrusion detection tools, namely Snort, Suricata, Zeek, Ossec, and Honeypot Cowrie. Each tool is selected individually and installed with its respective configurations. Subsequently, comprehensive testing assesses their performance in handling DDoS attacks, specifically through ICMP Flood and TCP SYN Flood.

Initiate the evaluation process, the server is configured with rules specific to each IDPS tool, and simulated attacks are launched from an attacker's PC to the server using the DDoS tool Hping3. The commands for the SYN Ddos attack and Icmp Dodos attack simulations are provided as follows in Fig. 4 and Fig. 5:

Fig. 4. SYN DDoS attack.

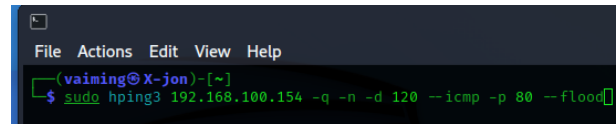

Fig. 5. ICMP DDoS attack.

The server's response to the attack is initially observed when protected by the Snort tool with the IPS command. The objective is to determine whether Snort can successfully detect and generate warnings for the simulated attacks. Once the results are obtained from the Snort testing, the same evaluation process is repeated using the other selected tools, Suricata, Zeek, Ossec, and Honeypot Cowrie, on the server.

### D. Data Collection

IDPS like Suricata, Zeek, Ossec, and Honeypot Cowrie play pivotal roles in safeguarding digital environments from malicious activities. They operate as the first line of defense, tirelessly monitoring network traffic and system logs. To assess the efficacy of these systems, metrics like the Detection Rate (DR) are paramount. In the context of this research, the Detection Rate (DR) emerges as a pivotal metric in assessing the performance of the IDPS. With 128,027 True Positives, signifying accurate identifications of actual intrusion attempts, and a relatively low 4,241 False Negatives (FN), which represent instances where genuine threats were not detected, the IDPS demonstrates a robust capability in effectively distinguishing malicious activities from benign network traffic. The DR, calculated as the ratio of True Positives to the sum of True Positives and False Negatives ( $TP / (TP + FN)$ ), reflects the system's ability to capture a high proportion of genuine intrusions. This value is a crucial requirement in this research, where achieving a DR of 128,027, or 97% of all intrusion attempts, is integral to minimizing the risk of false negatives and ensuring the thorough protection of digital assets.

In Table II and Table III, the performance of each IDPS tool was carefully observed during the ICMP flood attack. Snort exhibited a slight increase in RAM usage by 0.07%, followed by a slightly larger increase in CPU usage by 5.00%. Conversely, Suricata experienced a more pronounced rise in RAM usage by 0.19% and a substantial increase in CPU usage by 16.67%. Zeek demonstrated minimal fluctuations in RAM and CPU usage, with only 0.09% and 0.00% changes, respectively. OSsec recorded a moderate uptick in RAM and CPU usage, showing increases of 0.08% and 2.70%, respectively, highlighting its ability to manage ICMP flood attacks without significant overhead.

In contrast, Honeypot Cowrie displayed a noticeable increase in RAM usage by 0.13%, followed by a slightly more substantial rise in CPU usage of 3.61%. Network performance during the ICMP flood attack revealed diverse trends. Snort indicated a moderate upswing in network throughput, measuring 578.79 kb/s. Conversely, Suricata, Zeek, and Ossec experienced slight decreases in network throughput by 1.13 kb/s, 0.66 kb/s, and 0.05 kb/s, respectively. Remarkably, honeypot cowrie showcased a significant spike in network throughput, reaching 701.07 kb/s, underscoring its efficiency in addressing ICMP flood attacks.

TABLE II. COMPUTER PERFORMANCE BEFORE ATTACK

IDPS Tools	DDoS Attack	Before Attack		
		Ram (%)	Cpu (%)	Network (kb/s)
snort	icmp flood	27.30	0.17	32.38
	syn flood	27.56	0.22	36.4
suricata	icmp flood	32.19	0.66	34.39
	syn flood	36.26	0.82	35.40
zeek	icmp flood	32.69	0.22	32.78
	syn flood	32.57	0.52	32.61
ossec	icmp flood	32.57	0.37	32.70
	syn flood	33	0.22	32.65
honeypot cowrie	icmp flood	29.75	0.415	32.65
	syn flood	31.91	0.52	35.90

TABLE III. COMPUTER PERFORMANCE AFTER ATTACK

IDPS Tools	DDoS Attack	After Attack		
		Ram (%)	Cpu (%)	Network (kb/s)
snort	icmp flood	27.37	5.17	611.17
	syn flood	27.74	8.11	3238.76
suricata	icmp flood	32.38	7.67	856.26
	syn flood	36.4	9.02	3666.62
zeek	icmp flood	32.78	3.12	983.34
	syn flood	32.61	6.07	3569.07
ossec	icmp flood	32.65	8.08	566.89
	syn flood	32.39	7.73	3,596.54
honeypot cowrie	icmp flood	29.88	6.42	733.72
	syn flood	32.07	8.57	3452.69

Turning to the SYN Flood attack, the IDPS tools once again exhibited diverse patterns of performance adjustment. Snort displayed a slight increase in RAM usage by 0.18%, followed by a more substantial rise in CPU usage by 27.27%. Suricata showcased a more significant uptick in RAM usage by 0.74% and a noteworthy increase in CPU usage of 17.07%. Zeek demonstrated minimal RAM and CPU usage variations, with only 0.09% and 0.00% changes, respectively. Conversely, OSSEC recorded slightly decreased RAM usage by 0.22%, while CPU usage increased by 0.00%. HoneyPot Cowrie experienced a noticeable increase in RAM usage by 0.13% and a relatively significant rise in CPU usage of 6.59%.

Network performance during the SYN Flood attack also revealed distinct behavior. Snort and Suricata exhibited moderate increases in network throughput, measuring 2205.59 KB/s and 1587.86 KB/s, respectively, demonstrating their efficient responses to SYN Flood attacks. Zeek demonstrated a slight decrease in network throughput by 1.34 KB/s, while OSSEC experienced a significant surge in network throughput, reaching 1929.89 KB/s. Notably, honeyPot cowrie significantly increased network throughput, measuring 2413.52 KB/s, further highlighting its robustness in handling SYN Flood attacks.

These observations suggest differences in the tools' ability to detect and counter such attacks. In the case of ICMP Flood attacks, it was observed that certain IDPS tools experienced

notable increases in resource utilization, such as RAM, CPU, and network throughput, after the attacks. These observations imply varying sensitivity and adaptability of these tools to the attack type. Similarly, during SYN Flood attacks, the IDPS tools exhibited diverse patterns of resource usage alterations, suggesting differences in their ability to detect and counter such attacks. The observed changes in performance metrics underscore the need for a nuanced evaluation of IDPS tools under distinct attack scenarios.

This study in Fig. 6 conducted QoS measurements for throughput during ICMP Flood and SYN Flood DDoS attacks using different Intrusion Detection and Prevention Systems (IDPS) tools, namely Snort, Suricata, Zeek, Ossec, and HoneyPot. The results indicated variations in throughput values across these tools for both attack types. Among the tested tools, Snort demonstrated the highest throughput during ICMP Flood attacks, reaching 26,485 bits per second. At the same time, Suricata and Zeek showed similar throughput values at 32,400 and 32,438 bits per second, respectively. Ossec and HoneyPot yielded slightly lower throughputs at 26,052 and 39,897 bits per second, respectively.

For SYN Flood attacks, Snort exhibited the highest throughput of 29,701 bits per second, followed closely by HoneyPot at 34,701 bits per second. Suricata and Zeek yielded lower throughput values at 25,029 and 21,970 bits per second, respectively. Ossec demonstrated the lowest throughput among the tested tools for SYN Flood attacks, registering 21,970 bits per second.

Snort exhibited strong throughput values for both ICMP Flood and SYN Flood attacks, making it a viable choice for mitigating these attack types. Suricata and Zeek also demonstrated competitive throughput, indicating their potential effectiveness in handling DDoS attacks.

Fig. 6. Throughput DDoS attack.

The Delay values for different types of DDoS attacks were evaluated using various Intrusion Detection and Prevention Systems (IDPS), including Snort, Suricata, Zeek, Ossec, and HoneyPot Cowrie in Fig. 7. For ICMP Flood attacks, Snort exhibited a delay of 223.53 ms, Suricata had a delay of 183.85 ms, Zeek showed a delay of 45.59 ms, Ossec had a delay of 130.9 ms, and HoneyPot Cowrie displayed the lowest delay of 22.88 ms. Similarly, for SYN Flood attacks, Snort demonstrated a delay of 187.17 ms, Suricata had a delay of 104.59 ms, Zeek exhibited a delay of 17.9 ms, Ossec showed a delay of 60.8 ms, and HoneyPot Cowrie had a delay of 187.2 ms. These Delay values provide insights into the responsiveness of each IDPS in detecting and mitigating ICMP

and SYN Flood attacks. It is worth noting that Honeypot Cowrie consistently displayed lower Delay values, indicating its potential effectiveness in handling such attacks with minimal delay.

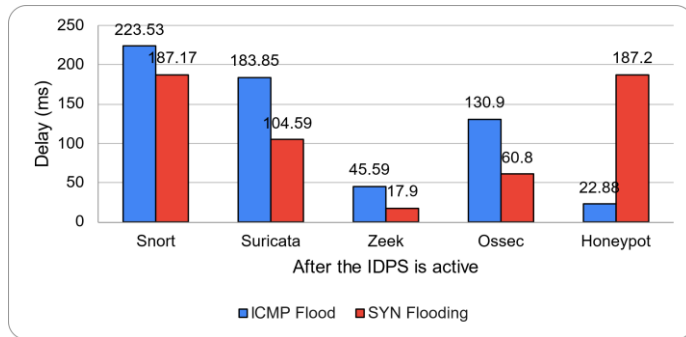

Fig. 7. Delay DDoS attack.

Analyzing jitter values across various DDoS attack scenarios and corresponding Intrusion Detection and Prevention Systems (IDPS) tools reveals distinct patterns in Fig. 8. In the case of ICMP Flood attacks, Zeek stands out with remarkably low jitter (0.88 ms), indicating stable and consistent packet delay. Conversely, Snort (7.37 ms), Suricata (1.8 ms), Ossec (1.01 ms), and Honeypot (11.5 ms) exhibit comparatively higher jitter values, suggesting potential fluctuations in delay times. A similar trend emerges during SYN Flooding attacks, where Zeek maintains its superior performance in jitter control (2.02 ms). Suricata (5.63 ms) and Ossec (6.08 ms) demonstrate increased jitter, while Snort (1.81 ms) and Honeypot (1.82 ms) exhibit relatively better control. These findings underscore Zeek's consistent jitter management capabilities across both attack types.

Fig. 8. Jitter DDoS attack.

The investigation into packet loss rates during ICMP Flood and SYN Flooding attacks, evaluated across a range of Intrusion Detection and Prevention Systems (IDPS) tools, yielded distinct outcomes. In Figure 9, Snort and Suricata exhibited minimal packet loss, recording percentages of 0.32% and 0.44% for ICMP Flood and 0.56% and 0.29% for SYN Flooding, respectively. Zeek displayed effective packet loss mitigation, with rates of 0.25% for ICMP Flood and 0.14% for SYN Flooding. Ossec and Honeypot Cowrie demonstrated slightly higher packet loss percentages, at 0.33% and 0.19% for ICMP Flood and 0.56% for SYN Flooding. These findings illuminate the diverse packet loss responses of IDPS tools to specific attack scenarios, empowering network administrators

and cybersecurity practitioners with valuable insights for optimizing DDoS protection strategies.

Fig. 9. Packet loss DDoS attack.

The Quality of Service (QoS) analysis of the network performance before and after different attack scenarios, as measured by various metrics, offers valuable insights into the effectiveness of the Intrusion Detection and Prevention Systems (IDPS) tools. Among the tested tools, Snort and Zeek consistently demonstrate a relatively robust ability to mitigate the impact of attacks on network Delay and Packet Loss. Suricata and OSSEC, on the other hand, exhibit more susceptibility to disruptions caused by the attacks, with increased Delay, Jitter, and Packet Loss, especially evident in SYN Flood attacks. Notably, Honeypot Cowrie proves adept at maintaining network stability during ICMP Flood attacks, showcasing lower Jitter and relatively stable Throughput. These observations underline the varying QoS responses of different IDPS tools to distinct attack types, providing crucial insights for making informed decisions regarding network defense strategies. The ICMP Flood attacks generally result in increased Delay and Packet Loss, while the SYN Flood attacks tend to affect Delay, Jitter, and sometimes throughput. Among the IDPS tools, Snort and Zeek exhibit relatively better network performance maintenance, while Suricata and OSSEC show more impact from the attacks. Honeypot Cowrie maintains network performance relatively well, particularly for ICMP Flood attacks. It is important to note that these observations provide insights into how each IDPS tool responds to specific attack types regarding QoS metrics.

### E. Data Analysis

The data analysis phase serves as the foundation of the investigation, shedding light on the performance dynamics of distinct intrusion detection tools when confronted with diverse cyber threats. This research systematically compared key performance metrics through meticulous experimentation and keen observation before and after simulated attacks. The analytical focus encompassed critical parameters, including delay, jitter, throughput, and packet loss, offering a comprehensive view of each tool's response. Notably, Snort exhibited commendable efficiency in managing ICMP Flood attacks, showcasing minimal network latency and jitter disruption. Suricata demonstrated adeptness in mitigating SYN Flood attacks with modest fluctuations. Zeek's proficiency shone through its stable network throughput during ICMP Flood scenarios.

Meanwhile, OSSEC displayed a robust defense mechanism against ICMP Flood attacks, containing packet loss within

acceptable bounds. HoneyPot Cowrie effectively mitigated packet loss while experiencing elevated jitter during ICMP Flood incidents. The analysis, bolstered by robust statistical techniques, revealed nuanced performance differences allowing us to conclude each tool's strengths and limitations. These insights offer essential guidance for practitioners configuring intrusion detection tools advancing cybersecurity defense strategies with precision.

This research analysis of countering ICMP DDoS and SYN Flood attacks highlighted varying degrees of efficacy among the IDPS tools. Snort stood out in addressing ICMP Flood attacks, effectively minimizing network disruption, latency, and jitter. Similarly, Suricata exhibited proficiency in mitigating SYN Flood attacks, maintaining stable network throughput, and responding to anomalous traffic patterns. On the other hand, Zeek displayed commendable network throughput during ICMP Flood scenarios but showed moderate fluctuation against SYN Flood attacks. While OSSEC contained packet loss during ICMP Flood incidents, it faced challenges maintaining network stability under SYN Flood onslaughts. HoneyPot Cowrie, resilient against packet loss, experienced elevated jitter during ICMP Flood attacks. These findings collectively suggest that Snort and Suricata are potent contenders for countering ICMP DDoS and SYN Flood attacks, offering consistent and robust responses. The nuanced strengths and limitations underscore the importance of tailored tool selection based on the specific threat landscape and operational requirements.

A comprehensive analysis of QoS data and computer/networking performance metrics reveals that Snort is a standout performer in countering ICMP Flood attacks. This conclusion is drawn from consistent and commendable results across various parameters. Snort effectively mitigated delays and jitter, ensuring optimal network responsiveness and maintaining impressive throughput levels, all while demonstrating minimal packet loss. Moreover, Snort efficiently utilized CPU and RAM resources, indicating its ability to handle ICMP Flood attacks without overstraining the system. These findings position Snort as the most robust IDPS tool for effectively countering ICMP Flood attacks, making it a compelling choice for defending against such threats and ensuring network stability and performance.

Similarly, the analysis indicates that Zeek is the most effective IDPS tool for countering SYN Flood attacks. Zeek consistently demonstrated remarkable performance in minimizing delays and jitter during SYN Flood attacks, maintaining stable network responsiveness. Additionally, Zeek maintained competitive throughput levels and remarkably low packet loss, showcasing its proficiency in managing SYN requests. From a computer and networking performance standpoint, Zeek efficiently allocated CPU and RAM resources, indicating its capability to handle SYN Flood attacks without burdening the system. Overall, Zeek's strong performance across QoS metrics and resource management makes it the optimal choice for countering SYN Flood attacks and safeguarding network stability.

In this comparative analysis of the results, we have examined this research alongside relevant previous studies.

The study by [28], [35] introduces an analytical model for assessing IDPS configurations, emphasizing theoretical modeling. In contrast, the results of this research delve into practical IDPS implementation within a networking system environment to defend against specific threats, emphasizing real-world application. The studies cited as [11], [12], [29], [30], [33], [36]–[38], on the other hand, differ significantly from this research outcome. Given these variations in goals and approaches, direct result comparisons can be challenging. This study's results highlight practical implementation and threat defense, distinguishing it from theoretical modeling and the differing contexts in previous studies.

#### IV. CONCLUSION AND FUTURE WORKS

This study undertook a comprehensive analysis of diverse Intrusion Detection and Prevention Systems (IDPS) tools, namely Snort, Suricata, Zeek, OSSEC, and HoneyPot Cowrie, with a primary focus on their effectiveness in countering Distributed Denial of Service (DDoS) attacks. Through a meticulous evaluation encompassing aspects of network traffic analysis, Quality of Service (QoS) metrics, computer performance, and attack mitigation, this research gained insights into the capabilities of these tools. In this assessment, research revealed distinct performance characteristics for each IDPS tool. Snort excelled in network-based intrusion detection, efficiently identifying and countering threats at the network level. Suricata demonstrated prowess in packet processing and rule matching, making it a strong contender for network security. With its emphasis on comprehensive traffic analysis, Zeek offered valuable insights into network activity. OSSEC showcased robust host-based intrusion detection capabilities, providing effective log analysis and threat identification. HoneyPot Cowrie displayed potential while highlighting areas for improvement in QoS metrics and computer performance. Regarding Quality of Service (QoS), the analysis unveiled Snort as the most effective IDPS tool in countering ICMP Flood and SYN Flood attacks, consistently exhibiting superior throughput, lower delay, minimal jitter, and commendable packet loss rates. These QoS metrics reflect Snort's adeptness in preserving network integrity and minimizing disruption during DDoS incidents.

Future research avenues include integrating advanced machine learning techniques into IDPS tools to optimize detection accuracy while minimizing false positives. Additionally, exploring the deployment of IDPS in dynamic cloud and hybrid environments, understanding their scalability, and adapting them to varying network conditions would provide valuable insights. In conclusion, this study provides valuable insights into the performance of diverse IDPS tools against DDoS attacks. By addressing identified limitations and pursuing avenues for future research, this research can advance the field of network security and contribute to developing resilient defense mechanisms against evolving cyber threats.

**Abstract**—This study explores the Traveling Salesman Problem (TSP) in Medan City, North Sumatra, Indonesia, analyzing 100 geographical locations for the shortest route determination. Four heuristic algorithms—Nearest Neighbor (NN), Repetitive Nearest Neighbor (RNN), Hybrid NN, and Hybrid RNN—are investigated using RStudio software and benchmarked against various problem instances and TSPLIB data. The results reveal that algorithm performance is contingent on problem size and complexity, with hybrid methods showing promise in producing superior solutions. Statistical analysis confirms the significance of the differences between non-hybrid and hybrid methods, emphasizing the potential for hybridization to enhance solution quality. This research advances our understanding of heuristic algorithm performance in TSP problem-solving and underscores the transformative potential of hybridization strategies in optimization.

**Keywords**—Travelling Salesman Problem; heuristic algorithms; hybridization techniques algorithm performance; route optimization

## I. INTRODUCTION

Irish and British mathematicians first introduced the Traveling Salesman Problem (TSP). They were William Rowan Hamilton and Thomas Penyngton in 1800. The Traveling Salesman Problem (TSP) involves a salesman who has to travel to several points. Each point is visited only once, and the salesperson must return to the starting point again by trying the minimum path. For every  $n$  number of points, the number of routes to be traveled is  $n!$ . This problem causes no optimal solution except to calculate every possibility. So, the discussion of TSP is growing exponentially.

In life, many TSP problems are found to solve passenger delivery and pickup problems [1]–[3], drone and truck combination trips in improving customer service [4], [5], land logistics delivery problems[6]–[9], air logistics delivery [10], [11], picking up trash cars [12], automating systems on mobile robotics [13], [14] and others. The traveling salesperson problem has become one of the most studied problems in combinatorial optimization. The search for TSP solutions offers many algorithms that are fast in their calculations and produce optimal solutions.

Many scientists have tried to solve the TSP problem. Various methods are used to obtain more optimal and faster results in the calculations [15], [16]. Zhang et al. [17]

presented a variable neighborhood discrete whale optimization algorithm for TSP. Teng and Li [18] proposed a discrete firefly algorithm combining genetic algorithms for solving TSP. Several other algorithms are offered in solving TSP, such as construction tour techniques based on the Convex-hull heuristic and Nearest Neighbor (CH-NN) [19], galaxy-based search algorithm (GbSA), and embedding new ideas called clockwise search processes and operations cluster crossover [20], optimal heuristic algorithm (2-opt) with Nearest Neighbor (NN) [21]–[24], tour construction Ant Colony Algorithm [25]–[27], and Cuckoo Search Algorithm [28].

Traveling Salesman Problem (TSP) research has witnessed significant advancements over the years, marked by the development of sophisticated heuristic algorithms and the establishing of benchmark datasets like TSPLIB. These algorithmic improvements, such as Nearest Neighbor (NN), Repetitive Nearest Neighbor (RNN), and hybrid approaches, have greatly enhanced our ability to find near-optimal solutions for TSP instances. However, several challenges and unresolved issues persist in this field. Scaling complexity remains a formidable challenge, particularly when dealing with large-scale TSP instances, where the problem's exponential nature poses computational hurdles. Furthermore, despite their efficiency, heuristic algorithms do not guarantee the global optimum, leaving room for further exploration to bridge the gap between heuristic and true optimal solutions. Additionally, dynamic TSP scenarios, where cities and distances change over time, demand adaptive heuristic approaches.

Given these challenges, the presented study focusing on TSP in Medan City, North Sumatra, Indonesia, assumes particular importance and novelty. Medan City's unique geographical layout and urban complexities present a real-world context that offers practical relevance for logistics, transportation, and urban planning. The study goes beyond theoretical analysis by rigorously evaluating four heuristic algorithms—NN, RNN, Hybrid NN, and Hybrid RNN—across various problem instances specific to Medan City. This empirical examination provides valuable insights into the algorithms' performance under the city's unique conditions, aiding decision-makers in optimizing routes efficiently. Moreover, the study introduces the novel concept of hybridization techniques within the context of TSP in Medan City. The successful application of hybrid algorithms

demonstrates their potential to yield high-quality solutions, contributing to the broader knowledge of computational optimization. In essence, this study not only addresses a complex optimization problem in a real-world setting but also pioneers innovative approaches, making it a noteworthy addition to the field of TSP research.

## II. MATHEMATICAL MODEL

In this study, the mathematical model of the TSP aims to minimize travel distances.  $x_{ij}$  is the decision variable on which vertex to traverse. The set decision variable is  $\{1,0\}$ . The decision is worth 1 if arc  $(i, j)$  is passed and 0 if arc  $(i, j)$  is not passed. The  $w_{ij}$  variable is the distance between points that are traversed using point distance calculations so that it can be written down like Eq. (1).

Parameter:

- $n$  : The number of points that the salesman needs to visit.
- $w_{ij}$  : The distance or cost between two points, calculated using the Euclidean distance formula.
- $x_{ij}$  : A binary decision variable that indicates whether the salesman travels from point  $i$  to point  $j$  ( $x_{ij} = 1$ ) or not ( $x_{ij} = 0$ ).
- $|V|$  : The number of elements in the subset.
- $(a_i, b_i)$  : The position of a point in terms of its horizontal ( $a_i$ ) and vertical ( $b_i$ ) coordinates.

Formula:

$$w_{ij} = \left( (a_i - a_j)^2 + (b_i - b_j)^2 \right)^{1/2} \quad (1)$$

In general, the mathematical model for the TSP problem can be seen in Eq. (2) to Eq. (5).

$$\min \sum_{i=1}^n \sum_{j \neq i, j=1}^n w_{ij} x_{ij} \quad (2)$$

$$\sum_{i=1, i \neq j}^n x_{ij} = 1, \quad j = 1, 2, 3, \dots, n \quad (3)$$

$$\sum_{j=1, j \neq i}^n x_{ij} = 1, \quad i = 1, 2, 3, \dots, n \quad (4)$$

$$\sum_{i \in V} \sum_{j \neq i, j \in V} x_{ij} \leq |V| - 1, \quad \forall V \subseteq \{1, 2, 3 \dots n\}, |V| \geq 2 \quad (5)$$

Eq. (2) is the objective function of TSP to minimize costs. Eq. (3) and Eq. (4) guarantee that each point is traversed exactly once and returns to the starting point of departure. Eq. (5) ensures that the number of traversed vertices is not more than or equal to the specified number of vertices minus one or can be written as  $|V| - 1$ .

## III. RNN ALGORITHM

RNN and Nearest Neighbor NN are commonly used algorithms for solving the shortest route problem on a map with many points. The NN algorithm works by starting from a random point and looking for the nearest neighbour to proceed to the next point. This process is repeated until all points are connected in a closed route. The NN algorithm is simple and fast but only sometimes produces the best solution.

The RNN algorithm is a variation of the NN algorithm that works by finding the nearest neighbour at each stage but with some modifications. This algorithm looks for the nearest

neighbours for the first point, returns to the starting point and looks for the nearest neighbours yet to be connected to the route. This algorithm is repeated until all points are connected in a closed route. The RNN algorithm is generally better at finding better solutions than the NN algorithm but requires a longer computation time.

Both are heuristic algorithms that can quickly solve the shortest route problem with many points. However, keep in mind that the solution provided by the heuristic algorithm is only sometimes optimal, especially in cases with many points or in cases with many constraints. The step-by-step construction of the RNN algorithm can be read in the following step sequence:

**Step 1:** Suppose  $V = \{v_1, v_2, v_3, \dots, v_n\}$  is the point of  $n$  locations and  $d(v_i, v_j)$  is the distance between location  $v_i$  and  $v_j$ , the notation  $v_i$  is the notation of the  $i^{th}$  site.

In this case, the search engine formulates  $n$  sub-routes and has one location in each. The set of sub-routes can be denoted as follows:

$$P_1 = \{v_i; i = 1, 2, \dots, n\} \quad (6)$$

**Step 2:** In the next step, each sub-route obtained in the previous step adds a network by finding the closest location that differs from the remaining spots. So this model can be formulated based on Eq. (7). The notation  $d(v_i, v_j)$  is the Euclidean distance between locations  $v_i$  and  $v_j$ . This distance is calculated in the formula in Eq. 1.

$$P_2 = \{v_i, v_j\}; \forall v_i \in R_1;$$

$$\min d(v_i, v_j), \forall v_j \in V; i \neq j; j = 1, 2, \dots, n \quad (7)$$

**Step 3:** In the last step, each sub-route from 2 locations in  $R_2$  is expanded by finding unvisited paths. The third sub-route built is notated in Eq. 8.

$$P_3 = \{v_i, v_j, v_k\}; \forall v_i, v_j \in R_1;$$

$$\min \{d(v_j, v_k)\}, \forall v_k \in V; j \neq k; j = 1, 2, \dots, n \quad (8)$$

where  $|P_3| = n$  is the total number of routes in the set  $R_3$ . The process of building the path is continued until every location is visited. Furthermore, when the  $n$ th step has been completed, a set of routes  $P_n$  will be obtained, where  $|P_n| = n$  and each path from  $R_n$  contains  $n$  locations. The algorithm added the initial site to each path's position  $(n + 1)$  in  $P_n$  to obtain a feasible TSP route solution. The steps are continued until the best route is obtained from a set of  $n$  possible TSP routes [29].

## IV. HEURISTICS 2-OPT

2-Opt is a straightforward local search method. Croes first introduced this method to solve the TSP in 1958. However, this algorithm is used to improve the shortcomings of other algorithms, which require a long computation time. 2-Opt heuristics is a heuristic technique to solve the shortest route problem by improving existing routes. This technique is named "2-Opt" because it considers two points on a route and tries to swap the path connecting those two points with an alternative path that may be more efficient. The 2-Opt

algorithm takes an initial route consisting of several points and then considers all possible combinations of two points on the route. After that, the algorithm tries to rotate the part of the route between the two points to produce a new route. Then, the algorithm compares the total initial route distance with the resulting new total route distance and chooses the route that has the shortest total distance. Fig. 1 is an illustration of the 2-Opt algorithm.

Fig. 1. An illustration of how the 2-Opt algorithm works.

In Fig. 2, there are four location points symbolized by  $v_1, v_2, v_3,$  and  $v_4$ . Initially, some edges intersect, namely  $v_1$  to  $v_2$  and  $v_3$  to  $v_4$ . This algorithm checks the distance between other adjacent points without adding new edges. The other closest sides to be checked are  $(v_1, v_3)$  and  $d(v_2, v_4)$ . The criteria for selecting the ideal side can be calculated by comparing the Euclidean distance-like Eq. (9). If the conditions in Eq. 9 are met, then the two sides  $(v_1, v_2)$  and  $(v_3, v_4)$  will be replaced with two new sides  $(v_1, v_3)$  and  $d(v_2, v_4)$ .

$$d(v_1, v_3) + d(v_2, v_4) < d(v_1, v_2) + d(v_3, v_4) \quad (9)$$

## V. HYBRID HEURISTICS

Hybrid NN is a heuristic algorithm which is a combination of two heuristic techniques, namely NN and 2-Opt. Hybrid RNN is a heuristic algorithm which is a combination of two heuristic techniques, namely RNN and 2-Opt. This algorithm is designed to solve the shortest route problem by using the advantages of both heuristic techniques. In the Hybrid Nearest Neighbor-2Opt approach, you will generate an initial solution using the NN method. Then, you'll refine this solution using the 2-opt method. This combination can be effective because the NN method provides a good starting point for the 2-opt method, which can refine the solution. The hybrid RNN-2-Opt algorithm begins by building an initial route using the RNN algorithm. After the initial route is built, the 2-Opt technique is applied to improve the route by finding a point on the route that can be exchanged so that the total route distance becomes shorter. This process is repeated until there are no more points that can be exchanged to shorten the route distance.

```
function RNN-2Opt(cities):
    best_tour = None
    best_distance = infinity
    for each city in cities:
        current_tour = NearestNeighborTour(starting from city)
        improved_tour = True
        while improved_tour:
            improved_tour = False
            for i=1 to number of cities in the tour - 1:
                for j=i+1 to number of cities in the tour:
                    new_tour = 2OptSwap(current_tour, i, j)
                    if distance of new_tour < distance of current_tour:
                        current_tour = new_tour
                        improved_tour = True
            if distance of current_tour < best_distance:
                best_tour = current_tour
                best_distance = distance of current_tour
    return best_tour
function NearestNeighborTour(starting city):
    create an empty tour
    add the starting city to the tour
    while there are unvisited cities:
        find the nearest unvisited city to the last city in the tour
        add the nearest city to the tour
    return the tour
function 2OptSwap(tour, i, j):
    return the tour up to i-1, followed by the section from i to j reversed, followed by the rest of the tour
```

Fig. 2. Pseudocode hybrid RNN.

This pseudocode follows the Hybrid RNN algorithm as follows [29]:

- 1) It starts from each city and generates a tour using the Nearest Neighbor (NN) heuristic.
- 2) Then it tries to improve this tour using the 2-Opt heuristic, making 2-Opt swaps as long as they improve the tour.
- 3) It keeps track of the best tour found so far, and once all cities have been used as starting points, it returns the best tour found.
- 4) The NearestNeighborTour function implements the Nearest Neighbor heuristic: starting from a given city, it repeatedly visits the nearest unvisited city.

## VI. EXPERIMENTAL RESULTS

In the discussion in this study, we present 100 locations in Medan city, North Sumatra, Indonesia. The locations will be analyzed for the shortest route based on location coordinates. The location to be calculated can be seen in Fig. 3. Customer location according to geographical coordinates can be seen in Fig. 3 (a), and Fig. 3(b) is the location transformation to the Cartesian point plane. This transformation makes it easy to illustrate Euclidean distance calculations.

There are four solutions proposed to be observed, namely NN, RNN, hybrid NN, and hybrid RNN. This study uses the Rstudio software with the TSP package and tspmeta for calculating heuristic solutions. A comparison of the total mileage obtained can be seen in Table I. In Table I, RNN and hybrid RNN methods have the best solution in the case of a combination of 100 location points in Medan city, North Sumatra Province, Indonesia. The table provides information about the heuristics used to solve the shortest route problem at

100 different points and the total distance travelled in kilometres. Four types of heuristics are used: NN, RNN, hybrid NN, and hybrid RNN. NN and RNN have different total distances travelled, where RNN produces a shorter total distance than NN (385.83 km compared to 435.91 km). The hybrid NN also produces a shorter total distance than the NN (414.09 km compared to 435.91 km), although it is still longer than the RNN. RNN-2Opt has the same total distance as RNN (385.83 km), so RNN-2Opt is the most effective heuristic in solving the shortest route problem at those 100 points. The results of data processing with Rstudio are visualized in Fig. 4. Fig. 4 is a travel route using the local search heuristic algorithm: NN, RNN, hybrid NN-2Opt, and hybrid NN-2Opt.

In the next stage, we tested several location points totaling 25, 40, 50, 75, 100, 150, 200, and 300 randomly generated around Medan city, North Sumatra Province. From the simulation results given, the total distance traveled in kilometers can be seen in Table II. The Table II has six problem instances, namely n25mdn, n40mdn, n50mdn, n75mdn, n100mdn, and n150mdn.

The total distance travelled by the four different algorithms is given for each problem instance. From the table, the algorithm's performance varies depending on the size of the problem instance. In the n25mdn problem instance, the hybrid NN algorithm produces the shortest total distance (202.28 km) compared to the other three algorithms. However, in the case of the n50mdn problem, the hybrid NN algorithm is no longer the best choice, while the hybrid RNN algorithm produces the shortest total distance (309.25 km). In more significant problem instances such as n100mdn, RNN and hybrid RNN beat the other two algorithms, producing the same total distance (385.83 km). At the same time, hybrid NN could only produce a total distance of 414.10 km, and NN produced a longer total distance of 435.92 km. However, remember that

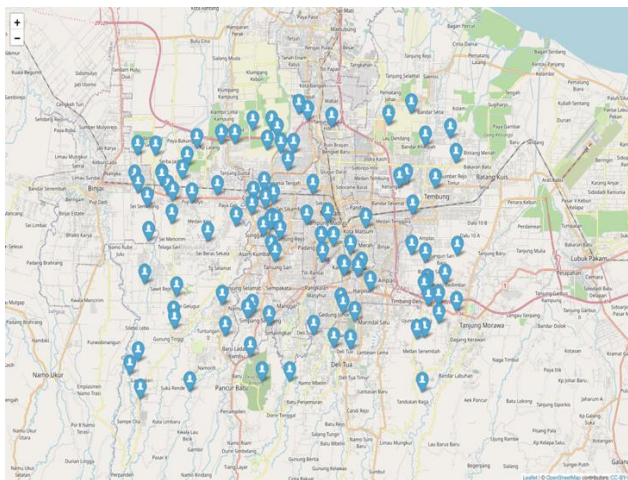

the algorithm's performance depends on the particular problem instance, so choosing an algorithm based on the characteristics and size of the problem instance to be solved is better. To find out the capabilities of this method to quickly calculate the minimum mileage. So we tested the problem with some data from TSPLIB and tried to compare the best-known solutions with our proposed method. The results of the simulation carried out can be seen in Table III.

TABLE I. TOUR LENGTH

Heuristics	n	Total Distance (km)
NN	100	435.91
RNN	100	385.83
hybrid NN	100	414.09
hybrid RNN	100	385.83

From the Table III, it can be seen that the performance of the algorithm varies depending on the particular problem instance. In Berlin52, the Hybrid NN and RNN Algorithm, algorithms have the best performance, producing a total value of the shortest distance of 8182.19. However, in Ch150, the Hybrid RNN algorithm produced the best total shortest distance, 6695.24, while the NN Algorithm produced the longest total distance (8025.45). In larger problem instances such as pr299, the Hybrid NN and RNN Algorithm, algorithms can beat the other two algorithms, where both produce a better total distance value compared to the NN Algorithm and Hybrid RNN. However, these methods still need to be revised to the best-known solutions. To see a comparison of the methods is presented in Fig. 5. In Fig. 5, it can be seen that the error weight is calculated by Eq. (10). The hybrid method can reduce the error rate.

$$Error (\%) = \frac{Proposed\ Method - Best\ Known}{Best\ Known} \times 100\% \quad (10)$$

n300mdn	300	844.22	691.48	767.99	692.26

TABLE III. SIMULATION RESULTS FOR CALCULATING TOUR LENGTH USING TSPLIB DATA

Problem Name	Num. of City	Best Known	NN	Hybrid NN	RNN	Hybrid RNN
Berlin52	52	7542	8182.19	7713.03	8182.19	8182.19
Ch150	150	6528	8025.45	7656.96	7078.44	6695.24
pr299	299	48191	57901.3	49555.9	56199.22	50566.20
pr264	264	49135	54491.5	52084	54124.53	53431.19
pcb442	442	50778	58953	53044.4	59947.47	53898.70
bier127	127	118282	133971	122072	127708.80	125030.50

Fig. 5 states that the percentage errors of the NN, RNN, Hybrid NN, and Hybrid RNN algorithms in solving some shortest route problems using several datasets. The percentage error indicates how far the results produced by the algorithm are from the known best (best-known solution) for each problem. The lower the error percentage, the better the results produced by the algorithm. Based on the Fig. 5, it can be seen that hybrid NN and hybrid RNN tend to give a lower error percentage than NN and RNN. Hybrid NN even produces the lowest error value on the Berlin52 dataset, and hybrid RNN produces the lowest error value on the Ch150 dataset. This shows that using hybridization techniques can improve the quality of the solutions produced by the algorithm.

Fig. 5. Comparison of the heuristic method errors offered.

In aggregate, there is an average difference between non-hybrid and hybrid methods. The simulation results using RStudio using the `t.test()` function obtained a value of  $t = 2.8056$ ,  $df = 27$ , and  $p - value = 0.0092$  at a 95% confidence level. The t-value indicates the magnitude of the difference between the means of the two groups, in this case, the non-hybrid and hybrid methods. A larger t-value indicates a greater difference between the means. The degrees of freedom (df) represent the independent observations to estimate a parameter. In this case, it indicates the number of observations minus the number of parameters estimated, which is equal to 27. The p-value is the probability of obtaining a t-value as extreme as or more extreme than the observed t-value, assuming the null hypothesis is true. In this case, the null hypothesis is that there is no significant difference between the means of the non-hybrid and hybrid methods. A p-value of 0.0092 suggests that the probability of obtaining such an extreme t-value under the null hypothesis is less than 0.01. Therefore, the result is statistically significant at a 95% confidence level. In summary, the simulation results

suggest a significant average difference between non-hybrid and hybrid methods in terms of their performance, with the hybrid methods outperforming the non-hybrid methods on average.

## VII. DISCUSSION

In this study, the authors delve into the challenging Traveling Salesman Problem (TSP) using a variety of heuristic algorithms. Their research focuses on 100 locations in Medan city, North Sumatra, Indonesia, and aims to find the shortest route based on geographical coordinates. We transform geographical coordinates into Cartesian points to facilitate this analysis, making Euclidean distance calculations more accessible. Four heuristic solutions are proposed for examination: Nearest Neighbor (NN), Repetitive Nearest Neighbor (RNN), Hybrid NN, and Hybrid RNN. RStudio software, coupled with the TSP package and `tspmeta`, is employed for heuristic solution calculations. The study sheds light on the performance of these algorithms, particularly focusing on the total mileage obtained, which is compared across different problem instances and known benchmarks.

The results of this study reveal that the performance of heuristic algorithms is contingent upon the specific problem instance under consideration. In smaller problem instances, such as `n25mdn`, the Hybrid NN algorithm proves to be the most efficient in producing the shortest total distance. Nevertheless, as problem instances grow in complexity, like `n50mdn` and `n100mdn`, the RNN and Hybrid RNN consistently outperform the other algorithms, yielding identical total distances in the case of `n100mdn`. The choice of the algorithm should be tailored to the problem's characteristics and scale, highlighting the nuanced nature of TSP problem-solving.

The study evaluates the proposed heuristic methods with known best solutions from the TSPLIB data. This comparative analysis offers valuable insights into algorithmic performance under standardized benchmarks. For instance, the Berlin52 dataset demonstrates that Hybrid NN and RNN algorithms attain the best results, aligning with the best-known solution. Conversely, in the Ch150 dataset, the Hybrid RNN algorithm emerges as the frontrunner, boasting the best total shortest distance. This highlights the potential of hybridization techniques, like combining NN and RNN with 2-Opt, to yield superior-quality solutions and reduce error rates vis-à-vis non-hybrid methods.

The paper augments its findings with statistical rigour, employing a t-test to substantiate the significance of differences between non-hybrid and hybrid methods. The results confirm that, on average, hybrid methods surpass their non-hybrid counterparts, underscoring their potential for achieving more optimal solutions.

This study carries substantial implications for addressing TSP and akin optimization challenges. Algorithm selection should be a nuanced process tailored to the problem's size and intricacies. The fusion of heuristic algorithms, as demonstrated in hybridization techniques, holds promise for elevating solution quality. Benchmarking against established datasets like TSPLIB serves as a litmus test for algorithmic reliability. Importantly, while heuristic methods may not always secure the global optimum, their swiftness renders them indispensable for tackling real-world routing and scheduling problems. This research advances the understanding of heuristic algorithm performance within the TSP domain and underscores the transformative potential of hybridization strategies in optimization problem-solving.

### VIII. CONCLUSION

TSP is a complex combinatorial problem in calculations to find the best combination. Because it is challenging to calculate the final solution with the shortest tour length globally, however, the heuristic approach method can be used. This heuristic method is a method that can calculate a solution quickly with a pretty good solution. However, it is still inferior to modern and exact metaheuristic methods in finding solutions, but the speed of finding solutions cannot be doubted because they can calculate quickly. Therefore this method is still widely used in various applications in the real world. The results of this study indicate that the offered hybrid method can correct errors from the usual heuristic methods. The combination of NN and RNN algorithms with 2-Opt provides a better solution. The hybrid method minimized the percentage of errors compared to the non-hybrid method. The 2-Opt technique can be used in combination with other heuristic algorithms such as NN or RNN to improve the quality of the resulting solutions. However, although the 2-Opt technique can increase the efficiency and quality of solutions, this technique does not guarantee that the given solution will always be optimal.

**Abstract**—The word aquaponics means the growth of aquatic organisms as well as plants in the controlled environment. As the nutrients used for sustainable plant growth is obtained from aquatic organisms and the nutrients that are absorbed by the plants remediate the water for the aquatic life. The advancement in the computational studies plays a vital role in every field of life. The aim of the proposed study is to deeply analyze the computational studies that used IoT, AI, Machine learning and deep learning for aquaponic systems between the years 2019 to 2022. The literature survey deeply discuss the proposed methodology, comprehends the fundamental researches, tool, advantages, limitations, concepts, and results of the recent studies proposed by the researchers in context of aquaponic system. The proposed study extract 41 research articles from these libraries based on year of publication, title, methodology, citation, paper quality and abstract. These articles are collected from seven different research article libraries including Google Scholar, Worldwide Science, IEEE Xplore, Google Books, Refseek, ACM digital Library and Science Direct. This study develops a state of the art research for the next researchers to work on the loopholes of the previous researches in an efficient manner. The results of the proposed study shows that the implementation of IoT based machine learning and deep learning framework shows state of the art results for the nutrients regulation, sensing, monitoring and controlling of the aquaponic environment. It is concluded from the proposed study that there need to be develop ensemble learning model with an efficient dataset in context of aquaponic environment.

**Keywords**—Aquaponics; machine learning; internet of thing (IoT); message queue telemetry transport; sensors; SMART aquaculture

### I. INTRODUCTION

The growth of the human population is expected to cross 10 billion till 2062. This increase in the population will create the challenge of energy, food and water for human. Computational field has a huge impact in every field of life [1] [2]. Agriculture is suffering from many problems including consumption of water, lack of land, lack of workforce etc. It is the most water consuming field that uses about 70% of water in different contexts. The word aquaponic refers to two words “Aquaculture” means to grow the water culture organisms in controlled environment and “Ponics” means growth of soil less media. The word aquaponics means the growth of aquatic organisms as well as plants in the controlled environment [3].

It is a combined production system of plant and aquatic animals in which most of the nutrient used for the development are obtained from each other. As the nutrients used for sustainable plant growth is obtained from aquatic organisms and the nutrients that are absorbed by the plants remediate the water for the aquatic life. This technology was firstly developed by the scientist in United States of America in early 1970's. The aim of this process is to create a sustainable and economic environment by efficient usage of water and nutrients, increase the profitability, Farm diversification, use of wastage, lowered the environmental impact and increasing the production to agricultural fish and plant production [4] [5] [6]. This is one of the main methods to solve the food and environmental crisis of the nature adopted by many countries worldwide. The Nutrient flow in the aquaponic system is measured constantly for the regulating the growth of the plants as the nutrients generated by the fishes is not sufficient for the growth of the plants. There are hundreds of studies proposed by the researchers for the identification and regulation of the flow of the nutrients in the aquaponic system. Fig. 1 describes the all-time interaction of the aquaponic system with computational industry [7].

Fig. 1. Industrial revolution in the aquaponic system.

To find the best design, implementation of that design with management and maintenance is the key factor for the success of an aquaponic environment [8]. Many researcher in past

focus on different computational, statistical and mathematical tools and techniques to ensure the efficient working of an aquaponic system. The smart working of an aquaponic system based on different factors including the water quality, temperature, pH level, air flow, predictors, light intensity, humidity, Air quality, IoT sensors etc. The aim of the study is to develop a systematic survey on the latest researches proposed by different researchers for aquaponic environment. This study provides the deep analysis of the methodology, advantages and limits of the study that will create a benchmark for the new researchers in this field. A total of 41 quality research articles are deeply reviewed in this research.

The list of abbreviations used in the proposed study is illustrated in Table I

TABLE I. LIST OF ABBREVIATIONS

Word	Abbreviation
RFE	Recursive Feature Elimination
IoT	Internet of things
XGBoost	Extreme Gradient Boosting
PA	Precision Agriculture
SAR	Sodium Absorption Ratio
LDA	Linear Discrimination Analysis
BLOO	Bolstered leave one out
DTC	Decision Tree Classifier
WSN	Wireless Sensor Network
DCNNs	Deep convolutional neural networks
DB-SMOTE	Density Based Synthetic monitoring over sampling technique
SDC	Stochastic Gradient Descent
R-CNN	Regional Convolutional Neural Network
LR	Logistic Regression
SMR	Standard Metabolic
ADC	Analogue to digital convertor
US	Univariate Selection
FI	Feature importance
GNB	Gaussian Naïve Bayes
CPS	Cyber-Physical Systems
MQTT	Message Queue Telemetry Transport
NGSI	Next Generation Service Interface
ANFIS	Adaptive Neuro Fuzzy Inference System

## II. RESEARCH PLANNING

The aim of this study is to presents the latest IoT based machine learning and deep learning presented by different researcher in advancement of aquaponic system. The review method developed by Brereton et al. [9] is used in this research for reviewing the articles. This is one of the most widely used approaches for systematic literature review. This process includes five steps which are [10] discussed here in the below section.

The first phase of the research survey is planning a systematic model for work. The process of research planning include identification of the research questions, the include exclude criteria of selection, quality measurements,

identification of relevant studies and analysis of these studies. Fig. 2 explain the selection criteria of research for the proposed study [11].

Fig. 2. Selected criteria for systematic literature review.

The first thing is to generate the research questions. The research questions for the proposed study are

RQ1: What is an Aquaponic culture?

RQ2: How the aquaponic environment works?

RQ3: What is the purpose of the proposed study?

RQ4: What are the advantages of aquaponic system?

RQ5: What are the computational studies proposed for the aquaponic system?

RQ6: What are different IoT based studies using machine learning and deep learning for aquaponics?

RQ7: What are the methodologies, advantages and loopholes of those studies?

RQ8: Comparison of the results of the previous studies?

RQ9: What are the research possibilities?

RQ10: What is the conclusion of this study?

RQ11: What are the research questions raised for the new researchers regarding aquaponic system?

The quality of the systematic literature reviews completely depend upon the selection of the related articles. In context of this, the proposed study extracts the research articles from most of the authentic and widely used article database sources. The articles are selected from seven different articles websites including Google Scholar, Worldwide Science, IEEE Xplore, Google Books, Refseek, ACM digital Library and Science Direct.

The selection is based on the quality of the research article. For searching articles from these sites different combination of words used including “Aquaculture, Aquaponics, SMART Aquaponics, IoT Based Aquaponic, Machine learning for aquaponic system, Deep learning for aquaponic system,

Nutrients regulation in Aquaponic system, Monitoring and sensing in aquaponic system, Accurate segmentation, Real time semantic, Neural network for aquaponic systems”. After applying these keywords on database libraries hundreds of articles appear. The articles are included on the basis of the relevant studies that are proposed for systematic review. This includes, excluded criteria of these articles as given below:

- Language must be English.
- Authentic Journal papers, Conference papers, Books etc.
- Papers using IoT based SMART technology
- The paper with ML and DL methods of aquaponic culture
- Papers after year 2019

The papers chosen for the proposed study are between the years 2019 and 2022. The paper published in English language and use IoT, ML, AI and DL methods are accepted for processing.

Exclude:

- Paper in language other than English
- Papers published before 2019
- Paper with method other than AI, IoT, ML and DL.

In the proposed study a total of 2,002 articles are screened from the article databases. From the selected papers 1,106 are rejected due to the publication year was before 2019. Rest of 896 articles is processed and 602 articles are rejected because of their irrelevancy of the subject. 294 selected articles are further processed and 79 out of them are selected based on IoT, ML, AI and DL methods used by the studies. 38 papers are rejected due to the low quality of paper. After the overall selection process overall 41 articles are processed for systematic literature review.

Fig. 3 explains the study flow of different phases using PRISMA [12] diagram for the article selection.

Fig. 3. Article selection criteria for systematic literature review.

### III. LITERATURE REVIEW

There are a number of computational studies developed by different researchers for the development of smart aquaponic system. In this section of the research the latest studies developed by the researchers based on IoT, Machine learning, deep learning and AI based methods between the years 2019 and 2023 are discussed. This paper deeply analyzes the advantages and disadvantages of the proposed models developed by the recent researchers.

Commercial aquaponic system helps to increase the profitability and sales revenue of aquaponic system by increasing the production. The most revenue is generated by the aquatic animals including tilapia, catfish, ornamental fish, perch, bass, trout, and bluegill [13]. The regulation of the nutrients in the aquaponic environment is one of the most discussed topic in recent years. S. B. Dhal *et al* [14] presents an IoT based system used for nutrient supply in the commercial aquaponic environment. The dataset for the study is taken from three different farms at Southeast Texas (Aquatic Greens Farm, Wolff Family Farms and Texas US Farms). This data was generated from the farms weekly over a year. From the dataset 12 predictors (Ca, Mg, Na, K, B,  $NaHCO_3$ ,  $HCO_3$ ,  $SO_4$ , Cl,  $NO_3$ ,  $NH_4$ ,  $PO_4$ ) and 211 observations are generated. On this dataset the features are extracting using pairwise correlation matrix and Recursive Feature Elimination (RFE). Machine learning algorithm XGBoost is used for generating F-score of the features and ExtraTreesClassifier is used for RFE [15]. The experiment was carried out in the cycle of 21 days. Two predictor calcium and ammonium is identified and regulate by using this system. The cost of the proposed model is decreased by 75% as compared to the existing models that are used for nutrient regulation [14].

M. A. Zamora-Izquierdo, J. Santa, J. A. Martínez, V. Martínez, and A. F. Skarmeta presents [16] IoT based on edge computing system to enhance PA. The model works on three tiers. The local plans the CPS system connects with the aquaponic crops to collect the data and perform atomic control actions. The Edge plane used for monitoring and managing the PA task and cloud plane host and record the data in FIWARE deployment. MQTT and NSGI protocols are used communicating and accessing with the cloud. The working of this system is shown in Fig. 4 [16].

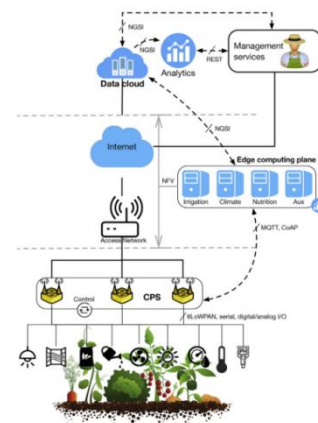

Fig. 4. Precision Agriculture based on IoT and edge computing.

The experiment is carried in Greenhouse of CEBAS-CSIC, Spain. Nutrient solution unit, irrigation unit, disinfection unit, purification unit and climate unit is used to facilitate the greenhouse environment. This research provides the water saving of more than 30% with upto 80% nutrients. This study provides the new path for the researcher to implement the PA platform in future crops. R. Barosa, S. I. S. Hassen, and L. Nagowah [17] combine hydroponic with conventional agriculture system to develop Plantabo Aevum system. The IoT devices are used for continue monitoring the environmental factor and providing the real time feedback. Live cameras are used for continue image capturing that is used for image processing. With the detection of the main features of the plant leaf the system detect the disease in it and generated the report on mobile application. The dataset is taken from the 50 leafs of four different type of plants including chilli, eggplant, mandarin and citrus. Machine learning algorithm decision tree is used for the classification. The working is implemented on OpenCV toolbox. This study detect the leafs of different species of plants accurately using machine learning system. The implementation of deep learning on the method was the loophole of that study. A researcher developed a web based monitoring system of pH, temperature and dissolved oxygen in aquaponic system [18]. Arduino microprocessor is used for measuring the environmental factors that send the measurements to local host server. Raspberry Pi is use as a network backbone of this process that transmit the information and display the live sensor data to the website on every half second [19]. In another research [20] statistical tools with machine learning algorithms are used for the nutrient regulation for the optimal growth of plants. The dataset for that study is taken from aquaponic farms of Bryan, Caldwell, and Grimes counties in Texas. The data is collected from the plant bed and fish tanks of the farms. From the collected dataset 143 observations are collected for 24 predictors out of which 11 are chemical predictors, eight are solutions, two of them measure the hardness, and other are SAR, Alkalinity and total dissolved salt. Different dimension reduction techniques [21] i.e. XGBoost and pairwise correlation matrix applied on the dataset for defining the nutrient concentration of the solution. The working of the model is explained in the Fig. 5 [20].

The predicators with less importance in the dataset are removed. Error calculation techniques including Bolstered resubstituting error estimation, BLOO error estimation and Semi-bolstered Resubstitution error estimation [22] are applied on the dataset for selecting the best methods. The results show that Semi-Bolstered Resubstitution Error estimation technique gives best result for Linear Support Vector Machine. A CNN based model using machine vision is also proposed to measure the fish length [23]. This study uses the dataset of European sea buss using camera. R-CNN gives the mIoU value of 93% for fish detection. Reduction of precision bias and increasing the precision using machine vision was the loophole of that study.

A. Taufiqurrahman, A. G. Putrada, and F. Dawani [24] proposed DT regression based model for stabilizing the water temperature for trees and fishes in an aquaponic environment. Adaptive Boosting [25] algorithm is applied with DT to avoid

the model over fitting. Swirl filter and bioball filter is installed in the fish tank for extracting the waste and nitrification of bacteria from the water. Temperature sensor is installed to detect the water temperature, water heater use to heat the water when the temperature get down, fans are used to lower the water temperature if the temperature goes high. The results of the model show that the DTR model with AdaBoost shows MSE value of 0.0045 and R-square value of 0.92.

Researcher [26] proposed a deep learning model with ResNet, SegNet18 and Inceptionv3 [27][28] for monitoring and diagnosis of the nutrient deficiency in lettuce plant of aquaponic system. The dataset used by the study consists of 3000 images that are classified into four groups. These groups are based on the images with full nutrients, Phosphate deficiency, nitrogen deficiency and potassium deficiency group. The images of the dataset are divided into training, testing and validation dataset and passed through image segmentation method for labeling the images [29]. Different features are extracted from the segmented images. These features include texture features (entropy, contrast, correlation, energy), morphological features (area, parameter) and color features are extracted. The results shows the accuracies of 98.30%, 98.90%, and 97.70% of SegNet, Inceptionv3, and ResNet18 for training set and 99.29%, 98.00% and 92.5% for validation set respectively.

S. B. Dhal, M. Bagavathiannan, U. Braga-Neto, and S. Kalafatis [30] present a comparative analysis of nutrient control in aquaponic system. The dataset of this study consists of 32 predictors taken from 201 observations. DB-SMOTE algorithm applied on the dataset for balancing the dataset values [31]. RFE with ExtraTreeClassifier shows more than 90% correlation between the predictors. M. F. Taha *et al.* [32] present machine learning model for the content detection of based on spectral data. The experiment for the study was proposed at Zhejiang University china. The working of this model is completely explained in Fig. 6.

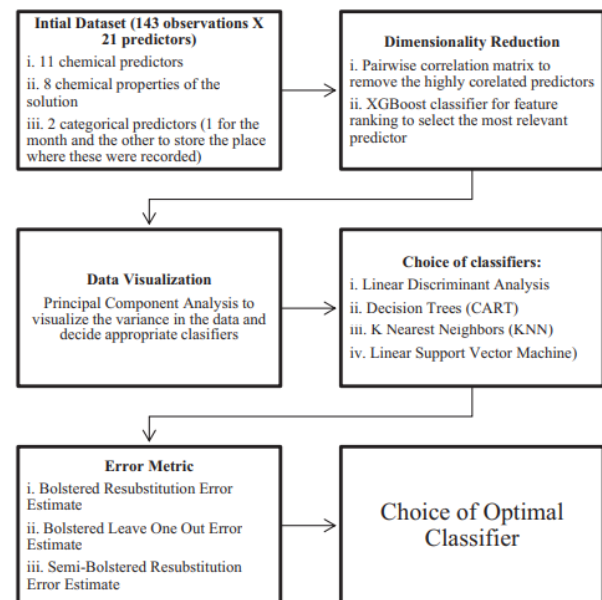

Fig. 5. The process of decision support system for nutrients regulation in aquaponic system.

Fig. 6. The working of machine learning based Nutrient content detection model.

The spectral reflectance of the leaf [33] is measure by FieldSpec4, Pro FR portable spectroradiometer. Three machine learning models including Random Forest (RF), partial least square regression (PLSR) and backpropagation neural network (BNN) is used to classify the nutrients. The BNN algorithm shows the highest predictive accuracy of 97.2 for nitrogen content. While the highest predictive value of 0.94 and 0.96 for phosphate and potassium is obtained by RF algorithm.

In another research machine learning vision based system is employed for the lettuce growth classification. The process of lettuce development took around 45-55 days for the growth in vegetative, development and harvest cycle. The dataset of lettuce images for the study contains 300 images taken from the aquaponic system developed by Rizal, Philippines. The data extractions from these images are done by using different machine learning based feature extraction techniques in MATLAB. This classification is performed by three machine learning algorithms KNN, L-SVM and LR. The model gives the classification accuracy of 91.67% by KNN algorithm, 80% with L-SVM and 66.7% with LR algorithm [34].

Wireless technology also have a vital role in the aquaponic farming. In the latest researches the researchers presented an IoT Based system for the monitoring, regulating and controlling of the aquaponic systems [35]. T. Khaoula, R. A. Abdelouahid, I. Ezzahoui, and A. Marzak [36] presents AI and IoT based system for controlling the water quality of aquaponic system using different sensors and actuators. The system consists physical layer that consists of sensors, gateway layer that includes NodeMCU for data collection, the middleware layer that is responsible for publishing the semantics done by MQTT and the application layer use for providing the interface. There are different types of sensors including pH sensor, water level sensor, humidity sensor, temperature sensor, EC sensor, soil measure etc. used in the study for collecting the data. Haryanto, M. Ulum, A. F. Ibadillah, R. Alfita, K. Aji, and R. Rizkyandi, presents smart IoT-based system for controlling the nutrients in aquaponic system. The working of this model is explained in Fig. 7 [25].

The results of this model shows the accuracy value of 99.94% for ultrasonic sensor and 92.53% for pH sensor. In IoT based deep learning approach use edge computing for aquaponic monitoring system. The system contain four subsystems for greenhouse sensors form plant growth, aquaponic control, growth monitoring and data uploading. DHT11 sensor is used for temperature sensing, BH1750 is

used for light sensing, HC-SR04 is used for ultrasonic sensing, and SEN0161 is used for sensing pH in the current scenario. Mask-RCNN architecture is used for instance segmentation from the 250 images of fish dataset. The model shows the precision, recall and F1 score of 0.94, 0.96 and 0.95, respectively [38].

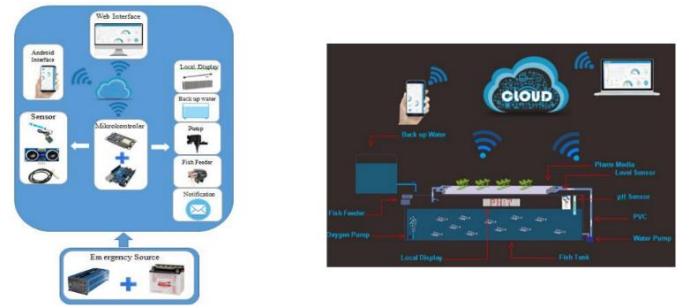

Fig. 7. System design of smart IoT based aquaponic system.

C. Lee and Y. J. [39] also present the cloud system for fish based IoT metabolism in aquaponic system through oxygen transfer rate model. IR distance sensor is used in the fish tank for finding the locomotion of the fishes in water tank. ADC is used to convert the IR signals to integer value. The dataset used in the study obtained from 27 fishes of different types in the water tank. The fish metabolic rate is used to determine the oxygen consumption level of fishes. The study shows that the pH, temperature of water and dissolved oxygen affect the metabolic activity of fishes in aquaponic system. The periodic regression of the model is carried out on ThingSpeak cloud computing platform [40]. Wang P. Mpofu, S. H. Kembo, S. Jacques, and N. Chitiyo [41] suggest IoT based household aquaponic system for food production. This was an offline-First system for overcoming the challenges of cloud computing systems in low budget household scenarios by using the Edge and Fog computing [42]. This system is deployed using LAN connection to remove the dependency of active internet connection. Edge computing is utilized to constantly check the water flow in the water pumps. This detection was based on the sound detection scenario of water in the water pumps. Raspberry Pi network is used for Fog computing. This research shows that the Edge and Fog computing system shows the cheap and efficient results in household aquaponic system.

S. C. Lauguico, R. I. S. Concepcion, J. D. Alejandrino, R. R. Tobias, and E. P. Dadios [43] classify the lettuce life in aquaponic system using machine learning for texture classification. The dataset used for the study is taken from Morong, Rizal, Philippines aquaponic farms. Haralick Texture Feature is used to extract the features from RGB images [44]. RFE, US and F1 feature extraction methods are used for extracting the features from the texture attributes. The extracted features are classified using machine learning algorithms GNB, SGD, LDA and DTC. Hold-Out validation and cross validation is applied on these algorithms for generating the results in the form of accuracy and F1 score. The best accuracy classification accuracy of 87.9% is obtained from DTC.

A. Reyes-Yanes, P. Martinez, and R. Ahmad [45] present computer vision based system to determine weight and growth rate of the fish and crops of little gem romaine lettuce the aquaponic environment. There are three basic methodology used in the model as model building for image preprocessing, image training and model training, prediction- correlation for image segmentation and parameter estimation for feature extraction. A total of 3150 instances of data is obtained from 1350 image dataset. The results of this system show the overall error of 18.7% mm for size of crop and 8.3% for weight of the fish. R. Abbasi, P. Martinez, and R. Ahmad [46] present ontology model for aquaponic grow beds. This knowledge modelling system automatically detects the required characteristics for an aquaponic crop. The AquaONT system is developed for decision making, GUI developed used inferred, and the design parameters are obtained by mathematical equations. The results of this research shows that the correct grow bed design gives the high crop yield and quality. In one of the latest research, industry 4.0 [47] method is implemented on the aquaponic environment. This method combines the latest computational studies including big data analysis, deep learning, robotics, IoT, AI and cloud computing for aquaponic environment. This research use the methontology model [48] to evaluate the AquaONT. The overall working of this whole process is shown in Fig. 8 [7].

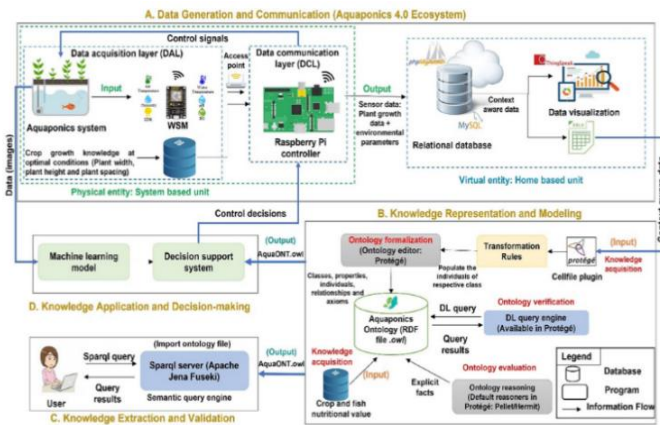

Fig. 8. An overview of AquaONT system.

This model gives the information about optimal operation of IoT devices, taking required actions on qualitative issues of fish and crops in aquaponic environment, and design configuration of grow beds based on crop characteristics while merging them with a suitable interface. These results helps the farmers to control the system of aquaponic environment in efficient manners.

A research is designed IoT based model to monitor modularization, miniaturization, and low-cost features of aquaponic system. The architecture of the model is shown in Fig. 9 [49].

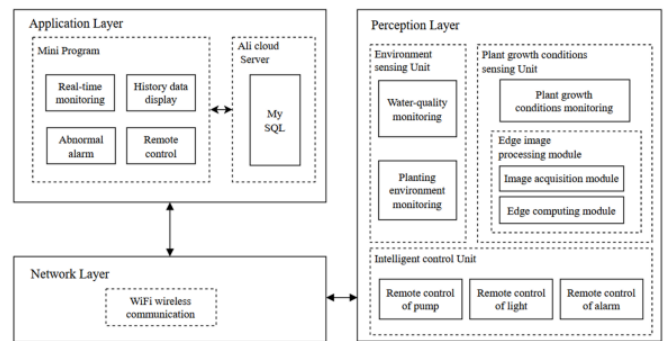

Fig. 9. Architecture of Embedded Edge computing based in IoT monitoring for aquaponic system.

The IoT based sensing consists of three layers including Application, Network and Perception layer allow the system to communicate and pass information without human interaction [50]. For this study there are three units of environment sensing, plant growth sensing, and intelligent control unit in perception layer. The model shows the environmental error rate of 5%. This system works on the edge computing using monitoring nodes, that provides the base line for the next researchers to use more nodes with strong edge sensing for the aquaponic modularization. P. Debroy and L. Seban [51] presented machine learning based study for the prediction of fruit biomass for enhancing the profit and production. The mathematical model is used to generate the dataset consists of parameters and weight of tomato in aquaponic system. Machine learning algorithm ANN and ANFSI is used for the classification. The model shows the MAE value of 0.1079 and RMSE value of 0.4582 with ANN model.

In one of the latest research AI based surrogate models [52] are implied with IoT for smart aquaponic to overcome the labor problem. This system provides the real time monitoring of water quality, temperature, pH and other parameters in aquaponic system. Fig. 10 explain the whole setup of IoT based smart pound with automatic control [53].

Fig. 10. IoT based smart aquaponic system.

Five sensors, five actuators along with Arduino Mega2560 are used in the system for sensing and monitoring the data. The result of the research shows  $R^2$  value of 0.94 and a MSE value of 0.0015. The comparison of latest models for the studies is explained in Table II.

TABLE II. LITERATURE REVIEW TABLE

Paper Title	Year of Publication	Methods	Dataset	Result
Smart aquaponic system based Internet of Things (IoT) [37]	2019	IoT cloud based system	Live sensors for collecting the data.	The accuracy of 99.94% for Ultrasonic sensor and 92.35% for pH sensor.
Smart Aquaponics with Disease Detection [17]	2019	IoT based system with machine learning classifier	Real time Firebase database	Detect leafs of different species for disease detection.
Smart farming IoT platform based on edge and cloud computing [16]	2019	IoT based Edge computing	Greenhouse of CEBAS-CSIC	Saving more than 30% and 80% nutrients.
Using Machine Vision to Estimate Fish Length from Images using Regional Convolutional Neural Networks [23]	2019	Machine vision using R-CNN	European sea bass image dataset	mIoU value of 93%
Lettuce life stage classification from texture attributes using machine learning estimators and feature selection processes [43]	2020	REF, US and F1 feature extraction model with GNB, LDA, DTC and SGD algorithms	Data instances from Morongo, Rizal, Philippines aquaponic farms	DTC shows the classification accuracy of 87.9%
Real-time growth rate and fresh weight estimation for little gem romaine lettuce in aquaponic grow beds [45]	2020	Computer vision based system including image processing, deep learning and regression analysis	Image dataset created by Department of environmental science of University of Alberta	The overall error of 18.7% mm for size of crop and 8.3% for weight of the fish
A Comparative Analysis of Machine Learning Algorithms Modeled from Machine Vision-Based Lettuce Growth Stage Classification in Smart Aquaponics [34]	2020	KNN, L-SVM with LR	Images dataset developed by Rizal, Philippines	Classification accuracy 91.67%
Decision Tree Regression with AdaBoost Ensemble Learning for Water Temperature Forecasting in Aquaponic Ecosystem [24]	2022	DT Regression with AdaBoost Ensemble learning	Experimental based aquaponic system at Telkom University lab	DTR model with AdaBoost shows MSE value of 0.0045 and R-square value of 0.92.
Edge Computing Based Smart Aquaponics Monitoring System Using Deep Learning in IoT Environment [38]	2020	AutoML model with gradient boost Machine learning algorithm	Images of fish dataset from Singapore Bioimaging Consortium, Singapore,	Precision, recall and F1 score of 0.94, 0.96 and 0.95 respectively.
Development of a Cloud-based IoT Monitoring System for Fish Metabolism and Activity in Aquaponics [40]	2020	Cloud based IoT monitoring system using ThingCloud Computing	Data from 27 fishes in the aquaponic environment from National Sun Yat-sen University	The pH, temperature of water and dissolved oxygen effect the metabolic activity of fishes in aquaponic system.
Utilizing a Privacy-Preserving IoT Edge and Fog Architecture in Automated Household Aquaponics [41]	2021	Edge and Fog computing based IoT system	St Peters Mbare IoT Maker space	Edge and Fog computing serve best for household aquaponic system
An Ontology model to support the automated design of aquaponic grow beds [46]	2021	Knowledge modeling approach AquaONT	LIMDA, University of Alberta	The correct grow bed design gives the high crop yield and quality.
A Machine-Learning Based IoT System for Optimizing Nutrient Supply in Commercial Aquaponic Operations [14]	2022	XGBoost and ExtraTreesClassifier With pairwise correlation matrix and Recursive Feature Elimination	Aquatic Greens Farm , Wolff Family Farms and Texas US Farms	Calcium and Ammonium predictors are identified and cost is decreased by 75%.
Nutrient optimization for plant growth in Aquaponic irrigation using Machine Learning for small training datasets [20]	2022	XGBoost and pairwise correlation matrix for dimension reduction and LDA, CART, KNN, SVM for the classification	Bryan, Caldwell, and Grimes counties	semi-Bolstered Resubstitution shows the error values of zero

Using Deep Convolutional Neural Network for Image-Based Diagnosis of Nutrient Deficiencies in Plants Grown in Aquaponics [26]	2022	Deep convolutional neural networks	3000 images of lettuce plant captured by camera (PowerShot SX720 HS)	Accuracy of 96.5%
Can Machine Learning classifiers be used to regulate nutrients using small training datasets for aquaponic irrigation? A comparative analysis [30]	2022	XGBoost and ExtraTreesClassifier	Farms in Texas	More than 90% correlation between the predictors
Using Machine Learning for Nutrient Content Detection of Aquaponics-Grown Plants Based on Spectral Data [32]	2022	Random Forest, Partial least square regression and Back propagation neural network	Spectral data self-obtained from the plant leaves.	The predictive value of $R^2p = 0.97$ for nitrogen is obtained by BNN. While RF gives $R^2p = 0.94$ for phosphate and $R^2p = 0.96$ for potassium
An ontology model to represent aquaponics 4.0 system's knowledge [7]	2022	AquaONT model with methontology approach following deep learning, computer vision and machine learning approaches	Data taken from different farms of Canada	The model show best results for optimal operation of IoT devices, qualitative issues of fish and crops, and design configuration of crop beds grow beds
Tomato Fruit Biomass Prediction Model for Aquaponics System Using Machine Learning Algorithms [51]	2022	ANN with AFNIS		MAE value of 0.1079 and RMSE value of 0.4582
A Modularized IoT Monitoring System with Edge-Computing for Aquaponics [49]	2022	Embedded Edge computing based in IoT monitoring	Real time data collection	Environmental error rate 5%.
Development of smart aquaculture farm management system using IoT and AI-based surrogate models [53]	2022	AI based surrogate model with deep CNN and IoT	Real time monitoring and collecting data	$R^2$ value of 0.94 and a MSE value of 0.0015,

IV. ANALYSIS AND DISCUSSION

Fig. 11 explain the overall working of systematic literature review for the proposed study.

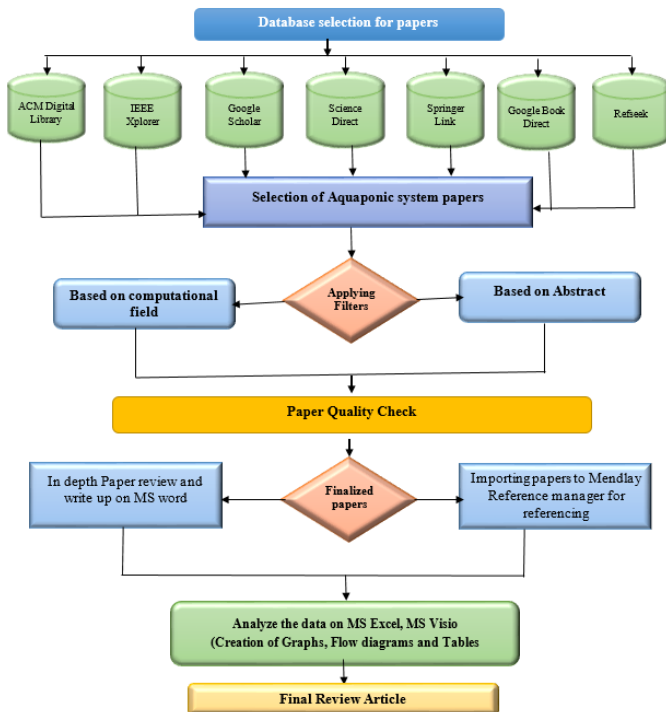

Fig. 11. Workflow of the proposed model.

In the very first step, the papers are selected from seven different known article databases. After applying different queries on these articles only 41 articles are future processed for systematic literature review. These papers are reviewed deeply as discussed in the Literature review section and the methodology, pros and cons of this study are extracted. The final draft of the study present a state of the art article for the new researchers in field of aquaponic culture to analyze the latest methods deeply and find a new direction in context of their working. All the papers that are selected are between years 2019 to 2022. The frequency distributions of the papers are shown in Fig. 12.

Fig. 12. Workflow graph of the proposed model.

All of the selected study gives an efficient result for aquaponic environments. Each study has its own benefits as well as drawback for the upcoming researchers. All the papers are chosen for the study are collected from high source journals and conferences with maximum citations are used in this study for maintaining the quality of the research. The heatmap diagram of the proposed study is illustrated in Fig. 13.

Figure illustrates the publication in context of year with the proposed algorithm. The selected papers are taken from different journal or conferences. The most cited papers among all along with the publishing source are explained in Table III.

In the table from 2019, it may be observed that, till date the most cited research article was IoT based edge detecting system that is published on biosystem engineering journal. Following this [23] [45] [34] has 47, 34, 31 citations respectively considered as best research articles regarding to the field.

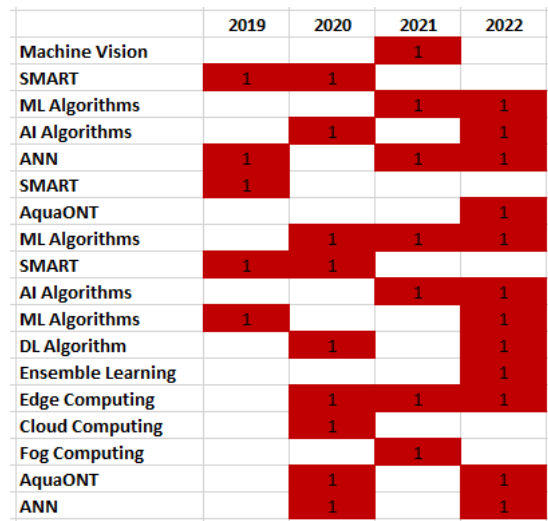

Fig. 13. Heatmap diagram of the proposed selected studies.

TABLE III. ARTICLES WITH MOST CITATIONS AND THEIR PUBLICATION JOURNALS

Author	Paper Title	Year of Publication	Methods	Journal Conference
M. A. Zamora-Izquierdo, J. Santa, J. A. Martínez, V. Martínez, and A. F. Skarmeta [16]	Smart farming IoT platform based on edge and cloud computing	2019	IoT based Edge computing	biosystems engineering
G. G. Monkman, K. Hyder, M. J. Kaiser, and F. P. Vidal [23]	Using Machine Vision to Estimate Fish Length from Images using Regional Convolutional Neural Networks	2019	Machine vision using R-CNN	Methods in Ecology and Evolution
A. Reyes-Yanes, P. Martinez, and R. Ahmad [45]	REAL-TIME GROWTH RATE AND FRESH WEIGHT ESTIMATION FOR LITTLE GEM ROMAINE LETTUCE IN AQUAPONIC GROW BEDS	2020	Computer vision based system including image processing, deep learning and regression analysis	Computer and Engineering in Agriculture
S. C. Lauguico, R. S. Concepcion, J. D. Alejandrino, R. R. Tobias, D. D. Macasaet, and E. P. Dadios [34]	A Comparative Analysis of Machine Learning Algorithms Modeled from Machine Vision-Based Lettuce Growth Stage Classification in Smart Aquaponics	2020	KNN, L-SVM with LR	International Journal of Environmental Science and Technology
C. Lee and Y. J. [40]	Development of a Cloud-based IoT Monitoring System for Fish Metabolism and Activity in Aquaponics	2020	Cloud based IoT monitoring system using ThingCloud Computing	International Journal of Environmental Science and Technology
S. C. Lauguico, R. I. S. Concepcion, J. D. Alejandrino, R. R. Tobias, and E. P. Dadios [43]	Lettuce life stage classification from texture attributes using machine learning estimators and feature selection processes	2020	REF, US and F1 feature extraction model with GNB, LDA, DTC and SGD algorithms	Methods in Ecology Evolution

### V. CONCLUSION

Aquaponic system is the growth of aquatic organisms as well as plants in the controlled environment to overcome the problem of nutrients regulation, consumption of water, lack of land, lack of workforce etc. It is one of the major discussed topics in the current scenario. This study is proposed to review the latest computational studies proposed by different researchers in aquaponic system providing the baseline for the next researchers. A total of 41 high quality research articles are choose from seven different articles database to review for the study. After deeply analyzing these researches the aim, objectives, limitations and future work of these articles are generated as illustrated in Tables II and III of the research.

It is seen in the proposed study that the most of the researchers use different IoT sensors including water quality sensor, temperature sensor, pH sensor, air flow, predictor’s sensor, light sensor, humidity sensor for constant monitoring of the aquaponic environment. There are different machine learning and deep learning models proposed by the researchers for regulating the predictors in aquaponic system.

The results of the proposed study stated that the highest sensor accuracy 99.4% for IoT ultrasonic sensor is obtained by research presented by Haryanto, M. Ulum, A. F. Ibadillah, R. Alfita, K. Aji, and R. Rizkyandi [37]. The highest classification accuracy of 96.5% is obtained by paper titled Using Deep Convolutional Neural Network for Image-Based

Diagnosis of Nutrient Deficiencies in Plants Grown in Aquaponics [26]. Paper presented by S. C. Lauguico, R. S. Concepcion, J. D. Alejandrino, R. R. Tobias, D. D. Macasaet, and E. P. Dadios [34] and S. C. Lauguico, R. I. S. Concepcion, J. D. Alejandrino, R. R. Tobias, and E. P. Dadios [43] gives the detection accuracy of 91.67% and 87.9% respectively. Smart farming IoT platform based on edge and cloud computing [12] shows the mostly cited research article use IOT based edge computing system for nutrients regulation and save upto 80% nutrients. The study [51] give the MAE value of 0.10 while [53] gives the MSE value of 0.005.

## VI. FUTURE WORK

It is seen from the proposed study that most of the researchers used real time IoT sensors for continue capturing the data and process. A few of them uses a dataset to train the ML and DL model. So to develop and use an efficient dataset in context of aquaponic environment is one of the major needs of the aquaponic study. It was also seen from the literature review that none of the research use ensemble learning method implemented on different deep learning and machine learning algorithms for aquaponic system. Deep learning algorithms with different RNN methods are not implemented by any researcher for all time in aquaponic environment.

This is the guideline for the new researcher to develop a more secure IoT based model that can use either of the ensemble learning or deep learning with RNN and CNN models to make aquaponic system more secure and sustainable.

**Abstract**—Cocoa cultivation is of immense importance to the people of Côte d'Ivoire. However, this culture is experiencing significant challenges due to diseases spread by various agents such as bacteria, viruses, and fungi, which cause considerable economic losses. Currently, the methods available to detect these cocoa diseases force farmers to seek the expertise of agronomists for visual inspections and diagnostics, a laborious and complex process. In the search for solutions, many studies have opted for using convolutional neural networks (CNNs) to identify diseases in cocoa pods. However, an essential advance is to develop hybrid approaches that combine the advantages of a CNN with sophisticated classification algorithms. This research stands out for its innovative contribution, combining MobileNetV2, a convolutional neural network architecture, with algorithms, such as Logistic Regression (LR), K Nearest Neighbors (KNN), Support Vector Machines (SVM), XGBoost, and Random Forest. The study was conducted in two distinct phases. First, each algorithm was evaluated individually, and then performance was measured when MobileNetV2 was merged with the algorithms mentioned. These hybrid approaches complement and amplify MobileNetV2's capabilities. To do so, they draw on MobileNetV2's inherent capabilities to extract key features and enhance information quality. By combining this expertise with the classification methods of these other models, hybrid approaches outperform individual techniques. Accuracy rates range from 72.4% to 86.04%. This performance amplitude underlines the effectiveness of the synergy between the extraction characteristics of MobileNetV2 and the classification skills of other algorithms.

**Keywords**—Cocoa pods diseases; MobileNetV2; classification algorithms; machine learning; hybrid method

## I. INTRODUCTION

Cocoa pod diseases are a significant problem for farmers and the cocoa industry [1]. These diseases can lead to yield loss, reduced cocoa bean quality, and higher production costs. Many methods are available to combat cocoa pod diseases, including pesticides, fungicides, and organic practices. However, these methods can be costly and difficult to apply.

Computer vision, generally based on machine learning and deep learning [2], is now being exploited for various agriculture, botany, and ecology tasks. These tasks include assessing the health of plants in our various crops. This new technology is proving necessary to improve crop yields in general. Researchers have already conducted numerous studies to identify disease risk factors, such as adverse weather

conditions [3], insect pests, and weeds. By identifying these risk factors, farmers can take steps to reduce or eliminate them, thus helping to prevent disease.

Indeed, Machine Learning and Deep Learning algorithms have shown enormous potential in agriculture by helping to develop effective treatments for crop diseases. They provide an innovative and powerful approach to combating crop diseases. Their ability to process complex data, detect anomalies early, and customize treatments significantly benefits crop health, agricultural sustainability, and food security [4] [5].

Applying Machine Learning (ML) and Deep Learning (DL) algorithms for detecting cocoa pod diseases offers tangible benefits for improving cocoa quality, increasing selling prices, and improving farmers' incomes. This approach supports farmer profitability and contributes to the sustainability of the cocoa sector by enhancing the quality and reputation of the cocoa produced.

More specifically, this study contributes to the sustainability of the cocoa sector by improving the quality and reputation of the cocoa produced. Early detection of disease enables farmers to take corrective action, reducing production losses and improving cocoa quality

Our research focuses mainly on identifying and detecting diseases affecting cocoa pods. It has several important implications. Firstly, it shows that the hybrid approach is promising for cocoa pod disease detection. Secondly, it suggests that CNNs can be used to improve the performance of conventional machine learning algorithms. Finally, it paves the way for new applications of machine learning and deep learning in the cocoa sector. Our contributions will be broken down into the following aspects:

As a first step, we will extract images from each pod using data augmentation techniques. This step will be crucial to establish the dataset that will serve as the basis for our study.

We will combine classic Machine Learning algorithms and a convolutional neural network (CNN) such as MobileNet.

We will explore hybrid approaches aimed at merging the capabilities of the MobileNetV2 network with the set of classic Machine Learning algorithms already in use.

Finally, we will evaluate the performances of different methods by analyzing the impact of integrating MobileNet in the fusion of the approaches.

The organization of our study is outlined as follows. Following the introductory section outlining the issue tackled in this paper (Section I), we delve into existing research on identifying specific cocoa diseases (Section II). Subsequently, we present and expound upon the methodology in Section III. Elaborate findings are disclosed in Section IV.

A comprehensive discussion is laid out in Section V, and ultimately, Section VI addresses the research goals and derives conclusions from the conducted study.

## II. RELATED WORK

Cocoa farming is a vital sector for the Ivory Coast and an essential resource for our farmers. Unfortunately, this crop is sometimes threatened by diseases that cause enormous losses for our farmers and Côte d'Ivoire, the world's leading cocoa producer. To preserve the gains made and further improve the production of this crop, a great deal of work has been carried out.

Godmalin et al. [6] carried out a study based on a deep learning algorithm to tackle the automatic classification of the state of a cocoa pod. Their experimental research method relies on a convolutional neural network for training. The model can classify three states of a given cocoa pod image: healthy, attacked by black pod disease, and shot by a pest. The results of their experiment showed an accuracy of 94%. However, the study did not assess the impact of weather conditions on the algorithm's performance. The algorithm's performance may vary according to weather conditions. Please do not revise any of the current designations. Sandra Kumi et al. have proposed a method using machine learning techniques to detect and diagnose two significant diseases affecting cocoa production, namely Swollen Shoot and Black Pod [7]. A mobile application with integrated ML techniques is offered to cocoa farmers to take a photo of the pod and upload it for diagnosis, which takes place on a cloud backend service. Four CNN models were built and trained for automatic disease detection and diagnosis. The results of this study showed that the MobileNet V2 SSD gave the best accuracy rate, with a score of 80%. However, the study was conducted in a controlled environment, and the algorithm may need to be more accurate in a real-life setting, where conditions can vary.

Amoako et al. [8] studied a model based on VGG19 to classify cocoa diseases using images. Then, other pre-trained models, such as VGG16 and ResNet50, are compared. Their study is a step in the right direction toward developing a technology that could positively impact the cocoa industry. With further research, it is possible to improve the accuracy of machine learning models and make them more applicable to a wide range of environments. This could lead to a significant reduction in losses due to cocoa diseases and an improvement in the quality of the cocoa produced. Basri et al. [9] proposed a study comparing the results of four feature extraction models in the case of early recognition of disease attacks on cocoa fruits. The image extraction models used include:

- Local binary pattern (LBP).
- Gray level co-occurrence matrix (GLCM).
- Hue saturation value (HSV).

Gray level co-occurrence histograms (GLCH).

In addition, the support vector machine (SVM) model was applied to the classification technique to measure the extraction results from the cocoa image dataset. SVM classification results revealed the best performance for HSV feature extraction for all types of SVM kernels applied (linear, RBF, and polynomial), with the highest accuracy being 80.95% for the RBF kernel.

Baba et al. [10] have studied a model based on image processing techniques for identifying early symptoms of pests and diseases in cocoa fruit from mobile applications. This research showed that the system's accuracy in recognizing cocoa fruit-shaped objects reached 100% in identifying cocoa fruit and 83% database for images of normal conditions at 83.75%, disease attack at 84.87%, and pest attack at 80.80%. Their study showed that image-processing techniques can accurately identify early symptoms of pests and diseases in cocoa fruit. However, the study also revealed areas for improvement in this approach, namely that many images can drag the model. In addition, the images need to be of high quality and well-lit. If this is not the case, the model may need to identify pests and diseases correctly. Gunawan et al. set up an expert system based on the Certainty Factor (CF) algorithm to identify the factor of cocoa pests and diseases that cannot be identified and prevented in advance [11]. Based on the results of the accuracy test, the proposed model can produce an accuracy rate of 86.67% in diagnosing pests and diseases on cocoa plants. However, the study used a simple algorithm, the certainty factor, which may not be able to detect all pests and diseases. Mohammad Yazdi et al. [12] have proposed a model for building a system to detect pest and disease types in cocoa pods. This study uses digital image processing techniques to extract color characteristics from digital images of cocoa pods. The method used to extract hue, saturation, and value (HSV) color characteristics and the classification algorithm used is K-Nearest Neighbor (KNN). One hundred fifty images were divided into 70% training data and 30% test data. Based on test results using k values of 5, 7, 11, and 13 in the restraint method, the best accuracy is 84.44% with a k = 5 value. However, the images used in the study are limited to a single type of cocoa tree, which could limit the generalizability of the results to other types of cocoa. It should be noted that the KNN algorithm is used to classify the images, but this simple algorithm may not detect the more complex pests and diseases. Godmalin et al. studied an experimental search method to train a convolutional neural network capable of classifying three levels of cocoa pod infection: low, moderate, and severe [13]. The results of this model achieved 91% accuracy in correctly classifying the condition of cocoa pods.

Overall, this study is a step in the right direction. Still, more work needs to be done to develop automatic detection methods for cocoa pod infection that are reliable and usable in real-life conditions.

## III. MATERIAL AND METHOD

### A. Materials

The database used for our study is Cocoa Diseases [14], an online database launched in 2020 by the Autonomous

University of Bucaramanga, Colombia. It comprises 312 images with 1,591 tagged objects belonging to three classes: healthy, phytophthora, and monilia. The experiments used Python programming on a THINPAD laptop with an Intel(R) Core i7-10700 processor running at 2.90 GHz, 32 GB memory, and a 512 GB SSD hard disk.

## B. Methods

The machine learning methods we used in our study are as follows.

1) *SVM* : A support vector machine (SVM) is a supervised machine learning algorithm [15] that can be used to solve classification and regression problems. SVMs are a generalization of linear classifiers. The principle behind SVMs is to find a hyperplane that optimally isolates data from two classes. The optimal hyperplane corresponds to the one that optimizes the margin between the data of the two classes [16]. The data closest to the hyperplane are called support vectors. SVMs are effective for solving classification and regression problems with non-linear data. They also adapt well to new data. Effective for solving classification and regression problems with non-linear data, it is an algorithm capable of generalizing well to new data. SVMs are used in various applications, such as image classification, facial recognition, object detection, text classification, and regression.

2) *Random forest* : The Random Forest algorithm is a supervised machine learning algorithm that uses a set of decision trees to make predictions [17]. It is known for its accuracy and robustness and is used in various fields, including classification, regression, and anomaly detection. The algorithm starts by creating a set of decision trees. The number of trees in the set is a parameter the user can adjust. Each decision tree is trained on a random subset of the training data. Data that is not used to train a decision tree is called test data. The algorithm then uses the test data to evaluate the accuracy of each decision tree. The algorithm then averages the predictions of all the decision trees to make a final prediction. The advantage of the Random Forest algorithm is that it can make more accurate predictions than the individual decision trees. The decision trees are uncorrelated, so they don't make the same errors. The Random Forest algorithm is also robust to noisy data. This is because the decision trees in the ensemble can adapt to variations in the data. The Random Forest algorithm is a powerful tool that can be used to solve various machine learning problems. It is renowned for its accuracy, robustness, and ease of use.

3) *XGBoost*: XGBoost is an improved model of the Gradient Boost algorithm. This machine-learning algorithm can solve common commercial problems using minimal resources [18]. Extreme Gradient is a method used to reduce the number of errors in predictive data analysis. XGBoost is an assembly of decision trees (weak learners) that predict residuals and correct mistakes in previous decision trees. The unique feature of this algorithm lies in the decision tree used. This recently introduced machine learning algorithm has proved very powerful for modeling complex processes in other

research fields [19]. It is a robust algorithm that can solve various machine learning problems. It is known for its accuracy, speed, and flexibility.

4) *KNN*: The KNN (k-nearest neighbor) algorithm is a supervised learning algorithm used for classification and regression [5]. It works by calculating the distance between an unknown point and known points in the training dataset. The k points closest to the unknown point are then used to predict the class or value of the unknown point. The KNN algorithm is non-parametric, meaning that it makes no assumptions about the distribution of the data [2]. It is also a computationally inexpensive algorithm, making it suitable for large quantities of data. It works by calculating the distance between an unknown point and known points in the training data set. The k points closest to the unknown point are then used to predict the class or value of the unknown point. The result is a computationally inexpensive algorithm, making it suitable for large amounts of data.

5) *Logistic regression* is a supervised learning algorithm [20] used to predict the probability of an observation belonging to a particular class. It is often used for binary and multiclass classification [21]. It is a linear model, which means that the probability of class membership is modeled as a linear combination of the input variables. The probability function is a logistic function, which is a non-linear function that takes a value between 0 and 1 [22]. Logistic regression is a robust algorithm that can solve many problems. The algorithm begins by calculating the model weights. Weights are coefficients that measure the importance of each input variable. The weights are then used to calculate the probability of belonging to each class. The observation is classified in the category with the highest probability. The choice of weights is important for model performance. Weights can be optimized using a technique called gradient descent. Gradient descent is an optimization technique for finding weights that minimize model error. Logistic regression is a robust algorithm that can solve many problems. It is easy to implement and understand, making it popular with data scientists.

6) *MobileNetV2*: MobileNet V2 is a lightweight convolutional neural network model developed by Google AI [23]. It was first introduced in a research paper published in 2018. MobileNet V2 is based on the original MobileNet architecture but introduces several improvements, namely the use of a new convolution block called "bottleneck" and that of a learning technique called "transfer learning". MobileNet V2 has been designed for mobile devices such as smartphones and tablets. It can achieve performance comparable to larger models while being much lighter and more energy-efficient [24]. The bottleneck convolution block is a convolution block [25] that reduces the width and height of the input signal while retaining the depth. This reduces the number of model parameters while maintaining performance. MobileNet V2 is a powerful and versatile model that can be used for various tasks, such as image classification, object detection, and facial

recognition. It is lightweight and energy-efficient, making it ideal for mobile devices.

The methodology adopted in this study is based on several well-defined phases, providing a solid and rigorous foundation for our research. Detection techniques are studied to enable the system to detect and identify cocoa pod diseases. A comprehensive outline of these stages is provided in Fig. 1:

Our methodological approach is based on a series of carefully developed steps:

- Database preparation: In this phase, each image was segmented to identify each pod in different images precisely. To improve the quality of our data, each series of images associated with a pod was subjected to a data augmentation step.
- Data Augmentation: Data augmentation is an essential element of our approach. In this step, random transformations were applied to images. Each image was subjected to random horizontal and vertical flipping, allowing left and right as well as top and bottom inversions. In addition, a random rotation was applied to each image, with a maximum rotation angle of 0.4 radians (approx. 23 degrees) clockwise.
- Data Division: For the training and evaluation of our models, we have divided our data into three sets: the

training set, the validation set, and the test set. This division enables us to evaluate and validate the performance of our models.

- Using Various Algorithms: To tackle our pod disease detection task, we adopted a varied approach using traditional Machine Learning algorithms such as SVM, Random Forest, KNN, Logistic Regression and XGBoost, and deep methods based on the MobileNetV2 network.
- Hybrid Methods: In recognition of the complementary power of the approaches, we have also explored hybrid methods that merge the potential of the MobileNetV2 network with the set of Machine Learning algorithms mentioned above.
- Performance Evaluation: To assess the effectiveness of each model, we carefully evaluated their ability to detect pod diseases. This crucial phase enabled us to quantify and compare the performance of each approach.

Our methodology is built on a solid foundation, from careful data preparation to thorough model evaluation to detect pod diseases accurately.

Fig. 1. Illustration of our methodology.

C. Evaluation Metrics

In evaluating the outcomes of our investigation, we employed various metrics. We included accuracy, precision, recall, F1 score, and Matthew's correlation coefficient (MCC) within this set of measures. The differential equations are outlined as follows:

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} \quad (1)$$

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

$$F1\ score = 2 * \frac{Precision*Recall}{Precision+Recall} \quad (4)$$

$$MCC = \frac{TP*TN-FP*FN}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \quad (5)$$

$$MSE = \frac{1}{n} \sum_{i=1}^n (Y_i - \hat{Y}_i)^2 \quad (6)$$

The Receiver Operating Characteristic (ROC) curve is a graphical representation showcasing the performance of a binary classification model. It illustrates the relationship between the true positive rate (sensitivity) and the false positive rate across various classification thresholds. An ideal ROC curve aligns with the upper left corner of the graph, indicating high sensitivity and specificity.

The confusion matrix is a tabular summary that encapsulates the outcomes of a classification model's predictions. It assesses the model's predictions against the actual values in the dataset, categorizing them into four groups: true positives, true negatives, false positives, and false negatives. The confusion matrix compares the model's precision, recall, specificity, and accuracy.

IV. RESULTS

Our findings will be presented in two distinct sections, each exploring a specific area in depth:

A. Individual Algorithm Performance

The first part of our results will be dedicated to evaluating and comparing the performance of the various Machine Learning algorithms we have used. These algorithms include SVM, Random Forest, KNN, Logistic Regression, XGBoost, and the MobileNetV2 Deep Learning algorithm. Each algorithm has been tested and analyzed, enabling us to determine its specific effectiveness in detecting pod diseases. We will evaluate each algorithm's key metrics, giving us a comprehensive view of its ability to meet this challenge. Table I shows the metric measurements for each model.

Fig. 2 shows the confusion matrices and shows the ROC curves for the three best accuracies.

TABLE I. CASE OF INDIVIDUAL ALGORITHM METRIC RESULT

Models	Accuracy (%)	Precision (%)	F1 score (%)	Recall (%)	MCC (%)	MSE
SVM	67,09	66,78	66,78	67,09	48,49	0,81
Random Forest	59,53	63,28	63,28	64,17	43,54	0,91
KNN	46,96	39,54	39,54	46,96	18,07	1,47
Logistic Regression	54,65	53,71	53,71	54,65	29,06	1,08
XGBoost	68,61	67,79	67,79	68,61	50,95	0,77
MobileNetV2	<b>81,66</b>	<b>81,4</b>	<b>81,4</b>	<b>81,65</b>	<b>72,09</b>	<b>0,4</b>

Fig. 2. Confusion matrix and ROC curve of individual algorithm.

The analysis reveals significant variations in the performance of each model. The MobileNetV2 model displays the highest accuracy at 81.66%, closely followed by logistic regression and SVM. However, when considering measures such as recall and F1 score, MobileNetV2 stands out, suggesting its ability to identify true positives well. Furthermore, the MCC, which assesses the overall prediction quality, puts MobileNetV2 in the lead with 72.09%.

On the other hand, KNN's performance could be better regarding precision, recall, and F1 score, suggesting difficulty discerning true positives. The lowest MCC also corroborates this among the models tested.

In sum, these results highlight the superiority of MobileNetV2 in terms of overall performance. Still, they also underline each model's specific strengths and weaknesses in the pod disease detection task.

### B. Hybrid Method Performance

The other part of our results will focus on an in-depth examination of hybrid methods. This section will explore the synergies between the Deep Learning-based MobileNetV2 network and the previously mentioned machine learning algorithms. The performance of these hybrid methods will be rigorously analyzed, revealing whether their combination can achieve even higher detection levels. This evaluation will give us a significant perspective on the added value provided by the fusion of these approaches.

Table II shows the metric measurements for each model.

Fig. 3 shows the confusion matrices and shows the ROC curves for the three best accuracies

TABLE II. CASE OF HYBRID METHOD ALGORITHM METRIC RESULT

Models	Accuracy (%)	Precision (%)	F1 score (%)	Recall (%)	MCC (%)	MSE
<b>MobileNetV2 - SVM</b>	<b>86,04</b>	<b>85,88</b>	<b>85,88</b>	<b>86,03</b>	<b>78,53</b>	<b>0,33</b>
MobileNetV2 - RF	77,60	76,44	76,44	77,59	65,6	0,49
MobileNetV2 - KNN	72,4	71,59	71,59	72,4	61,03	0,76
MobileNetV2 - LR	85,88	85,71	85,71	85,87	78,29	0,31
MobileNetV2 - XGBoost	79,38	78,99	78,99	79,38	68,11	0,45
MobileNetV2	81,66	81,4	81,4	81,65	72,09	0,4

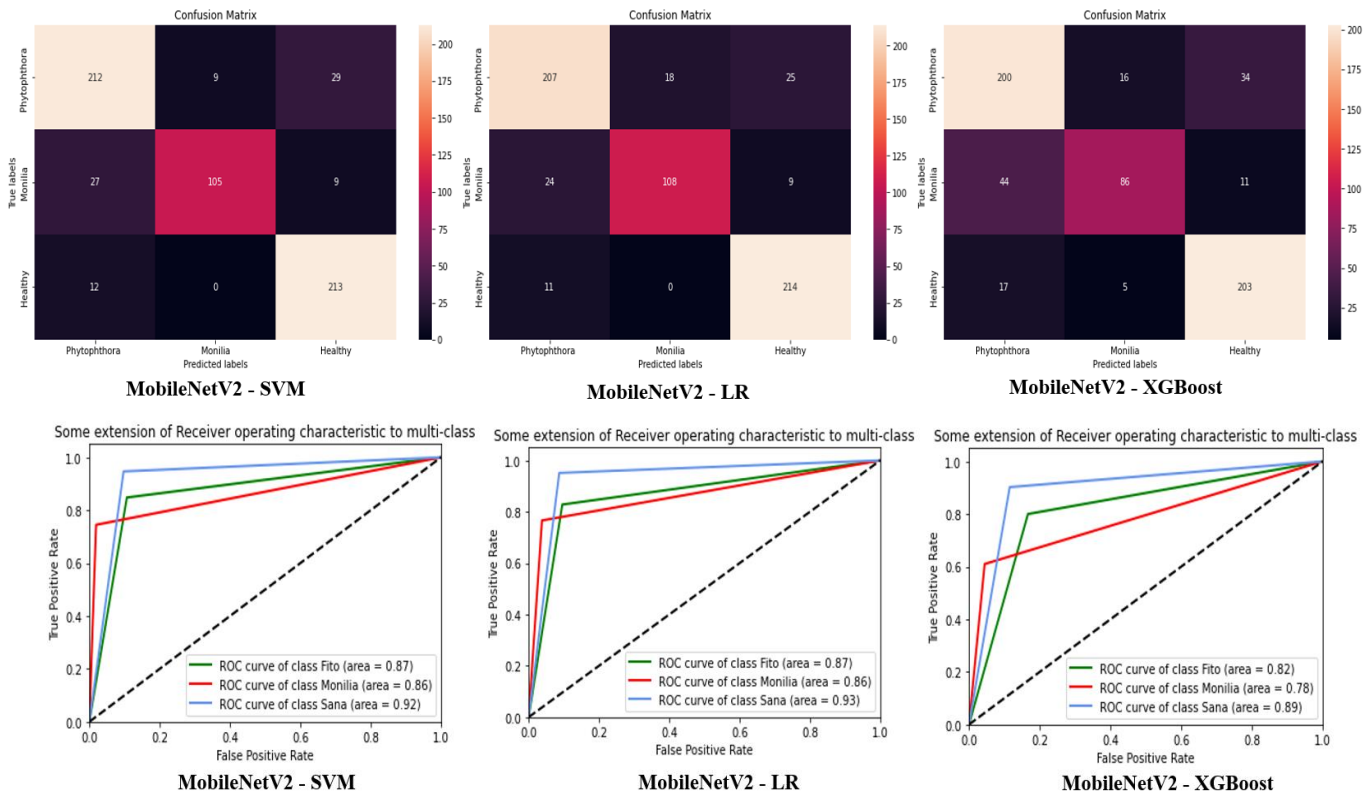

Fig. 3. Confusion matrix and roc curve of hybrid method algorithm.

Analysis of the table above highlights the performance and trends of the various models, including combinations of MobileNetV2 with multiple algorithms and the performance of MobileNetV2 as a stand-alone model. Each combination presents distinct characteristics regarding the accuracy, precision, F1 score, recall, Matthews Correlation Coefficient (MCC), and Mean Square Error (MSE).

The combination of MobileNetV2 with SVM is the most efficient, with an accuracy of 86.04%. This means that it can correctly classify 86.04% of images. Precision, F1 score, and recall are also high, indicating that the model can accurately identify true positives and minimize false positives and false negatives. The combination of MobileNetV2 with Random Forest is also effective, with an accuracy of 77.60%. However, the precision, F1 score, and recall measures are slightly lower compared with the MobileNetV2-SVM combination. This means the model is less accurate at identifying true positives but more likely to minimize false positives.

The combination of MobileNetV2 with KNN is less effective, with an accuracy of 72.4%. Precision, F1 score, and recall measures are all relatively similar, indicating that the model can detect true positives and negatives with comparable precision.

The combination of MobileNetV2 with LR is effective, with an accuracy of 85.88%. The high accuracy associated with this combination indicates an ability to avoid false positives. The high F1 and recall scores show that the model can effectively detect true positives. The combination of MobileNetV2 with XGBoost is comparable to other hybrids, with an accuracy of 79.38%. Precision, F1 score, and recall demonstrate a balanced ability to identify true positives and minimize false positives and negatives. As a stand-alone model, MobileNetV2 is effective, with an accuracy of 81.66%. Other measures, including precision, F1 score, recall, and MCC, also show balanced performance.

## V. DISCUSSION

The results reveal key aspects concerning the performance of the different models evaluated for pod disease detection. These results highlight distinct strengths and weaknesses of each model, providing important information to guide the optimal mode selection.

In terms of individual performance, MobileNetV2 had the best overall performance of all the models evaluated. Its high accuracy of 81.66% indicates its ability to deliver accurate predictions. In addition, its high F1 score and balanced recall (81.4% and 81.65%, respectively) indicate its ability to identify

true positives while maintaining a balance with false negatives. The high MCC of 72.09% reflects an excellent correlation between predictions and actual observations. Although MobileNetV2 performs well, it may require higher computing resources due to its complex architecture.

**SVM and Logistic Regression:** These traditional Machine Learning models show stable and balanced performance, with precision, F1 score, and recall rates around 67%. They can be considered reliable options for the detection of pod diseases.

However, their inability to achieve the same levels of accuracy as MobileNetV2 may suggest limitations in their ability to capture subtle image features.

**Random Forest and XGBoost:** These ensemblistic models show comparable results, with F1 scores and balanced recalls. They show a certain robustness in detecting true positives.

However, their slightly lower accuracy could mean that they tend to identify some false positives.

Although KNN has the lowest accuracy among the models evaluated, its relatively high MCC reveals a specific relevance in detecting pod diseases.

However, its low recall and F1 score underline its difficulty correctly identifying all true positives.

Model performance varies according to method and architecture. While MobileNetV2 stands out for its high accuracy and correlation, traditional Machine Learning models offer a solid and stable option. By considering the strengths and weaknesses of each model, informed decisions can be made to maximize the quality of pod disease detection.

Fig. 4 presents the histogram of the metrics of classical algorithms.

Combining MobileNetV2 with models such as SVM, LR, or XGBoost improves overall performance compared with MobileNetV2 alone. This is due to how these models complement MobileNetV2's capabilities, leveraging the power of MobileNetV2's computer vision and the more traditional classification methods of these other models.

The combination with SVM seems particularly effective in terms of Accuracy and MCC, showing how the SVM approach can enhance MobileNetV2's classification capabilities. MobileNetV2 combined with KNN or Random Forest also shows improvements, but performance is still inferior to that obtained with SVM or XGBoost.

Fig. 5 presents the metric histogram of the hybrid methods.

Fig. 5. Model performance histogram of the case of hybrid method algorithm.

## VI. COMPARISON WITH EXISTING APPROACHES

The results of our work exceeded those of several related studies, including previous research on the detection and identification of cocoa pests and diseases.

Table III shows the results. The results clearly show that our model outperforms that of the other two authors.

TABLE III. COMPARISON OF RESULTS WITH PREVIOUS RESEARCH

Method	Accuracy (%)
Basri B, et al [26]	82.50
RY Montesino et al[27]	83
Our method	86.04

## VII. CONCLUSION

This study represents a significant step forward in the fight against cocoa diseases in Côte d'Ivoire. By combining the intelligence of MobileNetV2's convolutional neural networks with the advanced classification capabilities of algorithms such as Logistic Regression, K-nearest Neighbors, Support Vector

Machines, XGBoost, and Random Forest, we have succeeded in significantly improving the accuracy of disease detection.

The results obtained are promising, highlighting the effectiveness of hybrid approaches in tackling complex agricultural problems. This innovative method offers an alternative to traditional methods of laborious visual inspection, enabling farmers to take more targeted measures to protect their crops.

However, it is important to note that further research is needed to refine these hybrid approaches and adapt them to the seasonal and environmental variations to which cocoa is exposed. In addition, additional validation on varied datasets and real field conditions would reinforce the conclusions' robustness. This study lays the foundations for a new era in cocoa disease monitoring and management, with potentially positive implications for farmers, local economies, and food security. As technology continues to evolve, this approach could serve as a model for solving similar problems in other areas of agriculture and beyond.

The prospects of this study could pave the way for the development of new applications of machine learning and deep

learning in the cocoa sector. Indeed, the hybrid approach developed by the researchers proved effective in detecting disease in cocoa pods. This approach could be used to develop new applications, such as a mobile diagnostic tool that would enable farmers to detect cocoa pod diseases on the spot or to monitor the spread of cocoa diseases.

**Abstract**—Wireless Capsule Endoscopy (WCE) is a diagnostic technique for identifying gastrointestinal diseases and abnormalities. Gastroenterologists face a considerable challenge when reviewing a lengthy video to identify a disease. The solution to this problem is generating an automated video summarization technique that generates the WCE Video summaries. This paper presents a Video Summarization technique that summarizes the WCE video. The proposed method uses transfer learning and a Random Forest classifier. Using a computationally light and pre-trained MobileNetV2 for feature extraction helped deliver results quickly. Managing small datasets and mitigating the overfitting risk was effectively addressed using Random Forest. The Random Forest's hyperparameters are optimized through the use of Bayesian optimization. The approach proposed has achieved an accuracy of 98.75% in disease prediction while significantly reducing the viewing time for the video summary. Furthermore, it has attained an average F-Score of 0.98, demonstrating its efficacy and reliability.

**Keywords**—Bayesian optimization; capsule endoscopy; MobileNetV2; random forest classifier; transfer learning

## I. INTRODUCTION

Wireless Capsule Endoscopy [1-3] is a technology used for performing the endoscopy of a patient to diagnose an illness. A pill-sized capsule camera captures the video of the gastrointestinal tract and assists the doctor in diagnosing any gastrointestinal abnormality. Capsule Endoscopy is effortless and does not interfere with a person's routine; due to this, it is getting more popular. However, specific challenges are associated with it - the battery may get low, and the capsule may get stuck in the gastrointestinal tract, and analyzing the long endoscopy video to identify the disease. An automated process for analyzing and generating the WCE video summary may save the doctor's time spent analyzing the video. Many researchers have utilized machine learning and deep learning methods to summarize WCE videos. Numerous studies aim to identify a particular ailment from a WCE video, like abnormal bleeding, tumor, polyp, or ulcer. However, if a problem-specific method is adopted, that proposed framework can only be applied to identifying a specific type of disease. One such approach was adopted in [4] for polyp detection having a lower false-positive rate. Since polyps are rounded or curved growths in the colon, the author also utilized the shape and texture features for polyp identification and localization. Similarly, [5] developed a classification method for polyp detection by using the textural characteristics of polyps and an improved bag of features. [6] Used Uniform Local Binary Pattern (LBP) to detect the polyps' texture. A method to detect Crohn's disease

using a deep convolutional network is proposed in [7]. According to a study [8], two critical factors can aid in detecting tumors: color and textural features. To achieve this, the SVM utilizes the LBP operator's feature maps. This approach has proven to be quite effective in accurately identifying tumors. It achieved an accuracy of 92.4% in detecting tumors. A saliency map-based ulcer detection method was proposed in [9]. A multilevel approach was used for detecting saliency and identifying ulcers. In [10], a CNN-based approach for bleeding detection is proposed. The CNN developed has a low complexity because the input to the CNN is a single patch, and it outputs a segmented patch of the same size. An approach for detecting multiple bleeding detection was proposed in [11]. For detecting the small intestine lesions, [12] used AlexNet. The model achieved an accuracy of over 95.16%. [13] Proposed a technique for lesion detection using the high-level features extracted by ResNet50 [14] and InceptionV4. The lesion and non-lesion frames are classified by using the SVM classifier.

Specific video summarization approaches focus on keyframe extraction. A key frame is the most informative and relevant frame. [15], used a keyframe extraction approach for video summarization. The irrelevant frames are discarded in the first phase of image quality assessment. From the remaining frames, keyframes are extracted using low-level and deep features. Another keyframe extraction-based video summarization technique is proposed in [16]. Convolutional autoencoder is used to extract high-level features and shot boundary detection. A shot is part of a video having similar content. Motion profiles are used to extract keyframes from each shot. In [17], temporal segmentation of the video into shots was accomplished with the Prune Exact Linear Time (PELT) algorithm, and the high-level features were extracted by using pre-trained VGG19. A temporal segmentation of endoscopy video for detecting abnormal video segments was proposed by [18]. The abnormal shot covers any gastrointestinal abnormality. To identify the abnormality a Graph Convolutional Network (GCNN) was used. A keyframe selection strategy for polyp identification by utilizing the depth information of polyps is proposed in [19]. One approach for constructing keyframes of endoscopic videos uses pre-trained InceptionV3 to create feature maps of WCE images, which are then fed into a K-means algorithm implemented in [20].

A machine learning model's efficiency largely depends upon the amount of data used to train the model. If the training dataset is prominent, the model may learn adequately; otherwise, it may overfit, leading to inaccurate results with the

test data. Nevertheless, in certain situations and domains, immense amounts of training data are unavailable; training a deep learning model for that problem becomes tedious. Transfer learning is the solution in such cases. Transfer learning is transferring knowledge from a learned model to a new one. However, both models should perform similar kinds of tasks. Applying transfer learning has several advantages over making a model learn from scratch. Training a model from scratch is time-consuming and requires tremendous training data. Moreover, there is no point in training a model from scratch if it performs a task similar to that performed by some other model.

The main objective of this research paper is to create a computationally efficient model that delivers precise results quickly. The proposed solution aims to overcome the following challenges:

1) One of the challenges in developing a machine-learning model for WCE is the need for adequate training data. With sufficient data, it is possible to train the model effectively. However, transfer learning is a solution to this problem. One can overcome the data shortage by leveraging pre-trained models with their weights and still successfully train a model.

2) Timely delivery of final results is crucial for the diagnostic procedure of endoscopy. Any delays are deemed unacceptable and can have serious consequences. MobileNetV2 [21] is a lightweight model in terms of computational requirements. Despite this, it can provide accurate solutions on time.

3) Machine learning models need a lot of computational resources. However, a model that requires significantly less computational resources and is so computationally light that it can be used in a mobile device is a favored solution.

This paper proposes a WCE video summarization technique that extracts the frames' deep features using the MobileNetV2 model. Further, the extracted features are provided as input to a Bayesian hyperparameter-optimized Random Forest Classifier. The Random Forest Classifier categorizes frames into classes based on features and then sorts frames by entropy values within each class. However, outliers may occasionally contain valuable information. The proposed approach examines frames from each predicted class to avoid discarding crucial information owing to outliers.

The rest of the paper is structured as follows: Section II details the methodology employed for WCE video summarization. Section III presents the experimental results and provides a thorough analysis. The final section summarizes the main conclusions drawn from this study.

## II. RELATED WORK

There have been several studies that aim for video summarization in WCE. The approaches for video summarization can be categorized into two categories: The first is a Generic approach that primarily focuses on Keyframe extraction or Shot Segmentation, and the second is Disease identification specific. Several approaches use keyframe extraction techniques for video summarization. Keyframe extraction is a technique for video summarization that involves

extracting the most informative frames from a long video that has many redundant frames. Researchers have explored various criteria and algorithms for selecting keyframes representing essential video information.

### A. Generic Approaches

A general approach to video summarization in WCE is keyframe identification or Shot Segmentation. Keyframes are the frames that contain the most informative part of the video and can be considered as a representative frame of the entire video. On the other hand, Shot segmentation is dividing a long video into small shots. A shot is a part of the video that contains similar frames. A technique for keyframe extraction that uses depth maps not only for keyframe identification but also for localization of the polyps was proposed in [19]. The proposed approach detects the keyframes that contain the polyps. In addition to the depth information, the proposed technique utilizes the image moments and edge magnitudes to select the keyframes.

The author in [20] proposed a method for generating video summaries by utilizing the deep features extracted by using InceptionV3 and then using the K-Means clustering algorithm to group similar frames in one cluster. Frames from the clusters are selected to generate a final summary. A technique for keyframe extraction that first extracts the deep features of the frames using a Convolutional Autoencoder Neural Network (CANN) was used in [16]. The frames are then grouped into similar and dissimilar frames, representing shots of the WCE video. From each shot, keyframes are then selected using motion analysis.

### B. Disease-Specific Approaches

Specific approaches focus on disease identification along with video summarization. One of the most common signs of gastrointestinal abnormality is bleeding. Several researchers worked towards identifying bleeding regions, polyps, ulcers, erosions, and tumors in the WCE Videos.

1) *Bleeding detection*: The author in [10] proposed a method for automatically detecting and segmenting bleeding regions by leveraging a CNN structure. The CNN utilized by the author is of low complexity.

2) *Polyps*: Most polyp detection approaches utilize the shape or texture features for polyp identification. However, [4] used an approach that considers both the context and shape of the polyp. Using a context-based reduces the chances of misclassifying some other polyp-like structure as a polyp. Whereas shape features help to capture the geometric information of polyps.

In [5] the author used a synthetically designed high-dimensional feature using Local Binary Patterns – Local, Uniform, and Complete, combined with the Histogram of oriented gradients (HOG). The high-dimensional descriptors provide the visual words as output, after they are fed as an input of the K-means clustering method. Finally, SVM and Fisher's linear discriminated analysis (FLDA) are used for polyp classification. The author in [6] combined the textural features and the Local Fractal Dimensions. The proposed method first detects the keypoints of the frames using SIFT

followed by the textural feature extraction of the neighborhood of the keypoints. In the end, the classification is carried out by an SVM classifier.

3) *Ulcers*: A two-staged automated ulcer detection system was proposed in [9]. In the first stage, superpixels are identified. A superpixel is a group of pixels under some restriction of local image features such as color, intensity, or texture. Then, the saliency regions are identified based on texture and color. The color and texture-based saliency maps are fused together to create a better salient representation of the ulcers. In the second stage, ulcer classification is done using a Bag of Words Model. A CNN-based approach to detect small intestinal ulcers and erosion in WCE images was proposed in [12].

4) *Crohn's disease*: The authors in [7] developed a CNN (Convolutional Neural Network) to classify WCE images into two categories- normal images and the images that are likely to have evidence of Crohn's lesions.

5) *Tumor*: A tumor is a mass of abnormal cells. They can be cancerous in rare situations. Researchers are exploring this field to develop techniques for automated detection of tumors in the WCE images. The author in [8] exploit the image's color and textural features; later, a support vector machine (SVM) is utilized for feature selections for tumor detection.

Considering the different approaches for WCE video summarization it can be concluded that a generic approach that is able to identify the abnormal frames of a WCE video is a better approach for video summarization. An approach that identifies only a specific disease cannot find other diseases, there may be a case where a patient has multiple abnormalities. Therefore a generic method for WCE video summarization is a better approach for generating WCE video summaries. The video summaries generated by a generic method can further be evaluated by the gastroenterologist for pinpointing the particular ailment.

### III. METHODOLOGY

The proposed method leverages the benefits of classification for video summarization. It generates a video summary of a long video. A video is an ordered set of frames. For processing a video, the first step is to generate the frames from the videos. CEV is the Capsule Endoscopy Video, which can be represented as

$$CEV = \{f_1, f_2, f_3, \dots, f_n\}$$

Where,  $\{f_1, f_2, f_3, \dots, f_n\}$  represents the ordered set of frames. Video summarization is the process of extracting the informative frames of the video. Let VS be the Video summary

then,  $VS \subset CEV$ , and  $VS = \{f_1, f_2, f_3, f_4, \dots, f_k\}$  where  $k < n$ . We may assume this by renumbering the frames.

Fig. 1 depicts a block diagram of the proposed video summarization approach.

#### Algorithm 1

Step 1: Generating frames from the video.

$CEV = \{f_1, f_2, f_3, \dots, f_n\}$ , where  $f_1, f_2, f_3, \dots, f_n$  are the video frames.

Step 2: Extract features from the frames by using pre-trained MobileNetV2.

For  $i=1$  to  $n$  do

$y_i \leftarrow M(f_i)$ ,  $M(f_i)$  represents the MobileNetV2 used for feature extraction

Projecting each feature vector  $y_i$  to embedding  $\gamma$

$\gamma_i \leftarrow y_i$

$\gamma = \{\gamma_1, \gamma_2, \dots, \gamma_n\}$

Step 3: The Random Forest algorithm processes the input as feature vectors extracted from frames in Step 2.

Step 4: Identifying the best parameters for the Random Forest using Bayesian Optimization.

Step 5: Testing the Model and generating Video Summaries.

#### C. MobileNetV2

MobileNet architecture was introduced by Google in 2018. As the name indicates, MobileNet is a lightweight convolutional neural network developed for mobile or embedded devices. It works efficiently with devices that have limited computational resources. MobileNetV2's first layer is a depth-wise convolution that performs lightweight filtering by applying a single convolutional filter per input channel. The second layer is point-wise convolution, which computes linear combinations of the input channels to generate new features. The fewer parameters and matrix multiplications significantly contribute to reducing the complexity of MobileNetV2. Some key features of MobileNetV2 are:

- The depth-wise convolution layer applies a separate filter to each input channel, producing intermediate feature maps. A point-wise convolution followed them to combine these features linearly. This two-step convolution approach significantly reduces the number of parameters and computations compared to traditional convolutional layers.
- Inverted residual blocks of MobileNetv2 are capable of capturing more complex patterns. An inverted residual block consists of a bottleneck layer, which downsizes the number of input channels followed by a depth-wise separable convolution and a linear projection layer to upsize the number of channels back. Skip connections are also used to retain low-level features.

Fig. 1. Block diagram of video summarization.

- There are two hyperparameters in MobileNetV2- width multiplier and resolution multiplier. The width multiplier reduces the number of channels in each layer. The resolution multiplier scales down the input image size. Due to the resolution multiplier, some spatial information is sacrificed. The hyperparameters reduce the model's complexity and the computational requirements.

#### D. Random Forest

Random Forest [22] is a supervised machine-learning algorithm developed by Leo Breiman. It uses an ensemble of multiple decision trees for generating predictions. Ensemble means combining multiple models. Thus, a Random Forest uses a collection of decision trees to make predictions rather than an individual decision tree. The random forest algorithm delivers a precise and cohesive output by aggregating these tree's outputs. Fig. 2 shows the working of a random forest classifier. The Random Forest classifier classifies an image in one out of the different output classes. Every decision tree casts a vote to which the input vector belongs. However, in the WCE video, multiple frames need to be classified; there may be a part of a video that contains redundant information, and a small part of the video contains abnormality. In other words, the outlier may contain the most informative information. To avoid missing any informative part of the endoscopic video, a technique for video summarization is adopted that incorporates a change in the voting module of the random forest. The proposed voting module calculates the entropy of each image. The total number of votes an output class received is sorted based on the entropy values, and the top 10% frames from each class are combined to generate the video summary.

#### Algorithm 2

*Step 1: In the Random forest model a subset of features are randomly selected and decision trees are constructed from each sample.*

for  $t=1$  to  $T$  do

$D = \{D_1, D_2, D_3, \dots, D_T\}$ , where

$D$  is the set of decision trees

$T$  is the total number of decision trees

$D_t \subset \gamma$ , where  $1 < t < T$

*Each decision tree is constructed from a subset of feature embedding  $\gamma$ .*

*Step 2: For each input image, each decision tree will generate an output and cast a vote to one of the output classes.*

If  $L = \{L_1, L_2, L_3, \dots, L_k\}$  and  $C = \{C_1, C_2, C_3, \dots, C_k\}$  represents the set of labels of the Output class and  $C$  represents the count for each class label then,

for  $i=1$  to  $n$  do

for  $t=1$  to  $T$  do

$P_{it} \leftarrow D_t(y_i)$ ,  $P$  is the predicted Label for  $y_i$  and  $P_{it}$  it takes value from  $L$ , and update the corresponding Label's count

*Step 3: Final output is considered based on Majority Voting for Classification. However, for every  $L_i$ , where  $1 < i < k$  The proposed voting module also calculates the entropy-based ranks for each vote cast for each class.*

*Step 4: The top 10% of the total votes (frames) that a class got are selected to generate a final video summary. And the final summary VS is generated for the video VCE.*

Fig. 2. Working of random forest classifier.

Each decision tree of the Random forest is constructed by using a different random sample from the training data every time, reducing the chances of overfitting. This tree construction task can be run on multiple CPU cores, reducing the training time. Random forests' voting and aggregation feature helps them effectively deal with missing and noisy data. A Random forest's most significant advantage is dealing with small sample sizes, high-dimensional feature space, and complex data structures.

#### E. Hyperparameter Tuning

Hyperparameter tuning is finding a hyperparameter setting for a machine-learning model to increase its accuracy. There are several techniques of hyperparameter optimization. Grid Search and Random Search are the most reliable techniques for hyperparameter tuning. Grid Search is an exhaustive technique; it considers each possible combination of hyperparameters to determine the optimum value. However, Random Search explores random values of the hyperparameters in a given search space. Both techniques are not adaptable; the results generated every time are independent of the previous outcomes. Random and Grid searches are significantly slow because of their exhaustive nature for search space exploration. Bayesian optimization [23] uses a probabilistic model to guide the search, which helps explore the hyperparameter space more intelligently and reduces the number of evaluations needed, making it one of the computationally efficient techniques. The optimized values of hyperparameters after Bayesian optimization are depicted in Table I.

#### IV. EXPERIMENTS AND RESULTS

The experiments were implemented in Python, and the training and validation dataset was obtained from Kaggle

(WCE Curated Colon Disease Dataset Deep Learning) [24]. This data set consists of images a wireless capsule captures during endoscopy to diagnose abnormal conditions. It has three sets: training set, test set, and validation set. The WCE dataset has labeled images. The dataset has four labels: Normal, Ulcerative Colitis, Polyps, and Esophagitis.

TABLE I. HYPERPARAMETER OPTIMIZATION RESULTS

Hyperparameter	Optimized Value	Significance
n_estimators	174	Number of trees in the forest
min_samples_split	2	Minimum number of samples required to split an internal node.
max_depth	15	Maximum depth of the tree
random_state	42	Controlling the randomness

The performance of the Random Forest is presented in the confusion matrix of Fig. 3. The predicted labels are close to the true labels of the images. It represents a model with high accuracy. The model obtained an accuracy of 98.75% over 50 iterations.

Fig. 3. Confusion matrix.

The model's performance is also compared over Precision, Recall, and F-score (Table II). F-Score is computed using (1). It is computed based on recall (2) and precision (3). Recall measures the proportion of actual positive instances that were correctly predicted as positive by the model.

$$F\_Score = \frac{(2 * Recall * Precision)}{(Recall + Precision)} \quad (1)$$

$$Precision = \frac{TP}{(TP + FP)} \quad (2)$$

$$Recall = \frac{TP}{(TP + FN)} \quad (3)$$

TABLE II. CLASSIFICATION REPORT

	Precision	Recall	F-Score
Normal	1.00	1.00	1.00
Polyps	0.97	0.97	0.97
Ulcerative Colitis	0.97	0.97	0.97
Esophagitis	1.00	1.00	1.00

True Positives (TP) are the positives that are correctly predicted as positives. False Positives (FP) are the negatives incorrectly predicted as positives. True Negatives (TN) are the negatives that are correctly predicted as negatives. False Negatives (FN) are the positives that are incorrectly predicted as negatives.

The average value of the F-score is obtained as 0.985. The classification report indicates that the model is 100% precise in predicting the Normal and Esophagitis labels.

The proposed voting module of the Random Forest Classifier not only votes for a particular class but also calculates the entropy of each image. Fig. 4 shows the predicted frames of the output classes: Polyps, Ulcerative Colitis, and Esophagitis according to the decreasing entropy values. The Final summary is generated by combining the top 10% of the frames from every predicted class, as shown in Fig. 5. The selection of 10% of the total images of a particular class was experimentally determined. The contribution of each output class to generate the final summary ensures that outliers don't get missed.

Fig. 5 shows a video summary of a patient suffering from Esophagitis. Although the disease identified is esophagitis the video summary generated has an abnormal bleeding part of the esophagus, which may otherwise have been missed.

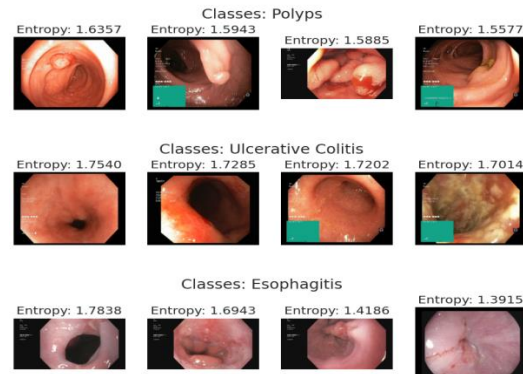

Fig. 4. Images from different output classes in decreasing order of entropies.

Fig. 5. Video Summary generated for an esophagitis patient.

## V. CONCLUSION

This paper introduces a WCE Video Summarization technique that uses transfer learning, random forest, and an entropy-based ranking mechanism to select informative frames and generate the video summary. Using MobileNetv2 for feature extraction allowed for prompt and efficient results to be obtained with excellent computational efficiency. Moreover, employing a Random Forest reduces the chances of overfitting. Selecting the most informative frames from each predicted class prevents the exclusion of outliers with valuable content. The proposed approach obtained an accuracy of 98.75% in

classifying the disease, and the Video summary generated by the model has a significantly reduced viewing time. In the future, a scalable WCE video summarization technique can be proposed that predicts the disease and maintains the temporal relation of the frames.

Postgraduate Program of Information Technology-Bina Darma University, Palembang, Indonesia<sup>5</sup>

**Abstract**—The top tier of the English football league division is occupied by the English Premier League (EPL). It has become a global phenomenon with exhilarating skills and has been one of the most-watched professional football leagues on the planet. The possibility of a player temporarily playing for a club other than the one to whom they are now contracted is known as a "loan player" in the English Premier League (EPL) hence, each player has a market value. Market value is an estimate of how much a player costs when a club wants to buy his contract from another club. The purpose of this study is to determine the factors that influence a player's market value at the conclusion of a loan period. With the Transfermarkt player transfer record dataset for the years 2004 through 2020, we use linear regression analysis. Our study found that a football player's market worth at the end of a loan period is influenced by several aspects, including market value at the beginning, goals, appearances, and total loan.

**Keywords**—Data analytics; predicting market value; English Premier League; loaned out players; consumption; resource use

## I. INTRODUCTION

Football is one of the most popular team sports worldwide [1]. According to research conducted by Nielsen Sports, more than 40% of people aged 16 or older in countries with high populations and large markets said they are "interested" or "very interested" in following football [2]. The most prominent and well-known football league in the world is the English Premier League (EPL). The EPL has a lot of fans all over the world. According to the official website of the English Premier League, the cumulative global audience of EPL for season 2018/2019 was over 3 billion [3]. Due to the huge fans and excitement of the EPL, it has succeeded in attracting the interest of investors. Matchday revenue, broadcast deals, and commercial activity are some of the ways a club can generate a lot of profit [4].

To maximize revenue, the club must be popular among the viewers and have winning matches. Therefore, every owner strives to strengthen their club squad to be competitive and have a successful season. One way to strengthen a club is to buy good and talented players. Some of the examples we saw recently when Manchester City bought Jack Grealish from Aston Villa with a figure of €117.50m, Chelsea bought Romelu Lukaku from Inter Milan for €115.00m, and Manchester United bought Jadon Sancho for €85.00m from the German club, Borussia Dortmund [5].

Each player has a market value. Market value is an estimate of how much a player costs when a club wants to buy his contract from another club [1]. The price does not apply if a club only loans a player. If a club wants to loan a player, they are most likely only required to pay the player's salary for the duration of the loan. However, the player will still carry a market value that can go up or down when playing at the loan club. During the loan period, the player might perform extraordinarily and make many appearances and therefore, his market value will increase and vice versa. In every transfer window, every club in the EPL is likely to loan out their players to make room for their squad or give players a chance to build a reputation at another club. For this study, we use the market value published by the Transfermarkt website. The market values provided by the website are economically relevant and are viewed as having a fine reputation in the sports industry [6]. A study by Peeters revealed that Transfermarkt crowd valuation is referenced privately by club officials during player contract negotiations because it is more accurate than other valuations such as FIFA ranking and the ELO rating [7].

The academic community has found the football transfer market to be an engaging subject [8]. Additionally, we believe that additional investigation into the market value of football players would be an intriguing topic to pursue. Fortunately for us, the information required to do so is readily accessible through websites devoted to the sport of football. The general contributing aspects to a player's market value are not often covered in academic publications, nevertheless. Since the market value at the conclusion of the loaned time in EPL is greater than average, we are looking for contributing causes for that higher market value in this study.

### A. Data Availability Statement

The data collected for the model is from Transfermarkt, a German Website that provides football information and data, such as scores, league tables, club squads, and many more using web scraping. Football-related research has used this website as its source data. The website incorporates crowdsourcing to estimate a player's market value in several professional football leagues. This means that every person can join the community and discuss the market value of any football player.

## II. PREVIOUS STUDIES

There were studies on the subject of prediction of the market value of a football player that aligned with this research. Such as one from Singh and Lamba that suggested consistency, popularity, crowd estimation, and performance parameters enhance the prediction accuracy of the market value of football players [9]. While Felipe et. al. stated in their paper that the playing position (attacking midfielders) and age of the player (born in the first quarter of the year) are the most economically valued in terms of current value and maximal value [10]. Müller, Simons, and Weinmann stated that there are three categories of indicators of the market value of a player. There are the player characteristics (age, height, position, footedness, nationality), player performance (playing time, goals, assists, passing, dribbling, dueling, fouls, and cards), and player popularity (news, internet links) [1]. Further study on the popularity component, Frenger et. al. suggested that social media activities significantly influenced a football player's market value on the site [11].

A study on the player performance is also done by Richau et. al. which emphasized the actual performance of a football player to determine their market value, the paper stated that the actual performance is measured through individual player's age, minutes played, offense, defense, and team and analyzed using boosted regression trees [12]. They found that individual player performance indicator does not have the highest influence on the market value; instead, they found that team dimension average rank influences market value. Along this line, Metelski tried to find factors affecting the value of football players in the transfer market for the Polish Football League using descriptive statistics and several statistical tests. The writer uses the position on the pitch, age at transfer, year of transfer, the destination country, and selling club as the indicators. They found that the age of the player is a significant factor in the football players' values [13]. Moreover, Behravan and Razavi used the FIFA 20 dataset of various performance ratings of 18,278 players. Their novelty is the use of an automatic clustering algorithm in the first phase which they called APSO-clustering, and further training of a hybrid regression method called PSO-SVR for each cluster [14] that can estimate the players' value with an accuracy of 74%.

## III. METHOD

Fig. 1 illustrates the methods we use for this study. These steps will be more specifically described afterward.

### B. Data Collection

The data collected for the model is from Transfermarkt, a German Website that provides many footballs information and data, such as scores, league tables, club squads, and many more using web scraping. Football-related research has used this website as their source data, such as in [14] [15][16][6][17]. The website incorporates crowdsourcing to estimate a player's market value in several professional football leagues. This means that every person can join the community and discuss the market value of any football player. Everyone can suggest a market value for a player with good arguments and reasons to justify the player's estimation [6]. However, not everyone's opinion has the same value. The Transfermarkt website has

data on past loan players' performance in the EPL from the season 2004/2005 to 2021/2022. However, as the EPL 2021/2022 season is still ongoing at the time of the writing of this paper, we will limit the data to season 2020/2021.

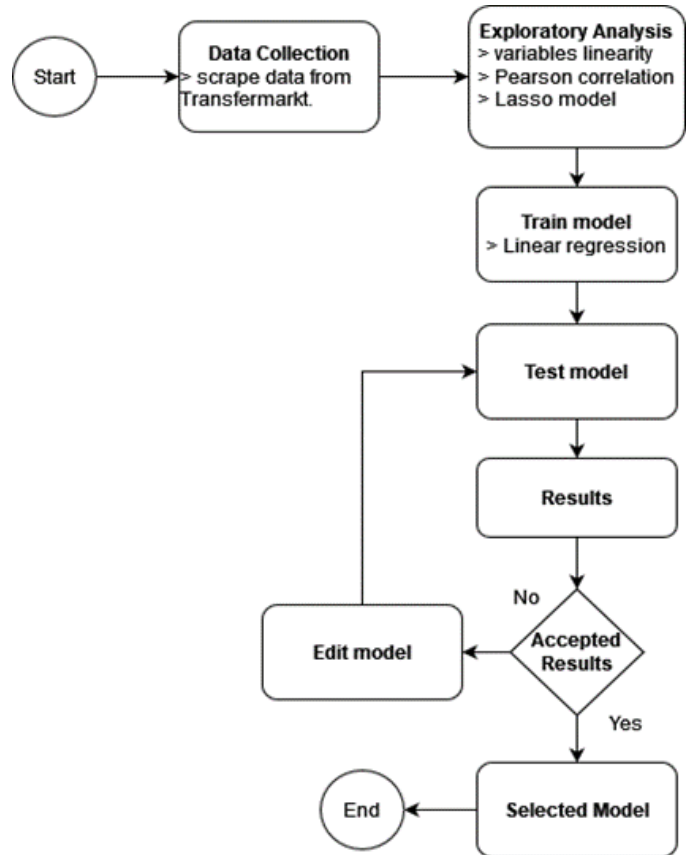

Fig. 1. Flowcharts of an applied method for the research.

There are 10 variables in the data as captured in Table I. In this study, we want to predict the last variable, which is the total market value of the loaned-out players from a club in a season. Therefore, the first nine variables are labeled as the explanatory variables and the last variable is our target or dependent variable.

### C. Exploratory Analysis

In this section, we explore the data that we have. Our data has 339 rows and 10 columns, which means we have a total record of 339 data of all clubs who loaned out their players from season 2004/2005 to 2020/2021. Every season consists of 20 clubs and because the EPL uses a promotion and relegation system, there can be more than 20 unique clubs in the data. The first thing we have done is to list and count every unique club in the data. The outcome is that we have 40 unique clubs that will be trained in the Linear Regression model. We start exploring our data with the perspective of the relationship between variables, the data distribution, the correlation among variables, Least Absolute Shrinkage and Selection Operator (LASSO) in identifying features that may be the contributing factors to predicting market values of the loaned players.

TABLE I. SUMMARY OF THE AFM INFORMATION OF CDS QDS

Variable Name	Description
name	The club's name
year	The year of loaned out players data of a club (ranging from 2004 to 2020)
total_loan	The total loaned-out players from the club in the respective year
average_loan (in years)	The average number of loan periods of all loaned out players from the club in the respective year
appearances	The total number of appearances from all loaned-out players from the club in the respective year
starting_formation	The total number of appearances in the starting formation from all loaned-out players from the club in the respective year
goals	The total number of goals from all loaned-out players from the club in the respective year
average_minutes_played	The average minutes played by all loaned-out players from the club in the respective year (the maximum is 90 as a football match is played for 90 minutes)
market_value_at_start (in M €)	The total market values at the start of the loan period from all loaned-out players from the club in the respective year
market_value_at_end (in M €)	The total market values at the end of the loan period from all loaned-out players from the club in the respective year

D. Checking the Relationship between Variables using Scatter Plots

We start by checking the bivariate relationships between eight variables of our data. The total loan personnel, average loan time in years, number of appearances made by the players, starting formation of the players, goals made, average minutes played, market value at the start, and the last variable is the market value at the end. As we can see from the scatter plot in Fig. 2, there are three types of relationships shown, discrete relationships, random, and linear.

The discrete plot was obtained from the total loaned variables as there were only two values in these variables as the players were loaned only for 1 year or 2 years. The random relationship is shown by the total loaned players' variable against average minutes played, market value at the start, and market value at the end. The random relationship we see with average minutes played against all other variables. While the rest of the bivariate combinations showed some kind of linear relationship.

In this paper, we focused on the relationship between the market value at the end with the rest of the variables, so we found that the market value at the end has a strong linear relationship with the market value at the start. We explore the relationship more in the sections below.

Fig. 2. Bivariate relationship of variables data.

E. Checking the Univariate Distribution using Histogram

To see if the observed data represent a random sample from the population; we use the histogram to check the distribution. Fig. 3 below shows the distribution of seven variables that we consider from the data; we did not include the name and year variables because they are categorical. The initial histogram showed left and right skewed data, so we do a log transformation on the variables to stabilize the variance, such as seen in [18] and [19]. Ensuring the log transformation, the average minutes played variable is still left skewed, while the average loan years is discrete.

Fig. 3. Log transformed data distribution of market value predictors.

F. Pearson Correlation

The next thing we do in our exploratory step is to see the Pearson correlation to determine the precise extent or degree of any connection between any two variables, indicating its presence or absence.

that model 1 has the least R2 values, at an average of 88.9%, 87.9%, and 87.2% for respective 3, 5, and 10 folds. The percentage showed how well the dependent variable, market value at the end can be accounted for by the nine predictors. Model 2 came second with the average R2 values of 89.6%, 88.7%, and 88.3% accounted for by seven predictors, and model 3 has the highest average R2 values of 90.5%, 90.3%, and 90.1% accounted for by five predictors.

In terms of accuracy, the mean RMSE for model 1 for 3, 5, and 10 folds, respectively are 8.69525, 7.91934, and 7.24353. For Model 2, the mean RMSE are 8.10107, 7.51161, and 6.84796, respectively. For Model 3, the mean RMSE are 0.33339, 0.32948, 0.31620, respectively. Model 3 accuracy is higher than the two previous models. Therefore, we can conclude that removing the two variables average minutes played, and average loan years, is the right decision. With model 3 we come up with this linear equation:

$$\begin{aligned} \text{market\_val\_at\_end} = & (-2.282 - 0.04653 * \text{total\_loan}) + (0.5237 * \\ & \text{appearances}) - (0.00007325 * \text{starting\_formation}) + (0.1056 * \\ & \text{goals}) + (0.8716 \text{ market\_val\_at\_start}) \end{aligned} \quad (1)$$

With the use of the aforementioned equation, we can observe that while every variable affects the market value at the end, the market value at the beginning, objectives, appearances and total loan all has positive correlations and significant contributions. This differs slightly from our initial hypotheses based on the Pearson correlation, which was initial market value, early appearances, and initial formation.

The majority of the contributing factors to the loan player in the ELP have generally been identified by our investigation. With this investigation and its outcome, we have discovered a previously unknown association. We have identified which variables are connected to or have the strongest relationships with, and we may be able to identify patterns within the dataset as a result of this understanding.

## V. CONCLUSION

In this study, we identified the elements that contributed to a football player's market worth in the English Premier League at the end of the loan period. Market value at launch, goals, appearances and total loan is among them. The market worth of a football player after a loan has been made is something we can forecast using exploratory research and a linear regression model. To discover the best predictor, we tested three distinct models. Our study revealed that the predictors differed slightly from what we had initially thought. Although linear regression is simple to comprehend and explain, we believe the model is adequate for use in this investigation. In future experiments, we hope to incorporate more data into our model, as the current data is very limited. We can also implement other models to better understand the contributing factors of a football player's market value.

# Exploring the Challenges and Impacts of Artificial Intelligence Implementation in Project Management: A Systematic Literature Review

Muhammad Irfan Hashfi, Teguh Raharjo

Faculty of Computer Science, Universitas Indonesia, Salemba, 10430, Indonesia

**Abstract**—This paper presents a systematic literature review (SLR) investigating the challenges and impacts of implementing artificial intelligence (AI) in project management, specifically mapping them into the process groups defined in the Project Management Body of Knowledge (PMBOK). The study aims to contribute to the understanding of integrating AI in project management and provides insights into the challenges and impacts within each process group. The SLR methodology was applied, and a total of 34 scientific articles were analyzed. The results and analysis reveal the specific challenges and impacts within each process group. In the Initiating Process Group, AI tools and analysis techniques address challenges in risk assessment, cost prediction, and decision-making. The Planning process group benefits from various tools and methodologies that improve risk assessment, project selection, cost estimation, resource allocation, and decision-making. The Execution process group emphasizes the importance of advanced tools and techniques in enhancing productivity, resource utilization, cost reduction, and decision-making. The Monitoring and Controlling process group demonstrates the potential of advanced tools in achieving efficiency, cost reduction, improved quality, and informed decision-making. Lastly, the Closing process group emphasizes the importance of utilizing advanced tools to minimize waste, optimize resource utilization, reduce costs, improve quality, and project closure success. Overall, this research provides valuable insights and strategies for organizations seeking to implement AI in project management, thereby enhancing the potential for success within the PMBOK Process Group.

**Keywords**—Artificial intelligence; project management; PMBOK process groups; challenge; impact

## I. INTRODUCTION

Industry 5.0 is an evolution of Industry 4.0, focusing on a more human-centric approach while leveraging advanced technologies like Artificial Intelligence (AI) and big data. It aims to create a sustainable and resilient industry by combining technological advancements with human needs [1], [2]. Project management has experienced a paradigm shift because of the quick development of AI technology. The way projects are planned, carried out, and controlled may be completely transformed using AI [3], [4]. The incorporation of AI into project management techniques, however, comes with a unique set of difficulties and has a big influence. Organizations need to address these challenges to fully harness the potential of AI in project management [5], [6]. Therefore, it is essential to investigate and understand the challenges faced and impacts

observed during the implementation of AI in project management [6].

Given the transformative impact of AI, there is an increasing significance in studying the process of AI adoption. Numerous studies have been conducted to explore the driving factors, barriers, challenges, and overall performance impact associated with AI implementation in organizations [6], [7]. The accuracy and appropriateness of data pertaining to project management tools are crucial. Initial AI tools for project management heavily depend on individuals to accurately input data, timely update tools, and make necessary corrections [8].

The integration of Artificial Intelligence (AI) into business operations has given rise to the emergence of intelligent environments, including advanced monitoring systems for project management. Similarly, AI has been embraced in the field of project management, offering promising prospects for the future of project management activities [3], [9]. Moreover, AI has the capability to monitor project status and make adjustments when required. Integrating AI into project management allows for minimal human intervention by utilizing intelligent machines and large data sets to automate decision-making and task management. This automation enables AI to play a guiding role in projects, automating tasks and aiding in decision-making processes [6], [10], [11].

This paper aims to conduct a systematic literature review (SLR) to investigate the challenges faced and impacts observed during the implementation of AI in project management, specifically mapping them into the process groups defined in the PMBOK [12], [13]. The research questions derived from this objective are as follows:

RQ1: What are the challenges faced and impacts observed during the implementation of AI in project management?

RQ2: How does the implementation of AI in project management incorporate the mapping of challenges and impacts into the process groups defined in the PMBOK?

By conducting a comprehensive review of existing literature, the findings will provide insights into the challenges and impacts specific to each process groups, helping organizations effectively address these challenges and leverage the potential benefits of AI in project management.

This paper follows a systematic process, commencing with a Literature Review section that evaluates existing studies on AI implementation and process groups in project management.

Then the Methodology section consists of three phases: planning the Systematic Literature Review (SLR), executing the SLR, and presenting the SLR findings. Within the Results and Analysis section, two subsections are delineated. The first subsection maps AI tools, implementation challenges, and impacts based on prior research, while the second subsection aligns AI tools, challenges, and impacts with PMBOK Process Groups (initiating, planning, execution, monitoring and controlling, closing). Lastly, the paper concludes by summarizing key findings, discussing their implications for project management, and suggesting directions for future research.

## II. LITERATURE REVIEW

### A. Artificial Intelligence and Data Mining

Artificial intelligence (AI) is a field within computer science that aims to develop intelligent machines for the benefit of humans. However, there is ongoing debate among researchers regarding the definition of AI due to its evolving nature. Various definitions exist in the literature, reflecting researchers' specializations and interests, all striving to explain the concept of AI and provide a wide range of technologies that enhance performance and interaction within organizations [3], [14]. AI has traditionally been approached from four perspectives: thinking and acting, which encompass thought processes, reasoning, and behavior. These perspectives can be further categorized into a human-centered approach based on human behavior observations, and a rationalist approach combining mathematics and engineering concepts [1].

Data mining is a branch of Machine Learning and Artificial Intelligence that involves analyzing a dataset using algorithms to uncover patterns and relationships. It allows users to analyze data from multiple perspectives, categorize information, and draw conclusions. The process involves searching for correlations between different fields in a database to extract valuable insights and information [15]–[17]. Machine learning enables the categorization of data processing methods in data mining into distinct categories such as classification, regression analysis, association rules, and clustering. Each of these mining methods can be executed using various machine learning techniques [18].

### B. Process Groups of Project Management

Project management procedures are organized into logical groups of inputs, tools and techniques, and outputs that are tailored to the needs of the organization, the project, and the stakeholders. Instead of being interchangeable with project phases, these process groups work together during each stage of the project's life cycle. In order to maintain flexibility and adaptation throughout the project, the number of iterations and interactions across processes can change based on the demands of the project [12], [13]. As shown in Fig. 1, participation with the remaining Process Groups is required to fully realize the collaborative aspect of project management.

Projects that adopt a process-based approach can be structured into five groupings based on different processes:

1) The initiating phase of a project involves defining and obtaining authorization for a new project or phase [12]. This

phase includes creating a project charter and implementing a formalized project initiation process to support project management decisions and ensure project success [19].

Fig. 1. Project management process groups [13].

2) The planning phase of a project involves establishing the project's scope, refining objectives, and determining the necessary actions to achieve those objectives [12]. This phase encompasses defining the course of action, making decisions, and formalizing the project's direction. Planning is a crucial step in project management, involving the conscious determination of actions to accomplish goals, and it is typically conducted after business planning and before project execution in fields such as construction [20].

3) The execution completing the tasks listed in the project management plan in order to comply with the project's criteria [12]. It encompasses the actual performance of project tasks and activities as outlined in the plan to fulfill the project's objectives [20].

4) The monitoring and controlling phase of project management involves tracking progress, reviewing performance, and making necessary changes to ensure project success [12]. Studies have emphasized the importance of timely control information and the ability to handle unexpected crises as critical factors in effective monitoring and control [20].

5) The closing phase of project management involves formally completing all activities and closing the project, phase, or contract [12]. Research conducted by Amponsah [21] focused on project failure/success factors in Ghana's agriculture, banking, and construction sectors. The study identified project management tools, techniques, and methods used by project managers and recommended that companies in Ghana focus on improving their project management activities for better outcomes.

### C. Challenges and Impact of AI Implementation in Project Management

Over time, project management has undergone significant changes and has become increasingly valuable to organizations. The collaboration between humans and machines in the face of major technological advancements presents significant opportunities for both businesses and individuals. One such advancement is Artificial Intelligence (AI), which is expected to greatly influence the role of project managers [6]. AI, despite its complexities, has the potential to

increase productivity and reduce errors in various fields, including software development projects. By providing insights into probable outcomes and removing extraneous information, AI improves project management and enables a focus on relevant facts [22].

The challenges of implementing AI in project management include barriers such as limited data availability, high costs of operation and equipment, and potential unemployment as AI replaces human workers. The successful adoption of AI requires technical staff with specialized skills and experience, along with a clear understanding of system integration and interoperability challenges [3]. While AI offers benefits like cost-effectiveness and reliability, it also raises issues of uncertainty and highlights both the positive and negative aspects of its adoption [23].

The adoption of AI in project management enhances decision-making quality by providing insights and support for potential outcomes. AI systems streamline information by eliminating redundancy, and auto-scheduling improves the robustness of project planning. Planning tools powered by AI, including hybrid computer systems, facilitate project control and objective configuration [8]. While contemporary management strategies like continuous alignment and agile approaches help overcome uncertainties, predictive analytics and machine learning contribute to better project outcomes in areas like KPIs, resource management, and estimate [3], [24].

### III. METHODOLOGY

This section explains the literature review process using the Systematic Literature Review (SLR) method. This method is used to evaluate and interpret all research related to the research questions, topic areas, or desired phenomena [25]. The goal of Systematic Literature Review is to generate accurate evaluations of the research topic using reliable, meticulous, and auditable methodologies. It is divided into three parts based on the Kitchenham [25] and references [26], [27]: Planning, Implementation, and reporting of SLR stages.

#### A. Planning the SLR

In this stage, keyword generation is conducted based on the main keywords and synonyms obtained at the beginning of the research, namely Artificial Intelligence and Project Management. Subsequently, these keywords are combined using "AND" to connect the main keywords and "OR" for each synonym or simpler word. The keywords and their synonyms or equivalents are as follows:

- “Artificial Intelligence”, synonym: “data mining”, “machine learning”
- “Project Management”

These keywords and their synonyms are combined to form the search keywords as follows:

(“artificial intelligence” AND “project management”) OR (“data mining” AND “project management”) OR (“machine learning” AND “project management”)

Then the search is conducted on several reputable literature and journal websites, based on title, abstract, or keywords. The

databases are IEEE Xplore, Springer Link, Emerald Insight, SAGE Journals, Science Direct, Scopus, and ACM Digital Library.

After determining which databases to use for the search, the researcher proceeds with the study selection process. This is intended to identify key studies within a research as direct evidence related to the previously obtained keywords [25]. The criteria for the study selection process in this research can be seen in Table I.

TABLE I. CRITERIA FOR STUDY SELECTION

Inclusion Criteria	IC1	Publications written in English
	IC2	Publications starting from 2018 until 2023
	IC3	Publications that truly focus on the keywords: artificial intelligence / data mining / machine learning and project management
	IC4	Publications that increasingly focus on the root problem, specifically discussing the challenges and impact of AI / DM / ML on project management
Exclusion Criteria	EC1	Research not written in English
	EC2	Research that discusses topics other than AI / DM / ML and project management
	EC3	Research published before 2018

#### B. Implementation of SLR

In the second phase of the Systematic Literature Review (SLR), the focus is on conducting an extensive search and selecting relevant literature. This involves identifying pertinent studies, extracting relevant information, and synthesizing the findings to obtain a comprehensive understanding of the research topic. Fig. 2 represents the flow diagram illustrating the selection process conducted from the initial data collection in various databases using the inclusion and exclusion criterias specified in Table I.

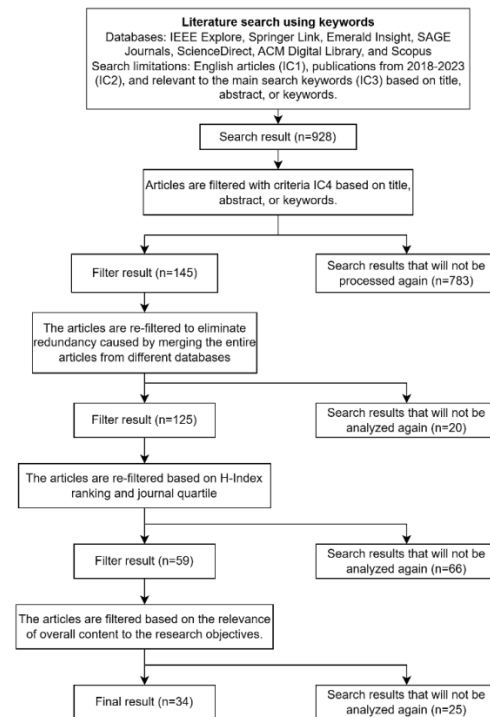

Fig. 2. Flow diagram of SLR implementation.

The total number of articles that will undergo further analysis related to the challenges and impacts on project management amounts to 34 articles, obtained from various high index journals and proceedings based on Scimago.

### C. Reporting the SLR

The final step of the Systematic Literature Review (SLR) is reporting the results. Table II presents a summary of all relevant article titles aligned with the research objectives, including information on the year and reference citation coding.

TABLE II. SUMMARY OF ALL RELEVANT ARTICLES

No	Title	Year	Index	Code
1	A BIM-data mining integrated digital twin framework for advanced project management	2021	Q1	[28]
2	A Machine Learning Study to Enhance Project Cost Forecasting	2022	Q3	[29]
3	A new hybrid ahp and dempster—shafer theory of evidence method for project risk assessment problem	2021	Q2	[30]
4	Activity classification using accelerometers and machine learning for complex construction worker activities	2021	Q1	[31]
5	An Approach Based on Bayesian Network for Improving Project Management Maturity: An Application to Reduce Cost Overrun Risks in Engineering Projects	2020	Q1	[32]
6	Application of Data Mining Technology in Field Verification of Project Cost	2021	Q4	[33]
7	Application of lean techniques, enterprise resource planning and artificial intelligence in construction project management	2019	Q4	[34]
8	Automated progress monitoring of construction projects using Machine learning and image processing approach	2022	Q2	[35]
9	Combined machine-learning and EDM to monitor and predict a complex project with a GERT-type network: A multi-point perspective	2023	Q1	[36]
10	Comprehensive project management framework using machine learning	2019	Q4	[37]
11	Data on Field Canals Improvement Projects for Cost Prediction Using Artificial Intelligence	2020	Q2	[38]
12	Data-driven project buffer sizing in critical chains	2022	Q1	[11]
13	Decision support system for final year project management	2019	Procd	[39]
14	Development and comparative of a new meta-ensemble machine learning model in predicting construction labor productivity	2022	Q1	[40]
15	DevOPs project management tools for sprint planning, estimation and execution maturity	2020	Q2	[41]
16	Empirically Exploring the Cause-Effect Relationships of AI Characteristics, Project Management Challenges, and Organizational Change	2021	Procd	[5]
17	Estimating production and warranty cost at the early stage of a new product development project	2021	Q3	[42]
18	Estimation of Risk Contingency Budget in Projects using Machine Learning	2022	Q3	[43]
19	Explainable machine learning for project management control	2023	Q1	[44]
20	Forecasting the scheduling issues in engineering project management: Applications of deep learning models	2021	Q1	[9]
21	Information Technology (IT) Governance Framework with Artificial Neural Network and Balance Scorecard to Improve the Success Rate of Software Projects	2022	Procd	[45]
22	Intelligent purchasing: How artificial intelligence can redefine the purchasing function	2021	Q1	[46]
23	Machine learning in project analytics: a data-driven framework and case study	2022	Q1	[47]
24	Project engineering management evaluation based on GABP neural network and artificial intelligence	2023	Q2	[48]
25	Project management: openings for disruption from AI and advanced analytics	2021	Q1	[49]
26	Proposal of a framework and integration of artificial intelligence to succeed IT project planning	2019	Q4	[50]
27	Recommendation of Project Management Practices: A Contribution to Hybrid Models	2022	Q1	[51]
28	Safety risk factors comprehensive analysis for construction project: Combined cascading effect and machine learning approach	2021	Q1	[52]
29	Symbiotic organisms search-optimized deep learning technique for mapping construction cash flow considering complexity of project	2020	Q1	[53]
30	The effectiveness of project management construction with data mining and blockchain consensus	2021	Q1	[54]
31	The impact of entrepreneurship orientation on project performance: A machine learning approach	2020	Q1	[55]
32	The value of data from construction project site meeting minutes in predicting project duration	2022	Q2	[56]
33	Using an Artificial Neural Network for Improving the Prediction of Project Duration	2022	Q2	[57]
34	Visual System Development for Construction Project Management by Using Machine Learning Algorithm	2022	Q2	[58]

Furthermore, the distribution of the scientific articles based on their publication years is presented in Fig. 3.

Fig. 3. Distribution of study per year.

#### IV. RESULTS AND ANALYSIS

In accordance with the objective of this research, a thorough mapping and analysis of the literature obtained will be conducted using the Systematic Literature Review (SLR) method described in the previous chapter. The outcomes obtained from this process will be divided into the mapping of AI tools used, challenges, and the impact of AI implementation on each article, as well as their summaries.

##### A. Mapping the AI tools, Implementation Challenges and Impacts based on Related Studies

Table III presents the further analysis results of the articles obtained in the previous SLR process, where the analysis is conducted regarding the AI tools used in the referenced studies, as well as the challenges and impacts of implementation in those studies. These AI tools can include algorithms, software, models, or others.

TABLE III. MAPPING THE AI TOOLS, CHALLENGES, AND IMPACT OF THE AI IMPLEMENTATION

Ref	AI Tools	Challenge	Impact
[28]	BIM, IoT, DM techniques, process mining, time series analysis, fuzzy miner algorithm, ARIMAX model	Real-time IoT data mapping and complexity management in large-scale projects.	AI enables early bottleneck detection, future workload prediction, and proactive decision-making for enhanced efficiency and adaptability.
[29]	Moving averages, schedule and cost performance factors	Nonlinear budget acquisition and cost growth patterns not accurately captured by traditional index-based models.	AI provides reliable and accurate cost estimates, improving project cost forecasting and maintaining positive stakeholder relationships.
[30]	Hybrid PCA-agglomerative unsupervised ML algorithm, Delphi method, statistical analysis, Taguchi Method	Uncertainty and variability of risk factors not accurately addressed by traditional decision-making methods.	AI quantifies risk factors for more informed project selection and improved decision-making, potentially enhancing project success rates.
[31]	Machine learning algorithms (e.g., K-Nearest Neighbors, Gradient Boosting), wearable accelerometers, feature selection techniques	Dealing with realistic scenarios, bias minimization, imbalanced datasets, and optimizing classifier performance with activity transitions.	AI enhances project decision-making, resource management, worker performance, and safety in construction, contributing to automation and process-level knowledge.
[32]	Bayesian networks	Integrating PMM models with Bayesian networks, formalizing expert knowledge, and addressing sector-specific factors and project drifts.	AI-based PMM diagnoses and predicts project performance failures, identifies drifts, and suggests corrective actions for comprehensive project success analysis.
[33]	Statistical data mining technology (not specified)	Developing a comprehensive organizational structure, implementing advanced management practices, improving cost communication, and addressing cost verification shortcomings.	AI introduces a data-driven approach, improving visualization, resource management, data collection, and cost control in project management.
[34]	Voice command, optical character recognition, LiDAR sensors	Integrating multiple systems, ensuring compatibility, overcoming resistance to change, and addressing complexity and uncertainty in construction projects.	AI minimizes waste, optimizes resource utilization, reduces costs, improves delivery time and quality, and enhances productivity in the construction industry.
[35]	Deep learning models, supervised CNN classifiers, image processing techniques	Reluctance, data standardization, and accuracy of automated tracking	Supervised CNN classifier improves activity recognition, enhancing supervision and progress tracking in construction projects.
[36]	Monte Carlo simulation, machine learning regression algorithms	Analyzing complex networks and selecting suitable algorithms	AI improves project monitoring, deviation identification, and completion time estimation, enhancing project performance and decision-making.
[37]	Artificial Intelligence (AI), machine learning models, online solutions (not specified)	Model selection, training, integration, data accuracy, and user interface development.	AI improves planning, decision-making, automation, and holistic solutions for project management.
[38]	Machine learning and AI techniques (Regression, Fuzzy, ANN, SVM, and others)	Dataset quality, algorithm selection, and interpretation/validation.	Understanding factors influencing project outcomes improves planning and resource allocation in sustainable projects.
[11]	Full-factor design of experiments, Monte Carlo simulation, regression techniques	Designing experiments, simulations, and ensuring model validity,	AI-based buffer sizing improves project planning and timeliness compared to traditional methods.
[39]	Naïve Bayes algorithm, JSP technology	Database organization, accuracy of Naïve Bayes, and technical issues.	AI platform for matching students with project topics and supervisors improves the quality and efficiency of final year research projects.
[40]	Ensemble machine learning algorithms	Preprocessing, algorithm selection, converting models, and case studies.	Accurate labor productivity prediction and influential factors guidance improve construction project management and overall productivity.

[41]	Real-time project data analysis, sprint estimation techniques, sentiment analysis	Real-time data analysis, accurate predictions, consensus, and sentiment analysis.	AI tools streamline project timelines, increase productivity, and improve decision-making in a DevOps environment.
[5]	AI techniques, machine learning algorithms, data analysis methods	Addressing AI's characteristics and implications in organizational settings.	Understanding the relationships between AI characteristics, project management practices, and organizational change improves AI implementation and decision-making.
[42]	Artificial neural network, linear regression techniques	Defining variables, acquiring data, and simulating cost variants.	Systematic consideration of cost factors and constraints improves cost estimation and optimization in new product development projects.
[43]	Machine learning algorithms, Monte Carlo simulation	Defining risks, selecting algorithms, and ensuring accuracy	Integration of machine learning techniques enhances Contingency Budget estimation accuracy and risk management in projects.
[44]	Monte Carlo simulation, statistical/machine learning models, explainable machine learning with SHAP	Integrating simulation and explainability, selecting models, and handling complexity.	Integration of Monte Carlo simulation, machine learning, and explainable machine learning improves project control and decision-making in uncertain environments.
[9]	LSTM and GRU models	Forecasting model selection, data quality, and interpretation.	LSTM and GRU models enable effective scheduling, resource allocation, and decision-making, improving overall project efficiency.
[45]	Artificial Neural Network (ANN) method, Balanced Score Card framework	Top management commitment, solution finding, and data availability.	AI integration in software project management enables informed decision-making and better outcomes, leading to the development of new project life-cycle solutions.
[46]	Automated systems for purchasing, and decision support	Resistance, integration, data quality, and training.	AI systems redefine purchasing roles, improve decision-making, supplier relations, and interdepartmental collaboration, highlighting the potential of AI capabilities in supplier management.
[47]	Machine learning algorithms (e.g., support vector machine, logistic regression, neural networks) using Python's Scikit-learn package	Limited evaluation, feature selection, and data imbalance.	AI-driven data analysis improves decision-making and understanding in construction project management.
[48]	BP neural network, genetic algorithms	Data availability, neural network limitations, and minimizing subjectivity.	AI-based system optimizes time, personnel, and resource utilization, improving engineering project management efficiency.
[49]	Software tools with AI and analytics features	Project managers adapting to software features	AI and analytics tools enhance project management with increased support, automation, and adaptive practices, emphasizing stakeholder relations and risk management.
[50]	Knowledge base, questioning system	Data acquisition, correctness, and risk management.	AI-based solution improves accuracy and efficiency of IT project planning, reducing failure rates and enabling cost savings.
[51]	Cluster analysis, association rule technique	Data collection, accuracy, and validation.	Guidance for selecting practices to enhance project management agility and effectiveness, suggesting avenues for further research in customizing hybrid models.
[52]	Machine learning, safety risk factor mining, AON networks	Abundant data, algorithm optimization, and quantifying risk impact.	AI improves safety risk analysis in construction projects, enhancing risk management, with further research needed for data independence and cost considerations.
[53]	Symbiotic organisms search (SOS) algorithm, LSTM, neural networks	Cash flow, model optimization, and data availability.	AI model accurately forecasts and controls cash flow in construction projects, improving cost management, decision-making, and resource allocation.
[54]	AI middle office, AI algorithms, blockchain technology, BIM	Data availability, integration, and consensus building.	Integration of AI middle office, BC technology, and BIM technology enhances trust, transparency, accuracy, security, and project management efficiency.
[55]	Machine learning algorithms (e.g., lasso, ridge, support vector machines, neural networks, random forest)	Algorithm selection, performance metrics, self-assessment, and generalizability.	AI techniques provide insights into operations and project management research, highlighting the potential of predictive analytics and entrepreneurial orientation for project success.
[56]	Data mining algorithms, random forest	Meeting minute data extraction, time-consuming capture, and data quality.	AI enables accurate project duration prediction, facilitating timely actions and improving project planning, leadership, and governance.
[57]	Artificial neural networks, genetic algorithms	Diverse datasets, adaptation to different organizations, and validation.	AI accurately predicts project duration for different organizations, adapting to various methods and datasets, enhancing project management decision-making.
[58]	Graph neural network, deep learning algorithms	Complex building data, accuracy of traditional algorithms, and limited early-stage.	Integration of complex data and machine learning algorithms improves building management efficiency, information access, communication, energy conservation, and safety.

Artificial intelligence tools in project management based on the related studies mentioned include BIM, IoT, DM techniques, process mining, time series analysis, fuzzy miner algorithm, ARIMAX model, moving averages, schedule and cost performance factors, hybrid PCA-agglomerative unsupervised ML algorithm, Delphi method, statistical analysis, Taguchi Method, machine learning algorithms (such as K-Nearest Neighbors and Gradient Boosting), wearable accelerometers, feature selection techniques, Bayesian

networks, voice command, optical character recognition, LiDAR sensors, deep learning models, supervised CNN classifiers, image processing techniques, Monte Carlo simulation, artificial neural networks, full-factor design of experiments, Naïve Bayes algorithm, ensemble machine learning algorithms, real-time project data analysis, sprint estimation techniques, sentiment analysis, software tools with AI and analytics features, knowledge base, questioning system, cluster analysis, association rule technique, safety risk factor mining, symbiotic organisms search (SOS) algorithm, LSTM,

AI middle office, lasso and ridge regression, support vector machines, random forest, data mining algorithms, genetic algorithms, and graph neural network.

From a project management standpoint, AI has the capability to replicate human cognitive functions such as decision-making and problem-solving [3]. These tools bring advanced capabilities to project management, enabling tasks such as data analysis, risk assessment, decision-making, performance monitoring, and optimization [42], [49]. They leverage AI, machine learning, and statistical techniques to improve project planning, resource allocation, cost estimation, risk mitigation, and overall project outcomes [43], [52]. These tools enhance efficiency, accuracy, and insights in project management processes, ultimately leading to improved project success rates and delivery [50], [54]

### B. Mapping AI Tools, Challenges, and Impacts of Articles based on PMBOK Process Group

Next is to map the process groups of PMBOK, which according to the literature are divided into 5, namely Initiating, Planning, Execution, Monitoring and Controlling, and Closing [12]. This mapping aims to integrate project management processes and product-oriented processes, ensuring proper coordination and alignment. The function of mapping the process group is to achieve this integration throughout the project lifecycle by tailoring the application of processes to meet the project's specific requirements and actively managing process interactions and tradeoffs to meet stakeholder needs [13]. The mapping results are presented in Table IV.

Based on the mapping results of the reference articles to the Process Groups in PMBOK, the next step involves reviewing the summaries of AI Tools used in each stage of the Process Group. Additionally, the challenges and their respective impacts on each process will be explored based on the conducted literature study.

TABLE IV. MAPPING RELATED STUDIES TO PROCESS GROUP

No	Process Group PMBOK	Reference	Freq
1	Initiating	[30], [38]	2
2	Planning	[5], [11], [29], [30], [32], [34], [37], [38], [41]–[43], [46]–[52], [54]	19
3	Execution	[34], [37], [39]–[41], [49]	6
4	Monitoring and Controlling	[9], [28], [31], [33]–[36], [44], [45], [49], [53]–[58]	16
5	Closing	[34], [49]	2

1) *Initiating process group*: In the Initiating process group of the PMBOK, both papers discussed the application of AI tools and analysis techniques to address challenges in risk management and cost prediction in projects.

The first paper [30] utilized a hybrid AHP and Dempster-Shafer methods along with various AI tools such as machine learning algorithms, Delphi method, statistical analysis, and Taguchi Method to tackle the challenge of uncertainty and variability in risk factors. These AI tools had a significant impact by offering a more reliable approach to project selection through the consideration and quantification of risk factors,

enabling informed decision-making and potentially improving project success rates.

Similar to the first article, the second paper [38] used Machine Learning and AI methods to estimate and forecast the cost and length of field canal development projects. These methods included regression, fuzzy logic, artificial neural networks, support vector machines, and others. Despite challenges related to dataset quality, algorithm selection, and interpretation/validation, the application of these techniques positively influenced the understanding of factors influencing project outcomes, leading to improved planning and resource allocation in sustainable projects.

In summary, within the Initiating process group, the integration of AI tools and analysis techniques in project management addresses challenges in risk assessment, cost prediction, and decision-making. These advancements provide more reliable approaches for project selection, considering and quantifying risk factors, and improving the overall success rates of projects. Additionally, the utilization of Machine Learning and AI techniques enhances the understanding of project outcomes and aids in better planning and resource allocation. However, challenges such as uncertainty, variability, and dataset quality need to be carefully addressed to ensure accurate predictions and interpretations in project management.

2) *Planning process group*: This comprehensive analysis summarizes the key findings and contributions of 19 scientific papers related to project management. These papers utilize various tools and techniques such as machine learning, artificial intelligence (AI), data mining, and statistical analysis to address challenges and enhance the process of group planning within the PMBOK framework. By leveraging these advanced tools, project managers can enhance decision-making, risk assessment, resource allocation, and project planning.

The application of these tools and methodologies in project management has significant impacts. By incorporating hybrid models, advanced algorithms, and statistical techniques, projects can benefit from improved risk assessment, more reliable project selection, accurate cost estimation, optimized resource utilization, and enhanced decision-making [29], [30], [38]. These advancements contribute to higher project success rates, improved project outcomes, and efficient resource allocation.

Furthermore, the integration of machine learning, artificial intelligence, and data analytics in project management processes enhances real-time data analysis, sentiment analysis, and decision support. This results in streamlined project timelines, increased productivity, and improved project management within a DevOps environment [41]. Additionally, the adoption of AI and advanced analytics tools in project management opens opportunities for disruption, automation, adaptive practices, and better stakeholder relations and risk management [32].

The construction industry also benefits from the application of AI, machine learning, and lean techniques. These

technologies enable the optimization of resource utilization, reduction of project costs, improvement of project delivery time and quality, and enhancement of overall productivity and efficiency [34], [52]. Moreover, the integration of AI in the South African construction project management industry contributes to job security, accident reduction, automation of high-risk tasks, and the creation of new job opportunities, thereby fostering regional development [59].

In summary, the 19 scientific papers examined showcase a wide range of tools and methodologies that address various challenges in project management. The application of these tools has a profound impact on risk assessment, project selection, cost estimation, resource allocation, decision-making, and overall project success rates. Additionally, the integration of AI and data analytics enhances real-time analysis, automation, adaptive practices, and stakeholder relations in project management processes. These advancements contribute to improved project outcomes, increased productivity, and regional development within the construction industry.

3) *Execution process group*: The analysis reveals valuable insights into the application of various tools, challenges, and impacts associated with the execution process group in PMBOK. These findings shed light on the utilization of tools such as lean techniques, enterprise resource planning (ERP), artificial intelligence (AI), machine learning models, and decision support systems to enhance project execution, productivity, process streamlining, and decision-making in different domains.

However, the implementation of these tools is not without challenges. The papers [34], [39] emphasize the challenges of integrating multiple systems, ensuring compatibility, overcoming resistance to change, addressing complexity and uncertainty, and dealing with technical issues. For example, a research [40], focuses on the challenges related to preprocessing, algorithm selection, converting models, and conducting case studies in the context of predicting construction labor productivity using ensemble machine learning models. These challenges necessitate comprehensive strategies and skillful implementation to successfully employ the identified tools in project execution.

Despite the challenges, the implementation of the identified tools brings about significant impacts on the execution process group. The papers highlight outcomes such as minimizing non-value-added efforts and waste, optimizing resource utilization, reducing project costs, improving project delivery time and quality, enhancing overall productivity and efficiency, and improving decision-making [34], [40], [41], [49]. For instance, a paper [34] discusses the impact of lean techniques, ERP, and AI in construction project management, which results in minimizing waste, optimizing resource utilization, reducing project costs, and improving project delivery time and quality within the construction industry.

Furthermore, the papers emphasize the potential of AI and advanced analytics tools in disrupting project management practices. These tools enhance productivity, support decision-making, automate processes, and emphasize stakeholder

relations and risk management [37], [49]. A paper specifically highlights the opening for disruption from AI and advanced analytics tools, underscoring their potential to transform project management practices through increased support, automation, and adaptive practices [49].

In summary, the analysis of the six papers highlights the significance of employing advanced tools and techniques in the execution process group in PMBOK. While the adoption of these tools offers numerous benefits, challenges related to system integration, resistance to change, and technical issues need to be addressed. The positive impacts resulting from their implementation include improved productivity, resource utilization, cost reduction, and enhanced decision-making. Further research and focused efforts are required to overcome the identified challenges and fully harness the potential of these tools for effective project execution.

4) *Monitoring and controlling process group*: The analysis of the 16 papers reveals significant insights into the utilization of tools, challenges, and impacts related to the monitoring and controlling process group in PMBOK. These papers highlight the application of various advanced tools and techniques such as Artificial Intelligence (AI), Building Information Modeling (BIM), Internet of Things (IoT), Data Mining (DM), machine learning, and image processing algorithms. These tools offer promising capabilities in enabling effective project control and monitoring in the construction domain. They facilitate complex data analysis, performance prediction, bottleneck detection, risk identification, and decision-making support.

However, the integration of these tools into project management practices is not without challenges. The papers emphasize the challenges associated with system integration, resistance to change, technology adoption, data accuracy, and project complexity [33], [34], [58]. The integration of multiple systems [45], [54], including voice command, optical character recognition, and LiDAR sensors, as mentioned in the certain paper [34], necessitates the overcoming of compatibility issues and resistance to change. Furthermore, the complexity and uncertainty inherent in construction projects pose additional challenges that demand comprehensive strategies and skilled implementation.

Despite these challenges, the implementation of the identified tools brings about significant impacts on the monitoring and controlling process group. The papers highlight outcomes such as enhanced efficiency, cost reduction, improved project quality, and timely delivery [9], [33], [34], [53], [57]. Moreover, the utilization of these tools fosters better decision-making, efficient resource management, improved stakeholder relations, and enhanced risk management [49], [57]. Other paper based on literature review [59] discusses the impact of AI integration in the construction industry, leading to improved job security, reduced accidents, automation of high-risk tasks, and the creation of new job opportunities.

In summary, the comprehensive analysis of the 16 papers underscores the significance of employing advanced tools and techniques for the monitoring and controlling process group in

PMBOK. While the adoption of these tools holds immense potential in project control and monitoring, challenges pertaining to system integration, resistance to change, technology adoption, and project complexity necessitate strategic interventions. However, the positive impacts resulting from their implementation include increased efficiency, cost reduction, improved quality, and informed decision-making, thereby driving effective project management. Further research and focused endeavors are required to address the identified challenges and fully harness the potential of these tools for improved project outcomes.

5) *Closing process group*: The two papers discussed the application of various tools and technologies in the Closing Process Group of project management according to the PMBOK. First paper [34] highlighted the use of tools like voice command, optical character recognition, and LiDAR sensors for what-if scenarios in construction project management. The challenges identified in this paper included integrating multiple systems, ensuring compatibility, overcoming resistance to change, and addressing complexity and uncertainty in construction projects. The impact of these tools was seen in minimizing non-value-added efforts, optimizing resource utilization, reducing project costs, improving project delivery time and quality, and enhancing overall productivity and efficiency within the construction industry.

Second paper [49] focused on the disruptions caused by AI and advanced analytics tools in project management. The tools discussed in this paper were software tools incorporating AI and analytics features. The main challenge highlighted was project managers adapting to these software features. However, the impact of these tools was significant, enhancing project management through increased support, automation, adaptive practices, and emphasis on stakeholder relations and risk management in the closing phase.

In summary, both papers emphasized the importance of utilizing advanced tools and technologies in the Closing Process Group of project management. The tools offer solutions to challenges such as system integration, resistance to change, and adaptation to software features. Moreover, the impacts mentioned, such as minimizing waste, optimizing resource utilization, reducing costs, improving quality, and enhancing productivity, align with the desired outcomes of the Closing Process Group in PMBOK.

## V. CONCLUSION

The findings of this systematic literature review (SLR) provide significant insights into the implementation of AI within the process groups defined in the PMBOK. The result highlights the importance of utilizing advanced tools and techniques in each process group and emphasizes the need to address specific challenges for successful AI implementation. Within the Initiating process group, AI tools and analysis techniques were effective in addressing challenges related to risk assessment, cost prediction, and decision-making. In the Planning process group, the application of AI and data analytics tools improved risk assessment, project selection, cost

estimation, resource allocation, and decision-making. The Execution process group experienced improved productivity, resource utilization, cost reduction, and enhanced decision-making through the use of advanced tools and techniques. The Monitoring and Controlling process group also demonstrated the potential of advanced tools and techniques in achieving increased efficiency, cost reduction, improved quality, and informed decision-making. Lastly, the Closing process group highlighted the value of incorporating AI, lean techniques, ERP, and machine learning, resulting in benefits such as cost reduction, efficiency improvement, and project closure success.

Overall, this SLR provides valuable insights for organizations aiming to integrate AI into their project management practices. By aligning the challenges and impacts with the PMBOK process groups, this research offers a structured framework that allows organizations to navigate the implementation of AI effectively. Understanding the specific challenges and impacts associated with each process group can help organizations address these issues and capitalize on the potential benefits of AI in project management, ultimately leading to improved project outcomes and increased productivity.

### A. Limitations of Study

The limitation of this study is that it should be noted that the authors have not explored or presented specific solutions to address the identified challenges discussed in the literature.

### B. Future Works

In future research, it is important to conduct a bibliographic analysis to identify relevant tools and map them into a specific framework. Additionally, creating a comprehensive mapping of the identified challenges within the framework will provide a better understanding of their origins and facilitate the search for effective solutions.

**Abstract**—In the realm of financial markets, the precise prediction of option prices remains a cornerstone for effective portfolio management, risk mitigation, and ensuring overall market equilibrium. Traditional models, notably the Black-Scholes, often encounter challenges in comprehensively integrating the multifaceted interplay of contemporary market variables. Addressing this lacuna, this study elucidates the capabilities of a novel Deep Residual Convolution Long Short-term Memory (DR-CLSTM) network, meticulously designed to amalgamate the superior feature extraction prowess of Convolutional Neural Networks (CNNs) with the unparalleled temporal sequence discernment of Long Short-term Memory (LSTM) networks, further augmented by deep residual connections. Rigorous evaluations conducted on an expansive dataset, representative of diverse market conditions, showcased the DR-CLSTM's consistent supremacy in prediction accuracy and computational efficacy over both its traditional and deep learning contemporaries. Crucially, the integration of residual pathways accelerated training convergence rates and provided a formidable defense against the often detrimental vanishing gradient phenomenon. Consequently, this research positions the DR-CLSTM network as a pioneering and formidable contender in the arena of option price forecasting, offering substantive implications for quantitative finance scholars and practitioners alike, and hinting at its potential versatility for broader financial instrument applications and varied market scenarios.

**Keywords**—Deep learning; CNN; LSTM; prediction; option price

## I. INTRODUCTION

Option pricing, an intrinsic component of financial markets, serves as the fulcrum upon which significant economic decisions, from individual investments to institutional strategies, hinge [1]. These derivative contracts, which bestow upon the holder the right, but not the obligation, to buy or sell an underlying asset at a specified price before a predetermined date, play a pivotal role in portfolio diversification, risk hedging, and speculative ventures [2]. Historically, the Black-Scholes model has been emblematic in the realm of option pricing, a seminal formula that established a theoretical framework for determining the fair market value of a European-style option [3]. However, as financial markets evolved, becoming increasingly complex and intertwined, driven by a plethora of factors ranging from geopolitical

dynamics to technological innovations, the limitations of such traditional models have become conspicuously palpable.

The metamorphosis of financial markets into data-dense ecosystems, replete with myriad variables and indicators, necessitates predictive models with a capacity for high-dimensional data processing and the discernment of intricate temporal relationships [4]. The recent resurgence in artificial intelligence, more specifically in deep learning, offers a promising vista for addressing these challenges. Deep learning architectures, distinguished by their hierarchical structure and ability to autonomously extract salient features from raw data, have been progressively permeating various domains, ranging from image recognition to natural language processing [5]. Within the financial sphere, their application promises to harness the vast expanses of data to render more nuanced and accurate predictions.

In this milieu, the Deep Residual Convolution Long Short-term Memory (DR-CLSTM) network emerges as a potent amalgamation of several cutting-edge deep learning paradigms. By intertwining the feature extraction capabilities of Convolutional Neural Networks (CNNs) [6] with the temporal relationship discernment offered by Long Short-term Memory (LSTM) networks [7], and further augmenting this synergy with deep residual connections, the DR-CLSTM aspires to provide a holistic solution to the option price prediction quandary. The convolutional layers, renowned for their prowess in spatial hierarchies discernment, sieve through vast datasets, isolating pertinent features integral to option pricing. Concurrently, the LSTM layers, celebrated for their ability to capture long-term dependencies by combating the vanishing gradient problem, harness these features to forecast temporal sequences, thereby rendering predictions [8]. The addition of deep residual connections further augments this architecture. By allowing activations to bypass one or more layers, these connections expedite the training process, ensuring faster convergence and fortifying the network against potential gradient diminution.

This paper seeks to explore and substantiate the efficacy of the DR-CLSTM network in the realm of option price prediction. In doing so, it aims to contribute a novel tool to the arsenal of quantitative finance, fostering enhanced market efficiency, informed investment decisions, and a deeper

comprehension of the intricate tapestry of factors influencing option prices. Furthermore, by juxtaposing the DR-CLSTM with both traditional computational models and contemporary deep learning architectures, this study endeavors to provide a holistic perspective on the trajectory of option price prediction methodologies, underlining the transformative potential of hybrid deep learning structures.

The ensuing sections will delve into the theoretical underpinnings of the DR-CLSTM, elucidating the individual components and their synergistic interplay. This will be followed by a comprehensive methodology section, detailing the dataset employed, the evaluation metrics, and the comparative models. Subsequent sections will present the empirical findings, discussions, and potential implications for both academia and industry. The paper will culminate with a conclusion, encapsulating the key insights gleaned and charting potential avenues for future research in this dynamic and ever-evolving domain.

## II. RELATED WORKS

The ever-evolving landscape of financial modeling and forecasting has witnessed a plethora of innovations and methodologies over the years. As we delve into the intricate world of option price prediction, it is imperative to ground our discussions within the context of prior research and explorations in this domain [9]. The "Related Works" section endeavors to provide readers with a comprehensive overview of seminal works, pioneering methodologies, and noteworthy contributions that have shaped the trajectory of this field. By juxtaposing our current study with these foundational works, we aim to highlight both the advancements made and the gaps that our research seeks to bridge. Let us embark on this journey of retrospection, understanding the milestones that have been achieved and setting the stage for the novel contributions of our study.

### A. Traditional Models for Option Pricing

Option pricing, a central facet of financial mathematics, has been subject to rigorous academic scrutiny for decades. It revolutionized this arena with their eponymous model, providing a closed-form solution for European option pricing [10]. The Black-Scholes model, predicated on certain assumptions such as constant volatility and interest rates, quickly became a cornerstone of financial markets. However, the assumptions underlying the model often diverge from real-world market conditions, leading to potential mispricing [11]. This inherent limitation paved the way for alternative stochastic volatility models, which attempt to address the constant volatility constraint [12].

### B. Emergence of Machine Learning in Financial Forecasting

With the exponential growth of computational capabilities and the proliferation of vast financial datasets, machine learning has transitioned from a theoretical concept to an instrumental tool in financial forecasting. Over the past two decades, the field has seen a marked departure from traditional econometric models towards more adaptive and self-learning algorithms. Next research advanced the argument that neural networks possess the capacity to model complex non-linear relationships inherent in financial markets, a dimension often

inadequately captured by traditional methods [13]. Next study specifically applied Recurrent Neural Networks (RNNs) to the domain of option pricing, highlighting the technology's aptitude for capturing intricate temporal sequences [14]. This evolution indicates a paradigmatic shift in financial forecasting methodologies, illustrating the potential of machine learning techniques to address the increasingly multifaceted nature of financial markets.

### C. Deep Learning and Financial Markets

In the expansive sphere of machine learning, deep learning stands out, characterized by its multi-layered neural networks adept at handling high-dimensional data. Originating from image and video recognition tasks, as underscored by LeCun et al. (2015), these algorithms have witnessed a significant adaptation to financial analytics [15]. The strength of Convolutional Neural Networks (CNNs) lies in their autonomous feature extraction capabilities, which have found resonance in financial time series analysis. A new study successfully applied CNNs to forecast stock price movements, underscoring their superiority over conventional methods [16]. This adaptation of deep learning to finance not only signifies its versatility but also heralds a new era in financial forecasting. Embracing these sophisticated architectures promises a more nuanced understanding of financial market intricacies, catalyzing more informed and data-driven decision-making processes in the sector.

### D. Residual Networks in Deep Learning

Within the intricate tapestry of deep learning architectures, Residual Networks (ResNets) have carved a distinctive niche. The transformative nature of ResNets lies in their "shortcut connections", which allow activations to bypass certain layers, facilitating the learning of identity functions [17]. This innovative approach, originally tailored for visual tasks, has significantly mitigated challenges associated with training deeper neural networks, predominantly by averting performance degradation. Its adaptation to financial applications, though still burgeoning, shows immense potential. The principal virtue of these networks is their ability to combat the notorious vanishing gradient problem, thus enhancing the depth and complexity of models without sacrificing accuracy. The foray of ResNets into financial forecasting stands as testament to the evolving landscape of deep learning, offering fresh perspectives and tools to navigate the multifarious nature of financial data.

### E. Hybrid Deep Learning Architectures

As the deep learning domain continues its relentless evolution, the emergence of hybrid architectures signifies a pivotal juncture. These models, synergizing distinct deep learning techniques, aim to harness the individual strengths of each component, resulting in a more comprehensive and potent analytical tool. Gosztolya et al. (2017) pioneered in this space, presenting a confluence of Convolutional Neural Networks (CNNs) and Long Short-term Memory networks (LSTMs) for nuanced time series forecasting [18]. Their work highlighted the hybrid model's capability to simultaneously capture spatial features and temporal dynamics. Yet, the realm of hybrid architectures is expansive, with the potential for myriad combinations. As these integrated frameworks gain traction,

they promise to redefine the boundaries of what deep learning can achieve, paving the way for more sophisticated, adaptable, and accurate solutions in diverse application areas, including finance.

#### F. Challenges in Option Price Prediction

Option price prediction, central to financial analysis, is fraught with complexities. Despite the sophistication of existing models, accurate forecasting remains an elusive goal, owing to the non-stationary nature of financial markets. A multitude of variables, both foreseen and unforeseen, continually impact option prices, making their behavior highly unpredictable. Traditional models, exemplified by Black-Scholes, while groundbreaking, have faced criticism for their stringent assumptions, as highlighted [19]. Emerging machine learning models, despite their adaptability, are not immune to challenges, notably overfitting and susceptibility to market anomalies. Dhiman et al., (2020) elucidate these limitations, stressing the need for models that are both adaptive and robust [20]. As the financial landscape grows increasingly intricate, the pursuit of a holistic, accurate, and resilient option pricing model remains a quintessential challenge, beckoning further research and innovation.

#### G. Gap in Current Literature

Within the vast expanse of academic literature dedicated to financial forecasting and particularly option price prediction, certain gaps persistently emerge. The trajectory of research has indeed traversed from traditional mathematical formulations to sophisticated computational architectures, yet complete solutions appear to remain on the horizon. While many studies, such as those by Black and Scholes, have laid foundational pillars, and others have delved deep into the capabilities of machine learning and deep learning techniques, a comprehensive amalgamation seems somewhat elusive.

Most evident is the lack of extensive exploration into hybrid deep learning frameworks, particularly in their application to financial markets. The combination of multiple neural architectures, each with its inherent strengths, presents a promising frontier. Kumar et al. (2023) offered a glimpse into the potential of these combined structures, but the literature remains scant in its entirety [21].

Furthermore, while there is an abundance of studies leveraging individual deep learning structures, the integration of residual connections within these architectures is a relatively uncharted territory, especially in financial forecasting contexts [22]. Current methodologies exhibit a propensity to lean heavily towards either feature extraction or temporal sequence modeling. Rare are the models that harmoniously intertwine both facets.

This paucity in holistic models underscores the pivotal gap in the existing literature. The quest remains for a unified model, like the DR-CLSTM, that seamlessly melds the strengths of various deep learning techniques, thus addressing the multifaceted challenges of option price prediction. This present study aims to contribute to bridging this gap, offering a fresh perspective grounded in both retrospective analyses and forward-looking innovations.

The trajectory of option price prediction methodologies has witnessed a paradigm shift from traditional mathematical models to sophisticated computational frameworks, epitomized by deep learning techniques [23]. As financial markets continue to evolve, becoming increasingly intricate, the need for robust, adaptive, and comprehensive models becomes paramount. The DR-CLSTM network, as explored in this paper, emerges in response to this exigency, grounded in a rich tapestry of academic research spanning diverse domains. By weaving together the strengths of CNNs, LSTMs, and ResNets, this study aims to contribute a novel perspective to the discourse on option price prediction, anchored in both historical precedents and contemporary innovations.

### III. MATERIALS AND METHODS

The crux of any research endeavor lies in the robustness of its methodologies and the quality of the materials employed. In this "Materials and Methods" section, we elucidate the systematic approaches, tools, and datasets harnessed to facilitate our investigative journey into option price prediction. Serving as the backbone of our study, this section ensures replicability and offers a transparent window into the foundational processes that underpin our findings. Herein, we meticulously detail the data sources, the preprocessing techniques adopted, and the intricacies of the analytical methods applied. By offering this in-depth exposition, we aim to provide a roadmap for researchers, practitioners, and enthusiasts alike, enabling a clear understanding of the mechanisms that drive our research forward. Let us navigate through the critical phases and elements that constitute the scientific rigor of our study.

#### A. Problem Statement

In the realm of derivative pricing, a model is recognized as being aligned with a set of benchmarking instruments when the calculated parameters, within its structure, coincide with prevailing market values. Calibration can be conceptualized as the act of juxtaposing a model against these benchmarking entities. The act of defining parameters to affirm measuring conditions encapsulates the essence of model calibration [24]. While derivative pricing may be perceived as the prospective challenge, calibration can be seen as its antithesis. Hypothetically, given the prices of Call options across all strikes and durations, the calibration quandary can be directly tackled through an inverse formulation. Yet, confronted with a restricted set of derivative valuations, calibration becomes an indeterminate challenge, necessitating the deployment of regularization techniques in real-world settings.

The integration of machine learning in predicting option prices has demonstrated potential, enhancing model precision, agility, and resilience. Notwithstanding, existing models grapple with obstacles such as the requisite for vast and varied datasets, heightened sensitivity to inputs and settings, and the intricacy of encapsulating intricate interactions affecting the option price [25]. Subsequent inquiries should prioritize crafting resilient and comprehensible models, assimilating supplementary data avenues, external variables, and broadening the application horizons of machine learning within financial domains.

Conceptually, this mirrors determining the apex solution for a given conundrum. Supposing we possess a roster of Call options market valuations  $C_M$  for specific durations  $T_i$ ,  $i = 1, \dots, n$  and strike values  $K_{i,j}$ ,  $j = 1, \dots, m_i$  which align with prevailing market metrics like  $S$ ,  $r$ ,  $q$ , among others. Given this classification, the assortment of exchanged strikes  $K_{i,j}$  may differ based on the duration  $T_i$ . If we take into account calibrating the model  $M$  delineated in Section I, it encompasses model parameters  $p$  in conjunction with input data metrics. We differentiate  $p$  and based on their intrinsic implications: while parameters  $p$  is derived through calibration, the input metrics symbolize discernible market constants, such as  $S$ ,  $r$ ,  $q$ ,  $T$ , and  $K_3$ .

Given the relevant inputs for  $p$  and, the model  $M$  can formulate the mathematical framework for Call option valuations  $C$ . To ascertain the model's calibrated parameters, it's imperative to resolve the associated optimization conundrum:

$$\arg \min_p \sum_{i=1}^n \sum_{j=1}^{m_i} w_{i,j} \| C_M(\theta_{i,j}) - C(\theta_{i,j}, p) \quad (1)$$

In this context,  $i$  and  $j$  represent weight coefficients, and  $L_2$  stands as a normative measure for  $k$  and  $k$ , employed in the formulation given by Eq. (1). Broadly, to address the intricacies of the non-linear function, it becomes imperative to adopt global optimization strategies. Such a need arises as the multi-faceted objective (or loss) function could potentially harbor multiple localized minima. Moreover, this challenge may be inherently bounded, a phenomenon frequently observed when deriving the implied volatility surface from market data points.

### B. The Proposed Model

Financial assets intrinsically exhibit stochastic behavior, necessitating representation through intricate nonlinear and multivariate functions, thus rendering option pricing an exceptionally complex challenge. Traditional approaches often rely heavily on numerous statistical presuppositions concerning market or data dynamics. In stark contrast, deep learning excels in its capacity to model nonlinearities, accomplishing this without such restrictive assumptions. This section succinctly outlines the non-parametric models employed in the referenced studies.

In the initial publication of this research, a Convolutional-LSTM model was introduced to address the dual complexities of spatial and temporal data modeling. Fig. 1 shows the proposed Convolutional LSTM network for option price prediction. The data architecture remains consistent here, interpretable as encompassing  $C$  channels, given its bidimensional configuration. Thus, the comprehensive dataset serving as input adheres to the structure [26]. The 2D convolution operation is executed across the  $D$  and  $E$  parameters, spanning each row and layers of the representation.

Alternatively, the dataset related to the option lacks a dimension, crucial for effective Convolutional-LSTM processing. Its sole permissible structure is  $(T;C;N;D)$ . A pragmatic resolution involves adapting the Convolutional-LSTM algorithm to harness 1D convolution, foregoing the 2D pooling layers. This unidimensional convolutional operation predominantly traverses the  $D$  component. Such convolution is consistently applied across pertinent inputs, cell outputs, hidden outputs, and gates. When centered on discerning correlations within market data, this 1D convolution proves markedly advantageous, bolstering performance over mere vector-based input methodologies.

The computational process unfolds in the subsequent manner delineated herein:

$$\begin{aligned} i_t &= \sigma(W_{xi} * X_t + W_{hi} * H_{t-1} + W_{ci} * C_{t-1} + b_i) \\ f_t &= \sigma(W_{xf} * X_t + W_{hf} * H_{t-1} + W_{cf} * C_{t-1} + b_f) \\ C_t &= f_t \circ C_{t-1} + i_t \circ \tanh(W_{xc} * X_t + W_{hc} * H_{t-1} + b_0) \\ H_t &= o_t \circ \tanh(C_t) \end{aligned} \quad (2)$$

Where the symbol  $*$  denotes the unidimensional convolution occurring between the latent phase and the convolutional kernels.

For the purpose of ensuring coherence in comparison, the input data is further reshaped to adopt the following configuration:  $(N; 1; T; C D) = (N; 1; 10; 15)$ . In essence, this consolidates all parameters into a unified channel. This modification aims to test our methodology's efficacy in feature representation

In our research, we utilized data sourced from the Chinese stock and fund markets between April 2018 and June 2020, with a specific emphasis on 50ETF option and stock option data [27]. Initially, the dataset comprises 55,047 entries and 34 distinct variables. We focused on selections with an effective duration of a minimum of 20 days, resulting in 829 such choices. Of these, the first 600 are designated for training, with the subsequent 229 allocated for testing purposes. This data is reshaped according to the specifications detailed in Section 3(B), resulting in a final training set with 33,210 entries and a test set with 11,386 entries. The data for this study was procured from Yahoo Finance [28].

Prior to the commencement of our experiments, it was imperative to normalize each variable within the dataset. This normalization is essential to counteract potential imbalances or asymmetries in the neural network. For illustration:

$$\begin{aligned} \tilde{x} &= (x - \mu) / \sigma \\ \mu &= \frac{1}{n} \sum_{i=1}^N x_i, \quad \sigma^2 = \frac{1}{n} \sum_{i=1}^N (x_i - \mu)^2 \end{aligned} \quad (3)$$

Fig. 1. The proposed convolutional-LSTM network for option price prediction.

#### IV. EXPERIMENTAL RESULTS

In this section, we present the empirical outcomes of our study, offering a rigorous evaluation of the conducted experiments. The results elucidated herein provide a comprehensive insight into the efficacy of the proposed models in light of the research objectives. By scrutinizing these outcomes, readers can glean an understanding of the model's robustness, accuracy, and adaptability in various scenarios. Moreover, the results will be juxtaposed with established benchmarks and previous studies, serving as a comparative framework. This comparative analysis aims to underscore the advancements and potential shortcomings of the current research. Without further ado, let us delve into the detailed exposition of the experimental findings.

##### A. Evaluation Metrics

Mean Squared Error (MSE) stands as one of the paramount metrics in quantitative assessment, especially when the objective is to measure the average magnitude of error between predicted and actual observations [29]. Mathematically defined as the average of the squared differences between the forecasted and observed values, MSE serves as an indicator of the accuracy of a model's predictions. One of its distinctive characteristics is its amplification of larger errors, due to the inherent squaring of discrepancies. Consequently, models with a lower MSE are preferred as they suggest a closer fit to the actual data. However, it's essential to note that while MSE is profoundly informative, its sensitivity to outliers can sometimes overemphasize large errors. As such, it is often considered in conjunction with other evaluation metrics to provide a more comprehensive assessment of a model's performance.

$$MSE = \frac{1}{N} \sum_{i=1}^N (y_i - \hat{y}_i)^2 \quad (4)$$

Mean Absolute Error (MAE) is a critical metric employed in the realm of predictive modeling to gauge the average magnitude of errors between forecasted and actual observations [30]. Unlike the Mean Squared Error (MSE), which squares discrepancies, the MAE takes the absolute value of these errors. As a result, it provides a linear score where all individual differences have equal weight. This ensures that the metric is not disproportionately influenced by outliers, rendering it less sensitive to large deviations compared to MSE. Essentially, the MAE quantifies the average vertical distance between each point and the identity line in a prediction plot. Lower MAE values indicate a model that is adept at making predictions closely aligned with actual outcomes. Given its intuitive nature and resistance to the undue influence of outliers, MAE often serves as a pivotal parameter in many evaluation frameworks, particularly when the objective is to obtain a straightforward understanding of prediction accuracy.

$$MAE = \frac{1}{N} \sum_{i=1}^N |y_i - \hat{y}_i| \quad (5)$$

Root Mean Squared Error (RMSE) stands as a prominent metric in predictive analytics and modeling, serving to evaluate the magnitude of error between predicted and actual outcomes [31]. Derived from the Mean Squared Error (MSE), the RMSE is computed by taking the square root of the averaged squared differences between forecasted and observed values. This operation preserves the unit of the measurements, facilitating a more intuitive interpretation of the error magnitude. By emphasizing larger errors due to its squared components,

RMSE is particularly sensitive to significant discrepancies and outliers. As such, a lower RMSE denotes a model's superior predictive accuracy, suggesting its predictions are in closer proximity to observed data. However, given its sensitivity, RMSE is often juxtaposed with other metrics, such as the Mean Absolute Error (MAE), to ensure a well-rounded assessment of a model's performance, especially in datasets with pronounced outliers.

$$RMSE = \sqrt{\frac{1}{N} \sum_{i=1}^N (y_i - \hat{y}_i)^2} \quad (6)$$

Mean Absolute Percentage Error (MAPE) is a quintessential metric in the analytical domain, primarily utilized to gauge the accuracy of forecasting methods in terms of percentage [32]. It calculates the average absolute percentage discrepancy between observed and predicted values relative to the actual value. This metric offers a scale-independent perspective on errors, enabling comparisons across varied units and magnitudes. A salient feature of MAPE is its intuitive interpretation, as it directly quantifies the prediction error as a percentage, facilitating easy comprehension of the model's performance in practical terms. Lower MAPE values are indicative of superior predictive accuracy, suggesting that predictions closely mirror actual observations. However, one caveat associated with MAPE is its potential to produce undefined or infinite values when the actual observation is zero. Moreover, it can sometimes disproportionately penalize underestimations compared to overestimations. Despite these nuances, MAPE remains a favored choice in many scenarios, especially when

stakeholders seek a percentage-based evaluation of predictive accuracy.

$$MAPE = \frac{1}{N} \sum_{i=1}^N \left| \frac{y_i - \hat{y}_i}{y_i} \right| \quad (7)$$

Beyond the aforementioned metrics, it's imperative to conduct comprehensive model assessments employing methods like cross-validation, testing on unseen samples, and juxtaposing the model's outputs against conventional approaches or established benchmarks. Such rigorous evaluations bolster the model's resilience and its capacity to generalize across diverse datasets, thereby enhancing the precision and dependability of option price forecasts in real-world financial scenarios.

### B. Experimental Results

In this section, we delve into the analytical outcomes of the suggested model as elaborated in the preceding segment. Fig. 2 delineate the efficacy of the ConvLSTM model in forecasting option prices, juxtaposing the accuracy during training and validation phases across 200 epochs. The amalgamation of CNN and LSTM networks' capabilities renders the proposed model especially adept for option price prognostications, given the pivotal role of historical prices and prevailing market dynamics in influencing future option valuations. Notably, the model manifests a precision rate of approximately 92% for option pricing over 200 epochs. Remarkably, even at a mere 20 epochs, the precision remains commendably high at around 90%. Hence, the data suggests that the ConvLSTM model can achieve substantial accuracy with a limited epoch count.

Fig. 2. Train and validation accuracy.

Within the ambit of financial predictive modeling, the Convolutional Long Short-Term Memory (ConvLSTM) model has emerged as a promising tool. Fig. 3 delves deep into a systematic examination of this model, particularly focusing on the intricacies of its training and validation losses across a span of 200 learning epochs. This graphical representation has been meticulously curated to elucidate the nuanced dynamics of the ConvLSTM model's learning process, offering a comprehensive view of its progressive enhancement in forecasting accuracy.

The primary intent behind Fig. 3 is manifold. First, it offers researchers, financial analysts, and readers an empirical visual assessment of how the model refines its predictive capabilities over successive epochs using the training dataset. By juxtaposing this with the model's performance on previously unseen validation data, the illustration provides a holistic perspective on the model's capacity to not only internalize data-driven patterns but also to generalize them effectively to new datasets. This aspect of generalization is pivotal in the real-world financial sphere, where the prediction model must navigate and adapt to constantly fluctuating market dynamics.

As one scrutinizes the trends depicted in Fig. 3, a clear attenuation in both training and validation losses becomes evident. This decline is not just indicative of the model's ability to reduce error margins over time, but it also underscores its robustness and adaptability in the face of evolving financial

data. It's noteworthy to mention that the sheer subtleness in the trajectory of these losses speaks volumes about the model's inherent stability and the efficiency of its learning algorithm.

Another salient observation from the figure is the relatively slight divergence between the training and validation losses. In the complex realm of deep learning, such congruence is often heralded as a testament to a model's consistent performance. A substantial gap could have implied potential overfitting, where the model becomes overly tailored to the training data and falters on new data. However, the narrow divergence observed reaffirms the ConvLSTM model's balanced approach, ensuring it retains its predictive accuracy even when confronted with unfamiliar financial datasets.

In summation, Fig. 3 stands as a pivotal piece of empirical evidence in this research. It not only attests to the ConvLSTM model's superior predictive capabilities but also illuminates its potential as a reliable tool for financial forecasting in a world characterized by uncertainty and rapid market fluctuations.

In the complex world of predictive modeling, understanding a model's accuracy and its capacity to generalize its learning is paramount. Fig. 4 serves as a compelling visualization of the Convolutional Long Short-term Memory (ConvLSTM) model's evolution in this regard, specifically focusing on the trajectory of its training and validation Root Mean Squared Error (RMSE) in the context of option price prediction [33].

Fig. 3. Train and validation loss.

The figure meticulously chronicles the RMSE values over a delineated range of epochs. This choice of visualization enables a nuanced interpretation, offering readers an opportunity to juxtapose the model's learning curve (as evidenced by training RMSE) against its ability to adapt and predict new, unseen data (as evidenced by validation RMSE). Such a comparative study is vital in ascertaining the robustness and reliability of a predictive model, especially in dynamic domains like financial forecasting where precision is non-negotiable.

A foundational expectation in the realm of predictive analytics is that, as a model undergoes more training iterations (or epochs), its understanding of the data deepens, leading to enhanced prediction accuracy. This theoretical construct is manifestly demonstrated in Fig. 4. Both the training and validation RMSE values demonstrate a marked descent, which, in analytical parlance, signifies the ConvLSTM model's growing adeptness at decoding underlying data patterns and its prowess in translating this understanding into accurate forecasts.

The ConvLSTM architecture, hailed for its sophistication, has proven its mettle through the figure's depiction. Its RMSE values, even in initial epochs, are commendably modest, attesting to the architecture's inherent strength [34]. What further bolsters the ConvLSTM's credibility is the observed trend: as the model is exposed to more epochs, there's a palpable contraction in the RMSE. This diminishing RMSE trend, in conjunction with the relative proximity between

training and validation values, speaks volumes about the model's consistency and its adeptness at preventing overfitting.

In conclusion, Fig. 4 stands as a testament to the ConvLSTM model's exceptional capabilities in option price prediction. Through its clear delineation of RMSE progression, the figure elucidates the model's journey from initial understanding to mature precision, highlighting its potential as a dependable tool in the demanding sphere of financial analytics. Such insights underscore the significance of meticulous model evaluation and the promise that advanced architectures like ConvLSTM hold for future research endeavors.

Within the realm of financial forecasting, the veracity of a predictive model is often gauged by its ability to approximate real-world values. Fig. 5 serves as a visual testament to this critical evaluation, offering an intricate comparison between the ConvLSTM model's predicted option prices (rendered in blue) and the observed, actual option prices (depicted in red).

The visual portrayal in Fig. 5 invite a meticulous examination of the parallel trajectories of the forecasted and real option prices. The frequent confluence points between the blue and red lines provide compelling evidence of the model's predictive accuracy. Such intersections are not mere graphical intersections; they symbolize moments of congruence between predictive estimations and real-world observations. When a model's predictions consistently intersect with or closely trail the actual values, it is indicative of its robustness and precision.

Fig. 4. Root mean squared error changes.

Fig. 5. Predicted and actual results for option pricing.

This observed alignment is not a trivial accomplishment, especially in the volatile domain of option pricing. The inherent unpredictability of financial markets makes the task of forecasting option prices a daunting challenge. Hence, the observed consistency between the model's estimations and the actual values underscores the ConvLSTM's superior modeling capabilities and its adeptness in capturing intricate market dynamics.

Moreover, the frequency of these intersections lends further credence to the ConvLSTM model's reliability. Infrequent matches could be dismissed as fortuitous, but the recurrent overlap observed in Fig. 5, suggests a pattern of sustained accuracy. Such consistency in predictions is emblematic of a model that has successfully internalized complex data patterns and can replicate this understanding in diverse scenarios.

Drawing from the insights garnered from Fig. 5, it becomes palpable that the ConvLSTM architecture's advanced design and computational prowess make it a formidable tool in the sphere of option price prediction. The close alignment between its forecasts and real prices is not merely a favorable outcome; it signifies the model's potential as a reliable instrument for long-term, practical applications in financial forecasting.

In conclusion, Fig. 5 stands as a testament to the ConvLSTM model's empirical efficacy. By providing a visual representation of the model's predictive prowess in the face of real-world data, the figure reinforces the notion that advanced predictive architectures like ConvLSTM are poised to revolutionize the landscape of financial analytics.

## V. DISCUSSION

The research undertaken here delves deep into the intricate facets of option price prediction using the Convolutional Long Short-term Memory (ConvLSTM) model, a hybrid deep learning architecture. The journey of analyzing, training, and testing the model has opened up avenues for reflections and discussions on both the capabilities of the model and the complexities associated with option pricing in financial markets.

Foremost, the accuracy metrics employed (e.g., RMSE, MAPE) offered crucial insights into the model's predictive performance. Notably, the ConvLSTM model showcased a capacity to capture both spatial and temporal aspects of the financial data. This is significant, as financial data streams inherently possess these dual characteristics. Traditional models often struggle with time-series data that also has spatial features, which makes ConvLSTM's accomplishment notable. The ability of the model to achieve around 92% precision in option pricing over 200 learning epochs stands as a testament to its robust nature. Further, its adeptness at reaching 90% precision in just 20 epochs underscores its efficiency.

The train and validation graphs over epochs – whether in terms of precision, loss, or RMSE – illuminated the model's learning curve. A significant observation was that the disparity between training and validation scores was minimal, hinting at minimal overfitting [35]. This implies that the model generalizes well to unseen data, a crucial factor in the volatile

world of financial markets where prediction robustness can translate to substantial economic implications.

The graphical representation comparing the predicted option prices with the actual values further reaffirmed the model's strength. The convergence of the blue and red lines not only indicates effective learning but also suggests the model's adaptability to evolving market dynamics.

Nevertheless, as with all models, it is essential to view these results in the broader context of financial modeling. The realm of option pricing is replete with volatility, influenced by an array of external factors such as geopolitical events, monetary policies, and global market trends [36]. While the ConvLSTM model has showcased commendable accuracy in this research, it is worth pondering how it might perform in extremely volatile scenarios or in the face of black swan events [37].

Another point of reflection is the comparison of the ConvLSTM model with traditional option pricing models like the Black-Scholes model [38]. While deep learning models like ConvLSTM offer adaptability and can work without strict assumptions, traditional models come with theoretical foundations deeply entrenched in financial theories. Would it be advantageous to integrate features from both worlds to achieve a more balanced, adaptable, yet theoretically sound model?

Data preprocessing, especially the normalization of parameters, was an essential step in this research. Neural networks, like the one employed in our ConvLSTM model [39], often require data to be structured and normalized to prevent issues like vanishing or exploding gradients [40]. It paves the path for a potential area of exploration: the development of models that are more resilient to raw or semi-processed data. Given the real-time nature of financial decisions, reducing preprocessing time without compromising accuracy could be invaluable.

Furthermore, the choice of data – specifically from the Chinese stock and fund market – brings forth questions about the model's adaptability to other global markets [41]. Financial behaviors and influences can vary across regions, affected by cultural, economic, and political differences. Hence, would the model retain its efficacy if trained on data from, say, the American or European markets?

In conclusion, the ConvLSTM model's potential in option price prediction, as evidenced by this research, is undeniably impressive. Its hybrid nature capitalizes on the strengths of both CNNs and LSTMs, making it a formidable tool for financial forecasting. However, it is imperative to continually evaluate and adapt the model, considering the ever-evolving landscape of global financial markets. The journey of this research serves not just as a testament to what has been achieved but also as an inspiration for the myriad possibilities that lie ahead.

## VI. CONCLUSION

The exploration into the predictive prowess of the Convolutional Long Short-term Memory (ConvLSTM) model for option price forecasting has yielded insightful revelations.

This research has undeniably demonstrated the potential of leveraging advanced deep learning architectures in the intricate and volatile realm of financial markets. As showcased, the ConvLSTM model adeptly captures the spatial and temporal nuances of financial data, achieving commendable accuracy levels over a minimal number of epochs.

A notable takeaway from this study is the synergy between the spatial feature detection capabilities of Convolutional Neural Networks (CNNs) and the sequential pattern recognition of Long Short-term Memory (LSTM) networks. The integration of these characteristics into the ConvLSTM model has proven to be particularly potent for forecasting in the dynamic domain of option pricing. The close alignment between the model's predictions and actual option prices underscores its viability as a tool for practical financial applications.

However, as with all predictive models, the ConvLSTM's performance should be perceived within the broader framework of financial analytics. While its adaptability and precision are commendable, continuous iterations and refinements are imperative, considering the multifaceted influences on financial markets. The model's ability to adapt to diverse global markets and unforeseen volatile events remains an avenue for future exploration.

In essence, this research has illuminated the vast potential that modern deep learning models hold for financial forecasting. It has set a benchmark, proving that with the right architecture and data, neural networks can be invaluable assets in the financial sector. As we advance, it is this confluence of finance and technology, exemplified by models like ConvLSTM that promises to redefine the contours of financial analytics and decision-making.

# Factors and Models Influencing Value Co-Creation in the Supply Chain of Collection Resources for Library Distribution Providers Under Data Ecology

Xiaoyun Lin\*

Library

Guangzhou College of Technology and Business  
Guangzhou, 510850, China

**Abstract**—Under the data ecology, the advancement of relevant technology and the utilization of relevant resources have provided more efficient technical services for various industries. However, with the proliferation of data resources, problems such as information pollution and data redundancy have arisen in the process of supply chain services for collection resources. For solving such problems and enhancing the collection resource supply efficiency of librarians, the study uses data mining technology combined with improved K-Means clustering algorithm to design a value co-creation model of library collection resource supply chain for librarians under data ecology. The outcomes indicate that the shortest running time of traditional K-Means algorithm is 40ms and the longest running time is 115ms in Wine dataset, and the running time of improved K-Means algorithm is stable at 59ms; the shortest running time of traditional K-Means algorithm is 26 ms and the longest running time is 58ms in Iris dataset, and the running time of improved K-Means algorithm is stable at 53 ms. The clustering accuracy of the improved K-Means algorithm in the Wine data set is 98.2%, which is 0.3% exceeding the traditional K-Means algorithm, which is 97.9%; the clustering accuracy in the Iris data set is 100%, which is 2.4% exceeding the traditional K-Means algorithm, which is 97.6%. In summary, it can be seen that the studied data ecology has a good application of the factors and models influencing the value co-creation of the supply chain of library resources for library dispensers.

**Keywords**—Resource supply chain; data mining; value co-creation; K-Means clustering algorithm; pavilion dispenser

## I. INTRODUCTION

With the big data's reach, the use of data resources changed the current human lifestyle and cognitive level, and data resources have become an important asset [1]. The advancement of relevant technology has led to the increasing participation of users in the network, and the phenomenon that everyone has data but everyone lacks data has emerged in various industries [2]. The increase in data transparency and freedom and the increasing circulation of data have led to information pollution and data redundancy in the current data ecosystem [3]. Therefore, the traditional library resource management model cannot satisfy the needs of efficient resource integration for the massive library collection resources nowadays. Data mining (DM) is a data-centered mode of thinking, which can rely on algorithms to effectively refine and integrate generous data to maximize the benefits of

data resources [4]. The integration of resources based on DM technology is the service goal of the supply chain of collection resources of the librarians, and the deep combination of DM and supply chain resource management to explore a high-efficiency and low-cost resource supply chain management model is the method for realizing the relevant value of collection resources. The K-Means (KM) algorithm is extensively utilized classical classification clustering algorithms (CA). It can effectively solve the low clustering accuracy and simple for falling into local solutions [5]. The problem and goal of this article are to improve the efficiency of collection resource supply for library distributors. The significance and contribution of this study are to propose the connotation of value co-creation (VCC) in the collection resource supply chain of library distributors, provide readers with a better knowledge service environment, and provide theoretical basis and direction guidance for future research on the collection resource supply chain. Therefore, in this context, the factors and models influencing the VCC in the supply chain of library resources for library distributors under the data ecology are studied to improve the use rate and realize the VCC in the supply chain of library resources. The second part is a review of the research of resource supply chain and DM technology at home and abroad; the third part is a study on the VCC model of library resource supply chain based on the data ecology. The first section analyzes the factors affecting the VCC of library resource supply chain based on the Decision-making Trial and Evaluation Laboratory (DEMATEL)\_ method; the second section is the constructing of the VCC model of library resource supply chain for library distributors. The fourth part is the validation of the VCC model of the supply chain of library resources for library service providers based on the data ecology.

## II. RELATED WORKS

The resource distribution link of the resource supply chain introduces new-age technologies such as logistics technology and Internet of Things. Therefore, the resource supply chain based on data and emerging technologies has gained the attention of many domestic and foreign experts and scholars, and researchers have carried related research on it. Nandi M L and other scholars proposed integrating relevant technology into its corresponding supply chain system to improve the supply chain performance and construct a resource-based

supply chain system framework. It is based on 126 secondary information cases and a qualitative content analysis of these 126 supply chain system cases using a retrospective approach. The outcomes illustrated that the method is useful in improving information sharing in supply chain and has reference value in supply chain integration [6]. The research team of Agyabeng-Mensah Y, to test the influence of green human resource management on internal green supply chain, proposed an equation modeling software with partial least squares structure, which utilized a relevant method to collect data in supply chain and used partial least squares structure for analyzing the data. The outcomes showed that the method tested the internal green supply chain and was feasible [7]. Mehrotra S et al. proposed to establish a stochastic optimal allocation model with sharing function for enhancing the system of the ventilator supply chain, which was mainly used for the allocation of ventilator resources during the new coronary pneumonia pandemic. The outcomes indicated it could enhance the allocation efficiency of the ventilator supply chain [8].

DM techniques possess an essential influence in resource supply chain research. Zhao Y's research team proposed a building energy fault diagnosis model based on DM techniques for enhancing the operation of energy systems in the building industry. Then the model utilized unsupervised DM techniques to construct a framework for building energy operation pattern identification and energy load diagnosis, and the model was tested in a dataset Validation. The outcomes indicated that the model possessed excellent accuracy of building energy load prediction [9]. Liu J and other scholars proposed a privacy-preserving DM algorithm in view of Bayesian analysis and logical analysis for addressing the data privacy protection. The core of the method was for letting DM technology become data and strengthen the management of DM technology. The outcomes indicated that the method improved the security of privacy protection by 20% and is feasible [10]. Rong Z and other researchers proposed a multi-layer fuzzy evaluation model in view of AI DM, which integrated fuzzy information such as learning, recognition, correlation and adaptive to evaluate the ideological education of undergraduates, in response to the problems of unclear evaluation system and single evaluation method of

undergraduates. The outcomes illustrated that the model achieved the desired effect with scientific validity [11].

In summary, DM techniques are often applied in supply chain research in various fields, but research on using big DM techniques to build a VCC model for the supply chain of library resources is quite rare. In this context, the factors and models influencing the VCC of the supply chain of collection resources for library dispensers under the data ecology are studied to achieve better application results.

### III. RESEARCH ON THE VCC OF THE SUPPLY CHAIN OF LIBRARY RESOURCES IN VIEW OF THE DATA ECOLOGY OF LIBRARY DISPENSERS

In this chapter, the structure of the supply chain of library resources of library dispensers under the data ecology is studied, and the factors influencing the VCC of the supply chain of library resources are analyzed using the DEMATEL method, and the construction of the VCC model of the supply chain of library resources of library dispensers is carried out using the improved KM CA.

#### A. Analysis of the Factors Influencing the VCC in the Supply Chain of Collection Resources based on the DEMATEL Method

Data ecology is evolved from the digitization of knowledge resources, which is generated as an outcome of the combination of resource digitization and information technology (IT). Data ecology is based on big data carriers, forming a community of interest for data sharing and collaboration to achieve the purpose of VCC [12]. From the perspective of supply chain, libraries can be regarded as logistics distribution centers, and the resource supply chain links upstream collection suppliers and downstream library customers. The theory of VCC in the supply chain of collection resources can be used in the library distribution industry, where libraries and distribution providers work together to provide quality collection resources to library customers and create social value to improve social and economic benefits [13]. The supply chain structure of library resources for library distributors under data ecology is shown in Fig. 1.

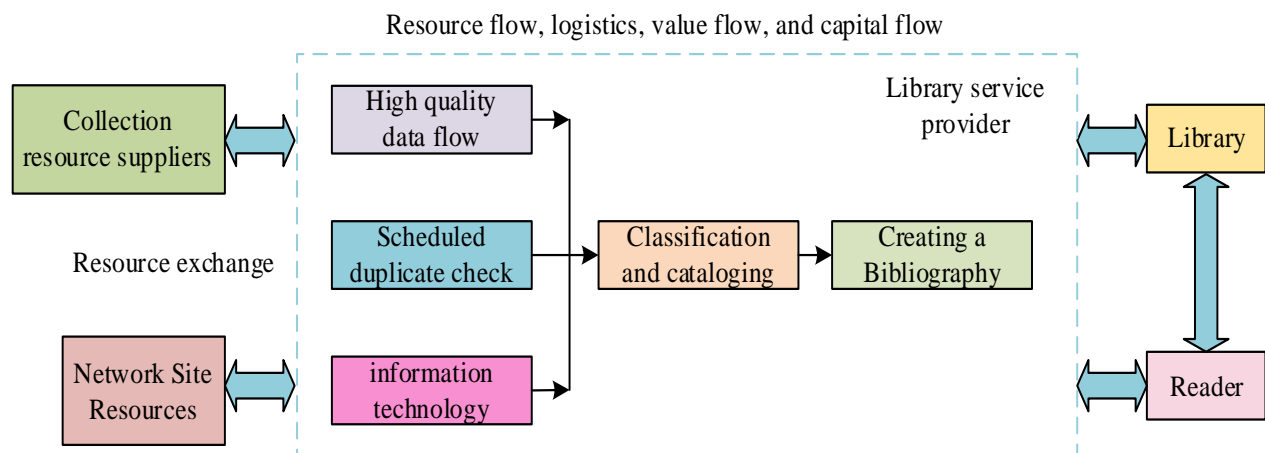

Fig. 1. The supply chain structure of collection resources for library distributors in the data ecology.

As shown in Fig. 1, the major part of the supply chain structure of collection resources mainly contains libraries, library distributors, library customers and collection suppliers. The collection resources mainly include book resources, e-book resources and library intelligent auxiliary devices provided by the collection suppliers. To realize the VCC in the supply chain of collection resources, it is essential for bringing into play the supply efficiency of collection resources and ensures the effective circulation of resource flow, capital flow, logistics and value flow in the supply chain of collection resources [14]. According to the root theory, nine factors can be derived to influence the supply chain VCC: the construction and integration of supply chain resources, the advancement and applying of supply chain service technology, the applying of data for supply chain VCC, the quality of staff in the supply chain, the concept of supply chain VCC, the construction of supply chain VCC platform, the interaction of the main body of supply chain VCC, the demand of readers for supply chain VCC, and the environmental constraints of supply chain VCC, etc. [15]. DEMATEL is a way of systematic analysis using matrix tools and graph theory, which can calculate the influence degree of each factor based on the logical relation in the elements [16]. For identifying the key factors in the supply chain VCC from the nine factors, the degree of correlation between the factors is calculated using the DEMATEL method. The mathematical expression of the normalization matrix is shown in Eq. (1).

$$H = \frac{X}{\max_{1 \leq i \leq n} \sum_{j=1}^n x_{ij}} \quad (1)$$

In Eq. (1),  $X$  denotes the influence relationship matrix while  $H$  means the normalized one.  $x_{ij}$  denotes the degree of influence of factor  $i$  on factor  $j$ . The relevant formula is demonstrated in Eq. (2).

$$S = \lim_{k \rightarrow \infty} (H + H^2 + \dots + H^k) = \sum_{k=1}^{\infty} H^k = H(K - H)^{-1} \quad (2)$$

In Eq. (2),  $K$  denotes the unit matrix and  $S$  indicates the combined influence matrix. The method for calculating the influence degree of each factor is shown in Eq. (3).

$$Q = \sum_{j=1}^n s_{ij} \quad (i = 1, 2, \dots, N) \quad (3)$$

In Eq. (3),  $Q$  denotes the influence degree vector of factors and  $N$  expresses the total of factors. The influenced degree vector is shown in (4).

$$W = \sum_{i=1}^n s_{ij} \quad (j = 1, 2, \dots, N) \quad (4)$$

In Eq. (4),  $W$  indicates the vector of factors' influence degree, and the centrality and the reason degree can be calculated according to the influence degree of the factors. Reason degree illustrates the influence of the factor on other factors, and a positive reason degree illustrates that the element possesses an impact on other elements, while a negative reason degree illustrates that the element is affected by other elements [17]. The relevant formula is showcased in Eq. (5).

$$U_i = Q_i + W_i \quad (5)$$

In Eq. (5),  $U$  indicates the value of centrality. The relevant formula is showcased in Eq. (6)

$$V_i = Q_i - W_i \quad (6)$$

In Eq. (6),  $V$  indicates the value of the cause degree. The combined importance of the system elements can be counted from the values of centrality and causality, as shown in Eq. (7).

$$Z_i = \alpha U_i + \beta V_i \quad (7)$$

In Eq. (7),  $Z_i$  represents the combined importance of system factors;  $\alpha$  denotes the pendulum weighting coefficient of centrality, and  $\beta$  refers to the pendulum weighting coefficient of cause. Based on the maximum and minimum values of the centrality and the reason degree, the optimal and the worst solutions can be derived, and then the swing weight coefficients are used to assign weights to the indicators of the two solutions. Then the final weight values of the centrality and the reason degree can be obtained by normalizing the two assigned weights. Based on the key factors identified by the DEMATEL method, a model of co-creation influence factors of the supply chain value of the collection resources based on the DEMATEL method is designed as shown in Fig. 2.

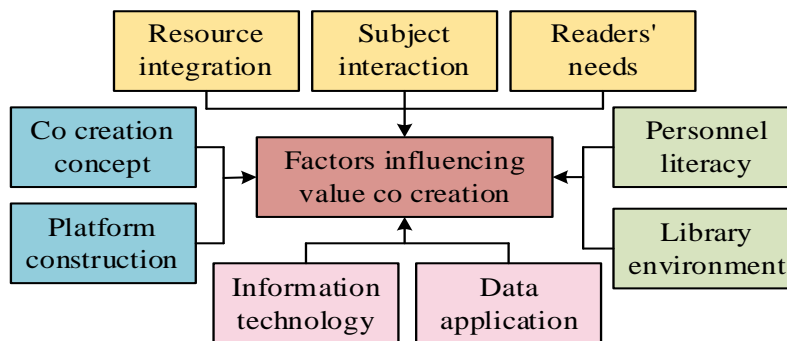

Fig. 2. A model of factors influencing the VCC of collection resources supply chain based on DEMATEL method.

As shown in Fig. 2, in the VCC influence factor model, platform construction and co-creation concept are the key factors of supply chain VCC of library resources; readers' demand, subject interaction and resource integration are the drivers of supply chain VCC; platform environment and staff literacy are the direct factors of supply chain VCC; and data applying and IT are the indirect factors of supply chain VCC.

**B. The Construction of the VCC Model of the Supply Chain of Library Resources for Library Distribution Providers**

The realizing of VCC in the supply chain of collection resources under the data ecology cannot be achieved without the influence of nine factors, while the complexity of the operation and management of the supply chain of collection resources brings challenges to the realization of VCC. For reaching the purpose of providing readers with quality resources in the resource supply chain, DM technology is utilized for exploring the VCC in the collection resource supply chain and build a model of VCC in the collection resource supply chain with DM. DM is a data-centered mode

of thinking, and DM relies on algorithms and technologies to effectively refine and integrate massive amounts of data to maximize the benefits of data resources [18]. For achieving the VCC process of the supply chain of collection resources under the data ecology, the VCC model of the supply chain of collection resources for library distribution providers is constructed as shown in Fig. 3.

As shown in Fig. 3, the data base in the VCC model of the supply chain of library resources contains equipment operation data, organization operation data, reader behavior data and resource integration data. Effective DM of the collection resources under the big data ecology is beneficial for the library distributor to understand the information of readers' needs and library business weaknesses, and it can also enhance the communication efficiency among the supply chain subjects. The core idea of DM technology is mining potentially useful information from generous disordered and incomplete data using relevant algorithms. The relevant basic process is showcased in Fig. 4.

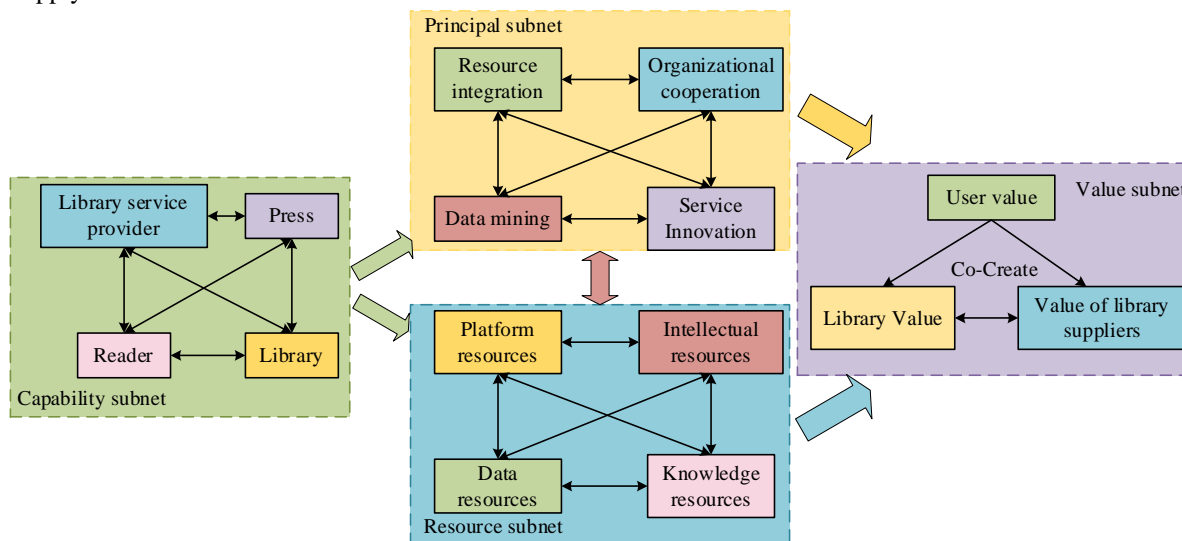

Fig. 3. The VCC model of collection resources supply chain for library distributors.

Fig. 4. The basic process of DM.

Fig. 4 indicates that the DM includes steps of data collection, data pre-processing, construction of DM models and output of results. The algorithms for building DM models are generally divided into four categories, such as CA, association rule algorithms, classification and regression algorithms, and CA [19]. The KM algorithm is extensively utilized CA as its simple principle and easy implementation [20]. The CA is an indirect clustering division method, which can measure the similarity between samples using Euclidean distance (ED) and transform it by means of data distance metric for better calculation of data. The CA utilizes distance as a criterion for evaluating the metric of sample similarity. The closer the distance in two samples, the higher the similarity between the samples. The most used distance formulas in CA are ED and Manhattan distance, and the mathematical expression of ED is indicated in Eq. (8).

$$D(i, j) = \sqrt{(x_{i1} - x_{j1})^2 + (x_{i2} - x_{j2})^2 + \dots + (x_{in} - x_{jn})^2} \quad (8)$$

In Eq. (8),  $D$  denotes the ED,  $i$  and  $j$  denote the data objects, and  $n$  denotes the dimensionality. The mathematical expression of the Manhattan distance is shown in Eq. (9).

$$D'(i, j) = |x_{i1} - x_{j1}| + |x_{i2} - x_{j2}| + \dots + |x_{in} - x_{jn}| \quad (9)$$

In Eq. (9),  $D'$  denotes the Manhattan distance. If no end criterion is set in the KMA, the distance calculation of Eq. (8) and Eq. (9) will be repeated, and reaching the end mark means that the algorithm has reached convergence. The flow chart of the KMA is illustrated in Fig. 5.

Fig. 5. Flowchart of KM algorithm.

Fig. 5 indicates that the algorithm first prepares the data, determines the number of classifications and sets the clustering centers, then counts the range in each data point and the clustering center, and groups the closest points into the

initial centroids. After that, the clustering centroids are recalculated and the convergence is judged. If the convergence is not reached, the above steps are repeated until convergence is achieved. The most common method used in CA to determine whether convergence is achieved is the error-sum-squared criterion method, and the mathematical expression of the error-sum-squared criterion method is shown in Eq. (10).

$$J_D = \sum_{i=1}^D \sum_{k=1}^{m_i} \|x_k - m_i\|^2 \quad (10)$$

In Eq. (10),  $D$  denotes the sample set;  $J$  denotes the objective function;  $m_i$  serves as the mean value of the sample, and the formula for calculating the sample mean is shown in Eq. (11).

$$m_i = \frac{1}{n_i} \sum_{i=1}^{n_i} x_i \quad i = 1, 2, \dots, D \quad (11)$$

According to Eq. (10) and Eq. (11), the value of the objective function depends on the sample centroid, and the larger the sample centroid, the larger the objective function and consequently the larger the error; conversely, the smaller the sample centroid, the smaller the objective function, and consequently the smaller the error. For reducing the probability of error in the calculation, the traditional KM algorithm is enhanced by using the weighted squared average distance method to reduce the search range in the calculation. The expression of the weighted squared average distance method is shown in Eq. (12).

$$J_i = \sum_{i=1}^D P_i A_i^* \quad (12)$$

In Eq. (12),  $A_i^*$  denotes the mean squared distance between samples and  $P_i$  denotes the prior probability. The formula for calculating the mean squared distance is shown in Eq. (13).

$$A_i^* = \frac{2 \sum_{x \in X_i} \sum_{x' \in X_i} \|x - x'\|^2}{n_i (n_i - 1)} \quad (13)$$

In Eq. (13),  $n_i$  denotes the number of data samples, and  $\sum_{x \in X_i} \sum_{x' \in X_i} \|x - x'\|^2$  denotes the sum of distances between samples. The mathematical expression of the interclass distance and criterion is shown in Eq. (14).

$$J_{\delta 1} = \sum_{i=1}^D (m_i - m)^T (m_i - m) \quad (14)$$

In Eq. (14),  $m$  denotes the mean value of the distance between samples, and  $m_i$  denotes the mean value of the distance between samples of  $i$ . The weighted interclass distances and criteria are shown in Eq. (15).

$$J_{\delta 2} = \sum_{i=1}^D P_i (m_i - m)^T (m_i - m) \quad (15)$$

As shown by Eq. (15), the weighted interclass distance and criterion is the association of adding a priori probability to the interclass distance and criterion formula. The larger the value of  $J_{\delta}$  corresponds to the greater the degree of variation, then the more obvious the clustering analysis results.

#### IV. VALIDATION OF THE VCC OF THE SUPPLY CHAIN OF LIBRARY RESOURCES IN VIEW OF THE DATA ECOLOGY OF LIBRARY DISTRIBUTORS

For verifying the performance of the VCC model of the supply chain of library resources based on the data ecology, the performance of the traditional KM algorithm was compared with that of the improved one. The total samples in the Wine dataset were 440, and there were four clusters of the same size and no isolated points in the dataset; the total number of samples in the Iris dataset was 300, and there were three clusters of the same size and five isolated points in the dataset. The specific the relevant outcomes are showcased in Table I.

The traditional and the improved KM algorithms were run ten times in each of the two training sets, and the comparing of the CA of the two algorithms run ten times in the data set is shown in Fig. 6. Fig. 6(a) illustrated that the traditional KM

algorithm showed an up-and-down state in the Wine dataset, with the highest CA of 70.3% and the lowest of 53.5%, while the CA of the improved KM algorithm was stable at 71%. In Fig. 6(b), the traditional KM algorithm achieved the lowest CA of 65% at the sixth run in the Iris dataset, and the CA fluctuated around 89% for the other runs, while the CA of the improved KM algorithm remained at 90%. Collectively, it illustrated that the traditional KM algorithm was not stable enough and the improved KM algorithm had more stability.

For comparing the performance of the traditional and the improved KM algorithms more comprehensively, the running times of the two algorithms were studied. The running time comparison of the two algorithms run ten times in the dataset is indicated in Fig. 7. Fig. 7(a) showcased that the running time of the traditional KM algorithm in the Wine dataset still presented an unstable state, in which the shortest running time was 40 ms and the longest running time was 115 ms, while the running time of the improved KM algorithm was stable at 59 ms. Fig. 7(b) indicated that the traditional KM algorithm in the Iris dataset had the shortest running time of 40 ms and the longest running time of 115 ms, while the running time of the improved KM algorithm was stable at 59 ms. The shortest running time of the traditional KM algorithm was 26ms and the longest running time was 58ms, while the running time of the improved KM algorithm stayed at 53ms. Collectively, it illustrated that the improved KM algorithm had stronger robustness compared to the traditional KM algorithm.

TABLE I. EXPERIMENTAL ENVIRONMENT

Experimental Environment	Configuration
Operating system	Windows 10
Memory	16G
GPU	NVIDIA TITAN BLACK GPU
CPU	Intel(R) Core (TM) i5-4460
Programming Language	Python
Algorithm testing tools	PyCharm

Fig. 6. Comparison of CA between two algorithms running ten times.

Fig. 7. Comparison of the runtime of two algorithms in the dataset.

To observe more intuitively the performance comparing between the traditional and the improved KM algorithms, the performance metrics of the two algorithms were compared and analyzed with the number of iterations. The comparison results are showcased in Table II. From Table II, the average CA of the improved KM algorithm was 71% and 90% in the Wine dataset and Iris dataset, respectively, which was 9.1% and 3.4% higher than the average CA of the traditional KM algorithm. And it showcased that the improved KM algorithm had higher CA, and the improved KM algorithm only runs the best clustering effect could be achieved by running only once. In terms of the number of iterations, that of the improved KM algorithm was smaller than the average iteration times of the traditional KM algorithm. Although the average running time of the improved KM algorithm was 53 ms in the Iris dataset, which was 8.6 ms longer than the average running time of 44.4 ms of the traditional KM algorithm, the improved KM algorithm could achieve the best clustering effect after only

one run. Therefore, the improved KM algorithm still achieved a more desirable performance in terms of running time.

From verifying the traditional and the improved KM algorithms in practical applications, the two algorithms are compared and analyzed in simulation experiments in the Wine dataset. The outcomes of the simulation experimental runs of the two algorithms in the Wine dataset are shown in Fig. 8. Fig. 8(a) indicated that the clustering result of the Wine dataset contained four clusters of almost the same size and no isolated points in the dataset. Fig. 8(b) illustrated that the clustering results of the traditional KM algorithm in the Wine dataset produced misclassification rates of 1.2%, 3.5%, 1.3% and 2.5% for cluster 1, cluster 2, cluster 3 and cluster 4, respectively, and the CA was 97.9%. As seen in Fig. 8(c), the clustering results of the improved KMA in the Wine dataset yielded misclassification rates of 1.3%, 3.5%, 0 and 2.1% for cluster 1, cluster 2, cluster 3 and cluster 4, with a CA of 98.2%.

TABLE II. COMPARISON OF PERFORMANCE INDICATORS BETWEEN TRADITIONAL AND IMPROVED KM ALGORITHMS

Performance Index	Data Set	Traditional KM Algorithm			Improved KM Algorithm		
		Minimum	Highest value	Average	Minimum	Highest value	Average
Iterations	Wine	4	12	8.3	7	7	7
	Iris	5	13	9	8	8	8
Clustering accuracy/%	Wine	53.5	70.3	61.9	71	71	71
	Iris	65	90	86.6	90	90	90
Run time/ms	Wine	40	115	75.4	59	59	59
	Iris	26	58	44.4	53	53	53

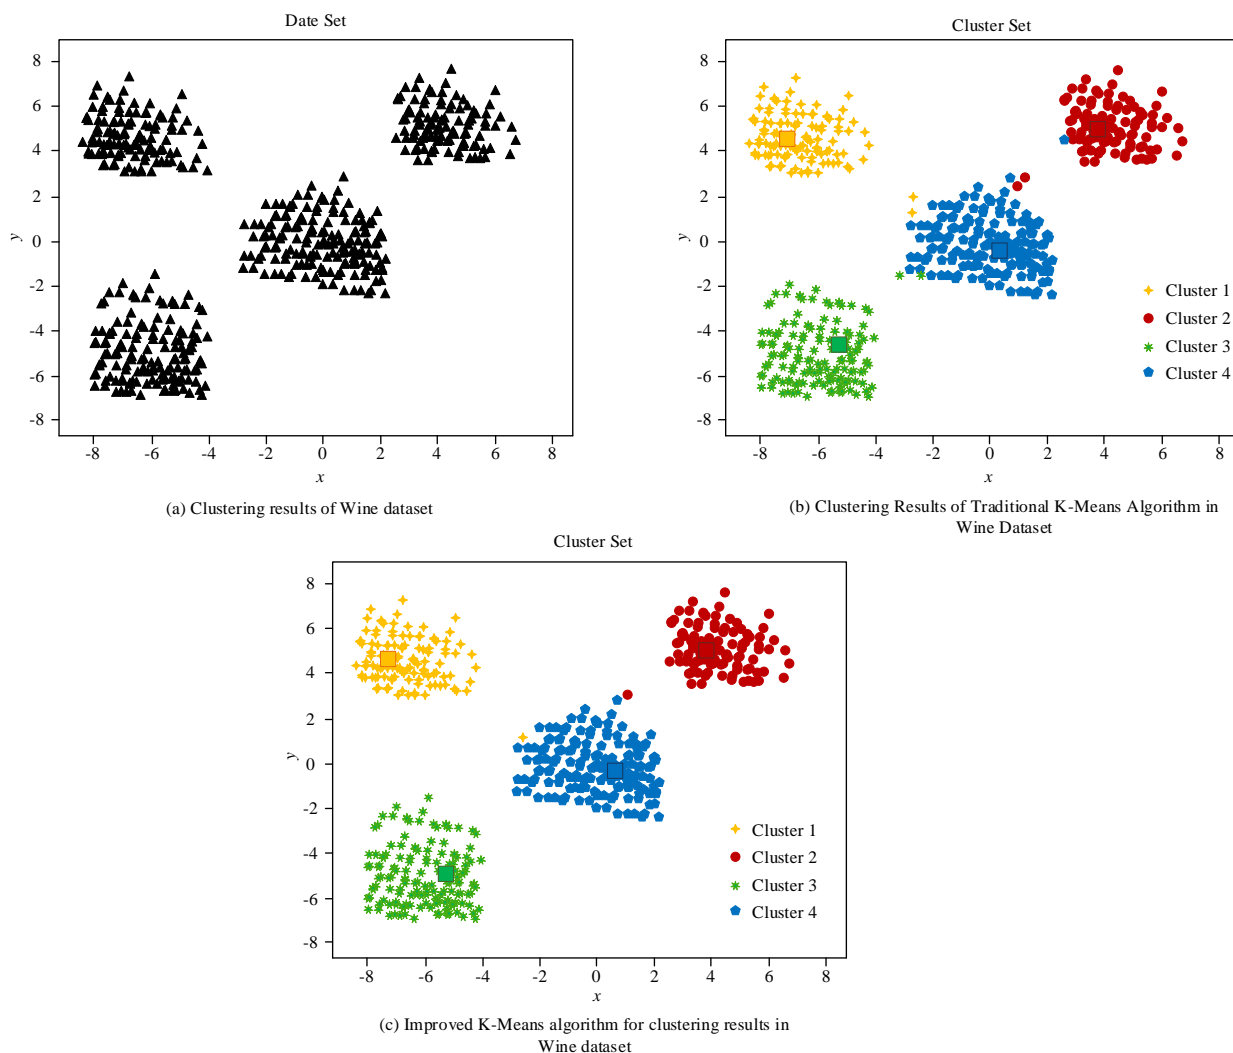

Fig. 8. Simulation experimental results of two algorithms in Wine dataset.

For more comprehensively verifying the traditional and the improved KM algorithms in practical applications, the two algorithms were compared and analyzed in simulation experiments on the Iris dataset. The results of the simulation experimental runs of the two algorithms in the Iris dataset are shown in Fig. 9. Fig. 9(a) demonstrated that the clustering outcome of the Iris dataset contained three clusters of almost the same size and there were five isolated points in the dataset. In Fig. 9(b), the traditional KM algorithm's clustering outcomes on the Iris dataset yielded misclassification rates of 2%, 1.1%, and 4% for clusters 1, 2, and 3, respectively, with a CA of 97.6%. Fig. 9(c) showcased the clustering outcomes of the improved KM algorithm in the Iris dataset, cluster 1, cluster 2, and cluster 3 all produced a misclassification rate of 0, respectively, with a CA of 100%.

For more intuitively observing the comparison of effectiveness of the traditional and the improved KM algorithms in practical applications, the clustering results in the two datasets were evaluated. The clustering evaluations of the traditional and the improved KM algorithms are shown in Table III. Table III illustrated that the CA of the improved KM algorithm in the Wine dataset was 98.2%, which was 0.3% higher than the CA of 97.9% of the traditional KM algorithm. In the Iris dataset, the CA of the improved KM algorithm reached 100%, which was 2.4% higher than the CA of 97.6% of the traditional KM algorithm. Collectively, the CA of the improved KM algorithm significantly exceeded that of the traditional KM algorithm in practical applications.

Fig. 9. The clustering results of two algorithms in the Iris dataset.

TABLE III. CLUSTER EVALUATION OF TRADITIONAL AND IMPROVED KM ALGORITHMS

Data Set	Crowd Together	Traditional KM Algorithm			Improved KM Algorithm		
		Misclassification rate (%)	Purity (%)	Clustering accuracy	Misclassification rate (%)	Purity (%)	Clustering accuracy
Wine	Cluster 1	1.2	98.8	97.9	1.3	98.7	98.2
	Cluster 2	3.5	96.5		3.5	96.5	
	Cluster 3	1.3	98.7		0	100	
	Cluster 4	2.5	97.5		2.1	97.9	
Iris	Cluster 1	2	98	97.6	0	100	100
	Cluster 2	1.1	98.9		0	100	
	Cluster 3	4	96		0	100	

### V. CONCLUSION

In the context of data ecology, the proliferation of data resources has led to the problems of information pollution and data redundancy in the supply chain service of collection resources. For solving the data redundancy issue and enhancing the collection resource supply efficiency of librarians, the study used DM technology combined with improved KM CA for designing a VCC model of library collection resource supply chain for librarians under the data ecology. The experiment illustrated that the CA of the traditional KM algorithm in the Wine dataset was 70.3% at the highest and 53.5% at the lowest, and the CA of the improved KM algorithm stable at 71%; the CA of the traditional KM

algorithm in the Iris dataset was 65% at the lowest and 89% at the highest, and the CA of the improved KM algorithm was maintained at 90%. The running time of the traditional KM algorithm in the Wine dataset was 40ms at the shortest and 115 ms at the longest, and that of the improved KM algorithm is stable at 59 ms; the running time of the traditional KM algorithm in the Iris dataset was 26 ms at the shortest and 58ms at the longest, and that of the improved KM algorithm was maintained at 53 ms. The clustering effect of the improved KM algorithm in practice was 98.2% in the Wine dataset, which was 0.3% higher than the 97.9% CA of the traditional KM algorithm, and 100% in the Iris dataset, which was 2.4% exceeding the 97.6% CA of the traditional KM algorithm. 2.4%. In summary, it illustrates that the studied

VCC model of the supply chain of library resources in view of the data ecology of the library dispensers has better resource supply efficiency, but the experiments use fewer comparison sample data. The experimental results are not objective enough, and further improvement is needed in this aspect. This article studies and explores the influencing factors and mechanisms of VCC in the supply chain of library collection resources from the perspective of data ecology and VCC. Based on the current low utilization rate of library collection resources, differentiated reader needs, and service VCC, improvement strategies are proposed. The conclusions of the study are as follows: firstly, the influencing factors of VCC in the supply chain of library resources mainly include nine major factors: resource construction and integration in the supply chain, development and application of supply chain service technology, data application of supply chain value co creation, staff literacy in the supply chain, concept recognition of supply chain VCC, construction of supply chain VCC platform, subject interaction of supply chain VCC, the reader needs of supply chain VCC and the environmental constraints of supply chain VCC. Secondly, based on the shared supply chain platform and reader decision-making procurement, a VCC model for the collection resource supply chain has been constructed. This model can not only meet the personalized needs of readers, but also improve the utilization rate of collection resources, making the value of the library more fully realized.

# A Flexible Manufacturing System based on Virtual Simulation Technology for Building Flexible Platforms

Zhangchi Sun

Engineering Training and Innovation Education Center, Shanghai Polytechnic University, Shanghai, 201209, China

**Abstract**—Flexible manufacturing systems have become relatively mature in the industrial field, representing the most advanced research achievements in the development of the manufacturing industry. But currently, there are few resources and high costs in universities to create a system that is more practical, and it cannot meet the practical teaching requirements of students in multiple majors. In response to the above issues, this study first designed a flexible manufacturing system from the overall architecture, then introduced and integrated virtual simulation technology, and utilized multi-objective genetic algorithm for cargo location optimization to improve the work efficiency of the flexible system. The research results indicate that after 213 iterations of the proposed algorithm, the iteration curve of the total objective function value tends to be stable, and the effect of cargo location optimization is relatively ideal. At this time, the total objective function value is 142.5. In addition, as the scale expands, the corresponding number of iterations for multi-objective genetic algorithm at its maximum scale is 411.2. The application effect of virtual flexible manufacturing system in practical teaching in universities is good, and visual learning methods can better attract students' attention.

**Keywords**—Flexible platform; virtual simulation technology; manufacturing control system; multi-objective genetic algorithm; slotting optimization

## I. INTRODUCTION

With the advent of the Fourth Industrial Revolution and the rapid development of the social economy, people have put forward higher requirements for the richness of the industrial industry. This has led to a shortened lifespan of industrial products, and currently traditional single production and manufacturing technologies are no longer able to meet industrial production needs [1-2]. Therefore, to improve industrial production efficiency and meet the flexible requirements of production manufacturing systems, Flexible Manufacturing Systems (FMS) have emerged and received widespread support in related fields. FMS is a set of CNC machine tools and other automated process equipment, which is an organic combination of computer information control system and automatic material storage and transportation system. It has the advantages of high equipment utilization rate, high product quality, flexible operation, stable production capacity, and large product response capacity [3-4]. However, universities lack relevant technology and funding to learn flexible manufacturing technology, resulting in a lack of theoretical knowledge and practical application for students in related majors [5-6]. And the cost of the flexible

manufacturing system close to the actual production is very expensive, which cannot meet a large number of teaching tasks, which hinders the path of cultivating mechanical automation talents in Colleges and universities, and does not meet the needs of social development. To reduce damage to flexible manufacturing equipment caused by improper operation by students and avoid personal injury, this study introduces Virtual Simulation Technology (VST) to construct a Virtual Flexible Manufacturing (VFM) system, to meet the combination of physical control system of virtual equipment and practical teaching. This paper aims to address the limitations of flexible physical systems in practical training and teaching in universities, create FMS that is more in line with practical production, and cultivate the professional and practical abilities of comprehensive talents. There are two main innovative points in the study. The first point is to propose a VFM system that integrates VST, which can interact with physical control systems, receive control commands, and feedback virtual sensor signals. The second point is to use multi-objective genetic algorithm (MOG) for cargo location optimization to improve the efficiency of flexible systems. The structure of the study mainly consists of four parts. The first part is a review of relevant research results. The second is about the design of VFM that integrates VST, as well as the optimization of cargo space in the VFM system based on MOG. The third is to verify the effectiveness and applicability of the proposed method; the final part is a summary of the entire content.

## II. RELATED WORK

With the acceleration of informatization and industrialization, the performance of industrial products is becoming increasingly complex, and traditional physical manufacturing systems are unable to meet the current production needs of industrial products. FMS has emerged as the times require. It enhances the competitiveness of enterprises, which also puts higher requirements on the application abilities of relevant practitioners and professional students. Numerous scholars have conducted in-depth research and exploration on this topic. H. Wang et al. found that there are many factors unrelated to processing in flexible manufacturing systems, resulting in significant differences in the formulation and implementation of production plans. Therefore, a study proposed an improved genetic algorithm with local search to optimize scheduling data based on discrete manufacturing enterprises. The experimental results show that compared with the current scheduling strategy of

the enterprise, the scheduling strategy proposed by this algorithm has an average improvement of 29.61% in minimizing completion time, 44.8% in minimizing transportation time, and 44.64% in machine load balancing [7]. C. Zhu et al. proposed an integrated optimization method to plan and schedule a hybrid flexible manufacturing system for producing nylon components, in order to minimize energy consumption and completion time. The effectiveness and feasibility of the proposed method were verified through practical cases [8]. Setiawan A proposes an FMS based on a stacker crane model to establish a learning production system. The maximum error of this model in the x-axis and y-axis directions is 2mm [9]. Daniyan I et al. proposed an FMS including assembly, Lean manufacturing, logistics and quality assurance to adapt to the dynamic of manufacturing operations. The system can properly perform the sequence of assembly and quality assurance operations with minimal interruption and manual intervention during the manufacturing of rail car components [10].

VST is the mapping activity of a virtual simulation environment on a computer. By constructing actual device models in virtual environments and utilizing the excellent data processing capabilities of computers, VST can achieve the same results as real application scenarios, making it a new technology in various fields. M. Wei et al. innovatively introduced a virtual simulation platform to teach the power system analysis course in order to improve students' understanding of knowledge, hands-on ability, and research skills. After conducting the reform teaching, students were very satisfied with the new teaching method and believed that it could effectively stimulate students' enthusiasm for learning [11]. J. Wood et al. found that the confidence and stress levels of providers are related to the survival outcomes of patients. Therefore, they innovatively utilized virtual simulation technology to create training opportunities to enhance providers' confidence and reduce stress. The research results showed that this method can effectively enhance trust in resuscitation training and reduce stress [12]. Wang Y and others proposed a multi Kinect fusion algorithm to achieve robust full body tracking in virtual reality assisted assembly simulation, and applied distributed computing to improve computational efficiency in the algorithm. Compared with other similar algorithms, this algorithm has better fusion performance [13]. To improve the performance of online art Design education system, Yang C built an online art Design education system based on 3D VST. The constructed model can meet the current needs of online art education, and the functional modules can also be continuously optimized in the future [14].

In summary, there are many research results on FMS and VST, but currently there is relatively little research on VST for FMS in universities. To shorten the design cycle of flexible production lines and improve their design accuracy, this study introduced VST to construct a VFM system.

### III. DESIGN OF VFM INTEGRATING VST

At present, China's research and application on FMS is rapidly advancing. But there is no flexible manufacturing platform in various universities in China that meets the actual

production line for teaching, resulting in the inability of students to apply their professional knowledge in practice. Therefore, the research first designs the overall scheme of VFM system, then uses VST technology to build the system, and finally proposes a MOG algorithm for VFM system to optimize the storage location.

#### A. Design of FMS Integrated with VST Technology

In order to design the VFM system for teaching and training links and scientific research projects, the research requires that it cannot only carry out single electrical course training, but also have the ability to integrate multiple courses. Based on the teaching tasks of college students, the following requirements are proposed for the VFM system. Firstly, it needs to not only have flexibility in processing and manufacturing, but also consider flexibility in teaching practice. Secondly, in the teaching curriculum, the theoretical content includes various mechanical and software control methods, so it is necessary to achieve teaching and practical training for different purposes in the design of VFM systems. Finally, flexible manufacturing technology is also constantly developing, and the speed of system updates and iterations is also accelerating. This requires the design of the VFM system to meet the requirements of photography technology updates to achieve the upgrade of the system. In university teaching, the physical manufacturing teaching system may have drawbacks, such as high teaching costs, resource shortages, slow security and system upgrade iterations in student practice [15-16]. To address the above issues, the study introduces VST in the design of VFM, enabling students to conduct virtual simulations of VFM through virtual simulation software. In addition, the research selected the current mainstream computer 3D display technology and placed virtual devices with the same functions and attributes as flexible devices in a virtual environment to build a VFM system. At the same time, by adding virtual devices to upgrade and optimize the system, each computer can be seen as a set of flexible systems, which effectively solves the problems of high cost and limited resources in traditional flexible systems. According to its functions, it can be divided into three parts: logistics warehousing, production manufacturing, and control systems. The logistics warehousing system in the VFM system is its advantage, with high intelligence and freedom, which can distinguish various types of workpieces for mixed transportation. This link can use the information processing of computers and controllers, and perform intelligent control of multiple devices at the same time; The system can also transport processed parts in different functional areas, and the three-dimensional warehouse can improve its storage space utilization and workpiece processing efficiency through an intelligent automatic warehouse information relationship system. The production and manufacturing system includes flexible production lines, six axis CNC machining centers, robots, and inspection devices. The control system is the command core of VFM. Design VFM by analyzing its impact on the functionality and work efficiency of the system, and study the optimization of warehouse locations in the system to improve the efficiency of flexible system work by improving the efficiency of goods in and out. From this, the VFM design process in Fig. 1 can be obtained.

The virtual development platform used in this study is a specialized simulation software for electromechanical systems. It is based on the latest virtual debugging and simulation technology and provides users with a fully open virtual device development platform. The 3D model is based on the development of mainstream 3D modeling software, and uses the latest 3D rendering technology and Physics engine to show the most realistic simulation effect. Compared with other simulation software, electromechanical integration simulation software and physical controllers have better information exchange capabilities, which can simplify the implementation of external controllers' motion control of virtual devices in virtual software. The hardware equipment in the designed VFM system uses computers and HTC VIVE. Computers provide a running environment for simulation software; HTC VIVE is the implementation of Virtual Reality (VR) functionality in simulation systems. From this, the overall framework of the virtual simulation system can be obtained, as shown in Fig. 2, which is composed of a model layer, a data layer, and a human-machine interaction layer.

### B. Construction of FMS Integrating VST

The proposed VFM system has novelty. Virtual flexible devices not only have the same mechanical structure and

motion mode as actual devices, but also interact with physical control systems for signals. It also has the function of receiving control commands and feedback virtual sensor signals. In the 3D modeling process of the VFM system, the modeling results generate a large amount of redundancy, and exporting them can also generate a large amount of data. After being imported into simulation software, it will occupy a large amount of computer memory, causing problems such as crying and incomplete animation display when the virtual simulation system runs. Therefore, this study will achieve lightweight processing by converting 3D models into 3DXML format. Therefore, the research realizes the lightweight processing by converting the 3D model into 3DXML format, which only contains the entity information of the 3D model and the assembly features of the mechanical structure, and its storage space is reduced by 90% compared with the traditional CAD and manifest formats. There are many 3D shapes in 3D modeling, which are not necessary for the simulator and can greatly reduce the display effect. Therefore, the most commonly used method for simplifying 3D models is the edge folding algorithm. Its principle is as follows: let a plane  $Q$  be (1) [17].

Fig. 1. VFM system design process.

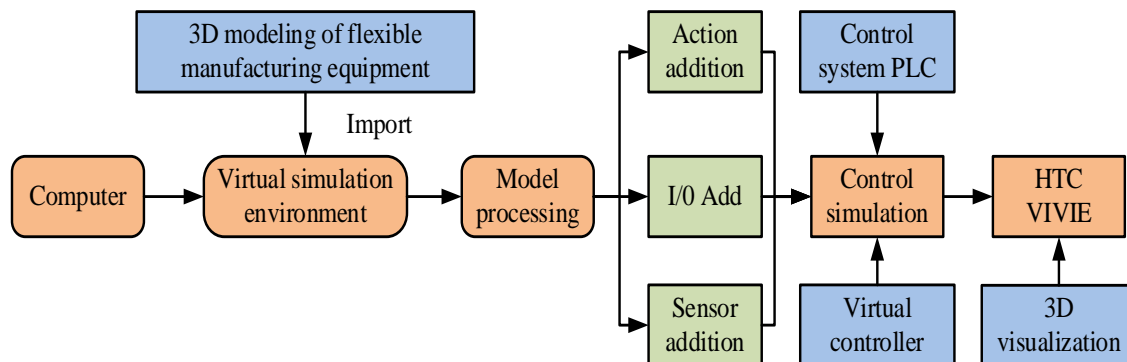

Fig. 2. The overall framework of virtual simulation systems.

$$\begin{cases} ax+by+cz+d=0 \\ a^2+b^2+c^2=1 \end{cases} \quad (1)$$

In (1),  $d$  represents a constant. By setting the coordinate of point  $p$  as  $(x, y, z)$ , the distance from it to  $Q$  can be obtained, as (2).

$$d(p) = |ax+by+cz+d| \quad (2)$$

By (2),  $Q = [abcd]^T$  can be gaibed. If the other vertex is  $\bar{g} = [xyz1]^T$ , the square of the distance from  $\bar{g}$  to  $Q$  is obtained as (3).

$$d_Q^2(\bar{g}) = \bar{g}^T D_Q \bar{g} \quad (3)$$

In (3),  $D_Q$  is a Symmetric matrix of  $4 \times 4$ , as (4).

$$D_Q = \begin{bmatrix} a^2 & ab & ac & ad \\ ab & b^2 & bc & bd \\ ac & bc & c^2 & cd \\ ad & bd & cd & d^2 \end{bmatrix} \quad (4)$$

When folding edge  $(g_1, g_2)$  to  $\bar{g}$ , the quadratic error matrix of  $\bar{g}$  is obtained. Then simplify the operation and take matrix  $L(g_1)+L(g_2)$  as the quadratic error matrix between the new vertex and  $(g_1, g_2)$  to obtain the folding cost of  $(g_1, g_2)$ , as (5).

$$\Delta(\bar{g}) = \bar{g}^T (L(g_1 + Lg_2)) \bar{g} \quad (5)$$

To perform edge folding operation, a position must be selected for  $\bar{g}$ . Since the Error function is a Quadratic function, the minimum value of  $\Delta(\bar{g})$  can be calculated from its partial derivative, as (6).

$$\frac{\partial \Delta(\bar{g})}{\partial x} = \frac{\partial \Delta(\bar{g})}{\partial y} = \frac{\partial \Delta(\bar{g})}{\partial z} = 0 \quad (6)$$

Assuming matrix  $h$  is (7).

$$h = \begin{bmatrix} h_{11} & h_{12} & h_{13} & h_{14} \\ h_{12} & h_{22} & h_{23} & h_{24} \\ h_{13} & h_{23} & h_{33} & h_{34} \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (7)$$

If  $h$  is an invertible matrix, the new vertex  $\bar{g}'$  can be obtained as (8).

$$h = \begin{bmatrix} h_{11} & h_{12} & h_{13} & h_{14} \\ h_{12} & h_{22} & h_{23} & h_{24} \\ h_{13} & h_{23} & h_{33} & h_{34} \\ 0 & 0 & 0 & 1 \end{bmatrix}^{-1} \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} \quad (8)$$

If  $h$  is an irreversible matrix, select two breakpoints or key points of  $(g_1, g_2)$  as new vertices. The 3D models of different flexible devices are processed and rendered in a lightweight manner to obtain a virtual model, as Fig. 3.

Fig. 3 includes a three-dimensional warehouse, CNC machining center, conveyor belt, conveyor robot, and visual gripper robot. The development of VR functions in virtual simulation systems requires the application of HTC VIVE virtual reality devices for assistance. Compared with the traditional VR equipment, students can freely carry out mechanical equipment through the Head-mounted display and can observe the mechanical structure closely. The data collection and transmission structure of HTC VIVE is Fig. 4. The connection between HTC VIVE hardware and computer ports is the foundation for VR interaction.

### C. Optimization of Cargo Location for VFM

To further explore methods to improve the efficiency of VFM work, this study focuses on the problem of low efficiency in managing goods in flexible systems. The VFM system is used as the research object and the MOG algorithm is used for cargo location optimization. After running the VFM system for a period of time, due to the use of automatic mode, manual mode, and cargo in and out functions during the teaching process, the flexible system may experience scattered storage of goods and unreasonable distribution of cargo locations. Therefore, the study introduces MOG to optimize the allocation of warehouse locations in the VFM system, thereby improving the warehousing efficiency of the warehouse and ultimately achieving the goal of improving the efficiency of VFM work. The research will optimize the efficiency of goods in and out of storage, as well as the stability of cargo locations. The former increases the frequency of goods entering and leaving the warehouse in the warehousing system, and allocates them to a location closer to the warehouse entrance and exit, in order to shorten the time for goods entering and leaving the warehouse. In the optimization of cargo space stability, in order to better align with practical applications, it is necessary to study adding physical attributes such as mass and friction to the virtual cargo model. Therefore, the study also needs to consider the stability of warehouse shelves in different cargo weights. In response to the above, lighter goods will be prioritized in the upper part of the shelf, while heavier goods will be allocated in the lower part of the shelf. This placement method not only improves the stability of the shelf, but also reduces the power consumption of the warehouse during inbound and outbound operations. Genetic algorithm (GA) currently performs well in global search and can effectively reduce the probability of getting stuck in local search for the optimal solution. Compared with other algorithms, this algorithm is more suitable for solving complex combinatorial problems and can search for the optimal solution more quickly. Due to the multi-objective nature of the cargo location optimization problem in VFM, the research chose the MOG algorithm based on GA for solution [18-20]. Fig. 5 shows the structural flow of a standard GA.

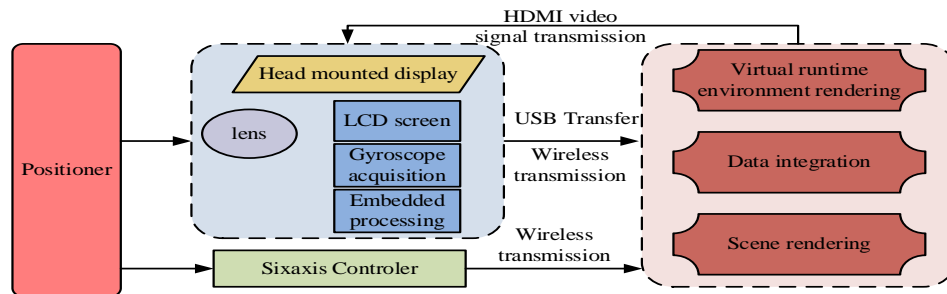

Fig. 4. Data Collection and transmission structure of HTC VIVE.

Before optimizing the storage space, it is first necessary to determine the optimization object and its key information attributes. According to the three-dimensional warehouse of the VFM system, the objects of cargo location optimization are the stacker, the goods processed by the system, and the cargo spaces included in the shelves. Key information includes the X-axis and Y-axis speeds of the stacker, as well as the origin position. The goods include weight, model, and delivery rate; The storage location contains a number. The study designed three types of processed goods in VFM and added physical properties to them, so that the goods had different qualities and met optimization requirements, as Fig. 6.

The objective of cargo location optimization is to optimize the efficiency of goods in and out of storage and the stability of cargo locations. The multi-objective mathematical model established is (9).

$$\begin{cases} f = \omega_1 f_1 + \omega_2 f_2 \\ f_1 = \sum_{x=1}^a \sum_{y=1}^b \sum_{z=1}^c R_{xyz} t_{xyz} \\ f_2 = \sum_{x=1}^a \sum_{y=1}^b \sum_{z=1}^c (m_{xyz} \times n_{xyz} \times z) \\ \omega_1 + \omega_2 = 1 \end{cases} \quad (9)$$
