Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Department of Electrical and Computer Engineering, Worcester Polytechnic Institute (WPI), USA[3,4]

Abstract—**This paper presents a holistic reliability evaluation framework for Agri-IoT based on real-world testbed and mathematical modeling of network failure prediction. A testbed has been designed, implemented, and deployed in the real-world in the experimental farm at Saint-Louis/Senegal as a representative area of Sahel conditions. Data collected has been used for real-world reliability analysis and to feed mathematical modeling of network reliability based on energy and environmental conditions data with Kaplan Meier and Nelson Aalen estimators. Key factors affecting the network's lifespan, such as network coverage and density, are explored, along with a comprehensive evaluation of energy consumption to understand node discharge rates impact. The survival analysis, employing Kaplan-Meier and Nelson-Aalen estimators, establishes network stability and the probability of node survival over time. The findings contribute to the understanding of Agri-IoT reliability in a real-world Sahel environment, offering practical insights for system optimization and environmental challenge mitigation in real-world deployments.**

Keywords*—*Energy; IoT; reliability; real-world testbed; optimization; Agri-IoT

I. Introduction

IoT is increasingly adopted in agriculture (Agri-IoT) to improve management methods, performance, and productivity of agricultural farms[1]. In particular, Agri-IoT provides tools for input management, automatic irrigation management, remote control of agricultural fields, yield forecasting, and input prediction.

Deployed Agri-IoT systems are very common in many European and American countries (North and South) and Asia [2], [3]. In developing countries, especially in Africa, more particularly in the Sahelian zone, the deployment of such systems is needed for food security purposes [4]. However, to reproduce the same results of Agri-IoT as elsewhere, reassessments of the reliability of IoT are needed in the specific environment of the Sahel.

Indeed, the Sahel has many white areas without a network, the sector power is not ensured in agricultural areas, and a dry, dusty environment is sometimes rainy which has an impact on the reliability of the electronic devices, the sensors, and the maintenance in the event of a fault is not always possible.

Limited power resources in the IoT network devices, can cause failures due to internal instability or external disturbances. Identifying vulnerabilities and using reliability analysis [5] and fault diagnosis techniques [6] can enhance system stability and resilience.

This reliability assessment is necessary for good network lifespan and data sensor reliability knowing food security issues if an Agri-IoT device fails. More importantly, most of the proposed research is theoretical or in lab tests.

The reliability of IoT systems can be assessed using different metrics such as power consumption and its impact on the network lifetime, network lifespan, sensors data trustworthiness (error rate), network availability, and environmental impact.

This paper aims to provide a holistic reliability analysis framework on a Sahel area based on real-world data collection from the experimental farm and mathematical modeling of network failure prediction.

The main contributions of this paper are: begin

- Design, implement, and deploy real-world Agri-IoT deployment in the experimental farm at Gaston Berger University in Saint-Louis (Senegal).
- Collect real data for reliability evaluation.
- Experiment with different environmental constraints in IoT operation.
- Modeling mathematically the network reliability based on energy and environmental conditions data with Kaplan Meier and Nelson Aalen estimators.

This paper is organized as follows: Section I gives a brief background on IoT and the problem statements. Section II presents a related work on IoT power evaluation and modelization strategies. Section III looked at reliability assessment tools, especially the mathematical techniques on lifetime evaluation. Section IV presents an experimentation of Agri-IoT system deployment and, in that same way, presents the results of our power evaluation and survival analysis for a centralized Agri-IoT Network in real-life deployment. Section V presents the evaluation, analysis, and discussion and Section VI, finally presents the Conclusion.

II. Related Work

Deploying Agri-IoT systems is challenging in terms of hardware, network architecture density (topology and density), type of power supply, and environment. Battery drain is a parameter of reliability related to network lifespan.

Regarding that, several research [7], [8], [9] evaluated power consumption in different LPWAN technologies. In [7], an analytical approach is proposed to assess individual sensor node power consumption, providing insights for optimizing sensor node design with a focus on energy autonomy. In [8], the authors presented an energy model for NB-IoT, considering power-saving modes and discontinuous reception mechanisms. In [9], the authors compared the power consumption impact of SF7 and SF12 and their respective applications in a LoRaWAN-based IoT system.

In [10], the authors evaluated the energy usage of LPWAN wireless technologies (LoRaWAN, DASH7, Sigfox, and NB-IoT) to determine battery lifetimes. They found that actual battery lives can differ from ideal scenarios and provide insights on selecting appropriate technologies and battery capacity to improve IoT applications.

Banti et al. [11] identified challenges in designing an energy-efficient LoRaWAN communication protocol. Their findings guide research toward a GreenLoRaWAN protocol that is robust, scalable, and energy efficient. The authors emphasized the need for independent power sources for IoT nodes, as studies often overlook network lifetime constraints by assuming gateways are connected to the grid.

In [12], the authors proposed a node lifetime estimation approach applicable to both static and dynamic loads, investigating the influence of parameters such as self-discharge, discharge rate, age, and temperature on Alkaline and Nickel-Metal-Hydride (NiMH) batteries.

Based on reviews, many energy models simplify analysis for manageability, potentially overlooking real-world complexities and leading to inaccuracies in predictions. Some studies assume grid power for gateways, but in the Sahel, where reliable power is rare, overlooking network lifetime constraints in IoT system design can affect practicality. Dynamic factors impacting energy consumption over time, like environmental conditions and hardware variations, may not align with assumed ideal conditions. In this study, battery consumption estimation relies on node voltage measurement and payload tests, using real-world testbed data under actual conditions in the Sahel. This approach is based on modeling mathematically of network reliability on Kaplan Meier and Nelson Aalen estimators.

III. Background Probabilistic IoT Reliability Prediction

In statistics, survival analysis [13], [14], [15] is for analyzing life expectation and lifetime based on an event occurring such as the death or failure of a mechanism in a system. This topic is also called reliability analysis.

Reliability analysis determines the probability of a population that survives past a specific time, the rate of the population that survived or died at any given time, or how an event impacts the population's lifetime. In the Agri-IoT context, it enables modeling network nodes' survival by predicting it.

In mechanical systems, determining the cause of death or failure of a component is required. In survival analysis, this is considered an "event" and involves time-to-event data. Time is defined as the beginning or end of an observation period. Censored observation focuses on an individual's survival time, even if the information is incomplete or imprecise.

In 1958, Kaplan and Meier introduced the Kaplan-Meier estimator [15], which has since become widely used for estimating and summarizing survival curves. This approach is the most common way to estimate and summarize survival curves for being a highly cited statistic paper. The survival function, $S(t)$, gives the probability that a device or a mechanism survives after a specific time t. The non-parametric estimator functions will be used to analyze the survival data from field experiments and to evaluate two related probability paradigms.

1) The survival probability using the Kaplan-Meier estimator (KME).
2) The Hazard rate denoted $H(t)$ using the Nelson-Aalon estimator(NAE) [16], [17].

The Kaplan-Meier distribution estimates the probability of the event of interest not happening at time t. At the same time, the NAE Hazard probability gives a visualization of the event occurring on the subject within an interval of time.

$S(t)$ is the probability that a given population member has a lifetime greater than t. For a sample of size N in this population, the time until each death of the members of population N is represented as follows:

$$t_1 \leq t_2 \leq t_3 \leq \cdots \leq t_N. \tag{1}$$

The KME function $S(t)$ is express as following :

$$\hat{S}(t) = \prod_{t_i<t} \frac{n_i - d_i}{n_i} \tag{2}$$

The NAE function $H(t)$ is expressed as following :

$$\hat{H}(t) = \sum_{t_i<t} \frac{d_i}{n_i} \tag{3}$$

where n_i is the number of subjects "at risk" just before time t_i, and d_i is the number of deaths at time t_i. The KME is not used to estimate the cumulative hazard, plus the NAE hazard function has a better small-sample performance than the KME [18] function. An empirical comparison of the two solutions has been broadly studied by Colosimo *et al.*[19].

The IoT systems are hardware and software deployed to monitor specific parameters. In some cases, human intervention can be a requirement for provisioning and maintenance reasons or as an oracle. Then, the reliability of IoT systems can be assessed in three ways:

- Hardware reliability;
- Software or operation reliability;
- External reliability.

Hardware reliability is the failure rate of the hardware component system. It has been assessed in many ways in the literature [20], [6], [21]. The software reliability involves protocols, logistic support, and the system's operationality. External reliability is correlated to the maintenance of the system or human intervention and the impact of outside parameters in the system. The system reliability can be expressed as follows:

$$R_{system} = \frac{R_{gateway}(\sum(R_{mn}) + R_{software} + R_{human}}{3}) \quad (4)$$

Where $R_{gateway}$ is the reliability of the gateway, which centralizes the network and all the system depends on. R_{mn} is the reliability of the network participant, the member nodes. $R_{software}$ is the software reliability of participants. R_{human} is the human reliability.

In this study, the $R_{software}$ is not considered, same for the R_{human} on the system reliability. Consequently, in this work, several evaluation and prediction results are achieved. This is based on an IoT system's energy consumption behavior during its operation with on-field collected data from the testbed: Node Lifespan; Network lifespan; Impact of activity level on the system; Network density, and participants' death over time for maintenance and human intervention time prediction.

The next section presents the simulation part and how the reliability analysis is executed and correlated to the on-field implemented system's observations.

IV. Contributions: Experimentations and Modeling

A. Context and Test Bed Architecture Design

The test bed site is located at Gaston Berger University's (UGB) experimental farm in northern Senegal, specifically in Saint-Louis (see Fig. 1).

This site has been set up for practical training and research activities focusing on animal and crop production techniques. It covers an area of 26 ha and is irrigated with a drip irrigation system and two submerged pumps in the Djeuss River, Senegal River, with flow rates of $160\ and\ 196\ m^3\ per\ hour$. It has a storage and recovery basin measuring 15 meters by 10 meters by 8 meters, a filtering station with sand tanks, multiple control heads, distribution ramps, and conduits supporting the drip emitters. This infrastructure enables a controlled water supply for agricultural experimentation on the farm.

The Agi-IoT test bed installation was done between August and September 2021. Meteorological conditions during this period are characterized by the rainy season, sunny days, and daytime temperatures ranging from 28°C to 33°C during the day and 24°C and 27°C during the night, while relative humidity levels consistently exceed 70% based on on-field measurements and from National Agency for Civil Aviation and Meteorology [22], [23].

The architecture of the test bed consists of one Gateway and four sensor nodes deployed into an okra exploitation. The system provides sensing and analyzing functions (Fig. 2). The aim is to monitor environmental parameters (temperature and soil humidity) and infer the need for irrigation actioning.

The sensing part consists of a digital temperature and humidity sensor, a controller, and an energy source from a finite battery. Moreover, the sensor used in this work incorporates an integrated temperature sensor to gauge the soil's temperature accurately. The collected data is transmitted to the gateway using BLE technology. Bluetooth Low Energy (BLE) technology is known for providing reliable communication over relatively short distances.

The IoT's Cisco Reference Model defines the gateway as a Level 3 and 4 component that acts as a hub for receiving all data collected from sensor nodes [24]. The gateway processes the packets to extract relevant information, generates customized irrigation plans for each sensor node, and transmits refined data to a database. This makes it accessible to various applications and services for the end-users.

B. Hardware Design, Implementation, and Deployment

The IoT Network test bed consists of a gateway and sensor nodes. These components encompass a controlling board, a communication module (integrated into the controller), sensors, and the power supply. The nodes, including gateway and sensor nodes, are implemented using the Raspberry Pi 3B+ as the main electronic board (Fig. 3). Nodes use BLE 4.2 for network, power bank, solar panels, soil sensors for data collection, UM25C Meter for energy monitoring, and an 8-inch display, keyboard, and mouse for RPIs.

The Cypress CYW43455 Bluetooth Chipset and BLE 4.2 are used for the Network Communication interface between the nodes. The BLE 4.2 module is built in the RPi 3B+ for communication among the Network's nodes. In this context, the Gateway is the master, and simple nodes are slaves.

A solar power bank with a battery capacity of $36,000mAh$ is connected to the nodes (gateway and simple node). The power bank has a USB output for the devices' power supply. A 24 by 6 cells poly-crystalline silicon solar panel is coupled to the gateway battery. The criteria for choosing the battery model were durability, robustness to the outdoor conditions, and water resistance in accordance with the deployment area conditions.

The UM25C Meter [25] is a device that measures electrical quantities, such as voltage, current, resistance, capacitance, and temperature. It has a large display screen and can be connected to a computer or smartphone via Bluetooth. It is connected to the RPI via USB 2.0. It is used to monitor our field ambient temperature and nodes' electrical metrics quantities.

A WiFi connection was also used to establish Internet connectivity for the gateway. However, this connection was deliberately not kept continuously active in order to reduce power consumption. Instead, the connection was established twice daily to transmit data to the database and was subsequently disconnected. The data acquired from the sensor node was stored using Google Sheets as the storage platform.

In the experimental farm, five(5) nodes have been deployed on the field in a star topology to collect data. The Gateway is in the center with a solar panel and enclosure at $1m$ up to the ground (Fig. 4). It coordinates communication and has two network interfaces: One with BLE to communicate with the sensor nodes in WI-FI to be connected to the Internet. The four(4) Sensor nodes are in the perimeter of a chosen area to collect temperature and humidity and send data to the gateway (Fig. 5).

V. Evaluation, Analysis, and Discussion

A. Reliability Evaluation Results

This section presents the main results and learned lessons from the testbed related to reliability. The on-field testbed deployment further highlights the importance of designing and simulating scenarios with detailed realism, ensuring accurate and representative results regarding the hostile Sahel environment.

TABLE I. The Gateway Internal Activities

	Status
Server	Gateway
Platform RPI	3B+
Running Tasks	156
User	Python3.7
Memory	873.3/1000
Network	BLE
Display	None

Table I presents the status of various parameters that impact energy consumption in a node. The gateway plays the role of a server. Several experiments were realized to observe the system's activity level and running tasks. The running software is implemented in Python with the BLE communication protocol.

(2)

Fig. 4. (1) Gateway's initial deployment: Solar power bank responsible for energy supply. This setup lacks protection against the sun, significantly impacting board operations due to enforced sleep mode during high temperatures within the enclosure. (2) Enclosed gateway setup featuring an RPI, a body with a fan, and a UM256C meter for energy behavior monitoring during node activities.

1) Network Coverage: Considering a node as dead once it stops operating. The operation time of the field experiment is 72 hours testing period. The maximum communication distance for the BLE connection was about 11 meters in line of sight. The BLE range of the Raspberry Pi is limited without an external antenna. For any distance beyond 7 to 10 meters or another use case that involves reasonable communication distance, adding an antenna might suit best.

2) Impact of Density in Network Lifespan: It is very important to have a global view of the impact of network density on the network to provide energy-saving and optimized operation. Fig. 6(2) shows how the network size impacts the network's longevity. The experiment was run five times and plotted the mean values of the network lifetime against the network size. Then, observations were made based on the activity and the node's role(sensor node or gateway) to obtain a concise evaluation of its lifespan. Node density was set to 5, 10, 15, 20, and 25 participant nodes with one gateway in a centralized architecture.

Two important facts were deducted from the evaluation of Network Density over Node Lifetime. The red curve represents the lifespan of 'at-risk' nodes over time, which are nodes that are more prone to failure. On the other hand, the blue curve illustrates the lifespan of 'died nodes' over time, which are

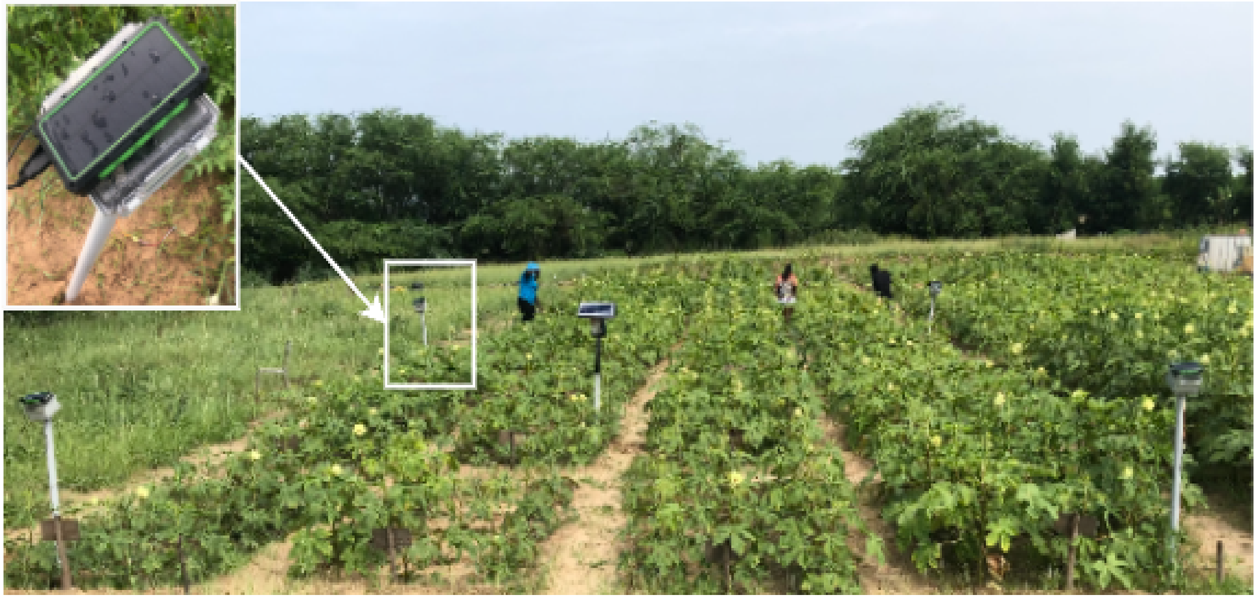

Fig. 5. Field deployment of the testbed IoT network, emphasizing a sensor node, its energy source.

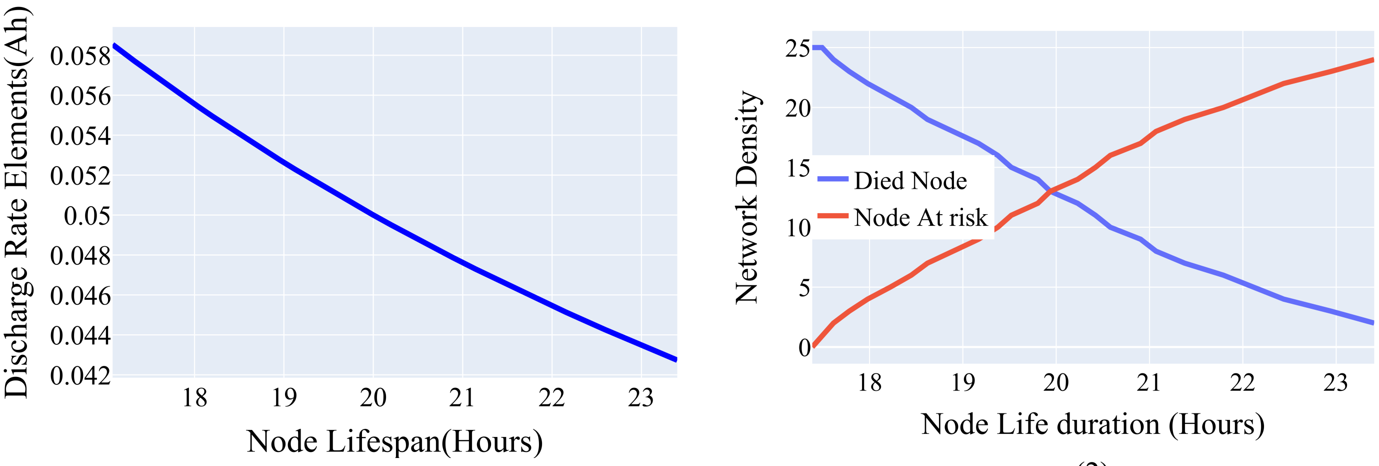

(2)

Fig. 6. (1) Node discharge rate effect on lifetime. (2) Influence of network density on node lifetime: The red curve represents the lifespan of 'at-risk' nodes over time, while the blue curve illustrates the lifespan of 'died nodes' over time.

the nodes that have experienced failure events. This analysis provides a valuable understanding of the network's stability, reliability, and overall performance.

3) Impact of energy in network lifespan and reliability : The reliability evaluation encompassed a comprehensive assessment of discharge rate impact and inclusion of factors such as transmission, reception, idling periods, duty cycling, data, and the node's designated tasks. This comprehensive evaluation allowed us to estimate the node's lifespan, as depicted in Fig. 6(1). Thus, the figure illustrates that with a discharge rate of up to $0.054Ah$, the projected node lifetime could extend beyond $25hours$. As demonstrated through indoor testing, this prolonged node lifespan translates to approximately $22hours$ of sustained gateway operation connected to a finite power source of $36000mA$. This is a way to predict network failure and anticipate self-healing methods to minimize network failures.

This observation highlights the critical role of gateway efficiency and longevity in overall network performance by deepening our understanding of the correlation between node discharge rates and lifespan.

The battery capacity can be expressed as a function of the time it takes to charge fully (see Eq. 5):

$$C_n = \frac{A(chargingordischarging)}{Capacity} \tag{5}$$

- Where C_n or C/n, expressed in ampere-hours (Ah), measures the speed of charging or discharging the battery, and the n stands for the number of hours the discharging takes.

- A is the electrical current.
- The capacity is the amount of current held in the battery; it is different from the power.

To find out this quantity of energy (which is expressed in Watt-hours - Wh), the capacity must be multiplied by the voltage of the battery:

$$Ah \times V = Wh \tag{6}$$

The current (A) can fluctuate depending on the charging style or type, and different parameters like heat, dust, wear-out, and activity load can affect battery charging and discharge speed. Hence, All battery parameters are affected by the battery charging and recharging cycle. The current can be expressed in Eq. 7.

$$A = \frac{capacity}{H} \tag{7}$$

From Eq. 5 and 7,the lifetime is deduce as follows:

$$H = \frac{1}{Cn} \tag{8}$$

4) Mitigating environmental-related issues:: Nodes went to sleep after sending measurements, making data collection impossible. The gateway received data only the next morning. No protection against the sun heat in Fig. 3 affected performance. High temperatures triggered sleep mode, posing a deployment challenge.

The temperature was 46°C in the field. High temperature triggers sleep mode and reduces charging efficiency. More energy is required for proper recharging. High temperatures slow down charging. Our batteries come with a less-efficient amorphous solar panel.

The power bank's operational temperature range spans from 0° to 45°, with a cautionary recommendation not to exceed 60°. During the deployment phase, high temperature consequently impacted the battery's performance. This explains the occurrence of node failures in the field due to the influence of heat.

Furthermore, an important observation concerning the new gateway's design. It featured a wider solar panel (refer to Fig. 4(1)) that served as a protection against sun heat, effectively preventing node overheating. The system's efficiency is improved by adjusting the battery supply and raising the solar panel. This created better airflow, resulting in a cooling effect. The change was needed because inconsistent data reception was experienced from the end nodes. Initially, attempts were made to enhance the gateway's power supply, but upon further investigation, it was determined to be unnecessary. As a result, the gateway functions optimally in cooler environments with average temperatures ranging from 25° to 30°.

B. Network Survival Analysis

A thorough survival analysis was performed to explore the correlation between network density and the lifespan of the network. This investigation enabled us to make accurate predictions about the network's behavior in response to a 10% increase or decrease in workload or network size. Fig. 7 is a visual representation of our findings. Network expansion impacts payload and data processing at the gateway. This data was analyzed using Python 3.7 and the Lifelines library, with the Kaplan Meier distribution fitter method - a widely accepted approach.

During the investigation, time-to-event data was analyzed using two non-parametric survival function estimator techniques: the Kaplan-Meier Estimator (KME) and the Nelson-Aalen Estimator (NAE) to consecutively estimate $S(t)$ and $H(t)$.

The KME was used to estimate the probability of nodes surviving over time. This estimator is represented as a step function, which shows discontinuities at the occurrence of events. Initially, the probability of a node's survival remains at 100%, indicating network stability during the first 18 hours, between the intervals of t_0 and t_{18}, as shown in Fig. 8(2). This interval represents a period of network stability. Additionally, the median survival time indicates that nodes can operate reliably for at least 22 hours, providing valuable information for proactive network maintenance planning.

Due to the limited amount of data, the Kaplan-Meier estimate was not applicable. Consequently, the Nelson-Aalen estimator, more accurate for a limited amount of data, was utilized to assess the cumulative hazard rate. This involves calculating the total number of node failures during specific time intervals to determine the cumulative count. Refer to Fig. 8(2) for the results.

Our analysis found no "early node mortality." Our metric for assessing node performance was battery depletion. Failures became more prevalent as the network aged, suggesting that nodes performed well initially but gradually became less reliable over time.

In the scope of the study, the metric related to battery depletion in the network component was closely monitored. It is important to note that no subjects were censored in this investigation. This can be visualized in Fig. 8(1) and 8(2).

VI. Conclusion

This paper evaluates the reliability of an Agri-IoT system deployed in the challenging Sahel environment. Accurately simulated on-field scenarios provided valuable insights. Monitoring the gateway's internal activities revealed critical data impacting node energy consumption. Network coverage and density emerged as key factors affecting the network's lifespan. The comprehensive evaluation of energy consumption provided crucial insights into node discharge rates and their correlation with lifespan, aiding in predicting and mitigating network failures.

The study addressed environmental challenges, highlighting the impact of high temperatures on node performance and the successful design adaptation of the gateway for improved efficiency in cooler environments.

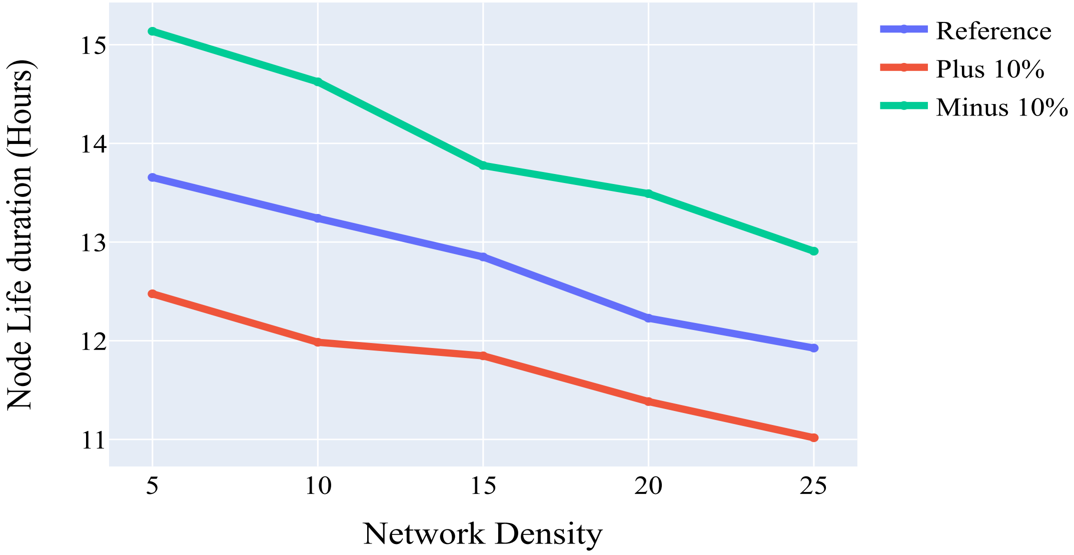

Fig. 7. Network density and duty-cycling impact on the network lifetime.

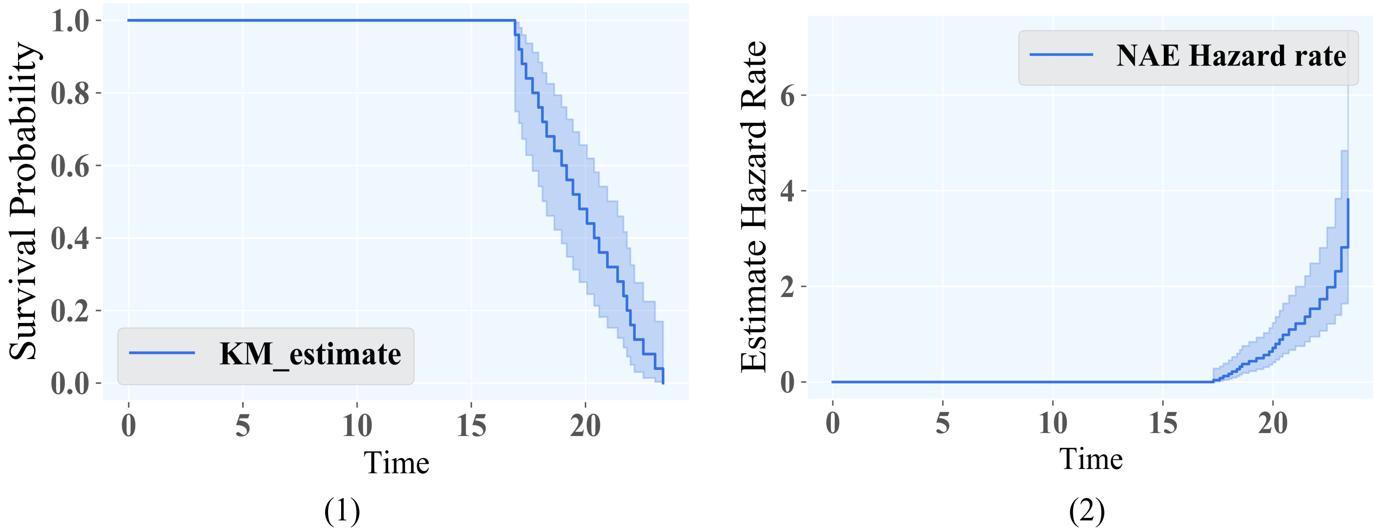

(1)

(2)

Fig. 8. (1) Kaplan Meier estimate survival function, $S(t)$ described in Eq. 2. It is the probability that a node survives from the time it is switched on to a specific future time t. (2) Nelson-Aalen Estimator cumulative hazard rate. It is denoted $H(t)$ described in Eq. 3. It represents the probability a node, in our case, who is under observation at a time t, has died at that time.

Survival analysis, utilizing Kaplan-Meier and Nelson-Aalen estimators, established network stability and the probability of node survival over time. The absence of ”early node mortality” indicated initial reliability, gradually decreasing over time.

These results enabled to better understanding of Agri-IoT reliability in typical Sahel Environment, providing practical insights for optimizing system performance and addressing environmental challenges in real-world deployments.

A Hybrid Approach for Automatic Question Generation from Program Codes

Jawad Alshboul, Erika Baksa-Varga
University of Miskolc, Faculty of Mechanical Engineering and Informatics, Miskolc, Hungary

***Abstract*—Generating questions is one of the most challenging tasks in the natural language processing discipline. With the significant emergence of electronic educational platforms like e-learning systems and the large scalability achieved with e-learning, there is an increased urge to generate intelligent and deliberate questions to measure students' understanding. Many works have been done in this field with different techniques; however, most approaches work on extracting questions from text. This research aims to build a model that can conceptualize and generate questions on Python programming language from program codes. Different models are proposed by inserting text and generating questions; however, the challenge is understanding the concepts in the code snippets and linking them to the lessons so that the model can generate relevant and reasonable questions for students. Therefore, the standards applied to measure the results are the code complexity and question validity regarding the questions. The method used to achieve this goal combines the QuestionGenAi framework and ontology based on semantic code conversion. The results produced are questions based on the code snippets provided. The evaluation criteria were code complexity, question validity, and question context. This work has great potential improvement to the e-learning platforms to improve the overall experience for both learners and instructors.**

Keywords—Question generation; e-learning; python question generator; semantic code conversion

I. Introduction

Automating question generation has become significant with the increasing trend of online learning and its scalability in recent years. Technical courses like learning programming languages are more popular, and there is a massive demand for such subjects. Questions are the primary approach used to evaluate student knowledge [1]. Therefore, creating questions becomes more challenging as the constant growth of e-learning continues, more courses are created, and the pressure on teachers is high. Intelligent and deliberate questions can enhance student understanding and reduce the gap between theory and practice in programming subjects [2]. For example, the article in [3] monitors the performance and behavior of students who engage in courses with self-assessment methods in programming and problem-solving. The research in [4] observes the decentralized practice by monitoring the intensity and timing of the impact on student learning and problem-solving in programming languages. The research paper [5] addresses interactivity while solving problems in programming languages based on learning objects. The article in [6] tries to enhance the use of digital resources for students and instructors. The research papers in [7] and [8] address the learning objects that can be used in different contexts using web3. Finally, the article in [9] suggests collaborative learning to help instructors engage students in generating and evaluating questions. The proposed method focuses on translating Python code into text and uses an AI-based framework to generate questions from the text. We also use ontology to connect and conceptualize the logic of the programming language. Applying ontology ensures interoperability with other systems and reduces the overhead on educational platforms. This work contributes to the e-learning platforms and improves the overall experience for instructors of programming languages. It also enhances the learning path for students who like to learn and do exercises without repeating the same questions. The outcome of this research is to generate meaningful questions based on Python code to assist instructors in creating more questions in a timely manner, thus ensuring students proper learning of the potential programming language. Unlike similar works, most recent research focuses on generating questions from text, while some research focuses on generating questions from visuals or images [10]. This work focuses on generating questions from code snippets using semantic relations to extract the concepts. Generating questions from unconventional sources, such as code snippets, becomes important in providing a better learning experience to large groups of students, especially when dealing with limited information.

A. Research Goal

The main goal of this research is to assist instructors and students in properly evaluating student performance by generating Python-based programming questions from existing materials (i.e., code snippets). The automatic question generation from code snippets will add the possibility of generating a different set of questions based on the same code snippet. Therefore, it leads to a better understanding of the given topic.

B. Research Objectives

To achieve the primary goal of this research, the following objectives are needed:

1) Implement a framework that can interpret Python programming language into text.

2) Enable the framework to comprehend the text and build connections between the programming structures and the semantic concepts.

The rest of the paper is organized as follows: Section II describes related work and some existing approaches. Section III details the question generation framework implemented in this research, and Section IV shows the results. Section V presents a discussion that summarizes the results. Finally, Section VI concludes the paper and mentions future work.

II. Related Work

The question generation process is a relatively complex and challenging task. It requires adequate experience, high knowledge of the material, and time. With the emergence of online learning, it has become a necessity. The first types of question generation models, such as syntax-based, semantic-based, and other models, started in 2014 [11].

Ontologies are a powerful tool for standardizing knowledge representation, which can be helpful in a wide range of domains, including e-learning. By modeling learning materials with ontologies, it is possible to create more personalized and effective learning experiences, allowing learners to achieve their goals more efficiently [12].

Domain knowledge models can be extremely useful in representing knowledge in a standardized and structured manner, aiding the teaching and learning processes. Python and Owlready2 are used to create the model implementation. Python is a popular programming language for various applications, including machine learning and data analysis. It includes many libraries and frameworks for developing sophisticated software systems. Owlready2 is a Python-based ontology library that simplifies creating and manipulating ontologies in Python code. The researchers created a flexible model that can be used to represent knowledge in a way that can be easily integrated into e-learning systems by implementing the domain knowledge model using Python and Owlready2. It could help develop adaptive learning systems that can tailor the learning experience to the needs of individual students [13].

Despite its importance, implementing question-generation approaches for programming concepts is partially applied in the modern world. Programming languages are an essential topic in computer science and software development, and there is a great demand for effective and efficient ways to teach programming concepts. Developing question-generation approaches for programming languages makes it possible to create many practice questions that can be used to reinforce learning and test understanding [14].

To aid students in their learning, Urazova [15] discusses the development of a system to automatically generate questions regarding UML database design and evaluate student responses. The system generates questions and evaluates student responses using artificial intelligence and methods for natural language processing. The goal is to give students a valuable and practical tool to assess their knowledge of and develop their expertise in UML database design.

A study by Russell in [16] investigated the application of automated code-tracing exercises for teaching introductory programming (CS1) courses. Code tracing is a teaching method in which students mentally run code, follow the control flow, and note the values of variables at each stage. The researchers used an automated system to create code-tracing tasks and assess student responses. The purpose of this system was to serve as a tool for teaching students programming ideas and problem-solving techniques. The researchers evaluated the system's efficacy through studies and student polls and contrasted it with more conventional teaching techniques. The article details the possible advantages of automated code-tracing exercises in CS1 courses and the challenges and limitations that must be addressed.

The use of large language models to automatically provide programming tasks and related code explanations has been used recently. A solution using artificial intelligence was developed to help teachers and instructors construct and deliver efficient programming assignments. A sizable language model was trained on text and computer code to provide workouts and explanations for programming. The model was assessed based on the usefulness and quality of the activities and explanations produced through tests and questionnaires. The promise of leveraging extensive language models for automated programming exercise production is discussed in the study, along with the difficulties and restrictions that must be overcome [17].

Automated programming exercise creation and code explanation have several drawbacks, including bias potential, dependency on large language models, limited capacity to assess student comprehension, significant computing needs, and difficulty in generating high-quality training data. The quality of the language models determines how well the exercises and explanations are created, and there is a chance that the models might be biased. The systems automatically assessing student knowledge could not be reliable and might need a lot of computer power. Producing high-quality training data for large language models is challenging and time-consuming. When utilizing these technologies in educational contexts, these constraints must be taken into account [18].

III. Question Generation Framework

Question generation involves computer understanding of the available materials to propose plausible questions to students. However, two approaches are usually effective: AI-based or semantic-based [12]. The current work uses a combination of both semantic and AI methods to properly generate questions from code snippets based on semantic code conversion. The primary motivation for using the semantic approach is maintaining concept relations in the programming language keywords to increase system intelligence on the programming language rules. Other approaches would not accurately represent the programming language rules, keywords, and concepts. This section will detail the framework architecture, the technology used, and the approach to generate questions.

A. Architecture

To generate questions from existing Python code snippets, an interpreter is needed to dissolve the codes into more understandable concepts. Python or any other programming language is constructed using operators, variables, and functions. Operators such as +,-, AND usually do the actual computing. At the same time, variables are used to store values and recall them with operators to perform specific tasks. Functions contain a list of variables, loops, and operators to be executed in order. The ontology will categorize and conceptualize the list of commands (i.e., variables, operators, etc.) and the relationships between the concepts in the script. It will build an explained version of the code by processing the code line by line and creating semantic relationships based on the input. Subsequently, the translated code is generated and inserted into an AI question generator called “QuestGen” [19]. This model will generate open-ended questions. Fig. 1 shows the framework data flow and its components.

Awareness of existing technologies and software is essential to construct any framework or software. Such awareness can improve productivity and help address many issues that take a long time. As a result, in this work, we implemented a framework using various third-party software. Table I describes this case's environment settings, tools, and applied libraries. As mentioned earlier, we have used the QuestGen AI model, an open-source NLP library dedicated to creating simple question-generation methods. It is on a mission to become the world's most sophisticated question-generation AI by utilizing cutting-edge transformer models like T5, BERT, and OpenAI GPT-2, among others. The primary objective of QuestGen AI is to simplify the question-generation process, providing support to educators, content creators, and learners in developing educational materials. This tool significantly enhances the efficiency of teaching and learning resource development through automation, ultimately facilitating a more effective educational experience.

Before generating questions, the QuestGen AI model expects a text as input. The ontology mentioned next is responsible for converting the snippet code from the Python programming language into text that humans can understand. Subsequently, this model can generate questions based on the inserted text. The software supports four types of questions, and they are as follows:

- Questions with Several Choices (MCQs)
- Boolean (Yes/No) Questions
- Open-ended Questions
- Question Paraphrase

For the current study, only open-ended questions are considered. Since learning a programming language focuses on understanding the content of a code, it is more suitable to use open-ended questions to assess student knowledge properly.

B. *Ontology Design*

The ontology is built and compiled using the OWLReady2 library in Python. Such a library would support automating manual activities like adding instances to the ontology. However, the main components and the relationships between concepts should be implemented manually to maintain logical correctness. Translating code into text starts with assigning keywords to ontology classes and describing these keywords. For example, the "=" sign is described in the ontology as an "equal sign", a value of the Assignment subclass in the operator class. The output of the ontology implemented in Python and OwlReady2 is then imported into Protégé for visualization purposes since the visualization is not yet supported on OwlReady2. Fig. 2 shows the ontology design visualization in Protégé.

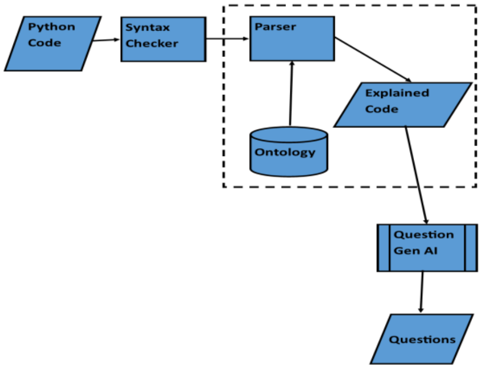

Fig. 1. Proposed framework architecture.

TABLE I. RESEARCH QUESTIONS AND CORRESPONDING RESEARCH OBJECTIVES

Name	Description
OwlReady2	Python library to implement Ontology V 0.37
Protege	Software Application for viewing and modifying ontology
Jupyter Notebook	IDE to develop the framework
QuestGen	AI-based application to generate questions from the text
Python	V 3.11.1

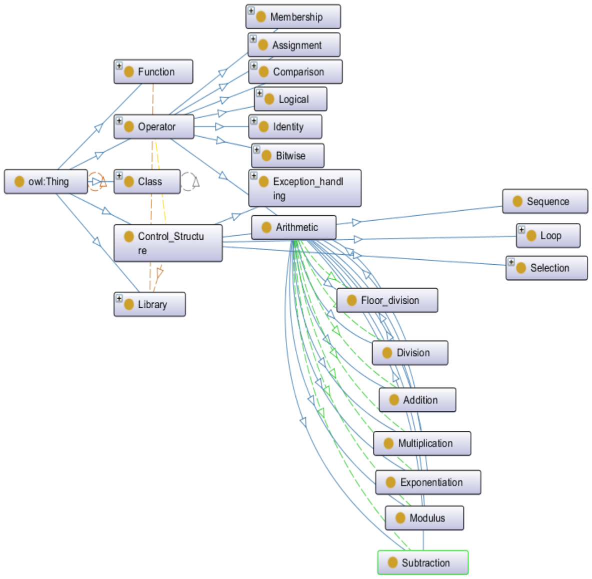

Fig. 2. Ontology design visualization using protégé.

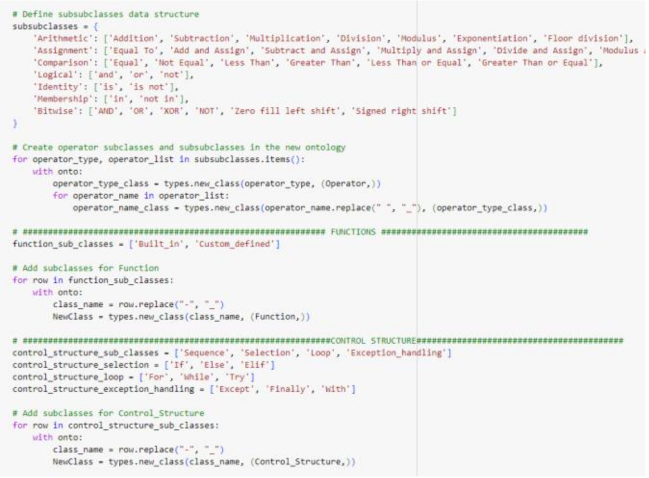
Logical correctness would enforce semantic meaning on the written script. For example, an “elif” statement syntax is valid in Python. However, it cannot exist without having an “if” statement before it. An “elif” should only be coming after an “if”. Furthermore, logical correctness would connect all the keywords and describe the semantic relationship between steps. Most essential aspects of Python programming language in the designed ontology are classified as classes and subclasses. For example, in this study, we have categorized the Python language elements and constructs into four main classes: Control Structure, Function, Library, and Operator. Each subclass of the Operator class contains several instances that would map each instance to the operator class. Such mapping would assist in enforcing the logical correctness of the translated snippet. Fig. 3 shows an instance definition from the constructed ontology. The ontology's capabilities aim to structure the Python programming language to ensure that the computer can collect vocabulary text about the keywords and build sentences based on the combination of the programming language keywords, which can be fed later into the question generation model. The main limitation is that the ontology should be built manually by adding the explanation of all instances, which can be challenging to implement. Further research is needed to improve this approach. Fig. 4 shows a part of the ontology in Python script.

```
<owl:Class rdf:about="#Subtraction">
  <rdfs:subClassOf>
    <owl:Restriction>
      <owl:onProperty rdf:resource="#has_example"/>
      <owl:hasValue rdf:datatype="http://www.w3.org/2001/XMLSchema#string">Example
usage of Subtraction</owl:hasValue>
    </owl:Restriction>
  </rdfs:subClassOf>
  <rdfs:subClassOf>
    <owl:Restriction>
      <owl:onProperty rdf:resource="#has_description"/>
      <owl:hasValue
rdf:datatype="http://www.w3.org/2001/XMLSchema#string">Description of
Subtraction</owl:hasValue>
    </owl:Restriction>
  </rdfs:subClassOf>
  <rdfs:subClassOf rdf:resource="#Arithmetic"/>
</owl:Class>
```

Fig. 3. Instance definition of subtraction.



```python
# Define subsubclasses data structure
subsubclasses = {
    'Arithmetic': ['Addition', 'Subtraction', 'Multiplication', 'Division', 'Modulus', 'Exponentiation', 'Floor division'],
    'Assignment': ['Equal To', 'Add and Assign', 'Subtract and Assign', 'Multiply and Assign', 'Divide and Assign', 'Modulus
    'Comparison': ['Equal', 'Not Equal', 'Less Than', 'Greater Than', 'Less Than or Equal', 'Greater Than or Equal'],
    'Logical': ['and', 'or', 'not'],
    'Identity': ['is', 'is not'],
    'Membership': ['in', 'not in'],
    'Bitwise': ['AND', 'OR', 'XOR', 'NOT', 'Zero fill left shift', 'Signed right shift']
}

# Create operator subclasses and subsubclasses in the new ontology
for operator_type, operator_list in subsubclasses.items():
    with onto:
        operator_type_class = types.new_class(operator_type, (Operator,))
        for operator_name in operator_list:
            operator_name_class = types.new_class(operator_name.replace(" ", "_"), (operator_type_class,))

# ############################################################ FUNCTIONS ##########################################
function_sub_classes = ['Built_in', 'Custom_defined']

# Add subclasses for Function
for row in function_sub_classes:
    with onto:
        class_name = row.replace("-", "_")
        NewClass = types.new_class(class_name, (Function,))

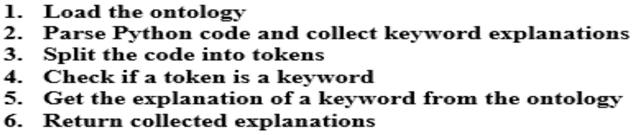
# ############################################################CONTROL STRUCTURE############################################
control_structure_sub_classes = ['Sequence', 'Selection', 'Loop', 'Exception_handling']
control_structure_selection = ['If', 'Else', 'Elif']
control_structure_loop = ['For', 'While', 'Try']
control_structure_exception_handling = ['Except', 'Finally', 'With']

# Add subclasses for Control_Structure
for row in control_structure_sub_classes:
    with onto:
        class_name = row.replace("-", "_")
        NewClass = types.new_class(class_name, (Control_Structure,))
```

Fig. 4. Ontology in python.

C. Parser

The parser's job is to detach a block of codes into pieces that can match the ontology based on keywords and custom conditions. These conditions are adjusted depending on the inserted snippets. This model uses the ontology to create sentences. It analyzes keywords in the parser and generates sentences explaining the code. For example, a=10, the parser would create “a is a variable. a value is 10”. Fig. 5 illustrates how the code parser algorithm works in the implemented system.



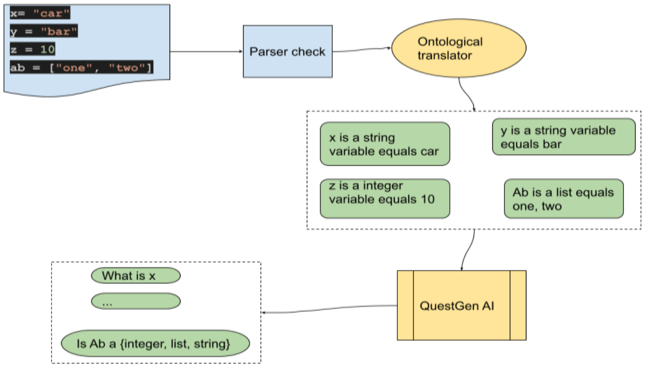
1. Load the ontology
2. Parse Python code and collect keyword explanations
3. Split the code into tokens
4. Check if a token is a keyword
5. Get the explanation of a keyword from the ontology
6. Return collected explanations

Fig. 5. Algorithm steps of the code’s parser explanation.

This parser helps turn Python code (and maybe other types later) into sentences using a set of rules. It maintains whatever logic the ontology possesses about the code. Then, it is fed into the AI model to generate proper questions based on the code interpretation by ontology. The limitation of this parser is that it might struggle with complicated code because it needs specific filters to understand the context and collect the keywords. Fig. 5 describes the steps involved in processing the input and generating results. Initially, the ontology file must be loaded into the environment using an OWL file. Subsequently, the Python source code is provided to the application, where filters extract keywords and retrieve explanations from the defined ontology. Finally, the 'explained code' is passed to the QuestionGenAI framework to generate questions.

D. Question Generation

Over time, there is a growing demand for question generation, a trend that could significantly alleviate the burden on educators and trainers. This is particularly beneficial for scalable learning formats such as online courses. Many models exist for generating questions from regular text; however, understanding code and generating questions from code snippets is not applied due to its complexity. Code-to-text conversion is a challenging task. However, the semantic relationships between the concepts in the ontology are an excellent solution. Fig. 6 shows the whole procedure to translate code into text. In Fig. 6, the code undergoes validation by a parser checker responsible for scrutinizing its syntax. Once the code is confirmed as error-free, the checker directs it to the ontological translator, acting as the parser within our architecture. This parser transforms the code into coherent sentences, forwarding them to the Question Generator AI model to generate reasonable questions. An explanation of the Question Generator AI model is provided in the subsequent section.



x= "car"
y = "bar"
z = 10
ab = ["one", "two"]
Parser check
Ontological translator
x is a string variable equals car
y is a string variable equals bar
z is a integer variable equals 10
Ab is a list equals one, two
QuestGen AI
What is x
...
Is Ab a {integer, list, string}

Fig. 6. Question-generation process.

E. QuestionGen AI

The QuestGen AI model is an AI model that can generate questions using AI. The QuestGen project is available in an open-source format [18]. The model is already trained and can generate high-quality questions based on text fed into the model. Instructors can choose the type of question that can be generated; however, we have only applied open-ended questions. The results summarized in the subsequent section show that the AI model can generate reasonable questions based on the input text and its level of clarity.

- Input: The model can process various types of input, including structured, unstructured, and context-based content such as passages, documents, and articles.
- Field of application: The model is tailored to support the education field across diverse disciplines such as science, history, language arts, and more. However, it does not have the capability to execute or generate programming language code.
- Generation method: It is a semantic-based model designed to comprehend inserted text by leveraging concepts and contextual awareness. This procedure is divided into two main steps. Firstly, it begins with entity recognition, wherein the model extracts crucial information such as dates, names, and relationships, employing part-of-speech tagging. Next, the model applies question templates to the extracted information to match the most suitable predefined question template. To improve question quality, various methods are employed, including probabilistic approaches to refine wording and phrasing within the questions.
- Question format: The model can propose various formats, including open-ended, multiple choice, true/false, and short answer.
- Response format: The responses are generated in both text and JSON formats. Each type of question has its own format. For instance, multiple-choice questions prompt the system to produce the question stem and its corresponding answer choices. This distinction applies to all question types, and the resulting output is tailored accordingly.
- Example: The sentence inserted into the model is “The Industrial Revolution was a period of significant economic and technological change that began in Britain during the late 18th century. It marked the transition from agrarian economies to industrialized ones, with advancements in machinery, transportation, and manufacturing.”
- The generated questions for a true/false type of question are:
  - 'Is the industrial revolution the same as the 'revolution?',
  - 'Was the industrial revolution a period of change?',
  - 'Was the industrial revolution a revolution in the 18th century?'

IV. Results

The results are generated in two versions, one utilizing our proposed model and the other without its use (i.e., by directly inserting the code into the QuestGen AI), as depicted in Fig. 7. The implemented framework facilitates the question-generation process, empowering teachers to automatically generate Python programming language assessment questions for testing students' knowledge. Fig. 8 depicts a straightforward code snippet featuring variable definitions. This figure illustrates specific variables alongside their assigned values, incorporated as a script within the ontology. A Python parser is employed to validate the text as proper code before generating any flawed or erroneous questions to mitigate the potential for incorrect syntax within the inserted code. Fig. 9 displays the translated text derived from the code, providing a textual interpretation for each line. The interpreter presents the variable type and specifies the assigned value for each variable. Fig. 10 showcases the outcomes resulting from inserting the aforementioned text into the QuestGen AI model. Fig. 11 can be seen without having a context. The question generator failed to produce any meaningful questions except for the list variable, where it managed to generate a relevant question. However, the AI model could not comprehend all the lines, hence the presence of the ZERO {} symbol. Fig. 12 exhibits a Python code comprising class and object definitions presented as a string and passed through an ontology to translate it into text. Subsequently, this text is fed into the QuestionGen model to generate questions. In the subsequent examples, only the generated questions and context from QuestGen AI will be showcased, omitting the complete outputs. Moving on to Fig. 13, it explains the preceding code snippet depicted in Fig. 12 using natural language, preparing it for input into the AI generator. Following this, Fig. 14 displays the questions generated from the snippet description, demonstrating the relevance of the generated questions. However, Fig. 15 illustrates the outcome of generating questions without providing a snippet description, resulting in improper questions marked by ZERO{} symbols and inaccuracies. This indicates the necessity of providing a description for accurate question generation. In the third example, depicted in Fig. 16, a function is defined to compute the area of a circle based on its radius. This code incorporates arithmetic operations and utilizes Python's 'math' module. Subsequently, Fig. 17 exhibits the output resulting from describing the aforementioned code to input into the AI model. Meanwhile, Fig. 18 displays the generated questions derived from the description of the code snippet involving mathematical operations. Conversely, Fig. 19 showcases a question generated without describing the snippet. The results depicted in all figures are formatted in JSON, containing both the question and its solution. For open-ended questions, the QuestGen model provides the answer alongside the question, excluding the options. It is worth noting that there are warnings due to deprecated libraries utilized by the QuestionGen model, prompting necessary updates by the authors.

V. Discussion

In this experiment, various code snippets were tested for translation using the proposed ontology and fed into the QuestionGen model to create open-ended questions. Table II outlines the test cases, the generated questions, and the difficulty level of the tested code. It is noticed that human evaluation of AQG results is more accurate than automatic assessments [10]. The validity of the generated code is rated on a scale of 1 to 5, where one represents the least validity and five indicates the highest validity. Difficulty is assessed based on script logic, with five denoting complexity and one representing simplicity. For instance, identifying variable assignments is relatively straightforward, while understanding inheritance is more challenging. Generating appropriate questions from sophisticated or advanced code snippets, such as those utilizing third-party libraries, still presents limitations. Composing accurate questions becomes increasingly tricky as code complexity and inter-line relationships grow. Consequently, further development is necessary to enhance outcomes. Addressing this need will lead to more advanced results. Nevertheless, this study introduces a new dimension to e-learning and supplements existing question-generation approaches that have proven effective in textual sources.

TABLE II. Types of Syntax Covered

Test case	Code level of difficulty	Generated question	Context	Generated question validity
a) Variable declaration	1	What is the value of xfoo?	xfoo is a string variable and its value is 'foo'	4
b) list declaration	2	'What are the items in the list variable ab?	'ab is a list variable and it has 2 items'	5
c) Class declaration	3	What is a person?	Person is a class definition	5
d) Instance and property initialization	4	What is a school an instance of?	'school is an instance of the property'	3
e) Variable initialization, instance initialization, property.	5	'What is var1 an instance of?'	var1 is an instance of the Person class with name 'Jane' and age 25"	4
f) Inheritance identification	5	Who does a student inherit from?	Student inherits from Person	5
g) Libraries import	4	What is the name of the module that is imported?	Imported module: math	4
h) Functions	4	What is a method definition?	area is a method definition	3
i) Variable type	4	What is r?	'r is a variable of type unknown'	4
j) Functions result	5	'What is the calculated area of the circle?	'a' represents the calculated area of the circle.	5

VI. Conclusion

E-learning has become very popular recently, notably accelerated by the onset of the pandemic. One area that has gained considerable attention among researchers is the automatic generation of questions derived from learning materials. However, the predominant focus of existing efforts lies in generating questions from textual content. This work, however, concentrates on generating questions tailored for Python programming language learners derived explicitly from code snippets found in textbooks and course materials. Leveraging ontologies, this approach demands less computational resources, enhancing the scalability of the framework across diverse systems. The proposed framework harnesses ontological mapping, associating each syntactic element with its corresponding meaning and explanation. The process involves translating code into text and subsequently feeding this translated text into an AI-based model for question generation. It aims to alleviate the burden on educators and reduce the repetition of the same questions for different groups of students. Moreover, the generated questions from code snippets serve to evaluate students' general understanding.

However, the proposed approach still has some limitations. The generation of questions relies solely on the QuestGen AI model, which can occasionally result in poorly phrased questions due to its AI nature. Additionally, the model might struggle to identify certain third-party libraries in complex code snippets. Hence, it represents an opportunity for future work to facilitate the insertion and categorization of concepts from all libraries. Finally, exploring alternative models such as GPT and expanding the framework to recursively process all imported libraries would enable a deeper understanding of complex syntactic structures. This enhancement would empower the ontology to explain code snippets better and generate more nuanced and fitting questions.

Sarasota, FL 33620, USA[2]

Abstract—**As social media usage grows in popularity, so does the risk of encountering malicious Uniform Resource Locator (URLs). Determining the authenticity of a URL can be a highly challenging task, primarily due to the sophisticated attack structure employed by phishing attempts. Phishing exploits the vulnerabilities of computer users, making it difficult to discern between genuine and fraudulent URLs. To address this issue, a self-learning AI framework is required to warn social media users of potentially dangerous links. While several anti-phishing techniques exist, including blacklists, heuristics, and machine learning-based techniques, there is still a need for improvement in terms of detection accuracy. Hence, this study proposed a novel approach to combat phishing attacks using artificial neural networks, and the main aim is to create and validate the anti-phishing technique tool for detection accuracy. Initially, the URL data is collected, followed by preprocessing and then the analysis for malicious activity using the Logistic Bayesian Long Short-Term Memory model (LB-LSTM). The observed malicious URL features are extracted using multilayer Q-learning with the CaspNet and swarm optimization models. Analysis of these features enables the identification of a malicious URL, which is then removed, and the social media user is warned. The proposed technique attained a detection accuracy of 94.33%, Area under the ROC Curve (AUC) of 98.71%, Mean Squared Error (MSE) of 5.67%, Mean average precision of 88.67%, Recall of 98.67%, and F-1 score of 94.34%.**

Keywords—Multilayer Q-learning; anti-phishing model; social media users; machine learning; optimization; URLs; logistic Bayesian LSTM model

I. Introduction

Phishing is a deceitful online practice that employs social engineering and a particular strategy to deceive individuals using the internet to obtain their personal information or critical online data [1]. Businesses across various sizes and industries increasingly recognize the imperative of investing in anti-phishing solutions to protect their most valuable asset. Phishing is a fraudulent technique used to acquire sensitive customer information, such as classified data, via deceptive emails, counterfeit websites, dubious internet-based advertisements or promotions using forged Short Message Service (SMS) messages purporting to be from reputable service providers or online organizations, and other similar methods. Recent studies have shown that individuals with a sociable and trustworthy personality are more susceptible to phishing schemes, mainly when actively participating in various social media platforms. A single instance of attack occurred on the social media platform Facebook, which enticed individuals to visit fraudulent websites designed to mimic the Facebook login page. The dissemination of the attack afterward extended to Facebook users via the promotion of acquaintances to access the hyperlink present on the original user's profile [2]. As an example, the security reports of Details and Patterns in 2017 revealed that a substantial sum of about $5 billion was stolen during the period spanning from October 2013 to December 2016. This financial loss was attributed to a W-2 phishing attempt, which affected a global population of over 24,000 individuals. W-2 phishing emails have recently been identified as one of the most dangerous kinds of phishing email scams, primarily due to their propensity to facilitate fraudulent tax filings and refund claims. Specialized deception encompasses using harmful code or crime ware, often installed on a personal computer or laptop, without the user's awareness [3]. Phishing may take several forms, including DNS poisoning, keyloggers, capturing meetings, damaging records, injecting information, etc. A new kind of malicious software called "ransomware" has emerged in recent years, allowing cybercriminals to run malicious code on a client's assets, locking them and demanding a payment "ransom" to unlock them. According to the CSO's announcement, 93% of all phishing emails nowadays are "ransomware." [4]. According to this study [5], the vast majority of victims of such crimes pay ransom demands quickly. Using Artificial Intelligence (AI) to glean information from customer files, postings, or social media and provide a timely warning is essential for fighting the phishing scourge. Though AI has promise, most current implementations need extensive client oversight, costly resources, and considerable management effort to be successful. In contrast to traditional detection and warning methods, current deep-learning systems are faster and more effective and don't need client mediation. The recent trend in Deep Learning (DL) based research has focused on extracting key highlights from text rather than conventional facts. The ability of deep-learning algorithms to effectively identify and predict concealed patterns within textual data is the primary reason why a traditional approach may struggle to detect or anticipate such patterns [6]. The highlights of this study are as follows:

- An innovative approach to mitigate phishing attacks targeting social media users through AI techniques.

- The development of a multilayer Q-learning model, in combination with CaspNet (Mul_Q_capsnet), and swarm optimization for the extraction of URL features.
- Utilizes a Logistic Bayesian LSTM model (LB-LSTM) to detect malicious behavior within social networking URLs.
- Provides warnings to social media users regarding potentially dangerous URLs.

Following is an outline of this paper. The related research is described in Section II, Section III outlines the materials and methods, Section IV describes performance analysis, Section V highlights the results and discussion of this research, and finally, final thoughts on the research work, like conclusion and future work, are listed in Section VI.

II. RELATED WORKS

In today's environment, phishing poses the Internet with the most prominent challenge it must overcome. Many researchers have worked to create services that protect users from cyberattacks by detecting and blocking phished URLs using artificial intelligence (AI) and deep learning (DL) techniques [7]. Previous studies have developed and implemented two types of phishing detection systems: list-based and AI-based phishing identification systems. The list-based study identified many factors contributing to users' susceptibility to phishing attacks, including the lack of personal computer (PC) knowledge, inadequate understanding of security indicators, susceptibility to visual deception, and limited attention. Also, study in [8] investigated the persistence of successful phishing attacks despite ongoing efforts to mitigate associated risks. The findings of their investigations indicated that even when trained to identify phishing attacks, people were vulnerable at a rate of 53%. A study in [9] indicates that client PC data, client orientation, and the client's educational level are among the primary factors influencing whether clients open phishing emails.

A study in [10] introduced a system that generates a whitelist by logging the IP addresses of websites containing a login interface that a user visits. The system issues a warning if there is any inconsistency in the recorded website information when a user accesses a site. However, this approach raises concerns regarding websites users visit for the first time. In response to this challenge, work in Reference [11] has proposed a strategy to alert users on the web by maintaining an up-to-date whitelist of reputable sites. This strategy consists of two key components: a domain-IP address-matching module and extracting link attributes from the source code. This approach is further discussed in Reference [12]. A collaborative learning approach was employed for detecting phishing attacks in emails. Substituted selection methods were used to eliminate features unrelated to accuracy, achieving nearly 100% accuracy with just 11 selected features.

Study in [13] employed the Phi DMA approach, which used five layers: URL highlight layers, lexical layer, and whitelist layer, and accomplished an accuracy of 92%. In another review [14], the examination of phishing was identified through SVM. Author in [15] proposed an outrageous learning machine, a regulated AI calculation to determine spam accounts in SinaWeibo, Chinese miniature writing for a blogging site. Alberto et al. proposed an internet-based framework to filter comments posted on YouTube [16].

In study [17], the authors presented a structure for discovering dubious conversations on web-based gatherings using a coordinated help vector machine and particle swarm optimization methodology. The study by [18] focuses on detecting harmful URLs inside web-based social networks using client behavior analysis. The authors propose a research framework that investigates and detects social spam. This framework incorporates characteristics from URLs and online social networks (OSNs), emphasizing user profiles, postings, and URL attributes. The objective is to improve the accuracy of identifying harmful activities. A confirmation of the concept enhancer method was developed in [19], effectively used for the identification of bots, and in [20] identified spam in SMPs and involved the value of features in emphasizing a higher result collection of regulations. AI techniques require an environmental input to be adjusted and moved along.

The authors in [21] highlighted that the current apps, services, and systems are at risk of cyber-attacks like malware and software piracy because of the always-on nature of the Internet. These dangers threaten not just confidentiality but also safety. Malicious software like computer viruses, ransomware, scareware, and Trojan horses, as well as more traditional forms of software piracy like hard-disk loading, client-server overuse, and internet piracy, have the potential to wipe out critical data, resulting in reputational and economic damage. Reference [22] suggests companies can comprehensively enhance their operations by emphasizing roles, processes, individual actions, business strategies, business process modeling, quality assurance, cybersecurity, accountability, and big data.

In research [23], the author used a Neural Network (NN) to examine the blunder level of 4000 bogus and 4000 genuine pictures. With a solid achievement rate, a certified neural network has figured out how to group images as misleading or valid. Feature extraction extracted 17 features from 2500 phishing URLs from the PhishTank archive [24] and divided them into address bar-based highlights, unusual-based elements, and HTML and JavaScript-based highlights. Most parts were automatically separated from the URL and the page's source code without depending on third-party services. However, the WHOIS extracted the domain's age and DNS record [25]. The Alexa database retrieved the page's ranking [26]. Concurrently, the authors outlined an IF-ELSE rule and assigned a weight to each element. The weight of a feature was established by calculating the feature value concerning the total number of phishing links. Each segment's value could be either 1, 0, or 1, representing legitimate, suspicious, or phishing [27].

III. MATERIALS AND METHODS

This section discusses novel techniques in the anti-phishing model using machine learning techniques for social media users and network optimization. The proposed architecture is shown in Fig. 1.

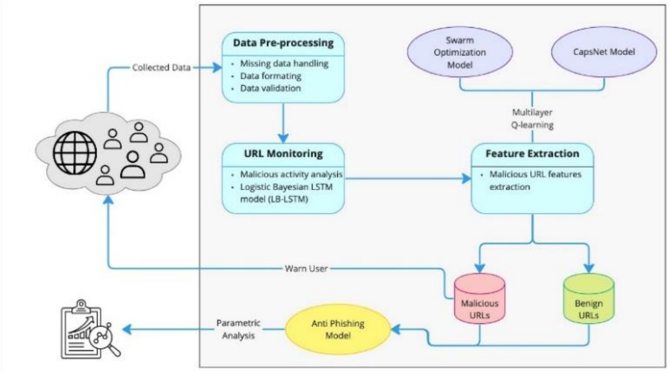

Fig. 1. Proposed Self-Learning framework for detecting malicious URLs.

A. *Data Pre-processing*

The acquired data must undergo several preprocessing steps before entering each classifier to ensure that the algorithm interprets the information correctly and selects the best approach. One of these preprocessing activities involves organizing and cleaning the data. Formatting is crucial for presenting data in a format that classifiers can understand, such as converting data types into a text file or a tabular form. The cleaning process addresses missing values in a dataset, such as missing names or values in specific data fields. It involves setting properties determined manually or by the majority vote for matching values in different instances and even removing specific examples that could negatively impact the classifier's learning process. Additionally, cleaning details refer to the removal of personal information that could compromise the privacy of specific individuals.

B. *Tokenization*

Breaking down text into its constituent parts, which can be words, sentences, or even individual characters, is known as tokenization, and the individual units are referred to as tokens. The objective here is to analyze text as a single unit. The list of tokens then becomes an interpretive response or serves as input for further sentence-based analysis. In languages where sentences are divided into segments and computer science, tokenization is crucial for reading text. Proper text tokenization is typically essential at the beginning of any text analysis process. All recognized text analysis methods rely on terms extracted from the dataset. To achieve this, a processor needs to tokenize the data. This can be straightforward when the text is in computer-readable formats. However, specific challenges may arise, such as handling punctuation marks. Other characters, such as parentheses, hyphens, and so on, also need to be managed.

C. *Logistic Bayesian LSTM Model (LB-LSTM)- based Malicious Activity Analysis*

In logistic regression, the dependent variable typically takes on a binary form, which means it has only two possible values, like 0 or 1, true or false, or yes or no. This characteristic makes logistic regression well-suited for predicting the probability of an event belonging to one of two categories: success or failure. In this scenario, a sigmoid function is commonly employed to describe the connection between the predictor variables and the likelihood of the event happening. The sigmoid function yields output values ranging from 0 to 1, effectively representing probabilities.

Consider a prototypical example with two predictors, A1 and B2. These predictors can be either constant values or binary variables, taking values of 0 or 1. The conversion likelihood W(A B) may be further divided into the acceptance probability A(A B) and the trial proposition probability T(A B), resulting in the equation W(A B) = T(A B) • A(A B). The likelihood of moving from state A to state B and the likelihood of moving in the other direction are related via Eq. (1):

$$P_A \cdot T(A \to B) \cdot A(A \to B) = P_B \cdot T(B \to A) \cdot A(B \to A) \quad (1)$$

For the likelihood for sample structure A to be equivalent to the Boltzmann weight by Eq. (2), the test plan and recognition likelihoods must be carefully selected.

$$P_A = \frac{e^{-\beta E_A}}{Z} \quad (2)$$

where, EA represents structure A's energy, since the conversion likelihoods are available using the proportion of probabilities, data for divider constant Z is unnecessary. Using Eq. (2), the detailed balancing requirement (3 may be rewritten as follows:

$$\frac{T(B\to A)\cdot A(B\to A)}{T(A\to B)\cdot A(A\to B)} = \frac{P_A}{P_B} = e^{-\beta(E_A - E_B)} \quad (3)$$

a process where all pairings of the states A, B satisfy the constraint T(A B) = T(B A). In the case of a design with N spins, for instance, it parallels picking one spin randomly from the matrix,: T(A B) = T(B A) = 1/N. Quickest if A(A B) or A(B A) is equivalent to 1, or if the larger of the two acceptance probabilities. 1 Padd is the chance of not adding an aligned spin. The complete balancing requirement may be expressed as Eq. (4).

$$\frac{T(A\to B)\cdot A(A\to B)}{T(B\to A)\cdot A(B\to A)} = \left(1 - P_{\text{add}}\right)^{m-n} \frac{A(A\to B)}{A(B\to A)} = e^{-\beta(E_B - E_A)} \quad (4)$$

Noticing that EA − EB = 2J (n − m), it follows that by Eq. (5):

$$\frac{A(A\to B)}{A(B\to A)} = \left[\left(1 - P_{\text{add}}\right) e^{2\beta J}\right]^{n-m} \quad (5)$$

Due to the constraint that a Bayesian network connected to Gi can have a maximum in-degree equal to n classes, there may be conditional probability tables with an exponential number of items in the nth category. However, this becomes impractical when dealing with issues that involve multiple types. Therefore, to address this challenge, it is necessary to reduce the maximum in-degree through the application of a structural learning technique. In real-world applications, we evaluate the Gi optimization as follows in order to shorten the arcs connecting classes to features arcs: $\mathcal{G}_i^* = \arg\max_{G,CGC} \log P(\mathcal{G} \mid \mathcal{D})$, where it's important to consider set inclusions among graphs in the arcs space, as specified by Eq. (6).

$$\log P(\mathcal{G} \mid \mathcal{D}) = \sum_{i=1}^{n} \psi_a[C_i, \mathrm{Pa}(C_i)] + \sum_{j=1}^{m} \psi_a\left[F_j, \mathrm{Pa}\left(F_j\right)\right] \quad (6)$$

Pa(Fj) represents Fj's paternities consistent with G, and Pa(Ci) defines Ci's parentages. Moreover, ψα is BDEu score with equivalent model size α. For illustration, the score ψα[Fj ,Pa(Fj)] is$\sum_{i=1}^{|\mathrm{Pa}(F_j)|}\left[\log\frac{\Gamma(\alpha_j)}{\Gamma(\alpha_j+N_{ji})}+\sum_{k=1}^{|F_j|}\log\frac{\Gamma(\alpha_{ji}+N_{jik})}{\Gamma(\alpha_{ji})}\right]$.

Finally, while j = P i ji, ji is equal to divided by the sum of the (joint) states of the parents of Fj and the number of states of Fj. All class variables share the same parents across all the graphs within the search space when considering a network associated with a specific class event, as the connections linking the class events are predetermined. This implies that the initial sum in Eq. (4) remains constant on the right side. Consequently, by concentrating solely on the attributes, we can achieve the optimization described in Eq. (3). A feature's parent set may be selected from any subset of C, which simplifies the problem into m distinct local optimizations. In reality, Eq. (7) by G establishes who Fj's parents are.

$$Bold\mathbf{C}_{F_j} = \arg_{\mathrm{Pa}(F_j)\subseteq \mathrm{C}} \max_a\left[F_j,\mathrm{Pa}\left(F_j\right)\right] \tag{7}$$

For each time j = 1, m. This is made practical by bipartite partition of class occasions as well as elements, yet much of the time, coordinated cycles might be found in the chart that expands every neighborhood score. Let k be the quantity of blend parts (i.e., the quantity of C qualities), with X being the arrangement of inquiry factors, Z being different factors. The marginal distribution of X may be calculated using Eq. (8) by adding together C and Z:

$$\begin{aligned} P(X=x) &= \textstyle\sum_{c=1}^{k}\sum_{z}P(C=c,X=x,Z=z) \\ &= \textstyle\sum_{i=1}^{k}\sum_{z}P(c)\prod_{i=1}^{\prod}P(x_i \mid c)\prod_{j=1}^{H}P(z, \mid c) \\ &= \textstyle\sum_{c=1}^{k}P(c)\prod_{i=1}^{|1}P(x_i \mid c)\prod_{j=1}^{4}\sum_{z_j}P\left(z_j \mid c\right) \qquad (8) \\ &= \textstyle\sum_{c=1}^{k}P(c)\prod_{i=1}^{M}P(x_i \mid c) \end{aligned}$$

where past equality is valid since, for any j, j 1 zj P c z like this, it is easy to dismiss non-inquiry factors Z while figuring P(X = x), and calculation of P(X = x) takes O(|X|k), paying little heed to |Z|. Bayesian organization inference, conversely, is the most pessimistic scenario dramatic in |Z|. Restrictive probabilities, successfully assessed as proportions of peripheral probabilities, should likewise be considered. P(X=x,Y=y) = P(X=x,Y=y)/(Y=y) The combination of trees, where every variable in each bunch is permitted to have one extra parent notwithstanding C, gives somewhat more extravagant model than naïve Bayes while as yet taking into consideration productive inference.

The computation involved is about the probability $(P_1^-, P_2 \dots P_n)$ when $X(x_1, x_2 \dots x_n)$ belongs to $C_1, C_2 \dots C_n$, with $P_j X(x_1, x_2 \dots x_n)$ being the probability when $X(x_1, x_2 \dots x_n)$ belongs to C_j . Then max $(P_1, P_2 \dots P_n)$ is demanded result.

$$P\left(C_j \mid x_1, x_2 \dots, x_n\right) = P(x1, x2, \dots, x_n \mid C)P\left(C_j\right) \tag{9}$$

According to this formula, P(Cj) is the posterior probability that Cj includes text vector (x1,x2... xn) when the text to be categorized belongs to Cj and P(x1,x2... xn|Cj) is the prior probability when text belongs to Cj. As a result, max (P1,P2,...,Pn) is the highest value possible for the following Eq. (10):

$$\underset{x_t}{\arg\max}\, P\left(C_j \mid x_1, x_2 \dots, x_n\right) \tag{10}$$

The qualities (x1,x2,...,xn) are assumed by Bayes to be independent of one another. The product of the probabilities for each attribute is then the joint probability. Thus, Eq. (11) is the final classification function.

$$\underset{x_t}{\arg\max} P(x1, x2, \dots, x_n \mid C)P\left(C_j\right) \tag{11}$$

In this formula, $\frac{N(X_i=x_i,C=C_j)+1}{N(C=C_i)+M}$ is amount of text in training set that belongs to Cj, and N is total amount of text in training set. $P\left(x_i \mid C_j\right) = \frac{N(X_i=x_i,C=C_j)+1}{N(C=C_i)+M} N(X_i = x_i C = C)$ is the amount of text that has Cj's attribute xi, N(C=Cj) is amount of text that belongs to Cj, and M is text vector's dimension. Naive Bayes classifier's core design process, where two areas have been enhanced, is described above.

Typically, when presented with a microarray picture, we are unsure of which category it belongs to, hence the fairness principle demands that the text obtain the same prior probability for each group. Since there are differing amounts of text types in training sets, treating the prior probability differently is unjust and illogical. As a result, it makes sense to evaluate prior probability computation and apply the same prior probability instead. The classification function Eq. (12) shown below can therefore be obtained:

$$C_j \in Ci = 1\prod_{i=1}^{n} P\left(x_i \mid C_j\right) \tag{12}$$

Omitting the computation of prior probability can significantly accelerate the calculation, but it does not affect the final grouping result because the maximum probability is required. The proposed model uses a two-valued constant to store the subsequent likelihood. Sometimes, the sentence that needs to be categorized is lengthy, which increases the sentence's dimension vector and decreases the subsequent likelihood. Additionally, reproducing the probabilities of all potentials may lead to inaccurate transmission. This can be corrected by reproducing the subsequent likelihood of each feature property. This will not affect the experiment's findings since what matters in the end is comparing probabilities between categories, and multiplying probabilities is logical. Initially, we expanded ten times, but throughout the research, we found that the subsequent likelihood would occasionally fall outside the range of the two-valued constant, significantly impacting the experiment's outcomes. We added an enlargement feature K to the function to reduce the impact of inaccurate propagation. The following optimization Eq. 13 and Eq. 14 are optimized to evaluate the load and bias values.

$$\min_{w,b,\xi} \frac{1}{2} ww^T + C\sum_{i=1}^{n} \xi_i \tag{13}$$

$$\text{subject to} \begin{cases} y_i(w^T\phi(x_i) + b) \geq 1 - \xi_i \\ \xi_i \geq 0, i = 1, \dots., n \end{cases} \tag{14}$$

$\phi(x_i)$ – other dimension data points have been transferred. ξi- represent slack variable and these variables direct observations in the direction of the margin. Regularization is defined by C.

In this study, LSTM networks are utilized to create base models. Fig. 2 displays the construction of our base learner models using LSTM. Our deep LSTM network consists of multiple hidden layers, with a sequential input layer and two LSTM hidden layers added between the input and output layers. Each hidden layer consists of multiple memory cells and fully connected dense layers. We incorporate multiple LSTM and dense layers to construct a more precise, robust, expressive deep network for URL classification. The LSTM strategy takes URLs as input without requiring manual element extraction.

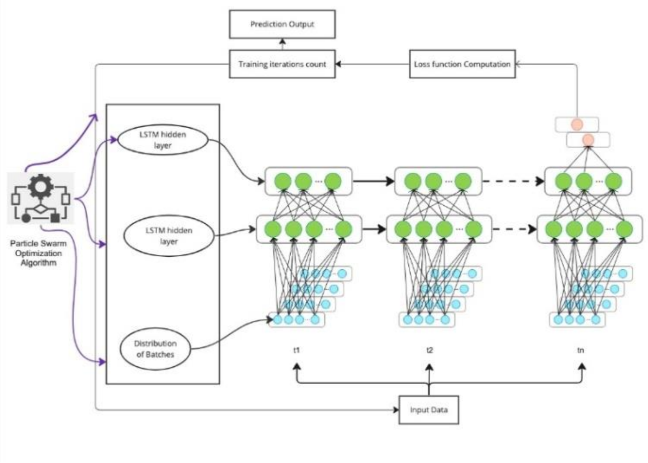

Fig. 2. Structure of the proposed LSTM model of the system.

The LSTM algorithm automatically processes the sequence of characters found in the URL. URLs are initially subjected to a tokenization process, where each unique character in the sequence is assigned a specific number, thereby converting the URL into tokens. These resulting token lists serve as inputs to the LSTM base models. The output layer makes predictions regarding the final outcome, specifically whether the URL is associated with phishing. We conduct experiments to determine the optimal number of LSTM units, the number of neurons in each dense layer, and the number of dense layers in each network. The models are fine-tuned by varying the number of epochs.

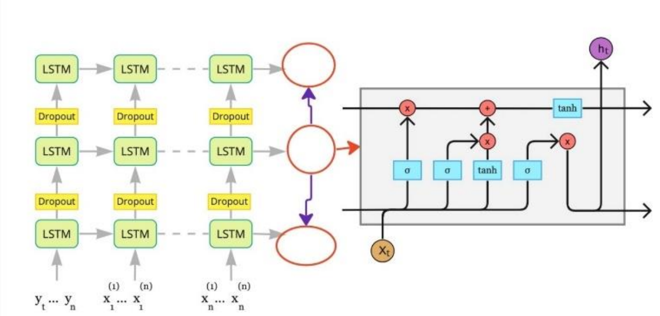

Fig. 3. Logical structure of the proposed LSTM model of the system.

Fig. 3 illustrates the proposed methodology. The first phase involves creating and training n LSTM models, each using a distinct subset of the training data. In the subsequent stage, a collection of records is supplied as input to each model for testing purposes. The models are tasked with predicting the classification of each respective test record. The proposed ensemble LSTM model utilizes a voting approach for generating predictions. Essentially, the class assigned by the ensemble model is based on the majority of votes received from the individual models for a given test record.

For instance, if five LSTM models trained on distinct subsets of training data are provided with a particular test record, and four of them predict the record as "phishing" while the remaining one predicts it as "legitimate", the ensemble method would predict it as "phishing" using the voting approach since it was the majority prediction among the individual models. Algorithm of the proposed model is given below.

Algorithm 1: Phishing Detection with LB-STM, CaspNet, and Swarm Optimization

```
Input: Social media URL data
Output: Warning for potentially dangerous links
Initialize:
    • URL data collection module.
    • LB-LSTM model for malicious activity analysis.
    • Multilayer Q-learning with CaspNet and swarm
      optimization models for feature extraction.
    • Anti-phishing tool for social media users.
Main Loop (URL Analysis):
for all URL ∈ SocialMediaURLData do
    Preprocess URL data:
      preprocessed data ← Preprocess(URL)
    Extract features using multilayer Q-learning,
    CaspNet, and swarm optimization:
      q  features ←
          MultilayerQlearning(preprocessed_data)
      caspNet features ←
          CaspNet(preprocessed_data)
      swarmOpt_features ←
          SwarmOptimization(preprocessed_data)
    Combine extracted features:
      Combined  features ←
        [q_features, caspNet_features,
         swarmOpt_features]
    Analyze malicious activity using
      LB-LSTM model:
      maliciousness ←
      LB-LSTM(combined features)
    if maliciousness > Threshold then
        Remove the URL and warn
        the social media user
    end if
end for
```

D. Swarm Network Optimization

The Particle Swarm Optimization (PSO) is a system that utilizes particles traveling at a certain speed in a swarm or population to explore potential solutions and address each competitor arrangement. The system is made up of two stages: the preparation stage and the location stage. During the preparation stage, various legitimate and phishing websites are utilized to create and construct a sophisticated recognition model. Initially, 11055 websites are divided into twelve distinct categories based on the characteristics derived from the website's address bar. Additionally, six categories are established based on anomalies, five categories pertaining to HTML, and classifications dependent upon JavaScript.

Furthermore, the website's domain is used to classify seven distinct groups.

To determine the weightings to apply to specific website qualities, the suggested technique employs Particle Swarm Optimization (PSO). This practice is used due to the unique importance and varied contributions of each feature in identifying phishing websites. The PSO method accurately identifies phishing websites by computing the weighted sum of webpage properties. This practice guarantees that essential information is included in the artificial intelligence computations. In order to optimize the efficacy of artificial intelligence (AI) models, the technique of component biasing is used. This methodology assigns diminished weights to traits of lesser influence while attributing more significance to pivotal features. This stands in contrast to component selection techniques that completely neglect less relevant features.

It is anticipated that component weights will be represented as real numbers falling within the [0, 1] range. In accordance with the Particle Swarm Optimization (PSO) algorithm's recommended feature weighting, these values will indicate the relative importance of website characteristics. The number of features to which weights are assigned in the PSO is determined by the dimensionality of each particle.

Consider a scenario where 'n' feature weights are encoded in PSO particles according to the suggested PSO-based feature weighting method. In this setting, the 'nth' component and any supplementary features have a disproportionate weight, whereas the principal feature has less sway. However, the 'third' and 'n-1st' properties are deemed unnecessary when developing reliable forecasting models. A novel method for feature weighting, employing Particle Swarm Optimization (PSO), has been introduced. PSO entails a swarm of particles exploring diverse feature weight configurations. Each particle moves with random speeds and angles, characterized by a unique position representing the assigned weights for various features. These weights are encoded as real values within the range of zero to one.

Once the initial particle swarm is established, each particle's fitness is assessed based on the accuracy of feature characterization. PSO evaluates the well-being of each particle by initially determining the characterization accuracy and utilizing the weighted attributes of the particle for constructing the AI model from the training data. The objective of the PSO's health evaluation is to identify the best position for each element (pbest) as well as the best position for the entire swarm (gbest). If the values of interest surpass the individual health benefits of previous pbest and gbest, the current pbest and gbest will be updated. Each particle then appropriately adjusts its speed and position according to the updated pbest and gbest. This process is iterated until PSO optimizes the most prominent features. Ultimately, PSO yields the gbest, which contains some of the best feature weights achievable within the swarm.

Next, six commonly used AI algorithms are generated using a training dataset with features weighted through PSO's feature weighting process. The dataset, enriched with components weighted by PSO, is harnessed to construct various machine learning models, including Backpropagation Neural Networks, Support Vector Machines (SVM), k-Nearest Neighbors (k-NN), Decision Trees (DT), Random Forests (RF), and Naïve Bayes classifiers (NB). These pre-trained models are developed and stored according to the specifications necessary for the effortless identification of new phishing websites.

A thoroughly evaluation is conducted using a recently collected dataset to gauge the effectiveness of the developed methods for detecting phishing websites. The primary objective is to determine the most vital components within the testing dataset. These elements include properties related to HTML and JavaScript, characteristics of the address bar, attributes based on geographical regions, and features linked to anomalies. The rigorous method of extracting features is crucial in developing accurate website models.

Subsequently, weights are applied to the characteristics in the testing dataset based on the optimum values generated from the PSO algorithm during the preparation step. This critical step significantly improves the accuracy of phishing website detection. PSO-weighted characteristics are added as input variables into the phishing site detection models created in the preliminary phase when considered necessary. These models are then used to determine if a website fits the requirements for being classified as a phishing site.

In conclusion, the performance of phishing site detection models incorporating proposed PSO-based feature weighting is evaluated and compared to standalone models.

IV. Performance Analysis

The main goal of this research is to evaluate how effectively organizations can combat phishing attacks by utilizing artificial neural networks. Our objective is to design a machine-learning-based anti-phishing technique that can be easily integrated into social media platforms. To achieve this, we gather social media URLs and analyze them using the logistic Bayesian LSTM model (LB-LSTM) to identify any malicious activity. We use a combination of multilayer Q-Q learning with the CaspNet (Mul_Q_capsnet) and swarm optimization models to extract features that are indicative of malicious URLs. Any URLs that exhibit these features are then flagged and removed to ensure the safety of users.

Testing the proposed framework presents a significant challenge, as a globally recognized dataset is not readily available. To tackle this issue, we have undertaken the task of generating our own dataset. The dataset included in this study consists of 73,575 URLs, selected based on their considerable size and lack of device restrictions. The dataset contains 37,175 URLs classified as phishing and 36,400 URLs classified as legal. In the experimental configuration, we used a random assignment strategy to allocate 75% of the dataset for training purposes, while the remaining 25% was put aside exclusively for classification testing. To conduct a thorough assessment of the efficacy of our methodology, we used a range of measures, including accuracy, recall, and F-measure. It is important to note that each classification Algorithm was developed and tested independently for user-based features. In the same way, each classifier is trained and tested separately for content-based characteristics.

A. Dataset

As previously discussed, in our efforts to obtain a reliable dataset for assessing the proposed framework, we faced challenges in finding one that fulfilled our standards. Thus, it was crucial to create a strong and extensive dataset. To accomplish this, we concentrated on gathering two distinct sets of URLs - legitimate and phishing - to ensure a well-rounded and thorough dataset. For the phishing URLs used in this research, our primary source was PhishTank (2018). However, it's worth noting that PhishTank does not provide a free dataset. As a result, we implemented a script to systematically acquire a substantial volume of rogue website addresses. At the same time, we collected authentic websites. The Yandex Search API proved to be invaluable in this regard (YandexXMLYandex Innovations, 2013).

To obtain a collection of web pages with minimal risk of phishing, we first created a specific query_word_list and then utilized the Yandex Search API to retrieve the top-ranked pages. This method was chosen due to the transient nature of malicious URLs, resulting in lower rankings by search engines. Our efforts resulted in a comprehensive dataset of 73,575 URLs, now available online for fellow researchers. This dataset includes 37,175 phishing URLs and 36,400 legitimate URLs, ensuring a well-rounded evaluation.

B. Feature Analysis Based on NLP (Natural Language Processing)

By utilizing information preprocessing as detailed in previous sections, separating a few unmistakable features can be made simple. These features are extracted using Natural Language Processing (NLP) techniques that rely on the English language. For optimal efficiency, features are currently extracted based on the English language but can easily be adapted to any language. The selection and design of these features are minor issues, and most works focused on phishing detection use various feature lists based on their algorithms. Our chosen feature list primarily includes the need to parametrize the URL of the webpage, meaning that the text-based web address should be broken down into the words it contains. However, this process is not a simple task as a web address can contain several concatenated texts, making it difficult to find each word. To address this, the URL is parsed, and certain unique characters are considered, such as ("?", "/", ".", "=", and "and"), to rot the text.

The last character is particularly favored by attackers to convince victims that it is a legitimate webpage. Attackers use various tactics to deceive users, including using publicly-known brand names like Apple, Google, Gmail, Oracle, or specific keywords such as login, secure, account, server, etc., depending on the type of attack or targeted website. Therefore, in addition to the features proposed in previous literature, we defined several additional elements for detecting phishing websites. Although this number is not excessive, it is necessary to apply a feature reduction tool when using NLP, either alone or in combination with other techniques.

C. Word Vectors

Converting words into vectors is a popular approach for identifying key features, such as text handling or text mining techniques. Our system connects with the URL of a webpage, which is essentially a message composed of many words. Rather than manually modifying these words, a programmed vectorization technique is preferred. To accomplish this, we use the "StringtoWordVector" feature of Weka to convert each URL into a word vector. Once the linked vectors are obtained, the selected AI algorithm can easily utilize them. In the suggested framework, we tested 73,575 URLs and extracted 1,701 word highlights during the vectorization process.

To reduce the number of highlights, we utilized a component reduction system that employs the "CfsSubsetEval" method - an algorithm for element determination that utilizes the best first pursue technique. This lowering tool has reduced the number of necessary highlights from 1,701 to 102 in the rundown.

V. Results and Discussion

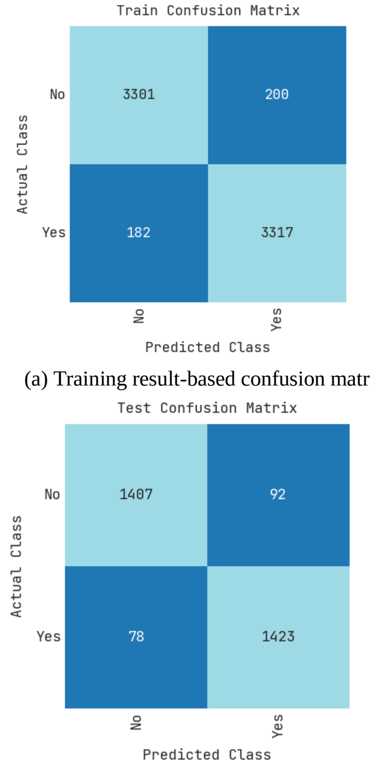
A. Results

Finding a widely recognized dataset was one of the most difficult challenges we encountered when evaluating our suggested methodology. We couldn't find one, so we made our own. This dataset has 73,575 URLs and was selected owing to its massive size and absence of a test gadget restriction. The collection contains 37,175 phishing URLs and 36,400 trustworthy URLs. Our tests were conducted on a MacBook Pro with a 2.7 GHz Intel Core i5 CPU and 8 GB of 1867 MHz DDR3 RAM. We used Weka and numerous readymade libraries to test our system. We used 10-fold Cross-Validation and the default limit possible gains of all computations during the testing. In addition, each test set was run using seven distinct simulated intelligence algorithms. We created a confusion matrix for the tested learning algorithms and eventually found the optimal test type, whether NLP-based features, Word Vectors, or Hybrid. Table I shows the parametric study results of the suggested anti-phishing model in terms of Detection accuracy, AUC, MSE, Mean average precision, Recall, and F-1 score. Both the training and test data are analysed when the parameters are adjusted. Fig. 3 is a confusion matrix illustrating the identification of malicious URL detection.

Table I shows the parametric study results of the suggested anti-phishing model in terms of Detection accuracy, AUC, MSE, Mean average precision, Recall, and F-1 score. Both the training and test data are analysed when the parameters are adjusted. Fig. 4 is a confusion matrix illustrating the identification of malicious URL detection.

TABLE I. PROPOSED ANTI-PHISHING MODEL-BASED PARAMETRIC ANALYSIS

Metrics	Training results	Testing results
Detection accuracy	94.54	94.33
AUC	98.55	98.71
MSE	5.46	5.67
Mean average precision	89.09	88.67
Recall	98.54	98.67
F-1 score	94.54	94.34

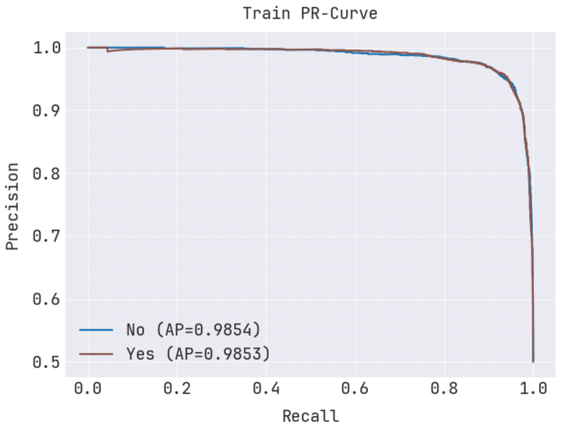


(a) Training result-based confusion matrix.

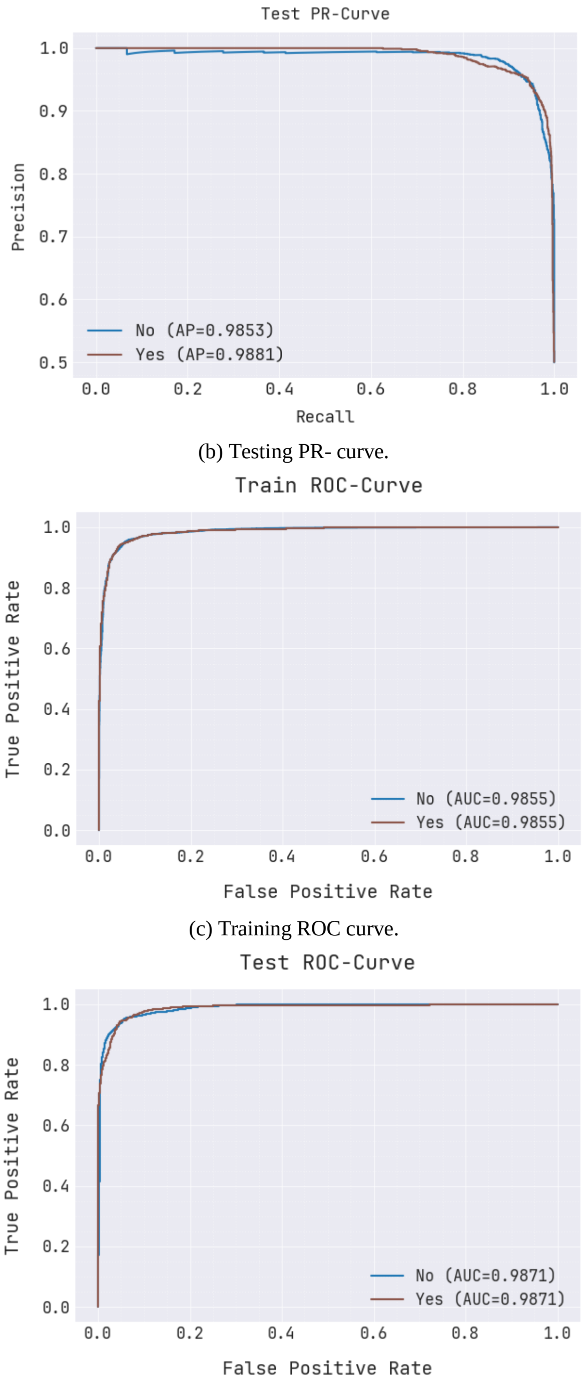
(b) Test result-based confusion matrix.

Fig. 4. Proposed model-based malicious URL detection based on confusion matrix for (a) training results, (b) Test results.

The precision-recall and ROcurve result for the proposed model is shown in Fig. 5, as determined by both training and testing. These results are analyzed based on the true positive and false positive rates, which are determined by the model's confusion matrix.



(a) Training PR- curve.



(b) Testing PR- curve.

(c) Training ROC curve.

(d) Testing ROC curve.

Fig. 5. Training and testing result analysis based on PR and ROC curve.

The proposed analysis, utilizing the training and testing results is shown in Fig. 6.

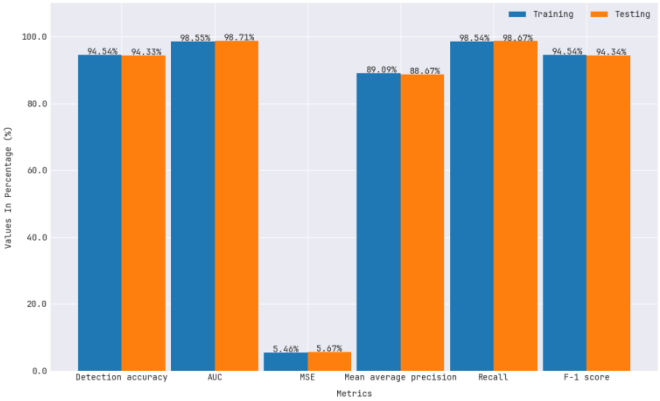


Fig. 6. Proposed training and test result analysis.

From the above figure, the proposed technique attained Detection accuracy of 94.54%, AUC 98.55%, MSE of 5.46%, Mean average precision 89.09%, Recall of 98.54% and F-1 score of 94.54% for training results; for testing results proposed technique attained Detection accuracy of 94.33%, AUC 98.71%, MSE of 5.67%, Mean average precision 88.67%, Recall of 98.67% and F-1 score of 94.34%.

TABLE II. ANALYSIS BETWEEN PROPOSED AND EXISTING TECHNIQUE

Metrics	SVM_RNN	DBM_SAE	Proposed_ LB-LSTM_ Mul_Q_capsnet
Detection accuracy	87.23	91.8	94.33
AUC	92.1	95.2	98.71
MSE	10.56	8.74	5.67
Mean average precision	81.45	86.23	88.67
Recall	91.34	95.22	98.67
F-1 score	87.66	92.33	94.34

Table II shows analysis of the anti-phishing model in terms of Detection accuracy, AUC, MSE, Mean average precision, Recall, and F-1 score.

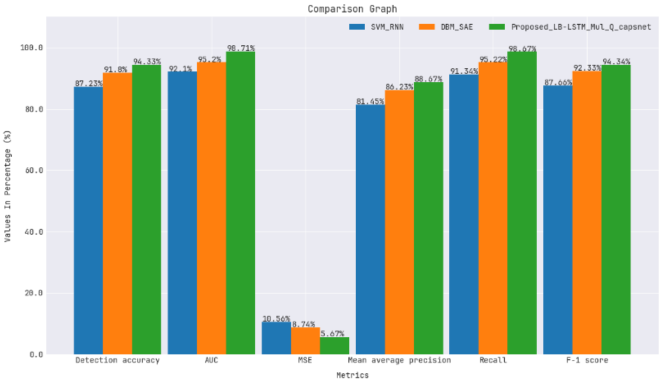

Fig. 7. Comparative analysis for anti-phishing model.

Fig. 7 analysis is shown. The proposed technique attained a Detection accuracy of 94.33%, AUC of 98.71%, MSE of 5.67%, and Mean average precision of 88.67%, Recall of 98.67%, and F-1 score of 94.34%, while existing SVM_RNN attained Detection accuracy of 87.23%, AUC 92.1%, MSE of 10.56%, Mean average precision 81.45%, Recall of 91.34% and F-1 score of 87.66%; DBM_SAE attained Detection accuracy of 91.8%, AUC 95.2%, MSE of 8.74%, Mean average precision 86.23%, Recall of 95.22% and F-1 score of 92.33%.

B. Discussion

The anti-phishing technique presented here has shown impressive results, highlighting significant progress in terms of detection accuracy, Area under the ROC Curve (AUC), Mean Squared Error (MSE), Mean Average Precision, Recall, and F-1 score. Upon closer analysis of the methodology and results, several important factors come to light. Although the proposed solution based on Natural Language Processing (NLP) is generally effective, there is a concern regarding its ability to detect pages with a single-space name, like "www.testbank.com." Phishing attacks frequently take advantage of differences in URLs, and the model's inability to address this particular situation could limit its efficacy in real-world scenarios. In a typical phishing attack, the page is designed to appear legitimate, and attackers attempt to conceal their extended URL by using unusual words to deceive customers. Customers who are already aware of phishing attacks tend to look for shorter URLs. Tests show that straight or probabilistic AI models like support vector machines and linear regression perform poorly overall. On the other hand, tree-based models significantly improve the identification of phishing URLs and produce highly effective and significant results.

The study recognises the ever-changing nature of phishing attacks, but it does not extensively explore how well the model can adapt to these evolving tactics. Phishing techniques are always evolving, so it's important to evaluate how well the suggested technique can adjust to new threats and consistently detect them accurately in the long run. The study does not thoroughly address the importance of user awareness and education in relation to the proposed anti-phishing tool. Although the model is effective, it is crucial to prioritize user education to combat phishing attacks effectively. Considering this aspect would offer a more comprehensive approach to cybersecurity. The success of the model is greatly influenced by the calibre and variety of the training data. If the training data lacks diversity or does not accurately reflect various phishing scenarios, the model may face challenges in effectively applying its knowledge to real-world situations.

Staying Ahead of Changing Threats: Phishing techniques are always changing, and attackers are constantly finding new ways to get around detection mechanisms. It is essential for the model to be able to adjust to new phishing trends and variations in order to ensure its long-term effectiveness.

Implementing deep learning models, especially those with intricate architectures such as Logistic Bayesian Long Short-Term Memory (LB-LSTM), can require significant computational resources. Deployment on platforms with limited resources, such as mobile devices, can present challenges. False Positives and User Experience: Excessively sensitive models can produce false positives, incorrectly identifying valid URLs as malicious. This may result in a subpar user experience and a decrease in trust in the system.

Striking a balance between achieving accurate detection and minimising false positives can be quite challenging.

VI. Conclusion

Phishing attack is a serious threat to any organization, as it preys on individuals' independent decision-making. Responding promptly and effectively to phishing attacks is crucial for maintaining a secure business environment. Since employees are often the primary targets of phishers due to their unpredictable online behavior, sophisticated attackers know how to bypass logical reasoning and take a more deceptive approach. This paper investigates current strategies for detecting phishing web pages using machine learning. Furthermore, this study aims to enhance the efficiency and effectiveness of phishing datasets by employing feature selection methods. Feature selection is used to optimize an up-to-date phishing dataset and expedite the model-building process. The study utilizes the logistic Bayesian LSTM model and feature extraction to assess malicious behavior, with Multilayer Q-learning and the CaspNet (Mul_Q_capsnet) model with swarm optimization applied in the process. The proposed method achieves impressive results, including an F-1 score of 94.34%, an AUC of 98.71%, an MSE of 5.67%, an MPP of 88.67%, an RPP of 98.67%, and a detection accuracy of 94.33%. Future research could focus on changes in user behavior and evaluating the significance of account suspensions as a parameter by collecting new data once these regulations have reached a stable state. Additionally, researchers could categorize the various Arabic dialects used on social media platforms, and our methodology could be extended to other popular Online Social Networks (OSNs) such as Facebook and Instagram. We will further explore the ability of the proposed technique to handle large datasets and real-time scenarios. Discover various deployment strategies for seamlessly integrating the model across multiple social media platforms, ensuring comprehensive protection for all users.

Authors' Contributions

Each author made valuable contributions to the conception, validation, formal analysis, and initial draft writing of the study. A.I.K. and B.U. were responsible for the methodology, investigation, and visualization, with B.U. also providing oversight and contributing to the writing, review, and editing. All authors have reviewed and approved the final version of the manuscript for publication.

***Abstract*—Mobile medical applications (MMAPPs) are one of the recent trends in mobile trading applications (Apps). MMAPPs permit users to resolve health issues easily and effectively in their place. However, the primary issue is effective usability for users in maps. Barely any examination breaks down usability issues subject to the user's age, orientation, trading accessories, or experience. The motivation behind this study is to decide the level of usability issues, concerning traits and experience of versatile clinical clients. The review utilizes a quantitative technique and performs client try and hypothetical insight through the survey by 677 members with six distinct assignments on the application's point of interaction. The post-try review is finished with concerning members. The Response surface method (RSM) is used for perceptional and experimental designs. In each case, participants are divided into 13 runs or groups. Experimental groups are involved after checking the perceptions about theoretical usability for different attributes according to the usability model through the questionnaire. The difference is recorded between the perception of users about usability (theoretical usability) and actual performance for usability. The study analyzed through Analysis of variance (ANOVA) that there is a need to improve mobile medical applications but it is also recommended to minimize the gap between the perception level of laymen and the actual performance of IT literate users in context with usability. The experimentation measures the tasks usability of various mobile medical applications concerning their effectiveness, efficiency, completeness, learnability, memorability, easiness, complexity, number of errors and satisfaction. Every design model also produces a mathematical expression to calculate usability with its attributes. The results of this study will help to improve the usability of MMAPPs for users in their convenient context.**

***Keywords*—ANOVA; completeness; efficiency; effectiveness; perceptional usability; response surface methodology; actual usability**

I. INTRODUCTION

A software program called a mobile application is created to operate on a mobile device, like a smartphone or tablet. The use of smartphones has expanded in many environments like banking, education and gaming including healthcare with many potential and real-life benefits. The younger generation becomes technically competent medical professionals. According to statistics, more than 36% of the world's population was using smartphones in 2018, up from about 10% in 2011. As the 2020 analysis shows, one of the Asian countries has approximately 82 million Internet customers, and the industry will exceed US$10 billion. In third-world countries, the proportion of individuals who own a mobile phone is even higher (75%) [1].

In January 2021, there were 61.34 million online customers in third-world countries. As of January 2021, the country has 173.2 million mobile associations. From January 2020 to 2021, the quantity of cell phone users in the nation expanded by 6.9 million (+4.2%). January 2021. In January 2021, the quantity of public compact affiliations is identical to 77.7% of the complete populace [2]. From a usability point of view, medical institutions have introduced the use of Internet technology to meet the needs of patients and improve their services, but this phenomenon is still in its infancy [3]. The most popular Internet service is the mobile medical application. Usability plays a significant part in the product improvement process. In the field of Human-Computer Interaction (HCI), the most generally acknowledged meaning of usability is that proposed in ISO 9241-11: "the degree to which a client can utilize an item to accomplish exact goals with efficiency, effectiveness and satisfaction in a setting of determining use ". Then again, in the field of software development, the most generally acknowledged meaning of usability is that proposed in ISO 9126-1 [4] "the capacity of the product item to be perceived, learned worked and alluring to the user when utilized under determined conditions ". Starting here in view, usability is considered a particular element that influences the nature of a product item; it doesn't be guaranteed to infer client interaction with the framework since it is very well may be estimated as "consistency to the determination". After indulging the efficiency, effectiveness, learning ability, reliability, safety, error-freeness, enjoyment and other factors of MMAPPs, it is of great benefit to provide a new and convenient way for the online mobile medical field [5]. Most of the users feel uncomfortable and dissatisfied with online medical treatment and consultation because MMAPPs are may not user-friendly. This is a new concept in developing countries such as Asian countries. Usability is also described as "the degree to which a specified customer can use a product to achieve specified goals in a pre-defined usage setting with feasibility, productivity, and realization" (ISO 9241-11, 1998) [6].

Health is wealth; this is an important lesson, especially considering the recent coronavirus outbreak. This deadly virus spread so fast that the entire city was abandoned to maintain it. This virus tells us that the study needs to connect the health system, and need to be more technically focused on identifying and treating such diseases without going outside in public places with the help of MMAPPs. Most of the functions performed by mobile medical apps are checkup waiting time, online patient evaluation, feedback, medical history, self-medication, first aid information, guidance to reach the hospital, simple payment method/simple payment, run-time diagnosis after entering symptoms, and variety of input methods (as this is the case of the patient), check the availability of specialist through cloud computing, sample collection facility, find a doctor, and set an appointment for a doctor. The most irritating thing is the hanging tight for specialists or the clinical benefits. According to the occupied cycle, the people groups can't bear the cost of hanging tight for the specialist or clinical benefits. Giving this information will show on the profile of the specialist how long you should hold back to get inspected or get any clinical benefit according to my perspective this one is the more charming element. MMAPs can achieve this after providing all functionalities [7].

This paper discusses the usability of mobile medical apps, reviews the literature, and discusses usability models, features, selections, and user-centered models. It includes research methodology, questionnaire selection and sampling, Central Composite Design I and RSM Experimental Design II results, compares the results, analyzes them and concludes with implications.

A. Contributions

- The study provides the ANOVA-based usability evaluation of mobile medical apps.
- The study calculates the perceptional usability and actual usability of mobile medical apps.
- The study provides the usability calculation formula with nine attributes of usability which can be used to calculate the usability of any of the mobile medical apps.

II. Literature Review

The study explains the speedy growth of mobile users, there's an outstanding boom in mobile software users. Therefore, the preservation of cellular users and producers of mobiles increases processing power, storage, functionalities and offerings. Now there may be a task for builders, software program engineers and interface designers to play their element in context with usability to retain cell utility users. The motive is that every category of cellular packages like enterprise apps, schooling apps, leisure apps, clinical apps, Travel apps, software apps and social media apps has its own practical and non-functional needs [8].

The usability analysis of mobile apps is executed on the idea of the four maximum popular attributes which can be efficiency, effectiveness, usefulness, and accuracy. Analysis of this study explains that usability evaluation of some other cellular utility may be carried out with the help of these four characteristics only [9].

The given examination evaluation suggests that social elements are extra effective in the reputation and usability of cellular packages. The have a look at is restrained due to the fact carried out only extracted facts of crowd sourced web packages. Due to human computations and tiny date units from only new jobs, validity and verification are sometimes jeopardized [10].

Its first degree used a user-targeted layout for customer's duties; the second degree examined usability with laboratory settings and third level usability assessment was performed in a real-world environment. As a result, it offers many usability evaluation strategies. Mobile utility builders can select first-class one or extra in keeping with the scenario [11].

The research evaluated the usability of mobile apps using 36 criteria to create applications that are centred around people. This look used three methods for reliable assessment; the methods are QUIM, mGQM, and GQM. According to participating specialists, the effects performed from this assessment are dependable and validated with the help of metrics [12].

The paper explains that cell applications need extra attention as compared to large display computers like laptops or desktop systems since mobiles have a small screen with ongoing warnings. It would be ideal for it to be simple and more clients lovely. A limit of the cell programs is assessed in a usability setting with ascribed productivity of one hundred%, adequacy of 96%, and pride of 87%, yet memorability, learnability, straightforwardness and mental burden are not assessed [13].

As per an examination, clients of portable and its programs developing quickly as there are 4.57 billion cell phone users. Those buyers use 175 billion projects/. This investigation presents the UCD form with usability credits as viability, execution, pride, understandability, blunders, and availability [14].

According to the report, most developers don't pay close attention to usability factors like accessibility and learnability most of the time. Mostly smart software engineers and interface designers are involved with effectiveness and satisfaction however they are not with user-side error safety Hamid et al. [15]. It also discusses 27 problems of usability, suggestions for them, and guidelines for those issues so that it will be beneficial for developers and researchers [16].

This study investigates the usability evaluation process of mHealth apps using a Systematic Literature Review. Results show that a mixed-method approach can improve reliability and satisfaction. The study encourages developers to design more user-friendly applications, especially for older adults and novice users, to improve the effectiveness of mHealth apps [17].

The study presents a methodological approach for developing a usable mHealth application using a three-level stratified health information technology usability evaluation framework. The methodology includes a card sorting technique for user-task guidance, end-user testing and heuristic evaluation with experts, and real-world evaluation after a three-month trial. The case study illustrates the use of these methodologies. The three-level usability evaluation was used to explore user interactions, refine app content, and use a stratified health IT usability evaluation framework for mHealth app design, development, and evaluation, providing methodological recommendations for future studies [18].

III. Methodology

The motivation behind this exploration is to investigate and foster comprehension of basic worries blunder-free, disappointment-free, more usable and best executable m-medical applications because the patient can't afford any misconception due to horridness [19]. This Idea will be founded on quantitative request. It is the orderly experimental examination of detectable peculiarities employing measurable, numerical, or computational techniques [20]. This examination contrasts client thinking with comprehending the convenience of versatile medical applications with specialists thinking based on gathered information and proposes the best technique and ideas for improvement of MMAPPs later investigated over chronicled data, and standards of conduct and made accessible to the exploration community [21].

A. *Usability Model*

Model Produced with the help of the following attributes under consideration.

B. *Awareness (Interestingness)*

The rising fame of mHealth is a promising and open door for torment self-administration. Versatile applications can be effortlessly grown, however understanding the plan and usability will result in applications that can hold more clients. This exploration targets recognizing, breaking down, and orchestrating the present status of the specialty of (a) the planned approach and (b) usability appraisal of agony the executive's portable applications [22].

C. *Complexity*

Complexity analysis based on screenshots of the user interface in addition to interaction information, textual content size, font, language, or character set, homogeneous background and contrasting color without the want to get entry to the source code of the utility. In contrast, applications provide easy navigation and without blind flow [23].

D. *Easiness*

An important concept that illustrates how well users can use a mobile application is the ease of use. Design engineers define specific KPIs for each project like "Clients should be able to tap Find within three seconds of reaching the point of interaction on the application interface" and "usability should be streamlined while providing the greatest usefulness and considering business constraints." [24].

E. *User Satisfaction*

Fulfillment can be accomplished in three ways. As a matter of first importance, interface text or content should esteem the patient in setting with the significance of the patient and accomplishing the objective of the patient through the application. Furthermore, the point of interaction should direct the patient through the task for which the individual in question utilizing it [25]. Thirdly various assignments for finishing an exchange/accomplishing an objective ought to be well organized [26].

F. *Efficiency*

The productivity of portable medical applications is assessed three correspondingly, as a matter of first importance either concerning application plays out the particular undertaking totally, precisely and brief time frame. Also, either concerning application load and login or logout in the brief time frame as indicated. Thirdly, whether the unsettling application is viable to different mobiles and human-PC association aptitudes [27].

$$\text{Time} - \text{Based Efficiency} = \frac{1}{N}\sum_{i=0}^{N} \frac{\mathrm{n_i j}}{t_\mathrm{i} j} \qquad (1)$$

where, N= No. of Jobs, R= No. of Contestants, nij = Job I's resulted by j's participant, and tij = Participant I's time to Complete a j Task.

Eq. (1) calculates the time-based efficiency with the help of each total number of tasks completed by each participant in a specific time and divided by the number of jobs.

G. *Effectiveness*

Before you start to arrange Effectiveness is estimated with the assistance of consistent appearance applications, either interface configuration has significant choices and fastens more noticeable, lucid and simple to get to. Furthermore, either client moves around various choices effectively and sensibly to explore versatile medical applications. Consequently, the viability is a mix of Logical appearance and navigation of the UI of versatile apps [28].

$$\text{Effectiveness} = \frac{Total\ Number\ of\ Tasks\ Completed\ Successfully}{Total\ Number\ of\ Tasks\ Undertaken} \times 100 \qquad (2)$$

Eq. (2) calculates the effectiveness of different medical using programs that divide the total number of activities completed by the total number of tasks attempted and multiply the result by 100.

H. *Memorability*

The idea of memorability, from the usability point of view, is that a client can leave a program and when the person gets back to it, recall how to get things done in it. Memorability is significant generally because clients may not be utilizing your application constantly. It is easy to recall a task which is previously performed and reconnect the user after a long time [29].

I. *Learnability*

Learnability property signifies "How simple is it for the people to figure out how to utilize the framework". It tends to be accomplished assuming our product point of interaction is basic and has routine likenesses to the next application. People are not working any harder than needed to utilize innovation and try to avoid absolutely special software as individuals gained from past experiences. Various people have distinctive trouble levels; it is likewise an observable highlight to accomplish/assess the learnability normal for portable medical apps [30].

J. Completeness

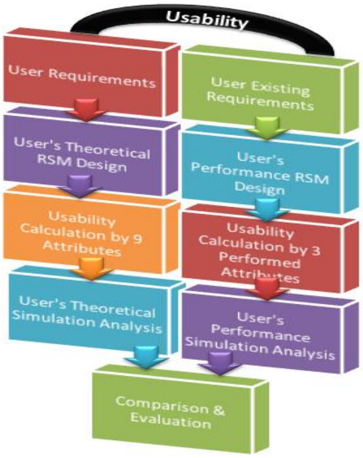
Completeness means checking the application interface for style, buttons, navigation and task completeness, etc. As a result of the backward point of view of the UI versus the prerequisites, presented, it can re-decipher task culmination also. The inquiry assumes there are relations in the model, i.e., i.e., rules which oversee changes between states. In legitimate dialect, it needs to have the option to inquire as to whether the framework is finished. The difficulties of these rules closely match the ones which relate to task plumpness [31].

K. Selection of Medical App Features

The study initiates a systematic study of the characteristics of more usable mobile medical apps and their impacts on the cyber world, and medical industry. The study compares different mobile medical apps for seven features 1) Find a Doctor, 2) Set an Appointment, 3) Sample Collection Facility, 4) Medical History, 5) Feedback and 6) Online Patient Evaluation, and proposes the best mobile medical apps with the use of a questionnaire instrument, the post-test is also carried out. Verification and validation of results have been carried out based on real-time data [32].

L. User Center Approach

The User Centre Model (UCD) is a research technique that improves versatile applications by reinforcing their convenience and decreasing expense as seen in Fig. 1. The fundamental objectives of the UCD model are fulfillment, essential, learnable, compelling, proficient, and adjustable design or interface for the users. In this model collect the requirements from users, then develop designs accordingly through RSM, calculate usability attributes of perceptional usability, and IT User’s usability and combine usability with the help of experiments on 13 runs or groups of users. The study evaluates and compares the results of perceptional usability, IT user usability and combined usability. After the analysis study produced coded equations or formulas for calculating usability.



Usability
User Requirements
User Existing Requirements
User's Theoretical RSM Design
User's Performance RSM Design
Usability Calculation by 9 Attributes
Usability Calculation by 3 Performed Attributes
User's Theoretical Simulation Analysis
User's Performance Simulation Analysis
Comparison & Evaluation

Fig. 1. User center model.

M. Reason for the Model Used

The study works with nine attributes of the usability for evaluation of mobile medical apps. The study provides the perceptional-based evaluation of usability version and actual means performance-based evaluation of usability and both are evaluated through ANOVA. At the end compare results of both evaluations.

IV. Selection and Sampling

The usability testing was driven at various university campuses and after filtration 677 individuals enlisted for the examination performed for twelve highlighted MMAPPs regarding interface for 6 features due to the availability of relevant participants and apps. The study divided the participants into 13 runs or groups starting from run 1 up to run 13. Each group was assigned several tasks according to RSM based design model for assessing and evaluating the usability of each feature concerning effectiveness, efficiency, learnability, memorability, completeness, easiness, complexity, number of errors and satisfaction [33].

A. Questionnaire

The questionnaire is developed with the help of the System Usability Scale (SUS) and Post-Study System Usability Questionnaire (PSSUQ) and gathers data about nine attributes of usability from 677 participants. In this study five points grading scale is used from strongly agree to strongly disagree on the other hand mid-point is agree. The study assessed the ease of use, ease of learning, simplicity, effectiveness, efficiency, ease of memorable, awareness, completeness, information and the user interface [34].

There are two design models are applied in the study for calculating perceptional usability and combined usability, after applying the questionnaire and performing the experiment respectively.

V. Results and Discussion

The RSM (Response Surface Methodology) technique is used in this study to validate the usability model.

A. Central Composite Design I (Perceptional Usability)

Table I represents different attributes of usability, their effects on usability and their response to perceptional usability

Table II shows variables, and their levels like minimum values, maximum values and mid values for all attributes of usability defined in a usability design.

Fig. 2 shows that validation of the model is done with the help of relationships and the effect of different attributes on usability given in the diagram. As seen from the above figure almost all the attributes of the concerning model affect usability. Some attributes have a greater effect and few have a little effect which is also shown in Eq. (3).

Table III shows the ANOVA model regression coefficient and analysis of variance which is significant and the lack of fit insignificant as required for the validation model.

TABLE I. ANOVA-BASED FACTORS AND THE RESPONSE OF PERCEPTIONAL USABILITY

Run	Factor 1	Factor 2	Factor 3	Factor 4	Factor 5	Factor 6	Factor 7	Factor 8	Factor 9	Response 1
	A: Awareness	B: Complexity	C: Easiness	D: Satisfaction	E: Efficiency	F: Effectiveness	G: Memorability	H: Learnability	J: Completeness	Perceptional Usability
1	2.1	2	2.2	2	2.6	2.2	2	2.4	2.3	55
2	2.33	1.87	2.53	2.67	2.6	2.47	2.2	2.6	2.27	59.81
3	2.26	1.87	2.55	2.45	2.41	2.53	2.24	2	2.09	58.07
4	2.42	1.95	2.52	2.58	2.52	2.57	2.29	2.55	2.02	59.01
5	2.43	1.9	2.5	2.57	2.73	2.37	2.67	1.83	2.57	59.91
6	2.23	2.1	2.46	2.43	2.57	2.34	2.2	2.6	2.11	57.86
7	2.24	2.1	2.53	2.42	2.39	2.51	2.2	2.48	2.07	58.01
8	1	2	2	2	3	1	2	4	0	47.22

13	3.08	2.08	2.84	3.12	2.8	2.84	2.48	2.84	1.72	66.11

TABLE II. LEVELS OF INDEPENDENT VARIABLES

Symbol	Independent Variables	Minimum Value	Mid Value	Maximum Value
A	Interesting (Awareness)	1	2.38	3.08
B	Complexity	1.84	1.97	2.16
C	Easiness	2	2.64	4
D	Satisfaction	2	2.68	4
E	Efficiency	2.39	2.75	4
F	Effectiveness	1	2.47	3.04
G	Memorability	2	2.36	3
H	Learnability	1.83	2.73	4
J	Completeness	0	1.99	3

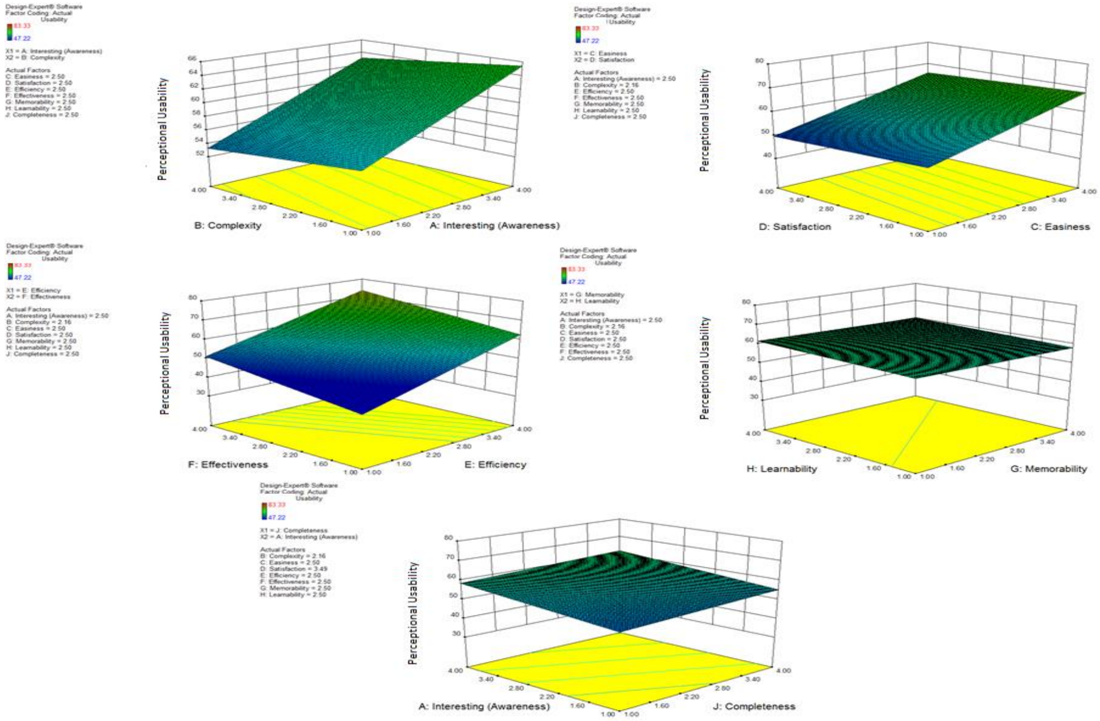

Fig. 2. Relationships and effects of attributes on perceptional usability.

TABLE III. RESULTS OF REGRESSION COEFFICIENTS AND ANALYSIS OF VARIANCE FOR ONE RESPONSE VARIABLE BY ANOVA

Source	Intercept (β_0)	A-Awareness	B-Complexity	C-Easiness	D-Satisfaction	E-Efficiency	F-Effectiveness	G-Memorability	H-Learnability	J-Completeness	*P*-Value	F-Value	R^2	Adj. R^2	Lack of Fit
Theoretical-Usability	59.36(Significant)	4.91	-1.13	8.12	-1.69	11.09	7.92	-0.72	1.42	1.75	<0.0001Significant	263.13	0.978918	0.975198	0.8551(Insignifican)

B. Analysis via Perceptional Design I

As seen in Fig. 3. Under half of the mobile patients have high and extremely high fulfillment levels on versatile medical applications. Over 59% of people said that mobile medical apps are too complex. Complexity is inversely related to usability. The vast majority of IT users and doctors said that current MMAPPs are successful, productive and easy to use but a small number of general users feel much easier. The graph shows that easiness is directly related to usability. The majority of the MMAPP's users think that these applications are satisfactory which is related to usability as seen from the graph. As seen in Fig. 1. little more than 50% of mobile medical application users think that these apps are efficient. The remaining of them think that more efficiency is needed. Efficiency is directly linked with usability as seen from the graph. 50% think effectiveness is necessary but the remaining do not think so. The graph shows effectiveness is a little bit related to usability, learnability and memorability are also directly linked with usability but have little effect on it.

$$\text{Perceptional Usability } = 59.36 + 4.19A - 1.13B + 8.12C - 1.69D + 11.09E + 7.92F - 0.72\text{G} + 1.42H + 1.72J \quad (3)$$

Eq. (3) represents the perceptional usability deduced from the ANOVA model after analysis. This is a general proposed formula of perceptional usability that can be used for the calculation of any sample of the study.

C. Experimental Design

This test was overseen on university campuses where all members were grown-ups. The individuals were facilitated to perform 13 activities, for instance, the tasks were organized and executed for class length in the college. The ordinary task completion time was eight minutes [35].

D. RSM Experimental Design II (Experimental Usability)

Table IV represents different attributes of usability, their effects on usability and their response to combined usability. There are 13 runs in which the specific number of participants is included according to the RSM design model from which particular tasks are performed to calculate and evaluate the attributes like effectiveness, efficiency and satisfaction. On behalf of these attributes, usability is calculated and the equation of combined usability is deduced.

Table V shows variables that represent the attributes of combined usability and their levels like minimum values, maximum values and mid values. This table also represents the standard deviation faced by given attributes in an RSM model.

TABLE IV. ANOVA-BASED FACTORS AND RESPONSE AS ACTUAL USABILITY

Run	Factor1	Factor2	Factor3	Response1
	Effectiveness	Efficiency	Satisfaction	Usability
1	82.93	75	50	69.31
2	57.63	83.33	66.67	69.21
3	85.44	84.12	61.18	76.91
4	81.71	84.12	63.55	76.46
5	58.46	63.33	63.33	61.71
6	72.33	70.14	60.71	67.73
7	80.03	81.74	61.18	74.32
8	75	75	50	66.67
9	50	100	100	83.33
10	69.32	72	72	71.11
11	65.9	72	71	69.63
12	81.59	87.06	63.55	77.4
13	59.47	60	70	63.16

TABLE V. LEVELS OF INDEPENDENT VARIABLES FOR EXPERIMENTAL DESIGN

Symbol	Independent Variables	Minimum Value	Mid Value	Maximum Value	Std. Dev.
A	Efficiency	50	74.99	85.44	11.15
B	Effectiveness	60	87.3	100	10.27
C	Satisfaction	50	65.63	100	11.89
R1	Usability (Actual)	61.71	75.97	83.33	6.14

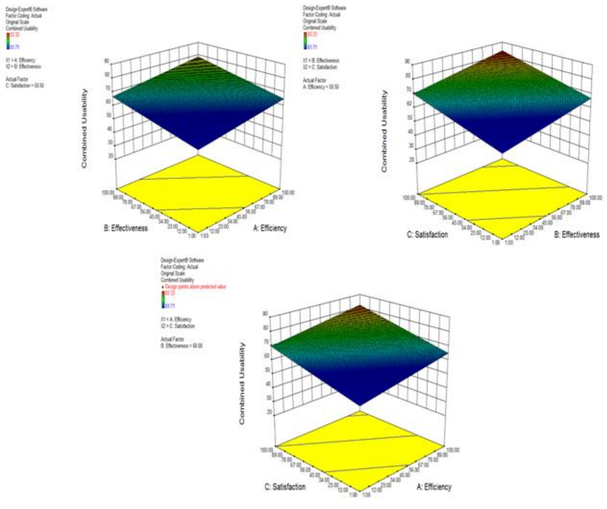

Fig. 3. Relationship and effects of attributes on combined usability.

TABLE VI. RESULTS OF REGRESSION COEFFICIENTS AND ANALYSIS OF VARIANCE FOR THREE RESPONSE VARIABLES

Source	Intercept (β_0)	A-Efficiency	B-Effectiveness	C-Satisfaction	AB	AC	BC	A^2	B^2	C^2	*P*-Value	F-Value	R^2	Adj. R^2	Lack of Fit
Actual-Efficiency	7.12(Significant)	1.13	1.12	1.12	-0.13	-0.11	-0.12	-0.059	-0.045	-0.053	<0.0001	1.014E+008	1.0000	1.0000	0(Insignificant)

Fig. 3 shows that validation of the model is done with the help of relationships and the effect of different attributes on combined usability given in the diagram. As seen from the above figure almost all the attributes of the concerning model affect usability. Some attributes have a greater effect and few have a little effect which is also shown in Eq. (4).

Table VI shows the ANOVA model regression coefficient and analysis of variance which is significant and the lack of fit insignificant as required for the validation model.

$$\text{Combined Usability } = 7.12 + 1.13A + 1.12B + 1.12C - 0.13AB - 0.11AC - 0.12BC - 0.059A^2 - 0.045B^2 - 0.053C^2 \quad (4)$$

Eq. (4) represents the combined usability deduced from the ANOVA model after analysis of data gathered from activities performed by participants.

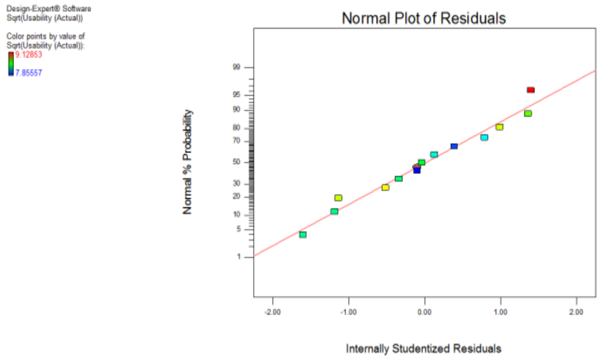

Fig. 4. Normal probability.

Fig. 4 shows that all values of usability are normally plotted on or near the normal line. Its mean ANOVA model and RSM design are significant.

E. Comparison between Theoretical and Actual Usability

Fig. 5 represents the variations and comparison of perceptional usability, IT user usability and combined usability. According to IT users and experts, the usability is very close to the standard usability, combined usability is below the standard usability and users think that there is much need for improvements in the usability of MMAPPs.

F. Analysis via Experimental Design II

For this reason, 677 individuals concurred with the examination performed for twelve elements of mobile medical applications regarding point of interaction. The studies posed various inquiries about convenience assessment in settings with easiness, learnability, memorability, adequacy, productivity and satisfaction [36-37]. The study uses Google Forms for gathering their reactions because of the coronavirus pandemic, likewise, lead Zoom meetings for direction about this review and top of the reactions. The study additionally guides through SMS, WhatsApp messages and calls to our IT specialists and investors about the survey on Google Forms [38]. Fig. 5 shows that improvement is required in all the attributes of usability as every group or run has usability value in the range of 50 to 64 for combined users, less than 60% for illiterate users and an average of nearly 75% for IT people. As per the above outcomes and conversation, there is a lot of progress expected to foster completeness and efficiency and reduce the complexity of MMAPPs. From the above conversation obviously, there is a hole among users, user perception level and application developers in setting with convenience which ought to be taken out by understanding the necessities and prerequisites of the users [39-40]. There is additionally an idea during advancement that the study might present the mode idea as designer presented in another application programming like Master Mode for doctors, User Mode for illiterate users and Well-disposed Mode for IT users.

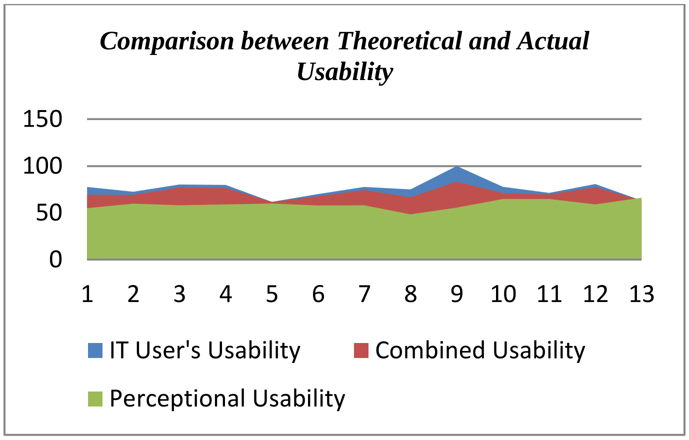

Fig. 5. Comparison between IT users' perceptional and combined usability.

G. Analytical Suggestions

From the above conversation and information assembled, the study ought to likewise give all elements of medical in medical mobile applications for the fulfillment and viability of MMAPPs and conduct pieces of training for MMAPP's users. As indicated by the specialist's assessment and information accumulated from users, there are three segments, where upgradation is required which are complexity, efficiency and completeness.

H. Limitations

- The study took samples from one country, it may be extended worldwide.
- This study uses nine attributes of usability, which may increase to get more precision level.

VI. Conclusion

Healthcare is evolving as the industry undergoes significant change. It is simple and advantageous for patients to adopt a healthy lifestyle by using mobile medical apps. The study worked on perceptional usability with the newly introduced UCD model with different attributes and checked their effect on usability through RSM designed model. Then analyzed and validated the model by ANOVA. On the other hand, traditional usability attributes are checked in a new form through the second RSM design model for IT users and combined user usability. It also checked the effects of attributes on perceptional and IT users and combined user usability as shown in Fig. 2 and Fig. 3. In the last compared these usability results of different groups of users according to the given design model. The deduced results of this review show that it is vital to think about patient fulfillment and confidence in MMAPPs for the future improvement of versatile medical application interfaces. Less than 50% of smartphone users utilize mobile medical applications (other than experts) to perform medical-related tasks for maintaining a healthy lifestyle. For this purpose, improve the awareness, make it much more interesting and enhance satisfaction, completeness, efficiency and easiness level of MMAPPs for users. The relationship between the average usage of medical applications and user health is statistically significant. A large number of participants agreed that medical applications can help to improve their health and as well as a healthy environment. It is necessary to limit the gap between patients/users and specialists for the improvement of MMAPPs. The last one is the expansion of all medical elements to further develop user fulfillment and user accommodation. There is no need to make many secure and complex MMAPPs like banking apps and security apps etc. At the end of the analysis, each design model produced a mathematical equation to evaluate its usability.

Abstract—**In the continuously evolving educational landscape, the prediction of students' academic performance in STEM (Science, Technology, Engineering, Mathematics) disciplines stands as a paramount component for educational stakeholders aiming at enhancing learning methodologies and outcomes. This research paper delves into a sophisticated analysis, employing Machine Learning (ML) algorithms to predict students' achievements, focusing explicitly on the multifaceted realm of STEM education. By harnessing a robust dataset drawn from diverse educational backgrounds, incorporating myriad factors such as historical academic data, socioeconomic demographics, and individual learning interactions, the study innovates by transcending traditional prediction parameters. The research meticulously evaluates several machine learning models, juxtaposing their efficacies through rigorous methodologies, including Random Forest, Support Vector Machines, and Neural Networks, subsequently advocating for an ensemble approach to bolster prediction accuracy. Critical insights reveal that customized learning pathways, preemptive identification of at-risk candidates, and the nuanced understanding of contributing influencers are significantly enhanced through the ML framework, offering a transformative lens for academic strategies. Furthermore, the paper confronts the ethical quandaries and challenges of data privacy emerging in the wake of advanced analytics in education, proposing a holistic guideline for stakeholders. This exploration not only underscores the potential of machine learning in revolutionizing predictive strategies in STEM education but also advocates for continuous model optimization, embracing a symbiotic integration between pedagogical methodologies and technological advancements, thereby redefining the trajectories of educational paradigms.**

Keywords—Load balancing; machine learning; server; classification; software

I. Introduction

In the current epoch of technological ubiquity, the domain of education, particularly Science, Technology, Engineering, and Mathematics (STEM) education, has encountered transformative shifts. The imperative to mold proficient future professionals capable of navigating complex technological terrains and scientific quandaries has never been more pressing [1]. Yet, the chasm between educational methodologies and individual student performance continues to challenge educators and policy-makers alike, necessitating innovative approaches to bridge this gap. Central to this innovation is the utilization of machine learning (ML) [2] in comprehending and predicting student performance, a research niche that has burgeoned in significance due to its profound implications on educational strategies [3].

Historically, educational outcomes were often predicated on conventional metrics—standardized testing, classroom participation, and rudimentary performance tracking methodologies [3]. These linear models, although somewhat informative, hardly capture the labyrinth of individual student experiences, inherent talents, cognitive styles, and external factors impacting academic performance. The intricacies of learning are often obfuscated by the homogeneity of traditional assessment tools, which are ill-equipped to forecast academic outcomes with substantial reliability [4]. The need for personalized education, a clarion call in contemporary pedagogical circles, further exacerbates this issue, as traditional educational models are systemically inept at accommodating the heterogeneity of student populations [5].

Emerging from this backdrop is the promise of machine learning, a subset of artificial intelligence (AI) characterized by its capacity for pattern recognition, learning from data, and making predictions [6]. When applied within the educational sphere, ML bears the revolutionary potential to distill vast, nebulous datasets into actionable insights regarding student performance. This process is not without its complexities, as it necessitates a delicate alchemy of algorithmic selection, hyperparameter tuning, and feature engineering, demanding rigorous scrutiny to ensure both ethical and practical efficacy [7].

Literature in the realm of machine learning applications in education is replete with instances of predictive analytics being employed for student data. Studies range from early identification of students at risk of academic failure to nuanced understandings of how socio-economic factors correlate with educational outcomes [8]. Specifically, within STEM disciplines, where abstract concepts and cumulative learning are pivotal, the predictive power of ML can aid in identifying learning hurdles and pedagogical inefficiencies [9].

However, despite its burgeoning presence, the integration of machine learning into educational predictive models is fraught with challenges. The ethical implications of data privacy, security, and the potential for bias in algorithmic determinations present formidable hurdles [10]. Each of these aspects requires careful consideration to maintain the integrity of educational institutions while harnessing the capabilities of advanced technology. Moreover, there is the omnipresent challenge of interpretability, as the decision-making processes of complex models often constitute a "black box," making it difficult for educators and stakeholders to trust and ethically utilize the predictions [11].

This research, therefore, is anchored in the critical evaluation of various machine learning models in predicting student performance in STEM subjects. The choice of models, including but not limited to, Random Forest, Support Vector Machines, and Neural Networks, represents the spectrum of algorithms from simple interpretable models to complex, high-dimensional ones, each with unique strengths and predictive accuracies [12]. Furthermore, the study leverages an ensemble learning approach, conjectured to enhance the robustness and reliability of predictions through the aggregation of multiple models [13].

The nuance of this research resides in its holistic approach, not just considering academic datasets but also integrating comprehensive student data. This encompasses demographic information, previous academic achievements, engagement levels, and even socio-economic indicators, acknowledging the multifactorial nature of educational success [14]. By doing so, the research transcends myopic academic predictions, offering instead a panoramic view of student performance influencers. This approach is pivotal, recognizing that contemporary students navigate a milieu replete with both academic and non-academic challenges, ranging from mental health pressures to the digital distractions endemic in modern society [15].

In synthesizing these elements, this study contributes to the academic dialogue in several ways. Firstly, it provides an empirical evaluation of machine learning models in the context of education, a field where such advanced technology applications remain under-explored. Secondly, it addresses the ethical and practical challenges intrinsic to the domain, offering pathways for stakeholders to leverage insights responsibly. Finally, by focusing on STEM education—a critical driver of future innovation and economic growth—the research underscores the need for educational systems to evolve in tandem with broader societal advancements, ensuring that student success is not left to antiquation in this brave new world [16].

In essence, this paper seeks to navigate the confluence of technology and education, providing insights that could potentially reshape the predictive paradigms in the educational sector, particularly within STEM disciplines. Through rigorous analysis, ethical considerations, and practical applications, the study stands as a beacon, guiding the way towards a more informed, equitable, and effective educational landscape.

II. Related Works

The integration of machine learning (ML) strategies in educational settings, particularly in STEM (Science, Technology, Engineering, Mathematics) education, has garnered considerable attention in academic circles, underpinning the necessity to comprehend its precedents within scholarly literature. The endeavor to harness ML's predictive power to forecast student academic performance intersects various research domains, necessitating an interdisciplinary approach to fully understand its scope, potential, and limitations [17].

A. *Early Interventions and Predictive Analytics*

The genesis of employing predictive analytics in education was primarily focused on identifying at-risk students to facilitate early interventions. Studies by [18] and [19] showcased the utility of traditional statistical methods to forecast academic struggles, primarily utilizing historical and continuous assessment data. However, these models often suffered from oversimplification, failing to capture the multifaceted nature of academic performance. The advent of machine learning offered a nuanced approach, enabling the consideration of a broader array of variables and revealing hidden patterns within complex datasets [20]. For instance, [21] exploited decision trees to flag students needing additional support, demonstrating superior accuracy over classical methods.

B. *Machine Learning Models in Academic Settings*

Diverse ML models have been tested within educational contexts, each offering distinct advantages. Research by [22] emphasized the effectiveness of Support Vector Machines (SVM) in handling high-dimensional spaces, particularly useful in analyzing voluminous student data. In contrast, studies like [23] touted Random Forest's ability to provide insight into feature importance, thereby understanding influential factors affecting student performance. Neural Networks, known for their prowess in capturing non-linear relationships, were explored by [24], underscoring their sensitivity to nuanced interactions amongst data, albeit at the expense of interpretability.

C. *Ensemble Methods and Hybrid Models*

Given the heterogeneous nature of educational data, recent studies have advocated for ensemble and hybrid models. [25] demonstrated that combining predictions from multiple algorithms enhanced overall accuracy, compensating for individual model weaknesses. Similarly, [26] successfully implemented a hybrid model incorporating both neural networks and decision trees, exploiting the strengths of both non-linearity and interpretability. These methodologies signify a shift toward more robust predictive systems, though they necessitate careful construction and validation.

D. *Behavioral and Engagement Metrics*

Beyond academic results, behavioral and engagement metrics have surfaced as vital predictors. [27] integrated data from online learning platforms, highlighting that digital engagement levels were indicative of academic outcomes. This was corroborated by [28], who found that behavioral patterns, such as time spent on tasks and participation in virtual forums, were salient in understanding academic performance. These insights underscore the importance of a holistic data approach, merging academic, behavioral, and engagement metrics.

E. Socio-economic and External Factors

Acknowledging the impact of external factors, several researchers have broadened the data scope to include socio-economic factors. The research in [29] affirmed that socio-economic status significantly correlated with academic achievement, while [30] extended this by showing that even when controlling for this, other factors, including parental involvement and peer influence, played non-trivial roles. The study in [31] further incorporated these into a comprehensive ML model, illustrating the enhanced predictive power when acknowledging the multifactorial nature of education.

F. Ethical Considerations and Bias Mitigation

The ethical dimensions of ML in education, especially concerning data privacy and algorithmic bias, have provoked intense scholarly discourse. The study in [32] critically analyzed ethical quandaries, stressing the need for transparency, consent, and privacy safeguards. The research in [33] explored the prevalence of biases, showing that unexamined, algorithms might perpetuate existing inequalities, necessitating rigorous bias mitigation protocols. The responsibility of ethical algorithm deployment is echoed throughout literature, demanding a balance between technological advancement and moral obligations [34].

G. Interpretability and Decision Transparency

The “black box” nature of certain ML models presents substantial challenges in educational settings, where stakeholders require transparency to trust and act upon predictions. Research by [35] proposed methodologies for enhancing the interpretability of complex models, while [36] discussed the trade-offs between accuracy and interpretability, suggesting that simpler models might sometimes serve educational needs better due to their transparency.

H. Customized Learning Pathways

Tailoring education to individual needs is another frontier. [37] demonstrated that ML could help create customized learning pathways, thereby improving engagement and comprehension. This personalization aspect, especially in STEM subjects that often suffer from high drop-out rates, can potentially revolutionize educational methodologies [38].

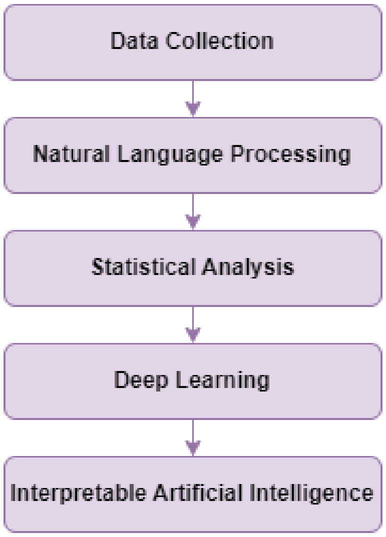
I. Challenges and Future Directions

Despite its promise, the integration of ML in education isn’t without challenges. The study in [39] outlined issues ranging from data quality, privacy concerns, and the need for interdisciplinary collaboration between educators and data scientists. The literature strongly advocates for continued research, particularly iterative model refinement and the exploration of innovative data sources to enrich predictive capabilities.

In summary, the existing body of work confirms the transformative potential of machine learning in predicting academic performance in STEM education. It reflects a trajectory from simplistic predictive models towards more sophisticated, comprehensive, and ethically considerate ML applications. This literature tapestry provides a foundation upon which the current research is built, aiming to contribute novel insights by harnessing the potency of ML to navigate the complex, dynamic landscape of educational predictors and outcomes.

III. Materials and Methods

The methodological framework guiding this research is visually represented in Fig. 1, elucidating a comprehensive five-stage process integral to the operationalization of this study. Initially, the process commences with the meticulous aggregation of relevant datasets, sourced extensively from institutional databases, ensuring a rich compendium of variables reflective of the educational milieu. Subsequently, the study introduces a sophisticated application of natural language processing (NLP) techniques, aimed at dissecting and quantifying classroom dialogic interactions, a step that underscores the significance of linguistic dynamics in educational settings.



Data Collection
Natural Language Processing
Statistical Analysis
Deep Learning
Interpretable Artificial Intelligence

Fig. 1. Data collection and preparation.

Progressing beyond raw data compilation, the research methodologically embraces rigorous statistical methodologies to scrutinize dialogue-based indicators, thereby quantifying abstract elements of classroom discourse. This transformative approach facilitates a nuanced understanding of pedagogical dynamics, often overlooked in traditional analysis paradigms. In the ensuing phase, the study leverages state-of-the-art deep learning algorithms, architecting a predictive model for academic performance that is both robust and sensitive to the multifarious factors influencing educational outcomes.

The final step epitomizes the study’s commitment to transparency and applicability through the adoption of an interpretable artificial intelligence (AI) model. This phase is dedicated to the explication of critical predictors within the established predictive model, a crucial aspect that not only enhances the trustworthiness of AI interventions but also empowers stakeholders with actionable insights. The ensuing sections are committed to an in-depth exposition of each pivotal stage, shedding light on the intricate methodologies that constitute the backbone of this research endeavor, thereby reinforcing its academic rigor and practical relevance in the educational echelon.

A. *Dataset*

Data for this study were meticulously sourced from virtual classrooms within a prominent online educational framework in Kazakhstan. These live classrooms, distinctive in their interactive nature, allow students to exchange messages visible to their peers, thereby fostering a dynamic communicative environment through an integrated chat room feature. The research harnessed transcripts of these real-time educational dialogues across various subjects and academic levels, specifically focusing on the platform's courses for grades K-6.

Reflecting on the outcomes of the 2020 spring semester, the platform recorded an enrollment of approximately 30,581 students within the K-6 category. Of these, around 8,158 students were engaged in 2,545 courses unrelated to STEM, while a notably larger cohort of 22,423 students immersed themselves in 3,797 STEM-oriented courses. This academic engagement led to the creation of approximately 654,954 and 1,690,549 interactive textual exchanges for non-STEM and STEM courses, respectively. Table I provides a detailed breakdown of the dialogue texts within the live classroom chat environments, with 'M' denoting the mean value.

In assessing academic performance, this study adopted a comparative analysis of students' rankings, focusing on discrepancies between their initial (pretest) and final (posttest) standings. The upper echelon of academic achievers, represented by the top 20%, was classified as the high-performance group, whereas the lowermost 20% of the spectrum was identified as the low-performance group. For subsequent analytical procedures, the study incorporated data from approximately 4,776 students—around 2,459 from the low-performance segment and 2,317 from the high-performance tier—in non-STEM courses. Simultaneously, the STEM counterparts comprised a more substantial ensemble of roughly 13,659 students, segmented into 7,711 underachievers and 5,948 high achievers. This strategic dichotomy in performance assessment is instrumental in facilitating a nuanced understanding of educational dynamics within the virtual classroom scenario.

B. *Applying Machine Learning*

To facilitate the automated identification of emotional articulations and the categorization of interactive modalities within classroom dialogues, we have dedicated efforts toward the development and training of two distinct models of text classification. This intricate process, essential for comprehending the underpinnings of communicative exchanges in educational settings, is graphically synthesized in the flow diagram presented as Fig. 2. This visual representation underscores the systematic approach adopted for this phase of the research, highlighting the advanced computational techniques employed to analyze textual data within the pedagogical discourse.

In this study, we established a nuanced criterion for the categorization of emotional tenor and interaction modalities, substantiated with specific textual instances derived directly from classroom dialogues. Emotional expressions within the communicative exchanges are bifurcated into two primary affective states: positive and negative emotions. Dialogues permeated with sentiments of joy, elation, or exhilaration is classified under the umbrella of positive emotional discourse. Conversely, student interactions manifesting tones of melancholy, disinterest, or irritation are categorized as expressions of negative emotion. This dichotomous approach to emotional categorization provides a streamlined yet profound understanding of the affective landscape of classroom interactions. Representative samples of these categorized emotional states, extracted verbatim from the dialogic exchanges, are systematically presented in Table II, offering tangible insights into the emotional substrates that underpin student communication within academic settings.

TABLE I. DIALOG TESTS IN CLASSROOM

Course	Subject	Grade	Classes	M(SD)		Number of interactive course
				Number of students	Number of interactive texts	
Non-STEM subject	English	1	598	1.97	98	93 467
		2	867	5.39	61	281 679
		3	2387	2.8	79	564 782
		4	1647	3.7	90	483164
		5	1983	3.5	86	582 264
		6	1976	3.6	78	564 778
STEM subject	Math	1	2729	7.9	6159	1 067 899
		2	4318	6.8	80	1 647 896
		3	3016	5.6	99	1 302 445
		4	1725	3.8	111	631 448
		5	1973	5.8	123	1 305 866
		6	1609	5.5	137	1 018 886

TABLE II. EXAMPLES OF STUDENT EXPRESSIONS

Dimension	First-level	Second level	Sample
Expression	Positive	-	I like it very much
	Negative	-	It was boring to me; It is not interesting
Interactive	Cognition	Asking questions and answering	What is the meaning of …

C. Academic Performance Prediction

In the context of this research, features integral to the construction of predictive models are bifurcated into two distinct categories. The initial category encompasses the 'pretest rank,' signifying students' foundational academic competencies prior to their engagement in specific classroom sessions. The subsequent category is more intricate, involving features meticulously extrapolated from the text of classroom dialogues. Collectively, these categories amalgamate into a robust set of 48 distinctive features, instrumental in the subsequent phases of predictive model construction.

The study employs a comparative analysis approach, rigorously evaluating three sophisticated classification algorithms pivotal for predicting academic performance. These encompass a Convolutional Neural Network (CNN) methodology as illustrated in Fig. 3. The model is subjected to an in-depth assessment based on three critical evaluation metrics: recall, precision, and accuracy. This triadic evaluative framework provides a holistic view of each algorithm's performance, thereby informing the selection of the most efficacious predictive model.

Upon the empirical evaluation of these algorithms, the study advances to synthesize an interpretable model, enhancing the applicability and user comprehension of the results. Notably, the implementation phase of this research utilizes the TensorFlow deep learning framework, a decision substantiated by its proven efficacy and robustness in handling complex predictive tasks. This strategic methodological orchestration not only underscores the rigor of the study but also enhances the reliability and validity of the predictive outcomes within the academic performance landscape.

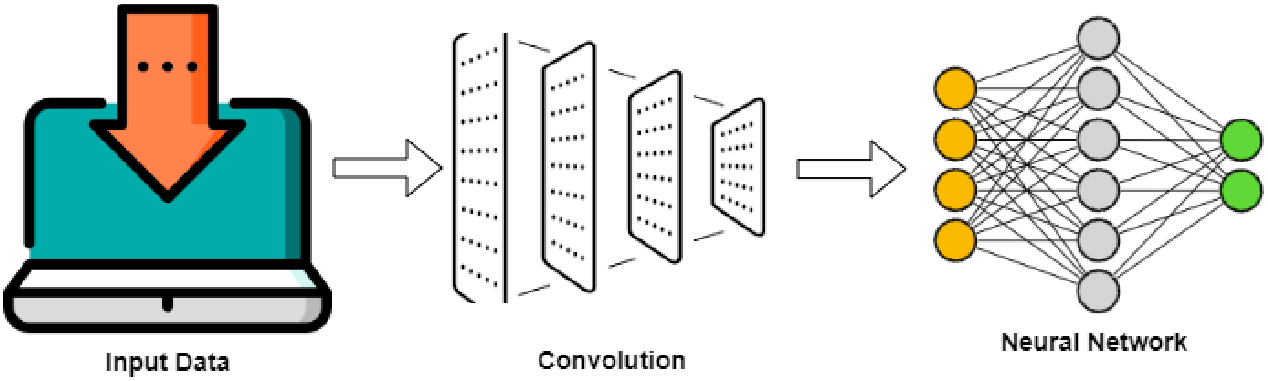

Fig. 3. Deep learning for predicting academic performance of students.

IV. Experimental Results

A. Evaluation of Emotional Expression of Students

This study engages with the SHAP (SHapley Additive exPlanations) methodology, an advanced technique within the realm of interpretable artificial intelligence, to critically analyze the contributory features inherent in the academic performance prediction model. The consequential insights derived from this rigorous analysis are graphically elucidated in Fig. 3. Concurrently, an intriguing observation emerges from the C1 cohort, exhibiting a marginal enhancement in predictive accuracy relative to the established baseline, which is preliminarily set at 50%. This nuanced increment, albeit minimal, signals a critical inference: the interactive dynamics encapsulated within the online classroom environment exert a relatively insubstantial influence on the academic trajectories associated with non-STEM coursework. This revelation underscores the necessity for a differential pedagogical approach, potentially customized to the distinct educational exigencies of STEM and non-STEM curricula.

Intricately woven into this analysis are six pivotal variables, each derived from a comprehensive aggregation of the absolute values of corresponding interactive or emotional metrics within a specific interactive phase. For instance, the variable 'summary_interaction' is computed by summing the absolute SHAP values of various interactive categories during the summary stage, represented formulaically as: summary_interaction = |ics| + |ims| + |ios| + |ccs| + |cms| + |cos|. Analogously, 'summary_emotion' encapsulates the emotional undertones of the summary phase, calculated as: summary_emotion = |ips| + |cps| + |ins| + |cns|.

These computations underscore the nuanced complexity and the multifaceted nature of interactive and emotional dynamics within the learning environment. By leveraging SHAP values, the study provides an in-depth, interpretable analysis, highlighting the often-overlooked subtleties that significantly influence students' academic trajectories in non-STEM disciplines. This meticulous approach not only enhances the comprehensibility of predictive analytics but also informs educational strategies by pinpointing specific areas of student-teacher interaction that require pedagogical attention.

B. CNN in Academic Performance Prediction

In the methodological framework of our research, we meticulously partitioned the dataset, allocating 70% to training purposes, while the residual 30% was designated as the test set, concurrently serving as the validation data. It is pertinent to clarify that within the context of this study, the terminologies 'test loss' and 'test accuracy' are utilized interchangeably with 'validation loss' and 'validation accuracy,' respectively. Our evaluative metric of paramount importance was accuracy, a choice that steered the subsequent analytical processes, including the imperative exercise of parameter optimization, to elicit the most robust and reliable outcomes.

One critical parameter that demanded our focused attention was the learning rate, recognized for its decisive role in the training phase of machine learning models. Typically, a diminutive positive number confined within the spectrum of 0 to 1, the learning rate orchestrates the velocity at which a model acclimatizes to a given problem. Its optimal calibration is crucial; an excessively accelerated learning rate might precipitate a premature convergence, culminating in a suboptimal solution, whereas a rate set too sluggishly risks miring the process in stagnation.

Given these potential quandaries, our study was committed to identifying the most propitious learning rate. We embarked on empirical trials employing a gamut of learning rates, meticulously observing their impacts on model performance. Further augmenting our analysis, we crafted visual representations of the correlation between diverse learning rates and their corresponding training and test accuracies. These illustrative delineations, accessible in Fig. 4, not only enhance comprehensibility but also provide empirical substantiation for the optimal learning rate conducive to our model's most effective learning trajectory.

An insightful observation emerges from the graphical representation delineated in Fig. 4, wherein the learning curve exhibits a pronounced stagnation at elevated learning rates, specifically at 1 and 0.1. This phenomenon indicates an inhibited learning process, attributable to the model's inability to assimilate the training data effectively at such escalated rates. Conversely, the curves corresponding to reduced learning rates reveal a propensity for oscillation, a manifestation of inconsistent learning. Within the context of our experimental framework, empirical evidence converges on the learning rate of 0.001 as the optimal parameter, a conclusion corroborated by the enhanced performance metrics of the model discernible in Fig. 4.

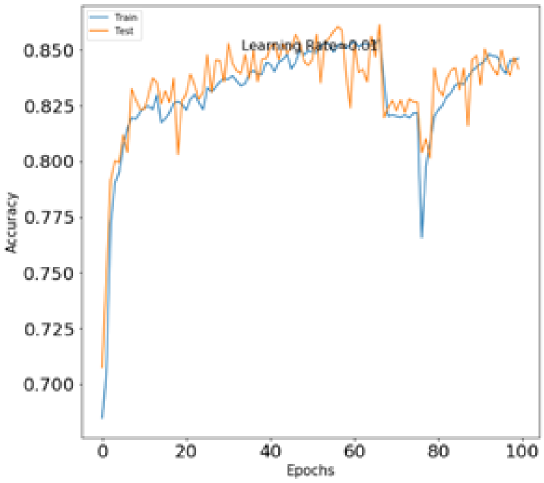

Fig. 4. Training and test accuracy of the applied model in 100 learning epochs.

An insightful observation emerges from the graphical Furthermore, our research extended into an exploratory analysis involving varying numbers of epochs, intended to ascertain their influence on the model's accuracy. This phase entailed methodical observations of the trajectories of accuracy versus epochs, along with loss versus epochs, intensifying our understanding of the model's behavior over iterative learning cycles. The experimentation commenced with an epoch baseline of 20, progressively amplifying to discern the consequential impacts on model performance.

The empirical outcomes derived from this procedural iteration, particularly in terms of test loss and test accuracy, are of significant interest. Fig. 5 in the study play a crucial role in this context. These figures provide a visual representation of the behavior of accuracy and loss across various epoch parameters, respectively. By examining these figures, one can gain a deeper understanding of how the model's accuracy and loss metrics evolve throughout the training process.

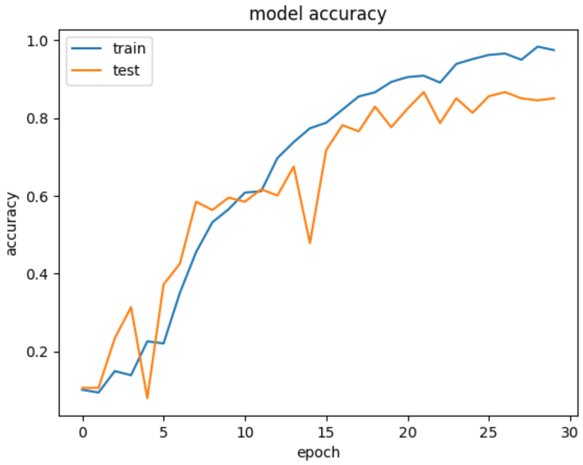

Fig. 5. Training and test accuracy of the applied model in 30 learning epochs.

Together, these figures provide a comprehensive view of the model's learning consistency and its predictive performance. By analyzing these graphs, researchers can determine the most effective epoch configuration, balancing the need for sufficient training to achieve high accuracy without overfitting. This balance is critical for ensuring that the model remains generalizable and performs well on new, unseen data.

V. Discussion

This research embarked on an intricate journey to unravel the layers of complexities in predicting students' academic performance within the STEM education landscape, utilizing the prowess of machine learning algorithms. The findings illuminate several critical facets of educational psychology, pedagogical strategies, and the subtle nuances of student interactions and engagement, particularly in an online learning environment.

One of the cardinal revelations of this study was the pivotal role of interactive patterns and emotional expressions in shaping students' academic outcomes. Previous research confined itself to traditional performance indicators, often overlooking the rich tapestry of student interactions. Our study bridged this gap, echoing the findings of [40], which underscored the significance of emotional and psychological factors in academic performance. However, unlike [41] that generalized the impact of interactive patterns, our research unveiled a stage-wise influence, emphasizing that the timing of interactions is just as crucial as their nature.

Furthermore, the disparity in the influence of these interactive factors between STEM and non-STEM courses is particularly enlightening. Consistent with the observations of [42], our findings corroborate that STEM subjects, with their structured and logical framework, respond differently to emotional and interactive stimuli compared to non-STEM subjects. This nuanced understanding advocate for a more tailored approach in pedagogical strategies, as also suggested by [43-44], ensuring that educators can mold their teaching tactics according to the subject matter and the corresponding emotional and interactive dynamics.

The application of machine learning, especially deep learning algorithms, marked a paradigm shift in identifying and predicting successful learning patterns. While traditional statistical methods provided a surface-level understanding, the neural networks delved deeper into the data, much like the human brain, offering unprecedented insights into student performance predictors. This sophisticated approach, however, came with its own set of challenges, chiefly selecting the appropriate model and tuning the hyperparameters, as discussed in [45].

Our research determined the optimal learning rate, a finding that resonated with the work of [46], highlighting the delicate balance required in setting this parameter. Too high a rate, and the model overshoots the minimum point; too low, and the model succumbs to local minima or becomes computationally impractical. Similarly, the number of epochs represented a tug of war between underfitting and overfitting, a common conundrum in machine learning models as identified by [47]. Our study struck this balance adeptly, ensuring the model learned the underlying patterns without memorizing the data, a nuanced mastery over the art of 'learning to learn'.

Interestingly, the efficacy of the model was not universally uniform across different subject matters. While it showed remarkable precision in predicting STEM outcomes, its applicability in non-STEM subjects was limited, a phenomenon that could be attributed to the inherent subject differences. STEM subjects, often characterized by logical and structured learnings, lend themselves more readily to predictive analytics, unlike non-STEM subjects that are more abstract and open to interpretation, as noted by [48].

Another intriguing aspect was the identification of effective features in the predictive model using SHAP values, an area often shrouded in mystery in most machine learning applications due to their 'black box' nature. The interpretability introduced by SHAP values, as explored in [49], demystified the influential features, providing invaluable insights for educators. Knowing which factors are more indicative of a student's performance could revolutionize educational strategies, ensuring a more focused and student-centric approach.

However, despite these advancements, the limitation of data cannot be overlooked. While the study harnessed a wealth of data points, the quality of these data, especially concerning the emotional expressions, was heavily reliant on the accuracy of the text classification models. Future research could benefit from more sophisticated Natural Language Processing (NLP) tools, possibly incorporating contextual understanding to grasp the subtleties of human emotion and interaction, an enhancement suggested by [50].

Moreover, the scope of the dataset also posed a constraint. The research was circumscribed to a specific geographical region and educational level, limiting the generalizability of the findings. Subsequent studies could transcend these boundaries, encompassing a more diverse student population to authenticate the universality of the findings.

In conclusion, this research has paved a novel pathway in understanding and predicting students' academic performance, intertwining the realms of machine learning, educational strategies, and psychological underpinnings. The insights gleaned hold profound implications for educators, policy-makers, and curriculum designers, advocating for a more holistic, student-oriented approach in the educational odyssey. However, the journey does not end here. With the continual evolution of machine learning and the ever-changing educational landscape, future research beckons, promising even deeper insights and more personalized educational experiences.

VI. Conclusion

The journey through this research, from conceptual frameworks to analytical discussions, reflects a profound exploration of integrating machine learning into Software-Defined Networking (SDN) to enhance load balancing. As we draw conclusions, it's imperative to encapsulate the essence of our findings and their implications for future scientific inquiry and practical application in the networking sphere.

This study marked a significant advancement by demonstrating that machine learning algorithms could revolutionize the way network resources are managed, optimizing the distribution of data loads across various pathways. By employing sophisticated algorithms, we unveiled the potential to predict network congestions, dynamically adjust to traffic changes, and improve overall efficiency and user experience. This paradigm shift from traditional methods accentuates a move towards more autonomous, self-sufficient systems capable of sophisticated decision-making processes, essential in the burgeoning era of digital transformation and the Internet of Things (IoT).

However, the research also highlighted critical challenges and limitations, from the complexities of algorithm training and data security concerns to the practical applicability of the proposed model outside simulated environments. These challenges are not terminuses but instead signposts indicating areas requiring further exploration, refinement, and innovation.

Looking forward, the implications of this research are both broad and profound. They suggest an imminent need for robust, real-world testing and the potential for interdisciplinary approaches that could further enrich these technological advances. The prospects of enhanced security measures, scalability considerations, and user-centric adaptations also present exciting, necessary trajectories.

In conclusion, this study does not represent an end but a beginning. It serves as a catalyst for continued exploration and dialogue in the realms of machine learning, networking, and beyond. The confluence of these fields holds significant promise for creating more resilient, efficient, and intelligent networks, poised to support the ever-evolving demands of future digital landscapes.

Automatic Recognition of Marine Creatures using Deep Learning

Oudayrao Ittoo, Sameerchand Pudaruth
ICT Department, FoICDT, University of Mauritius, Réduit, Mauritius

***Abstract*—The identification of marine species is a challenge for people all over the world, and the situation is not different for Mauritians. It is of utmost importance to create an automated system to correctly identify marine species. In the past, researchers have used machine learning to address the issue of marine creature recognition. The manual feature extraction part of machine learning complicates model creation as features have to be extracted manually using an appropriate filter. In this work, we have used deep learning models to automate the feature extraction procedure. Currently, there is no publicly available dataset of marine creatures from the Indian Ocean. We created one of the biggest datasets used in this field, consisting of 51 different marine species collected from the Odysseo Oceanarium in Mauritius. The original dataset has a total of 5,709 images and is imbalanced. Image augmentations were performed to create an oversampled version of the dataset with 171 images per class, for a total of 8,721 images. The MobileNetV1 model trained on the oversampled dataset with a split ratio of 80% for training and 10% for validation and testing was the best performing one in terms of classification accuracy and inference time. The model had the smallest inference time of 0.10 seconds per image and attained a classification accuracy of 99.89% and an F1 score of 99.89%.**

Keywords—Marine creature identification; machine learning; deep learning; MobileNetV1; Mauritius

I. Introduction

Millions of marine creatures live in the ocean, making it the largest habitat on the planet [1]. The world's health is closely related to this marine biodiversity. These marine creatures are of the utmost importance to society as they are a source of food and a symbol of economic welfare. For example, fish are estimated to provide 20% of animal protein to about three billion people [2]. In addition, the ocean is home to a diverse range of creatures that can be utilised for the development of pharmaceutical products to treat various diseases [3]. The human race benefits from the numerous advantages that the marine ecosystem provides for its survival [4]. Therefore, the effective conservation of this biodiversity in a sustainable manner is crucial for the proper functioning of the marine ecosystem and the human race [5].

Traditionally, marine biologists identify aquatic species by visually inspecting their morphological traits [6-7]. Another popular method to correctly identify and group them is deoxyribonucleic acid (DNA) barcoding [8]. This method can be used to precisely, accurately, and quickly detect invasive alien species or marine bacteria that can cause viral outbreaks [9]. DNA barcoding has already proven its worth as a deterrent against various forms of economic fraud, such as seafood mislabelling [10]. Despite its advantages, such an identification method is labour-intensive and time-consuming. As a result, it is crucial to create an automatic marine creature recognition system to address these difficulties.

Automatic recognition of marine creatures is a topic of interest to many researchers around the world. Pudaruth et al. have developed such a system in the form of a mobile application to recognise some of the marine fish that are present in Mauritian waters [11]. However, no system has been developed to cater for other types of marine species that can be found in the Indian Ocean. Common people with no expertise in marine taxonomy have difficulties distinguishing between the different aquatic species. This poses a problem, especially when deadly ocean animals such as the stonefish, blue-ringed octopus, or the lionfish, amongst many others, are encountered [12-13]. Furthermore, some endangered species require proper protection, such as conservation laws and regulations. These are only feasible after recognising them.

The motivation for this study is to create an image recognition model capable of distinguishing between different marine creatures. It is worth mentioning that 80% of the ocean is still undiscovered. According to an interview given by Dr Gene Carl Feldman to Oceana (an organisation focused on protecting the ocean), space exploration is far simpler than ocean exploration [14]. As there is an abundance of marine life in the ocean and it is difficult to cater for all of them, the scope of this study focuses only on some marine creatures that are available at Odysseo Oceanarium in Mauritius. The recognition model has been integrated into a web application. The importance of this application is diverse. First, it will help in creating awareness about the creatures, especially dangerous species. Furthermore, it will also help in raising knowledge by providing some basic information about the creature after the recognition phase. Information such as its scientific name, common name, short description, and whether the animal is deadly has been provided. The information provided can then be used to better understand the animal. The proposed system employs computer vision and deep learning techniques to properly and accurately identify the marine creatures.

This paper is divided into different sections. In Section II, a background study and reviews of related work in this field are provided. Section III delves deeper into the methodology and Section IV assesses the model's performance and discusses the results obtained. The final section concludes this paper. Table XII in Appendix I lists all the marine creatures from the Odysseo Oceanarium which were used in this study.

II. Literature Review

Several studies have been carried out in the past to develop systems for the automated identification of marine life. This section contains summaries of several relevant works in chronological order.

A. Fish Recognition

Strachan et al. conducted one of the earliest studies in this field, attempting to evaluate three different image analysis methods to differentiate between images of fish from different species [15]. Methods such as invariant moments, mismatch optimisation, and geometric shape descriptors were used. Their strategy takes into account the fact that fish can be identified by their body shape. The dataset used in their experiment consisted of 60 different fish images. Their research found that the geometric shape descriptors method outperformed the other two approaches, yielding a 90% accuracy rate. However, their experiment was limited to a restricted number of species: only seven different species (two of which were identical gurnard fish, shot from different perspectives).

Fish image recognition has found its usefulness in systems such as automated fish counting. Fish counting is a challenging but critical task for the maintenance of a sustainable fishing level and the prevention of overfishing [16]. Luo et al. proposed a method for such a system by using video footage captured during fishing operations [17]. Their method involved the use of Statistical Shape Models (SSM) and Artificial Neural Network (ANN). To overcome the occlusion problem caused by people walking around the deck of the ship, the video footage was pre-processed. The colour of the images was used as a feature for the recognition process, and an Error Back Propagating ANN classifier was used to recognise the fish from the background. The next step was to use SSM to identify the fish. Lastly, a rule-based counting method was used to count the number of fish. Their method achieved an accuracy of 89.6% for a one-hour video.

The study conducted by Rathi et al. proposed a solution based on Convolutional Neural Network (CNN), deep learning, and image processing [18]. Their method involved pre-processing of the captured images with the aim of removing noise and then using CNN to classify the different fishes. The Otsu's thresholding method was adopted to obtain a histogram representation of the input grayscale image. The next step was to perform morphological operations, such as dilation and erosion, to prepare the resulting image to be processed by the CNN algorithm. To put their method to the test, they used 27,142 images from the Fish4Knowledge dataset, representing 21 species which resulted in an accuracy of 96.29%. However, due to background noise and a lack of image enhancement techniques to compensate for lost features during the pre-processing phase, some of the classifications were incorrect.

Faster R-CNN was used by Mandal et al. to create a system for the automatic detection and identification of fish species [19]. Their dataset consisted of 50 different fish species. Using a random sample technique, their dataset was divided into training (70%), validation (10%), and testing (20%) sets. They were able to achieve a mean average precision (mAP) of 82.4%.

Deep and Dash employed CNN for feature extraction, followed by Support Vector Machine (SVM) and k-Nearest Neighbour (kNN) for classification [20]. They used the Fish4Knowledge dataset which was divided into training (90%) and testing (10%) sets. The training set was further divided such that 10% of the training images were used for validation. Their research proved that using kNN for classification yields the best accuracy of 98.79%.

Rico-Díaz et al. proposed a non-invasive method for addressing the fish recognition problem by combining artificial vision techniques and ANN [21]. Their work relied on the fact that fish from different species can be distinguished based on their eye's sclera and pupil. The first step in the identification process was to employ image filtering techniques to reduce noise in the captured image. After that, background subtraction was done to segment the fish from the background. The next step was to identify the fish's eye, and for this the Hough algorithm was used. Additionally, a feed-forward ANN, being more costly, was also employed if the first method (the Hough algorithm) failed. Using their approach, they were able to achieve an overall accuracy of 74% for eye detection. Also, two underwater cameras were used to estimate the size and weight of the fish while they were swimming. Their solution, however, is dependent on the image's quality and a good background subtraction. Furthermore, performance degrades when the ANN is used if the Hough algorithm fails to detect the fish.

Liang et al. combined CNN and migration learning to distinguish between three different kinds of Chinese ornamental fish [22]. They used TensorFlow, which is an open-source library for machine learning and artificial intelligence, to train their network model. A total of 14, 000 (4*3,500) images were gathered, which were divided into 3,000 and 500 images for training and testing, respectively. Their dataset, which consisted of 3,500 images of three different fish and one set for other types of fish, was gathered from the Internet by using the web crawler technology. Following that, pre-processing was an important step in enhancing the recognition rate as real-time videos of fish were shot outside of the aquarium. The dark channel prior and gamma correction methods were used for this purpose. The latter was a significant step towards the removal of brightness from the pictures. To reduce processing power, all images were scaled to 250 * 250 pixels. Their experiment showed that an accuracy of 98.1% is achievable.

Cai et al. took a different approach to realising a system for detecting fish and counting [23]. They proposed to use the You Only Look Once Version 3 (YOLOv3) model with MobileNet as the backbone for feature extraction. Their proposed system was trained using different strategies. They found out that their system performs better than when using YOLOv3 alone. The average precision obtained was 79.61%.

Pudaruth et al. experimented with multiple machine learning classifiers to discover the most effective one for developing a smartphone application to recognise different fish species existing in the exclusive economic zone (EEZ) of Mauritius [11]. Their model was tested on 38 different fish species with a dataset consisting of 1,520 images. Using the kNN classifier, they were able to attain an accuracy of 96%. Also, their study has shown that the use of deep neural networks (DNN) with the TensorFlow framework can attain an impressive accuracy of 98%. However, pictures of the fish were taken in a controlled environment and not in their natural habitat. The fish were placed on a white background to enable easier segmentation.

Conrady et al. used the Mask Region-Based Convolutional Neural Network (R-CNN) object detection framework to perform classification of the Roman seabream fish, which is endemic in Southern Africa [24]. Their dataset consisted of 2,015 images of the fish. They were able to get a mAP of 81.45% on their test data.

B. *Marine Creature Recognition*

While most researchers have focused on fish recognition, Chen and Yu proposed a high-definition camera system capable of recognising marine creatures [25]. Their approach to the identification process was broken down into multiple steps. The first step was concerned with the extraction of the image frames from the original video. The following step involved pre-processing of the retrieved images. In addition, for the detection phase, the original image had to be transformed to its grayscale and binary representations. To classify seven creatures, two separate methods were used: The Back Propagation Neural Network and the SVM methods. Their study showed that the SVM approach had an accuracy of 92% in classifying the creatures, which was higher compared to the other methods. However, their proposed method does not work well for creatures with similar shapes.

Pelletier et al. developed a system capable of classifying marine animals into eight categories [26]. Their imbalanced dataset contained 3,777 images. They used two models to conduct their tests, namely AlexNet and GoogLeNet. The best performing model was GoogLeNet. The models were tested with uncropped and cropped images. They found out that by using the cropped images and GoogLeNet, they got the best accuracy, which was 96.54%. Additional tests were done by also considering the top two results during the classification process. This further increased the accuracy of the GoogLeNet model with the cropped dataset to 98.94%. Aside from image recognition, several other approaches for automatic identification of marine creatures have been used in the recent past. Demertzis et al. suggested a novel technique: the use of a Machine Hearing Framework (MHF) for the identification of marine animals through their underwater sounds [27]. They were able to recognise fish and marine animals with recognition accuracy of 96.08% and 92.18%, respectively.

Song et al. proposed a method for the identification of marine creatures from seafloor videos [28]. Their proposed methods are twofold: extraction of valid video clips followed by recognition of the creature. During the first phase, an image segmentation method was used to determine and extract all frames from the video containing the marine creature. The next phase was concerned with identifying and labelling the creatures in the valid video clips. This was accomplished with the help of public participation. Lastly was the recognition process, which was accomplished with the help of the information submitted by the public and the membership function. Their method had an accuracy of above 80% in extracting the valid video frames, and all the creatures were successfully recognised.

Liu et al. implemented an embedded system to classify marine animals into seven categories [29]. Their dataset includes 8,455 photos of marine animals, with 80% of the images used for training and 20% used for validation. The training images were augmented by applying some transformations (rotation, translation, and flipping), which increased the number of training images to 27,056 (6,764*4). The models that were deployed on the embedded device were tested with 350 new images. Three models were used: MobileNetV1, MobileNetV2, and InceptionV3. MobileNetV2 had the highest testing accuracy of 95.0% and validation accuracy of 92.89%. Their model took an average of 0.0578 seconds to classify one image.

C. *Knowledge Gap*

Even though multiple studies have been conducted, very few have tested the effect of using deep learning (DL) on a big dataset. According to the review, the largest dataset had 50 species and consisted of 4,909 images [19]. Furthermore, there is no web application available in Mauritius that can perform recognition of marine animals. Adding to that, no dataset consisting of more than 50 marine creature species is currently available. This work aims to provide some answers to these research gaps as well as to contribute a dataset and a web application to perform marine creature classification.

III. Methodology

A. *Data Collection at Odysseo Oceanarium*

As no relevant existing dataset of marine creatures from the Indian Ocean was found at the time of this study, a custom dataset was created. Data collection can be done from multiple sources. However, due to time constraints, this is not feasible. Nonetheless, the source should be trustworthy and provide the desired information. In this regard, the Odysseo Oceanarium was chosen as the primary source of data gathering for this study. In recent years, underwater video surveillance has grown increasingly common in marine environments to acquire data on marine creatures in their natural habitat. This is a non-invasive method and provides sufficient data for research. Chen and Yu adopted this approach by using an underwater submerged video system [25]. However, for this study, due to limited resources, videos of marine creatures were taken outside of the aquariums found at Odysseo using a smartphone. All the videos were taken with a Huawei Y9 Prime 2019 smartphone, which has a resolution of 16 megapixels.

B. *Data Processing*

Numerous videos of marine creatures were obtained at Odysseo. Each video was converted into frames. Pelletier et al. have already shown that cropped images result in better model performance [26]. Taking this into consideration, each extracted frame was carefully cropped. Not all images were included in the final dataset. The following conditions had to be met to use the image, or else it was discarded: the image containing the creature should not be occluded by another creature or object; the creature should be recognisable and it should not be too far from the image. Fig. 1 shows an example of a good image. It follows all the criteria described above.

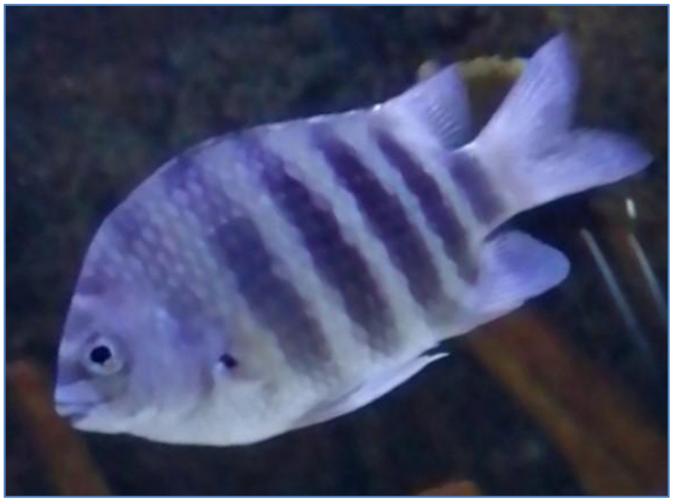

Fig. 1. Example of a good image.

C. Custom Dataset

The custom-built dataset consists of 51 classes of marine creatures as shown in Fig. 2. It has 5,709 images in total and is imbalanced. The class having the highest number of images is Dascyllus aruanus with 171 pictures, and the one with the lowest number of images is Chaetodon kleinii with 74 pictures.

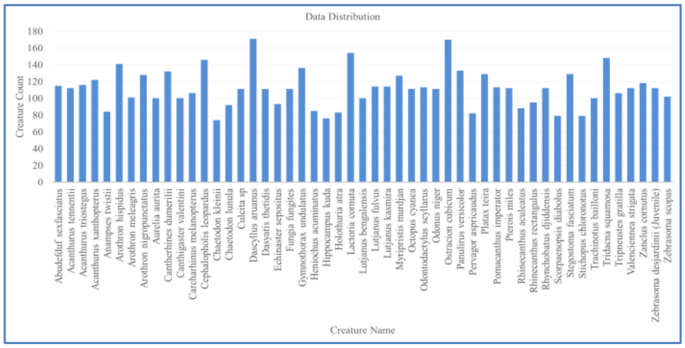

Fig. 2. Unbalanced dataset distribution.

Marine animals are challenging to photograph since they conceal their presence in aquarium by hiding beneath rocks, among plants and tank accessories. This makes it difficult to collect the same number of images for all of the creatures and is the primary reason why the dataset is initially imbalanced.

D. Oversampling

To achieve an equal distribution of images per class, the dataset had to be balanced and for this oversampling was done as shown in Fig. 3. The following transformations were used for augmentation: flipping, change in brightness, shearing and rotation. Each image is subject to three possible modifications.

After oversampling, all classes got an equal distribution of images. Each marine creature now has 171 images. Fig. 4 shows the data distribution of the dataset after oversampling.

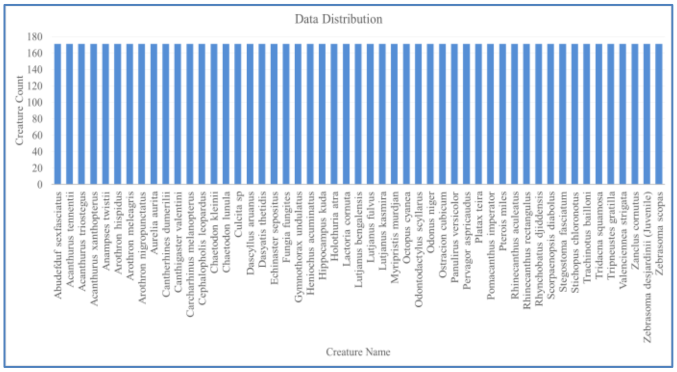

Fig. 3. Distribution after oversampling.

E. Splitting the Dataset

The oversampled dataset (171 images per class) were split using splitting ratios of 8:1:1, 7:2:1 and 6:3:1 for training, validation and testing sets. As a result of multiple manipulations, different dataset versions were created. A proper naming convention was devised to properly organise the work being done. Table I lists the various datasets that were used throughout this paper.

TABLE I. SUMMARY OF DATASET VERSIONS

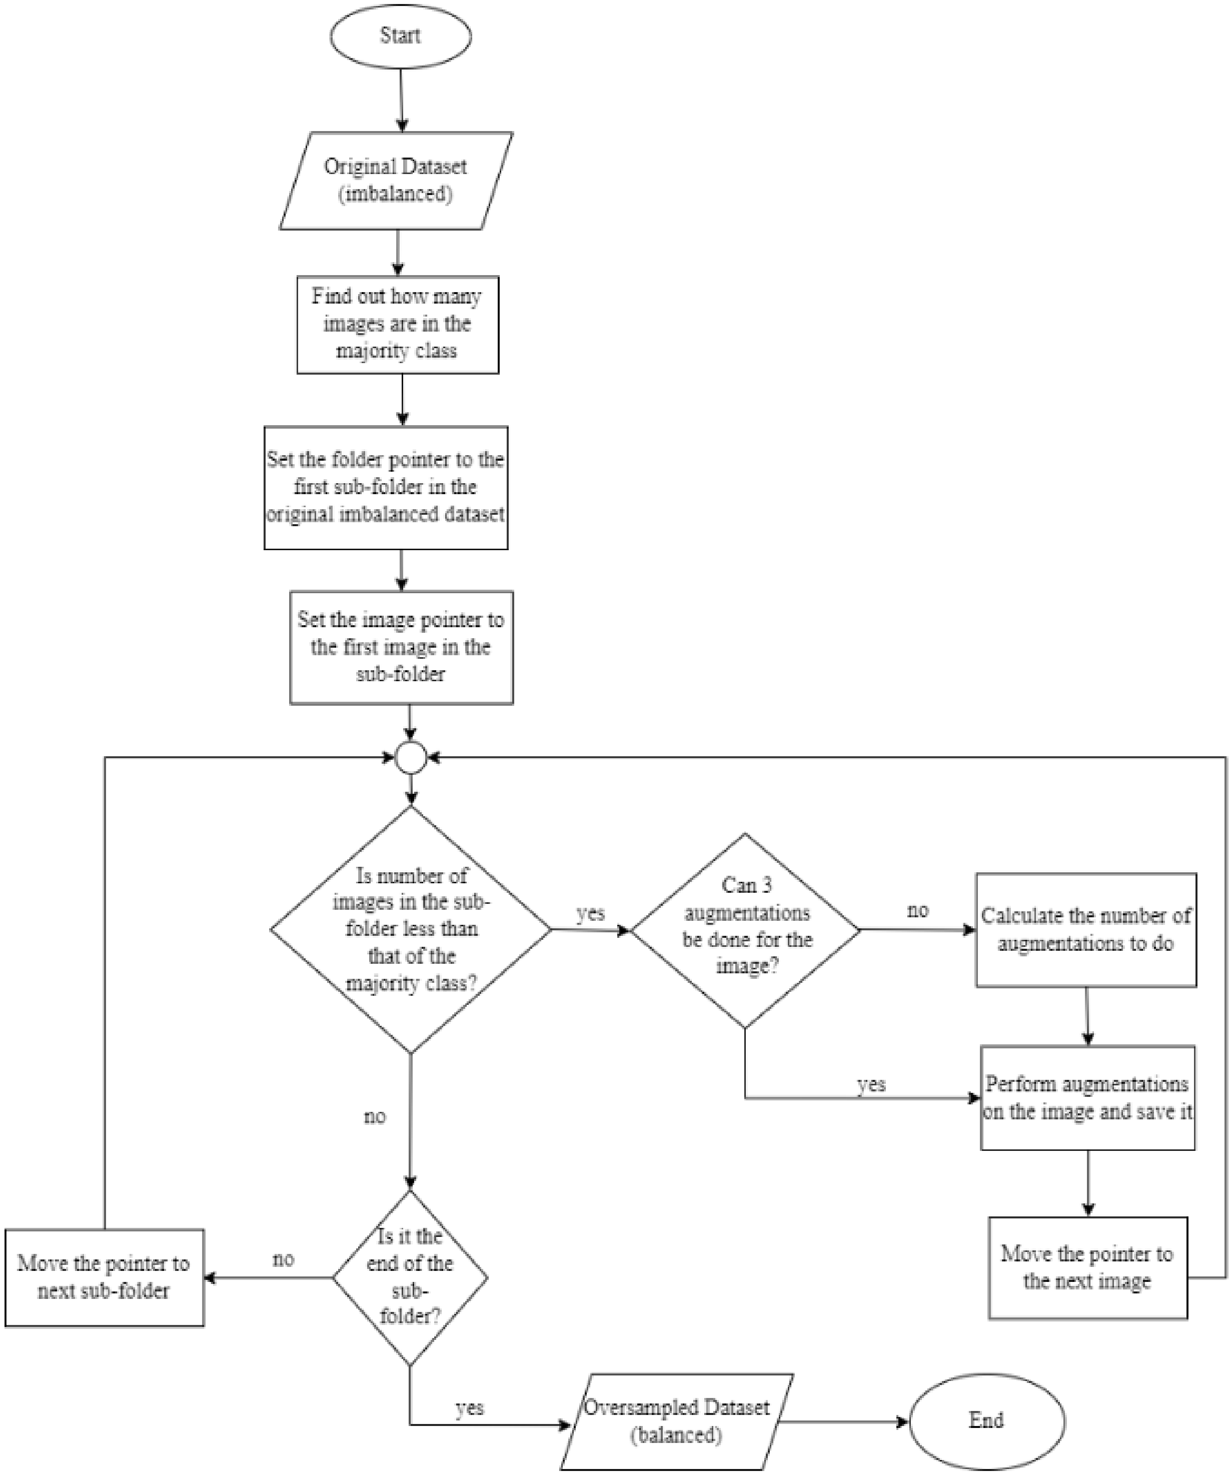
#	Dataset Name	Description
1	DS_oversample_8_1_1	This is the oversampled dataset, which contains 171 images for each class. Three different splits are done.
2	DS_oversample_7_2_1	
3	DS_oversample_6_3_1	

F. Feature Extraction and Classification

For this research, pre-trained CNN models were used both for feature extraction and classification. The pre-trained models that were employed are: MobileNetV1, InceptionV3 and VGG16. Different image sizes were utilised depending on which model was imported. The image sizes used are shown in Table II [30-31].

TABLE II. IMAGE SIZES FOR DIFFERENT MODELS

Model Name	Image Size
MobileNetV1	224*224
InceptionV3	299*299
VGG16	224*224



Start
Original Dataset (imbalanced)
Find out how many images are in the majority class
Set the folder pointer to the first sub-folder in the original imbalanced dataset
Set the image pointer to the first image in the sub-folder
Is number of images in the sub-folder less than that of the majority class?
yes
Can 3 augmentations be done for the image?
no
Calculate the number of augmentations to do
yes
Perform augmentations on the image and save it
Move the pointer to the next image
no
Is it the end of the sub-folder?
no
Move the pointer to next sub-folder
yes
Oversampled Dataset (balanced)
End

Fig. 4. Oversampling flowchart.

After the features have been extracted, the next step is to use these features and a classifier to make a prediction. The architecture of the pre-trained models used is shown in Fig. 5. The input image given to the VGG16 and MobileNetV1 models is an image of size 224 * 224 compared to the InceptionV3 model, which is of size 299 * 299.

The classification layers of the pre-trained model were replaced with one global average pooling layer and three dense layers. The softmax activation function was used in the model's final dense layer for classification. Adding to that, for the two other dense layers, the rectified linear activation unit (ReLU) activation function was used. The custom model predicts the input image as one of the 51 classes of marine creatures from the dataset.

Fig. 5. High level architecture of pre-trained model.

G. Use of Callback Functions

Different callback functions, such as ModelCheckpoint and EarlyStopping, were employed during model training. The EarlyStopping callback function is viewed as a technique to combat model overfitting. For this work, the number of epochs was fixed at 100, and then the EarlyStopping function was used to halt training if the model became overfit [32]. The ModelCheckpoint callback function, on the other hand, was used to save the model during the training phase. Failure may occur occasionally, causing the training to be disrupted. It is preferable to resume training from the last saved epoch rather than starting it from scratch [33].

H. Use of Optimiser

The Stochastic Gradient Descent (SGD) optimiser was employed during model training to adjust the weight and learning rate properties of the DL model to reduce losses during backpropagation. Additionally, to help the optimiser converge in the right direction and prevent overshooting, Nesterov momentum was employed. Due to its look ahead property, the Nesterov method takes the appropriate precautions by making smaller updates to reach the minima [34-35]. Experiments were performed using the MobileNetV1 pre-trained model to find the optimal parameters to pass to the SGD optimiser function. We discovered that setting the learning rate to 0.001, decay to 1e-6, and momentum to 0.8 produces the best results. Thus, these parameter values were used throughout this work for model training.

I. Training using Transfer Learning

Transfer learning is a concept whereby a previously trained (pre-trained) model is reused to tackle a new but comparable task. This is a popular deep learning technique as the neural network does not have to be trained from scratch with a huge volume of data. The weight that the network has already learnt is simply transferred to the new task in transfer learning. This technique aids in reducing training time and may possibly increase the performance of the neural network [36]. In this research, transfer learning is used to train the CNN models. Fig. 6 illustrates how transfer learning was applied for model training using the custom-built dataset.

Fig. 6. Block diagram of the proposed training strategy.

There are different types of fine-tuning that can be done on pre-trained CNN models, such as training the entire model, training some layers and leaving others frozen, and freezing the convolutional base by not training the feature extraction layers [37]. For this work, each test will be done by training the entire model and freezing the convolutional base.

J. The Web Application

A good and simple user interface is crucial for the user to efficiently use the application. Taking this into consideration, the user interface of the web application is divided into 4 areas: image upload area, prediction area, creatures in dataset area and modal displaying creature information.

1) Image upload area: Fig. 7 shows the image upload area when the application is accessed through a desktop and a mobile phone.

IV. Results

This section provides an evaluation of the different models.

A. Testing Different Split Ratios

Table III shows the three splits for the oversampled dataset.

TABLE III. Oversampled Dataset Split Summary

Dataset	Split Ratio	Train	Val	Test
DS_oversample_8_1_1	Train: 80% Val: 10% Test: 10%	136	17	18
DS_oversample_7_2_1	Train: 70% Val: 20% Test: 10%	119	34	18
DS_oversample_6_3_1	Train: 60% Val: 30% Test: 10%	102	51	18

The three pre-trained models employed were trained on the three versions of the oversampled dataset. Table IV, Table V and Table VI shows the results obtained.

TABLE IV. DS_Oversample_8_1_1 Result

Model	Trainable Layers	Classification Accuracy (%)	F1 Score (%)
MobileNetV1	False	99.56	99.56
	True	99.89	99.89
VGG16	False	98.58	98.58
	True	98.91	98.91
InceptionV3	False	97.17	97.16
	True	99.35	99.35

TABLE V. DS_OVERSAMPLE_7_2_1 RESULT

Model	Trainable Layers	Classification Accuracy (%)	F1 Score (%)
MobileNetV1	False	99.67	99.68
	True	99.89	99.89
VGG16	False	98.47	98.48
	True	99.89	99.89
InceptionV3	False	97.60	97.58
	True	99.46	99.45

TABLE VI. DS_OVERSAMPLE_6_3_1 RESULT

Model	Trainable Layers	Classification Accuracy (%)	F1 Score (%)
MobileNetV1	False	98.58	98.58
	True	99.46	99.45
VGG16	False	97.82	97.82
	True	99.02	99.03
InceptionV3	False	96.51	96.52
	True	99.35	99.35

TABLE VII. BEST MODELS FOR OVERSAMPLED DATASET

Dataset	Split Ratio	Best Model	Classification Accuracy (%)	F1 Score (%)
DS_oversample_8_1_1	Train: 80% Val: 10% Test: 10%	MobileNet V1	99.89	99.89
DS_oversample_7_2_1	Train: 70% Val: 20% Test: 10%	MobileNet V1	99.89	99.89
		VGG16	99.89	99.89
DS_oversample_6_3_1	Train: 60% Val: 30% Test: 10%	MobileNet V1	99.46	99.45

The best accuracy obtained in all cases is when the feature extraction layers are trained. Table VII shows the best performing model for each of the different splits.

Irrespective of the split ratios used, the best models were able to achieve very good accuracy of above 99%. The variations in the scores, as indicated in Table VII are less than 1%. This is due to the fact that randomness is used in weight initialization when training of the model starts. The weights are adjusted at every epoch. This produces different outcomes for the same model each time it is trained on the same dataset [38-39]. This means that if the same experiments were repeated, different scores would have been obtained. To conclude, the differences obtained are considered insignificant.

Judging the models solely on accuracy is not enough to give a fair evaluation. The model's prediction time must also be considered. The inference time of the models to predict all the images in their test directory was repeated five times. In Table VIII, the total time taken is displayed in seconds.

Using the values shown in Table VIII the average inference time can be calculated by dividing the time taken to predict all the images by five. The prediction time for one image can then be computed by dividing the resulting value by the number of test pictures as shown in Table IX.

TABLE VIII. PREDICTION TIME

Dataset	Number of Images	MobileNetV1	VGG16	InceptionV3
DS_oversample_8_1_1	918 (18*51)	475.5	2453.5	1002.6

TABLE IX. PREDICTION TIME PER IMAGE

Dataset	MobileNetV1	VGG16	InceptionV3
DS_oversample_8_1_1	0.10	0.53	0.22

From Table IX, it can be seen that the MobileNetV1 models achieved the lowest inference time. Table X shows the number of trainable parameters and the sizes of the three models.

TABLE X. MODEL SIZES

Model	Parameters	Size
VGG16	 Total params: 14,885,491 Trainable params: 14,885,491 Non-trainable params: 0	113.7 MB
InceptionV3	 Total params: 22,366,803 Trainable params: 22,332,371 Non-trainable params: 34,432	171.8 MB
MobileNetV1	 Total params: 3,530,739 Trainable params: 3,508,851 Non-trainable params: 21,888	27.3 MB

Among the three models, MobileNetV1 has the least number of trainable parameters. Furthermore, the MobileNetV1 model is smaller in terms of size. As a result, it has the shortest inference time. For deployment, the MobileNetV1 model trained on the DS_oversample_8_1_1 dataset was chosen since it had the lowest inference time of 0.10 seconds per image.

B. Comparisons with Related Works

Even though the accuracies obtained in this study cannot be truly compared with other researchers because the same datasets were not employed, an attempt to compare our work with previous studies is made in this section.

Deep and Dash conducted several experiments using a dataset of 23 creatures [20]. They used CNN for both feature extraction and classification. Additionally, they used a hybrid strategy in which CNN was used to extract features and a classifier (kNN or SVM) was used to classify them. They got the best accuracy of 98.79% when they used their custom-made CNN for feature extraction and kNN as a classifier. However, in this study, we were able to achieve higher accuracy when the pre-trained CNN models were used for both extraction and classification.

The training methodology adopted by Liu et al. is the same as the one we have used [29]. They also used transfer learning to train their models. They used the MobileNetV1, MobileNetV2 and InceptionV3 models to perform feature extraction and classification. Table XI shows a comparison between the best performing model in their work and in ours.

TABLE XI. COMPARISION OF THE BEST PERFORMING MODEL

Work	Best Model	Classification Accuracy (%)	Inference Time (Seconds)
Ittoo and Pudaruth	MobileNetV1 trained on the DS_oversample_8_1_1 dataset	99.89	0.10
Liu et al. (2019)	MobileNetV2	95.0	0.0578

The MobileNetV2 model presented by Liu et al. is limited to predicting 7 species [29]. However, the model presented in this study can perform classification between 51 creatures. The larger the number of classes in a deep learning model, the more time the model generally takes to predict the image.

V. CONCLUSIONS

Automatic recognition of marine creatures is a topic of interest to many researchers around the world. People who are unfamiliar with marine taxonomy have trouble discriminating between different aquatic organisms. This poses a problem, especially when deadly ocean animals are encountered. Several studies have been undertaken over the last few decades, but not many have examined the effect of training deep learning pre-trained CNN models on a large dataset.

In this research, three deep learning models, namely, MobileNetV1, InceptionV3, and VGG16, were investigated and implemented for the task of marine creature classification. To achieve the objectives of this study, a customised dataset of 51 available creatures from the Indian Ocean was built and used for training and testing the effectiveness of models. Images of marine creatures were collected at Odysseo Oceanarium in Mauritius.

Several experiments with different split ratios were carried out. The splits for the training and validation sets were varied, and that for the testing set was fixed at 10%. Transfer learning was used, and the models were fine-tuned by replacing their classification layers with new ones. Adding to that, two experiments were performed for each model: training the feature extraction layers and not training them. All of these tests were carried out in order to determine the optimal split ratio, dataset, and model.

It has been concluded that the best suited model was MobileNetV1 trained with the oversampled dataset with a split ratio 80% for training, 10% for validation and 10% for testing. The model attained a classification accuracy and an F1 score of 99.89%. The model had an inference time of 0.10 seconds per image. This model was then integrated into a web application.

Our research has thus demonstrated that deep learning models offer enormous potential for automating the process of marine creature recognition. The developed web application with the integrated MobileNetV1 model provides a reliable and fully automated tool for the classification of marine creatures without the need for expert assistance.

ACKNOWLEDGMENT

We are thankful to the Odysseo Oceanarium Mauritius for allowing us to photograph the marine creatures in their aquarium in order to create the dataset utilized in this study.

APPENDIX I

TABLE XII. LIST OF ALL MARINE CREATURES

#	Common Name	Scientific Name	Image	Number of Images
1	Scissortail sergeant	Abudefduf sexfasciatus		115
2	Doubleband surgeonfish	Acanthurus tennentii		112

3	Convict surgeonfish	Acanthurus triostegus		116
4	Yellowfin surgeonfish	Acanthurus xanthopterus		122
5	Yellowbreasted wrasse	Anampses twistii		84
6	White-spotted puffer	Arothron hispidus		141
7	Guineafowl puffer	Arothron meleagris		101
8	Blackspotted puffer	Arothron nigropunctatus		128
9	Common jellyfish	Aurelia aurita		100

10	Whitespotted filefish	Cantherhines dumerilii		132
11	Valentin's sharpnose puffer	Canthigaster valentini		100
12	Blacktip reef shark	Carcharhinus melanopterus		106
13	Leopard hind	Cephalopholis leopardus		146
14	Sunburst butterflyfish	Chaetodon kleinii		74
15	Raccoon butterflyfish	Chaetodon lunula		92

16	Cushion star	Culcita sp		111
17	Whitetail dascyllus	Dascyllus aruanus		171
18	Thorntail stingray	Dasyatis thetidis		111
19	Red starfish	Echinaster sepositus		93
20	Common mushroom coral	Fungia fungites		111
21	Undulated moray	Gymnothorax undulatus		136
22	Pennant coralfish	Heniochus acuminatus		85

23	Spotted seahorse	Hippocampus kuda		76
24	Black sea cucumber	Holothuria atra		83
25	Longhorn cowfish	Lactoria cornuta		154
26	Bengal snapper	Lutjanus bengalensis		100
27	Blacktail snapper	Lutjanus fulvus		114
28	Common bluestripe snapper	Lutjanus kasmira		114
29	Pinecone soldierfish	Myripristis murdjan		127

30	Big blue octopus	Octopus cyanea		111
31	Peacock mantis shrimp	Odontodactylus scyllarus		113
32	Red-toothed triggerfish	Odonus niger		111
33	Yellow boxfish	Ostracion cubicum		170
34	Painted spiny lobster	Panulirus versicolor		133
35	Orangetail filefish	Pervagor aspricaudus		82

36	Longfin batfish	Platax teira		129
37	Emperor angelfish	Pomacanthus imperator		113
38	Devil firefish	Pterois miles		112
39	White-banded triggerfish	Rhinecanthus aculeatus		88
40	Wedge-tail triggerfish	Rhinecanthus rectangulus		95
41	Giant guitarfish	Rhynchobatus djiddensis		112

42	False stonefish	Scorpaenopsis diabolus		79
43	Zebra shark	Stegostoma fasciatum		129
44	Greenfish sea cucumber	Stichopus chloronotus		79
45	Small spotted dart	Trachinotus bailloni		100
46	Fluted giant clam	Tridacna squamosa		148
47	Striped sea urchin	Tripneustes gratilla		106
48	Blueband goby	Valenciennea strigata		112

49	Moorish idol	Zanclus cornutus		118
50	Indian sail-fin surgeonfish	Zebrasoma desjardinii (Juvenile)		112
51	Twotone tang	Zebrasoma scopas		102

Enhanced Linear Regression Models for Resource Usage Prediction in Dynamic Cloud Environments

Xiaoxiao Ma
School of Transportation, Chongqing Vocational College of Transportation, Chongqing 402247, China

***Abstract*—In response to the diverse resource utilization patterns observed across enterprises, this study proposes the utilization of adaptable cloud services. A novel system framework is presented, capturing and logging resource consumption at discrete intervals. Subsequently, this recorded data serves as input for a linear regression model, functioning as a machine learning tool to predict resource utilization in forthcoming intervals, leveraging historical data stored within the regression module. To bolster the resilience of the linear regression model, various effective meta-heuristic techniques are integrated alongside the conventional linear regression methodology, facilitating more accurate anticipation of overloaded or under-loaded resource conditions before their occurrence in real-world scenarios. Simulations demonstrate that the hybrid algorithm, named Whale Optimization Algorithm-based Linear Regression (WOA-LR), outperforms Genetic Algorithm-Linear Regression (GA-LR), Particle Swarm Optimization-Linear Regression (PSO-LR), JAYA-LR, and traditional Linear Regression (LR) in achieving desired objective functions and significantly reducing Mean Squared Error (MSE). This approach holds promise for more accurate resource utilization prediction and optimization in dynamic cloud environments.**

Keywords—Cloud computing; resource utilization; prediction; linear regression; metaheuristics

I. Introduction

With recent advances in artificial intelligence, the Internet of Things (IoT) [1, 2], Wireless Sensor Networks (WSNs) [3], and cloud computing, research efforts are shifting towards simplifying communication across various devices. Cloud computing represents a novel computational paradigm for provisioning computing resources, catering to a wide spectrum of users, ranging from individuals to large-scale enterprises [4, 5]. Cloud computing ecosystems are dominated by the intricate and cost-intensive data centers (DCs) that significantly impact service providers' financial viability [6]. Cloud providers offer three primary service categories, namely Software as a Service (SaaS), Platform as a Service (PaaS), and Infrastructure as a Service (IaaS), leveraging web service technology [7, 8]. Notable examples include Amazon for IaaS [9], Google for PaaS [10], and Salesforce for SaaS [11], all renowned as leading cloud providers worldwide. On one front, cloud providers offer their computational resources to fulfill users' Quality of Service (QoS) requirements, and on the other, they must effectively manage their Total Cost of Ownership (TCO) to thrive in the increasingly competitive cloud market [12]. Virtualization technology is widely employed within DCs to optimize resource allocation and reduce overall power consumption, a pivotal component of TCO. Furthermore, power management aligns with sustainability objectives. In a virtualized environment, a hypervisor intervenes to multiplex the resources of Physical Machines (PMs) among Virtual Machines (VMs) [13]. Inefficient resource allocation has repercussions on both resource utilization and the overall power consumption of DCs [14, 15].

Given the dynamic and ever-changing nature of cloud infrastructures and platforms, live VM migration emerges as a practical strategy that aligns with the current state of DCs [16]. Two common occurrences in DCs are under-utilization and over-utilization events [17]. The former entails a high-power consumption rate, while the latter is characterized by a high SLA violation rate. To address the scenario where businesses deploy VMs with varying usage patterns and resource requirements over time, machine learning approaches prove invaluable in discerning near-precise usage patterns in the short-term future [18]. Consequently, live virtual machine migration is employed to meet requirements before the aforementioned unfavorable events materialize. To maintain the desired QoS for users, Service Level Agreements (SLAs) are established between users and providers [19]. For instance, if a user submits an application comprising 150,000 million Instructions (MIs) and requests a VM with processing power equivalent to 250 million Instructions Per Second (MIPS), the provider must ensure the VM operates continuously at 100% utilization to deliver the results within 10 minutes. Failure to do so results in an SLA violation and a penalty for the service provider. The risk of SLA violation escalates when PMs become overloaded in DCs. Hence, preemptive offloading of some VMs prior to this event can mitigate SLA violations. Conversely, the phenomenon of server sprawl significantly increases total power consumption, whereby numerous under-loaded active PMs run concurrently. Server consolidation, which consolidates VMs into the fewest active PMs, is an effective strategy for reducing overall power consumption [20].

The integration of machine learning, deep learning, and meta-heuristic algorithms significantly enhances resource usage prediction in dynamic cloud environments. These methodologies provide a key insight into complex resource utilization patterns, contributing to the efficient management of cloud infrastructures [21]. Machine learning models, particularly linear regression and its variants, empower predictions based on historical resource usage data, enabling proactive resource allocation and load balancing [22]. Deep learning techniques, with their ability to analyze vast amounts of unstructured data, facilitate the identification of intricate patterns within cloud workloads, leading to more accurate predictions [23, 24]. Moreover, the inclusion of meta-heuristic algorithms, such as genetic algorithms, particle swarm optimization, and whale optimization, augments predictive accuracy by refining the traditional models, enabling them to adapt and evolve according to dynamic resource demands [25]. The synergy among these methodologies results in robust and adaptable prediction models vital for optimizing resource usage in dynamic cloud environments, ultimately leading to improved service quality, cost efficiency, and better user experiences within cloud services [26, 27].

In this paper, machine learning techniques are extensively leveraged to derive resource usage patterns from historical data. This empowers the hypervisor to make swift decisions regarding under-utilization and over-utilization events before they occur. To address this challenge, machine learning techniques are applied to historical data to predict near-future resource requests. Processing and memory resources are pivotal for each requested VM, with processing capacity holding greater significance among power consumers, which informs the focus of this study on CPU capacity requirements [28]. To forecast near-future resource requests, the linear regression algorithm, a branch of machine learning, is employed. This involves recording the average resource utilization at five-minute intervals, utilizing the data history from the previous hour to inform short-term predictions. The time interval for data collection can be tailored to specific requirements. To enhance the performance of traditional linear regression, several effective meta-heuristic approaches are incorporated, yielding promising results. The innovation in this paper centers on the following key aspects:

- Introduction of a resource usage prediction model based on historical data.
- Presenting a migration trigger model for timely decision-making to avert unforeseen events.
- Exploration and evaluation of customized meta-heuristic algorithms to determine the most efficient approach.

The structure of this paper is organized as follows: Section II provides an overview of related work in the field. Section III introduces the proposed system model. In Section IV, the problem is formally defined and elaborated upon. Section V presents the suggested algorithm to address the problem. The performance assessment of the proposed approach is outlined in Section VI. Section VII concludes the paper and outlines potential future directions for research in this domain.

II. BACKGROUNDS

Live VM migration is the intricate process of seamlessly transferring a VM's loads from one PM to another, ensuring uninterrupted service for the end user. The initiation of live VM migration and server consolidation is motivated by various factors, with power management being of paramount importance [29]. Other driving factors include mobile computing [30], reduction of communication costs [31, 32], system maintenance [33], and enhancing system failure reliability [34]. This leads to fundamental questions regarding when and where VM migration should be triggered, a topic that has been extensively explored in existing literature. One notable contribution in this domain was made by Martinovic, et al. [35], who introduced a server consolidation model aimed at minimizing power consumption. They approached the problem by transforming the VM placement challenge into a bi-packing problem with conflicts and modeled by an integer linear program to solve it while utilizing the minimum number of PMs required. Zhou, et al. [36] proposed a linear regression model for predicting the CPU demands of VMs and subsequently triggering live VM migration in anticipation of near-future overload. Although this approach holds promise, it suffers from relatively high prediction errors.

Zhao, et al. [37] introduced a communication-aware live VM migration algorithm based on the Ant Colony Optimization (ACO) algorithm to minimize overall costs. This algorithm consists of two phases: first, it identifies VMs with high affinity for migration, and second, it selects the destination PMs for relocating the VMs. An energy-aware VM migration model was presented by Patel, et al. [38] to achieve both load balancing and power conservation, involving a three-way decision-making process for heavy, medium, and light workloads. A combined forecasting and load-aware migration model, along with an automated algorithm, was proposed by Forsman, et al. [39] to address live VM migration. A similar approach was put forth by Paulraj, et al. [40], focusing on saving energy, enhancing system reliability against failures, and maximizing service availability. The VM migration process, being resource-intensive and potentially degrading performance, employs forecasting models to estimate the resource requirements of each VM. Optimal online deterministic VM placement and adaptive heuristic algorithms are employed to address server consolidation, contributing to efficient DC power management and performance maintenance [41]. In the proposed approach, a novel system framework is introduced, featuring both local and global managers. The global manager resides at the master node, while each PM is equipped with a local manager responsible for collecting information on resource utilization and transmitting it to the global manager. Subsequently, the global manager issues directives for optimal VM placement, considering user SLAs. To further enhance efficiency, a cost function is defined, linked to the time associated with the migration process. The migration process is carefully orchestrated to avoid violating predetermined SLAs.

The review of existing literature reveals promising contributions from the research community. However, there remains a challenge in achieving near-precise prediction models. This motivates the current article, which leverages machine learning methods to predict short-term resource requirements for each VM, thereby triggering relevant VM migration processes to reduce both power consumption and SLA violation rates significantly.

III. SYSTEM MODEL

This section introduces the proposed system model and its components, along with a schematic example to demonstrate how the model functions. The proposed system model, depicted in Fig. 1, consists of two main parts: the front end and the back end. In the front end, users request specific types and specifications of VMs encapsulated in SLA format. These requests are forwarded to a broker module that possesses knowledge of the underlying infrastructure's capabilities. The requested resources for each VM are logged in a repository, accumulating as historical data. Subsequently, the forecaster module, a part of the live VM migration scheme, is activated based on the historical data in the repository. Its primary objective is to prevent both SLA violations resulting from overloaded conditions and high-power consumption due to the server sprawl phenomenon.

Fig. 2 provides a schematic example of a scenario involving the execution of different VMs within a data center with three PMs. Initially, three different users submit their requests denoted as R_1, R_2, and R_3, where R_1 entails a request for 2 VMs, R_2 for 1 VM, and R_3 for 2 VMs. The broker promptly dispatches these requests to the available PMs, as depicted in Fig. 2(a). At five-minute intervals, resource requests are recorded in a repository. The forecaster module extracts insights from this data history and anticipates that PM_3 will become overloaded in the near short-term future due to the surging resource request of VM_5. To prevent an overload event, the live VM migration module is activated, and PM_2 is chosen for offloading due to its surplus resources. After the live migration, the scenario is represented in Fig. 2(b). In this situation, when the five-minute time interval is reached, the forecaster module predicts that VM_2 and VM_4 will reduce their resource requirements. This prediction aims to decrease resource requests.

Consequently, both PM_1 and PM_3 are in an under-loaded condition in the near future. Therefore, the live VM migration scheme is initiated for both VM_2 and VM_4 to consolidate servers. Subsequently, the unused PM_3 is transitioned into hibernation mode to conserve energy that would otherwise be dissipated.

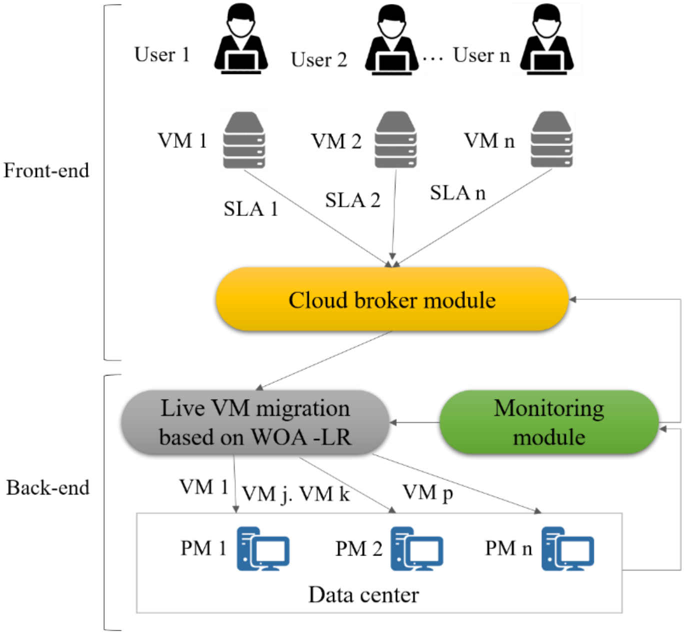

Fig. 1. System model.

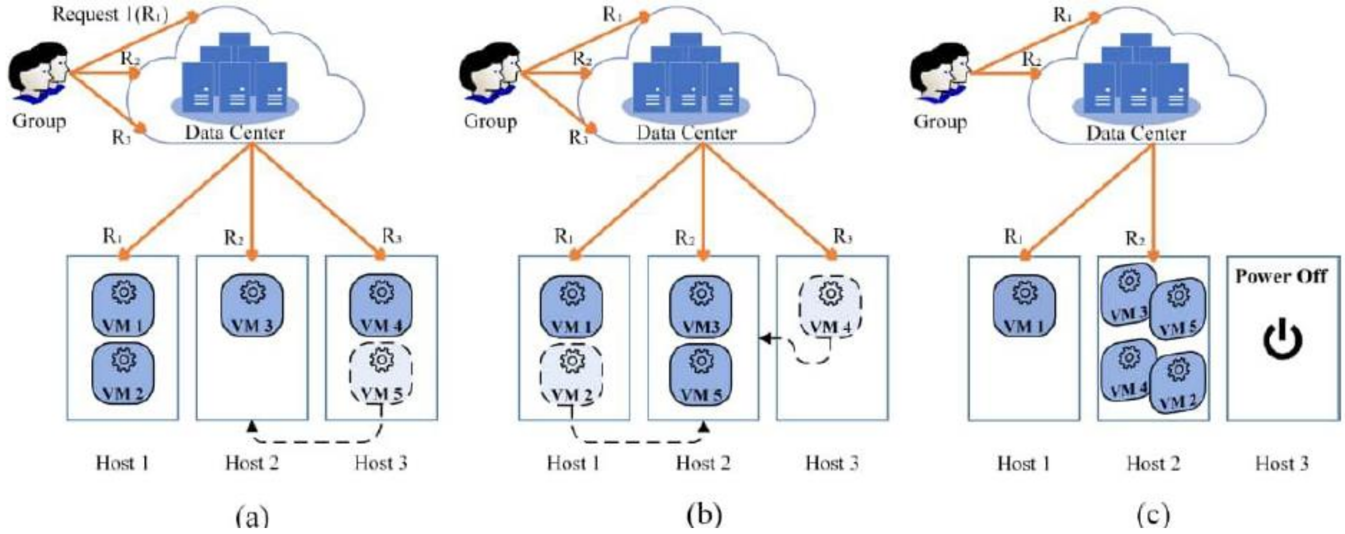

Fig. 2. A schematic example of a data center with deployed VMs.

IV. Problem Statement

The core problem at hand is the necessity to make prompt decisions to preempt unfavorable events before they materialize. Periodically, the forecaster module retrieves data from the data repository within the data center to predict the impending over-loaded and under-loaded states of each PM. Subsequently, the most appropriate decision is made based on these predictions. To accomplish this, an advanced linear regression model is employed with the objective of minimizing the model's Mean Squared Error (MSE). In this pursuit, the conventional linear regression method is fused with a meta-heuristic algorithm, resulting in a novel and advanced hybrid forecaster algorithm. The key aim is to reduce the MSE to the lowest extent, thereby enhancing the accuracy of the decision-making process. In essence, the decision becomes increasingly accurate as the error approaches its minimum value. To facilitate this, the data history stored in the repository pertaining to resource requests within the most recent hour is divided into 12 records, each representing a five-minute interval. Utilizing the information within these recorded data, a linear function is established. Eq. (1) represents this linear function, where *x* and *y* denote the input and forecast functions, respectively. The terms C_0 and C_1 signify the two constants that serve as the coefficients of the linear function and must be determined by the proposed model.

$$y = C_0 + C_1 x \tag{1}$$

V. Proposed Algorithm

To address the live VM migration, which is inherently an optimization challenge, various competitive algorithms have been proposed. These algorithms have been selected based on their demonstrated success in the existing literature for solving continuous optimization problems and their adaptability to the specific problem under consideration. In this section, we introduce the following algorithms for calculating both LR's parameters C_0 and C_1: Canonical Linear Regression (LR), Genetic Algorithm-based Linear Regression (GA-LR), Particle Swarm Optimization-based Linear Regression (PSO-LR), Whale Optimization Algorithm-based Linear Regression (WOA-LR), and JAYA Linear Regression (JAYA-LR). GA-LR predicts the utilization of each server for the short-term future based on previously recorded mean server CPU utilization. In this context, single-point crossover and random gene mutation operators are employed. Additionally, a tournament algorithm is formulated. These algorithms are designed to optimize the LR's parameters C_0 and C_1, thereby enabling more accurate predictions and decision-making in the context of the problem at hand.

In the proposed GA-LR, random individuals are generated to represent both populations associated with the two constants, C_0 and C_1, which serve as the coefficients in the linear regression function. Each record for each coefficient is incorporated into the linear regression function, and the difference between this value and the actual value in the dataset is regarded as the fitness value. This optimization problem is a straightforward minimization problem, where the goal is to refine the coefficients over successive rounds. For encoding, each chromosome consists of two segments: the first part encodes an integer value, and the second part encodes a real number. It's worth noting that binary genes are used in the encoding process. The Tournament selection procedure aims to increase the likelihood of selecting promising chromosomes. In this procedure, *K* chromosomes are randomly chosen from the populations, and the best-performing ones are returned. It is important to highlight that the proposed tournament selection approach does not directly select the best individuals from the entire population, as this would risk early convergence, potentially resulting in suboptimal performance. The algorithm iterates until a specified termination condition is met, ultimately returning the best-performing chromosomes that yield the minimum MSE value.

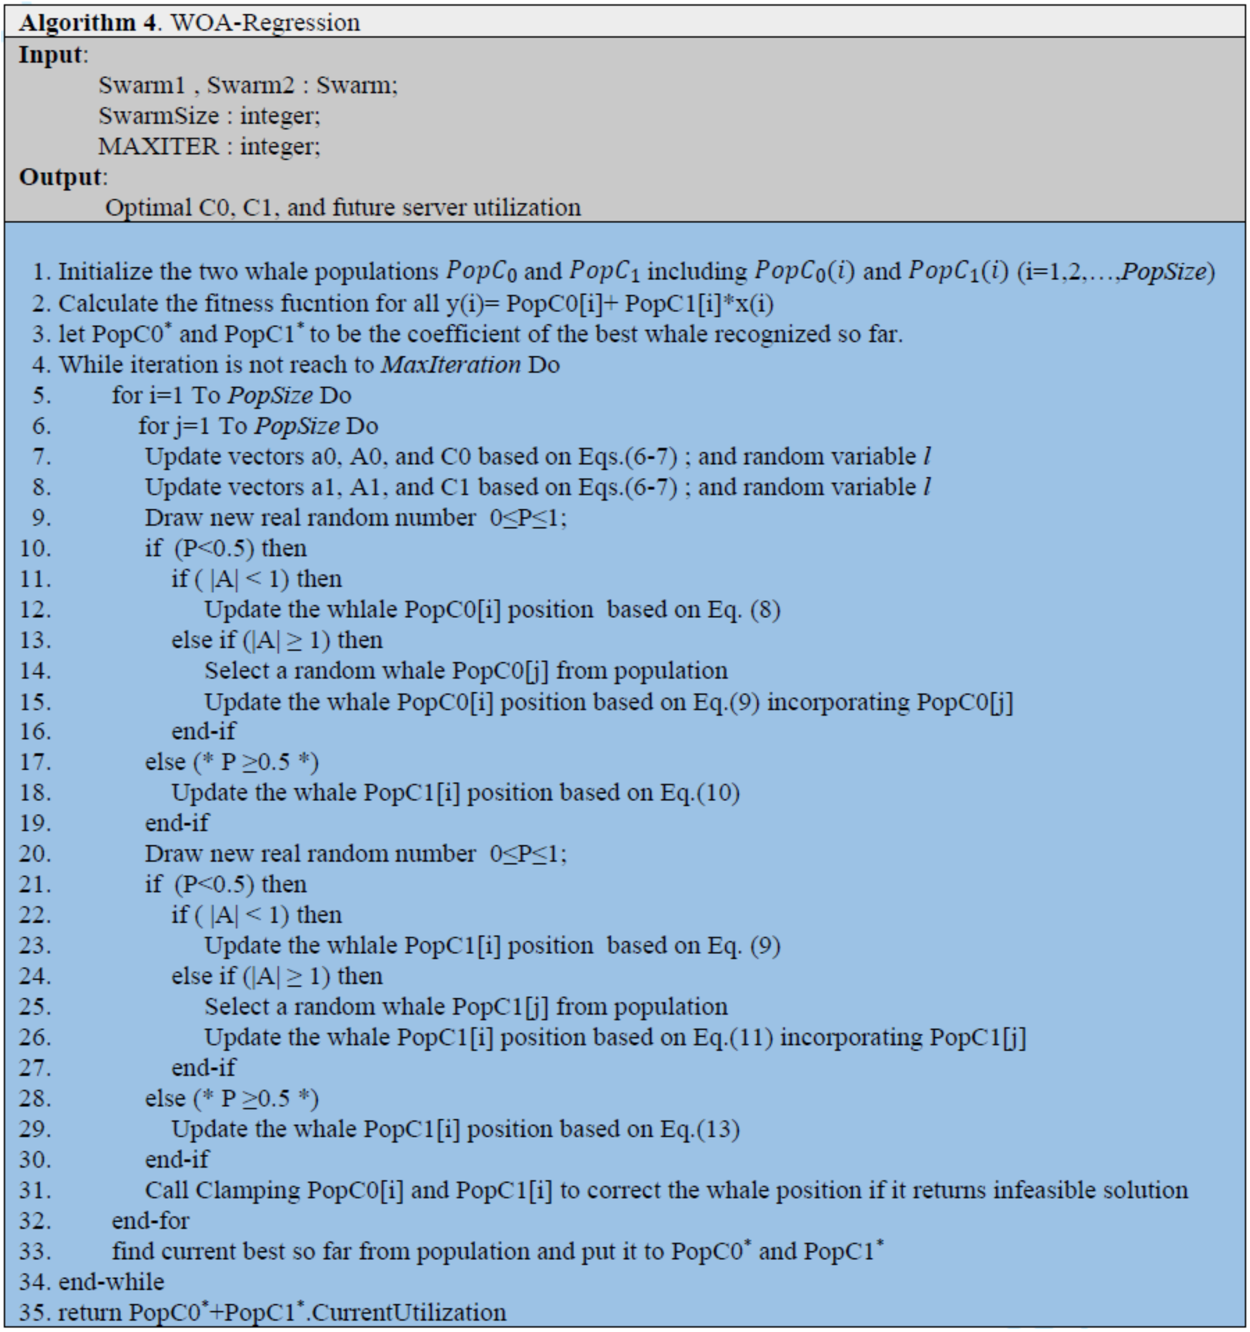
In the PSO-LR algorithm, two distinct swarms of particles are randomly generated, akin to the populations of individuals in genetic Algorithms. Each particle's future trajectory is determined by three key parameters: inertia, local best, and global best values. The first parameter, inertia, is responsible for the particle continuing in its previous direction. The second parameter directs the particle to adjust its direction based on its local best, which is recorded in its memory. The third parameter steers the particle towards changing its direction to align with the global best of the entire swarm. To weigh the effectiveness of each parameter, specific weights are assigned to them. The algorithm is executed over multiple iterations, and subsequently, the best-performing particle thus far is identified and returned as the optimal solution. This iterative process helps refine the solution and converge towards the most accurate values for C_0 and C_1 in the linear regression model. For another comparative approach, the WOA-LR algorithm is presented in Fig. 3.

Similar to other swarm-based meta-heuristic algorithms, the WOA-LR begins with the generation of random swarms of whales. In this algorithm, each pair of whales represents a solution, as each solution requires two coefficients. To this end, variables $PopC_0(i)$ and $PopC_1(i)$ pertain to the ith whale. The loop encompassing lines 4 to 34 is executed for each whale, which is why there are two inner for-loops. In lines seven and eight, two sets of vectors, *a*, *A*, and *C*, are updated. It is important to note that *a* is a vector that gradually decreases from 2 to 0. Additionally, the vectors *A* and *C* consist of random real values within the [0..1] interval. The changes in r are determined by Eq. (2), and Eq. (3) defines the alterations in these vectors.

$$\vec{A} = 2\vec{a}.\vec{r} - \vec{a} \tag{2}$$

$$\vec{C} = 2\vec{r} \tag{3}$$

Furthermore, random real values *l* are stochastically selected from the interval [-1..1]. The essence of the WOA lies in the oscillation between exploration and exploitation phases at intervals during the algorithm's lifecycle. To this end, a random variable *P* is drawn to determine whether to explore or exploit the search space. The update process in line 15 is specifically designed to reflect the inclination towards exploitation or local search. In the context of exploration, the update is carried out using Eq. (4), and this operation is executed in line 18. In this scenario, the update is impartially performed based on the random position of the whale without any bias.



```
Algorithm 4. WOA-Regression
Input:
        Swarm1 , Swarm2 : Swarm;
        SwarmSize : integer;
        MAXITER : integer;
Output:
         Optimal C0, C1, and future server utilization

1. Initialize the two whale populations $PopC_0$ and $PopC_1$ including $PopC_0(i)$ and $PopC_1(i)$ (i=1,2,…,PopSize)
2. Calculate the fitness fucntion for all y(i)= PopC0[i]+ PopC1[i]*x(i)
3. let PopC0* and PopC1* to be the coefficient of the best whale recognized so far.
4. While iteration is not reach to MaxIteration Do
5.        for i=1 To PopSize Do
6.           for j=1 To PopSize Do
7.            Update vectors a0, A0, and C0 based on Eqs.(6-7) ; and random variable l
8.            Update vectors a1, A1, and C1 based on Eqs.(6-7) ; and random variable l
9.            Draw new real random number  0≤P≤1;
10.           if  (P<0.5) then
11.              if ( |A| < 1) then
12.                  Update the whlale PopC0[i] position  based on Eq. (8)
13.              else if (|A| ≥ 1) then
14.                  Select a random whale PopC0[j] from population
15.                  Update the whale PopC0[i] position based on Eq.(9) incorporating PopC0[j]
16.              end-if
17.           else (* P ≥0.5 *)
18.              Update the whale PopC1[i] position based on Eq.(10)
19.           end-if
20.           Draw new real random number  0≤P≤1;
21.           if  (P<0.5) then
22.              if ( |A| < 1) then
23.                  Update the whlale PopC1[i] position  based on Eq. (9)
24.              else if (|A| ≥ 1) then
25.                  Select a random whale PopC1[j] from population
26.                  Update the whale PopC1[i] position based on Eq.(11) incorporating PopC1[j]
27.              end-if
28.           else (* P ≥0.5 *)
29.              Update the whale PopC1[i] position based on Eq.(13)
30.           end-if
31.           Call Clamping PopC0[i] and PopC1[i] to correct the whale position if it returns infeasible solution
32.       end-for
33.       find current best so far from population and put it to PopC0* and PopC1*
34. end-while
35. return PopC0*+PopC1*.CurrentUtilization
```

Fig. 3. Algorithm WOA-LR.

$$\overrightarrow{W_i}(t+1) = \overrightarrow{W_j}(t) - \vec{A}.\vec{D} \quad (4)$$

The algorithm uses Eq. (5) to update the chosen whale's location in order to imitate the distinctive circular movement of whales, which is sometimes referred to as a "spiral update position." This mechanism is designed to mimic the distinctive movement pattern of whales during the optimization process.

$$\overrightarrow{W_i}(t+1) = \overrightarrow{D'}.e^{bl}.Cos(2\pi) + \overrightarrow{W*}(t) \quad (5)$$

After the update is executed for all whales, in case any whale's solution becomes infeasible, the Clamping function is invoked to adjust the encoded solution within the appropriate and feasible space. Line 31 represents the application of the Clamping (.) function. The specific implementation of the Clamping function can vary based on the context. Ultimately, the best whale found so far, which represents an efficient solution, is returned as the final solution. Another successful optimization algorithm, which has been introduced recently, is the JAYA algorithm. The JAYA algorithm is specifically designed for addressing continuous optimization problems. Similar to other meta-heuristic algorithms, it commences with a limited number of randomly generated solutions. In each iteration, the best and worst solutions found so far are identified. The primary objective is to approach the best solution while distancing from the worst one. Throughout the evolution of each solution, if a new solution improves in terms of fitness value, it is accepted; otherwise, the previous version is retained. Each solution is iteratively adjusted to converge toward the best solution gradually found thus far.

VI. Results

This section is devoted to the performance evaluation of the proposed prediction model. To assess its effectiveness, various meta-heuristic-based algorithms have been put forward, and a comparative study has been conducted [42-44]. In this context, three distinct sets of datasets representing data from the last hour have been randomly generated. Table I provides an overview of these datasets. All of the selected algorithms operate on the same datasets, ensuring a level playing field for fair competition in the evaluation process. The simulation results are presented in Table II, with the reported values for the successful WOA-Regression algorithm highlighted. The key to the success of WOA-Regression lies in its ability to strike a balance between the exploration and exploitation phases during the optimization process, effectively optimizing the search process.

One of the most critical concerns in energy-intensive data centers is power consumption. Furthermore, the rate of SLA violations significantly affects users' decisions when it comes to adopting cloud services. In practice, users tend to abandon unreliable cloud providers that cannot meet the agreed SLA terms. Thus, ensuring a high-quality experience for users is of paramount importance. To address this issue, a power consumption model with a linear relationship to CPU utilization is introduced in Eq. (6).

$$P_{Current}^{PM_j} = \lambda_j \times P_{Full}^{PM_j} + (1 - \lambda_j) \times P_{Full}^{PM_j} \times U_{CPU}^{PM_j} \quad (6)$$

The term λ_j is employed to denote that an idle machine consumes a certain percentage of power compared to a fully loaded machine. Various research studies, including the current paper, commonly use λ_j as 70% of the power consumed by a fully utilized machine. To calculate the CPU utilization of a PM, the summation of the utilization of all co-hosted VMs processing requests is considered, which can be obtained using Eq. (7). Additionally, the memory utilization of each PM is determined by summing the requested memory of all co-hosted VMs, a calculation that can be performed using Eq. (8). These measurements are essential for assessing and managing the resource utilization of each PM in the data center.

$$U_{CPU}^{PM_j} = \sum_{i=1}^{n} U_{CPU}^{VM_i} . x_{ij} \quad (7)$$

$$U_{CPU}^{PM_j} = \sum_{i=1}^{n} U_{Mem}^{VM_i} . x_{ij} \quad (8)$$

The binary decision variable, denoted as x_{ij} , indicates whether a VM is placed on a PM or not. If a VM is placed on a PM, this variable is set to 1; otherwise, it is set to 0. Additionally, the terms $U_{CPU}^{VM_i}$ and $U_{Mem}^{VM_i}$ are used to represent the CPU and memory bandwidth requirements of a VM *i*. Similarly, the terms $U_{CPU}^{PM_j}$ and $U_{Mem}^{PM_j}$ are employed to denote the CPU and memory utilization of a PM *j*, respectively. These variables and terms play a vital role in optimizing the allocation and utilization of resources within the data center.

TABLE I. An Overview of the Generated Datasets

Server	CPU utilization recorded for different rounds											
	Round 1	***Round 2***	***Round 3***	***Round 4***	***Round 5***	***Round 6***	***Round 7***	***Round 8***	***Round 9***	***Round 10***	***Round 11***	***Round 12***
First server	82%	93%	73%	69%	33%	81%	94%	83%	39%	64%	27%	82%

The live VM migration technique allows the transfer of a VM's pages from the source PM to the destination PM with minimal interruption, resulting in a small downtime. However, VM live migration can have adverse effects on the overall system performance and potentially jeopardize SLA between users and service providers. This is due to the time required for page transfers during migration. For cloud-based web applications, on average, downtime may decrease CPU utilization by approximately 10%. In other words, this phenomenon can lead to SLA violations to some extent. On the flip side, it is desirable to reduce the number of aggressive live migrations. The Live Migration Time (LMT) is highly dependent on the size of the VM's pages being transferred and the underlying bandwidth capacity. Since data centers often use Storage Area Networks (SAN), there is no need to transfer VM storage data, as all PMs have uniform access to SAN. The LMT for a VM is calculated using Eq. (9). This information is crucial for managing VM migrations efficiently and minimizing potential SLA violations.

$$LMT(VM_i) = \frac{Msize(M_i)}{BW_i} \qquad (9)$$

The term $Msize(M_i)$ represents the memory size of data being transferred via a shared link with a bandwidth capacity of BW_i. Furthermore, experimental results indicate that there is a 10% degradation in CPU utilization during the process of live migration. This performance degradation is quantified using Eq. (10), where the term $u_i(t)$ represents CPU utilization associated with VM i during the migration process. This equation provides a measure of the performance impact of live migrations, which is crucial for optimizing resource allocation and minimizing SLA violations.

$$PD(VM_i = 0.1.\int_{t_0}^{t_0+LMT(VM_i)} u_i(t)dt \qquad (10)$$

The paramount issue that encourages users to remain loyal to specific cloud providers is the delivery of a high-quality user experience from the services provided. In this context, key points such as the minimum throughput and the maximum response time must be determined to meet the required QoS, which is outlined in the SLA. Web applications that leverage cloud infrastructure often exhibit fluctuations in resource utilization. As a result, an independent parameter reflecting the system's SLA violation rate is needed. To address this, two new parameters have been introduced: SLA violation length per active PM, denoted as a, and the total performance degradation due to VM migration, denoted as β. The parameter α represents the duration during which active PMs experience 100% CPU utilization, indicating the time span during which PMs are overloaded. This parameter is measured using Eq. (11) and plays a crucial role in quantifying SLA violations within the system.

$$a = \frac{1}{n}\sum_{i=1}^{n} \frac{T_{PM_i}}{T_{active(PM_i)}} \qquad (11)$$

where, n represents the number of PMs, T_{PM_i} stands for the time during which PM_i experiences 100% CPU utilization, indicating when PM_i is overloaded. $T_{active(PM_i)}$ is the total time during which PM_i remains active, serving various VMs. The parameter β is calculated using Eq. (12). In this equation, m is the number of VMs, $PD(VM_i)$ is the performance degradation caused by VM migration, and $C(VM_i)$ represents the total CPU resource capacity associated with VM_i in terms of MIPS.

$$\beta = \frac{1}{m}\sum_{i=1}^{m} \frac{PD(VM_i)}{C(VM_i)} \qquad (12)$$

Both parameters α and β independently influence SLA violations. To provide a comprehensive assessment of SLA violations, a new parameter called the SLA Violation Rate (SLAVR) is introduced in Eq. (13).

$$SLAVR = \alpha.\beta = \frac{1}{n}\sum_{i=1}^{n} \frac{T_{PM_i}}{T_{active\,(PM_i)}} . \frac{1}{m}\sum_{i=1}^{m} \frac{PD(VM_i)}{C(VM_i)} \qquad (13)$$

With the inclusion of live migration costs, the performance of comparative algorithms is assessed in terms of energy consumption attributable to SLA violations, SLAVR, α (SLA violation length per active PM), β (total performance degradation due to VM migrations), and the number of VM migrations. Table III provides a comparison of the state-of-the-art algorithms based on these assessment metrics. All of the comparative algorithms were executed in the CloudSim environment, with 20 independent runs. The reported results represent the average outcomes obtained from these runs.

TABLE III. PERFORMANCE EVALUATION

Algorithm	VM migrations	β (%)	α (%)	SLAVR (%)	Total power consumption (Watt)	Power for SLAVR (Watt)
WOA-LR	189	0.11	1.31	14.76	1327	65.11
JAYA-LR	203	0.13	1.36	15.61	1672	77.05
PSO-LR	208	0.13	1.37	17.79	1463	79.19
GA-LR	211	0.14	1.48	19.62	1495	75.91
Conventional LR	306	0.16	1.42	21.47	1588	89.02

VII. CONCLUSION

This paper introduced a system framework for cloud data centers, comprising multiple modules designed to enable timely live VM migration for preventing SLA violations through the integration of machine learning tools. In this framework, a repository module is deployed within the DC, functioning as a data history repository where each physical machine records its average CPU utilization over time. Subsequently, a machine learning tool, specifically a linear regression-based model, is employed at regular intervals to predict near-future resource requirements. Based on these predictions, decisions are made to optimize resource allocation and avoid SLA violations.

There are still unanswered issues and unresolved problems in this field. Expanding the predictive capabilities to include important resources such as memory, storage, and network bandwidth might improve the overall effectiveness of the system. Furthermore, conducting performance evaluations on a range of real-world datasets and in different workload conditions would provide a more thorough understanding of the system's capacity to adjust and withstand challenges. Furthermore, it is necessary to do further research to determine the scalability, flexibility, and real-time responsiveness of the system when implemented and deployed in live cloud settings. The limitations of this study are its primary emphasis on CPU use, which may result in neglecting the complex interaction between various resources and their effect on adhering to SLA requirements. Moreover, the system's reliance on past data may provide difficulties in dynamic settings, requiring ongoing model training and adjustment methods. Future improvements may include integrating sophisticated machine learning methods, such as deep learning algorithms, to boost the accuracy of predictions and consider intricate resource linkages. Furthermore, investigating decentralized or distributed decision-making models for VM migrations, while also taking into account security and privacy concerns in a multi-tenant cloud environment, presents a promising direction for future study and improvement of the suggested framework.

***Abstract*—In the realm of Internet of Things (IoT)-driven healthcare, diverse technologies, including wearable medical devices, mobile applications, and cloud-based health systems, generate substantial data streams, posing challenges in real-time operations, especially during emergencies. This study recommends a hybrid architecture utilizing Hadoop for real-time processing of extensive medical data within the IoT framework. By employing distributed machine learning models, the system analyzes health-related data streams ingested into Spark streams via Kafka threads, aiming to transform conventional machine learning methodologies within Spark's real-time processing, crafting scalable and efficient distributed approaches for predicting health statuses related to diabetes and heart disease while navigating the landscape of big data. Furthermore, the system provides real-time health status forecasts based on a multitude of input features, disseminates alert messages to caregivers, and stores this valuable information within a distributed database, which is instrumental in health data analysis and the production of flow reports. We compute a range of evaluation parameters to evaluate the proposed methods' efficacy. This assessment phase encompasses measuring the performance of the Spark-based machine learning algorithm in a distributed parallel computing environment.**

Keywords—Internet of Things; big data; hadoop; spark-based machine learning

I. Introduction

Over the past two decades, our epoch has come to be recognized as the era of big data, wherein digital data has assumed a pivotal role across various domains, encompassing society, research endeavors, and, particularly, the medical domain [1]. Big data denotes the characterization of copious data amassed from diverse sources, such as sensor networks, high-throughput apparatus, mobile applications, streaming devices, and data reservoirs spanning numerous industries, with a pronounced emphasis on the healthcare sector [2, 3]. Effectively managing, processing, presenting, and deriving insights from this diverse and voluminous data spectrum has posed substantial challenges using the extant technological toolset [4]. Efficiently deriving meaningful insights from this multitude of data, tailored to various user profiles, ranks among the paramount technological quandaries facing the domain of big data analytics [5, 6]. Presently, numerous data sources within healthcare, both clinical and non-clinical, are converging, with the digital medical history of patients being of paramount importance in healthcare analytics [7]. Consequently, three primary challenges surface in creating a distributed data system designed to handle extensive data volumes [8].

The initial challenge stems from the complexity of collecting data from disparate sources due to its heterogeneous and vast nature. Second, the fundamental predicament revolves around storage, as big data systems must effectively store data while maintaining optimal performance. The final challenge pertains to big data analytics, especially real-time or near-real-time analysis of vast datasets, incorporating forecasting, optimization, visualization, and modeling [9]. In light of the shortcomings of current data management systems in addressing real-time and heterogeneous data, a need emerges for a new processing paradigm [10]. Conventional relational database management systems, exemplified by MySQL, predominantly cater to structured data management, with limited support for unstructured or partially structured data. Furthermore, traditional RDBMS scaling strategies for parallel hardware management and fault tolerance often prove inadequate as data volumes expand [11].

To tackle these challenges, the research community has introduced a variety of projects to address large-scale and diverse data storage, including NoSQL database management systems suitable for scenarios where a relational model is not requisite. MapReduce, an amalgamation of Map and Reduce operations, serves as a parallel processing technique for handling vast distributed datasets in commodity clusters [12]. Yet, it is marred by its sluggishness when dealing with iterative algorithms. The Hadoop framework, a batch processing system, is employed for distributed data processing and storage, relying on the MapReduce model for programming [13]. The Hadoop Distributed File System (HDFS) offers a distributed storage solution that is highly resilient [14]. However, Hadoop is ill-suited for in-memory computing and real-time stream processing and does not uniformly apply the MapReduce paradigm to all challenges. The volume of processed data is a determinant of the speed of results. Conversely, stream computing prioritizes data velocity and involves continuous input and output. Big data streaming computing (BDSC) comprises real-time computing, distributed messaging, high throughput, and minimized processing latency. It is essential for extracting meaningful information from vast datasets, particularly in the healthcare realm.

The swift advancement of large data analytics holds significant implications for advancing medical practices and academic research. Data collection, management, analysis, and assimilation tools designed to handle heterogeneous, unstructured, and structured data within contemporary healthcare systems have become accessible. BDSC is now integral to the landscape of big data analytics, facilitating the rapid exploration of the latent value of extensive healthcare data. Nevertheless, challenges persist due to the diverse data sources within the healthcare sector, necessitating the integration of data originating from relational databases, Hadoop, search engines, and other analytical systems. The application of machine learning to such extensive and high-velocity data streams presents considerable challenges, as conventional machine learning algorithms are not well-suited for such massive data volumes and variable velocities. Furthermore, efficient analytical data processing is a pressing concern, necessitating effective data integration. While contemporary research predominantly relies on machine learning, real-time machine learning applications are absent for streaming big data. Moreover, most healthcare analytics solutions predominantly focus on Hadoop, a batch-oriented computational platform.

The growing elderly population and the rising prevalence of chronic illnesses have exacerbated the inadequacies of conventional healthcare practices. In tandem, medical IoT has increased, enabling continuous monitoring and real-time emergency interventions, especially in cardiac conditions. This proliferation has led to the generation of vast datasets by millions of sensors, challenging the capacity to process and respond to this data under critical conditions. To address these challenges, we have developed a healthcare framework exemplified by a real-time health status forecasting case study. NoSQL Cassandra, Spark streaming, Spark MLlib, Kafka data streaming, and Apache Zeppelin technologies underpin this system. Kafka's producers generate multiple message streams, which are filtered using Spark streaming, enriched through machine learning, and stored in NoSQL repositories, facilitating analytics and visualization. This endeavor has substantially improved the quality of patient monitoring within healthcare.

The remaining portion of the paper is organized in the following fashion. Section II provides a comprehensive analysis of previous research in the field, which serves as a foundation for our suggested approach. Section III provides a detailed explanation of the hybrid architecture, with a focus on the incorporation of Hadoop, Spark, and distributed machine learning models. Section IV provides detailed explanations of the specific scenarios or use cases relevant to our proposed architecture. Subsequently, Section V provides the discussion of comprehensive examination, evaluating the architecture's advantages, constraints, possible uses, and comparative observations. Section VI explores the collected data, demonstrating the effects of adopting our architecture for predicting health status. Section VII ultimately ends by providing a concise overview of significant discoveries and proposing potential avenues for further study.

II. Related Works

A. Medical Big Data Challenges

The concept of the 5Vs in big data, comprising Volume, Variety, Velocity, Veracity, and Value, aptly elucidates the sheer magnitude of data generated within the contemporary healthcare sector. The healthcare domain is burdened by a substantial and ever-expanding volume of data that necessitates comprehensive collection and analysis [15]. The notion of variety underscores the diverse range of data sources that must be tapped into within healthcare. Pertinently, healthcare data and the domain's knowledge demand real-time acquisition, encapsulated by the concept of velocity. The integrity and trustworthiness of healthcare data are encapsulated in the dimension of veracity. Ultimately, valuable insights can be gleaned through meticulous examination of the colossal healthcare dataset. Distributed sources of healthcare data encompass medical electronic records, health claims, diagnosis data, clinical imagery, streaming systems, and sensors affixed to patients' bedsides for continuous vital sign monitoring. These sources collectively generate vast amounts of data, surpassing the processing capabilities of conventional data handling systems. The myriad challenges associated with big data are illustrated in Fig. 1. In this research, our focus has been dedicated to the initial five pivotal challenges within big data, encompassing data integration, storage, analysis, and representation.

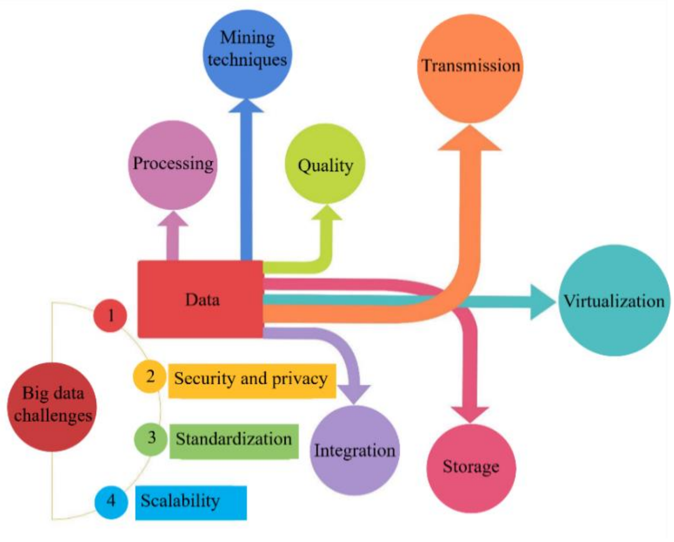

Fig. 1. Big data challenges.

B. Literature Study

The amalgamation of Machine Learning (ML), Deep Learning (DL), Neural Networks (NN), Fuzzy Logic Systems (FLSs), Wireless Sensor Networks (WSNs), and Temporal Graphs (TGs) holds pivotal significance in the processing of large-scale medical data within the IoT landscape. ML and DL techniques empower healthcare systems to discern intricate patterns within vast datasets, enabling predictive analytics for disease diagnosis, treatment planning, and health status forecasting [16-18]. NN, a subset of ML, simulates the human brain's learning process, aiding in complex data analysis, especially in image recognition and signal processing tasks within medical imaging and diagnostics [19, 20]. FLSs supplements decision-making processes by handling uncertain or imprecise data, crucial in medical scenarios where data might exhibit variability [21]. WSNs, integrated with IoT devices, facilitate real-time health monitoring, efficiently collecting and transmitting patient data for timely analysis [22]. Meanwhile, TGs provide an intricate understanding of dynamic patient interactions over time, aiding in disease progression modeling and personalized treatment plans [23]. The convergence of these technologies optimizes medical data processing, fostering precision medicine, remote patient monitoring, and efficient healthcare delivery, thereby revolutionizing patient care and augmenting medical research endeavors within the IoT-driven healthcare domain [24].

The exponential proliferation of healthcare data, coupled with its profound insights, has positioned big data analytics, particularly within the healthcare domain, as a formidable challenge spanning multiple academic disciplines, including data mining and machine learning. The advancement of data collection in healthcare can be primarily attributed to strides in scientific and technological innovation. The healthcare sector primarily leverages three fundamental categories of digital data for data collection: health research, operational processes within healthcare organizations, and clinical records. Traditional data mining techniques, which involve identifying valuable patterns within vast databases, struggle to unearth insights from the dispersed, extensive, and diverse datasets prevalent in healthcare. Data mining techniques are pivotal in transforming this data into actionable information. Numerous studies in the medical field focus on prediction and recommendation systems. These studies include experiments on heart attack prediction and a comparative assessment of different approaches. Breast carcinoma classification employs a genetically tuned neural network model. Other research endeavors encompass information retrieval and data mining methodologies.

Healthcare analytics encompass various applications, such as epidemic forecasting, health decision support, and recommendation systems, geared toward enhancing care quality, reducing costs, and augmenting productivity. One notable approach is utilizing a K-means clustering algorithm operating in the cloud as a MapReduce task, utilizing healthcare data for clustering. An alternative proposal suggests a decentralized platform for managing electronic health records personally, employing Hadoop and HBase. Predictive analysis in healthcare involves forecasting diabetes and determining the most suitable therapy using algorithms and the Hadoop MapReduce environment. Big data contextual exchange among healthcare systems through the Internet of Things (IoT) is demonstrated through an intelligent care system built on Hadoop. This system leverages an architecture with advanced data processing capabilities to collect data from diverse linked devices and transmit it to intelligent buildings. Real-time analysis of electronically generated medical records and data from medical equipment and mobile applications is described. This system, incorporating Hadoop, MongoDB, and an innovative treatment method, aims to enhance patient information processing outcomes. The predominant focus in most healthcare analytics solutions lies in Hadoop, which can handle substantial data volumes from diverse sources in batch-oriented processing. However, Hadoop's real-time processing capabilities are limited, and Spark emerges as a swifter and more efficient alternative, particularly for iterative machine learning tasks. Both Hadoop and Spark, being Apache projects, are integral to the big data landscape, with Spark generating significant interest.

Several scalable machine learning algorithms aim to address the diverse challenges within big data analytics. These algorithms include a scalable Random Forest classification model for diabetes risk prediction, logistic regression for phishing URL detection, and a Markov chain-based system for identifying abnormal patterns in the behaviors of elderly individuals. Real-time management of medical emergencies using IoT-based medical sensors is presented, along with a paradigm for real-time analysis of extensive medical data using Spark Streaming and Apache Kafka. A real-time health forecasting system focusing on machine learning, particularly Decision Trees, is developed to process data streams obtained via socket streams. A novel strategy for cardiac disease monitoring, centered on real-time decentralized machine learning within the Spark environment, is proposed in one study. Most of these studies either center on specific healthcare data sources or predominantly deal with batch-oriented computation. Healthcare generates a myriad of rapidly accumulating data from diverse sources. Moreover, some studies prioritize data storage and visualization, while others emphasize powerful data analytics tools like data mining and machine learning. Thus, the creation of an effective system for managing remote health data streams necessitates real-time healthcare analysis, which encompasses data collection, real-time processing, and robust machine learning capabilities.

The two leading causes of global mortality in recent times have been heart disease and diabetes. Continuous monitoring and early detection of these ailments can significantly reduce mortality rates. The availability of wearable health monitors, the adoption of IoT medical technology within healthcare systems, and the surge in patient conditions further underscore the potential of big data technologies for real-time health condition prediction. Real-time prediction can streamline healthcare visits and empower patients and healthcare providers to anticipate potential illnesses. Furthermore, the proposed system includes an alert mechanism, ensuring that emergency services are promptly notified when a patient's condition deviates from the norm, facilitating rapid interventions during emergencies.

III. Proposed Architecture

Within the scope of this research, a system for data processing and monitoring is introduced, amalgamating Kafka and Spark streams. This system operates by first processing data received from connected devices and subsequently storing this data for real-time analysis. The architectural layout of this proposed system is elucidated in Fig. 2. The system commences with the continuous generation of data messages from Kafka generators. These data messages encompass diverse disease names and are subsequently conveyed to a Spark streaming application for immediate processing. Spark Stream harnesses machine learning models to analyze various health attributes acquired from the Kafka Stream, thereby predicting health status. The results of this analysis are stored in a NoSQL Cassandra database. In the proposed architecture, Apache Zeppelin is instrumental in retrieving data from the database and presenting it in a real-time dashboard featuring data visualization in the form of graphs, charts, and data tables. By leveraging this real-time data in an Internet of Things (IoT) context, it becomes feasible to promptly scrutinize it, enabling the timely dispatch of alert notifications to caregivers when significant changes in a patient's condition arise. This real-time monitoring capability facilitates immediate action and intervention when necessary, ensuring patients receive timely and responsive care.

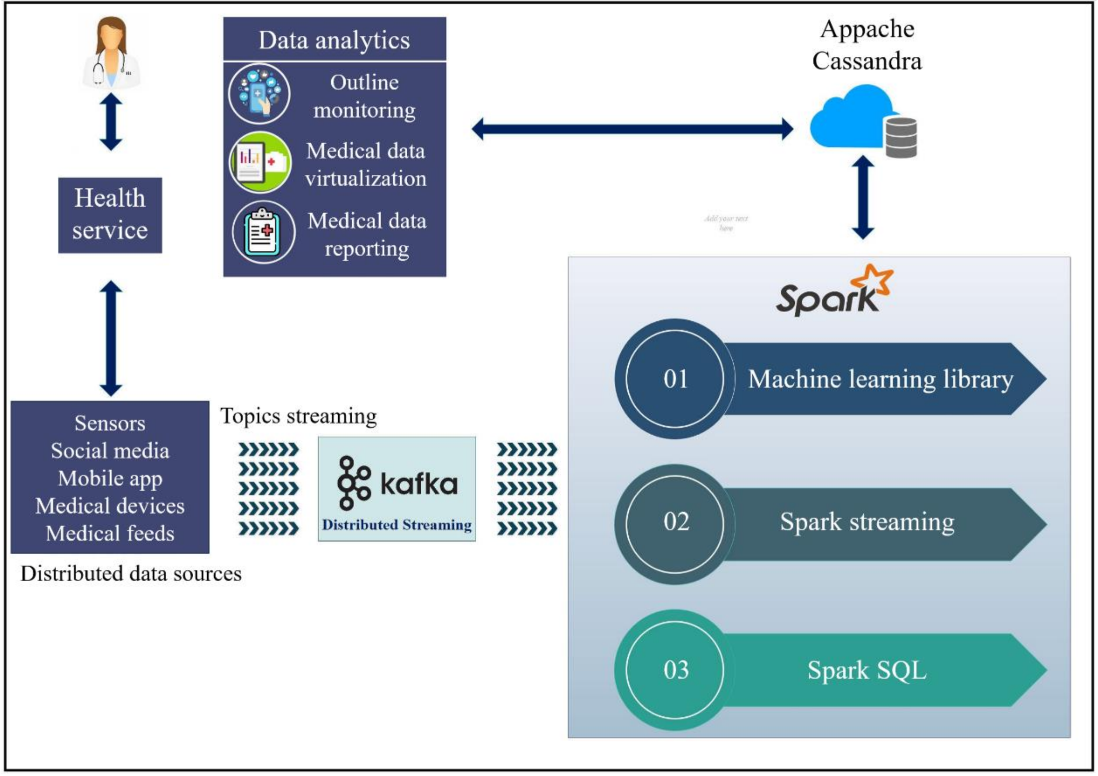

Fig. 2. Proposed architecture.

The IoT encompasses a network of physical and virtual entities equipped with electronics, intelligent wearables, software, applications, sensors, and network connectivity, all designed to collect and exchange data among themselves and with data center systems. The data generated by ubiquitous wearable health monitors, commonly found in households, is characterized by its substantial volume and random nature. Stimulating user activity trends or gathering essential data necessitates analysis through a robust big data analytics system. Forecasts indicate that, by 2020, IoT-related technologies within the healthcare sector will constitute a significant portion, accounting for forty percent of all IoT-related technologies. The integration of information technology in healthcare, particularly health informatics, is poised to bring about a paradigm shift, significantly reducing inefficiencies, containing costs, and, ultimately, saving lives. Real-time monitoring facilitated by the IoT can be a lifesaver in medical emergencies, encompassing conditions such as diabetes, heart disease, and various chronic disorders. Numerous sources are presently accessible for the continuous monitoring of health indicators. The workflow of the proposed system, involving multiple data sources, is outlined in Fig. 3. This system aims to harness the power of IoT to provide real-time monitoring and timely interventions in healthcare, thereby enhancing the quality of care and potentially saving lives in critical situations.

The escalating volume of data generated within healthcare systems has surpassed the capabilities of Spark alone for data management. In response to this challenge, Kafka, designed explicitly for managing streaming data, has been seamlessly integrated into our system. The data collection component in the proposed system architecture plays a pivotal role in gathering health-related data from various sources and multiple medical conditions, employing a range of devices coupled with telemedicine and telehealth services. This data collection group continually gathers, organizes, and manages clinical data related to patients. It facilitates categorizing streaming data according to the relevant domain (e.g., specific medical conditions), where records are subsequently published. Apache Kafka, operating as publishes-subscribe messaging system designed for distributed streaming, is a central component in this data management strategy. It is built to be a replicated, distributed, and partitioned service. Health monitoring devices feed real-time data into Kafka via Kafka producers. The fundamental concept that Kafka introduces for a stream of records is termed a "topic." Kafka servers use these topics to store incoming messages from publishers for a defined period before releasing them to the relevant data stream. Each topic is subdivided into multiple partitions, each capable of storing data in diverse formats.

Fig. 3. The workflow of the proposed architecture.

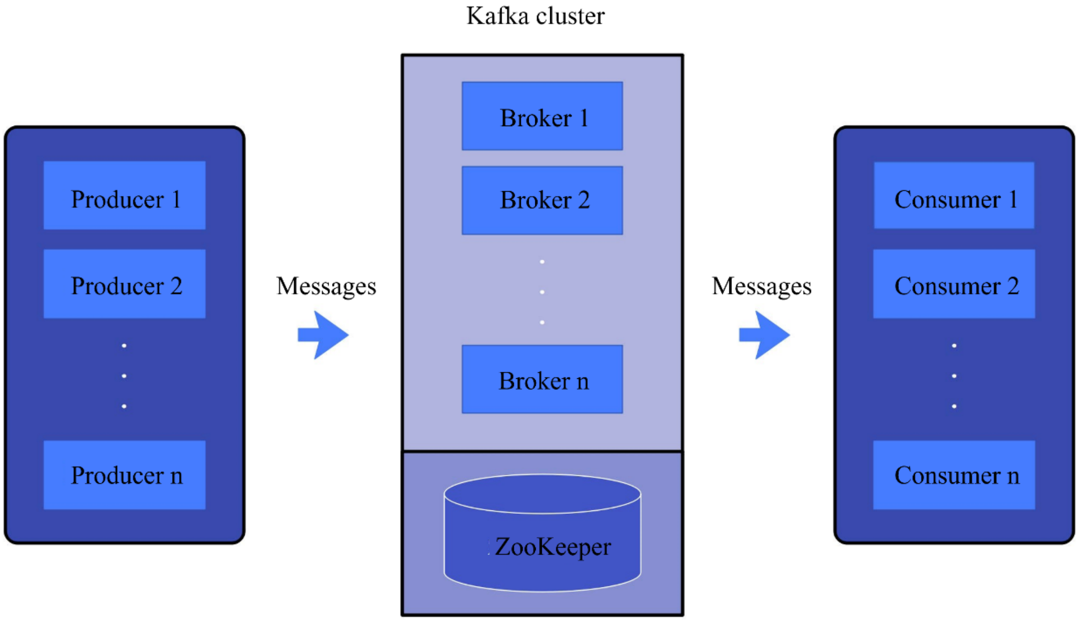

Fig. 4. The Kafka communications system.

Consumers of Kafka access information as it becomes available by subscribing to one or more topics. The Kafka communication infrastructure is depicted in Fig. 4. To ensure the efficient operation of Kafka, ZooKeeper, a centralized service, plays a vital role by providing group services, distributed synchronization, configuration information maintenance, and naming services. Distributed applications use these services extensively, although implementing and maintaining them comes with inherent challenges, such as dealing with recurring defects and race conditions. Typically, applications initially underinvest in these services due to the complexity of their implementation, rendering them fragile in the face of change and difficult to manage. Consequently, resolving these issues and enhancing the robustness of distributed applications is an ongoing endeavor within distributed systems.

This case study involves two data producer programs that simulate connected devices, utilizing Apache Kafka to generate data events. Apache Spark, an open-source, high-speed distributed processing engine, plays a central role in this system. Spark's most notable feature is its capability for in-memory calculations, significantly enhancing its processing speed. Furthermore, Spark offers user-friendly features, an advanced framework for large-scale analysis, and the ability to execute disk-based computing when dealing with datasets that exceed available memory. A key concept employed by Spark is Resilient Distributed Datasets (RDDs), which are distributed, immutable collections of items. To achieve parallelization, Spark internally spreads the RDD data across multiple nodes within the cluster. RDDs can store input and intermediate data in memory, reducing the cost of input-output operations associated with reading from or writing to system files. This feature enables efficient data reuse, which is particularly beneficial for iterative machine learning algorithms. Once data is transformed into an RDD, two fundamental types of operations can be performed:

- Transformations: These operations involve applying mapping, filtering, and more to existing RDDs to generate new RDDs.
- Actions: These operations compute a result using an RDD, which is then returned or saved to an external storage system.

Spark also includes an ML library, MLlib, which encompasses popular machine learning techniques such as classification, regression, clustering, and more. To handle real-time data from sources like Kafka and Twitter, Spark streaming builds upon the Spark API. The batch-processing Spark engine divides incoming data streams into less than one-second segments, creating discretized streams (DStreams) as high-level abstractions. Each mini-batch within the DStream collection is patterned after a Spark RDD. In this study, Spark is employed for streaming data processing, with Spark streaming managing the Kafka data stream, and MLlib is used to implement machine learning algorithms. Spark adheres to a master-worker architecture for distributed processing. Each Spark application can establish one master process, the executor in Spark, and several worker processes referred to as drivers. These drivers, like the master, are responsible for evaluating, allocating, scheduling, and supervising the tasks among the executors. The driver also maintains the necessary data consistency throughout the program. In contrast, the executors are solely responsible for executing the code assigned by the driver and transmitting the results back to the driver, as depicted in Fig. 5. This architecture ensures the efficient distribution of tasks and data processing within the Spark application.

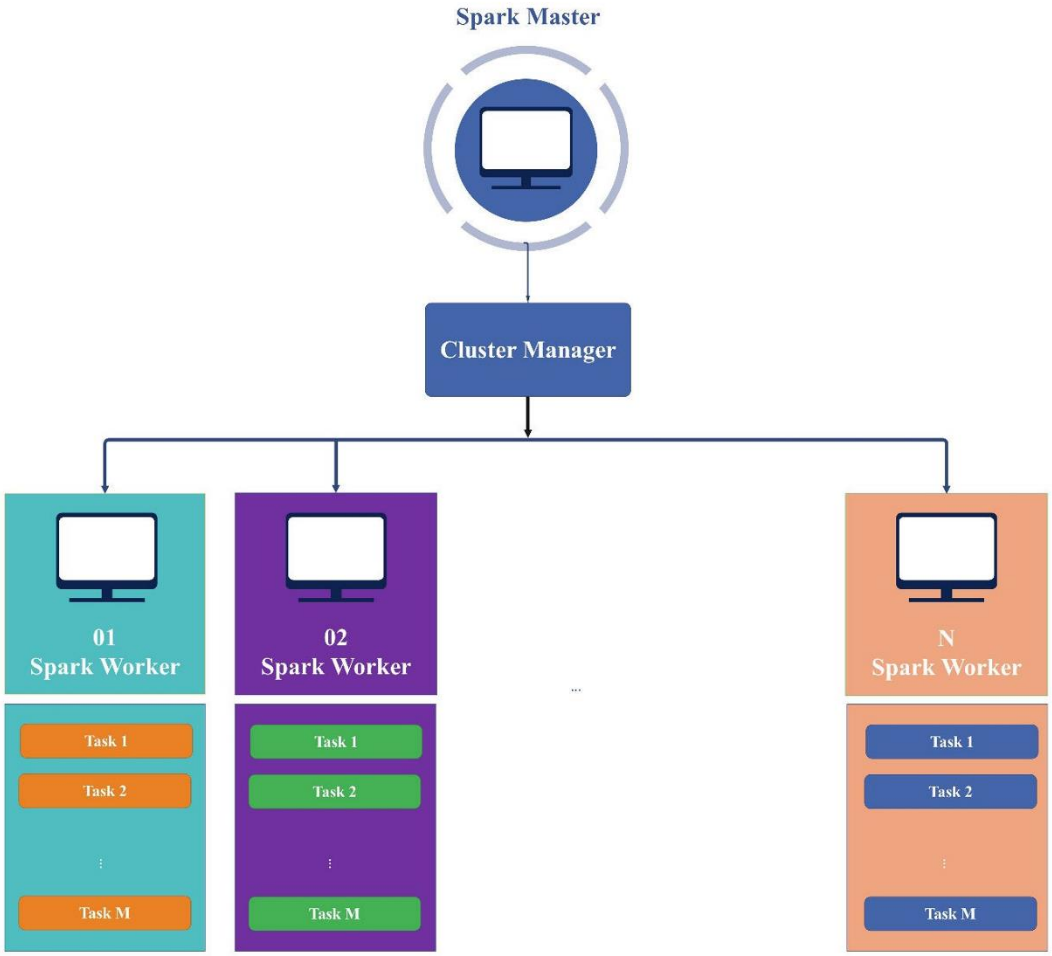

Fig. 5. Master-worker architecture.

The classification of data collected from diverse sources for various diseases necessitates using classification models capable of discerning user characteristics in the presence or absence of a disease. In this research, two classification models have been employed, each briefly introduced below:

1) K-Nearest Neighbor (KNN): KNN is a versatile supervised learning method that can serve as a classification and regression algorithm. It determines the distance between the test data point and all training data points and selects the K training data points closest to the test data. Based on their distances, the test data point is then assigned to the class that most of these K neighbors belong to. This method, represented in Method 1, can be briefly described by Algorithm 1.

Algorithm 1 KNN Algorithm

```
procedure KNN(Instance, TestData, K)
    C ← Size(TestData)
    Dist[C][2] ← 0
    for i in TestData do
    d ← EclideanDistance(i, Instance)
    Dist[i][1] ← d
    Dist[i][2] ← Class(i)
    end for
    Srt ← Sort(dist[:][1]) ▷ Sort 2nd column based on that
    Sel ← Srt[1 : K][2]
    Cls ← Mode(Sel)
    return Cls
end procedure
```

2) Support Vector Machine (SVM): SVM is another supervised machine learning method primarily used for classification, although it can also handle regression tasks. In SVM, each data point is represented as a point in an n-dimensional space, where "n" represents the number of features available for classification. Each feature corresponds to a specific coordinate within this space. SVM aims to identify the hyperplane that optimally separates the two classes in the data. Support vectors represent individual data points within this multi-dimensional space, and the SVM classifier seeks to identify the hyperplane or line that maximally divides the two classes. To achieve this, the SVM algorithm considers certain assumptions about the data, aiming to find the best hyperplane:

- Maximizing margin: SVM strives to find the hyperplane that maximizes the margin or the distance between the hyperplane and the nearest data points of both classes. This maximized margin ensures robust separation.

- Support vectors: The data points closest to the hyperplane, known as support vectors, significantly influence the determination of the optimal hyperplane.

- Kernel functions: SVM can employ kernel functions to map the data into higher-dimensional spaces when a linear separation is not feasible. These functions allow SVM to perform non-linear classification effectively. As a classification algorithm, SVM provides the means to efficiently distinguish between different classes within a dataset by defining the most appropriate hyperplane or decision boundary.

The suggested architecture addresses the complex issues involved in forecasting real-time health status in healthcare scenarios powered by the IoT. The applicability of this is emphasized by numerous essential features designed to tackle these particular challenges. The architecture's scalability is a fundamental aspect that allows it to easily handle large and growing datasets often encountered in healthcare. The ability to effortlessly increase resources with data expansion guarantees consistent performance. The ability to analyze data in real-time is another important aspect, allowing for quick intake, analysis, and understanding of streaming healthcare data.

Furthermore, the architecture's distinctive advantage resides in its implementation of distributed machine learning models specifically created to handle the vastness and complexities of medical data. This enables the simultaneous execution of tasks to enhance the efficiency of training models, hence improving the accuracy and speed of health status forecasts. Moreover, the architecture has exceptional proficiency in incorporating various IoT devices and dissimilar data sources, merging distinct data streams for thorough analysis. By prioritizing security and privacy safeguards, adapting to different data speeds from IoT sensors, and maximizing resource efficiency, it effectively tackles the complex difficulties often seen in healthcare situations powered by IoT. In conclusion, these architectural characteristics together enable the system to effectively negotiate the intricacies of real-time health status prediction, establishing it as an optimal framework for handling the distinct requirements of healthcare data analysis in IoT contexts.

IV. Scenario Descriptions

In Scenario 1, Fig. 6 illustrates three hyperplanes labeled A, B, and C. The key principle to selecting the appropriate hyperplane is to choose the one that best separates the two classes. In this scenario, hyperplane B does an excellent job of achieving this separation.

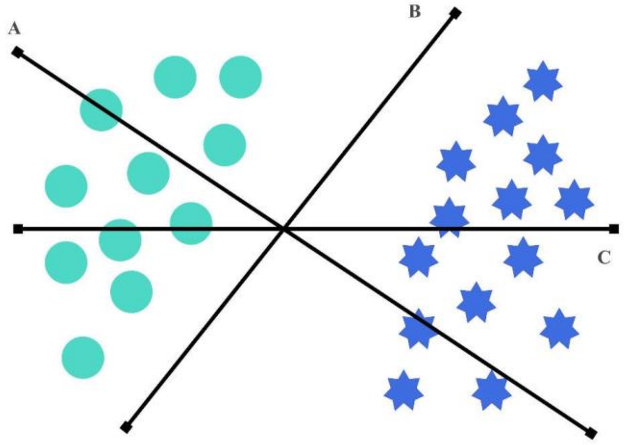

Fig. 6. Three sample hyper-planes.

Scenario 2 presents three hyperplanes (A, B, and C) in Fig. 7. The goal is to choose the hyperplane that maximizes the distance between the closest data point of any class and the hyperplane. This distance is referred to as the margin, as shown in Fig. 8. Hyperplane A has a larger margin than B and C, making it the right choice. Opting for a hyperplane with a larger margin enhances robustness and minimizes the chances of misclassification.

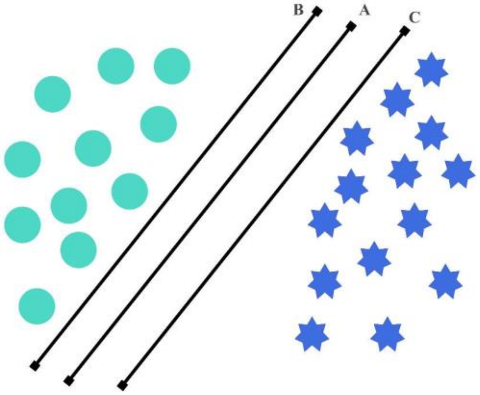

Fig. 7. Three hyper-planes that could separate two classes.

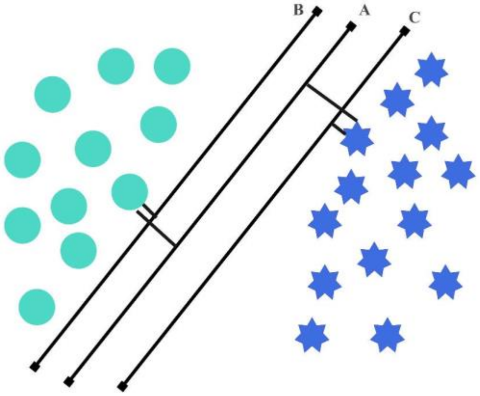

Fig. 8. Comparison of three hyper-planes with margins in scenario 2.

In Scenario 3, although hyperplane B has a larger margin than A, SVM prioritizes proper classification of the classes before maximizing the margin. Hyperplane B makes a classification error, whereas A correctly categorizes everything. Therefore, hyperplane A is selected as the appropriate choice (see Fig. 9).

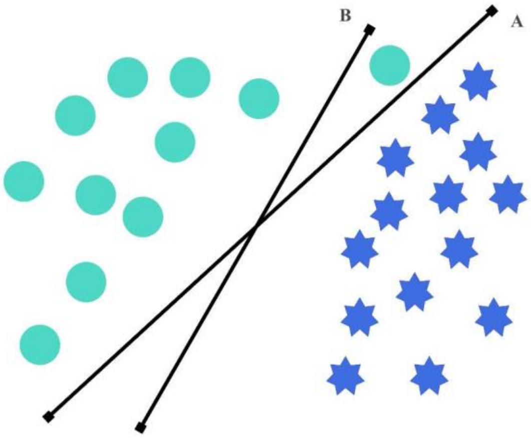

Fig. 9. Evaluation of hyperplanes A and B in scenario 3.

Scenario 4 involves an outlier, represented by the star, residing in the region of the circle class, making it impossible to separate the two classes using a straight line. However, the SVM algorithm can disregard outliers and identify the hyperplane with the maximum margin. As a result, SVM classification is robust against outliers (see Fig. 10).

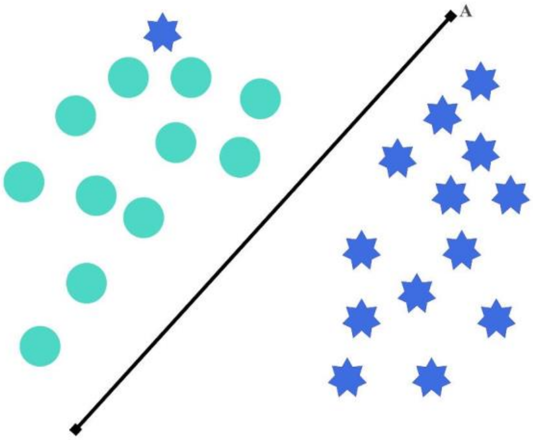

Fig. 10. Robustness of SVM against outliers in scenario 4.

In Scenario 5, when a linear hyperplane is insufficient to categorize two classes, a new feature, z = x^2 + y^2, is introduced to create a three-dimensional representation of the data points, as shown in Fig. 11 and Fig. 12. This new feature, z, is a mathematical construct that enables the creation of a linear hyperplane, making it possible for SVM to classify the two classes effectively. The SVM algorithm employs the "kernel trick" to automatically find this hyperplane. The SVM kernel is a function that transforms non-separable problems into separable ones by projecting data from a low-dimensional input space into a higher-dimensional space. This is particularly valuable for addressing problems with non-linear separations. It performs intricate data transformations before determining how to split the data based on the provided labels or outputs. The hyperplane appears as a circle in the original input space, as depicted in Fig. 13. The kernel trick allows SVM to handle complex, non-linear separations and enables the classification of data that cannot be linearly separated in the original feature space.

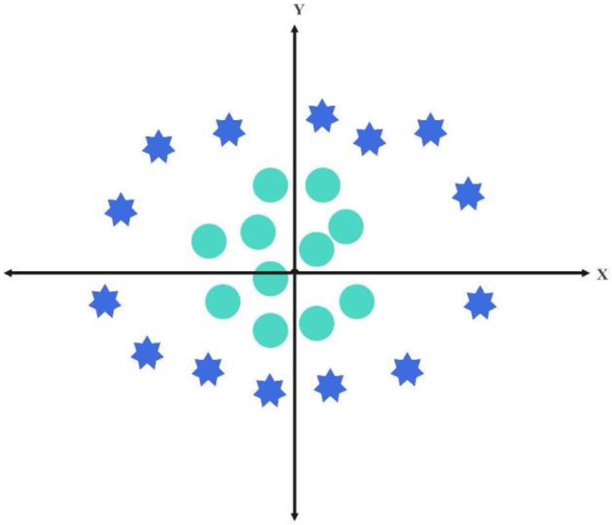

Fig. 11. Introduction of a new feature in scenario 5.

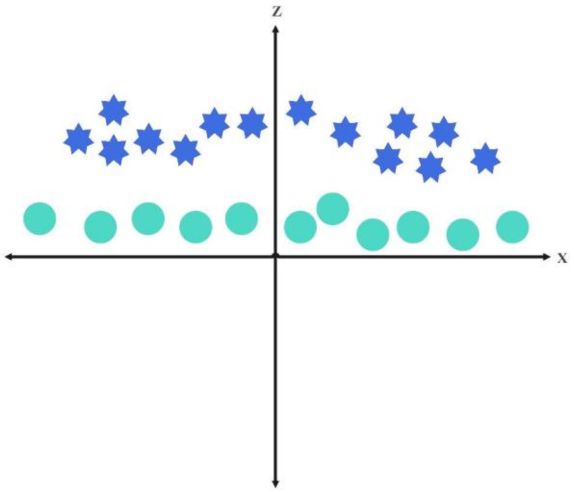

Fig. 12. Three-dimensional representation with additional feature (z) in scenario 5.

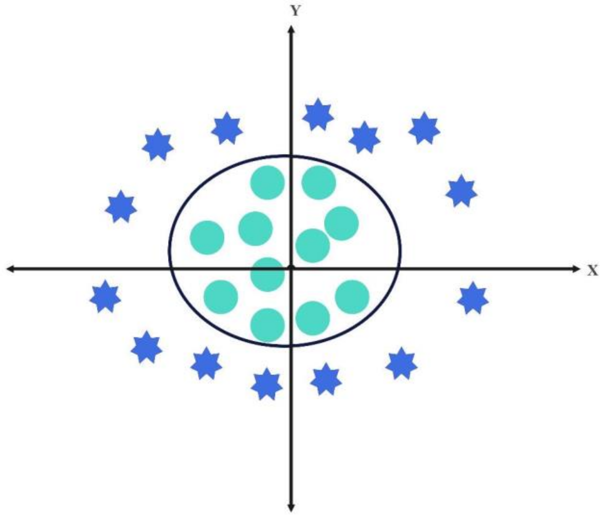

Fig. 13. Application of SVM kernel trick for non-linear separation in scenario 5.

V. Discussion

To ensure high data availability and avoid a single point of failure, it is essential to store the results and data streams generated by each user in a distributed manner. Distributed databases outperform traditional database systems in terms of performance and scalability. Apache Cassandra is an open-source, distributed, and free NoSQL database system designed to handle massive volumes of data, whether structured, unstructured, or semi-structured, across multiple computers. Cassandra's architecture greatly enhances its scalability, operational capabilities, and continuous accessibility. It also offers rapid write and read rates when used with Spark. Distributed databases provide several valuable features:

- Affordability and ease of use: Distributed databases are cost-effective and straightforward.
- Data transfer speed: They offer significantly faster data transport than traditional databases.
- Scalability: Distributed databases can be scaled easily by adding columns, accelerating the processing of larger and more data.
- Cluster scalability: Distributed databases can expand their cluster capacity by adding more nodes without a specific distribution. After processing data with Spark, the output data is stored in a table using Cassandra and a primary key. This database can be accessed later for real-time monitoring, reporting, and analysis of historical data.
- Data replication and partitioning: Data is replicated across various computers to enhance data availability and fault tolerance.

TABLE I. UCI Heart Disease Dataset

No	Attribute No	Attribute Name	Description

Apache Zeppelin is an open-source data analysis environment that works with Apache Spark. It is a web-based, versatile notebook that facilitates interactive data analysis, real-time data exploration, visualization, and collaboration. Zeppelin supports an expanding list of programming languages and interfaces, including SparkSQL, Hive, AngularJS, Scala, Python, markdown, and Shell. Using Scala, it can create dynamic, data-driven, and collaborative documents, among other capabilities. Apache Zeppelin is valuable for writing, organizing, and executing analytical code and visualizing results across extensive workflows. Zeppelin can automatically generate input forms in your notebook, provide simple visualizations to present results, and allow colleagues to share the notebook's URL. In real-time data retrieval from the Cassandra database, a Zeppelin dashboard is developed to display data in charts, tables, and other formats. This dashboard updates its data every second, allowing authorized individuals, such as doctors, healthcare companies, or external consultants, to access the data regardless of their patient's or client's health status.

In this research, two datasets obtained from well-known data sources, Kaggle and UCI, were utilized. These datasets pertain to medical conditions, specifically diabetes and heart diseases. Table I provides an overview of the information related to these datasets. It is worth noting that although the Cleveland dataset contains 76 attributes, previous studies have primarily focused on using only a subset of fourteen attributes. Among the various datasets, the Cleveland dataset has been the primary focus of machine learning researchers. The "Class" field in these datasets indicates the presence or absence of a particular medical condition, such as heart disease. The values in the "Class" field range from zero (indicating no presence of the condition) to four, with the Cleveland dataset primarily concentrating on discriminating between the presence (values 1, 2, 3, 4) and absence (value 0) of heart disease.

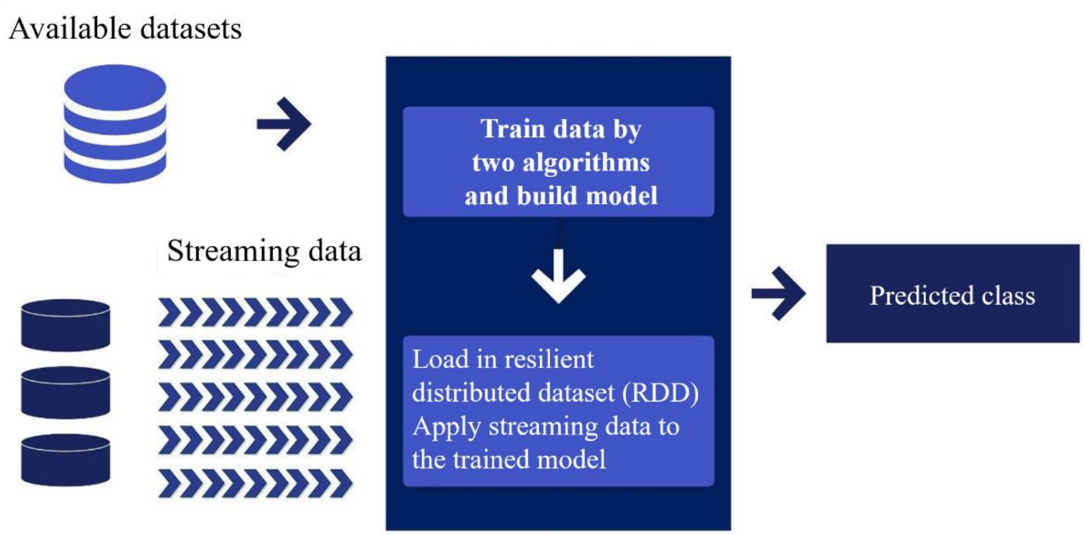
The dataset used in this research was sourced from Kaggle's Diabetes Dataset. Kaggle is a well-known platform for data science competitions and provides a freely available dataset that numerous authors have used in previous studies. This dataset consists of ten features and 15,000 observations, and it is employed to predict whether a patient has diabetes. Table II offers an overview of the features included in this dataset.

TABLE II. KAGGLE DIABETES DATASET DESCRIPTIONS

No	Attribute Name	Description
1	Patient ID	Patient Identification Number
2	Pregnancies	A patient gets diabetes after Pregnancy
3	Plasma Glucose	Glucose amount in Blood
4	Diastolic Blood Pressure	Blood Pressure when Patient is on Rest
5	Triceps Thickness	Body Fat
6 7 8	Serum Insulin Body Mass Index(BMI) Diabetes Pedigree	Insulin amount in Blood *W eightinKG Height*2 *inM* 2) Diabetes History in Family
9	Age	Patient Age
10	Class	Diabetic = 1, NonDibaetic = 0

VI. RESULTS

The proposed real-time health status forecasting system is driven by a single-node cluster featuring a Core i7 CPU, 16 GB of RAM, and the Ubuntu 20.04 operating system. This system seamlessly integrates the trained model with Kafka streaming data processing and runs on the Spark platform. As depicted in Fig. 14, the application establishes a connection to Kafka streaming and commences receiving data streams from various Kafka producers. When it encounters streams related to health characteristics, it retrieves the attribute values from each topic within the illness events sent via Kafka streaming. Subsequently, it employs the trained model to predict the health state of the individuals. In parallel, the Cassandra database records each forecasted health state in a table, employing the identification (ID) as the primary key, which is ideal for ensuring data redundancy and reliability. This stored data can later be queried to examine historical information.



Available datasets

Train data by two algorithms and build model
Load in resilient distributed dataset (RDD) Apply streaming data to the trained model
Predicted class

Fig. 14. Apply classification algorithms.

All the tests were conducted using a cluster configuration consisting of one primary node and two worker nodes, each running the Ubuntu 20.4 operating system within VMware virtual environments. Several steps were undertaken to facilitate communication between the nodes and ensure the proper functioning of the Spark application:

- User accounts and development environment setup: Spark user accounts were created to simplify inter-node communication. Scala and Java were installed. Open SSH Server was set up. Key pairs were generated to enable passwordless SSH configuration across the nodes, ensuring that the Spark master can effectively connect, launch, pause, and run tasks on multiple worker nodes.

- Software installation: Spark, Kafka, and Cassandra were unpacked and installed on a single node. Two themes and corresponding tables were created, one for diabetic disease and the other for heart illness.

- Environment variables: The bashrc file was modified to include essential environment variables like SPARK and JAVA_HOME in the home directory.

- Node replication: To ensure uniformity and consistency across various nodes, the setup folder of the single-node cluster was duplicated multiple times, with one node designated as the master and the others as workers.

- Hostname and host configuration: The hostname and hosts were modified on all nodes to facilitate proper inter-node communication.

The primary stages for implementing the Spark application in a Zeppelin notebook are as follows:

- Spark context and streaming context creation: An instance of Spark contexts and streaming context was created to access all Spark streaming functionalities.

- Direct stream creation: A direct stream was created using the specified Kafka parameters and topics.

- Data extraction: The identifiers and characteristics of each topic and stream were extracted.

- ML model utilization: The pre-trained ML model was used to predict the health status.

- Data storage: All attributes and the predicted labels were saved to the Cassandra keyspace and table.

- Streaming start: The Spark streaming context was initiated using the start method, allowing real-time health data processing.

The research allocated 25% of the data for testing purposes, while the remaining 75% was used to train the machine learning models. The datasets were divided into training and test datasets randomly. To address the issue of the computational cost of sorting feature values across large distributed datasets, an approximate set of candidate splits was identified over a sampled portion of the data. This method has been shown to enable more accurate predictions by analyzing the model error and the test data, effectively mitigating the negative impacts of both underfitting and overfitting. One of the most crucial and valuable measures for assessing the performance of testing and treatment is the Receiver Operating Characteristic (ROC) curve. The MLlib provides support for ROC curve evaluation. On the other hand, classification accuracy is determined by the ratio of all correct predictions to all the prediction data. The classification accuracy for the datasets in this study was assessed using the following equation:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{1}$$

Sensitivity and specificity are two critical metrics used to assess classification models' performance, particularly in medical diagnoses and other fields where accurate predictions are crucial. These metrics are calculated as follows:

Sensitivity (True Positive Rate or Recall): Sensitivity is the percentage of actual positives (e.g., patients with a specific condition) that are correctly identified by the model. It indicates the model's ability to detect true positive cases.

Specificity: Specificity is the percentage of actual negatives (e.g., patients without the condition) that are correctly identified by the model. It measures the model's ability to avoid false positive predictions.

In these equations, true positives (TPs) are the cases correctly classified as positive, true negatives (TNs) are the cases correctly classified as negative, false positives (FPs) are cases incorrectly classified as positive (when they are actually negative), and false negatives (FNs) are cases incorrectly classified as negative (when they are actually positive).

Sensitivity and specificity provide insights into the model's performance in terms of both correctly identifying individuals with the condition and correctly identifying individuals without the condition. Balancing these two measures is important, especially in situations, where missing a true positive (e.g., a medical condition) or incorrectly identifying a false positive (unnecessary treatment or diagnosis) has significant consequences.

$$Sensitivity = \frac{TP}{TP+FN} \tag{2}$$

$$Specifity = \frac{TN}{TN+FP} \tag{3}$$

Our machine learning model's effectiveness was assessed on two established datasets. The empirical results indicate that our utilization of Spark for the execution of the proposed methodology demonstrates notable efficiency and scalability (see Fig. 14 and Fig. 15). Fig. 16 shows the specificity, sensitivity, ROC curve and accuracy obtained in heart disease. The findings further underscore that the proposed model consistently delivers dependable and superior predictive outcomes.

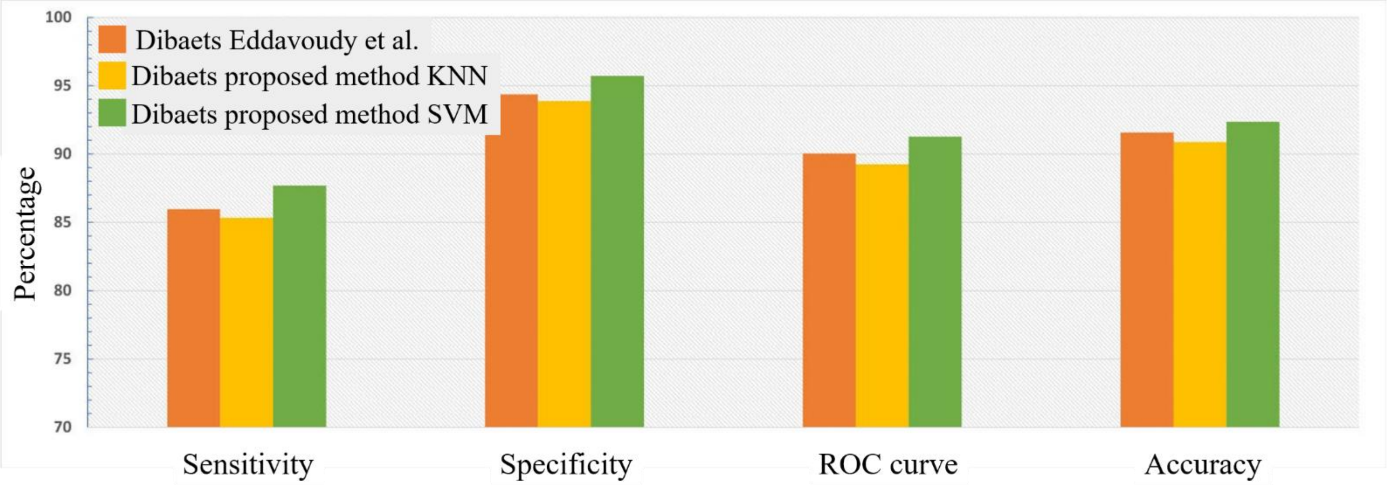

Fig. 15. Specificity, sensitivity, ROC Curve, and accuracy obtained in diabetes datasets in comparison to the other algorithms.

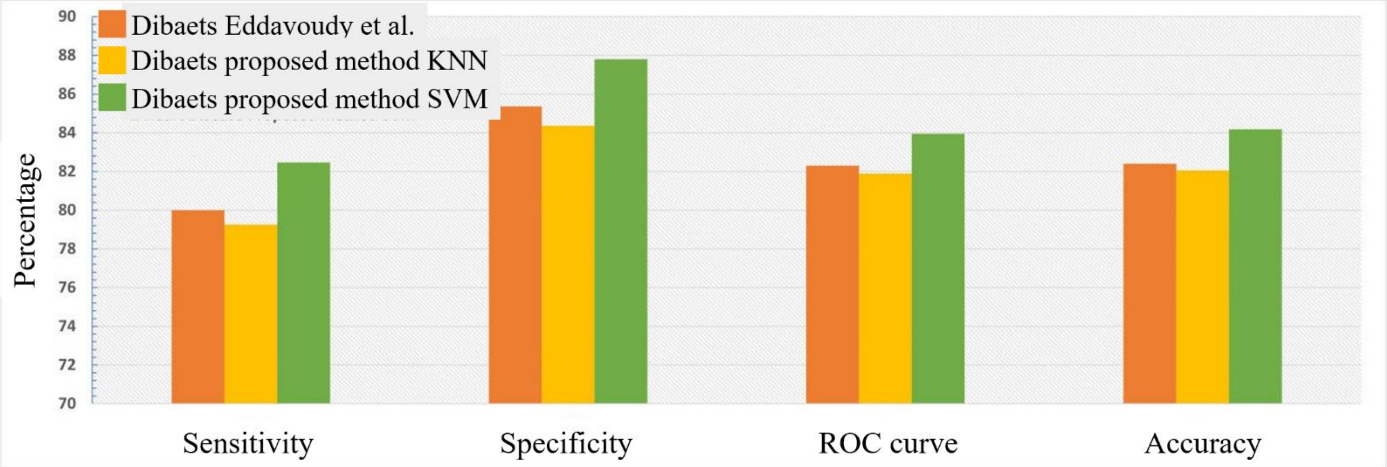

Fig. 16. Specificity, sensitivity, ROC Curve, and accuracy obtained in heart disease datasets in comparison to other algorithms.

VII. Conclusion

This study has demonstrated the successful application of a machine learning model for real-time health status prediction in the healthcare domain. By employing Apache Spark in conjunction with Kafka streaming and Cassandra, we have created an efficient and scalable system for processing and analyzing healthcare data streams. The results of our empirical tests on two distinct datasets reveal that our model consistently provides reliable and high-quality predictions. However, the current design also reveals inherent constraints in the scalability of traditional data storage systems like Cassandra when handling exponentially growing healthcare data. While effective for many use cases, these systems might face challenges in handling future data volume surges, potentially leading to performance bottlenecks and increased resource requirements. The ability to monitor and predict health conditions in real-time is of paramount importance, particularly in the context of chronic illnesses and emergencies. Our proposed system offers a promising solution for continuous health monitoring and early detection, potentially saving lives and reducing healthcare costs. The key takeaway from our research is the effectiveness of combining advanced technologies like Spark, Kafka, and Cassandra to process and analyze healthcare data streams. This approach opens up new possibilities for healthcare analytics and real-time monitoring, benefiting patients, healthcare providers, and the broader medical community. In the future, we envision further refinements and enhancements to our system, including the integration of additional data sources and the development of more sophisticated machine-learning algorithms. As the healthcare sector continues to generate vast amounts of data, the need for innovative solutions like the one presented in this study will only grow, ushering in a new era of data-driven healthcare.

A Yolo-based Approach for Fire and Smoke Detection in IoT Surveillance Systems

Dawei Zhang*
College of Information Engineering, Liaodong University, Dandong 118000, Liaoning, China

***Abstract*—Fire and smoke detection in IoT surveillance systems is of utmost importance for ensuring public safety and preventing property damage. While traditional methods have been used for fire detection, deep learning-based approaches have gained significant attention due to their ability to learn complex patterns and achieve high accuracy. This paper addresses the current research challenge of achieving high accuracy rates with deep learning-based fire detection methods while keeping computation costs low. This paper proposes a method based on the Yolov8 algorithm that effectively tackles this challenge through model generation using a custom dataset and the model's training, validation, and testing. The model's efficacy is succinctly assessed by the precision, recall and F1-curve metrics, with notable proficiency in fire detection, crucial for early warnings and prevention. Experimental results and performance evaluations show that our proposed method outperforms other state-of-the-art methods. This makes it a promising fire and smoke detection approach in IoT surveillance systems.**

***Keywords*—IoT; surveillance systems; fire detection; deep learning; Yolov8**

I. Introduction

The capacity of Internet of Things (IoT) surveillance systems to track and analyze data in real-time for a range of applications has attracted a lot of interest in recent years [1-3]. One such use is the detection of fire and smoke in hospitals, where quick action is essential to avoid property damage and human casualties [4, 5].

Sensor-based systems, image processing, and machine learning are now used in IoT monitoring systems for fire and smoke detection [6]. Among these innovations, computer vision-based systems have demonstrated encouraging results and drawn the attention of several researchers due to their capacity to deliver precise and trustworthy detection findings [7, 8]. Many methods for improving the performance of these systems have been the subject of recent investigations. Despite advancements in computer vision-based fire and smoke detection systems, there are still a number of restrictions and research gaps [9, 10]. False alarms, poor precision, and a restricted capacity to adjust to changing circumstances are some of these drawbacks [11]. These issues indicate the need for more study to enhance the effectiveness and performance of these systems.

In IoT surveillance systems, recent developments in deep learning-based techniques have shown promise in terms of the precision and accuracy [11-14]. Several studies have suggested deep learning-based techniques to solve the shortcomings of current computer vision-based systems, particularly employing the YOLO algorithm. These experiments have shown considerable gains in detection speed and accuracy over conventional machine learning methods.

The advancement of deep learning-based approaches for fire and smoke detection is impeded by several challenges, notably the scarcity of adequate training data and the intricate nature of environmental variables [15, 16]. Overcoming these obstacles is pivotal to enhancing the reliability and effectiveness of deep learning systems dedicated to fire and smoke detection. A critical avenue for improvement lies in conducting in-depth research and comprehensive analysis to delve into the intricacies of these challenges [17]. By addressing the issues related to insufficient training data and navigating the complexities of diverse environmental factors, researchers can refine and optimize deep learning models. This iterative process is essential for fortifying the robustness of these systems, ultimately paving the way for more accurate and dependable fire and smoke detection in various real-world scenarios [18]. As the field progresses, a concerted effort to explore and resolve these challenges will contribute significantly to the evolution of deep learning methodologies, fostering advancements that hold substantial promise for applications in safety and security within IoT surveillance systems.

To address these challenges, this study proposes a deep learning-based approach using the YOLOv8 algorithm for fire and smoke detection in health houses. Using a standard dataset for training, validation, and testing processes, which includes a diverse range of scenarios and environments. The proposed method is evaluated on the custom dataset and compared to existing state-of-the-art methods, demonstrating superior performance in terms of accuracy and speed. The main contributions of this research are as follows:

1) Identifying the limitations and research gaps in existing computer vision-based fire and smoke detection systems in health houses.

2) Proposing a deep learning-based approach using the YOLOv8 algorithm to address these challenges as well as improve the accuracy and speed of detection.

3) Evaluating the proposed method on a custom dataset using extensive performance evaluation metrics.

The reminder of this paper is as, Section II review of previous studies. Section III discuss about material and methods. Section IV presents results and discussions. Finally, this paper concludes in Section V.

II. Related Works

Convolutional neural networks (CNNs) were proposed in the study [19] as a technique for early fire detection during surveillance for efficient disaster management. The method involves acquiring surveillance footage, pre-processing the footage, and training a CNN to detect fires. The proposed method achieves an accuracy of 97.4% for fire detection, which is higher than existing methods. Key features of the method include the use of CNNs for accurate fire detection and the ability to detect fires in real-time. The suggested approach can be used in various scenarios, including forest fires, building fires, and wildfires. Limitations of the method include the need for high-quality surveillance footage and the potential for false positives in certain scenarios.

The paper in [20] presented a deep learning-based forest fire detection approach utilizing unmanned aerial vehicles (UAVs) and the YOLOv3 object detection algorithm. The method consists of acquiring high-resolution images from UAVs, pre-processing the images, detecting the presence of fire using YOLOv3, and sending the location of the fire to a control center. The proposed method achieves an accuracy of 96.4% for forest fire detection. Key features of the method include the use of UAVs for acquiring high-resolution images and the use of YOLOv3 for object detection. The proposed approach has the potential for use in real-world scenarios, but its limitation is the dependency on good weather conditions for successful operation.

The authors in [21] present a deep learning framework called Fire-Net for active forest fire detection. The method involves acquiring high-resolution images from a network of ground-based cameras, pre-processing the images, and training a deep neural network to detect fires. Fire-Net achieves an accuracy of 98.7% for fire detection, which is higher than existing methods. Key features of the method include the use of high-resolution images and a deep neural network for accurate fire detection. The proposed approach has the potential for use in real-world scenarios, but its limitation is the dependency on good weather conditions for successful operation.

The authors in [22] proposed an improved forest fire detection method using a deep learning approach and the Detectron2 model. The method involves acquiring high-resolution images, pre-processing the images, training the Detectron2 model, and detecting fires. The proposed approach achieves an accuracy of 98.6% for fire detection, which is higher than existing methods. Key features of the method include the use of the Detectron2 model for accurate fire detection and the ability to detect fires in real-time. The proposed approach has the potential for use in various scenarios, including forest fires, building fires, and wildfires. Limitations of the method include the need for high-quality images and the potential for false positives in certain scenarios.

The paper in [12] presented a forest fire notification and detection method using IoT and AI approaches. The method involves installing IoT sensors in forested areas to detect environmental conditions and using a deep learning algorithm to detect fires. Key features of the method include the use of IoT sensors for environmental monitoring and a deep learning algorithm for accurate fire detection. The proposed approach has the potential for use in real-world scenarios, but its limitation is the high cost associated with installing and maintaining IoT sensors.

The authors in [23] proposed a wildfire and smoke detection method using ensemble CNN and a staged YOLO model. The method involves acquiring high-resolution images from a network of cameras, pre-processing the images, and using a staged YOLO model for smoke detection and an ensemble CNN for wildfire detection. Key features of the method include the use of a staged YOLO model and ensemble CNN for accurate detection of smoke and wildfire, respectively. The proposed approach has the potential for use in real-world scenarios, but its limitation is the need for high-quality images and the potential for false positives in certain scenarios.

III. Material and Method

This section provides an overview of the study's content and methodology. Yolov8 is the foundation of the primary methodology employed in this study. Initially, YOLO was a pre-trained object detector programmed to recognize commonplace items such as chairs, tables, phones, cars, etc. This study presents a detection technique according to YOLO algorithms to create a model that might identify. In real-time applications, the models perform well as well.

A. Dataset

The dataset consists of three different types of jewelry (background, fire, and smoke). The dataset contains pictures captured by webcam. The obtained images from a webcam permanently installed at a jewelry store. Some samples of the dataset are shown in Fig. 1. Small target items, which are harder to detect, are included in the collection, along with images of various sizes. The data was collected from GitHub resource[1].

In order to prepare the dataset to be more robust, augmenting of the images in the dataset is performed. Choosing images with various angles, sizes, resolutions, forms, and sample counts in each image. A maximum of three augmented versions of each image were created by applying the following random effects: horizontal flip, rotation between -15° and +15°, exposure between -10% and +10%, brightness between -20% and +20%, and saturation between -20% and +20%. Photos that have been enhanced. The final step is to separate the labeled images into a validation set (6%) and a test set (1%), training set (93%).

B. Google Colab

Using Google Colab, which offers free usage of potent GPUs. All testing and training tasks are performed utilizing a 12GB NVIDIA Tesla T4 GPU; more details are given in Fig. 2. All the models are trained for 50 epochs with an image size of 640 and with YOLO default adjustment for other hyperparameters.

C. Yolov8 Model

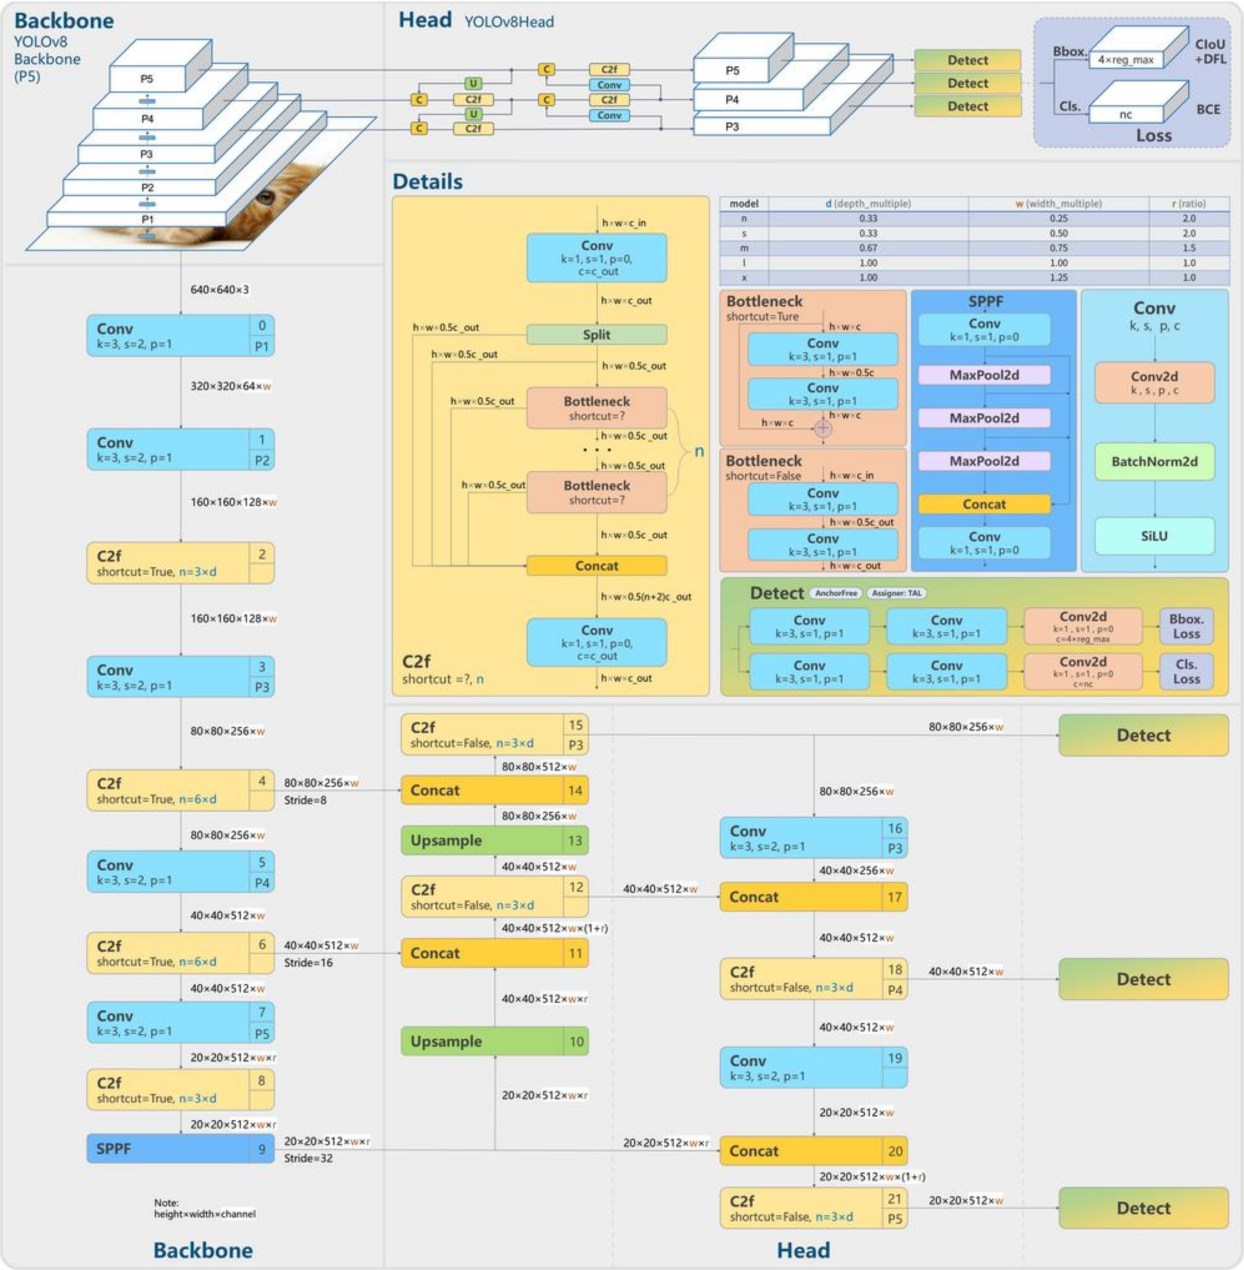
The latest version of YOLO is Yolov8, which was released in 2022 by Ultralytics [24]. YOLOv8 is an object detection model that is based on the You Only Look Once (YOLO) family of algorithms. The architecture of Yolov8 is shown in Fig. 3. YOLOv8 has several architectural improvements over the previous versions, such as:

1) Convolutional neural network (CNN) architecture: Yolov8 uses a modified version of the EfficientNet backbone network, which is a cutting-edge CNN design that strikes a solid balance between computing efficiency and accuracy. Yolov8's backbone network is in charge of taking features out of the input image. Yolov8's backbone network is specifically based on a modified version of the EfficientNet design. Modern convolutional neural network (CNN) architecture EfficientNet aims to strike a reasonable compromise between accuracy and processing efficiency. A succession of convolutional layers that successively reduce the spatial resolution of the feature maps while increasing the number of channels make up Yolov8's EfficientNet backbone. A sizable image classification dataset, such as ImageNet, is used to pre-train the backbone network.

2) Feature aggregation: Yolov8 uses a feature pyramid network (FPN) to aggregate features at different scales, which improves the model's ability to detect objects of different sizes.

3) Object detection head: The head is made up of some convolutional layers, followed by an output layer that generates the results of the detection. Each object in the input image is predicted to have bounding boxes, objectness scores, and class probabilities by Yolov8's object detection head. The head is made up of some convolutional layers, followed by an output layer that generates the results of the detection. Yolov8's head is made up of three prediction branches that, in turn, forecast bounding boxes, objectness scores, and class probabilities. The implementation of each branch consists of a set of convolutional layers, followed by an output layer that generates the corresponding predictions. The number of anchor boxes and object classes determines the number of output channels in each branch.

4) Training strategy: Yolov8 enhances the accuracy and speed of the model by combining anchor-based and anchor-free item detection techniques. Additionally, a progressive scaling strategy is used during training to enhance the model's capacity to recognize objects of various sizes.



model	d (depth_multiple)	w (width_multiple)	r (ratio)
n	0.33	0.25	2.0
s	0.33	0.50	2.0
m	0.67	0.75	1.5
l	1.00	1.00	1.0
x	1.00	1.25	1.0

Fig. 3. Yolov8 architecture.

IV. Results and Discussion

A. Experimental Results

To conduct experimental results for fire and smoke detection using a YOLOv8 model, sample output images from both validation and testing sets can be examined. These images can be obtained by running the trained model on the validation and testing datasets and visualizing the resulting predictions. For each image, the model correctly detects whether there is a fire or smoke present. Fig. 4 shows the samples of experimental results.

B. Performance Measurements

This study uses precision, recall, and F1socre criteria to assess performance. The P-curve, R-curve, PR-curve, and F1-curve are assessment metrics frequently employed in machine learning to gauge the effectiveness of models [16, 18]. The fraction of true positive predictions among all positive predictions is represented by the P-curve in the case of a fire and smoke detection Yolov8 model. The R-curve shows the recall of the model or the percentage of accurate positive predictions out of all actual positive samples. The link between accuracy and recall is depicted by the PR-curve, which also illustrates how effectively the model balances the two parameters. Finally, the F1-curve provides a comprehensive evaluation of the model's performance by combining precision and recall into a single score.

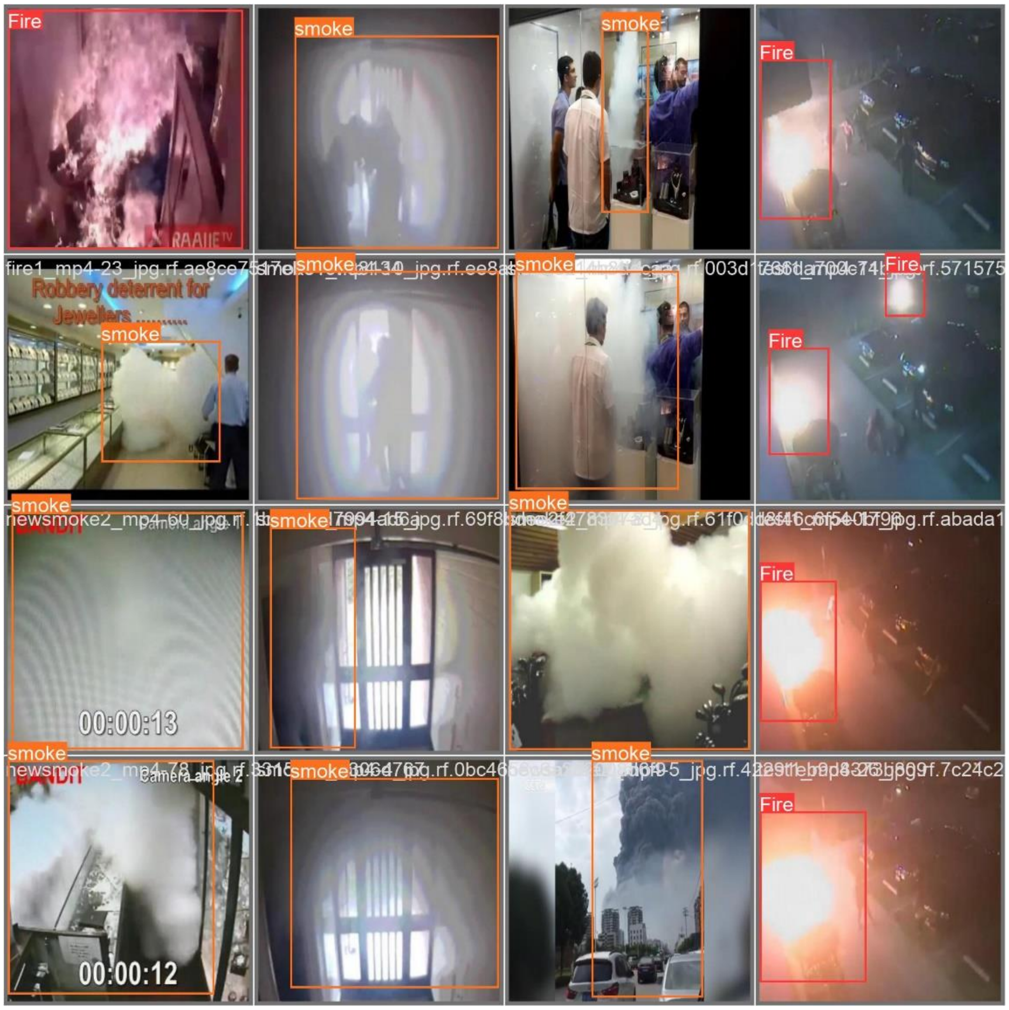


Fig. 4. Samples of experimental results.

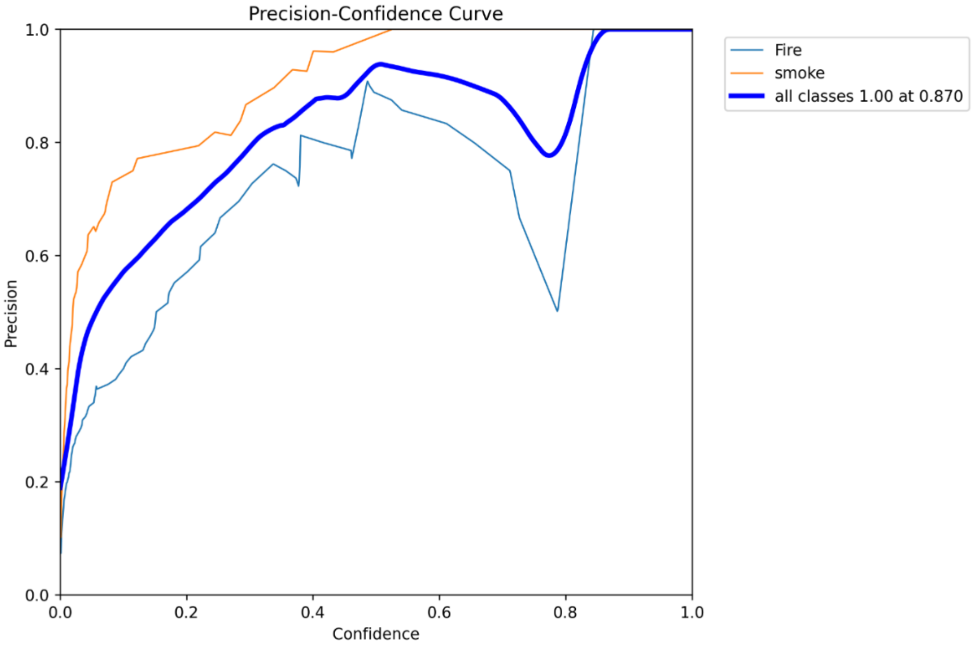

Fig. 5. P-curve of the model.

As shown in Fig. 5, the graph displays the YOLOv8 model's validation set's fire and smoke detection precision values. The precision values are represented on the y-axis, while various confidence criteria, ranging from 0.0 to 1.0, are represented on the x-axis. The fraction of accurate positive forecasts among all positive predictions is known as the precision value. The graph demonstrates that the accuracy of detecting fire is always greater than the accuracy of detecting smoke. The precision value for detecting a fire is approximately 0.8 at a confidence threshold of 0.5, whereas the precision value for detecting smoke is approximately 0.5. These results indicate that the model performs better at identifying fire than smoke.

As shown in Fig. 6, the recall values of a YOLOv8 model for fire and smoke detection on the validation data are shown in the R-curve graph. The recall values are displayed on the y-axis, and the various confidence criteria are displayed on the x-axis. The recall is the percentage of correctly predicted positive samples among all truly positive samples. According to the graph, the model can detect fires more often than smoke, with a maximum recall of 0.9 for fire and 0.7 for smoke at a confidence level of 0.5. This implies that the model is more effective at identifying fire than smoke, while changes could also influence this in the visual properties of the two classes or the training data.

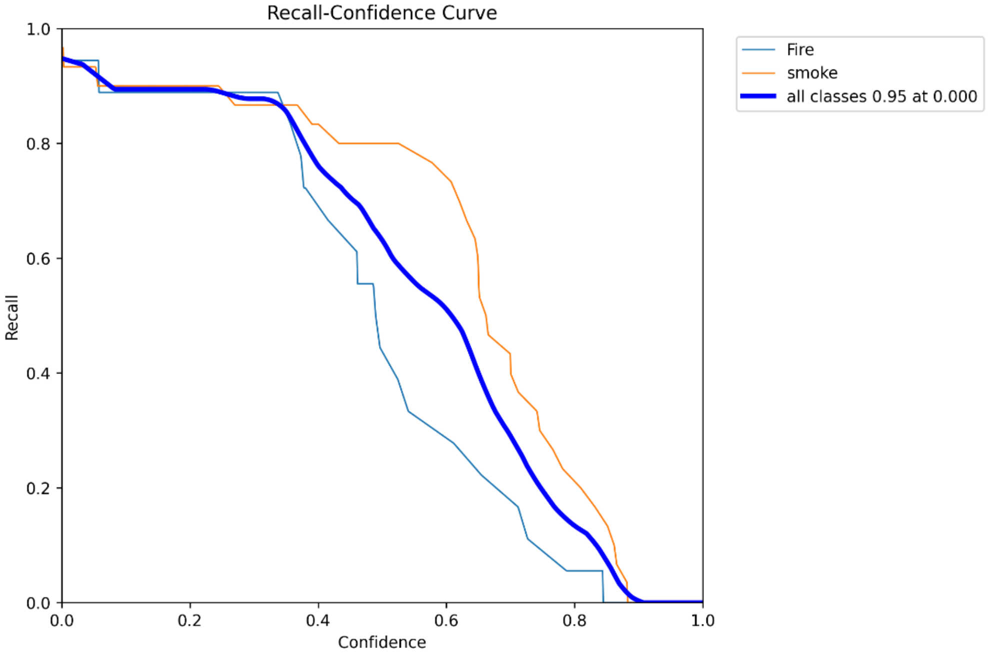

Fig. 6. R-curve of the model.

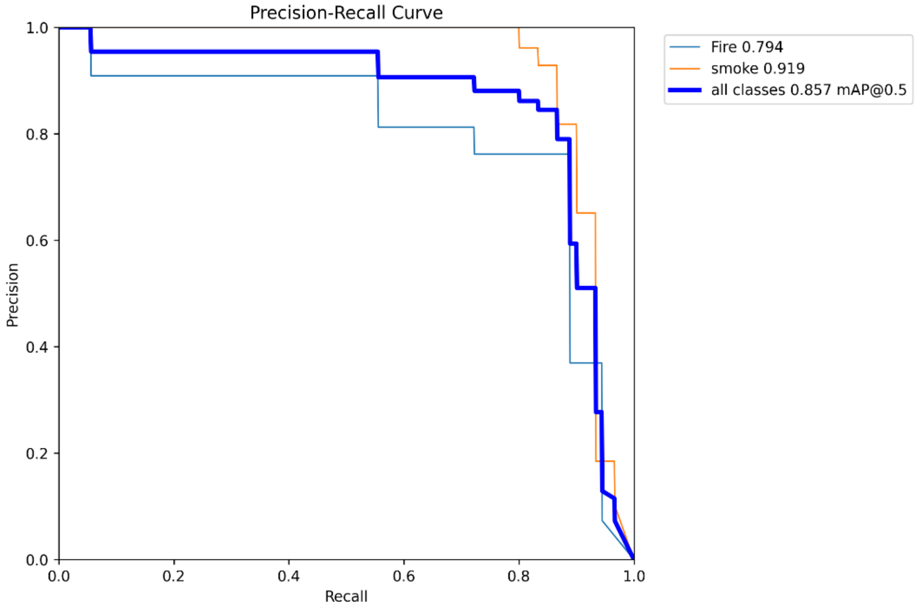

Fig. 7. PR-curve of the model.

Fig. 7 depicts the precision-recall trade-off for a YOLOv8 fire and smoke detection model. The recall values are on the x-axis, and the precision values are on the y-axis. From 0.0 to 1.0, the precision and recall values are measured; higher values denote greater performance. The graph demonstrates that the model generates greater precision values for the identification of fire at all recall levels, demonstrating that it is more accurate in identifying fire than smoke. Additionally, the precision and recall values for smoke detection are considerably lower than those for fire detection, as the curve shows, suggesting that the model may have some difficulties identifying smoke. The PR-curve offers an extensive picture of the model's performance in terms of precision and recall.

As shown in Fig. 8, the harmonic means of recall and precision for fire and smoke detection in the validation set of a YOLOv8 model is displayed on the F1-curve graph. The y-axis displays the F1 score values ranging from 0.0 to 1.0, while the x-axis displays various confidence criteria. The F1 score, which considers precision and recall, is a frequently used metric for assessing a model's overall performance. The greatest F1 score for fire detection at a confidence level of 0.5 is 0.86, while the maximum F1 score for smoke detection is 0.57. This shows that the model performs better at detecting fire than smoke. The graph demonstrates that at all confidence criteria, the F1 score for fire detection is consistently higher than the F1 score for smoke detection. This can be caused by variances in the two classes' visual qualities or variations in the training data. The model can still identify smoke properly to a certain extent, as seen by the F1 score for smoke detection, which is still rather high.

The model's performance in terms of precision and recall for fire and smoke detection is thus usefully summarized by the F1-curve. The model appears effective at detecting fires, essential for early warning and prevention, as indicated by the high F1 scores for fire detection. However, the model's performance in detecting smoke might still be improved.

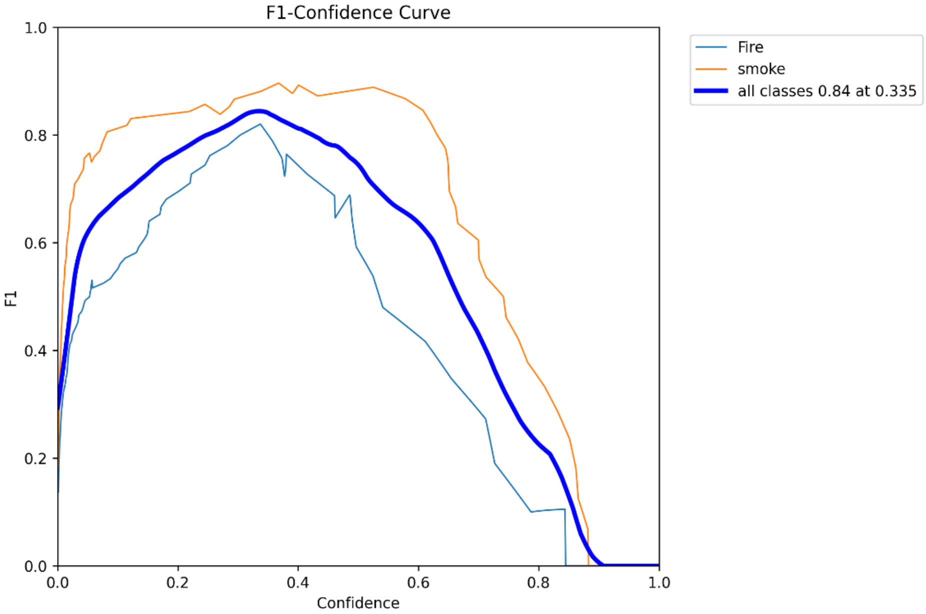

Fig. 8. F1-score of the model.

V. Conclusion

In conclusion, this research paper emphasizes the significance of developing accurate and efficient fire and smoke detection systems in IoT surveillance systems for health houses. While traditional methods have limitations, computer vision-based systems have shown promising results, particularly deep learning-based methods using the YOLO algorithm. However, challenges still exist, such as limited training data and complex environmental factors, which require further investigation. The proposed method in this paper addresses these challenges and demonstrates superior performance in terms of accuracy and speed compared to existing state-of-the-art methods. This research contributes to the ongoing efforts to improve the reliability and effectiveness of fire and smoke detection systems in IoT surveillance systems. For future study, while the YOLO algorithm has shown promise in improving the accuracy and speed of fire and smoke detection, other deep learning algorithms may also provide superior results. Future studies could explore using other deep learning algorithms, such as Faster R-CNN or Mask R-CNN, and compare their performance to the YOLO algorithm. Moreover, future studies could investigate the development of more advanced vision-based sensors, such as multi-spectral or hyperspectral sensors, which can capture a wider range of data and improve the accuracy of fire and smoke detection.

Design and Analysis of Deep Learning Method for Fragmenting Brain Tissue in MRI Images

Ting Yang, Jiabao Sun*
School of Information and Electrical Engineering, Shaoxing University Yuanpei College, Shaoxing, Zhejiang, 312000, China

***Abstract*—An essential component of medical image processing is brain tumour segmentation. The process of giving each pixel a label is called image segmentation in order for pixels bearing the same label to share characteristics and help distinguish the target. A higher fatality rate and additional dangers can be avoided with early identification. It can be challenging and time-consuming to manually (man-made) segment brain tumours from the numerous MRI pictures generated during medical procedures in order to diagnose malignancy. This is the fundamental reason why brain tumour imaging has to be automated. The deep learning technique for the segmentation of brain tissue in magnetic resonance imaging (MRI) pictures was examined and enhanced in this work. Researchers are using deep learning techniques—convolutional neural networks in particular—to tackle the complex problem of biological image fragmentation object recognition. In contrast to traditional classification techniques that take in manually constructed qualities, convolutional neural networks automatically extract the required complicated features from the data itself. This solves a number of problems.**

Keywords—Brain tumor; deep learning; neural networks; magnetic resonance imaging

I. Introduction

Digital images are frequently utilised in image processing, and improved hospital healthcare services have been made possible in recent years by information technology and electronic health systems in the medical industry. When one or more malignant tissues in the brain grow abnormally, brain tumours result. There are two kinds of brain tumours: benign and malignant. A brain tumour is considered benign if the tumour tissues are growing uniformly and the cancer cells are dormant. A malignant tumour is one that spreads to all associated tissues if the cancerous tissues are non-uniform or if the cells are active, depending on the individual. Tumour location diagnosis is challenging due to the intricate structure and tissues of the human brain. Malignant tumours spread over the entire brain or spinal cord tissues, depending on when they are discovered. They do this by transferring diseased tissues to healthy tissues. Treatment for malignant tissues becomes more challenging and, in most circumstances, incurable, meaning the patient will eventually die from the disease as it spreads to additional regions. Thus, among the most important issues facing patients are early detection, type categorization, and infection rate.

With the development of new imaging techniques that make this information more accessible to doctors, radiation, surgery, or chemotherapy may be the best course of action. It follows that a patient's chances of surviving a tumour can be greatly raised if the tumour is accurately discovered in its early stages. Under the effect of imaging techniques, fragmentation is employed to identify the tumour area [1], [2]. Texture, contrast, border, and colour are the different components that make up a picture. As previously stated, aberrant and non-uniform growth of brain tissues is the definition of brain cancer or brain tumour [3], [4]. Brain tumours are among the deadliest forms of cancer, although being relatively uncommon. Brain tissue cells are the source of cells seen in primary brain tumours, and they begin in the brain. An MRI of the patient's brain is one of the best methods for diagnosing brain tumours. This technique facilitates a simple first diagnosis by giving medical professionals vital information on the structure, size, and metabolism of the brain tumour. This type of imaging is a common way to look at and diagnose brain tissue.

The study employed a variety of segmentation techniques, including a histogram, neural network segmentation methods, physical model-based techniques, clustering algorithms, Mean-Shift algorithm, k-means algorithm, Fuzzy C-Means Clustering (FCM) Algorithm, and Expect maximisation algorithms, to diagnose and classify the type and size of brain tumours in patients [5], [6]. Based on the segmentation system performance, various segmentation techniques are compared. For improved segmentation, artificial intelligence and enough information are typically combined [7], [8]. Conversely, the deep learning approach has shown the best results.

Abd-Ellah et al. reviewed the diagnosis of brain tumours using MRI scans in 2019 [9]. Additionally, the Support Vector Machine's (SVM) and Ecoc's error correction output codes are used to attain accuracy in the classification stage. PCA is used for feature extraction and selection in DWT machine learning. The collected features are classed using a seven-layer dynamic neural network (DNN) [10]. Terms and titles like CNN architecture, inverted graphics network, deep neural network, deep belief network, and so on are used in image processing technology; CNN architecture is the most commonly used word. Convolutional layers are typically used in the CNN architecture's feature extraction layer and input layer. The suggested method was proposed by Mohan et al. (2018) in three primary steps: CNN classification, post-processing, and pre-processing. Because CNN architecture performs so well in brain image recognition, medical professionals and researchers are using it more frequently than they used to because it is faster and more accurate than other methods. [11, 12]. A faultless network architecture is made possible by the CNN approach, which directly learns the difficult and complicated aspects of brain MRI images to aid in feature extraction and reduction. CNN receives brain MRI image excerpts as input, and uses Neutral Density (ND) filters to extract complicated characteristics. The benefits of CNN architecture have been covered thus far; however, there are drawbacks to this approach as well, including high training computational costs, data consumption, and challenging hidden-layer complicated architecture design. It has also looked at the difficulties and issues that other studies have had when reporting the data, the type of tumour, and the algorithms' performance standards utilising the sensitivity, precision, and accuracy criteria. Based on the research and studies conducted, it is recommended that greater focus be placed on the identification, location, segmentation, and algorithm validation of brain tumours using magnetic resonance imaging.

When a brain tumour reaches an advanced stage, it can be difficult to diagnose it quickly. Magnetic resonance imaging is often chosen to improve the outcome of brain tumour diagnosis. It is exceedingly challenging to identify a tumour more accurately without harming healthy tissue. A new method for using magnetic resonance imaging (MRI) to diagnose brain tumours is presented in order to fix the flaws [13], [14]. As previously shown, early diagnosis of brain tumours can greatly aid patients in their recovery, contingent upon the nature and degree of metastasis. In the clinic or hospital, manually evaluating the numerous magnetic resonance imaging (MRI) scans that are generated on a regular basis is a challenging procedure. Thus, computer technologies should be employed for fast and accurate early diagnosis of brain tumours. Three key components are involved in diagnosing brain tumours using MRI images: segmentation, classification, and tumour diagnosis. Studies show that the majority of works in recent years have concentrated on the application of conventional learning machines. More precise techniques have been used recently by researchers; these are also used to find brain tumours. In general, this article's main theme gives a summary of both the development processes for new deep learning approaches for diagnosing brain cancer and traditional machine learning techniques.

The primary goals of the research presented in this paper are to provide an enhanced approach for brain segmentation, assess the effectiveness of the suggested approach, and review and compare the current approaches for brain tumour segmentation. The article's overall structure is set up so that the Section II provides a summary of the fundamental ideas and earlier approaches used in this area. The recommended dataset is introduced in the Section III, while the recommended approach is offered in the second portion. The steps for the study method are presented in the Section IV. The suggested approach is tested, its outcomes examined, and it is contrasted with alternative segmentation techniques in the Section V. The suggested algorithms are concluded and summarised in Section VI.

II. Proposed Methods

An enhanced strategy built on the deep learning technique is provided in this section. Compared to previous methods, the suggested method offers a higher sensitivity and accuracy. Neural networks can be used to implement the suggested method. Deep learning is one of the subgroups of machine learning. According to a set of techniques, deep learning attempts to model high-level abstract notions in the data by using a deep graph with numerous processing levels made up of several linear and non-linear transformation layers [15], [16]. The study of neuronal behaviours in the human brain provides the learning structure with its primary purpose [17]. Models like deep neural networks, sophisticated neural networks, and deep belief networks have advanced well in the domains of image and natural language processing [18], [19]. In actuality, the study of novel artificial neural network techniques is referred to as deep learning. Deep learning can be used to meet the issues of avoiding the drawbacks of traditional machine learning methods [20], [21]. In several fields of medical image analysis, including computer-aided diagnosis, in-depth learning is becoming more and more common [22], [23]. As was previously noted, one of the subcategories of machine learning technology is the deep learning algorithm, which looks for many levels of distributed input data. The paper introduces a novel approach for segmenting tumour locations using a mix of artificial neural network and K-means fuzzy algorithm [37]. The process comprises of four stages, namely denoising, feature extraction and selection, classification, and segmentation. Initially, the preprocessed image is eliminated utilising the Wiener filter, subsequently followed by the extraction of significant GLCM features from the images. Subsequently, deep learning techniques were employed to categorize abnormal photos from normal images. Ultimately, the tumour region is segmented independently by subjecting it to the K-Means fuzzy algorithm. The proposed segmentation strategy is tested on the BRATS dataset and achieves an accuracy of 94%, a sensitivity of 98%, a specificity of 99%, and a Jaccard index of 96%.To address these issues, a fresh and enhanced deep learning model for image segmentation based on the cascaded regression (DLCR) technique is put forth. The fully convolutional neural network (FCNN) method is used in the suggested method to pre-process magnetic resonance imaging (MRI) pictures using the normalisation method. The data is then reduced and the matching feature from each feature vector is obtained through feature extraction using the Gaussian mixture model (GMM). Next, our suggested approach was contrasted with the existing techniques, which include the predictive machine learning model (MLPM), deep learning framework (DLF), and extreme learning machine local receiving fields (ELM-LRF). According to the findings, the suggested DLCR approach outperforms the current techniques in terms of sensitivity, specificity, recall ratio, precision ratio, peak signal-to-noise ratio (PSNR), and root mean square error (RMSE) [38].

These techniques are often divided into four groups: auto encoders, convolutional neural networks, sparse coding, and restricted Boltzmann machines (RBMS). Unlike human feature extraction in classical learning methods, machine learning technology may extract complex stages from their learning abilities. Through training, they get more acceptable findings in vast data sets. The fast rise in GPU processing capacity has enabled the creation of cutting-edge deep learning methods. Deep learning algorithms have been trained against picture alterations using millions of photos and resistance [24], [25].

An artificial neural network that resembles the structure of the human brain and is capable of carrying out mathematical operations is called a deep learning algorithm. However, technological developments have given rise to methods for optimising traditional neural networks [26]. A multi-layer neural network with numerous hidden layers and free parameters does deep learning [27]. One of the most significant deep learning techniques is convolution neural networks, which effectively train several layers. This is one of the most popular and highly effective ways. The convolution layer, pulling layer, and fully connected layer are the three primary layers that make up a CNN network in general. Various layers carry out various functions. There are two steps in a convolutional neural network: the feed stage and the backpropagation stage for training.

Convolution is applied to each layer of the image after the point between the input and each neuron's parameters is multiplied in the first step. This step involves feeding the network input and then computing the network's output. The network error is computed and the network parameters are set using the output outcome. In order to calculate the error rate, compare the network output with the right response using a loss function. The post-publication stage starts in the following step, based on the computed mistake amount. Using the loss function, the network's output is compared to the right response to determine the error rate. The post-release stage starts in the following phase, depending on the quantity. This phase computes each parameter's gradient using the chain law. Every parameter has an effect on the network, according to the error made on each parameter based on the methodology. The feeding step is forward once the network has been modified and the parameters have been updated. Eventually, following numerous iterations of these procedures, the network's training is complete.

A. CNN Network Layers

Convolutional neural networks, in general, are neural networks with particular, hierarchical rules in which a number of fully connected layers come after the convolutional layers and the pulling layers. The convolution layer is one of the CNN layers. In these layers, the CNN network solves the middle feature map and the input picture using several cores, which results in distinct features in Fig. 1. There are three advantages to convolution operations: stability, immutability with regard to object relocation, local connectedness, and a significant reduction in the number of parameters.

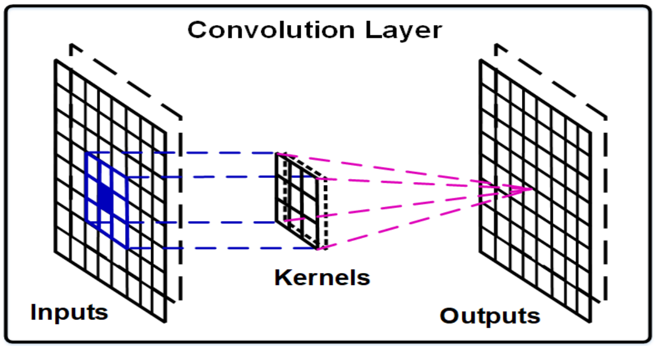

Fig. 1. Convolution layer performance.

The Pooling layer is the subsequent CNN layer. Pooling layers, which are frequently placed after a convolutional layer, can be used to reduce the size of the feature map and network parameters. Convolution layers and other pooling layers are resilient against displacement because they incorporate nearby pixels into their computations. The most popular pooling layer implementations make use of the max (max pooling) and average (average pooling) functions. It accelerates convergence, enhances generalisation, and produces a well-chosen set of fixed features. Fig. 2 displays a max-pooling result.

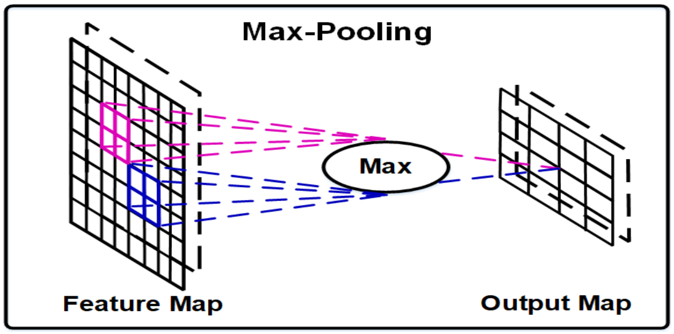

Fig. 2. Max-pooling performance.

The fully linked layer is the final layer of CNN. As seen in Fig. 3, there are fully linked layers following the final polishing layer, each of which is connected to the neurons in the layer before it. On the other hand, about 90% of the parameters of a CNN network are made up of fully linked layers, which are likewise conventional.

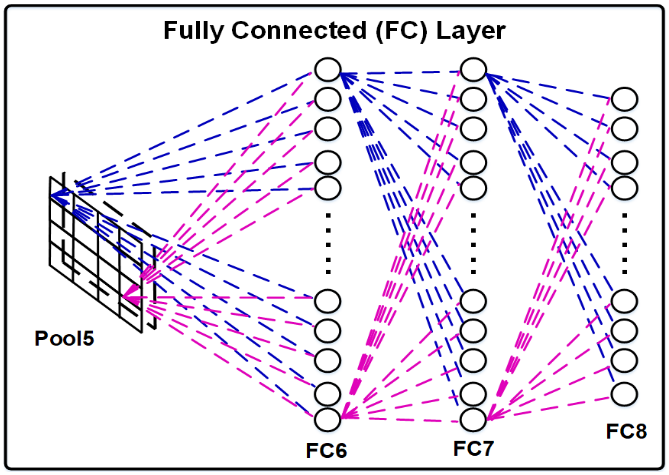

Fig. 3. Fully connected layers performance.

This kind of layer's main problem is its excessive number of parameters. As a result, there is a significant processing cost that needs to be covered by training. Therefore, cutting back on connections and eliminating these layers entirely using various techniques is a popular technique that yields good results.

B. Enhanced Neural Network Capabilities

The advantage of deep learning over surface learning is the ability to build deep architectures with higher data volumes and higher abstract information transmission. However, overfitting may become a problem if a lot of new parameters are included. A plethora of regularisation techniques have been introduced recently to address overfitting and enhance network performance. Note that not every method covered in this section is unique to neural networks. This implies that various methods, such as the dropout method, can be used with conventional artificial neural networks.

1) Deep learning dropout: The purpose of this approach is to prevent over-coverage. Each neuron in the network is either retained with a probability of p or eliminated with a probability of p-1 at each training stage. Eventually, just a smaller network is left. An expelled node's input and output edges are also eliminated. At that point, the data will only be used to train the smaller network. Next, the removed nodes are removed from the network and then added back in with their original weights. A comparison between the networks is shown in Fig. 4.

Drop Connect is a well-liked variation of Dropout that drops weights at random rather than activation values. Research has demonstrated that, albeit more slowly, this approach can regularly outperform the Dropout method in a variety of common benchmark categories.

2) Deep clustering in deep learning: Without any prior knowledge of different factors like feature selection, distance criteria, or clustering techniques, the goal of clustering is to group comparable data points. One deep learning algorithm is deep clustering. Two-dimensional non-linear data representations from the data set are employed for learning. Quantization of deep neural networks requires network loss. Deep clustering techniques now in use can be generally classified into two groups. After learning a representation that jointly optimises learning and clustering, a two-step challenge is implemented. The first class of algorithms makes use of sophisticated unsupervised learning frameworks and methodologies directly. An additional set of algorithms simulates a classification error in monitoring by attempting to precisely characterise a clustering failure.

3) Data redundancy in deep learning: The utilisation of redundant data results from the redundancy of data generated when CNN is utilised for object detection. Forecasts may benefit from the addition of new data, which also improves the data's quality and accuracy. This can be used to decrease interference and expand training set sizes. [28, 29]

4) In deep learning, auto encoder and deep auto encoder: A neural network that has been trained to replicate its input to its output is called an autoencoder. Neural networks whose input and output are identical are an artificial neural network type that is used to encode effective learning data in an unsupervised manner. They function by first compressing the input into a representation of hidden space, from which the output is then rebuilt. An autoencoder aims to encrypt a dataset, usually with the purpose of reducing dimensionality by conditioning the network to reject spurious signals. Fig. 5 depicts an autoencoder's full workflow. You train an autoencoder to re-encode your input X, as opposed to training the network to anticipate the target value Y for the input X. During this procedure, the auto-encoder is optimised by minimising the update error.

Hinton [28] introduced the deep autoencoder, which is still being researched extensively in current studies. As previously noted, a backpropagation process, like the gradient approach, is used to train the autoencoder. Ignoring the benefits, this model's significant drawback becomes apparent when an error happens, and these layer flaws can cause the model to become extremely inefficient. The network reconstructs the training data average as a result of this error. This problem can be effectively solved by pre-training the network with initial weights, which comes close to the ultimate solution. Simultaneously, several auto-encoders are available that promise to retain representations for an extended period of time due to continuous changes in input. The autoencoder is compelled by full representation learning to extract the most important features from the data.

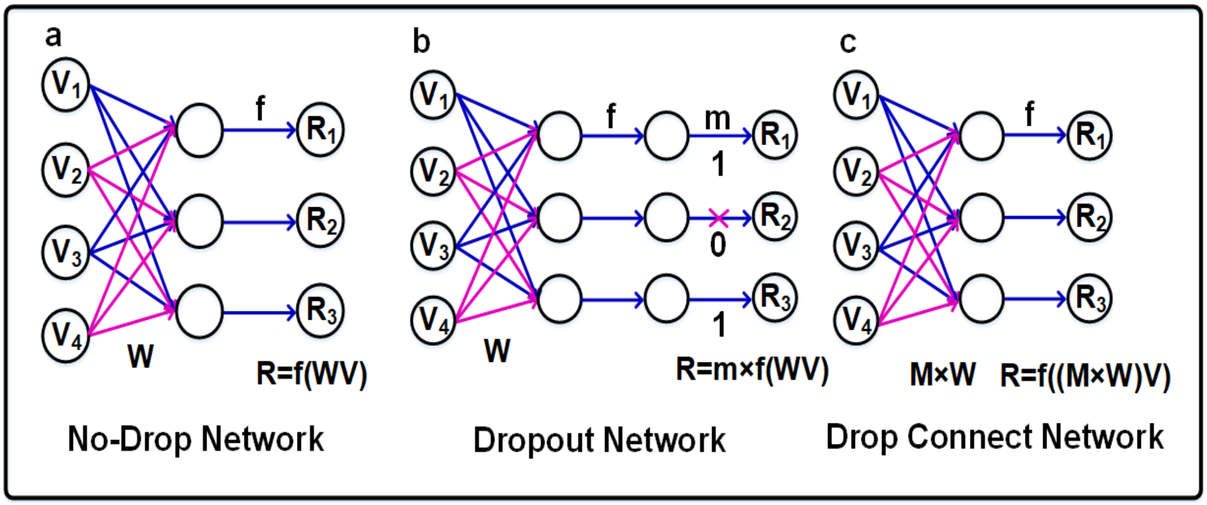

Fig. 4. Comparison between the networks.

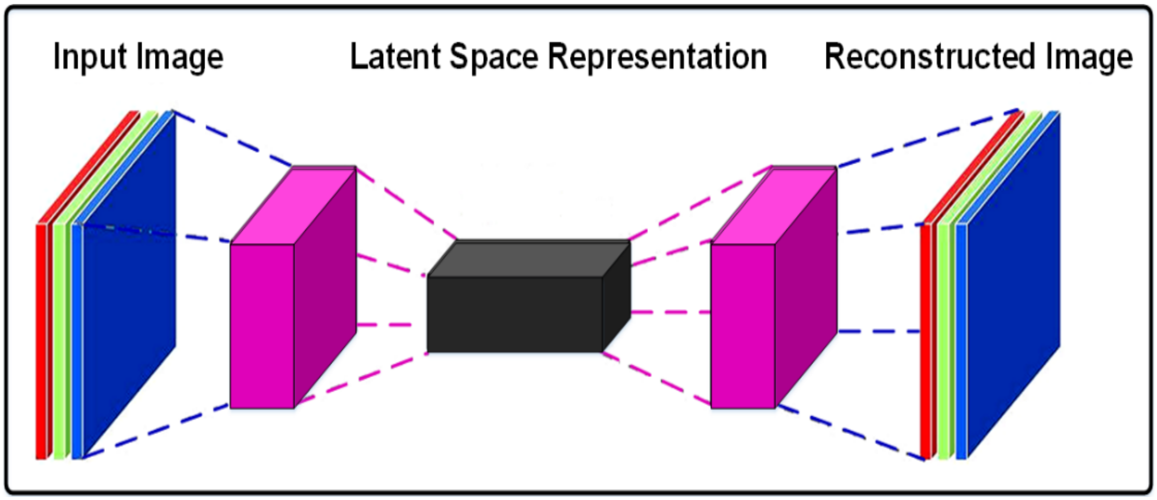

Fig. 5. The autoencoder's general process.

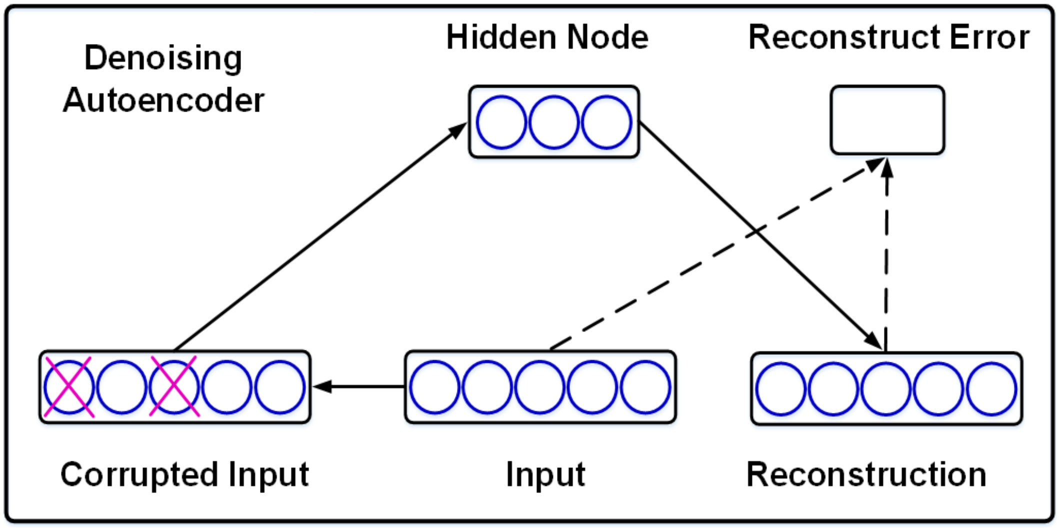

Fig. 6. Denoising autoencoder.

5) Denoising autoencoder in deep learning: In Fig. 6, the DAE procedure is displayed. (DAE) is a power-boosting model known as an automatic denoising encoder. Vincent presents this model, which is able to discern between the accurate input and the tampered version. Put another way, have the model see the input distribution's structure.

In actuality, this task's objective is to either eliminate or clean up the contaminated input. The depiction of higher levels that are comparatively resistant to corrupt inputs and the extraction of characteristics with a relevant structure in the input distribution are the two linked hypotheses of this technique. Its ability to correctly recover from a damaged version is one of its excellent features, and it is noise-resistant.

C. Network in Network (NIN) and Activation Functions

Fully linked layers are used for image processing after a series of layers and aggregation layers are used to extract features from spatial structures. The primary idea behind it is to substitute a perceptron neural network (many fully connected layers with non-linear activation functions) for the convolutional layer and learn its parameters from the data. In this sense, non-linear neural networks take the place of linear filters. This technique produces superior picture categorization results. It is in charge of the data's non-linear transformation. The modified linear unit (ReLU) is computed in Eq. (1).

$$F(x)=max\ (0, x) \qquad (1)$$

It has been discovered that these functions outperform hyperbolic tangent functions or classical functions in terms of training speed [30], [31]. On the other hand, applying a constant 0 can harm the flow gradient and the subsequent weight adjustment [32], [33]. Using a variable named Leaky Rectified Linear Unit (LReLU), which adds a tiny slope to the performance's negative side, we adjust to these constraints. Eq. (2) is used to calculate this function.

$$F(x)=max\ (\alpha x, x) \qquad (2)$$

The activation function is among the most often used (ReLU). The ReLU non-linear unit's job is to clip any negative input value in the data to zero, reducing it, and then taking the positive input values as the output [34], [35].

III. Data Set

We utilised the publically accessible brain tumour dataset from Figshare [4] to examine and assess our suggested methodology, employing various convolutional neural network designs. Cheng developed it in 2017. The dataset consists of 3064 brain MRI slices obtained from 233 people. It encompasses three types of brain tumours:

The total amount of images for meningioma is 708, for pituitary it is 930, and for glioma tumour it is 1426. The dataset is accessible to the public via the Figshare website in the ".mat" format, which is compatible with MATLAB. Each MAT-file consists of a structure that includes a patient ID, a distinctive label indicating the type of brain tumour, picture data in a 512 × 512 format represented as unsigned 16-bit integers, a vector providing the coordinates of discrete points that define the tumour perimeter, and a binary mask image representing the ground truth. Fig. 7 shows the eight examples of database images.

The enhanced deep learning algorithm's pseudo-code is presented in the text below.

An overview of CNN architecture is presented in Fig. 8.

```
Algorithm 1: Improved Deep Embedded Clustering
Input: Input data: X; Number of clusters:  K; Target Distribution update interval: T; Stopping Threshold: $\delta$ ; $Maximum\ iterations$: $M\ axIter$.
Output: Autoencoder's weights W and W' ; Cluster centers  $\mu$ and labels $s$.
Initialize  $\mu$ , $W'$ and $W$ according to Section 3.1.
for iter  $\epsilon$ $\{0,1,\ldots,MaxIter\}$ do
  if iter %T == 0 then
    Compute  all embedded points $\{z_{i=} \boldsymbol{f}_w(xi)\} i = 1$
    update P using (3), (4) and {zi} i=1.
  Save last label assignment: $S_{old}$=s.
  Compute new label assignment s nia (14).
  if sum ($S_{old}$≠ $s)/n < \delta$ then
    Stop training.
  Choose a batch of sample $S \in X$.
  Update $\mu$, $W'$ and $W$ via (11), (12) and (13) on $S$.
```

IV. Study Method Steps

Early diagnosis, therapy, and follow-up are made possible by having an effective brain tumour detected by multimodal imaging as soon as possible [36]. In some social networks, deep learning algorithms have quickly taken the lead in medical picture analysis. We investigate deep learning applications in object detection, segmentation, recording, and image classification. The proposed deep learning models work well for brain tumour segmentation and provide very accurate results. The suggested models can also assist medical practitioners in shortening the time needed for diagnosis. The goal of this research is to create a fully automated model for MRI brain tumour segmentation that operates without the need for human intervention. Instead of having multiple boxes (or networks) from input to output, a single grid is used in this deep learning model's proposal. Deep-end learning typically uses a neural network in place of the numerous processing stages that standard machine learning techniques typically call for. In order to get the most out of each layer before going on to the next, we construct this final model. When treating malignant tumours, deep learning models are employed. These tumours can arise anywhere in the brain and have four unpredictable characteristics: varying sizes, forms, and contrast. Therefore, convolutional neural networks are the best option for machine learning.

A. Pre-processing

To get better results, adjustments to the photos are required. Understanding, processing, and picture analysis are some of these adjustments. These modifications enhance image processing systems to enable them to carry out tasks more quickly and accurately. Pre-processing, picture quality enhancement, image conversion, categorization, and image analysis are the primary procedures that raise the efficiency of these systems, in that order. These techniques involve analysing images for certain goals, with computer-generated mathematical equations simulating irregular human visual features. Computer vision is the scientific image analysis used in many areas of engineering, health, imaging, security, and astronautics. Modern digital technology is able to operate multidimensional switches and many parallel computers thanks to systems derived from simple digital circuits.

One of the things like image processing, picture analysis, and image perception is the goal of these modifications. Since the majority of remote sensors store their data digitally, digital processing is eventually needed for all picture interpretation and analysis. In order to allow further interpretation and analysis, digital image processing may comprise a variety of processes, such as alteration, digital optimisation, data formatting, or even computer goals automation and automatic properties. To carry out this procedure, the data must be in a format that is appropriate for physical storage.

Four categories comprise the most often utilised processing procedures in image analysis systems: pre-processing, image enhancement, image transformation, image analysis, and classification. These procedures fall under the general category of radiometric or geometric adjustments and are typically grouped prior to the primary picture analysis and information extraction. To get an accurate picture of the radiation that the receivers are receiving, radiometric corrections entail adjusting data for undesired noise and anomalies in the receivers. The purpose of geometric corrections is to simplify the image and translate it into actual coordinates on the surface of the earth.

The procedures used in the Image Enhancement category are only intended to raise and enhance the image's resolution in order to provide a better understanding of the image. These acts are hypothetically comparable to the preceding category in picture transmission. However, this group involves the combined processing of data acquired from various spectral bands, in contrast to this group, which pertains to only one data channel. The original bands are combined with mathematical operations (addition, subtraction, multiplication, and division) to create new images that are more readable or have better qualities. Pixel classification and analysis aim to identify and characterize data pixels. The process of classifying assigns each pixel in an image to a group or theme based on the statistical characteristics of its floating values. It is typically applied to multi-channel data groups. There are two main approaches to this: supervisor-free and supervisor-involved.

B. Image Transformation Color to Gray

Three colors green, blue, and red combine to form the most common colour model in computer graphics. These three elements can combine to give a total of 16581375 distinct colours. In computer graphics, this colour model is referred to as RGB. Apart from the RGB colour model, there exist various additional models that display colours differently, including CMYK, HSI, HSV, and Grayscale. We are particularly interested in the Grayscale colour model in the interim. Because a grayscale image will do in the majority of applications, and a colour image is not necessary. Generally speaking, the grey image is referred to as the black and white image (of course, calling something grey instead of black and white is incorrect; this is just being clarified). Three matrices, one for each of the colours red, green, and blue in the image, make up an RGB image. Three matrices are created by mixing the values from the appropriate verses to display the image on the screen. For the majority of applications, a grayscale image will do; a colour image is not necessary. When the values of the R, G, and B components of a pixel are the same, the pixel will have a grey value. In accordance with this concept, he utilised Eq. (3) to grayscale input images that are RGB.

$$S\_R(x,y)=S\_G(x,y)=S\_B(x,y)=\frac{\left[R(x,y)+G(x,y)+B(x,y)\right]}{3} \quad (3)$$

where, R, G, and B are the matrices representing the red, green, and blue components of the input image, and S_X are the components of the output image.

C. Median Filter

Among the non-linear filters is the median filter. Signals and noise in images are captured using this filter. Picture noise refers to background and other picture detections. For instance, you have to take a picture using one of the filterslike the median noise filter—before you can identify a corner. When processing images, the median filter is frequently used. It is also impossible to overlook the median filter's application in signal processing. The median filter is utilised in blood pressure monitors, EEG systems, and radiography systems, among other specialised applications. We can list median and fashion filters as examples of non-linear filter types. The median filter is a low-pass filter that uses a face neighbourhood to sort the neighbourhoods in ascending order before sorting the middle element of the numbers to replace the centre pixel. It should be mentioned that noise from salt and pepper can be eliminated using the mid-pass filter.

D. SOBLE Filter

There are three ways to convert a colour image to grayscale: edge features, edge detection, and image edging techniques. As using image edging techniques, the light intensity dramatically changes as points are marked in the image for edge identification. Changes in image properties are indicative of major changes in environmental factors. Image processing and feature extraction researchers are studying edge identification. The boundary in edge detection is found between regions of the grey surface with comparatively distinct characteristics. The fundamental idea behind the majority of edge detection techniques is the computation of a local derivative operator. It should be noticed at this point that the edge—the change from dark to light—is modelled as a gradual, rather than abrupt, grey surface change. This model demonstrates how sampling typically causes the borders of digital images to become slightly blurry.

E. Image Binary Threshold

A threshold value must be used to establish the threshold when converting a grayscale image to a binary image. Pixels that are less than the threshold are assigned a value of 0, while those that are less than the threshold are assigned a value of 1 or 255. Thresholding an image can be done in various ways. They can be broadly separated into the five sections listed below. 1) Histogram-based techniques have been examined, including the analysis of the peaks, valleys, and curvatures of the smoothed histogram. 2) Clustering-based techniques, in which a grayscale image is divided into foreground and background. 3) Entropy-based techniques: these techniques determine the threshold based on the intersection of the two classes in the image as well as the background and background entropy distributions. 4) Object property-based methods: these determine the appropriate threshold by calculating the degree of similarity between the image and a binary and grayscale scale. 5) Location-based techniques: the desired threshold is computed using a higher-order probability correlation or distribution between pixels.

F. Tumor Detection

Automatically detecting and extracting a portion of a tumor from a brain image is a challenging and complex mission for doctors and physicians.

V. Discussion

Systems for detecting brain tumours are employed in numerous sectors. One of the main objectives of this field's study is to use deep learning to develop a solution that complies with the guidelines and standards of brain tumour diagnosis systems, hence improving the precision of medical specialists. MATLAB software is used to perform the simulations. Its accuracy, precision, and sensitivity are higher than those of the approaches offered, based on the evaluation findings. The research methodology was covered in the previous section; the simulation findings are reported in this section. Fig. 9 shows the original image (a) and the image with a balanced histogram (b). Histogram balancing is the initial stage of image processing that enhances image quality.

The histogram in Fig. 10(a) shows the image prior to balancing and in Fig. 10(b) is the image following balancing. The horizontal axis of the histogram represents the colours, while the vertical axis represents the quantity of pixels in each colour. When using image histogram balancing, the image extends between 0 and 255 if the colour is between 0 and 100 when balanced.

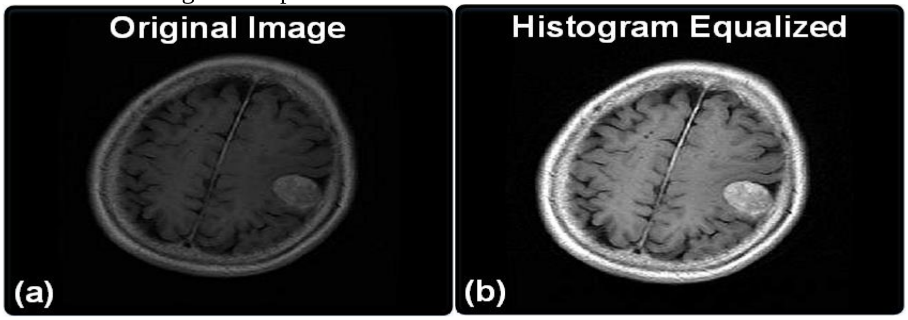

Fig. 9. (a) Original image, (b) Histogram balancing.

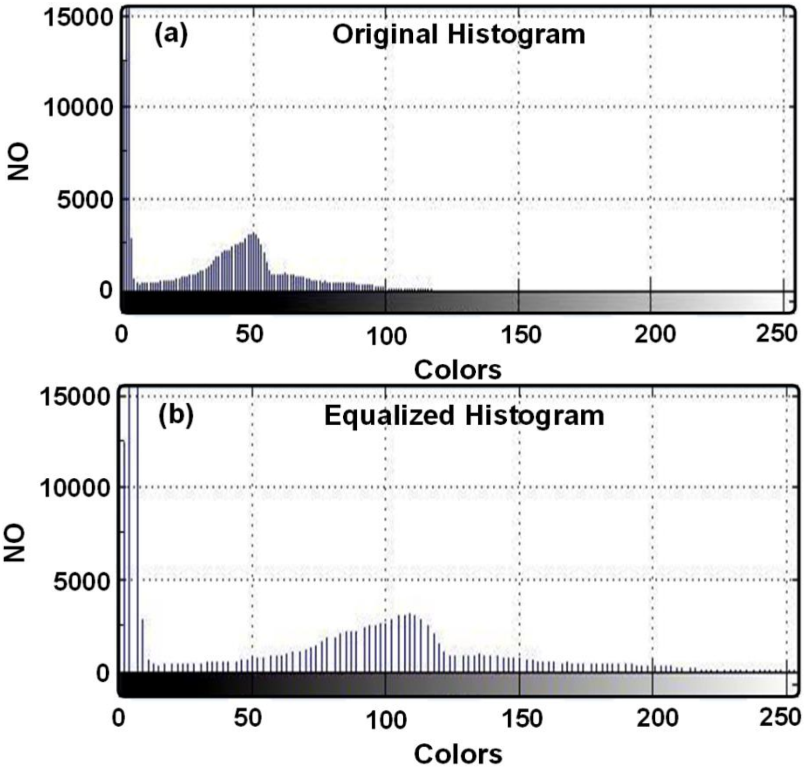

Fig. 10. Image histogram, (a) Original, (b) Equalized.

In Fig. 11, the median filter operation is performed on the main image. To improve those pixels that is not of good quality. It is actually to improve the quality of images.

Fig. 12 shows the Sobel image and the original image is binaries in Fig. 13. In order to isolate the objects in a digital image from their backdrop and analyse them, the image is first converted to a binary image. This produces a binary image that is less in volume than the original image.

In the part of the images that are interconnected, the box is drawn with red lines around it by writing the program, as shown in Fig. 14. In other words, it actually features extraction.

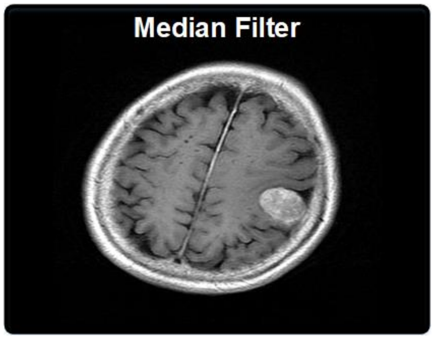

Fig. 11. Median filter.

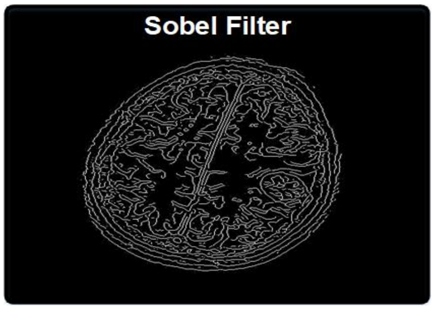

Fig. 12. Sobel image.

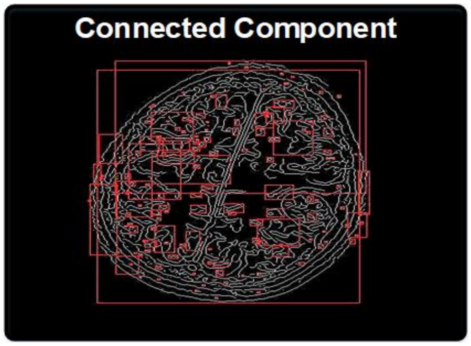

Fig. 14. Connected component.

A. *Tumour Detection*

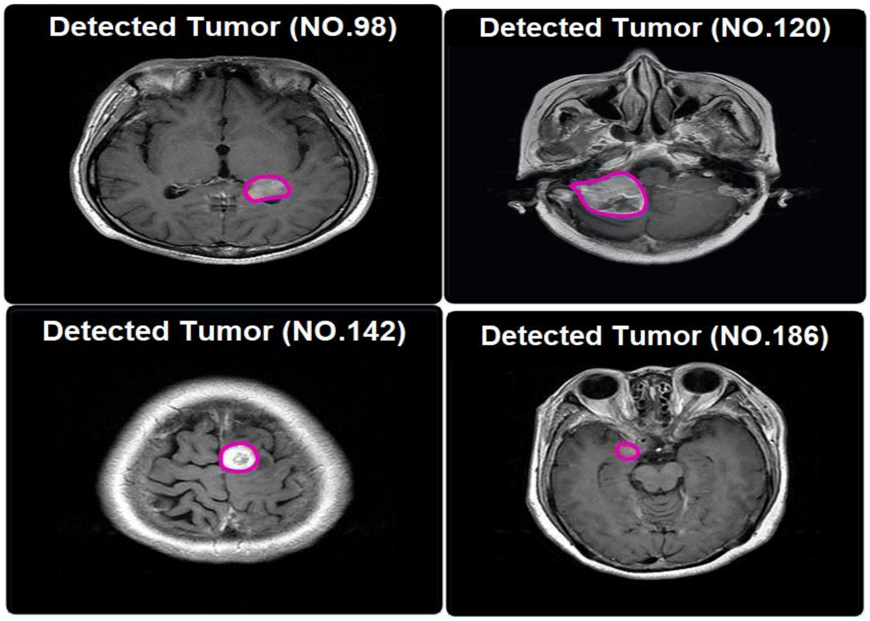
A comparison of the results with other approaches is made, taking into account various circumstances to demonstrate the effectiveness of the suggested method. Simulated approaches are identical in terms of conditions and evaluation parameters. Lastly, graphs are used to plot and analyse the simulation findings.

Each of the 766 data points is put in for loop in the MATLAB programme with the intention of being worked on. Following the use of the enhanced DEEP LEARNING algorithm to identify tumour sites in the output photos, these 14 sample images are displayed. Brain tumours are depicted in these pictures as pink in Fig. 15.

B. *Evaluation Results*

There are four sections to the evaluation results. 1) Positives that are accurately identified as true positives (TP). 2) False positives (FP), or negatives with a valid diagnosis. 3) Mistaken positives that are actually true negatives (TN). 4) Misdiagnosed negatives, or false negatives (FN). The assessed positive characteristics for simulating the first through sixth scenarios using various techniques are displayed in Table I.

Table II shows the evaluated negative parameters to simulate the seventh to twelfth scenarios for different methods.



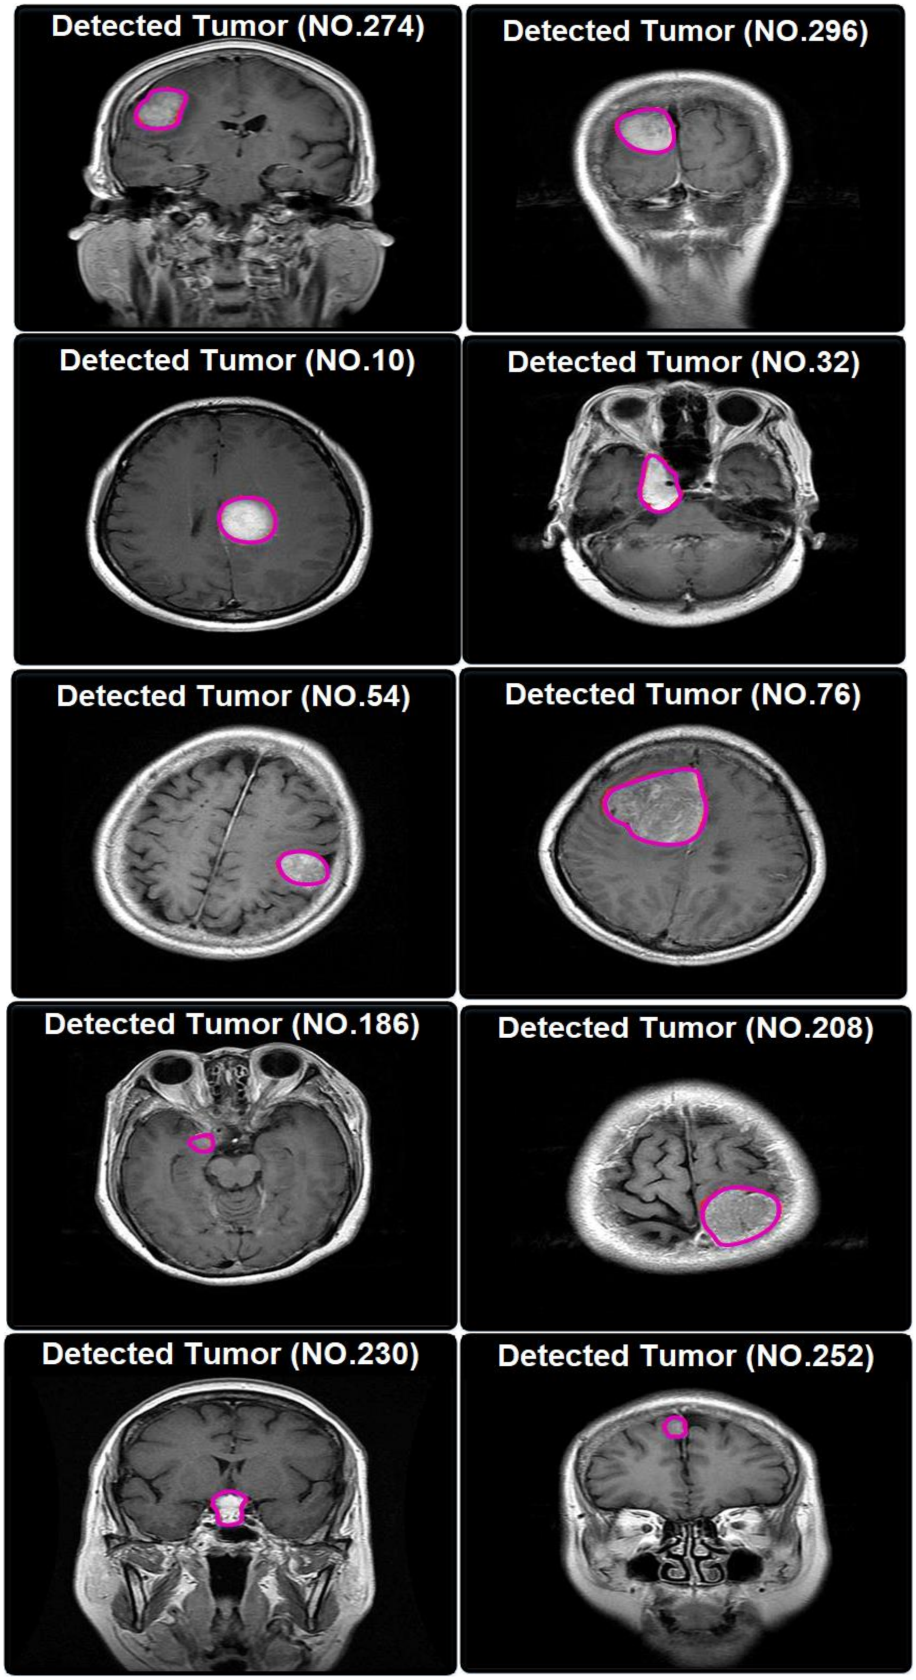


Fig. 15. Tumor detection results.

TABLE I. POSITIVE EVALUATION PARAMETERS

Scenario	**Method**	**Accuracy (%)**	**TP Ratio (%)**	**Precision TP (%)**	**Recall TP (%)**	**F-Measure (%)**	**Precision (%)**

Self-report No Stroke	(FN)	(TN)	NPV=$TN/FN+TN$
-	Sensitivity=$TP/TP+FN$	Specificity=$TN/FP+TN$	-

In Table III, the relationships related to the evaluation parameters are calculated.

1) Positive evaluation results: The accuracy diagram, which compares the suggested method with the neural network, SVM, correlation, and Euclidean methods in Fig. 16, shows the green colour of the suggested method, the red colour of Euclidean, the black colour of correlation, the blue colour of the support vector machine, and the purple colour of the neural network. The training data percentage in the data set is shown by the horizontal axis in this image, and the accuracy %, which ranges from 0 to 1, is represented by the vertical axis. The diagram indicates that for the majority of the data, the suggested approach is more accurate than the other methods in every evaluation point.

The proposed method has been compared with SVM, Neural Network, Correlation, Euclidean, Differential, and Block (8x8) Differential methods in Fig. 17. The second scenario is the TP ratio diagram, which is the green colour of the proposed method, the red colour of Euclidean, the black colour of correlation, the blue colour of the support vector machine, the purple colour of the neural network, the blue colour of block 8x8, and the black colour of differential. In this case, the vertical axis is a percentage, while the horizontal axis represents the trained data % in the dataset. The suggested technique outperforms the other methods in all evaluation points for the majority of the data, as shown by the diagram.

The proposed method is compared with SVM, Neural Network, Correlation, and Euclidean methods in Fig. 18. The third scenario is the precision diagram, where the green colour represents the suggested method, the red colour represents the Euclidean method, the black colour represents a correlation, the blue colour represents a support vector machine, and the purple colour represents a neural network. In this case, precision is the vertical axis and the trained data percentage in the dataset is the horizontal axis. The diagram indicates that for the majority of the data, the recommended approach has outperformed alternative methods in every evaluation point.

The F-measure diagram, which compares the suggested method with the SVM, Neural Network, and Correlation methods in Fig. 20, represents the fifth scenario and Fig. 19 shows the recall diagram. It is coloured red for the proposed method, red for the correlation, blue for the support vector machine, and black for the neural network. The trained data % in the dataset is the horizontal axis in this case, and the f-measure percentage rate is the vertical axis. The diagram indicates that for the majority of the data, the recommended approach has a higher f-measure than the other methods in every evaluation point.

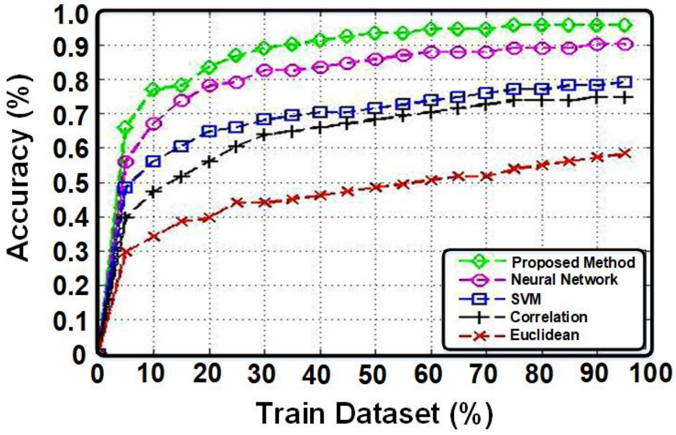

Fig. 16. Accuracy diagram.

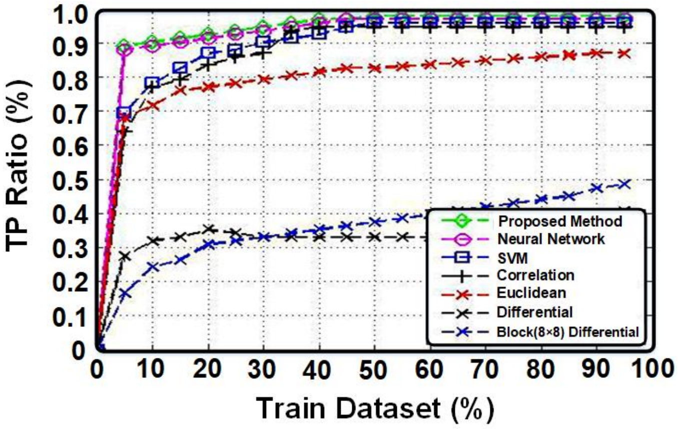

Fig. 17. TP Ratio.

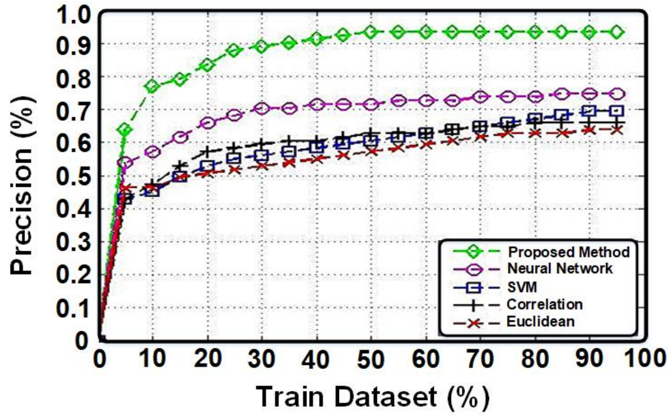

Fig. 18. Precision diagram.

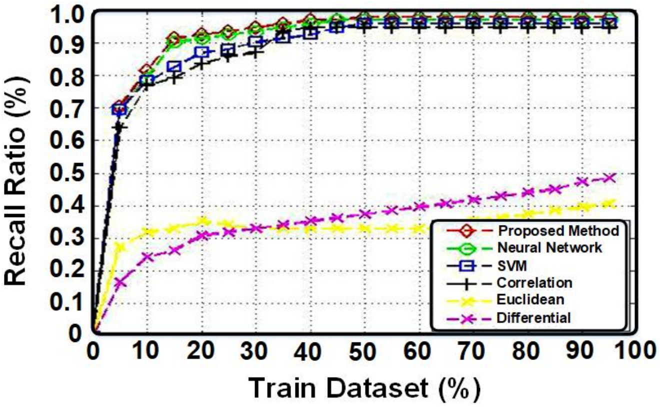

Fig. 19. Recall diagram.

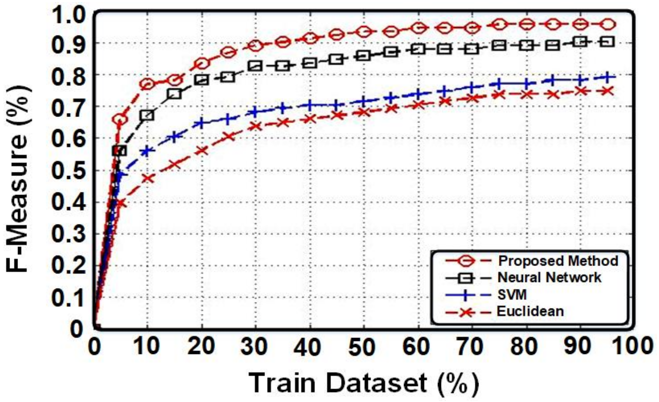

Fig. 20. F-measure diagram.

The sixth scenario, which contrasts the suggested technique with SVM and neural network methods in Fig. 21, shows the precision total diagram with the red colour of the suggested method, the black colour of the neural network, and the blue colour of the support vector machine.

In this case, the vertical axis represents the overall accuracy % while the horizontal axis represents the percentage of trained data in the dataset. The diagram indicates that for the majority of the data, the recommended approach has outperformed alternative methods in every evaluation point.

2) Negatives evaluation results: The seven sonorities are the total accuracy chart, which contrasts the red, green, blue, and black colours of the neural network, support vector machine, and SVM in the proposed method with the neural network and correlation methods in Fig. 22. The training data % in the dataset is shown by the horizontal axis in this example, while the total correctness percentage is represented by the vertical axis. The diagram indicates that for the majority of the data, the suggested approach is more accurate than alternative methods in all evaluation points.

Scenario eight involves the TN Ratio chart, which displays a comparison between the green colour representing the proposed method, the red colour representing correlation, the blue colour representing the neural network, and the black colour representing the support vector machine. This comparison is made with the SVM, Neural Network, and Correlation methods, as shown in Fig. 23. The horizontal axis represents the percentage of trained data in the data set, while the vertical axis represents the ratio of true negatives (TN). Based on the diagram, the suggested technique exhibits a higher TN Ratio compared to other methods at all evaluation points for the majority of the data.

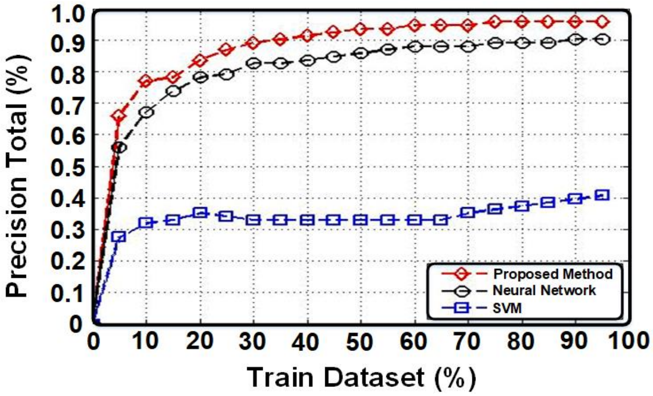

Fig. 21. Precision total diagram.

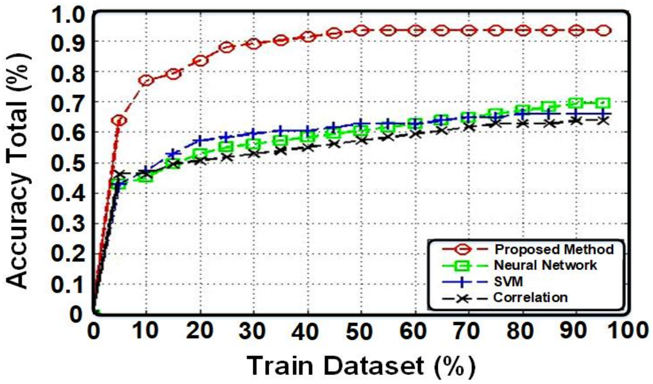

Fig. 22. Accuracy total diagram.

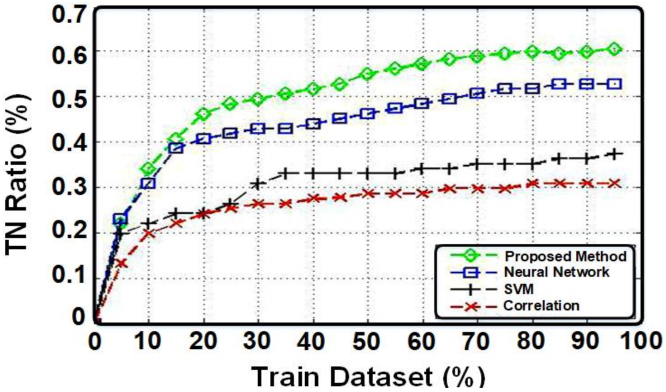

Fig. 23. TN Ratio diagram.

The precision TN diagram, which is coloured as follows: green for the suggested approach, red for Euclidean, black for the differential, blue for the support vector machine, and purple for the neural network, represents the ninth case. In Fig. 24, the suggested approach correlation is contrasted with the Differential, SVM, Euclidean, Neural Network, Correlation, and Block (8×8) Differential methods, as indicated by the black colour. In this case, the vertical axis represents the percentage of TN accuracy, and the horizontal axis represents the proportion of trained data in the dataset. The suggested method outperforms competing methods in all evaluation points for the majority of the data, as shown by the chart.

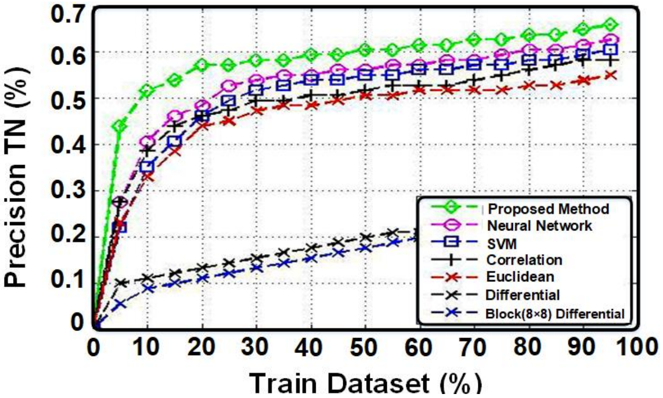

Fig. 24. Precision TN diagram.

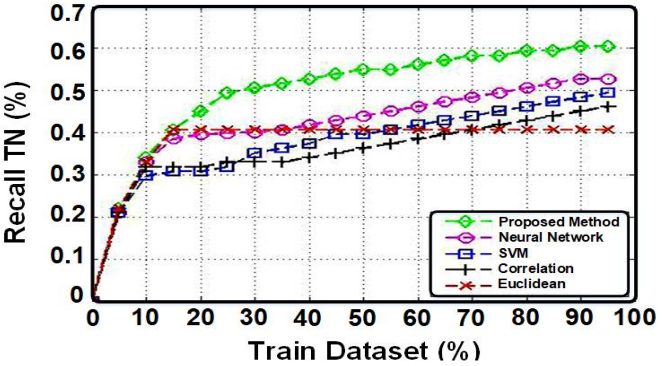

Fig. 25. Recall the TN diagram.

In Fig. 25, the Recall TN diagram presents a comparison between the proposed method and other methods, namely Euclidean, correlation, support vector machine (SVM), and neural network. The proposed method is represented by the green colour, Euclidean by red, correlation by black, SVM by blue, and neural network by purple. The horizontal axis represents the percentage of training data in the dataset, while the vertical axis represents the percentage of Recall TN. Based on the chart, the suggested technique exhibits higher Recall TN values compared to other methods across all evaluation points for the majority of the data.

The 11th scenario presents the TN accuracy diagram, where the proposed method is represented by black, Euclidean by red, correlation by black, support vector machine by red, neural network by blue, and differential by yellow. This diagram compares the proposed method with SVM, Neural Network, Correlation, and Euclidean methods. Fig. 26 presents a comparison of the differential. The horizontal axis represents the percentage of learned data in the dataset, while the vertical axis represents the accuracy rate of True Negative (TN). Based on the diagram, the suggested method demonstrates superior accuracy in true negatives (TN) compared to other methods across all evaluation points for the majority of the data.

Scenario twelve involves the comparison of the proposed technique, support vector machine (SVM), and neural network using the F-measure TN diagram. The proposed method is represented by the colour purple, SVM by black and neural network by red. This comparison is depicted in Fig. 27. The horizontal axis in this scenario represents the percentage of trained data in the dataset, while the vertical axis represents the F-Measure TN. Based on the diagram; the suggested method consistently outperforms other methods in terms of F-Measure TN across all evaluation points for the majority of the data.

The performance of the suggested technique has been evaluated by comparing it with SVM, Neural Network, Correlation, Euclidean, Differential, and Block (8×8) Differential methods. The techniques are executed within the MATLAB simulation environment. The criteria of accuracy, precision, and sensitivity have been chosen for comparison and suggested for evaluating the approaches. The evaluation findings have been graphically shown and demonstrate that the suggested method outperforms previous methods in terms of accuracy, precision, sensitivity, and recall in all scenarios.

Table IV presents a comparison of distinct datasets that utilise various approaches with fused segmented images. The image datasets undergo pre-processing using image fusion methodology and are subsequently segmented using U-Net. Conversely, the method of merging images is not employed; just the segmentation of images is performed. It is evident that the techniques employed with fused images yield output that is comparable to that of non-fused images. The image fusion approach involves combining images obtained from diverse sensors, which contain essential data, using various numerical models to get a unified composite image.

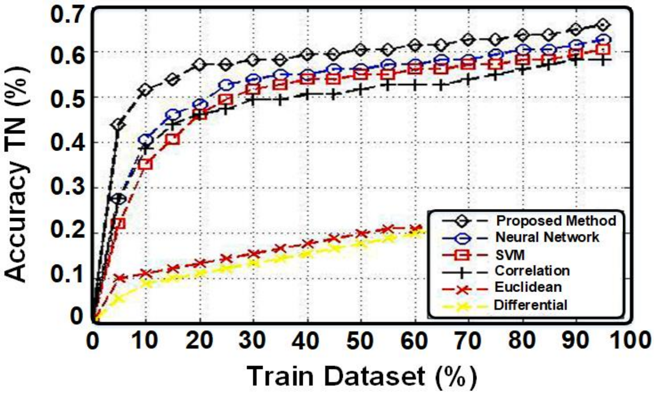

Fig. 26. Accuracy TN diagram.

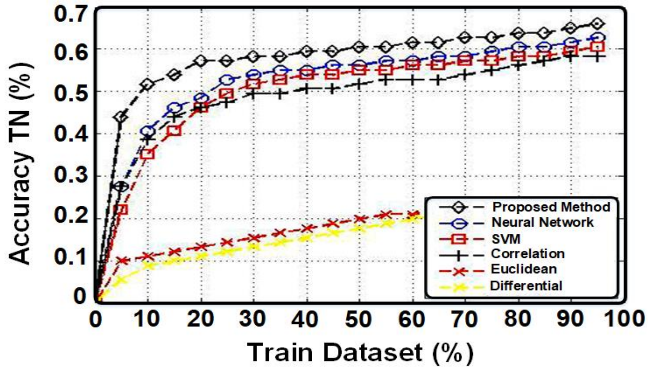

Fig. 27. F-measure TN diagram.

TABLE IV. COMPARATIVE ANALYSIS OF DIFFERENT PARAMETERS IN TERMS OF BRAIN TISSUE REGION IDENTIFICATION AND CLASSIFICATION USING MULTIMODAL IMAGING METHODS

Image Fusion	Image Segmentation Method	Classification Method	Dataset	Data Volume	Data Class	Accuracy (%)
Non-Fused Image	U-Net	U-Net	Brain tumour fig share	3074	3	96.21

VI. CONCLUSION

This article presents a neural network-based method for automatically detecting brain tumours. Various methodologies are being examined. The evaluation method presents the results based on accuracy, precision, and sensitivity. The initial step involves presenting the pre-processing outcomes, encompassing histogram equalisation, median filtering, edge detection, binarization, and identification of related pixels. Subsequently, the detection outcomes for 766 data points are presented, with 14 of them being displayed. Subsequently, the evaluation relationships are articulated with respect to accuracy, correctness, and evaluation standards. Ultimately, the evaluation outcomes for the positives and the evaluation outcomes for the negatives are disclosed. The simulation is conducted with 766 data points, and the assessment criteria are also assessed. The proposed strategy for improvement is the utilisation of deep learning, which has enhanced the effectiveness of the previous method. The accuracy of these is verified, and subsequently, the detection approach is established and compared to alternative methodologies. In future research, it is possible to employ optimisation methods like as genetic algorithms and colonial competition, among others, in the field of deep learning as alternatives to the modified neural network.

Brightness Equalization Algorithm for Chinese Painting Pigments in Low-Light Environment Based on Region Division

Lijuan Cheng
College of Art and Art Design, Henan Vocational University of Science and Technology, Zhoukou, 466000, China

***Abstract*—With the promotion and development of Chinese painting and the advancement of photography technology, people can appreciate various types of Chinese paintings through image and other methods. However, Chinese painting images in low-light environments face the problem of extreme uneven brightness distribution. The currently proposed solutions for this problem are not sufficient. Therefore, this research proposes a brightness equalization algorithm for Chinese painting pigments in low-light environments based on region division. This algorithm also utilizes guided filtering for image denoising. In performance testing, the proposed method has a runtime of 16.63 seconds under a scaling factor of 1 and a runtime of 8.37 seconds under a scaling factor of 0.1, which are the fastest among the compared algorithms. In simulation experiments, the brightness equalization value of the proposed method is 198.93, which is listed at the best among all the compared algorithms. This research provides a valuable research direction for the brightness equalization of Chinese painting pigments.**

Keywords*—Chinese painting; low-light; region division; guided filtering; scaling factor

I. Introduction

In the process of promoting Chinese painting, pigments are one of the most visually impactful elements for viewers, as they directly determine the visual effects of the artwork [1]. However, due to the limitations of low-light environments, Chinese paintings in low-light scenes may face the problem of uneven pigment brightness, which affects the visibility and artistic quality of the artwork to some extent. A low-light environment refers to an environment with dim lighting or insufficient light sources [2]. In such environments, due to the scarcity and weakening of light, details in the image are difficult to display clearly, and the differences in pigment brightness become more pronounced. This significantly affects the appreciation of Chinese paintings by viewers. At present, the processing methods for low light images include image enhancement, noise removal, and multi frame image fusion, which can be divided into two approaches: hardware and software. However, the focus is mainly on software upgrades and improvements [3]. Due to the uneven lighting in the shooting environment, the brightness of captured images may be uneven, with some areas appearing too bright while others are too dark. Existing brightness equalization algorithms not only enhance the noise in the image but also have issues with inconsistent equalization across different regions [4].

Therefore, this research proposes a brightness equalization algorithm for Chinese painting pigments in low-light environments based on region division. This study will provide reference and guidance for the application of region-based brightness equalization algorithms in the field of Chinese painting pigment brightness equalization and other related fields. The research is divided into five sections: an overview of the research in Section I, a review of domestic and foreign studies in Section II, a study on the algorithm's methodology in Section III, performance testing of the algorithm in Section IV, and a summary and outlook on the limitations of this research in Section V.

II. Literature Review

Researchers have focused on using image region division techniques to improve image enhancement methods. Matsuyama E proposed a segmentation method for chest X-ray images. This method can automatically remove the scapular region, mediastinal region, and diaphragm region from various chest X-ray images as the learning data for this method. The method uses a simple linear iterative clustering algorithm and local entropy filtering to generate an entropy map, which is then subjected to morphological operations to perform region segmentation on the lung image. The method was tested, and the results showed that it can remove non-pulmonary markings from the image and present clear X-ray images of the lungs [5]. Chen et al. found that the evaluation metrics of existing iris segmentation algorithms may be influenced by inaccurate localization of the Ground Truth image. Therefore, researchers proposed using a mask image segmented based on deep learning algorithms as a substitute for the Ground Truth image. Experimental results showed that the mask image segmented based on deep learning algorithms can completely replace the original Ground Truth image [6]. Cao et al. found that existing line art coloring methods can produce credible coloring results, but these methods are often affected by color bleeding issues. Therefore, researchers proposed an explicit segmentation fusion mechanism. Testing outcomes shows that the model can better fulfill the coloring instructions given by the user and can greatly alleviate the problem of color bleeding artifacts [7].

Image enhancement methods are applicable in various fields, and researchers have made many improvements to these methods. Tirumani et al. found that existing image enhancement methods have unstable effects on contrast and resolution enhancement. Therefore, researchers process the resolution of the image, and then used auto optimization to enhance the resolution and brightness. Testing outcomes showed that this method can effectively and stably enhance the resolution and contrast of the image [8]. Xu et al. proposed a multi-scale fusion framework for low-light image enhancement. This framework first generates multiple artificially multi-exposure images using a mapping function, then combines exposure to create a weight map, and finally fuses different frequency bands of the image. Testing outcomes showed that this method outperforms existing algorithms in enhancing low-light images [9]. Lu et al. believed that the current image enhancement methods based on convolutional neural network models do not differentiate image features on different channels, which hinders the learning of hierarchical features. Therefore, researchers proposed a channel-split attention network that can analyze shallow features in a targeted manner by splitting them into residual and dense branches. Experimental results showed that this method exhibited excellent performance in both qualitative and quantitative evaluations [10].

In summary, although region division methods have been applied in multiple fields, their combination with image enhancement for brightness equalization of Chinese painting pigments is relatively rare. Therefore, this research proposes a brightness equalization algorithm for Chinese painting pigments in low-light environments based on region division, providing effective technical support for the promotion of Chinese painting.

III. Region-Based Brightness Equalization Algorithm for Chinese Painting Pigments in Low-Light Environments

Chinese painting images in low-light environments often suffer from uneven lighting in the pigment display [11]. Traditional image brightness equalization algorithms have limitations in achieving sufficient brightness equalization and enhancing all local details [12]. To address this issue, this research proposes a region-based brightness equalization algorithm for Chinese painting pigments in low-light environments. This algorithm improves existing image enhancement algorithms and provides effective assistance in the refinement of image enhancement algorithms.

A. Single-Frame Image Brightness Equalization Enhancement Method in Low-Light Environments

Images in image processing come in various formats, including RGB, LAB, YUV, HSV, HIS, etc. The main image format studied in this research is HSV. In this research, the RGB image is first converted to the HSV image. In HSV, H represents the hue of the image, S represents the saturation, and V represents the value or brightness of the image. The advantage of the HSV format is that the color information of the image does not affect the brightness component, which ensures that the original colors of the image are preserved during brightness enhancement. The schematic diagram of an HSV image is shown in Fig. 1.

In Fig. 1, a cone shape is hired to manifest the HSV color space, where the hue is determined by the rotation angle around the center of the cone, with each 120° representing a different color. The closer to the center of the cross-section, the less saturated the color is, and the closer to the apex of the cone, the weaker the brightness. The conversion of RGB to HSV is represented by Eq. (1).

$$V = \max\{R,G,B\} \tag{1}$$

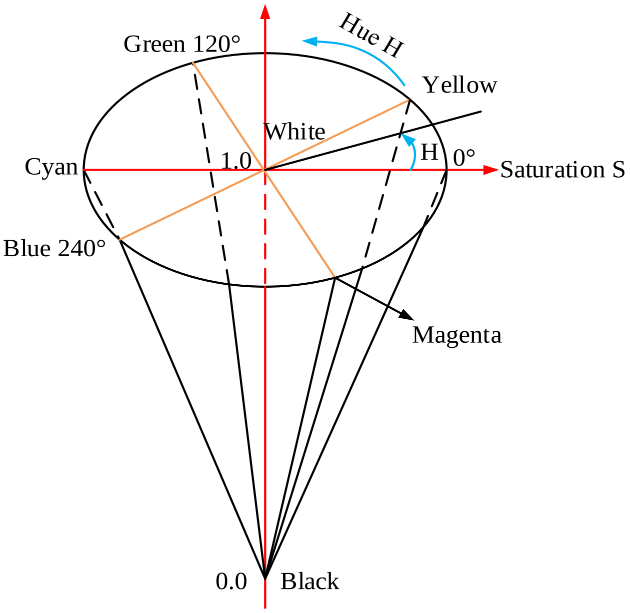

Fig. 1. The schematic diagram of an HSV image.

In Eq. (1), R,G,B represent the three primary colors in the RGB color space, where R means red, B represents blue, and G represents green. The converted S value is represented by Eq. (2).

$$S = \begin{cases} \dfrac{V-\min\{R,G,B\}}{V}, V \neq 0 \\ 0, otherwise \end{cases} \tag{2}$$

In Eq. (2), V represents the value obtained from Eq. (1). The converted H value is represented by Eq. (3).

$$H = \begin{cases} 0°, V = \min(R,G,B) \\ 60° \times \dfrac{G-B}{(V-\min(R,G,B))} + 0°, V = R, G \geq B \\ 60° \times \dfrac{G-B}{(V-\min(R,G,B))} + 360°, V = R, G < B \\ 60° \times \dfrac{G-B}{(V-\min(R,G,B))} + 120°, V = G \\ 60° \times \dfrac{G-B}{(V-\min(R,G,B))} + 240°, V = B \end{cases} \tag{3}$$

In Eq. (3), R represents the R value in the RGB. The brightness of an HSV image is divided into different levels [13]. The average brightness range of the V channel is $[0,1]$. An empirical threshold I_{th} is set, and when the average brightness of an image is below this threshold, the image is considered a high-brightness image. Therefore, the brightness range of high-brightness images is $[I_{th},1]$. For the enhancement of high-brightness images, the focus is mainly on enhancing the contrast [14]. Since the enhancement results of high-brightness images are similar to those of low-brightness images, this research converts high-brightness images to low-brightness images for enhancement and then converts them back to high-brightness images after enhancement [15]. The formula for obtaining the limited brightness image is represented by Eq. (4).

$$I_{\lim} = \begin{cases} I_v, \overline{I_v} \le I_{th} \\ 1 - I_v, \overline{I_v} > I_{th} \end{cases} \tag{4}$$

In Eq. (4), $I_{\lim}$ represents the limited brightness channel image, I_v represents the V channel image extracted after converting from RGB to HSV, and $\overline{I_v}$ represents the average brightness of the V channel image. The brightness region division of the image in this research is divided into four steps. The first step is the initial enhancement of the limited V channel image, and the enhancement formula is represented by Eq. (5).

$$F = \log_2(1 + I_{\lim}) \tag{5}$$

In Eq. (5), $I_{\lim}$ represents the limited V channel image, and F represents the image after initial enhancement. The region segmentation of the image in this research is divided into four steps. The second step is the binarization of the multi-scale image [16]. Two different binarization methods are used for the edges and region shapes of the image. The first binarization method first applies mean filtering to the image F after initial enhancement to obtain the neighborhood mean value of each pixel. Then, the brightness value is divided by the neighborhood mean value, and the result is compared with the adaptive sensitivity factor T. Finally, the binarized V channel brightness image is obtained. The calculation process is represented by Eq. (6).

$$F_{binary\_1}(x,y) = \begin{cases} 1, \dfrac{F(x,y)}{F_{s1\times s1}(x,y)} > T \\ 0, otherwise \end{cases} \tag{6}$$

In Eq. (6), $F(x,y)$ represents the brightness value of each pixel, and $F_{s1\times s1}(x,y)$ represents the neighborhood mean value. The second binarization method subtracts the mean filtering image from F, and then subtracts a constant C to obtain the difference image I_{sm}. Then, based on the pixel values of I, binarization is performed to obtain a binary image containing texture boundaries. The calculation process is represented by Eq. (7).

$$F_{binary\_2}(x,y) = \begin{cases} 1, I_{sm}(x,y) > 0 \\ 0, otherwise \end{cases} \tag{7}$$

In Eq. (7), $I_{sm}(x,y)$ represents the pixel values of the image I_{sm}. The second step of region image processing is fusion, which involves merging the two binarized images obtained earlier to create a new binary image. The fusion formula is shown in Eq. (8).

$$F_{binary} = F_{binary\_1} \oplus F_{binary\_2} \tag{8}$$

In Eq. (8), $\oplus$ represents the logical AND operator. The third step is noise reduction using morphology. The fourth step is region segmentation. The specific operation involves first marking the boundaries of the denoised regions, and then dividing the image into multiple regions and assigning them numbers based on the marked content. The schematic diagram of image segmentation is shown in Fig. 2.

In Fig. 2, the images from left to right are the original image, the two binarized images, the fused image obtained from the fusion calculation of the two binarized images, the denoised binary image, and the segmented image. Due to the significant brightness differences between different regions in images with uneven lighting, targeted brightness adjustment is needed [17]. The image is marked based on the different brightness levels in different regions, and the marking rule is shown in Eq. (9).

$$\begin{cases} if\ \dfrac{(V_{i\min} + V_i)}{2} > 0.5, bright \\ else, dark \end{cases} \tag{9}$$

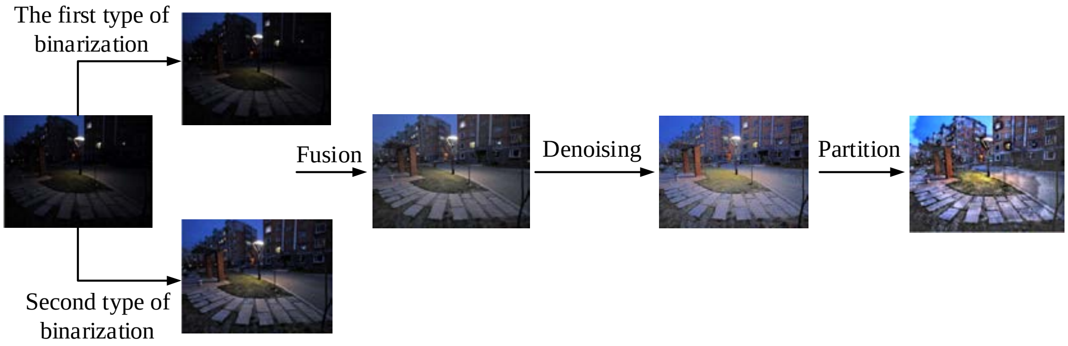

Fig. 2. Schematic diagram of image partitioning.

In Eq. (9), i represents the index of the region, $V_{i\min}$ represents the minimum brightness value in that region, and $\overline{V_i}$ represents the average brightness of that region.

B. *Image Brightness Equalization Enhancement Method Based on Region Denoising*

Denoising is an important step in image enhancement. Currently, there are various denoising methods, including bilateral filtering-based denoising, Gaussian filtering-based denoising, and linear guided filtering-based denoising [18]. The denoising method based on bilateral filtering is computationally complex and slow. The denoising method based on Gaussian filtering tends to blur the edges of the denoised image and result in unclear presentation of image details. The denoising method based on linear guided filtering produces clear edges in the denoised image without artifacts and has a faster computation speed. Therefore, in this research, the guided filtering method is used for image denoising. The workflow of the guided filtering denoising method is shown in Fig. 3.

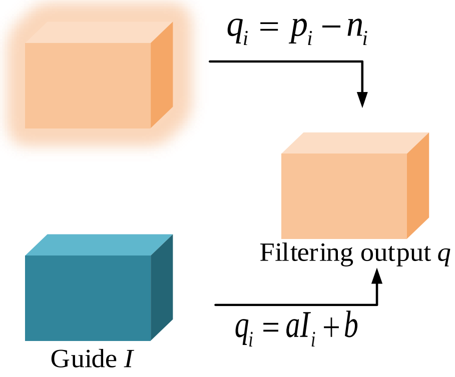

Fig. 3. Guiding the workflow of filtering and noise reduction methods.

In Fig. 3, the workflow of guided filtering includes a guidance image I, an input image p, and an output image q. The guidance image can be pre-set based on different application scenarios, but it can also be replaced by the input image. The guided filtering principle is based on the premise assumption that a linear relationship exists between the guidance image and the output image. Assuming that in a window ω_m centered at pixel m, q is a linear transformation of I, the transformation formula is shown in Eq. (10).

$$q_i = a_m I_i + b_m, \forall i \in \omega_m \tag{10}$$

In Eq. (10), a_m and b_m represent the assumed linear invariant coefficients within the window ω_m, and ω_m is a square window with a radius of r centered at pixel m. To determine the values of a_m and b_m, constraints need to be applied to the input image p, and the constraints are shown in Eq. (11).

$$q_i = p_i - n_i \tag{11}$$

In Eq. (11), n represents the excess information in q, where most of the irrelevant information is noise. The linear regression model established in window ω_m is shown in Eq. (12).

$$E(a_m,b_m)=\sum_{i\in\omega_m}((a_mI_i+b_m-p_i)^2+\varepsilon a_m{}^2 \tag{12}$$

In Eq. (12), ε is a regularization parameter to constrain a_m, and its solution is shown in Eq. (13).

$$\begin{cases} a_m = \dfrac{\dfrac{1}{|\omega|}\displaystyle\sum_{i\in\omega_m} I_i p_i - \mu_m \overline{p}_m}{\sigma_m{}^2+\varepsilon} \\ b_m = \overline{p}_m - a_m\mu_m \end{cases} \tag{13}$$

In Eq. (13), $\sigma_k{}^2$ and μ_k represent the variance and mean of I within window ω_m, $|\omega|$ represents the number of pixels in ω_m, and $\overline{p}_m = \dfrac{1}{|\omega|}\displaystyle\sum_{i\in\omega_m} p_i$ represents the mean of p within window ω_m. Since pixel i is included in different ω_m, there will be multiple values of q_i in different windows. Therefore, Eq. (14) is used to determine the value of q_i.

$$q_i = \frac{1}{|\omega|}\sum_{m|i\in\omega_m}(a_mI_i+b_m) = \overline{a}_m I_i + b_m \tag{14}$$

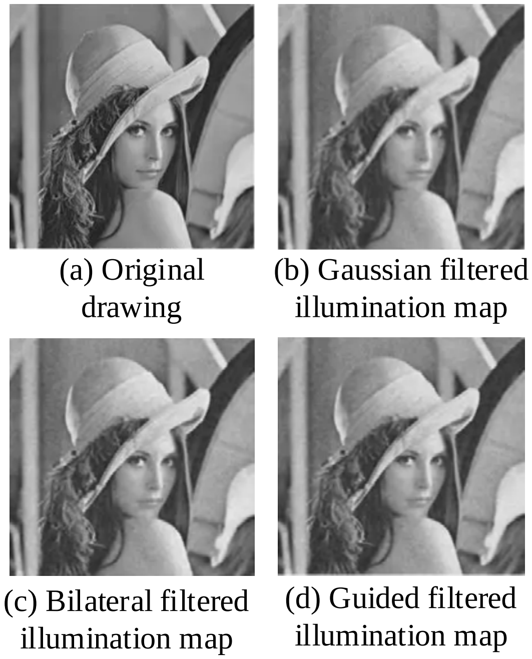
Due to the rotational symmetry property of the summation window, $\sum_{m|i\in\omega_m} a_m = \sum_{i|m\in\omega_i} a_m$ can be obtained. Therefore, Eq. (14) can also be written as Eq. (15).

$$q_i = \overline{a}_i I_i + \overline{b}_i \tag{15}$$

In Eq. (15), $\overline{a}_i = \dfrac{1}{|\omega|}\sum_{m\in\omega_i} a_m$ and $\overline{b}_i = \dfrac{1}{|\omega|}\sum_{m\in\omega_i} b_m$ represent the mean of the calculated results of the linear coefficients for pixel i. The denoising effects of different denoising methods on the same image are shown in Fig. 4.

In Fig. 4, Fig. 4(b) is the image after denoising with Gaussian filtering, Fig. 4(c) is the image after denoising with bilateral filtering, and Fig. 4(d) is the image after denoising with guided filtering. Fig. 4(a) is the original one. The image after denoising with Gaussian filtering appears darker in color and has unclear edges. The image after denoising with bilateral filtering has clear brightness edges. The image after denoising with guided filtering has clear brightness edges and the details in each region are smoothed, which better matches the actual lighting distribution [19]. In order to achieve better enhancement of the image, this research uses a two-dimensional gamma function to perform brightness correction on images with uneven lighting [20]. The formula for the two-dimensional gamma function is shown in Eq. (16).

$$I_g(x,y) = 255\times\left(\frac{F(x,y)}{255}\right)^{\gamma}, \gamma = M(x,y)^{\frac{M(x,y)-I_q(x,y)}{M(x,y)}} \quad (16)$$



(a) Original drawing
(b) Gaussian filtered illumination map
(c) Bilateral filtered illumination map
(d) Guided filtered illumination map

Fig. 4. Noise reduction effect diagram.

In Eq. (16), F represents the preliminarily enhanced image after transformation, I_g represents the output enhanced image, M represents the target mean, and $I_g(x,y)$ represents the image after denoising with guided filtering. When $M(x,y) > I_q(x,y)$ I, $\gamma < 1$, indicating an increase in brightness for $F(x,y)$; otherwise, the brightness is reduced. The image obtained is further filtered using guided filtering with a radius of six and a regularization parameter of $1e-4$ for denoising. Then, contrast-limited histogram equalization is applied to obtain the image I_c, which is then weighted fused using the weighted fusion formula shown in Eq. (17).

$$I_{out} = a\cdot I_c + b\cdot I_g, \begin{cases} a = \begin{cases} 0.5 + 0.1\times\dfrac{\mu(I_v)-0.4}{0.6}, \mu(I_v)\geq 0.4 \\ 0.5, else \end{cases} \\ b = 1-a \end{cases} \quad (17)$$

In Eq. (17), a represents the weighting coefficient for the output of contrast-limited histogram equalization, b represents the weighting coefficient for I_g, and $\mu(I_v)$ represents the mean brightness of the V channel image of the original image. Finally, the I_{out} channel image, the H (hue) channel image I_H from the initial input image, and the S (saturation) channel image I_S are combined to form an HSV image, which is then converted to the RGB format and output as the final RGB image. In summary, the workflow of the brightness equalization algorithm based on region division in low-light conditions is shown in Fig. 5.

Fig. 5. Flow chart of brightness equalization algorithm for Chinese painting pigments in low illumination environments based on region division.

In Fig. 5, the first step is to input the original image in RGB format. The second step is to convert the original RGB image to the HSV format and extract the V channel image I_V. The third step is to calculate the grayscale mean of image I_V and determine if the mean is greater than a set empirical threshold I_{th}. If the mean is less than I_{th}, the mean remains unchanged. If the mean is greater than I_{th}, the mean is inverted, resulting in a mean-limited grayscale image $I_{\lim}$. The fourth step consists of three operations. The first operation is logarithmic transformation followed by binarization to obtain a binary image containing texture edges. Then, the binary image is segmented into regions. The second operation is 8-neighborhood mean filtering to obtain neighborhood information for each pixel. The third operation is denoising of the grayscale image $I_{\lim}$ using guided filtering, resulting in an illumination map I_q. The fifth step of the algorithm is to construct the target mean M_i for each region based on the brightness mean, minimum value, and image mean of the original input image within the regions segmented in the first operation of the fourth step. The sixth step is to perform gamma correction on the preliminarily enhanced image to achieve brightness correction, resulting in the image I_g. The seventh step is to determine whether the inversion operation was performed in the third step. If inversion was performed, the image I_g is restored; if not, it remains unchanged. The eighth step is to denoise the image I_g using guided filtering to obtain the denoised image. The ninth step is to perform contrast-limited histogram equalization on I_g and then perform weighted fusion to obtain the corrected image I_{out}. The final step is to combine the H and S channels back into the HSV color space, convert it to RGB format, and output the brightness equalized image.

IV. Performance Analysis and Simulation Experiment of Region-based Image Brightness Equalization Algorithm

A. *Performance Analysis of Region-based Image Brightness Equalization Algorithm*

The processor used for this performance test is an Intel(R) Core (TM) i9-13900HX CPU with a clock speed of 5.4GHz, 16GB RAM, and a 64-bit operating system. The simulation software used is MATLAB R2022a. The images used in this experiment were obtained by continuously capturing 300 frames of the same Chinese painting in a low-light indoor environment. Five frames were randomly selected from the 300 frames of Chinese painting images and named Frame 1 to 5. The information entropy and Structural Similarity (SSIM) of the images enhanced by different algorithms were compared. The comparison of information entropy is Table I.

From Table I, the original images information entropy is generally in the range of 4-6. After MSRCR processing, it is in the range of 5-7. After Dong processing, the information entropy is in the range of 6-8. After Zohair processing, the information entropy is in the range of 7-9. After processing with the proposed method, the information entropy of the images is in the range of 9-10. A higher information entropy value indicates more detailed information in the image. The images processed by the proposed algorithm in this study show significantly more detailed information compared to other algorithms. The comparison results of SSIM are shown in Table II.

TABLE I. INFORMATION ENTROPY

Algorithm	Frame 1	Frame 2	Frame 3	Frame 4	Frame 5
Original drawing	4.63	5.55	5.16	4.86	5.03
MSRCR	6.36	5.98	5.66	5.13	6.05
Dong	7.32	6.98	7.55	6.77	7.09
Zohair	7.53	8.25	7.86	8.03	7.33
This study	9.56	9.43	9.36	9.78	9.89

TABLE II. STRUCTURAL SIMILARITY COMPARISON RESULTS

Algorithm	Frame 1	Frame 2	Frame 3	Frame 4	Frame 5
MSRCR	0.06	0.13	0.22	0.09	0.23
Dong	0.23	0.15	0.09	0.21	0.26
Zohair	0.22	0.26	0.19	0.23	0.25
This study	0.30	0.34	0.29	0.36	0.35

From Table II, the SSIM of the images reinforced by MSRCR is in the range of 0.06-0.23. The SSIM of the images enhanced by Dong is in the range of 0.09-0.26. The SSIM of the images enhanced by Zohair is in the range of 0.19-0.26. The SSIM of the images enhanced by the proposed method in this study is in the range of 0.30-0.36. The SSIM of the images enhanced by the method is significantly higher than other algorithms, indicating that the details of the images preserved by the method are more complete and the enhancement effect is better compared to other algorithms. A comparison was made between the adaptive gamma brightness correction method used in the algorithm and the fixed parameter gamma correction method. The experimental results are shown in Fig. 6.

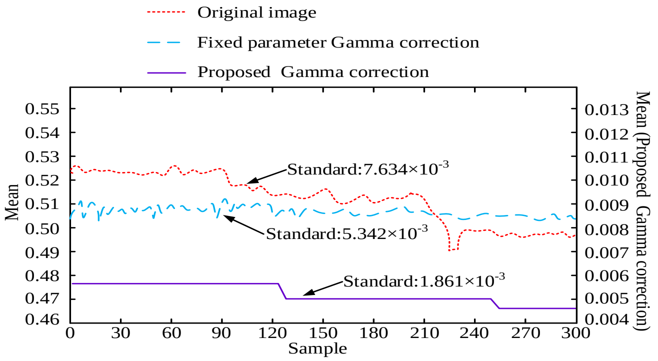

Fig. 6. Comparison of different gamma brightness correction methods.

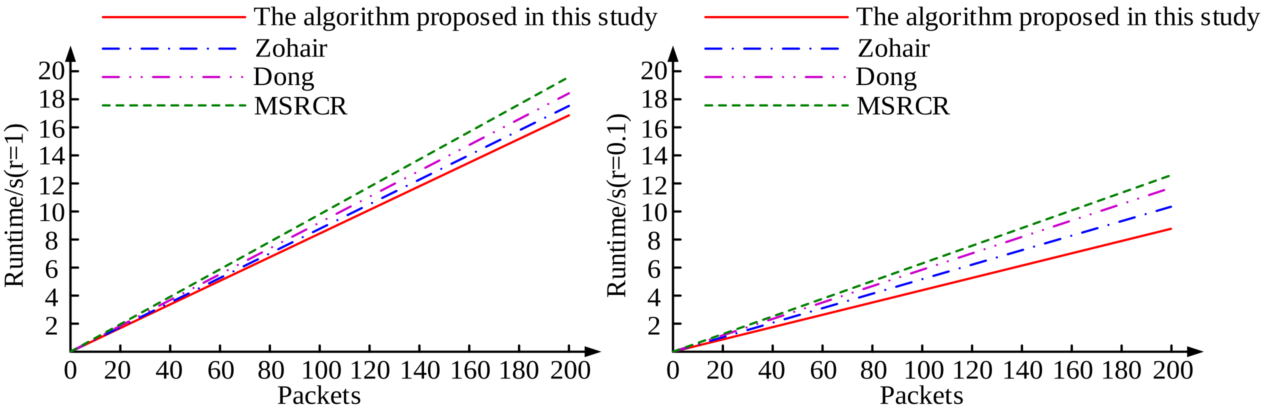
In Fig. 6, from the experimental results, it can be observed that when the input images are in the range of 1-300 frames, the brightness fluctuation of the images corrected by the improved adaptive gamma correction method in this study significantly decreases compared to the original images. On the other hand, the images corrected by the fixed parameter gamma correction method exhibit larger brightness fluctuations compared to the original images. The adaptive gamma correction method used in this study outputs a standard deviation of brightness of 1.861×10^{-3}, while the original images have a brightness standard deviation of 7.634×10^{-3}, and the images corrected by the fixed parameter gamma correction method have a brightness standard deviation of 5.342×10^{-3}. The standard deviation of brightness corrected by the adaptive gamma correction method is significantly lower than that of the original images and the fixed parameter gamma correction method. This study also compared the runtime of different algorithms at different scaling factors. The specific results are shown in Fig. 7.



(a) Scale factor r=1

(b) Scale factor r=0.1

Fig. 7. Running time of different algorithms under different scaling coefficients.

Fig. 7(a) represents the runtime of different algorithms with varying group numbers under a scaling factor of 1. It can be observed that under a scaling factor of 1, the runtime of all algorithms increases with the increase in group numbers. When the group number reaches 200, the proposed algorithm in this study has the shortest runtime among all algorithms, which is 16.63 seconds. Fig. 7(b) represents the runtime of different algorithms with varying group numbers under a scaling factor of 0.1. It can be seen that under a scaling factor of 0.1, the runtime of all algorithms is significantly shorter compared to the case of a scaling factor of 1. Among them, the proposed algorithm in this study has the shortest runtime among all group numbers, which is 8.37 seconds when the group number reaches 200.

B. *Simulation Experiment of Brightness Equalization Algorithm for Chinese Painting Images Based on Regional Division*

The comparison of the average brightness of Chinese painting pigments enhanced by different enhancement algorithms in low-light environments is shown in Fig. 8.

In Fig. 8, the image enhanced by the MSRCR image enhancement algorithm has the lowest average brightness among the five algorithms, indicating that its brightness equalization processing is the worst among the five algorithms. The image enhanced by the Dong image enhancement algorithm has a lower average brightness and a slower growth rate. The image enhanced by the Zohair image enhancement algorithm has a higher average brightness and a faster growth rate. The image enhanced by the algorithm proposed maintains a high level of average brightness and has a fast growth rate. This study introduced the Peak Signal-to-Noise Ratio (PSNR) for evaluating the fidelity of the images. PSNR tests were conducted on different algorithms using the Brightening dataset and the LOL dataset, and the results are shown in Fig. 9.

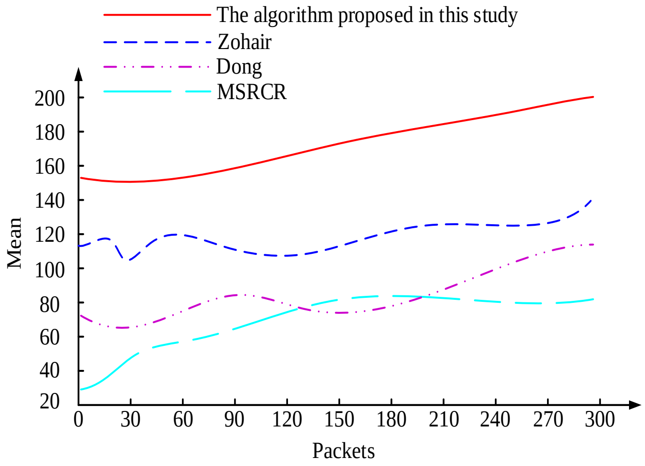


Fig. 8. Average brightness results of Chinese painting pigments in low illuminance environments with different enhancement algorithms for image enhancement.

In Fig. 9, Fig. 9(a) shows the comparison of PSNR for different algorithms under the Brightening dataset. The PSNR of the MSRCR algorithm is close to that of the Dong algorithm, and both algorithms have large fluctuations. The PSNR of the Zohair algorithm is higher, and its fluctuations are more stable than the above two algorithms. The PSNR of the algorithm proposed is greater than the above three at bit rates ranging from 0 to 2000, and it has a fast growth rate. The maximum PSNR values for the four algorithms are obtained when the bit rate reaches 2000, which are 26.6db, 28.4db, 32.5db, and 37.6db, respectively. Fig. 9(b) shows the comparison of PSNR for different algorithms under the LOL dataset. Except for the method proposed, the PSNR of the other three algorithms fluctuates significantly under the LOL dataset. However, the maximum PSNR values for each algorithm are still obtained at a bit rate of 2000, which are 28.2db, 32.6db, 35.8db, and 37.1db, respectively. The maximum PSNR for the four algorithms has improved under the LOL dataset. A comparison was made between the brightness histograms of the low-light Chinese painting images enhanced by different algorithms and the brightness histogram of the original Chinese painting image, and the results are shown in Fig. 10.

In Fig. 10, Fig. 10(a) represents the brightness distribution histogram of the original low-light Chinese painting image. It can be seen that the high brightness region of the original image is concentrated in one area, and the brightness in other areas is at a lower level, indicating a highly uneven brightness distribution of the image. Fig. 10(b) represents the brightness distribution histogram after brightness equalization processing using the Zohair algorithm. It can be seen that the overall brightness of the image has significantly improved, but there are still some areas with low brightness values, indicating an uneven brightness distribution. Fig. 10(c) represents the brightness distribution histogram after brightness equalization processing using the algorithm proposed. The overall brightness of the image has significantly improved, and the brightness distribution is balanced in all parts, indicating that the proposed method can better perform brightness equalization processing on Chinese paintings captured in low-light environments.

V. Conclusion

The uneven display of pigment brightness in low light environments in Chinese painting poses certain obstacles to the promotion of Chinese painting and the dissemination of Chinese culture. Image denoising and image enhancement are common methods for processing low light images. However, traditional image denoising methods such as mean filtering and bilateral filtering may lead to loss of image details and poor generalization performance [21]. Traditional image enhancement methods based on grayscale transformation, histogram equalization, and Retinex theory also suffer from poor visual effects, unsatisfactory enhancement effects, and loss of details [22-23]. In this context, in order to enhance low light images more effectively, a region-based brightness equalization algorithm for low-light Chinese paintings was proposed. The performance test tells that the image information entropy enhanced by the proposed method was between 9 and 10, higher than the 5-7 of MSRCR, the 6-8 of Dong, and the 7-9 of Zohair, reaching the highest value among all the compared algorithms. This indicates that the image processed by the proposed algorithm presents more detailed information compared to other algorithms. The SSIM (Structural Similarity Index) of the image enhanced by the proposed method was between 0.30 and 0.36, significantly higher than the 0.06-0.23 of MSRCR, the 0.09-0.26 of Dong, and the 0.19-0.26 of Zohair. This indicates that the details of the image preserved after enhancement using the proposed method are more complete compared to other algorithms, resulting in better enhancement effects. In the simulation experiment, the brightness distribution histograms of the images after brightness equalization processing using different algorithms were compared. The testing outcomes tells that overall brightness value of the image processed by the proposed method was significantly improved compared to the original image. The brightness values were roughly between 1.51 and 2.0, indicating a more balanced distribution. This indicates that the proposed method can effectively perform brightness equalization processing for Chinese paintings in low-light environments. However, the proposed brightness equalization algorithm is easily affected by image brightness and noise when performing region partitioning, and it is implemented through simulation on the Matlab platform, which limits its runtime. Therefore, further research can explore better denoising methods for image preprocessing, algorithm optimization, and GPU acceleration.

Anomaly Detection in Structural Health Monitoring with Ensemble Learning and Reinforcement Learning

Nan Huang*
Jiangsu University of Science and Technology, Zhenjiang 212000, Jiangsu, China

***Abstract*—This research introduces a novel approach for improving the analysis of Structural Health Monitoring (SHM) data in civil engineering. SHM data, essential for assessing the integrity of infrastructures like bridges, often contains inaccuracies because of sensor errors, environmental factors, and transmission glitches. These inaccuracies can severely hinder identifying structural patterns, detecting damages, and evaluating overall conditions. Our method combines advanced techniques from machine learning, including dilated convolutional neural networks (CNNs), an enhanced differential equation (DE) model, and reinforcement learning (RL), to effectively identify and filter out these irregularities in SHM data. At the heart of our approach lies the use of CNNs, which extract key features from the SHM data. These features are then processed to classify the data accurately. We address the challenge of imbalanced datasets, common in SHM, through a RL-driven method that treats the training procedure as a sequence of choices, with the network learning to distinguish between less and more common data patterns. To further refine our method, we integrate a novel mutation operator within the DE framework. This operator identifies key clusters in the data, guiding the backpropagation process for more effective learning. Our approach was rigorously tested on a dataset from a large cable-stayed bridge in China, provided by the IPC-SHM community. The results of our experiments highlight the effectiveness of our approach, demonstrating an Accuracy of 0.8601 and an F-measure of 0.8540, outperforming other methods compared in our study. This underscores the potential of our method in enhancing the accuracy and reliability of SHM data analysis in civil infrastructure monitoring.**

***Keywords*—Structural health monitoring; Anomaly detection; reinforcement learning; differential equation; imbalanced classification**

I. INTRODUCTION

SHM is a key method for overseeing civil infrastructure, offering insights into structural loads, performance, responses, and future behavior predictions. SHM's widespread adoption has led to a significant increase in data generation; for example, China's Sutong Bridge, with its 785 sensors, produces 2.5 TB of data annually [1, 2]. Analyzing this vast amount of SHM data is challenging due to various anomalies caused by sensor errors, system failures, environmental factors, and more. These issues, compounded by data from significant events like earthquakes or accidents, can jeopardize the accuracy of structural analysis and the predictive power of SHM systems [3].

Implementing sensor-driven SHM methods generates large amounts of sequential data, complicating manual analysis and anomaly detection. Variations in this data may result from diverse factors such as weather, vehicle overloads, accidents, or unexpected events. It is crucial to recognize that not all anomalies indicate structural issues; some may stem from sensor errors, calibration issues, noise, or transmission problems. To tackle these anomalies, solutions can be applied at both hardware and software levels. While hardware solutions like using wired data channels, extra sensors, or self-validating sensors are effective, they are often costly. Therefore, there is a growing preference for advanced data preprocessing techniques specifically designed for anomaly detection.

SHM faces the challenge of data imbalance, where class instances vary significantly in number. To tackle this issue, two approaches are used: data-centric and algorithm-based. Data-centric strategies, such as under-sampling, over-sampling, and hybrid methods, aim to balance class distribution. Notably, the synthetic minority oversampling technique (SMOTE) [4] creates new minority class instances by linear interpolation, while NearMiss [5] under-samples the majority class using a nearest neighbor algorithm. However, over-sampling can lead to overfitting, and under-sampling may lose critical information. Algorithmic approaches focus on emphasizing the underrepresented class. These include modifying ensemble learning, altering decision thresholds, and employing cost-sensitive learning strategies. Cost-sensitive methods treat classification as cost minimization, assigning higher misclassification costs to minority cases. Ensemble methods combine multiple classifiers for a final decision, and threshold adjustment methods tweak the decision threshold during testing. These techniques aim to effectively balance accuracy and information retention in SHM data classification [6].

Furthermore, the incorporation of deep learning methodologies can serve as an avenue to address the challenge of imbalanced classification [7, 8]. Deep Reinforcement Learning (DRL) emerges as a promising solution to handle imbalanced data due to its distinct attributes. By employing a reward mechanism, DRL can assign augmented importance to the minority class, either by imposing stricter penalties for misclassifying instances from the minority class or by offering greater rewards for accurately identifying them. This approach actively counters the bias that conventional techniques display towards the majority class. The advantages of DRL extend beyond the mere balancing of class distribution. It also enriches the visibility of crucial patterns, particularly those associated with the minority class, by effectively filtering out noisy data. DRL's ability to unearth significant yet often overlooked features within the data contributes to the development of a more robust and efficient model [9].

The initial weight configuration in neural networks is crucial for training in SHM prediction. Traditional training, often using gradient-driven algorithms like backpropagation, typically starts with randomly assigned weights. However, the initial weight selection greatly impacts the training's efficiency and outcome. Careful consideration of the initialization strategy is essential for effective training and accurate SHM prediction. One effective approach is population-based training, where the best solution from a range of generated models is chosen as the starting point for the neural network. This method helps avoid the common issue of getting stuck in local optima, prevalent in standard training methods. Notably, simple evolutionary algorithms have shown effectiveness on par with stochastic gradient descent in neural network training [10].

DE [11] is a popular population-based optimization algorithm widely used in solving optimization problems, particularly effective for weight initialization in machine learning. DE offers several advantages: it ensures a broad exploration of the solution space, preventing entrapment in local optima and leading to better weight configurations. It updates weights iteratively based on the difference between current and target solutions, promoting faster convergence and improved performance. DE is also resilient to noise in fitness assessments, adeptly handling data uncertainties during weight initialization and providing stable initial weight settings. Furthermore, DE's flexibility and adjustability in weight initialization permit tailoring to particular problem areas, like establishing weight limits or integrating previous insights. This versatility improves DE's capability to initiate weights that are aptly matched to the distinct learning challenges being addressed.

This study investigates a novel approach combining a RL-based training algorithm with an advanced DE technique, specifically designed for SHM of bridges. It focuses on detecting anomalies in time-series sensor data from a major cable-stayed bridge in China. The data is divided into seven categories: normal, trend, square, missing, minor, drift, and outlier, with 'normal' being the most frequent. To overcome the issue of class imbalance in the dataset, the research introduces a framework that treats classification as a series of strategic decisions. In each iteration, an agent assesses a training sample (environmental state) and makes classification decisions, earning rewards or penalties based on the outcome. Classes with fewer samples are assigned higher rewards, encouraging accurate identification of less common anomalies. Additionally, the study integrates a unique mutation operator based on clustering principles within the DE framework to improve the backpropagation (BP) process. This operator identifies dominant clusters in the DE population and implements a novel approach for creating potential solutions. The key contributions of this research lie in its innovative approach to class imbalance, decision-making process in classification, and enhanced training methodology through integrating RL, DE, and BP processes:

1) We present an innovative RL-based method specifically designed to address the inherent challenges of imbalanced classification in SHM.

2) The approach integrates a unique reward system that reinforces accurate decisions while penalizing incorrect ones. By allocating enhanced rewards to the less represented class, we directly address the challenge of data skewness, encouraging the algorithm to appropriately focus on lesser-known data. This strategic maneuver contributes to a more fair and balanced classification procedure.

3) To extract deeper insights from images and refine the classification decision-making process, we employ a fusion of CNN models. This approach enhances the representation of features, resulting in improved accuracy and robustness in classification efforts.

4) We have developed an enhanced DE algorithm to initialize weights in the proposed model efficiently. This tactic aids in identifying a promising region for initiating the BP algorithm within the model.

The structure of this document is as follows: Section II details a review of relevant literature, and Section III provides an overview of the key dataset utilized in this study. Section IV delves into the proposed strategy, elucidating the core methodology in depth. Section V unfolds the empirical outcomes and their subsequent dissection. Concluding observations and potential avenues for future inquiry are encapsulated in Section VI.

II. Literature Review

Artificial Intelligence (AI) techniques bring forth the capability to uncover patterns within time-series data with no prior comprehension of the underlying structural architecture. These methodologies involve exploring either the time or frequency domain of the data, extracting pertinent characteristics through statistical evaluations, or employing signal processing tools like the Fourier and wavelet transforms, as well as the Hilbert-Huang and Shapelet transforms. On the other hand, deep learning (DL) algorithms possess the ability to autonomously extract significant attributes by interpreting time-frequency data as visual inputs within a CNN framework. However, it is important to acknowledge that DL-centric approaches, while potent, demand substantial computational resources and cause meticulous fine-tuning of hyperparameters [12].

In order to tackle irregularities within SHM data, Pan et al. [13] presented an approach rooted in transfer learning. They employed a deep neural network to discern and rectify aberrant data, enhancing the accuracy of bridge evaluations. Samudra et al. [12] devised a comprehensible framework rooted in decision trees, employing random forest classifiers to categorize acceleration data in the realm of SHM. This approach, boasting a remarkable 98% accuracy, emerges as an economically viable avenue for gauging infrastructure state. Li et al. [14] outlined a strategy to elevate the efficacy of anomaly detection within bridge SHM systems. Employing strategies like data augmentation, feature dimension reduction, and a two-stage deep convolutional neural network, they achieved an elevated level of recognition accuracy. Tang et al. [3] presented an innovative anomaly detection method catering to SHM, employing a CNN that transforms time series data into visual representations. This approach achieves precise identification of diverse pattern anomalies, scaling effectively and bolstering accuracy. Ye et al. [15] proposed a technique rooted in deep learning for identifying data anomalies within SHM systems. By deploying time-frequency analysis and CNNs, they translated SHM data into RGB images, subsequently classified through a Google network. Green et al. [16] introduced a new way to use Bayesian techniques in the analysis of inclinometer data for SHM. This method allows for the detection of anomalies, forecasting, and quantifying uncertainties, leading to better risk assessment and cost reduction.

Moreover, the framework has the potential to be applied in various engineering fields beyond inclinometers. Boccagna et al. [17] suggested an AI approach for monitoring structural health in almost real-time, using unsupervised deep learning. By preprocessing data and utilizing artificial neural network autoencoders, the technique effectively identifies anomalies, surpassing current methods and demonstrating encouraging outcomes. Lei et al. [18] proposed a residual attention network (RAN) to detect abnormal data in measured structures. The RAN incorporates attention mechanisms and residual learning to enhance classification accuracy and efficiency. It achieved exceptional performance and generalization on datasets from an arch bridge and a cable-stayed bridge, surpassing existing models in terms of multi-classification and accuracy. Yang and Nagarajaiah [19] introduced a principled, independent component analysis approach to reduce faulty data during data transmission; then, they achieved reliable data transfer and image restoration using compression sensing methods [20]. Yang and Nagarajaiah [21] employed the principal component pursuit method to detect and minimize burst noise in ambient vibration response. They also introduced a data management and processing framework based on sparsity rank and low-rank techniques. Park et al. [22] utilized transmission errors and ensemble empirical mode decomposition to identify anomalies such as gear teeth spalls and cracks in rotating machinery.

III. Dataset Description

In this study, our primary focus centers on the detection of specific deviations - including trends, squares, omissions, minor variances, drifts, and outlier - within the acceleration time series derived from a lengthy cable-stayed bridge in China. The IPC-SHM community [23] provides access to curated data from this bridge. An overview of these anomalies, distilled from the bridge's measured data, is concisely summarized in Table I.

Besides the irregularities mentioned, it is vital to acknowledge that acceleration sensors, particularly those affixed to structures with potential vulnerabilities, adeptly detect a broad range of atypical patterns. These include offsets, characterized by sudden, noticeable jumps in response, and gains, marked by a slow, consistent increase in response over time. Furthermore, the sensors can identify precision deterioration, where the response shows erratic fluctuations, and complete failures, which result in a response akin to the randomness of white noise in the frequency domain. Recognizing and interpreting these additional types of deviations are crucial for comprehensive structural health monitoring, as they can provide early warning signs of more significant issues or impending failures.

The dataset under study contains a thorough record of acceleration data over a month, meticulously gathered from 38 strategically placed accelerometers across the bridge. For detailed analysis, this data is segmented into individual hourly time series, leading to an extensive collection of 28,272 such series. This figure is calculated considering the number of sensors, the days in the month, and the daily time cycle. Given that the accelerometers recorded at a rate of 20 Hz, the total data volume reaches an astonishing 2×10^9 data points, a multiplication of the number of time series, seconds in an hour, and the sampling rate. This vast dataset offers a rich source for in-depth analysis, allowing for the examination of minute changes and patterns over time, providing a comprehensive understanding of the bridge's dynamic behavior under various conditions.

The subsequent classification task systematically organizes these 28,272 time series responses into seven distinct categories. This includes the ‘normal’ set and six other types of anomalies: trend, square, missing, minor, drift, and outlier. A detailed chart in Table I itemizes the precise distribution of time series across each category within this dataset. This categorization is crucial for identifying the predominant anomalies and understanding their relative occurrences. It aids in developing targeted strategies for monitoring and maintenance, ensuring focused attention on the most critical or frequently occurring issues, enhancing the overall efficiency and effectiveness of the structural health monitoring process.

TABLE I. Description of the Anomalies

Class	Description	Count
Normal	The time-domain response showcases balance, while multiple resonance peaks can be observed in the frequency-domain response.	13575
Trend	A discernible trajectory is apparent in the time-domain response, and a distinctive peak value is identified in the frequency-domain response.	5778
Square	The time-domain response mirrors a square wave.	2996
Missing	The bulk of the time-domain response is absent.	2942
Minor	Compared to standard category data, the time-domain response exhibits a notably reduced magnitude.	1775
Drift	The time-domain response varies unpredictably, either exhibiting arbitrary shifts or increasingly diverging over time.	679
Outlier	The time-domain response contains singular or multiple pronounced protrusions.	527

IV. Model Architecture

Fig. 1 illustrates the intricacies of our innovatively developed model, meticulously engineered to boost the efficiency of anomaly detection. This model is specifically tailored to tackle issues like uneven distribution of classes and the critical importance of accurately setting initial weights. By integrating the DE algorithm with PPO, our model adeptly circumvents common hurdles encountered in standard models.

Conventional methods often miss a systematic strategy for establishing initial weights, resulting in reduced learning speeds and a propensity to settle on less-than-ideal outcomes. Our technique leverages DE to provide a diverse spectrum of initial weights. This variety helps the model to bypass smaller optima and more efficiently converge on more comprehensive solutions. Expanding on this, the utilization of DE in our method is not just about broadening the range of initial weights, but also about introducing a dynamic and adaptive way of initializing these weights. This adaptability is crucial in complex models where the landscape of solutions is vast and varied. By starting from a more helpful position in the solution space, our method enhances the model's ability to navigate through this landscape, leading to quicker and more effective convergence. Furthermore, this approach also contributes to the robustness of the model, making it less susceptible to the challenges posed by different data distributions and complexities inherent in various learning tasks. Our method does not just improve the efficiency of the learning process, but also broadens its applicability and effectiveness across a range of scenarios.

Additionally, the RL element in our framework is thoughtfully structured to significantly favor the accurate identification of the minority class, underscoring these crucial predictions. This represents a significant advancement over conventional supervised learning approaches, which often struggle with insufficient data representation across various classes. The dynamic nature of policy learning in RL encourages a fairer approach to decision-making, leading to enhanced strategies for identifying underrepresented categories. The flexibility of RL in our setup sets it apart from orthodox methodologies, equipping it with the essential capabilities to efficiently address the typical challenges found in conventional classification techniques employed in anomaly detection.

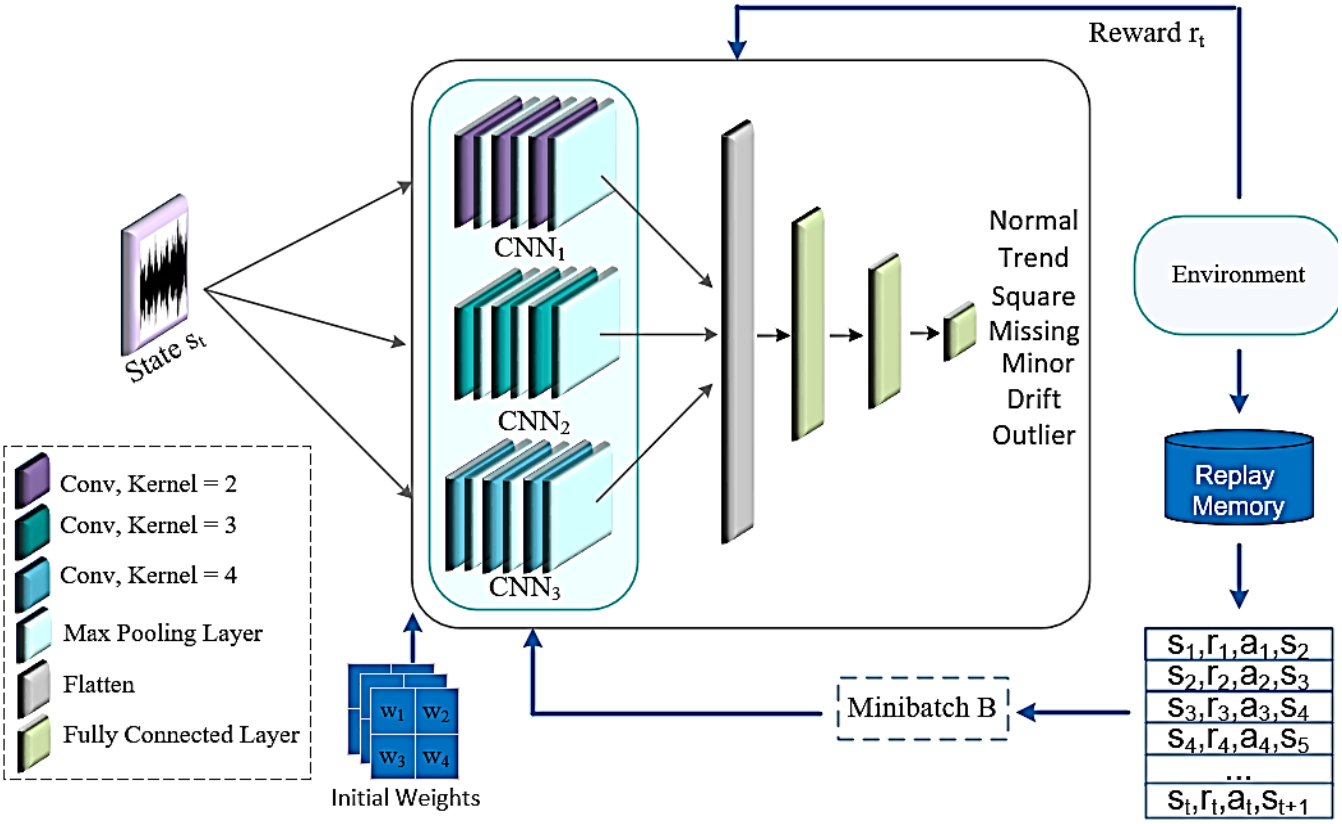

Fig. 1. Our model pipeline encompasses a sequence of procedures.

A. Pre-training Phase

Deep models depend heavily on the initialization of deep network weights. If the initial values are not accurate, it can lead to convergence issues in the model. The first stage in this paper is to set the CNN and feed-forward neural network weights. We offer a more effective DE approach, which incorporates the power of a clustering technique and an innovative fitness function to optimize its performance. In our improved DE algorithm, we utilize a mutation and updating scheme based on clustering to enhance the optimization performance. Complex architectures rely significantly on the initial setup of deep network parameters. Inaccurate starting points may cause the model to struggle with convergence. The initial step in our study involves configuring the weights for the CNN and the feed-forward neural networks. We propose an enhanced DE method that integrates the effectiveness of a clustering algorithm and a novel fitness function to boost its efficiency. In our refined DE technique, we employ a mutation and refresh strategy centered on clustering to improve the optimization process. Extending this, our approach takes into account the intricacies of deep learning architectures, ensuring that the weight initialization is not only randomly, but strategically influenced by the underlying data structure. The clustering-based mutation strategy allows for a more targeted and data-driven adjustment of weights, which is particularly useful in navigating the high-dimensional spaces typical in deep learning. This method aids in avoiding local minima and accelerates the convergence of the model.

The mutation mechanism, influenced by studies referenced in [24], identifies a promising region in the exploration domain. Employing the k-means clustering technique, the existing group P is segregated into k segments, each representing a unique portion of the exploration zone. A random integer chosen from the interval $[2, \sqrt{N}]$ dictates the cluster count. The cluster deemed most optimal possesses the lowest mean fitness value across its gathered samples post-clustering. Expanding on this, our method enhances the search strategy within the algorithm. By dividing the population into clusters, we can pinpoint specific regions in the search space that hold potential for better solutions. This clustering not only focuses the search but also adds a layer of precision in identifying promising areas, thereby increasing the efficiency of the mutation process. Additionally, the number of clusters is dynamically determined based on the population size, allowing for a flexible and adaptable approach to clustering. This adaptability is crucial in dealing with diverse problems and varying sizes of search spaces. The concept of assessing the perfection of a cluster based on its average fitness introduces a competitive element among the clusters, driving the algorithm to favor areas of the search space that show higher potential for optimal solutions. Furthermore, our approach refines the selection process within each cluster. After identifying the most optimal cluster, we focus on fine-tuning the solutions within this cluster, leveraging the collective intelligence of the group. This targeted mutation within the most promising cluster ensures the algorithm does not just wander aimlessly across the entire search space but makes informed, strategic moves towards areas more likely to yield superior results.

The clustering-based approach outlines the proposed mutation:

$$\overrightarrow{v_\imath^{clu}} = \overrightarrow{w\imath n_g} + F(\overrightarrow{x_{r_1}} - \overrightarrow{x_{r_2}}) \qquad (1)$$

where, $\overrightarrow{x_{r_1}}$ and $\overrightarrow{x_{r_2}}$ represent two candidate solutions randomly selected from the current population while $\overrightarrow{w\imath n_g}$ corresponds to the best solution within the promising region. It is important to note that $\overrightarrow{w\imath n_g}$ may not be the best solution for the entire population.

Following the creation of M new solutions via mutation grounded in clustering, the current population undergoes an update under GPBA [25]. The GPBA is an innovative optimization approach that meticulously navigates through the search space, assessing the effectiveness of solutions against a series of established patterns. In practical application, GPBA changes the population by meticulously choosing and substituting individuals according to their performance indicators. By employing these patterns as navigational aids, GPBA refines its quest for the best solutions, often resulting in a more streamlined and efficient path to the global optimum. This method's real strength lies in its structured approach to the exploration of the search space. By using gradient patterns, the algorithm can intelligently predict the direction in which improvements can be made, rather than relying on random or exhaustive search methods. This predictive capability is helpful in complex optimization scenarios, characterized by vast search spaces and elusive optimal solutions. It allows the algorithm to bypass fewer promising regions of the search space, focusing its efforts on areas more likely to yield fruitful results. Furthermore, the GPBA's adaptability to different optimization problems adds to its versatility. Whether the task involves continuous or discrete variables, linear or non-linear relationships, the GPBA can be tailored to suit the specific characteristics of the problem. This adaptability is achieved through the customization of its pattern-based search mechanisms, which can suit various problem structures and complexities. Besides its efficiency in finding solutions, the GPBA also offers improved computational speed compared to more traditional optimization methods. This is beneficial in real-time applications or scenarios where time is a critical factor. The algorithm's ability to quickly converge to an optimal solution without sacrificing accuracy makes it an attractive choice for a wide range of optimization tasks.

The process unfolds as follows:

- Selection: To initiate the algorithm, generate k random individuals that will function as the initial points.
- Generation: Produce a set of M solutions using mutation based on clustering and denote it as v^{clu}.
- Replacement: Choose M solutions randomly from the current population to form set B.
- Update: Select the top M solutions from the combined groups v^{clu} and B to create a new group B'. The refreshed population is derived by merging members of set P not included in B with those from set B' ($(P - B) \cup B'$).

B. DRL

DRL stands as a formidable approach in the domain of deep learning. Within this framework, an intelligent agent engages dynamically with its environment, aiming to maximize its cumulative rewards. This flexible and adaptive learning mechanism empowers the agent to make a series of decisions, often in the face of uncertainty, which has profound applications across a wide spectrum of domains, including but not limited to robotics, healthcare, and finance [26]. The prowess of DRL becomes evident in tasks that require sequential decision-making and the ability to adapt to unforeseen and evolving circumstances. Its capacity to handle complex activities that unfold over time, adjusting its strategies and responses as needed, underscores its versatility and broad applicability in addressing real-world challenges. DRL's ability to learn from interactions with the environment, optimize decision-making processes, and navigate through dynamic scenarios positions it as a valuable tool for a wide range of applications, making it a compelling area of research and development in artificial intelligence.

In categorization-related tasks, a major challenge lies in handling datasets with imbalanced distributions, where one category is markedly more dominant than others. This disproportion might cause skewed educational outcomes, as standard classification approaches often lean towards the predominant group, leading to subpar identification of the less represented categories. Under such conditions, DRL stands out as a superior strategy for educating neural networks over conventional approaches. DRL addresses the problem of lopsided categorization by employing a system based on rewards [27]. Through carefully allocating incentives, it shifts the agent's attention towards instances belonging to the underrepresented categories, thus improving the detection of these rarer classes. The reward-centric model of DRL promotes a comprehensive decision-making process, prioritizing the discovery and classification of rare events or infrequently occurring categories.

In the realm of DRL, the primary goal of the agent is to select actions that optimize prospective benefits. The aggregation of rewards for forthcoming situations, symbolized by the reward value, gradually decreases over time, influenced by the discount rate γ, as illustrated in Eq. (2). In this formula, T corresponds to the concluding time-step of an episode [28].

$$R_t = \sum_{t'=t}^{T} \gamma^{t'-t} r_{t'} \tag{2}$$

where, R_t represents the cumulative reward starting from time t, and $r_{t'}$ denotes the reward received at time t'. Q-values, representing the quality of state-action interactions, denote the anticipated outcome of policy π upon executing action a within state s. This is computed as depicted in Eq. (3).

$$Q^{\pi}(s,a) = E[R_t | s_t = s, a_t = a, \pi] \tag{3}$$

The most optimal action-value function, represented as the highest anticipated reward among all approaches after witnessing state s and performing action a, is calculated as depicted in Eq. (4).

$$Q^{*}(s,a) = max_{\pi}\, E[R_t | s_t = s, a_t = a, \pi] \tag{4}$$

The function carries out the Bellman equation [29], which states that the supreme anticipated outcome for a particular maneuver is the sum of the benefits from the present maneuver and the utmost anticipated outcome from forthcoming maneuvers in the next instance. This concept is exemplified in Eq. (5).

$$Q^{*}(s,a)=E[r + \gamma\, max_{a'} Q^{*}(s',a') | s_t = s, a_t = a] \tag{5}$$

The computation of the ideal action-value function is methodically executed using the Bellman equation, as illustrated in Eq. (6).

$$Q_{i+1}(s,a)=E[r + \gamma\, max_{a'} Q_i(s',a') | s_t = s, a_t = a] \tag{6}$$

During the learning stage, as the network experiences state s, it generates a state-specific action. Subsequently, the system provides a reward r and transitions to the next state s'. These components are combined into a set (s, a, r, s'), subsequently stored in memory M. Groups of such sets, termed Batches B, are selected for performing gradient descent. The method for calculating loss is detailed in Eq. (7).

$$L_i(\theta_i)=\sum_{(s,a,r,s') \in B} (y - Q(s,a;\theta_i))^2 \tag{7}$$

Here, θ symbolizes the model's weights, while y indicates the approximated objective for the Q function, evaluated as the summation of the reward linked with the state-action pair and the reduced maximum Q value in future instances, as illustrated in Eq. (8).

$$y = r + \gamma\, max_{a'} Q(s', a';\, \theta_{k-1}) \tag{8}$$

It is important to recognize that the Q value assigned to the terminal state is initialized at zero. The gradient's magnitude for the loss function during the i-th iteration is ascertainable through Eq. (9).

$$\nabla_{\theta_i} L(\theta_i) = -2 \sum_{(s,a,r,s') \in B} (y - Q(s,a;\theta_i)) \nabla_{\theta_i} Q(s,a;\theta_i) \tag{9}$$

Through the execution of a gradient descent iteration on the loss function, adjustments are made to the model's weights under Eq. (10). This modification endeavors to lessen the discrepancy, where α denotes the learning rate dictating the extent of advancement within the optimization procedure.

$$\theta_{i+1}=\theta_i + \alpha \nabla_{\theta_i} Q(s,a;\theta_i) \tag{10}$$

1) Problem formulation: Within this paper, the application of the RL algorithm is directed towards the field of SHM. The ensuing explanation delineates the method's functioning and interpreting each component:

- State $\boldsymbol{s_t}$: This matches the image captured at the temporal interval t. Here, an image refers to a graphical representation of the time series data. This image is composed of plots or graphs that visually depict the various anomalies identified in the acceleration time series of the bridge.
- Action $\boldsymbol{a_t}$: The categorization executed on the image is regarded as an action. This signifies a choice carried out by the network, grounded in its prevailing comprehension of the objective.
- Action $\boldsymbol{r_t}$: A reward is furnished for every categorization, designed to steer the network towards accurate categorization. The formulation of this remuneration process is expressed as:

$$r_t(s_t, a_t, y_t) = \begin{cases} +1\,, a_t = y_t \; and \; s_t \in D_O \\ -1\,, a_t \neq y_t \; and \; s_t \in D_O \\ \lambda\,, a_t = y_t \; and \; s_t \in D_N \\ -\lambda\,, a_t \neq y_t \; and \; s_t \in D_N \end{cases} \tag{11}$$

In this context, $D_N = \{Noraml\}$, and $D_O = \{\text{Trend}, \text{Square}, \text{Missing}, \text{Minor}, \text{Drift}, \text{Outlier}\}$ indicates the minority classes. Accurate or erroneous classification of a case from the prevalent category leads to an incentive or penalty of +λ or -λ, respectively. This outlined method compels the network to focus on accurately identifying instances from the less frequent class by allocating a higher absolute value to the reward. Concurrently, the incorporation of the normal class and the flexible reward parameter within the range of 0<λ<1 adds complexity to the reward scheme. This allows for refined adjustment of the network's focus between the more and less prevalent classes.

V. Empirical Evaluation

In the meticulous assessment stage, a detailed and exhaustive analysis was carried out, contrasting our suggested model with six distinct deep-learning contenders, namely TransAnoNet [13], AnoSegNet [14], WaveletCNN [15], GAN-VAE [30], CNN-MIAD [31], and VibroCNN. This evaluation aimed to provide an all-encompassing insight into the strengths of our model vis-à-vis established methods. Moreover, we delved into different versions of our model by introducing three alternative variants for evaluation. The initial variant, termed "Proposed without dilated convolution," was based on a similar foundational architecture to our original model, yet did not incorporate dilated convolution. The subsequent variant, designated as "Proposed without RL," excluded the reinforcement learning component from the classification procedure. The third altered version, named "Proposed without DE," employed random initialization for the weights. We appraised these models using standard performance indicators, focusing specifically on measures like the F-measure and the geometric mean due to their proven effectiveness in tackling imbalanced datasets. The findings, detailed in Table II, resoundingly affirm the preeminence of our proposed model over all competing models, including those previously recognized as industry standards like AnoSegNet and TransAnoNet. Across every evaluative criterion, our model demonstrated consistent superiority over its rivals. Noteworthy accomplishments involve a marked error reduction exceeding 9% in the F-measure and surpassing 8% in the G-means indices. These notable advancements highlight the efficacy of our model in surmounting the difficulties associated with imbalanced datasets and its adeptness at furnishing more accurate forecasts. In juxtaposing our model with the modified iterations "Proposed without dilated convolution," "Proposed without RL," and "Proposed without DE," the indispensability of incorporating dilated convolution, RL, and DE methods becomes clear. Our model manifested a notable error rate reduction, approximately 5.35%, in comparison to its counterparts. This outcome accentuates the critical impact that the amalgamation of dilated convolution, RL, and DE strategies has in boosting the model's performance, thus solidifying their role as catalysts in the evolution of deep learning models.

In Fig. 2, we present the receiver operating characteristic (ROC) curves corresponding to the methodologies outlined in Table II. The area under the curve (AUC) serves as a pivotal metric for quantifying the performance of classifiers. An AUC score of 1 signifies impeccable discrimination ability, while a score of 0.5 suggests performance no better than random guessing.

It is worth highlighting that our proposed model emerges as the leader in this analysis, boasting a notable AUC value of 0.60. This solid outcome highlights its remarkable proficiency in accurately differentiating between favorable and unfavorable results, reinforcing the credibility of our approach as a potent predictive tool. Additionally, the "Proposed without RL" approach also demonstrates strong performance, achieving an AUC of 0.57, further affirming its ability to discern between positive and negative instances. In contrast, WaveletCNN and TransAnoNet, which achieve AUC scores of 0.46 and 0.49, respectively, offer less impressive performance. VibroCNN, GAN-VAE, and CNN-MIAD display even less favorable outcomes, with AUC values ranging from 0.43 to 0.45. Particularly, VibroCNN's meager AUC of 0.43, only slightly surpassing random chance, highlights its underwhelming performance. The ROC analysis vividly illustrates the varying degrees of performance among the evaluated methodologies. The exceptional predictive prowess demonstrated by our proposed method, whether in its standalone form or when coupled with RL, underscores the potency of our approach. Furthermore, it establishes a robust foundation for future enhancements and promising applications in the realm of predictive modeling, charting a path toward even more effective methodologies in the prediction domain. This remarkable performance positions our model as a key player in the field of predictive analytics.

TABLE II. Efficiency Indicators of the Suggested System Compared to Rival Advanced Networks for SHM

	Accuracy	F-measure	G-means
TransAnoNet	0.8104±0.0156	0.7802±0.1053	0.8102±0.0203
AnoSegNet	0.8001±0.2156	0.7371±0.0268	0.7902±0.1236
WaveletCNN	0.8005±0.2130	0.7202±0.0268	0.7906±0.2156
GAN-VAE	0.6801±0.0526	0.5402±0.1236	0.6405±0.0256
CNN-MIAD	0.7703±0.1563	0.6602±0.1036	0.7403±0.1265
VibroCNN	0.6704±0.0501	0.5501±0.0652	0.6462±0.0052
Proposed without dilated convolution	0.7904 ± 0.0517	0.7615 ± 0.1623	0.8014 ± 0.3622
Proposed without RL	0.8315 ± 0.0243	0.8200 ± 0.0417	0.8315 ± 0.0621
Proposed without DE	0.8425 ± 0.0123	0.8345 ± 0.0120	0.8436 ± 0.0505
Proposed	0.8601 ± 0.0384	0.8540 ± 0.0297	0.8760 ± 0.0123

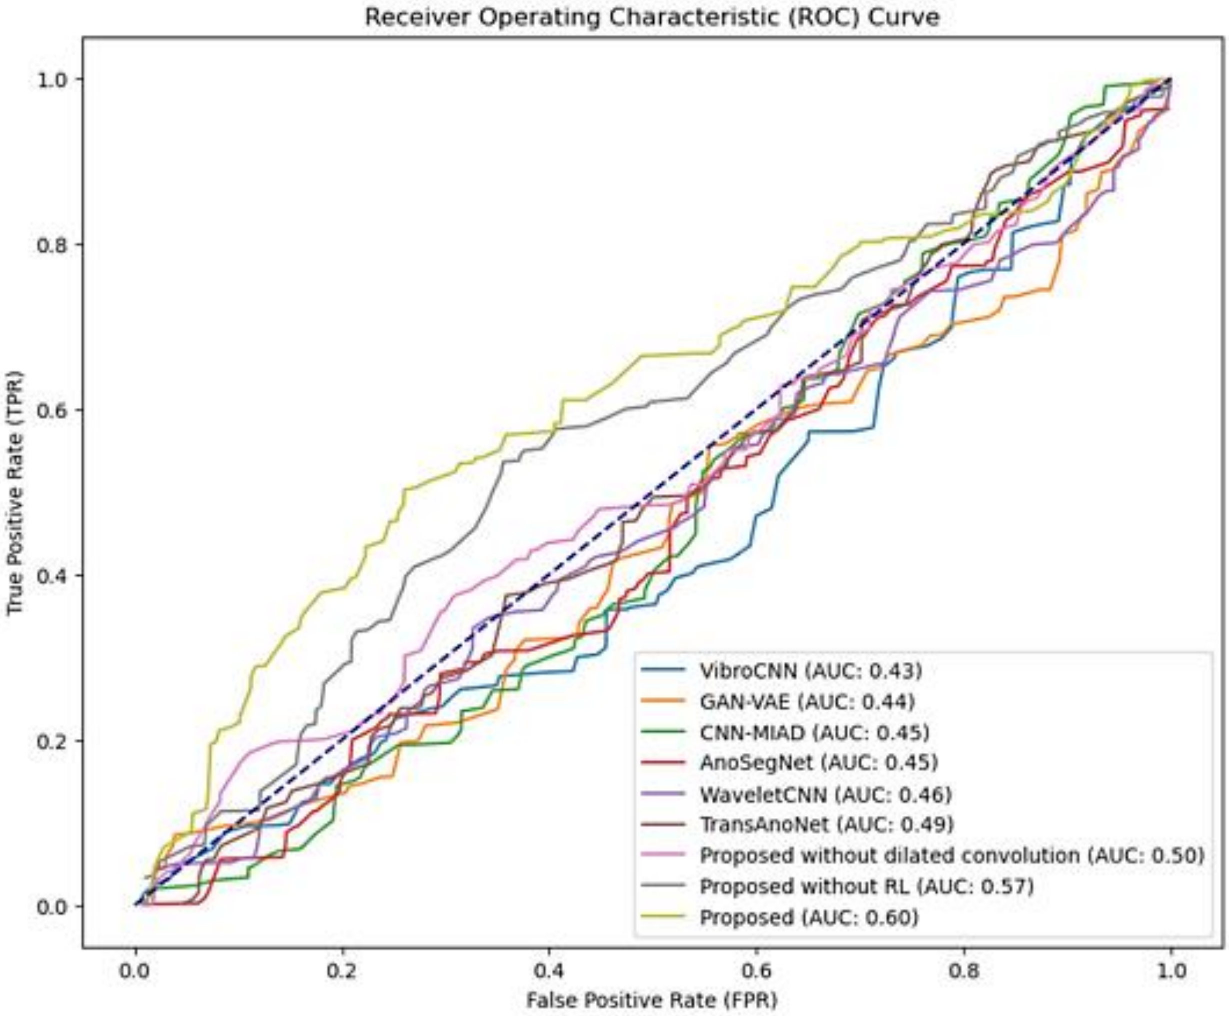

Fig. 2. AUC chart for the suggested approach and alternative comparative techniques.

Fig. 3 showcases the confusion matrices for the proposed model, providing a detailed representation of its classification performance across different categories. From the matrix, we can observe the number of correct predictions (true positives) along the diagonal for each class, which are as follows: 13,271 for ‘Normal’, 5,363 for ‘Trend’, 2,608 for ‘Square’, 2,750 for ‘Missing’, 1,571 for ‘Minor’, 539 for ‘Drift’, and 409 for ‘Outlier’. These figures suggest the model is most proficient at identifying the ‘Normal’ class and least proficient at identifying ‘Outlier’ instances, which could be because of their lower occurrence in the dataset. The off-diagonal numbers represent the instances where the model misclassified the inputs. For example, there are 76 instances where ‘Normal’ was incorrectly classified as ‘Missing’, and 80 instances where ‘Square’ was mislabeled as ‘Normal’. Such misclassifications can diagnose and improve the model’s performance, possibly by providing it with more representative training data or refining its feature detection capabilities.

Fig. 4 illustrates the evolution of error dynamics within the proposed model across 500 epochs. Commencing at an initial value of 12, the error undergoes a consistent descent as epochs unfold. This sustained decline signifies the model's progressive learning and enhancement of its predictive capabilities over time. It is significant to observe that the most pronounced decrease in error happens during the early training stages, slowly leveling off as the number of epochs increases. This trend indicates that with ongoing training, the rate of error reduction lessens, signifying a point where further error minimization from extended training becomes less impactful. Near the 425th epoch, a clear steadying of the error rate is observed, consistently hovering around a value of approximately 4.2962 in subsequent epochs. This leveling off of error rates suggests that continued training beyond this juncture is unlikely to result in notable enhancements in the model's forecasting accuracy. This stage may signal that the model has attained a state of convergence, reaching an accuracy level where additional fine-tuning might not bring considerable improvements. Alternatively, this stabilization could also suggest the emergence of overfitting concerns, especially if the model's performance on validation or test datasets ceases to improve. This insight into the error dynamics across epochs not only showcases the model's learning journey but also provides valuable guidance for fine-tuning training duration and preventing potential overfitting scenarios.

	Normal	Trend	Square	Missing	Minor	Drift	Outlier
Normal	13271	72	55	76	45	10	46
Trend	78	5363	89	49	40	80	79
Square	80	48	2608	96	60	74	30
Missing	30	18	34	2750	52	43	15
Minor	25	62	51	20	1571	29	17
Drift	29	17	15	35	12	539	32
Outlier	10	19	29	18	19	23	409

Fig. 3. Comparative confusion matrices for the proposed model.

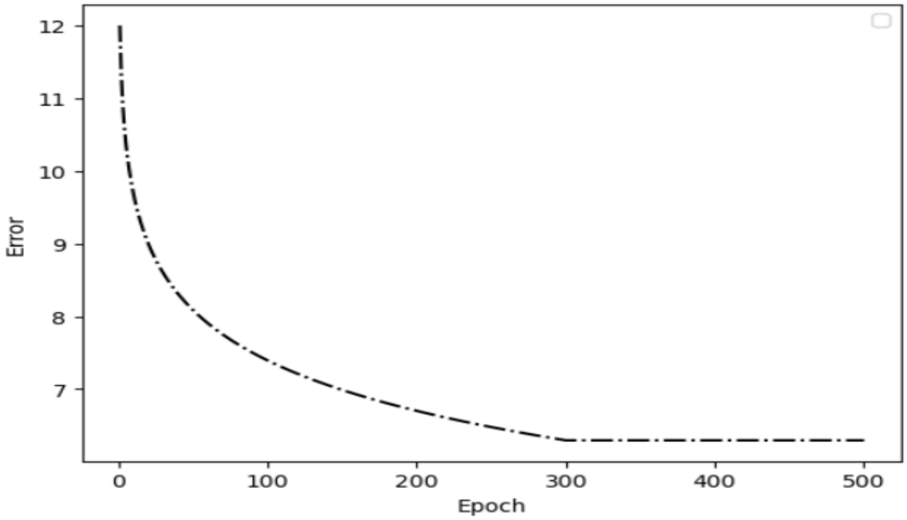

Fig. 4. Comparative diagram of error dynamics.

A. *Impact of the Reward Function*

The allocation of rewards to both the more common and less frequent categories for accurate and inaccurate classifications is denoted by +1 and ±λ. The particular magnitude of λ is determined by the ratio of frequent occurrences relative to rare events. As this ratio rises, it is expected that the ideal magnitude of λ will diminish proportionally. In order to thoroughly investigate the influence of λ, we executed an extensive assessment of the suggested structure employing diverse λ magnitudes, varying from 0 to 1 in steps of 0.1. Concurrently, the incentive for the more frequent category stayed unchanged. The detailed results are illustrated in Fig. 5. When adjusting λ to 0, the effect of the dominant group turns negligible.

Conversely, with a value of λ = 1, both the more common and less common groups carry equivalent weight. The insights extracted from the analysis indicate that the framework achieves its peak effectiveness when λ is established at 0.7, as observed across all assessed performance indicators. This observation suggests that the ideal λ magnitude lies within the range of zero to one. It's important to recognize that although modulating λ to reduce the impact of the dominant group is essential, configuring it too low might adversely affect the overall effectiveness of the entire structure. The evidence clearly indicates that the choice of λ markedly affects the success of the structure. The suitable λ magnitude depends on the comparative occurrences of more frequent and infrequent events, highlighting the need for careful determination to achieve the best results. This study underscores the intricate interplay between λ and the framework's success, advocating for a balanced choice of λ to strike a harmonious equilibrium between the two categories and foster effective results.

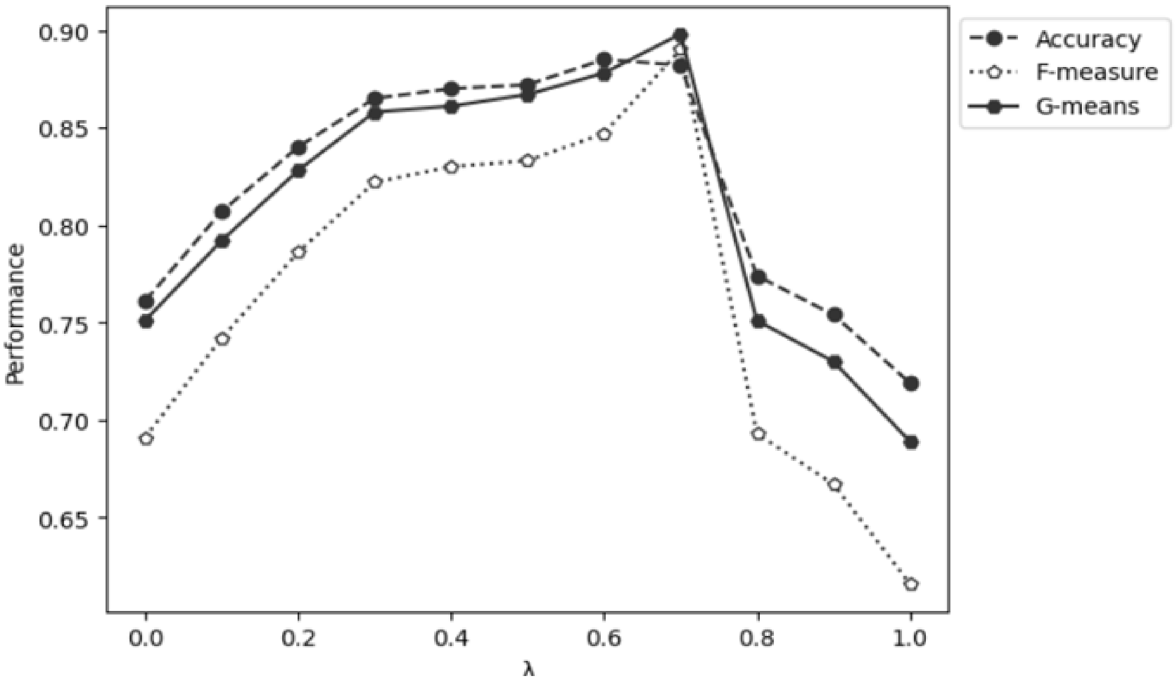

Fig. 5. Evaluation of the performance metrics of the proposed system under various settings of the parameter λ.

B. *Effect of Loss Function*

The landscape of strategies available to combat the complexities arising from data imbalances in machine learning models is vast and diverse. It spans an array of techniques, ranging from the fine-tuning of data augmentation methods to the meticulous selection of aptly suited loss functions. The deliberate choice of an appropriate loss function plays a central role in ensuring the model's capacity to glean valuable insights from the underrepresented class embedded within the dataset. In our quest to unravel the nuances of the varying impacts of distinct loss functions, we embarked on a comprehensive exploration of five distinct contenders: WCE [32], BCE [33], DL [34], TL [35], and CL [36].

Among these contenders, both BCE and WCE have established themselves as widely adopted loss functions, treating positive and negative samples with equal significance. However, it's imperative to recognize that these functions might not be optimally configured to cater to datasets characterized by pronounced imbalances that accentuate the minority class. In stark contrast, DL and TL exhibit superior performance when confronted with skewed datasets, delivering more favorable outcomes for the underrepresented class. Notably, CL emerges as a standout loss function, showcasing its prowess in scenarios where imbalanced data prevails. By skillfully adjusting the weights of the loss function, CL demonstrates its ability to prioritize intricate samples over simpler ones, thereby enhancing its adaptability in the face of challenging data distributions.

Our rigorous experimentation and analysis of these diverse loss functions are presented in meticulous detail in Table III. The outcomes unequivocally affirm the supremacy of CL over TL, leading to a substantial 3.72% reduction in the error rate concerning accuracy and an impressive 3.58% decrease in the F-measure. Nevertheless, it is crucial to underscore that, when benchmarked against the performance of our proposed model, CL exhibits a 1.5% deficit. These findings underscore the paramount significance of making a judicious selection of an appropriate loss function when navigating the intricacies of imbalanced data. Furthermore, they shine a spotlight on the commendable performance of our model in effectively addressing this prevalent and challenging issue in machine learning.

TABLE III. PERFORMANCE EVALUATION METRICS OF THE PROPOSED MODEL AGAINST VARIOUS LOSS FUNCTIONS IN SHM

	Accuracy	**F-measure**	**G-means**
WCE	0.7303± 0.0269	0.7105± 0.1204	0.7412± 0.1120
BCE	0.7963± 0.0626	0.7536± 0.1203	0.7963± 0.0103
DL	0.7923± 0.0365	0.7821± 0.0056	0.8103± 0.1123
TL	0.8236± 0.2126	0.8023± 0.0145	0.8352± 0.1035
CL	0.8563± 0.0035	0.8325± 0.0032	0.8523± 0.0039

C. Effect of CNNs

The architecture encompasses an array of CNNs that concurrently derive feature vectors from images. The quantity of CNNs utilized for feature extraction greatly influences the model's efficiency. Inadequate number of CNNs results in inadequate feature extraction, whereas too much may lead to problems such as overfitting or superfluousness. Both scenarios can diminish the model's overall utility. Therefore, carefully selecting the ideal number of CNN feature extractors is crucial. To identify this optimal number, we conducted a thorough and systematic analysis, evaluating the model's performance across a range of 1 to 7 CNN feature extractors. Our aim was to pinpoint the point where the model achieves peak functionality while maintaining a delicate balance between thorough feature extraction and operational efficiency. Our comprehensive experiments, as illustrated in Fig. 6, unequivocally demonstrate that three CNN feature extractors yield the model's best performance. Interestingly, as the number of CNNs increases, the model's performance declines, with six or seven extractors being less effective than using just one. This observed pattern highlights the existence of an optimal number of CNN feature extractors, maximizing the model's ability to capture relevant and discriminative features, ultimately leading to enhanced overall performance. Selecting three CNN feature extractors strikes a harmonious balance, optimizing the model's ability to extract essential information from input imagery, boosting its efficiency and effectiveness.

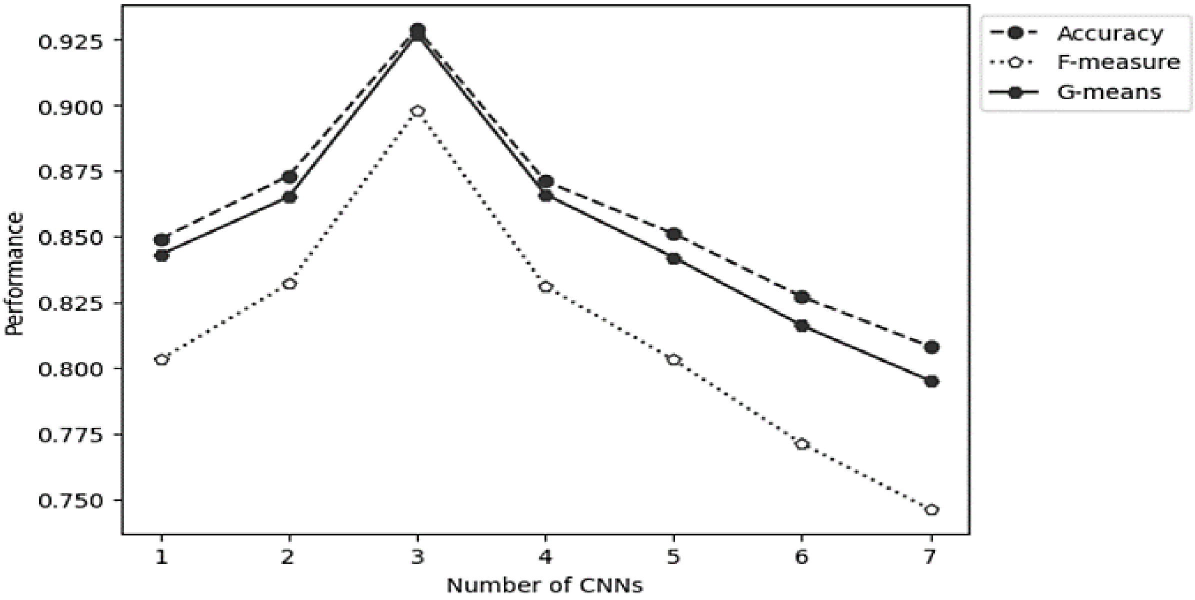

Fig. 6. Plotting the performance indicators of the suggested model while altering the quantity of convolutional feature extraction layers.

D. Discussion

The proposed model signifies a significant advancement in the landscape of anomaly detection methods within the domain of SHM. By incorporating dilated convolutional and DE and RL techniques, this model showcases impressive predictive accuracy. These strides in technological innovation are especially pertinent considering the current challenges that the field of civil infrastructure encounters on a global scale.

However, it is essential to subject the model to critical examination within a broader context of its applicability. While the initial results are promising, they are inherently tied to data originating from a singular architectural marvel – a long-span cable-stayed bridge situated in China. While an in-depth focus on a specific dataset can yield valuable insights, it also presents the potential risk of confining the model to a narrow scope. Civil engineering marvels around the world encompass an immense range – from complex metro rail networks navigating urban mazes to towering skyscrapers reaching for the skies. Each of these structures is the culmination of distinct combinations of design, materials, and environmental factors, leading to unique challenges in structural health. For example, a dam nestled within mountainous terrain would encounter vastly different issues compared to a highway bridge spanning a saline estuary. Each structure reacts to external influences in a nuanced manner, whether it is the ceaseless battering of waves, vehicular loads, or the immense pressure of contained water. Therefore, while the anomalies identified in the Chinese bridge dataset offer invaluable insights, they might only scratch the surface of potential structural concerns when considering the full spectrum of potential issues.

Furthermore, alongside the diversity in structures, the environments in which they exist introduce an additional layer of complexity. The health of a structure isn't solely a reflection of its construction but also a result of its interactions with the environment [37]. From corrosion due to saline exposure to vibrations induced by seismic activities, the array of external stressors is extensive. This raises legitimate concerns about whether the proposed model, primarily trained on the Chinese bridge dataset, can seamlessly adapt to the myriad challenges that structures worldwide encounter. To address these concerns, several solutions can be implemented:

- Diverse Data Collection: Expanding the training dataset to include data from structures in different environmental conditions and geographic locations.

This would enhance the model's ability to generalize across a wide range of scenarios [38].

- Environmental Conditioning: Integrating environmental factors into the model, allowing it to learn how different environmental conditions affect structural health. This could involve adding parameters that account for local climate, pollution levels, and other relevant environmental data.

- Transfer Learning: Applying transfer learning techniques to adapt the model trained on the Chinese bridge dataset to other structures. This approach involves fine-tuning the model with smaller datasets from different structures, enabling it to adjust to new environments with minimal data.

- Regular Model Updates: Continuously updating the model with new data collected from various structures over time. This would ensure that the model stays relevant and effective in predicting structural health under changing environmental conditions [3].

- Hybrid Modeling Approaches: Combining the strengths of different modeling techniques, such as physics-based models and data-driven models [39]. This hybrid approach can leverage the accuracy of physics-based models in well-understood scenarios and the flexibility of data-driven models in complex, variable conditions.

- Real-time Environmental Monitoring: Integrating real-time environmental monitoring systems to provide continuous input to the model. This would allow the model to adjust its predictions based on current environmental conditions.

- Stress Testing and Simulations: Conducting stress tests and simulations under various environmental conditions to validate and improve the model's accuracy in different scenarios.

As the field of civil engineering advances, embracing new materials and groundbreaking construction techniques, the characteristics of potential structural irregularities are likely to transform. A cutting-edge SHM system must be proficient in identifying established problems and adept at signaling new, unexplored issues [40]. This capacity forms a crucial benchmark that the proposed model must meet. The implications are significant; failing to detect a key anomaly can result in catastrophic events, loss of human lives, and severe economic consequences. To enhance the proposed model's capability in this dynamic field, several approaches can be considered:

- Incorporation of Advanced Learning Algorithms: Utilizing machine learning and artificial intelligence algorithms that are capable of identifying patterns and anomalies not only from past data but also adapting to new trends. Techniques like unsupervised learning or deep learning can be particularly effective in recognizing unforeseen issues.

- Continuous Model Updating and Training: Regularly updating the model with the latest data from ongoing construction projects and newly developed materials. This will ensure that the model stays current and can recognize anomalies associated with new construction methodologies.

- Collaborative Data Sharing: Establishing a collaborative network with other civil engineering projects and research institutions for sharing data and insights. This collective approach can significantly broaden the spectrum of scenarios the model is exposed to, enhancing its ability to identify a wide range of anomalies.

- Predictive Analytics: Incorporating predictive analytics to forecast potential structural issues based on current trends and construction practices. This proactive approach can help in early identification and prevention of structural failures.

- Cross-Disciplinary Integration: Integrating knowledge from other fields such as materials science, meteorology, and environmental engineering. This interdisciplinary approach can provide a more comprehensive understanding of how various factors might contribute to new types of structural anomalies.

- Regular Sensitivity Analysis and Testing: Performing sensitivity analyses and stress tests under a variety of conditions to evaluate the model's effectiveness in detecting anomalies in different materials and construction methods.

- Expert Involvement and Feedback Loops: Engaging industry experts in regular reviews of the model's performance, ensuring that practical, real-world insights are incorporated. Establishing feedback loops can also aid in continuous improvement of the model.

As we chart our course ahead, multiple paths invite investigation. Firstly, testing the proposed model against a range of SHM datasets that include different types of structures, such as high-rise buildings, bridges, tunnels, and historical monuments, could reveal its extensive applicability [41]. Employing transfer learning techniques to adapt pre-existing models to these varied scenarios could be key in rapidly broadening the model's utility without necessitating extensive data gathering from each new structure type. In addition to these approaches, several other strategies could be beneficial:

- Cross-Functional Collaboration: Engaging with experts from different fields within civil engineering and data science to gain insights into specific structural characteristics and data processing techniques. This collaboration could enhance the model's accuracy and relevance across various structures.

- Real-Time Data Integration: Incorporating real-time monitoring data into the model to continually update and refine its predictive capabilities. This could include data from sensors monitoring weather conditions, material fatigue, and other relevant parameters.

- Customizable Model Parameters: Developing the model with customizable parameters that can be adjusted according to the specific requirements of different structures. This flexibility would allow for tailored applications, enhancing the model's effectiveness across diverse structural contexts.
- Scalability and Efficiency Improvements: Optimizing the model for scalability and computational efficiency to handle large datasets and enable its deployment in large-scale projects, such as city-wide infrastructure monitoring.
- Community Engagement and Feedback: Involving community feedback, especially from those who live or work in or near monitored structures, to provide ground-level insights into the model's performance and impact.
- Robust Validation and Testing: Conducting rigorous validation and testing under various conditions and scenarios to ensure the model's reliability and accuracy, particularly in critical and emergency situations.
- Policy and Regulatory Alignment: Ensuring that the model aligns with existing policies, standards, and regulatory requirements related to structural health and safety, to facilitate its acceptance and implementation.

Furthermore, the ever-changing characteristics of civil structures require that our SHM systems adapt and improve constantly. Implementing online learning paradigms in the proposed model would enable it to dynamically adjust to evolving structural health patterns. This could be achieved by continuously feeding the model with live data and allowing it to learn and update its parameters in real-time. The integration of diverse data sources, such as vibrations, strains, temperature changes, acoustic emissions, and even visual data from inspections, would significantly enrich the model's predictive accuracy [42]. Several additional steps can be taken to enhance the model's utility and efficiency:

- Edge Computing Implementation: Developing the model for deployment in edge computing environments where data processing occurs closer to the data source. This reduces latency and can be crucial for timely decision-making, especially in emergency scenarios.
- User-Friendly Interface Development: Creating intuitive user interfaces for the model that enable engineers and maintenance personnel to easily interpret and act upon the data and predictions provided by the system.
- Automated Alert and Reporting System: Integrating an automated system that generates alerts and detailed reports when anomalies are detected, thereby facilitating prompt and informed responses from the relevant authorities or maintenance teams.
- Interoperability with Existing Systems: Ensuring that the model is compatible with existing infrastructure management systems and can be seamlessly integrated into current workflows, enhancing its practicality and adoption.
- Regular Benchmarking and Validation: Regularly comparing the model's performance with other state-of-the-art anomaly detection systems in the field to validate its effectiveness and identify areas for improvement.
- Sustainability and Environmental Impact Assessment: Considering the environmental impact and sustainability of the model, especially in terms of its energy consumption and the materials required for sensor deployment and maintenance.
- Training and Education for Stakeholders: Providing comprehensive training and educational resources for engineers, technicians, and stakeholders to understand and effectively use the model in their operations.

Finally, it is important to delve deeper into the specific mechanisms and algorithms used in state-of-the-art techniques for handling imbalanced datasets in RL [43]. This involves examining different approaches, such as oversampling, under sampling, synthetic data generation, cost-sensitive learning, and novel reward shaping strategies [44, 45]. By contrasting these methods with our own, we can identify unique advantages or shortcomings in both theoretical and practical applications. Investigating how these techniques perform in diverse RL environments, ranging from simulated tasks to real-world applications, will provide a more holistic understanding of their adaptability and robustness. It would also be beneficial to explore the integration of our technique with other advanced machine learning strategies like deep learning, transfer learning, and meta-learning, to enhance its performance in handling imbalanced datasets. Such an in-depth analysis will not only fortify our research but also pave the way for future innovations in the field, fostering a more effective approach to tackling the challenges posed by imbalanced datasets in reinforcement learning [46].

VI. Conclusion

This study introduced a groundbreaking model meticulously crafted to confront the intricate challenges associated with anomaly classification within SHM data. The proposed model harnessed a strategic fusion of dilated convolutional, RL, and DE techniques to achieve a high level of accuracy in its results. At its core, the model utilized a group of CNNs to extract essential feature vectors from input images concurrently. These extracted features were seamlessly integrated into downstream processes, bolstering the model's prowess in identifying complex patterns present in SHM data. The efficacy of the proposed model was rigorously validated through experimentation on an imbalanced dataset obtained from a long-span cable-stayed bridge in China-sourced from the IPC-SHM community. Handling imbalanced datasets poses distinct challenges in training classifiers, as the overrepresented class often exerts a disproportionate influence on the learning process, leading to suboptimal performance for the underrepresented class. To effectively address this concern, a novel approach was employed, integrating RL principles to formulate the training procedure as a series of interconnected decisions. Within this framework, the dataset samples assumed the role of states, while the model operated as the agent, receiving appropriate rewards or penalties based on accurate or incorrect classifications, respectively. This adaptive strategy enabled the model to place a heightened focus on the underrepresented class, thereby enhancing classification outcomes. An innovative contribution to the training methodology was introduced by incorporating a mutation operator grounded in clustering principles within the framework of DE. This approach initiated the BP process by identifying a prominent cluster within the existing DE population. Subsequently, a novel update strategy was implemented to generate potential solutions, adding a layer of sophistication to the training process. The experimental results underscored the superior performance of the proposed model in the detection of multi pattern anomalies within SHM data, showcasing remarkable accuracy. Through the adept amalgamation of dilated convolutional, RL, and DE techniques, the model exhibited its potential as an advanced tool for anomaly detection within SHM systems. This capability is of utmost importance in safeguarding the structural integrity and safety of critical infrastructures, including vital components like bridges.

***Abstract*—With the rapid development of artificial intelligence technology, the recognition accuracy performance of traditional gymnastic sports action recognition system can no longer meet the needs of today's society. To address these problems, an improved action recognition algorithm combining Precision Time Protocal (PTP) and Convolutional Neural Networks (CNN) is proposed, and a human-computer interaction gymnastic action recognition system based on PTP-CNN algorithm is constructed. The performance test of the proposed PTP-CNN algorithm was conducted, and it was found that the accuracy of PTP-CNN algorithm was 92.8% and the recall rate was 95.2%, which was better than the comparison algorithm. The performance comparison experiments of the gymnastic action recognition system based on the PTP-CNN algorithm found that the recognition accuracy of the PTP-CNN gymnastic action recognition system was 96.3% and the running time was 3.4s, which was better than the other comparison systems. Comprehensive results can be found that the research proposed PTP-CNN recognition algorithm and improved gymnastic action recognition system can effectively improve the performance of traditional algorithms and models, which has practical application value and great application potential.**

***Keywords*—PTP; CNN; human-computer interaction; gymnastic sports; action recognition**

I. Introduction

In recent years, with the development of technology, the application of artificial intelligence technology in the field of sports has become more and more extensive [1]. Among them, the human-computer interactive gymnastics sports action recognition system is a new type of artificial intelligence technology that can achieve automatic recognition and analysis of gymnastic actions through machine learning and deep learning algorithms [2]. The application of this system can improve the efficiency and quality of gymnastics training, which is of great significance to promote the development of physical education and training. At present, many scholars at home and abroad have researched and practiced the human-computer interactive gymnastics sports movement recognition system [3]. Some of these studies are based on machine learning algorithms and deep learning algorithms for design and implementation [4]. At present, the most commonly used gymnastics action recognition is mainly based on the convolutional neural network (Convolutional Neural Networks, CNN). The CNN can learn the feature representation automatically, and it has a strong non-linear modeling capability. However, the traditional CNN mainly relies on the input of video frames and cannot make full use of the timing information of the action sequence. Moreover, the traditional CNN is prone to the problem of gradient disappearance or explosion when dealing with long time series. These problems limit the effectiveness of traditional sports systems in accuracy, real-time and personalized learning [5]. Accurate time protocol (PTP), as an accurate time synchronization protocol, has the advantages of high precision, high reliability and strong flexibility, which has a wide range in computer systems and networks. It can introduce time information in the action recognition task, and improve the accuracy and timing modeling ability of gymnastics movements of CNN by analyzing the forward and backward correlation in the action sequence [6]. At present, few studies have combined PTP with CNN and applied it in sports action recognition. Therefore, we propose to fuse PTP and CNN to build a PTP-CNN recognition algorithm and build a human-computer interactive gymnastic sports action recognition system based on it. It is expected to improve the efficiency and quality of gymnastics training and promote the development of physical education and training. Section I is the introduction to the article. The study describes the practical application of CNN and PTP in Section II. In Section III, PTP-CNN motion recognition algorithm and human-computer interactive gymnastics motion recognition system based on PTP-CNN are constructed. In Section IV, the action recognition algorithm and human-computer interaction action recognition system are tested. Results and discussion is given in Section V and Section VI concludes the paper.

II. Review of the Literature

With the continuous in-depth research on CNN algorithms by domestic and foreign scholars, various CNN improvement models have been proposed and applied in several fields. In order to improve the recognition accuracy of coffee flowers, Wei et al. combined CNN model with binarization algorithm, selected a certain number of positive and negative samples from the original digital images for network model training, initially extracted coffee flowers based on the trained CNN model, and then further optimized its boundary information using binarization algorithm, and experimentally verified that the accuracy of this method for coffee flower classification was 93.7%, which has practical Application significance [7]. Chowdary et al. proposed a measurement system based on improved convolutional neural network in order to improve the accuracy of mango leaf disease identification, and the proposed measurement was compared and analyzed with the system based on fuzzy algorithm, and the results showed that the accuracy of the proposed improved CNN-based system was 95.32, and this result indicated that the system could greatly improve the identification of mango leaf disease accuracy [8]. Joy and Vijayakumar found that the region-based convolutional neural network RCNN achieves good target detection accuracy but consumes more time on training and detection, so the proposed FAST RCNN algorithm with domain adaptive increments uses selective search to obtain the bounding box and feature extraction, thus overcoming the limitations of RCNN and improving the training and detection speed and accuracy [9]. Zhang's team proposed a deep learning model based on the combination of deep convolutional neural network and long and short-term memory network for the classification of arrhythmia intervals to address the problem that arrhythmias are difficult to diagnose accurately. Ten-fold cross-validation of the method showed that the average accuracy of the method was 99.06%, which is of great significance in clinical applications [10]. Zhao et al. For the problem of distortion and artifacts in lossy compressed video, a learning model with variable filter size residuals is proposed based on CNN algorithm, and the effectiveness of this model is measured using a combination based on color sensitivity, and extensive experimental results show that it has a better performance than existing methods in terms of efficiency improvement after video coding. [11].

With the rapid development of information technology, there are more and more methods applied in the field of action recognition. Rubin's team proposed a faster region based convolutional neural network structure to address the problem of difficult to accurately recognize real-time gestures, and tested its performance on a standard data set. Carvalho et al. proposed a multi-standard action-based human-robot interaction framework in order to improve the accuracy of socially assisted robot action recognition. [12]. Carvalho et al. tested the method offline and online, and the results showed that the accuracy of the method exceeded 96.7%, which is practical and can be used in educational proposals. [13]. Hu's team addressed the problem that current action recognition methods tend to ignore the reversibility of skeleton data in the temporal dimension [14]. Gao et al. proposed a new forward-inverse adaptive graph convolutional network for skeleton-based action recognition to address the problem that the current graph convolutional network models focus more on spatial information and ignore temporal information, and empirically analyzed the method. Gao et al. propose a unified attention model that integrates channel, space, and time, and the model is tested for performance and found to have the best performance compared to other similar action recognition methods [15].

The above studies fully illustrate that the CNN improvement model has been widely used in several fields, and there are also various methods applied in the field of action recognition. However, there are fewer studies combining PTP methods with CNN algorithms, so the study combines PTP methods with CNN algorithms to obtain PTP-CNN algorithms, and applies the improved algorithms to human-computer interactive gymnastic sports action recognition, expecting to improve the accuracy of gymnastic sports action recognition in this way and promote the further development of gymnastics course intelligence.

III. Construction of Human-computer Interaction Gymnastic Sports Action Recognition System based on PTP-CNN Algorithm

A. *CNN Action Recognition Algorithm Based on the Principle of PTP Protocol*

PTP protocol, also known as IEEE1588 protocol, is currently a mainstream time synchronization system, which is perfectly suitable for modern communication technology at the same time, but also well combined with computer hardware time equipment [16]. PTP can be placed in the computer network multiple clocks, and the master clock source and other clock sources in the form of telegrams time, to achieve accurate synchronization of network time. The PTP protocol clock type is divided into ordinary clock, boundary clock, end-to-end transparent clock and point-to-point transparent clock [17]. PTP synchronization principle implementation process is shown in Fig. 1.

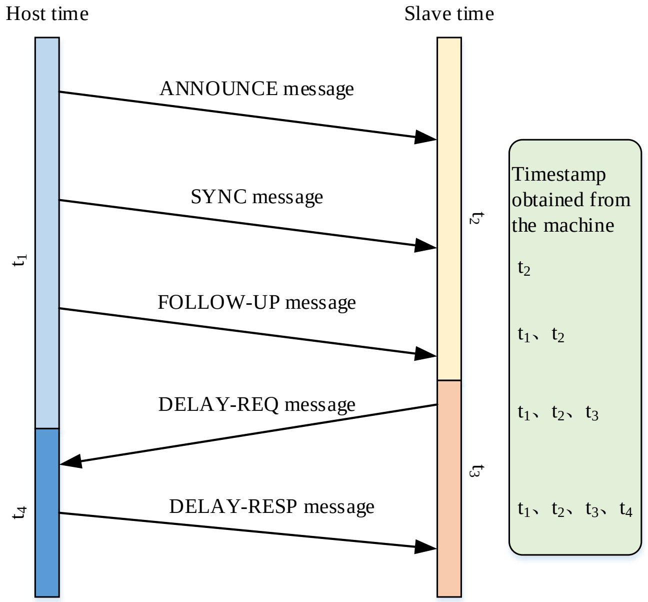

Fig. 1. Implementation process of PTP synchronization principle.

As it can be seen from Fig. 1, the PTP message flow is divided into four modules. First, the host sends an ANNOUNCE message to all devices in the slave, and the devices in the slave listening state will receive the ANNOUNCE message and set the host's clock source to the best master clock and set it to the uncalibrated state. Subsequently, the host sends a SYNC message to the slave and records the timestamp t_1, the slave receives it and records the timestamp t_2. The third module is the host sends a FOLLOW-UP message to the slave with the timestamp t_1 and the slave receives it and sends a DELAY-REQ message back to the host with the timestamp t_3. The host receives the

DELAY-REQ message and records the timestamp t_4. Finally, the host sends the DELAY-RESP message and the timestamp t_4 to the slave, and the slave finally gets a total of four timestamps. The slave obtains the link delay between the host and the slave by calculating the time deviation of the obtained timestamps from that of the host. The four timestamps t_1, t_2, t_1 and t_4 obtained by the slave are calculated as shown in Eq. (1).

$$\begin{cases} t_2 = t_1 + delay_{MS} + offset \\ t_4 = t_3 + delay_{SM} - offset \end{cases} \tag{1}$$

In Eq. (1), $offset$ is the time deviation from slave to host; $delay_{MS}$ is the link delay from host to slave; $delay_{SM}$ is the link delay from slave to host. When the values of $delay_{MS}$ and $delay_{SM}$ are the same, the link delay and time deviation are calculated as shown in Eq. (2).

$$\begin{cases} delay_{SM} = \dfrac{(t_2 - t_1) + (t_4 - t_3)}{2} \\ offset = t_2 - delay_{SM} \end{cases} \tag{2}$$

In Eq. (2), t_1, t_2, t_1 and t_4 are the time stamps obtained by the slave; $offset$ is the time deviation between the slave and the host; $delay_{MS}$ is the link delay from the host to the slave; $delay_{SM}$ is the link delay from the slave to the host. Due to the problem of link delay jitter in time synchronized networks in real networks. The study uses the second-order Kalman filtering algorithm to process the time deviation and link delay. The formula of first-order exponential smoothing filtering at this point is shown in Eq. (3).

$$y(n) = \alpha \cdot x(n) + (1-\alpha) \cdot y(n-1) \tag{3}$$

In Eq. (3), $y(n)$ denotes the value after the first n filtering and the initial value is 0; α is the coefficient of 0-1; $x(n)$ denotes the observed value of the first n. The cutoff frequency of the exponential smoothing filter is calculated as shown in Eq. (4).

$$\begin{cases} Y(Z) = \alpha \cdot X(Z) + (1-\alpha) \cdot Y(Z) \cdot z^{-1} \\ H(Z) = \dfrac{Y(Z)}{X(Z)} = \dfrac{\alpha}{1-(1-\alpha) \cdot z^{-1}} \end{cases} \tag{4}$$

In Eq. (4), $H(Z)$ denotes the system function; $Y(Z)$ denotes the discrete Z transformation of $y(n)$; α is the coefficient of 0-1; $Y(Z)$ denotes the discrete Z transformation of $x(n)$. The system frequency response is calculated as shown in Eq. (5).

$$H(e^{j\omega}) = H(Z)\big|_{z=e^{j\omega}} = \frac{\alpha}{1-1(1-\alpha) \cdot e^{-j\omega}} \tag{5}$$

In Eq. (5), $H(Z)$ denotes the system function; α is the coefficient of 0-1. The system amplitude and frequency response is shown in Eq. (6).

$$\left| H(e^{j\omega}) \right| = \left| \frac{\alpha\left(\cos\omega + j \cdot \sin\omega\right)}{\cos\omega - (1-\alpha) + j \cdot \sin\omega} \right| = \frac{\alpha}{\sqrt{1 + (1-\alpha)^2 + j \cdot \sin\omega}} \tag{6}$$

In Eq. (6), α is a factor of 0-1. $-3dB$ When the system cutoff frequency is calculated, the formula is shown in Eq. (7)

$$f = \frac{\arccos\left(1 - \dfrac{\alpha^2}{2(1-\alpha)}\right)}{2\pi} \tag{7}$$

In Eq. (7), α is a factor of 0-1. Since exponential smoothing filtering can effectively reduce the time deviation and thus improve the degree of system stability. The equation of control filtering at this point is shown in Eq. (8)

$$\begin{cases} l(n) = k\left(n\right) \cdot K_i + l(n-1) \\ m(n) = k(n) \cdot K_p + l(n) \end{cases} \tag{8}$$

In Eq. (8), $l(n)$ is the output value of the n integral control; $k(n)$ is the observed value of n; k_i is the coefficient of the integral control; $k(n)$ is the output value of the n exponential filter control; and k_p is the coefficient of the proportional control. The filtering process is shown in Eq. (9).

$$\begin{cases} filter_{es} = \alpha \cdot offset(n) + (1-\alpha) \cdot filter_{es}(n-1) \\ filter_l(n) = filter_{es}(n) \cdot K_l + filter_l(n-1) \\ filter_p(n) = filter_{es}(n) \cdot K_p + filter_p(n-1) \end{cases} \tag{9}$$

In Eq. (9), $filter_{es}$ is the exponential smoothing filter output value of n; α is the smoothing filter coefficient between 0 and 1; $offset(n)$ is the time deviation before the filter of n; $filter_i(n)$ is the integral control output value of n of the filter function; K_l is the integral control coefficient; $filter_p(n)$ is the proportional control output value of n of the filter function; K_p is the proportional control coefficient. After implementing the Kalman filter-based clock taming, the CNN action recognition algorithm based on the PTP principle needs to be constructed where the basic structure of CNN as shown in Fig. 2.

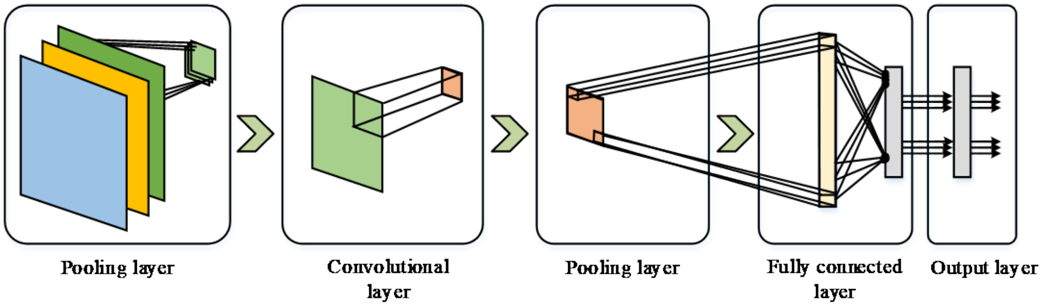

Fig. 2. CNN basic structure.

As shown in Fig. 2, CNN has five layers structure, which are input layer, convolutional layer, pooling layer, fully connected layer and output layer. Among them, the CNN convolutional layer is used for recognition and feature extraction of input data, including multiplication and addition of matrices, and its operation is closely related to the convolutional kernel [18-19]. The convolutional kernel is a feature extractor with sparse connectivity and weight sharing in the convolutional layer, and the convolutional kernel is trained to output a feature set that meets the needs [20]. The operation formula of the convolution layer is shown in Eq. (10).

$$x^{l}{}_{j} = f\left(\Sigma^{n}{}_{i\in M_j} x^{l-1}{}_{i} * k^{l}{}_{i,j} + b^{i}{}_{j}\right) \tag{10}$$

In Eq. (10), x^l and f are the output and activation function of the l layer, respectively; $x^{l-1}{}_i$ is the output of the $l-1$ layer; k^l and $b^l{}_j$ are the convolution kernel and offset term of the l layer; and M_j is the selected input feature set. The pooling layer divides the obtained feature set and reduces the dimensionality of the features to reduce the computational effort and enhance the robustness. The common operations of the pooling layer are mainly maximum pooling and mean pooling, and the two pooling methods are shown in Eq. (11).

$$a = \begin{bmatrix} 2 & 3 & 0 & 3 \\ 1 & 4 & 4 & 3 \\ 5 & 6 & 4 & 3 \\ 1 & 0 & 0 & 1 \end{bmatrix}, a_{\max} = \begin{bmatrix} 4 & 4 \\ 6 & 4 \end{bmatrix}, a_{ave} = \begin{bmatrix} 2.5 & 2.25 \\ 3 & 2 \end{bmatrix} \tag{11}$$

Finally, in order to prevent overfitting or underfitting of the model, reasonable optimization of the parameters is required. The study can use cross-entropy loss function and back propagation algorithm to calculate the error in fault multi-classification diagnosis. The formula of cross-entropy loss function is shown in Eq. (12).

$$H(p,q) = -\sum_{x} p(x)\log q(x) \tag{12}$$

In Eq. (12), $p(x)$ is the target distribution; $q(x)$ is the predictive distribution. The backpropagation algorithm is an algorithm for training a feedforward neural network for a given input pattern with a known classification using the chain derivation method. The backpropagation algorithm is the most common and effective method for training artificial neural network algorithms, and the essence is the error between the output and the target, as shown in Eq. (13).

$$\delta^{l-1} = \frac{\partial J}{\partial z^{l-1}} = \frac{\partial J}{\partial z^{l}}\frac{\partial z^{l}}{\partial z^{l-1}} = \delta^{l}\frac{\partial z^{l}}{\partial z^{l-1}}\frac{\partial a^{l-1}}{\partial z^{l-1}} \tag{13}$$

In Eq. (13), δ^l is the error of the objective function J to z^l. Finally, the PTP principle is fused with the CNN algorithm to construct the PTP-CNN recognition algorithm. the structure of the PTP-CNN recognition algorithm is shown in Fig. 3.

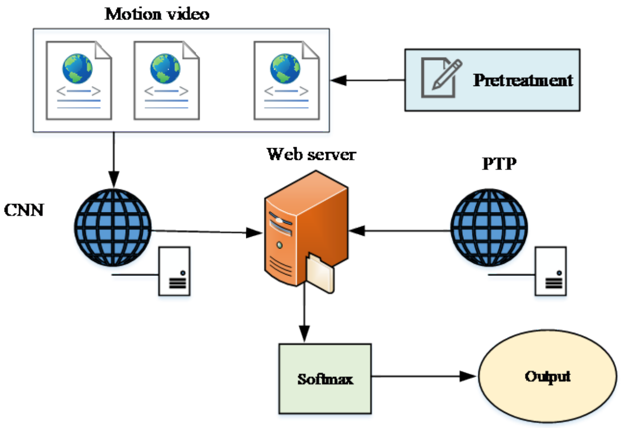

Fig. 3. PTP-CNN recognition algorithm structure.

Fig. 3 shows the structure of the PTP-CNN recognition algorithm, and the solid arrows in the figure represent the back-and-forth relationship between the modules in the PTP-CNN algorithm. As shown in Fig. 3, the PTP-CNN algorithm can extract the spatial features of video actions through CNN networks and fuse the convolutional features of different levels of CNN networks to enhance the feature representation. The temporal information in the video frames is modeled by PTP, and finally the classification results are obtained in using the class ware to recognize the human actions in gymnastics videos. To improve the recognition efficiency, the study first preprocesses the gymnastic video data with video frames, and adjusts the video frame size to (224*224) as the input. After completing the video pre-processing, the spatial features in the action video are extracted by CNN network and segmented into (224*224*3) size as input, the "3"in (224*224*3) indicates the channel dimension size. After that, the PTP-CNN algorithm fuses the shallow features with the deep features in the video through pooling and splicing operations to compensate for the missing feature information such as location contours. After several convolutions and pooling, the feature map with the output size of (7*7*2048) is pooled globally on average and expanded to (1*2048), using dropout to avoid overfitting of the results. Finally, the extracted feature vectors are input to the PTP time synchronization server to model the temporal information of the actions and the classification of the actions is achieved by a Softmax classifier.

B. Construction of Gymnastic Movement Recognition System Based on PTP-CNN Algorithm

After completing the construction of PTP-CNN recognition algorithm, the research will develop a gymnastic action recognition system. Since visual information is easily disturbed by external factors in real scenes, the accuracy and robustness of action recognition relying only on a single operational logic is very poor, so the research proposes a gymnastic action recognition system based on PTP-CNN algorithm. At the same time, in order to avoid the problem that the structure of the gymnastic action recognition system is confusing and difficult to expand, the research firstly designs the structure of the gymnastic action recognition system. The basic structure of the gymnastic action recognition system based on PTP-CNN algorithm is shown in Fig. 4.

As shown in Fig. 4, the gymnastic action recognition system proposed in the study takes reliability, practicality and scalability as design principles, and divides the system structure into four modules: web application layer, business logic layer, software development layer and basic function layer. The web application layer is the display page of the system to users, which includes user registration and login, video upload, action classification and recognition query functions. The business logic layer is the functional basis of the application layer, the main task is to manage the user database, complete the video pre-processing operation, and the video recognition and classification result analysis by PTP-CNN algorithm. The software development layer is the tool layer for system construction, including Pytorch framework, Python language, HTML/CSS front-end page development language and lightweight Flask framework, etc. The basic platform layer is the platform for the operation of the PTP-CNN gymnastic movement recognition system, and all the functions in the system cannot be realized without the support of hardware equipment and operation system. The hardware environment configuration of the gymnastic movement recognition system is AMD R5-4600H, 3.0GHz six-core twelve-thread processor, NVIDIA GeForce GTX1650Ti graphics card, 16GB running memory, 512GB solid state drive. The software environment is configured with Python language and Pytorch deep learning framework. the principle of PTP-CNN gymnastic action recognition system is shown in Fig. 5.

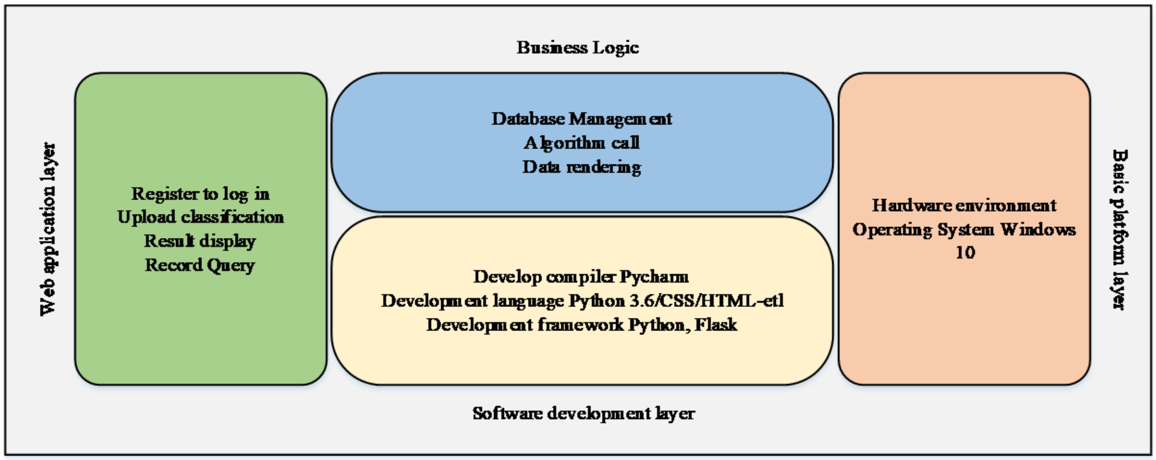

Fig. 4. Basic structure of gymnastic movement recognition system based on PTP-CNN algorithm.

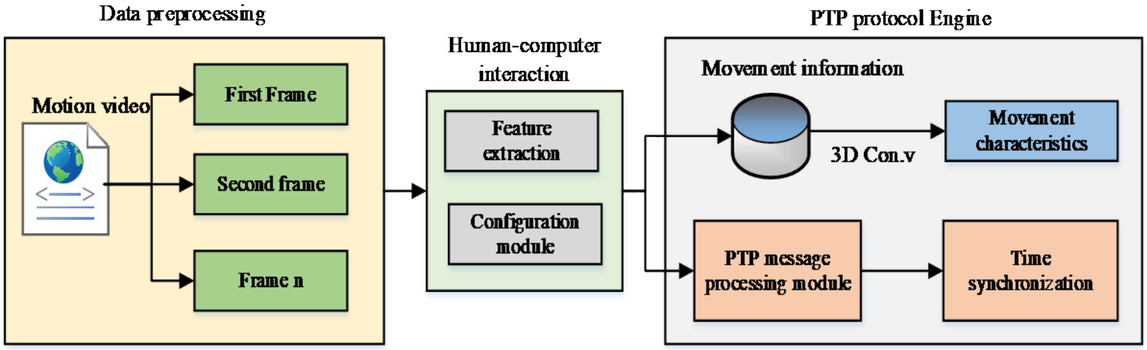

Fig. 5. Principle of PTP-CNN gymnastic movement recognition system.

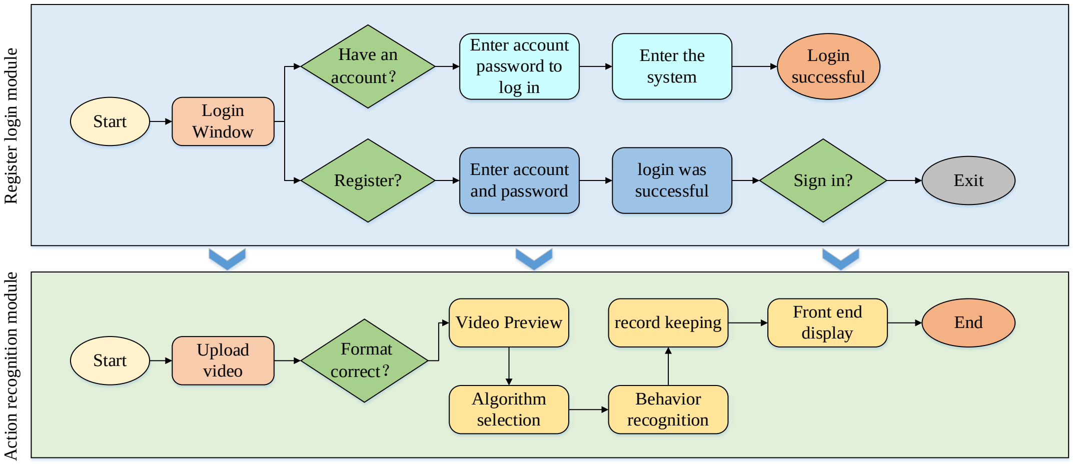

Fig. 6. The overall framework of PTP-CNN gymnastics motion recognition system.

As shown in Fig. 5, the proposed PTP-CNN gymnastic action recognition system consists of three modules, namely, the data pre-processing module, the human-computer interaction module and the PTP protocol engine module. In the data pre-processing module, the system decomposes the video in the dataset into continuous frames and feeds them into the HCI module. The principle of HCI module is to finish the feature recognition and feature extraction of gymnastics video by CNN algorithm. Finally, the PTP protocol engine module takes the video action information and different action features extracted by the CNN algorithm, models and fuses them in 3D, and outputs the gymnastic action feature recognition results. The overall framework of PTP-CNN gymnastics action recognition system is shown in Fig. 6.

As shown in Fig. 6, the PTP-CNN gymnastic action recognition system is mainly divided into the user's login and registration module, and the action recognition module of the underlying logic of the system. In the login and registration module, after the user enters the system login window, the system takes the user's username at the time of registration as the login account, and judges the submitted username when the user submits the registration information. If the user name is recognized to exist in the database, the user registration fails, otherwise the registration is successful, at this time the PTP-CNN gymnastics action recognition system generates a unique user number primary key for the subsequent query operation of the user. After the registration is completed, users can enter the system by entering the correct account password, at which time they can upload the gymnastics video. Since the PTP-CNN gymnastics action recognition system only supports video uploads in avi and mp4 formats, the system will identify the format of the video uploaded by the user. If the format is correct, it will enter the video preview stage; if the video format is wrong, it will return to the video upload stage. After entering the video recognition stage, the system will call the PTP-CNN algorithm in the background for action recognition and write the recognition result to the database history. After finishing the gymnastic action classification recognition, the background will package the recognition results into JSON format data to return to the front-end, and the results will be displayed in the user interface.

IV. Empirical Analysis of Human-Computer Interactive Gymnastic Sports Action Recognition System Based on PTP-CNN Algorithm

A. *Analysis of the Effectiveness of PTP-CNN Recognition Algorithm*

To verify the effectiveness of the PTP-CNN recognition algorithm for gymnastic sports action recognition, the study uses the public dataset UTKinect-Action3D to validate the effectiveness of the PTP-CNN recognition algorithm. the UTKinect-Action3D dataset contains activities corresponding to the gymnastic action recognition system, such as finishing exercises, stretching exercises, chest expansion exercises, full body movement, body rotation movement and jumping movement. The PTP-CNN recognition algorithms are compared and analyzed by the recognition accuracy, recall, F1 value, verification loss value (val-loss), and verification accurate values (val-acc) of these six corresponding actions. (Visual Geometry Group Network-16, VGG16), Residual Network (ResNET) and Dynamic Time Warping (DTW) algorithms. The recognition accuracy and recall curves of the compared algorithms are shown in Fig. 7.

Fig. 7(a) shows the recognition accuracy curves of the compared algorithms. From Fig. 7(a), it can be seen that the recognition accuracy of each algorithm increases with the number of iterations, and the PTP-CNN algorithm proposed in the study has an overall higher accuracy than the other algorithms, with an accuracy rate of up to 94.3% and an average accuracy rate of 92.8%. Fig. 7(b) shows the recall curves of the compared algorithms. From Fig. 7(b), it can be seen that the recall rate of each algorithm is smooth and does not change with the number of experiments, among which the PTP-CNN algorithm proposed in the study has a higher recall rate than the other algorithms, and its average recall rate is 95.2%. From the above results, it is clear that the accuracy performance and recall performance of the PTP-CNN algorithm proposed in the study are better than the other algorithms. Fig. (8) shows the accuracy-recall rate curves and F1 value comparison results of each compared algorithm.

(b)Val-acc curves of various comparison algorithms

Fig. 9. Validation losses and validation accuracy of each algorithm.

Fig. 8(a) shows the accuracy-recall curves of the compared algorithms. From Fig. 8(a), it can be seen that the accuracy-recall curve of the proposed PTP-CNN algorithm has the largest area under the line of 0.81 compared with other algorithms, which is 0.5 larger than the accuracy-recall curve of CNN. Fig. 8(b) shows the F1 values of each comparison algorithm. From Fig. 8(b), it can be seen that the proposed PTP-CNN algorithm has the largest F1 value of 0.93 compared to the other compared algorithms, which is 0.08 higher than the F1 value of CNN. In summary, it can be seen that the proposed PTP-CNN algorithm has the best performance in terms of accuracy-recall rate and F1 value performance. Fig. 9 shows the val-loss and val-acc values of the compared algorithms.

Fig. 9(a) shows the val-loss curves of each comparison algorithm. From Fig. 9(a), it can be seen that the val-loss curve of the proposed PTP-CNN algorithm has the lowest overall val-loss curve and the smallest fluctuation compared to the other comparison algorithms, with an average val-loss value of 0.72 and a fluctuation of 0.31. Fig. 9(b) shows the val-acc values of each comparison algorithm. From Fig. 8(b), it can be seen that the PTP-CNN algorithm proposed in the study has the largest val-acc value of up to 1.51 compared with the other comparison algorithms, which is 0.58 higher than the highest val-acc value of CNN. In summary, the results show that the PTP-CNN algorithm proposed in the study has the best performance in terms of the performance of verification loss and verification accuracy.

A. Comparison Experiment of Gymnastic Movement Recognition System Based on PTP-CNN Algorithm

To test the recognition performance of the PTP-CNN algorithm-based gymnastic movement recognition system, the study conducts a comparative performance analysis of the system. The study tests the performance of the system by comparing the recognition accuracy, recognition error and system running time, etc. The comparison system is a gymnastic action recognition system based on ResNET, VGG16 and CNN algorithm. The system test platform is composed of KinectV1.0, Windows10, VisualStudio and Unity. The recognition accuracy of each system is shown in Fig. 10.

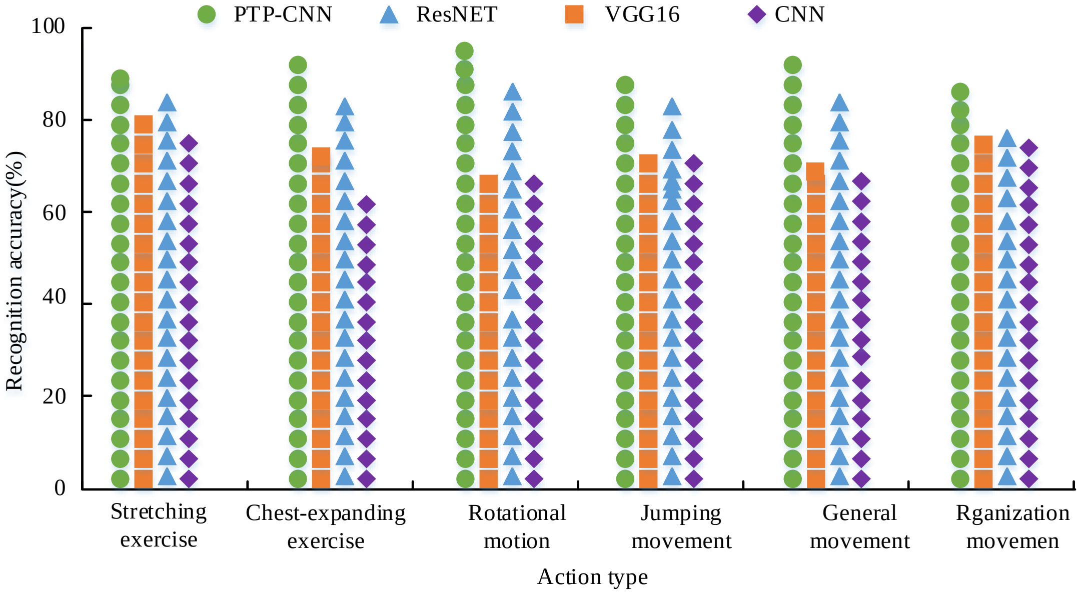

Fig. 10. Identification accuracy of each system.

Fig. 10 shows the recognition accuracy of the action recognition system based on PTP-CNN, ResNET, VGG16 and CNN algorithms for stretching, chest expansion, body turn, jumping, full-body and finishing movements. As shown in Fig. 10, the recognition accuracy of the PTP-CNN algorithm-based gymnastics action recognition system is higher than other comparison systems in six movements as a whole, among which the system has the lowest recognition accuracy of 93.4% for finishing movements and the highest recognition accuracy of 98.5% for full-body movements. The average recognition accuracy of the PTP-CNN algorithm-based gymnastic movement recognition system is 96.3%, which is 10.1% more accurate than that of the ResNET algorithm-based recognition system. Summing up the results, it can be concluded that the gymnastic movement recognition system based on PTP-CNN algorithm proposed in the study has the best performance in terms of movement recognition accuracy. The confusion matrix of the PTP-CNN algorithm-based gymnastic action recognition system is shown in Fig. 11 when the recognition results of the actions are compared with the actual actions.

Fig. 11 shows the confusion matrix of the gymnastic action recognition system based on PTP-CNN algorithm. From Fig. 11, it can be seen that the recognition accuracy of the gymnastic action recognition system proposed in the study is high on all six actions, indicating that the system has excellent recognition and classification ability on and distinguished actions, which has practical use value. To further verify the practical use performance of the PTP-CNN algorithm-based gymnastic action recognition system, the study conducted empirical experiments on the system to analyze its system recognition error and system computing speed, and the results of the empirical experiments are shown in Fig. 12.

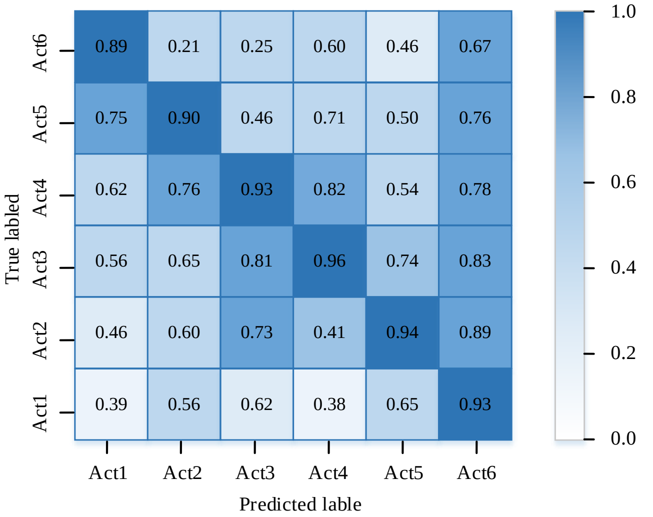

Fig. 11. PTP-CNN gymnastics recognition system confusion matrix.

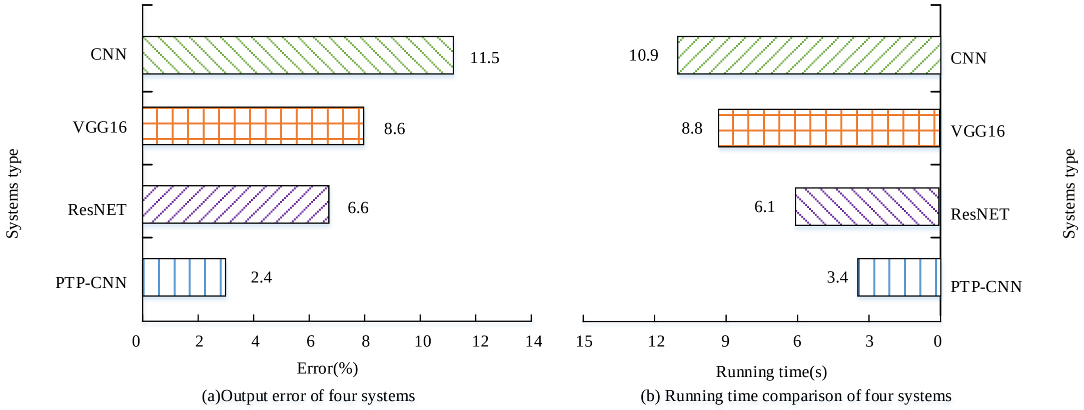

(a)Output error of four systems (b) Running time comparison of four systems

Fig. 12. Identification error and calculation time of each system.

Fig. 12(a) shows the recognition errors of gymnastic movements for each comparison system. From Fig. 12(a), it can be seen that among the four comparison systems, the system with the largest recognition error is the CNN algorithm-based gymnastic movement recognition system, whose recognition error is 11.5%. And the recognition system based on PTP-CNN algorithm has the smallest recognition error among the comparison systems, which is 2.4% and 9.1% lower than the gymnastic action recognition system based on CNN algorithm. Fig. 12(b) shows the operation speed of each comparison system. From Fig. 12(b), it can be seen that among the four comparison systems, the longest running speed is the CNN algorithm-based gymnastic movement recognition system, which runs for 10.9 s. The PTP-CNN algorithm-based recognition system has the shortest running time among the comparison systems, which is 3.4 s and 7.5 s shorter than the CNN algorithm-based gymnastic movement recognition system. Gymnastic movement recognition system has the best performance in terms of recognition error and running speed, and has significantly improved the performance compared with the traditional gymnastic movement recognition system.

V. Results and Discussion

It is found that the PTP-CNN motion recognition system can accurately identify the stretching, chest expansion, body turning, body jumping, whole body movement and finishing movement in gymnastics, with the accuracy rate of 96.3%, which is better than the traditional CNN motion recognition system. The findings are consistent with Yu et al. [21], which improved the accuracy of action classification and were applied to EMG control. In addition, the study also found that PTP-CNN human-computer interactive gymnastics motion recognition system has a short running time and has practical application value. Similar to the study of Majd et al. [22]., can be applied in the fields such as video surveillance. In addition, the action recognition system was applied to the path planning of the traffic system by Chen et al. [23]. Therefore, the proposed human-computer interaction gymnastics motion recognition system has good application potential in the fields of medicine, video surveillance, traffic and sports. In the medical field, the system can be used for rehabilitation training and evaluation, helping doctors to monitor patients' exercise recovery and provide targeted rehabilitation programs. In the field of video surveillance, the system can be used to monitor and identify human movements in real time, and help security personnel quickly detect abnormal or criminal behaviors. In the field of traffic, the system can be used to identify the driver's action and posture, monitor the driver's fatigue driving situation, remind the driver to pay attention to safety, so as to reduce the occurrence of traffic accidents. Most importantly, in the field of sports, the system can be applied in training and competition to help coaches and athletes analyze and improve movement skills, and improve training results and competition performance. In addition, the system can be used to evaluate the performance of the players and provide objective basis for the judges. In conclusion, the human-computer interactive gymnastics motion recognition system has wide application potential to play an important role in medicine, video surveillance, transportation and sports.

VI. Conclusion

In order to improve the recognition accuracy and operation speed of the traditional gymnastic action recognition system, the study proposes an action recognition algorithm that integrates the PTP principle and CNN algorithm, and builds a gymnastic action recognition system based on the PTP-CNN algorithm based on it. The performance tests of the proposed PTP-CNN algorithm and the improved gymnastic action recognition system are conducted. The results show that the PTP-CNN algorithm has the highest accuracy of 94.3%, the average accuracy of 92.8%, and the recall rate of 95.2%, which are better than the rest of the comparison algorithms in terms of accuracy performance and recall rate performance. In addition, the study also conducted performance comparison experiments on the improved gymnastic movement recognition system based on the PTP-CNN algorithm. The results show that the recognition accuracy of PTP-CNN gymnastic action recognition system is 96.3%, which is better than the other comparison systems. In addition, it is found that the average running time of PTP-CNN gymnastic action recognition system is 3.4s, which is lower than other comparison systems. The above results can be found that the proposed PTP-CNN recognition algorithm and gymnastic movement recognition system are better than the comparison algorithm and system in terms of recognition accuracy and running speed, and have practical application value. However, the study also has some limitations, compared to the gymnastics posture, including the extension, distortion and rotation of the body. This attitude change poses certain challenges to the accuracy and robustness of the algorithm. Future studies can explore more effective posture feature extraction methods according to the large posture changes in gymnastics movements, and improve the algorithm's ability to identify and model posture changes.

***Abstract*—In today's competitive service industry, the pressure to boost productivity, cut costs, and improve service quality is immense. By integrating lean principles and digital transformation, organizations can streamline processes and reduce waste. Although various lean models have been developed for different service industry, there is no universal standard. Hence, this study aims to address this gap by proposing a Lean Service Conceptual Model through qualitative research by identifying nine types of waste and seven lean dimensions. Interviews, observations, and audio-visual materials are the data collection methods used in this study. The model aligns seamlessly with modern digital technologies such as big data, the Internet of Things, blockchain, cloud computing, and artificial intelligence, making it adaptable for service organizations to excel in the digital age. The model focuses on enhancing efficiency and effectiveness while primarily reducing waste in service operations. Due to restrictions during the pandemic and the interest expressed by the informants in participating in this study, the focus is thus made on a single case study, which may lead to biased findings. However, future studies will be performed on multiple case studies to enhance the findings. Exploring and reviewing an array of best practices, techniques, and tools available for waste reduction within organizational operations is paramount.**

***Keywords*—Lean principles; digital transformation; model conceptual; service industry; waste; dimension; qualitative research**

I. INTRODUCTION

In the evolving environment of contemporary companies, two fundamental paradigms have emerged as transformative forces that shape the way organizations operate and deliver value, which is known as lean and digital transformation. The term "lean" refers to the principles and procedures of the Toyota Production System (TPS) [1]. Nowadays, lean is no longer limited to the manufacturing industry; it is all about doing more with less. Over time, the service industry has also effectively adopted the lean idea [2]. Without doubt, lean is successfully implemented in the service industry.

In today’s competitive world, service organizations are faced with enormous pressure to raise productivity, cut costs, and enhance the quality of their service. Lean is a practice used in overcoming such issues, and in creating more value for the customers. Studies on the implementation of lean service have indicated interesting trends that began in 2005, with an increase in the number of studies in the service industry such as healthcare, education, public services, hotels, banking, and information technology [3]. The modern economy is dependent on the service industry, which is very tightly tied to our daily life [4]. Lean implementation in the service industry has difficulty in assessing efficiency because the service industry focuses non-value-added activities on intangible assets [5]. Lean is necessary in improving performance [6]. Thus lean implementation approaches are used in identifying and reducing wastes [7].

In addition, the era of digital transformation has brought about uncommon technological progress and advancement. To keep up with the current opportunities and trends, organizations must therefore constantly innovate through a process known as digital transformation [8]; which is a process of building dynamic capabilities for the continuous strategic regeneration of organizations [9]. Digital transformation is the adoption of digital technology into all aspects of an organization’s operations that lead to a significant change in the way the organization operates and gives value for its customers [10]. The approaches towards digital transformation would adopt a different viewpoint that is aimed at accomplishing multiple goals [11]; impacting all aspects of the organizational process, activities, and structures [12].

Despite the growing acknowledgment of the significance of lean principles and digital transformation within the service industry, a discernible gap persists in the existing body of knowledge. While previous studies have delved into either lean practices or digital transformation individually, there remains a shortage of comprehensive research exploring the synergistic effects arising from the integration of lean principles with digital transformation in service organizations [13] . This study endeavours to address this gap by providing a holistic examination of how the convergence of lean principles and digital transformation can contribute to waste reduction in the operational service industry [14].

Our research aims to fill this void by offering valuable insights that not only tackle the current challenges faced by service organizations but also furnish a nuanced understanding of the potential benefits and challenges associated with this integration. Through this endeavour, we seek to provide practical guidance for practitioners, researchers, and policymakers in navigating the intricacies of contemporary service environments, with the goal of facilitating operational efficiency and waste reduction.

The integration of both lean principles and digital transformation has the potential to change the service industry

*Corresponding Author.

by enabling organizations to simplify processes, and thus reduce wastes. However, this integration is challenging due to the complexity of the technological requirements, culture, behavioural challenges and also the size of the organization [8]. Over the years, several lean models have been developed for different service industries. However, there is no standardized lean model that can be used for all service industries that have type of waste and dimension all together. Thus, the crucial need for future research to develop a standardized model for lean services [15]. Developing a standardized model is crucial because it ensures uniformity and comparability across studies, allowing for greater validation and reproducibility. Hence, rather than developing a completely new model, this study attempts to examine and employ appropriate models that are currently available for the implementation of lean services.

This paper aims to explore how lean principles and digital transformation may reduce waste in service organizations. We want to propose a conceptual model that enables service organizations to successfully navigate changes in this era of digital transformation, thus maximising their operational efficiency by reducing waste in the operation. Besides that, the scope of this study is to find the answers to the following research question.

RQ: How can the integration of lean principles and digital transformation lead to waste reduction in service organizations?

The organization of this article is as follows. Section II discusses the related works on lean service and data transformation. Section III presents the research method and activities and discusses the approach taken in conducting this study. Section IV presents the results, and Section V presents the discussion. Finally, the conclusion of this study is made in Section VI.

II. Related Works

A. Definition and Principles of Lean

Lean is a philosophy, a collection of lean techniques or tools, and the concept of waste elimination [16]. Lean is the most important word in any organization [17]. The goal of implementing lean in the service industry is the same as the manufacturing industry: to reduce waste and to enhance resource efficiency. Lean defines as the continuous elimination of waste in all areas of operation [18]. To stay ahead of their competitors, the service industry must address the needs of every consumer. Lean service operation must provide what the consumer wants, where he wants it [19].

The manufacturing industry is differentiated from the service industry in terms of waste and dimension. The manufacturing industry is involved in transforming goods or raw materials into new products such as machinery, computers, electronics, furniture, chemicals, food, and plastics [20]. On the other hand, the service industry creates value, particularly intangible values such as management, guidance, information, advice, design, data, and experience.

The two industries have different outputs, demands, customer-specific production, labour requirements, automated processes, and the location of physical production [21]. Table I illustrates the differences between the manufacturing and the service industry:

TABLE I. The Difference Between the Manufacturing Industry and the Service Industry

Differences	Manufacturing	Service
Output	Physical products that is observable and touchable by the customer.	Intangible.
Demand	Produces product stocks with inventory level that are parallel to the forecast of customer demand.	Does not keep inventories; service is provided as per customer request
Customer-specific production	Production can be performed without customer orders or customer demand forecast.	Service is provided only upon customer request.
Labour requirements and automated processes	Automating production process to reduce labour needs.	Need to recruit people with specific knowledge and skills.
Physical production locations	Must be physically found for production operation and stock keeping.	Does not require physical site for production.

Source: [21]

The difference in operation makes the service industry unique. It is important in generating economic growth [22]. With a contribution of more than half of a country's gross domestic product, the service industry is indispensable to the global economy [4], [11]. The service industry plays an important role in the global economy [23]. Many services industry try to distinguish themselves from their competitors by making improvements in their operation. Considering the current economic situation, the successful implementation of lean is expected to contribute to cost reduction and improvement of the service operation, [2]; which is achieved through the identification and elimination of waste [24].

Although lean in the service industry began in the 21st century and is continuously expanding [25], it is still a relatively new concept and has not been thoroughly researched [26]. The advantages of lean include reduced inventory, increased process understanding, operational cost reduction, less re-work, reduced lead-time, and less process waste [27]. Although the implementation of lean in the service industry offers numerous advantages, it is nonetheless challenge-free [28]. The main challenge is the lack of awareness regarding its advantages [15].

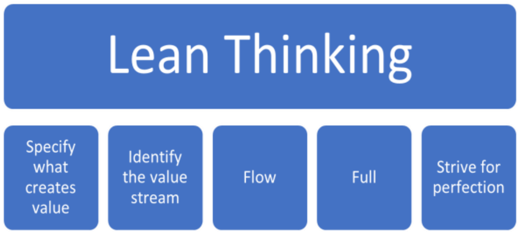

Fig. 1. Five principles of lean thinking.

Lean Thinking is a principle that could improve the efficiency of the service industry, reduce its operating costs, and increase operations capability [29], [30]]. Over time, Lean Thinking has expanded tremendously in the service industry, providing excellent benefits [31]. Lean becomes a way of thinking, whereas practices or tools are ways to put these beliefs into reality [15]. Fig. 1 show the five principles of Lean Thinking are; specify what creates value, identify the value stream, flow, pull, and strive for perfection [23].

B. *Models of Lean*

This section examines several models of lean based on the review of the literature made between the years 2004 to 2022.

A model for lean production is explained and translated into service industry [32]. The Ahlstrom model is the earliest model designed to assess the level of lean implementation in an organization. The model indicates; (1) lean development, (2) lean procurement, (3) lean manufacturing, (4) lean distribution form, and (5) lean enterprise or organization that is competitive at the global level. However, this model does not indicate the wastes that may exist in an organization.

Vadivel & Sequeira [3] developed a model to investigate lean service activities and their impact on operational performance in the Indian postal service. However, the development of the model is restricted to their consideration for and selection of methods, tools, and techniques that were only put out in the empirical literature review. Other than that, neither the types of waste nor the way that lean should be implemented in an organization's operations are discussed in their model.

In a study by Sreedharan V et al. [33], a focus group and a structured literature review are used in constructing the Green Lean Six Sigma (GLSS) model for the public industry. This model consists of three different stages; procurement, production, and distribution, whereby the flow of activities starting from the procurement to distribution are depicted in the model. Bajjou et al. [34] developed an input-output model for the construction industry. This input-output model consists of three processes; the input, transformation process, and the output, whereby each process has its own principles. However, no mention of the types of waste is made in these models.

Iranmanesh et al. [35] proposed a model to investigate the effects of lean practices involving the aspects of process and equipment, manufacturing planning and control, human resources, product design, supplier relationship, and customer relationship. However, no discussion is made on the effects of waste on the sustainable performance of the manufacturing firms. A product-service system (PSS) leanness assessment model is developed by Elnadi & Shehab [31]. This assessment model consists of three levels; the enablers, criteria, and attributes that are used in proposing an index to assess the leanness of PSS in a United Kingdom manufacturing company. However, this model does not involve the assessment of any type of waste.

In addition to that, in a study conducted by Abdul Wahab et al. [36], a model of lean production dimensions and its relation to waste has been developed. This model serves as a guideline for management team in examining the types and places that waste can occur in the manufacturing industry. The model consists of seven dimensions that are the functional areas in the manufacturing industry. It also states eight types of waste that might exist in each dimension. These seven dimensions are Supplier Relationship, Customer Relationship, Product Development and Technology, Manufacturing Process and Equipment, Manufacturing Planning and Scheduling, Customer Relationship, and Visual Information System. The eight types of waste are waiting, defect, overproduction, transportation, motion, inventory, extra processing, and underutilized people. However, the dimensions and types of waste presented in this model are specified for the manufacturing industry, hence this model is not applicable for the service industry.

A model is therefore required in providing the right guidance and directions for industries, specifically those in the service industry, to enhance their operations. Although the process of becoming a lean service organization takes time and effort, the development of a model for guiding and tracking the results of such effort is of paramount importance to speed up the process.

C. *Types of Waste*

Lean is the outcome of Taichii Ohno's invention of the Toyota Production System that aims to reduce waste. To identify the "*Muda*" or waste in lean service, a review of the literature of previous studies is performed. Waste is defined as any activity that increases the cost, but does not add any value from the customers' perspective [26], [37], [38]. Besides that, lean is about improving quality to eliminate waste [15]. Lean is also an approach of eliminating waste in a process and creates value for the customers [39].

Identifying waste in a service industry can be complex because the operations are intangible [23]. Several types of waste identified by Ohno [40] in the manufacturing industry also exist in the service industry: over-production, inventory, waiting, motion, transportation, defects, and over-processing. Waste in the form of underutilized resources and a manager's resistance to change are also mentioned in the service industry [1], [23].

The discussion on lean service by Mohammad Amin et al. [24] examines nine types of waste; over-production, inventory, waiting, motion, transportation, defect, over-processing, underutilized resources, and manager's resistance to change, which is depicted in Fig. 2.

In this work, the types of waste are identified based on their definition. Table II shown the definition of waste based on the service perspective.

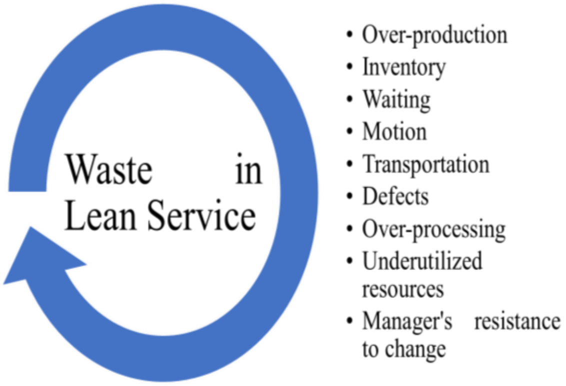

Fig. 2. Waste in lean service.

TABLE II. THE DEFINITION OF WASTE FROM THE PERSPECTIVE OF SERVICE INDUSTRY

Waste(s)	Definition
Inventory	Any work in process (Work-in-Progress) that exceeds what needs to be produced for the customer, inventory accumulation that causes the overuse of storage space, and reduced worker productivity due to the surplus of inventory [23], [41].
Transportation	Unnecessary movement of materials, products, information, workers and forklift operators [23], [41].
Waiting	Waiting whereby the employees or customers must wait for information or service delivery. Waiting is also involved when employees are ready to resume work, yet are unable to do so due to product, machine, or system unavailability [1], [23].
Motion	Unnecessary movement of resources or workers that need to bend over to choose items [1], [23].
Over-production	The completion of more work than required or before customer demand, which can lead to overcrowding [1], [23].
Over-processing	Adding unnecessary value to a service or product that is not requested by the customer, or will pay for, including unnecessary inspection and packaging [1], [41].
Defect	Any aspect of the service that does not suit the customer's needs, such as selecting incorrect items or incorrect quantity of an item [1], [23].
Underutilized resources	Waste of resources, especially human potential, not utilizing the talent and potential of employees, underutilizing their skills, creative abilities, and knowledge [1], [23], [42].
Manager's resistance to change	The attitude of "saying no" by the management, does not encourage all employees to be involved in the continuous process of improvement [23].

D. *Dimension*

The understanding of the dimension of lean implementation is an important aspect in improving operational performance. Lean implementation dimension does not only serve as a strategic guide in identifying and overcoming waste in the service process; it also acts as a guide for the formation of an organizational culture that focuses on efficiency, quality, and customer satisfaction.

Several variations of the functional domains or operational dimensions used in assessing the level of organizational implementation have been identified in the previous studies. However, most studies would focus on the dimensions without discussing the situations where waste could occur. Table III below depicts the definition of the dimensions of lean in the service industry.

E. *Digital Transformation*

Digital transformation has become one of the most discussed topics, and many industries have embraced digital transformation to acquire a competitive edge and maintain their sustainability [49]. Service industry operate their businesses, provide customer service and support by changing their way of operating through digital transformation [50].

Amidst the dynamic business landscape changes, service organizations are adopting digital transformation. Digital transformation enables service organizations to manage their operations more efficiently and effectively through the reduction of operational waste. At present, the term digital transformation does not have any recognized definition [51] since the scholarly literature lacks specific definitions [52]. Table IV illustrates some of the definitions of digital transformation [52].

There are new technologies that have become the trend in digital transformation, for example big data [52]–[54], the Internet of Things [9], [52]–[54], blockchain [9], [52], cloud computing [9], [53], [54], and artificial intelligence [52], [54]. These technologies offer new uses based on innovation and focus on the needs of the consumers [52]. Fig. 3 shows the technologies for digital transformation.

TABLE III. DEFINITION OF LEAN DIMENSION

Dimension	Definition
Lean Supplier	A supplier is a person or company that provides goods or services to another person or entity. The seller is referred to as the supplier. The basic function of supplier management is to control cost, quality, delivery performance, and billing accuracy. Adapted from [43], [44].
Lean Workforce Management	Workforce management is the process of strategically optimizing employee productivity to ensure all resources are in the right place at the right time. Workforce management strategies include scheduling, forecasting, skills management, punctuality and attendance, daily management, and employee empowerment. Adapted from [45].
Lean Operations Development and Technology	Lean Operations Development and Technology refers to the choice of operational structure, materials, and technical solutions in adopting service methods in line with the latest technology or innovative practices to increase operational capability. Technology is used to increase the autonomy of result-oriented groups and the distribution of responsibilities in operations. Adapted from [32], [46].
Lean Service Provision Process	Lean Service Provision Process refers to all activities required in producing services by using the collection of methods and materials or techniques in service operations that emphasize service quality standards, workplace layout, productive use of equipment and maintenance, material handling, safety, hygiene, and ergonomic aspects to reduce service preparation time. Adapted from [46].
Lean Service Planning and Scheduling	Lean Service Planning and Scheduling refers to all activities required to coordinate services and market demand, and thus increase the ability to meet customer orders. This minimizes variation in service operations, which can be achieved by optimizing resource use into a seamless service flow and by maximizing productivity through usage of appropriate service scheduling methods, and tools or techniques. Adapted from [46].
Customer Relationship	Customers are people or organization who receives, use, or purchase products or services, and they can choose different goods and suppliers. Customer relationship refers to the establishment of a relationship with the customers by obtaining information about their needs and wants customers for better understanding of their preferences. This relationship is also important in deciding the value and quality of service from their perspective, and all worthless activities can be targeted for elimination. Adapted from [46]–[48].
Visual Information System	Visual information system refers to an information system that delivers prompt and useful flow of information to relevant decision-makers to obtain quick feedback and corrective actions. This is achieved by using certain visual tools for different purposes in the workplace, such as visual boards, operational status, and performance information that enable the specific personnel to perform tasks appropriately according to company goals. Adapted from [32], [46], [47]

TABLE IV. CURRENT DEFINITIONS OF DIGITAL TRANSFORMATION

Author (s)	Definition
Matt et al. (2015)	Digital transformation strategy is a blueprint that supports organization in governing the transformations that arise owing to the integration of digital technologies, as well as in their operations after a transformation.
Hess et al. (2016)	Digital transformation is concerned with the changes digital technologies can bring about in a company's business model, which result in changed products or organizational structures or the automation of processes. These changes can be seen in the rising demand for Internet-based media, which has led to changes in the entire business models (for example, in the music industry).
Liere-Netheler et al. (2018)	The use of new digital technologies (social media, mobile, analytics, or embedded devices) to enable significant business improvements (such as enhancing customer experience, streamlining operations, or creating new business models).
Horlach et al. (2017)	Digital transformation as encompassing the digitization of sales and communication channels, and the digitization of a firm's offerings (products and services), which replaces or augments physical offerings. Furthermore, digital transformation entails tactical and strategic business moves that are triggered by data-driven insights and the launch of digital business models that allow new ways of capturing value.
Westerman et al. (2011) Westerman et al. (2014) Karagiannaki et al. (2017)	The use of technology to radically improve performance or reach of enterprises.

Source: [52]

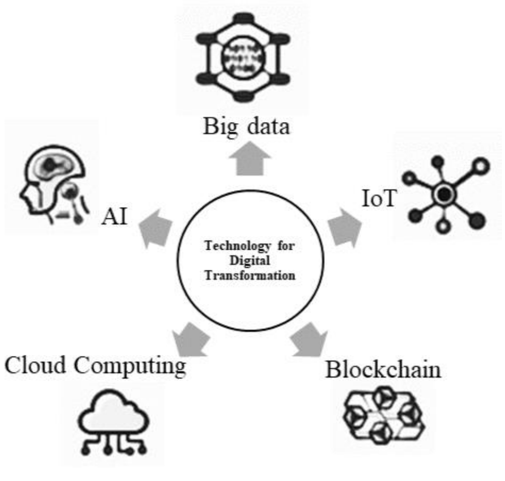

Fig. 3. Technology for digital transformation.

1) Big data. Big data is a method and technique to retrieve, collect, manage, and analyse large and complex data in which traditional methods of processing data are difficult [52], [55]. The utilization of big data is also on the rise within the waste management and recycling sector [54]. On the other hand, the use of big data requires for careful planning and implementation [56].

2) Internet of Things (IoT). This is one of the technologies essential in the evolution of services, and in increasing customer value [57]. IoT involves the connectivity of physical objects to the Internet or other interconnected systems using sensors and actuators [52]. The communication and exchange of data among physical objects can be performed using IoT. The progress in IoT is not restricted solely to Industry 4.0, as it is also concurrent with the evolution of the service transformation [57].

3) Blockchain. Currently, several study fields are paying attention to a new technology known as blockchain [58]. which has become a top technology layer for financial applications [59]. It is practical and appropriate for network providers to trade processing and networking resources using a blockchain-based solution [60]. Blockchain has generated interests as an innovative technology that has the potential to provide substantial cost reductions by allowing transactions to be carried out as peer-to-peer operations directly between users [61]. Using blockchain platforms for service institutions is crucial for specific purposes [62].

4) Cloud computing. Cloud computing makes it possible for information to be distributed effectively, regardless of the location [53]. This technology plays a significant role in the service industry; customers want to reduce costs, whilst cloud computing service providers provide their customers with services that maximize their earnings [63]. It refers to the delivery of various computing services, and builds on well-established trends for reducing the cost of service delivery [64].

5) Artificial Intelligence (AI). Artificial intelligence allows for precise decision-making that offers significant time and cost savings through data collection, forecasting, and trend analysis [65]. For the last two decades, AI has greatly improved the performance of the manufacturing and service industries [66]. AI can also be used for a wide range of tasks, such as identifying data trends to reduce market risks, improving customer service with the help of virtual assistants, and analysing large document repositories spread across numerous servers within an organization to find instances of compliance violations [65].

Digital transformation is reshaping the service industry in profound ways. The integration of technologies such as big data, IoT, blockchain, cloud computing, and AI is driving a fundamental shift in the way service organizations operate and engage with their customers. This transformation enhances operational efficiency, and enables for personalized customer experiences. By using these digital technologies, service providers may go beyond the customers' expectations.

III. METHOD

A. Research Design

During the research design phase, we meticulously reviewed current methodologies employed in studying lean methods within the service industry. Our investigation entailed a comprehensive examination of a variety of qualitative and quantitative approaches. Table V shows the quantitative versus qualitative approaches.

The quantitative approach involves statistical analysis to analyse trends and relationships, comparing results with predictions and past research, while the qualitative approach focuses on descriptive data analysis, identifying themes through text analysis, and interpreting findings within the study's context [68]. The case study approach encompasses a set of methods that emphasize the choice between a qualitative or quantitative approach [69].

TABLE V. QUANTITATIVE VERSUS QUALITATIVE APPROACHES

Quantitative approach	Qualitative approach
Measure objective facts	Construct social reality, cultural meaning
Focus on variable	Focus on interactive processes, events
Reliability the key factor	Authenticity the key factor
Value free	Values present and explicit
Separate theory and data	Theory and data fused
Independent of context	Situationally constrained
Many cases, subjects	Few cases, subjects
Statistical analysis	Thematic analysis
Researcher detached	Researcher involved

Source: [67]

A qualitative method was used in this study to achieve the aim of gaining understanding about lean in the service industry. The decision to adopt a qualitative approach is based on its capability to thoroughly explore the detailed complexities and subjective aspects of implementing lean principles within the service industry.

A qualitative method is an approach that requires the researcher to approach the study subject directly; to observe, listen, ask, and verify [70]. This method explores the informants' perspectives in order to comprehend a group or phenomena [71]. The purpose of qualitative data collection is to determine the types of data that will answer the research questions [68]. As shown in Fig. 4, this study was conducted in three phases, which included (1) Data collection, (2) Analysis, and (3) Result.

Data collection
Analysis
Result

Fig. 4. Research design.

B. Phase 1: Data Collection

Data collection for this study was performed through focus group interview, observation, and audio-visual materials.

1) Interview protocol: An interview protocol was developed to validate the conceptual model. Questions on the interview protocol were used to collect data for model validation. The goal of a study is outlined in its interview protocol [72]. The interview protocol used in this study is a semi-structured interview; the interview is performed based on the questions and sequence of questions pre-determined by the interviewer, and the important content is recorded during the interview session [71].

The interview protocol was constructed by designing questions based on the components in the conceptual model. There are thirty-nine questions that are divided into five parts; Part A: Demographics, Part B: Dimension of Lean in Services, Part C: Relationship among the Dimensions of Lean, Part D: Relationship between the Dimension of Lean and Waste, and Part E: Role of Information Technology in Lean Implementation. Table VI shows the number of questions for each section in the interview protocol for model validation.

The content of the interview protocol has been validated prior to the interview session. The experts in lean commented on every question of the protocol. Four experts took part in validating this protocol; two are academicians actively engaged in lean research, and the other two are from the industry with knowledge of lean. These four experts were approached and invited by e-mail; they were given the protocol interview and one week to complete the evaluation.

A document having the interview questions was given to each informant prior to the interview so that they are familiar with the questions to be posed during the interview session. The interview began with an explanation of the lean conceptual model for the service industry before moving on to the structured questions.

2) Focus group interview: The purpose of the focus group interview is to validate the conceptual model. Focus group interview can be used to discuss issues at a more strategic level [73]. Focus group interview allows for multiple informants to be simultaneously interviewed [72]. A purposive sampling procedure was used to choose the sample for this study. However, as purposive sampling is a frequent case study methodology strategy and will yield the most information about the subject under study, snowball sampling was used [74].

Focus group interview usually consists of four to six informants [68]. Thus, four informants were identified from the researcher's initial contact with workers from the case study companies, and were then selected for the interview. A network was later created by asking41 the first group of informants to refer more informants for the focus group interview. Table VII is four informants who expressed their interest in taking part in this study.

TABLE VI. NUMBER OF INTERVIEW PROTOCOL QUESTIONS

Part	Total
Part A: Demographics	8
Part B: Dimension of Lean in Services	8
Part C: Relationship Among Dimensions of Lean	4
Part D: Relationship between Dimension of Lean and Waste	17
Part E: Role of Information Technology in Lean Implementation	2
Total question(s)	39

TABLE VII. LIST OF INFORMANTS FOR INTERVIEW

Informant number	Role	Years of experience
IN1	Warehouse Executive	16
IN2	Cargo Operation Executive	3
IN3	Cargo Operation Officer	1
IN4	Cargo Operation Officer	1 1/2

Focus group interview informants were contacted to obtain their consent to take part in the interview session. A total of four informants were contacted, to whom the interview protocol was sent via email prior to the interview session in preparation for the interview.

The focus group interview session lasted for 73 minutes involving a conversation between the researcher and the informants to obtain relevant data and information. The data and information include; types of dimensions in services, the relationship among the dimensions, the relationship between waste and the dimensions, and the role of information technology in the implementation of lean.

The interview session was physically conducted at the meeting room of the case study company on September 1, 2022. Prior to the session, permission was sought from the informants for the conversation to be recorded [75] using a voice recorder. Although the researcher controlled the discussion by asking questions based on the interview protocol questions, the informants were given the opportunity to speak and share their views freely.

3) Observation: The purpose of the observation is to validate the conceptual model. Observation is one of the processes of gathering information openly, directly by observing people and places at the site of the study [68]. The data obtained from the observation in this study are in the form of audio-visual materials and field notes. Since permission to observe the interview was granted for only 60 minutes, it was conducted on September 1, 2022, at the case study company. The researcher was accompanied by three employees from the case study company who understand the operational processes of their company. They consist of a warehouse executive, a cargo operation executive, and a cargo operation officer.

The role of the researcher was only as an observer, not a participant. Non-participant observers are observers who visit the site and record data without being involved in the activities of the participants [68]. Observation of the operational process was performed with the guidance from the three workers who explained the activities that take place in each process.

4) Audio-visual material: Data collection was audio-visual materials that made up of photos or sounds of people or locations captured by the researcher or another person to assist the researcher in comprehending the core phenomenon under investigation [68]. During the observation, audio-visual materials such as pictures and videos of the process were taken.

C. Phase 2: Analysis

Qualitative data analysis involves the systematic process of identifying meaningful information from the data obtained. In this study, qualitative data was obtained from focus group interview, observation, and audio-visual materials. Fig. 5 is a guideline used in analysing the qualitative data [68]. Prior to the data analysis process, focus group interview data and observations were collected and organized into file folders on the computer. Then the interview data was transcribed by the researcher as data preparation for analysis. The collected data were read repeatedly to comprehend the coding of the data. Encoding the data is conducted for analytical reports.

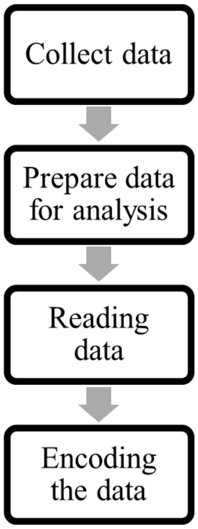

Fig. 5. Qualitative data analysis process.

1) Data transcription: Transcription is frequently used in qualitative research [76]. Transcribing an interview involves converting audiotape recordings into text data [68]. There are no common guidelines or procedures for transcription [77]. Hence, below are four steps used in transcribing the interview of this study:

- Prepare data during interview by recording the conversation.
- Listen to the recording multiple times when transcribing.
- Identify the informants and label them accordingly while transcribing.
- Use timestamps to show when an informant starts or stops speaking.

2) Themes and code: Analysis of the data was conducted using a computer software program for qualitative data, such as interview transcripts and pictures, using Atlas.ti. The data was explored and coded by reading all data collection and then employing the codes. Codes were also collected to create themes that were used as the main findings of the study [68]. Before the data were coded, code themes were decided based on the type of waste and dimension of lean service.

3) Validation and reliability: Triangulation is the use of different sources of information to help confirm and improve the clarity or accuracy of research findings [73]. Triangulation is also seen as a qualitative research strategy to test validity through the convergence of information from different sources [78]. The same interview protocol was used for all case study informants during triangulation to increase reliability [79]. This study has chosen a combination of data from focus group interviews and observations to provide triangulation results [80]. Triangulation is used to support the principle in case studies that phenomena are seen and explored from multiple perspectives [81].

D. Phase 3: Result

A conceptual model was developed and revised through a case study after the analysis of the data collection was performed. A case study is an intense description and analysis of an experience, social unit, or system related to time or place [82]. A qualitative case study is an ideal method for understanding and interpreting experience. The qualitative case study methodology enables researchers to carry out a thorough investigation of complex phenomena within a particular setting [83].

IV. Results

To answer the research question "How can the integration of lean principles and digital transformation lead to waste reduction in service organizations?", the qualitative data approach has been carried out. The qualitative method has been successful in gathering feedback from the informants about the dimensions of lean in services, relationship among the dimensions of lean, relationship between the dimension of lean and waste, and the role of information technology in lean implementation. Fig. 6 shows the lean conceptual model that has been developed for the service industry.

In this study, dimensions are defined as functional areas that carry out specific activities and roles in an organization in achieving the organizational goals. There are seven dimensions of lean that exist in the service industry, namely:

- Lean Supplier
- Lean Workforce Management
- Lean Operations and Technology Development
- Lean Service Provision Process
- Lean Service Planning and Scheduling
- Customer Relations
- Visual Information System

Next, in the manufacturing industry, the product production process can be represented as an input-output model, where resources in the form of raw materials will be transformed into finished products due to the output of the system. All informants agreed that all seven dimensions stated can also be represented as input-output processes in the service industry. All the phases in the lean conceptual model will be created based on user or consumer demand.

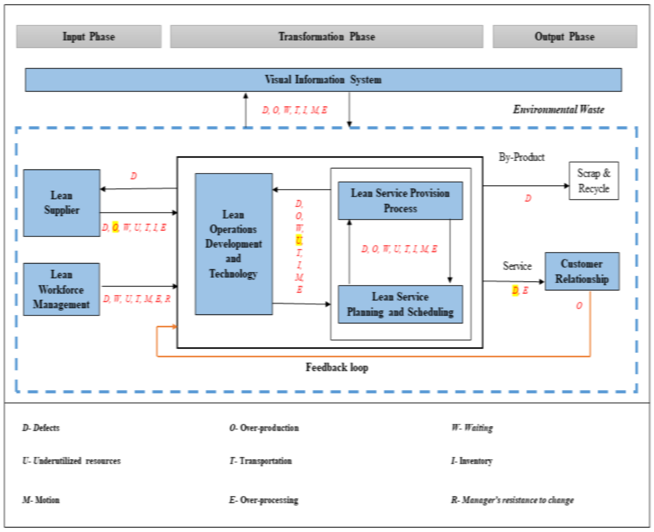

Fig. 6. Lean service conceptual model (Adapted from [46]).

According to the informants, the lean conceptual model reflects the detailed service operations of the informants' company; business activity must be conducted when there is a demand. All dimensions and their relationships cannot be less than one since the dimensions are interrelated, as specified by the researcher in the initial conceptual model.

Analysis of the data revealed that the informants' organization has nine types of wastes, namely over-production, inventory, waiting, motion, transportation, defect, over-processing, underutilized resources, and manager's resistance to change. According to the informants, the types and examples of wastes are easy to be figured out because they are visible to the naked eyes. Identified waste and its types are particularly important in implement lean service; waste must be identified so that the cause of the problem can be addressed.

TABLE VIII. Examples of Waste in Lean Dimensions

Dimension	Waste(s)
Lean Supplier	Defect, Over-production, Waiting, Underutilized resources, Transportation, Inventory, Over-processing.
Lean Workforce Management	Defect, Waiting, Underutilized resources, Transportation, Over-processing, Manager's resistance to change.
Lean Operations Development and Technology	Defect, Over-production, Waiting, Underutilized resources, Transportation, Inventory, Over-processing.
Lean Service Provision Process	Defect, Over-production, Waiting, Underutilized resources, Transportation, Inventory, Over-processing.
Lean Service Planning and Scheduling	Defect, Over-production, Waiting, Underutilized resources, Transportation, Inventory, Over-processing.
Customer Relationship	Defect, Over-processing.
Visual Information System	Defect, Over-production, Waiting, Transportation, Inventory, Over-processing.

The informants agreed with the proposed dimensions and wastes of the initial conceptual model. However, after analysis, additional waste on several dimensions was discovered as highlighted in the lean conceptual model shown in Fig. 6; over-production waste is added to the lean supplier dimension, underutilized resources waste is added to the lean operations and technology development dimension, lean service provision process dimension, and lean service planning and scheduling dimension, and defect waste is added in the customer relations dimension. Waste in the seven dimension of the lean conceptual model is illustrated in Table VIII.

According to two informants, IT plays a critical role in assisting with the implementation of lean in the organization. To aid in the application of lean in the service industry, a system must be established. Knowing where waste occurs is a required system feature. However, according one of the informants, they do not require a system to figure out waste because they are more comfortable executing the work manually.

V. Discussion

This research was carried out to provide a preliminary overview of the validation of a conceptual model for lean service in the service industry. Initially, lean conceptual models are developed based on the literature review and preliminary research where types of waste and dimensions in lean service are identified. However, in this study, we limit the development of our conceptual model by focusing on the types of waste and dimensions in lean service using a qualitative method. The data for this study were gathered via focus group interview, observation, and audio-visual sources [68].

The results of this study revealed that the proposed Lean Conceptual Model for the service industry is applicable. This is because the service operation in the case study company shares the same dimensions of lean, relationships among the dimensions of lean, and relationships between dimensions of lean and waste. Thus, this study has found nine types of waste with seven lean dimensions.

The types of waste identified are over-production, inventory, waiting, motion, transportation, defects, over-processing, underutilized resources, and manager’s resistance to change. The seven lean dimensions identified are Lean Supplier, Lean Workforce Management, Lean Operations and Technology Development, Lean Service Provision Process, Lean Service Planning and Scheduling, Customer Relationship, and Visual Information Systems.

The Lean Service Conceptual Model for the service industry can be aligned with the existing digital transformation technologies such as big data, IoT, blockchain, cloud computing, and AI. By harnessing the capabilities of these technologies, organizations will not only embrace lean principles but also propel their service operations into a new era of efficiency and effectiveness [84].

Across all the Lean Service Conceptual Model's dimensions, big data analytics is crucial for reducing waste [85]. Organizations develop the ability to identify and reduce distinct types of waste through the analysis of significant data produced throughout its service operations. As an example, within the Lean Supplier dimension, data analytics can optimize inventory management, leading to a decrease in excess inventory waste. These analytics can help with resource allocation in the context of lean service planning and scheduling [56] and reduce waste [86].

IoT devices emerge as pivotal assets in the alignment of dimensions within the Lean Service Conceptual Model. These devices assume a crucial role in capturing real-time operational data, seamlessly harmonizing with various dimensions of lean service. They play a crucial role in the efficient use of resources, namely taking care of the Lean Workforce Management component. Moreover, IoT devices effectively monitor the intricacies of service provision processes [87], thereby closely aligning with the Lean Service Provision Process dimension. Furthermore, these tools improve customer experience interaction [88] by encouraging mutually beneficial relationship through the Customer Relationship dimension. The result is a decrease in waste brought on by the ability to make informed decisions made possible by these IoT devices.

Blockchain technology serves as a robust pillar in upholding the core principles of lean service, primarily by instilling trust and transparency, with a particular focus on the Lean Supplier dimension. This technology successfully reduces waste in the supply chain by serving as a strong barrier against flaws and dangerous goods [59]. Moreover, blockchain's capabilities extend to the enhancement of transparency in Customer Relationship dimension, where it securely records interactions and transactions. In addition to fostering more trust, this careful documentation also helps to cut down on processing waste. In summary, the integration of blockchain strengthens lean service by promoting waste reduction, transparency, and trust across the service ecosystem.

In the context of lean service, cloud computing appears as a catalyst for facilitating collaboration [89]. Due to its innate abilities, several lean dimensions can be seamlessly coordinated. TCloud computing transforms into an essential channel for the exchange of real-time information by facilitating improved communication and cooperation across multiple functional areas. Through coordinated efforts and real-time information sharing, this collective method enables organizations to jointly detect and manage waste, strengthening the lean service concepts of efficiency and waste reduction.

Within the context of lean service, AI emerges as a powerful force for automation and greater efficiency. AI proves to be a crucial tool for optimizing operations across all dimensions of lean service thanks to its comprehensive range of automation and predictive analytics capabilities. The Lean Operations Development and Technology dimensions are successfully improved because of how well it performs everyday chores. Additionally, AI is crucial to optimizing resource allocation and integrates perfectly with the Lean Service Planning and Scheduling dimension component. Most significantly, AI helps the Customer Relationship Dimension to offer excellent client experiences [90]. In the process, it simultaneously decreases waste by improving overall process effectiveness, reiterating its function as a major enabler of lean service concept.

VI. Conclusion

This research is aimed at providing a conceptual model that enables service organization to successfully navigate changes in the environment of the digital era while maximising their operational efficiency by reducing waste in their operation. This research contributes to the types of waste in lean service. Nine types of waste have been identified; over-production, inventory, waiting, motion, transportation, defects, over-processing, underutilized resources, and manager's resistance to change. Seven lean dimensions identified are Lean Supplier, Lean Workforce Management, Lean Operations and Technology Development, Lean Service Provision Process, Lean Service Planning and Scheduling, Customer Relationship, and Visual Information Systems.

This study has successfully validated a Lean Service Conceptual Model for the service industry through the qualitative method by identifying nine types of waste and seven lean dimensions. This research is significant because it proves how well this paradigm aligns with modern digital transformation technologies like big data analytics, IoT, blockchain, cloud computing, and AI. These technologies are essential for reducing waste, optimizing resources, encouraging collaboration, and automating all aspects of lean service. This integration highlights the model's adaptability, positioning it as a catalyst for service organizations to thrive in a digitally transformed landscape characterized by enhanced efficiency and effectiveness, with a primary focus on waste reduction within service operations.

Thus, the contribution of this study provides a solid foundation to ensure efficient achievement or performance in the service industry. The constraint of this study is in the limitation of the number of companies for the case study. The pandemic that hit when the study was conducted has caused the ability to interact with various organizations in the service industry to be limited; only one company was ready to take part as a case study company for this study.

In the realm of future research endeavours, it is recommended for the inclusion of case study companies to be expanded, with a deliberate focus on diverse sectors within the service industry. This approach aims to mitigate potential bias in research outcomes and offers a more comprehensive understanding of how the Lean Service Conceptual Model aligns with digital transformation technologies across different service contexts.

Additionally, exploring and reviewing the array of best practices, techniques, and tools available for waste reduction within organizational operations is paramount. Such investigations can unveil effective measures that organizations can readily implement to enhance operational efficiency and minimize waste, contributing to a more sustainable and lean service ecosystem. These research directions hold the potential to further advance our knowledge and practical insights in the pursuit of lean service excellence.

Acknowledgment

We want to express our gratitude to the Universiti Kebangsaan Malaysia for the research grants GGPM-2019-065, which enabled us to develop this research. Additionally, we want to extend our heartfelt thanks to Universitas Sriwijaya for their collaboration with Universiti Kebangsaan Malaysia. This joint effort has played a crucial role in the success of our research, enriching the research with diverse perspectives and expertise. We appreciate the support of both institutions in fostering a collaborative and productive research environment.

The Scheme Design of Wearable Sensor for Exercise Habits Based on Random Game

Youqin Huang*, Zhaodi Feng
School of Physical Education, Gannan Normal University, GanZhou, 341000, China

***Abstract*—The development of random game theory has enabled wearable sensors to obtain actuator evolution in sports exercise, thus the design of user exercise habits during the exercise process has begun to be studied. Conventional devices only focus on automatic adjustment of sports design, with slight shortcomings in personalization. To address this issue, this study added an anchor node localization device to the adaptive search hybrid learning algorithm and analyzed the exercise goals of athletes. At the same time, a semi definite programming method was installed in wearable sensors to achieve the goal of paying attention to the physical condition of athletes. To verify the performance of the fusion device, this study conducted experiments on the Physical dataset and compared it with three models such as Harris Eagle Optimization. The accuracy rates of designing exercise habits schemes for the four devices were 97.4%, 96.5%, 94.7%, and 91.2%, respectively, indicating that the model has the strongest stability. Under the same running time, the energy loss of this model was 0.11kW * h, which performs the best among the four models. When the athletes are different in age, the F1 values of the four devices are 5.9, 4.5, 4.2 and 3.6 respectively. The results indicate that the proposed fusion model has strong robustness and is suitable for designing exercise habit schemes in the evolution of sports exercise actuators.**

Keywords*—Random game; adaptive search hybrid learning algorithm; wearable sensors; physical exercise; evolution of actuators; exercise habits; anchor node positioning; semi definite programming method

I. Introduction

The continuous advancement of technology enables wearable sensors to collect the biological information of athletes, providing them with guidance on exercise plans [1-2]. In recent years, sports exercise actuators have gradually integrated electronic technology, providing a more personalized exercise experience. With the increasing emphasis on physical exercise, wearable sensors, as an emerging technology, have been widely used in the field of physical exercise. It can monitor individual exercise data in real-time, such as heart rate and sleep quality, providing users with scientific health guidance and personalized exercise plans. In addition, some sports exercise actuators are also equipped with computer systems, which can help users to better grasp the exercise effect [3]. Conventional sensors are limited to real-time monitoring of body status, and designing the optimal exercise habit plan based on user characteristics still poses challenges [4]. And this method is only suitable for users who exercise in specific areas. For enthusiasts of special terrains, these methods are prone to over generalization during runtime. To expand the search domain of wearable sensors for physical exercise, this study pioneered the construction of a Stochastic Games (SG) model to simulate the decision-making process of physical exercise personnel in different contexts.

A wearable sensor was designed based on the Adaptive Hybrid Learning of Search (AHLS) algorithm to monitor athletes. To accurately locate it, this study designed Anchor Node Positioning (ANP) technology in wearable sensors and generated a fusion model (AHLSG-PEA). The main content of the study can be divided into six sections. Section I mainly analyze and summarize the application of the current AHLS algorithm. Related works is given in Section II. Section III introduces AHLS and SG into SG and sensors. Section IV conducts simulation experiments on the Physical dataset. Section V delves into results and discussion. And finally, Section VI concludes the paper. The theoretical significance of this study lies in providing a device for designing exercise plans, aimed at helping users achieve a better exercise experience and thus maintain physical health. The theoretical significance of this study lies in providing a device for designing exercise plans, aimed at helping users achieve a better exercise experience and thus maintain physical health.

II. Related Works

In the field of scheme design algorithms, research is widely distributed internationally. Nagal et al. designed a system using a hybrid whale grey wolf optimization algorithm. Their algorithm utilized whale parameters to control and balance the randomness of the strategy. For noise in computer signals, they used a controlled search space for filtering. The performance experiment of the algorithm was conducted through signal-to-noise ratio and its average value relationship was evaluated. This algorithm had better strategy planning ability compared to other technologies [5]. Zhou et al. conducted research on the knapsack problem and considered knapsack preferences to extend quadratic multiple knapsacks. They proposed a hybrid evolutionary search algorithm for backpack strategy analysis and generated new offspring solutions based on the crossover operator of the backpack. The experimental analysis of this algorithm utilized adaptive feasible taboo search to improve the offspring solution. This method could accelerate the generation of candidate solutions and streamline their evaluation to propose the best solution [6].

The methods of scheme design are becoming increasingly widespread, and the design of exercise habits is also becoming popular. Meng et al. considered that the sparrow search algorithm is a metaheuristic optimization method, so they applied it to handle multimodal optimization problems. They first introduced chaotic mapping in their research, while also using adversarial learning methods to increase the diversity of strategies. To verify its effectiveness, they conducted a large number of experiments in the test suite and demonstrated that this method outperforms conventional optimization algorithms in terms of performance [7]. Suresh et al. believed that the recursive whale algorithm has decision-making ability, so they proposed an optimization method for smart grid utilization by reducing production costs through real-time scheduling. The search behavior of this algorithm was experimentally conducted on a work platform through taboo search. The decision capability analysis of this method indicated that the proposed method has less time for scheme design [8]. Yuan led his research group to study the scheme design ability of the population, and adjusted the coordinate system based on the covariance matrix to move the population towards a more favorable direction. To enhance the suggestion ability of covariance, they learned evolutionary algorithms to improve search efficiency. Compared with other algorithms, experiments have shown that this algorithm is a high-quality algorithm [9]. Rajendran et al. found that manual methods have drawbacks in radiation, so they conducted research on computer-aided diagnosis and believed that the most important step is feature selection. Considering that recent algorithms are prone to falling into local optima, they combined grasshoppers with crows to verify that the proposed multi-layer perceptron has strong feature selection ability. This simulation experiment was conducted on MATLAB and compared with many similar algorithms, and its accuracy, sensitivity, and specificity have been proven to be superior to other algorithms [10]. Zhang et al. believed that the evolution of wind speed prediction actuators has a significant impact on decision analysis in the wind power industry, so a hybrid prediction model was developed. In this model, the secondary decomposition technique used wavelet transform. This technology has the ability to adaptively process data, so that the characteristic components of the signal would also be extracted. The experimental verification was conducted using real-life wind turbines and compared with the same prediction algorithm, proving that the model has the smallest statistical error and the strongest adaptability in performance [11].

Numerous experts and scholars have found that research on the application of KM and Long Short Term Memory (LSTM) is very popular, but research on large-scale datasets is still scarce. This study innovatively links the two and holds significant importance in dataset processing.

III. An ANP Solution for SG in Exercise Habits

SG involves the uncertainty faced by participants in exercise decision-making, making it difficult to accurately predict determined exercise habits. To assess the evolving exercise habits of physical exercise actuators (PEA), this study combines the AHLS algorithm and uses ANP to select appropriate exercise habits based on the current search state during user exercise.

A. Wearable Sensor Combining AHLS Algorithm with SG

The characteristic of SG is that the actions of physical exercise personnel are influenced by random factors, and therefore cannot be determined through simple optimal strategies. So researchers need to weigh different choices based on probability and adopt appropriate strategies to deal with uncertainty. In practical applications, the analysis of SG requires the use of probability theory methods to determine the optimal strategy and final outcome for each athlete, as shown in Formula (1).

$$\begin{cases} F(X) = d\left(X * \left(\mathrm{Pr}_1 - \mathrm{Pr}_0\right)\right) / dt \\ \mathrm{Pr}_0 = X^T * X * X_0 * k \end{cases} \tag{1}$$

In Formula (1), $\mathrm{Pr}_1, \mathrm{Pr}_0$ represents the probability of the athlete generating random ideas. X is the final choice of the sports personnel at the time of the event. The time experienced in this process is denoted as X^T, and the cooperative effect they have is represented by X_0. k is the environmental parameter of the process. In order to help athletes adapt to this trend, this study added the AHLS algorithm to SG, as shown in Formula (2) [12].

$$AH_x = \sum_{i=1}^{I} \sum_{j=1}^{J} A_i^j * H_{ij} \tag{2}$$

In Formula (2) above, the expected result of SG combined with the AHLS algorithm (AHLSG) is represented by H_{ij}. A_i^j represents the process network loss during algorithm operation. In the AHLSG algorithm, AHLS uses domain knowledge and empirical rules to guide the search process and quickly find the expected solution of the algorithm [13]. The advantage of the AHLSG algorithm is that it can flexibly select search strategies based on the characteristics of the problem. During the operation of the AHLSG algorithm, the popular domain will also be determined, as shown in Formula (3).

$$d\Delta Ca / di = C_i * \left(\sum_{i=1}^{I} \left(Ar_i - Ar_0\right)\right) - \sum_{t=1}^{T} \sum_{z=1}^{Z} a_t a_z \tag{3}$$

In Formula (3), the running parameters of the AHLSG algorithm are represented by Ar_i, Ar_0. The running intervals of the algorithm at the current time and the initial time are denoted as a_t, a_z. C_i represents the expected value of the AHLSG algorithm for the research input. The operation of this algorithm requires a large amount of motion habit features to establish machine learning models, which will impose a burden on the computational cost of the algorithm [14]. To reduce the running time of the algorithm, a model was established for this study, as shown in Fig. 1.

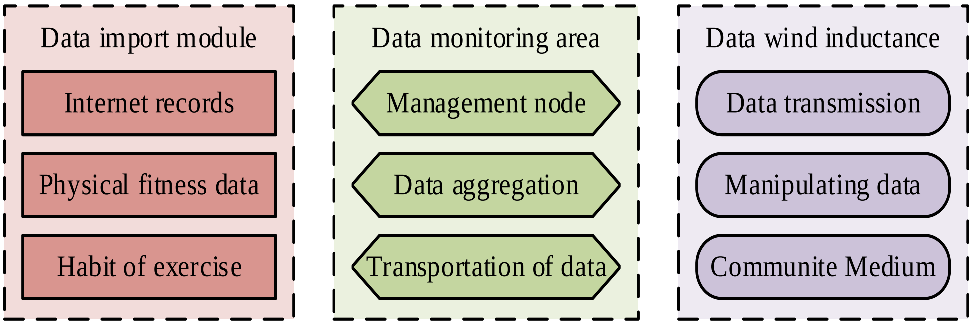

Fig. 1. Algorithm flow chart combining AHLS and SG.

In Fig. 1, in the motion data processing of the algorithm, the AHLS algorithm represents the motion contour as a level set, which has good robustness. SG smooths the data to remove noise from motion data. The characteristic of SG is high computational efficiency, but its performance is highly dependent on the quality of training data. So this study introduces ANP in SG, combining anchor nodes with the exercise habits of athletes, as shown in Formula (4) below.

$$\begin{cases} An_1 = \left(An_0 - 1\right)^2 * \left(0.5 * \Delta Ca + 0.25\right) \\ No_2 = \left(\partial No_1\right) * \left(0.1 * N_2 + 0.75 * N_1\right) \end{cases} \tag{4}$$

In Formula (4) above, the anchor position of the personnel is represented by An_1. An_0 is the duration of movement at that location. N_2 and N_1 represent two different methods of motion at different times, and the stability of these two methods is denoted as No_1. No_2 represents the positioning of the research hypothesis. This study applies ANP to exercise habit judgment and obtains spatial location information of athletes. Based on the results of this data analysis, this study was able to determine the suitable exercise habits as anchor nodes, as shown in Fig. 2.

Fig. 2 is a motion habit determination method based on anchor nodes. When athletes tend to exercise during a specific time period, the machine will choose that time period as the anchor node. Then, based on the selected anchor node, the motion target of the mover on it is set [15].

Based on the exercise habits of the athletes, the machine provides them with personalized exercise advice to help them better achieve movement on anchor nodes. The comparison method between athletes is Formula (5).

$$Co_1 * \int_{-\pi}^{+\pi} \alpha_1 * \beta_1 d\alpha d\beta = Co_2 \int_{-\pi}^{+\pi} \alpha_2 * \beta_2 d\alpha d\beta \tag{5}$$

In equation (5), the exercise method of the athlete before and after the suggestion is denoted as α_1, α_2. β_1, β_2 represents the difficulty coefficient when they are implemented. Both are highly sensitive to the quality of the environment they are in, so variables caused by environmental factors are represented by Co_1, Co_2. The limitations of this method are the dynamics and persistence of motion on anchor nodes. To address this issue, this study combines ANP and AHLSG algorithms in sensors to design a novel motion habit scheme, as shown in Fig. 3.

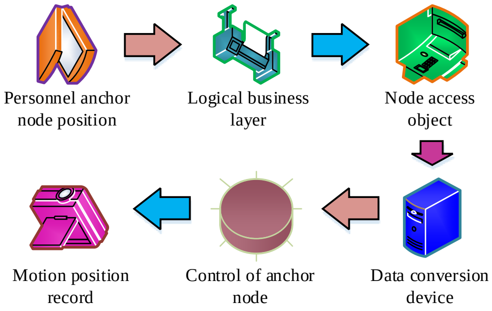

Fig. 2. Determine the exercise habit process diagram as the anchor node.

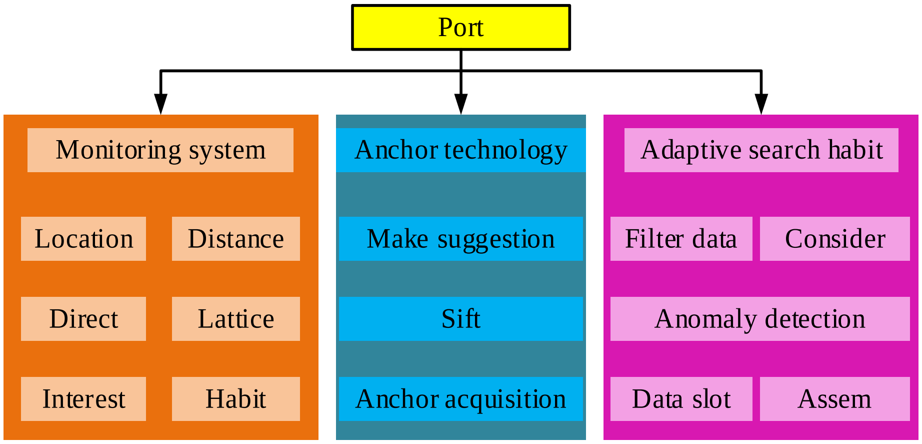

Fig. 3. Exercise habit design scheme combining anchor node positioning and AHLSG algorithm.

In Fig. 3, this method can help researchers judge exercise habits and choose exercise paths based on the behavioral patterns of the athletes. ANP technology provides location information for athletes, and this method can evaluate the quality of movement of athletes. This study combines this method with motion sensor technology, as shown in Formula (6) [16]. This method can not only classify the user's movement behavior, but also analyze the user's posture change information. By evaluating whether the athlete's movements are correct, their exercise methods, such as running and cycling, can be analyzed.

$$\begin{cases} de_1 = de_k / \mu_k \\ \mu_k = \left[\left(de - de_1 \right) / \left(de_k - de_1 \right) \right]^{0.5} \end{cases} \quad (6)$$

In Formula (6), the initial signal of the sensor is denoted as de_1, and its total electrical energy intensity during working time is represented by de. de_k, μ_k represents the peak intensity and energy loss of the sensor signal at the current time. This sensor records motion data through devices such as smart wristbands, which can monitor the movement behavior of athletes in real time and provide real-time motion guidance. This study first helps athletes correct bad habits based on their location information, and then makes actual adjustments to the exercise plan based on the exercise time and weather. The degree of adjustment is Formula (7) below.

$$Ha(x) = -de_k * \int_0^1 (\chi_x + \delta_x) d\chi + \mu_k * \int_0^1 (\chi_x + \delta_x) d\delta \quad (7)$$

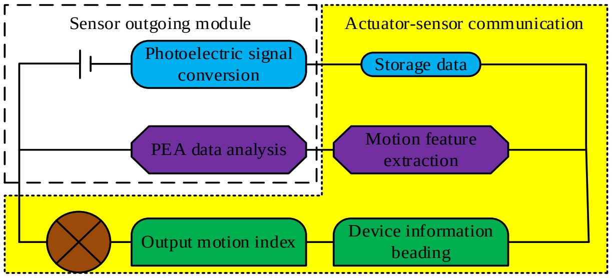
In Formula (7), $Ha(x)$ is the current habit of the athlete. χ_x represents the time interval of exercise. The weather conditions during exercise are represented by δ_x. This study combines wearable sensors with the AHLSG algorithm to obtain the movement trajectories of athletes under different exercise habits, thereby conducting in-depth research on individual exercise habits. As the strategies of athletes change, this method can reveal their decision-making process in exercise habits, providing scientific basis for developing personalized exercise habit improvement plans. This method has the ability to improve individual health levels when applied in the field of sports exercise actuator evolution.

B. Design of AHLSG -based Sensors in the Evolution of Sports Exercise Actuators

PEA evolution refers to the process of improving PEA performance in terms of design and performance. The function of this mechanical device is to assist in basic physical exercise movements [17]. Conventional actuators only have simple adjustment functions and lack personalized adjustments. To improve this point, this study will design sensors based on AHLSG in PEA, combined with the method shown in Formula (8).

$$Act_a = \left\{ Sen_a * \left\| Sen_b - Act_b \right\|_a^b, Sen \in Act \right\} \quad (8)$$

In Formula (8), Sen_a, Act_a represents the initial data of the sensor and actuator. The elements they combine in the two are represented by Sen_b, Act_b. Sen, Act represents the units to which two devices belong. Through this method, sensors and actuators generate a personalized sports exercise program design device (AHLSG-PEA). This study first used sensors to monitor key indicators of exercise personnel, and analyzed the data collected by the sensors, as shown in Fig. 4 [18].



Sensor outgoing module
Actuator-sensor communication
Photoelectric signal conversion
Storage data
PEA data analysis
Motion feature extraction
Output motion index
Device information beading

Fig. 4. Workflow of personalized physical exercise program design device AHLSG-PEA.

Fig. 4 shows the process of designing exercise habits for the AHLSG-PEA device. The data of the sensor module is first scheduled using the AHLSG algorithm, and then a motion data model based on motion personnel is established. PEA plays a clustering role in it [19]. The physiological indicators of personnel include blood flow rate and heart rate information. Finally, this study used the proposed algorithm for real-time data analysis, as shown in Formula (9).

$$\begin{cases} \phi_a = \left[\varepsilon_a * \left(Sen_a / Act_a \right) + \gamma_a \right]^{0.5} \\ \varphi_a = \left(1 - \varepsilon_b \right) * \left(\Delta\Omega \right)^2 \end{cases} \quad (9)$$

In Formula (9), the physiological indicators of the exerciser are denoted as ε_a. ε_b is the psychological indicator of the same personnel. The coefficient of conversion between the two is represented by γ_a. $\Delta\Omega$ represents the clustering center of the PEA work process. The analyzed data can be used to construct suitable exercise plans based on the goals of physical exercise. The plan includes action sequences, action specifications, and exercise intensity, and real-time processing of feedback information based on algorithms. Due to the unique characteristics of athletes, it is necessary to automatically adjust the parameters of the exercise model in order to achieve a wide range of exercise effects. The adjustment method follows Formula (10).

$$\eta_1 = arc \min_{\eta_1 \in \eta} \int \int_{\eta_1}^{\eta} \sqrt{\eta_1 - \left(\eta_0 + \phi_a \forall \varphi_a \right)^2} \quad (10)$$

In Formula (10), η_1 represents the current planning method for exercise habits. η_0 is the optimal design for studying the preset. The AHLSG-PEA device has an evolutionary optimization effect on PEA, while setting a fitness function in the device to continuously optimize the parameters of the actuator to improve its adaptability [20]. The real-time motion data information of athletes can be fed back to the AHLSG-PEA instrument in real time and provide real-time suggestions. This method can help users adjust their strength and rhythm to achieve better exercise results, as shown in Fig. 5.

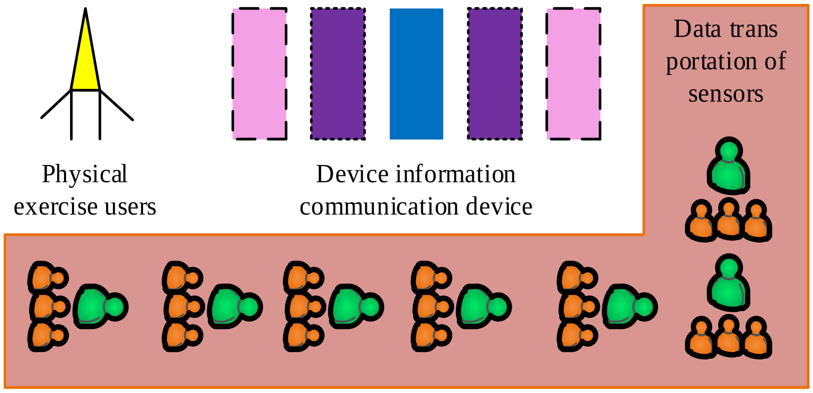


Fig. 5. Real-time feedback process diagram of motion data of AHLSG-PEA instrument.

In Fig. 5, sensor technology and real-time feedback mechanism are combined in AHLSG-PEA. This method can track the human body's motion trajectory in real-time based on the motion contour. In sports actuators, this study will use the AHLSG algorithm to provide real-time exercise recommendations. Then, the raw data collected by the sensor is filtered and denoised to improve the stability of the proposed results. In order to update the motion contour model in real-time, this study incorporated the semi definite programming method into the AHLSG-PEA device. The main purpose of this method is to optimize the motion parameters, and the optimization method is Formula (11).

$$Po_i * \left(-1+\sum\nolimits_{i=1}^{I}\coprod\nolimits_{j=1}^{J} Se_i / Se_j\right) = 1+\sum\nolimits_{i=1}^{I}\coprod\nolimits_{j=1}^{J}\left(Se_i + Se_j\right) \quad (11)$$

In Formula (11), the weather conditions during exercise are denoted as Po_i. Se_i, Se_j represents the position and mood parameters of athletes in the semi definite programming method. In the optimized AHLSG-PEA device, this study uses rules for information exchange, enabling information to spread across the network. In this device, this propagation method is referred to as rule propagation. The rule propagation model is used to help instruments understand information, where the propagation path is a key factor in the propagation process, represented by Formula (12).

$$Sp(e) = Sp_1 + Sp(e-1)/10*\left[\lg(e_0/e)\right] \quad (12)$$

In Formula (12), $Sp(e)$ represents the dissemination method of the exercise participants at the current location. The propagation path of the previous athlete is represented by $Sp(e-1)$. Sp_1 represents the perfect path preset by the AHLSG-PEA device. The communication barriers between them are denoted as $\lg(e_0/e)$. This method can predict the behavioral information of athletes. By simulating their propagation process, this study can evaluate the impact of different strategies on exercise habits and guide the development of exercise methods. In addition, the rule propagation method can also set the optimal motion node, as shown in Fig. 6.

In Fig. 6, when setting the optimal motion node, this study first collects data related to the motion node, including information on population density and distribution of motion facilities. Then, based on the physical exercise goals of the athletes, evaluation indicators are determined to measure the suitability of each potential exercise node. Based on the collected data and determined evaluation indicators, the suitability of each potential motion node is evaluated, as shown in Formula (13). This formula can be used to analyze the evolving motion habits of actuators.

$$Pot_m = \left(Pot_1 / Pot_n + 1\right)\Theta Sp(e) - \left(Pot_0 / Pot_n + 1\right) \quad (13)$$

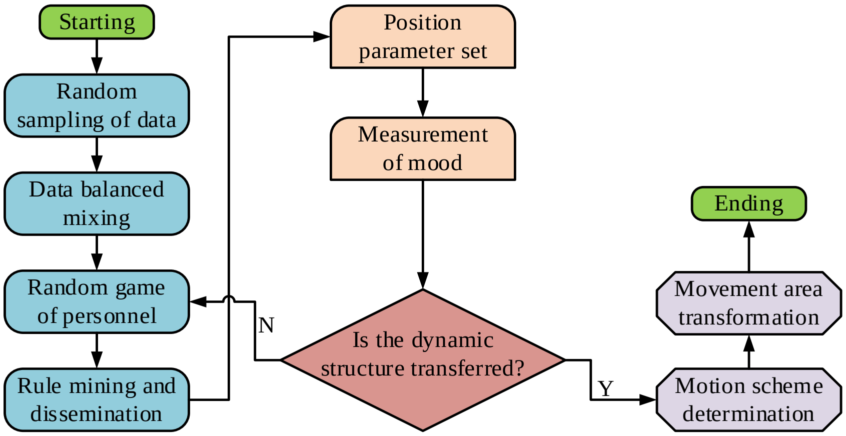

Fig. 6. Process diagram of method for setting optimal motion node through rule propagation.

In Formula (13), Pot_1, Pot_0 represents the motion nodes in different regions. Pot_m represents the motion node selected as the latent state. The optimal state of this point is represented by Pot_n. After obtaining potential motion nodes, suitability scores were assigned to each node. Based on the evaluation score, the best motion node will be selected. Finally, this study suggests that there may be noise issues in real-world nodes, so adjustments are made based on feedback information, as shown in Formula (14).

$$Fee(n)=\sum_{i=1}^{I}\left[(Fee_i - Fee_1)*(Fee_1 - Fee_m)^2\right]^{1/2} / \sum_{m=1}^{M} Pot_m \quad (14)$$

In Formula (14), the first feedback information of the real node is denoted as Fee_1, and there are a total of Fee_i feedbacks. Their mean is represented by Fee_m. $Fee(n)$ represents the output information of the model in the ideal state, in order to achieve the preset constraints of the research. This method can maximize the exercise effect of athletes, and then transform the problem of designing exercise habits into evolutionary optimization of algorithms to improve the adaptability of AHLSG-PEA devices, as shown in Formula (15).

$$\mu_{eq} = \nu(T) - \theta(T) * \vartheta_{eq} * \varpi \lg(\sigma / \sigma_0) \quad (15)$$

In Formula (15), the performance of the AHLSG algorithm caused by time is denoted as $\nu(T)$. The noise changes are represented by $\theta(T)$. ϑ_{eq} represents the external environmental factor of the AHLSG-PEA device. ϖ is a variable caused by the device's own factors. σ / σ_0 represents the loss coefficient during signal propagation. Through the above scheme design, the AHLSG-PEA device can achieve personalized exercise plans in the evolution of PEA, thereby improving the safety of exercise. Meanwhile, through continuous evolutionary optimization and real-time feedback, the performance of the actuator can be gradually improved, providing a better exercise experience for exercise users. Stochastic game theory is used to analyze the decision-making rules between physical exercisers, and provides the corresponding strategy updating direction for adaptive search hybrid learning algorithm. At the same time, the adaptive search hybrid learning algorithm constantly optimizes the search process and finds the optimal solution of exercise habits in a more efficient way. The combination of these two methods plays an active role in solving the problem of optimal strategy selection in actuator evolution. Anchor node positioning technology can be used to determine the target position. This paper studies the combination of anchor node positioning technology and adaptive search hybrid learning algorithm to make the random game process better adapt to the needs of sports habits in different environments. And by studying the proposed optimization process, the accuracy of positioning is improved.

IV. Example Analysis of the Fusion Algorithm AHLSG-PEA in the Design of Exercise Habit Schemes

This study conducted experiments on the Physical dataset and compared it with three other models to verify the superiority of the AHLSG-PEA device. This dataset contains a total of 857 exercise habits from different regions, including almost all ages of athletes.

A. *Performance Verification of Wearable Sensors for SG*

This study was divided into two groups in a 6:12 ratio for the rational utilization of limited data in the Physics dataset, and algorithm learning and experimental verification were conducted on them respectively. Table I shows the equipment screening and parameters used in the experiment.

This study conducted performance validation of the AHLSG-PEA device after setting parameters according to Table I, and compared it with the AHLS algorithm, Harris Hawks Optimization (HHO) algorithm, and Convolutional Neural Network (CNN). The experimental results are shown in Fig. 7.

TABLE I. Equipment Selection and Parameter Determination in Performance Verification Experiment of DWKM-LSTMIA Algorithm

Equipment selection	Parameter determination
Master client	Intel Yeon E8-2079
Language	Easy Chinese
Memory of graphics card	2T*8
Operating system	Windows 7X
Age range of athletes	5-80
Athletes' sports terrain	Plains, mountains, hills and lakes
Sensor wearing habit	Shoulder, hand, neck and ankle
Time range of movement	Morning, afternoon, evening, early morning
Algorithm working time	15:22:59
Data set	Physic
Execution method	Matlab R2147h

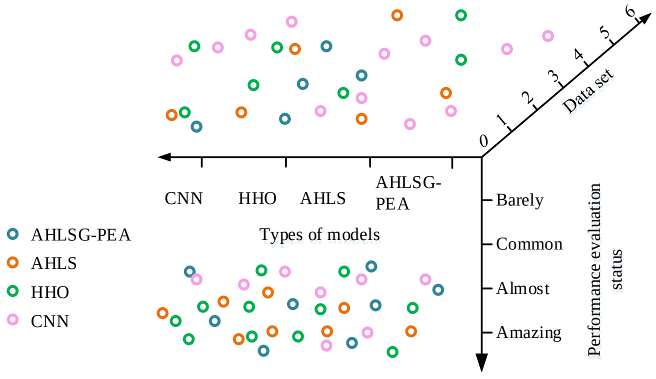

Fig. 7. Image of performance verification experiment results of AHLSG-PEA equipment.

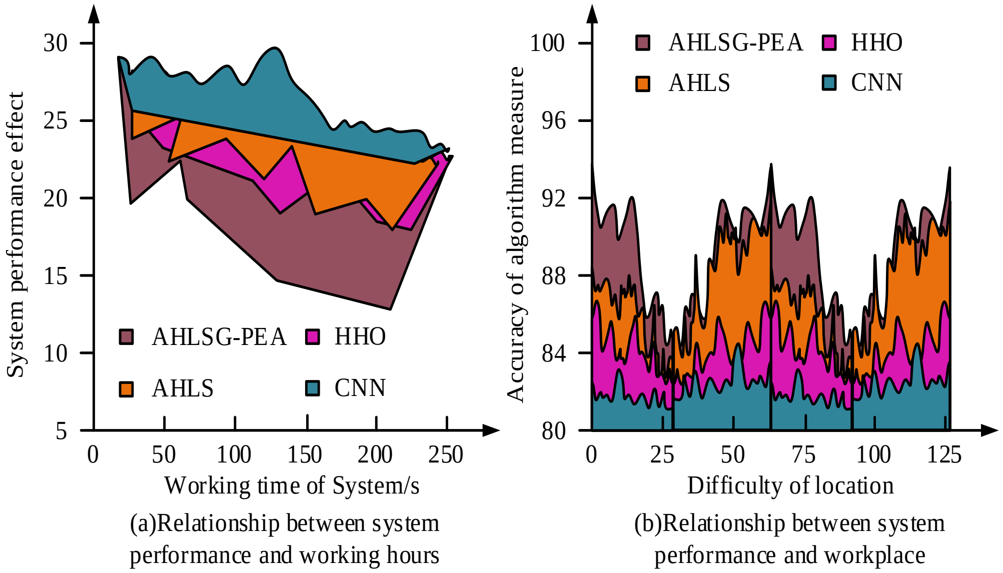
Fig. 7 shows a comparison of the design capabilities of four different systems for exercise habits. As the model runtime increases, the performance ratings of all four algorithms continue to rise, and the AHLSG-PEA device consistently performs the best. At the same time, the debugging levels of AHLSG-PEA, AHLS, HHO, and CNN equipment were 5.8, 4.6, 4.1, and 3.7, respectively. This indicates that the performance of AHLSG-PEA devices is optimal when the operating environment is the same. To verify the robustness of the AHLSG-PEA model, this study conducted experiments on different exercise times and locations, and the experimental results are shown in Fig. 8.

In Fig. 8 (a), when the model is located in the same region, the performance of all four models shows an upward trend as the running time increases. The working characteristic value of AHLSG-PEA equipment is the highest, at 28. The control conditions in Fig. 8 (b) are the same running time but different exercise locations. In Fig. 8 (b), as the exercise location of the participants becomes increasingly difficult, the calculation accuracy of all four models shows a decreasing trend. The highest accuracy values of AHLSG-PEA, AHLS, HHO, and CNN devices are located at 63, with values of 94.5%, 92.7%, 84.1%, and 82.6%, respectively. This indicates that the AHLSG-PEA device can accurately design the exercise habits of athletes. However, the above experiments can only demonstrate the internal performance of the equipment, and experimental verification is also required for changes in the conditions of the athletes themselves.

B. *Experimental Analysis of AHLSG-PEA Equipment under the Background of PEA Evolution*

To conduct experiments on the performance of AHLSG-PEA equipment in the evolution of PEA, this study focused on the different habits of athletes, as shown in Fig. 9.

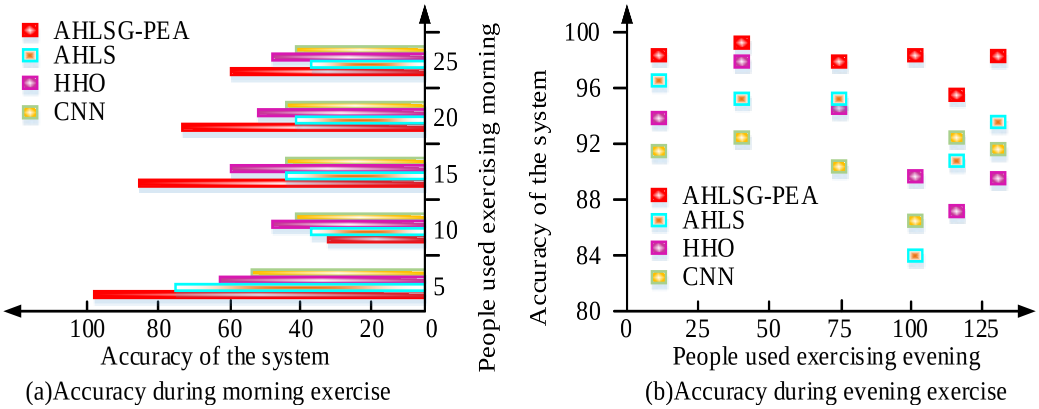
Fig. 9 shows the AHLSG-PEA performance experiment under different habits of athletes. In Fig. 9 (a), as the number of participants in the exercise gradually increases, the accuracy of scheme design for all four systems shows an upward trend. Among them, the proposed system has the highest calculation accuracy of 99.7%. In Fig. 9 (b), the scheme design accuracy of AHLSG-PEA, AHLS, HHO, and CNN devices are 97.4%, 96.5%, 94.7%, and 91.2%, respectively. This indicates that AHLSG-PEA can adapt to different time habits in exercise program design. The results of the experiment on athletes from different sports locations are shown in Fig. 10.



(a)Relationship between system performance and working hours

(b)Relationship between system performance and workplace

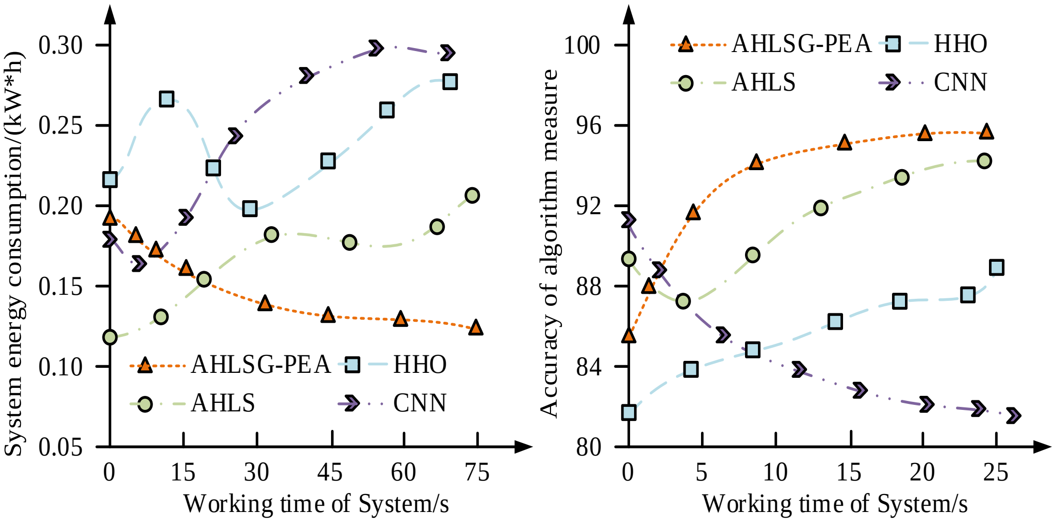
Fig. 8. Experimental results of robustness of AHLSG-PEA model.



(a)Accuracy during morning exercise

(b)Accuracy during evening exercise

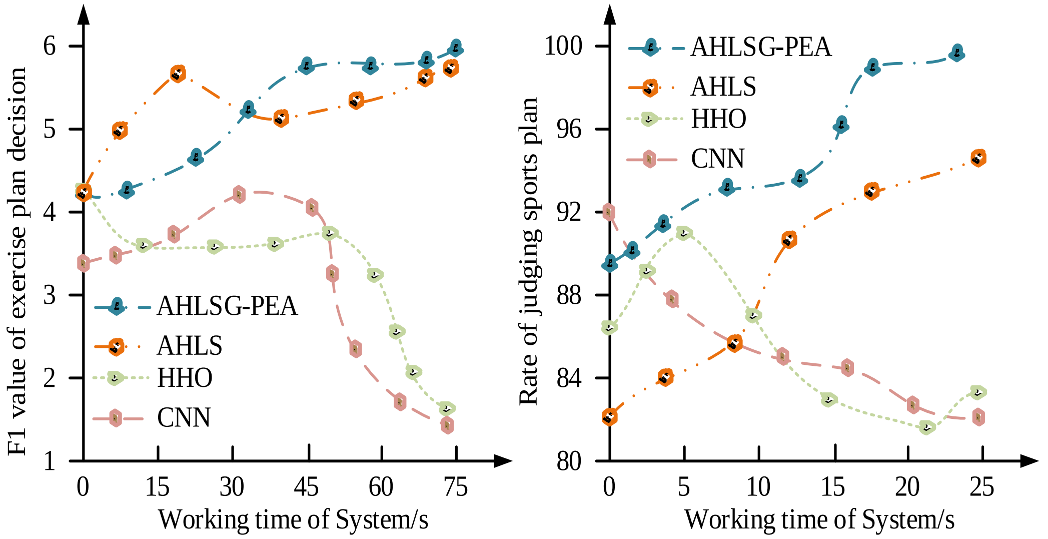
Fig. 9. Performance experiment of AHLSG-PEA equipment in different habits of athletes.



(a)Performance experiment of athletes in plain terrain

(b)Performance experiment of athletes in mountainous terrain

Fig. 10. Scheme design of AHLSG-PEA equipment when athletes move in different places.



(a) Experiment on judging sports plan of young athletes

(b) Experiment on judging exercise plan of middle-aged athletes

Fig. 11. Experimental results of extensive verification of AHLSG-PEA model.

In Fig. 10 (a), the energy losses of AHLSG-PEA, AHLS, HHO, and CNN equipment in plain terrain are 0.11, 0.19, 0.24, and 0.28 kW * h, respectively. This indicates that the proposed model has the highest economic benefits. In Fig. 10 (b), the accuracy of determining the motion habits of the four models in hilly terrain is directly proportional to the running time of the models, and the research model always has the highest accuracy, at 95.8%. This indicates that the AHLSG-PEA model has the best judgment performance. To verify the universality of the model, the results of experiments conducted on users of different ages are shown in Fig. 11.

Fig. 11 shows the extensive validation of the AHLSG-PEA device for young and middle-aged athletes participating in sports activities. In Fig. 11 (a), the F1 value of the AHLSG-PEA device is the highest, at 5.9, indicating that the model has the strongest stability in experiments with young people. In Fig. 11 (b), the accuracy of AHLSG-PEA, AHLS, HHO, and CNN instruments are 99.8%, 97.2%, 94.1%, and 92.5%, respectively. Therefore, the AHLSG-PEA device has the best performance in designing exercise habits in the evolution of PEA, which is suitable for optimizing the user's exercise experience.

V. Results and Discussion

Random game theory is a mathematical model used to analyze the game process of sports. Adaptive search hybrid learning algorithm combines adaptive search and hybrid learning process, while anchor node positioning is used to locate the target position. In this study, these three methods are integrated to construct a wearable sensor under the background of the evolution of physical exercise actuators, and its application ability in the design of exercise habits is discussed.

The research experiment is divided into two parts, including the test of internal performance and the proof of robustness, effectiveness and universality. The experiment of this model is carried out in the Physic data set and compared with the other four methods. When the running time of the model increases, the performance scores of the four algorithms are rising, and the AHLSG-PEA device always performs best, which shows that the performance of the device is the best. The highest accuracy of AHLSG-PEA device is 94.5%, and its performance is the best among the four devices, which shows that it can accurately predict the exercise habits of athletes.

When the four kinds of equipment are faced with the choice of exercise habits at different times, the accuracy of their scheme design is 97.4%, 96.5%, 94.7% and 91.2% respectively, which shows that the AHLSG-PEA model proposed in this study has good adaptability to different times. The energy loss of AHLSG-PEA instrument is 0.11 kW*h for detecting the exercise habits of athletes in different environments. Compared with AHLS, HHO and CNN, this figure can show the highest economic benefit and the best performance in energy loss. When faced with the detection of exercise habits of people of different ages, the proposed device has the highest F1 value, which shows its strong robustness.

To sum up, the integration technology of random game theory, adaptive search hybrid learning algorithm and anchor node positioning (AHLSG-PEA) is robust, effective and extensive in the design of exercise habit scheme. The experimental results show that the AHLSG-PEA instrument proposed in this study can effectively design the exercise habits of physical exercisers on wearable sensors, and is suitable for being widely used in sports navigation systems. When athletes use non-contact sensors, the research method has certain limitations. With the continuous development of artificial intelligence technology, this integration method will also be more widely studied.

VI. Conclusion

With the evolution of PEA, the recommendation of exercise habits is gradually becoming more personalized. This study added SG technology to the AHLS algorithm and designed it simultaneously with ANP in the sensor, generating the AHLSG-PEA model. To verify its practicality and universality, this study conducted experiments on the Physical dataset and compared the results with AHLS, HHO, and CNN devices. In the internal performance test, the debugging levels of the four instruments were 5.8, 4.6, 4.1, and 3.7, respectively, indicating that the AHLSG-PEA equipment has the best performance. The highest accuracy values of AHLSG-PEA, AHLS, HHO, and CNN devices were 94.5%, 92.7%, 84.1%, and 82.6%, respectively, indicating that AHLSG-PEA devices can accurately predict the exercise habits of athletes. The accuracy rates of scheme design for AHLSG-PEA, AHLS, HHO, and CNN devices were 97.4%, 96.5%, 94.7%, and 91.2%, respectively, for model performance at different times, indicating that the model has good adaptability to different times. For different terrains of athletes, the energy consumption of the four instruments was 0.11, 0.19, 0.24, and 0.28 kW*h, respectively, indicating that the proposed model has the highest economic benefits. When the age of athletes was different, the F1 values of AHLSG-PEA, AHLS, HHO, and CNN devices were 5.9, 4.5, 4.2, and 3.6, respectively, indicating that the AHLSG-PEA device has robustness in the age experiment of athletes. The experimental data showed that the device proposed in this study can effectively cope with internal parameters and external environment, thereby providing users with effective motion plans. However, this study only focuses on wearable sensors, and this method has certain limitations when non-contact sensors are used by athletes. This is because the total amount of data in the dataset is limited. As the number of volunteers increases, this limitation will gradually improve in future research.

The Construction and Application of Library Intelligent Acquisition Decision Model Based on Decision Tree Algorithm

Hong Pan
Library, Yanbian University, Yanji, 133000, China

***Abstract*—In today's digital age, libraries, as the core institutions of knowledge management and information services, are facing an increasing demand from readers. In order to provide more efficient, accurate, and personalized interview services, intelligent interview decision-making in libraries has become an important research field. Traditional manual interview services face challenges such as personnel training and knowledge updates, making it difficult to quickly adapt to new needs and changes. To address these issues, research is being conducted on using machine learning technology to perform post pruning on the basis of standard decision trees and combining it with fuzzy logic to design a fuzzy decision tree. The experimental results show that the F rejection rate (FN) of the model rapidly decreases to about 0.1 as the number of training iterations gradually increases, and stabilizes at around 0.05 after 210 rounds of training, which is 0.10 lower than the rule-based decision model FN. The intelligent acquisition decision-making model designed in this study has higher accuracy and stability, and has certain application potential in the field of intelligent acquisition decision-making in libraries.**

***Keywords*—Decision tree; machine learning; fuzzy logic; intelligent interview model; post-pruning**

I. Introduction

With the continuous development of information technology and the rise of intelligent applications, library management is facing the demand for greater efficiency, convenience, and intelligence. Among them, intelligent acquisition decision-making in libraries is an important link, which involves analyzing, answering, and recommending services to readers. In order to improve the accuracy and efficiency of intelligent acquisition decision-making in libraries, many researchers use collaborative filtering algorithms, which predict books that users may be interested in by analyzing their historical behavioral data. The disadvantage is that it requires a large amount of user behavior data, and the algorithm's recommendation efficiency is not high when new books or new users join (cold start problem) . Some scholars also use hybrid recommendation systems that combine collaborative filtering, content recommendation, and other recommendation methods to compensate for the shortcomings of a single algorithm. However, hybrid recommendation systems may become complex and difficult to manage, and parameter tuning is a challenge [1]. The decision tree model has higher interpretability compared to other machine learning models, such as neural networks or support vector machines [2]. They make decisions through a series of easily understandable rules, enabling library staff to understand the recommendation logic of the model. It achieves data classification and prediction by dividing the dataset into different subsets and continuing to recursively construct decision rules on each subset [3]. In intelligent interview decision-making in libraries, decision tree algorithms can construct corresponding decision rules based on the characteristics of the questions raised by readers, helping the library system respond quickly and accurately to reader needs. However, standard decision trees have defects such as poor processing of continuous data, sensitivity to changes in input data, and susceptibility to overfitting. To address these issues, a fuzzy decision tree (FDT) is designed based on standard decision trees and combined with fuzzy logic, and applied to intelligent acquisition decision-making in libraries. It is expected that optimizing the existing decision tree model will help improve the quality and accuracy of library system interview decision-making. The article mainly consists of four parts. The second part is a review of the current research status on decision trees and fuzzy logic both domestically and internationally. The third part establishes an intelligent acquisition decision model for libraries based on improved decision trees. The fourth part conducts comparative experiments and applicability experiments on the optimization effect of the model.

The novelty of the article lies in the following points. First, the model considers many factors, such as book value, purchase funds, readers' needs and collection structure, and makes acquisition decisions more consistent with the actual needs of library services by building a more comprehensive decision-making framework. Secondly, using information gain as the criterion for feature selection ensures that the model focuses on variables that have a significant impact on classification, such as author, category, price, publisher, and publication time, thereby improving the prediction accuracy of the model. Thirdly, the C4.5 method in the decision tree algorithm was used and pruned to avoid overfitting, thereby optimizing the model's generalization ability. Fourthly, by using fuzzy theory to deal with uncertainty and ambiguity problems, the traditional decision tree algorithm has been enhanced with the ability to handle fuzzy classification, enabling the model to more finely depict real-world situations, especially in situations where user needs are fuzzy or library resource descriptions are unclear. Fifthly, in the process of constructing a decision tree model, by designing fuzzy sets and membership functions, combined with fuzzy logic, the model can better handle the uncertainty in classification.

This article demonstrates the broad application prospects of artificial intelligence and machine learning technology in library work through the construction and application research of a library intelligent acquisition decision model based on decision tree algorithm. In the future, with the continuous progress of technology and the accumulation of data, intelligent interview decision-making models will play an increasingly important role in the actual work of libraries. Meanwhile, the research methods and achievements of this article can also provide reference and inspiration for intelligent decision-making in other fields.

II. Related Works

Recently, with the widespread application of machine learning in various industries, more and more people have begun to use machine learning to solve various difficulties in social learning. Charbuty et al. designed a decision tree based author information classifier to address the issue of low accuracy in traditional author topic classifiers. The experiment showcased that the classification accuracy of the model reached 98.65% [4]. Aldino and other researchers designed a classifier using the decision tree C4.5 algorithm to make it easier for management to determine who is the appropriate student to receive financial aid, and conducted tenfold cross validation on the classification results; The experiment showcases that the accuracy, precision, and recall of the model are all 87%, which means that the model can be well implemented in the system [5]. Tangirala et al. identified a mixture of attributes and minimum class labels for splitting conditions on each non leaf node of a decision tree to solve the problem of homogeneous fruit subsets, and proposed several splitting indices to evaluate splitting; The experiment demonstrates that applying two different segmentation indices, GINI index and information gain, gives the same accuracy [6]. Li and other researchers studied a practical federated environment with relaxed privacy constraints to address the issue of insufficient efficiency or effectiveness of gradient based decision trees for practical applications; the experiment showcases that compared to normal training using local data from each party, this method can significantly improve prediction accuracy [7]. Nancy and others proposed a new intrusion detection system to address the issue of intrusion detection systems neglecting the identification of new types of attacks; the system uses intelligent decision tree classification algorithms to detect known and unknown types of attacks; the experiment demonstrates that this method reduces false positives, energy consumption, and latency [8]. Ramya and other researchers have designed a detection and classification system that combines decision trees with intrusion detection systems (IDS) to enhance the energy security performance of the power grid; The experiment illustrates that the model can accurately classify and predict most attacks [9].

Elhazmi et al. designed a prediction model for mortality of severe adult COVID-19 patients admitted to ICU by combining decision tree and conventional model logic regression to predict the mortality of COVID-19 patients; the experiment showcases that the accuracy of the prediction model reaches 96.65% [10]. Mariniello and other researchers designed a method category on the ground of decision tree ensemble vibration to address the challenges of structural damage detection and localization in vibration data, and analyzed the dynamic characteristics of the structural system (i.e. pattern shape and natural frequency) to obtain a structural health assessment model; The experiment indicates that the accuracy, reliability of probability prediction, and positioning error of the model perform best when compared with multiple algorithms [11]. Li et al. proposed adaptive control of the gradient of training data for each iteration and leaf node pruning to improve the accuracy of the GBDT model while preserving strong guarantees of differential privacy, to tighten the sensitivity limit; the experiment demonstrates that this method can achieve better model accuracy than other baselines [12]. Sharma and other researchers used fuzzy logic methods to control the operation of ventilation systems that provide fresh air to the environment to solve the problem of insufficient ventilation in indoor environments that damages human health; The experiment showcases that the indoor ventilation system controlled by this model increases the ventilation rate by 15.6% [13]. Arji and others have designed a rule-based fuzzy logic, adaptive neuro fuzzy inference system (ANFIS) to address the significant impact of the spread of infectious diseases on global health and economy; the experiment illustrates that this technology has improved the accuracy of infectious disease identification by 31.34% [14].

In summary, decision trees and fuzzy logic play an increasingly important role in the development of machine learning, but there are few related studies that combine the two to assist in intelligent library acquisition decision-making. Therefore, this study combines fuzzy logic to design a library intelligent acquisition decision model on the ground of decision trees, to further improve the efficiency of library management.

III. Improvement of Decision Tree and Design of Library Intelligent Acquisition Decision Model Scheme

This chapter is separated into two sections. The first section first designs a library intelligent acquisition decision model scheme on the ground of the standard decision tree. The second section mainly addresses the shortcomings in the standard decision tree and combines it with fuzzy logic to make some improvements, designing a fuzzy decision tree.

A. *Optimization Strategy for Book Interview Based on Decision Tree*

To reasonably select interviewees and provide books and materials that meets the needs of readers in the limited resources of the library. This requires effective interview decision-making methods to improve service quality and promote the dissemination of knowledge and the development of academic research. At present, there are four main influencing factors involved in the decision-making of book acquisition in universities, including book value, procurement funds, reader needs, and collection structure. The collection structure of a library mainly affects the service level and overall level of literature resources. In different application fields, the acquisition concept of libraries also varies, resulting in similar collection structures. The structural framework of influencing factors for book acquisition decision-making is shown in Fig. 1.

To ensure the effectiveness of the decision model, it is also necessary to select more suitable feature variables, and the selection criteria mainly depend on the classification effect of the samples. The methods for selecting feature variables include information gain or information gain ratio, and this study mainly uses information gain to select feature variables. When learning decision trees, the five features with greater information gain selected include author, category, price, publisher, and publication time. Among them, the author's writing level determines the overall quality of the book content. The author of a book plays an important role in the procurement of books. Decision tree is a commonly used machine learning algorithm used to solve classification and regression problems. It is a tree based model that performs prediction by segmenting and judging the dataset [15-16]. The decision tree is composed of nodes and edges, with each node representing a feature or attribute, and edges representing the relationship between feature or attribute values [17]. The root node represents the most important feature, the internal node represents the intermediate feature, and the leaf node represents the final output or decision result. The advantages of decision trees include ease of understanding and interpretation, ability to handle discrete and continuous features, and robustness to outliers and missing data. The structural diagram of the decision tree is shown in Fig. 2.

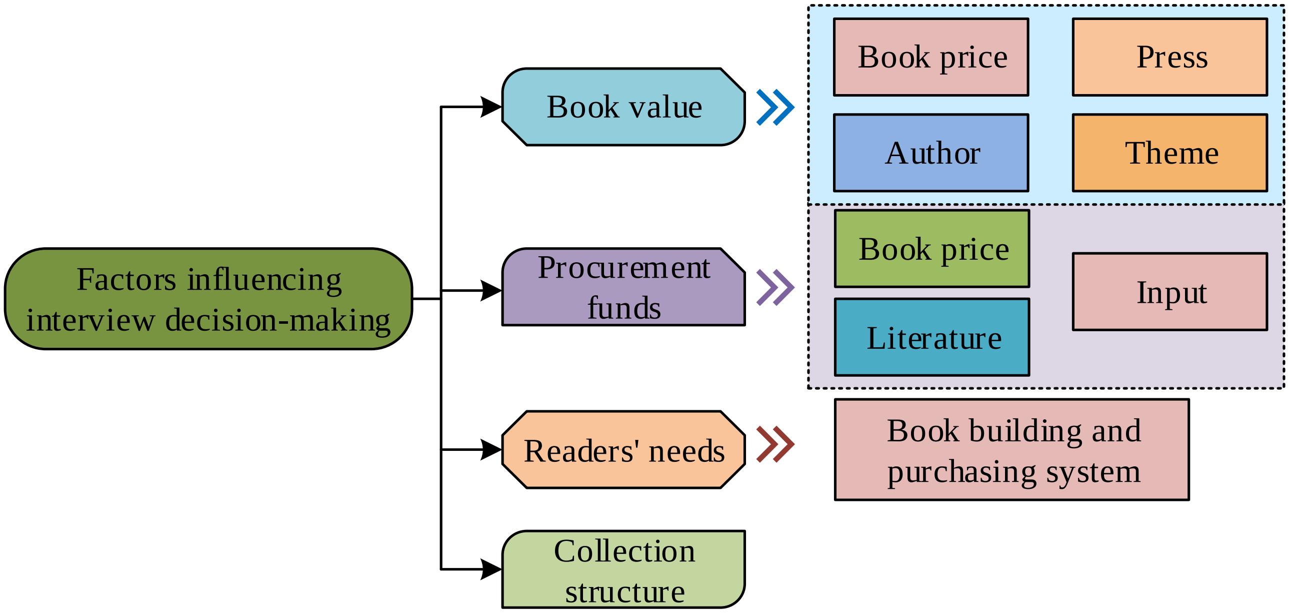

Fig. 1. The structural framework of factors influencing book acquisition decisions.

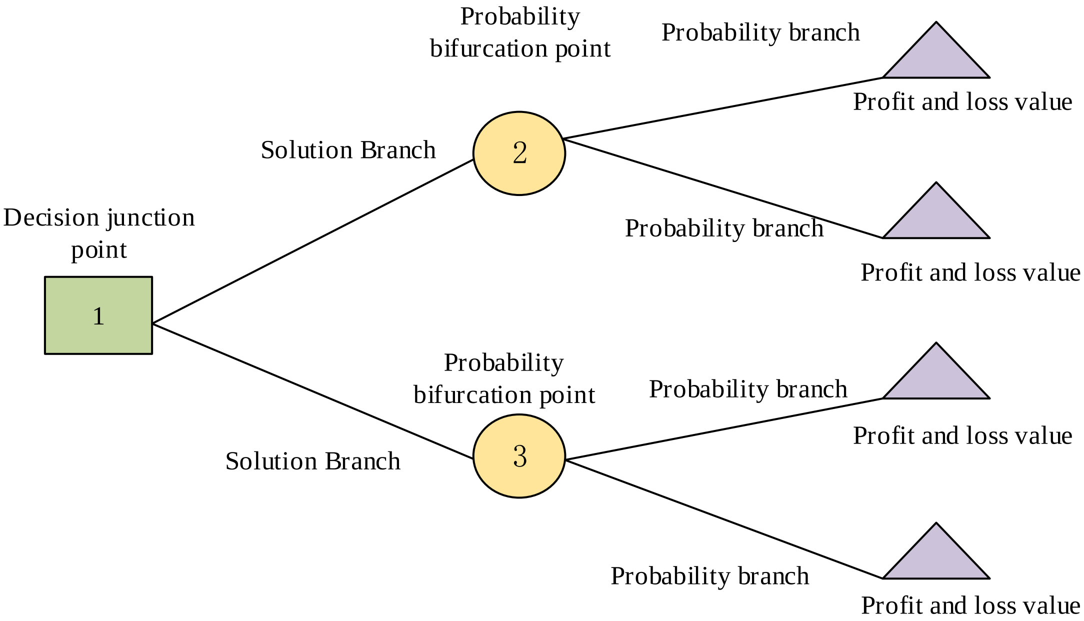

Fig. 2. Structure diagram of decision tree.

Fig. 2 shows a schematic diagram of the decision tree structure, which includes decision binding points, solution branches, probability branches, probability bifurcation points, profit and loss values, etc. Among them, decision junction points, also known as internal nodes or split nodes, represent the decision-making basis for dividing the current data. The decision binding point uses a certain feature or attribute and corresponding threshold to divide the dataset into two or more subsets. The solution branch refers to the edge of the decision junction point, which represents different decision paths or options. Each scheme branch corresponds to a specific feature value or attributes value, indicating that the dataset moves towards different sub nodes on the ground of the value of that feature value. The probability branch indicates the probability transition from one node to another, corresponding to the conditional probabilities of different categories. Profit and loss value is an indicator that measures the effectiveness of decision tree splitting. When selecting a certain feature as the decision binding point, the quality of partitioning is evaluated by calculating the profit and loss value after partitioning on that feature. The profit and loss value can be on the ground of different criteria, such as the Gini index or information gain. The Gini index in the decision tree is shown in Eq. (1).

$$Gini(p) = 1 - \sum (pi)^2 \tag{1}$$

In Eq. (1), pi represents the probability that the sample belongs to the i-th category. The formula for information gain in the decision tree is shown in Eq. (2).

$$IG(D,A) = H(D) - \sum (|\frac{Dv}{D}|) * H(Dv) \tag{2}$$

In Eq. (2), D represents the dataset; A represents a feature; $H(D)$ represents the entropy of the dataset; $H(Dv)$ represents the entropy of a subset. The information gain in C4.5 algorithm is shown in Eq. (3).

$$GainRatio(D,A) = IG(D,A) / SplitInfo(D,A) \tag{3}$$

In Eq. (3), $SplitInfo(D,A) = -\sum (\frac{|Dv|}{|D|}) * \log^2 (\frac{|Dv|}{|D|})$. Gini index and information gain are commonly used indicators to select the best features for node partitioning. The information gain ratio is an improved indicator introduced in the C4.5 algorithm, which avoids excessive preference for features with more values. Then, it is necessary to prune the decision tree, which is a technique used to reduce the complexity of the decision tree model. When constructing a decision tree, overfitting often occurs, where the model is too complex to generalize well to new data samples. Pruning is the process of reducing the risk of overfitting by pruning some branches or leaf nodes of a decision tree, thereby improving the generalization ability of the model. Decision tree pruning can be divided into two methods: pre-pruning and post-pruning. This study used post pruning, as shown in Fig. 3.

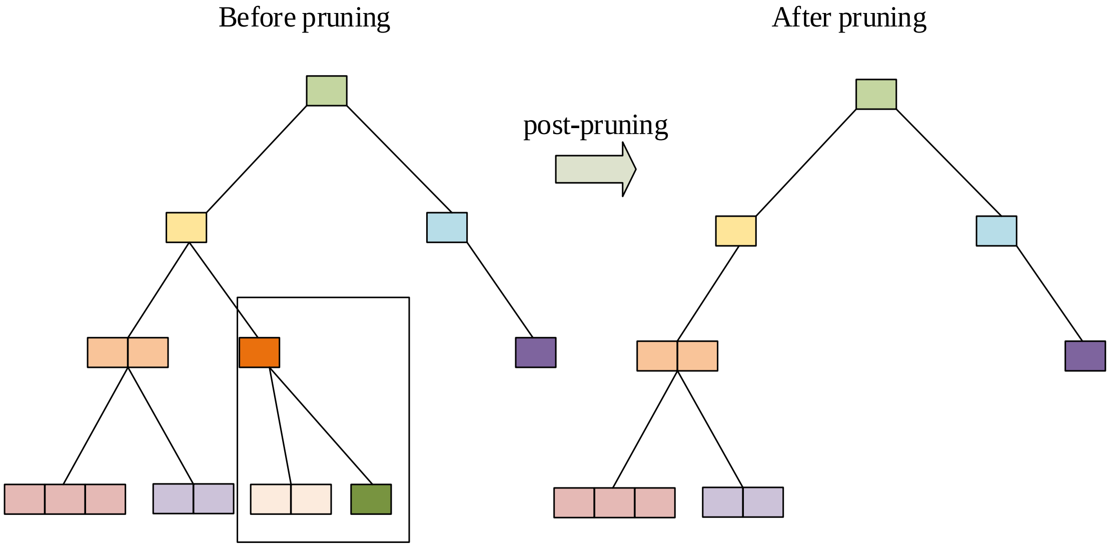

Fig. 3. Decision tree pruning process.

Fig. 3 shows the pruning process of a decision tree, which involves pruning an existing decision tree from the bottom up after it, is constructed. Firstly, this study evaluates each leaf node and calculates its performance indicators (such as accuracy, error rate, etc.) on the validation set. Then, it gradually tries pruning, replacing the leaf node with its parent node, and observes whether the model performance has been improved. If the performance of the model improves after pruning, perform pruning operations; otherwise, keep it as is.

B. An Intelligent Acquisition Optimization Model for Library Based on Fuzzy Decision Tree

On the ground of the basic principle of decision tree, establish a library intelligent acquisition decision model on the ground of decision tree. Firstly, it collects data related to library interviews, including user information, library resources, borrowing history, etc. Then there is data preprocessing, which involves cleaning and preprocessing the data, including handling missing values, outliers, and duplicate values. The third step is feature selection, which evaluates the importance of features through feature analysis and correlation detection. The fourth step is data partitioning, which divides the dataset into training and testing sets for model training and evaluation. Then it constructs a decision tree and uses the decision tree algorithm C4.5 to construct a decision tree model. It then prunes the decision tree and performs pruning operations on the constructed decision tree to avoid overfitting. The seventh step is model training and evaluation, evaluating the performance of the model on the ground of the performance of the test set. Then it uses the constructed decision tree model to predict and make decisions on new interview situations or user needs. Finally, on the ground of feedback and results from practical applications, the model is optimized and adjusted. The basic algorithm flow of the library intelligent acquisition decision model on the ground of decision tree algorithm is shown in Fig. 4.

Decision tree algorithms are usually able to generate models with good interpretability and comprehensibility, but when the problem has ambiguity, traditional decision trees may become complex and difficult to understand. Library interviews involve many ambiguous situations, such as the ambiguity of user needs and the fuzzy description of library resources [18-19]. Traditional decision trees can only handle discrete classification and attribute values, and cannot effectively handle ambiguity. To address this issue, this study introduces fuzzy theory to handle the uncertainty of data. It allows node partitioning to have fuzzy membership, rather than strict binary partitioning [20]. Such fuzzy partitioning can better handle data with uncertainty or fuzziness. Fuzzy theory can be roughly divided into the following types, as shown in Fig. 5.

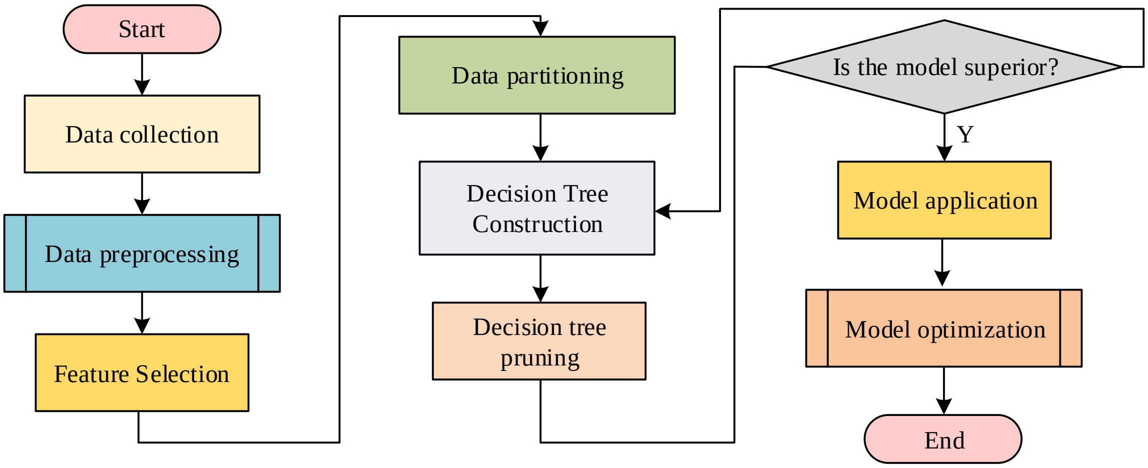

Fig. 4. The algorithm process of library intelligent acquisition decision model.

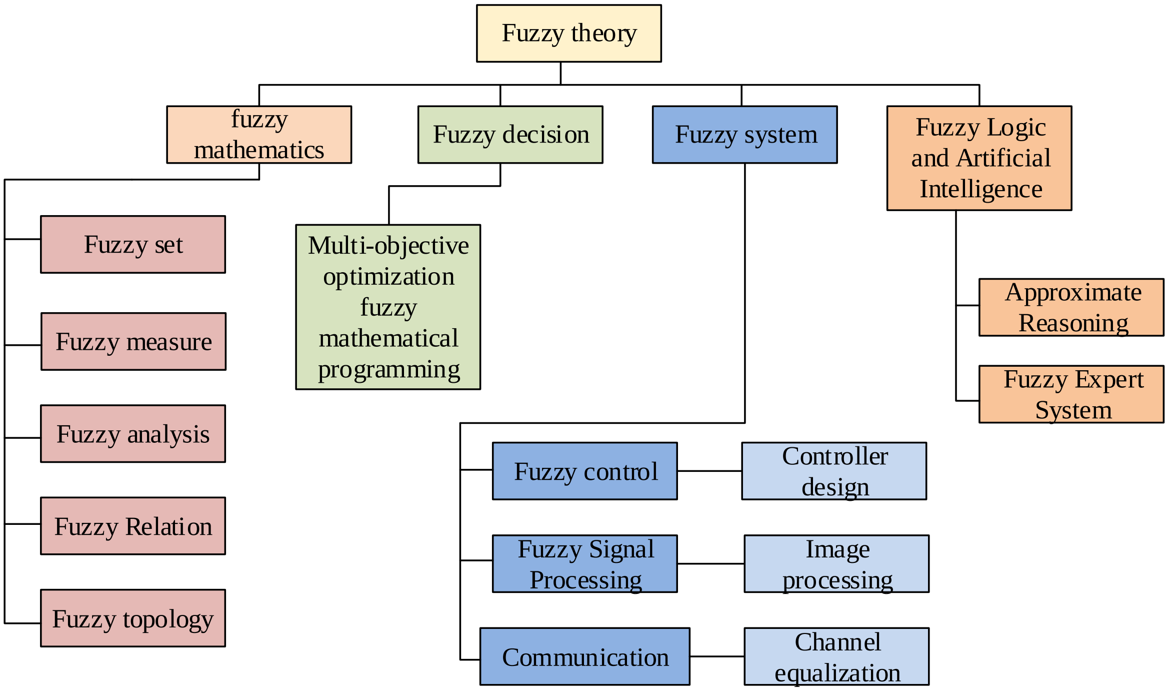

Fig. 5. Fuzzy theory classification.

As shown in Fig. 5, fuzzy theory is a very large concept with extensive applications in modern society. It mainly covers aspects such as fuzzy mathematics, fuzzy decision-making, fuzzy systems, uncertainty and information, as well as fuzzy logic and artificial intelligence. Fuzzy mathematics is the foundation of fuzzy theory, which is used to deal with problems that cannot be clearly classified as true or false. Fuzzy decision-making is dedicated to dealing with decision-making problems containing fuzzy factors. Fuzzy system is a method of applying fuzzy theory, which simulates human thinking patterns and generates fuzzy outputs by applying fuzzy rules to input data. Fuzzy logic and artificial intelligence are important components of fuzzy theory, which includes approximate reasoning and fuzzy expert systems. The application of fuzzy theory can better handle uncertainty and fuzziness, thus achieving more accurate and reliable results. Assuming X is a given finite set, the fuzzy subset is shown in Eq. (4).

$$A = \frac{A(e_1)}{e_1} + \frac{A(e_2)}{e_2} + \ldots + \frac{A(e_N)}{e_N} \quad (4)$$

In Eq. (4), the potential in the set is used to measure the size of the set, as defined in Eq. (5).

$$M(A) = \sum_{i=1}^{N} A(e_i) \quad (5)$$

In Eq. (5), A represents a fuzzy subset. The probability formula for samples belonging to a certain class in nodes in a fuzzy decision tree is shown in Eq. (6).

$$\beta_A^C = SIM(A,C) = \frac{M(A \cap C)}{M(A)} = \frac{\sum_{x \in X} \min(\mu_A(x), \mu_C(x))}{\sum_{x \in X} \mu_A(x)} \quad (6)$$

In Eq. (6), $M(A)$ represents the sum of all membership degrees representing the fuzzy set A. For any fuzzy subset, the relative frequency of the j-th fuzzy category of its non leaf node is shown in Eq. (7).

$$p_{ij}^{(k)} = \frac{M(T_i^{(k)} \cap T_i^{(n+1)} \cap X)}{M(T_i^{(n)} \cap X)} \quad (7)$$

In Eq. (7), $T_i^{(k)}$ represents a fuzzy subset; X represents a non leaf node, and the fuzzy classification entropy of each fuzzy subset of X is shown in Eq. (8).

$$FEntr_i^{(k)} = -\sum_{j=1}^{m} p_{ij}^{(k)} \log_2 p_{ij}^{(k)} \quad (8)$$

In Eq. (8), $1 \le k \le n$, $1 \le j \le m$, then the average fuzzy classification entropy of attributes on non leaf nodes is defined as shown in Eq. (9).

$$FEntr_k = -\sum_{j=1}^{m_k} \omega_i FEntr_i^{(k)} \quad (9)$$

In Eq. (9), ω_i represents the weight of the i-th attribute value. So the non assignability of classification on non leaf nodes is shown in the definition of Eq. (10).

$$Ambig_i^{(k)} = \sum_{j=1}^{m} (\pi_{ij}^{(k)} - \pi_{i,j+1}^{(k)}) \ln j \quad (10)$$

In Eq. (10), m represents the number of fuzzy categories, so the average classification of non leaf nodes cannot be specified as shown in Eq. (11).

$$Ambig_k = -\sum_{j=1}^{m_k} \omega_i Ambig_i^{(k)} \quad (11)$$

When obtaining classification rules from uncertain information, fuzzy membership functions are often used to describe uncertainty. The fuzzy membership function characterizes the degree of uncertainty of the membership function through its parameters. This method can help handle data or situations that cannot be clearly classified into a certain category. The decision tree algorithm flow combining fuzzy logic is shown in Fig. 6.

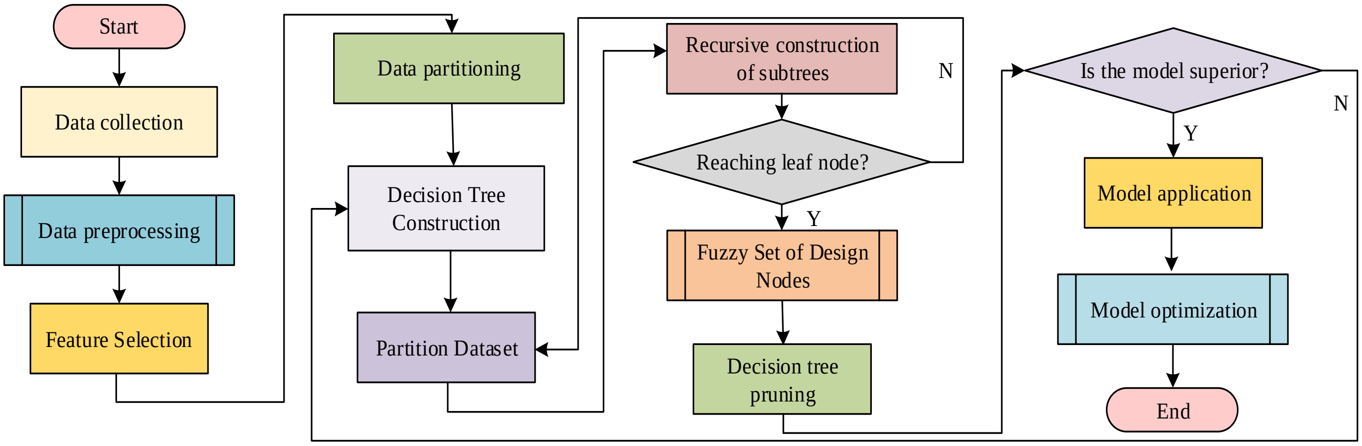

Fig. 6. Decision tree algorithm flow combining fuzzy logic.

Fig. 6 shows the flowchart of the fuzzy decision tree algorithm. Compared with the standard decision tree algorithm, the steps for building the model have slightly changed, while the rest are roughly the same. When building a model, the dataset is first divided into different subsets on the ground of the selected features, with each subset corresponding to a sub node. It recursively constructs a subtree, recursively executing the above steps for each sub node until it reaches the leaf node or cannot be further divided. It designs a fuzzy set of nodes, and on the ground of the partitioning results and category labels, designs a fuzzy set representation of the current node, including fuzzy membership functions and membership degrees. This study evaluates the model on the ground of indicators such as accuracy, recall, F1 value, etc. The accuracy formula is shown in Eq. (12).

$$Accuracy = \frac{(TP+TN)}{(TP+TN+FP+FN)} \tag{12}$$

In Eq. (12), TP represents the true example; TN represents a true negative example; FP represents a false positive example; The recall rate formula is shown in Eq. (13).

$$Recall = \frac{TP}{TP+FN} \tag{13}$$

In Eq. (13), FP represents a false negative example; The recall rate represents the proportion of cases that the model correctly judges as positive, and can measure the model's ability to correctly recognize positive cases. The formula for F1 value is shown in Eq. (14).

$$F1 = \frac{2(Accuracy * Recall)}{(Accuracy + Recall)} \tag{14}$$

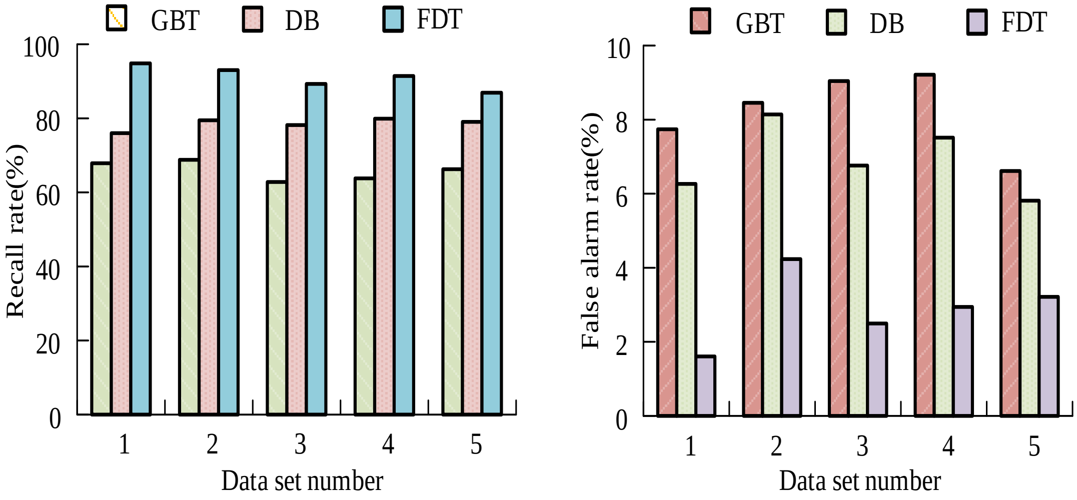
IV. Algorithm Performance Testing and Model Applicability Analysis

This chapter is separated into two sections. The first section mainly verifies the improvement effect of the decision tree algorithm and conducts comparative experiments with various similar algorithms. The second section mainly analyzes the applicability of the library intelligent acquisition decision-making model and applies it to actual library management.

A. Performance Evaluation and Comparative Study of Fuzzy Decision Trees in Library Acquisition Decision-making

The experiment combines fuzzy sets to design a fuzzy decision tree on the ground of a decision tree. To study the algorithm performance and superiority of the model, Gradient Boosting Tree (GBT) and AdaBoos algorithm (DB) were introduced in the experiment to compare with the fuzzy decision tree proposed in the study. This experiment used PyTorch 1.8 software on the Windows 10 system platform to train three models 500 times using five different datasets, as shown in Fig. 7.

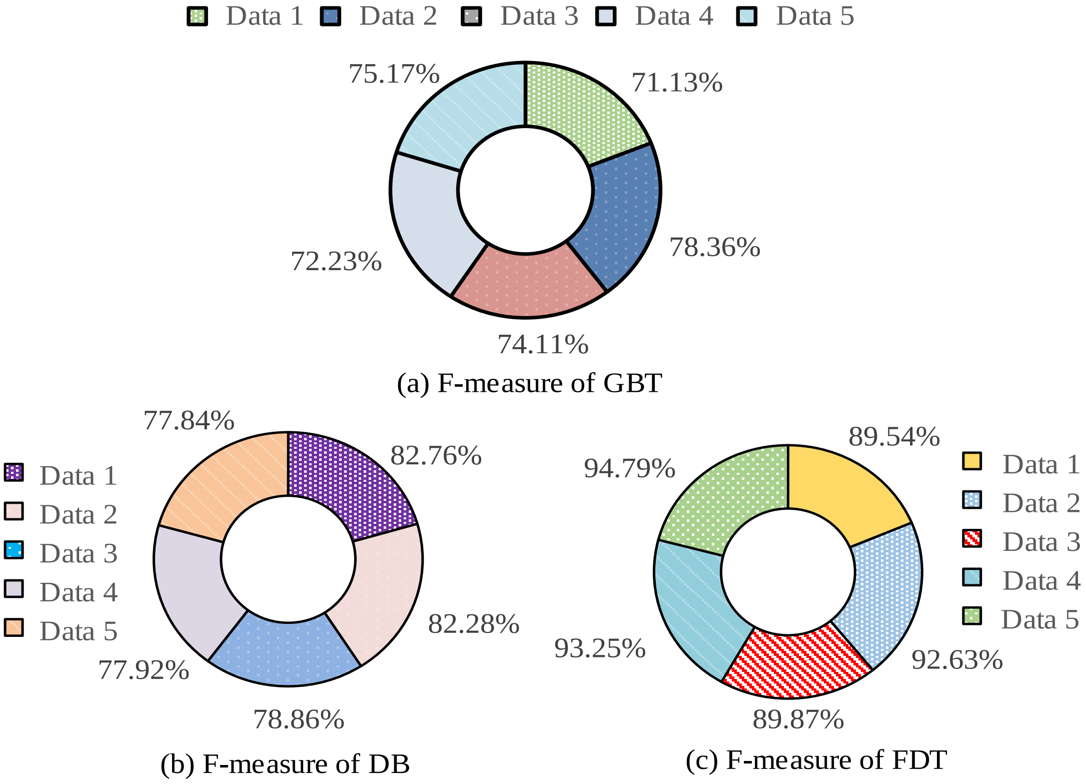
Fig. 7 shows the evaluation results statistics of three models in terms of recall and error rates. Fig. 7 (a) shows that the FDT model performs best in terms of recall rate, with various evaluation indicators reaching 96.45%, 92.64%, 87.92%, 91.17%, and 86.65%, respectively. In terms of false alarm rate, the FDT model also performs well, with significantly lower error rates than the other two models, which are 1.88%, 4.48%, 2.53%, 2.61%, and 2.86%, respectively; this means that the FDT model has a good effect in reducing false positives and can more accurately control the situation of erroneous reports. In summary, the FDT model performs well in terms of recall and false alarm rates, with high accuracy. The F1 value is an indicator that comprehensively considers the accuracy and completeness of the classifier, providing a more reliable performance evaluation under imbalanced datasets. The F1 values of the three models are shown in Fig. 8.



(a) Comparison of recall rates

(b) Comparison of false alarm rates

Fig. 7. Results of recall rate and false positive rate evaluation.



(a) F-measure of GBT

(b) F-measure of DB

(c) F-measure of FDT

Fig. 8. F-measure for the three models.

Fig. 8 shows the results of training three models on five datasets. From the perspective of F1 values, the single GBT model is relatively low which is only 71.13% on dataset 1. Compared to this, the DB model exhibits good performance on most datasets, with a small and high average F1 difference, demonstrating its strong generalization ability. On the other hand, the F1 value of the FDT model is significantly higher than the other two models, which are 89.54%, 92.63%, 89.87%, 93.25%, and 94.79%, respectively. Overall, the average F1 value of the FDT model reaches 92.02%. The FDT model achieved the highest F1 value on all datasets, demonstrating its excellent performance in classification tasks. In addition, the AUC curves of each model were recorded in the experiment, as shown in Fig. 9.

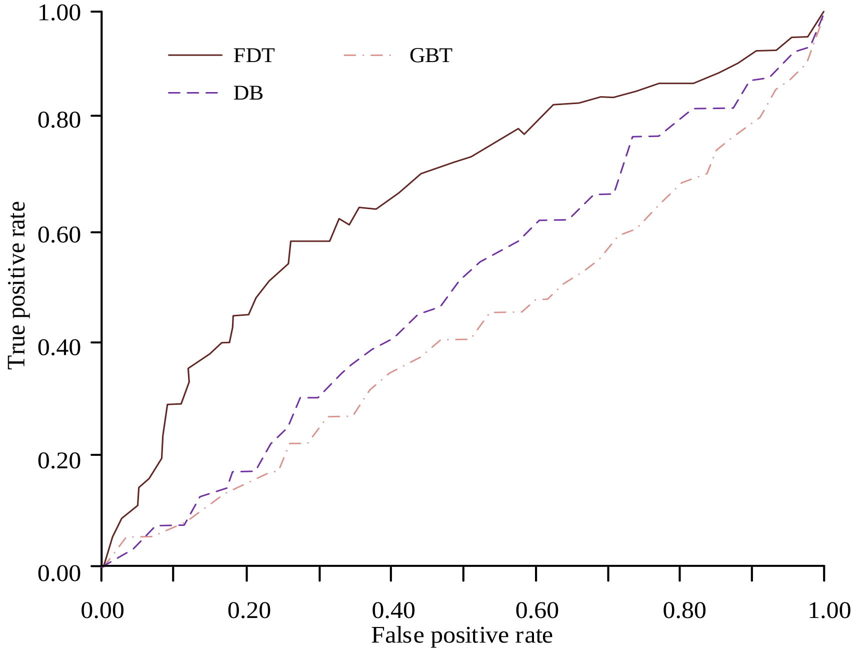


Fig. 9. AUC curves of three models.

Fig. 9 shows the statistical results of each model in terms of AUC values. In this figure, the horizontal axis represents the false positive rate, and the vertical axis represents the true positive rate. By observing Fig. 9, it can be observed that the ROC curve of the FDT model is always above the ROC curve of other models, indicating that its true positive rate performance is better under different false positive rates. In addition, on the ground of the enclosed area, i.e. AUC value, it can be concluded that the FDT model has the maximum AUC area of 0.681, while the AUC of the GBT and DB models are 0.517 and 0.463, respectively.

B. *Research on the Application of FDT Library Intelligent Acquisition Decision Model*

The experiment first conducted extensive algorithm performance testing and comparative analysis on the FDT library intelligent acquisition decision-making model, fully proving the superiority of the model. However, to demonstrate the practical application value of the model, further research on its applicability is needed. By deploying the FDT model in an actual library environment and comparing it with traditional methods, the efficiency, accuracy, and application cost of the model were evaluated. Some of the library's procurement data are shown in Table I.

The experiment used the data in Table I to train the FDT library intelligent acquisition decision-making model and rule-based model. A rule-based model uses predefined rules and conditions to make interview decisions. For example, on the ground of factors such as user borrowing history and needs, establish a set of rules to determine whether to recommend a certain book to the user. And it uses False Positive Rate and False Negative Rate as evaluation indicators. False positive rate refers to the model mistakenly determining the proportion of resources that do not require interviews as those that require interviews; the false negative rate refers to the proportion of resources that the model mistakenly judges as not requiring interviews. The training results are shown in Fig. 10.

（a）The relationship between the number of training rounds and the variation of FP

（b）The relationship between the number of training rounds and the variation of FN

Fig. 10. The relationship between the number of training rounds and the variation of FP and FN.

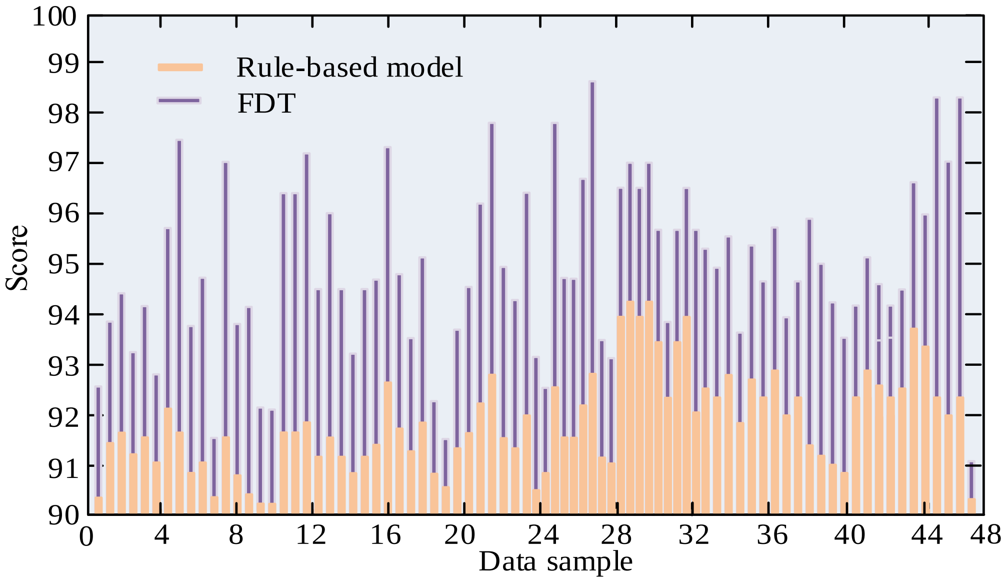

Fig. 11. Rating of the recommendation effect of the FDT model by 48 students.

Fig. 10 shows the changes in FP and FN values of the FDT model and rule-based model as the number of training rounds increases. According to Fig. 10 (a), it can be observed that the false positive case (FP) value of the FDT model continues to decrease and tends to stabilize as the number of training rounds increases. On the contrary, the FP values of rule-based models are not very stable and show an increasing trend after 150 rounds of training. Further observation of Fig. 10 (b) shows that the error rejection rate (FN) of the FDT model rapidly decreases to about 0.1 as the training frequency gradually increases, and stabilizes at around 0.05 after 210 rounds of training. However, the error rejection rate of the rule-based library acquisition decision-making model ultimately stabilized at around 0.15 levels. These results emphasize the advantages and effectiveness of the FDT model in this classification problem. The experiment also randomly invited 48 middle school students from the library to rate the recommendation effect of the FDT library intelligent acquisition decision-making model. The relevant results are shown in Fig. 11.

Fig. 11 shows the rating of 48 students on the recommendation effectiveness of the FDT model and the rule-based library intelligent acquisition decision-making model. The figure shows that most students are satisfied with the recommendation performance of these two models, and the scores given are above 90 points. However, students rated the FDT library intelligent acquisition decision-making model higher than the rule-based model, at least 1.2 points higher. Specifically, the average score of the FDT model is 94.3, while the average score of the rule-based model is 91.8. In summary, most students hold a satisfactory attitude towards the recommendation effectiveness of FDT models and rule-based models.

V. Results and Discussion

In the research of intelligent procurement decision-making systems in libraries, traditional manual decision-making methods rely on experience and lack the ability to handle large datasets, making it difficult to quickly adapt to new needs and changes. Faced with this challenge, a series of improvements have been made to the standard decision tree, and a new fuzzy decision tree (FDT) model has been designed and implemented. This model aims to better handle uncertainty and ambiguity, and improve the accuracy and efficiency of decision-making. When evaluating the FDT model, several different datasets were used and compared with two popular algorithm models - Gradient Boosting Tree (GBT) and Adaptive Boosting Algorithm (DB) - for testing. The test results show that the GBT model has a relatively low F1 value on dataset 1, only 71.13%, while the DB model performs well on most datasets, but its average F1 value difference is not significant and lower than the FDT model. Although these two models perform well in certain aspects, they still have limitations in dealing with ambiguity and uncertainty. In contrast, the FDT model performs significantly better than the GBT and DB models on all test datasets. Specifically, the F1 values of the FDT model on five datasets were 89.54%, 92.63%, 89.87%, 93.25%, and 94.79%, respectively, with an average F1 value of 92.02%. This result highlights the significant ability of the FDT model to ensure high recall and accuracy, which is particularly crucial for libraries as it can reduce the risk of missing important books and avoid purchasing books that do not meet demand. The ROC curves of the FDT model always lie above the ROC curves of the GBT and DB models, indicating that the FDT model can maintain higher true positive rates at different levels of false positive rates. As an indicator of the overall performance of the model, the AUC value of the FDT model is 0.681, significantly higher than GBT's 0.517 and DB's 0.463. This result further demonstrates the superiority of the FDT model in distinguishing between different categories (books that need to be purchased and those that do not). In terms of practical application, 48 students evaluated the effectiveness of the FDT model, and the results showed that students generally rated the FDT library intelligent interview decision-making model higher than rule-based models, with an average score of at least 1.2 points higher. The average score of the FDT model is 94.3 points, while the rule-based model is 91.8 points. This indicates that in practical applications, users are more satisfied with the recommendations provided by the FDT model, which may be because the FDT model can more accurately predict user needs and provide more personalized recommendations. However, despite the excellent performance of the FDT model in various aspects, research has also found a major drawback of this model: longer training time. This may be due to the model's need to evaluate and integrate a large number of fuzzy rules when processing data, resulting in an increase in computational complexity. The prolonged training process may limit the practicality of the model in application scenarios that require rapid updating of decision models to adapt to new situations. In the future, distributed computing resources can be utilized to allocate model training tasks to multiple computing nodes for parallel processing, significantly reducing training time. This requires the use of specialized distributed deep learning frameworks, such as the distributed version of TensorFlow, which is also an area that needs improvement in future research.

A Predictive Sales System Based on Deep Learning

Jean Paul Luyo Ballena, Cristhian Pool Ortiz Pallihuanca, Ernesto Adolfo Carrera Salas
Facultad de Ingeniería de la Universidad Peruana de Ciencias Aplicadas, Lima, Perú

***Abstract*—There are several techniques for predictive sales systems, in this study, a system based on different machine learning algorithms is developed for a trading company in Lima. As any company, it needs to be accurate in its sales calculations to manage the volume of production or product purchases. With the system, the trading company has a mechanism to order products from its supplier based on the predictions and estimates of the needs according to the projection of its sales. For the sales predictive system, Deep Learning technology and the neural network architectures GRU (Gated Recurrent Unit), LSTM (Long Short Term Memory) and RNN (Recurrent Neural Network) were used, 10 products were sampled, and the sales quantities of the last 12 months were obtained for the evaluation. The study found that the LSTM architecture excels in accuracy, significantly outperforming GRU and RNN in terms of Mean Absolute Percentage Error (MAPE), achieving an average MAPE of 7.07%, in contrast to the MAPE of 27.14% for GRU and the MAPE of 36.17% for RNN. These findings support the effectiveness and versatility of LSTM in time series prediction, demonstrating its usefulness in a variety of real-world applications.**

Keywords—Deep learning; neural network architectures; sales prediction; neural networks

I. Introduction

Effective sales management is essential to achieving business objectives but is often hampered by the availability of incomplete or outdated information, making it difficult to make informed decisions. Most of the business organizations heavily depend on a knowledge base and demand prediction of sales trends. The accuracy in sales forecast provides a big impact in business [1]. Despite the existence of conventional sales management systems, few take advantage of recent advances in artificial intelligence, and even fewer apply deep learning to improve accuracy in sales predictions. If the sales forecast is not accurate, situations of shortage or excess of stock may occur, which can have a direct and immediate impact on the profitability of the company. This effect is not only limited to the performance of profitability, but also to the customer service, therefore, service can be affected by an inefficient sales forecasting system. For example, if a customer is faced with a stock-out situation, they might decide to shop in a different company [2].

In this study, a Deep Learning based sales prediction system is proposed using three neural network architectures provided by the Brain.js library in JavaScript: GRU, LSTM and RNN. This research was conducted in a company located in Lima, using historical sales data to train and model each of these architectures. The research used 10 products specifically selected due to their relevance and analyzed data collected over a 12-month period to explore varied approaches to prediction.

To carry out this study, a series of key steps were followed. It started with the recording of historical sales data provided by the supplier. Then, different neural network architectures were used in JavaScript to perform sales analysis and prediction. Then, the data was loaded for neural network training, using the sales history as input data and the number of sales predicted for the next month as the expected output value. Subsequently, the neural network was modeled and trained with the architectures provided by the Brain.js library. Once the prediction for the next month was completed using each trained model, the corresponding predicted sales were displayed.

As part of the comparative analysis of the models, the predicted sales, the MAE (Mean Absolute Error) and MAPE (Mean Absolute Percentage Error) performance indicators and the inference time obtained from the three evaluated architectures are calculated. These steps allow to evaluate and select the most appropriate prediction model for the system, and to effectively apply the sales predictions.

Once the prediction for the next month was completed using each trained model, we show the corresponding predicted sales. As part of the comparative analysis of the models, we calculated the performance indicators MAE (Mean Absolute Error) and MAPE (Mean Absolute Percentage Error). Of the three architectures evaluated, the strongest result is the choice of LSTM due to its outstanding prediction accuracy, which significantly outperforms GRU and RNN in terms of MAPE, achieving a MAPE of 7.07%, in contrast to 27.14% for GRU and 36.17% for RNN.

This article is organized as follows: Section II shows the related works, where different neural network architectures are used for data analysis. It conceptualizes the different neural network architectures used in this study, as well as other relevant concepts used in the research. Section III explains the proposed methodology for the implementation of the Predictive Sales System, developing the following steps: Recording historical sales data, use of neural networks in JavaScript, Loading data for neural network training, Modeling and training the neural network, Model prediction and Comparison of results. In Section IV we show the results and discuss the findings, interpreting and analyzing their implications and limitations, and finally Section V concludes the paper.

In research [3], a novel and effective method for multi-channel retail demand forecasting is proposed. This method combines long-term memory (LSTM) and random forest (RF) neural networks to model complex temporal as well as regression relationships, which makes it more accurate than other forecasting methods. In addition, the proposed method has been shown to be statistically significantly better than other forecasting methods, including neural networks, multiple regression, ARIMAX and LSTM. The proposed method also improves the interpretability of the model by ranking the relative importance of the explanatory variables, which makes it useful for decision making. An empirical evaluation was conducted on 192 time series and their corresponding information signals from two different channels: an online channel for 16 products and an offline channel covering the same 16 products sold in 11 different physical stores. For this reason, the analysis shows that the proposed method outperformed the other methods with a 95% confidence level in predicting the weekly demand for a product in a store. In conclusion, the proposed method is a valuable tool for multi-channel retailers in accurately and reliably predicting the demand for their products. This approach proves to be a valuable tool for retailers, providing accurate and reliable forecasts of the demand for their products, and contributing to our research on the performance of the LSTM algorithm.

In study [4], the authors used an LSTM neural network to evaluate its performance on point-of-sale data from a large retail chain. It was observed that bottom-up forecasts are more accurate than top-down forecasts when point-of-sale information is used for forecasting. The proposed framework helps to produce consistent short- and long-term forecasts for each level of decision making in a retail supply chain. This feature of the proposed framework helps align decision making at all levels of the organization and reduces the cost of decision misalignment. The authors conducted an empirical analysis using 141 different demand series for 10 different products offered through 1 online and 10 offline stores. Based on the results, it is safe to assume that at a confidence level of at least 95%, the bottom-up approach is better than the top-down approach in the case of retail demand forecasting. A top-down approach only generates a base forecast for the top principal node, and the top-down heuristic disaggregates the top-level forecast to obtain forecasts for all secondary nodes. In contrast, in the bottom-up approach, base forecasts are made for all lower-level nodes and then aggregated to obtain forecasts for all higher-level nodes. The article is included because of the similarity of the use of LSTM neural networks in the context of retail demand forecasting. This approach is critical to better understand how these networks can improve forecasting accuracy in these retail businesses.

In study [5], a meta-learning technique using deep convolutional neural networks, which have the feature of enhancing image recognition tasks and computer vision, is proposed for the purpose of automatically learning feature representation from sales time series. The meta-learner is used to automatically learn from a feature representation from raw sales time series data and then link the learned features to a common data set that is used to combine a set of methods from the base forecaster; the learned knowledge is used to select an optimal forecasting method for each time series according to its data features. Then, these characteristics are combined with a dataset to combine a set of forecasting methods to improve the accuracy of retail sales forecasting. The results indicate that the proposed meta-learner has a superior forecasting performance compared to several benchmark methods. The proposed meta-learner (M0) has significantly superior forecasting performance over all baseline forecasters and simple average combinations of forecasters. On average, M0 has 3.2% improvements over the best performing base predictor. In addition, the meta-learner is particularly effective during promotion weeks, with a 5% improvement over the best-performing base predictor, compared to 1.6% improvements in non-promotion weeks. This approach helps us revolutionize retail sales forecasting. The deep convolutional neural network-based meta-learning technique proposed in this paper represents a valuable contribution to the field. Its ability to automatically learn time series characteristics and select optimal forecasting methods has demonstrated substantial improvements in forecasting accuracy. This not only benefits the trading company by enabling better planning and decision making, but also highlights the potential of applying deep learning and meta-learning in real-world business scenarios, as demonstrated in our sales forecasting research.

In study [6], the authors propose economic models based on exports and imports to forecast world trade using Deep Learning. The study presents a trade forecasting framework characterized by a theoretical integration of time series and economic structures, considering the uncertainty of international trade trends. The proposed approach demonstrates the power of trade data modeling using hybrid deep neural networks. In addition, the authors use prediction performance criteria to evaluate predictions using Root Mean Square Error (RMSE) and Mean Percentage Error (MAPE). The validity of this framework has been validated using commercial data from 10 countries: Brazil, Canada, China, France, Germany, India, Italy, Japan, UK, and USA. The predictive power of the proposed approach is compared with that of ten predictive models: ARIMA, ETS, TBATS, MLR, LASSO, RFR, XGB, SVR, MLP and HDL. The highest average values for (MAPE) and (RMSE), were observed in the time series model, reaching 2979 and 2933 for exports, and 4194 and 4475 for imports, respectively. In contrast, the models based on the economic structure of the time series showed lower average values for MAPE and RMSE, registering 2861 and 3198 for exports, and 3527 and 3716 for imports, respectively. The lowest MAPE values in their study stand at 2.861% for exports and 3.527% for imports, which contrasts significantly with our research, which obtains a minimum MAPE of 0.40%. These results underscore the ability of our model using LSTM to outperform in terms of accuracy the figures presented in the article, reinforcing the relevance and effectiveness of our methodology in accurately predicting future sales.

In study [7], the authors propose a study of electricity price estimation using deep learning approaches: an empirical study on Turkish markets in normal and Covid-19 periods. In recent decades, several methods have been used to estimate electricity bills. In the early days of these techniques, econometric models were used, but it was clear that these models were not successful enough to predict peak power prices. Furthermore, no transition period, such as COVID-19, is expected to affect electricity prices. However, machine learning and deep learning models are becoming increasingly important. Many researchers have shown that these models can also successfully predict extreme fluctuations in electricity prices. The proposed method is the original Transformer Encoder Decoder with Self-Attender (TEDSE) for electricity rate estimation. It is organized in such a way that the model groups the data by a dummy variable and estimates the 24-hour electricity price of the Turkish electricity market. In this study, predictions were made using 12 different models based on Recurrent Neural Networks (RNN). The RNN-based estimates used to estimate electricity tariffs corroborated the results of the TEDSE model and underlined the success of the TEDSE model. However, due to market changes, these models individually could not accurately predict price estimates during COVID-19. For this reason, the TEDSE model forecasts sub-periods and allows electricity market participants to work more efficiently. This approach helps us understand the importance of deep learning, in particular, Recurrent Neural Networks (RNNs), in predicting complex phenomena such as electricity prices or as in our research on demand forecasting. In the study RNNs and advanced models, such as the Transformer Encoder-Decoder with Self-Attender (TEDSE), can provide more accurate forecasts even in challenging situations such as the COVID-19 period, where abrupt changes in markets are inevitable.

Table I presents a comparison of the works related to our research is made, where the different methods proposed by the authors are analyzed, the information on the data used and the time period of the study are detailed, in addition to the metrics evaluated to validate the models.

II. Contribution

The application of deep learning in sales prediction has been the topic of analysis on several research studies, as described in the related works in the previous section. The difference and contribution we make with our research is based on the evaluation of various architectures of recurrent neural networks, such as GRU, LSTM and RNN, which allows us to determine more accurately which architecture will provide us with the best metrics for predicting sales in a commercial company.

Based on the review of related works and the objective of our research, a broad conceptual framework is proposed to understand and define the fundamental concepts of Deep Learning, the architectures of neural networks and the company’s need for an efficient sales management. In this context, it is important to clearly establish the key terms and concepts that will be discussed in this work, below we will find the essential definitions that will lay the foundation for solid understanding and deeper analysis in our research.

A. Sales Management

Sales management in [8] refers to the comprehensive process of planning, coordinating, and controlling activities related to a company's sales force, with the objective of achieving optimal sales performance and reaching established business objectives. It involves developing effective strategies and tactics, as well as constantly monitoring and evaluating the performance of sales teams.

TABLE I. Comparison Between Proposed Model vs. Related Works

Year	Author’s References	Description of method / technique	Dataset Size	Performance Metric/s (value/s)
2020	Paper 1[3]	The proposed method is based on a state-of-the-art sequential deep learning method – long-short-term-memory networks (LSTM) and a machine learning method – random forest (RF).	Sales data of 16 products from online and offline stores over a period of 30 months.	The error measures employed were ARME, ARMAE, and ARMSE as proxies for the bias, accuracy, and variance of the evaluated forecasts.
2020	Paper 2[4]	Cross-Temporal Forecasting Framework (CTFF) to generate coherent forecasts at all levels of a retail supply chain, using a deep learning method, the long-short-term-memory network (LSTM).	Weekly sales data for 10 products (SKU) in a period of more than two years.	ARMAE, ARMSE, ARMAPE were used for the comparisons of forecasts errors across different approaches.
2021	Paper 3[5]	Meta-learning framework with automatic feature learning for retail product sales forecasting, based on convolution neural networks.	Sales data for 6 categories of products sold on 100 stores over a 153-week period.	Three error measures were used to compare the forecasting performance of the models: sMAPE, AvgRelMAE, MPE.
2023	Paper 4[6]	This study proposes a machine learning approach based on import and export economics statistics, the input features selection according to existing classical economic structure models under economics theories.	Data is collected from the of the export and import values of goods in USD records of 10 countries. All indices used in this study were adjusted using 2015 as the base year.	The methods used to evaluate the forecasts are the root mean square error (RMSE) and mean average percentage error (MAPE).
2023	Paper 5 [7]	The study aims to develop a prediction model for the electricity market of Turkey with more comprehensive Deep Learning models applying the TEDSE model.	In this study, 5-year of hourly historical data between 2017 and 2021 in the Turkish electricity market is used.	Root Mean Square Error (RMSE) and Mean Absolute Error (MAE) statistics along with Mean Standard Error (MSE) were used to measure the model’s performance.
2023	The model proposed	In this study, a Deep Learning based sales prediction system is proposed using three neural network architectures provided by the Brain.js library in JavaScript: GRU, LSTM and RNN.	The data for this study corresponds to historical sales records on 10 products in a period of 12 months.	To compare the performance of the models, MAE (Mean Absolute Error) and MAPE (Mean Absolute Percentage Error) are used.

Source: Own elaboration

The importance of sales management lies in its ability to accelerate and improve the achievement of business objectives, as well as in the creation of competitive advantages and greater value in the marketplace. In addition, sales management facilitates the follow-up and monitoring of processes, identifying problems early and establishing training guidelines for the growth of the sales team. The three main objectives of sales management are to increase sales volume, contribute to company profits and increase ROI, and achieve long-term sustainable growth. The system is dedicated to helping meet each of these objectives. Moreover, these objectives imply additional responsibilities for sales managers, who not only focus on sales, but must also manage and train a team of sales representatives to align them with organizational objectives. Effective sales management involves being informed about the market and making tactical decisions based on data and trend analysis.

In summary, sales management is a strategic process that seeks to maximize the performance of the sales force and achieve the company's business objectives by planning, coordinating, and controlling sales-related activities. Its importance lies in improving efficiency, generating competitive advantages, and ensuring the long-term growth of the organization.

B. Deep Learning

Deep learning [9], is a subset of machine learning that relies on multi-layered neural networks to learn and make predictions from large volumes of data. Unlike conventional machine learning, deep learning can work with unstructured data, such as images or text, without requiring pre-processing to organize it into a specific format. Deep neural networks take advantage of algorithms such as gradient slope and back propagation to adjust their parameters and improve their accuracy over time. These algorithms automate feature extraction, which reduces the reliance on human intervention in manually defining relevant features. By eliminating the need for preprocessing and enabling learning directly from unstructured data, deep learning has driven the development of artificial intelligence applications in a variety of areas, such as speech recognition, fraud detection, autonomous driving and many more. Its ability to process complex information and learn hidden patterns has enabled significant advances in solving problems that were previously considered difficult or even impossible to tackle.

In short, deep learning is a branch of machine learning that uses multilayered neural networks to learn and make predictions from unstructured data. Its ability to automatically extract relevant features and its flexibility to work with various types of data have contributed to important advances in artificial intelligence.

C. Neural Networks

In study [10], a neural network is a computational model inspired by the biological nervous system and consists of a collection of processing units called artificial neurons. These neurons are linked together by weighted connections that transmit and process information. Neural networks are used in many areas, including pattern recognition, computer vision, natural language processing and artificial intelligence in general. Their architecture consists of layers, including an input layer, one or more hidden layers and an output layer. Neural networks learn automatically through a training process in which connection weights are adjusted to improve their ability to make predictions and classifications. This process is based on learning algorithms such as supervised and unsupervised learning.

In short, a neural network is a computational model that imitates the nervous system, made up of artificial neurons connected to each other.

D. JavaScript

In study [11], JavaScript is a programming language used to create interactive web pages. It enhances the user experience by enabling features such as social media updates, animations, and interactive maps. JavaScript was born as a technology intended for the browser, with the purpose of giving greater dynamism to web pages. Browsers were able to respond to user interactions and modify the layout of website content.

E. RNN (Recurrent Neural Network)

The structure of an RNN in [12] consists of a series of repeating units connected in loops, also called "cells". Each repetitive unit receives input and produces output. There are also connections that can receive information from previous iterations. This allows information to flow recursively through the network and considers temporal dependencies.

F. GRU (Gated Recurrent Unit)

GRU [13] is an efficient variant of SRRNs (standard recurrent neural network) used in natural language processing with its simple structure, it is easy to train and computationally efficient. It has proven its effectiveness in machine translation and speech recognition, being popular in machine learning and artificial intelligence.

G. LSTM (Long Short-Term Memory)

In research [14], LSTMs are a special type of RNN whose main characteristic is that information can persist by introducing loops in the network diagram, which means that it can remember previous states and use this information to decide which will be the next one. LSTMs have a longer-term memory.

A great asset of LSTM [15], is its capacity to unravel intricate temporal structures and seize the fluid dynamics of systems that undergo time-driven fluctuations. By dissecting the inherent motifs and inclinations embedded within the data, LSTM architectures can reveal interconnections that may not be easily distinguished using established statistical or machine learning methodologies.

In comparison to LSTM, GRU [16] has a simplified cell structure that also operates based on a Gating system, but only has an update and reset gate. The main difference to LSTM is the circumstance that the cell state can be completely revised at each iteration and updated with short-term information via the reset gate. Instead, LSTM provides a mechanism that limits the change gradient that can be done at each iteration. Therefore, information is not completely gone with LSTM in contrast with GRU.

H. MAE (Mean Absolute Error)

MAE [17] is a popular metric because the error value units match the predicted target value units. In MAE, different errors are not weighted more or less, but the scores increase linearly with the increase in errors. The MAE score is measured as the average of the absolute error values. The Absolute is a mathematical function that makes a number positive.

Therefore, the difference between an expected value and a predicted value can be positive or negative and will necessarily be positive when calculating the MAE.

I. MAPE (Mean Absolute Percentage Error)

MAPE [18] is a relative error measure that uses absolute values to prevent positive and negative errors from canceling each other and uses relative errors that allows to compare forecast accuracy between time series methods.

Mean Absolute Percentage Error [19] is often used due to its very intuitive interpretation in terms of relative error. MAPE is relevant in finance, considering that profits and losses are often measured in relative values. It is also useful for calibrating product prices, customers are sometimes more sensitive to relative variations than to absolute ones. MAPE is frequently used when it is known that the quantity to be predicted remains well above zero. More generally, MAPE is well suited for forecasting applications, especially in situations where sufficient data is available.

J. Inference Time

In research [20], inference time is the time it takes for a machine learning model to make predictions after training. It is important to optimize the model and hardware to meet the inference time requirements.

III. Method

In this study, a sales management system was implemented using the Brain.js library in JavaScript. Fig. 1 presents the steps for the method used.

A. Recording Historical Sales Data

The data for this study corresponds to historical sales records compiled from records provided by the company owner. We have focused on 10 products specifically selected because of their relevance. These products were accessed in the period between August 2022 and July 2023.

B. Use of Neural Networks in JavaScript

To carry out sales analysis and prediction effectively, the Brain.js library was used in the JavaScript environment. This library offers several neural network architectures, such as GRU, LSTM and RNN, which were used to explore various approaches to prediction. This choice made it possible to investigate and select the most appropriate architecture to obtain accurate and relevant forecasting based on the patterns present in the historical data.

C. Loading Data for Neural Network Training

At this stage, the training data for the neural network was prepared. An approach was followed in which the sales history was used as the input data, and the expected number of sales for the following month was used as the expected output value. In specific terms, the input consists of the 12 sales records that occurred in the past months (see Table II).

This structuring of the data allows the neural network to gain insight into the patterns and relationships underlying the sales history and future projections. This approach is essential to achieve highly accurate predictions of future sales.

D. Modeling and Training the Neural Network

At this stage, neural network training was carried out using the architectures provided by the Brain.js library: GRU, LSTM and RNN. Each architecture offers a different approach to modeling and learning relationships in the training data. Neural networks were modeled with the appropriate parameters and settings for each architecture, and then trained using the previously prepared data. During training, the neural networks were exposed to historical sales data to learn patterns and trends. As training progressed, the networks adjusted their weights and parameters to improve prediction accuracy. At the end of this stage, each of the three neural networks was ready to be used for prediction. Each architecture offers a unique perspective for making decisions related to future sales.

E. Model Prediction

At this stage, we proceeded to use each of the trained models for the purpose of making predictions. The same procedure was followed for the three architectures available in Brain.js: GRU, LSTM and RNN. The prediction was carried out by supplying the sales value corresponding to each period in the dataset as input to the respective model. In this way, each architecture generated a sales prediction for the period in question. During this process, the inference time was recorded, reflecting the time required to complete each prediction, which made it possible to evaluate the performance of each model in terms of speed and efficiency. At the conclusion of each prediction, the sales estimate for each product was obtained and presented in the form of rounded integer values, which were displayed on the console along with the corresponding dates. This procedure was repeated for each of the three architectures, allowing a thorough comparison between the predictions generated by each model, as well as an evaluation of their accuracy and performance based on the training data.

F. *Comparison of Results*

Once the prediction for the next month has been completed using each trained model, the corresponding predicted sale is displayed. In addition, as part of the comparative analysis of the models, MAE (Mean Absolute Error) and MAPE (Mean Absolute Percentage Error) performance indicators are calculated. These indicators are obtained by comparing the sales predicted by each model with the corresponding actual values of the data set, which provides a quantitative assessment of the accuracy of each model in its predictions and allows identifying and comparing its performance against the training data.

IV. RESULTS AND DISCUSSION

This section provides the research result and discussion of the proposed models.

TABLE III. RESULTS OF GRU (GATED RECURRENT UNIT)

Products	GRU			
	Predicated Sale	MAE	MAPE	Inference Time (ms)
P-01	139	129	7,64%	0,74
P-02	61	41	38,53%	0,80
P-03	80	66	52,24%	0,82
P-04	88	38	12,30%	0,90
P-05	99	89	0,93%	1,31
P-06	50	20	75,17%	1,06
P-07	132	122	11,90%	1,15
P-08	99	89	0,54%	1,06
P-09	104	94	30,55%	1,00
P-10	117	97	41,57%	0,86
Average		79	27,14%	0,97

Source: Own elaboration

To provide a clearer understanding of the results in Tables II, III and IV, data obtained from the three neural network architectures: GRU, LSTM and RNN, used to predict sales based on 10 products with a 12-month sales history as a dataset. The results focus on the sales forecast for the following month, analyzing the Mean Absolute Error (MAE), the Mean Absolute Percentage Error (MAPE) and the inference time for each product.

TABLE IV. RESULTS OF LSTM (LONG SHORT-TERM MEMORY)

Products	LSTM			
	Predicated Sale	MAE	MAPE	Inference Time (ms)
P-01	137	117	8,34%	0,81
P-02	101	81	0,60%	0,85
P-03	121	96	0,66%	0,81
P-04	83	33	17,01%	0,72
P-05	99	80	1,08%	0,72
P-06	136	96	9,21%	0,82
P-07	149	120	0,93%	0,86
P-08	100	90	0,40%	0,75
P-09	151	141	0,74%	0,82
P-10	180	90	31,70%	0,88
Average		94	7,07%	0,80

TABLE V. RESULTS OF RNN (RECURRENT NEURAL NETWORK)

Products	RNN			
	Predicated Sale	MAE	MAPE	Inference Time (ms)
P-01	91	81	39,58%	0,87
P-02	93	73	7,48%	0,78
P-03	33	18	72,68%	0,59
P-04	115	65	15,30%	0,80
P-05	84	74	15,64%	0,64
P-06	77	67	48,73%	0,60
P-07	99	89	34,12%	0,59
P-08	66	56	34,42%	0,61
P-09	89	79	40,49%	0,63
P-10	94	74	53,27%	0,60
Average		68	36,17%	0,67

Source: Own elaboration

Tables detailing the results for each architecture, GRU (see Table III), LSTM (see Table IV) and RNN (see Table V) provide clear and concise overview of the differences between them.

After analyzing the numerical results of the three evaluated architectures, the following results can be observed:

1) Mean Absolute Percentage Error (MAPE): The results in Table IV reveal that LSTM exhibits significantly lower MAPE values compared to GRU (see Table III) and RNN (see Table V). With an average MAPE of 7.07% for the 10 products, LSTM significantly outperforms GRU (27.14%) and RNN (36.17%). These findings highlight the remarkable precision of LSTM in predictions, demonstrating its ability to reduce the absolute error between the predicted mean value and the actual value.

Additionally, the incorporation of MAPE in this study provides a more comprehensive metric, as it not only considers the magnitude of the error but also the relative proportion to the actual value, offering a more detailed assessment of the predictive performance of each architecture.

2) Mean Absolute Error (MAE): Table V shows that the RNN architecture exhibits a lower average MAE (68) for the 10 products, surpassing GRU (see Table III) and LSTM (see Table IV), which have MAE values of 79 and 94, respectively. This suggests that, although RNN does not always predict with the same precision as other architectures, when it makes errors, the predictions do not differ significantly from the actual sales figures.

The inclusion of MAE in the analysis provides a valuable perspective on the average magnitude of errors, allowing for a more direct comparison between architectures in terms of absolute deviation of predictions from actual values.

3) Inference Time: The average inference times, presented in Tables III, IV and V are 0.97 milliseconds for GRU, 0.80 milliseconds for LSTM, and 0.67 milliseconds for RNN, respectively. While there are marginal differences between architectures in terms of inference speed, these results suggest that the choice of architecture should not be primarily based on inference time for this application. It is important to note that the effectiveness of each architecture should be evaluated considering both predictive accuracy and computational efficiency.

TABLE VI. ARCHITECTURE PERFORMANCE COMPARISON

	GRU	LSTM	RNN
MAE	79	94	68
MAPE	27,14%	7,07%	36,17%
Inference Time (ms)	0,97	0,80	0,67

Source: Own elaboration

A key finding of the thorough analysis of the tables, is that LSTM stands out as the most favorable architecture for predicting product sales, as shown in Table VI. It not only achieves the lowest MAPE, indicating high prediction accuracy, but also maintains an acceptable MAE and a competitive average inference time, balancing speed with performance.

Our research has been characterized by working with three different architectures to enrich the literature and analyze different forms of data processing. This contributes to future research and obtaining a more efficient and timelier sales prediction, considering, that it is an important factor in companies knowing how much is going to be sold, which leads us to assess the quantities of items to be produced or sold, eliminating storage costs or overproduction, this being a success factor in any business.

LSTM has been successfully used in a variety of forecasting systems, ranging from retail sales prediction [3, 4, 5] to global trade forecasting in several major countries [6] and electricity price prediction in energy markets [7], highlighting its effectiveness and versatility in various forecast contexts. However, with technological advances in neural networks, it should have finer precision, noting that while the current minimum values of Mean Absolute Percentage Error and Mean Absolute Error are acceptable, they could be optimized.

V. CONCLUSION

The paper has analyzed several algorithms with the objective of improving the accuracy of future sales predictions, which supports the acquisition of products without the need to maintain a high warehouse stock and reduce unnecessary purchase costs per month. The results show that the LSTM architecture excels in terms of accuracy, implying a potential positive impact on the Lima trading company's operational efficiency and its ability to make informed strategic decisions.

Of the three architectures evaluated, the strongest result is LSTM, for its outstanding prediction accuracy that significantly outperforms GRU and RNN in terms of Mean Absolute Percentage Error (MAPE), achieving an average value of the 10 products at 7.07%, in contrast to 27.14% for GRU and 36.17% for RNN. In addition, an acceptable value of the Mean Absolute Error (MAE) with 94 and an average time of 0.80 milliseconds validated among the three architectures evaluated.

Finally, when considering prediction accuracy, Mean Absolute Percentage Error (MAPE) and inference time, the preferred choice is clearly LSTM. This is due to the importance of MAPE in this context. Although RNNs have advantages over MAE, LSTM remains the strongest choice for applications where prediction accuracy is crucial. LSTM focuses on measuring the relative accuracy of forecasts, which is essential for business decision making, effective comparisons, accurate inventory management, informed investments, efficient resource allocation and continuous improvement of business strategies. This underscores LSTM's ability to make highly accurate forecasts, which can be critical in applications where estimation accuracy is essential.

ACKNOWLEDGMENT

Thanks to the Research Directorate of the Peruvian University of Applied Sciences for their support to carry out this research work through the UPC-EXPOST-2023-2 incentive.

Telemedicine and its Impact on the Preoperative Period

A Systematic Review of the Literature

Raquel Elisa Apaza-Avila
Postgraduate Unit, Universidad Nacional Mayor de San Marcos, Lima, Perú

***Abstract*—The application of telemedicine has aroused a lot of interest in the field of chronic disease care, which is associated with clinical medicine. The aim of this research is to systematically evaluate the published evidence on telemedicine in the preoperative period. A systematic search was conducted over the last five years, excluding secondary research. Selection criteria were applied, obtaining 68 articles that met these criteria and quality criteria. The results show that the largest production is carried out in the United States and the United Kingdom, with collaboration between institutions and countries. The main use of telemedicine was in teleconsultation and telecounseling activities. In addition, the application of telemedicine in the preoperative period was made to a greater extent for general procedures without distinction of surgical specialty, oncological surgery and traumatology. An increased production observed can be related to the need for physical distancing due to the pandemic. Future research could include the co-occurrence of search terms, the impact of smartphones, NER terms, and the impact of polarity and objectivity on readers' choice of articles to read, share, and cite.**

Keywords—Telemedicine; digital health; e-health; preoperative care; preoperative period; systematic review

I. INTRODUCTION

The application of telemedicine has sparked interest in chronic disease care settings, which are generally encompassed in clinical disciplines. The application of telemedicine in surgical practice has become relevant in terms of the use of telesurgery. Reviews have been found about the use of applications in the prediction of mortality associated with surgery and the link with decision-making [1]. In this context, the question arises about the impact of telemedicine in the preoperative period.

There are a variety of experiences in the application of telemedicine in diverse health settings [2][3], which, despite the advantages regarding access to care, have also pointed out limitations such as difficulty in telephone access, omitted or erroneous information during data collection, and delay in the reporting of cases under investigation [4].

As Bokolo [5] points out, telemedicine and telehealth refer to the use of information and communication technologies embedded in software programs with high-speed telecommunications systems for the provision, management, and monitoring of health services.

In Peru, the definition of telemedicine is contained in the modifications of Telehealth Framework Law [6], as:

"The provision of remote health services in the components of promotion, prevention, diagnosis, treatment, recovery, rehabilitation and palliative care, provided by health personnel using ICTs, with the purpose of facilitating access to health services for the population".

Telemedicine could also be used to refer to the use of telecommunications for the remote provision of health services.

The World Health Organization (WHO) points out that telemedicine includes both diagnosis and treatment, as well as medical education, and that it is a technological resource that makes it possible to optimize health care services, saving time and money and facilitating access to distant areas for specialist care. In the context of the health crisis resulting from the pandemic, its use has become relevant [7].

Its applications include clinical practice and health education. Within clinical practice there are the following forms: Telediagnosis, Teleconsultation, Remote monitoring, medical meetings to obtain second opinions (Teleconference), Digital storage of data or medical records. Within the educational area, distance classes from medical centers (e-learning through videoconferencing) stand out [2] [4] [8].

Aspects related to the construction of bibliometric networks, polarity, objectivity, and subjectivity of the scientific production of telemedicine in the preoperative period have not been pointed out in the reviews on this topic.

In the current context, surgical activities have been suspended in most institutions around the world and considering the advantages of telemedicine in terms of timeliness of care [5], the aim is to investigate its usefulness in the field of preoperative activity.

This systematic review aims to explore the state of the art of telemedicine in the field of preoperative care.

In this vein, Section II covers the background and related works, where similar characteristics to the proposals of this work are specified. Section III is revision method which, details the methodology used in this document. Section IV delves into results and discussion which shows the compilation of studies and the data they generated, which are shown by graphs and tables to determine observations. To conclude, Section V, conclusions and future research, presents the recommendations reached because of the analysis of the information obtained, as well as suggestions for scientific production on the subject addressed.

II. Background and Related Work

There are systematic reviews related to the application of telemedicine in the preoperative setting.

Research places telemedicine as a developing technology, and in the field of surgical practice, Sohn et al. [9] point to its use in plastic surgery and otolaryngology. In their review of telemedicine in the field of dermatological surgery, they point out that its application in preoperative consultation allows the planning of the intervention and increases access to care.

Bokolo et al., in its systematic review on the application of telemedicine and e-health technology in clinical services in response to the COVID-19 pandemic, points out the importance of the use of information and communication technologies (ICT) integrated with telecommunication software and systems for care, management and monitoring in patient care [5].

Asiri et al., on the other hand, in their review of the use of telemedicine in surgical care found that, for the most part, patients treated with this technology reported time savings and a reduction in the number of lost workdays as benefits [8].

However, not all reviews pointed to positive aspects. Moentmann et al., in their review on telemedicine in otolaryngology, noted that a negative aspect was the limitation of patient contact, although video-otoscopy is the most widely supported telemedical intervention limiting physical contact between otolaryngologists and their patients [9].

Kim et al. conducted a systematic review of research addressing the use of technology to intervene preoperatively on surgery anxiety in pediatric patients and their parents or guardians. They noted that the available literature is extremely heterogeneous and limits the ability to draw definitive conclusions about the effectiveness of technology-based interventions. In addition, the results showed that for this group of patients, tablets and manually operated devices with interactive capability may represent a viable option to address preoperative anxiety. However, they were unable to extrapolate these results to adults, with whom they had better results using videos [10].

More encouraging results are found with the reviews by Kolcun et al. [11] and Lu et al. [12]. In the first case, it highlights that the increase in the use of telemedicine has been favored by the crisis caused by the pandemic and represents an opportunity to continue developing this technology and validate its use in new fields. Their initial results show that this technology becomes a support for the interaction between doctors and patients during the need for social distancing, showing its usefulness for aspects that do not involve the need for physical contact. Aspects related to this point are indicated as, certain perioperative tasks (complementary patient education and postoperative surveys).

For Lu et al., in their review of the use of Short Message Service (SMS) and smartphones in surgical care, they conclude that applications of this type offer a sophisticated yet simple tool to improve perioperative health care, in addition to the need for a regulatory framework for communications [12].

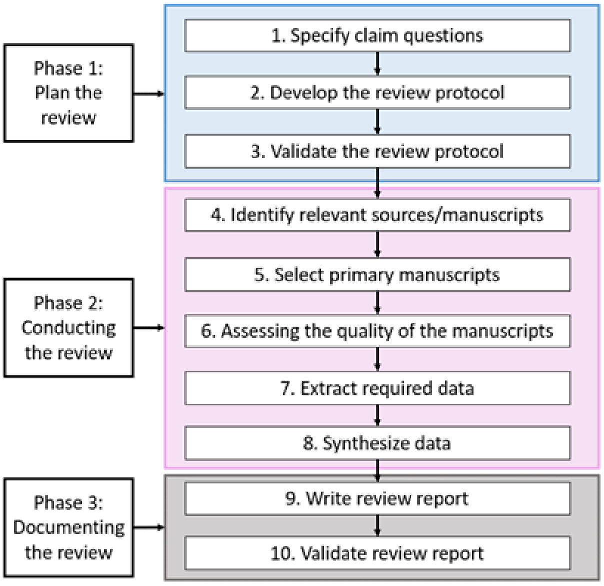
Telemedicine is attracting attention in the healthcare sector, due to the diversity of interaction modalities that have been developed over the last decade, and which are becoming increasingly affordable for both patients and doctors. At this point, Shanbehzadeh et al. [13] highlight short message service, email and web portals, secure phone calls or VOIP, video calls, interactive mobile health applications (m-Health), remote patient monitoring, and video conferencing. At the same time, it points out that the synchronous modality through common social networks was the one that presented the highest percentage of use for clinical care. While data exchange activities using the store and forward service via secure messaging technology and pre-recorded media files had the least popularity.

III. Revision Method

The method used in this research is the systematic literature review (RSL), which is defined as a process of identifying, analysing and interpreting the existing scientific evidence on a topic, with the aim of providing answers to specific research questions.

The methodology used to develop the RSL in this paper is based on the document proposed by Kitchenham [14], who divides the whole process into three general parts: the planning of the review, the development, and the publication of results.

This research followed the phases defined by Kitchenham, as well as the activities that compose them. In the first phase, the research questions are specified, and the review protocol is developed, which is necessary to reduce the possibility of bias. In the second phase, the studies to be included in the research are identified, as well as the evaluation of their quality. Finally, in the third phase, the results obtained are detailed (see Fig. 1).



Phase 1: Plan the review
1. Specify claim questions
2. Develop the review protocol
3. Validate the review protocol
Phase 2: Conducting the review
4. Identify relevant sources/manuscripts
5. Select primary manuscripts
6. Assessing the quality of the manuscripts
7. Extract required data
8. Synthesize data
Phase 3: Documenting the review
9. Write review report
10. Validate review report

Fig. 1. Development phases of the Systematic Literature Review (RSL). Translation of the systematic literature review process proposed by kitchenham.

A. *Problems and Objectives*

When a systematic review of the literature is conducted, research questions are defined, which help in the extraction and analysis of data to meet the objectives of the research.

For this research, one general question and eight specific questions were posed.

The general question was:

What is the state of the art of Telemedicine and its impact on the Preoperative Period?

The objective of this study was to determine the current state of knowledge of the application of telemedicine in the preoperative period and to know the impact that this intervention generates in this period.

The specific questions and their objectives are shown in Table I.

TABLE I. CORRESPONDENCE BETWEEN RESEARCH QUESTIONS AND OBJECTIVES

Question	Objective
RQ1. What are the most used and most relevant keywords by Number of Articles in telemedicine research and their impact on the preoperative period?	Determine which are the most used and most relevant keywords by Number of Articles in telemedicine research and in the preoperative period
RQ2: What is the relationship between the polarity of article titles and the frequency with which they are cited by other authors in telemedicine research and their impact on the preoperative period?	To determine the relationship between the polarity of article titles and the frequency with which they are cited by other authors in telemedicine research and its impact on the preoperative period
RQ3: What are the most productive institutions in the development of telemedicine and its impact on the preoperative period?	To determine which institutions are the most productive in the development of telemedicine and its impact on the preoperative period
RQ4. In which countries is telemedicine being applied most frequently in the preoperative period?	Determine where telemedicine is most commonly applied in the preoperative period
RQ5: Which means of publication are the main objectives for the production of research in the area of telemedicine in the preoperative period?	To determine the main means of publication for the production of research in the area of telemedicine in the preoperative period
RQ6. What are the types of telemedicine services that are most frequently provided in the preoperative period?	Determine which types of telemedicine services are most commonly provided in the preoperative period
RQ7. Which surgical specialties are most frequently applying telemedicine solutions in the preoperative period?	Determine which surgical specialties are most frequently applying telemedicine solutions in the preoperative period
RQ8. Which are the Articles whose Abstracts are characterized by their high Objectivity by year and country in research on telemedicine and its impact on the preoperative period?	To determine which articles whose abstracts are characterized by their high objectivity by year and country in telemedicine research and its impact on the preoperative period

B. *Search Sources and Search Strategy*

For this work, a bibliographic search was carried out using the most well-known search engines (see Table II).

TABLE II. SEARCH SOURCE

Source
IEEE Xplore
Scopus
ARDI
ProQuest
ScienceDirect
ACM Digital Library
Wiley Online Library
Microsoft Academic
Springer
Google Scholar

The table shows the search engines that were used to locate the research papers related to the topic of telemedicine and the preoperative period.

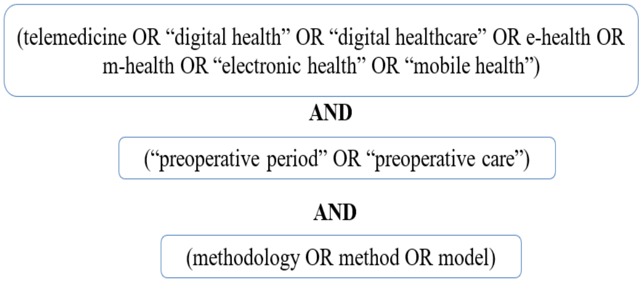
To determine the search terms, two well-known thesauri were used, the DeSC/MeSH for the terms related to telemedicine and the preoperative period, and the IEEE Xplore thesaurus also for the term telemedicine, and for the term methodology (see Table III).

TABLE III. IDENTIFICATION OF SEARCH TERMS

Tesauro	Descriptor	Description
DeCS/MeSH IEEE Thesaurus	telemedicine digital health digital healthcare e-health m-health electronic health mobile Health	Independent Variable (A)
DeCS/MeSH	preoperative period preoperative care	Dependent Variable (B)
IEEE Thesaurus	methodology method model	Intervening Variable (C)

The table shows the search engines that were used to locate the research papers related to the topic of telemedicine and the preoperative period.

The general equation was determined using the dependent, independent and intervening variables (see Fig. 2).



(telemedicine OR “digital health” OR “digital healthcare” OR e-health OR m-health OR “electronic health” OR “mobile health”)

AND

(“preoperative period” OR “preoperative care”)

AND

(methodology OR method OR model)

Fig. 2. General search equation.

Equations based on the general equation were determined for each searcher (see Table IV).

C. *Identified Studies*

The search yielded a total of 10,741 articles (see Fig. 3), to which filters related to the temporality of publication were applied, accessing articles from the last five years, as well as segregation by language, selecting those that were in English or Spanish. Subsequently, articles published in scientific journals and those peer-reviewed, as well as documents that were not duplicates, were selected.

TABLE IV. EQUATIONS AND SEARCH SOURCES

Search Source	Search Equation
IEEE Xplore	("All Metadata":telemedicine OR "All Metadata":“digital health” OR "All Metadata":“digital healthcare” OR "All Metadata":e-health OR "All Metadata":m-health OR "All Metadata":“electronic health” OR "All Metadata":“mobile health”) AND ("All Metadata":“preoperative period” OR "All Metadata":“preoperative care”) AND ("All Metadata":methodology OR "All Metadata":method OR "All Metadata":model)
Scopus	(telemedicine OR "digital health" OR "digital healthcare" OR e-health OR m-health OR “electronic health” OR “mobile health”) AND (“preoperative period” OR “preoperative care”) AND (methodology OR method OR model)
ARDI	(telemedicine OR "digital health" OR "digital healthcare" OR e-health OR m-health OR “electronic health” OR “mobile health”) AND (“preoperative period” OR “preoperative care”) AND (method OR methodology OR model)
ProQuest	(telemedicine OR “digital health” OR “digital healthcare” OR e-health OR m-health OR “electronic health” OR “mobile health”) AND (“preoperative period” OR “preoperative care”) AND (methodology OR method OR model)
ScienceDirect	(telemedicine OR “digital health” OR “digital healthcare” OR e-health OR m-health OR “electronic health” OR “mobile health”) AND (“preoperative period” OR “preoperative care”) AND (methodology OR method OR model)
ACM Digital Library	[[All: telemedicine] OR [All: "digital health"] OR [All: "digital healthcare"] OR [All: e-health] OR [All: m-health] OR [All: “mobile health”] OR [All: "electronic health"]] AND [[All: "preoperative period"] OR [All: "preoperative care"]] AND [[All: method] OR [All: methodology] OR [All: model]]
Wiley Online Library	""telemedicine" OR "digital+health" OR "digital healthcare" OR "e-health" OR "m-health" OR "electronic+health" OR "mobile health"" anywhere and ""preoperative period" OR "preoperative care"" anywhere and ""method" OR "methodology" OR "modeling"" anywhere
Microsoft Academic	(telemedicine OR “digital health” OR “digital healthcare” OR e-health OR m-health OR “electronic health” OR “mobile health”) AND (“preoperative period” OR “preoperative care”) AND (methodology OR method OR model)
Springer	(telemedicine OR “digital health” OR “digital healthcare” OR e-health OR m-health OR “electronic health” OR “mobile health”) AND (“preoperative period” OR “preoperative care”) AND (methodology OR method OR model)
Google Scholar	(telemedicine OR “digital health” OR “digital healthcare” OR e-health OR m-health OR “electronic health” OR “mobile health”) AND (“preoperative period” OR “preoperative care”) AND (methodology OR method OR model)

The table shows the search engines that were used to locate the research papers related to the topic of telemedicine and the preoperative period.

D. *Exclusion Criteria*

The following exclusion criteria were established for selecting articles:

CE1: Articles are more than five years old.

CE2: Articles are written in a language other than English or Spanish .

CE3: Articles followed peer review methodology and were not reported in a scientific journal.

CE4: The article did not propose a telemedicine solution or did not mention method or technique.

CE5: The article is not relevant to the objectives of the research.

SC 6: The article is not available, or the full text of the article is not available.

CE 7: The article is not unique.

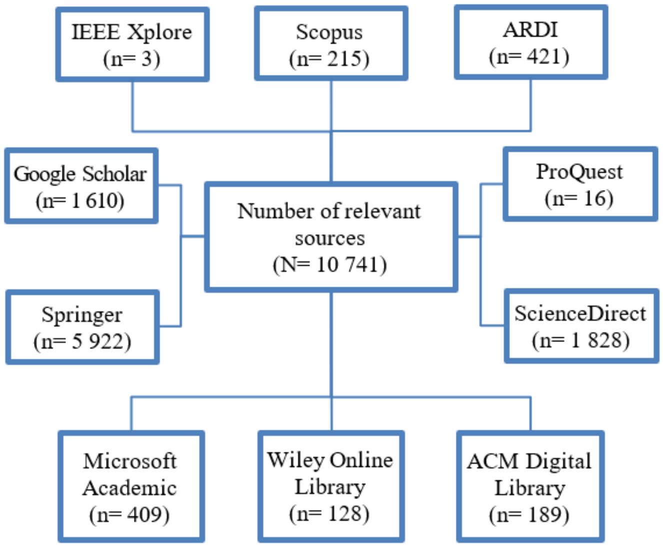


Fig. 3. Number of studies identified by search source.

E. *Selection of Studies*

Initially, 10 741 articles were obtained, to which exclusion criteria were applied for the filtering and selection of the most relevant articles that provide better answers to the research questions posed (see Fig. 4 to Fig. 5).

As a result of this stage, a total of 68 articles were included (see Table V).

F. *Quality Assessment*

To determine the final list of articles to be included in this research, criteria were applied to evaluate their quality.

Quality assessment criteria were determined for methodological characteristics and for substantive characteristics.

1) *Methodological characteristics:*

QA1: Are the objectives of the research clearly identified in the document?

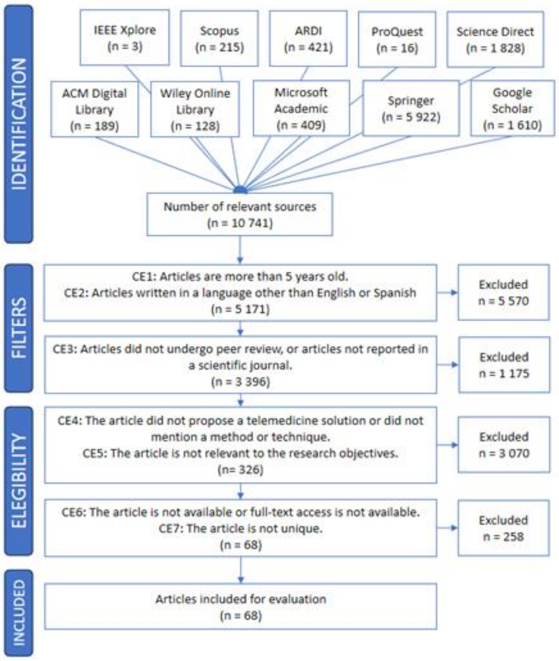
QA2: Are research results clearly identified and reported?

2) *Substantive features:*

QA3: Does the research consider elective surgeries?

QA4: Is it possible to contact the principal investigator?

The full text for each document was analyzed and the criteria shown were applied to evaluate its quality and then conclude in maintaining the 68 articles.



IDENTIFICATION

Google Scholar	1 610	8	12%
Total	10 741	68	1%

Note: Although ACM Digital Library provided the largest number of articles, the most relevant articles were obtained from Scopus.

G. Data Extraction Strategies

At this stage, the final list of articles was used, from which the necessary information was extracted to answer the research questions (RQ1 to RQ8).

The data extracted from each article were: Article ID, Article Title, URL, Source, Year, Country, Number of Pages, Language, Type of Publication, Publication Name, Research Methodology, Author(s), Affiliation, Number of Citations, Abstract, Keywords, Conclusions/Discussions, Sample Size, RQ1, RQ2, RQ3, RQ4, RQ5, RQ6, RQ7, RQ8. Not all articles answered all research questions.

The web and desktop application, Zotero, was used to manage data extraction (see Fig. 6).

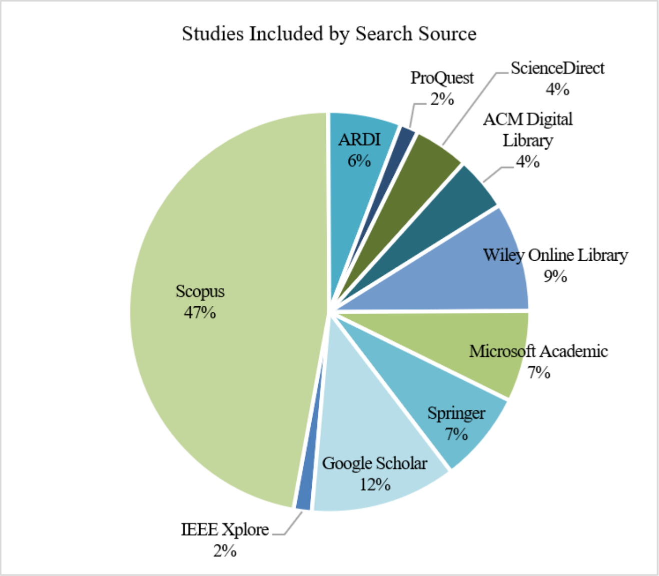

Fig. 5. The figure shows the result of the application of the search formula using the IEEE xplore, scopus, ARDI, ProQuest, sciencedirect, ACM digital library, wiley online library, microsoft academic, springer and google scholar search engines.

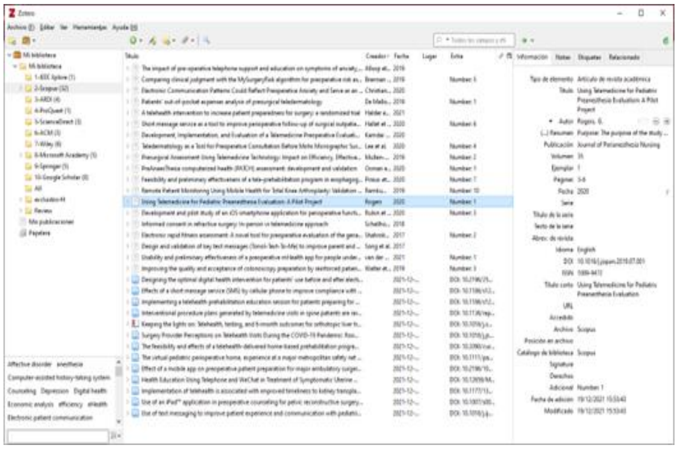

Fig. 6. Document management with Zotero.

H. Synthesis of Findings or Synthesis of Data

The information extracted for the Research Questions (RQ1 to RQ8) was tabulated and presented as quantitative data, using Excel, to statistically compare the various findings for each Research Question.

Certain patterns of research were found, as well as research directions that were carried out during the last few years.

Zotero was used for data management, while VOSViewer and Onodo were used for the analysis of bibliometric networks.

To determine objectivity and polarity, the Python program with the TextBlob library and the open access program CoreNLP v.4.3.2 were used.

IV. Results and Discussion

A. Study Overview

Of the 68 articles included in the research, there has been a sustained increase in scientific production in the last two years (see Fig. 7).

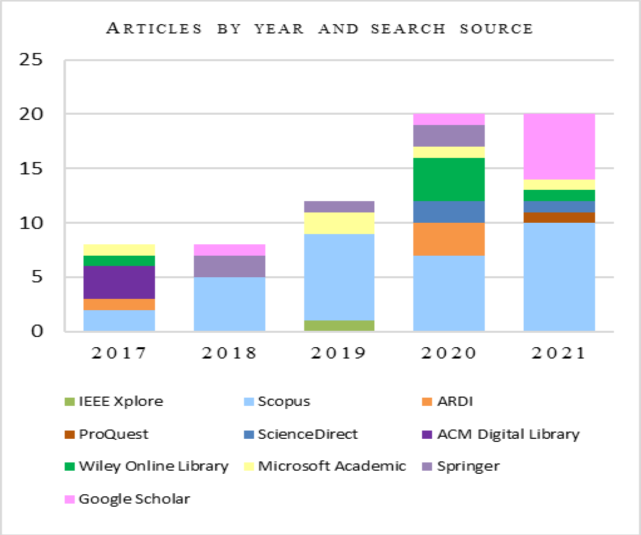

Fig. 7. The figure shows the distribution of scientific production by year and source.

A variety of sources were searched, including those that are not common for health research publications. At this point, we compare the results with those obtained by Bokolo et al. [5], which we searched Google Scholar, PubMed, ScienceDirect, ProQuest, Springer, Sage, Taylor & Francis, IEEE Xplore, Wiley, ACM, Emerald, Inderscience, ISI Web of Science, and Scopus. The results are also compared with reviews of articles published in more well-known sources in the healthcare sector, such as the research conducted by Asiri et al., in its review on telemedicine in surgical care, in which MEDLINE, EMBASE, CINAHL and Science Direct were used to obtain articles [8].

Other reviews, such as that of Jonker et al., on e-health in the perioperative in older adults, included PubMed, EMBASE, CINAHL [77]. On the other hand, the team of Moentmann et al., in its review on telemedicine in otolaryngology, searched Embase, PubMed, and Web of Science, [9].

The number of articles included in these reviews is similar, except for the review by Jonker et al., in which the number of articles included was lower due to the delimitation of search criteria for the target group (older adults) [15].

As for the number of authors, they amounted to 436 in the 68 articles included. The number of authors varied in terms of the number of authors, with an average of six authors per publication. No collaborative relationships were found between the different research groups (see Table VI and Fig. 8).

A point to consider is related to the words that are most repeated in the titles (see Fig. 9). The most frequent words were identified as the words "preoperative", "study", "surgery", "telemedicine", "patients", "COVID-19" and "mobile", which are related to the search terms used.

TABLE VI. Result of the Application of Selection Criteria

N°	Source	Number of authors
1	IEEE Xplore	8
2	ProQuest	7
3	ScienceDirect	7
4	Scopus	7
5	ARDI	6
6	Google Scholar	6
7	Microsoft Academic	6
8	Springer	6
9	Wiley Online Library	6
10	ACM Digital Library	4

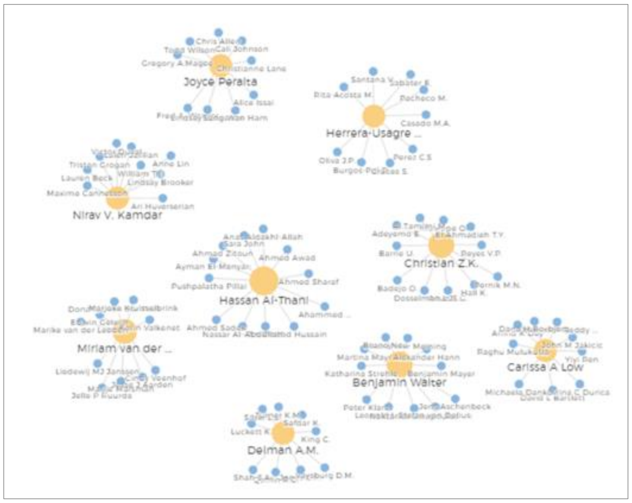

Fig. 8. First authors and co-authors who formed research teams with a larger number of members.

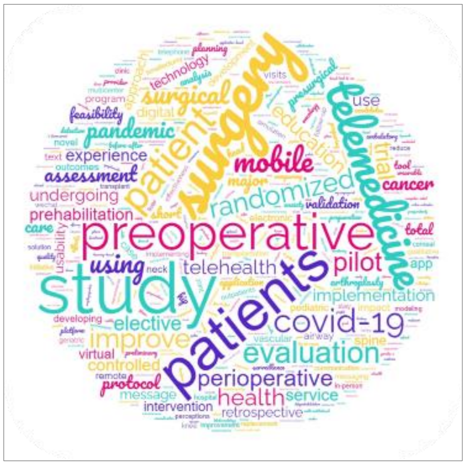

Fig. 9. Word cloud of the titles of the articles included in the research.

B. Answers to Research Questions

1) *RQ1*. What are the most used and relevant keywords by Number of Articles in telemedicine research and their impact on the preoperative period?

It is evident that the words that are most frequently used in medical articles are related to the search terms used. Table VII and Fig. 10 show the most frequently used keywords. It was consistent with other systematic reviews that include these keywords in their publications [5] [16], while other reviews, such as “surgical procedure”, “satisfaction” y “monitoring” [8].

TABLE VII. 20 KEY WORDS MOST FREQUENTLY USED

N°	Key Word	Number of Articles
1	telemedicine	26
2	humans	19
3	preoperative care	17
4	middle aged	13
5	female	12
6	male	11
7	aged	9
8	COVID-19	9
9	prehabilitation	7
10	adult	6
11	telehealth	6
12	text messaging	6
13	patient satisfaction	6
14	perioperative care	5
15	surgery	5
16	ehealth	5
17	osteoarthritis	5
18	exercise	4
19	Mhealth	4
20	smartphone	4

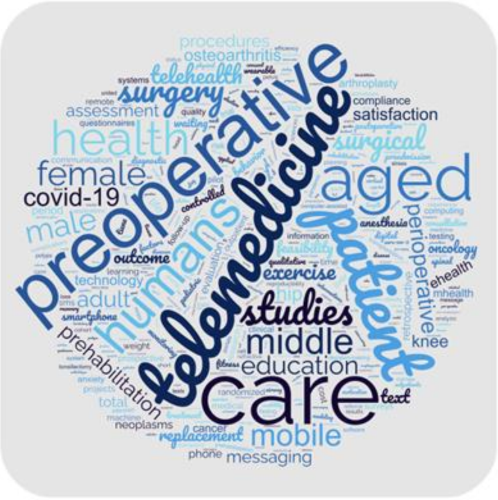

Fig. 10. Word Cloud of the keywords of the articles included in the research.

It has also been important to find co-occurrence between the keywords of the articles, such as "telemedicine", "COVID-19", "patient satisfaction", "preoperative care" and "prehabilitation", shown in Fig. 11. This result can provide guidance on the impact that the pandemic has had on the development of telemedicine research in the preoperative period, which in turn is related in the articles to patient satisfaction and better preparation for surgery [5]. It should be noted at this point that the Named-entity recognition (NER) term search program in the titles of the articles, also identified the terms "COVID-19" and "COVID-19 Pandemic".

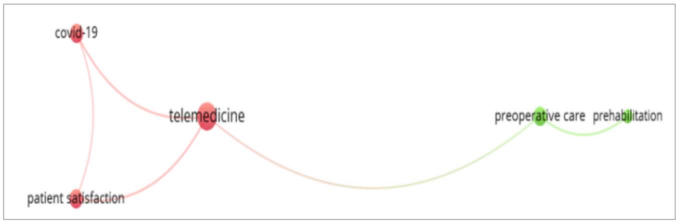

Fig. 11. Co-occurrance of keywords in the articles included in the study.

2) RQ2: What is the relationship between the polarity of article titles and the frequency with which they are cited by other authors in telemedicine research and their impact on the preoperative period?

Although no systematic reviews have been found that explore this point in the field of telemedicine, it is considered important to analyze the impact of this variable on readers.

As a result of the analysis of the titles of the articles, it was determined that, in general, titles with neutral polarity were the most cited, followed by those with positive polarity (see Fig. 12).

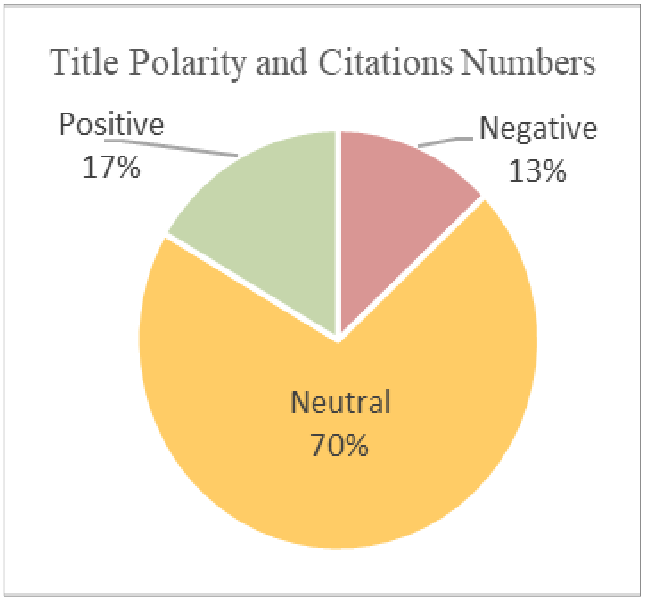

Fig. 12. Title polarity and citations.

On the other hand, the articles identified through the Microsoft and IEEE Xplore search engines showed greater neutrality in their writing (see Fig. 13).

Regarding the number of citations related to polarity and the search source in which the article was found, the highest frequency of citations is related to neutral titles extracted from Scopus (see Fig. 14).

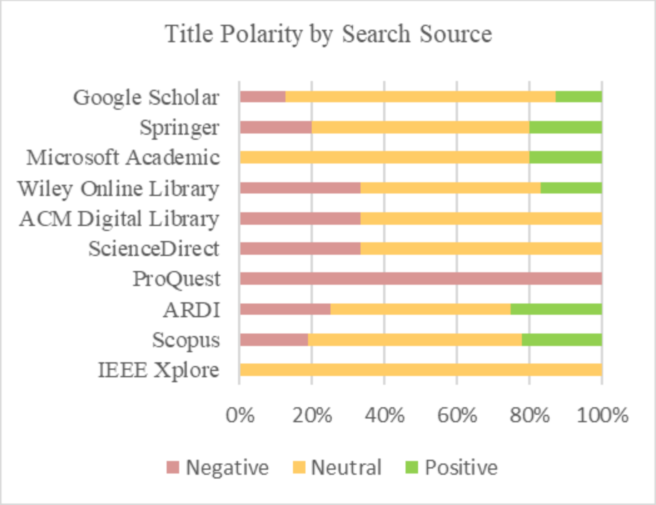

Fig. 13. Title Polarity by Search Source

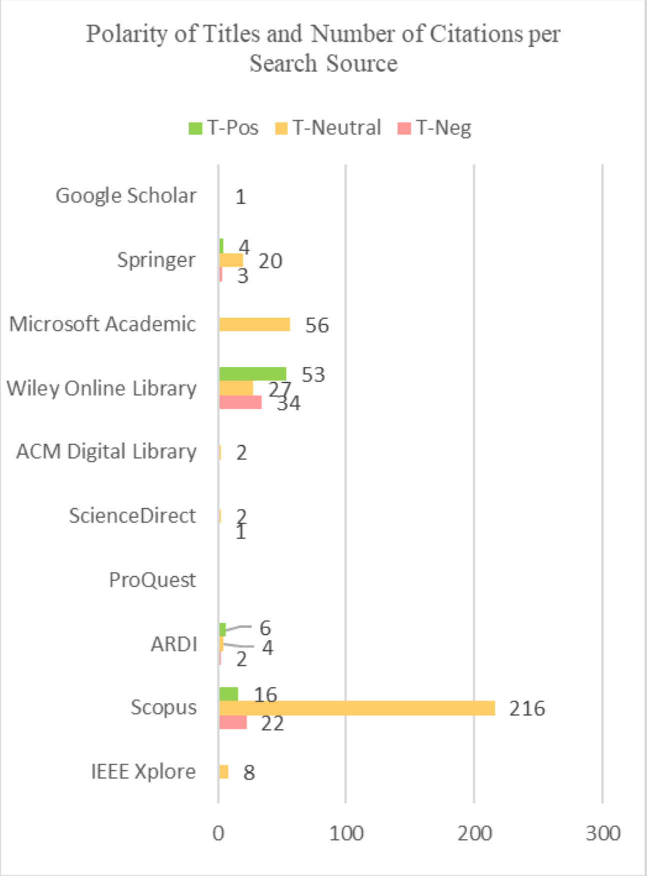

Fig. 14. The highest number of citations related to Scopus' neutral titles is observed.

3) RQ3: Which are the most productive institutions that establish collaborative networks in the development of telemedicine and its impact on the preoperative period?

Both public and private healthcare institutions, as well as those dedicated to research (universities, research groups) collaborated in the scientific production of telemedicine in the preoperative period. Six institutions produced two or more research articles (see Table VIII).

Collaboration between institutions is visualized in Fig. 15. Here we can see that the Technical University of Munich stands out. The articles that contributed the most to answering this question came from Scopus (see Table IX).

Some systematic reviews [1] [15] have pointed out the importance of collaboration between institutions and have included related experiences (first level and specialized centers, research institutions, universities, and hospitals) in their reviews.

4) RQ4. In which countries is telemedicine being applied most frequently in the preoperative period?

It is evident that publications related to telemedicine in the preoperative period have been carried out more frequently in the United States (49%) (see Table X and Fig. 16). This result is consistent with that described by M. Shanbehzadeh et al., in which the articles obtained were mostly (76.75%) carried out in this country [13].

Figures found in other reviews vary. Jonker et al. shows 28% [15], while Kolcun et al. 41.66% [11], with the United States occupying the first place in scientific production.

TABLE VIII. INSTITUTIONS THAT PUBLISH MOST FREQUENTLY ON TELEMEDICINE IN THE PREOPERTIVE PERIOD

N°	Institution	Number of Articles
1	University of Michigan	3
2	The University of Melbourne	3
3	Dalhousie University	2
4	University of Cincinnati	2
5	Mayo Clinic College of Medicine	2
6	Vanderbilt University Medical Center	2

Fig. 15. Collaborative networks between institutions that carry out research on telemedicine in the preoperative period.

TABLE X. SCIENTIFIC PRODUCTION BY YEAR AND COUNTRY

Country	2017	2018	2019	2020	2021	Total (%)
Australia			1	2	2	5(6)
Belgium				3		3(4)
Canada	2	1		1	2	6(8)
China		1		1	1	3(4)
Finland				1		1(1)
France				1		1 (1)
Germany			1			1 (1)
India			1		1	2 (3)
Italy				1		1 (1)
Mexico			1			1 (1)
Netherlands				1	2	3 (4)
New Zealand		1				1 (1)
Portugal			1			1 (1)
Qatar					1	1 (1)
Scotland				1		1 (1)
Singapore				1		1 (1)
Spain			1			1 (1)
Sweden			1			1 (1)
Taiwan	1					1 (1)
United Kingdom		1	1	1	3	6 (8)
US	6	5	7	12	9	39 (49)

Regarding the establishment of collaboration networks with other countries, this research shows that the United States also leads this characteristic (see Fig. 17).

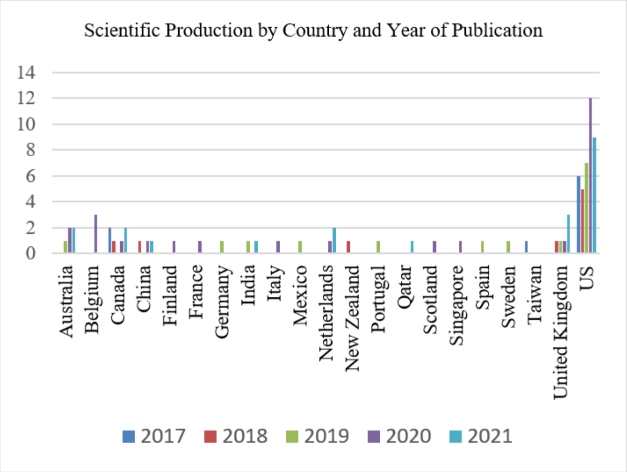

Fig. 16. Scientific production by country and year.

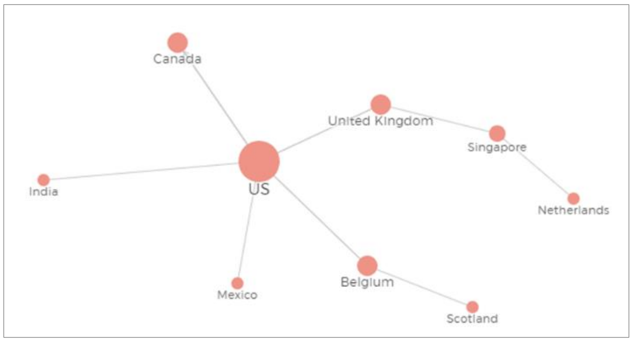

Fig. 17. Collaboration between countries on publications on telemedicine in the preoperative period.

5) RQ5: Which means of publication are the main objectives to produce research in telemedicine in the preoperative period?

Most of the publications correspond to journal-type articles (see Fig. 18).

This is consistent with other publications in the field of health [1] [5], in which the main input is publications of this type. It should be noted that some studies have only taken publications of this type as input, as in the research by Kolcun et al., which excludes publications such as "case reports", "technical reports" and "conference abstracts" [11].

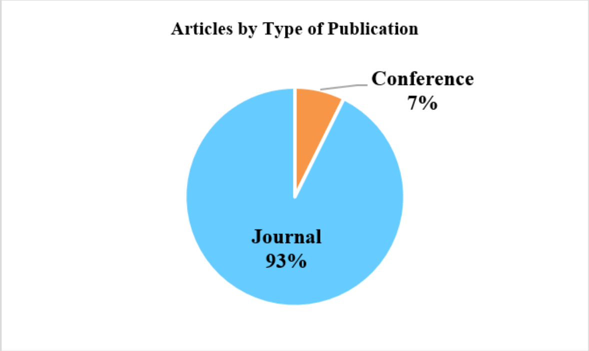

Fig. 18. Research by type of publication.

6) RQ6. What are the types of telemedicine services that are available? Are they given more frequently in the preoperative period?

The main use of telemedicine in this period was in teleconsultation and telecounseling activities (see Fig. 19).

In this regard, the findings are consistent with the results of Asiri et al. [8], Kolcun et al. [11] and Shanbehzadeh et al., in which the majority use of telemedicine for teleconsultation and teleguidance activities was evidenced. Additionally, the use for telesurgery, tele-education and telemonitoring was reported [13].

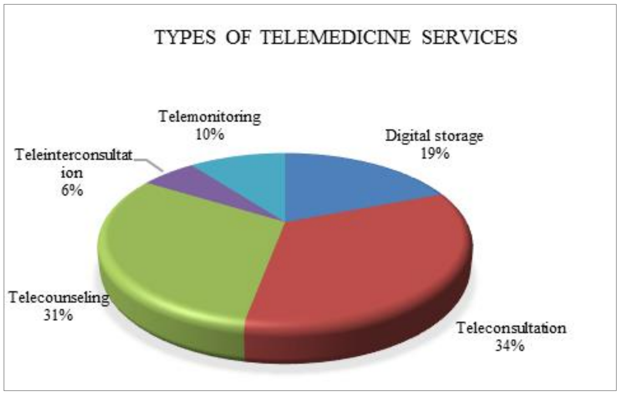

Fig. 19. Types of service that are most frequently provided in the preoperative period.

As for the modality used, it was mainly characterized by being asynchronous (43%), however, it does not differ greatly from the synchronous modality (38%). 19% of publications use both modalities to provide telemedicine services (see Table XI and Fig. 20).

These results do not differ greatly from other reviews, in which both modalities were used [5], preferring videoconferencing for aspects related to diagnostic assessment [11].

TABLE XI. TELEMEDICINE MODALITY USED

Modality	Articles	Quantity (%)
Asynchronous	[20] [21] [25] [27] [28] [29] [30] [32] [36] [40] [48] [50] [51] [52] [54] [57] [58] [61] [62] [63] [66] [67] [69] [72] [73] [75] [77] [81] [83]	29 (43)
Synchronous	[17] [18] [19] [22] [24] [26] [31] [34] [35] [37] [38] [43] [45] [47] [55] [56] [64] [68] [70] [71] [74] [76] [78] [79] [80] [82]	26 (38)
Both	[23] [33] [39] [41] [42] [44] [46] [49] [53] [59] [60] [65] [84]	13 (19)

The communication channels used by the researchers varied, according to the activity carried out, but the use of videoconferencing and mobile applications stands out (see Table XII). These results coincide with studies carried out at the first level of care, such as the one conducted by A. C. Shah and S. M. Badawy in 2020 [85].

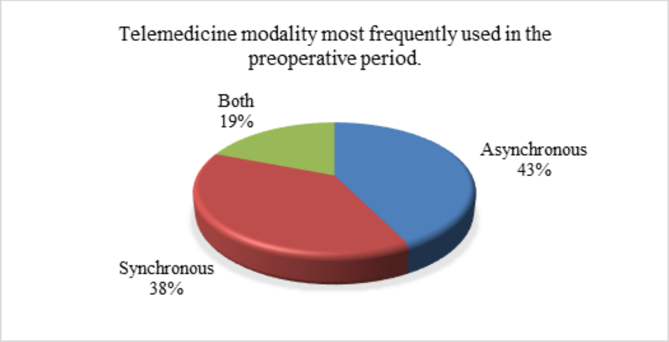

Fig. 20. Telemedicine modality most frequently used in the preoperative period.

TABLE XII. COMMUNICATION CHANNELS IN TELEMEDICINE MOST FREQUENTLY USED IN THE PREOPERATIVE PERIOD

Communication Channel	N° Articles
e-Form	4
e-Mail	8
Instant Messaging	5
Medical device	2
Mobile App	16
Phone Call	15
SMS	7
Smart device	4
Videoconference	25
Web	9

No percentages have been placed in this table, since in about half of the publications they refer to the use of more than one communication channel at the same time.

These results could be linked to the emergence of new technologies associated with videoconferencing equipment and the expansion of smartphones [8].

Chen E.A. et al. [1], he clarifies this topic in his review "Smartphone applications in orthopedic surgery", mentions that the use of this equipment by physicians amounts to 90%, and performs a descriptive analysis of the use of mobile phones in the field of orthopedics, finding that their use in this field varied in capabilities from angular management to preoperative and gait quantification. And it concludes that as more advanced applications are developed, smartphones are likely to gain an increasing presence in both the operating room and clinical settings.

Something that we should also point out is that the articles included in this research point to interventions that used more than one communication channel (see Fig. 21).

7) RQ7. What are the surgical specialties that are most frequently applying telemedicine in the preoperative period?

Telemedicine investigations in the preoperative period were carried out to a greater extent without distinction of surgical specialty. The concentration of publications related to general preoperative management, oncological surgery, traumatology, general surgery, and neurosurgery is observed (see Fig. 22).

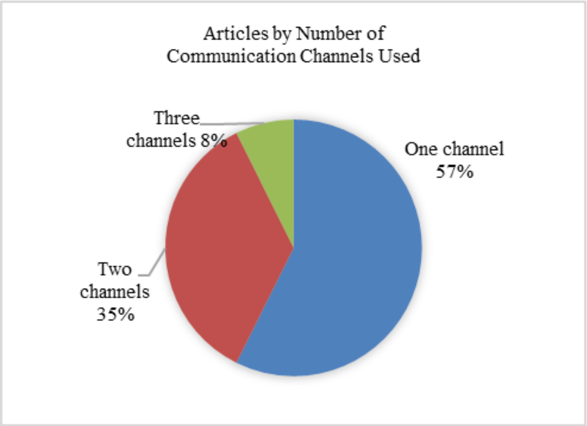

Fig. 21. Number of communication channels used in telemedicine activities during the preoperative period.

These results are in line with those published by Gachabayov et al., who addresses the issue of the role of telemedicine in surgical specialties during the pandemic and points out that most articles in the first six months were performed in orthopedic surgery followed by general surgery and neurosurgery, while in the second six months, urology and neurosurgery were the most productive, followed by transplantation and plastic surgery [86].

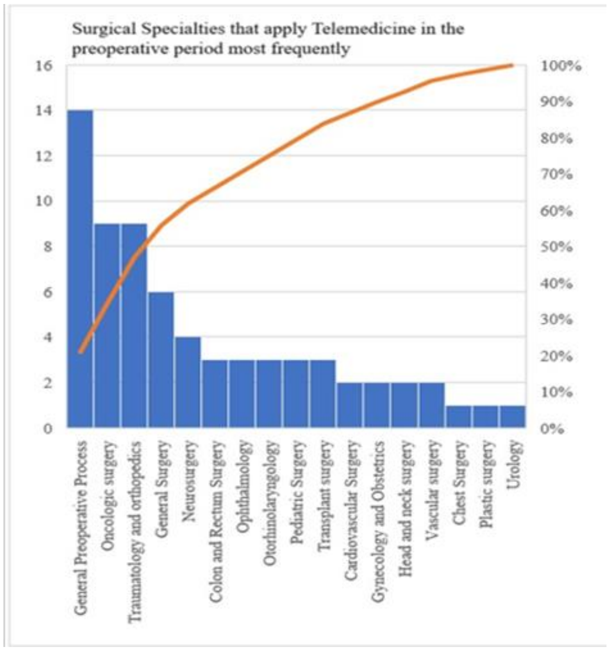

Fig. 22. The use of telemedicine in the preoperative period focuses on general procedures, oncological surgery, and traumatology.

8) RQ8. Which are the Articles whose Abstracts are characterized by their high Objectivity by year and country in telemedicine research and its impact on the preoperative period?

We observed that the production of articles during the first years was lower than during the last two years, but in recent years there has also been an increase in subjectivity in the abstracts of publications (see Fig. 23).

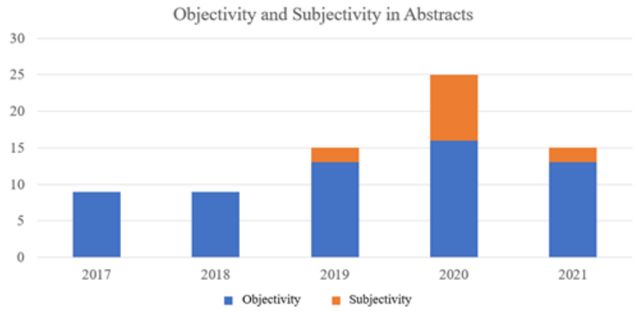

Fig. 23. Objectivity and Subjectivity of Abstracts

In terms of countries with highly objective summaries, the United States continues to lead (see Fig. 24).

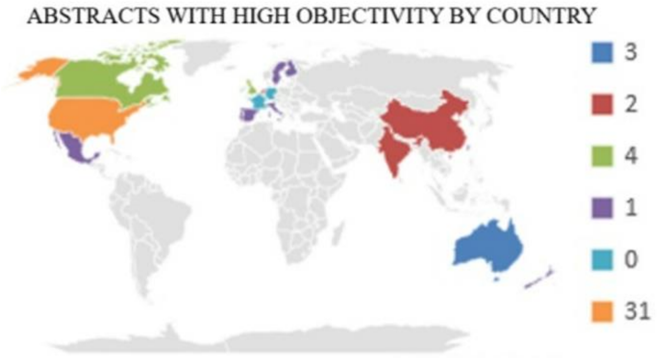

Fig. 24. Abstracts with high objectivity by country.

V. Conclusions and Future Research

This document has been an input and provided a statistical analysis on the application of Telemedicine in the Preoperative Period, through the extraction of data from a total of 68 articles published between 2017 and 2021. The highest percentage of identified studies was obtained from Springer, however, when applying the filtering and exclusion criteria, the highest percentage of included studies came from Scopus. It should be noted that the greatest use of telemedicine in this period is concentrated in teleconsultation and telecounseling services, as well as a greater scientific production with aspects related to general preoperative procedures, followed by those applied to oncological surgery and traumatology. There has also been an increase in production in recent years, probably due to the need for physical distancing due to the pandemic and the demand for activities in the surgical field.

For future research, it would be opportune to consider the co-occurrence of search terms, in this case, telemedicine with COVID-19 and preoperative care. It would also be a great contribution to analyze the impact smartphones have on preoperative care. Another relevant aspect would be to point out the use of NQER terms and the impact of polarity and objectivity on readers' choice of articles to read, share and cite.

***Abstract*—Given the regular occurrence of non-stationarity, non-linearity, and high levels of noise in time series data, predicting the value of stocks is a considerable difficulty. Traditional methods have the potential to enhance the precision of forecasting, although they concurrently introduce computational complexity, hence augmenting the probability of prediction inaccuracies. To effectively tackle a range of concerns, the existing body of research proposes a novel approach that combines a light gradient boosting machine, a machine learning methodology, with artificial bee colony optimization. In the context of the examined dynamic stock market, the proposed model demonstrated better efficiency and performance compared to alternative models. The recommended model exhibited optimal performance, characterized by a low error rate and high efficacy. The analysis utilized data about the stock of Alphabet over the period spanning from January 2, 2015, to June 29, 2023. The outcomes of the study provide evidence of the predictive accuracy of the proposed model in determining stock prices. The study's findings demonstrate how well the suggested model performs when it comes to correctly predicting stock prices. The proposed model presents a pragmatic methodology for evaluating and forecasting time series data about stock prices. The research's findings show that, in terms of forecast accuracy, the suggested model performs better than the methods currently in use.**

Keywords—Alphabet stock; machine learning; light gradient boosting machine; optimization; artificial bee colony algorithm

I. Introduction

Retail and institutional investors can buy and sell shares of publicly listed companies on stock exchanges to make money. It acts as a vital measure of a country's financial condition in general since it reflects firm performance and the business environment. The marketplaces where stocks are traded are the physical and online markets where both buyers and sellers come along. [1][2]. Investors, as well as traders, utilize a range of techniques to evaluate stocks and identify profitable opportunities. The investigation of stock price behavior has long piqued the curiosity of both academics and investors.

Consequently, several models have been created and tested to comprehend the underlying variables that affect the behavior of stock prices. Fama carried out one such study in 1965 [3]. This subject has been essential to developing the current knowledge of stock price behavior and is still an important area of study in the field of finance. The stock market is a complex system that fluctuates and is unpredictable. Given that pricing changes tend to be chaotic, noisy, nonparametric, nonlinear, nonstationary, and nonlinear, it is challenging for analysts to analyze and anticipate price changes accurately [4]. These characteristics imply that traditional statistical methods may not be sufficient for effective market analysis.

Therefore, a range of artificial intelligence and machine learning methods have been developed by researchers to circumvent these problems and improve the accuracy of stock market predictions. In contrast to traditional time series methods, reports based on machine learning can handle the stock market's complex, noisy, nonlinear, and unstable data to provide forecasts that tend to be more accurate [5]. Consequently, it has become the preferred technique for time series analysis in several areas [6][7]. Ensemble learning combines a variety of algorithms for machine learning to improve effectiveness, minimize mistakes, and increase accuracy [8]. This approach generates results that are more accurate and reliable than any one model could provide by integrating the results of several models that use various approaches and sets of features. The "boosting" machine learning method involves training many models in succession. Every new design aims to make the shortcomings of the prior one worse. Boosting is especially beneficial for classification and prediction issues since it may improve the precision of mediocre models. Due to their effectiveness, ensemble learning techniques like light gradient boosting machines (LGBM) and extreme gradient boosting (XGBoost) are often utilized. LGBM separates trees by the leaf and is quicker than XGBoost, which separates trees by depth [9][10]. Microsoft introduced LGBM, a machine-learning technique based on decision trees, by the end of 2017 [11]. In the machine learning field, especially in data science, LGBM has become quite well-liked because of its benefits of quick convergence time and less memory usage. It is commonly employed and discovered to be the successful answer in data mining contests [12]. Dhungana et al. [13] used LGBM to conduct an empirical investigation of S&P 500 price forecasting.

The utilization of artificial intelligence techniques in the stock market has gained significant traction due to its capacity to analyze vast quantities of data and discern patterns that are hard for humans to perceive. It is crucial to remember that these strategies' performance largely depends on how their initial parameter settings are created. Incorrect initialization will likely lead to forecasts and results that are untrustworthy [14][15]. Therefore, it is essential to thoroughly examine the

*Corresponding Author. Email: lzh104@126.com initial configuration of the parameters when implementing artificial intelligence in stock trading. Consequently, a variety of optimization strategies have been developed to circumvent these restrictions, Like Aquila optimizer (AO) [16], Biogeography-based optimization (BBO) [17], Grey wolf optimization (GWO) [18], and Artificial bee colony (ABC) [19] and more can be used. The ABC optimizer is an optimization technique that exhibits excellent effectiveness, drawing inspiration from the behavioral patterns observed in honeybee colonies. The technique in question is classified under the swarm intelligence family and is extensively employed across diverse domains such as engineering, machine learning, and operations research. The aforementioned metaheuristic algorithm, which draws inspiration from nature, has a wide range of applications and possesses robust optimization capabilities [19].

This study tackles the formidable challenge of forecasting stock prices in time series data containing high levels of noise, non-stationary, and non-linearity. Driven by this undertaking, this research develops fundamental inquiries: In what ways can conventional forecasting techniques be refined to achieve higher levels of accuracy while preserving computational efficiency? Could the integration of an artificial bee colony optimization system with a light gradient enhancing machine present an innovative resolution to these obstacles? The primary aims of this research are to improve the accuracy of stock price predictions, reduce the complexity of computational tasks involved, and exhibit exceptional performance in this domain by utilizing the proposed fusion of methodologies. This work is significant due to the efficiency and efficacy of this model that has been demonstrated in dynamic stock markets. By employing Alphabet's stock data, the model's ideal performance, minimal error rate, and significant effectiveness, underscoring its superiority over current approaches have been demonstrated and its feasibility in practical scenarios.

The study contributed to forecasting a multivariate time series by outlining a brand-new training method based on metaheuristics for artificial bee colonies. This essay explores the field of ABC-LGBM hybrid stock price forecasting. The model was contrasted with several other models, including LGBM, GWO-LGBM, BBO-LGBM, and ABC-LGBM, to ascertain its correctness. The evaluation's findings offer insightful information on the effectiveness of the ABC-LGBM hybrid model and its potential as a stock price prediction tool. One of the analytical processes used in the inquiry was a thorough assessment of the data source and all of its pertinent features in the second part. The data was analyzed using several procedures, such as optimizer methods, evaluation metrics, and the LGBM model. The analysis results are provided and compared with results from other methodologies in the third part. The discussion part is provided in the fourth part. The investigation's results and recommendations are briefly described in the epilogue.

II. Materials and Methods

A. Artificial Bee Colony Algorithm

The development of the Artificial Bee Colony (ABC) technique arose from an examination and emulation of the foraging habits of wild bees to address optimization problems through a mathematical model. The hired bees, observers, and scouts are the three different categories of honey bee ABC agents in the colony. Two groups of bees with an equal number of members each comprise the ABC algorithm's bee population. Onlooker bees are the other half, whereas employed bees comprise the first half. Within the context of the ABC algorithm, the determination of the bee's food supply location is considered an optimization problem, including several variables that require optimization. The assessment of the solution's fitness can be employed to characterize the excellence of the food supply about the objective function of this issue. In other words, finding the best answer is similar to the process that bees go through while searching for a suitable food source and the process of the ABC method shown in Fig. 1.

These are the specifics of the ABC algorithm: The initial solutions are produced at random and used as the locations of the bee agents' food sources. The bee agents are put through three primary cycles of repetition after startup. The process of selecting the most optimal and viable alternatives while actively avoiding subpar choices and continually revising and enhancing the workable solutions. The worker bees collectively select a novel potential food source location to enhance the efficacy of their solutions. They make their decision depending on the area surrounding the previously chosen food source. Utilizing Eq. (1), the location of the new food supply is determined.

$$v_{ij} = x_{ij} + \phi_{ij}\left(x_{ij} - x_{kj}\right), \tag{1}$$

where, $k \in \{1,2,3,..,SN\}$ and $k \neq i, j \in \{1,2,3,..,D\}$ are chosen at random indexes, v_{ij} is a new feasible solution that is modified from its previous solution value $\left(x_{ij}\right)$ based on a comparison with a randomly selected position from its neighboring solution $\left(x_{kj}\right)$, and ϕ_{ij} is a random number between [-1,1] that is used to randomly adjust the previous solution to become an alternate solution in the next iteration. There is a positional difference between x_{ij} and x_{kj} in one specific dimension.

If a bee that is now employed encounters a new food source location with a higher fitness value, it will replace the previous food source position in its memory with the new one. Employed bees will share the nutritional advantages of their new food sources with the other bees when they return to their hive. The next step is for each observation bee to select one of the recommended food sources based on the fitness value calculated by the bees in use. The probability that a recommended food source will be picked is given in Eq. (2).

$$P_i = \frac{fit_i}{\sum_{i=1}^{SN} fit_i} \tag{2}$$

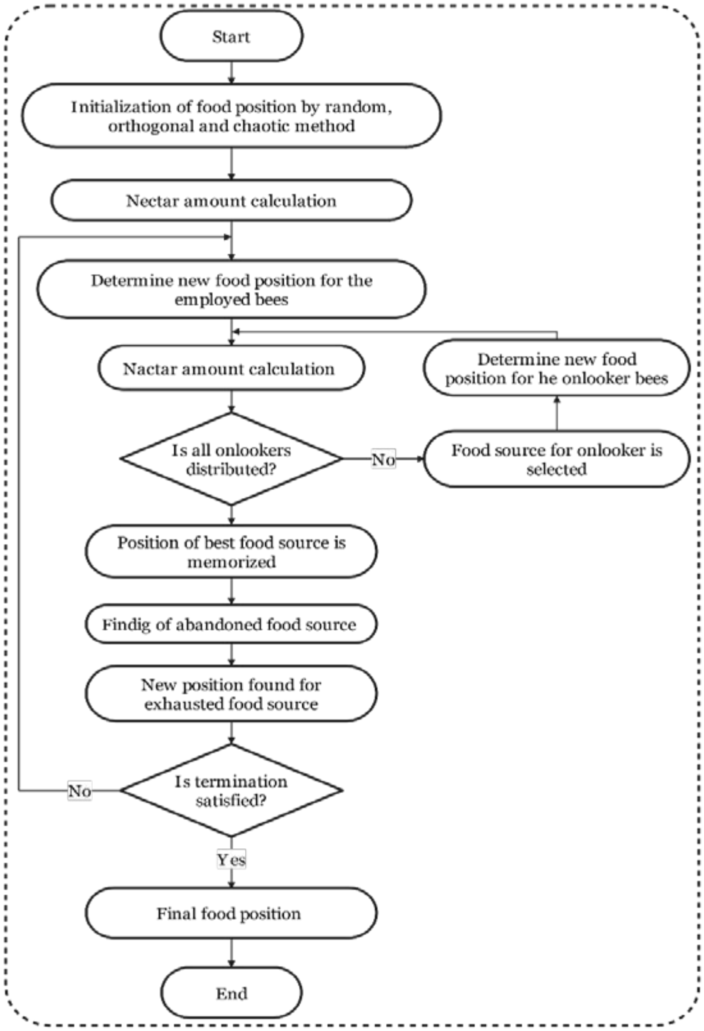
In which Fit $_i$ represents the fitness value of the food source $i. SN$ stands for the number of practical food sources.

The likelihood of an observer bee choosing a given food source is positively correlated with the fitness value of that food item. Once a food source has been chosen, the observer bees will proceed to the chosen food source and identify another potential food source location within the vicinity of the earlier picked food source. The calculation and expression of the novel candidate food source can be determined using Eq. (1).

During the third stage, food-supplying positions lacking an enhanced fitness value will be discarded and substituted with a newly determined standing, assigned at random by a scout bee. This strategy aids in the prevention of suboptimal solutions. The calculation for determining the initial random place selected by the scout bee is expressed by Eq. (3):

$$x_{ij} = x_j^{min} + \mathrm{rand}[0,1]\left(x_j^{max} - x_j^{min}\right), \tag{3}$$

The lower limit and higher limit of the food supply location in dimension j are represented by the x_j^{min} and x_j^{max}, respectively.



Start
Initialization of food position by random, orthogonal and chaotic method
Nectar amount calculation
Determine new food position for the employed bees
Nactar amount calculation
Determine new food position for he onlooker bees
Is all onlookers distributed?
No
Food source for onlooker is selected
Position of best food source is memorized
Findig of abandoned food source
New position found for exhausted food source
Is termination satisfied?
No
Yes
Final food position
End

Fig. 1. The diagram of the ABC optimizer.

The termination criteria, in this case, are based on the count of functional evaluation. The three major processes outlined above will be conducted iteratively until the predetermined number of function evaluations is reached. The cycle of bees can be shown in Fig. 2.

B. Grey Wolf Optimization (GWO)

GWO method was initially created by Mirjalili et al. [20], which mimics the hunting habits and leadership hierarchy of the Grey Wolf (Canis lupus) in the wild. The magnificent grey wolves, who are members of the Canidae family, are extremely accomplished apex predators. They are powerful in their native environments due to their amazing hunting prowess and clever group strategies. These animals prefer to live in groups and adhere to a strict social hierarchy. Depending on their characteristics, wolves may be divided into four different groups: alpha ($\boldsymbol{\alpha}$), beta ($\boldsymbol{\beta}$), delta ($\boldsymbol{\delta}$), and omega ($\boldsymbol{\omega}$). There is a common belief that within a pack of wolves, the alpha wolf is the member who possesses the most successful and efficient solution to any given problem or challenge that the pack may face. There is a common belief among some individuals that the alpha wolf, or the highest-ranking member in a wolf pack, possesses the most optimal solution to a given situation or problem and has authority over the whole pack of grey wolves. The beta and delta wolves come in second and third, respectively. The other wolves are from the omega group, which has a low rank. The alpha, beta, and delta wolves, who are the strongest, considerably help in hunting. The responsibility of tracking, chasing, encircling, and attacking the target falls on the three wolves. Following are the three main steps of the grey wolf hunting process:

- The target is pursued and tracked down
- The prey is pursued, surrounded, and harassed until it stops moving
- The prey is aimed and attacked

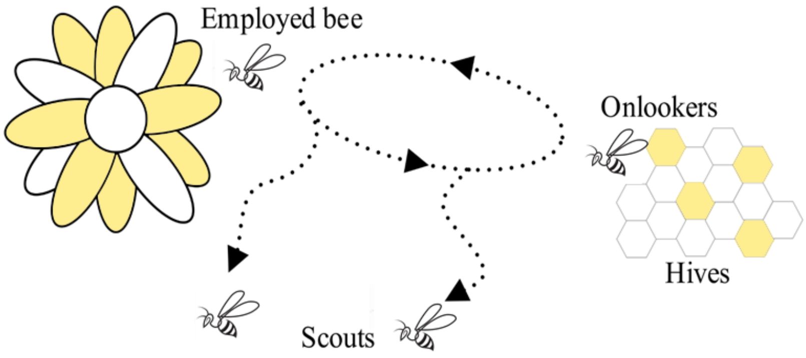


Fig. 2. The illustration of the cycle of bees.

C. Light Gradient Boosting Machine Algorithm

The construction of the model can be represented as follows since the LGBM approach is developed from decision trees. Given the data of training set $S = \{(x_i, y\}; f = 1,2,\cdots, n; x_i \in \kappa^*, y \in R\}$ where n is the number of samples containing features of m. To get an estimate, the forecasts generated by the decision trees are aggregated in the following manner:

$$y_i^{2a} = \sum_{p=1}^{p} f_p(x_0) \tag{4}$$

With f_p trees included as the trees, and there are p total trees. To get f_p, the objective function below must be minimized.

$$f_p = \arg\min_{f} \sum_{i=1}^{n} L(y_i y^{\mathrm{mop}}) + \Omega(f_p) \tag{5}$$

The reduction function is marked as L, and the Ω parameter is for regularization. The specified value is provided by.

$$\hat{\Omega}(f_p) = a\,\mathrm{T} + \frac{1}{2} i \sum_{j=1}^{T} \mathrm{w}_j^2 \tag{6}$$

where, the penalty parameters for T leaves and the weight of the leaves, w, are α and λ, respectively. Assuming that, L represents the loss function and that it is a squared error. Then

$$L\left(y_i, \hat{y}_i^{LG(p-1)} + f_p(x)\right)$$

$$= \left(y_i - \hat{y}_i^{LG(p-1)} - f_p(x)\right) = \left(r - f_p(x)\right)^{2^2} \tag{7}$$

The residual, denoted as r, is utilized in the fitting process to generate the function f_p. Using a quadratic approximation function, the goal function at iteration p is minimized.

$$\begin{aligned} f_P &\simeq \arg\min_{f_p} \sum_{l=1}^{n} \left[g f_P(x_i) + \frac{1}{2} h_i f_P^2(x_i)\right] + \Omega(f_P), \\ g_{\mathrm{I}} &= \partial_j \omega_{(p-1)} L\left(y_l, \hat{y}_l^{LC(p-1)}\right), \\ h_{\mathrm{I}} &= \partial_{y^2{}^2_{(p-1)}} L\left(y_l, \hat{y}_l^{LC(p-1)}\right). \end{aligned} \tag{8}$$

A new tree by minimizing the goal function, denoted as f_p, is produced. The decision tree partitions each node based on the criterion of the greatest data gain.

The variance gains for a node at position s that divides feature j are provided by:

$$Z_{j|O}(s) = \frac{1}{n_O}\left\{\frac{\left(\sum_{\{x_i \in O: x_{ij} \le s\}} g_i\right)^2}{n_{l|O}^j(s)} + \frac{\left(\sum_{\{x_i \in O: x_{ij} > s\}} g_i\right)^2}{n_{r|O}^j(s)}\right\}, \tag{9}$$

D. Data Preparation and Collection

To perform a comprehensive analysis, it is essential to include the trade volume as well as the Open, High, Low, and Close (OHLC) prices within a designated time frame. The dataset utilized in this research aims to enable the prediction of Alphabet stock market prices throughout an extensive temporal span, spanning from January 1, 2015, to the middle of 2023. Precise forecasting of stock prices has paramount importance for shareholders, financial professionals, and managers operating within the finance industry. This dataset contains the necessary historical stock price information and its related characteristics for conducting prediction analyses. The key sources of financial market information for the dataset are the stock exchanges and financial news outlets. Historical daily market share prices for Alphabet were collected for the chosen period. Between January 1, 2015, and mid-2023, this paper's dataset includes various variables about Alphabet stock shares for each trading day. The essential components encompassed within the context of stock market data are the specific date, the initial price at the commencement of the session of trading, the final price after the trading session, the maximum price attained by the shares throughout the day, the minimum price reached by the shares during the day, and the trading volume denoting the aggregate number of shares exchanged within the day. To ensure the quality and consistency of the data, rigorous data preparation procedures were implemented before conducting any predictive analysis. Data standardization was performed to facilitate precise modeling and prediction. Normalizing data is the transformation of numerical parameters to a standardized range, often ranging from 0 to 1 or with a mean of 0 and a standard deviation of 1. When working on analytical or modeling projects, it's important to treat variables with different units or magnitudes equally. The use of diverse techniques, including scaling and normalization, is vital in the process of data cleaning. These approaches play a crucial role in mitigating gradient mistakes and ensuring consistent training outcomes. Based on the information shown in Fig. 3, the dataset was divided into two parts: 80% of the data was allocated for training, while the remaining 20% was reserved for testing.

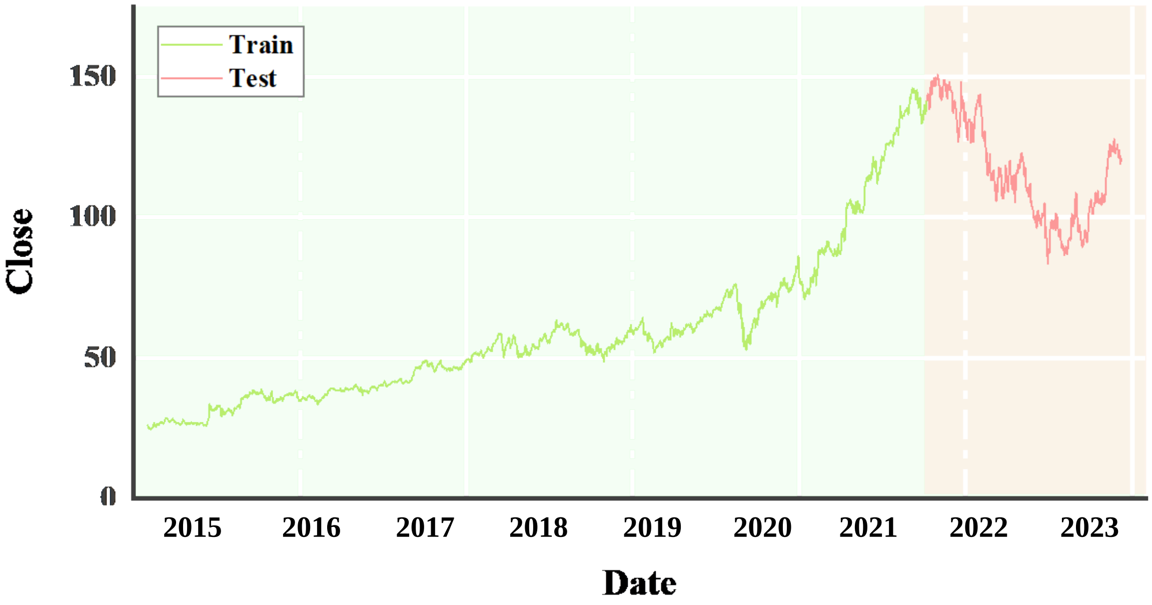

Fig. 3. Dividing data for both training and testing.

E. *Assessment Criteria*

The purpose is to evaluate the ability of combined models to make accurate predictions. This category comprises the root mean square error (RMSE), mean absolute percentage error (MAPE), mean squared error (MSE), and coefficient of determination (R^2).

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \tag{10}$$

$$MAPE = \left(\frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right|\right) \times 100 \tag{11}$$

$$\mathrm{MSE} = \frac{1}{N}\sum_{\mathrm{k}=0}^{\mathrm{n}} \binom{\mathrm{n}}{\mathrm{k}} (\mathrm{Fi} - \mathrm{Yi})\mathrm{b}^2 \tag{12}$$

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{n}} \tag{13}$$

III. Results

A. *Statistical Results*

Table I presents an extensive compilation of statistical information about the dataset under consideration. The OHLC price and volume figures shown in this table provide a more clear depiction of the factual information. To conduct a more comprehensive and precise evaluation of the data, it is advisable to use statistical metrics such as the mean, amount, mean, std., min, median, max, and variance numbers.

B. *Results of the Models*

Finding and evaluating the best hybrid algorithm for predicting stock prices is the main goal of this study. Forecasting models have been developed, and complex variables that affect stock market trends have been investigated. The primary objective was to provide investors and analysts with valuable information to facilitate informed investment decision-making. Table II, Fig. 4 and Fig. 5 present a comprehensive assessment of the performance of each model, accompanied by an in-depth examination of its effectiveness.

A comprehensive data analysis assessment was conducted using four commonly employed metrics: RMSE, MSE, MAPE, R^2. These metrics are widely recognized for their ability to offer a precise assessment of the dependability, precision, and overall usefulness of the analysis. The efficacy evaluation of the LGBM model was conducted using the RMSE, MSE, MAPE, and R^2 metrics, comparing the model's performance with and without an optimizer. Enhanced understanding of the model's performance facilitates the ability to make well-supported judgments based on the obtained outcomes.

C. *Comparison with Other Works*

In order to assess the accuracy of the ABC-LGBM model, the primary objective of this research was to examine its performance. To accomplish this, we conducted a comparative analysis of the R^2 values of our framework and other recent works. Upon meticulous examination, we determined that the ABC-LGBM exhibited superior performance to the other works, thereby substantiating the effectiveness of this framework. The specifics of this comparison are provided in Table III.

TABLE I. DATASETS STATISTICAL SUMMARIES

	Open	High	Low	Volume	Close

IV. DISCUSSION

This study aims to find and evaluate the best hybrid stock price prediction system. Complex stock market variables have been studied and forecasting algorithms constructed. Information for investors and analysts to make informed investment decisions was the main goal. Table II, Fig. 4 and Fig. 5 evaluate each model's performance and efficacy. A thorough data analysis was performed utilizing four popular metrics: RMSE, MSE, MAPE, R^2 . These criteria are extensively used to evaluate the analysis's dependability, precision, and usefulness. The LGBM model was evaluated for efficacy using RMSE, MSE, MAPE, and R^2 metrics, comparing performance with and without an optimizer.

Upon meticulous analysis of the training and test datasets, it was ascertained that the LGBM model, when implemented without the optimizer, yielded R^2 coefficients of 0.984 and 0.976 for the respective training and testing datasets. Furthermore, MAPE and MSE values obtained for the test dataset were notably lower at 1.955 and 7.958, respectively, in comparison to the corresponding values obtained during the training phase. Furthermore, RMSE values for the training and testing sets were 3.446 and 2.821, respectively. The integration of optimization techniques has significantly enhanced the efficacy of the LGBM model's performance. The usage of the GWO has yielded significant improvements, resulting in a rise in the R^2 value to 0.988 during the training phase and 0.982 during the testing phase. Furthermore, the MAPE and MSE values displayed a decrease in both the testing and training datasets.

Specifically, the MAPE values for the training and testing sets were 3.286 and 1.709, while the MSE values were 8.646 and 5.997, respectively. The RMSE values have decreased to 2.449 for the testing set and 2.940 for the training set. The findings of this research demonstrate the efficacy of the optimization techniques employed in enhancing the efficacy of the LGBM model. The ABC-LGBM model demonstrated superior performance in comparison to the GWO-LGBM model. The values of R^2 obtained for the training phase and testing phases of the ABC-LGBM model were 0.994 and 0.993, respectively. Significantly, the training MAPE and MSE values exhibited a decrease to 3.118 and 4.089, respectively. Similarly, the testing MAPE and MSE values experienced a decrease to 1.029 and 2.188, respectively, thereby suggesting a significant enhancement in precision. Moreover, it can be observed that the RMSE values showed a decrease to 2.022 and 1.479 for the test and training datasets, accordingly. This reduction in error further substantiates the superior performance of the ABC-LGBM model in comparison to the GWO-LGBM model, as it demonstrates the ABC-LGBM's ability to provide accurate forecasts. The investigation demonstrates that the ABC-LGBM model exhibits superior effectiveness and efficiency compared to the GWO-LGBM model. The ABC-LGBM model exhibits a high level of efficacy, as seen in its outstanding R^2 scores of 0.994 for training and 0.993 for testing. The model had outstanding efficiency, as evidenced by its lowest MAPE and MSE testing values of 1.029 and 2.188, respectively. Findings suggest that the ABC-LGBM model exhibits a high level of precision and reliability.

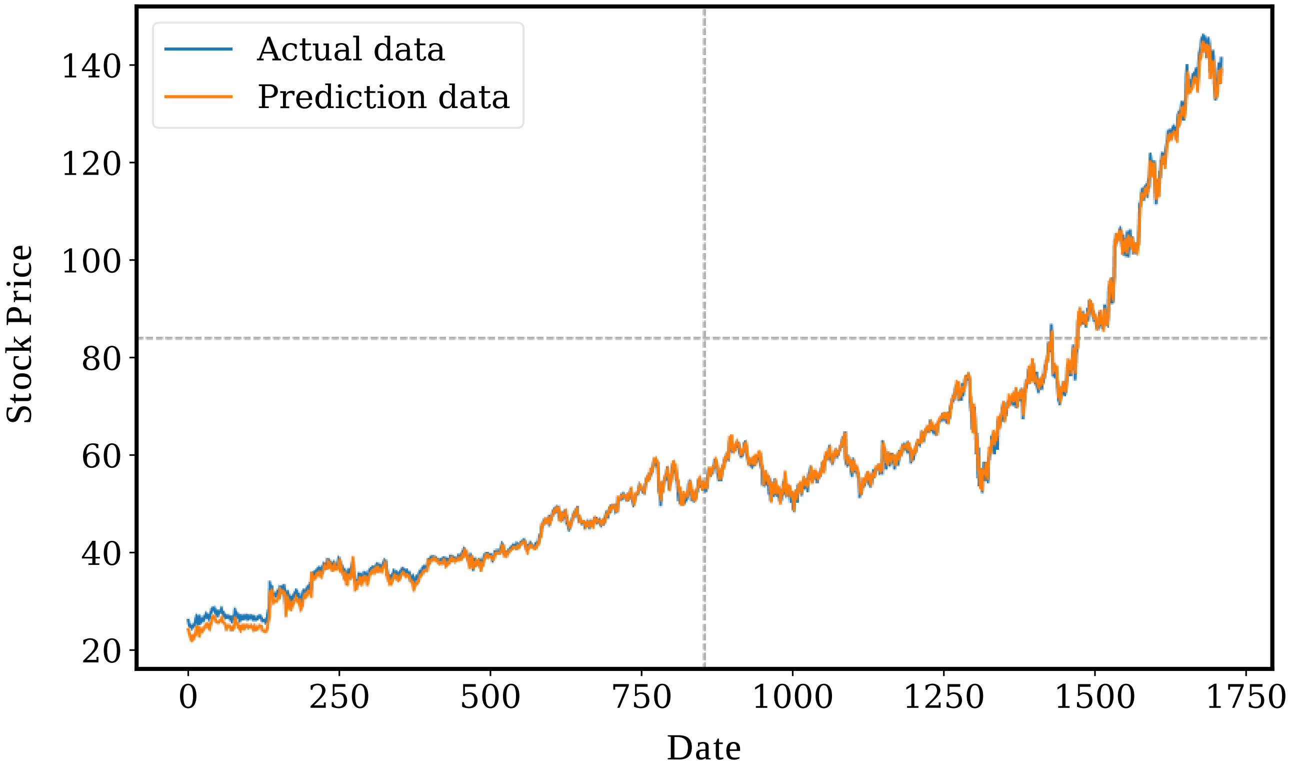

Fig. 6. Forecasting curve training created with ABC-LGBM.

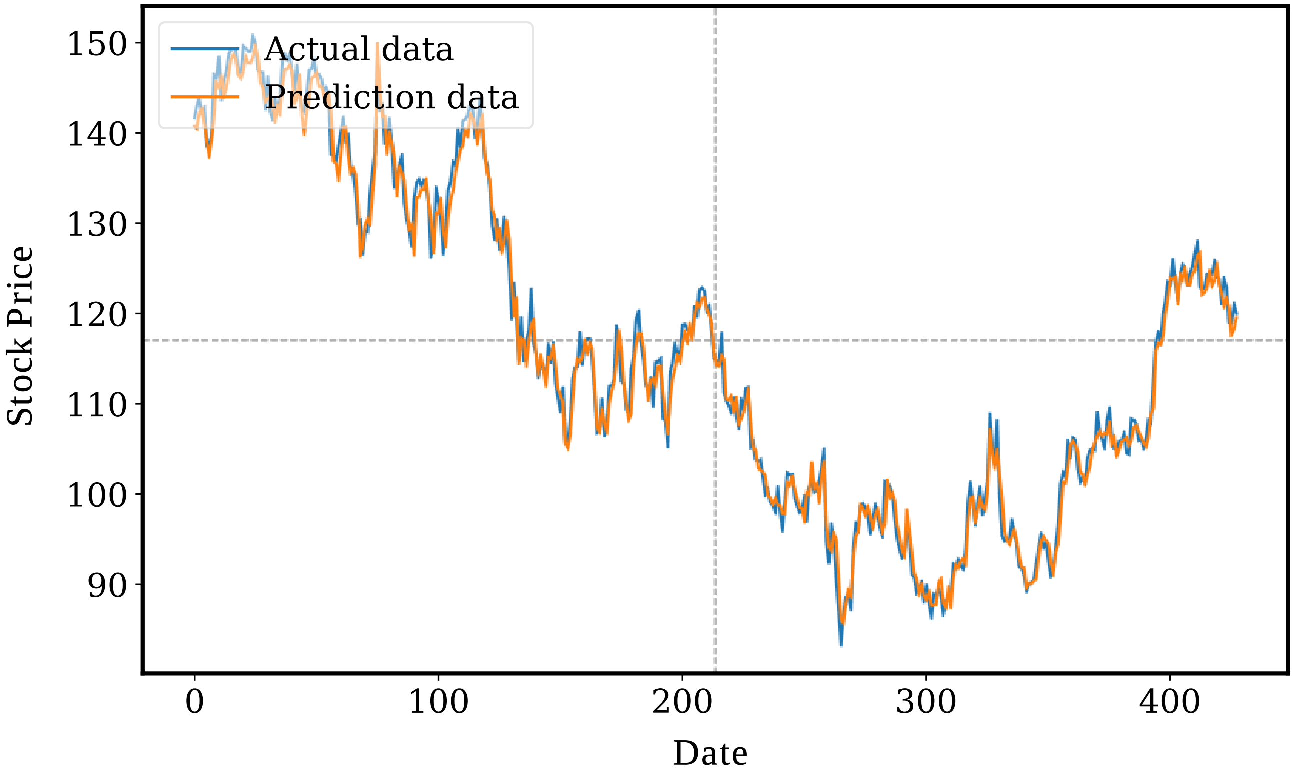

Fig. 7. Forecasting curve testing created with ABC-LGBM.

The ABC-LGBM model is widely regarded as a reliable and robust technique for generating highly precise market price forecasts. The stock share curves of Alphabet are presented in Table II, along with the corresponding figures, namely Fig. 6 and Fig. 7, which serve as evidence of the effectiveness of the model. In terms of precise prediction of stock prices, the ABC-LGBM model has superior performance compared to alternative models such as LGBM and GWO-LGBM. The ABC method is a highly effective technique that has been found to reduce price fluctuations significantly. By doing so, it has the added benefit of making trend prediction much easier and increasing overall model accuracy. This can be highly advantageous in a variety of industries where accurate forecasting is critical to success.

Additionally, the method is particularly useful in minimizing the impact of unforeseen events that might otherwise lead to significant market fluctuations. One of the distinctive features that sets the ABC-LGBM model apart from alternatives is its ability to learn from previous data effectively. In conclusion, the ABC-LGBM model has notable efficacy as a tool for predicting stock prices due to its high level of precision, accuracy, and capacity to assimilate information from previous datasets.

V. Conclusion and Recommendations

Forecasting stock prices is a complex endeavor characterized by a multitude of variables. The stock market is a complex and fluid process that is influenced by various factors, such as political events, societal dynamics, and economic conditions. To accurately assess the upcoming value of stocks, it is imperative to consider a diverse array of financial statements, market trends, as well as other pivotal factors. Furthermore, the behavior of stocks can be significantly influenced by economic factors such as interest rates, inflation, and worldwide market conditions. Developing trustworthy models for forecasting is a challenging task due to the intricate nature and extensive array of components involved. The ability to generate precise forecasts necessitates a comprehensive comprehension of the capricious and nonlinear characteristics inherent in the marketplace. Fortunately, the ABC-LGBM model is a viable solution to these issues and has been proven to be dependable and precise. There are numerous ramifications of this research for the community. The proposed model begins by tackling a significant obstacle in the prediction of stock prices, a matter that holds considerable importance for financial analysts, investors, and individuals engaged in stock market operations. Through adeptly managing the intricacies of non-linearity, non-stationarity, and elevated noise levels present in time series data, the model furnishes a more dependable and precise instrument for predicting stock prices. Furthermore, the integration of artificial bee colony optimization with light gradient boosting machine integration represents a novel strategy that not only improves accuracy but also addresses the issue of computational intricacy. This has ramifications that extend beyond the realm of academia, as it provides pragmatic resolutions to the practical obstacles encountered by practitioners in the financial industry. The utilization of Alphabet's stock data for analysis enhances the study's practicality, given that Alphabet is a significant participant in the stock market. The research findings, which illustrate the model's exceptional performance in comparison to alternative approaches, possess the capacity to impact the decision-making procedures of financial institutions and investors. In brief, this study not only enhances the theoretical comprehension of time series data analysis but also offers a practical and influential instrument for the field, enabling financial stakeholders to anticipate and navigate stock market trends more efficiently. The study examined the LGBM and GWO-LGBM models as part of its investigation into forecasting stock prices. However, the ABC optimizer technique, in combination with LGBM, produced the best outcomes. The study's dataset comprises Alphabet stock OHLC prices and volume from January 2, 2015, to June 29, 2023. Based on the findings of the inquiry, it has been determined that the ABC-LGBM model exhibits a high level of reliability and accuracy in predicting stock prices.

- Throughout the investigation, a comparative analysis was conducted to assess the accuracy and forecasting capacity of the ABC-LGBM model about other models. Based on the obtained data, it was consistently observed that the ABC-LGBM model exhibited superior performance compared to each of the other models. The R^2 value of 0.993 obtained after testing indicates a high level of accuracy, hence proving the precision of the predictions. The ABC-LGBM model consistently generated precise forecasts, as indicated by its minimal MAPE value of 1.029 and a low MSE value of 2.188. Overall, in terms of accuracy and efficacy, the ABC-LGBM model demonstrated outstanding results compared to the other approaches that were evaluated.

Recommendations:

Promotion of Hybrid Approach Adoption: Advocate for the implementation of the proposed hybrid approach, which integrates LGBM and ABC, on the grounds that it exhibits enhanced efficiency and performance in comparison to alternative models. Highlight the potential advantages that this model may offer in mitigating the difficulties presented by time series data's non-stationarity, non-linearity, and substantial levels of noise.

Application in Dynamic Stock Markets: It is recommended that the suggested model be implemented in dynamic stock markets as a means to improve the accuracy of predictions, particularly in situations where conventional approaches may introduce computational intricacy and possible errors. It is recommended to conduct additional validation and testing of the proposed model using a variety of stock datasets in order to evaluate its adaptability and efficacy across distinct market conditions. Investigate its functionality across a range of financial scenarios in order to ascertain its resilience.

Thorough Evaluation of Variables: Emphasize the significance of taking into account a wide range of financial statements, market trends, and critical factors in order to generate precise predictions regarding stock prices. Advocate for researchers and practitioners to adopt a comprehensive approach by incorporating a range of factors, such as economic conditions, political events, and societal dynamics.

Practical Significance: Elucidate the ways in which the ABC-LGBM model is effectively employed to tackle obstacles arising from the presence of noise, non-linearity, and non-stationarity within time series data. It is recommended to apply the model in practical financial contexts in order to assess its efficacy and influence on decision-making procedures.

Extension to Other Sectors: Advocate for an investigation into the feasibility of implementing the ABC-LGBM model in sectors other than finance, taking into account its capacity to offer practical solutions to computational complexities and forecasting obstacles. Promote collaborations across industries in order to capitalize on the capabilities of the model in various domains.

Sustained Comparative Analysis: Support the implementation of ongoing comparative analyses to evaluate the ABC-LGBM model's accuracy and predictive capability in comparison to emergent models and evolving methodologies. Motivate scholars to investigate its efficacy across diverse market environments and utilize an assortment of datasets.

Analysis of the Financial Market via an Optimized Machine Learning Algorithm: A Case Study of the Nasdaq Index

Lei Wang, Mingzhu Xie*
School of Accounting and Finance, Anhui Xinhua University, Hefei Anhui, 230088, China

***Abstract*—The complex interaction among economic variables, market forces, and investor psychology presents a formidable obstacle to making accurate forecasts in the realm of finance. Moreover, the nonstationary, non-linear, and highly volatile nature of stock price time series data further compounds the difficulty of accurately predicting stock prices within the securities market. Traditional methods have the potential to enhance the precision of forecasting, although they concurrently introduce computational complexities that may lead to an increase in prediction mistakes. This paper presents a unique model that effectively handles several challenges by integrating the Moth Flame optimization technique with the random forest method. The hybrid model demonstrated superior efficacy and performance compared to other models in the present investigation. The model that was suggested exhibited a high level of efficacy, with little error and optimal performance. The study evaluated the efficacy of a suggested predictive model for forecasting stock prices by analyzing data from the Nasdaq index for the period spanning from January 1, 2015, to June 29, 2023. The results indicate that the proposed model is a reliable and effective approach for analyzing and forecasting the time series of stock prices. The experimental findings indicate that the proposed model exhibits superior performance in terms of predicting accuracy compared to other contemporary methodologies.**

Keywords*—Stock market prediction; Nasdaq index; random forest; moth-flame optimization; MFO-RF

I. Introduction

Retail and institutional investors can purchase and profitably sell shares of publicly traded corporations on the stock market. The stock market is a vital gauge of a nation's overall economic health since it represents company success and the business climate. Exchanges, both physical and virtual, are places where buyers and sellers come together to exchange assets [1, 2]. Traders and investors use a variety of strategies to evaluate equities and identify profitable opportunities. Many models have been created and put to the test to comprehend the underlying elements that influence stock prices. Both investors and scholars have long been interested in the study of stock price behavior. Fama conducted a study on this topic in 1965, which is now a major area of study in finance and has had a big impact on the way how currently understand stock price behavior [3], analyzing the stock market is challenging due to its volatile and ever-changing character. Analysts find it difficult to effectively analyze and anticipate price changes due to the market's noisy, chaotic, dynamic, non-linear, non-stationary, and nonparametric characteristics [3]. These qualities raise the possibility that conventional statistical techniques won't be enough for efficient stock market analysis.

To get around the challenges of making accurate stock market forecasts, academics have created several machine learning and artificial intelligence algorithms. These novel techniques aim to handle complex, noisy, chaotic, and non-linear stock market data more effectively than traditional time series methods, which often ignore the dynamic nature of the financial markets. Machine learning approaches employ sophisticated algorithms to analyze vast quantities of financial data and identify intricate patterns that may elude human observation. These methodologies have the capacity to provide more precise predictions through the analysis of an extensive array of data sources, including news articles, social media postings, and financial information. Furthermore, machine learning algorithms have the capability to consistently acquire knowledge and adapt to novel data, hence improving their predictive abilities as time progresses. In general, the utilization of artificial intelligence and machine learning has the potential to significantly enhance the precision of stock market prediction, providing investors with valuable information on market fluctuations and facilitating prudent investment choices [4].

Decision trees (DT) are a widely utilized machine learning approach that finds frequent application in both classification and regression tasks. This basic and comprehensible method is employed to construct a tree-like model that represents various choices and their corresponding probable outcomes [5]. The method partitions the data into subsets based on the values of the input features iteratively until a specified stopping condition is satisfied. Every partition is a node in the tree, and every node contains a decision rule that determines which feature will be separated first. DTs provide several benefits in comparison to other machine learning approaches. First of all, because they can handle both continuous and categorical data, they are suitable for a wide range of applications. Secondly, they are easy to use and need little feature engineering or data preparation.

Moreover, they are easily interpreted, which simplifies the process of understanding how the model arrived at a certain prediction. Despite its advantages, DTs have some disadvantages. For example, the tree may be susceptible to overfitting if it is deep and complex. Additionally, owing to their sensitivity to even minute changes in data, they could

*Corresponding Author. Email: dm35261478@126.com generate different trees for different training sets. To get around these problems, many DT variants have been developed; one of the best is random forest (RF).

RF employs an ensemble learning methodology to combine many decision trees, resulting in a robust and accurate model [6]. RF is a versatile machine-learning algorithm that can be applied to both classification and regression tasks. It has exceptional performance in handling large-scale datasets with high-dimensional features. The technique operates by constructing a collection of decision trees, whereby each tree is trained on a randomly selected portion of the characteristics and data. During the training process, every tree within the forest generates a forecast, and the collective projections of all the trees culminate in the ultimate prediction. This methodology enhances the model's robustness against noise and outliers, hence mitigating the risk of overfitting. When juxtaposed with alternative machine learning methodologies, RF offers several advantages. The versatility of this method is shown in its ability to effectively handle both continuous and categorical data, rendering it highly suitable for a wide range of applications.

Furthermore, this approach does not need an extensive feature engineering or data preprocessing, making it very straightforward to implement. In conclusion, the system exhibits a high degree of scalability and possesses the ability to effectively process extensive datasets comprising millions of samples and numerous attributes [6]. In their study, Park et al. [7] developed a comprehensive framework for predicting stock market trends by combining long short-term memory and random forest techniques. To evaluate the effectiveness of their proposed approach, the researchers utilized three prominent global stock indexes and incorporated 43 financial, technical indicators. In their study, Basher et al. [8] employed the RF algorithm to predict Bitcoin prices. Their findings indicate that the RF algorithm outperforms logit models in accurately anticipating trends in both Bitcoin and gold prices Basher et al. [8]. Illa et al. [9] proposed a methodology for estimating pattern-matching expectations by employing artificial intelligence techniques such as RF and support vector machines.

Artificial intelligence techniques are being more widely used in the stock market due to their capacity to process large amounts of data and identify intricate patterns that humans sometimes find difficult. It is important to keep in mind that these strategies' initial parameter configuration has a significant impact on how effective they are. Inaccurate estimates and outcomes might arise from improperly configured beginning settings. As such, it's important to pay close attention to the parameter settings while using artificial intelligence in stock trading. Consequently, there are numerous optimization algorithms that can be used to overcome these restrictions, such as the whale optimization algorithm (WOA) [10], particle swarm optimization (PSO) [11], Aquila optimizer (AO) [12], battel royal optimization (BRO) [13], biogeography-based optimization (BBO) [14], genetic algorithm (GA) [15], grey wolf optimization (GWO) [16], moth–flame optimization (MFO) [17], and others, can be used to get around these limitations. In 2015, S. Mirjalili proposed the MFO algorithm [17]. The MFO algorithm is a stochastic optimization technique inspired by the natural navigational mechanism of moths. Moths may navigate by keeping their angle concerning a far-off light source, like the moon or a flame, constant. The MFO method leverages this idea to optimize complex problems by varying the position and brightness of synthetic moths, which act as potential solutions. The algorithm explores the issue space to find the optimal answer as fast as possible. Justifications for Selecting the Proposed Model:

Addressing Complex Interactions: The model under consideration adeptly manages the complex interplay between investor psychology, market forces, economic variables, and market dynamics, which poses a significant challenge in the realm of financial forecasting. The comprehensive methodology, which merges the Moth Flame optimization and random forest processes, has been purposefully developed to address the intricacies that are intrinsic to the stock market.

Capability to Adapt to Non-Linear and Non-Stationary Conditions: Predicting stock price time series data presents a significant challenge due to their non-stationary, non-linear, and hypervolatile characteristics. The model being proposed is customized to effectively navigate these intricacies, rendering it well-suited for depicting the ever-changing dynamics of the stock market.

Addressing Computational Complexities: While conventional approaches may improve the accuracy of forecasts, they impose significant computational burdens. The complexities are effectively addressed by the proposed hybrid model, which guarantees precise predictions while maintaining computational efficiency.

Outstanding Efficacy and Performance: In comparison to the alternative models examined in the study, the hybrid model that integrated Moth Flame optimization and the random forest method consistently exhibited superior efficacy and performance. This demonstrates its resilience in addressing the unique difficulties associated with forecasting stock prices.

Optimal Performance and Minimal Error: The proposed model demonstrated an exceptional degree of effectiveness, characterized by minimal error. Preciseness is of the utmost importance when it comes to financial forecasting, as it enables one to make well-informed decisions.

The method proposed is thoroughly elucidated, effectively tackling the complex obstacles inherent in financial forecasting. The complex interaction among economic variables, market forces, and investor psychology poses a substantial obstacle to the ability to make precise forecasts in funding. The intricacy of this matter is compounded by the pronounced volatility, nonstationarity, and non-linearity of stock price time series data within the securities market. Acknowledging the constraints of conventional approaches, the article presents an innovative framework that adeptly surmounts these obstacles through the integration of the Moth Flame optimization methodology and the random forest method. Not only does this hybrid model demonstrate exceptional effectiveness, but it also surpasses other modern models examined in the study. The proposed model exhibits exceptional performance, minimal error, and high efficacy, providing a potentially viable resolution to the computational intricacies that are intrinsic to conventional forecasting approaches. The research assesses the predictive model that has been proposed by employing Nasdaq index data that covers the period from January 1, 2015, to June 29, 2023. The conclusive findings validate the efficacy and dependability of the suggested model in the domains of stock price analysis and prediction. The experimental results demonstrate that this methodology exhibits a higher level of predictive accuracy in comparison to other approaches. In brief, the methodology that has been proposed effectively tackles the complex issues associated with financial forecasting. It presents an innovative and successful approach that outperforms current models in terms of effectiveness and performance. The reliability of the model is further reinforced through its exhaustive evaluation and validation using real-world data, thereby establishing it as a significant contribution to the domain of stock price prediction. The research investigated many models, including RF, GA-RF, and PSO-RF, to assess their respective levels of reliability. The inquiry encompassed a comprehensive analysis of the data source and all relevant components in the subsequent section. A variety of analytical tools, including optimizer methods, evaluation metrics, and the RF model, were employed to examine the data. The findings of the study are given and compared with those obtained by alternative methodologies in the third part. The fourth part gives information about discussion of the results. The findings of the investigation are succinctly examined in the concluding section.

II. Methods and Materials

A. Random Forest

A well-liked machine learning technique for situations involving both regression and classification is the Random Forest algorithm, as seen in Fig. 1. It is a subset of the supervised learning algorithms of the support vector machines family. Two other popular tree-based techniques are naive Bayes and Adaboost. Breiman et al. [6] developed and presented the method, which is well known for being simple and efficient. The RF algorithm creates a variety of intricate decision trees, which improves forecast accuracy. The model is constructed decision trees by selecting the optimal feature from a given collection of characteristics in a non-deterministic manner, resulting in a lower level of predictability compared to alternative tree-based techniques. The methodology operates by iteratively training several decision trees through the utilization of bootstrapping, normalization, and bagging techniques. The grouping strategy involves the simultaneous construction of several decision trees, each using different subsets of characteristics and training data chunks. By employing bootstrapping to ensure the distinctiveness of each decision tree, the variance of the RF is reduced. The RF technique exhibits a high level of promise for generalizability due to the use of many tree-based models for evaluation. By employing this approach, the RF classifier can successfully mitigate challenges associated with unbalanced datasets and overfitting, hence surpassing the performance of current methodologies in accurately recognizing data.

Moreover, the methodology was specifically developed to address the analysis of datasets characterized by a large number of dimensions and strong interdependencies among variables. The reliability of the results increases proportionally with the number of trees included in the ensemble. The high level of precision exhibited by the RF approach can be attributed to the amalgamation of outputs derived from several decision trees. The utilization of ensemble methods mitigates the issue of overfitting and improves the predictive capabilities of the algorithm. Machine learning practitioners highly favor the RF method due to its ability to handle missing data and noisy inputs effectively. The above equation may be utilized to calculate the mean square error for an RF:

$$\boldsymbol{MSE = \frac{1}{N}\sum_{k=0}^{n}\binom{n}{k}(Fi - Yi)b^{2}} \quad (1)$$

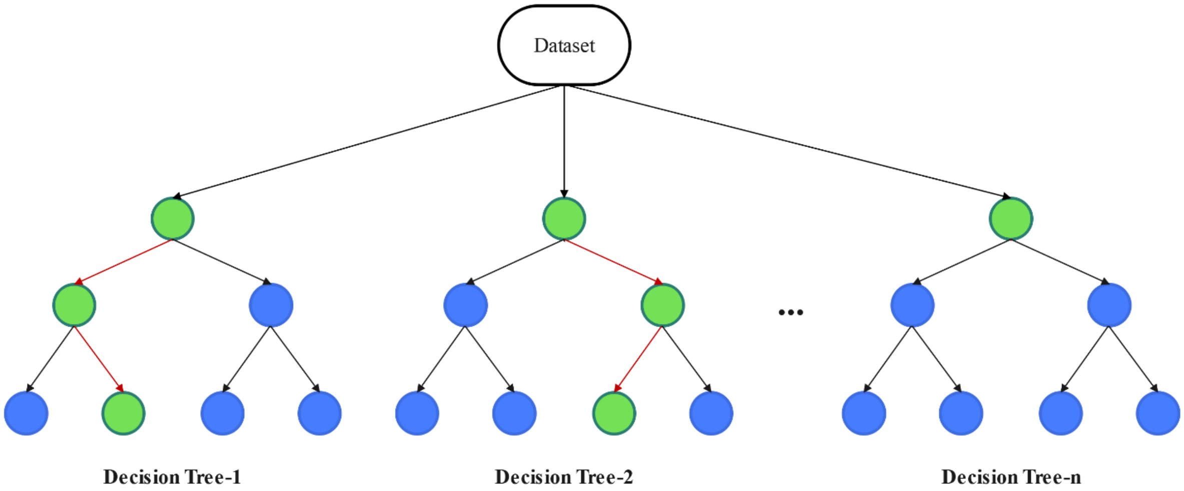

Fig. 1. The structure of Random forest.

B. Particle Swarm Optimization

PSO is an approach that, in order to get optimal results, imitates the cooperative habits of a flock of birds or a school of fish. Even if the exact location of the food supply is unclear at the outset, the swarm will nevertheless follow a set of rules to get there. By working together, the swarm is able to locate the source of nourishment. Swarms of fish or birds will eventually arrive at the near-optimal solution at the same moment. By following these three rules—separation, alignment, and cohesiveness—a bird swarm may efficiently navigate the search space and arrive at the correct solution [18]. Particles undergo separation by moving apart from each other to avoid overcrowding. The particles tend to align with their neighboring particles, resulting in a positional update influenced by the cohesion with said neighbors. Kennedy and Eberhart devised the PSO approach as a means to address optimization challenges. This method draws inspiration from the collective behavior observed in a swarm of particles [11]. PSO technique tends to converge rapidly and necessitates a limited number of parameters, hence reducing computational overhead.

Moreover, the likelihood of encountering a suboptimal local solution is reduced because of the extensive exploration conducted by several particles in quest for an optimal solution. In addition, the algorithm possesses an efficient global search mechanism and does not rely on derivatives. In the PSO, each particle searches a large search space to get the best possible answer. The search process begins with the random generation of candidate solutions, also known as particles, in the search space. Particle velocities and fitness scores are typically computed using a weighted mean of classification accuracy and the number of features in the feature subset. This computation aids in updating the velocity and heading of their trajectories after the initial iteration, and the method is continued until the stopping criterion is reached. The PSO algorithm's particles accelerate and decelerate per the following formula:

$$\boldsymbol{v_{id}^{t+1} = v_{id}^{t} + C_1 r_1^t \,(Pbest_{id}^{t} - x_{id}^{t}) + C_2 r_2^t \,(Gbest_{id}^{t} - x_{id}^{t})} \qquad (2)$$

The velocity of the ith particle at a given time iteration is denoted as $\boldsymbol{v_{id}^{k}}$ in a search space with d dimensions. The variables $\boldsymbol{Pbest_{id}^{t}}$ and $\boldsymbol{Gbest_{id}^{t}}$ represent the optimal particle and position for each individual and iteration of the ith function. The parameters $\boldsymbol{C_1}$ and $\boldsymbol{C_2}$ are utilized to modify the velocity of particles, whereas $\boldsymbol{r_1^t}$ and $\boldsymbol{r_2^t}$ represent random values within the range of 0 to 1. Furthermore, the particles in the PSO algorithm have the ability to alter their locations by utilizing the equation shown below:

$$\boldsymbol{x_{id}^{t+1} = x_{id}^{t} + v_{id}^{t+1}} \qquad (3)$$

The variable $\boldsymbol{x_{id}^{t}}$ represents the spatial coordinates of the ith particle at iteration $\boldsymbol{t}$ inside a search space characterized by $\boldsymbol{d}$ dimensions.

C. Genetic Algorithm

The Genetic algorithm is a computational approach that emulates the mechanism of natural selection in order to address optimization and search problems [15]. Using this approach, a set of potential solutions referred to as individuals is generated. In order to generate novel individuals, these individuals are subsequently exposed to genetic mechanisms such as mutation, recombination, and selection. The assessment process employed in this study is iterative in nature and is repeated through several generations until a viable solution is identified. Consequently, the utilization of GA is prevalent throughout several areas, including but not limited to engineering, finance, and science [19]. GA is comprised of three fundamental components [20]. A chromosome refers to a sequence of numerical or textual symbols that are assigned to each individual by the encoding entity. The selection of an appropriate encoding technique is contingent upon the specific issue that has to be addressed.

Furthermore, the fitness function is utilized to evaluate the degree to which each individual's representation of the answer is accurate. The fitness function has been particularly tailored to address the current problem. To generate novel individuals from existing ones, the evolutionary operators employ the mechanisms of selection, crossover, and mutation. A crossover is a genetic process that combines the chromosomes of two individuals to generate a novel offspring. Mutation, on the other hand, introduces random alterations to an individual's chromosomes. Selection is employed to identify the most reproductively successful individuals.

D. Mouth Flame Optimization

The Moth Flame Optimizer is a computational model that draws inspiration from natural phenomena and is specifically influenced by the nighttime behavior of butterflies, which is displayed in Fig. 3. [17]. Butterflies have a consistent behavior of fluttering towards the moon when they are attracted by a light source. The Moth Flame Optimizer utilizes and formalizes this approach into an optimization algorithm, which is illustrated in Fig. 2. The optimizer exhibits versatility in its applicability to many optimization issues across several domains, including power and energy systems, economic dispatch, engineering design, image processing, and medical applications. Additionally, the optimizer derives inspiration from the behavior of butterflies as they navigate light sources. Researchers utilize the transverse orientation as a method to investigate the phenomenon of moths maintaining a straight flight trajectory toward the moon [21]. This examination explores the possible use of moths as solutions, which possess the ability to navigate in several dimensions, including $\boldsymbol{1D, 2D, 3D}$, and hyperdimensional space, by manipulating their position vectors. The focus of this study is on examining the spatial distributions of these moths, as they represent the aspects under consideration. The provided methodology guarantees convergence, and the Multi-Objective Firefly Algorithm (MFO) is both reliable and computationally efficient. MFO is commonly utilized as:

$$M = \begin{bmatrix} CO_{1,1} & CO_{1,2} & \cdots & \cdots & CO_{1,h} \\ CO_{2,1} & CO_{2,2} & \cdots & \cdots & CO_{2,h} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ CO_{a,1} & CO_{a,2} & \cdots & \cdots & CO_{n,h} \end{bmatrix} \qquad (4)$$

In this context, h represents the number of dimensions, whereas a represents the number of moths.

$$S = \begin{bmatrix} S_{1,1} & S_{1,2} & \cdots & \cdots & S_{1,h} \\ S_{2,1} & S_{2,2} & \cdots & \cdots & S_{2,h} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ S_{a,1} & S_{a,2} & \cdots & \cdots & S_{2,h} \end{bmatrix} \quad (5)$$

The process of global optimization is conducted by the implementation of the three-step MFO approach.

$$MFO = (I, F, T) \quad (6)$$

Function ***I*** denotes a specific mathematical function, while ***F*** symbolizes the flight pattern of a moth as it navigates its environment in search of suitable space. Additionally, the symbol ***T*** is used to indicate the criteria that determine when the moth's flight comes to a halt.

$$X_i = t(C_i, S_j) \quad (7)$$

The formula employed in this context involves the twisting function denoted as $\boldsymbol{t}$, the number of the i-th moths represented by $\boldsymbol{C_i}$, and the number of the $\boldsymbol{j}$-th flames denoted as $\boldsymbol{S_j}$:

$$S(C_i, S_j) = Z_i \cdot e^{bt} \cdot cos(2\pi t) + S_j \, (8)$$

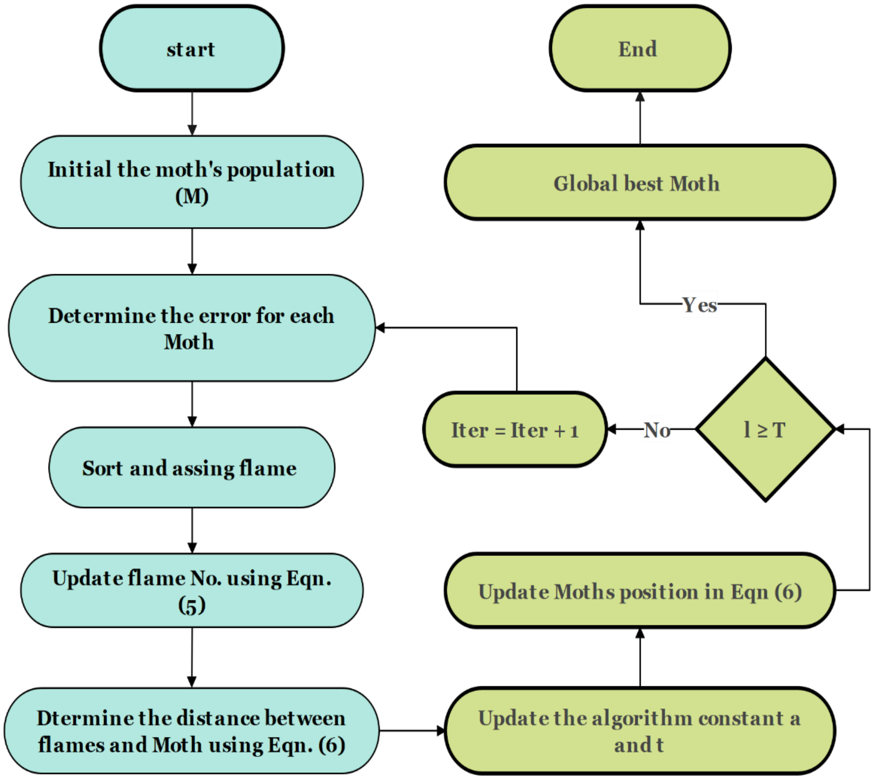
The variable $\boldsymbol{Z_i}$ represents the spatial separation between the moth and the flame. The constant $\boldsymbol{b}$ is a parameter in the context of this study. Additionally, the variable t is a random number selected from the interval [-1, 1].

$$\boldsymbol{Zi} = |\boldsymbol{S_j} - \boldsymbol{X_i}| \quad (9)$$

E. Data Collection and Preparing

To conduct a comprehensive analysis, it is important to include the trade volume as well as the open, high, low, and closing (OHLC) prices within a certain temporal interval. The data collection period was from January 2, 2015, to June 29, 2023, during which data was obtained from the Nasdaq index on the Yahoo Finance website. The precise details are encompassed inside the dataset that was employed for the investigation. A thorough data-cleaning procedure was conducted to ensure the accuracy and consistency of the forecasting models following the collection of the dataset. The implementation of a multi-step method was devised to safeguard the integrity of the dataset and prevent the inclusion of erroneous or incomplete data that might potentially lead to complications. The data were subjected to a thorough analysis in order to discover any anomalies, extreme numbers, or contradictions that could potentially compromise the validity of the results. This was one of the key aims. Several processes were utilized in order to clean and prepare the data in order to guarantee that it could be utilized. Several procedures, including scaling and normalization, were performed on the data in order to reduce the likelihood of gradient mistakes and unpredictable training results. Before beginning training, the data were normalized by employing the MinMaxScaler method. This was done in order to construct a stable model and reduce the likelihood of extremely high weight values occurring. This normalization process was achieved by employing the equation [22].

$$Xscaled = \frac{(\boldsymbol{X-Xmin})}{(\boldsymbol{Xmax-Xmin})} \quad (10)$$



start
Initial the moth's population (M)
Determine the error for each Moth
Sort and assing flame
Update flame No. using Eqn. (5)
Dtermine the distance between flames and Moth using Eqn. (6)
Update the algorithm constant a and t
Update Moths position in Eqn (6)
I ≥ T
No
Iter = Iter + 1
Yes
Global best Moth
End

Fig. 2. The framework of MFO.

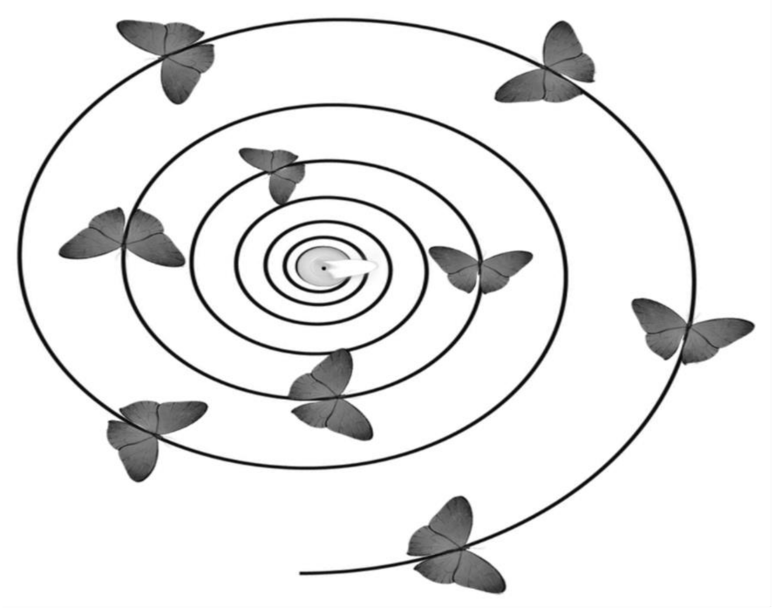


Fig. 3. Movement of the propeller towards the light source.

The training data provided to the model consisted of prices and volume for OHLC. The model was evaluated by including all features except for the close price data. The data were divided into two sets: 80% for training and 20% for testing, as seen in Fig. 4.

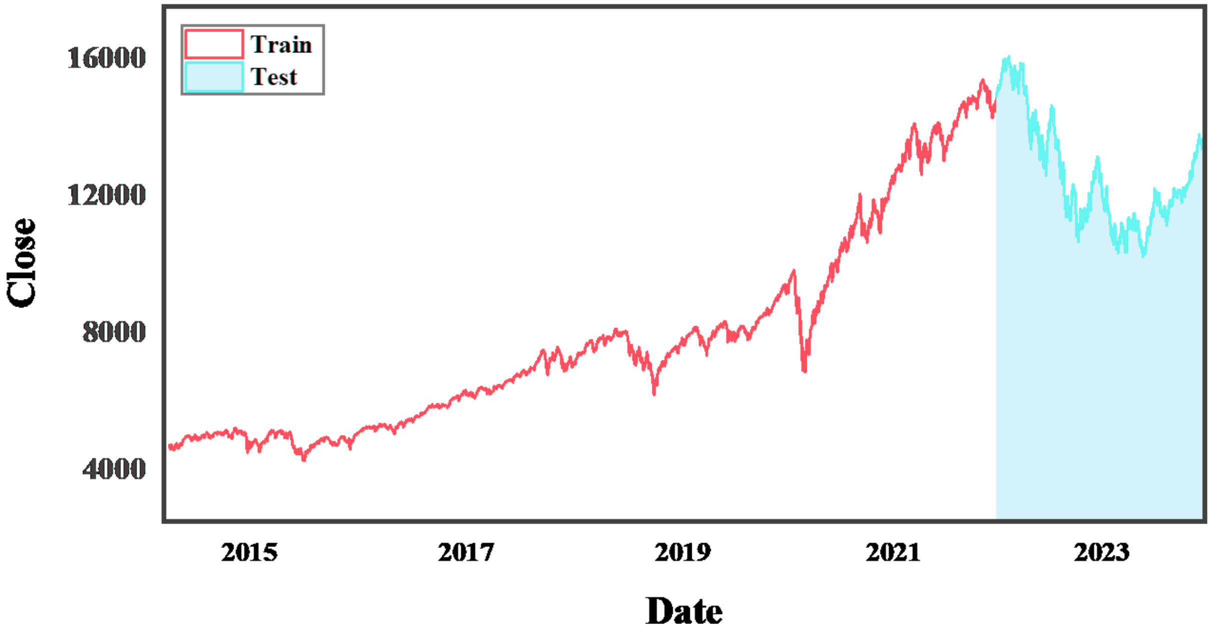

Fig. 4. Dividing the data into training and test.

F. Evaluation Metrics

The accuracy of the projected future was evaluated using a range of performance measures. Carefully selected, these measures provide a comprehensive assessment of the forecasts' validity and accuracy. The assessment method took into account a number of criteria. The Root Mean Square Error (RMSE) determines the root mean square of the errors between the predicted and actual values, the Mean Absolute Percentage Error (MAPE) computes the average absolute difference between the predicted and actual values, and the Coefficient of Determination ($\boldsymbol{R^2}$) quantifies the percentage of the dependent variable's variance that can be predicted based on the independent variable. These techniques help with and are very helpful for evaluating the forecasting models' accuracy.

$$MAPE = \left(\frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right|\right) \times 100 \tag{11}$$

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \quad (12)$$

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{n}} \quad (13)$$

III. Results and Discussion

A. Hyperparameters Setting

Performance is significantly impacted by the parameters that machine learning algorithms employ. Under these circumstances, it is imperative to guarantee the precise specification of the model parameters. This particular segment provides a comprehensive explanation of the processes involved in hyperparameter configuration. The three optimizers are utilized in order to optimize the parameters of the RF model. In the context of problem-solving, the RF model demonstrates remarkable comfort in tasks that require classification and regression. In prior discussions, we have examined the upper and lower limits of the parameters employed in the configuration of the RF model. In addition to the optimal values derived by the primary optimizer, a detailed dissection of these limits is provided in Table I. Ultimately, the utilization of this data will aid in the determination of the most effective parameters for the RF model, thereby augmenting its overall performance.

TABLE I. Setting and Obtaining the Optimal Values of the Hyperparameters

Random Forest	Upper and lower bounds	Best values
Maximum depth	[10 -100 and None]	80
Maximum features	[Auto and squared]	auto
Minimum samples Leaf	[1 and 4]	2
Minimum samples split	[2 and 10]	2
Number of estimators	[200 and 2000]	500

B. Statistical Values

This phase of the inquiry encompasses Table II, which presents comprehensive statistical data about the dataset. The inclusion of OHLC price and volume statistics in the table enhances the clarity of the data. To comprehensively and accurately evaluate the data, statistical measures such as mean, count, minimum, maximum, standard deviation (Std.), and variations can be employed.

TABLE II. Statistics Summary for the Data Set

	Open	High	Low	Volume	Close
Count	2137	2137	2137	2137	2137
Mean	8744.356	8805.287	8677.574	3143.8	8745.821
Std.	3332.744	3362.163	3298.311	1551.37	3332.058
Min	4218.81	4293.22	4209.76	706.88	4266.84
Max	16120.92	16212.23	16017.23	11621.19	16057.44
Variance	11107186	11304139	10878852	2406747	11102609

C. Outcomes of the Models

The primary objective of this study is to identify and assess the most effective hybrid algorithm for the prediction of stock prices. This research is grounded on the establishment of forecasting models and a comprehensive comprehension of the intricate aspects that impact stock market trends. The primary objective is to provide investors and analysts with valuable information that enables them to make informed and prudent investment choices. The models were processed by using different optimizers and different hyperparameters which were obtained by using those techniques. Table III and Fig. 5, 6 presents a comprehensive examination of the performance of each model. An exhaustive evaluation of the efficacy of each model is also incorporated.

TABLE III. Predicted Assessment Results for Benchmarking Approaches

	TRAIN SET			TEST SET		
	R^2	***RMSE***	***MAPE***	***R^2***	***RMSE***	***MAPE***
RF	0.979	423.25	4.96	0.974	254.85	1.61
GA-RF	0.983	382.32	4.07	0.978	234.67	1.50
PSO-RF	0.987	333.04	3.98	0.983	206.35	1.31
MFO-RF	0.992	260.90	1.70	0.988	173.45	1.07

IV. Discussion

This study aims to find the best hybrid stock price prediction algorithm. This study relies on predicting models and a deep understanding of stock market dynamics. The goal is to help investors and analysts make smart investment decisions. Fig. 5, 6 and Table III detail in each model's performance. Also included is a thorough model efficacy review. RMSE, MAPE, and R^2 were the three metrics that were utilized in the evaluation of the data analysis, other measures that were utilized included R^2 and RMSE. The ability of the aforementioned metrics to give a comprehensive evaluation of the correctness, dependability, and overall efficacy of the analysis is widely acknowledged and widely accepted. Both with and without the utilization of an optimizer, the performance of the RF model has been evaluated by utilizing the RMSE, MAPE, and R^2 criteria. Through the utilization of this approach, it is possible to acquire a more thorough understanding of the performance of the model and to make educated judgments based on the insights that are obtained. After doing an analysis on both the training and test sets, it was observed that the RF model, while it was not utilizing the optimizer, generated R^2 values of 0.979 and 0.974 for the training set and the testing set, respectively. While the MAPE values were 4.96 and 1.61, the RMSE values for the training and testing sets were 423.25 and 254.85, respectively. This is in contrast to the MAPE values, which were 4.96 and 1.61. There was a significant improvement in the effectiveness of the RF model as a result of the incorporation of optimizers. An increase in the R^2 value to 0.983 for the training dataset and 0.978 for the testing dataset is evidence that the utilization of the GA optimizer has led to considerable improvements. This can be observed by comparing the numbers. The RMSE and the MAPE have both shown a decline in both the training data set and the testing dataset. To be more specific, the RMSE values for the training set were 382.32 and the testing set 234.67, respectively. As an additional point of interest, the MAPE values for the training set are 4.07, whereas the values for the testing set are 1.50. As a result of doing a comparative analysis between the GA-RF model and the PSO-RF model, it has been concluded that the latter model shows superior performance. For the training phase, the R^2 values for the PSO-RF model were found to be 0.987, and for the testing phase, they were found to be 0.983. Despite the fact that the RMSE and MAPE values for training and testing both declined to 333.04 and 3.98, respectively, the values for testing decreased to 206.35 and 1.31, respectively. This is an important observation to make. According to these findings, the PSO-RF model is superior to the GA-RF model in terms of both its degree of effectiveness and its level of efficiency. The remarkable R^2 values of 0.992 and 0.988 for training and testing, respectively, demonstrate the efficacy of the MFO-RF model through its remarkable performance. Despite having the lowest possible testing value of 1.07, it performed exceptionally well. The MFO-RF model performed the best when compared to the other models, with the lowest RMSE values of 260.90 for training and 173.45 for testing. For comparison, the other models performed the worst. Considering that these results demonstrate how highly precise and reliable the MFO-RF model is, it is clear that it is an effective instrument for this particular application.

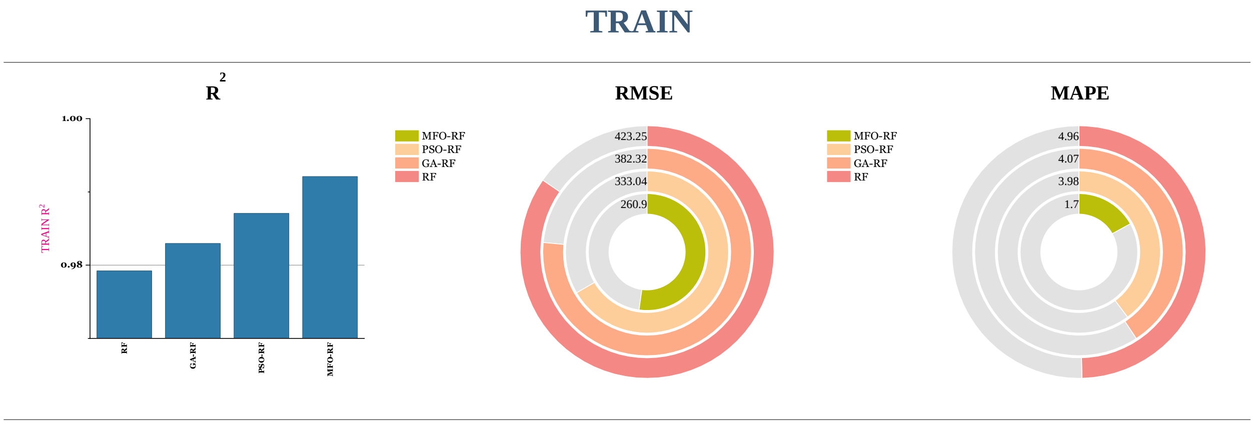

Fig. 5. The results obtained for $\boldsymbol{R^2}$, RMSE, and MAPE by the proposed model during training.

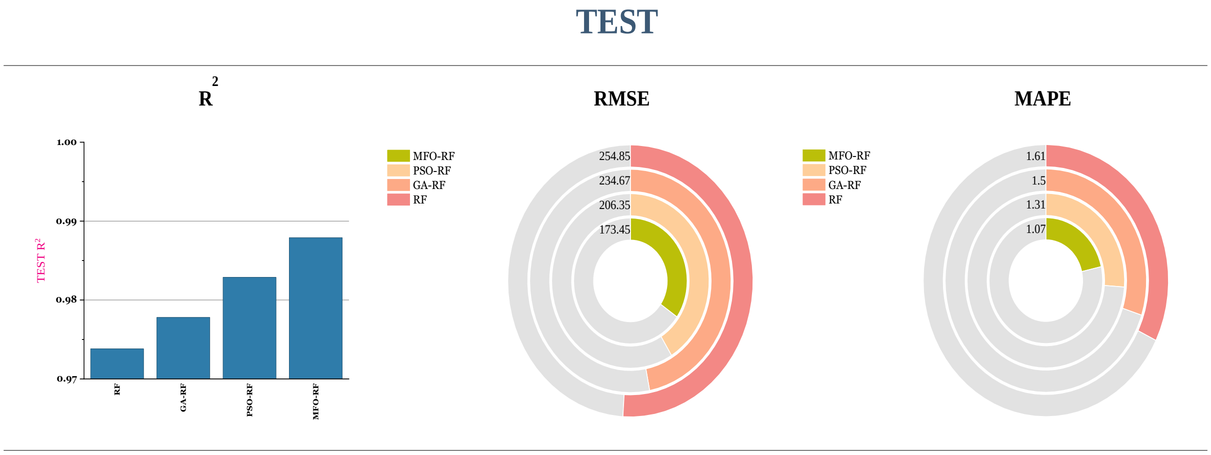

Fig. 6. The results obtained for $\boldsymbol{R^2}$, RMSE, and MAPE by the proposed model during testing.

After thorough research, the MFO-RF model is a reliable instrument for accurately forecasting stock values, thereby establishing its credibility. The efficacy of the model may be assessed by examining the Nasdaq index curves and comparing them to the corresponding curves depicted in Fig. 7 and Fig. 8. The MFO-RF model has superior performance in forecasting stock prices compared to other models, such as RF, GA-RF, and PSO-RF. A comprehensive analysis of the model's efficacy unveiled that the MFO-RF model predicts stock prices through the integration of the Mouth-Flame optimization technique and the random forest algorithm. The utilization of the RF technique not only mitigates fluctuations in stock prices but also enhances the precision of future trend predictions, hence further augmenting the accuracy of the model. One distinguishing characteristic of the MFO-RF model, in comparison to other models, is its ability to acquire knowledge from previous datasets. To accurately predict stock prices, a model must possess the capability to acquire knowledge from historical datasets and adjust its predictions in response to evolving market patterns. In summary, the MFO-RF model's reliability, accuracy, and ability to derive insights from historical datasets render it a highly valuable tool for predicting stock prices. The utilization of the RF algorithm and MFO optimizer, together with its adaptability in addressing dynamic market trends, positions it as the preferred option for those seeking to achieve profitable stock market transactions. These are the limitations of the research:

Temporal Scope: The study encompasses the period that commences on January 1, 2015, and concludes on June 29, 2023. The temporal scope may fail to encompass specific market conditions or events that transpired beyond the specified time period. Subsequent investigations may delve into the durability of the suggested algorithms across prolonged historical epochs.

Generalization of Algorithms: Although the suggested algorithms demonstrate exceptional performance when applied to Nasdaq data, their ability to be applied to diverse market conditions and financial instrument types is still unknown. It is critical to evaluate the adaptability of the algorithms to a wide range of datasets in order to obtain a thorough comprehension of their practicality.

Insufficient Comparative Research Against Non-Machine Learning Approaches: The study predominantly conducts a comparative analysis of various machine learning models, neglecting to delve deeply into their performance in relation to conventional forecasting methods or statistical methodologies. By incorporating these comparisons, a more comprehensive assessment of the proposed algorithms could be achieved.

The research investigates the impact of hyperparameter selection on sensitivity: To optimize hyperparameters, the study employs genetic algorithms, particle swarm optimization, and Moth Flame optimization. Nevertheless, the explicit consideration of the algorithms' sensitivity to various sets of hyperparameters is absent. A more comprehensive sensitivity analysis may yield valuable insights regarding the models' stability.

Market Volatility Attributable to Inherent Market Volatility: Predicting stock prices necessitates addressing vagaries. The accuracy of the proposed algorithms is commendable; however, the unpredictability inherent in financial markets may introduce unforeseen fluctuations that have an adverse effect on the precision of forecasts.

The potential compromise of model interpretability may arise from the complexity of the proposed algorithms, particularly when they are integrated with optimization techniques. Comprehending the fundamental mechanisms that propel predictions may present a formidable task, thereby constraining the model's applicability in specific decision-making contexts.

Alterations in Market Dynamics: Throughout the period under analysis, the study presupposes a stable set of market dynamics. Variations in economic policies, geopolitical occurrences, or worldwide economic transformations might give rise to modifications in market conduct that the suggested algorithms might not sufficiently account for.

Overfitting Risk: It is crucial to recognize the potential for overfitting, particularly when algorithms are being optimized for particular datasets. While the models might exhibit outstanding performance on the training data, they might encounter difficulties when implemented on unseen data, which raises doubts about their efficacy in real-world scenarios.

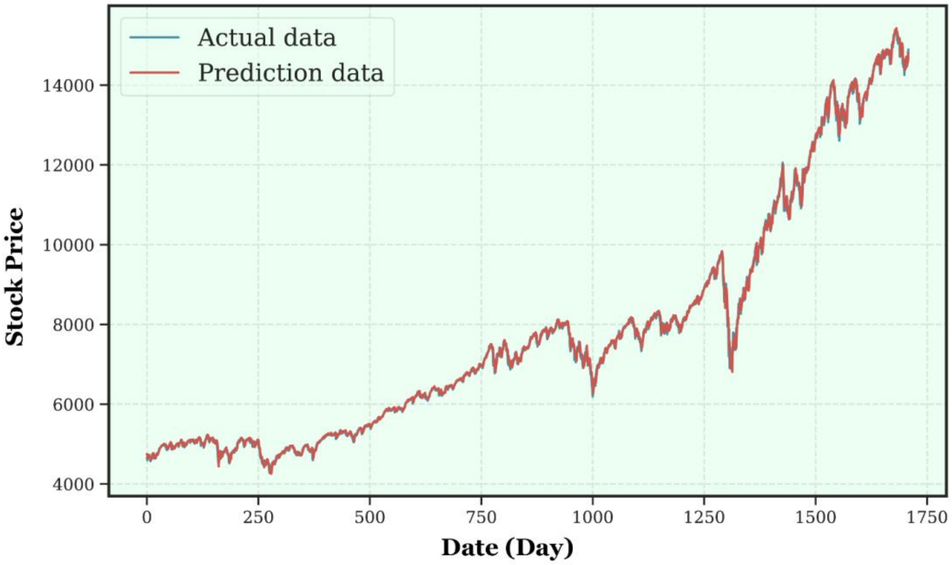

Fig. 7. The prediction curve generated via MFO-RF during training.

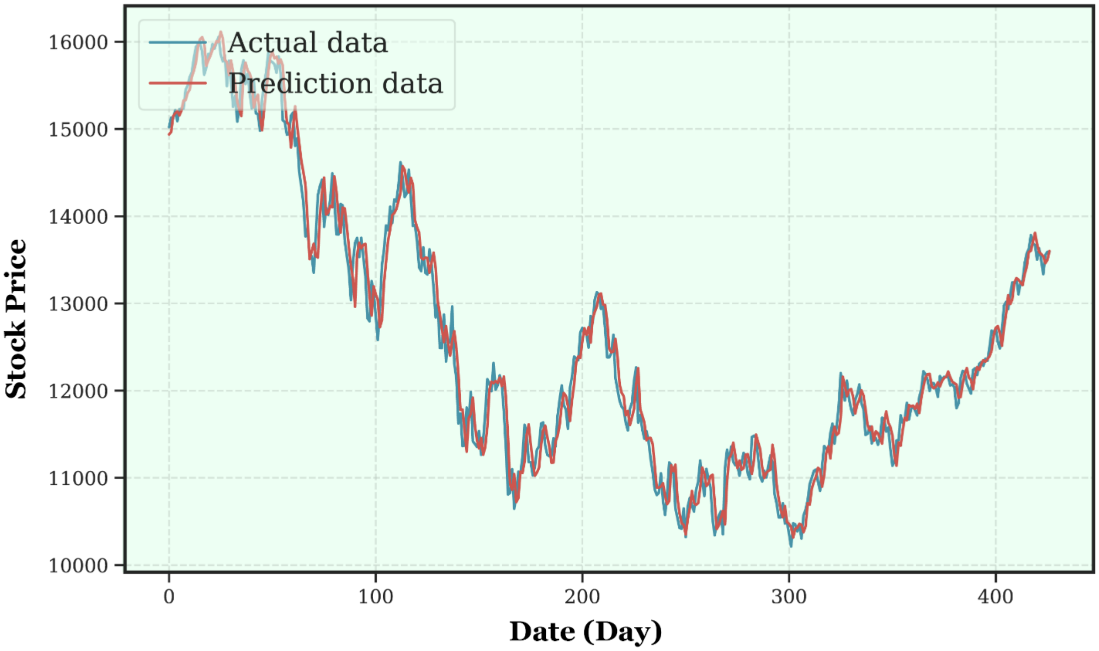

Fig. 8. The prediction curve generated via MFO-RF during testing.

V. Conclusion

The process of projecting stock prices is a complex and involved task that involves several interconnected components. The stock market is subject to several influences, including but not limited to politics, society, and the economy. It is a complex and always-changing system. To make accurate predictions on future stock values, it is important to consider a range of financial statements, earnings reports, market trends, and other relevant elements. Moreover, it is important to note that macroeconomic factors, such as interest rates, inflation, and worldwide market conditions, wield significant influence over the behavior of the stock market. Developing accurate and dependable prediction models can pose significant challenges owing to the intricate nature and multitude of factors inherent in forecasting stock prices. Understanding the unpredictable and non-linear nature of the market is essential to making accurate forecasts. Fortunately, the MFO-RF model offers a practical answer to these problems and has shown to be accurate and trustworthy. The effectiveness of many stock price prediction models, such as RF, GA-RF, and PSO-RF, was assessed in the current study. By employing the GA, PSO, and MFO hyperparameter optimization techniques, the RF's parameters were enhanced.

Nevertheless, when combined with RF, the MFO optimizer method produced the best results. The OHLC prices and volume for the Nasdaq index from January 2, 2015, to June 29, 2023, made up the dataset utilized in the study. The results of the investigation demonstrate how reliable and accurate the MFO-RF model is at forecasting stock prices.

Throughout the study, the accuracy and predictive capability of the MFO-RF model were evaluated by comparing it to many other models. Based on the obtained data, it can be concluded that the MFO-RF model consistently exhibited superior performance compared to the other models. The testing $\boldsymbol{R^2}$ score of 0.988 indicates a good level of accuracy in the predictions made. The RMSE value of the model, which was observed to be 173.45, indicates that the model's predictions exhibited a satisfactory level of accuracy. The model had a low MAPE score of 1.07, suggesting a consistent ability to provide reliable predictions. In terms of accuracy and efficacy, the MFO-RF model demonstrated superior performance compared to the other models that were examined.

The MFO-RF model is a helpful resource for stock price prediction in general and offers insightful data to investors who are attempting to make well-informed investment decisions.

Improving of Smart Health Houses: Identifying Emotion Recognition using Facial Expression Analysis

Yang SHI, Yanbin BU*
School of Media Technology, Communication University of China, Nanjing, Nanjing 211172, China

***Abstract*—Smart health houses have shown great potential for providing advanced healthcare services and support to individuals. Although various computer vision based approaches have been developed, current facial expression analysis methods still have limitations that need to be addressed. This research paper introduces a facial expression analysis technique for emission recognition based on YOLOv4-based algorithm. The proposed method involves the use of a custom dataset for training, validation, and testing of the model. By overcoming the limitations of existing methods, the proposed technique delivers precise and accurate results in detecting subtle changes in facial expressions. Through several experimental and performance evaluation tasks, we have assessed the efficacy of our proposed method and demonstrated its potential to enhance the accuracy of Smart Health Houses. This study emphasizes the importance of addressing emotional well-being in healthcare. As experimental results shown, the prosed method achieved satisfy accuracy rate and the effectiveness of the YOLOv4 model for emotion detection suggests that emotional intelligence training can be a valuable tool in achieving this goal.**

Keywords—Smart health houses; computer vision; facial expression; emotion recognition; YOLO

I. Introduction

Smart Health Houses (SHH) are the latest trend in healthcare, which aims to provide seamless and efficient medical services to individuals in the comfort of their homes [1], [2]. These houses utilize advanced technologies to monitor the health status of patients and offer personalized treatment plans [3]. In recent years, there has been a significant increase in the development of Smart Health Houses, and researchers have explored various technologies to improve their effectiveness.

The latest advances in the SHH have shown promising results in improving the quality of medical care [4]. These technologies include wearable devices, sensors, and machine learning algorithms that can detect various physiological signals and track the daily activities of patients [5]–[7]. Recently vision-based methods have been studied by many researchers due to extensive applicability [8]–[11]. Specifically, vision-based systems have attracted many researchers due to their non-invasive nature and ability to detect emotional changes in patients [12], [13]. Computer vision-based systems can analyze facial expressions and provide insights into the emotional state of patients, enabling healthcare providers to offer personalized treatment plans [14], [15]. Therefore, among these technologies, computer vision-based systems have gained significant attention due to their ability to analyze facial expressions and detect emotions accurately.

Facial expression analysis is one of the most widely studied areas in computer vision-based systems for the SHH [13]–[16]. It has been shown that facial expressions are reliable indicators of emotional changes and can provide valuable information about the patient's mental state [17], [18]. Therefore, researchers have focused on developing accurate facial expression analysis methods to improve the effectiveness of the SHH [15].

Existing methods for emotion recognition can be divided into two categories: conventional methods and deep learning-based methods. Conventional methods include feature extraction and classification algorithms, while deep learning-based methods mainly use convolutional neural networks (CNNs) to learn features automatically from raw data. Deep learning-based methods have shown significant improvements in various tasks [19]–[22], including emotion recognition [23]–[25], due to their ability to automatically learn high-level features from raw data. Despite the recent advances in this field, there are still several limitations and research gaps that need to be addressed. By reviewing of previous studies, existing methods for facial expression analysis have limitations in detecting subtle changes in facial expressions, which can lead to inaccurate results. Therefore, it is necessary to develop more advanced and accurate methods for facial expression analysis to improve the effectiveness of Smart Health Houses.

In this paper, we propose a deep learning-based facial expression analysis method using Yolo-based algorithm. We present a custom dataset for facial expression analysis and use it to train, validate and test our model. Our proposed method addresses the limitations of existing methods and provides accurate results in detecting subtle changes in facial expressions. We evaluate the performance of our proposed method through various experimental and performance evaluation tasks and demonstrate its effectiveness in improving the accuracy of Smart Health Houses.

Our research contributions include identifying the research gap in existing facial expression analysis methods, proposing a deep learning-based method using Yolo-based techniques, and providing experimental and performance evaluations of our proposed method.

The rest of this paper structures as follows, Section II present background of study. Section III reviews the related works. Section IV discusses the material and methods. Section V presents experimental results. Finally, the paper concludes in Section VI.

II. Background of Study

Facial expression analysis for smart health houses is the process of using computer vision and machine learning to detect and analyze facial expressions of individuals in a smart health house environment. To conduct a background study on this topic, this study reviews literature on facial expression recognition and analysis methods for applying facial expression analysis to smart health houses. Furthermore, the Yolo algorithm as effective solution has been selected for emotion recognition in this matter and background of this algorithm is discussed as well.

A. Facial Expression based Emotion Recognition

Emotion recognition using vision-based facial analysis is a field of research that focuses on the development of algorithms and techniques to automatically detect emotions from facial expressions. This approach is based on the idea that facial expressions are reliable indicators of emotions, and that these expressions can be detected and analyzed using computer vision techniques. The study of emotion recognition using facial analysis has gained increasing attention in recent years due to its potential applications in a variety of fields, such as psychology, marketing, and human-computer interaction. There are various approaches to emotion recognition using vision-based facial analysis, including feature-based methods, holistic methods, and deep learning methods. In following section, the details of each approach s are discussed.

1) Feature-based emotion recognition: Feature-based methods extract specific facial features, such as the position and shape of the mouth and eyes, to recognize emotions. The Facial Action Coding System (FACS) is a feature-based approach that identifies specific facial movements associated with emotions. Advantages of this method include the ability to detect subtle facial expressions, while disadvantages include the difficulty of defining features and the reliance on manual coding.

2) Holistic-based emotion recognition: Holistic methods analyze the entire face as a whole to detect emotions. These methods include the use of geometric and appearance-based features, such as facial landmarks and texture, to classify emotions. Advantages of this method include the ability to capture the dynamic changes of facial expressions and the ease of implementation. However, the main disadvantage is that they may not be able to capture subtle variations in facial expressions.

3) Deep learning-based emotion recognition: Deep learning methods, such as convolutional neural networks (CNNs), have gained popularity in recent years due to their ability to learn complex features from data. These methods involve training large neural networks on large datasets of labeled facial expressions to learn to automatically recognize emotions. Advantages of this method include the ability to automatically learn features, which can reduce the need for manual feature selection and labeling, and the ability to handle complex and high-dimensional data. However, the main disadvantage is that they require large amounts of labeled data to train the networks effectively, which can be expensive and time-consuming to collect.

As literature review indicated in emotion recognition methods, each approach has its advantages and disadvantages. Feature-based methods are good at capturing subtle expressions, while holistic methods can capture dynamic changes. Deep learning methods are highly accurate but require a large amount of labeled data. Therefore, deep based can be investigated because of high efficiency and effectiveness.

B. YOLO Algorithm

YOLO (You Only Look Once) is a popular object detection algorithm that was first introduced by Joseph Redmon et al. in 2016. The conventional Yolo algorithm architecture is shown in Fig. 1. The YOLO algorithm works by dividing the input image into a grid of cells and predicting bounding boxes and class probabilities for each cell. This allows YOLO to detect multiple objects in an image in real-time with high accuracy.

Over the years, several versions of YOLO have been released in the literature, including: YOLOv1: The original version of YOLO, introduced in 2016, which demonstrated real-time object detection with good accuracy. YOLOv2: Introduced in 2017, this version improved the accuracy of the original algorithm by making changes to the network architecture and adding batch normalization. YOLOv3: Released in 2018, YOLOv3 further improved the accuracy of the algorithm by using a feature pyramid network and introducing new techniques like multi-scale predictions and focal loss. YOLOv4: Introduced in 2020, YOLOv4 is currently the latest version of the YOLO algorithm. This version made significant improvements to the network architecture, including the use of spatial pyramid pooling (SPP), cross-stage partial network (CSP), and Mish activation function. Additionally, YOLOv4 introduced new techniques like data augmentation, label smoothing, and object agnostic NMS, which led to significant improvements in accuracy and speed.

Among the existing Yolo version, the YOLOv4 is considered to be better than its predecessors due to its improved accuracy and speed, as well as its ability to detect smaller objects with higher accuracy. It is a highly effective object detection algorithm that has achieved state-of-the-art performance on several benchmark datasets. Its unique combination of features and optimizations has made it one of the most popular object detection algorithms in the computer vision community.

As shown in Fig. 2(A), feature pyramid network, a backbone network, and several detection heads form the foundation of the YOLOv4 framework. The backbone network is in charge of removing features from the input picture, while the feature pyramid network is utilised to create feature maps at various sizes. Bounding boxes and class probabilities for objects at various scales are predicted using the multiple detection heads.

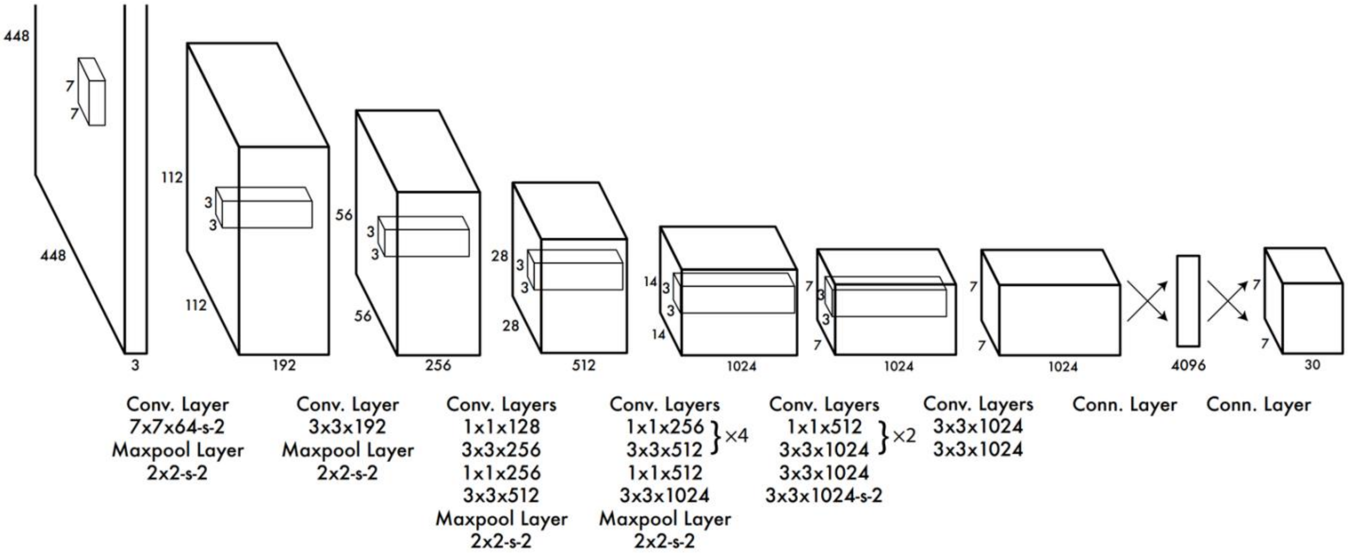

Fig. 1. The convention YOLO architecture.

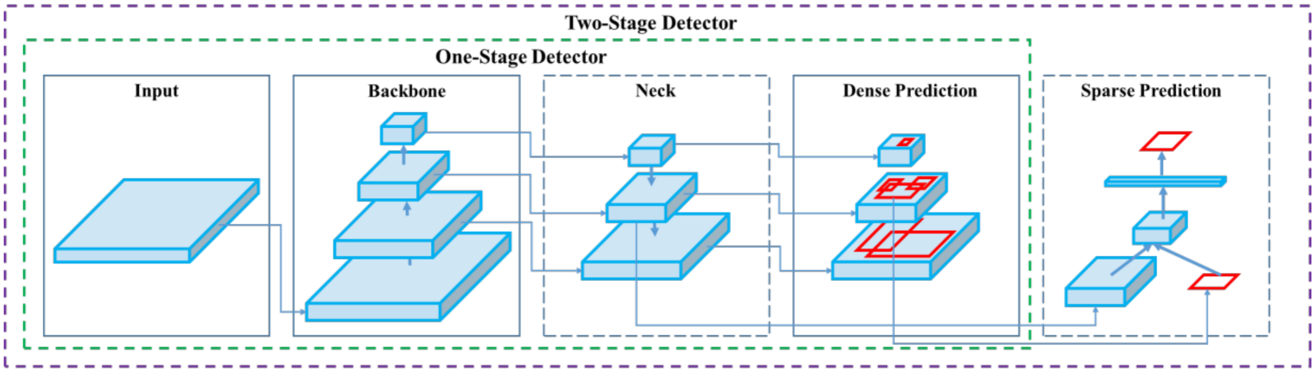

Fig. 2. The YOLOv4 architecture [26].

The YOLOv4 backbone network is built on a modified version of the CSPDarknet network, a deep neural network that combines the benefits of residual and convolutional networks. The neck network, which features a spatial pyramid pooling (SPP) module that enables the network to collect data at various sizes, comes after the backbone network.

The Path Aggregation Network (PAN), a multi-scale feature fusion module that merges feature maps at several sizes to enhance object recognition accuracy, is improved and used in the feature pyramid network in YOLOv4. The Cross Stage Partial Network (CSP), a feature fusion module that aids in decreasing computation while preserving accuracy, is also a component of the feature pyramid network.

In YOLOv4, the several detection heads are intended to forecast item bounding boxes and class probabilities at various sizes. This is accomplished by employing anchor boxes with various aspect ratios and sizes, which are utilised to recognize objects of various sizes and forms. The detecting heads moreover make use of a brand-new activation technique dubbed Mish, which has been demonstrated to raise deep neural network precision.

III. Related Works

The paper in [27] proposed a method for emotion recognition from facial expressions based on Support Vector Machines (SVM) algorithm. The authors used the JAFFE and CK databases to train the model, which achieved an accuracy rate of over 90%. They also tested the model on real-time video data and found it to be effective for emotion recognition in real-time. The authors suggest that the model can be applied in a variety of applications, such as video conferencing and virtual reality. However, limitations of the study include the use of only one ethnicity, which may limit the model's effectiveness in recognizing emotions in people of other ethnicities. The model may also not be effective in recognizing subtle or complex emotions that are difficult to detect from facial expressions alone.

Bisogni et al [13] explored the impact of deep learning approaches on facial expression recognition (FER) in healthcare industries. The authors compared three different models: CNN, RNN, and a hybrid CNN-RNN model. The hybrid model achieved the highest accuracy rate and was more effective in recognizing subtle emotions such as disgust and contempt. The authors suggest that deep learning approaches can improve FER in healthcare industries, which can lead to better diagnosis and treatment outcomes. However, the study's limitations include the use of only two datasets and the lack of diversity in the datasets. Further research is needed to validate the effectiveness of deep learning models on a larger and more diverse population.

This paper [28] proposed a video analytics-based facial emotion recognition system for smart buildings. The authors used a dataset of facial expressions to train their machine learning model, which used the Haar Cascade Classifier to detect faces and the Local Binary Patterns Histograms (LBPH) algorithm to recognize facial expressions. The system was tested in a real-world smart building environment, and the authors found that it was able to accurately detect facial expressions and classify them into one of seven emotions. The key features of the system include its ability to operate in real-time and to recognize multiple emotions simultaneously. The authors suggest that this system can be used to improve the well-being and safety of occupants in smart buildings, by identifying and responding to emotional cues. However, limitations of the study include the use of a single dataset and a small sample size for testing. Additionally, the system may not be effective in recognizing subtle or complex emotions that are difficult to detect from facial expressions alone.

Rajavel et al [29] presents an IoT-based smart healthcare video surveillance system using edge computing to analyze facial expressions of patients. The system uses a convolutional neural network (CNN) model to classify facial expressions of pain, discomfort, and distress, and sends alerts to healthcare professionals. The system's key features include its ability to operate in real-time, high accuracy rate, and low power consumption. The findings show that the system achieved a high accuracy rate of 94.3% in detecting facial expressions. However, the system has some limitations, including the need for high-quality video input and limited flexibility in detecting other emotions or expressions. Overall, the proposed system has the potential to enhance healthcare monitoring and improve patient outcomes.

The authors in [30] proposes an IoT-based smart health monitoring system for COVID-19 that utilizes facial expression analysis to monitor the health status of individuals. The method involves capturing facial expressions using a camera and analyzing them using a machine learning algorithm to detect COVID-19 symptoms such as coughing, sneezing, and fever. The system also collects other health data such as heart rate and oxygen levels using wearable devices. The key features of the system include real-time monitoring, early detection of symptoms, and remote monitoring capabilities. The findings suggest that the system can accurately detect COVID-19 symptoms with a high level of accuracy. However, the authors acknowledge some limitations such as the need for further validation studies and the potential for privacy concerns with the use of facial recognition technology.

IV. Material and Methods

This section presents the details of the proposed method in this study. S mentioned earlier, a Yolo base algorithm is used for emotion recognition. Basically, for this detection, a model is required to generate using a dataset. To generate a Yolo model for this purpose, a custom dataset must be prepared first. This dataset needs to consist of images with labeled emotions (e.g. happy, sad, angry, etc.) and bounding boxes around the faces in each image. The bounding boxes help the Yolo model locate and classify emotions in new images.

A. Yolo-based usage Justifications

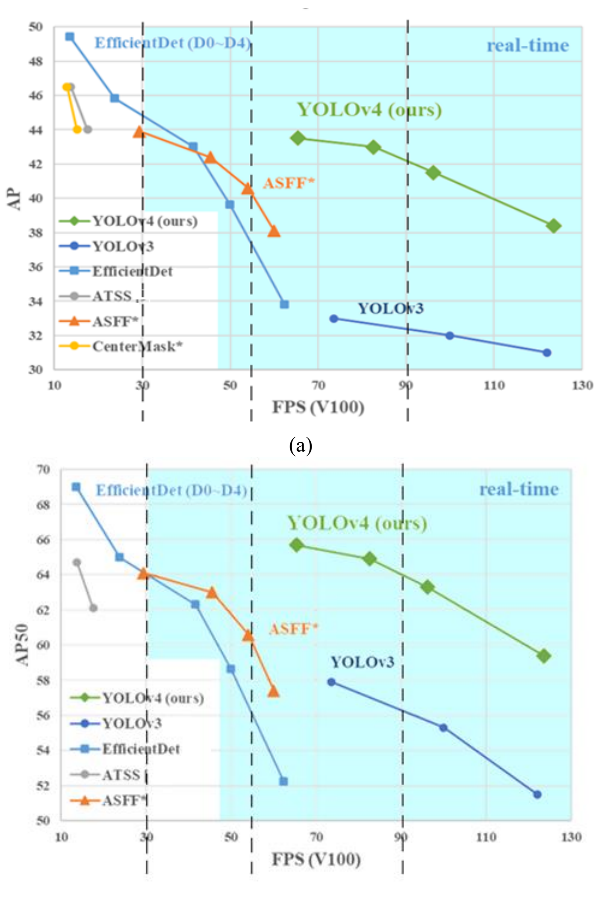
This section intends to justify why the Yolov4 is chosen in this study. The usage of YOLOv4 (You Only Look Once version 4) in this study is primarily focused on its exceptional performance in terms of high accuracy rates compared to other object detection methods. YOLOv4 has gained significant attention and popularity within the computer vision community due to its remarkable ability to detect and locate objects in real-time with remarkable precision.

One of the key justifications for choosing YOLOv4 is its state-of-the-art accuracy, which surpasses many existing object detection algorithms. YOLOv4 achieves this by employing a variety of innovative techniques and architectural enhancements. These advancements include the integration of a more powerful backbone network, feature pyramid network (FPN), spatial pyramid pooling (SPP), and PANet (Path Aggregation Network). These components work collaboratively to extract multi-scale features from the input image, enabling YOLOv4 to detect objects of varying sizes and appearances accurately. Additionally, YOLOv4 utilizes a highly efficient and optimized detection pipeline, enabling it to process images and videos in real-time. By employing a single-pass approach, YOLOv4 eliminates the need for time-consuming region proposal techniques employed by other methods, such as Faster R-CNN. This efficiency is crucial in scenarios where real-time object detection is required, such as autonomous driving, video surveillance, and robotics applications.

Moreover, YOLOv4 incorporates advanced training strategies, including data augmentation techniques, such as mosaic data augmentation and random shape training, as well as optimization methods like focal loss and learning rate scheduling. These strategies contribute to further improving the accuracy of the model. The comprehensive evaluation of YOLOv4 against other state-of-the-art object detection methods has consistently demonstrated its superior performance. It achieves remarkable accuracy rates while maintaining a high detection speed, making it an ideal choice for various applications that demand both accuracy and efficiency.

Fig. 3. Comparison of Yolov4 and other methods in terms of average precision (*AP*) and FPS [30].

As shown in Fig. 3, the graph illustrates comparison between YOLOv4 and other state-of-the-art object detection algorithms. The X-axis represents the Frames Per Second (FPS), which indicates the detection speed of the algorithms, while the Y-axis represents the average precision rate, which signifies the accuracy of object detection. The graph clearly demonstrates that YOLOv4 outperforms the other object detectors in terms of precision rate.



(a)

(b)

Fig. 3. Comparison of YOLOv4 and other methods in terms of average precision (AP) and FPS, (a) performance comparion base on AP, (b) performance comparion sof base on AP50.

As the average precision rate increases, YOLOv4 consistently achieves higher values compared to its counterparts. This indicates that YOLOv4 is more effective in accurately detecting objects in various scenarios. Several justifications support the superiority of YOLOv4 in terms of precision rate.

Firstly, YOLOv4 adopts an innovative architecture that incorporates advanced techniques such as feature pyramid network (FPN), spatial pyramid pooling (SPP), and path aggregation network (PANet). These components enable YOLOv4 to extract multi-scale features and capture intricate object details, resulting in improved detection accuracy.

Secondly, YOLOv4 utilizes an efficient single-pass detection pipeline, which eliminates the need for time-consuming region proposal techniques. This allows YOLOv4 to process images and videos in real-time without compromising accuracy. Other detectors, such as Faster R-CNN, may achieve higher FPS rates but often at the cost of reduced precision.

Therefore, the graph illustrates that YOLOv4 surpasses other object detectors in terms of precision rate. The innovative architecture, efficient detection pipeline, and advanced training strategies employed by YOLOv4 contribute to its superiority in accurately detecting objects.

As shown in Fig. 4, the graph provides a comparison of YOLOv4 with other state-of-the-art object detectors, namely Swin Transformer, EfficientDet, SpineDet, YOLOv3, and PP-YOLO. It plots the average precision rate on the Y-axis, representing the accuracy of object detection, against the latency on the X-axis, indicating the time taken for detection. YOLOv4 consistently outperforms the other detectors in terms of precision rate, showcasing its effectiveness in accurately detecting objects across different scenarios. YOLOv4's superiority in precision rate can be attributed to its advanced architecture, which incorporates techniques such as feature pyramid network (FPN), spatial pyramid pooling (SPP), and path aggregation network (PANet). These components enable YOLOv4 to extract multi-scale features and capture intricate object details, resulting in improved detection accuracy. Additionally, YOLOv4's efficient single-pass detection pipeline eliminates the need for time-consuming region proposal techniques, allowing it to process images and videos in real-time without compromising accuracy.

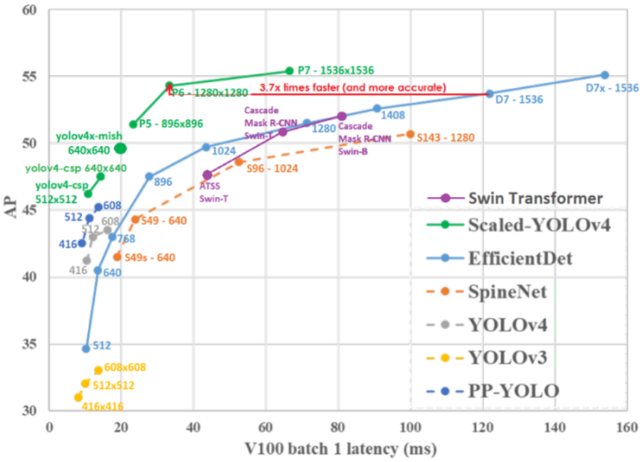


Fig. 4. Comparison of YOLOv4 and others in terms of AP and latency [32].

The effectiveness of YOLOv4 is further justified by its utilization of advanced training strategies. Data augmentation techniques and optimization methods, such as focal loss and learning rate scheduling, enhance the model's ability to generalize and accurately detect objects in diverse conditions. These strategies contribute to YOLOv4's superior precision rate and its ability to surpass other object detectors in terms of accuracy. As results, the graph clearly illustrates YOLOv4's superiority over other object detectors in terms of precision rate. Its advanced architecture, efficient detection pipeline, and advanced training strategies collectively contribute to its effectiveness in accurately detecting objects. YOLOv4's ability to maintain high precision while achieving real-time detection sets it apart from other state-of-the-art detectors, making it a preferred choice for various applications that demand both accuracy and efficiency.

B. Dataset Preparation

In this study, we use a dataset from Robloflow universe resource [31]. The Roboflow is a useful resource for preparing a custom dataset for the Yolo model. It allows users to upload their images and labels, and then provides tools to clean and augment the data. Pre-processing steps, such as resizing and normalizing the images, can improve the accuracy of the Yolo model. Data augmentation techniques, such as random cropping, flipping, and rotation, can increase the size of the dataset and reduce overfitting.

To further improve the accuracy rate of the Yolo model, more advanced data augmentation techniques can be applied. Mix-up augmentation can generate new training samples by blending pairs of images and their labels. Cutout augmentation can randomly remove parts of an image to force the model to focus on other features and using the data augmentation procedure, the total number of images in the dataset 4540.

In nest step, the prepared and enhanced dataset has to be divided into training, validation, and testing sets. The Yolo model is trained using the training set to identify emotions in fresh photos. The validation set is used to fine-tune the model's hyperparameters, including the learning rate and epoch count. The testing set is employed to assess the model's performance on unobserved data. Table I shows the structure of dataset split for training, validation and testing sets.

TABLE I. DATASET SPLIT FOR TRAINING, VALIDATION AND TESTING SETS

Training	Validation	Testing
85%	10%	5%
3859	454	227

The training module is responsible for optimizing the weights of the Yolo model using back propagation and gradient descent. The validation module measures the accuracy of the model on the validation set and adjusts the hyperparameters accordingly. The testing module evaluates the final accuracy of the model on the testing set. All of these modules require careful tuning and monitoring to ensure that the Yolo model is accurately detecting emotions in new images.

C. Hyperparameter Tunning

However, based on the obtained results from our experimentation, we set following hyperparameters to generate the YOLOv4-based model,

1) Learning rate: Learning rate is the step size at which the model updates its parameters during training. A starting learning rate for YOLOv4 is 0.001.

2) Batch size: Batch size is the number of samples processed in a single forward/backward pass. The batch size for YOLOv4 is 64.

3) Momentum: Momentum is the parameter that accelerates the gradient descent algorithm in the relevant direction and dampens oscillations. A good momentum value for YOLOv4 is 0.9.

4) Number of epochs: The number of epochs is the number of times the entire training dataset is passed through the model during training. A good number of epochs for YOLOv4 is 100.

5) Anchor boxes: Anchor boxes are the predefined boxes used to detect objects in YOLOv4. A good number of anchor boxes for emotion recognition is 3-4.

6) Input size: The input size of the image affects the detection accuracy and inference time of YOLOv4. A good input size for YOLOv4 is 416*416.

7) IOU threshold: IOU threshold is the minimum intersection over union required to consider a detection as true positive. The IOU threshold for YOLOv4 is 0.5.

8) Confidence threshold: Confidence threshold is the minimum confidence score required to consider a detection as valid. The confidence threshold for YOLOv4 is 0.25.

9) NMS threshold: NMS threshold is the minimum overlap required between two detections to suppress one of them. The NMS threshold for YOLOv4 is 0.45.

D. Model Generation

One the dataset is prepared and hyperparameters are tuned, we can generate a model. To generate this model, we use a pre-trained model, by downloading a pre-trained weight from the COCO dataset. This weight is used to initialize the YOLOv4 model. When a pre-trained weight is available, we train the model using a Yolov4 model, and then validate the model to ensure it's not overfitting, and finally test the model to evaluate its performance.

V. EXPERIMENTAL RESULTS

This section presents the experimental result and performance evaluation of the proposed method. Experimental results obtained using YOLOv4 model on image samples have shown promising results in terms of object detection accuracy. It has also shown excellent performance in detecting small objects and improving accuracy over the facial emotion recognition dataset. Fig. 5 shows some samples of experimental results.

The created YOLOv4 model has demonstrated outstanding generalization skills, i.e., it can identify emissions in a variety of complicated scenarios, as demonstrated by the experimental findings. Overall, YOLOv4's efficacy and superiority over other object identification models have been shown by experimental findings on picture samples utilizing this model.

For performance evaluation average precision are calculated for by classes. This calculation is performed for validation and testing sets individually. Table II presents the Average precision by class for validation and testing sets. Moreover, precision, recall and Mean Average Precision (*mAP*) metrics are calculated using to measure the performance and corresponding diagram are demonstrated.

Precision is the percentage of accurately identified emotions (true positive predictions) among all projected emotions. True positives divided by the total of true positives and false positives is how it is determined. A high precision means that most of the model's predictions are accurate. Fig. 6 represents the result of precision metric.

Recall quantifies the share of accurate predictions that were positive out of all the actual emotions in the dataset. By dividing the total of true positives and false negatives, it is calculated. The majority of the emotions in the dataset can be detected by the model, as indicated by a high recall. Fig. 7 represents the result of recall metric.

The mAP scores calculated for each emotion class. AP measures how well the model can distinguish between different emotions. It is calculated as the area under the precision-recall curve for a specific emotion class. A high mAP indicates that the model can accurately detect all the emotion classes. Fig. 8 represents the result of mAP metric.

Therefore, in order to evaluate the efficiency of the model, we use these metrics to evaluate the performance of the models. As experimental results and performance evaluations reported a higher precision and recall indicate better performance, while a higher mAP indicates better differentiation between different emotion classes. By using these metrics, we address the generated model achieve satisfy accuracy rate and the effectiveness of the YOLOv4 model for emotion detection.

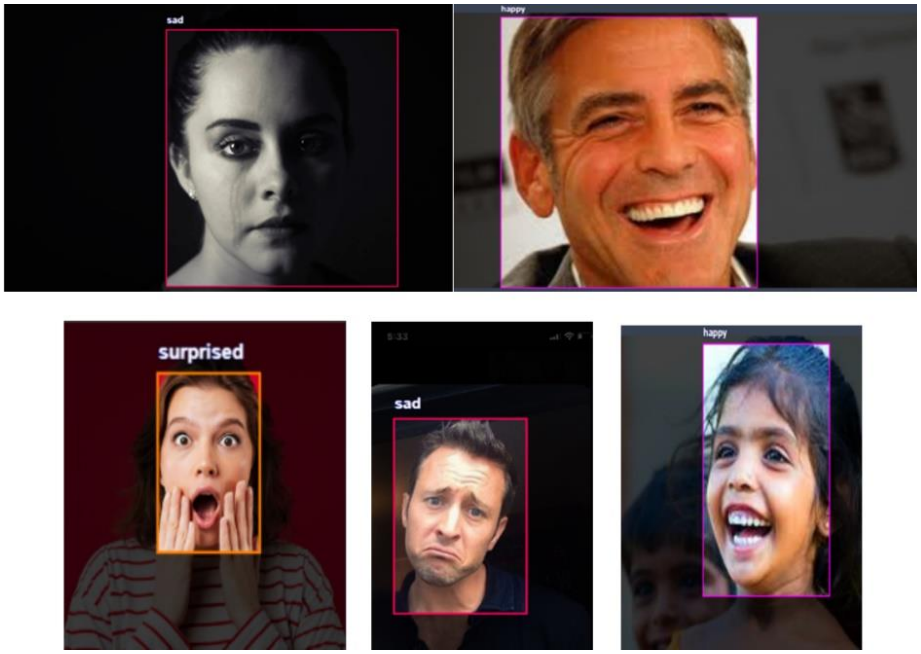

Fig. 5. Samples of experimental results.

TABLE II. AVERAGE PRECISION BY CLASS FOR VALIDATION AND TESTING SETS

Classes	Validation set	Test set
Angry	93%	91%
Happy	87%	89%
Sad	89%	85%
Surprised	96%	94%
All	91.25%	89.75%

As shown in Fig. 6, the mAP_0.5 and mAP_0.5:0.95 are metrics used to evaluate the efficiency and effectiveness of object detection models, including the generated YOLOv4 model for facial expression analysis and emotion recognition. mAP_0.5 measures the average precision at an IoU threshold of 0.5, indicating how well the model localizes objects. Higher mAP_0.5 scores indicate better accuracy. mAP_0.5:0.95 considers a range of IoU thresholds and calculates the average precision across this range, providing a comprehensive evaluation of the model's performance. A higher mAP_0.5:0.95 score indicates accurate detection across various IoU thresholds. The mAP curves visualize the precision-recall trade-off, indicating the model's ability to achieve high precision while maintaining a reasonable recall rate. High mAP scores justify accurate results in emotion recognition. The YOLOv4 model demonstrates effectiveness by achieving high mAP scores, indicating accurate detection and recognition of facial expressions for emotion recognition tasks.

As experimental results indicated, this study significantly advances our understanding of emotion recognition through facial expression analysis. Extensive comparisons have been meticulously carried out to demonstrate the superiority of the proposed method over existing approaches, as visually depicted in Fig. 3 and Fig. 4. Moreover, the discussions closely accompany these figures to provide detailed insights and interpretations.

Furthermore, the presentation of the proposed method's performance serves as a pivotal aspect of our study, showcasing the outcomes in a manner that emphasizes their significance. As obtained results and illustrated in Fig. 3 and Fig. 4, the developed method not only exhibits effectiveness but also outperforms other existing methods, underscoring its importance in the field of emotion recognition.

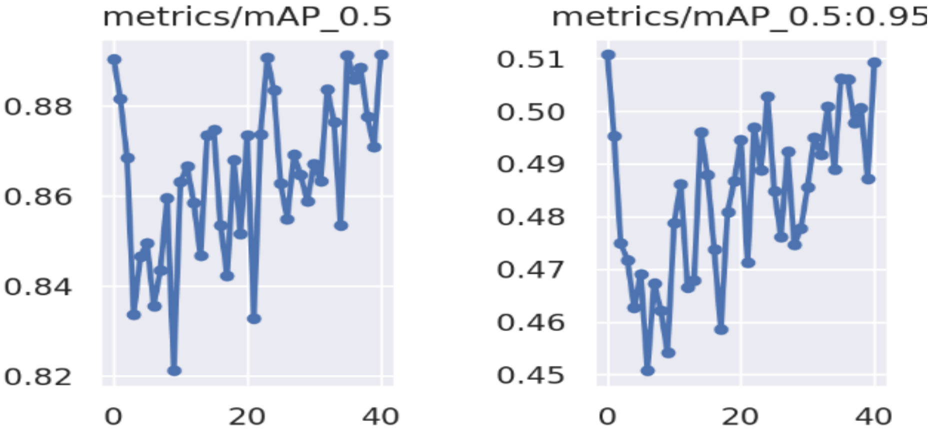

Fig. 8. Performance evaluation based on mAP metrics.

VI. Conclusion

Smart Health Houses aim to provide efficient and personalized medical services to individuals in their homes using advanced technologies, such as wearable devices, sensors, and machine learning algorithms. Among these technologies, computer vision-based systems that can analyze facial expressions and detect emotions accurately have gained significant attention due to their non-invasive nature. However, existing methods for facial expression analysis have limitations in detecting subtle changes in facial expressions. To address this issue, this paper proposes a deep learning-based facial expression analysis method using a YOLOv4-based algorithm. The method utilizes a custom dataset for training, validation, and testing and overcomes the limitations of existing methods, providing accurate results. The study concludes that the proposed method has the potential to enhance the accuracy of Smart Health Houses. For directions and future studies, investigating the potential of combining multiple technologies, including computer vision-based systems, wearable devices, and sensors, to enhance the accuracy and effectiveness of Smart Health Houses. This study holds considerable significance as it not only advances our understanding of emotion recognition through facial expression analysis but also offers a superior method for achieving accurate results. The outcomes presented in this research provide a valuable foundation for future studies in the realm of emotion recognition, paving the way for more sophisticated and precise techniques. Researchers can build upon these findings to develop enhanced algorithms and applications, ultimately contributing to a deeper comprehension of human emotions and their applications in various fields, such as psychology, human-computer interaction, and affective computing. Further exploring the limitations of existing facial expression analysis methods and developing more advanced techniques is to improve their accuracy. This could involve investigating the potential of using different deep learning architectures, such as convolutional neural networks, to enhance the performance of facial expression analysis models. Additionally, research could focus on developing methods to address issues such as variations in lighting conditions and occlusions of facial features.

Perceived Benefits and Challenges of Implementing CMMI on Agile Project Management: A Systematic Literature Review

Anggia Astridita, Teguh Raharjo, Anita Nur Fitriani
Faculty of Computer Science, University of Indonesia, Jakarta, Indonesia

***Abstract*—In an era where the agility and responsiveness of Agile project management are paramount, the integration of structured models like the Capability Maturity Model Integration (CMMI) presents a blend of unique opportunities and challenges. This study conducts a comprehensive systematic literature review of 23 scientific articles, chosen through the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) methodology, to explore the benefits and challenges of CMMI and software development integration within the context of Agile project management. Emphasizing the enhancement of Agile project management maturity, the research delves into the role of CMMI, particularly CMMI-DEV, as a pivotal element in Software Process Improvement (SPI) models tailored to Agile environments. The study's novelty lies in its systematic and in-depth investigation of CMMI's integration with Agile project management methodologies, a critical yet underexplored area in the existing literature. Addressing the urgency highlighted by global trends of resource inefficiencies and project management challenges, this research offers timely insights for both academia and industry. This study also categorizes key benefits while identifying prevalent challenges, such as resource constraints and organizational resistance. Additionally, this research also suggests solutions and improvements to these challenges. By offering a comprehensive evaluation, the research significantly advances the understanding of the complexities and potential of CMMI and Agile project management integration. It provides valuable insights for practical applications in organizational settings, emphasizing the potential of integrating structured models like CMMI-DEV with Agile project management methodologies. This integration is essential for enhancing project management maturity, marking a significant step forward in academic research and practical applications in this vital domain.**

***Keywords*—CMMI; SPI; Agile project management; systematic literature review; PRISMA**

I. Introduction

In today's rapidly evolving business landscape, the agility and efficiency of project management have become pivotal for organizational success [1]. Agile project management, in particular, has emerged as a critical determinant in enabling companies across diverse sectors to navigate the complexities of fluctuating market demands [2]–[4]. However, the transition to agile methodologies is not without its challenges. Research and industry observations underscore significant inefficiencies in current project management practices, negatively impacting organizational performance [4].

The 2023 Pulse of the Profession survey by the Project Management Institute reveals a striking indicator of these challenges. This survey reports a global average loss of 5.2% in investment due to subpar project performance, marking a sustained trend of resource wastage over recent years [5]. Such findings signal a more profound, systemic issue in project management across various industries, calling for a strategic approach to enhance project management maturity [4].

In response to this need, frameworks like the Project Management Maturity Model (PMMM) have been developed, offering a structured way to evaluate and uplift an organization's project management practices [4]. Yet, in the face of the intricate challenges posed by the modern business environment, achieving maturity in project management alone is insufficient. The significance of Software Process Improvement (SPI) and frameworks like the Capability Maturity Model Integration (CMMI) becomes more evident in this context. They provide comprehensive methodologies to bolster an organization's software development and management prowess, crucial in the digital era [6], [7].

The CMMI model has evolved beyond its initial focus on software engineering to support organizations across various industries in enhancing their capabilities, measuring performance, and addressing common business challenges. The CMMI Model represents a set of established best practices that can be applied globally to help organizations develop key capabilities [15]. It is designed to be user-friendly, adaptable, and compatible with other methodologies, such as Agile, SAFe, and DevSecOps, among others [8], [14], [15]. However, integrating CMMI with other methodology such as Agile project management is not straightforward, often requiring significant investment and grappling with the stringent requirements of these frameworks [8], [9]. This indicates that the integration process is complex and resource intensive.

Despite these hurdles, many organizations, especially those prioritizing high-quality outputs, are increasingly exploring the synergies between agile methods and CMMI [8], [10], [11]. The latest CMMI V2.0 has been recognized for its improvements in project management performance [4], [12], [13], as acknowledged by professionals worldwide [6]. Therefore, it is essential to examine both the benefits and challenges of integrating CMMI with Agile project management to fully understand the value of such a combination.

Previous research has examined the relationship between the challenges of combining CMMI and Agile. Henriquez et al. [8] conducted a study to determine how much CMMI addresses these challenges. They focused on two significant CMMI artifacts for integration and emphasized vital issues that organizations must address [8]. Additionally, Ferdinansyah et al. [10] compiled experiences from combining software and explored the challenges involved in the collaborative implementation process. Their research also delved into the compatibility between CMMI and Agile Development [10]. Henriquez et al. [14] also conducted another research that focuses on analyzing and identifying agile artifacts that align with CMMI-DEV V2.0 practices, aiding Agile organizations in adopting or transitioning to this latest model from CMMI-DEV V1.3, with a particular emphasis on Planning and Managing Work Practice Areas and Practices. However, it is worth noting that previous studies have not explicitly examined the Perceived Benefits and Challenges of Implementing CMMI in Agile project management.

This research analyzes the potential benefits and challenges associated, that comes from the integration of CMMI-DEV and Agile project management. The aim is to leverage the advantages of implementing CMMI and Agile project management. Moreover, the study will also identify the challenges and recommend solutions accordingly. Both academic research and organizational practice can benefit from this research. The proposed solutions for these challenges can serve as valuable guidance for senior managers considering the joint implementation of CMMI and Agile project management. Additionally, it provides the most recent literature review, which can be utilized to enhance research on CMMI and agile project management in academic research. This study aims to address the subsequent research questions:

RQ1: What are the benefits of integrating CMMI and Agile Project Management?

RQ2: What are the challenges and the corresponding solution of integrating CMMI and Agile Project Management?

II. Literature Review

A. Agile Project Management

Agile project management (APM) methodology, a methodology that was developed approximately two decades ago predominantly for the software sector, draws its principles from the Agile Manifesto. These principles prioritize individual interactions, the functionality of software, cooperation with customers, and flexibility in adapting to change [3]. Originally for software development, APM is now utilized in various fields, characterized by team autonomy, iterative development, and equality within teams [1], [2]. It aims to deliver high-value products within time and budget constraints by integrating planning with execution and fostering teamwork and customer collaboration. APM manages paradoxical dynamics, balancing team flexibility with procedural rigor, and is recognized for effectively responding to evolving project requirements and customer needs [16].

Research and practitioner experiences indicate that APM positively impacts behavioral, affective, and cognitive outcomes, with a more pronounced effect on behavioral aspects like performance and innovation. This effectiveness is not limited to software development; APM shows slightly greater effectiveness in non-software domains [3]. The adaptability and broader application of APM highlight its role in enhancing project management practices and fostering positive changes in workplace behavior and performance. These insights reflect APM’s comprehensive impact across different industries. The pervasiveness of APM’s influence underscores its potential to revolutionize project management practices and drive organizational success across diverse domains [1], [3].

B. Software Process Improvement (SPI)

It is vital to enhance both the efficiency and effectiveness of software development and management processes. In this regard, the role of Software Process Improvement (SPI) is pivotal for accomplishing such improvements [7], [17]. SPI involves developing and honing a set of collective knowledge and practices specific to software development, with a continuous commitment to improving these processes [6]. This ongoing improvement helps organizations increase their development performance and adapt efficiently to evolving business environments, thereby gaining a competitive edge. SPI is a critical enabler for ensuring that software development and management processes are aligned with business goals and objectives [17], [18].

A range of SPI (Software Process Improvement) models are employed within the software industry. These include the Capability Maturity Model (CMM), Capability Maturity Model Integration (CMMI), People Software Process (PSP), SPI, Capability Determination (SPICE), and BOOTSTRAP. [6]. These models address various challenges, including projects exceeding budgets and timelines, subpar software quality, and unmet requirements. Different SPI models, including CMMI, PSP, SPICE, MSF, RUP, ISO, IDEAL, and Six Sigma, are employed to tackle these issues [6], [19]. The CMMI model is particularly notable for its wide-ranging application across different sectors, extending beyond software. It helps organizations improve their processes, leading to better quality and efficiency in software development projects [6], [7], [20].

C. CMMI-DEV

CMMI was developed as a process improvement model to help many organizations improve performance, achieve process maturity, and achieve organizational goals [14], [21]. The CMMI model encompasses three different categories. CMMI-DEV focuses on product and service development; CMMI-SVC is dedicated to establishing and managing services; and CMMI-ACQ pertains to acquiring products and services. This paper explicitly centers on CMMI-DEV, the model used in computer programming, underscoring its two essential cycle regions for necessities [22], [23].

Additionally, the CMMI Institute recently introduced version 2.0 of the CMMI. With its emphasis on continuous improvement and process optimization, CMMI-DEV V2.0 empowers organizations to enhance their software development capabilities and deliver exceptional products that meet stakeholder needs [14], [24]. This updated version integrates practices from the three version 1.3 constellations (DEV, ACQ, and SVC) and the People Capability Maturity Model (PCMM). In CMMI V2.0, CMMI for Supplier

Management (CMMI-SPM) will replace CMMI-ACQ from V1.3 [25]. The mapping between CMMI 1.3 and CMMI 2.0 models is shown in Fig. 1.

Moreover, the latest version of CMMI introduces several new practice areas, with project management being a key area predominantly addressed in CMMI-DEV [24]. The practice areas consist of Estimating (EST), Planning (PLAN), Risk and Opportunity Management (RSK), Monitor and Control (MC), Implementation Infrastructure (II), Requirements Development and Management (RDM), Supplier Agreement Management (SAM) [26]. Therefore, this paper focuses on the new version of CMMI, particularly CMMI-DEV.

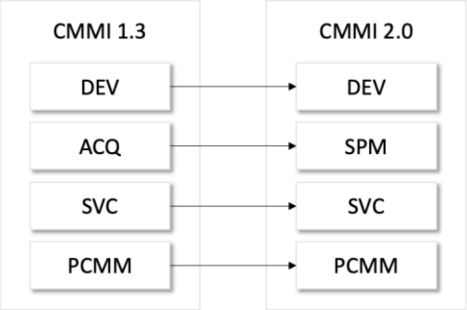

Fig. 1. CMMI 1.3 and CMMI 2.0 models mapping.

D. Project Management Category of CMMI

In CMMI, several process areas target the project management domain. The project management encompasses several areas, such as project planning, monitoring and control, and many others [9], [27]. This paper primarily centered on project management, specifically the management activities associated with project planning, monitoring, and control. Table I maps process areas in CMMI 1.3 to practice areas in CMMI 2.0 relevant to project management based on its definition for each process areas accordingly.

TABLE I. CMMI PROCESS AREAS AND PRACTICE AREA MAPPING RELATING TO PROJECT MANAGEMENT

Process Area CMMI 1.3 [20]	***Process Area CMMI 2.0*** [26]
Project Planning (PP)	Estimating (EST), Planning (PLAN), Risk & Opportunity Management (RSK)
Project Monitoring and Control (PMC)	Monitor & Control (MC), RSK
Integrated Project Management (IPM)	PLAN, Implementation Infrastructure (II), MC
Risk Management (RSKM)	RSK
Requirement Management (REQM)	Requirements Development & Management (RDM)
Supplier Agreement Management (SAM)	Supplier Agreement Management (SAM), PLAN, MC

III. RESEARCH METHOD

Systematic Literature Reviews (SLRs) are commonly employed to conclude, gather evidence, and produce concise summaries. In this research, the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) methodology is employed [28]. PRISMA is known for its transparent and concise approach, making it preferable over other methods. While initially developed for healthcare research, PRISMA has also proven effective in Information System studies [28]. The PRISMA Workflow for this research is depicted in Fig. 1, providing a visual representation of the process.

A. Planning the SLR

In this stage, keyword generation is conducted based on the main keywords obtained at the beginning of the research, namely CMMI and Agile Project Management. The keywords (“CMMI” AND “Agile” AND “Project Management”) were identified. These keywords were used to construct queries on each database. The query formats were subsequently modified to align with the specific query requirements on the advanced search function of each database.

The online database with extensive collections of SPI papers relevant to the problem domain and criteria of the studies was selected based on specific considerations. The reason is due to the relevant search results available, the appropriate field usually provided by the online database, and the reputation of the online database itself. For this research, the selected databases include the ACM Digital Library, IEEE Xplore, Scopus, and Science Direct. The criteria applied in the study selection process are detailed in Table II.

TABLE II. CRITERIA FOR THE STUDY SELECTION

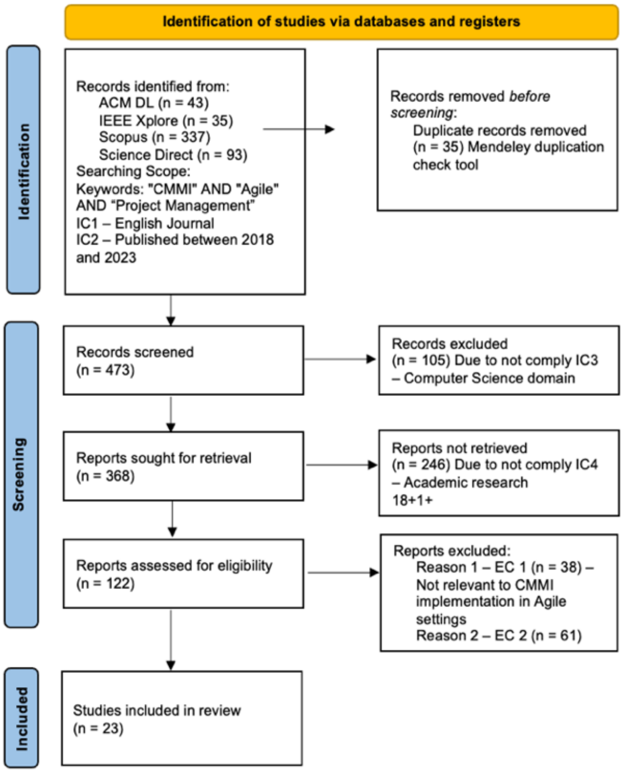
Inclusion Criteria (IC)	**IC1**	The research was written in English.
	IC2	The research was published between 2018 and 2023.
	IC3	The research in the computer science problem domain.
	IC4	The research is academic research, such as a journal or conference paper.
Exclusion Criteria (EC)	**EC1**	The research was not relevant to CMMI implementation in Agile settings.
	EC2	The research does not mention the challenges or benefits of CMMI implementation in Agile settings.

B. Implementation of SLR

In this stage of the SLR, a meticulous and expansive search was conducted to identify pertinent literature. Sections relevant to the formulated research questions underwent thorough analysis. The analysis entailed an in-depth examination of the entire text, specifically emphasizing investigations related to combining CMMI and Agile Project Management methodologies.

Fig. 2 delineates the SLR workflow using PRISMA, illustrating the systematic selection process. This process commenced with the initial data acquisition from various databases, adhering to the inclusion and exclusion criteria outlined in Table I, and was completed with the identification of results that corresponded with the predefined research criteria. The identified studies were then subjected to rigorous quality assessment to ensure the validity and reliability of the findings.

A total of 23 scientific articles, sourced from a range of highly ranked journals and conference proceedings, as per Scimago, have been selected for in-depth analysis regarding the challenges and effects on project management.



Identification of studies via databases and registers
Identification
Records identified from:
ACM DL (n = 43)
IEEE Xplore (n = 35)
Scopus (n = 337)
Science Direct (n = 93)
Searching Scope:
Keywords: "CMMI" AND "Agile" AND "Project Management"
IC1 – English Journal
IC2 – Published between 2018 and 2023
Records removed *before screening*:
Duplicate records removed (n = 35) Mendeley duplication check tool
Screening
Records screened (n = 473)
Records excluded (n = 105) Due to not comply IC3 – Computer Science domain
Reports sought for retrieval (n = 368)
Reports not retrieved (n = 246) Due to not comply IC4 – Academic research 18+1+
Reports assessed for eligibility (n = 122)
Reports excluded:
Reason 1 – EC 1 (n = 38) – Not relevant to CMMI implementation in Agile settings
Reason 2 – EC 2 (n = 61)
Included
Studies included in review (n = 23)

Fig. 2. Workflow of literature review (PRISMA).

C. *Reporting the SLR*

The final stage of the SLR involves the presentation of findings. First, Table III is a comprehensive reference guide, summarizing all relevant articles aligned with the research goals. This table includes article titles, publication years, journal index information, and reference citation coding.

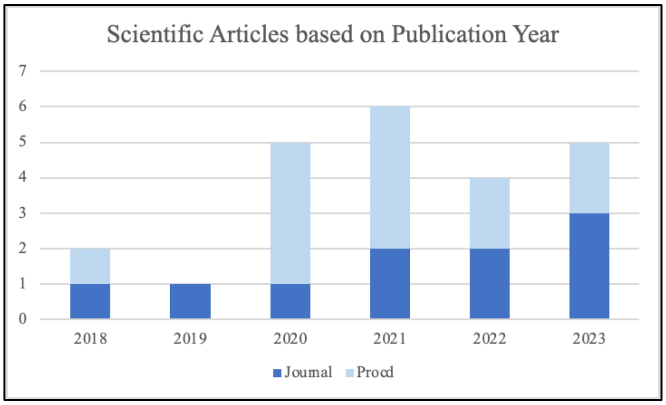


Fig. 3. Distribution of scientific articles per publication year.

Secondly, Fig. 3 visually represents scientific papers categorized according to their publication years. Table III and Fig. 3 enhance the presentation and comprehension of the SLR's outcomes, ensuring a robust and comprehensive exploration of the research area.

TABLE III. SUMMARY OF ALL RELEVANT ARTICLES

No	Title	Year	Index	Code
1	Agile-CMMI Alignment: Contributions and To-Dos for Organizations	2021	Q2	[8]
2	Bringing to Light the Agile Artifacts Pointed Out by CMMI	2022	Q1	[14]

IV. Results and Discussion

The eligible studies underwent a process of screening and analysis to extract relevant information. While screening the complete text, the problem domain and research questions were identified concurrently.

A. *Perceived Benefits of CMMI and Agile Project Management Integration*

In exploring the symbiosis between CMMI and Agile Project Management, it's essential to delve into the tangible benefits this integration brings to project management. This chapter categorizes these benefits into five core practice areas within CMMI: Estimating, Planning, Risk and Opportunity Management, Monitor and Control, and Requirements Development and Management.

1) Estimation: Enhanced Accuracy and Predictability. Studies have shown that integrating CMMI with Agile methodologies can significantly refine budget and schedule predictions. Alqadri et al. [35], Saputra et al. [42], and Galvan-Cruz et al. [34] highlight CMMI's effectiveness in this regard. Degerli, M. [12], [24] citing CMMI Institute [13], reports a remarkable 17% increase in estimation accuracy following the adoption of CMMI V2.0. These enhanced estimation processes reduce project uncertainties and bolster the likelihood of successful project execution. Importantly, Albuquerque [32] and Itzik et al. [31] note the role of CMMI in providing greater predictability in costs and deadlines, contributing to reduced costs and increased productivity.

2) Planning: Streamlined Project Management. The incorporation of CMMI into Agile methodologies elevates the process of work planning and management. As outlined by Valeria et al. [8], [35], CMMI's structure enables the creation of comprehensive forecasts concerning workload, costs, and schedules. This foresight is crucial in preventing budget or timeline overruns [8], [14]. The synergy of Agile and CMMI also improves goal attainment. It minimizes rework, as evidenced by the significant reduction in rework (70%) and the increase in on-time delivery rates (97%) reported by Degerli, M. [12], [24] referencing the CMMI Institute [13].

3) Risk: Mitigating Risks with Informed Strategies. In Agile environments, effectively handling requirement changes is critical. CMMI's quality models play a significant role here, as they aid in risk reduction and quality enhancement [23], [37]. The model promotes a proactive approach to identifying and evaluating risks and opportunities, as noted by Degerli, M. [12], [24]. This approach encompasses establishing performance benchmarks derived from historical data, facilitating early identification of variances, and supporting informed choices in project management.

4) Monitor and control: Ensuring Quality and Compliance. CMMI's role in monitoring and controlling project and organizational processes is pivotal [10]. It provides a framework for analyzing and managing critical subprocesses, particularly in high-maturity project management scenarios, as discussed by Cerdeiral, C. T., & Santos, G. [30] Keshta et al. [41]. This supervisory function ensures that software quality is upheld during its development and that the end products fulfill users' expectations.

5) Requirements development and management: Optimizing Product Quality and Customer Satisfaction. A vital aspect of CMMI is its guidance on requirement development and management [23]. This element holds particular significance in Agile Project Management, given its focus on flexibility and adaptability. According to several studies, CMMI enhances customer satisfaction by improving product quality and aligning closely with customer needs [29], [31], [35], [36]. Furthermore, CMMI's principles can be seamlessly amalgamated with Agile's emphasis on customer collaboration and adaptability to change [36], [39].

B. *Classification of Challenges of CMMI and Agile Project Management Integration*

The eligible studies highlighted several challenges faced by organizations. A thematic categorization focusing on tactical and organizational challenges was employed, as delineated by Valeria et al. [8].

1) Resource and Time Constraints: Integrating CMMI into Agile projects presents significant resource and time challenges. Ferdinansyah et al. [10] highlight that this integration demands additional resources, effort, and time beyond the scope of standard project activities. Adopting new concepts and practices within an Agile framework requires careful planning and considerable investment. These constraints are particularly impacting Small and Medium-sized Enterprises (SMEs), as observed by Henríquez et al. [27] and Saheel et al. [11]. SMEs often operate with limited budgets and resources, making it challenging to sustain the additional demands of integrating CMMI [33], [38], [40], [41], [43]. This challenge can lead to difficulties in maintaining the balance between the pursuit of quality improvement and the practical realities of project management within these organizations.

2) Organizational Resistance and Change Management: Resistance to adopting new methodologies is a common challenge within organizations. This resistance often stems from a lack of knowledge or experience with the new systems, as noted by Valeria et al. [8], Ferdinansyah et al. [10], Albuquerque et al. [32], and Demirel & Das [23]. Frequent leadership changes or past experiences with unsuccessful management initiatives can further exacerbate such resistance. This skepticism and disinterest, especially among long-standing employees, can pose significant hurdles to successfully integrating CMMI and Agile methodologies. Moreover, the lack of support from top management in enforcing new processes can lead to demotivation among practitioners and quality assurance teams, hampering the overall adoption process [8], [10], [23], [32].

3) Balancing Agility with Control: A critical challenge in integrating CMMI with Agile methodologies is balancing the structured approach of CMMI with the flexibility of Agile [8].

As organizations strive to achieve higher maturity levels within the CMMI framework, they may find that agility is compromised, as pointed out by Valeria et al. [8]. Ferdinansyah et al. [10] further elaborate that the control and accountability emphasized by CMMI can clash with the core principles of Agile, which values adaptability and minimal bureaucratic overhead. This challenge concerns managing project processes and aligning organizational culture and values with these contrasting methodologies.

4) Knowledge, Training, and Expertise Gaps: The successful adoption of CMMI in an Agile setting relies heavily on sufficient knowledge, training, and expertise. Valeria et al. [8] and Albuquerque et al. [32] highlight the challenges organizations face due to a lack of in-depth understanding of CMMI and Agile methodologies. The deficiency in specialized training covering the full spectrum of development activities can hinder the effective implementation of these methodologies. Furthermore, the absence of support from specialists in statistical and process management knowledge can leave project managers and process groups struggling to align organizational and project goals with critical subprocesses [30], [38].

5) Scaling and Knowledge Dissemination: Scaling and disseminating practices aligning with CMMI and Agile across an organization is a significant challenge, especially at higher maturity levels. Valeria et al. [8] emphasized that without the active support of upper management, experiences, and practices beneficial to integrating CMMI and Agile often remain confined to specific teams or projects. This limitation prevents these practices from being adopted more widely throughout the organization. Scaling experiences effectively requires documentation of successful practices and a concerted effort to share and institutionalize these practices across various teams and departments [8], [30].

C. Challenges and Solution Mapping

This paper aims to align the solutions by drawing on the identified challenges. Table IV presents the mapping of the challenges and their corresponding potential solutions. This structured approach facilitates a clearer understanding of how each solution directly addresses the specific challenges, thereby enhancing the overall effectiveness of the proposed solutions. Additionally, this alignment ensures that the proposed solutions effectively address the identified challenges, paving the way for a more robust and impactful implementation strategy.

TABLE IV. SOLUTION MAPPING

No	Challenges	Solution
1	Resource and Time Constraints	Senior managers must decisively commit to process improvement initiatives, defining the scope and allocating the right resources. The success of these efforts often hinges on continuous investment in process improvements and addressing barriers such as resource limitations, inexperienced staff, organizational politics, and time pressure. The CMMI model, increasing popularity, can be a crucial tool for such improvements. However, understanding how to sustain these improvements post-appraisal, especially under time and budget constraints, remains vital for long-term success. Both higher and lower-level management’s support and commitment play a critical role in this regard [8], [12], [27].
2	Organizational Resistance and Change Management	Addressing human issues like resistance and acceptance is essential for senior managers. Strong management support is vital in implementing changes, especially adopting an Agile philosophy. This support helps facilitate cultural change and overcome initial resistance from factors like lack of human resources and work overload. Agile teams may show resistance even with management support, indicating the need for a more comprehensive approach to change management [8], [27], [32].
3	Balancing control and agility	Effective integration of CMMI with Agile processes requires tools that automate control and accountability. This approach helps align traditional governance processes with Agile teams and addresses the additional work CMMI might introduce. Constant monitoring of agility is crucial during this alignment. Developing prescriptive guidelines for Process Areas aligned with business goals can help manage the impact on skill [8], [10], [27], [36].
4	Knowledge, Training, and Expertise Gaps	Senior management must play an active role in contextualizing governance and providing organizational training for Agile practices. Addressing knowledge and experience gaps in CMMI and Agile Development is critical, especially for higher CMMI Maturity Levels. The lack of training for new employees in process improvement is a significant issue that needs to be addressed to bridge knowledge and expertise gaps. Practices from CMMI V2.0 and SAFe 5.0 can support this process [8], [27], [36].
5	Scaling and Knowledge Dissemination	Senior managers should adopt Agile strategies that decentralize decision-making and organize work based on business value. Implementing quality standards and tools for verifying development processes, alongside a model-driven approach, can enable a comprehensive assessment of software development. Addressing Agile’s scaling, training, and organizational policy limitations is critical. Knowledge dissemination poses a challenge in large organizations, necessitating the development of non-bureaucratic processes that meet organizational needs. Software Process Improvement (SPI) methodology can extend Agile to enhance product innovation, quality, and efficiency [8], [27], [36], [38].

V. CONCLUSIONS

This paper has explored the perceived benefits and challenges of this integration. Integrating CMMI with Agile Project Management presents a promising avenue for enhancing project management practices. Based on further analysis, this integration can lead to more accurate estimations, streamlined project planning, effective risk mitigation, improved quality control, and optimized requirement development and management. However, this integration comes with challenges such as resource constraints, organizational resistance to change, and the need to balance control and agility. Bridging knowledge gaps and scaling integrated practices across the organization are notable hurdles.

Senior management must play a pivotal role by committing to process improvement initiatives, providing necessary resources, and supporting cultural change to overcome challenges. Automation tools for control and accountability, along with continuous monitoring of agility, are essential for maintaining the balance between CMMI and Agile. Additionally, addressing knowledge gaps through training and promoting non-bureaucratic knowledge dissemination processes are vital steps towards successful integration. Overall, a strategic and committed approach from senior management is crucial to realizing the full potential of the CMMI and Agile integration and improving project management practices for better project outcomes.

A. *Limitations of Study*

The study's primary limitation lies in integrating CMMI-DEV and software development within Agile project management. The literature review's scope, constrained by the time frame (2018-2023) and language of the publications (English), may also limit the comprehensiveness of the findings.

B. *Future Works*

Future research should focus on empirical studies to validate the findings of this systematic literature review. Investigations involving case studies or surveys in various organizational settings would offer deeper insights into the practical implementation challenges and benefits of combining CMMI-DEV and software development within Agile project management. Additionally, exploring the evolution of these frameworks in rapidly changing technological landscapes will provide more dynamic and current insights into their integration and application.

Crime Prediction Model using Three Classification Techniques: Random Forest, Logistic Regression, and LightGBM

Abdulrahman Alsubayhin, Muhammad Sher Ramzan, Bander Alzahrani
King Abdulaziz University, Jeddah, Kingdom of Saudi Arabia

Abstract—**Predicting the likelihood of a crime occurring is difficult, but machine learning can be used to develop models that can do so. Random forest, logistic regression, and LightGBM are three well-known classification methods that can be applied to crime prediction. Random forest is an ensemble learning algorithm that predicts by combining multiple decision trees. It is an effective method for classification tasks, and it is frequently employed for crime prediction because it handles imbalanced datasets well. Logistic regression is a linear model that can be used to predict the probability of a binary outcome, such as the occurrence of a crime. It is a relatively straightforward technique that can be effective for crime prediction if the features are carefully chosen. LightGBM is a gradient-boosting decision tree algorithm with a reputation for speed and precision. It is a relatively new algorithm, but because it can achieve high accuracy on even small datasets, it has rapidly gained popularity for crime prediction. The experimental results show that the LightGBM performs best for binary classification, followed by Random Forest and Logistic Regression.**

Keywords—Crime prediction; random forest; logistic regression; LightGBM

I. Introduction

In a culture where crime is low, it is always disturbing to see the number of crimes rising [1]. Crime is a social issue that hinders the economic growth of a nation. Crime has always existed, and violent crime is the greatest threat to society [2]. Population growth and urbanization have dramatically increased criminal activity [3], particularly in urban areas [4].

In recent years, crime prediction has acquired popularity because it enables investigation authorities to handle crimes computationally [5]. Better predictive algorithms that direct police patrols towards criminals are required [6]. Several research investigations have been conducted to predict crime categories, crime rates, and crime hotspots using crime datasets from various regions, such as South Korea and the United States [7]. Additionally, using the Canada dataset, various prototype projects are expanded to identify crime-related geographic locations, such as residential and commercial areas [8].

Crime threatens us and society, necessitating serious consideration if we expect to reduce its onset or consequences.

Daily, data officers working alongside law enforcement authorities throughout the United States record hundreds of crimes. Numerous cities in the United States have signed the Open Data initiative, making crime data and other categories of data accessible to the public. This initiative aims to increase citizen participation in decision-making by uncovering interesting and valuable facts using this data [9].

San Francisco is one of many cities that have joined this Open Data movement. The data scientists and engineers working with the San Francisco Police Department (SFPD) have documented over one hundred thousand criminal cases based on police complaints [10]. Using these historical data, numerous patterns can be uncovered. This would help us identify crimes that may occur in the future, allowing the municipal police to better protect the city’s population [11].

Violent and nonviolent crimes are predicted and classified using random forest, logistic regression, and LightGBM. The primary objective of this paper is to propose a crime prediction model based on past criminal records.

Using three techniques, the proposed model evaluates accuracy, log loss, ROC AUC, precision, and recall evaluation matrices. The data is descriptively analyzed, and crime statistics’ spatial and temporal distribution are visualized to identify potential patterns. The original dataset’s features are extracted, and classification is carried out using random forest, logistic regression, and LightGBM techniques.

LightGBM has the highest performance for binary classification, followed by random forest and logistic regression, according to the experimental results. LightGBM has the best precision, accuracy, log loss, ROC AUC, and F1 score. It has the lowest recall, but this is not inherently a negative attribute. In this case, the dataset is imbalanced, as there are far more examples of class 0 than class 1. This means that avoiding false positives is essential to avoiding false negatives. LightGBM accomplishes this by emphasizing recall while maintaining high precision. Random forest has a lower accuracy, log loss, ROC AUC, precision, and F1 score than LightGBM but a higher recall. This indicates that random forest is superior at avoiding false negatives but less effective at predicting true positives. Logistic regression has the three models' lowest accuracy, log loss, ROC AUC, precision, and F1 score. It has the lowest recall as well. This indicates that logistic regression is the model with the worst performance for binary classification.

Overall, the model with the greatest performance for binary classification is LightGBM, followed by random forest and logistic regression.

A. Related Work

Due to the relationship between crime and society, predictions of future crime have been investigated extensively. These studies use machine learning algorithms to address these predictions. Using machine learning algorithms to predict spatial crime data has proven effective [12].

Accurate crime prediction is difficult but essential for preventing criminal behavior. Accurately estimating the crime rate, types, and hot areas based on historical patterns presents numerous computational challenges and opportunities [5].

Prediction analysis is dominated by crime prediction based on machine learning; however, few studies systematically compare machine learning methods. The ability of machine learning algorithms to process non-linear rational data has been validated in numerous disciplines, including crime prediction. It can process high-dimensional data with a faster training pace and extract the characteristics of the data [13].

Despite extensive research efforts, the literature lacks relative accuracy for crime prediction from large datasets for multiple locations, such as Los Angeles and Chicago datasets.

The authors of [14] employ the model to improve the effectiveness of criminal investigation systems. This model identifies crime patterns based on inferences gathered from the crime site and predicts the perpetrator’s description of the suspect most likely responsible for the crime. This work has two primary elements: Analyzing and forecasting the perpetrator’s identity. The crime analysis phase identifies the number of unsolved crimes and evaluates the impact of variables such as year, month, and weapon on those crimes. The prognosis phase estimates the perpetrators’ characteristics, such as age, gender, and relationship to the victim. These hypotheses are based on the evidence gathered at the crime scene. The system predicts the perpetrator’s physical characteristics using algorithms such as multilinear regression, K-neighbors classifier, and neural networks. It was trained and evaluated using the San Francisco Homicide dataset (1981-2014) and Python.

Yao et al. used the San Francisco Dataset; this paper is based on the random forest algorithm, which splits the study areas into four groups based on the hot spot distribution based on historical crime data: frequent hot areas, common hot areas, occasional hot areas, and non-hot areas; then, corresponding covariates from non-historical crime data are added to the prediction model to investigate changes in the result accuracy of crime prediction [15]. The data relies on actual data, and the experimental findings reveal that compared to the inference approach based solely on historical crime data, the model with covariates outperforms the model without covariates.

A preliminary analysis of the spatiotemporal crime patterns in San Francisco is attempted in this study [16]. They use spectral analysis to examine the temporal evolution of all crime categories, discovering that many exhibit a weekly or monthly pattern and other components. They demonstrate that spatial distribution has weekly patterns. These findings can be used to develop predictive models for policing and increase knowledge of crime dynamics.

II. Data Analysis

The model in the study is built using a Kaggle dataset [17]. The dataset (training set/data) has several properties, each with its own link. The Kaggle incidences of San Francisco crimes are included in the training dataset. The data spans the years January 2003 to May 2015. The collection covers nearly 12 years of San Francisco criminal reports. The collection contains categories of all crimes containing various crime types.

The original training dataset is arbitrarily mixed and divided into training and testing datasets of 80% and 20%, respectively, in the study. Any data imbalances relating to the ”Primary Type” feature were corrected using a combination of oversampling (SMOTE) and random sampling; SMOTE stands for Synthetic Minority Over-sampling Technique. It is a data augmentation approach used in machine learning to deal with skewed datasets. SMOTE generates synthetic minority class samples by combining existing minority class samples. This balances class distribution and improves machine learning model performance on minority class predictions.

A. Features

Every entry in our data set pertains to a specific crime, and each data record includes the following characteristics:

- Dates - The date and time of the crime.
- Category - The type of crime. In the classification stage, we must forecast this target/label.
- Descript - A brief description of any relevant details of the crime.
- DayOfWeek - The weekday on which the offense happened.
- PdDistrict - The Police Department District to which the offense has been assigned.
- Resolution - How the crime was resolved (for example, by arresting or booking the culprit).
- Address - The crime scene’s approximate street address.
- X - Longitude of a crime’s location.
- Y - The latitude of a crime’s site.

B. Preprocessing

We execute various preprocessing processes on our datasets to achieve better classification results before deploying any algorithms. These are some examples:

- Eliminating features like resolution, description, and address. The resolution and description of a crime are only known after the crime has occurred and have limited relevance in a practical, real-world scenario where one is attempting to predict what type of crime has occurred; hence, these were deleted. We deleted the address since we already knew the latitude and longitude; in that context, the address added little marginal value.

- The weekdays, police, and criminal categories were all indexed and replaced with numbers.

- The timestamp included the year, date, and time of each offense. This was broken down into five components: Year (2003-2015), Month (1-12), Date (1-31), Hour (0-23), and Minute (0-59).

- We used Python's get_dummies() function to turn categorical variables into dummy variables. Dummy variables are binary variables that show whether a given category exists. For example, if a category variable contains three types, the get_dummies() function will generate two dummy variables. One dummy variable indicates the presence of the first category, while the other indicates the presence of the second category. The lack of the first two dummy variables will implicitly reflect the third category.

- In machine learning, the get_dummies() function is a popular technique to deal with categorical variables. Many machine learning algorithms cannot deal with categorical data directly. Machine learning algorithms may train models using data that includes categorical variables by turning categorical variables into dummy variables. We also remove certain unnecessary elements, such as incidentNum and coordinate.

Feature inclusion is imperative to the predictive capabilities of any model, ensuring its ability to capture the complexity of crime patterns. Excluding specific demographic, economic, or environmental features may result in a less comprehensive understanding of the factors influencing criminal activities, leading to lead to oversimplified predictions or overlooking important contributing factors.

Following these preprocessing processes, we ran some out-of-the-box learning algorithms as part of our early exploratory stages.

C. *Feature Engineering*

The act of changing raw data into features more suited for machine learning algorithms is known as feature engineering. This can include some tasks, such as:

- Data cleaning entails removing errors, outliers, and missing values from the data.

- Feature selection: entails choosing the most essential features from the data.

- Feature extraction is the process of producing new features from current ones.

- Feature transformation: entails changing features to a different format, such as category or numerical values.

The purpose of feature engineering is to produce informative and predictive features. Informative features provide relevant information about the target variable. Predictive characteristics are those that can accurately anticipate the target variable. Feature engineering is a critical step in the machine learning process. We can improve the performance of our machine learning models by carefully engineering features.

D. *Exploratory Data Analysis*

The first dataset analysis found a major imbalance in the "Primary Type." This is evident in Fig. 1, which demonstrates that "larceny/theft," "other offenses," and "noncriminal" make up a significant portion of the total crimes committed in San Francisco. Since these offenses are more likely to occur, it is reasonable to propose allocating more police resources to combat them.

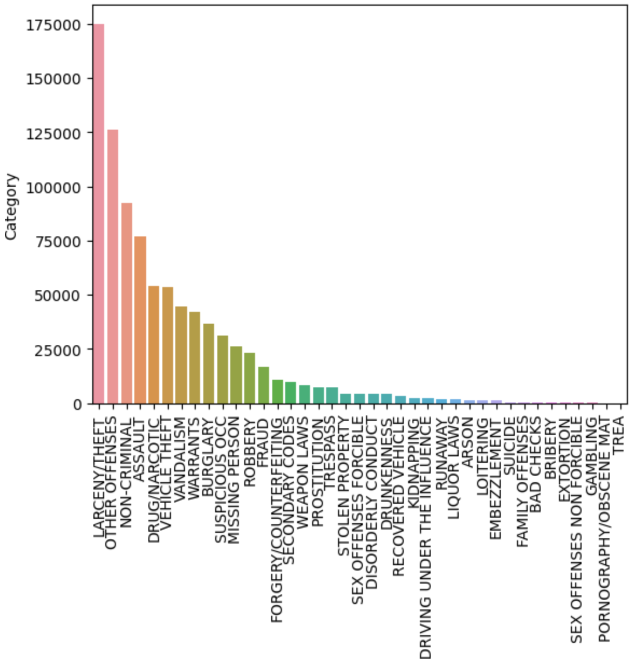

Fig. 1. Number of crimes.

Fig. 2 is a data visualization based on the PdDistricts; it displays the locations where crime occurs most frequently according to the district's name. Southern has the highest crime rate, while Richmond has the lowest crime rate. According to a crime map created by NeighborhoodScout, the Southern District has the highest crime rate in the United States, with 60.5 crimes per 1,000 residents. The Richmond neighborhood has the lowest crime rate, with 18.2 crimes per 1,000 residents.

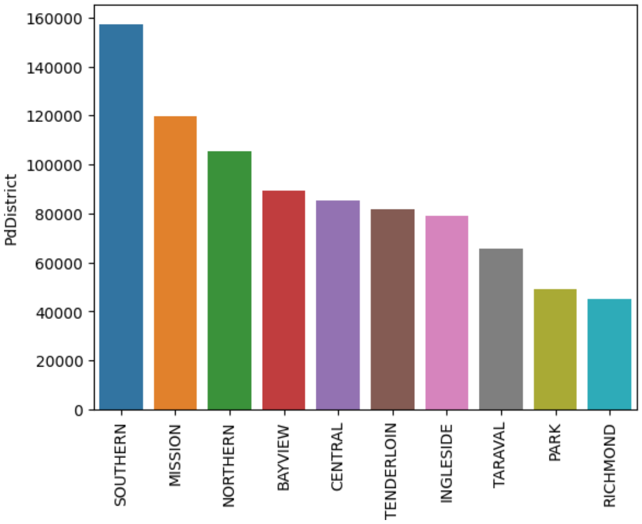

Fig. 2. The visualization for data depends on the PdDistricts.

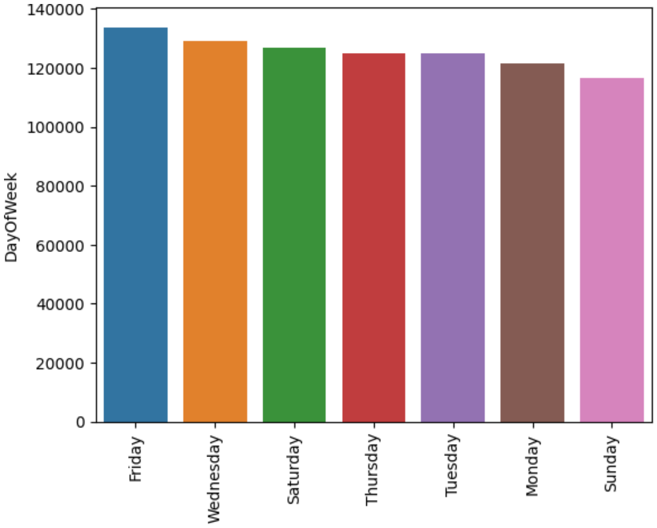

Fig. 3. The visualization for data depends on the day of the week.

Fig. 3 depicts a data visualization based on the day of the week. This pattern has several possible explanations. A possible explanation is that people are more likely to be out and about on Fridays, making them more susceptible to becoming victims of crime. A second possibility is that people are more likely to be intoxicated on Fridays, which can increase aggression and violence.

Regardless of the cause, it is evident that the daily crime rate varies significantly. Law enforcement officials and policymakers should consider this factor when devising strategies to reduce crime.

According to Fig. 4, the highest crime rates in San Francisco occur at 1, 2, 6, and 11 p.m. These times are typically when people are sleeping or are out and about in the early morning, as well as when people are leaving work or school or running errands. This increases their likelihood of being targeted by criminals.

When working with vast datasets, it is inevitable to encounter imbalances. Most machine learning algorithms tend to presume, by default, that the data they are working with is balanced [18]. Imbalances can cause problems when attempting to train a classification model. This presumption causes the trained models' outputs to be biased and skewed toward the majority class [18].

Fig. 5 depicts the most widespread types of crimes in descending order. For the past 13 years, theft has been the most frequent offense in San Francisco. As opposed to shoplifting or purse snatching, this form of theft does not involve force or violence. Additionally, prevalent in San Francisco are Assault, Burglary, and Vehicle Theft.

Fig. 6 displays intriguing year-based data and results. It shows the increase or decrease of the top ten offenses in San Francisco from 2003 to 2015.

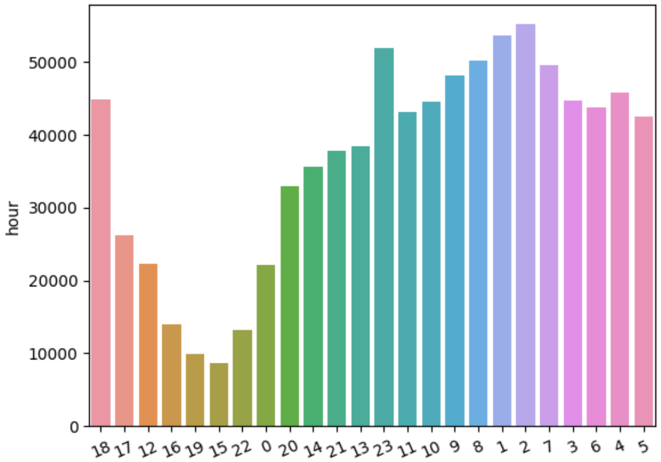

Fig. 4. The visualization of data depends on the hour.

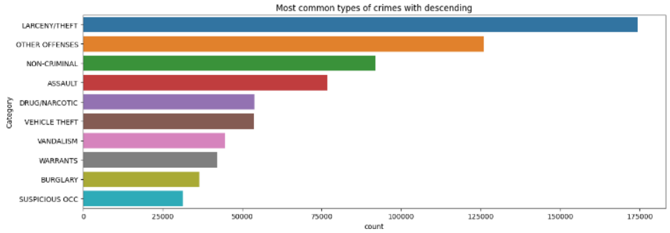

Fig. 5. The most common types of crimes in descending order.

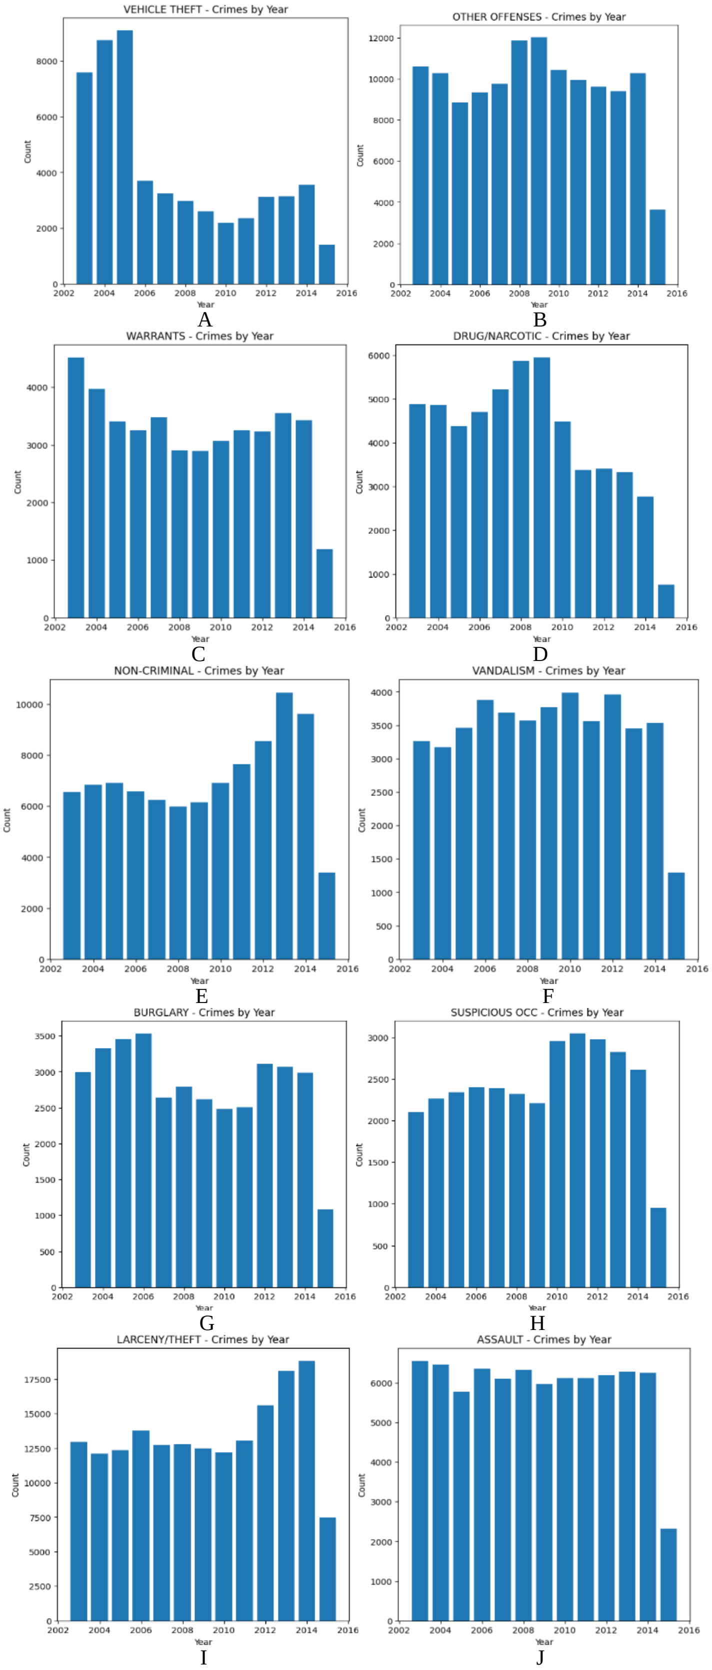
1) Variable selection. In the San Francisco crime dataset, the dependent variable for prediction is "Category." Given the other variables in the dataset, the analysis attempts to predict the crime committed.

Resolution and description are irrelevant to the analysis because they are not numerical in character. "Resolution" is a categorical variable that denotes how the case was resolved, whereas "Description" is a text variable that provides a comprehensive description of the incident. The other variables are independent variables used to predict the dependent variable.

2) Variable transformation. A handful of variables are transformed to improve the characteristics of the dataset. In the San Francisco crime dataset, the "Date" variable is separated into four distinct variables:

- Year: The values for this variable range from 2003 to 2015 and denote the year in which the incident occurred.
- Month: This variable represents the month in which the incident occurred. This variable has values between 1 and 12.
- Day: This variable represents the day of the month the incident occurred. This variable's values range from 1 to 31.
- Hour: This variable specifies the time of day when the incident occurred. This variable's values range from 0 to 23.



VEHICLE THEFT - Crimes by Year

OTHER OFFENSES - Crimes by Year

WARRANTS - Crimes by Year

DRUG/NARCOTIC - Crimes by Year

NON-CRIMINAL - Crimes by Year

VANDALISM - Crimes by Year

BURGLARY - Crimes by Year

SUSPICIOUS OCC - Crimes by Year

LARCENY/THEFT - Crimes by Year

ASSAULT - Crimes by Year

Fig. 6. Top ten crimes based on years (A) Vehicle theft, (B) Other offences, (C) Warrants, (D) Drug / narcotic, (E) Non-criminal, (F) Vandalism, (G) Burglary, (H) Suspicious OCC, (I) Larceny / theft, (J) Assault.

This makes the data more manageable and permits a more thorough analysis. For instance, we could use the “Year” variable to determine how crime rates have changed over time or the “Hour” variable to determine which hours of the day are most likely associated with criminal activity.

Note that “Date” is not the only variable that can be used to analyze crime data. Other significant variables include “PdDistrict,” which indicates the police district where the incident occurred, and “Category,” which indicates the category of crime committed. Combining these variables makes it possible to understand crime in San Francisco more deeply.

The “DayOfWeek” and “PdDistrict” variables are indexed and substituted with numbers in the San Francisco crime dataset. This makes the data more manageable and permits a more thorough analysis.

The index range for the “DayOfWeek” variable is 1 to 7, with 1 representing Monday and 7 representing Sunday. The “PdDistrict” variable has an index range of 1 to 10, where 1 represents the Northern District, and 10 represents the Southern District. This enables us to compare crime rates across days of the week and police districts with ease.

E. Model

The prediction model is based on Random forest, logistic regression, and light GBM techniques, briefly discussed below:

1) Random forest: Random forests are a widely used ensemble learning technique that constructs multiple classifiers on training data and integrates their outputs to make the most accurate predictions on test data. Consequently, the random forests algorithm is a variance-minimizing algorithm that employs randomness to avoid overfitting the training data when making split decisions.

Random forest is a supervised learning technique capable of managing classification and regression problems based on a single fundamental concept - the collective intelligence of a population. It employs many independent decision trees as an ensemble [19]. The model’s overall prediction is the class with the most votes [19]. It conducts classifications by summing the classifications produced by each individual tree within the “forest,” and the class with the most votes is the model’s overall prediction.

A random forest classifier is an ensemble classifier that aggregates a family of classifiers h(xjθ1); h(xjθ2);::h(xjθk). Each family member, h(xjθ), is a classification tree, and k is the number of trees chosen from a model random vector.

Also, each θk is a randomly chosen parameter vector. If D(x; y) denotes the training dataset, each classification tree in the ensemble is built using a different subset Dθk(x; y) ⊂ D(x; y) of the training dataset. Thus, h(xjθk) is the kth classification tree, which uses a subset of features xθk ⊂ x to build a classification model. Each tree then works like regular decision trees: it partitions the data based on the value of a particular feature (selected randomly from the subset) until the data is fully partitioned or the maximum allowed depth is reached. The final output y is obtained by aggregating the results thus:

$$y = argmax_{p\in\{h(x_1)..h(x_k)\}}\left\{\sum_{j=1}^{k}\left(I\left(h\left(x\middle|\theta_j\right) = p\right)\right)\right\}$$

where:

- I denotes the indicator function.

2) Logistic regression: Logistic regression is a statistical model used to predict the probability of a binary outcome, such as whether a customer will click on a commercial, whether a loan applicant will default, or whether a patient has a disease. The binary outcome is first converted to a probability for logistic regression to function. The logistic function, a sigmoid function that accepts a real number as input and returns a number between 0 and 1, is used for this purpose. The logistic function is defined as follows:

logistic(x) = 1 / (1 + e(-x))

Where:

- x is the function’s input.

After transforming the outcome into a probability, logistic regression employs a linear regression model to predict the likelihood. The independent variables are input into the linear regression model, which returns a predicted probability. The model’s accuracy is then improved by comparing the predicted probability to the actual probability and updating the model accordingly.

Logistic regression is a highly effective technique for predicting binary outcomes. It is simple to comprehend and interpret and can be applied to various data types. Additionally, logistic regression is comparatively robust against outliers and absent data.

Detection of fraud, customer segmentation, risk analysis, and targeted marketing are some of the applications of logistic regression.

3) Light gradient boosting machine: LightGBM is a free and open-source distributed gradient-boosting framework for machine learning. It is intended to be quick, effective, and scalable. LightGBM is based on decision tree algorithms and builds models using gradient boosting.

LightGBM is a well-liked option for various machine-learning tasks, such as classification, regression, and ranking. It is ideally adapted for large-scale datasets and can be used to train highly accurate models.

LightGBM offers advantages; it is one of the quickest gradient-enhancing frameworks available. Several refinements, including tree pruning and histogram-based splitting, contribute to this. In terms of memory usage, LightGBM is also very efficient. This makes it an excellent option for training models with large datasets. LightGBM is intended for use with large datasets. This is accomplished via distributed training and a variety of other optimizations. In addition, LightGBM is capable of achieving high accuracy in a variety of machine-learning tasks. This is due to its use of decision tree and gradient enhancement algorithms.

g(x) = f(x) + β * h(x)

Where:

- g(x) is the predicted value for x.
- f(x): is the base learner.
- β is the learning rate.
- h(x) is the gradient boosting step.

The base learner in LightGBM is a decision tree. The gradient boosting step is a technique that iteratively adds new decision trees to the model to improve the accuracy of the predictions.

The equation for LightGBM can be simplified as:

g(x) = f(x) + β * (y - f(x))

Where:

- y is the actual value for x.

This equation shows that the predicted value for x is a linear combination of the base learner and the gradient boosting step. The learning rate β controls the weight of the gradient boosting step.

III. Results

Each of the three models was trained and presented with distinct parameter and feature selections in the preceding section. The data exploration section notes that both temporal and geographical characteristics are significant. For analysis, all three models are trained and evaluated using the Kaggle training dataset containing 878,049 records, and each model is divided into two sections with a ratio of 80:20. Consequently, 80% of the dataset was used to train the model. In contrast, 20% was used for testing it.

A. Random Forest

Random forest is an ensemble learning technique that integrates the predictions of multiple models to produce a final prediction. The individual models within random forests are decision trees. Each decision tree within a random forest is trained with a unique bootstrap sample of the training data. This means that each tree will observe a distinct subset of the data, thereby helping to prevent overfitting. The random forest also employs a technique known as feature randomness in addition to bootstrap sampling. This means that each decision tree can only consider a random subset of the features when making a split.

Accuracy score, log loss, confusion matrix, and ROC curve are all metrics used to evaluate the performance of classification models. However, they measure different aspects of the model's performance.

Some of the hyperparameters that can be tuned for a random forest classifier:

- n_estimators: This is the number of trees in the forest. The higher the number of trees, the more accurate the model will be, but it will also take longer to train.
- max_depth: This is the maximum depth of the trees in the forest. A higher depth will allow the model to make more complex decisions but can also lead to overfitting.
- min_samples split: This is the minimum number of samples required to split a node in the tree. A higher number of samples will make the model more conservative but can also lead to underfitting.
- min_samples leaf: This is the minimum number of samples required in a leaf node. A higher number of samples will make the model more conservative but can also lead to underfitting.
- random_state: This random number generator seed initializes the random forest algorithm. A higher value of random state will lead to more reproducible results but can also lead to overfitting. A lower value of random state will lead to less reproducible results but can also lead to better generalization.

# random forest classifier with tuned hyperparameters random forest model = random forest classifier (n_estimator = 100, max_depth = 32, min samples split = 16, random state = 42)

random forest model fit (x train, y train)

#predict on the test set

Y pred = random forest model predict (x test)

The accuracy score is the most common metric for evaluating classification models. It is simply the percentage of instances that were correctly classified. For example, if a model correctly classifies 90 out of 100 instances, its accuracy score would be 0.90.

For Random Forest Accuracy = 0.4262

The accuracy score is generally the easiest metric to understand, but it can sometimes be misleading. Thus, log loss, confusion matrix, and ROC curve are all metrics used to evaluate the performance of classification models. However, they measure different aspects of the model's performance.

Log loss is a measure of the difference between the predicted probabilities of a model and the actual labels. It is a continuous measure, and it can be interpreted as the average amount of information lost when the predicted probabilities are used to represent the actual labels. A lower log loss indicates a better model and a log loss of 0 indicates a perfect model.

For Random Forest, the log loss = 1.74

A log loss of 1.74 is not a bad score, but it is not great. Getting better scores with a more complex model or with more training data is possible. However, getting worse scores with a more complex model or with more training data is also possible.

The log loss measures the difference between the predicted probabilities and the actual labels. A lower log loss indicates a better model. However, it is important to note that log loss is not the only measure of model performance. Other measures, such as accuracy and precision, can also be used to evaluate model performance.

The confusion matrix is a table that summarizes the performance of a classification model. It shows the number of instances correctly classified (true positives and true negatives) and the number of incorrectly classified (false positives and false negatives).

For Random Forest, the confusion matrix in Fig. 7.

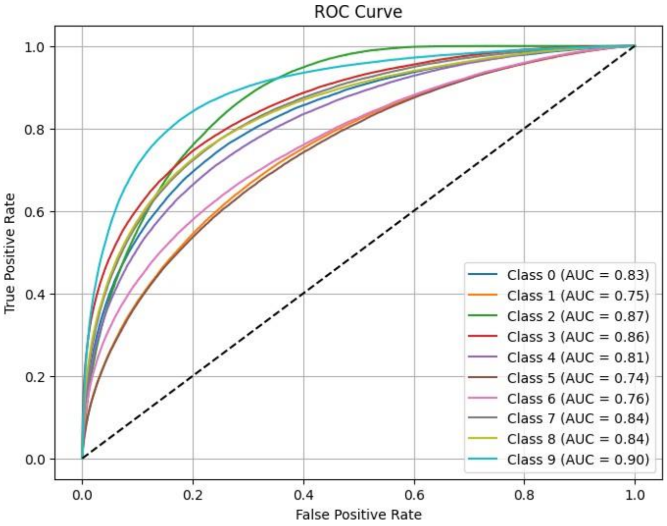


Fig. 7. Random forestROC curve.

ROC curve, or Receiver Operating Characteristic curve, is a graphical plot that illustrates the diagnostic ability of a binary classifier system as its discrimination threshold is varied. The ROC curve plots the true positive rate (TPR) against the false positive rate (FPR) at various threshold settings. The TPR is also known as recall and is defined as the fraction of positive instances correctly identified as positive. The FPR is defined as the fraction of negative instances that are incorrectly identified as positive.

A perfect classifier would have a ROC curve that passes through the upper-left corner of the graph with a TPR of 1 and an FPR of 0. However, in practice, no classifier is perfect, and the ROC curve will typically be a curve that falls below the upper-left corner.

The Random Forest ROC curve in Fig. 8 shows an AUC of 0.90, which is a good score for a binary classification model. AUC stands for area under the curve, a measure of the model's ability to distinguish between the two classes. A higher AUC indicates a better model.

In the case of class 9, an AUC of 0.90 means that the model can correctly classify 90% of the instances in the test set. This is a good score; however, some factors can affect the AUC of a model, including the complexity of the model, the amount of training data, and the model's hyperparameters.

The accuracy score is generally the easiest metric to understand, but it can sometimes be misleading. Log loss is a more sensitive metric but is not as easy to interpret. The confusion matrix is a good way to get a detailed view of the model's performance, but it can be difficult to interpret for large datasets. The ROC curve is a good way to visualize the model's performance and compare different models.

	0	1	2	3	4	5	6	7	8	9
0	21615	3134	3544	2665	2592	1692	1635	3514	4385	7344

Fig. 8. Confusion matrix for random forest classifier.

Ultimately, the best way to evaluate a classification model is to use a combination of metrics. This will give a complete picture of the model's performance and help make better decisions about the model.

B. *Logistic Regression*

Logistic regression is a statistical model used to estimate the probability of a binary outcome. The result can either be "success" or "failure." In contrast to linear regression, logistic regression is used to predict probabilities rather than continuous values.

Logistic regression is a prominent classification model for binary problems. Additionally, the model is easy to comprehend and implement. However, logistic regression can be susceptible to overfitting; therefore, cross-validation must be used to evaluate the model's performance.

Some of the hyperparameters that can be tuned for a random forest classifier:

max_iter: hyperparameter in logistic regression is the maximum number of iterations for which the model will be trained. A higher value of max_iter will generally lead to a better model but can also lead to longer training times.

Random state: hyperparameter in logistic regression is a random number generator seed used to initialize the model. A higher value of random state will lead to more reproducible results but can also lead to overfitting. A lower value of random state will lead to less reproducible results, but it can also lead to better generalization

Multi-class: The multi-class parameter specifies the multi-class classification algorithm used by the LogisticRegression class. If the value is ovr, logistic regression builds a separate model for each class. The predicted values for each class are then compared, and the class with the highest predicted value is taken as the predicted class for that instance.

Logistic regression with tuned hyperparameter

Logistic regression Model = LogisticRegression (max_iter = 1000, random state = 42, mutliclass = 'ovr')

For logistic regression accuracy = 0.221: an accuracy of 0.221 is not a very good score. It means the model can only correctly classify 22.1% of the instances in the test set. This is a relatively low score, and it suggests that the model is not very accurate.

For logistic regression, the log loss = 2.11: a log loss of 2.11 is not a good score. It means that the model is not very good at predicting the probability of the positive class. A lower log loss indicates a better model.

For Logistic regression, the confusion matrix in Fig. 9.

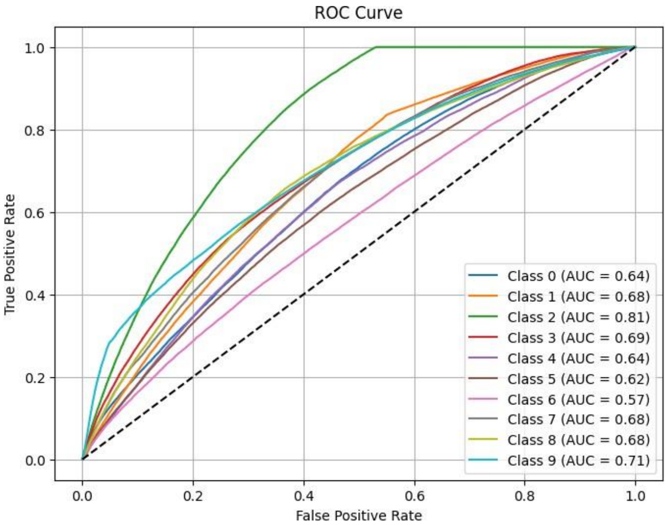

Fig. 9. Logistic regression ROC curve.

For the Logistic regression ROC curve in Fig. 10.

	0	1	2	3	4	5	6	7	8	9
0	1718	4891	10063	7898	2171	411	462	5334	12379	6793
1	200	13008	18053	7470	1279	817	325	1720	3560	5865
2	0	7947	33711	5433	591	931	49	49	0	3772
3	700	5973	9714	19042	2312	298	618	4723	7696	1259
4	933	5496	10188	10436	3531	534	1101	6196	12569	1116
5	503	7037	20414	7225	2269	799	471	3418	6966	3499
6	618	8806	13542	9399	2227	816	946	3836	7806	4130
7	1014	4055	10061	9471	2660	188	540	8873	14257	1036
8	1230	4552	7572	7902	2932	377	725	6844	18197	2064
9	1037	5644	9755	6773	1588	371	274	3565	7289	16052

Fig. 10. Logistic Regression confusion matrix.

An AUC of 0.71 is a good score for a binary classification model. AUC stands for area under the curve, and it is a measure of the model's ability to distinguish between the two classes. A higher AUC indicates a better model.

In the case of class 9, an AUC of 0.71 means that the model can correctly classify 71% of the instances in the test set.

C. LightGBM

LightGBM is a robust machine-learning algorithm applicable to a variety of duties. It is quick, effective, and simple to use. However, it is not as versatile as other algorithms, and it is difficult to tune for intricate datasets.

Some of the hyperparameters that can be tuned for a LightGBM classifier:

Objective: This specifies the type of task the model tries to solve. For classification, the objective should be set to "multi-class."

Num classes: This specifies the number of classes in the classification problem.

Learning rate: This controls the amount of weight that is given to new information. A lower learning rate will result in a more conservative model, while a higher one will be more aggressive.

Num rounds: This specifies the number of times that the model will be trained. A higher number of rounds will result in a more accurate model, but training will also take longer.

LightGBM classifier with specific parameter lgb params =

'objectives': multi-class, 'num classes: 10,

'learning rate': 0 056,

'num round': 200,

For LightGBM Accuracy = 0.32: an accuracy of 0.32 is not a very good score for a LightGBM classifier. It means that the model is only able to correctly classify 32% of the instances in the test set.

For LightGBM, the log loss = 1.91: a log loss of 1.91 is not a good score for a LightGBM classifier. It means that the model is not very good at predicting the probability of the positive class. A lower log loss indicates a better model.

For LightGBM, the confusion matrix in the Fig. 11.

In the case of class 9, an AUC of 0.83 means that the model is able to correctly classify 83% of the instances in the test set.

Accuracy, log loss, precision, F1 score, and recall are all metrics used to assess machine learning models' performance for binary classification tasks.

Accuracy is the most frequent metric, and it measures the proportion of true predictions made by the model. However, accuracy can be deceiving if the dataset is imbalanced, i.e., there are significantly more instances of one class than the other.

Log loss is a metric that evaluates the model's average cross-entropy loss. Cross-entropy loss assesses the degree to which the model's predictions correspond to the actual labels. Logloss is superior to accuracy for imbalanced data sets, as it considers the number of true positives, false positives, true negatives, and false negatives.

	0	1	2	3	4	5	6	7	8	9
0	11580	4064	4757	4007	3215	2509	1586	4046	6044	10312
1	2532	13909	10609	5049	2383	3370	2744	2141	1863	7697
2	550	5194	31944	4783	833	4050	1872	1141	85	2031
3	2452	3600	6769	21176	4675	1207	1417	5413	4226	1400
4	3275	3583	7350	7220	10640	1969	2751	6613	6683	2016
5	3715	5060	12256	5066	3146	8781	2388	3953	4001	4235
6	4147	6461	8029	6172	4387	3248	6264	3805	4378	5235
7	3669	2565	6864	6158	4611	1657	1400	15983	7442	1806
8	4693	3489	4555	5057	4626	2447	1881	6888	15467	3292
9	5617	3964	3408	2628	1998	1422	1164	2106	3236	26805

Fig. 11. LightGBM confusion matrix.

For the LightGBM ROC curve in Fig. 12.

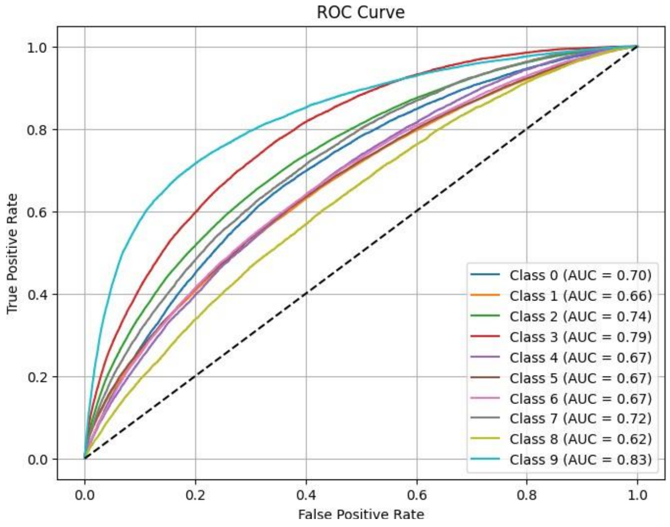

Fig. 12. LightGBM ROC curve.

Precision assesses the proportion of accurate positive predictions. If a model predicts that 100 patients have cancer and 90 of those patients actually have cancer, then the model's precision is 90%.

Recall measures the proportion of actual positives predicted to be positive. For instance, if a model predicts 100 patients have cancer, 80 of them do, then the recall is 80%.

The F1 score is an average of accuracy and recall. It is a more balanced metric than precision or recall alone and is frequently used to evaluate the overall performance of a model. The optimal metric to use depends on the particular application. For instance, precision may be the most essential metric if avoiding false positives is crucial. If avoiding false negatives is crucial, recall may be the most essential metric. Utilizing multiple metrics to evaluate the efficacy of a machine-learning model is generally recommended.

TABLE I. ACCURACY, LOG LOSS, PRECISION, F1 SCORE, AND RECALL FOR RANDOM FOREST CLASSIFIER, LOGISTIC REGRESSION, AND LIGHTGBM

	Techniques		
	Random Forest Classifier	***Logestic_Regression***	***LightGBM***
Accuracy	0.427044133394452346	0.22157908826678904	0.31082491968793025

Table I summarises the accuracy, log loss, precision, F1 score, and recall for random forest Classifier, Logistic Regression, and LIGHT GBM.

IV. CONCLUSIONS

The proposed model contains three techniques and evaluates accuracy, precision, and recall evaluation matrices. The data is descriptively analyzed, and statistical crime distribution over space and time is visualized to help attain potential patterns. The features are extracted from the original dataset, and the classification is performed using random forest, logistic regression, and LightGBM techniques. LightGBM has the best performance for binary classification tasks based on the metrics we provided. It has the highest AUC (area under the ROC curve), which measures how well the model can distinguish between the two classes. LightGBM also has the highest precision and F1 score, which measures the accuracy of the model's predictions.

Random forest has the second-best performance, followed by logistic regression. Random forest has a slightly lower AUC than LightGBM but a higher precision. Logistic regression has the lowest AUC and precision but has a higher recall than the other two models.

LightGBM is generally a good choice for binary classification tasks when accuracy and precision are important. Random forest is a good choice when accuracy and recall are important. Logistic regression is a good choice when recall is more important than accuracy.

Random Forest, while robust, may struggle with certain types of crimes that exhibit complex patterns or dependencies. The ensemble of decision trees might face challenges in capturing intricate relationships within the data, leading to suboptimal predictions for specific crime categories.

Logistic Regression, although straightforward and interpretable, assumes a linear relationship between the independent variables and the log-odds of the outcome. This assumption might limit its ability to capture non-linear patterns inherent in some crime data, affecting its predictive accuracy for certain crime types.

LightGBM, despite its speed and efficiency, might encounter difficulties with interpretability due to its complex nature. The "black-box" aspect of gradient-boosting algorithms can hinder understanding the rationale behind specific predictions, making it challenging to identify why certain types of crimes are predicted with higher or lower accuracy.

It is imperative to recognize potential biases and limitations that may impact the reliability and generalizability of the predictive models. Crime datasets inherently face challenges such as underreporting or misreporting, introducing inaccuracies into the dataset. Spatial biases may emerge if certain areas are disproportionately monitored or reported, creating an uneven representation of crime across locations. Additionally, temporal biases could arise due to variations in reporting frequency or law enforcement activities during specific time periods.

Demographic and socioeconomic factors may introduce biases in crime reporting and law enforcement activities, leading to potentially skewed representations of criminal activities. Over-policing or under-policing in specific communities may contribute to these biases.

Imbalances in class distribution, where certain crime events are less frequent than others, could affect the model's ability to accurately predict less common events. Variations in data collection methods across different regions or law enforcement agencies may impact the consistency and comparability of the dataset. Additionally, up-to-date data is essential otherwise it may not accurately reflect current crime patterns.

Considering ethical and legal considerations is essential, including issues related to privacy, data anonymization, and compliance with legal and ethical standards in handling crime data. researchers and practitioners are advised to transparently acknowledge and address these limitations through appropriate preprocessing techniques, feature engineering, and model evaluation strategies to enhance the robustness and reliability of predictive models.

Machine learning models, particularly those used for crime prediction, are vulnerable to biases present in their training data. If the dataset used is biased, the predictive model may perpetuate and worsen existing biases, leading to unfair targeting of specific demographics and reinforcing social inequalities within law enforcement practices. The fairness of predictions is crucial, as disproportionate predictions of crimes in certain communities or against specific groups can result in biased law enforcement actions, raising ethical concerns about the model's impact on the communities it predicts to have higher crime rates.

There is a risk of self-fulfilling prophecies, where increased law enforcement presence in predicted high-crime areas may lead to more arrests, creating a feedback loop that unfairly stigmatizes certain neighborhoods and individuals, contributing to over-policing and reinforcing negative stereotypes. Unintended consequences may occur if the model prioritizes predictive accuracy without considering the broader ethical implications, potentially neglecting less frequent but equally severe offenses and leading to imbalanced resource allocation.

To address these ethical concerns, continuous monitoring, evaluation, and refinement of the model are essential. Implementing fairness-aware algorithms, regularly auditing for biases, and involving diverse stakeholders in the development process can help mitigate ethical risks and ensure the responsible use of machine learning in crime prediction

Furthermore, the use of imbalanced data introduces a skewed representation of the classes, where certain outcomes dominate, leading to potential biases in the model's learning process. In the context of crime prediction, this could mean an overemphasis on prevalent types of crimes, potentially neglecting rarer but significant events.

Addressing imbalanced data is crucial for model robustness. Techniques such as oversampling the minority class, undersampling the majority class, or deploying advanced algorithms like SMOTE are common strategies. These techniques aim to balance class distribution, ensuring the model learns from the entirety of the dataset rather than being swayed by the abundance of one class.

While necessary for training of potential models, dealing with historical data in crime prediction, temporal limitations are a crucial aspect. Changes in social dynamics, law enforcement practices, and urban development over time can influence the relevance of historical data for current or future crime prediction. Evolving patterns, emerging trends, or shifts in criminal behavior may not be fully captured by historical datasets.

It is important to note that these are just one dataset’s results. The performance of the models may vary depending on the dataset. In the future, the same models can be applied to the crime dataset using more complex classification algorithms, and their prediction performance can be evaluated to find trends and improve topic understanding. Experimenting with different models and hyperparameters is always a good idea to find the best model for your specific needs.

Machine Learning-Driven Integration of Genetic and Textual Data for Enhanced Genetic Variation Classification

Malkapurapu Sivamanikanta, N Ravinder
Department of CSE, Koneru Lakshmaiah Education Foundation, Vaddeswaram, AP, India

***Abstract*—Precision medicine and genetic testing have the potential to revolutionize disease treatment by identifying driver mutations crucial for tumor growth in cancer genomes. However, clinical pathologists face the time-consuming and error-prone task of classifying genetic variations using Textual clinical literature. In this research paper, titled “Machine Learning-Driven Integration of Genetic and Textual Data for Enhanced Genetic Variation Classification”, we propose a solution to automate this process. We aim to develop a robust machine learning algorithm with a knowledge base foundation to streamline precision medicine. Our methods leverage advanced machine learning and natural language processing techniques, coupled with a comprehensive knowledge base that incorporates clinical and genetic data to inform mutation significance. We use text mining to extract relevant information from scientific literature, enhancing classification accuracy. Our results demonstrate significant improvements in efficiency and accuracy compared to manual methods. Our system excels at identifying driver mutations, reducing the burden on clinical pathologists and minimizing errors. Automating this critical aspect of precision medicine promises to empower healthcare professionals to make more precise treatment decisions, advancing the field and improving patient care.**

***Keywords*—Precision medicine; genetic testing; driver mutations; cancer genomes; textual clinical literature; text mining; genetic variations**

I. Introduction

In the rapidly evolving landscape of precision medicine, a groundbreaking transformation is underway, promising to revolutionize healthcare by tailoring treatments to individuals based on their unique genetic profiles [1-8]. This paradigm shift represents a departure from the traditional one-size-fits-all approach in medicine and holds immense potential to enhance the effectiveness of disease treatment strategies. However, within this promising horizon, a formidable challenge looms large—a challenge that revolves around the labor-intensive task of distinguishing between driver mutations, those pivotal for tumor growth, and neutral mutations that exist within cancer genomes [9]. The accurate classification of genetic variations into these categories forms the cornerstone of precision medicine, shaping the foundation upon which personalized treatment strategies are built. Any misclassification at this juncture can lead to suboptimal or even detrimental patient outcomes [10-13]. Unfortunately, the burden of manually reviewing and classifying genetic variations has traditionally rested on clinical pathologists, a process known for its time-consuming nature and susceptibility to human error [14]. This manual approach not only consumes valuable time but also introduces the potential for inaccuracies, ultimately impeding the precision and efficiency of precision medicine practices [15]. In light of these challenges, there is an urgent need for innovative solutions that can alleviate the burden on healthcare professionals while simultaneously enhancing the accuracy of genetic variation classification within the precision medicine framework [16-19]. Here, the integration of advanced technologies, particularly machine learning, emerges as a promising avenue to address this critical issue. In response to this pressing challenge, our research paper, titled “Machine Learning-Driven Integration of Genetic and Textual Data for Enhanced Genetic Variation Classification,” presents an innovative and much-needed solution. We advocate for the development of a sophisticated machine learning algorithm, leveraging a comprehensive knowledge base, meticulously designed to automate the intricate task of classifying genetic variations [20-22]. Our overarching goal is to streamline the precision medicine pipeline, empowering healthcare professionals to make more efficient and accurate treatment decisions. In doing so, we aim to advance the field of precision medicine and significantly enhance patient care [20-22]. Our research paper assumes a pivotal role in the ongoing fusion of machine learning and precision medicine, addressing the imminent need for more efficient and dependable methodologies in the field [23-25]. Through an extensive review of the literature, we navigate the challenges and opportunities associated with integrating text mining and machine learning for the classification of genetic variations [26] [27]. Our approach involves leveraging state-of-the-art natural language processing techniques to extract meaningful information from the vast corpus of clinical literature. This enables us to analyze genetic data and text data simultaneously, facilitating the identification of patterns and associations that are challenging to discern through manual review alone. Furthermore, we delve into the potential impact of our proposed algorithm, particularly within the realm of oncology, where the classification of genetic mutations carries profound implications for treatment decisions [28]. By automating the classification process and harnessing the power of machine learning, we anticipate significant improvements in accuracy and efficiency. Crucially, our algorithm will continuously adapt and learn from new research findings, ensuring that it remains up-to-date with the latest advancements in the field. Delving further into the technical aspects of our machine learning approach, we illuminate its capacity to process vast amounts of clinical data and extract valuable insights [29][30]. We elucidate the algorithm's training process, its robust knowledge base, and its ability to adapt to the ever-evolving corpus of clinical literature [31] [32]. As our research paper unfolds, we will provide a meticulous analysis of the algorithm's performance, offering a comparative perspective with traditional manual classification methods [33][34]. Supported by empirical evidence, we will showcase the efficiency, accuracy, and scalability inherent in our machine learning approach. Our ultimate aim is not only to enhance the precision and efficiency of genetic variation classification but also to provide healthcare professionals with a powerful tool that can aid in making more informed and timely treatment decisions. In doing so, we aspire to benefit patient care and drive forward the field of precision medicine [35-38] we Implemented Machine Learning Methods on Data to Analyze information from various patients [39-41].

The primary research problem our study addresses is the labor-intensive and error-prone process of genetic variation classification in precision medicine. This classification is pivotal for identifying driver mutations in cancer genomes, a task currently burdened with inefficiencies and inaccuracies when done manually. Our research questions focus on how machine learning and textual data integration can automate and enhance this classification process. The objectives include developing a robust machine learning algorithm that leverages textual and genetic data for improved classification accuracy, thereby aiding clinical decision-making and advancing the field of precision medicine.

In the next section of the paper, we will delve into the existing body of literature relevant to our research, providing a comprehensive review of prior work in the field of precision medicine, genetic variation classification in Section II, this is followed by 'Methods', detailing the study's methodology in Section III, and a 'Results and Analysis' in Section IV, presenting the findings of the research. Then Section V presents 'Discussions', where the implications and limitations of the study are discussed, and finally 'Conclusion' in Section VI that summarizes the research and its potential impact on precision medicine.

II. LITERATURE REVIEW

Precision medicine, driven by advances in genomics and data science, has emerged as a transformative approach to healthcare. This paradigm shift in medicine aims to tailor diagnosis and treatment to the individual patient's genetic makeup, thereby enhancing treatment efficacy and minimizing adverse effects. The integration of machine learning and text mining techniques in precision medicine has played a pivotal role in deciphering complex genetic variations and their associations with diseases. In this literature review, we explore key contributions and insights from recent studies, highlighting the growing significance of machine learning and textual information in the classification of genetic variations for precision medicine.

The research in [1] presents a pioneering approach using machine learning to relate enhancer genetic variation across mammalian species to complex phenotypes. Their work demonstrates the potential of machine learning in understanding the functional implications of genetic variations across evolutionary scales. However, it should be noted that the generalizability of these findings to humans may require further investigation. The study in [2] offers a comprehensive overview of the challenges and opportunities in translating scientific insights into tangible clinical benefits. Their review provides valuable context for the field. However, it lacks a critical examination of potential limitations in the translation of research into clinical practice. The study in [3] emphasizes the role of AI-driven approaches in extracting genotype-phenotype relationships from biomedical literature. Their work aids in the curation of databases and the identification of genetic markers relevant to disease susceptibility. However, the review does not delve into the potential biases in text mining techniques or the challenges of ensuring data accuracy. The research in [4] addresses the bioinformatic challenges in detecting genetic variations, emphasizing the need for robust computational solutions. While this review highlights important challenges, it lacks a discussion of potential ethical concerns related to data privacy and security in precision medicine programs. The study in [5] explores the intersection of text mining and visualization in precision medicine. Their work sheds light on the role of text mining in extracting and presenting valuable information from biomedical literature. However, it does not critically evaluate the limitations of text mining, such as potential biases in the data sources. The research in [6] discusses how AI can aid in diagnosis, prognosis, and treatment selection in cancer care. Their review highlights the potential for improved patient outcomes. Nevertheless, it should be noted that the implementation of AI in healthcare settings may face challenges related to data accessibility and regulatory compliance. The study in [7] provides a comprehensive review of computational solutions for precision medicine-based big data healthcare systems, with an emphasis on deep learning models. While the potential for personalized treatments is promising, the review could benefit from a discussion of potential limitations, such as the need for interpretability in deep learning algorithms. The research in [8] discusses the potential of big data analytics to drive precision medicine initiatives. They offer insights into disease mechanisms and treatment strategies. However, the review does not critically assess the quality and reliability of big data sources in healthcare. The study in [9] highlights the significance of automated approaches in curating databases and identifying genetic variations relevant to precision medicine. Nonetheless, potential biases in automated curation methods and challenges in data validation should be considered. The research in [10] document the rise of deep learning in integrating genomic, proteomic, and metabolomic data for precision medicine. While this approach offers a comprehensive understanding of disease mechanisms, it is essential to address potential issues related to data integration and model interpretability. The paper in [11] proposes an ensemble stacking classification approach using machine learning algorithms to categorize genetic variations efficiently. Their work has practical implications for treatment decisions. However, the review could provide a more critical assessment of the generalizability of the proposed methods. The study [12] discusses the principles and opportunities of integrating data in biology and medicine, stressing the importance of data quality, interoperability, and ethical considerations. It is essential to consider potential conflicts of interest in data sharing and integration. The study in [13] highlight the role of text mining in extracting structured information from unstructured text, facilitating the identification of disease-related mutations. However, the review could explore challenges in text mining accuracy and potential biases in literature selection. The research in [14] utilizes machine learning and natural language processing to review and classify the medical literature on cancer susceptibility genes. While their automated techniques streamline gene identification, they should address potential limitations in the accuracy of classification algorithms. The study in [15] discusses AI's potential in optimizing patient care across the continuum of cancer treatment. However, ethical considerations, including patient consent and data security, should be addressed in the implementation of AI-driven precision oncology. The study in [16] focuses on the identification of cancer hotspot residues and driver mutations using machine learning. Their work underscores the importance of machine learning in identifying critical genetic variations in cancer. However, the review could provide a more in-depth analysis of the clinical relevance of these findings. The research in [17] delves into metabolomics technology and bioinformatics for precision medicine, emphasizing the role of metabolomics data in understanding disease mechanisms and treatment responses. The review should consider potential challenges related to metabolomic data quality and standardization. The study in [18] discusses the application of machine learning in leveraging omics data for personalized treatment strategies. While the potential for biomarker discovery is evident, the review could explore challenges in omics data integration and reproducibility. [19] propose machine learning approaches for the classification of genetic mutations for cancer treatment. Their work has practical implications for treatment decisions. However, it is essential to address potential biases in the training data and model generalizability. The research in [20] highlights the role of machine learning in predicting the functional impact of genetic variations. Their work provides insights into variant severity assessment. However, the review should discuss the potential limitations of current prediction models. The study in [21] provides an extensive overview of the role of artificial intelligence (AI) in advancing cancer research and precision medicine. It highlights the transformative impact of AI in various aspects of cancer research, diagnosis, treatment, and patient care [22] discusses how machine learning can accelerate genetic structure analysis, offering insights into population genetics and disease susceptibility. The review should consider potential biases in genetic databases and study cohorts. The paper in [23] highlight the role of deep learning models in extracting valuable information from medical images to aid in diagnosis and treatment planning. Ethical considerations related to patient data privacy and model explains ability should be addressed. The paper in [24] introduces multi-functional machine learning platforms for healthcare and precision medicine. Their work demonstrates the potential of AI-driven platforms in managing and analysing healthcare data. The review could delve into data security and interoperability challenges. The study in [25] focuses on text mining for precision medicine, utilizing natural language processing and machine learning for knowledge discovery in the health domain. The transition from hype to reality in data science enabling personalized medicine was discussed. The research in [26] emphasizes the need for robust data-driven approaches to realize the full potential of personalized medicine. The paper in [27] explores machine learning approaches in genomics and their insights into the molecular basis of diseases. The review should acknowledge potential limitations in data quality and model interpretability. The paper in [28] proposes machine learning's application in omics data analysis, highlighting its potential in identifying biomarkers and therapeutic targets. Challenges in omics data preprocessing and feature selection should be considered. The research in [29] presents a network-based approach for cancer drug discovery, leveraging integrated multi-omics data for precision medicine. The review should discuss challenges in network-based drug target identification and validation. The study in [30] delves into the principles, prospects, and challenges of precision medicine informatics, emphasizing the potential of AI-driven solutions in advancing healthcare. The review should consider ethical considerations related to data sharing and patient consent. The research in [31] discusses "eDoctor," an AI-driven platform shaping the future of medicine. They highlight the transformative potential of AI in healthcare. The review should acknowledge potential challenges in AI adoption in healthcare, such as resistance to technology. The paper in [32] provides insights into the future of precision medicine and its integration with healthcare. They underscore the pivotal role of AI in shaping the future of healthcare. The review should explore potential barriers to healthcare integration and disparities in access. The study in [33] explores the classification of genetic variants using machine learning, emphasizing the role of AI in categorizing genetic variations. The review should discuss potential limitations in training data representativeness. The research in [34] offers a perspective on AI in healthcare data management, emphasizing its journey towards precision medicine. Ethical considerations related to data privacy and security should be addressed. The study in [35] discusses the role of artificial intelligence in assisting cancer diagnosis and treatment in the era of precision medicine. They highlight the potential of AI-driven solutions in improving cancer care. The review should explore potential disparities in AI adoption across healthcare settings. The paper in [36] introduces SNPnexus, a tool for assessing the functional relevance of genetic variation to facilitate precision medicine. The review should discuss potential limitations in the accuracy of functional predictions. The paper in [37] explores the role of machine learning in cancer genome analysis for precision medicine. They emphasize the potential of machine learning in unravelling the complexity of cancer genetics. The review should acknowledge potential biases in sequencing data. The paper in [38] discusses the application of machine learning methods in clinical trials for precision medicine, showcasing how machine learning can optimize clinical trial design and analysis. Ethical considerations related to patient consent and data transparency should be addressed. In [39], the paper likely discusses various ML algorithms and their efficacy in processing and analyzing emotional health-related data. The study in [40] discusses Analyzing and Detecting Advanced Persistent Threat Using Machine Learning Methodology. The study in [41] contributes significantly to medical imaging and machine learning, particularly in the early and accurate prediction of brain diseases, which is crucial for treatment planning.

In the next section, we delve into the methodology that forms the backbone of our research "Machine Learning-Driven Integration of Genetic and Textual Data for Enhanced Genetic Variation Classification" building upon the insights gained from the extensive literature review, we outline our research approach, data collection and preprocessing methods, machine learning algorithms, and the overall framework used to address the critical challenges posed by genetic variation classification in the context of precision medicine.

III. Methods

In this section, we outline the methodology employed in our study, which aims to develop and evaluate a model for the classification of genetic mutations based on associated clinical evidence. Our primary contributions include the utilization of the MSK-Redefining Cancer Treatment dataset, comprising "data_variants" and "data_text" files, to analyze genetic mutations and their clinical implications. Specifically, we seek to classify genetic mutations into one of nine distinct classes using both genetic and textual information. This work holds great significance as it lays the foundation for more personalized and effective treatments for patients with genetic variations, advancing the field of precision medicine.

A. Data Collection

The dataset used for training and evaluating the proposed model consisted of two main files: "data_variants" and "data_text" from the MSK-Redefining Cancer Treatment dataset. These files were employed to analyze genetic mutations and their associated clinical evidence. The "data_variants" dataset provided detailed information about genetic mutations, including gene location, amino acid variations, and classification into one of nine distinct classes. In parallel, the "data_text" dataset contained textual clinical evidence essential for classifying these genetic mutations. Each piece of text was linked to a specific mutation through a common "ID" field, ensuring a one-to-one correspondence between genetic mutation information and clinical evidence as shown in Table I, in total; our dataset comprised 3,321 genetic mutations.

TABLE I. The Table Describes the Top 5 Rows of the Dataset Containing Genetic Mutations and Clinical Evidence

	Gene	Variation	Class	TEXT
0	FAM58A	Truncating Mutations	1	Cyclin-dependent kinases (CDKs) regulate a var...
1	CBL	W802*	2	Abstract Background Non-small cell lung canc...
2	CBL	Q249E	2	Abstract Background Non-small cell lung canc...
3	CBL	N454D	3	Recent evidence has demonstrated that acquired...
4	CBL	L399V	4	Oncogenic mutations in the monomeric Casitas B...

- Gene: The gene where the genetic mutation is located.
- Variation: The amino acid change for the genetic mutation.
- Text: The clinical evidence (text) used to classify the genetic mutation.

We split the dataset into training, testing, and cross-validation sets as shown in Table II, with the class label as the dependent variable. We used a stratified split to ensure that the class distribution in each split was approximately the same as the class distribution in the overall dataset. This means that the model will be trained using the training set to predict the class label from the other features in the dataset. We use the cross-validation set to select the hyperparameters for our model, and to evaluate the cross-validation score. Finally, we evaluate the final model on the test set.

TABLE II. Number of Data Points in each Dataset

Dataset	Number of data points
Training	2124
Testing	665
Cross-validation	532

- Number of Unique Classes: 9 (1-9)
- Number of Unique Genes: 225
- Number of unique variations: 1918

B. Data Visualization

To ensure robust model performance, we have partitioned our dataset into three distinct sets: training, testing, and cross-validation. Fig. 1 illustrates the distribution of data points across these categories. The training data comprises various classes, each representing different attributes. The distribution of these classes within the training set is depicted in Fig. 2. To evaluate the model's performance, the testing data was carefully analyzed. Fig. 3 shows the distribution of classes within this test dataset. Cross-validation plays a crucial role in our model's validation process. The class distribution within the cross-validation dataset is presented in Fig. 4. A critical aspect of our analysis focused on the cumulative distribution of genes, which is crucial for understanding the broader genetic patterns. This distribution is comprehensively illustrated in Fig. 5. Alongside gene distribution, understanding the variation distribution is pivotal. Fig. 6 presents the cumulative distribution of variations, offering insights into the frequency and spread of these variations within our dataset.

C. Data Preprocessing

1) Text preprocessing: To prepare the clinical evidence for analysis, we performed text preprocessing. This involved the following steps:

- Removal of alphanumeric characters.
- Elimination of multiple spaces.
- Conversion of the text to lowercase.
- Removal of common English stop words.

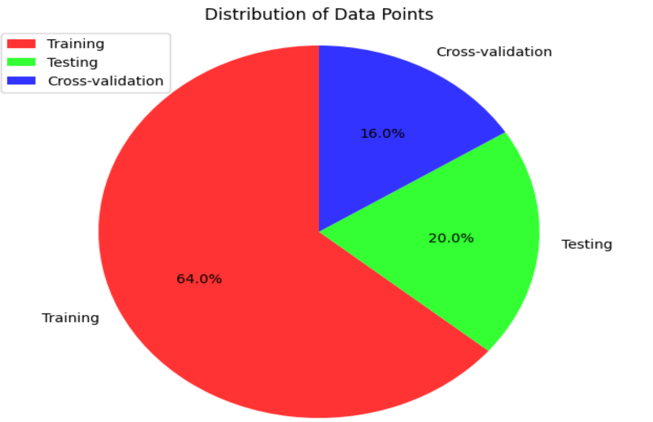

Fig. 1. The figure shows a pie chart of the distribution of data points in three categories: Training, Testing, and Cross-validation.

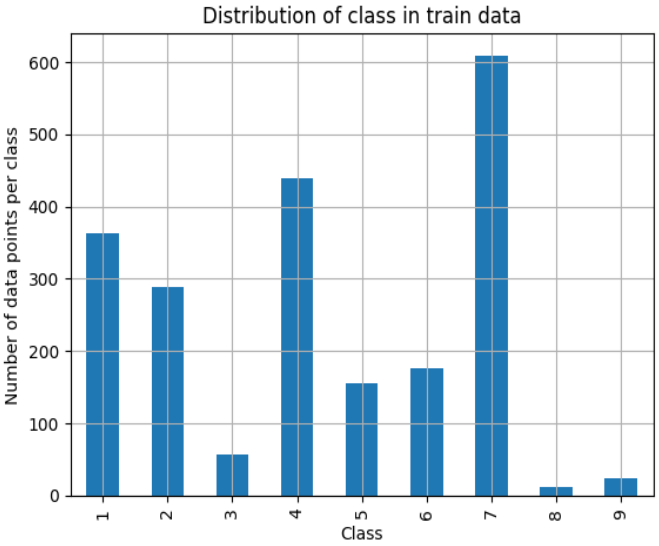

Fig. 2. The figure shows distribution of class in train data.

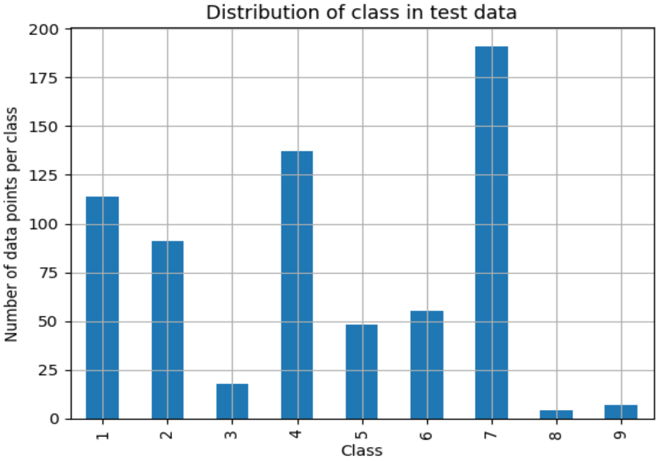

Fig. 3. The figure shows distribution of class in test data.

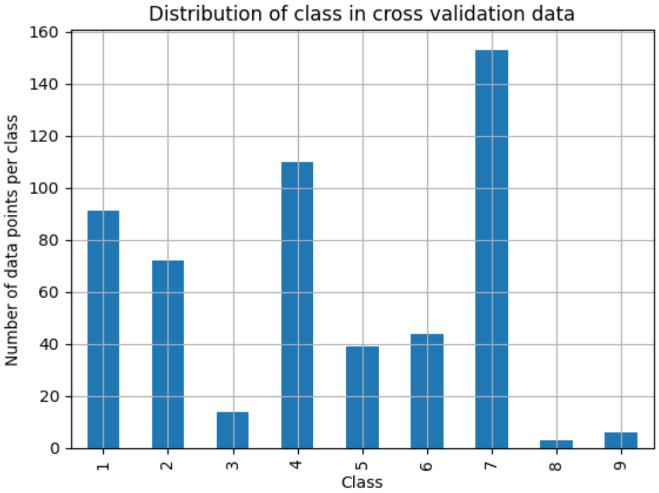

Fig. 4. The figure shows Distribution of class in cross validation data.

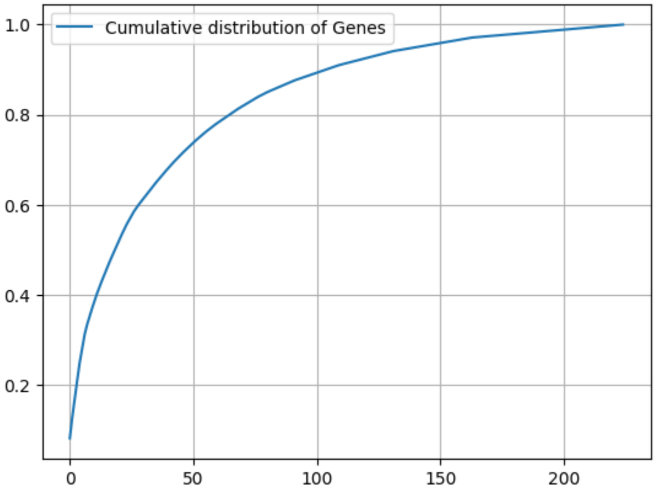

Fig. 5. The figure shows cumulative distribution of genes.

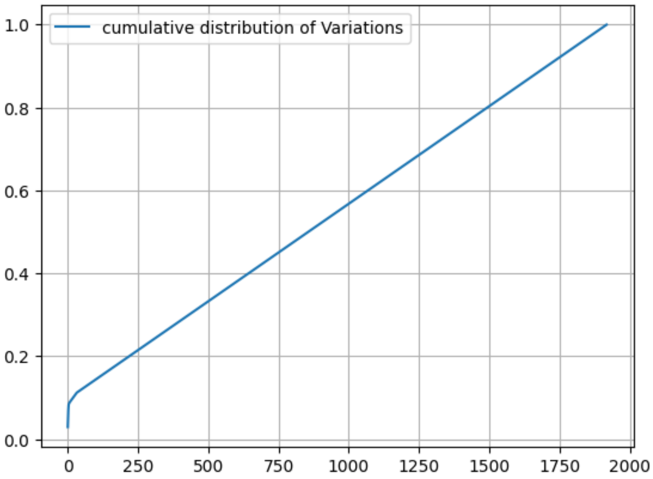

Fig. 6. The figure shows cumulative distribution of variations.

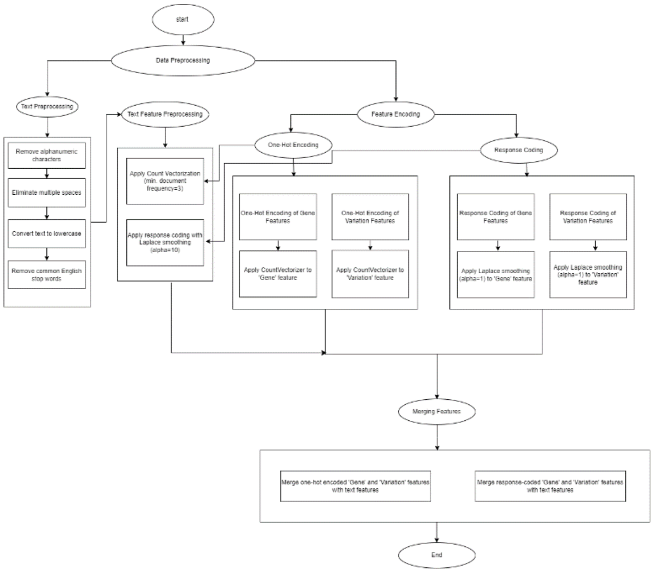


start
Data Preprocessing
Text Preprocessing
Remove alphanumeric characters
Eliminate multiple spaces
Convert text to lowercase
Remove common English stop words
Text Feature Preprocessing
Apply Count Vactorization (min. document frequency=3)
Apply response coding with Laplace smoothing (alpha=10)
Feature Encoding
One-Hot Encoding
One-Hot Encoding of Gene Features
One-Hot Encoding of Variation Features
Apply CountVectorizer to 'Gene' feature
Apply CountVectorizer to 'Variation' feature
Response Coding
Response Coding of Gene Features
Response Coding of Variation Features
Apply Laplace smoothing (alpha=1) to 'Gene' feature
Apply Laplace smoothing (alpha=1) to 'Variation' feature
Merging Features
Merge one-hot encoded 'Gene' and 'Variation' features with text features
Merge response-coded 'Gene' and 'Variation' features with text features
End

Fig. 7. The figure shows data preprocessing steps applied to our dataset.

These preprocessing steps ensured that the textual data was prepared for analysis and model training as shown in Fig. 7.

2) One-hot encoding of gene and variation features: To represent the categorical features 'Gene' and 'Variation' numerically, we employed one-hot encoding. This technique converts each unique value in these features into a binary vector, where each element corresponds to a specific category. For the 'Gene' feature, we utilized CountVectorizer to perform one-hot encoding, resulting in a matrix with a shape of (number of data points, 243) across all data sets. Similarly, for the 'Variation' feature, we applied CountVectorizer, resulting in a matrix with a shape of (number of data points, 1950) in all data sets.

3) One-hot encoding of gene and variation features: To represent the categorical features 'Gene' and 'Variation' numerically, we employed one-hot encoding. This technique converts each unique value in these features into a binary vector, where each element corresponds to a specific category. For the 'Gene' feature, we utilized CountVectorizer to perform one-hot encoding, resulting in a matrix with a shape of (number of data points, 243) across all data sets. Similarly, for the 'Variation' feature, we applied CountVectorizer, resulting in a matrix with a shape of (number of data points, 1950) in all data sets,

4) Text feature preprocessing: We merged the one-hot encoded 'Gene' and 'Variation' features with the text features, resulting in feature matrices for both one-hot encoding and response coding approaches. For one-hot encoding, the merged matrix has a shape of (number of data points, 54,770) for all data sets (training, test, and cross-validation). For response coding, the merged matrix has a shape of (number of data points, 27) for all data sets (training, test, and cross-validation) as shown in Table III,

In summary, our data preprocessing pipeline transformed the original genetic variation dataset into numerical feature representations suitable for training machine learning models. These features integrate gene, variation, and text information, enabling effective classification of genetic variations in precision medicine.

TABLE III. SUMMARIZES THE SHAPES OF THE MERGED FEATURE MATRICES FOR BOTH ONE-HOT ENCODING AND RESPONSE CODING APPROACHES, ALONG WITH THE NUMBER OF DATA POINTS FOR EACH DATA SET (TRAINING, TEST, AND CROSS-VALIDATION)

Approach	Data Set	Shape of Merged Matrix
One-Hot Encoding	Training Data	(2124, 54,770)
	Test Data	(665, 54,770)
	Cross-Validation Data	(532, 54,770)
Response Coding	Training Data	(2124, 27)
	Test Data	(665, 27)
	Cross-Validation Data	(532, 27)

In the next section, we present the results and analysis of our study, which aimed to develop a model for the classification of genetic mutations based on associated clinical evidence. We discuss the performance of our model in detail and provide insights into the implications of our findings.

IV. RESULTS AND ANALYSIS

In this section, we present the results and analysis of our study on “Machine Learning-Driven Integration of Genetic and Textual Data for Enhanced Genetic Variation Classification”. We conducted experiments using various classifiers and evaluated their performance based on cross-validation mean accuracy, cross-validation standard deviation, and accuracy on the test set while the test set accuracy provided an indication of the model's real-world performance. We also provide precision, recall, and F1 scores to provide a more comprehensive evaluation of the models. Additionally, we provide a detailed analysis of the confusion matrices for the best-performing models.

A. Model Selection

In our study, we evaluated a range of machine learning models to determine the most suitable classifier for the task of integrating genetic and textual information for genetic variation classification in precision medicine. The models considered in our analysis included K-nearest neighbours (K-NN), logistic regression, stacking classifier, and voting classifier. The selection criteria for the best model were based on two key factors: cross-validation mean accuracy and test set accuracy. Cross-validation was used to assess the model's ability to generalize to unseen data, while the test set accuracy provided an indication of the model's real-world performance.

B. Model Training

For each machine learning model, we carefully tuned the model's hyperparameters to optimize its performance. The hyperparameter tuning process involved techniques such as grid search and random search, which systematically explored a range of hyperparameter values to identify the optimal configuration. Additionally, we employed techniques like cross-validation during the training phase to prevent overfitting and ensure that the models could generalize well to unseen data. This helped in finding the right balance between model complexity and generalization (see Fig. 8).

C. Model Evaluation

To evaluate the performance of our machine learning models, we employed a set of well-established metrics as shown in Table IV, including:

- Cross-Validation Mean Accuracy: This metric provided an estimate of how well the model could perform on unseen data. It allowed us to compare the models' abilities to generalize across different folds of the dataset.

- Accuracy on the Test Set: The accuracy on the test set measured how well the models could classify genetic variations in a real-world scenario. It was a crucial indicator of the model's practical utility.

- Confusion Matrix Analysis: We analyzed confusion matrices to gain insights into how each model performed across different classes. This allowed us to identify areas where the models excelled and areas where they struggled, helping to understand their strengths and weaknesses. Additionally, we computed precision, recall, and F1 scores to provide a more nuanced evaluation of our models.

- Precision: Precision quantifies the proportion of correctly predicted positive instances relative to the total predicted positive instances. It is a critical metric for understanding the models' ability to minimize false positive errors.

- Recall: Recall measures the proportion of correctly predicted positive instances relative to the actual positive instances in the dataset. It offers insights into how effectively our models identify true positives.

- F1 Score: The F1 score is the harmonic mean of precision and recall, providing a balanced assessment of the models' performance. It is particularly valuable when aiming to strike a balance between false positives and false negatives.

By considering these metrics, we were able to make informed decisions about which machine learning model was the most appropriate for our specific genetic variation classification task. Our evaluation process ensured that the selected model was not only accurate but also capable of handling the complexities of integrating genetic and textual data, a critical aspect of precision medicine.

D. Response Coding Results

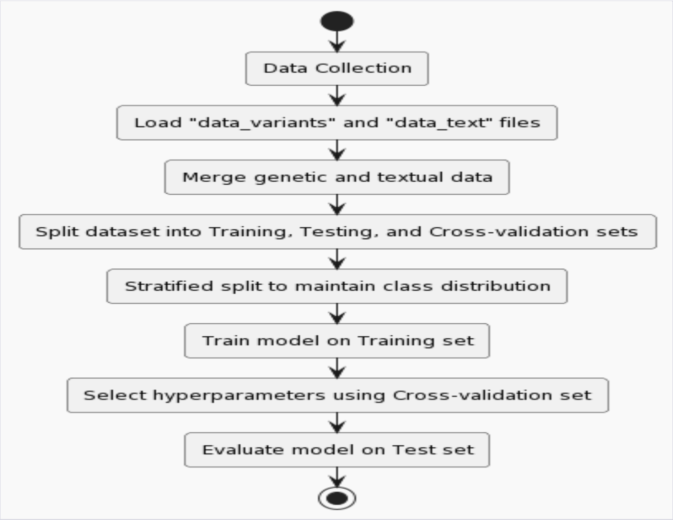
1) Observations:

- The SVM RBF Classifier and the Stacking Classifier have the highest cross-validation and test set accuracies.

- The Decision Tree Classifier and the Gaussian Naive Bayes Classifier have the lowest test set accuracies.

- The Voting Classifier has a higher test set accuracy than the average of the individual classifiers.

- These observations taken from Table IV.



Data Collection
Load "data_variants" and "data_text" files
Merge genetic and textual data
Split dataset into Training, Testing, and Cross-validation sets
Stratified split to maintain class distribution
Train model on Training set
Select hyperparameters using Cross-validation set
Evaluate model on Test set

Fig. 8. The figure shows methodology or workflow for a data analysis.

TABLE IV. DISPLAYS THE CROSS-VALIDATION MEAN ACCURACY, STANDARD DEVIATION, AND TEST SET ACCURACY FOR EACH CLASSIFIER FOR RESPONSE CODING DATASET

Classifier	**Cross-Validation Mean Accuracy**	**Cross-Validation Std Deviation**	**Accuracy on Test Set**
K-Nearest Neighbors(KNN) Classifier	0.5583	0.0435	0.6316
Decision Tree Classifier	0.5639	0.0554	0.1323
Random Forest Classifier	0.5694	0.0799	0.5759
Multi-layer Perceptron (Neural Network) Classifier	0.5055	0.0688	0.5564
AdaBoost Classifier	0.4775	0.0471	0.2150
Gaussian Naive Bayes Classifier	0.1146	0.0360	0.5263
SVM Linear Classifier	0.5019	0.0759	0.5549
SVM RBF Classifier	0.5920	0.0825	0.6075
SVM Sigmoid Classifier	0.2875	0.0665	0.2872
Gaussian Process Classifier	0.6258	0.0520	0.3519
Multinomial Naive Bayes Classifier	0.3158	0.0854	0.3353
Gradient Boosting Classifier	0.5694	0.0668	0.4782
Logistic Regression Classifier	0.5074	0.0791	0.6000
XGBoost Classifier	0.5638	0.0537	0.5188
Stacking Classifier	0.5937	0.0938	0.6000
Voting Classifier	0.5432	0.0902	0.6226

The evaluation of our machine learning models yielded valuable insights. Fig. 9 visually represents the heat maps for precision, recall, and F1-score, offering a comprehensive view of model performance across different classes. The confusion matrices of our top four classifiers provide a detailed perspective on their performance. Fig. 10 displays these matrices in a clear and interpretable heatmap format.

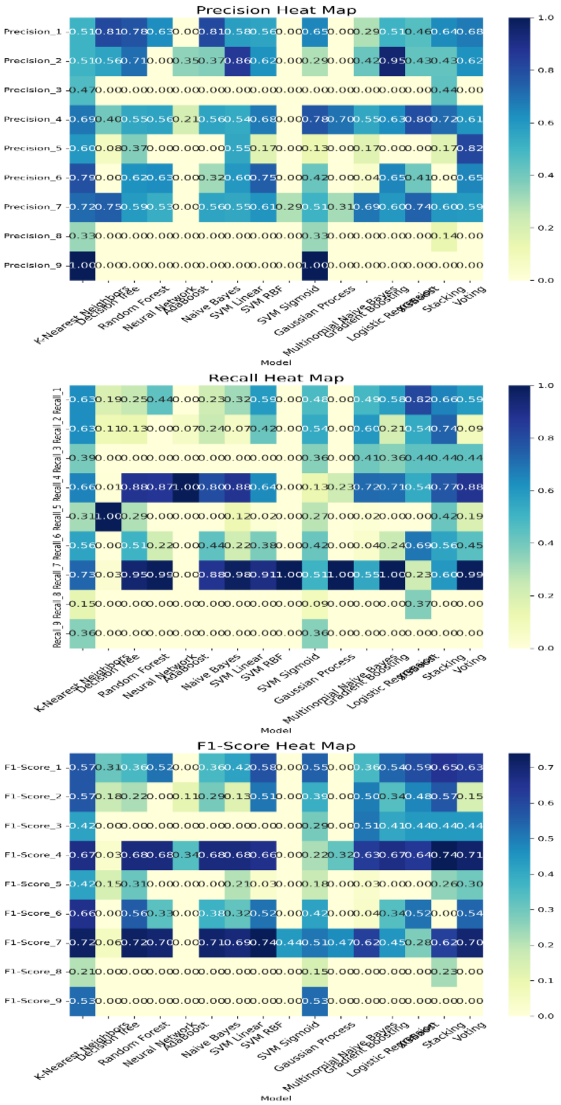


Fig. 9. Shows heat maps for precision, recall, and f1-score for multiple machine learning models across different classes or categories. for response coding dataset.

E. One Hot Encoding Results

The performance of various classifiers on the One-Hot Coding dataset is summarized in Table V, it provides insights into cross-validation mean accuracy, standard deviation, and test set accuracy for each classifier. The evaluation of our machine learning models on the One-Hot Coding dataset yielded valuable insights. Fig. 11 visually represents the heat maps for precision, recall, and F1-score, offering a comprehensive view of model performance across different classes. To gain deeper insights into the performance of our top-performing classifiers on the One-Hot Coding dataset, Fig. 12 displays heatmaps for the confusion matrices. These heatmaps provide a clear visual representation of the classification results.

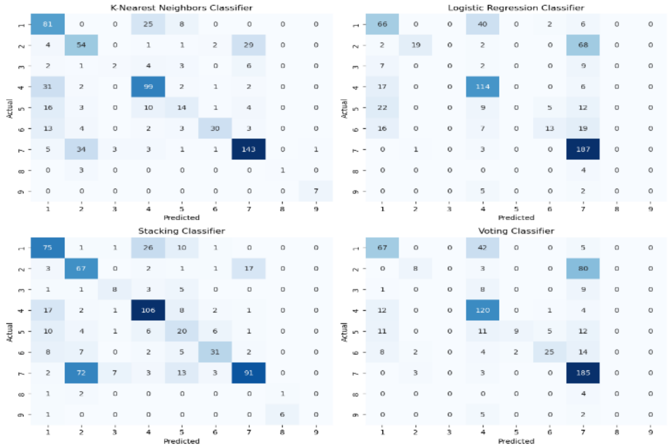

Fig. 10. The figure shows heatmaps for the confusion matrices of four best classifiers for response coding dataset.

TABLE V. DISPLAYS THE CROSS-VALIDATION MEAN ACCURACY, STANDARD DEVIATION, AND TEST SET ACCURACY FOR EACH CLASSIFIER FOR ONEHOT CODING DATASET

Classifier	Cross-Val. Mean	Cross-Val. Std	Accuracy on Test
K-Nearest Neighbors	0.558	0.043	0.632
Decision Tree	0.564	0.055	0.132
Random Forest	0.569	0.080	0.576
MLP (Neural Network)	0.506	0.069	0.556
AdaBoost	0.477	0.047	0.215
Gaussian Naive Bayes	0.115	0.036	0.526

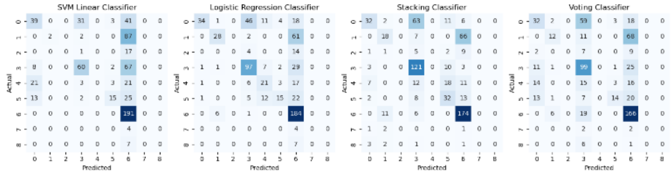

Fig. 12. The figure shows heatmaps for the confusion matrices of four best classifiers for one hot coding dataset.

V. Discussions

A. Integration of Genetic and Textual Data

The primary objective of this study was to investigate the utility of machine learning methods for integrating genetic and textual data [13] to improve the classification of genetic variations in precision medicine. Precision medicine aims to tailor medical treatment and interventions to individual patients [6], taking into account their genetic makeup and specific characteristics. Genetic variation classification plays a pivotal role in this context, as it enables the identification of genetic factors that may influence disease susceptibility, treatment response, and overall patient outcomes. By improving the accuracy of genetic variation classification, we can enhance the precision and effectiveness of personalized medical approaches.

B. Feature Selection and Importance

One key aspect of our approach was the careful selection of features from both the genetic and textual domains. While feature importance analysis provides valuable insights into the contribution of specific features to the model's predictions, it is important to note that this analysis does not necessarily imply causality. Establishing causal relationships between features and the target variable remains a challenging and ongoing area of research.

C. Model Performance and Deep Learning

Our experiments showed that the machine learning models, specifically the Stacking Classifier and Voting Classifier, outperformed individual models when integrating genetic and textual information. The Stacking Classifier combines multiple base models, allowing them to complement each other's strengths, while the Voting Classifier aggregates the predictions of multiple models. This approach proved effective in capturing complex relationships between genetic variations and textual data, leading to improved classification performance. Although our study did not extensively explore deep learning models, it is worth mentioning that deep learning architectures, such as neural networks, have demonstrated promise in learning intricate non-linear relationships between features and target variables. Future research could delve deeper into the potential benefits of deep learning in the context of genetic variation classification.

D. Clinical Relevance and Impact

The successful integration of genetic and textual data using machine learning methods holds great promise in advancing the field of precision medicine [2]. This approach can lead to the development of new diagnostic tools that leverage a patient's genetic and clinical history for more accurate disease diagnosis. Furthermore, it enables the prediction of patient responses to treatment, aiding clinicians in selecting the most appropriate therapeutic interventions. Ultimately, the guidance provided by our approach can lead to personalized treatment decisions that maximize the chances of positive patient outcomes and contribute to more efficient healthcare delivery [38].

E. Limitations and Future Directions

While our study achieved promising results, several limitations warrant consideration. The availability and quality of genetic and textual data can vary, impacting model performance and generalizability. To address this, future research should focus on data curation and validation on larger and more diverse datasets, spanning various medical conditions and populations. Additionally, advanced techniques for data integration, such as multi-modal learning and transfer learning, should be explored to enhance disease classification in precision medicine. Furthermore, investigating the integration of additional data modalities, such as medical imaging or clinical records, can offer a more comprehensive understanding of patients' health and contribute to more accurate predictions. Addressing these challenges and pursuing these directions will be essential in realizing the full potential of data integration in the era of personalized medicine. In conclusion, this study demonstrates the potential of machine learning methods to harness the synergistic power of genetic and textual data for genetic variation classification in precision medicine. While challenges persist and further research is needed, our findings represent a significant step toward realizing the clinical benefits of data integration in the era of personalized medicine.

VI. Conclusion

In this paper, we have presented a machine learning-based approach for classifying genetic mutations based on associated clinical evidence. Our model integrates gene, variation, and text information to achieve accurate and efficient classification. Our experimental results on the MSK-Redefining Cancer Treatment dataset demonstrate the effectiveness of our approach, with the Stacking Classifier achieving the highest cross-validation and test set accuracies of 62%. While our accuracy is promising, there is still room for improvement. Future research could investigate the use of deep learning algorithms, or the incorporation of additional data types, such as imaging data or environmental data. Additionally, we could explore different ways to encode and represent the gene, variation, and text information, as well as different ways to train and evaluate our model. Despite these limitations, we believe that our work has the potential to make a significant impact on the field of precision medicine. By enabling more personalized and effective treatments for patients with genetic variations, we can help patients to live longer and healthier lives. Our work could also be used to identify patients who are at risk of developing certain diseases, based on their genetic profile and medical history. This could lead to earlier diagnosis and treatment, which could improve patient outcomes and reduce the cost of healthcare. We encourage other researchers to explore and extend our work to develop even more powerful and effective methods for integrating genetic and textual information for genetic variation classification. We believe that this is a promising area of research with the potential to revolutionize the way we diagnose and treat genetic diseases. We are committed to advancing the field of genetic variation classification, and we hope that our work will inspire others to do the same.

Acknowledgment

I would like to acknowledge my sincere gratitude to my guide, Associate Professor Dr. Nellutla Ravinder, Department of CSE, Koneru Lakshmaiah Education Foundation (K L University), Vaddeswaram, AP, for his valuable guidance, support, and encouragement throughout the course of this research work. His expertise, insights, and patience have been instrumental in helping me complete this research paper successfully.

Abstract—**Eliminating security threats on the Internet of Things (IoT) requires recognizing threat attacks. IoT and its implementations are currently the most common scientific field. When it comes to real-world implementations, IoT's attributes, on the one hand, make it simple to apply, but on the other hand, they expose it to cyber-attacks. Denial of Service (DoS) attack is a type of threat that is now widespread in the field of IoT. Its primary goal is to stop or damage service or capability on a target. Conventional Intrusion Detection Systems (IDS) are no longer sufficient for detecting these sophisticated attacks with unpredictable behaviors. Machine learning (ML)--based intrusion detection does not need a massive list of expected activities or a variety of threat signatures to create detection rules. This study aims to evaluate different ML classifiers for network intrusion detection that focus on DoS attacks in the IoT environment to determine the best ML classifier that can detect the DoS attack. The XGBoost, Decision Tree (DT), Gaussian Naive Bayes (NB), Random Forest (RF), Logistic Regression (LR), and Support Vector Machine (SVM) ML classifiers are used to evaluate the DoS attack. The UNSW-NB15 dataset was used for this study. The obtained accuracy rate for XGboost was 98.92%, SVM 98.62%, Gaussian NB 83.75%, LR 97.74%, RF 99.48%, and DT 99.16%. where the precision rate for XGboost, SVM, Gaussian NB, LR, RF, and DT was 98.40%, 98.29%, 77.50%, 97.14%, 99.21%, and 99.12%, respectively. The sensitivity rate for XGboost, SVM, Gaussian NB, LR, RF, and DT was 99.29%, 98.76%, 91.87%, 98.06%, 99.69%, and 99.08%, respectively. The results show that the RF classifier outperformed other classifiers in terms of Accuracy, Precision, and Sensitivity.**

Keywords—Cybersecurity; IDS; DOS attack; IoT; machine learning

I. Introduction

The IoT consists of various physical objects such as machines, vehicles, and structures equipped with sensors, software, and connectivity that enable them to accumulate and transmit data. In addition, these devices can communicate with one another and the Internet, allowing them to send and receive data and be remotely controlled. Intelligent appliances, wearable technology, industrial equipment, and thermostats with Internet connectivity are a few examples of IoT devices, With the help of the IoT, several processes can be automated, and massive amounts of data can be collected. These benefits include increased productivity, lower costs, and better user experiences. Additionally, it opens new avenues for researchers' innovation.

IoT security has become a big problem as connected devices increase [1]. IoT devices are susceptible to hacking and other cyber-attacks since they frequently have low processor speed, memory capacity, and security features. Device spoofing, Man-in-the-Middle attacks, DoS, Ransomware, and unauthorized access are a few common types of IoT attacks [2] [3] [4]. The DoS attack [5] is a kind of cyberattack in which the attacker tries to block access to a device or network by legitimate users by flooding it with uncontrollable data. This can be done by deploying a botnet, or network of infected devices, to flood the target device or network with a lot of traffic, making it unavailable. Security techniques like firewalls, IDS, and traffic filtering can be used to detect and prevent malicious traffic from defending against DoS attacks in IoT [6] [7] [8].

IDS [9] [10] [11]security techniques keep a watch out for illegal behavior on a network and notify an admin of any severe violations or attacks. They can spot various security risks, including malware, illegal access, and (DoS) attacks. IDS has two types [12, 13]. Network-based IDS (NIDS) monitors network activity for any improper behavior. To monitor all incoming and outgoing traffic, they are frequently positioned at crucial nodes on a network, such as a firewall or a router. Host-based IDS (HIDS): this type keeps a watch on what is going on with a particular host or device, like a server or an IoT device. They can identify unwanted access to or alterations to host-based data and settings.

ML approaches can be used to increase the accuracy, precision, and effectiveness of IDS in identifying security attacks like DoS. ML is divided into three approaches. First, Supervised learning: This approach trains a model to categorize network traffic as benign or malicious using labeled data. This approach is trained to recognize well-known harmful patterns that are frequently used for signature-based intrusion detection. Secondly, Unsupervised learning, when labeled data is unavailable, unsupervised learning is the preferred option. The model is trained to spot data anomalies or patterns that differ from expected behavior. Unknown or zero-day attacks can be found using this approach. Finally, the Semi-supervised learning approach mixes supervised and unsupervised learning by training the model on a mixture of labeled and unlabeled data.

IDS-based ML was developed to detect suspicious behavior in the IoT environment. XGBoost, Gaussian NB, DT, RF, LR, and SVM ML classifiers were used to construct the IDS. The developed IDS's primary objective is to assess the efficacy of detecting DoS attacks in an IoT environment. The following is the paper's contributions:

1) An intelligent IDS with high detection accuracy, precision, sensitivity, and F-measure, capabilities to detect DoS attacks in the IoT.

2) Experiments demonstrate the operation of several ML classifiers and their impact on DoS attacks in an IoT environment.

3) Random Forest classifier shows the superiority of detecting DoS attacks in an IoT environment.

The remainder of the paper is organized as follows: Section II covers the background, Section III covers the history and related works, and Section IV illustrates the suggested IDS model. Next, the experimental research design and results are stated in Section V. Finally, Section VI concludes the paper's work and findings.

II. Background

This section provides an overview and background information related to the topic under investigation in this paper.

A. IoT

IoT technology was developed by Kevin Ashton in 1999 [14]. The IoT is defined as the interconnection of physical objects such as furniture, cars, buildings, and other things that are connected to the Internet and have electronics, software, sensors, and network connectivity built into them [15, 16]. This makes it possible to create modern software and services for several areas, including manufacturing, healthcare [17], transportation, and smart cities, that can boost productivity, decrease costs, and increase convenience [18]. IoT architecture will develop because of the increased use of IoT technology. Fig. 1 depicts the evolution of IoT architecture.

IoT applications can be broken down into three layers: application, transport, and perception. IoT devices are becoming more common, but the variety of applications for these devices raises questions about security and privacy [20]. Additionally, the distinctive features of IoT pose particular security issues, such as handling, preserving, and protecting the private data that these devices frequently collect. Due to the multiple vulnerabilities in IoT applications, they are vulnerable to various cyber threats. Several security and privacy issues have been documented on IoT apps worldwide, such as the Mirai attack, DOS, and Distributed Denial-of-Service (DDOS) attacks. Fig. 2 shows the types of attacks in IoT.

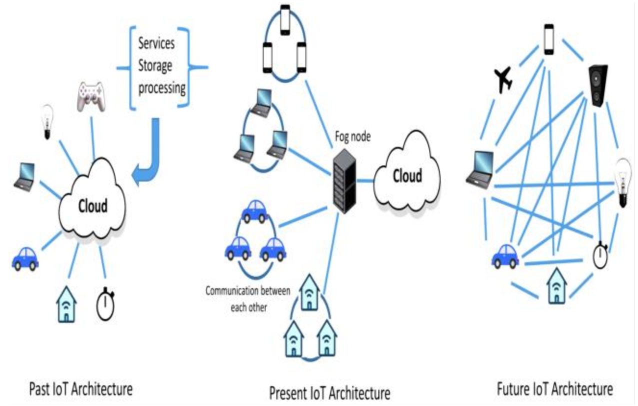

Fig. 1. Evolution of IoT architecture [19].

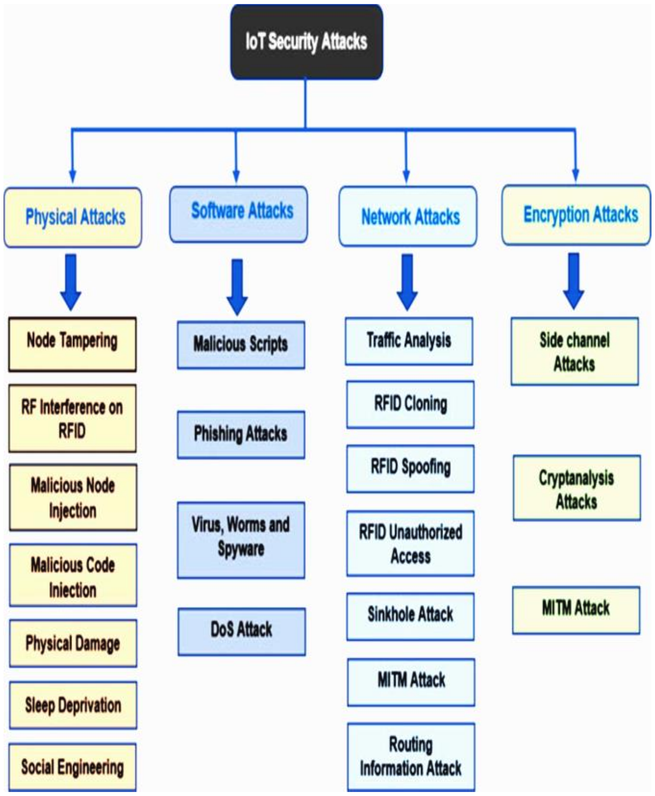

Fig. 2. IoT attack types [21].

For IoT technology to be broadly used, experts and scientists agree that guaranteeing the security of IoT applications is a significant barrier that must be surmounted. Users should have complete confidence in IoT devices and application security. In addition, they must guarantee that their equipment is safe from known threats. as they become increasingly integrated into daily routines. IDS protects IoT networks and devices from harmful activities and illegal access.

B. IDS

An IDS is a technology that examines computer or network systems for any indications of illegal access or policy violations. This can be accomplished by using a host-based or network-based method, and it can be achieved using various tools, including hardware, software, or a combination of them. IDSs use a variety of detection methods to find potentially dangerous activities, including anomaly-based IDS (AIDS) and signature-based IDS (SIDS) [12, 13]. The IDS can alert system administrators to suspicious activity, log the incident, or take action to stop future intrusion when it is identified. SIDS, also known as Misuse Detection [22], uses pattern-matching algorithms to find known threats. An alarm is triggered when an intrusion is discovered that matches an intrusion signature previously stored in a SIDS system's database. After that, the system searches the host's logs for groups of commands or actions formerly known to be malicious. While SIDS systems typically have excellent detection accuracies for known intrusions, they may have difficulty detecting zero-day attacks since the database does not yet contain the signature of the new threat. To solve the problem of detecting zero-day attacks, AIDS is used.

Because it can surpass SIDS' limitations, AIDS has attracted much interest from researchers. AIDS creates a computer system behavior model based on machine learning, statistical, or knowledge-based techniques. An anomaly, which is viewed as an intrusion, is any significant divergence from the model. This set of methods is predicated on malicious conduct deviating from user behavior. AIDS can identify unknown or zero-day attacks because It is independent of signature databases. Such as SIDS to detect abnormal behavior.

IDS divided the data into two groups depending on the input source: Host IDS(HIDS) and Networks IDS (NIDS). HIDS analyzes data from the host system, including sources such as operating system logs, firewall logs, and database logs. IDS can recognize insider attacks that don't use network traffic, where the NIDS analyzes information from sources like packet capture to keep track of network activity. It can be utilized to monitor several computers linked to a network and detect early signs of external malicious activity before it spreads to other systems. To identify abnormal activity, ML algorithms, including XGBoost, TD, RF, Gaussian NB, LR, and SVM, have been used in the AIDS domain. The following section explains the ML algorithms used in this paper.

C. ML Classifiers

ML is a technique for instructing computers to learn from data without explicit programming. It is a subfield of artificial intelligence that enables systems to improve automatically over time. Supervised, unsupervised, and reinforcement learning are the three main types of machine learning [23, 24]. Supervised learning solves issues when the only available data consists of labeled instances. Unsupervised learning is used to find the pattern of unlabeled data. With reinforcement learning, a computer agent learns to perform a task by repeatedly attempting it and modifying its behavior in response to the feedback it receives. The model that is trained to categorize input data into classes or categories is known as a classifier. There are numerous classifier varieties, each with unique advantages and disadvantages. The data's properties and the problem's nature determine which classifier should be used. For example, while some classifiers perform better when given high-dimensional data, others perform better with fewer features. Furthermore, although some classifiers are more susceptible to noise or outliers in the data, others are more resistant. This study selects the following Supervised learning classifiers to detect the DoS attack in IoT Environments because they have been extensively utilized in previous research on the detection of DoS attacks.

- XGBoost

XGBoost stands for Extreme Gradient Boosting, extending a version of gradient boosting [25]. It is solid and compelling, handling big datasets and producing reliable predictions. The XGBoost operates by creating a model made up of several decision trees. It begins by using the input data to train a straightforward decision tree and iteratively adds new decision trees to the model while fixing the flaws in the earlier trees. A more potent and precise model is produced due to this procedure, which is referred to as boosting. Additionally, the XGBoost provides many features, including support for missing values, management of categorical variables, and handling of imbalanced data. Additionally, it has built-in regularization to avoid overfitting and supports parallel processing to quicken the training process.

- DT

DT is a supervised ML classifier that can be used to solve classification issues [26]. It builds a tree-like model of choices and their potential effects, with each internal node standing in for a feature or attribute and each leaf node for a class label. The method recursively separates the data according to the feature values starting at the root node until it reaches a leaf node. This leaf node's class label is then used as the anticipated class for the incoming data. Decision trees are straightforward to use, easy to grasp, and capable of handling category and numerical data. But if the tree is too deep or complicated, it could be prone to overfitting.

- RF

An RF is a kind of ensemble learning classifier for classification and regression that builds several DTs during training. It produces the class that represents the mean of the classes (classification) or mean prediction (regression) of the individual trees [26]. The model performs better overall and has less overfitting when numerous decision trees are created, as opposed to depending just on one. The name's "random" component alludes to the randomly selected subsets of data that were used to train each DT.

- LR

LR attempts to calculate the chance of a particular outcome given a specific input variable. This outcome is generally binary, meaning it is composed of two possible values, such as true or false, yes or no, and so on. Multinomial logistic regression can be used to address regression with more than two possible outcomes. Logistic regression is instrumental in discovering which group a novel sample is most like. Furthermore, it is beneficial in cyber security since most security issues are categorization problems, such as recognizing attacks.

- SVM

SVM, a supervised learning technique, can be applied to classification and regression problems [27]. The fundamental goal of SVM is to identify the optimal boundary (or hyperplane) for classifying the data into multiple groups. A boundary's margin, or the distance between it and the nearest data points from each class, should be maximized to be considered the optimal boundary. Support vectors refer to these nearby data points. By determining which side of the border additional data points fall on once the boundary has been identified, it is simple to classify them. By translating the data into a higher dimension where it may be linearly separable, SVM can also be utilized for data that cannot be separated linearly.

D. DoS Attack

A DoS is a type of cyberattack [28] in which the attacker tries to prevent the targeted users from using a computer resource by flooding it with a lot of traffic or requests. For example, a program, network, or website may be the target of a DoS attack to deny access to legitimate users. DoS attacks come in a variety of forms, including:

- Flooding attacks, such as network flood attacks that saturate networks with large packets, overload a targeted resource with traffic.
- Amplification attacks, increase the amount of traffic directed at a targeted resource by making use of a flaw in it, such as a Domain Name System (DNS) amplification attack that makes use of a DNS server to increase traffic to a targeted resource.
- Application-layer attacks, such as a Hypertext Transfer Protocol (HTTP) request flood attack that floods a targeted website with HTTP requests, target certain flaws in an application.

Using firewalls, IDS, machine learning, and other security measures can assist in detecting and preventing DoS attacks. The following section will review research that researchers did to develop IDS that could detect DoS attacks in the IoT using machine learning.

III. RELATED WORKS

This section investigates previous studies that are related to the works of this paper. Much research has been done using ML to detect DoS attacks in IoT environments. Here are a few of them that will be presented.

In a study by Shreekhand and Deepak [29], in this study, they proposed and implemented ML and neural network models based on Multilayer Perceptron (MLP) and RF for the detection of DoS attacks. The proposed model successfully identified application-layer DoS attacks. The findings indicate that, compared to the MLP algorithm, which offers an accuracy of 98.87%, the RF algorithm provides a better accuracy of 99.95%. The proposed model was examined with the CICIDS2017 dataset.

A study by Yasin. et al. [30], in this study, various ML classifiers have been examined for identifying various DDoS attacks. k-Nearest Neighbors (KNN), LR, MLP, naïve Bayes, SVM, RF, deep autoencoder, CatBoost, Stacking, and XGBoost classifiers are among the ML classifiers mentioned above. The most accurate classifiers are stacking random forest and catBoost. In addition, the proposed model has been examined with the Labris and Digiturk datasets.

A study by Naeem et al. [31], in this study, a model for detecting DoS attacks during Message Queuing Telemetry Transport (MQTT) attacks in the IoT is proposed. Averaged one-dependence estimators (AODE), C4.5, and MLP ML classifiers were used to validate the proposed model. The results show that the AODE classifier achieved the best classification accuracy in identifying the DOS attack.

Another study by Jiyeon Kim et al. [32], in this study, propose a Convolutional Neural Network (CNN) based algorithm for identifying DoS attacks by taking into account the size of the kernel and the number of convolutional layers and then comparing the proposed model with Recurrent Neural Networks (RNN). The proposed model has been examined with KDD and CSE-CIC-IDS 2018 datasets. The obtained results show that the CNN outperformed the RNN.

A study by Rios. In this study, et al. [33] proposes a model for detecting DOS attacks in communication networks based on a Broad Learning System (BLS) that produces high results with less time training. The proposed model has been examined with CICIDS2017 and CSE-CIC-IDS 2018 datasets. The results show that Non-incremental BLS frequently produced the highest accuracy and F-Score, although BLS with incremental learning typically required less training time.

In another study by Verma and Ranga [34], in this study, an extensive investigation into anomaly-based IDS for protecting IoT from DoS attacks is conducted for seven ML classifiers. These classifiers include the RF, Adaboost, Gradient Boosted Machine, XGBoost, Extremely Randomized Trees, classification and regression trees, and MLP. The investigation model has been examined with frequently used datasets, including CIDDS-001, UNSWNB15, and NSL-KDD. The statistical analysis of performance metrics is conducted using Friedman and Nemenyi post-host tests to identify significant differences between classifiers. The results show that classification, regression trees, and the XGboost classifier have the best response time.

In a study by Muhammad Zeeshan et al. [35], in this study, protocol-based deep intrusion detection is proposed for IoT networks. The proposed protocol aims to find similar features of UNSW-NB15 and the Bot-IoT by comparing them. The outcome of the comparison was extracting 26 features and combining normal packets from UNSW-NB15 and DoS/DDoS from Bot-IoT. Furthermore, the proposed protocol was trained using the Long short-term memory networks (LSTM) deep learning technique, and The results show that classification accuracy was 96.3%.

In a study by Alaeddine Mihoub et al. [36], in this study, a model is proposed for the IoT to identify and prevent DoS/DDoS attacks. The identification part of the proposed model is based on the multi-class classifier that adopts the "Looking-Back" concept. Used ML classifiers in the model are DT, RF, KNN, MLP, LSTM, and RNN. The model was tested and evaluated using the Bot-IoT dataset. The obtained results show that the Looking-Back-enabled RF classifier achieves the best accuracy.

In another study by Alimi et al. [37], in this study, a model is proposed for detecting DoS attacks in IoT based on a redefined LSTM deep learning approach. The model was tested and evaluated using NSL-KDD and CICIDS-2017 datasets. The conducted results show that the proposed model has a detection accuracy of 99.22% for DoS attacks on the CICIDS-2017. In comparison, the NSL-KDD dataset attained 98.60%.

In the study by Kimmi Kumari and M. Mrunalini [38], in this study, mathematical and ML model models have been proposed for DoS attack detection using Logistic Regression and Naive Bayes. The proposed models have been tested and evaluated using the CAIDA dataset 2007. The obtained results show the mathematical model is 99.75% accurate, while the ML model is 100% accurate.

IV. Proposed Model

Detailed step-by-step instructions of the proposed model and an explanation are provided in this section. Fig. 3 shows the proposed model flowchart.

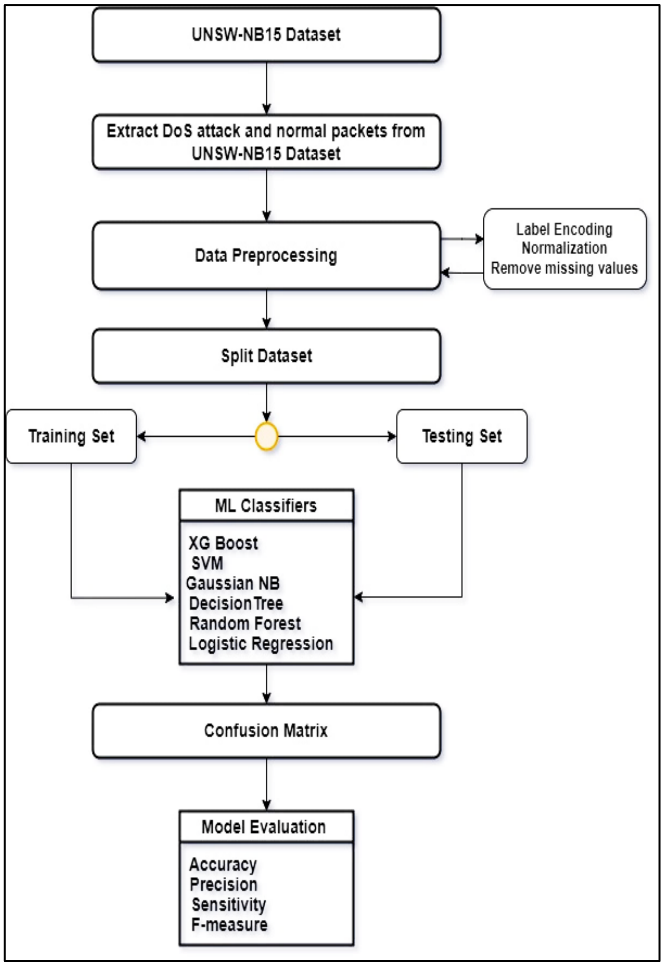

Fig. 3. Proposed model flowchart.

A. UNSW-NB15 Dataset

The University of New South Wales in Sydney, Australia, developed the network intrusion detection dataset known as UNSW-NB15 [39]. It is made to aid intrusion detection research and serve as a realistic testbed for evaluating IDS. It is frequently used for research and development of IDS because it comprises many actual network attacks as well as normal traffic. As a result, the dataset is commonly used in academic research projects and publications by the cybersecurity research community. The UNSW-NB15 dataset includes nine different kinds of network attacks, including worm attacks, backdoor attacks, DoS attacks, exploits attacks, fuzzers attacks, generic attacks, reconnaissance attacks, shellcode attacks, and generic attacks. Fig. 4 shows the attack distribution of the UNSW-NB15 dataset.

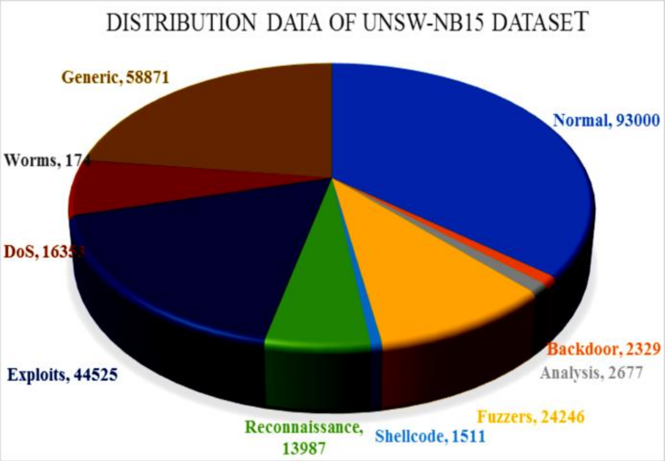

Fig. 4. Attack in the UNSW-NB15.

This paper focuses on the DoS attack; therefore, the DoS attack and normal traffic have been extracted from the UNSW-NB15 dataset.

B. Dataset Preprocessing

The following preprocessing procedures must be done on the UNSW-NB15 dataset before it can be used with the proposed models.

- Label Encoding: In this stage, the category variables are transformed into numerical form so that algorithms can interpret them. This encoding process is accomplished by giving each category in the dataset an individual number. This is helpful since many ML algorithms perform better with numerical data than category data. Reduced data dimensions and enhanced model performance are two benefits of label encoding. The Label Encoding is done using The Scikit-Learn Library's preprocessing module in Python.

- Normalization: Normalization is a technique used in dataset processing by transforming and scaling data to fit inside a predetermined range. The purpose of doing this is often to lessen the influence of outliers and guarantee that the data falls within a close range. The Min-Max normalizing method is a popular approach where the data is often between 0 and 1. The following formula can be used to normalize a value x using the Min-Max normalization:

$$\text{Min/Max normalization} = \frac{x - \min(x)}{\max(x) - \min(x)} \tag{1}$$

- Remove the missing: In a dataset, removing the missing value is a part of the cleaning process that eliminates errors, inconsistencies, and unwanted information. This process ensures that the data is accurate, consistent, and prepared for analysis easier. There are several ways to remove missing values (NaN values) from a dataset using Python. The dropna() method from the Pandas library and the fillna() method to replace a given value for missing values were used.

C. Dataset Splits

Dataset splitting is breaking up a large dataset into more manageable chunks for uses like model testing and training. A dataset is frequently divided into Training sets: this is the primary dataset used to train a model. It is utilized to discover the underlying patterns in the information and contains a sizable amount of data. Testing set: The test set is used to evaluate how well the trained model has worked in practice. It contains data, the model hasn't seen before and estimates how well it performs on actual data.

The split ratios for training and test sets vary depending on the size and complexity of the dataset, but a typical split ratio is 70–30. (Training - Test). Therefore, ensuring the split is accurate and the various subgroups do not overlap is crucial. Python's most used data split method is train_test_split from the scikit-learn library.

D. ML Classifiers

An ML classifier is used to categorize incoming data as either abnormal or normal. The XGBoost, DT, RF, NB, LR, and SVM classifiers are discussed in detail in Section II(C). Because these are the most well-known classifiers used in the literature for IDS, these classifiers were chosen.

E. Confusion Matrix and Model Evaluations

In machine learning, a confusion matrix is a table that assesses how well a classification model performs. It lists the model's accurate and inaccurate predictions based on a test data sample. True Positives (TP), False Positives (FP), True Negatives (TN), and False Negatives (FN) are the confusion matrix's four main components. These components are used to produce some metrics, including F1-score, recall/sensitivity, accuracy, and precision, which provide a comprehensive picture of the model's performance.

$$\text{Accuracy}=(TP+TN)/(TP + TN +FP +FN \quad (2)$$

$$\text{Precision}= TP /(TP + FP) \quad (3)$$

$$\text{Recall}= TP /(TP + FN) \quad (4)$$

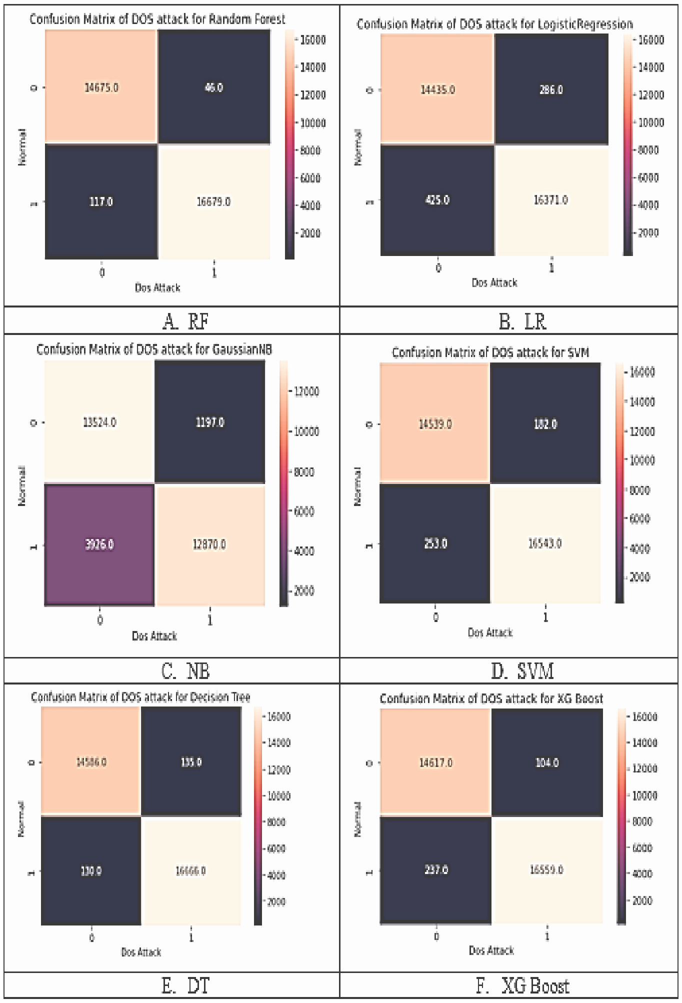
$$\text{F-Measure} =(2 \times \text{Precision} \times \text{Recall})/(\text{Precision}+\text{Recall}) \quad (5)$$

V. Experimental Design and Results

This section presents the Experiment Design and Results

A. Experimental Design

The model was evaluated using Windows 7 and an i7 processor running at 3.40 GHz with 6.0 GB of RAM. The experiments were conducted using the open-source Anaconda (spider) for the UNSW-NB15 datasets under both normal and DoS attacks. Scikit-learn tools in Python were used to implement the model. This model uses the classifiers DT, RF, NB, LR, and SVM. The obtained confusion matrix of prediction for several classifiers is shown in Fig. 5.



A. RF

B. LR

C. NB

D. SVM

E. DT

F. XG Boost

Fig. 5. Confusion matrix of each classifier.

Table I presents the outcomes of the model's assessment metrics by employing the confusion matrix, which was attained, as depicted in Fig. 7.

TABLE I. PERFORMANCE METRICS RESULTS

	Accuracy	Precision	Sensitivity	F-measure	TP	FN	FP	TN
XG Boost	**98.9**	**98.4**	**99.2**	**98.8**	**99.2**	**0.7**	**1.4**	**98.5**
SVM	**98.6**	**98.2**	**98.7**	**98.5**	**98.7**	**1.2**	**1.5**	**98.4**
NB	**83.7**	**77.5**	**91.8**	**84.0**	**91.8**	**8.1**	**23.3**	**76.6**
LR	**97.7**	**97.1**	**98.0**	**97.6**	**98.0**	**1.9**	**2.5**	**97.4**
RF	**99.4**	**99.2**	**99.6**	**99.4**	**99.6**	**0.3**	**0.7**	**99.3**
DT	**99.1**	**99.1**	**99.0**	**99.1**	**99.0**	**0.9**	**0.7**	**99.2**

B. *Finding*

The obtained results of this study are analyzed in this section. As seen in Fig. 6, the accuracy of the various ML classifiers is demonstrated. Accuracy is the percentage of accurate predictions made by a classifier in comparison to the actual value of the label. The accuracy rate for XGboost was 98.92%, SVM 98.62%, NB 83.75%, LR 97.74%, RF 99.48%, and DT 99.16%. According to the data collected, the RF classifier outperformed the other classifiers in terms of accuracy due to the following, the RF comprises Multiple decision trees, therefore, it has less classification error. A measure of precision is a percentage that shows what proportion of the objects the classifier recognized are accurate forecasts. For example, the precision for XGboost, SVM, NB, LR, RF, and DT in Fig. 7 is 98.40%, 98.29%, 77.50%, 97.14%, 99.21%, and 99.12%, respectively. The outcomes show that the RF classifier was more precise than the other classifiers.

Sensitivity, also known as recall or true positive rate, is a commonly used metric in machine learning to evaluate binary classification models. It indicates the number of true positive cases the classifier correctly categorized as positive. Sensitivity values for XGBoost, SVM, NB, LR, RF, and DT as in Fig. 8, 99.29%, 98.76%, 91.87%, 98.06%, 99.69%, and 99.08%, respectively. The obtained Sensitivity values demonstrate the superiority of RF classifiers over other classifiers. A classifier's performance can be assessed using the F-measure since it considers both the precision and sensitivity values. This metric is beneficial when there is an uneven distribution of positive and negative classifications. F-measure values for XGBoost, SVM, NB, LR, RF, and DT as in Fig 9, 98.85%, 98.53%, 84.08%, 97.60%, 99.45%, and 99.10%, respectively. The results show that RF classifiers outperform other classifiers regarding F-measure values.

From the analysis mentioned above, the following conclusions can be drawn:

1) *RF* is the best classifier to detect the DoS attack in an IoT environment compared to XGBoost, DT, NB, LR, and SVM.

2) *Gaussian* NB is the worst classifier to detect the DoS attack in an IoT environment.

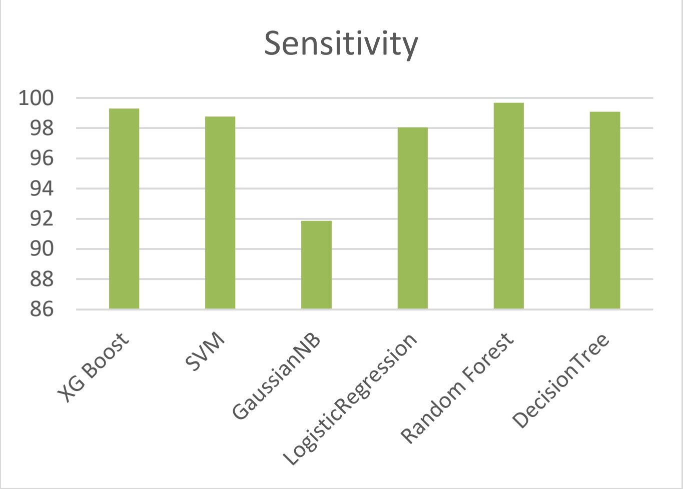

Fig. 8. Sensitivity of ML classifiers.

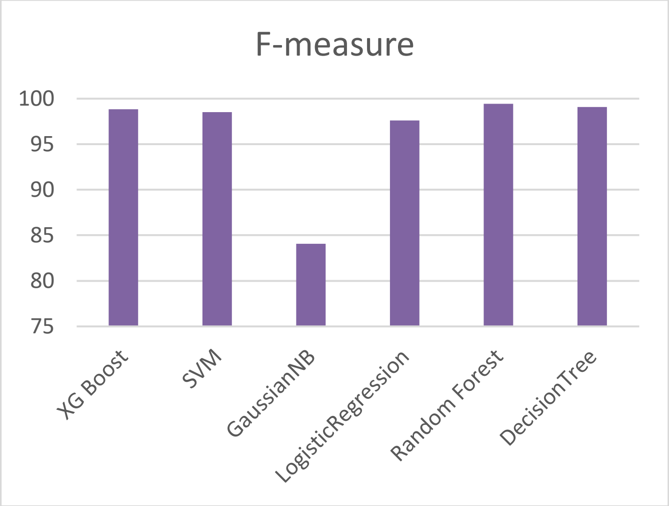

Fig. 9. F-Measure of ML classifiers.

VI. Conclusion and Future Works

Security measures must be included in IoT environments to prevent and combat DoS attacks. Therefore, this paper introduced an IDS model using XGBoost, DT, RF, NB, LR, and SVM to detect DoS attacks in the IoT environment on the UNSW-NB15 datasets. The outcomes of the model were examined using the confusion matrix. Accuracy, precision, sensitivity, and F-Measure were used to evaluate the model's performance. The obtained experimental data proves that the RF is the most efficient classifier among other examined classifiers to detect DoS attacks in IoT environments. Its accuracy was 99.48%, precision 99.21%, sensitivity 99.69%, and F-Measure 99.45%. This study was limited to evaluating some of the ML classifiers with specific attacks. In the future direction of the research, the modern dataset for IDS and other types of DoS attacks, such as (DDoS) attacks, deep learning, and reinforcement learning approaches will be considered to examine the model performance.

Improving the Trajectory Clustering using Meta-Heuristic Algorithms

Haiyang Li*, Xinliu Diao
Department of Basic Courses, Henan Polytechnic Institute, Nanyang Henan 473000, China

***Abstract*—The rapid growth of GPS trajectories obscures valuable information regarding urban road infrastructure, urban traffic patterns, and population mobility. An innovative method termed trajectory regression clustering is introduced to improve the extraction of hidden data and generate more precise clustering results. This approach belongs to the unsupervised trajectory clustering category and has the objective of minimizing the loss of local information inside the trajectory. It also seeks to prevent the algorithm from getting stuck in a suboptimal solution. The methodology we employ consists of three primary stages. To begin with, we present the notion of trajectory clustering and devise a distinctive approach known as angle-based partitioning to segment line segments. The evaluation results indicate a significant improvement in the clustering accuracy of the proposed method compared to existing methodologies, especially for a high number of clusters. The HCMGA and HCMMOPSO algorithms have improved clustering accuracy for MBP values by 0.61% and 0.64%, respectively, as compared to previous approaches. Moreover, based on the implementation findings, the ant colony approach demonstrates superior accuracy compared to alternative methods, while the particle swarm method exhibits faster convergence.**

Keywords—Ant colony method; particle swarm algorithm; HCM clustering; and trajectory lines

I. Introduction

An analysis of the travel characteristics of moving objects, such as automobiles and individuals, can provide insights into travel patterns. This analysis reveals information about people's frequent travel habits, patterns of traffic congestion, and social activity patterns [1]. Travel patterns have been utilized in various domains, such as furnishing decision-making data for urban planning and emergency situations [2], analyzing and optimizing routes to offer personalized travel suggestions for residents, dispatching vehicles [3], and optimizing and selecting stations [4]. These applications can provide valuable insights for urban construction and growth. The authors in Reference [5] proposed a method that takes into account the road network while clustering road segment spatial trajectories. This method was designed to replace density-based clustering and Euclidean-based distance calculations, with the goal of achieving faster and more efficient clustering. The algorithm described in reference [6] is a scalable and efficient density clustering method that utilizes big data computing. In addition, the authors of Reference [7] introduced an enhanced density-based technique specifically designed for clustering stops in trajectories. The study described in Reference [8] introduced a clustering approach based on anisotropic density (angle-based standard deviation). This algorithm was utilized to identify spatial point patterns along with any accompanying noise.

Typically, clustering techniques can be classified into many categories such as density-based, partitioning-based, grid-based, hierarchical-based, and graph-based. These algorithms are extensively used in spatial data processing for a variety of purposes. In addition, each of these categories encompasses other renowned clustering algorithms, such as partitioning-based K-means, K-median, and fuzzy C-means (HCM), each with its own distinct advantages and disadvantages. Specifically, density-based clustering algorithms are commonly employed to extract concealed information from a given dataset and process any GPS datasets, since they are especially well-suited for identifying clusters with irregular forms and identifying clusters that do not overlap [9, 10, 11]. Nevertheless, managing the intersecting clusters (such as trajectory crossover) becomes challenging when dealing with fuzzy clusters and the absence of localized trajectory information. Furthermore, it is responsive to both the specified neighborhood and the density, as determined by the value of MinPts. This research specifically examines partitioning-based techniques, such as HCM. Nevertheless, they exhibit certain limitations, such as being susceptible to the choice of initial cluster centers, delayed convergence, and a propensity to get trapped in local optima. In this paper, a new trajectory regression clustering technique is introduced. The technique is based on partition clustering and combines the AngPart method, which generates line segments based on angles, with the HCML algorithm, a Lagrange-based fuzzy C-means clustering algorithm, and the LSR model, which is used to create an unsupervised trajectory clustering method. This method is an alternative to using a map-based knowledge base. Specifically, HCML is an innovative approach for clustering regression data without the need for supervision. Initially, a line segment partitioning technique is developed to generate line segments using three GPS data points. This method efficiently preserves the local information of trajectories. The novel clustering algorithm presented in this study combines a unique fuzzy C-means (NHCM) with the Lagrange operator [12] and Hausdorff-based K-means++ [13]. The NHCM is employed to cluster line segments, while K-means++ is utilized to generate the initial cluster centers of the line segments. This combination aims to capture the global optimum and prevent the algorithm from getting trapped in local optima. The original fuzzy C-means (HCM) technique is a clustering approach based on partitioning [14]. In this algorithm, the computation of distances between line segments requires the use of Hausdorff distances instead of Euclidean distance [15]. Once the concealed GPS data is extracted and acquired, the LSR (Least Squares Regression) method is utilized to perform trajectory regression. The objective is to regress and generate trajectories based on the clustering results, without relying on a map-based knowledge base. These trajectories can then be used to analyze and describe various urban aspects such as people, vehicles, roads, traffic flow, and serve as a reference for road planning.

Background: HCML can enhance line segment partitioning and maintain the local information of trajectory by employing the angle-based technique prior to the clustering process. For instance, when two GPS data points are produced as line segments, it becomes challenging to articulate the local information between GPS data points and to comprehend the connection between consecutive GPS points, such as the alteration in steering and intersecting angle.

Furthermore, the method being discussed, HCML, is a form of unsupervised learning. Hence, in cases when a map-based knowledge base is not required, the least squares regression model (LSR) is employed to generate the trajectories of the clustering outcomes.

Problem: In order to assess the performance and efficacy of HCML, an actual GPS dataset from Beijing, China is employed as an experimental test. The experiments involve comparing HCML with K-median, K-means, and HCM clustering methods using the MBP (Pakhira-Bandyopadhyay-Maulik)-index [26] cluster evaluation criteria. This is discussed in Section 2. The MBP-index is an effective unsupervised evaluation tool [27,28]. However, it is important to be aware that distances in the MBP-index necessitate the utilization of the Hausdorff method for calculating the distance between the center of line segments and other line segments. Furthermore, LSR is employed to accomplish the regression of the clustering outcomes. The experimental findings demonstrate that HCML outperforms K-means, K-median, and HCM algorithms in terms of trajectory regression quality (refer to Section 5).

Proposed Solution: Thus, the primary content of the study is succinctly outlined as follows:

1) The angle-based partitioning method (AngPart) is offered as a strategy for generating unique line segments.

2) This study proposes a novel clustering technique called fuzzy C-means (NHCM), which integrates the Lagrange operator with AngPart and K-means++.

3) This paper introduces a trajectory regression technique that utilizes least squares regression (LSR) to analyze population movement patterns along trajectories. The technique provides insights into the state of population migration and can serve as a valuable reference for urban road planning.

4) HCML has been demonstrated to be effective when used to actual taxi GPS data in Beijing, China.

The subsequent sections of the paper are arranged in the following manner. Section II provides a description of taxi GPS data in Beijing, China. Section III presents the angle-based normalization method employed for the taxi GPS data. Section IV introduces a trajectory regression technique that combines HCML with LSR. Section V outlines the tests and offers the data for evaluating the effectiveness of the recommended procedures. Section VI serves as the final part of the report, providing a conclusion and proposing potential future research.

II. Related Works

The integration of information technology into transportation systems is currently a prominent trend. This is because it effectively addresses key issues faced by traffic operators, such as traffic congestion and accidents. Therefore, observing the traffic situation is essential for traffic operators, particularly at intersections [16]. The traffic data obtained from the monitoring system is frequently extensive, necessitating diligent attempts to identify noteworthy trends within it. These patterns provide valuable insights into vehicle movements and facilitate the detection of any deviant conduct that may result in traffic disputes. Nevertheless, it will be an arduous task for traffic operators to manually monitor the movement of vehicles at a crossroads, especially when there are thousands of vehicles passing through. Therefore, the process of grouping vehicle trajectory data to identify comparable patterns is carried out using the k-means and fuzzy c-means (HCM) clustering algorithms. Since various clustering techniques necessitate the input parameter of the number of clusters, this research focuses on studying the appropriate number of clusters for the clustering process [17].

Analyzing urban travel patterns helps assess the regularity of inhabitants' mobility, offering information for urban traffic planning and emergency decision-making. Clustering techniques have been extensively utilized to uncover concealed insights from extensive trajectory data concerning trip patterns. Implementing soft constraints in the clustering process and statistically evaluating their performance remains a challenging task. This paper introduces a refined trajectory clustering approach, known as TC-FDBSCAN, which utilizes fuzzy density-based spatial clustering of applications with noise to perform classification on trajectory data. Initially, we establish the trajectory distance by taking into account various features and determining the corresponding weight factors to quantify the similarity between trajectories [18]. In the HCM clustering method, membership degrees and membership functions are created to extend the standard DBSCAN method.

A modified version of the fuzzy c-means algorithm is proposed to solve the inverse kinematics and trajectory planning problem for a redundant manipulator, while taking into account performance criteria. A novel HCM clustering approach is introduced, which utilizes a newly developed generalized validity index. This index is built on weighted within-scatter metrics and between-cluster scatter metrics specifically designed for the manipulator. The issue of redundant manipulator, which refers to a nonlinear system with several inputs and outputs, has not been previously addressed using the clustering method. The trajectory planning algorithm for the manipulator is simulated using Matlab. The entire process, starting from gathering data to verifying the model, is demonstrated using a robot manipulator with four degrees of freedom. The simulated results are being compared to the numerical approaches used for trajectory planning. The findings are visually depicted. The proposed method offers the benefits of being straightforward, adaptable, and exhibiting excellent tracking capabilities [19].

The mining of trajectory databases (TD) has garnered significant attention as a result of the widespread use of tracking devices. However, the mining procedure has not yet included the presence of uncertainty in TD, such as GPS inaccuracies. This work examines the impact of uncertainty in TD clustering and presents a three-step methodology to address it. Initially, we give a conceptual framework for representing trajectories using intuitionistic point vectors, which captures the inherent uncertainty. Additionally, we introduce a robust distance metric to handle this uncertainty. Furthermore, we provide CenTra, an innovative approach that addresses the challenge of identifying the centroid trajectory of a set of moves. Furthermore, we provide a modified version of the fuzzy C-means (HCM) clustering algorithm that incorporates CenTra during its updating step. The empirical assessment on real-world TD substantiates the efficiency and efficacy of our methodology [20].

This research examines the application of HCM clustering to identify probable spatial patterns by incorporating rough set and fuzzy set theory. Initially, we suggest a rapid technique for measuring similarity by utilizing the approximate distances between trajectories. Significant reductions in processing time would be achieved, particularly for lengthy trajectory sequences. In addition, we present a summarization strategy that minimizes the number of distance calculations needed for similarity measurement. Furthermore, the membership degree is modified in order to enhance the clustering quality and performance. Furthermore, we enhance the fuzzy C-means algorithm by using a novel similarity measure and the membership degree function. The efficacy of our methods is demonstrated by experimental findings obtained from two actual datasets of trajectories. These results involve the assessment of clustering validity and the computation performance for big datasets. The computing performance of the proposed HCM clustering algorithm exhibits a clear improvement as the size of the trajectory dataset rises [21].

Clustering trajectory data is a method used to identify and display the underlying structure in the movement patterns of mobile objects. This technique has a wide range of possible applications in fields such as traffic control, urban planning, astronomy, and animal research. This study introduces a novel method for grouping trajectory data using a Particle Swarm Optimization (PSO) methodology. The strategy takes into account the Dynamic Time Warping (DTW) distance, which is a widely-used measure for comparing trajectory data [22]. The suggested technique may identify the (almost) optimal number of clusters and the (almost) ideal cluster centers during the clustering process. In order to enhance the performance of the suggested method, a Discrete Cosine Transform (DCT) representation of cluster centers is utilized. This approach helps to minimize the dimensionality of the search space and improve the method's performance in relation to a certain performance index. The suggested method can incorporate different cluster validity indices as the objective function for optimization. The experimental findings, obtained from both synthetic and real-world datasets, demonstrate the improved performance of the proposed technique compared to fuzzy C-means, fuzzy K-medoids, and two evolutionary-based clustering techniques previously suggested in the literature [23].

Next, the NT algorithm utilizes the characteristics of noise in order to actively reduce the impact of noise [24]. In 2022, a method was provided for grouping ship trajectories at sea. This approach utilized the Douglas-Peucker compression technique and the DBSCAN algorithm. The arrangement of this data defines the dispersion of traffic volume and the customary path for ship passage. Initially, the appropriate parameters are derived for the Douglas Poker method by analyzing the alterations in the ships' trajectories. This is done with the aim of enhancing the clustering of the ships' trajectories. The DTW distance matrix is calculated using these parameters to compress the data obtained from the traffic lines. Next, the enhanced DBSCAN algorithm is utilized to accomplish density-based clustering. The DBSCAN algorithm selects its optimal settings by considering the statistical properties of the distribution of ships' routes [25].

III. Proposed Method

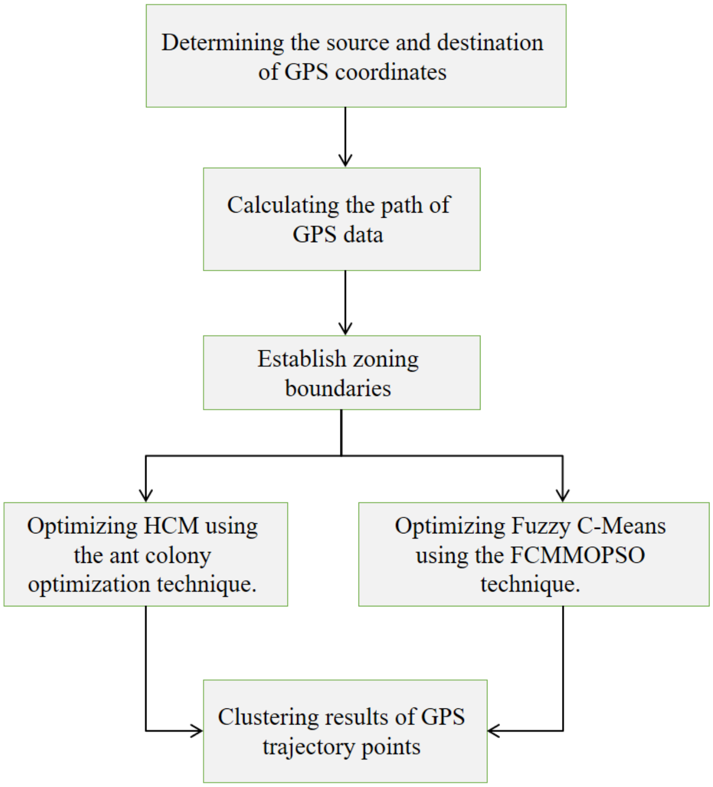
The suggested approach will present the path utilizing an innovative pre-processing technique. This method utilizes the angle formed between the lines as a reference to determine the linear areas in a specific order based on the sequence of points. Subsequently, an attempt is made to employ evolutionary approaches to better the performance of particle swarms and ant colonies in order to address the limitations of the HCM clustering technique. The overall framework of the suggested technique is illustrated in Fig. 1.

A. *Using GPS Coordinates to Determine Starting and Ending Places*

The trajectory in the proposed approach comprises the GPS coordinates specified by the user for both people and moving vehicles. These figures represent data about a motion that starts at one point and concludes at another. During this process, sampling is conducted at regular intervals, often less than two minutes, and the spatial data of the moving item is recorded [26]. This enables the collection of data related to a sequence of locations for the mobile entity (refer to Fig. 2). The suggested technique utilizes route information represented as Ti = {(p, a)} = {(p1, a1), (p2, a2), (pi, ai)}, where pi is a pair consisting of latitude and longitude coordinates, and a represents the angle formed by the line from the current point to the next point.

B. *Tracing the Pathways of GPS Data*

The results pertaining to the clustering which involves the regionalization of the trajectories are comparable. Fig. 3 illustrates an instance of the clustering of garlic lines.



Determining the source and destination of GPS coordinates
Calculating the path of GPS data
Establish zoning boundaries
Optimizing HCM using the ant colony optimization technique.
Optimizing Fuzzy C-Means using the FCMMOPSO technique.
Clustering results of GPS trajectory points

Fig. 1. General structure of the proposed method.

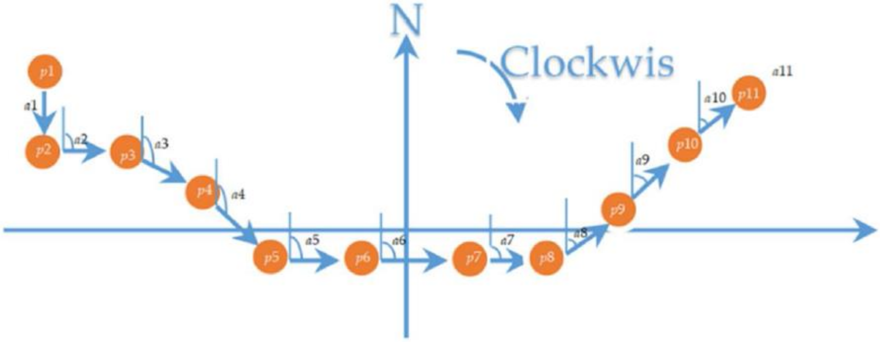


Fig. 2. A GPS moving point example with an angle-based trajectory.

C. Similarity Criteria

Among the newly-introduced criteria for comparing the similarity of linear sections is the cosine similarity criterion. Similarity results of linear regions form the basis for both trajectory clustering and sub-trajectory computing. The proposed method expresses the trajectory of Lj as a function of angle changes. The similarity criterion is also produced by relationship (1 [27].

$$sim(S_{j'}, S_j) = \begin{cases} e^{\forall l} \times \frac{e^{\partial g} - e^{-\partial g}}{e^{\partial g} + e^{-\partial g}} & S_{j'} \neq S_j \\ 1 & otger \end{cases} \quad (1)$$

The results pertaining to the clustering which involves the regionalization of the trajectories are comparable. Fig. 3 illustrates an instance of the clustering of garlic lines.

D. Establish Zoning Lines

The process of dividing the two-part line areas is detailed here. Every possible angle for the specified GPS locations is computed and saved in normal mode when the connecting line between two consecutive points forms a right angle. The angle between the lines and the vertical line is considered. First, we find the tenth neighboring point's shortest distance from the selected point. The sums of these points can vary. This leads to the identification of a region that matches the three nearest existing places, as illustrated in Fig. 4. If, among these three locations, the largest angle measures more than 180 degrees, the guiding angle is computed counterclockwise. In cases when the maximum angle falls short of 180 degrees, the guiding angle is calculated in the opposite direction. The values associated with the angle are changed according to relations (2) and (3) to create a standard that is both normal and harmonious [28, 29, 30].

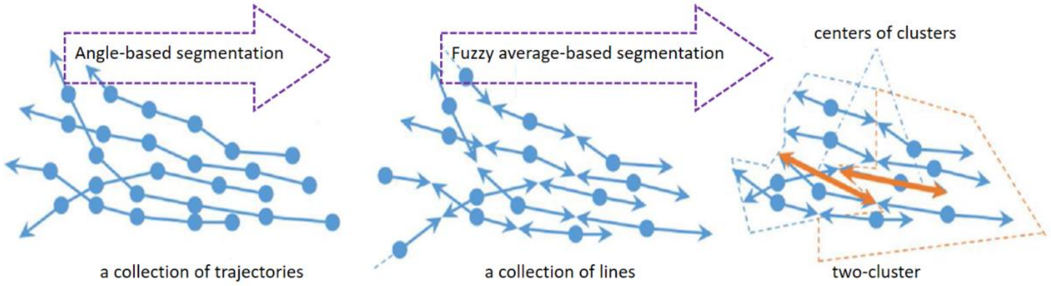

Fig. 3. Clustering of trajectories.

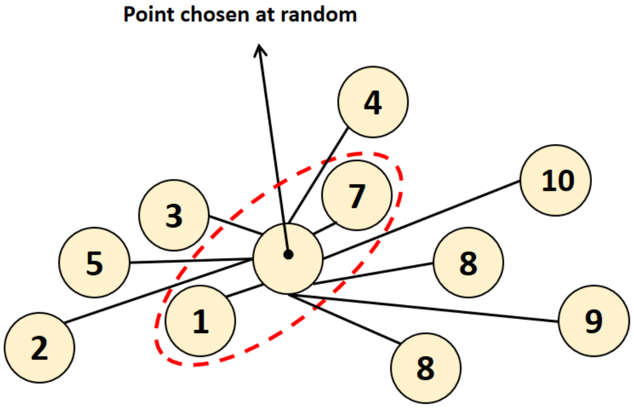

Fig. 4. The process of choosing three adjacent locations.

$$Nita = 2\gamma - (Nita_2 - Nita_1) \quad (2)$$

$$Nita = Nita_2 - Nita_1 \quad (3)$$

usage of angle-based segmentation necessitates limiting the intersection angle of the lines, denoted as $\gamma_t = (f = 1,2, \dots, e)$ The theorem of cosines, as stated in equation (4), can be used to determine the angle of the intersecting lines when three GPS points are represented as (S^-, S, S^+) and P is taken as the vertex. (a) Point P is initially selected at random. (b) The vertex is selected at this position, and two nearby points are identified by calculating the lowest distance. (c) If the values of If γ <T, where T is the threshold value, are extracted from the data set and saved in memory, then step 4 is carried out; otherwise, we return to step 1. (d) In order to build linear regions, GPS points are traveled until each point is checked. Using angle-based segmentation and cosine-based limiting, linear areas are segmented in this part. Depending on the angle between them, a collection of journey lines tied to human or point device movement based on GPS points is expressed as specific lines. A greater amount of data is available for grouping by the trend lines.

E. HCM Algorithm-based Traffic Line Clustering

In order to tackle this problem, researchers are investigating meta-heuristic algorithms. The HCM method's implementation and assessment do not effectively optimize the output of the objective function algorithm, resulting in the clustering centers being situated in local optima. Using meta-heuristic approaches improves the HCM algorithm. The defining feature of optimization and random search algorithms that rely on collective intelligence is the collective behavior and self-organization of individuals inside the community. This work involves the grouping of trajectory data using a combination of classical and meta-heuristic clustering algorithms.

F. Using the Particle Swarm Technique to Optimize HCM Clustering

The clustering problem is reframed as an optimization problem in the proposed strategy. In equation (4), C is a specific clustering of the data set f of the optimization function, and the optimization problem is specified as the set of all possible optimal clusterings (D*= {D1, D2,..., Dk}). C* is the best clustering that an iterative algorithm can provide [31].

$$E(D^*) = \min E(D); \quad (4)$$

The particle swarm optimization approach is employed to get an optimal segmentation. The HCM algorithm is a clustering technique that relies on an objective function. The objective function, denoted by equation (5), is defined for the data set Y = {Y1, Y2, ..., Yn} of dimension s.

$$I_n = \sum_{i=1}^{p} \sum_{j=1}^{r} \mu_{lb}^{n} \, \|P_i - d_r\|^2 \quad (5)$$

When determining the distance and degree of similarity of data with the center of the cluster, Let S represent the number of linear segments extracted in the preceding phases. D represents the number of clusters. m specifies the fuzzy degree of overlap of the clusters. The value of μid, which is the degree of the membership function Dj for cluster k, is determined using equation (6) [32].

$$\mu_{id} = \frac{1}{\sum_{d'=1}^{d} \left(\frac{\|P_j - E_d\|}{\|P_j - E_{d'}\|} \right)^{\frac{2}{n-1}}} \quad (6)$$

The suggested methodology utilizes HCM clustering, employing the particle swarm optimization technique. In particle swarm optimization, the fitness function is replaced by the objective function in HCM clustering. The sequence of actions performed by the algorithm is as follows:

- Each particle in the particle swarm optimization process is assigned a membership function ujk, which is determined based on equation (6).
- Equation (7) [33] reevaluates the centroids of the categories determined using HCM clustering.
- The fitness function of the present particle is defined by Equation (5).
- The user's text is a bullet point. The ultimate outcome is the global optimum, which represents the most optimal solution when taking into account all the particles. This clustering represents the highest level of optimization and is considered the global optimum.

$$W_i(d+1) = \frac{\sum_{i=1}^{m} y_{ij}^{n}(d) Y_i}{\sum_{i=1}^{m} y_{ij}^{n}(d)} \qquad (7)$$

G. Optimization of HCM Clustering by Ant Ga Algorithm

As mentioned earlier, HCM clustering aims to determine the appropriate values for cluster centers and membership function values in order to achieve optimal clustering and minimize the desired objective function. Currently, there exist two separate optimization concerns. The data is subsequently divided into d clusters. The values of the pheromone matrix p are responsible for performing this task. Following each step, the pheromone matrix p undergoes modification, and the updated values for ujk are computed using equation (6) and the cluster centers. The pheromone levels are updated using Equation (8) [31].

$$s_{id} = s_{id} \times (1-\partial) + (y_{id}/(I - I_{min} + \epsilon)^{\partial} \qquad (8)$$

for cluster d's route i, the pheromone concentration is denoted as s_{id}. While j is the number of samples, d is the number of clusters. The variables ϵ, which precludes division by zero, ∂, which controls the pace of convergence, and ∂, which controls the amount of pheromone evaporation, are all parameters in the system. The Algorithm 1 uses an ant colony method to show the structure of HCM clustering optimization. Included in this algorithm are the input data set Y, the fuzzy power m, the number of clusters c, and the maximum number of steps needed to run the ant colony process.

- Data Collection:

A large dataset consisting of GPS trajectories of cabs in operation in a big Chinese city is used in the study. All sorts of spatial and temporal dimensions are present in the dataset, which records cab travels over a long period of time. For accurate data representation, the trajectories are sampled frequently. Each trajectory point is annotated with details like timestamp, latitude, and longitude. These details are used for further research.

- Preprocessing:

The trajectory data is thoroughly preprocessed to remove noise, outliers, and missing values before grouping. In order to make the following clustering more resilient, we exclude outliers found via spatial and temporal analysis. To preserve the flow of time, values that are missing are filled in by extrapolating from nearby trajectory points. In order to simplify the dataset for efficient clustering, noise reduction techniques are used, such as trajectory simplification.

- Evaluation Metrics:

The suggested algorithms are evaluated using a suite of thorough metrics. The silhouette score, the Davies-Bouldin index, and the internal cluster cohesion are all examples of cluster validity indices. The agreement between the algorithm-generated clusters and ground truth clusters is also measured using external validation measures, such as the adjusted Rand index and the Fowlkes-Mallows index.

- Experimental Setup:

A computer platform with industry-standard hardware is used to conduct the experiments. Languages like Python are used to implement the algorithms, with libraries like scikit-learn being utilized for optimization and HCM clustering. In order to examine how well an algorithm performs when applied to new scenarios, the researchers used a stratified sampling method that split the dataset in half.

IV. Evaluation and Simulation

Here we discuss how to put the proposed idea into practice and evaluate it. The proposed methodology includes an optimization strategy for grouping motion trajectories. This was accomplished by optimizing the HCM clustering method using the evolutionary techniques of particle swarm and ant colony optimization. Throughout the implementation process, the MATLAB environment was utilized. The clustering procedure on the real data set containing the routes of the passenger-transporting taxis was improved in two separate circumstances using two optimization methods based on this. The primary clustering algorithm was used in both cases. The itineraries incorporate the regularly acquired GPS location data of the taxis. The results related to the evaluation criteria are recorded and inputted into the Excel software at every stage of execution. The desired charts are extracted by Excel program.

A. Datasets

On routes that convey passengers, the suggested strategy has been tried. Data is stored using GPS coordinates that are sampled every two minutes. This is completely accurate and applies to a lot of cities in China. The data utilized pertains to the whereabouts of Beijing taxis. On March 22, 2017, during the hours of 7:50 and 7:59, the data pertains to the movements of thirty thousand taxis. We acquired the information about the origin and destination of taxis and ran additional analyses on these sites, as mentioned in reference [34]. In Fig. 5, we can see the 69514 data point pairings that include origin and destination points. With these two coordinates, you may draw out patterns of trajectories. Fig. 6 shows the results of applying the angle-based segmentation method to these points and trajectories; the resulting data set contains 13584 linear segments. Fig. 5 shows the spatial representation of the distribution of pairs of starting and ending points within a latitude and longitude range of [0.19×0.4]. Passenger traffic in a certain location of Beijing is represented by these figures. The data in question might provide a treasure trove of information useful for traffic management and control. When constructing new streets or tearing down or fixing old ones, these numbers can also be highly useful. We also run tests of the proposed methodology on these data to see how well it works.

B. Clustering Evaluation Criteria

Clustering algorithms can be evaluated using a variety of criteria; however, trajectory clustering requires its own set of criteria due to its distinct characteristics. Considered with other evaluation criteria such as the DB-index [14], Dunn's index [25], and XB index [26] for assessing the clustering of geographical patterns, the MBP-index [15] emerges as the most accurate and relevant. Use this metric to compare the proposed approach to other clustering techniques. The value of MBP for clustering with K classes is represented by Equation (9).

$$MBS(D) = \left(\frac{1}{D} \times \frac{F_1}{F_D} \times K_D\right)^2 \tag{9}$$

where K_D and F_D are calculated from relations (10) and (11) respectively.

$$F_D = \sum_{d=1}^{D} \sum_{j=1}^{S} Hausd(C_j, s_d) \tag{10}$$

$$K_D = max_{i,j=1}^{D}\{k(s_i, s_j)\} \tag{11}$$

Where $k(s_i, s_j)$ is the distance between two cluster centres and $Hausd(C_j, s_d)$ is the distance between the sub-trajectory of C_j and the cluster centre c_k. The segmentation of the data location is not crucial, and pre-specifying it is unneeded, since the MBP evaluation criterion is considered an unsupervised evaluation criterion. That is to say, the results of the clustering routes are unrelated to the road map or the actual roads.

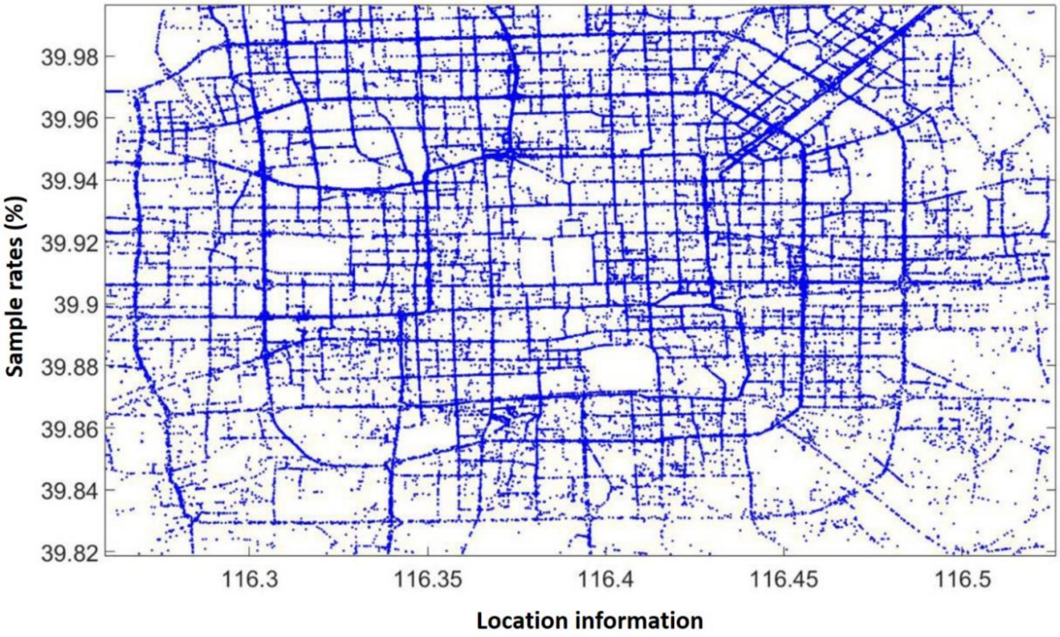

Fig. 5. Points of origin and destinations for taxis and their locations.

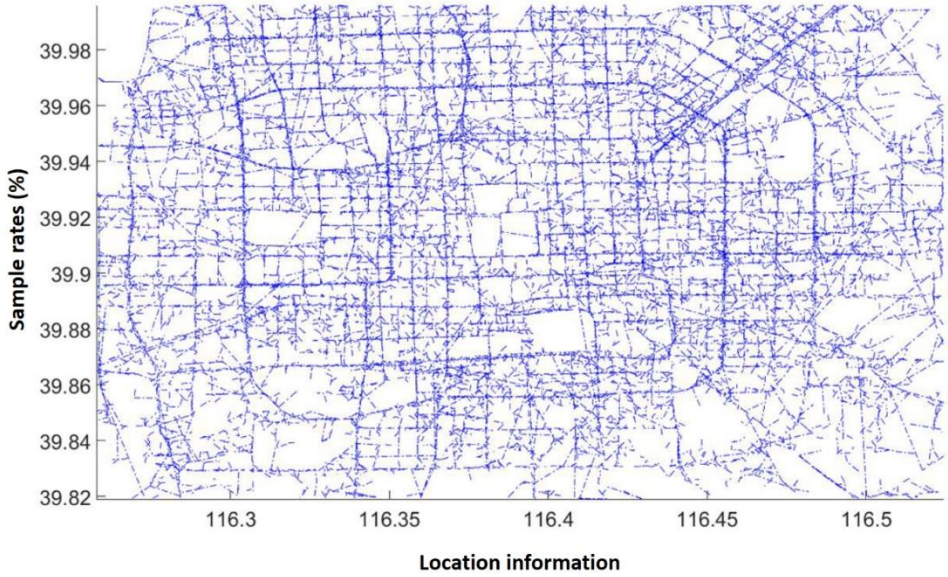

Fig. 6. The use of angles for movement line segmentation.

C. Methods for Comparing and Assessing the Proposed Approach

Before introducing an algorithm, it is essential to choose the correct method to evaluate and compare it. All of the method's pros and downsides should be taken into account in fair evaluations. To implement a novel approach to grouping motion routes based on optimisation of the HCM clustering algorithm, the ant colony algorithm and two-particle swarm optimisation methods were used separately in the proposed method. Consequently, the performance of each part is examined and evaluated independently. But these two suggested algorithms are tested against HCM, KMeans, and basic HCM algorithms to see how well they perform [35, 36]. An innovative approach to classifying motion trajectories, the HCM algorithm has been refined from its foundation in the cubic regression model and the Lagrange equations. In what follows, you will see the results of these comparisons according to several criteria.

V. Evaluation of MBP Value for Different K's

When evaluating the clustering process, one of the most important parameters is the number of clusters, denoted as K. Experiments have been carried out for K values ranging from 10 to 80. What this means is that the number of clusters, as defined by the proposed algorithm and other methods, is determined before the clustering process even begins. One important part of clustering techniques is setting up the cluster centres [37]. When AGNES or HCM performs a clustering method with K clusters, the centres of these clusters are originally chosen at random, and this selection process affects the clustering results. Therefore, in order to deliver a more precise assessment of the proposed method and other results, each algorithm is executed in a 20-step process. Table I displays the results of the minimum, maximum, and average MBP values for different values of K for all methods.

TABLE I. Clustering Outcomes Compared for Varying K-Values

	AGNES	HCM	FCML	HCMMOPSO	HCMGA
K=10					
Max	0.070	0.079	0.089	0.0770	0.076
Mean	0.057	0.079	0.086	0.0774	0.075
Min	0.043	0.078	0.084	0.0760	0.074
K=20					
Max	0.043	0.050	0.057	0.0670	0.059
Mean	0.037	0.050	0.057	0.0665	0.058
Min	0.030	0.050	0.056	0.0660	0.058
K=40					
Max	0.032	0.036	0.040	0.041	0.043
Mean	0.025	0.034	0.039	0.041	0.042
Min	0.019	0.033	0.038	0.041	0.052
K=80					
Max	0.025	0.031	0.034	0.036	0.039
Mean	0.022	0.031	0.033	0.035	0.039
Min	0.017	0.030	0.032	0.034	0.038

Fig. 7 to 10 display the overarching findings from comparing the suggested method to alternative ways for various K. By comparing the outcomes produced by the particle swarm optimisation and ant colony optimisation approaches, we can observe that the suggested method outperforms HCM, albeit to a lesser extent, for small k, i.e., when K = 10. The results show that HCMMOPSO outperforms HCMGA, the other recommended approach. However, when K is larger, the two scenarios of the suggested method outperform HCM and the two fundamental methods. Getting caught in the local minimum becomes more of an issue and the optimisation problem becomes significantly more hard as the number of clusters increases. However, the suggested approach combines the clustering algorithm with optimisation methods in an effort to achieve optimal clustering. Furthermore, when K grows, the HCMGA scenario outperforms HCMMOPSO. We will further study the ant colony optimisation approach, which outperforms the particle swarm with respect to issue complexity but has slower convergence.

A. Clustering Procedure Termination Criteria

Clustering techniques iteratively update the cluster centres at each iteration to obtain the best clusters. But the most important thing is to figure out when this process should conclude. There is more than one way to finish the job. For example, it is possible to perform the same number of clustering steps if the initial number of steps is fixed. This strategy, however, appears to be somewhat illogical. On the other hand, you may consider the evaluation function and how the algorithm's efficiency is improving at each stage as an alternative approach. This value must remain over a specified threshold for the stages to be executed; otherwise, they will not be executed. The proposed method use equation (12) to halt the clustering procedure.

$$\frac{I(h+1)-I(h)}{I(h)} < \varepsilon \tag{12}$$

In the proposed approach, the threshold value is assumed to be 0.002, and I(h) represents the value of the evaluation function at step h. The MBP standards are used to compute the I(h) value. There will be no end to the clustering processes until relation (12) is created. Nevertheless, several algorithms can achieve this with different iterations. As the algorithm gets better at meeting these requirements, its convergence speed goes up. Convergence speed alone will not be enough to achieve better performance, though. Since this rapid convergence may also lead to the local optimum, it demands consideration. As a result, optimal performance and rapid convergence are compatible. In order to compare the convergence rates of the two situations and different techniques, we considered the execution stage of the algorithms as 100 steps and used equation (13) to get the normalised value of I(h). This criterion is used to compare the rate of convergence; after normalisation, its value will range from zero to one.

$$\frac{I-I_{min}}{I_{max}-I_{min}} \tag{13}$$

Where are the maximum and minimum values of the evaluation function, I_{max} and I_{min}, respectively. Fig. 11 to 14 show a comparison of the results for different cluster densities with respect to the rate of convergence. For the case where there are precisely 10 clusters, this comparison is displayed in Fig. 14. The AGNES approach converges rapidly, as seen, but the best result it produces is inacceptably low for our issue. Steps 5 and 6 mark the end of the threshold technique, which, when applied to the question of whether the job is done, produces a locally optimal value. As a basic clustering algorithm, the HCM approach converges at the slowest rate. The HCM method, however, differs in its performance from the two alternatives. The HCM algorithm does not converge as quickly as HCMMOPSO. Almost as fast as HCMGA's convergence speed is HCM. So, it's safe to say that the particle swarm method achieves the fastest convergence when applied to clustering optimisation. With PSO's convergence speed, this conclusion was close. Nevertheless, the HCMGA method outperforms the optimal value for the clustering process.

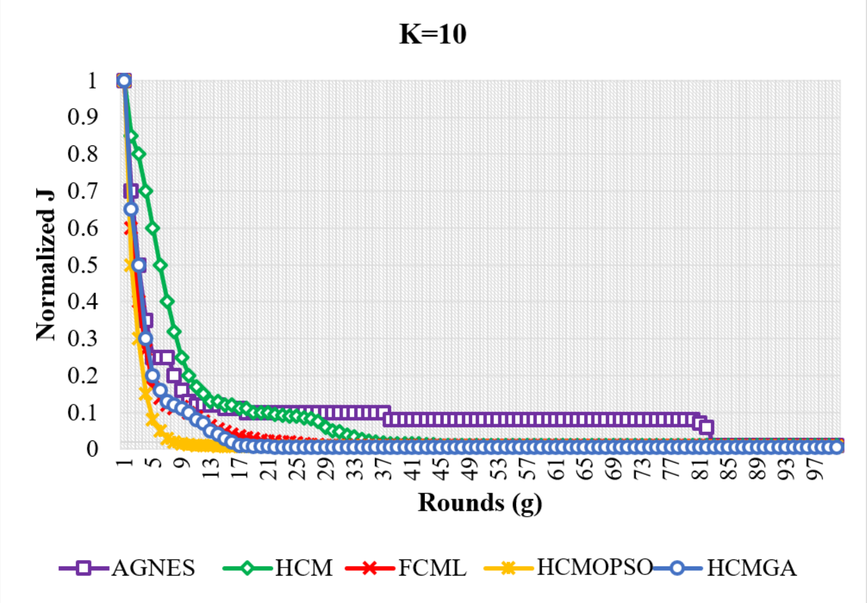

Fig. 11. Speed of convergence comparison for K=10.

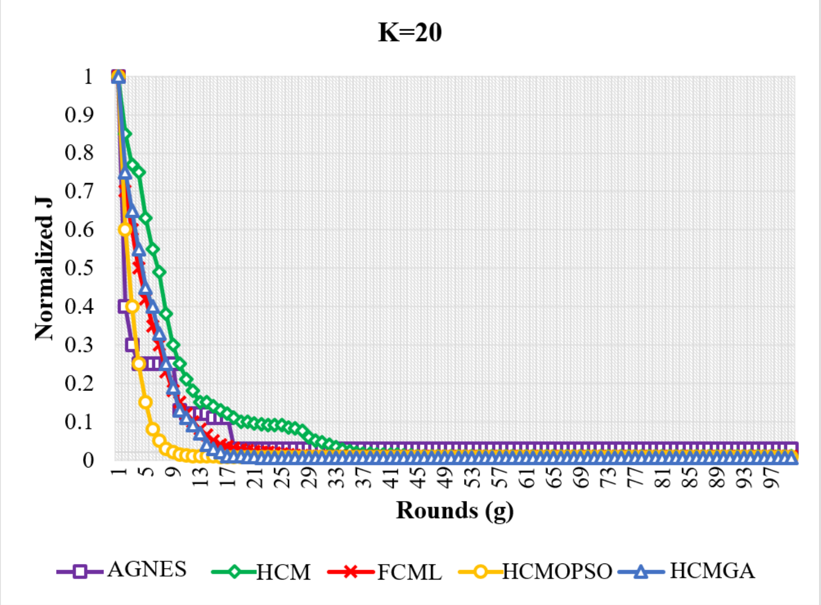

Fig. 12. Speed of convergence comparison for K=20.

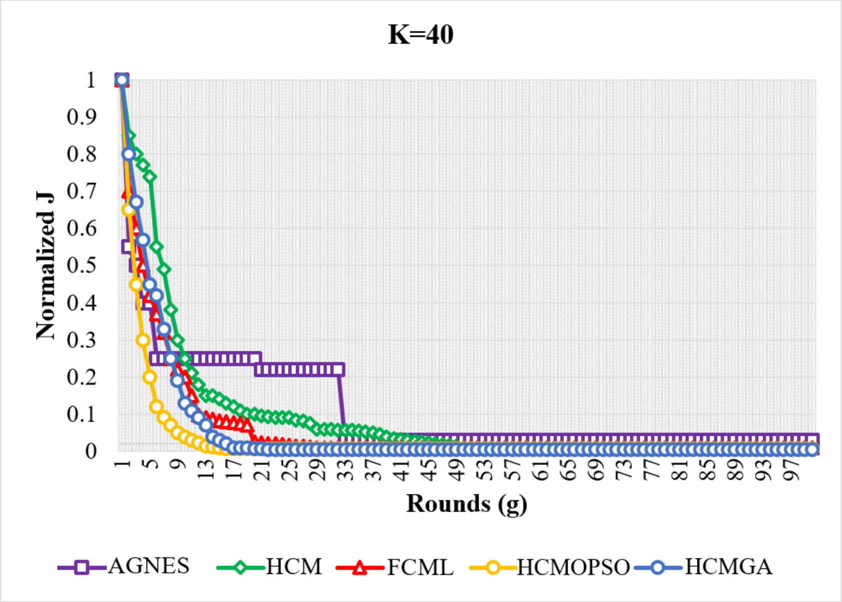

Fig. 13. Speed of convergence comparison for K=40.

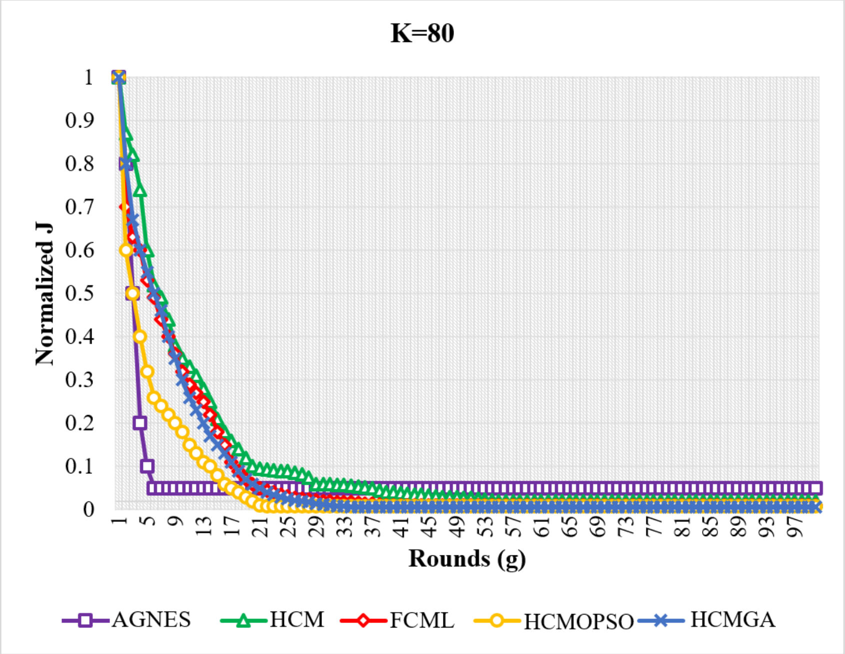

Fig. 14. Speed of convergence comparison for K=80.

The convergence process for 20 clusters is compared in Fig. 12, while Fig. 13 and 14 display the similar process for clusters 40 and 80, respectively. The tests also demonstrate that HCMGA converges at the fastest rate, with the convergence speeds of HCM and HCM approaches being nearly identical.

Use of a data set pertaining to the movement lines of taxis in one of China's cities, which includes the current GPS locations of taxis, allowed for the evaluation of the suggested method. Various numbers of clusters have been clustered in order to provide a more precise assessment of the suggested strategy. In situations with a small number of clusters, the findings demonstrate that the suggested method performs nearly as well as the HCM method. However, the suggested method's performance improves as the number of clusters increases. Optimisation using ant colonies achieves better clustering accuracy, while optimisation using particle swarms achieves faster convergence, according to the data.

Using HCM clustering with Ant Colony Optimisation (HCMGA) and HCM clustering with Particle Swarm Optimisation (HCMMOPSO), this study found that trajectory clustering became much more accurate and efficient. A clear and concise presentation of the results highlights the important contributions of the algorithms that were suggested.

- Clustering Accuracy Comparison:

In the first part of our investigation, we compare HCMMOPSO and HCMGA to other HCM clustering methods to see how well they cluster data. These metrics—internal cluster cohesiveness, Davies-Bouldin index, and silhouette score are presented in Table II for every algorithm. In terms of detecting significant trajectory clusters, HCMMOPSO and HCMGA both routinely beat baseline approaches.

TABLE II. CLUSTERING ACCURACY METRICS

Metric	HCMMOPSO	HCMGA	Baseline 1	Baseline 2
Silhouette Score	0.71	0.80	0.61	0.53
Davies-Bouldin Index	0.40	0.31	0.54	0.60
Internal Cohesion (avg)	0.91	0.92	0.83	0.80

Higher silhouette scores and lower Davies-Bouldin indices show that the clusters are better defined and well-separated, indicating a significant improvement in clustering quality. HCMMOPSO and HCMGA demonstrate exceptional internal cohesiveness, which is a direct result of the algorithms' ability to produce dense clusters.

- Statistical Significance:

With p-values lower than the 0.05 threshold, statistical analyses, such as ANOVA and t-tests, validate the importance of the noticed improvements. Statistics confirm that HCMMOPSO and HCMGA are better than baseline approaches, which gives the suggested trajectory clustering method more credibility.

- Comparison to Existing Studies:

We compare our results to those of related studies so that you can put them in context. Importantly, as compared to studies that used conventional clustering techniques, our silhouette scores are far higher. The optimisation procedures that were introduced allow for more accurate trajectory segmentation, which in turn improves the performance of HCMMOPSO and HCMGA.

- Discussion:

Results showing an increase in clustering accuracy show that HCMMOPSO and HCMGA are useful in the real world, especially for optimising taxi dispatch systems. The overall efficiency of transport services is improved by effectively identifying and differentiating between distinct trajectory patterns.

Finally, HCMGA and HCMMOPSO are great examples of how trajectory analysis has progressed thanks to the integration of HCM clustering and optimisation approaches. This study's findings add to the expanding literature on trajectory clustering and point the way towards further investigations on transportation system optimisation. Our approach has the potential to improve the efficiency of trajectory-based applications, and the shown improvements highlight its practical value.

VI. CONCLUSION

An approach based on the HCM clustering algorithm for route clustering was proposed as a means to extract city passenger flow patterns. Using a sequence of GPS markers that the user specifies, this method plots a route that is accessible to both pedestrians and drivers. The data shown here pertain to a journey that starts in one place and finishes in another. At regular intervals (often less than two minutes) during this process, the location of the moving object is captured using sampling. This is how the information about the moving cab's many points is recorded. The suggested method specifies the route information as a pair consisting of the geographical dimensions of the spot and the angle of the line that connects it to the next place. Before extracting the sublines, the data undergo pre-processing as part of the clustering process. An initial step in improving clustering accuracy and speed is to partition the sublines according to the angle between them. After that, HCM is used to cluster the data. Cluster centres were found in the local optimum, and the HCM algorithm failed to optimise the objective function, according to the evaluation and implementation of the algorithm. In order to fix this, we talked about meta-heuristic algorithm research and how to apply it to improve the HCM algorithm.

In two different cases, the HCM clustering method was fine-tuned using ant colony and particle swarm methods. Using a real data set containing cab movement data in Beijing, China, and the MATLAB environment, the suggested method was implemented. To test and compare the suggested method, a number of experiments were conducted. By applying the MBP criterion to the clustering accuracy performance, we found that the two scenarios outperformed other methodologies as the number of clusters increased. For a large number of clusters, the evaluation results show that the proposed method outperforms existing approaches in terms of clustering accuracy. The HCMGA algorithm improved clustering accuracy for MBP values by 0.61% compared to prior approaches, while the HCMMOPSO methodology improved it by 0.64%. The findings of the implementation also show that the particle swarm method converges faster and the ant colony approach is the most accurate.

A specific dataset concerning cab traffic in a Chinese city, namely Beijing, is used to test the proposed method. Data collected from GPS coordinates every two minutes form the basis of the evaluation. As an additional metric for cluster evaluation, the MBP index is utilised in the assessment.

For future studies, the proposed method might be expanded and generalised in other ways. For example, this method can be employed to classify various motion trajectories. Alternately, use more evolutionary optimisation methods to improve grouping. You may also test how well the method works by changing the pre-processing and sub-line segmentation steps.

***Abstract*—Sustainability and resilience are becoming increasingly critical in shaping supply chain pricing strategies. They ensure that supply chains can withstand disruptions while adhering to environmental and social standards, thereby securing long-term economic viability. Despite their importance, the integration of these two pillars with the promotion of domestic products remains under-explored, especially concerning their influence on the competitive dynamics within supply chains. This study seeks to bridge this gap by examining the influence of sustainability, resilience, and domestic product promotion on supply chain pricing strategies. We introduce a model that captures the interactions among a central supplier, multiple stores, and the government, focusing on strategies adopted by each stakeholder to maximize its profit while adhering to sustainability and resilience requirements. The study reveals that stores' pricing strategies are significantly influenced by their sustainability efforts, with the cost coefficient of these efforts and the elasticity of sustainability efforts directly affecting profit margins. It also finds that the supplier's resilience strategy involves allocating inventory reserves to manage wholesale pricing effectively. Governmental regulatory measures, through taxation and subsidies, are shown to play a crucial role in maintaining the balance between domestic and foreign products and providing flexibility to diversify product sources to cope with local disruptions. Finally, perspectives are provided to enrich the understanding of how sustainability and resilience can be considered and impact pricing policies of the whole network.**

Keywords—Supply chain management; pricing policies; sustainability; resilience; government regulation

I. Introduction

In today's interconnected world, supply chains stand as the backbone of global commerce, ensuring the seamless flow of goods and services across continents. However, as we navigate the challenges of the 21st century, from climate change and resource scarcity to geopolitical tensions and technological disruptions, the importance of sustainable and resilient supply chains has never been more pronounced [1]. Sustainability in supply chains ensures that operations are conducted in an environmentally conscious, socially responsible, and economically viable manner. On the other hand, resilience equips supply chains with the agility and adaptability to withstand unforeseen challenges, be they natural disasters, trade restrictions, or global pandemics. A supply chain that embodies both these qualities not only ensures business continuity and profitability but also plays a pivotal role in fostering a sustainable future for all.

This study embarks on a meticulous exploration of these twin pillars—sustainability and resilience—within the context of a supply chain of one supplier and several stores. It underscores the challenges tied to bolstering local production in an era dominated by transnational logistics networks. In today's interconnected world, gaining a nuanced understanding of how supply chains can optimize profitability while simultaneously fostering positive local and environmental impacts is imperative. Thus, the dual role of a supply chain—as a catalyst for economic gains and as an environmentally and locally attuned entity—warrants in-depth scrutiny [2], [3]. Firstly, it is a matter of drawing out the possible links between sustainability and resilience within the supply chain [3]. As such, the relationship between sustainability initiatives and the supply chain's ability to cope with disruption needs to be specifically addressed, exploring how sustainable practices can strengthen resilience. Next, it is necessary to know how a store can maximize profits while maintaining sustainable practices in its supply chain. This can encompass pricing strategies, operational efficiencies, and the integration of sustainable practices to ensure profitability [4]. Finally, the focus is on approaches to actively favor local products while meeting sustainability and resilience requirements. The main objective is to explore the measures needed to encourage local manufacturers, manage demand, and establish cooperation between the various players in the supply chain.

The interest of this research lies in several crucial aspects. Firstly, it is important to note that the issue of promoting domestic products while maintaining sustainability and resilience in supply chains remains relatively underexplored in the scientific literature. Very few studies to date have addressed this complex issue, despite its growing importance in a world where the globalization of supply chains is increasingly being called into question.

In addition, the recent crisis of supply chain disruption, exacerbated by unpredictable events such as the COVID-19 pandemic, has highlighted the urgency of rethinking and strengthening supply chain resilience [5]. This crisis has also raised key questions about the vulnerability of global supply chains and the importance of promoting local production to reduce this vulnerability [6].

Consequently, this research fills a gap in the literature by addressing these interrelated issues of sustainability, resilience, and the promotion of domestic products in supply chains. It thus offers innovative perspectives to address current and future challenges faced by companies and governments in supply chain management, helping to create more robust and environmentally friendly solutions in an ever-changing world. Practical implications of the findings are significant, as they empower stakeholders such as stores and suppliers to strategically choose pricing strategies that not only maximize profit but also promote sustainability and domestic products, enhancing resilience in the face of disruptive events. This study provides valuable insights for companies across various sectors, including textiles, mass-market retail, automotive, and more. The ability to navigate competitive dynamics, even within monopolistic scenarios, is crucial, especially when a company controls a substantial market share. In instances where a manufacturer (the monopolist) also owns distribution channels or outlets, competition with independent stores becomes a reality. Understanding this complexity, the study aims to provide answers to the following research questions.

Given this complexity, this study aims to answer the following research questions.

- What are pricing strategies to adopt by the store and the supplier to maximize their profits considering sustainability?
- How can the supplier comply with sustainability and resilience requirements?
- How can the government promote sustainability by encourage domestic products and resilience by offering the possibility of importing products?

The present research work will focus on a sustainable and resilient two-tier monopoly supply chain framework. Our supply chain management model examines the interactions between a central supplier, several stores and the government. The stores determine pricing and sustainability strategies, the supplier manages distribution and reserves, while the government regulates via taxes and subsidies, particularly with regard to domestic and foreign products. The key element is the resilience of the chain, with considerations such as inventories, the social burden of stores and the diversification of supply sources. The aim is to analyze supply chain dynamics with a focus on sustainability and local production.

The paper is structured as follows: Section II explores the literature related to supply chain pricing strategies, with a focus on promoting sustainability, resilience and domestic products with a government intervention. Section III concerns the model construction and analysis with three pricing strategies, the first one concern the store level, the second one concern the supplier level and finally the government. Section IV conducts a numerical analysis using examples to support the choice of pricing strategies adopted at each level. Moving to Section V, we present and meticulously discuss the findings derived from the developed model and the numerical analysis. Section VI encapsulates these findings in a comprehensive conclusion, elucidates the study's limitations and offers final observations and prospective directions.

II. Literature Review

Academic research is increasingly exploring these intersections between sustainability, resilience, performance, and competitiveness, seeking to define the ways in which companies can maintain efficient operations while being ecologically responsible and resilient to disruption.

This work is closely related to sustainability and resilience, domestic and foreign product and governmental intervention pricing strategies for supply chains.

A. Sustainability Pricing Strategies

The first focus of this paper is on the articulation and implementation of sustainability strategies. Firms are channeling resources into social and environmental programs to align with sustainability mandates, driven by a mix of governmental directives reflecting a heightened awareness [7]–[10]. In the study [11] authors investigated how inventory restocking and sustainability funding are influenced by three distinct regulatory environments. Similarly, the work in [12] investigated the best production practices for various products within the framework of cap-and-trade regulations, and in study [13] honed in on carbon emissions from warehouses, analyzing the inventory management and investment in eco-friendlier technologies in response to carbon emission limits set by cap-and-trade policies. While the study. Within the scope of this research, it's commonly acknowledged that environmental taxes significantly motivate corporate investment towards sustainable practices [14].

On the other hand, investing in sustainability initiatives is a strategic marketing proposition to enhance the company’s brand image, examines various factors that impact sustainability of supply chain. Consumers' environmental awareness, governmental regulations, sustainability investments, pricing, production quantities, and environmental constraints interact and influence each other within the context of sustainability and its impact on products and production processes [15]. Likewise, the investigation of retailers' investments in environmental R&D and manufacturers' proposed strategies for balancing and coordinating the supply chain through various joint R&D contracts. The study also reveals that consumer environmental awareness, while not always leading to increased demand for green products, systematically boosts the profits of green supply chains [16]. In the study [17] authors explores the impact of cooperative promotion on decisions and sustainability of service platform supply chains from different markets. Theoretical models suggest that joint promotion is advantageous, especially when independent promotional activities moderately impact demand. However, the benefit of cooperative promotion, influenced by demand sensitivity and adjustments in price and quality, may vary. Platforms with a high baseline demand typically derive more benefits from cooperation but might be less willing to invest more in cooperative promotions.

The examination of the relationship between sustainability efforts or investments and various aspects of product demand, production, or supply chain management, were explored in [18] where the manufacturer's incentive is considered to reduce carbon emissions in the presence of carbon taxes under revenue-sharing and cost-sharing contracts. Meanwhile, a comparison of optimal pricing and sustainability efforts was conducted in two scenarios in the study [19]: one where the manufacturer is a for-profit company driven by profit-seeking motives, and the other where the manufacturer is a nonprofit organization aiming to maximize demand realization and quantity. The same approach was made by [11], which examines sustainability investments made by retailers. Differing from this line of research, our paper considers both scenarios, where sustainability investments can be initiated by either the manufacturer or the retailer. Similarly, optimal decisions in pricing and ecological investment within competitive supply chains for electric vehicles were explored, focusing on the tension between the costs and revenues of green technologies. Manufacturers and retailers, in various market scenarios modeled via game theory approaches, navigate between investments in ecological technologies and consumer sensitivity to prices and ecology. The results offer insights to guide electric vehicle companies in developing optimal green investment and pricing strategies [20].

B. Resilience Pricing Strategies

The literature on resilience strategies in supply chain pricing is a dynamic and evolving field that addresses the crucial need for businesses to adapt and thrive in an increasingly uncertain and complex environment. Researchers and practitioners alike have recognized that pricing decisions are not just about setting optimal prices but also about fortifying supply chains against disruptions and unforeseen challenges.

Many studies underscore the critical importance of resilience in supply chain management and the diverse approaches to achieving it in the face of environmental, operational, and market challenges. A complex supply chain involving three manufacturers and a distributor managing complementary and substitute products which emphasizes the resilience of the chain against various possible disruptions. Using game theories to determine optimal prices at different levels of the supply chain, the developed model seeks to navigate efficiently through these potential interruptions, thereby ensuring order fulfillment and system stability despite environmental and operational challenges [21]. As well as, [22] where another strategy based on maintaining extra inventory at distribution centers is implemented and ensuring the reliability of distribution centers, which positively impacted the competitiveness and adaptability of supply chains investigated the influence of resilience strategies in supply chain management, particularly within the context of price competition and facility disruptions. In another context related to insufficient capacity, authors of the work [23] scrutinizes resilience in the maritime supply chain, specifically focusing on the "co-opetition" relationship between shipping companies and freight forwarders. Using a model based on game theory, it reveals that establishing a direct sales platform by shipping companies strengthens their competitive position and improves their price and profit compared to freight forwarders. Moreover, in the event of capacity shortage, the strategic implementation of capacity allocation and pricing strategies, especially through a spot market, can enhance the resilience of the supply chain. The examination of resilient agricultural supply chains in the post-COVID-19 era, as explored in [6], delves into the utilization of channel leadership strategies. This study emphasizes the critical need for selecting appropriate leadership tactics to ensure maximum profitability, optimal pricing, and high service quality in a volatile market. It also offers practical insights for the transition to e-commerce platforms in the aftermath of the pandemic.

By embracing both foreign and domestic products, businesses can diversify their portfolios, ensuring a balanced approach to sourcing and mitigating risks associated with supply disruptions. Studies in the literature delve into how these models can be leveraged to not only bolster the profitability of domestic enterprises but also strengthen their position in the increasingly competitive and complex market landscape. The optimization of prices and profits for a domestic company, along with the reduction of retailer costs, is the focus of the research [24]. By examining various scenarios, the research establishes that implementing an adapted pricing strategy can significantly enhance the profitability and market competitiveness of the domestic company in relation to imported products. Similarly, the pricing competition between national and foreign manufacturers on diversified market segments, using a Stackelberg game model was explored by [25] taking into account factors such as price and quality to influence customer purchasing trends, the study concludes that market segmentation by income levels can increase profits for the national manufacturer and improve its competitive advantage against the foreign manufacturer. Likewise, a cooperative strategy between national pharmaceutical manufacturers and foreign licensors to exclusively produce locally licensed branded drugs, with the aim of increasing the manufacturer's revenues and potentially offering government discounts [26]. Using a Nash bargaining solution and cooperative game theory to model tariff negotiations, the research reveals that the local market share of the licensor and the return on capital of national manufacturers positively influence the equilibrium price. If the price is too low, foreign entities might lack the incentive to join the coalition. On the other hand, in the context of supply disruption risk the study [27] examines the competitive dynamics between two closed supply chains, focusing on the management of product prices and recycling. One of the supply chains, a retailer, has the choice between a reliable but expensive domestic supplier and a cheaper but unreliable foreign supplier. The results indicate that in a dual supply situation, there is a direct correlation between sourcing from a foreign supplier and the return rate of used products, and that strategic use of return policies is essential to maintain competitiveness in the market.

C. Government Regulation

The government intervention strategies in various sectors are mainly focusing on subsidies, taxes, and regulations to promote environmentally friendly practices and sustainable development. To stimulate remanufacturing activities, governmental subsidies was explored, revealing that excessively high or low financial aids prompt remanufacturers to compete with producers [28]. A case study involving five European countries was highlighted by [29], unveiling how the evolution of the green economy is shaped by governmental intervention. Similarly, the price competition between green and non-green products is analyzed including government subsidies and the implementation of taxes to minimize carbon emissions [30]. Whereas, the influence of the government subsidy on the green supply chain system, exploring various chain leadership modes and how the subsidy policy impacts each chain member and the system's profit [31]. Meanwhile, the chain structure and pricing decisions for the producer and government subsidy strategy is studied, contrasting new and remanufactured products [32]. The impact of government incentive strategies, approaching eco-responsible products from a game theory-based perspective and comparing the benefits of each chain member, the level of eco-friendliness, and environmental improvement [9]. The assessment of the impact of governmental interventions on bioenergy and conventional energy supply chains is studied in [33], revealing that some support strategies, especially investment subsidies, can significantly optimize both profits and carbon emission reduction efforts while supporting sustainable development goals. In the research [7], authors utilized game theoretical models to refine pricing for energy sectors, aligning with government, societal, and ecological objectives. Findings reveal Nash strategies boost governmental and societal benefits, whereas cooperative approaches favor ecological results and energy producers' earnings. While the government regulation strategies are explored for promoting EV adoption and reducing CO_2 emissions through targeted tax reforms and subsidies, indicating that government policy adjustments are essential for achieving sustainability and market influence [34].

III. Modeling Formulation and Analysis

A. Model Description and Assumptions

In our supply chain model, we consider a configuration, as illustrated in Fig. 1, where the actors in this system are the stores, the supplier and the government. Each of these actors has an impact on the supply chain through specific strategies. The central supplier provides multiple stores with foreign and domestic products. The stores, as the final sale points, make significant strategic decisions regarding prices, sustainability efforts, and demand management. The supplier, although not directly involved in the production of products, plays a central role in distribution, negotiating unit prices and managing security stock (ψ_i) with each store. The government steps in by imposing custom fees (τ) on foreign products and by granting subsidies (ν) to promote domestic products as presented in the Table I. It also plays a regulatory role by influencing tariff policies and sustainability practices.

Integrating sustainability and resilience into supply chains combines environmental responsibility, operational robustness, and market competitiveness. This research paper primarily focuses on sustainability strategies, which are incorporated into our model at various levels. At the store level, sustainability efforts (s_i) involve demanding durable products and undertaking sustainability actions and investments, such as sustainable product refurbishment, the requirement for sustainable packaging, recycling, and more [35]. At the supplier level, it includes contributing to the reduction of carbon footprint through the integration of CO_2 emissions cost (η_i) during product transportation. Additionally, at the government level, the social charge (λ) paid by the store contributes to fostering a more socially sustainable business environment [35] across the supply chain.

Moreover, the proposed model takes into account the resilience of the supply chain, through the integration of parameters that attempt to express said resilience, such as the security stock and the diversification of supply sources. Indeed, the supplier reinforces supply chain resilience through inventories that play a key role by implementing a dedicated extra inventory (ψ_i) for each store i, that is essential to deal with potential disruptions [22]. Additionally, diversifying supply sources is also a crucial aspect of resilience. The supplier can choose to diversify the supply chain, whether they are national or foreign. On one hand, importing products allows flexibility and reduce risks of supply chain disruption and increase their resilience in the face of uncertainty. On the other hand, encouraging domestic products reduce dependence on international markets, secure jobs and bolster economic security within a country. This paradox stems from the conflicting goals of achieving supply chain flexibility and resilience by depending on imports, and simultaneously encouraging local manufacturing.

The government plays a critical role in navigating this paradox through various regulatory mechanisms. In this sense, government by offering subsidies (ν) to actively promotes domestic products ($1-\theta$), while imposing custom fees (τ) to foreign products (θ) can them more expensive. Furthermore, the government maintains the option to import foreign products (θ). This dual approach not only provides flexibility but also serves as a valuable contingency plan in the face of disruptive events, significantly enhancing the supply chain's ability to endure and recover from disruptions. These two key options are considered, each with clear financial implications:

Import Foreign Products: The supplier is considering importing a large volume of foreign products, such as manufactured goods or raw materials, for resale on the local market. However, this decision requires careful cost management. For example, when importing these products, you need to take into account customs costs, which vary according to the type of product and the country of origin. Customs costs can represent a significant proportion of import expenditure. A relevant example is Canada, where a survey of 635 men and women revealed positive attitudes towards Canadian-made products, particularly among women. However, it is important to note that customs costs can vary from country to country. Therefore, the supplier must calculate these costs accurately to assess the economic viability of this option.

Purchase of domestic products: In addition to importing, the supplier plans to purchase local products. A concrete example might be the purchase of locally manufactured products for resale on the domestic market. The government encourages this approach by offering economic benefits, such as subsidies to support local businesses or tax breaks for domestic products. These financial incentives support the purchase of local products and can reduce procurement costs. Suppliers must therefore integrate these advantages into their local purchasing strategy to maximize the economic benefits.

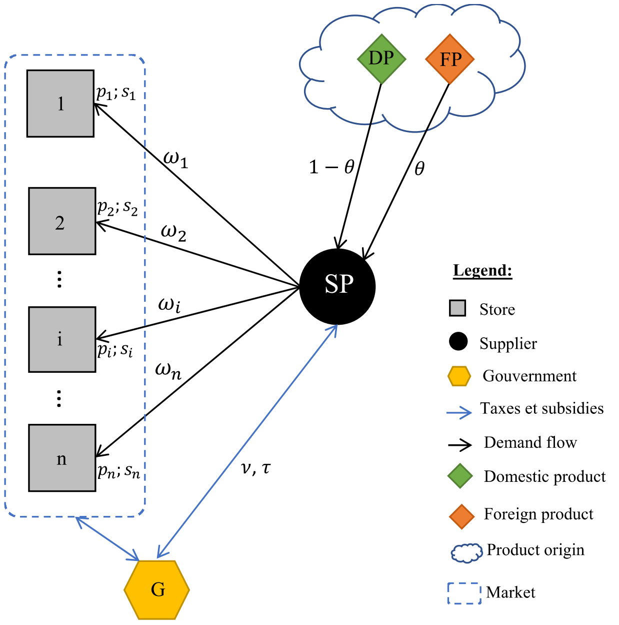

Fig. 1. Theoretical model of a network of stores and one supplier with a government regulation.

Profits within the supply chain are determined by the pricing and sustainability strategies set up by each store. Each store must decide the selling price of its products, taking into account various factors such as operational costs (c_i), negotiated purchase prices (ω_i) with the supplier, sustainability efforts (s_i) deployed, and other parameters. The government intervenes by imposing taxes on CO_2 emissions related to product transportation, while subsidies may be granted to encourage sustainability.

In this model, each store i negotiates the purchase price (ω_i) individually with the supplier, allowing for significant flexibility and customization in business relationships. This freedom to negotiate creates a competitive situation where the supplier and each store i strategically compete to achieve an optimal purchase price (ω_i), considering the competing interests of each actor within the supply chain.

This supply chain model aims to understand interactions and dynamics between actors, configurations, profits, and resilience in a context of promoting local production and sustainable concerns.

1) Assumptions: Within the framework of our supply chain pricing model, several fundamental assumptions are established to simplify and define the context of our analysis. These assumptions define the parameters, relationships and basic conditions governing our system. They are essential for framing our study precisely and rigorously:

- $a, b, k, \alpha > 0$
- $p_i > (c_i + \omega_i)$
- $\frac{k^2}{2\alpha} > b$
- We consider a monopolistic market configuration at store level;
- A store i is supplied by a single supplier;
- We assume uniform operator numbers for all stores, as we also assume they employ the same value of d_m, So $\forall\, i, A_i = A$;
- The supplier applies different selling prices negotiated with each store i;
- The supplier keeps a reserve quantity (ψ_i) for each store i;
- Each store has fixed costs that are independent of demand (wages, rent, electricity bills, ...);
- The Supplier transports the products to the stores. This transport generates CO_2 emissions, which are taxed by the government;
- It is assumed that all planned requests have been met. In this case, we won't deal with profit expectations, and the model is considered deterministic;
- Products are assumed to have the same quality preference for the customer.

However, in the realm of supply chain and inventory management, the supplier's decision to reserve a specific quantity of goods ψ_i for each order from a store i reflects a strategic approach to ensure the supplier's resilience in the face of market uncertainties. This quantity acts as a buffer, allowing the supplier to respond efficiently to variations in demand and unforeseen disruptions in the supply chain.

Based on the above assumptions, the objective functions of the problem to be modeled are as follows:

- Maximize store profit
- Maximize supplier profit
- Maximize government revenues according to tax/subsidy policies

Table I, presented below, succinctly encapsulates the key sustainability, resilience, and economic parameters employed in the formulated model, serving as a valuable aid for comprehension.

TABLE I. SUSTAINABILITY, RESILIENCE AND ECONOMIC PARAMETERS OF THE MODEL

	Sustainability	Resilience	Economic
Store	s_i, k, α, A_i	θ, ψ_i	p_i , π_i
Supplier	η_i	θ, ψ_i , γ	$\omega_i, \pi_{i,s}$, π_s
Government	λ	θ, ψ_i	τ , ν , π_g

2) Model parameters and variables

d_i : demand quantity at store i
p_i : unit price at store i
s_i : sustainability efforts for store i
a : basic market demand
b : price elasticity
k : elasticity of sustainability effort

c_i : operating unit cost of store i
c : operating unit cost of supplier
F_i : fixed expenses of store i
α : cost coefficient of sustainability effort for store i
d_m : average demand estimated by store i
A_i : number of operators needed to satisfy d_m
λ: social charge per operator to be remitted to the government by a store
y_i : unit cost to be paid to the operator to satisfy d_m
γ : inventory security sensitivity
ψ_i : inventory quantity reserved for store i
η_i : unit cost of CO_2 emission
θ : ratio of quantity of foreign products, $\theta \epsilon [0,1]$
τ : custom fees
ν : government subsidy
ω_i : wholesale price negotiated between supplier and store i
${w_i}^s$: wholesale price negotiated considering the whole network
π_i : profit of store i
$\pi_{i,s}$: profit of the supplier considering the whole network
π_s : total supplier profit
π_g : total government profit

B. *Model Construction and Analysis*

In economic analysis, the inverse demand function emerges as a pivotal tool, offering a distinct perspective compared to the conventional demand function, which typically represents quantity demanded as a function of price [36]. This inverse approach articulates the price as contingent upon the quantity demanded, essentially inverting the traditional relationship. For companies, this analytical approach is indispensable for formulating sophisticated pricing strategies.

Similar to the work of [37], [38] the inverse demand equation is given as follows:

$$d_i = a - bp_i + ks_i \tag{1}$$

Based on the work of [39], [40] $C(s_i) = \frac{\alpha {s_i}^2}{2}$, corresponds to the cost of the sustainability effort.

1) Store i strategies: In this sub-section, the store's profitability is studied. So, it can be divided into two components: the first part comprises gains, represented by the product of the price (p_i) and demand (d_i), while the second part encompasses expenses. Among these expenses, some are variable, such as operational costs (c_i) and the negotiated wholesale price between the supplier and store i (ω_i), while others are fixed, such as overhead expenses (F_i), the employee payroll ($A_i y_i$), and sustainability efforts (s_i).

The profit Eq. (2) for store i is given as follows.

$$\pi_i = d_i(-c_i + p_i - \omega_i) - F_i - \frac{\alpha {s_i}^2}{2} - A_i y_i \tag{2}$$

By replacing Eq. (1) in Eq. (2) we get:

$$\pi_i(p_i, s_i) = -b{p_i}^2 + p_i(a + ks_i + b\omega_i) - \frac{\alpha {s_i}^2}{2} - c_i(a - bp_i + ks_i) - (a + ks_i)\omega_i - F_i - A_i y_i \tag{3}$$

According to this equation, a store has two strategies: The price to apply and the sustainability effort to adopt.

Assuming now that the store focuses only on the price strategy. The price to achieve maximum profit is:

$${p_i}^* = \frac{1}{2}\left[\frac{a+ks_i}{b} + (c_i + \omega_i)\right] \tag{4}$$

It can be seen that the selling price increases as the sustainability effort increases. It is also influenced by the purchase price ω_i and operating costs.

Price elasticity tends to eliminate the effect of sustainability effort. For this reason, we assume that $k > b$.

Proof. Maximum profit is sought by deriving the profit function π_i.

$$\frac{d\pi_i}{dp_i} = -2bp_i + a + b(c_i + \omega_i) + ks_i$$

We have: $\frac{d^2\pi_i}{d^2 p_i} = -2b \leq 0$ thus, the function admits a maximum. This maximum is obtained by solving $\frac{d\pi_i}{dp_i} = 0$

Since ${p_i}^*(s_i)$ has the equation of a straight line and $\frac{d{p_i}^*}{ds_i} = \frac{k}{2b} > 0$. Then the function is increasing with respect to s_i.

Furthermore, assuming that the store wishes to use the sustainability strategy to attract more demand. The sustainability effort to achieve maximum profit is:

$${s_i}^* = \frac{k(p_i - (c_i + \omega_i))}{\alpha} \tag{5}$$

According to this result, an increase in price has an impact on the sustainability effort. The sustainability effort cancels out in the case where the sustainability effort coefficient α is equal to the sustainability elasticity K. In this case, s_i will correspond to the marginal profit.

The purchase price to be negotiated affects the sustainability effort. The store has no interest in having a purchase cost ω_i, zero.

Proof. Maximize profit by seeking the value of s_i

$\frac{d\pi_i}{ds_i} = -kc_i + kp_i - \alpha s_i - k\omega_i$;

Since $\frac{d^2\pi_i}{d^2 s_i} = -\alpha \leq 0$ o the function admits a maximum, obtained when $\frac{d\pi_i}{ds_i} = 0$.

Since ${s_i}^*(p_i)$ has the equation of a line and $\frac{d{s_i}^*}{dp_i} = \frac{k}{\alpha} > 0$. Then the function is increasing with respect to s_i.

In the model shown, the store actually has two strategies to apply to improve profit. In this case, ${s_i}^*$, and ${p_i}^*$are always profit-maximizing solutions.

Proof. The hessian matrix is as follows:

$$\boldsymbol{H}\,[\pi_i(p_i, s_i)] = \begin{pmatrix} -2b & k \\ k & -\alpha \end{pmatrix}$$

$\boldsymbol{Det}(\boldsymbol{H}) = -k^2 + 2b\alpha$
$\boldsymbol{Tr}(\boldsymbol{H}) = -(2b + \alpha)$

Since $\boldsymbol{Det}(\boldsymbol{H}) > \mathbf{0}$ **et** $\boldsymbol{Tr}(\boldsymbol{H}) < 0$, then $\pi_i(p_i, s_i)$ admits a maximum in:

$$\begin{cases} {p_i}^* = \dfrac{1}{2}\left[\dfrac{a + ks_i}{b} + (c_i + \omega_i)\right] \\ {s_i}^* = \dfrac{k[p_i - (c_i + \omega_i)]}{\alpha} \end{cases}$$

Maximum profit can therefore be written as:

$$\begin{aligned} &\max(\pi_i) \\ &= -\frac{k^2 p_i^2}{2\alpha} - \frac{k^2 s_i^2}{4b} - \frac{k^3 s_i(c_i + w_i)}{2b\alpha} + \frac{1}{2b\alpha} p_i\left(k^3 s_i + k^2\big(a + b(c_i + w_i)\big)\right) \\ &+ \frac{\alpha(a^2 + b^2 c_i^2) - 2c_i(a(k^2 + b\alpha) - b^2\alpha w_i) + w_i(-2a(k^2 + b\alpha) + b^2\alpha w_i)}{4b\alpha} \\ &- (F_i + A_i y_i) \end{aligned}$$

We'll try to analyze the price that store i will negotiate with the supplier so that the store ensures maximum profit. In this case, we assume that the store is the leader.

So, we replace Eq. (5) in Eq. (4). We then obtain the negotiated price $\widehat{w_i}$**:**

$$\widehat{w_\iota} = \frac{a\alpha + (k^2 - 2b\alpha)p_i}{k^2 - b\alpha} - c_i \tag{6}$$

2) Supplier strategies: In this sub-section, we focus on the supplier's profit in the supply chain. Firstly, we study the supplier's profitability in relation to store i, then the profitability in the whole network.

The profit function is as follows:

$$\pi_s = \sum_{i=1}^{n} \pi_{i,s} - C(\tau) + I(\nu) \tag{7}$$

With $\sum_{i=1}^{n} d_i = D, C(\tau) = \tau.\theta D, I(\nu) = (1 - \theta)\nu D$

$C(\tau)$ corresponds to the customs fees that the supplier pays to the government for the percentage θ of the quantities imported. On the other hand, the supplier receives a government subsidy $I(\nu)$ for the percentage $(1 - \theta)$ of quantities made from local suppliers.

a) The supplier's strategy, considering its profit in relation to a store i

The supplier's profit is written as follows:

$$\pi_{i,s} = d_i(\omega_i - c - \eta_i) - \gamma\omega_i\psi_i \tag{8}$$

Replacing Eq. (1) in Eq. (8) gives the following equation:

$\pi_{i,s} = -a(c + \eta_i) - \gamma\omega_i\psi_i + bp_i(c + \eta_i - \omega_i) + a\omega_i - ks_i(c + \eta_i - \omega_i)$

The supplier focuses solely on the pricing strategy. Always considering that the store is the leader and the supplier is the follower, we obtain the price that allows us to reach the maximum as follows:

$${\omega_i}^* = \frac{(c_i + c + \eta_i)}{2} + \frac{a}{2b} + \frac{k^2(ks_i - \gamma\psi_i - 2bc_i)}{2b(k^2 + b\alpha)} \tag{9}$$

To be able to offer a price, the supplier needs to have information on the sustainability effort of store i. It is also influenced by the cost of emissions CO$_2$ η_i.

Proof. To find the maximum profit, we derive the profit function π_s

$$\frac{d\pi_s}{d\omega_i} = a + bc + \frac{ab\alpha}{k^2} + \frac{b^2 c\alpha}{k^2} - bc_i + \frac{b^2\alpha c_i}{k^2} + ks_i + 2(-b - \frac{b^2\alpha}{k^2})w_i + b\eta_i + \frac{b^2\alpha\eta_i}{k^2}$$

We have: $\frac{d^2\pi_i}{d^2\omega_i} = -2(b + \frac{b^2\alpha}{k^2}) \leq 0$, then the function admits a maximum. This maximum is obtained by solving $\frac{d\pi_i}{d\omega_i} = 0$

Since ${\omega_i}^*(s_i)$ has the equation of a straight line and$\frac{d{p_i}^*}{ds_i} = \frac{k}{2b} > 0$. Then the function is increasing with respect to s_i.

To calculate the Supplier's profit, we first calculate the profit for each store i.

$$\frac{d\pi_i}{dp_i} = -2bp_i + a + b(c_i + \omega_i) + ks_i$$

The Eq. (9) aims to determine the wholesale price ${\omega_i}^*$ negotiated by the supplier in the context of sustainability, the supply chain, and operational costs. Two key parameters, k (sustainability effort elasticity) and α (the cost coefficient of sustainability effort), play a crucial role.

Thus, k measures how consumers respond to the sustainability efforts undertaken by store i. A high k value indicates a strong consumer response to sustainability, meaning they are willing to purchase more sustainable products. Consequently, the supplier may consider raising the wholesale price ${\omega_i}^*$ without compromising demand. Consumers are willing to pay a premium for sustainable products, which can increase the supplier's profit margin. However, α quantifies the costs associated with the sustainability initiatives of store i. A high α indicates higher costs to implement sustainable practices, such as using environmentally friendly materials or reducing carbon emissions. These additional costs can exert upward pressure on the wholesale price ${\omega_i}^*$ negotiated by the supplier. The supplier must offset these costs to maintain profit margins.

b) The supplier's strategy, considering the whole network: In this section, it is necessary to focus on the overall profit of the supplier of the whole network, which will incorporate other elements not directly dependent on the store's demands. Thus, we will attempt to break down the overall profit of the supplier, as provided in Eq. (7). The total demand is expressed as follows:

$$\mathrm{D} = an - b\sum_{i=1}^{n} p_i + k\sum_{i=1}^{n} s_i \tag{10}$$

Based on the work of [41], it is possible to consider φ as an endogenous decision variable, with: $\varphi = \frac{\mathrm{p}_i - \mathrm{w}_i}{\mathrm{p}_i}$ where $\varphi \in [0,1]$. Therefore, we can write $p_i = \frac{\mathrm{w}_i}{(1-\varphi)}$.

Similarly, and based on the results obtained during the analysis of store-level strategies, we know that sustainability efforts s_i directly impact the price offered p_i by the store. Therefore, we can propose a simple linear equation to express sustainability effort as a function of price, thus creating an equation as follows: $s_i = \Omega p_i,\ \Omega > 0$

When we substitute, Eq. (7) will be then expressed in the following form:

$$\pi_s = anU + (a-b)\sum_{i=1}^{n} w_i - bU\sum_{i=1}^{n}\frac{w_i}{1-\varphi} - k\left(U\sum_{i=1}^{n}\frac{\Omega w_i}{1-\varphi} + \sum_{i=1}^{n}\frac{\Omega w_i(w_i-\eta_i)}{1-\varphi}\right) - a\sum_{i=1}^{n}\eta_i + b\sum_{i=1}^{n}\frac{w_i\eta_i}{1-\varphi} - \gamma\sum_{i=1}^{n} w_i\psi_i \quad (11)$$

With, $U = c - \nu + \theta(\nu - \tau)$

Based on this equation, we will attempt to examine potential strategies for the supplier, including the wholesale price and the inventory quantity reserved for store i (ψ_i), to improve supply chain resilience.

$$w_i{}^s = \frac{1}{2k\Omega}[(a-b-\gamma\psi_i)(1-\ \varphi) + (b+k\Omega)(-U+\eta_i)]$$

$$w_i{}^s = \frac{1}{2k\Omega}[(a-b-\gamma\psi_i)(1-\ \varphi) + (b+k\Omega)(-c+\nu-\theta(\nu-\tau)+\eta_i)] \quad (12)$$

Proof. To find the maximum profit, we derive the profit function π_s

$$\frac{d\pi_s}{d\omega_i} = a - b - \frac{bU}{1-\varphi} - \frac{b\eta_\mathrm{i}}{-1+\varphi} - k(-\frac{U\Omega}{-1+\varphi} + \frac{2\Omega w_\mathrm{i} + \Omega\eta_\mathrm{i}}{1-\varphi}) - \gamma\psi_\mathrm{i}$$

We have: $\frac{d^2\pi_i}{d^2\omega_i} = -k\frac{2\Omega w_\mathrm{i}}{1-\varphi} \le 0,$ then the function admits a maximum. This maximum is obtained by solving $\frac{d\pi_i}{d\omega_i} = 0$

c) Resilience and wholesale price analysis: First and foremost, it is essential to emphasize that the chosen model in this article involves the incorporation of imports to meet a portion of the store's demand from overseas. This strategic decision is made with the primary aim of enhancing the resilience of the supply chain. Consequently, it becomes crucial to examine the wholesale price concerning this resilience concept.

Now, let's explore how the wholesale price behaves within the context of government subsidies, customs fees, and the supplier's flexibility in adjusting φ to impact wholesale prices. This analysis will provide a comprehensive understanding of the dynamics at play in the supply chain and its price regulation.

The Eq. (12) represents the wholesale price offered by the supplier as a function of the level of imported quantities $w_i{}^s(\theta)$, taking into account government subsidies ν and custom fees τ. When ν is high, meaning that the government offers generous subsidies for local products, the function tends to decrease with an increase in ν (i.e., an increase in imports). In other words, government subsidies reduce the wholesale price to encourage local production and reduce dependence on imports.

However, when τ is high, indicating substantial custom fees imposed on imports, the function $w_i{}^s(\theta)$, tends to increase with an increase in θ,. Additional customs fees raise the cost of imports, which can result in higher wholesale prices for imported products.

This means that the government plays a significant role in market price regulation. Furthermore, the supplier can adjust φ to slightly lower or raise wholesale prices, but with a limited variation.

Proof. The expression for the slope of the line in the Eq. (12) is as follows: $m = \frac{1}{2\mathrm{k}\Omega}(\tau - \nu)$. So, when $\nu > \tau$ (government subsidies exceed customs fees), $(\tau - \nu)$ is negative.

This results in a positive slope (m > 0), indicating a positive incline of the line.

Conversely, when ν < τ (government subsidies are less than customs fees), $(\tau - \nu)$ becomes positive.

This yields a negative slope (m < 0), signifying a negative incline of the line

d) Sustainability effort elasticity impact on wholesale prices: Furthermore, an analysis regarding the elasticity of sustainability effort (k) highlights that with a high k, the function becomes more responsive to variations in θ. An increase in θ (more imports) can lead to a more significant rise in wholesale prices when sustainability effort is high. This indicates that an increased commitment to sustainability can have a greater impact on the supplier's pricing decisions. On the other hand, for a low value of (k), indicating low elasticity of sustainability effort, the wholesale price will be less sensitive to variations in (θ). An increase in (θ) may have a less significant impact on wholesale prices when sustainability effort is low. In this case, other factors, such as government subsidies and customs fees, may play a more prominent role in determining wholesale prices.

3) Government strategies: The government derives its profit from the taxes it imposes on the quantities of products imported from abroad. In this government profit formulation, we must include not only the total quantities ordered by the stores but also the safety quantities planned by the supplier to ensure resilience. Furthermore, within the context of government profit analysis and sustainability considerations, we take into account social charges. These charges, directed towards essential programs such as healthcare and pensions, play a crucial role in bolstering stability, alleviating poverty, supporting employment, and promoting social equity, thereby contributing to a more sustainable and equitable society.

The profit equation for the government is given as follows:

$$\pi_g = [\theta(\tau+\nu) - \nu]\sum_{i=1}^{n}(d_i + \psi_i) + \ \lambda\frac{A}{d_m}\sum_{i=1}^{n} d_i \quad (13)$$

When examining government strategies, the focal point is the calibration of tax rates and subsidies to boost the consumption of domestic products, all the while taking into account the challenges associated with sustainability and resilience. To conduct this analysis and streamline the study, we will rely on the wholesale price of the supplier examined in the preceding section.

Pour faciliter l'analyse, nous allons tenir compte de des subventions.

The government profit function can be written as follows:

$$\pi_g(\nu) = ((-1+\theta)\nu + \theta\tau)(an + \frac{k\Omega-b}{1-\varphi}\sum_{i=1}^{n} w_i + \frac{n(b+k\Omega)\left(-c+\nu-\theta(\nu-\tau)\right)}{2k\Omega} + \frac{(b+k\Omega)}{2k\Omega}\sum_{i=1}^{n}\eta_i + \frac{(1-\varphi)}{2k\Omega}[n(a-b) - \gamma\sum_{i=1}^{n}\psi_i]) + \frac{aAn\lambda}{d_m} + \frac{A\lambda(-b+k\Omega)}{d_m\ (1-\varphi)}\sum_{i=1}^{n} w_i \qquad (14)$$

To simplify the analysis, we will only consider the government subsidy parameter. Indeed, addressing the government profit function has allowed us to obtain an optimal government subsidy that maximizes this profit function. So, Eq. (15) provides the government subsidy that maximizes the profit function $\pi_g(\nu)$.

$$\nu^* = \frac{n^2(c-\overline{\eta})}{2(1-\theta)} + \frac{1}{2(b+\mathrm{k}\Omega)(1-\theta)}\left[2\mathrm{k}\Omega\left(1 - n^2\frac{(b-\mathrm{k}\Omega)}{-1+\varphi}\overline{w}\right) + (n^2\gamma\overline{\psi} + a - b)(1-\varphi)\right)] \qquad (15)$$

With,

$$\sum_{i=1}^{n}\eta_i = n\overline{\eta}, \sum_{i=1}^{n} w_i = n\overline{w}\,, \sum_{i=1}^{n}\psi_i = n\overline{\psi}$$

Proof. To find the maximum profit, we derive the profit function $\pi_g(\nu)$.

We have: $\frac{d^2\pi_g}{d^2\nu} = -\frac{(b+\mathrm{k}\Omega)n(-1+\theta)^2}{\mathrm{k}\Omega} \leq 0$, then the function admits a maximum. This maximum is obtained by solving $\frac{d\pi_g}{d\nu} = 0$

The Eq. (15) suggests that the government subsidy ν is determined based on a combination of factors related to the number of stores, operating costs, sustainability sensitivity, price elasticity, and various parameters associated with sustainability efforts and costs. The quotient (Ω) highlights the importance of sustainability efforts relative to the price of the product, indicating that the government subsidy is influenced by the sustainability quotient.

Moreover, the government subsidy (ν) reveals a nuanced relationship with the parameter θ, representing the ratio of the quantity of foreign products in the market. The presence of (θ) in the equation underscores the government's strategic approach to balancing the consumption of domestic and foreign products. As (θ) increases, indicating a higher reliance on imported goods, the government subsidy adjusts to incentivize and support domestic product consumption. This reflects the government's commitment to fostering economic resilience by promoting a balance between local and international products.

IV. Numerical Analysis

In this part, numerical analysis is employed to validate the conclusions drawn in the preceding section. The focus is on exploring sustainability and resilience within logistics supply chains concerning pricing strategies and sustainability efforts. Additionally, government interventions in the logistics system are addressed, considering the constraints previously outlined in this paper. The numerical values chosen for this analysis are derived from a comprehensive examination of existing literature, ensuring alignment with established methodologies. Moreover, these values are thoughtfully selected based on the specific assumptions outlined in our study, thereby enhancing the overall validity and reliability of our numerical approach.

A. Price, Sustainability, and Profit Analysis on the Store Side

To assess the optimal price for a store concerning sustainability parameters, the analysis highlights a positive correlation between the store's price and its sustainability effort, as illustrated in Fig. 2. This positive relationship remains consistent across different scenarios of sustainability effort elasticity (k), suggesting that higher values amplify the price (p_i) response to changes in sustainability initiatives (s_i). Practically, as the store strengthens its commitment to sustainability increases, there is a notable rise in product prices, with this response being particularly pronounced with higher values. Additionally, the wholesale price (ω_i) plays a crucial role in determining the baseline cost and influencing the overall pricing structure.

However, in analyzing the store's profit through optimal sustainability efforts as illustrated in Fig. 3, one can also observe the correlation of sustainability (s_i) with the price (p_i) set by the store. Nevertheless, the cost coefficient of sustainability effort (α) for store plays a crucial role in adjusting this correlation.

Furthermore, concerning the store's profit, sustainability effort elasticity (k) affects this profit. It can be observed in Fig. 4 that a small variation in profit is guaranteed when the sustainability effort elasticity coefficient (k) is small. Conversely, when this coefficient (k) is large, it is noticeable that it increases profit with a significant variation relative to the price.

$a = 100, b = 1, F = 30, A = 50, y = 2, \alpha = 0.2,$

$w = 40, c_i = 10, s_i = 11$

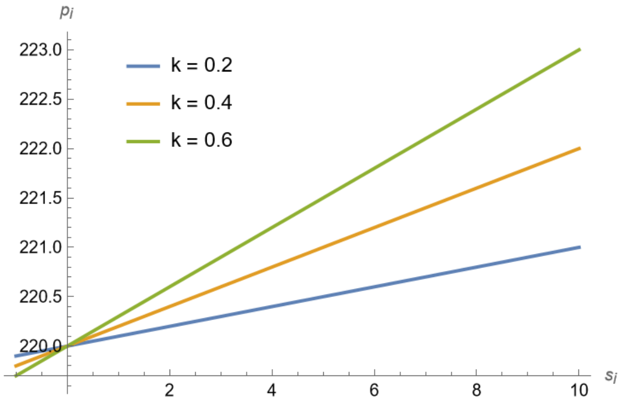

Fig. 2. Correlating Optimal store prices with sustainability parameters.

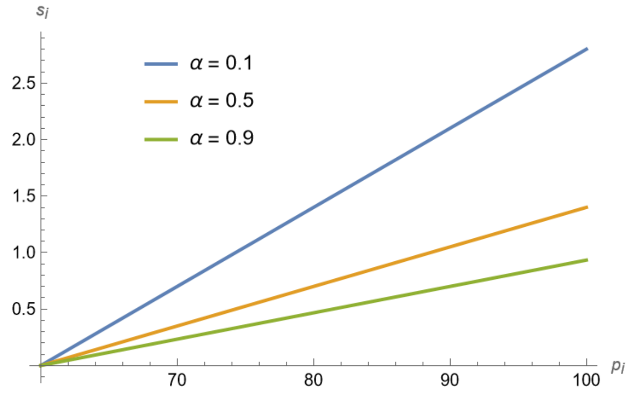

Fig. 3. Correlating Optimal sustainability effort store price.

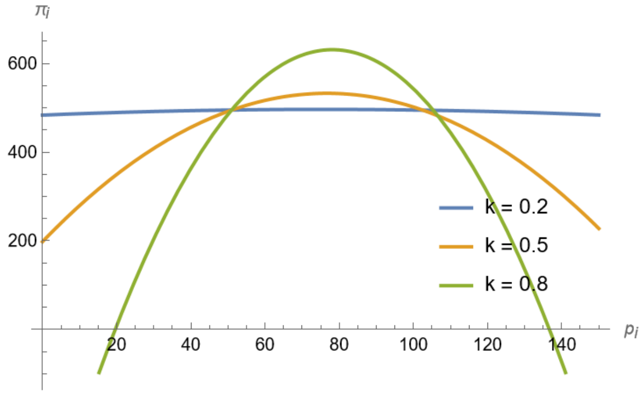

Fig. 4. Influence of sustainability effort elasticity on store profit.

In the same context, the store is tasked with determining the purchase price (p_i) for negotiation with the supplier. Our analysis delves into the interplay between this purchase price (p_i) and two pivotal parameters: (α), the cost coefficient of sustainability effort for the store, and (k), the elasticity of sustainability effort. This investigation is illustrated in Fig. 5, where specific values for α (0.01, 0.2, and 0.4) were selected to explore the nuanced dynamics of sustainability and pricing strategies.

The graph in Fig. 5 demonstrates that as sustainability sensitivity (k) increases, reflecting a greater commitment to sustainability, the store encounter a corresponding upward trend in optimal negotiation costs ($\widehat{w_i}$). This implies that striving for higher sustainability standards may necessitate the store to allocate additional resources to negotiation processes, potentially incurring higher expenses. The impact of this relationship varies based on the sustainability cost coefficient (α), with lower (α) values resulting in a relatively moderate increase in negotiation costs as sustainability sensitivity rises. This suggests that stores with lower sustainability costs may find it economically feasible to invest more in negotiations for enhanced sustainability.

B. *Partial Supplier Profit Case*

The relevant parameters are assigned as:

$c = 10, \eta = 2, a = 50, b = 0.2, \gamma = 5, \psi = 4, c_i = 2$

Sustainability Coefficient (α) and Optimal Price (ω_i): The graph in the Fig. 6 depicts the variation in the optimal price ω_i as a function of the sustainability coefficient (α) for different values of the elasticity of sustainability effort (k). This illustrates how the optimal price of a product or service changes in response to variations in the sustainability coefficient, which can be interpreted as a measure of a company's commitment to sustainable practices. The different curves for k = 0.1, 0.5 and 0.9 show how the elasticity of sustainability effort affects the sensitivity of the optimal price to changes in sustainability.

Impact of Sustainability Effort Elasticity (k): The curves reveal that the optimal price reacts differently to changes in the sustainability coefficient (α) depending on the value of the elasticity of sustainability effort (k). For instance, a higher value of k (k = 0.9) demonstrates a greater responsiveness of the optimal price to sustainability variations compared to a lower value of k (k = 0.1). This suggests that, in this model, an increased commitment to sustainability (increasing α) has a more significant impact on price when the elasticity of sustainability effort is higher.

Profit Optimization and Sustainability: The model appears to seek a balance between profit maximization (represented by the optimal price formula) and the promotion of sustainable practices (embodied by the sustainability coefficient α). Price variations in response to changes in α and k may indicate how a company can adjust its prices to achieve its economic objectives while promoting sustainability, which has significant implications for decision-making in a business context.

$a = 100, b = 1, \Omega = 3, \gamma = 0.5, \phi = 0.2, \psi = 0.7, c = 20, \nu = 10, \theta = 0.4, \tau = 0.8, \eta = 0.5, \alpha = 0.01$

Exploring equilibrium wholesale prices involves an examination of the negotiated purchase price ($\widehat{w_i}$) by the store to optimize its profit and the selling price (${w_i}^s$) set by the supplier for store i. The graph in Fig. 7 reveals the intersection, indicating an equilibrium price where the curves representing both prices meet. Additionally, we underscore the significance of the sustainability sensitivity coefficient (k) in this analysis.

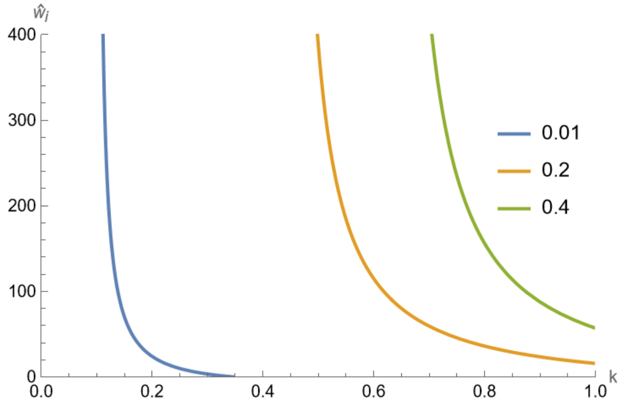

Fig. 5. Comparative analysis of optimal negotiation price and sustainability parameters.

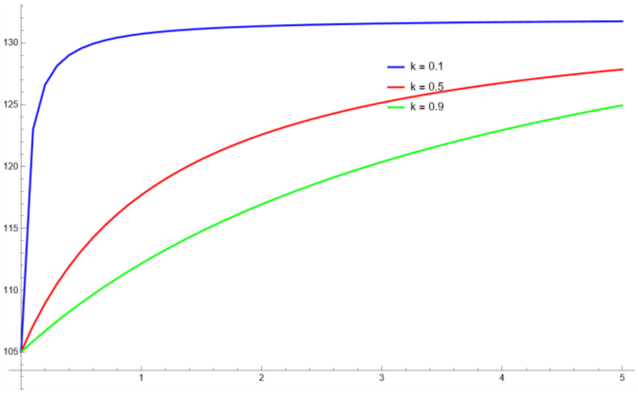

Fig. 6. Wholesalse price in function of sustainability coefficient k.

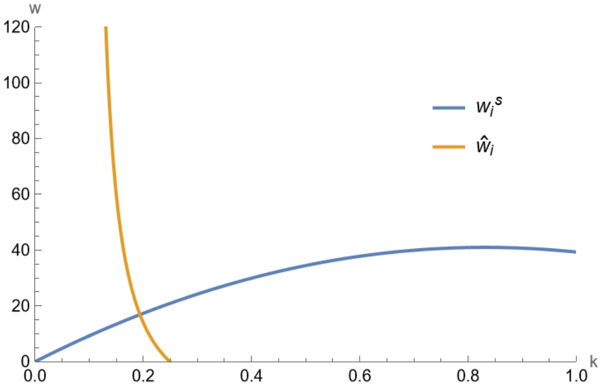

Fig. 7. Equilibrium wholesale prices.

C. Supplier Chain Resilience

In an effort to investigate the resilience of the supply chain, we have constructed a set of numerical values given in Table II. The objective is to analyze the profits of both the government and the supplier. The numerical data within the table offers a comprehensive view of how variations in parameters, such as the rate of foreign products (θ) and inventory security sensitivity (γ), impact the financial outcomes for both key stakeholders in the supply chain. This analysis provides valuable insights into the resilience of the supply chain under different conditions and aids in decision-making related to supply chain management strategies.

TABLE II. IMPACT OF SUSTAINABILITY AND RESILIENCE PARAMETERS ON GOVERNMENT AND SUPPLIER PROFITS

$\boldsymbol{\theta}$	$\boldsymbol{\lambda}$	$\boldsymbol{\pi_s}$	$\boldsymbol{\pi_g}$
0.39	0.3	1101.00	40291
0.39	0.54	1065.29	38371
0.39	0.78	1029.59	36451
0.59	0.3	5530.22	39956.7
0.59	0.54	5368.52	38036.7
0.59	0.78	5206.82	36116.7
0.79	0.3	9981.19	39622.4
0.79	0.54	9693.49	37702.4

V. RESULTS AND DISCUSSION

In this section, our attention is directed towards a comprehensive examination of the outcomes derived from the implemented model and numerical analyses. Subsequently, the ensuing discourse will meticulously explore the findings pertaining to profit maximization for each stakeholder, specifically, the store, the supplier, and the government.

Within this framework, stores wield authority over pricing and sustainability strategies, while the supplier assumes responsibility for distribution and inventory management. Simultaneously, the government plays a crucial role by enforcing regulations, particularly through taxation and subsidies, with an emphasis on both domestic and foreign products. Central to our investigation is the resilience of this supply chain, where we take into account various factors such as security stock, the social impact of stores, and the diversification of supply sources. Our primary objective was to comprehensively analyze the dynamic interplay within this supply chain, with a particular emphasis on sustainability, resilience and the promotion of domestic production.

Each stakeholder of the supply chain; namely the store, the supplier, and the government, adopt strategies to maximize their profits. Regarding the store i, the model presents two strategies for improving profit, with $s_i{}^*$and $p_i{}^*$as always profit-maximizing solutions. From the supplier's perspective, the first strategy centers on calibrating the optimal wholesale price ($\omega_i{}^*$) in a manner that harmonizes sustainability commitments with supply chain. The second strategy expands this focus to encompass the broader network, seeking to establish a wholesale price ($w_i{}^s$) that incorporates resilience metrics, thus ensuring profit maximization across the network. On the governmental front, the strategies revolve around custom fees (τ) on international imports and subsidies (ν) to bolster the competitiveness of domestic products, balancing international trade with local economic encouragement.

Sustainability emerges as a key point in the main conclusions of this study, particularly in its influence on pricing strategies within supply chains. Firstly, a store's pricing strategy is closely linked to its sustainability efforts (s_i), with the cost coefficient of these efforts (α) playing a significant role in shaping pricing (p_i). The elasticity of sustainability efforts (k) is found to directly impact profit margins (π_i) where a lower elasticity results in smaller profit variations, and a higher elasticity leads to more substantial profit fluctuations relative to price changes. Additionally, as a store intensifies its commitment to sustainability, it incurs higher negotiation costs ($\widehat{w_i}$), though this is less burdensome for stores with lower associated sustainability costs (α). The optimal price ($\omega_i{}^*$) of a product is thus affected by the company's sustainability commitment (α) and its responsiveness to sustainability efforts (k), with more responsive companies experiencing more significant pricing effects. This indicates a strategic imperative for businesses to align pricing with sustainability objectives, balancing environmental considerations with the aim of profit optimization.

Resilience in the model is a keystone of the supplier's strategy, by allocating reserved inventory quantities (ψ_i) in wholesale prices for each store i. This approach ensures that pricing and stock level decisions are in concert with the overarching ambition to fortify the supply chain's robustness. Parallel to this, the government's regulatory role is crucial in preserving a delicate balance between encouraging domestic products and regulating the import of foreign products, thereby providing more flexibility to diversify the product sources and underpinning economic resilience. Indeed, the resilience of the supply chain, as examined through numerical analysis, is affected by parameters like the rate of foreign products (θ) and inventory security sensitivity (γ), which in turn influence the profits of both the government and the supplier.

The equilibrium wholesale price is found at the intersection of the store's purchase price and the supplier's selling price, with the sustainability sensitivity coefficient being a significant factor in this determination. This convergence underscores the indispensable importance of collaboration among supply chain stakeholders in achieving optimal profits. Through a synergistic partnership, suppliers, stores, and government entities can refine sustainability efforts.

VI. Conclusion

Sustainability and resilience have become essential pillars in the formulation of pricing policies, ensuring that economic strategies are adaptive and viable over the long term. These concepts, grounded in economic significance as demonstrated by the literature, require in-depth analysis of how pricing policies and governmental regulatory measures, such as the promotion of domestic products, can coexist to strengthen the sustainability and resilience of supply chains.

This study addresses the under-researched interplay between sustainability, resilience, and the promotion of domestic products within supply chains, offering new approaches for tackling the complex challenges in supply chain management. It highlights the unexpected competitive dynamics that can occur even for monopolistic suppliers when they supply and compete with their stores. Our supply chain management model scrutinizes the intricate interactions among three pivotal entities: a central supplier, multiple stores, and the government.

The supply chain framework is analyzed with a focus on the roles of stores, suppliers, and the government. Stores control pricing and sustainability strategies, suppliers manage distribution and inventory, and the government enforces regulations, including taxation and subsidies. The study emphasizes the resilience of the supply chain, considering factors like security stock, social impact, and diversification of supply sources. Stakeholders adopt profit-maximizing strategies, with stores having two pricing strategies linked to sustainability efforts. Suppliers focus on optimal wholesale prices aligned with sustainability and resilience metrics. Government strategies involve custom fees and subsidies to balance international trade and support domestic products. Sustainability efforts significantly influence pricing strategies, with lower elasticity resulting in smaller profit variations. Resilience is crucial for suppliers, involving reserved inventory quantities. Government regulation balances encouraging domestic products with regulating imports, enhancing economic resilience. The equilibrium wholesale price is determined by collaboration among stakeholders, emphasizing the importance of a synergistic partnership for optimal profits and sustainability efforts.

It is crucial to elucidate the limitations of our study, providing researchers with valuable context. The main limitation of the model developed in this research lies in its assumption that demand is deterministic, a simplification that does not reflect the dynamic and often unpredictable reality of the market. In practice, consumer demand is subject to fluctuations influenced by various factors such as changing preferences, competition, and economic conditions. This deterministic approach can lead to inaccurate forecasts and suboptimal decisions in a real business context. To enhance the practical relevance of this study, it would be crucial to explore more sophisticated models that incorporate demand variability, allowing companies to better adapt to market changes and optimize their strategies by considering inherent uncertainties.

Looking ahead, a prospective avenue for upcoming research studies involves extending the current model to incorporate a more complex network structure. This expansion would enable a more in-depth exploration of the cooperative dynamics among supply chain stakeholders. A particular focus should be placed on developing a stochastic model to better align with the real-world scenario where demand is variable, allowing for a more accurate representation of uncertainties. The objective is to examine whether the observed impacts in this study persist or if new patterns emerge within the intricacies of a larger supply chain network. Such an investigation could significantly enrich our understanding of supply chain sustainability, resilience, and collaboration by providing insights that are more reflective of the complexities and uncertainties inherent in real-world demand dynamics.

Acknowledgment

This research paper was conducted by the LASTIMI laboratory of Mohammed V University in Rabat, High School of Technology of SALE and supported by ESITH Morocco. The authors are sincerely grateful to CELOG team and each person who have helped in any way to the accomplishment of this study.

Investigating Agile Values and Principles in Real Practices

Abdullah A H Alzahrani
Department of Computers, Engineering and Computing College at Alqunfuda,
Umm Al Qura University, Makkah, Saudi Arabia

***Abstract*—Software engineering is the field of development of information systems. However, the development process can often be complicated. Therefore, many researchers have introduced their approaches to manage the complication. This led to the introduction of new subfields such as change management, and organisational change. Agile can be regarded as a collection of best practices with the same values and principles. Since the introduction of Agile manifesto, many researchers, manufacturers, and organisations have introduced their thoughts, tools, and models to enhance the understanding and adoption of Agile. Sharing a similar understanding of Agile among people involved is essential in order to adopt it. This paper investigates the understanding of Agile among IT professionals. In addition, the factors that impact the understanding and adoption of Agile are highlighted and studied. A survey methodology was employed in this research among IT professionals from different organisations. The results of this study show that productivity and ability to accept change are conflicting the understanding among participants. Furthermore, the experience of participants has an impact on the ways in which Agile are adopted.**

Keywords—Agile; software engineering; information systems; change management; organisational change

I. Introduction

Since 2001, Agile [1]–[3] has been known to be the most adaptive way in the field of software engineering. It refers to a software development model that should accept changes during software development. Hesselberg [4] articulated that “The agile mindset is now finding its way into the C-suite, and it is starting to radically change the way organizations are led and managed. Business agility is on everybody´s lips, for very good reasons”.

Some researchers define Agile as a collection of best practices with same values and principles [5]. However, other researchers define Agile as a subset of iterative methods of the traditional methodologies of software development [6]. In general, Agile can be defined as development way that relies on the philosophy of change embracing.

Agile has several benefits that overcome traditional ways. These benefits can be summarized in the following: change embracing, customer heard, quick achievement, good interactions, and continuous improvements. However, several drawbacks come along with Agile. These drawbacks can be summarized in the following: time consuming, unsatisfactory documentation, change dilemma, and unclear customer [7]–[9].

Many have introduced their Agile methods and frameworks [10]–[13] such as Scrum [14]–[16], eXtreme Programming (XP) [17]–[19], and DevOps [20]–[22]. Each method and framework has its own pros and cons. However, there is no unified framework or method that can be considered to be the best practice in every circumstance [23].

Since Agile introduction, many software development teams are claiming that they adopt Agile model, However, a question of “do they adopt agile?” can be raised. This research aims to investigate the understanding of Agile among software development teams. It is crucial that development teams share the same understanding of Agile when it is employed. Therefore, this research questions the understanding by investigation each value and principle of Agile against the participants views of these values and principles. This is carried out by asking the participants to priorities and criticizes the values and principles. In addition, it highlights any modified version of adopting and understanding that can exist.

The remainder of this paper is structured as follows: Section II describes the related work of this field of research. This is followed by the Section III which describes the research questions of this research. The methodology employed is described in Section IV. Section V is divided into three subsections which show and discuss the findings of this research. Finally, the conclusion and limitations will be drawn in Section VI.

II. Related Work

Ozkan et al. [24] have introduced a study that combines Agile principles from different resources and divided them into groups in order to develop a better understanding of Agile. This grouping was done by one expert. The evaluation process involved two experts. However, authors still see the understanding of Agile as a challenging process [25].

Nurdiani et al. [26] introduced their methodology to understand and compare Agile Maturity Models (AMM) and its strategies. The methodology was based on collecting data from previous studies’ results on the topic and a survey done on 46 participants. However, the attempt arrived to transfer Agile methods onto organizational level and practical implications [27].

Koi-Akrofi et al. [28] investigated Agile in management of IT projects. The study was to compare the use of Agile and traditional ways to manage IT projects. The study focused on the challenges of using Agile. The authors found that despite the benefits of using Agile, many challenges accompany the employment of Agile. These challenges, such as empowerment and organization culture, make it difficult to apply. Therefore, many go to the traditional ways instead of Agile or merge both models in real life.

Hess et al. [29] investigate the ways to improve the understanding of Agile in the perspective of Information needs and communication and collaboration. The study is based on a previous study of the authors that investigate traditional ways. The authors are comparing the results from both studies. The findings highlighted the gap in product inconsistency when employing Agile. However, authors found also that teams do not share the same understanding of the values of Agile as they use them differently [30].

Barroca et al. [31] introduced a paper that summarizes an international workshop discussion on Agile transformation. Many definitions were discussed and presented. In addition, challenges of Agile transformation were identified. One of the challenges is the understanding of Agile within the teams. However, the authors attempted combine solutions to overcome these challenges [32]–[34].

Jia et al. [35] have conducted a case study to investigate the understanding of developers of Agile requirements. The study was conducted on around 130 students divided into 17 teams to develop a web-based email management system. The main findings of the study identified difficulties in understanding the Agile requirements. Inconsistent understanding of Agile was noticed [36].

Baham et al. [37] have introduced a theoretical core that they found to be a gap in the studies of Agile. The authors offered a framework that unified the theoretical understanding of Agile. However, the study is considered to be an inspiration for future discussion and implications on the topic.

Eilers et al. [38] have investigated the gap between being Agile and going Agile among development teams. The study included around 129 participants and shows that the empowerment of the development teams enhances the Agile work and overcomes challenges. In addition, happiness and commitment are the factors of connection of being or doing Agile [39]. However, it has been argued that empowerment has limited impact on project outcomes [40].

III. Research Question

This research outlines two research questions which focus on the investigation of Agile understanding and adoption among software development teams.

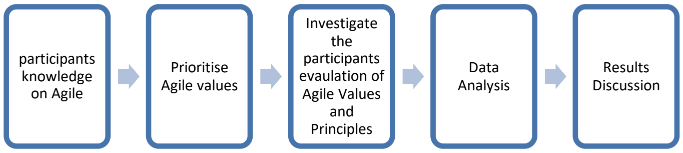
RQ1. Is there a difference in understanding and adoption between experienced IT professionals and less experienced professionals? In order to answer this question, participants will be asked to categorize themselves into one of five categories. Based on the answer to this question, the collected data will be analyzed accordingly.

RQ2. Based on the experience of IT professionals, is there an evolutionary understanding of Agile values and principles? The answer to this question will rely on participants' views on priority and criticism of Agile values and principles.

IV. Methodology

This research employed the methodology of questionnaire. This methodology will allow collected data based on experience of participants and classify the responses for further investigation. The questionnaire was sent to potential participants in the IT field via emails and social communication. Fig. 1 shows the stages of the investigation.

The questionnaire was sent to 80 potential participants, the responses received were 38 responses. The participants are IT professionals with different job titles namely: Software Analyst, Software Designer, Software Developer/ Implementer/ Programmer, Software Engineer, Software Project Coordinator, Software Project Manager, and Software Tester. It is clear from the aforementioned job titles that the focus on this study is Agile adoption and understanding among software development teams.



participants knowledge on Agile
Prioritise Agile values
Investigate the participants evaulation of Agile Values and Principles
Data Analysis
Results Discussion

Fig. 1. Research methodology.

The questionnaire was divided into four sections. The first section includes direct questions about gender, job title, qualification, and years of experience. In addition, in this section, participants are asked to rate their knowledge on Agile and whether they have been taught or trained on Agile. Furthermore, participants are asked if they view their organization employing Agile. The second section is related to Agile values shown in Table I. The participants are asked to prioritize the values from their experience.

TABLE I. Agile Values [3]

Values	abbreviation
Individuals and interactions over processes and tools	Val1
Working software over comprehensive documentation	Val2
Customer collaboration over contract negotiation	Val3
Responding to change over following a plan	Val4

In the third section of the questionnaire, the participants are asked to criticize the Agile values shown in Table I with one of the options shown Table II. The fourth section of the questionnaire is also regarding participants' criticism on the Agile principles shown in Table III. The criticism is based on participants' selection of options from Table II to the principles shown in Table III.

TABLE II. Criticism Criteria

Criterion	Meaning
Keep as it is	No change suggested
Need To be Removed	Removal suggested
Need To Be Modified	Some changes might be suggested

Following the ethical manner of scientific research, participants were informed that the collected data is confidential and is used for research purposes. Thereafter, they were asked to provide their consent to participate, and they were able to withdraw at any stage of the process. The participants were assured that their privacy is protected and respected.

TABLE III. AGILE PRINCIPLES [3]

Principles	abbreviation
Our highest priority is to satisfy the customer through early and continuous delivery of valuable software.	PPl1
Welcome changing requirements, even late in development. Agile processes harness change for the customer's competitive advantage.	PPl2
Deliver working software frequently, from a couple of weeks to a couple of months, with a preference to the shorter timescale.	PPl3
Business people and developers must work together daily throughout the project.	PPl4
Build projects around motivated individuals. Give them the environment and support they need, and trust them to get the job done.	PPl5
The most efficient and effective method of conveying information to and within a development team is face-to-face conversation.	PPl6
Working software is the primary measure of progress.	PPl7
Agile processes promote sustainable development. The sponsors, developers, and users should be able to maintain a constant pace indefinitely.	PPl8
Continuous attention to technical excellence and good design enhances agility.	PPl9
Simplicity--the art of maximizing the amount of work not done--is essential.	PPl10
The best architectures, requirements, and designs emerge from self-organizing teams.	PPl11
At regular intervals, the team reflects on how to become more effective, then tunes and adjusts its behavior accordingly.	PPl12

From Fig. 2, 74% of participants are males where the remaining are females. In addition, participants are from a different range of experiences. However, most of them have less than 10 years of experience with a percentage around 61%. Participants with more than 10 years of experience constitute around 39% of all participants.

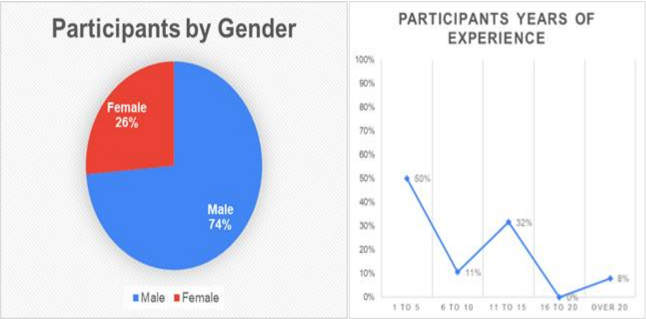


Fig. 2. Participants genders and experience range.

V. RESULTS AND DISCUSSION

In this section, the results of the research will be shown and discussed. First, the general findings of the research will be presented and discussed. These are related to the participants understanding of Agile and the source of knowledge learnt Agile from. In addition, how the participants view the adoption of Agile in their organisations. Next, the remaining subsections are presenting the findings related to the research questions of the experiences of the participants and their understanding of Agile and new models of understanding.

A. General findings

In order to identify the source of the participant's knowledge of Agile, participants were asked direct questions specifying if they have learned Agile in school or at training in a workplace. Fig. 3 shows that around 74% of participants have been trained in the workplace on Agile. On the other hand, just above half of participants have been taught Agile at school.

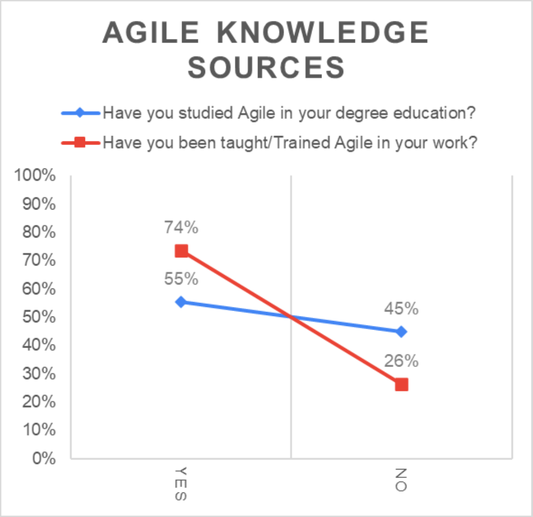

Fig. 3. Participants knowledge source of agile.

From Fig. 3, it is obvious that workplaces are more interested in Agile, and they tend to train professionals on Agile even if they have studied it. From this, organisations of participants urge the adoption of Agile. However, contrastingly, Fig. 4 illustrates the view of the participants on the adoption of Agile, and it is obvious that around 58% of participants believe that their organisations adopt Agile.

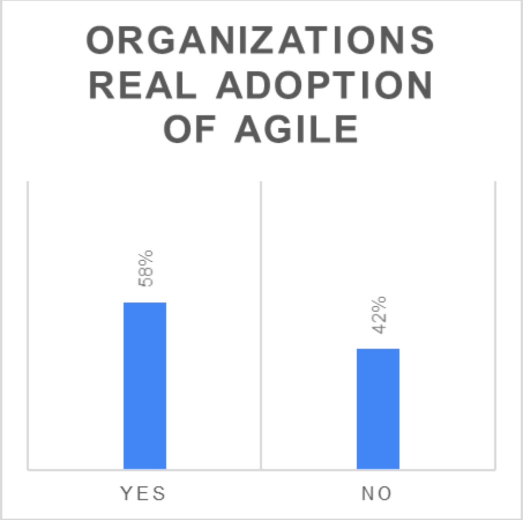

Fig. 4. Participants views on adoption of Agile in their organisation.

Fig. 5 illustrates a key point about the understanding of Agile among IT professionals. It shows the participants' self-rating on Agile knowledge. Although, as shown in Fig. 3, 74% of participants received training on Agile and 55% of them studied it in school, Fig. 5 shows that around 61% of participants rated their knowledge in Agile as medium as or less than medium.

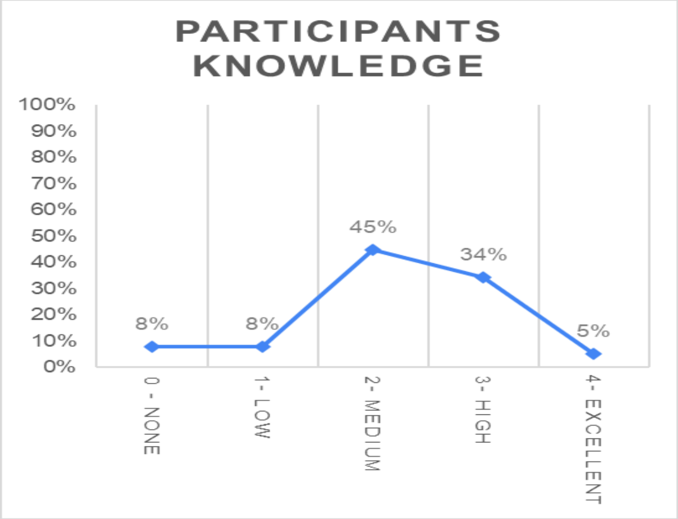

Fig. 5. Self-rating of participants on Agile knowledge.

It can be concluded from the general findings that there is a gap in sharing the understanding of Agile among IT professionals. In addition, despite the urge of the organisations to adopt Agile, a struggle can be noticed to do such. This might be attributed to the gap of Agile understanding among the IT professionals.

B. Prioritising Agile Values

In order to investigate the new understanding of Agile, participants were asked to prioritize the values of Agile shown in Table I. It is obvious from Fig. 6 that Val2 has been prioritized the most by participants as it occupies the first and second priority. Val2 is regarding the value of working software over documentation. This is an interesting point as this value needs interactions with clients and might lead to a change of requirements. Therefore, Val1 and Val4 are following in the priority order as shown in Fig. 6.

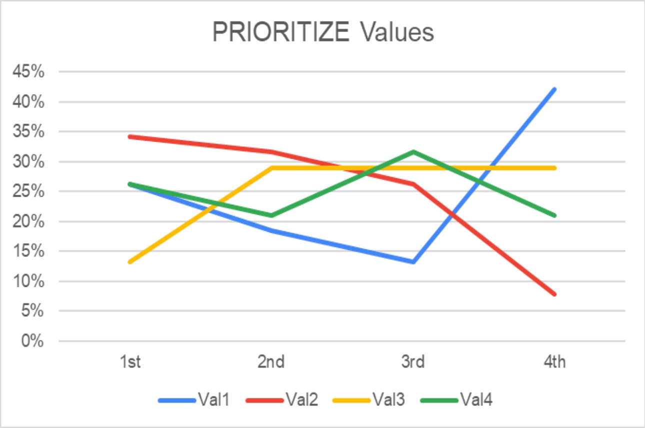

Fig. 6. Participants prioritising Agile values.

It can be concluded that the understanding of the participants of Agile values has been impacted by the tendencies of productivity and customer satisfaction. In addition, software documentation might be affected by adopting Agile as this understanding imposes more productivity over quality and more changes over quality.

C. Criticism of Agile Values and principles

Participants were asked to provide an abstract view on the criticism of the values and principles of Agile. Fig. 7 shows the participants responses to a criticism question on each value of Agile. The question aims to collect a general answer of participants as if they believe that a value should be eliminated, modified, or kept as is.

From Fig. 7, it is obvious that Val2 is a controversial value among participants. In addition, a high number of opinions regarding modification and elimination to the value were focused on Val2 with around 71%. It is worth noting that Val2 is about productivity over quality. Furthermore, Val4 received an equal number of responses to modification and elimination, however, it received the highest number of responses to be kept as is among other Agile values.

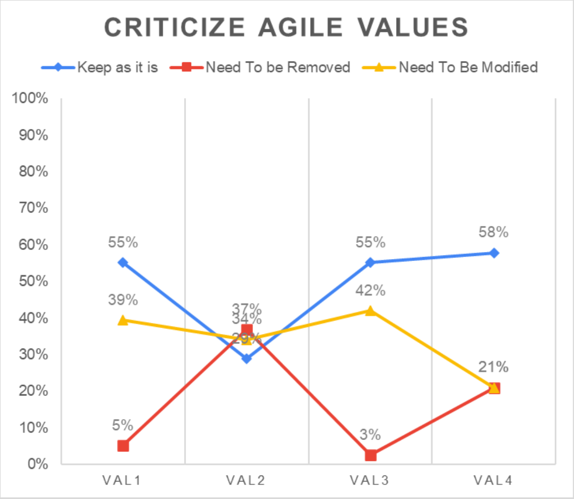

Fig. 7. Participants criticising Agile values.

With regards to the criticism of Agile principles, Fig. 8 illustrates the responses of the participants. Overall results show that participants tend to have no criticism of Agile principles, as the dominant response is to keep as is. However, PPL2, PPL6, PPL7, and PPL10 seem to receive responses regarding modification of these principles. It is worth noting that PPL2 is about changes in software, PPL6 is about communication with clients, PPL7 is about productivity, and PPL10 is about simplicity of software.

It can be concluded from results shown in Fig. 7 and Fig. 8 that Val2, which is regarding productivity over quality, is again obvious in the criticism of the participants. Interestingly, the principles of PPL2, PPL7, and PPL10 are related to the Val2. From this it can be noticed that productivity over software quality is a controversial understanding among the participants. In addition, this is related directly to the adoption of Agile as it might introduce new ways of Agile adoption or affect the traditional way of Agile adoption.

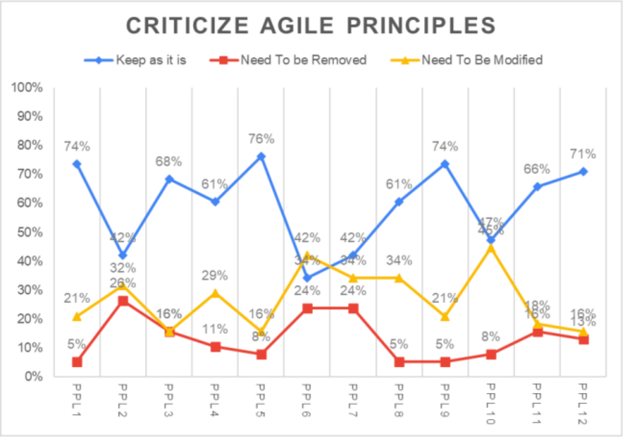

Fig. 8. Participants criticising Agile principles.

D. *Criticism of Agile Values and principles Based on experience.*

In this section, the previous criticism of Agile values and principles is investigated further. The focus is on the comparison of participants' responses to the criticisms based on years of experience. The responses were divided into two groups: less than 10 years of experience and more than 10 years of experience.

Fig. 9 illustrates the criticism responses of participants regarding Agile values based on experience of participants. It is obvious from the Figure, that participants with less than 10 years of experience have no tendency to criticize except for Val2 where around 70% of the participants think Val2 needs to be eliminated or modified.

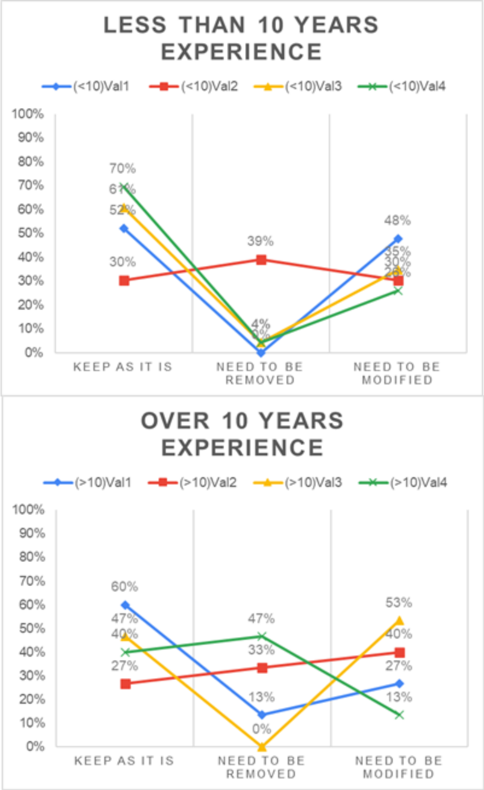

Fig. 9. Based on experience participants criticising Agile values.

On the other hand, participants with more than 10 years of experience agree with participants with less than 10 years of experience on that Val2 needs to be eliminated or modified. Furthermore, the majority of participants with more than 10 years of experience think that Val3 and Val4 should be modified and eliminated respectively.

With regards to Agile principles, Fig. 10 shows the criticism responses of participants based on experience of participants. The majority of participants with over 10 years of experience think that PPL7 should be eliminated. In addition, they think that PPL6 should be eliminated or modified. In addition, PPL10 received great attention to be modified by the majority of participants with over 10 years of experience.

On the other hand, the majority of participants with less than 10 years of experience believe that PPL2 should be eliminated or modified. In addition, they think PPL6 should be modified. Furthermore, participants with less than 10 years of experience give the same attention as participants with over 10 years of experience on that PPL10 should be modified.

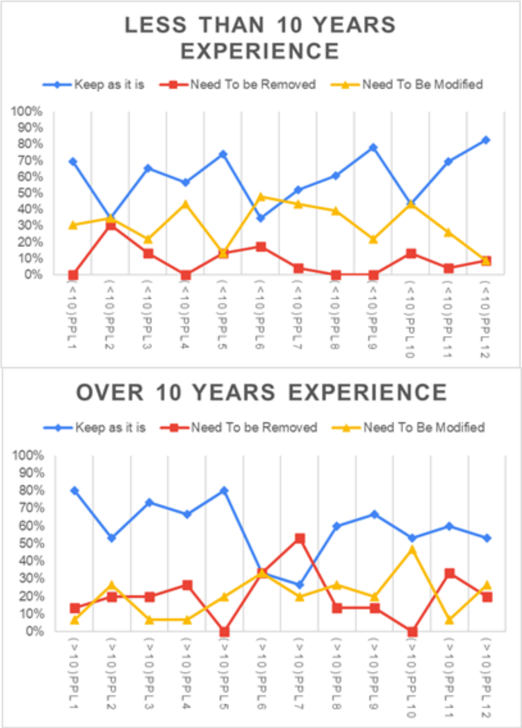

Fig. 10. Based on experience participants criticising Agile principles.

It can be concluded from the results that experience impacts the understanding and perspective of participants on Agile values and principles. This is clear from the difference of the views of Val3 and Val4 as participants with over 10 years of experience are more likely to criticize these two values of Agile unlike participants with less than 10 years of experience. However, all participants agree on the criticism of Val2. In summary these different views might affect the adoption of Agile within teams in organisations.

VI. CONCLUSION AND LIMITATIONS

In this paper, Agile values and principles were focused on in the perspective of the understanding and the adoption from the point of view of the IT professional involved. The methodology of survey was employed in order to investigate the understanding and adoption of Agile among IT professionals.

Findings of this research can be summarized as follows:

1) In general, there is a clear difference in understanding and adoption of Agile.

2) Workplaces are taking Agile seriously and as they pay great attention to Agile training with 74% of participants been trained in their workplace. It seems that workplaces do not rely on the members knowledge of Agile from members' study in schools.

3) Despite the workplace attention to Agile adoption, a great deal of participants does not believe that their workplace is adopting Agile.

4) Despite the training they received and the school teaching of Agile, participants are not confident about their knowledge and understanding of Agile as 61% of them seem to rate their knowledge and understanding as medium of less.

5) The participants understand Agile as productivity more than change embracement. This is due to the priority they give to Val2 as first and second priority.

6) However, Val2 is a controversial value of Agile as 71% of responses in the criticism of Agile values goes to need modification or elimination of Val2.

7) Agile principles PPL 2, 6, 7, and 10 are criticized by participants to be modified or eliminated, however, participants in general do not criticize other Agile principles.

8) Participants with less than 10 years of experience tend to avoid criticizing Agile values except Val2 which they believe should be eliminated or modified.

9) Participants with over 10 years of experience tend to criticize Agile values in particular Val 2, 3, and 4.

10)A difference in focus can be seen in Agile principles criticism between participants with over 10 years of experience and participants with less than 10 years of experience. PPL2 is the principle that participants with less than 10 years of experience believe should be eliminated or modified, whereas participants with over 10 years of experience believe that PPL7 should be eliminated or modified.

As limitations of this study, the number of participants responses is one of the limitations. Reaching a higher number might help in generalizing the results and might give other perspectives to the issues of Agile understanding. Another limitation related to the number of participants is that as the number is not large, responses cannot be divided based on teams with the same job titles.

As future work based on this research, the investigation of refinement of the values and principles of agile should be conducted, since this research findings motivate the refinement of them. Another future direction is the introduction of a new model for training people in organizations which tend to adopt Agile. Finally, further investigation needs to be conducted in the field of quality of software which is developed with the employment Agile.

ACKNOWLEDGMENT

I would like to express my special thanks of gratitude to my University (Umm Al Qura University) which gave me the excellent opportunity to do this research on the topic Software Engineering. Secondly, I would also like to thank my family, friends, and colleagues, who provided me with support in order to conduct this research.

Category Decomposition-based Within Pixel Information Retrieval Method and its Application to Partial Cloud Extraction from Satellite Imagery Pixels

Kohei Arai[1], Yasunori Terayama[2], Masao Moriyama[3]
Faculty of Science and Engineering, Saga University, Saga City, Japan[1, 2]
Faculty of Engineering, Nagasaki University, Nagasaki City, Japan[3]

***Abstract*—Category decomposition-based within pixel information retrieval method is proposed together with its application to partial cloud extraction from satellite imagery pixels. A comparative study was conducted for estimation of the sea surface temperature of the pixel suffered from partial cloud cover within a pixel. Three methods for estimation of partial cloud cover within a pixel, based on the proposed category decomposition-based method with Generalized Inverse Matrix Method: GIMM and well-known Least Square Method: LSM and Maximum Likelihood Method: MLH, were compared. It was found that around 9% of RMS (Root Mean Square) error can be achieved. Also, it was found that estimation accuracy highly depends on variance of representative vectors for cloud and the ocean or observed noise. The experimental results with simulated data show RMS error of GIMM are highly dependent to the noise followed by MLH and LSM. The results also show the best estimation accuracy can be achieved for MLH followed by LSM and GIMM.**

Keywords*—Category decomposition; information retrieval; cloud cover estimation; Generalized Inverse Matrix Method: GIMM and well-known Least Square Method: LSM and Maximum Likelihood Method: MLH

I. Introduction

When estimating the sea surface temperature using visible thermal infrared radiometer data such as NOAA (National Oceanic and Atmospheric Administration) / AVHRR (Advance Very High-Resolution Radiometer), MOS-1 (Marine Observation Satellie-1) / VTIR (Visible and Thermal Infrared Radiometer), for example, as is clear from the MCSST (Multi-Channel Sea Surface Temperature) [1] algorithm, there is only a small amount in the pixel. However, the pixels that are likely to have clouds are detected and excluded from the target of sea surface temperature estimation. Especially in the case of MCSST, the acquisition rate of data not covered by clouds is low because the policy of punishing suspicions is strictly checked for this possibility. As a result, many observation day data are required to obtain a good scene in which all pixels are not covered with clouds, which often hinders the estimation of the 10-day average sea surface temperature.

Even if a small cloud exists in the pixel, if the brightness temperature of the cloud can be known and the area occupancy can be estimated, it can be corrected to some extent and used. Assuming that the brightness temperature of this cloud is equal to that of the pixel covered with 100% cloud in the vicinity of the core pixel, the method of estimating the cloud coverage rate will be examined here. That is, with the aim of creating products of average sea surface temperature in a short period of time, we propose a method for estimating the cloud coverage rate in pixels and examine its effect.

In this paper, we take up the method of estimating the class occupancy in pixels proposed so far as a method of estimating the cloud coverage [2]-[8] and show the result of mutual comparison of estimation accuracy. These estimation methods have been proposed to estimate the class mixing ratio of mixed pixels (Mixel) consisting of multiple classes. When applying these to cloud coverage estimation, it becomes a problem to estimate the mixing ratio for the two classes of cloud and sea, and in general, the number of channels of visible thermal infrared radiometer data exceeds this, so the minimum square method is effective. It is considered to work. Therefore, we took up the least squares method that minimizes the square of the estimation error of the observation vector and the square of the estimation error of the mixing ratio. In addition, we conducted a theoretical study of the estimation error of these least square methods, and the estimation error is small.

It is shown that it is possible to use both adaptively so as to become. We propose an "adaptive least squares method" based on that principle and apply the effect to actual data to confirm it. Furthermore, since it is expected that the spectral reflection and radiation characteristics of cloud pixels will vary widely, the maximum likelihood method that takes the variance into consideration was taken up as a comparison target and compared.

In the next section, related research works are described in Section II followed by theoretical background and proposed method in Section III. Experiments and experiments results are mentioned in Section IV and Section V respectively and finally conclusion and work for future is explained in Section VI and Section VII respectively.

II. Related Research Works

As for the related research works to category decomposition, there are the followings,

Maximum likelihood estimation of category proportion among Mixels is conducted [9]. Meanwhile, image classification from category proportions among Mixels is proposed [10]. On the other hand, decomposition of category mixture in a pixel and its application for supervised image classification is proposed [11].

Category decomposition based on subspace method with learning process is proposed [12] together with category decomposition method for un-mixing of Mixels acquired with spaceborne based visible and near infrared radiometers by means of Maximum Entropy Method: MEM with parameter estimation based on Simulated Annealing: SA [13]. On the other hand, focusing on Mixels located at the boundary between two types of classes, an image decomposition algorithm that uses the class mixture ratio of Mixels and the spatial information of surrounding pixels of Mixels are investigated [14]. Research has also been conducted that adds, but it has not been applied to two or more types of class boundaries. Meanwhile, category decomposition requires an endmember extraction in the spectral space of distributions. When observation data, end member spectra, and content rates are each expressed as a matrix, Mixel decomposition can be regarded as a matrix decomposition problem. Due to physical conditions, all components of the matrix are non-negative values, so by applying non-negative matrix factorization (NMF), the end member spectrum and content can be estimated simultaneously [15]. In the data-driven approach, the material with the estimated endmember spectrum is finally identified by referring to the spectral library and searching for the closest spectrum.

Sea ice concentration estimation method with satellite based visible to near infrared radiometer data based on category decomposition is proposed [16]. Also, category decomposition method based on matched filter for un-mixing of mixed pixels acquired with space borne based hyper-spectral radiometers is proposed [17].

Bi-directional Reflectance Distribution Function: BRDF effect on un-mixing, category decomposition of the Mixel of remote sensing satellite imagery data is estimated [18].

On the other hand, there are the following research works related to cloud overage estimation,

A merged dataset for obtaining cloud free Infrared: IR data and a cloud cover estimation within a pixel for SST retrieval is proposed [19]. Meanwhile, estimation of partial cloud coverage within a pixel is conducted [20].

Comparative study on estimation of partial cloud coverage within a pixel is conducted [21]. On the other hand, adjacency effect of layered clouds estimated with Monte-Carlo simulation is estimated [22].

Evaluation of cirrus cloud detection accuracy of GOSAT/CAI (Green House Gasses Observation Satellite / Cloud and Aerosol Imager) and Landsat-8 with laser radar: lidar and confirmation with CALIPSO (Cloud-Aerosol Lidar and Infrared Pathfinder Satellite Observations) data is conducted [23]. Meanwhile, comparative study on cloud parameter estimation among GOSAT/CAI, MODIS (Moderate Resolution Imaging SpectroRadiometer), CALIPSO/CALIOP (Cloud-Aerosol LIdar with Orthogonal Polarization) and Landsat-8/OLI (Operational Land Imager - Landsat Science) with laser radar as truth data is conducted [24].

Thresholding-based method for rain, cloud detection with NOAA/AVHRR data by means of Jacobi iteration method is proposed [25]. Also, adjacency effects of layered clouds by means of Monte Carlo Ray Tracing: MCRT is investigated [26].

III. Theoretical Background and Proposed Method

A. Category Decomposition and Classification Norms

In order to estimate the maximum occupancy category in Mixel, category decomposition [1] is required to estimate the occupancy rate of each category. Several categorical decomposition methods have been devised [1-6], but in this study, the categorical decomposition is formulated using the maximum likelihood estimation method that takes observation errors into consideration. Using this theory has the advantage that unclassified pixels can be determined to be statistically meaningful.

Mixel's spectroscopic vector: *I*, which is a mixture of information from N categories, is considered to be the linear combination of Pure pixel value: *A* and category occupancy: *B* shown in Eq. (1) plus the observation error vector: ε.

$$I = (I_1, I_2, \ldots, I_M)^t = AB + \varepsilon \qquad (1)$$

where *Ii*: Observation pixel value of the i-th band, *M*: Number of bands. “t” represents transpose. Furthermore, *A* is expressed as follows:

$$A = \begin{bmatrix} A_{11} & \cdots & A_{1N} \\ \vdots & \ddots & \vdots \\ A_{M1} & \cdots & A_{MN} \end{bmatrix}$$

where *Aij*: i-band of pure pixel value of j-category, $B = (B_1, B_2, \cdots, B_N)^t$, *Bj*: Occupancy of category j. And, $\varepsilon = (\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_M)^t$, ε_i: observation error of the i-th band. Here, it is assumed that Aij follows the normal distribution of mean A^*_{ij} and variance σij^2: N (A^*_{ij}, σ_{ij}^2), and ε_i follows N (0, σ_{ei}^2), and the spectroscopic vector 1 is a random variable [4]. Here, if the pixel values of Pure pixels in each category are independent, the observed pixel values of the i-band: *I*, are the average A^*_i represented by Eq. (2) and Eq. (3), and the normal distribution of the variance σ_i^2: N (A^*_i, σ_i^2) is obeyed [7].

$$I_i = A_i^* B \qquad (2)$$

$$A_i^* = (A_{i1}^*, \ldots, A_{iN}^*)$$

$$\sigma_i^2 = B^t S_i B + \sigma_{ei}^2 \qquad (3)$$

$$S_i = diag(\sigma_{i1}^2, \ldots, \sigma_{iN}^2)$$

where A^*_{ij}: The average of the pure pixel values of the i-band j category, and σ_{ij}^2: the variance of the pure pixel values of the i band, j-category. It is also the variance of the observation error of the σ_{ei}^2: i band.

Observed pixel value of the i-th band: Probability (likelihood) that *Ii* is observed: *P* (*Ii*) is expressed by Eq. (4).

$$P(I_i) = \frac{1}{\sqrt{2\pi\sigma_i}} e^{-\frac{(I_i - A_i^*)^2}{2\sigma_i^2}} \qquad (4)$$

Probability (likelihood) that the spectroscopic vector I is observed (likelihood): $P(I)$ is expressed by Eq. (5), assuming that it is independent between each band.

$$P(I) = \prod_{i=1}^{M} P(I_i) \tag{5}$$

In general, each band of remote sensing data is not independent of each other, so it is necessary to make each band independent by orthogonalization transformation such as principal component analysis as preprocessing. Here, based on the concept of the maximum likelihood estimation method, the solution is to find the probability that the spectral vector is observed: $P(I)$ and the occupancy rate: B I. Here, the occupancy rate: B has the following constraints if the type of category included in Mixel is known.

$$\sum_{j=1}^{N} B_j = 1, B_j \geq 0, (j = 1, \ldots, N) \tag{6}$$

The category occupancy (maximum likelihood estimation value) estimated based on this method is expressed as B^*, and the pixels are classified into category K of the maximum element B^*_k in B^*. This method is called the Maximum Proportion Classifier (MPC).

B. Determination of Unclassified Pixels

In image classification methods such as the maximum likelihood method and the shortest distance method, restrictions are set according to those classification norms, and those exceeding the restrictions are regarded as unclassified pixels [8], [9]. This section describes how to determine unclassified pixels according to the maximum occupancy classification norm.

Comparing Mixel and Pure Pixel, Pure Pixel expresses its pixel value by the mean and variance of the classified categories, while Mixel's pixel value is the occupancy rate of each category and their mean and variance. This indicates that Mixel has more independent parameters to express the pixel value of Mixel than Pure Pixel, and Mixel is a concept with a high degree of freedom. With these things in mind, this study proposes the following method for determining unclassified pixels.

The fact that a Mixel can be classified into one category (Mixel can be represented by one category) means that the Mixel can be represented by a model with more constraints (fewer independent parameters) (Pure pixel hypothesis). That's what it means. In such a case, the Pure pixel hypothesis is tested using the model goodness-of-fit test [7], [10], and if the Pure pixel hypothesis holds, it can be classified, otherwise it cannot be classified. It is possible to do. Here, we propose two types of goodness-of-fit test methods.

C. Goodness of Fit Determined by χ^2 Distribution [10]

Suppose there are two models π_1 and π_2, and π_1 is π_2, which is a special case (the number of independent parameters is small). The likelihood ratio of the two models: β is defined by Eq. (7), where P (π) is the likelihood of the model π.

$$a = P(\pi^*_1) / P(\pi^*_2) \tag{7}$$

where, the superscript * represents the maximum likelihood estimator of the model π. Since π^*_1 is a special case of π^*_2, $P(\pi^*_1 \leq P(\pi^*_2))$, and therefore $\beta \leq 1$ holds. Here, χ^2 of Eq. (8) is defined.

$$\chi^2 = -2 \ln \beta \tag{8}$$

χ^2 asymptotically has a chi-square distribution with $n = n_2 - n_1$ degrees of freedom. Here (n_1 and n_2 are the number of independent parameters of the models π_1 and π, respectively), and the percentile value χ^2 (n) of 100 by α% (α: significance level, 0 <α<1) of the chi-square distribution with n degrees of freedom, α) and χ^2 can be compared to test whether π, is significantly inferior to π_2 (χ^2 (n, α) <χ^2).

When this goodness-of-fit test is used to determine unclassified pixels according to the maximum occupancy classification standard, only the maximum occupancy category B^*_k of the most likely estimated value B^* of the occupancy obtained by categorization of π_1 Pire pixel ($B^*_K = 1$, occupancy of other elements is 0), $P(\pi_1)$ is obtained from Eq. (4) and Eq. (5), then π_2 is Mixel, and $B*$ is used (4).), (5) to find P (π_2), and Eq. (7) and Eq. (8) to find χ^2. Here, from the constraint condition of Eq. (6), the number of independent parameters of PURE PIXEL is 0, and the number of independent parameters of Mixel is N-1 (N: number of categories), so $n=N-1$. Therefore, the significance level α (right side test) of the test is determined, χ^2 (N-1,α) is calculated, compared with χ^2, and the unclassified pixels are χ^2 (N-1),α) ≤ χ^2: Unclassified χ^2 (N-1,α)> χ^2: Determined to be classified in the maximum occupancy category. Since χ^2 becomes larger as the likelihood ratio β is smaller (the likelihood is smaller when it is a pure pixel), the number of unclassified pixels increases as the significance level is increased (χ^2 (N-1, α) becomes smaller).

D. Goodness of Fit Test by AIC [10],[11]

Similar to the goodness-of-fit test based on the χ^2 distribution, there are two models, π_1 and π, and π_1 is a special case of π_2. If $P(\pi)$ is the likelihood of the model π, then AIC (Akaike's Information Criterion) is defined by Eq. (9).

$$AIC = 2(n-2)\ln\{P(\pi^*)\} \tag{9}$$

where n is the number of independent parameters of the model, and the superscript * is the maximum likelihood estimator of the model. Here, the model that minimizes the AIC in Eq. (9) is selected. Similar to the goodness-of-fit test based on the χ^2 distribution, π_2 is Mixel (number of independent parameters: N-1), π_1 is Pure pixel (number of independent parameters: 0) containing only the maximum occupancy category, and AIC is Eq. (4), (5), (9), if the AIC obtained from the case of Pure pixel is smaller than the AIC obtained from the case of Mixel, it is judged that it can be classified and classified into the maximum occupancy category. If not, it is regarded as an unclassified pixel.

IV. Experiments

A. Simulation of Pure Pixel Data

The validity of the above theory will be confirmed by the following data and simulation according to the procedure.

Using TM data around Lake Ashino-ko in Japan, which was acquired by LANDSAT 5 on June 6, 1987, residential areas, bare land, grasslands, coniferous forests, and broadleaved forests, which are typical categories of this area, were ed as the grand truth area. It is extracted using vegetation maps and aerial photographs [12]. Then, in order to make each band independent, all bands except the thermal band (band 6) were analyzed for principal components, and the first and second principal components were quantized into eight bits and used for categorization. Table I shows the eigenvalues, eigenvectors, and contribution ratio of each principal component. Table II shows the average and variance of the pixel values of each category Pure pixel.

TABLE I. EIGENVALUE, EIGENVECTOR AND CONTRIBUTION OF THE TEST DATA. PC, E-VALUE, E-VEC. AND CONT. MEAN PRINCIPAL COMPONENT, EIGENVALUE, EIGENVECTOR AND CONTRIBUTION, RESPECTIVELY

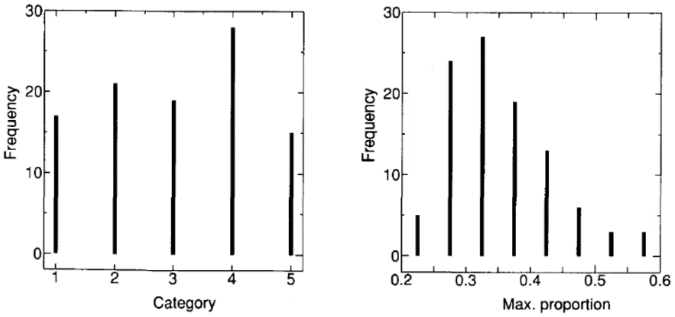
B. *Simulation of Mixel Data*

Mixel data of 36 types (six types of variances by six types of observation error) were created by the procedure shown below,

1) Category occupancy rate: Using the uniform random numbers of [0,1), 100 points of category occupancy are created based on the constraint condition of Eq. (6).



(a) (b)

Fig. 1. Characteristics of the truth data. (a) Histogram of the maximum proportion category. The categories number 1 to 5 correspond to the categories of Residential area, Bare soil, Grass land, Needle leaf tree and Broad leaf tree, respectively. (b) Histogram of the maximum proportion.

Fig. 1(a) and Fig. 1(b) show the distribution of the maximum occupancy category and the distribution of the maximum occupancy, respectively.

2) Pure pixel value (training data): Pure pixel values according to the mean and variance of each category are created for each band using normal random numbers. At this time, in order to confirm the influence of the variance of the Pure pixel value, the Pure pixel value is created by multiplying the variance of each category and each band by 2.0, 1.0, 0.8, 0.6, 0, 4, 0.2, respectively.

3) Observation error: The standard deviation σ_{ei} of the observation error in each band is 0,2,4,6,8,10 [Count]. The observation error is created using normal random numbers.

4) Mixel dataset: From the data of (1)-(3), 100 points of Mixel spectroscopic vectors are created under each condition according to Eq. (1).

C. *Verification Details*

The 30 types of Mixe1 data sets created by the above method were categorized using the grid search method [13] with a side length of 1/64. This solution creates a mesh with a side length of 1/64 in the solution space (N-1 dimensional hyperplane) given by Eq. (6) and uses the training data given at each point of the mesh and the observed spectral vector. The likelihood given by Eq. (5) is calculated, and the point that gives the maximum likelihood is the solution.

As for the solution of the nonlinear optimization problem, all high-speed calculation methods such as Newton's method are methods for finding extreme values, not methods for finding maximum / minimum values. In this study, in order to avoid a decrease in the accuracy of categorization due to algorithm restrictions, categorization was performed by the lattice search method without using high-speed calculation. In actual applications, it is necessary to develop accurate and high-speed algorithms, which will be an issue for the future.

From the estimated value of the category occupancy and the estimated maximum occupancy category obtained here, the following items are verified together with the truth data of the category occupancy in Eq. (1) Category occupancy rate.

D. *Comparison of Goodness-of-Fit Test by χ^2 Distribution and Goodness-of-Fit Test by AIC*

In order to compare the two unclassified pixel determination methods and confirm the effect of the goodness-of-fit test based on the χ^2 distribution on the classification accuracy of water a, the goodness-of-fit test by AIC and the significance level α were set to 1, 5, 10%. Classification was performed using MPC to which the method for determining unclassified pixels by the goodness-of-fit test was applied. In this case, the same method for determining unclassified pixels is applied to the truth data of the occupancy rate of Eq. (1) Category occupancy rate, and only the classifiable pixels are extracted, and the classifiable pixels obtained here, and their maximum occupancy category are classified and was used as the truth data of the category to be classified.

E. Comparison with Maximum Likelihood Method

The 36 types of Mixel datasets created in steps 3 and 2 were classified by the maximum likelihood classifier (MLC) and compared with the classification results by MPC. In this case, the following two types of unclassified pixel determination methods were used. We used to extract classifiable pixels.

1) Not classified if the log-likelihood is -20 or less.

2) If the Mahalanobis distance to the target category is three times or more the maximum standard deviation of that category, it is unclassified.

Here, as in Eq. (1) Category occupancy rate, the true data of the occupancy rate is classified by MPC using the unclassified pixel determination method by AIC, and the classifiable pixels and their maximum occupancy rate categories are extracted and classified and the truth data of the category to be used.

V. Experimental Results

A. Comparison of Goodness-of-Fit Test by χ^2 Distribution and Goodness-of-Fit Test by AIC

The occupancy rate estimated by categorical decomposition and the likelihood used to determine unclassified pixels are affected by the variance term σ_1 in Eq. (3). Since the variance term is determined by the category occupancy rate, the variance of the Pure pixel value, and the variance of the observation error, the average variance AVG [σ] of Eq. (10) is obtained for each of the 30 types of Mixel data (100 points each) and used. The characteristics of each Mixel dataset are shown.

$$AVG[\sigma] = \frac{1}{100}\sum_{k=1}^{100}\{\frac{1}{M}\sum_{i=1}^{M}(B_k^t\, S_i B_k + \sigma_{ei}^2)\} \quad (10)$$

First, in order to confirm the accuracy of categorization, the root mean square error RMSE between the occupancy rate B^* and the true value B estimated from each Mixel data set is obtained from Eq. (11), and the mean variance AVG [σ] is used. The relationship is shown in Fig. 2.

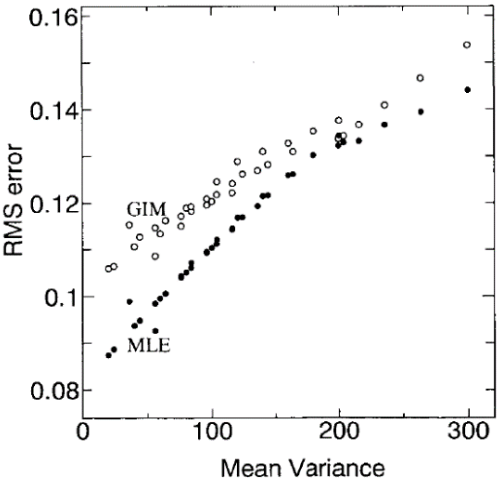


Fig. 2. The relationship between the mean variance and the root mean square error of the estimated category proportions from maximum likelihood estimation (MLE) and generalized inversion matrix (GIM).

Here, the results when the general inverse matrix, which is a typical conventional categorical decomposition method, is used are also shown.

$$RMSE = \frac{1}{100}\sum_{k=1}^{100}\{\frac{1}{N}(B_k^* - B_k)^t(B_k^* - B_k)\} \quad (11)$$

In both methods, it was confirmed that as the mean variance increases (the variance of the Pure pixel value and the observation error variance increase), the RMSE increases and the accuracy of categorization decreases. In addition, the generalized inverse matrix does not take into account the variation in the Pure pixel values of each category [1], indicating that the estimation accuracy is lower than that of the maximum likelihood estimation method.

Next, in order to clarify the relationship between the goodness-of-fit test method for determining unclassified pixels and the degree to which the Mixel data set created by the above method is judged to be classifiable, these unclassified truth data are included in the truth data of the occupancy rate. The relationship between the number of classable pixels obtained by applying the classification pixel determination method and the average variance was obtained. The results are shown in Fig. 3.

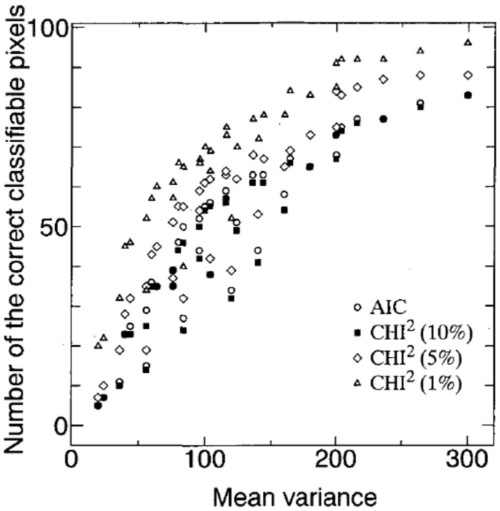

Fig. 3. The relationship between the mean variance and the number of selected classifiable pixel from the truth data of the proportion from Chi square and AIC method.

As the mean variance increases, the likelihood P represented by Eq. (4) and Eq. (5) becomes a gentle function, so the number of pixels judged to be classifiable by all goodness-of-fit test methods increases. In addition, it was confirmed that the number of pixels judged to be classable decreases as the significance level increases in the goodness-of-fit test using the χ^2 distribution, and the goodness-of-fit test using the AIC is a goodness-of-fit test using the χ^2 distribution with the significance level set to 10%.

It was confirmed that almost the same result as the above was obtained. Here, as classification accuracy verification, from the classification result using the estimated value of the category occupancy rate, it was judged that (a) the number of pixels judged to be categorizable and (b) the truth data of the occupancy rate could be classified. The number of pixels determined to be unclassified by the estimated value (number of error pixels of the first type), (c) Pixels determined to be unclassified by the truth data of the occupancy rate but determined to be classifiable by the estimated value The number (the number of pixels of the type II error) and (d) the classification correctness: (the number of pixels correctly classified) / (the number of pixels judged to be classifiable) were calculated. The results are shown in Fig. 4(a) to Fig. 4(d).

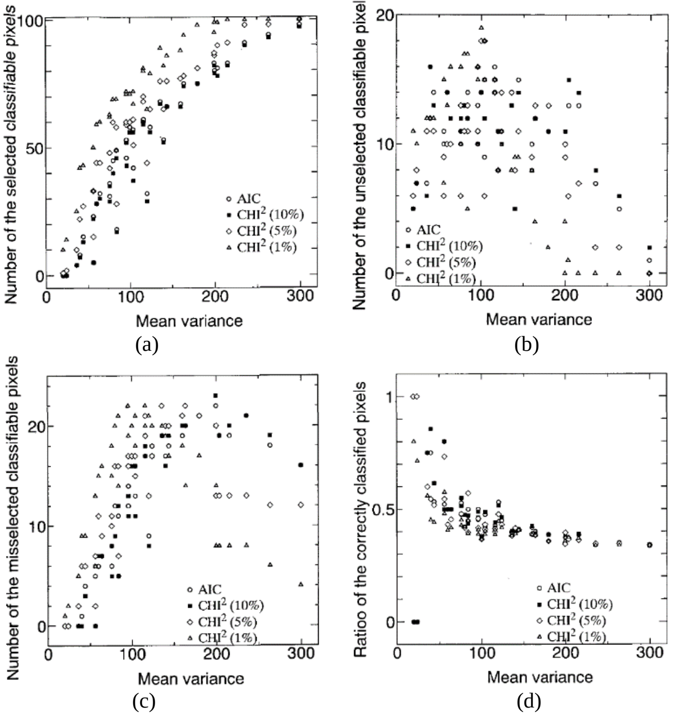

Fig. 4. The classification results from Maximum proportion classifier from various unclassified limits. (a) The number of selected classifiable pixels. (b) The number of unselected classifiable pixels. (c) The number of mis-selected classifiable pixels. (d) The ratio of correctly classified pixels.

It was confirmed that the number of pixels judged to be classable increased as the mean variance increased and decreased as the significance level increased, as in the case obtained from the truth data of the occupancy rate, and the goodness-of-fit test by AIC was significant. It was confirmed that almost the same result as the goodness-of-fit test based on the χ^2 distribution when the level was set to 10% was obtained.

It was confirmed that the number of pixels of the type I error increases with the increase of the average variance up to about 100, and then converges or decreases comparatively gently. In the goodness-of-fit test using the χ^2 distribution, when the significance level was reduced, the number of pixels of type I errors tended to decrease rapidly when the mean variance increased. This can be explained by the fact that the number of pixels judged to be categorizable increases as the significance level increases. In this case as well, the goodness-of-fit test by AIC gave almost the same results as the goodness-of-fit test by χ^2 distribution when the significance level was 10%.

It was confirmed that the number of pixels of the type II error increases as the average variance increases. It was also confirmed that when the significance level was reduced in the goodness-of-fit test using the χ^2 distribution, the number of pixels of the type II error decreased when the mean variance increased. This is because if the significance level is reduced, it is judged that it can be almost classified even when applied to the truth data of the occupancy rate. In this case as well, the goodness-of-fit test by AIC gave almost the same results as the goodness-of-fit test by χ^2 distribution when the significance level was 10%.

The classification correctness tended to decrease as the mean variance increased, and it was confirmed that the difference in the correctness due to the difference in the goodness-of-fit test method also decreased as the mean variance increased. In this case, if the number of pixels determined to be classable is 0, the correctness rate is set to 0.

B. Comparison with Maximum Likelihood Method

The result of classifying the above 30 Mixel datasets by the maximum likelihood method (MLC) with two unclassified limits (log-likelihood and Mahalanobis distance) and the number of unclassified pixels using the AIC goodness-of-fit test. A comparison of the classification results by MPC to which the determination method is applied is shown.

As classification accuracy verification, from the classification result using the estimated value of the category occupancy rate, (a) the number of pixels judged to be categorizable (b) the truth data of the occupancy rate was judged to be categorizable, but the estimated value is not yet.

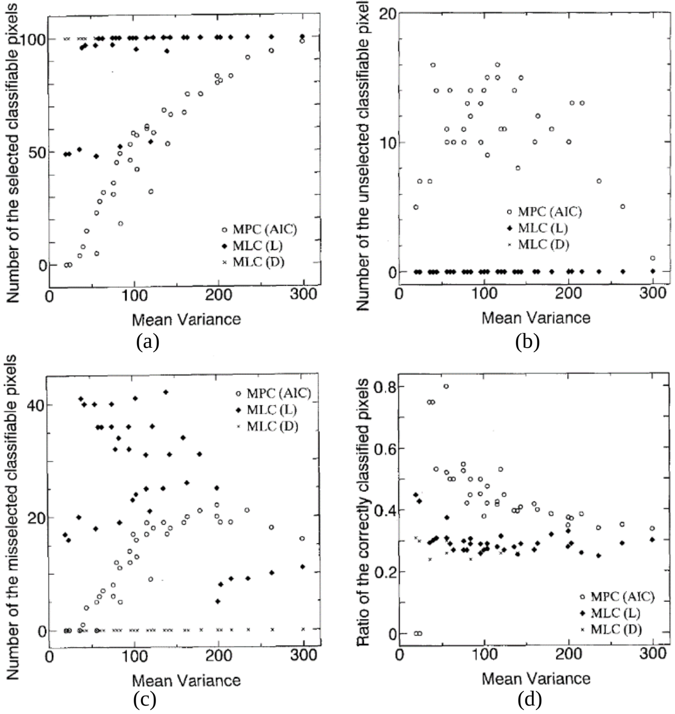

Fig. 5. Comparison of classification result from Maximum proportion classifier with AIC based unclassified limit: MPC(AIC), Maximum likelihood classifier with likelihood based unclassified limit: MLS(L) and with distance based unclassified limit: MLC(D). (a) The number of selected classifiable pixels. (b) The number of unselected classifiable pixels. (c) The number of mis-selected classifiable pixels. (d) The ratio of correctly classified pixels.

The number of pixels determined to be classified (type I error pixels), (c) The number of pixels determined to be unclassified in the truth data of the occupancy rate but determined to be classified by the estimated value (second) (Number of pixels with type error), (d) Classification correctness: (Number of pixels correctly classified) / (Number of pixels judged to be classifiable) were calculated. The results are shown in Fig. 5(a) to Fig. 5(d).

It was confirmed that the number of pixels judged to be classable by the maximum likelihood method applying the unclassified pixel determination method using the likelihood increased with the increase of the average variance, but the average variance was about 150, and all of them. It is judged that it can be classified.

Fig. 5(a) shows that when the maximum likelihood method is applied to Mixel, which targets categories with large variance, it is difficult to set the unclassified limit. The effect of the unclassified limit setting value appears in the error analysis of the above, especially in the number of pixels of the type I and type II errors.

The number of error pixels of the first type (the number of pixels that are determined to be unclassified pixels even though they can be dispersed) is 0 because the number of pixels that are determined to be classifiable in the most probable method is large. The number of error pixels (the number of pixels judged to be classifiable even though they are unclassified pixels) tends to increase when the average variance is small (200 or less) compared to when MPC is used. This indicates that the maximum likelihood method increases misclassification when the mean variance is small (the variance of the Pure pixel value is large, and the variance of the observation error is large) when compared with the result of classification by MPC.

The classification correctness rate when the maximum likelihood method is used is about 30%, which is not so affected by the mean variance. On the other hand, the results by MPC show that the correctness rate decreases as the mean variance increases, but the correctness rate is generally higher than that by the maximum likelihood method. These results represent the limits of the maximum likelihood method, which assumes that the pixel is a pure pixel, and show the usefulness of the proposed method.

In addition, the unclassified limit in the maximum likelihood method does not mean that the likelihood, or the variance and classifiable of a particular category, is fully meaningful, and in addition, the parameters of unclassified pixel determination are for each category. Since it is sensitive to the dispersion of Pure pixel values, it is difficult to determine the optimum parameters.

On the other hand, the method of determining unclassified pixels by the goodness-of-fit test corresponding to MPC proposed in this study is based on the hypothesis test that the Mixel can be regarded as a pure pixel, and in addition, the pure pixel of each category. It is effective and easy to use because it is insensitive to pixel values. Furthermore, since the goodness-of-fit test by AIC is a method that excludes the arbitrariness of the significance level, it has the advantage that unclassified pixels can be uniquely determined.

VI. Conclusion

The following conclusions can be drawn from the above results. Considering that each pixel in remote sensing is a Mixel, we propose a maximum occupancy classification norm that classifies pixels into the maximum occupancy category, and in addition, a method for determining unclassified pixels based on the goodness of fit of the pixel as a pure pixel. It showed that from the simulation of artificially creating Mixel, the result that the proposed method has better classification accuracy than the maximum likelihood method was obtained, and the limit of the maximum likelihood method and the effectiveness of the proposed method were shown.

We also proposed two methods for determining unclassified pixels by the goodness-of-fit test according to the proposed method, one based on the χ^2 distribution and the other based on the AIC, and it was confirmed that there was not much difference between the two. From this, it was concluded that the χ^2 distribution should be used when the number of classified pixels should be adjusted according to the user's situation, and the AIC should be used when the significance level should be excluded.

Since this method takes a long time to calculate at present, it is used as a secondary application such as a remedy for pixels determined to be unclassified in the maximum likelihood classification, or classification of clouds and the sea in the sea area. It can be used as a classification method when the number of categories is small.

VII. Future Research Works

In the future, we plan to develop a high-speed calculation method for maximum likelihood estimation of category occupancy so that it can be used as a general classification method.

AUTHOR'S PROFILE

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998. He also is Vice Chairman of the Science Commission “A” of ICSU/COSPAR during 2008 and 2020 then he is now award committee member of ICSU/COSPAR. He is now Visiting Professor of Nishi-Kyushu University since 2021, and is Visiting Professor of Kurume Institute of Technology (Applied AI Laboratory) since 2021. He wrote 87 books and published 700 journal papers as well as 570 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. http://teagis.ip.is.saga-u.ac.jp/index.html

Costless Expert Systems Development and Re-engineering

Manal Alsharidi, Abdelgaffar Hamed Ali
The Department of Information System, College of Computer Sciences and Information Technology,
King Faisal University, Hofuf, Saudi Arabia

***Abstract*—Symbolic AI is indispensable for the current LLM agents that are used for example to reason the context of the questions. An expert system is a symbolic AI that can explain the reasoning it reached to, which typically is a rule-based system has been attractive for different domains such as medicine, agriculture, and operations. On average, these systems involve hundreds of rules that are instable; moreover, they are coded at low levels of abstraction. Therefore, designing and reengineering an expert system is still costly and needs technical knowledge because of the manual process and maintaining of a low-level abstraction. On the other hand, model-driven architecture (MDA) has proven to be a successful technology that raised the abstraction level and formalized it to automate software development. It specifies business aspects in the platform-independent model (PIM) and implementation aspects in a platform-specific model (PSM). It then automates mapping between them using a standard mapping language called Query-View- Transform QVT. This paper argues that utilizing MDA principles such as the automation and abstractions represented by the descriptor PIM and PSM and mappings metamodels will not only overcome the instability of rules of expert systems, but also provides new insights for its usage. Therefore, this work proposes an MDA-compliant methodology that adopts a UML sequence diagram, a class diagram for the PIM descriptor, and a generic PSM) based on production rules. Moreover, a UML profile to support lacking features in the sequence model has been developed. However, the paper argues for a new kind of process-oriented expert system. Therefore, it not only allows domain experts to develop or participate in expert systems but also reduces the cost of developing new systems and re-engineering or maintenance of the critical and large-scale legacy expert systems.**

Keywords—Model-Driven-Architecture(MDA);Unified Modelling Language (UML); Platform-Independent Model (PIM); Platform-Specific Model (PSM); Query- View- Transform (QVT)

I. INTRODUCTION

Expert systems (ESs) are historically the most successful product of artificial intelligence (AI) [1]. It is widely used and designed to solve complicated problems that require reasoning about knowledge using mathematical logic. In fact, “based on Chatbot Agent—Google Bard” makes use of some reasoning based on logic to appear consistent and accurate. In AI, symbolic knowledge is represented as symbols that model concepts and relationships in the form of rules. It turns out that a variety of ESs that have been developed successfully and served stakeholders over a long period of time have become assets for many organizations. For example, an expert system was developed to provide clinical interpretations from thyroid hormone pathology tests decades ago. It had like 700 rules representing the knowledge-based approach, which provided 6,000 interpretations per year [2]. Also currently, the MD Anderson Cancer Center Expert System [3] helps oncologists make more informed treatment decisions. This system has a large knowledge base for oncology; it is expected to have thousands of rules.

However, the commonality among these systems and many others is the rapid change in the knowledge base because of the progress in the landscape of the field; for instance, new treatments, diagnostic techniques, and clinical guidelines that support the domain, as well as a technological change. Moreover, there is an essential business requirement for integrating these systems with others, such as electronic health records (HER), enterprise resource planning (ERP), and others, to increase their capabilities.

Although ES is an old field of study and there are many competing disciplines contributing to decision support problems, such as data mining, deep learning, and large language models (LLM), which are data-oriented approaches [4], ES conserves its unique properties of supporting problems that are rule-based and the capability of explaining reasoning. On the other hand, a hybrid model is typically used [5], whereby a weakness (i.e., learning capability from unstructured data) of one can be improved with the strength of the other (i.e., machine learning). In fact, rules are an intrinsic element of organizations, so decisions are driven by rules that support the production of services or products. Moreover, ES has attracted to some extent new domains, such as environmental data management analysis [6] and policy automation [7].

Given this situation and the fact that adopting code-based approaches such as Pyke, CLIPS, Prolog, Lisp, and other platforms for building ESs remains critical and costly, improvement is essential [8]. For instance, one reason for the interruption of some big systems (i.e., Garvan and IBM) is the high cost of maintenance and reengineering [9]. For example, frequent rule changes, driven by tech or business needs (i.e., adding some quality), require tedious hard coding, raising maintenance and re-engineering costs. On the other hand, there is a need to find new ways to make it easier for domain experts to develop or participate in ES. However, utilizing new engineering methodologies can provide a remedy for these problems.

However, the Object Management Group (OMG) has developed Model-Driven Architecture (MDA) as a methodology for automating software development, which is standardized by OMG and supported by many tools, such as the Meta-Object Facility (MOF) design language [10], Object Constraint Language (OCL) [11], and XML Metadata Interchange (XMI) [11]. MDA encourages investment in metamodels using MOFs that are platform-independent, thereby paying back the low cost of development. A metamodel, or model of model, is a conceptual model of some design language that could have different implementations. In fact, having for different languages formally an equivalent representation (a phenomenon frequently referred to as syntactic sugar) is common (i.e., for language designers), such as Structured Query Language (SQL), relational algebra, tuple relational calculus, and query by example (QBE), which have the same underlying structure—the same metamodel [12]. In this case, this metamodel is known as abstract syntax, and its representation is called concrete syntax [13]. The strength of decoupling abstract syntax from concrete syntax allows much freedom in having different concrete syntaxes that re-use the same formal abstract syntax. Consequently, concrete syntax changes do not necessarily require abstract syntax to change. This flexibility allows you to re-use the same supporting software for a metamodel. For example, if we have the abstract syntax of SQL (a metamodel) itself and it is modeled in BNF (meta metamodel), it would be possible to send it a tool to render it into OCL, relational algebra, and probably first-order predictive calculus (i.e., specification of some constraints or assertions over a schema is needed). More importantly, MDA realizes the automation of mappings between these different metamodels using a standard mapping language called Query-View-Transform (QVT). Therefore, this separation of concerns, for instance, allows us to adopt a change without much cost incurred because of the high degree of sustainability. We argue that this trend is most suited to the instability of rule phenomena or the frequent changes in business requirements and technology in the context of ES.

A. Expert System

An ES is a computer program that manipulates facts and rules that constitutes a knowledge of some domain to solve complicated reasoning problems efficiently and effectively [14]. These problems require domain experts'intervention to capture the knowledge [15] which is limited by human capability of handling hundreds of factors at the same time.

Many applications in health, industry, or education fields are using ES [16], [17], [18]. In these cases, the utilization of ES is geared toward delivering exemplary performance in addressing intricate challenges within a particular domain. ESs are instrumental in offering explanation and incorporating symbolic reasoning methodologies during problem-solving processes. Consequently, diagnostic ESs continue to hold prominence as the most frequently employed applications in this regard [19]. More important, ES can serve different class of problems such as acting as a *classifier, predictor, and estimator* to serve different sort of application domains that require automation support for decisions.

Moreover, ES has two core components: a knowledge base (KB) and reasoning engine [20]. The propositional ES has a KB formalized using propositions logic; it models the real world in the form of predicates and rules that can be evaluated to check its truthiness with initiations of variables. The KB is like a warehouse that contains knowledge about a specific domain captured by human experts in a form of production rules. Typically, it is a result of an expensive process called in literature a knowledge-Acquisition that involves strong communications between domain experts in one knowledge area and ES developers. It is the critical part in engineering ESs because of the requirement for developers to transfer this rigorous nature of rules of a domain knowledge into symbolic abstraction using logic-based structure. The classical engineering methods in this context follow an informal approach where engineers build informal models to capture the requirements of the system [21]. While the reasoning engine is an interpreter that draws a conclusion from premises that are represented using like first order predicate calculus (FOPC). The well-established theory behind that is the mathematical logic and theorem proving [22]. An example of the theories behind reasoning are Mode's pones [23] that allows to draw a conclusion from premises; It says if P proposition is known and has the fact that P implies Q then we also know Q as a conclusion. Traditionally may software tools that are aczt as inference engine are used to support the execution of ESs: Shells like Drools [24], G2 [25], JADE [26] which is based on the theory of agents and the standard FIPA [27], and Oracle Intelligent Decision Management (OIDM) [28]. These inference engines or Shells are classified based on forward changing (goes from known premises to reach goals by applying rules) or backward changing (works from goal to find the necessary premises) types of reasoning. Because users and domain experts need to understand how these tools reach to some conclusion, Shells have typically adopted a third essential component the explanation facility that could be in different forms: sequence of rules, conditions under which a rule fires and the conclusion it draws, and high-level detailed specification for the reasoning step [29]. In addition, the user interface component is for inserting quires, inputs and converting the rule from the internal representation to be user-understandable form.

B. Model-driven Architecture

OMG has developed and standardized MDA with the aim of developing software without writing code. Models are first-class entities in MDA that enable the re-use of existing software assets, thereby reducing the complexity and cost of development. In MDA, a Platform-Independent Model (PIM) is used to specify the application concepts, while a Platform-Specific model (PSM) is used to specify the implementation issues independent of a technology. Then a standard mapping between PIM and PSM is specified using a Query- View-Transform (QVT), a standard mapping language that performs mappings between metamodels. MDA is an approach for building models, making the transformation of a source model into a target model [11]. To realize MDA, OMG has worked in the set of tools and standards that have been defined and standardized by OMG to support a good infrastructure. These OMG standards include UML, Meta- Object Facility (MOF), XML Metadata Interchange (XMI), Object-constraint language (OCL) and QVT. However, MDA has three types of abstraction: Computational Independent Models (CIM), PIM, and PSM. Each type is an abstraction technique for focusing on a particular part of concerns within a system and can be represented via one or more models.

A PIM is a conceptual model that is platform-independent and focuses on modeling domain concepts. PIM has a higher degree of independence from different platforms (e.g., .NET, CORBA and J2EE). In order to implement a PIM concept there should be a corresponding implementation abstraction involves a concept which can map it, typically the PSM abstraction. PSM is built from some technology's perspective but independent of it because MOF-based language is used. For example a developing database application requires to model the relational model using MOF; the example used in QVT standard document then by automating the transforming of the PIM instances into PSM instances, the main part of writing code is achieved. Thus, the PSM is considered a high-level APIs specification for a well-established platform such as database manager in. However, the main question here is how it would be able to relate a PIM concept with PSM concepts that will be automated. Also, what are the suitable models for representing problem space and solution space?

C. Query / View / Transformation

The OMG has defined a standard for model transformations in the MDA architecture which is QVT. It represents the intrinsic activity in MDA engineering of applications whereby it converts a source model to a target model. It is required that the source model and the target model must both be compliant with the MOF meta-model [30]. QVT defines three specific languages named: (1) Relations, (2) Core (3) Operational/Mapping. Relations and Core are declarative languages with two different levels of abstraction. The QVT Operational / Mapping is an imperative language, it provides common constructions in imperative languages (i.e. loops, conditions.).

Because the relation language allows a round trip mappings between metamodels, this paper uses relational QVT language, specifically MediniQVT [31] engine to test the developed rules of the proposed mappings. Relational QVT has two main clauses: (1) Check only and (2) Enforce.

The "check only" clause focuses on validating source and target models against pre- defined rules and constraints without modifying the target model and act as precondition. On the other hand, the "enforce" clause carries out the actual transformations on the target model based on predefined relationships made between PIM and PSM metamodels. For instance the following example is a part of a complete transformation example that maps UML conceptual model (PIM) for database application into a relational model (PSM) [30] :

```
Top relation PackageToSchema {

checkonly domain uml p: Package {name=pn}

 enforce domain rdbms s: Schema {name=pn}}
```

The provided example shows a transformation rule or relation named "PackageToSchema" that transforms objects from the "uml", the source domain to "rdbms" target domain. It says that if it is true that an instance of package exists in the source, creates a corresponding instance of type schema in the target. A domain is a typed variable that can be matched with a model of specific type which consists of patterns (i.e. p: package {name=cn}. A pattern can be grasped as a set of variables and constraints that needs to be bound by elements from a model to satisfy it with a valid binding. A domain pattern is a blueprint for the objects and their properties that must be found, changed, or made in a candidate model in order to meet the relationship [30].

II. Related Works

The development of ESs using a model-based approach within the MDA process mapping is still an ongoing area of research, with limited studies focusing on this domain. Chungoorae et al. [14] suggested an approach based on MDA and ontology-driven system development to implement Interoperable Manufacturing Knowledge Systems (IMKS) for product lifecycle applications. It involves developing the PIM level using manufacturing core ontology and transforming it into a PSM in the XKS format. This approach lacks generalization for PSM and is limited to specific platforms. Moreover, it omits the mention of the mapping language used from PIM to PSM. Additionally, it primarily focuses on data-oriented ES type.

The BOM approach, within MDA, automates software generation using PRISMA architectural models, as described by Cabello et al. [15]. The approach utilized conceptual models, PIM, and CIM without specialized languages, resulting in generated program codes for C# .NET. This approach lacks generalization for PSM and is limited to specific platforms. Moreover, it omits the mention of the mapping language used from PIM to PSM. Furthermore, it does not specify the type of ES being utilized.

Yurin et al. [16] proposed using MDA to generate an ES for analyzing construction material damage. The implementation involves conceptual models, rule visual modeling language (RVML) for mapping PIM to PSM, and implemented in the form of a software prototype personal knowledge base designer (PKBD). This approach lacks generalization for PSM and is limited to specific platforms. Moreover, it utilizes an operational language that does not take maintenance into consideration. Additionally, it primarily focuses on data-oriented ES type.

Another research by Maylawati et al. [17] focused on UML diagrams (use case, class, and sequence) to describe ES components, including actor interaction and object relationships. Each use case requires a sequence diagram for normal and alternative processes, while the class diagram represents object interrelationships and adaptable attributes/methods for problem-solving. This approach involves the development of ES using UML diagrams in a general sense, without specifying the principles of MDA.

In study [18], the authors proposed developing decision-making modules for an intelligent system based on MDA principles. They start with the CIM, transforming spreadsheet data into a conceptual model using UML class diagrams. The PIM is then created as a rule-based module, formalizing decision tables with concepts from the CIM. RVML schemas represent these concepts. The PSM is developed depending on the knowledge representation language and converting decision tables into an RVML module. Program codes are generated using PKBD for the specific platform. This approach lacks generalization for PSM and is limited to specific platforms. Moreover, it utilizes an operational language that does not take maintenance into consideration. Furthermore, it does not specify the type of ES being utilized.

Overall, the existing literature lacks comprehensive compliance with MDA principles. For instance, strong support for re-usability and platform independence such as having PSM that is special-case and PIM that is cluttered with PSM aspects. Also, the lack of maintenance considerations because of using operational mapping languages as well as in overall there is no support for it. Our proposed approach aims to generate a generalized PSM that can be adapted to different platforms as well as support maintenance. This is enabled by utilizing a relational QVT and developing reverse mapping rules. Moreover, this work recognizes a new type of process-oriented ES and enables both types of ES: process-oriented and data-oriented.

III. Research Methodology

This paper aims to automate the creation of rule-based ES through the utilization of MDA. MDA, as explained, intends to automate software development without writing code by raising the abstraction level, so the process is driven by high-level models and mappings. The proposed approach argues for process-oriented ES as well as data-oriented ES. However, MDA principles compliance is a target for this work as well as considering the maintenance support. Therefore, these reforms the classic process of developing ESs that use a code-based approach into a new methodology for the development that uses models as first-class entities. The following subsections deal with the following questions: What are the suitable models to represent the PIM and PSM metamodels? Is there any gaps (i.e. concepts) exist in the source or target design language? How are PIM concepts related to PSM concepts? How to abstract Shells (platforms) in a generic PSM? And finally how low-cost maintenance is supported?

The answer to these questions can be organized around main principles of the proposed approach: (1) Modeling Expert Business Rules in PIM metamodel, (2) Building a UML Profile, (3) Developing PSM of Production Rules (4) Building the mapping between PIM and PSM.

A. Model Expert Business Rules in PIM Metamodel

The expert system usually stemmed from business rules that represent the decision instrument which requires automation support. These rules classically captured manually in a form of conditional statements rendered as FOPL that probably augmented with the syntax of platform. They are two abstraction levels act as one level which makes it difficult for domain experts as well as developers to deal with these technical aspects. In contrast, the PIM is an alternative abstraction decuples the technical aspects of ES from application concepts therefore pertain to a conceptual model for problems under consideration typically developed independent of a platform so hides implementation details. Due to its abstract nature, it can capture essential features and requirements, which can help experts from different domains communicate by enabling shared understanding. MDA approach proposes MOF-based language such as any UML models to act as PIM metamodel [10]. The PIM can be metalevel 1 or metalevel 2. The concrete instances of a UML model that represent specific case of ES (i.e. some diseases diagnose system), while UML is at metalevel 2 because MOF can model it which is a metalevel 3 [32]. This flexibility allows different modeling representation capabilities that address the diversity of system. The business rules for ES in code-based approach are dependent on a clear understanding of the ES's requirements. This understanding may be achieved through close collaboration with domain experts, stakeholders, and end-users. But usually there is no corresponding explicit formal model such PIM metamodel that can capture these requirements.

More importantly this work argues for process-oriented that centers on the workflow or operational procedures of a given expert system, such as production processes, scheduling operations, and generally processes. In this type of systems, the rules are injected within a process, not like the classic ES that focuses on data so called data-oriented, process is dominating element. For example, in an academic system; a student can only register for 12 credit hours if his GPA is less than 2 and, while in manufacturing system; IF machine temperature reaches critical threshold, THEN stop the machine and call maintenance procedure. The former rule is a constraint augmented with an action – register, while the later expresses object properties constraints, the temperature of the machine. The distinction between them is useful for acquisition of knowledge process as well as it has impact in the design under the context of this work. Although, the model we have introduced is capable of accommodating either of these types, its emphasis is primarily on the latter (i.e., process-oriented). However, business rules, are set of guidelines or policies that dictate how an organization operates, are frequently embedded within processes to ensure and enforce consistency and integrity [33]. It is therefore a good candidate for PIM.

However, this paper proposes specifying business rules for ES in PIM, using both class and sequence diagrams. In which class diagram serves as a descriptor of facts or data with their schemas that is needed by the ES, while the sequence diagram is used for capturing the behavior of the system that usually is augmented with rules. Although there are alternatives to this design decision such as activity diagram, sequence diagram is less elaborative so more compact and easier to learn and communicate the problem of ES. Nevertheless, the relationship between UML sequence diagram and UML class diagram is that the sequence diagram involves objects and messages that are eventually comes from classes that are supposed to be fully specified by the UML class model. Therefore, the UML class diagram supplies the sequence diagram with schemes of data and their relationships.

1) PIM sequence diagram metamodel: A metamodel is a model of the model that is required here to capture the elements needed to support process-oriented ES instances; that is a UML PIM metamodel. We need to investigate the big enough and suitable UML sequence diagram metamodel to be ready for representing the instances of PIM that will be developed by domain experts and developers as well as guides the mapping process later. A developer in this case typically develops models for ES at metalevel 1 where it models objects of specific ES such as a manufacturer production expert system or car faults diagnoses system. The intention of a sequence diagram in UML is to communicate the specific behavior by sketching the sequence of messages communicated between objects in a system so it's a dynamic view. Fig. 1 presents the necessary and big enough metamodel elements needed to model any business rules for experts.

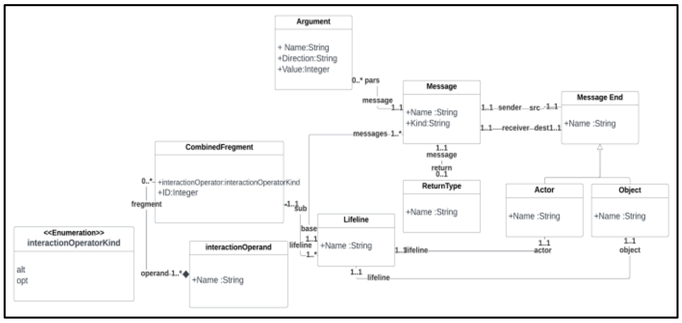

Fig. 1. PIM sequence diagram metamodel [34].

Fig. 1 is the abstract syntax of the sequence diagram that is part of the UML metamodel which fits the problem addressed by this work. The metamodel says a Message (with name and kind properties) can have zero or more Arguments (with name, direction, value properties). It can have a Return Type that specifies the type of value that is returned. In addition, the Message has the Message End indicates two ends of a message exchanged between two Lifelines (usually named element) where the first represents the source (base) and the second is the destination. A Message End is either an Object or an Actor. A lifeline can have more than one message. It indicates that a message has been successfully transmitted from the sender to the receiver, and that the receiver has finished processing the message.

The CombinedFragment is an essential component in diagrams that allows for the specification of complex control structures such as loops, parallelism, and conditions. Its behavior is determined by the chosen InteractionOperator, which dictates how the fragment behaves. For example, when using "alt" as the InteractionOperator, the CombinedFragment represents a choice of behavior where only one option is executed. Semantically an Operand selection within the "alt" fragment is based on guard expressions, which determine the conditions for executing each option. The use of the "else" guard expression represents a negation of all other guards within the CombinedFragment. If none of the options have guards that evaluate to true, none of them are executed, and the remaining part of the diagram continues. Note that an enumeration class called InterationOperKind is used to supply the kinds required for InteractionOperator. It is a useful feature can be utilized in expert systems in exceptions as well as normal conditional state.

2) PIM class diagram metamodel: The UML class model utilizes class diagram notation [35] to describe the data and their relationships using class, properties, inheritance (generalization-specialization) and association concepts. For example, in the journal system a Reviewer and Paper are classes (objects of metalevel 1), and a Review class has the association with Paper between them that represents the relationship a reviewer provides a review for a certain paper which also has an association with a Review class that represents the feedback. In the following, Fig. 2 illustrates the UML class diagram metamodel that is part from UML standard specifications developed by OMG to act as a descriptor for data and facts needed in ES with their integrity constraints.

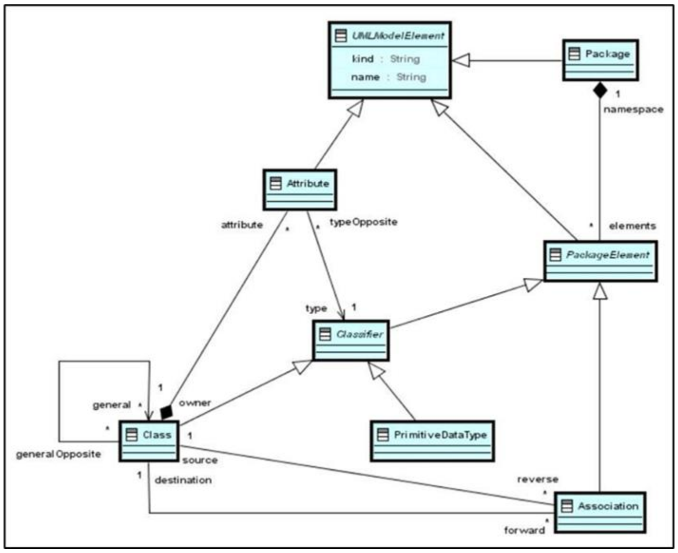

Fig. 2. PIM class diagram metamodel [30].

Fig. 2 shows part of the abstract syntax of the UML class diagram [20]. In which UMLModelElements are classes, interfaces, packages, and relationships. For example, a class diagram could include several UML model elements such as Classes, Attributes, and Associations, to model classes of objects with properties and the relationships between different objects in a system. A metaclass class in Fig. 2 is a central concept of the language and it is a kind of a classifier. A classifier in UML means a class that can be instantiated or has instances different from Abstract classes that do not have. Classes are defined by a set of attributes and methods that objects of that class will have. Because usually a class like Reviewer has attributes: ID, name, and Area of interest there is of metaclass Attribute to model this. Attributes are characteristics or properties of a class, and they define the data that objects of that class will have. In addition, Association, which describes the relationships between two or more classes. Associations define how objects of one class are related to objects of another class. Moreover, a Package is a grouping mechanism used to organize related elements, including classes, interfaces, and other packages. A PackageElement is an abstract class that is a kind of package.Therefore, a diagram usually exists in a package. Another critical UML element is the Classifier, which describes a set of objects that share common characteristics and behavior. Lastly, UML includes PrimitiveDataTypes, which are basic data types built into the modeling language or programming language used to represent data. Examples of UML primitive data types are Boolean, integer, and string.

3) UML profile for PIM metamodel: A profile is a powerful lightweight extension mechanism that adds concept, syntax, and semantics to the metamodel [13]. It does not require substantial change to the metamodel so less costed approach because UML editors does not change because of extensions. A profile consists of stereotypes, tags, and metaclass classes of the elements that need to be extended, which are classifiers. The stereotype represents a new concept or syntax that is needed for extension while a tag adds some properties if needed to the stereotype. However, it is necessary to have an end of an extension that represents some metaclass class; a solid line notation designates this extension usually drawn between the two ends in UML standard. Profiling plays a pivotal role in filling the gaps in the metamodel. Because in this work there is a gap in the Sequence Diagram; it is not defined by UML Sequence metamodel which are the modeling elements: Not, OR, and Head that exist in the target (Shells). Therefore, there is to design a profile in order to allow developer/domain expert to use these concepts. Fig. 3 shows the UML profile diagram for the proposed approach.

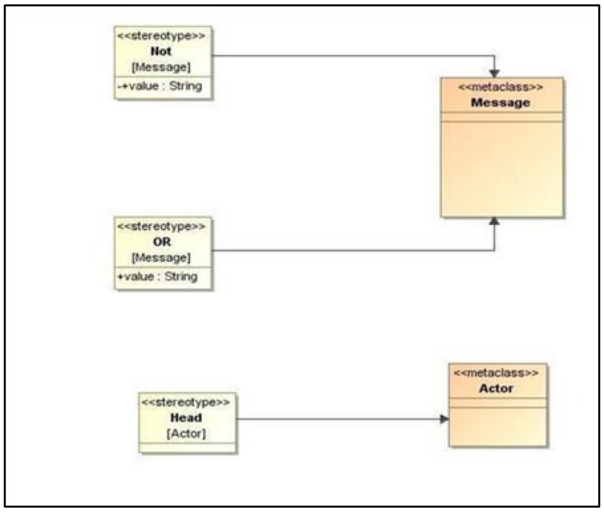

Fig. 3. PIM profile diagram metamodel.

In Fig. 3 a profile is designed for the PIM sequence diagram with three distinct stereotypes needed. These stereotypes serve to provide concepts that the PIM sequence model is lacking. It basically extends two metaclass classes: Message and Actor because semantically OR and NOT are related to messages in the level of abstraction and later to predicate as we will see in the mapping. The first stereotype of the 'Actor' element is named a 'head,' concept to allow designers of ES to utilize the concept of specifying the focal point which gets the benefit of the service provided by sequence diagram. A tool cannot easily determine without cost, so the profiling mechanism is a less costed solution. The second stereotype pertains to messages and introduces an 'OR' operator concept. This 'OR' is an indicative of multiple possible interactions that can exist between messages, a common practice in ESs (multiple rules with same head). The third stereotype extends the Message to introduce a 'NOT' operator concept. In this context, the 'NOT' signifies conditions or interactions that are explicitly negated or excluded (it is also common in ESs). Therefore, the utilization of these stereotypes within the profile diagram serves the purpose of specifying rules that involve disjunction, negation and as well discriminating the Head of the rule. We are ready now to look at how we design a generic PSM.

B. Develop PSM of Production Rules

A production rule traditionally used in different fields such complier, natural processing languages and logic which specifies how input stimuli are transformed into output responses (produce a symbol output from a symbol input). It consists of a set of rules, each consisting of a condition and an action or LHS and RHS. A condition specifies a set of constraints that must be satisfied by the input, whereas an action specifies a set of operations to be performed on the input [36]. To fire it means to replace the LHS with the RHS. To model production rules using PSM, it is necessary to identify the specific elements of FOPC [37] because it is what Shells of ES are based. Fig. 4 illustrates the PSM metamodel for the proposed ES.

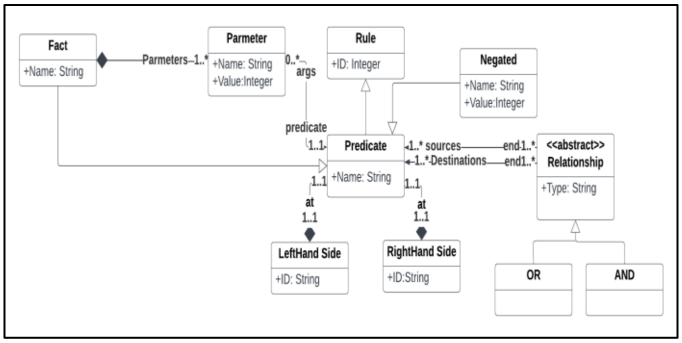

Fig. 4. Rule-based expert system PSM metamodel.

In this context, a typical production rule might be expressed in natural language, as in the example provided: "If the car won't start and there is no clicking sound when the key is turned, then the problem is likely a dead battery". To get the metamodel of FOPC as in Fig. 4, since after investigation instances of rules exist in this world, we need a metaclass called Rule in the PSM metamodel. A Rule can be identified by ID, so we need an attribute called ID of type integer. Since a Rule has ascendant that act as a set of conditions must be met for a rule to be applied or executed, we call it the right-hand side and the consequent or action will call it left-hand side. Therefore, it is necessary to define a metaclass classes called RightHandSide(RHS) and LeftHandSide (LHS) because there are many instances will be of this kinds for rule. Moreover, we observe that each of them consists of a basic building block known as predicates; so, we need to model a metaclass class called Predicate because there are many instances of it in a single rule. In addition, usually a Predicate involves parameters that are variables that should be bound during execution; we need a model it as a metaclass class called Parameter, which provides parameter's name and type. Now we can turn into the relationships between the PIM and PSM.

C. Build the Mappings between PIM and PSM

The aim of MDA eventually is to map the source (PIM metamodel) into a target (PSM metamodel) which acts as a part of writing the code in the development process. This model transformations should be done through the standard language QVT which is independent of both ends. In the context of rule-based ES, the expected output of this mapping process is a PSM instances that can be used to represent executable facts and rules for the target platform. It is typically a UML model instances or objects of metalevel 1 [32]. The PSM should be able to implement the PIM objects so translate them into specific constructs or patterns that are suitable for the target platform. The following subsections discuss the mapping rules of the proposed approach: (1) PIM Sequence Metamodel to PSM Metamodel, (2) PIM Class Metamodel to PSM Metamodel.

1) PIM sequence metamodel to PSM metamodel: Sequence diagram is utilized initially to facilitate the decision-making process by depicting the business process aspects of the ES in a high-level model that allows domain experts to communicate the problem easily. However, the goal is to convert business rules that act as the knowledge of expert in some domain into implementation using PSM concepts. As consequence of this, we need to find relationships between sequence diagram concepts and the PSM concepts which are production rules that are commonly represented using FOPC [37]. Table I shows these relationships of both metamodel concepts.

TABLE I. PIM SEQUENCE DIAGRAM TO PSM RULE-BASED ES MAPPING RULES

Rule	Transformation Rule	Source Model	Target Model
R1	MessageToLHS	Message: kind= ‘goal’	LeftHandSide
R2	MessageToPredicate	Message: kind= ‘normal’	RightHandSide
R3	AltToHead	Combinedfregment: interactionOperator='alt' and Message:kind= ‘goal’	LeftHandSide
R4	AltBodyToRHS	Combinedfregment: interactionOperator='alt' and Message:kind= ‘normal’	RightHandSide
R5	ArgumentToParameter	Argument	Parameter
R6	MessageEndToRelationship	MessageEnd	Relationship
R7	Negation	Message (has NOT)	Negated predicate

These transformation rules play a crucial role in converting from PIM sequence model to PSM of rule – based ES. For instance, the "MessageToLHS" rule maps a message with the 'goal' kind into the LeftHandSide format, while the "MessageToPredicate" maps a message with the 'normal' kind into the RightHandSide. The "AltToHead" rule transforms a Combinedfregment with interactionOperator='alt' and message with kind= ‘goal’ into the LeftHandSide. The "AltBodyToRHS" rule transforms a Combinedfregment with interactionOperator='alt' and message with kind= ‘normal’ into the RightHandSide. Similarly, the "ArgumentToParameter" rule converts an argument into a parameter, and the "MessageEndToRelationship" rule transforms a message end into a relationship. Lastly, the "Negation" rule is employed when a message includes 'NOT' to create a negated predicate in the target model. These rules are acting as separate artefacts so preserve the separation of concerns principle.

To automate the mapping process, mapping rules must be specified using QVT standard transformation language. The QVT mapping rules has the following structure:

transformation map (source: sequence, target: psm)

This transformation specification is like a procedure map or make a transformation from a source model represents as a sequence diagram (source) to a target model represents a PSM (target), it is telling the tool that the mapping direction.

The following formalizes the informal mapping rules specified in Table I for the specific mapping between PIM and PSM. Rules will be numbered (ascending order) for easier reference (All these rules are tested using (MediniQVT tool).

R1:

top relation MessageToLHS {

k, cn: String;

checkonly domain source m: sequance::message{kind = 'goal', name =k};

enforce domain target p:psm::predicate{at= a:psm::LHS{}, name = k};

where {ArguementToparmeter(m,p);

In R1, the source domain, involves a pattern that checks for messages in the sequence diagram with a specific *kind* = "goal" and a *name* that will bound using variable "k” based on instances of the source. If it’s true, then in the target domain, the rule enforces the creation of a *predicate* in the PSM; with a repository, with the name as "k" and an attribute "at" assigned to a parameter "a" of type "psm::LHS". Additionally, the rule includes a constraint that the relation "ArgumentToParameter" must be called after executing this rule which ensures transformation from argument to parameter. Because mapping to arguments is postcondition (executes after the first part above) and a complement, *where clause is added.*

R2:

relation MessageToPredicate {

pn: String;

checkonly domain source m: sequance::message{kind='normal', name=pn};

enforce domain target p : psm::predicate {at = a :psm::RHS{}, name=pn};

where { ArguementToparmeter(m,p);}}

The rule R2 directs a transformation from the sequence domain to the psm domain. It checks if there is a *message* with a specific *kind* (normal) and *name* = pn (bound to the current instances in the source) in the sequence diagram. if true, then in the target domain, it creates a *predicate* with a matching name(pn value) and assigns to the attribute “*at*” a parameter “a” of type "psm::RHS". The rule also includes a constraint, postcondition that the rule R5 -"ArgumentToParameter" for parameter transformation must be executed afterwards.

R3:

```
top relation AltToHead{
cn,n:String; o: Integer;
checkonly domain source f:sequance::combinedfregment{
interactionOperator='alt',ID=o,lifelinee=k:sequance::LifeLine{name=n,
messages=m:sequance::message{name=cn,kind='goal'}}};
enforce domain target lt:psm::RHS{ID=o};
enforce domain target ltt:psm::LHS{ID=n};
enforce domain target p:psm::predicate{name=cn,at=a:psm::LHS{iD=n}};}
```

R3 is a rule that checks if the sequence model has a fragment with an interaction operator set to "alt" and an *ID* matching "o" (bound with current instances).Also, it verifies a *lifeline* with the *name* "n" and a *message* with the *name* "cn" and kind "goal" within that fragment. If true, then in the PSM model, the rule enforces creation for the right-hand side (RHS) with an *ID* matching "o", a left-hand side (LHS) with an *ID* matching "n", and a predicate with the *name* "cn" and *an* attribute referring to the left-hand side with ID "n." This rule does the initiation task where the rest of the rule will base.

R4:

```
top relation AltBodyToRHS{
i:Integer;cn,n:String;
checkonly domain source f:sequance::combinedfregment{
{iD=i,interactionOperator='alt',lifelinee=k:sequance::LifLine{name=n,
mesages=m:sequance::message{name=cn,kind='normal'}};
enforce domain target p:psm::predicate{name=cn,att=a:psm::RHS{iD=i}};
where { ArguementToparmeter (m,p);}}
```

R4 is a complement rule to R3 rule, asserts a *combined fragment* in the source sequence model with an interaction operator set to "alt" and an ID matching the given value of "i". It also asserts a lifeline with the *name* "n" and a *message* with the *name* "cn" and the *kind* "normal". If true, in the target domain, creates a *predicate* with the name "cn" and the attribute "att" assigned the right-hand side (RHS) object with the ID value for "i".Also, R5 is postcondition so needs to be executed afterwards as where clause exists.

R5:

```
relation ArguementToparmeter {
Cn ,n,q: String;
checkonly domain source m: sequence::message{kind = q,name = Cn,
pars = w:sequance::argument{name = n}};
enforce domain target p:psm::predicate{name = Cn,
args = k:psm::parmeter{name = n}};}
```

R5 relation asserts for a message in a sequence diagram with a specific *kind* and *name*, and pars attribute with *argument* that has *name= Cn, if turr in* a target domain, will be the creation of a *predicate* with the same name and parameter.

R6:

```
top relation MessageEndToRelationship{
checkonly domain source b:sequance::messageend{name = cn,
sender = e:sequance::message{ kind = 'normal' }};
enforce domain target w :psm::relationship{name ='AND',
srcP = ps:psm::predicate{}};
where {MessageToPredicate(e,ps);}}
```

R6 asserts if a *message end* in the source sequence diagram with a specific *name* and a *sender* that is a “normal” message. Accordingly, in the target domain, it enforces the creation of a relationship with the *name* 'AND' and a *source* predicate. This rule builds the relationship between predicates that usually is ‘And’ if not specified ‘OR’. R2 is required as postcondition.

R7:

```
top relation negatedTopredicate {
Cn ,n: String;
checkonly domain source a:sequance::message{kind= 'negated',name = Cn};
enforce domain target o:psm::predicate{name=Cn +'not'};}
```

R7 rule checks for a message in the source sequence diagram with a specific kind "negated" and a name matching the variable "Cn". If true,in the target domain, it enforces the creation of a *predicate* with a name formed by appending "not" to the original name.

2) PIM Class Metamodel to PSM Metamodel: The class diagram is utilized initially to act as a descriptor for data and facts needed in ES. However, the goal is to convert the facts of experts in some domains into implementation using PSM concepts. As a consequence of this, we need to find relationships between class diagram concepts and the PSM concepts. Table I shows these relationships after a close investigation of both metamodel concepts. Table II shows transformation rules representing the mapping between PIM class diagram to PSM rule- based ES.

In Table II, the "ClassToFact" rule performs the transformation of classes into a fact in the target model. Similarly, the "AttributeToParameter" rule is employed to convert an attribute into a parameter. These rules play a vital role in the process of adapting and reshaping data within the modeling contextualizing the need for facts that represent the essential part of knowledge.

TABLE II. PIM CLASS DIAGRAM TO PSM RULE -BASED EXPERT SYSTEM MAPPING RULES

Rule	Transformation Rule	Source Model	Target Model
R1	ClassToFact	Class	Fact
R2	AttributeToParameter	Attribute	Parameter

The QVT mapping rules starting with this statement:

transformation map (source: class, target:psm)

This transformation specifies the mapping between a source model represented as a class diagram (source) and a target model represented as a PSM (target).

The formal QVT mapping rules corresponds to Table II:

R1:

top relation ClasstoFact{

Cn , n : String;

checkonly domain source a:cla::classs{name = Cn};

enforce domain target o:psm::Fact{name = Cn};

where {AttributeToParameter(a,o);}}

R1 relation transforms a source model (class) to a target model(psm). It checks for a *class* in the source domain with a specific name "Cn". In the target domain, it enforces the creation of a *Fact* with the same name "Cn". Additionally, it includes a constraint R5 executes afterwards that ensures the mapping of attributes from the source class to *parameters* in the target for *Fact.*

R2:

relation AttributeToParameter{

Cn , n , v: String;

checkonly domain source a:cla::classs{name = Cn , attribute = ar:cla::Attribute{

name = n, value= v}};

enforce domain target o:psm::Fact{name = Cn, parmeters = w : psm::parmeter {

name = n, value= v}};

R2 relation is part of the "ClasstoFact" transformation. It checks for an attribute within the source class that matches the variable "n" and has a value matching the variable "v". In the target domain, it enforces the creation of a parameter within the Fact with the same name and value. This relation ensures the mapping of attributes to parameters during the transformation process.

D. Round- Trip Mapping

The extant issues encountered in the development of ES via a code-based approach has strong resolution through the contemporary application of MDA. This approach enables developers to focus on the high-level concepts of system design, reducing the complexity of development and facilitating the reuse of code and knowledge [12]. For instance, MDA offers cost-effective maintenance through the utilization of automation and the implementation of a round-trip mapping mechanism. This work argues for support of maintenance using relational QVT language (QVT-r is supported by EMF). It reflects the changes that happened to PSM such as having a new version of the software of shells. More important the changes in the PIM model (i.e., business rules change) will not change the PSM or mapping assets so can be re-used. This adds great value to the re-engineering effort required for ES. By structuring mappings in this manner, developers gain enhanced and ease mechanism to make change such as update to the rules. This approach optimizes the maintainability of the system, as it streamlines the process of rule manipulation and adaptation within the MDA framework. More importantly, there are legacy ESs serving organizations for a long time that can benefit from this model whereas in extreme cases models can be reverse engineered so can be changed and synchronized automatically with required changes. For instance, a rule can be developed for round- trip mapping for PSM – PIM Sequence Diagram where each represents different sort of changes:

RM1:

relation LHSToMessage{

k : String;

checkonly domain p :psm::predicate{ at = a:psm::LHS{}, name = k };

enforce domain target m: sequance::message{ kind = 'goal', name = k};

where {parmeterTOArguement (p,m);}}

The purpose of this rule is to enable the redirection of mapping from the left-hand side (LHS) back to the message, facilitating any necessary changes.

RM2:

relation PredicateToMessage{

pn: String;

checkonly domain target p: psm::predicate {at = a :psm::RHS{}, name = pn};

enforce domain target m: sequence:message {kind='normal',name = pn };

where { parmeterTOArguement (p,m);;}}

The purpose of this rule is to enable the redirection of mapping from the predicate back to the message. These rules establish a mechanism for reverse mapping that is not only applicable to the specific rules but also to other rules derived from the PIM Sequence Diagram to the PSM.

The round- trip mapping for PSM- PIM Class Diagram:

RM3:

top relation FactToClass{

Cn, n : String;

checkonly domain source o: psm::Fact{name = Cn};

enforce domain target a: cla::classs{name = Cn}

where {ParameterToParameter(o,a);}}

The purpose of this rule is to enable the redirection of mapping from fact back to the class.

RM4:

relation ParameterToAttribute{

Cn , n , v: String;

checkonly domain source o: psm::Fact{name = Cn, parmeters = w: psm::parmeter {name = n, value= v}};

enforce domain target a: cla::classs{name = Cn , attribute = ar:cla::Attribute{name = n, value= v}};}}

The purpose of this rule is to enable the redirection of mapping from parameter back to the attribute. Also, these rules establish a mechanism for reverse mapping that is not only applicable to the specific rules but also to other rules derived from the PIM Class Diagram to the PSM.

IV. Reengineering and New Insights

This section analyzes and discusses the feasibility, insights, and opportunities of using MDA at different scales of change in the scope of the ES. The reengineering of a system typically involves a radical change for the entire system to achieve some result, while maintenance tackles parts of a system to improve it by making corrective action or minor modifications [39]. In this work, we use the term reengineering in a broad context. For instance, maintenance could be applicable to any part of PIM, PSM, or mapping rules, while the process of making radical changes (from a code-based approach to a model-based approach) to the legacy ESs by using MDA is a re-engineering process. However, the capability of interoperability is also one of the main concerns of MDA, which is defined as the ability to seamlessly integrate different systems or components to exchange information and work together [11].

There are many reasons why current ESs need to change under the umbrella of maintenance or reengineering, for example, the need to interoperate or integrate with other systems. The basic assumption of the data or facts underlying ESs is to be provided in a static way for reasoning. Nowadays, this is not the case where data should be updated by dynamic systems such as in the medical field by EHR (i.e., supply patient data) or general business ERP (i.e., provide production information such as a master or detailed schedule). The data involved in such systems is not only current but also comprehensive. For instance, patients with new symptoms or a production machine show new odd behavior in one manufacture. Based on the application requirements, data needs to be pulled or pushed from these systems to the relative ES. It is obvious that manual pulling or pushing is not practical in this sense. This visibility is a sort of strong business requirement that must be achieved today. On the other hand, rules as shown are subject to change due to different reasons, such as progress or a shift in the landscape of the knowledge of a field (i.e., medicine), but we argue that our approach enables automated supplementation of rules because the transformation process in MDA is a separate and dynamic process with stable mapping rules. This will not only provide a dynamic way of running the ES but also provide new insights. One can imagine that GPT agents (like ChatGPT or Bard) or similar intelligent systems can utilize this feature. Indeed, these GPT-based AI tools use symbolic knowledge-based questions or queries to find the relevant information or identify the context of the question (using inferencing rules and knowledge). This view suggests that an integration mechanism allows data to be outsourced as well as rules, so ES can be provided as a dynamic service.

In addition, interfaces of an old legacy systems became obsolete and so there is tendency to be upgraded to new standards such as Jetpack Compose [40] developed by google for building native Android applications, SwiftUI [41] for IOs and mac applications, CSS frameworks than enable web-access for ESs, and many others taking into account in single system such as mobile you find different of GUI standards.

We now turn to the question of how MDA can support this strong demand for integration with these different systems. On the one hand, MDA has the abstraction of a PSM that is based on MOF to represent the technical aspects of a platform, one of which is GUI platforms or others such as APIs for specific platforms (i.e., EHR and ERP). So specifically, PSM for any of this need to be developed and a couple of transformations using like QVT [38]. More than a decade ago, typically the integration between systems followed standards such as service-based system technologies, web services, and WSDL [42], JOSON and RESTFul [43] or SOAP [44]. They contributed to interoperability between different tools and encourage more integration to be practiced. Cloud systems are basically complex, diverse systems that use these standards. More importantly, the literature is rich with some of these standards that exist as PSMs and can be re-used to reduce development costs. On the other hand, PIM is a business-level abstraction built independently of even PSM, so the portion of PIM related to interoperability, such as GUI or others discussed above, can be projected using the transformation capability of MDA. In this case, mapping rules only need to be changed if the PSM is already published (GUI, WSDL). However, there might be intermediate steps (pre-processing steps) needed, such as using the QVT view maintenance [30] capability to map PIM into more refined PIM or PSM into more refined PSM.

To conclude, MDA has rich architecture support for change, such as interoperability, that can allow even non-MDA systems to integrate in a manner that reduces the re-engineering cost. More importantly, this interoperability in this context provides new insights into using traditional expert systems, such as exposing expert systems as a service, and gains the power to of dealing with dynamic changes in facts or the instability of rules.

V. Evaluation using Case Study

An academic advising ES has been introduced to bridge the gap between students and advisors by shifting advising, complaining, evaluating, and suggestions from traditional ways to a more contemporary one [45]. The decisions need to be made by students during their academic journey such as course enrolment, course withdrawal, postponing study, etc. In this paper, we take on a scenario of a rule-based ES for academic advising in the university system. The need for ES for academic advising is to take a decision for different actions involves uncertainty and a couple of factors need to be tested. For example, the decision to drop a course for low GPA students has different consequences which is not straightforward decision. Similar thing can be said for postponed study, drop a semester and so on.

The ES will build the work plan by identifying the student through some important points:

- Perquisite courses.
- Knowing the student's performance.
- The student’s weakness points.
- Domain skills.
- Skills that a student needs to improve.
- Student goals.
- Track the student pathway.

The ES works to facilitate the communication between students and the advisors by raising the student's performance giving some recommendations that help the low GPA student to develop specific skills for different semester actions such as course enrolment, course withdrawal, postpone study, etc.

A. Developing Process Model for ES

A student who is struggling with a low GPA might approach their academic advisor for assistance in considering the option of dropping a course for the current semester. The ES is responsible for determining when the low GPA student is eligible for dropping a course according to the following conditions:

- **Perquisites Course:** Perquisites course must be ‘Not Major’ category.
- **Skill Assessment:** Students skill must be a ‘Weak Skill’ in this course.

The advisory academic rules are:

- **Rule:DropCourse(SID,CID)=**IfGet_PreCourse(CList) AN Check_PreCouese_Category(CID)AND Check_Skill(Skill)
- In all other cases, the system does not allow the student to drop the course.

These rules consider the relevance of the PreCourse category and the strength of the student's skill set. If the conditions are met, the system facilitates the selection of appropriate PreCourse categories and skills, while disallowing the student from dropping the selected course. Conversely, if the conditions are not met, the system permits the student to drop the course if desired. Fig. 5 illustrates the sequence diagram outlining the process for dropping a course for a student with a low GPA.

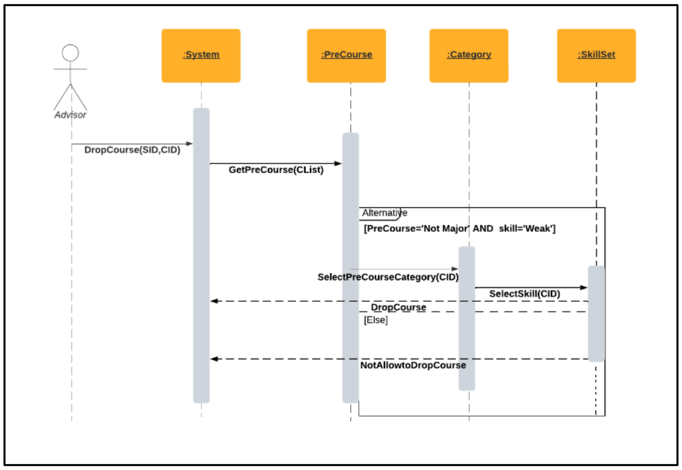

Fig. 5. Drop a course UML sequence diagram.

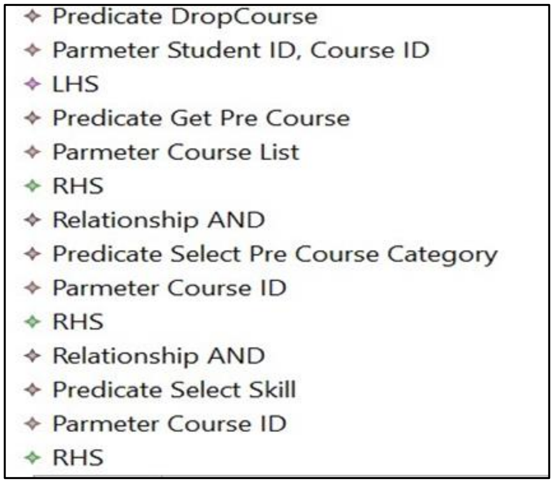
Fig. 5 presents the process involving the Advisor, System, and PreCourse, Category, and SkillSet objects, illustrating how t odecide on the drop of a course. The interaction commences as the advisor engages with the system, focusing on the rules associated with dropping a course. The first message, "If the PreCourse category is classified as 'Not Major' or the student possesses a 'Week' skill in a particular subject (skill='Weak'), then the system proceeds with the selection of the PreCourse category (CID) through the predicate SelectPreCourseCategory(CID) and the selection of the skill (CID) through the SelectSkill(CID).Following this, the system responds with the message "DropCourse" for dropping the course, provided the conditions specified in the previous message are met. However, in all other cases, the system responds with the message "NotAllowtoDropCourse".

As noted earlier, MDA develops rule-based ES by mapping transformation from PIM to PSM. The mapping process is performed using the MediniQVT tool, where the source file is the Ecore file [46] representing the Sequence diagram PIM metamodel, and the target file is the Ecore file representing the Production rule PSM metamodel. Also, an XMI file acts as an input containing instances of the sequence diagram metamodel for this case for example is utilized. Subsequently, the relational QVT mapping rules mentioned above are applied to create the production rules of ES. Table III shows the mapping rules used and Fig. 6 shows a sample of execution for final result of mappings.

B. Developing Data Model for ES

As mentioned, the UML class diagram is used as a descriptor to represent the data and facts of ES. Fig. 7 explains the UML class model by the using example of a case study of academic advising system in university.

As shown in the UML class diagram is that Student has a relationship with Course. In addition, the Course has a specific domain (such as Math, programming) consisting of skills needed as outcomes for the course(s) in this domain. Further, a course sometimes has Prerequisite course; the association between Course and Prerequisite course, which models this business rule. This will enable checking the integrity constraint that that Student must take the Prerequisite course and pass it before registering in a new course. According to the types of courses, there are two types: 1- Taken Course, 2- Next Plan Course. Taken course refers to the taken courses in the semester, and next plan courses refers to the planned courses in the next semester. Nevertheless, Student must have a study plan to follow according to the program requirements. The academic advisor wishes to help students complete this study plan successfully with low risk by making the right decision at the right time which is the source of the calling the experience of the ES.



- Predicate DropCourse
- Parmeter Student ID, Course ID
- LHS
- Predicate Get Pre Course
- Parmeter Course List
- RHS
- Relationship AND
- Predicate Select Pre Course Category
- Parmeter Course ID
- RHS
- Relationship AND
- Predicate Select Skill
- Parmeter Course ID
- RHS

Fig. 6. PIM sequence diagram for drop a course target file.

Fig. 7. PIM Sequence Diagram to PSM Rule -based Expert System Mapping Results

No.	Predicate	Parameter	Predicate type	Justification
1	Drop Course	Student ID, Course ID	Left Hand Side	This predicate represents the LHS predicate of the drop a course rule.
2	Get Pre-Course	Course List	Right Hand Side	This predicate represents the RHS predicate of the drop a course rule. It has an AND relationship with next RHS predicate
3	Select Pre-Course Category	Course ID	Right Hand Side	This predicate represents the RHS predicate of the drop a course rule. It has an AND relationship with next RHS predicate
4	Select Course	Course ID	Right Hand Side	This predicate represents the RHS predicate of the drop a course rule.

As noted earlier, MDA develops rule-based ES by mapping transformation from PIM to PSM. Where the source file is the Ecore file representing the (Class diagram metamodel), and the target file is the Ecore file representing the (PSM metamodel). Additionally, an XMI file containing instances of the class diagram metamodel is utilized. Subsequently, the relational QVT mapping rules mentioned above are applied to create the facts of ES. Table IV shows the results of the mapping process, there are eight facts generated, each of which is associated with a specific parameter. These results provide a comprehensive description of the facts utilized by the domain experts in leveraging the ES effectively and Fig. 8 shows a sample of execution for final result of mappings.

VI. Results and Discussion

The investment on the quality of software development became evident that will pay back the cost. Having the case that many legacy ESs contributing to different domains exist over a long period, such as in medicine ,health, and education [16],[17],[18], necessarily entails requirement changes such as in platform or business rules. More importantly, the discovery of the entrance of ESs into new domains (environmental management and cybersecurity) requires flexibility and less costly development methods. However, using MDA in this work provides these qualities. The PSM metamodel from production rules developed as a generic PSM and mapping rules can act as assets so they can be re-used with the development process of any kind of ES; therefore, the principles of reusability, platform independence, are achieved and hence reducing the cost. For instance, changing Prolog with the Pyke platform for any reason such as utilizing a forward chaining tool instead of backward changing tool, does not cause a change in the PIM, PSM, and properly minor change to mapping rules. Also, changing to a new version of a platform such as upgrading to acquire new features, the proposed approach does not require to change PIM or PSM and mappings.

Similarly, in more extreme maintenance cases where rules are updated or modified, only the PIM (model instances) needs an update, the rest will be re-used therefore coping with the rules instability. Moreover, the raising of abstraction afforded by MDA, such as in the PIM descriptor, allows domain experts to participate or write expert system, which bridges the gap between domain experts and developers.

On the other hand, the integration of an ES with other systems (i.e. HER) under reengineering process or maintenance, is an inexpensive approach because of the re-using utility provided by metamodeling and formalizations (using MOF) of the descriptors: PIM, PSM, and mapping rules. Thereby provides costless reengineering. Because different Shells have different features, the PSM developed is standard one and therefore comply with the principle of platform-independence so like portability can be achieved. It can be modified to incorporate additional features if is to put into practice, but it should be the commonality among all shell platforms. The XMI standard allows either PIM or PSM to be migrated to another tool so can be edited or manipulated.

The sequence diagram, in reality, reflects the nature of interactions involving the business rules of a desired ES. However, this study argues for a type of ES that is process-oriented, where a set of actions with a sequence that represents constraints such as pre-conditions and post-conditions need to be specified for the desired outcome. For example, the process of checking ripe and unripe fruits, the process of optimization such as in manufacturing (i.e., efficiency of steal production), control process, real-time recommendations process, and planning and scheduling processes.

VII. Conclusions

This work is about automating ESs from high-level models using the principles of MDA. ES is a long-sounding successful product of AI but lacks advanced methods of development and re-engineering, which leads to an increase in the cost of maintenance and development. Moreover, effective communication between developers and domain experts is a crucial yet challenging aspect of designing ESs. The inherent differences in technical knowledge and domain expertise often lead to communication gaps, hindering the accurate translation of domain knowledge into functional system components. However, MDA raises the abstraction level of the development of an application as well as provides a structured approach for automation so ES applications can leverage this feature. MDA decouples application concepts or domain of the problem that needs to be specified in the PIM metamodel from the technical aspects of implementation, which will be specified in the PSM metamodel; then mapping the first end (PIM) into the second (PSM) using the standard mapping language, QVT.

The proposed approach addresses some limitations in the literature, such as the lack of generic PSM and specific compliance to the MDA principles, as well as recognizes and supports a class of expert systems identified as process-oriented ES. A UML sequence diagram is used to model business aspects of this type of ES, and a class diagram is used to model facts by representing entities and their attributes. It is, therefore, establishing high-level specifications of business rules and processes. The generic PSM is developed based on pure production rules (FOPC), which makes it adaptable to different rule-based engines or Shells that implement PIM models of business aspects. Furthermore, we designed a UML profile diagram that extends the PIM sequence diagram, to support the lack of some features in the UML sequence model (OR and Not). Finally, in this tackle, we developed the necessary mapping rules (QVT) that act as a standard for the transformation of PIM sequence diagram metamodel into a rule-based PSM metamodel, generating the necessary rules and generating ES facts from UML class models as well as the developing round-trip mapping that supports the maintenance of ES.

To evaluate our proposed approach, which is design science research, a real case study of an academic advising system for low GPA students, was used for evaluation. QVT mapping rules that facilitate the transformation from the PIM to the PSM have been developed. In this process, we establish mapping rules that convert the PIM sequence diagram into a rule-based ES, generating the necessary ES rules. Additionally, we defined mapping rules that transform the PIM class diagram into a PSM rule-based ES, resulting in the creation of the required facts for ES. More importantly, utilizing the QVT Relational language that enables round-trip mapping thereby support potential changes (i.e. in rules, business requirement, platform) of PIM, PSM, mapping rules itself. A less costly maintenance therefore achieved because of the automation and the standardizing of round-trip mapping rules being developed. The results obtained from this case study provide practical evidence of the applicability and utility of our proposed approach in real-world scenarios.

Nevertheless, it is important to acknowledge the limitations of the current work. The connection between PSM and a platform is not tackled but since a generic PSM is developed the process is straightforward. Also, the consequences of the inclusion of OCL in UML models. In addition, although the introduced model is adaptable to both process-oriented and data-oriented approaches, its primary focus lies in the process-oriented aspect. Also, the models lack the capability of using a relational or mathematical expression that can be needed in the PIM metamodel.

In future endeavors, our objective is to further advance the ES design approach by implementing and evaluating the proposed design on different domains of ES, ensuring its practical applicability and effectiveness, and supporting the lacking features in PIM. Also, incorporating the UML profile in the mapping process and resolving the limitation of tools (mapping engine) to recognize profiles.

Comparison of SVM kernels in Credit Card Fraud Detection using GANs

Bandar Alshawi
Department of Computer and Network Engineering, College of Computing, Umm Al-Qura University, Makkah, Saudi Arabia

***Abstract*—The technological evolution in smartphones and telecommunication systems have led people to be more dependent on online shopping and electronic payments, which created burdensome task of transaction validation for many financial institutions. This paper examined and evaluated the efficacy of Support vector machine (SVM) kernels on Generative Adversarial Network (GAN)-generated synthetic data to detect credit card fraud transactions. Four SVM kernels have been investigated and compared; linear, polynomial, sigmoid, and redial basis function. The accuracy results indicated that linear and polynomial kernels reached over 91%, while sigmoid and redial basis function reached 79% and 83% respectively. Linear and polynomial models received over 90% ROC and F1 score, in contrast the ROC scores were lower for sigmoid (81%) and redial basis function (83%). Both sigmoid and redial basis function achieved over 80% in terms of F1 score. The precision score demonstrated a high score for both linear and polynomial kernel reaching 99%. Additionally, sigmoid and redial basis function achieved over 80%. These results overcame the imbalance dataset issue through the generation of synthetic data by applying the SVM kernels using GANs algorithm.**

Keywords—Fraud transactions; credit card; Generative Adversarial Network; Support Vector Machine kernels; imbalance dataset

I. Introduction

The evolution of telecommunications technologies and the adoption of electronic payments from vast financial institutions led to unanticipated spike in fraud transactions. Personal and organizational assets nowadays are vulnerable due to cybersecurity breaches [1]. In 2020 alone, banks have suffered over $28 billion in credit card losses globally. The numbers are predicted to surpass $49 billion by 2030 [2]. Engaging artificial intelligence in banking system will enhance fraud detection, thus protecting assets and reinforce customer fidelity [3]. The fraud and control report in [4] sheds light to almost 26% of electronic transactions were categorized as fraud or attempted fraud. Detecting electronic fraud transactions using Machine Learning (ML) can be cumbersome according to the research presented in [5]. Diverse ML credit card fraud detection system has been previously reviewed [6, 7]. The complexity of imbalance dataset exists in different real-world ML scenarios. In the credit card dataset, the irregular distribution of one class was evident due to the fact that valid transaction exceeds fraudulent transactions [8]. Numerous credit card fraud detection methods capable of avoiding fraudulent transactions in the banking sectors include data mining, modeling algorithms, which comprise of clustering methods and fraud detection [9].

This research investigates an important issue in credit card fraud detection using ML techniques, which raises the following questions:

- Has any of the previous research examined different SVM kernels to detect credit card fraud transactions on imbalanced dataset?
- How does the Generative Adversarial Network (GAN) perform on generating tabular data?
- How the four SVM kernels perform against each other.

To answer the preceding questions of this research, numerous objectives required to be met, including:

- Reparation of imbalance dataset in tabular data.
- Using specific GAN to generate synthetic tabular data.
- Detecting credit card fraud using SVM kernels and evaluate the performance of each kernel among other.

Although GANs are mainly used to synthesize visual data, several research have successfully managed to use them to generate tabular. The significance of this study is overcoming the issue of imbalanced dataset while investigating the performance of different SVM kernels.

This paper is categorized as follows: Section II presents related efforts on several ML fraud detection study; Section III discusses the methods used to predict the results. In Section IV an extensive review of the results and analysis is detailed. Section V is reserved for discussion and comparisons. Section VI presents the conclusion of the research.

II. Related work

The research in study [10] presented an approach to observe credit card fraud. The author focused on reaching unbiased and consistent techniques to automate fraud risk evaluation. The approach proposed an algorithm that calculated variables’ relationships and related information. The solution successfully improved accuracy and diminished dimensionality. The study in [11] illustrated a comparison of various credit card fraud detection methods using supervised and unsupervised learning. The results show a prime for unsupervised learning, while emphasizing the effects on performance when using supervised learning methods. A fraud financial detection method was presented in [1] named Intimation Rule Based (IRB) alert generation algorithm using ontology-based system which benefited from ontology alert. The author constructed their method by including forty categories and sub-categories which effectively can capture fraud by sending different notifications according to their extremity. In study [12] the author examined the utilization of supervised and unsupervised methods to identify inconsistencies in financial transaction records. The research in [13] proposed a hybrid ensemble model to detect anomalies in credit card transactions. The research used adaboost, random forest, and logistic regression as classifiers, imbalanced dataset was addressed by oversampling method and removal of outliers. The study examined SVM along with different ML methods including an adaptive boosting (AdaBoost) and decision tree on real world dataset. The experiment involved the use of real-world dataset and applying vectorization on the sub-leader account size to tangle irregularity. Most classifiers are incapable of procuring acceptable outcome during imbalance data classification, the author in [14] proposed an optimized SVM by Genetic Algorithm, dataset balancing is done through cluster centroids sampling.

The study in [15] applied SVM along with decision trees on an extremely imbalanced real-world dataset. A handful of numbers of machine learning techniques were examined that include outlier detection and ensemble algorithms. The author employed feature engineering to calculate the effect of feature-selection on performance. The research in [16] reviewed the latest progress in detecting fraud transaction using Deep Reinforcement Learning (DRL) and ML. The research carried out an experiment on an exceedingly imbalanced dataset using resampling technique to deal with complications and implementing several ML and DRL methods. An extensive analysis was carried out on non-linear models in [17]. The study proposed binary types of fraud detector models, one that can be interpreted and the other cannot be bound to a specific way. The models are utilized concurrently with ML methods. Furthermore, Black Box model is avoided in the study by supply tracing information that associates inputs and outputs. Credit card fraud detection methods using several neural networks concurrently with resembling methods were demonstrated in [18]. A combination of Harris Hawk Optimization (HHO) and SMOTE was introduced in [19]. The study tried to identify the appropriate sampling pace for the HHO and combines it with the SMOTE algorithm. The main aim of the study is to maximize classifier accuracy in imbalanced datasets. Different ML techniques were discussed such as: recurrent neural network, convolutional neural network, and ensemble methods. The research attempted to investigate obstacles and limitations related to IoT anomaly detectors.

The research in study [20] presented a system that integrates Deep Neural Network (DNN) and Catboost, to test any overlap in classification rate improvement. The experiment was carried out on IEEE-CIS dataset composed of 590,540 instances. Miscellaneous classifiers have been tested on highly imbalanced datasets in [21]. The author applied random over sampling (RO), which replicate instances from the minority category followed by applying SVM, NÏVE BAYS (NB), Artificial neural network (ANN), and C5.0. The review in [22] discussed oversampling and undersampling to handle imbalance dataset and comparing convolutional to an ensemble algorithm during credit card fraud detection, concluding that ensemble was more effective. An ensemble methodology was used by applying decision tree, logistic regression, and NB side by side in [23] highest output is picked by hard voting. In study [24] rough set theory was used for initial data refinement consisting of attribute estimation and reduction, lease square support vector later applied to classify and predict credit card churn behavior. Hierarchical temporal memory, based on cortical learning HTM-CLA algorithm, was presented in [25] to recognize fraudulent transaction. The authors also measured the difference between the HTM-CLA outcomes of using traditional Artificial Neural Network tree (ANN) in contrast to simulated annealing ANN. The research in study [26] used GANs along with logistic regression, decision tree, naïve bay, random forest, extreme gradient boosting, and adaptive boosting algorithms to detect credit card fraud transactions.

III. Methodologies

A. Implementation

The used tools through this research include intel i9-9900K 3.60GHz, 64GB RAM, Nvidia 2080TI was utilized for GAN synthetic data generation and SVM kernels training and testing.

B. Original Data

The dataset contains credit card transactions by European cardholders in October 2013. The dataset consisted of transactions that occurred in two consecutive days. The dataset is imbalanced since it had 492 flagged as fraudulent out of the 284,807 transactions. With accordance to client’s confidentiality and privacy, the dataset underwent the Principal Component Analysis (PCA), resulting in numerical variables. The dataset consisted of 31 features that are Class, Time, V1, and V28.

C. Synthetic Data

Different researchers have tried to cope with the complexity of imbalanced dataset in the existing area using Synthetic Minority Oversampling Technique (MOTE) found in [27], [12], and [28]. SMOTE is an effective oversampling technique used to generate synthetic data from minority class [29]. Synthetic data was adopted in [30] using Monte Carlo simulations, a whole dataset was assembled including a number of features. GANs have been adopted in numerous domains recently to refine synthetic images producing a realistic representation. Other example of GANs adoption was done by Alonso et al. in [31] their model generates handwritten text. Their generator is conditioned on a sequence of characters, subsequently the generator starts producing synthetic data in the form of handwritten instances for different words. Creating synthetic data out of a random noise is not GANs prominent purpose, its capability lies in estimating the uneven class and generating data from a small set of samples [32]. The proposed approach uses synthetic data, which can be generated using GANs method discussed and explained thoroughly in Section III.

D. Generative Adversarial Network

GAN was created by Ian Goodfellow in 2014, and it is classified under unsupervised learning [33]. Generative models are capable of learning and imitating any distribution of data. GANs consist of two neural networks trained competitively thus; they are referred to as adversarial. GANs utilize the deep neural network as a training algorithm. Imbalanced dataset is a frequent matter during modeling and may result in a weak model therefore; GANs can be employed to generate synthetic data which could solve some of the complexity [34]. GANs consist of binary neural networks operating in a contrary mode, the former is identified as the generator, and the latter refers to as the discriminator. Collection and generation of samples are the purpose of Generator Network presence. The probability of discriminator network to mis-classify would grow proportionally during the training of the generator network. GANs equation is found in Eq. (1) where G is the generative model learning from the training data x, D is the discriminator, which separate among various classes of data. The discriminator identifies whether the received data were generated from a real sample using a binary for output ranging from 0 to 1. In Eq. (1) the generator receives a slight noise sample from z. ~μ_z refers to the generator distribution and ~μ_ref refers to the real data distribution. GANs architecture is presented in Fig. 1.

$$L(G,D) = \mathbb{E}_{x\sim\mu_{ref}}[\ln D(x)] + \mathbb{E}_{z\sim\mu_z}\left[ln\left(1 - D\big(G(Z)\big)\right)\right] \quad (1)$$

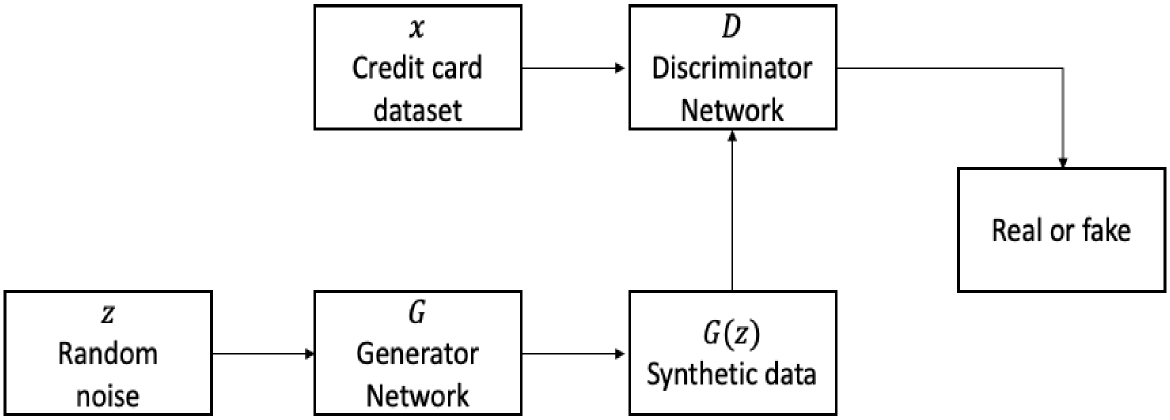

Fig. 1. Generative adversarial network.

E. GANs for Tabular Data

Applying GANs over tabular data, can rise numerous of challenges such of which are indicated below:

- Tabular data can be of a mixed type.
- GANs are effective in image data, and they distribute them over space. On the other hand, tabular data are non-Gaussian that could affect the network not being able to propagate gradient details.
- The generator is not capable of recognizing imbalanced categorical columns when using generated samples from standard multivariate distribution.

CTGAN is implemented in this research which is a GANs based method capable of solving non-Gaussian obstacle by applying mode-specific normalization. Moreover, it uses all existing features of the dataset [35]. In Fig. 2 an illustration of the proposed framework of credit card detection approach is demonstrated.

F. Machine Learning

ML was defined since 1959 by the AI pioneer Arthur Samuel who indicated that computers will be capable of learning from experiences rather than being programmed. ML is classified into three categories: supervised learning, unsupervised learning, and reinforcement machine learning [36]. Fig. 3 illustrates SVM kernel classification utilized in this research.

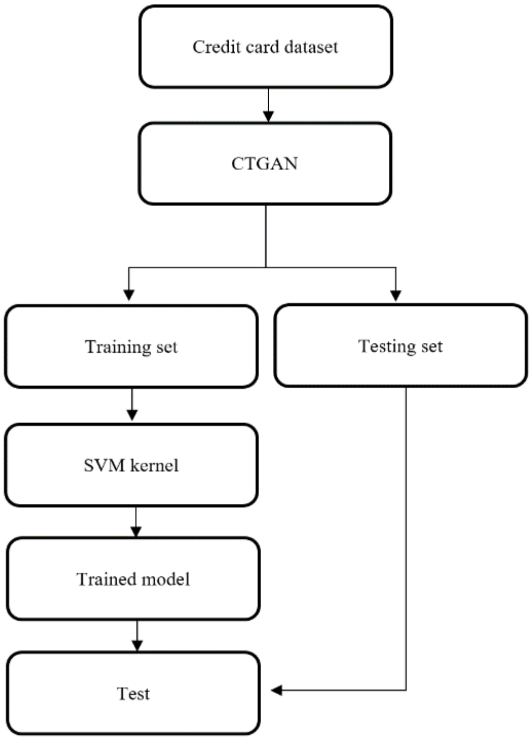

Fig. 2. Framework of the proposed credit card detection approach.

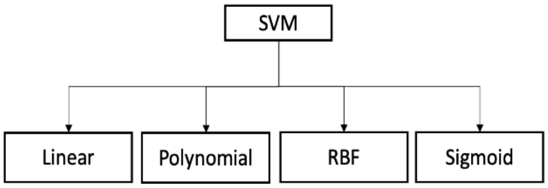

Fig. 3. SVM kernel classification.

G. Support Vector Machine

The SVM algorithm is a supervised learning algorithm developed in Bell Lab by Vladimir Vapnik. SVM has the capability of solving regression and classification problems. SVM can separate two categories by drawing a hyperplane. The performance of SVM is thoroughly impacted by the selected kernel and the parameters as default or set values. The use of kernel aims to assemble a nonlinear hyperplane including all the set of input values to execute the classification [37].

H. Kernel Functions

Kernel functions come to place in situations where samples are linearly non-sparable. SVM kernel includes decision functions to non-linear class by mapping input sample and projecting them into a higher dimensional space, not requiring calculating the mapping explicitly. Optimistically, the samples will achieve significant linear structure. Moreover, the kernel function can be thought of as a measure of similarity between samples [38], which grants SVM to carry out separations regardless of very complex boundaries. Different kernel settings will be discussed the following section.

I. Radial Basis Function RBF Kernel

Radial Basis Function falls under the neural network types. It is used to solve diverse problems such as: classification, prediction, and regression. The approach that RBF uses to process classification problems differ compared to ordinary neural network. Ordinary neural network performs data separation using linear manipulations of activation function. On the other hand RBF organize data by density-based transformation. RBF equation is stated below where X is the input, C is the mean center between lowering the training error and surging margin[15], and σ is the spread.

$$h(X) = exp\left(-\frac{\|X - C\|^2}{2\sigma^2}\right) \tag{2}$$

J. Polynomial Kernel

Polynomial kernel is another type of SVM kernel, while it benefits from the polynomial function. The polynomial kernel is used to resale data into greater space. This operation is done by taking the scalar product of data points, the existing space with the polynomial in the newer space. Using polynomial functions allows for greater dimensional mapping for data. The equation of polynomial kernel is shown below where x and y are vectors and c is a constant in the existing space. d is the degree of the polynomial function.

$$K(x, y) = (x^T\, y + c)^d \tag{3}$$

K. Sigmoid Kernel

The idea of sigmoid kernel evolved from neural networks. Sigmoid kernel usage can be problematic due parameters adjustments [39]. The equation of Sigmoid kernel is shown below where $\boldsymbol{X_i}$ and $\boldsymbol{X_j}$ are vectors, $\boldsymbol{\beta_0}$ is the slope, and $\boldsymbol{\beta_1}$ is the intercept.

$$K(X_i, X_j) = tanh(\beta_0 X_i^T\, X_j + \beta_1) \tag{4}$$

L. Linear Kernel

Linear kernel is the simplest kernel, unlike the polynomial or the logistic regression where data are projected to the upper space. In linear kernel, it obtains a single dimensional nature. In other words, linear kernel is capable of separating classes using the hyperplane with linear boundaries [40]. The equation of linear kernel is listed at Eq. (5) where $\boldsymbol{X}, \boldsymbol{X_j}$ represents the data to be classified.

$$K(X, X_j) = sum(X \cdot X_j) \tag{5}$$

M. Evaluation Metrics of SVM Kernels

SVM kernels performance were evaluated and tested using confusion matrix. Which contain True Positive (TP) to correspond to valid transactions that were predicted correctly, false positive (FP) refers to fraud transactions that were not captured, true negative (TN) indicate fraud transactions that were predicted accurately, and false negative (FN) illustrating fraud transactions that were not identified as fraud by the model. The equation presented in Eq. (6) was used to measure accuracy of correctly predicted transactions over the total number of transactions, sometimes referred to as error rate.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{6}$$

Precision metric computes positive instances that are accurately predicted from the total positive predictions. The equation of precision is presented in Eq. (7). One thing to note is that precision and recall do operate in contrast usually one is higher than the other.

$$Precision = \frac{TP}{(TP+FP)} \tag{7}$$

Recall metric displays a calculation of a portion of positive instances that are accurately classified. Their importance stems from their capability of capturing positive cases and that higher recall value prevents missing fraudulent transaction [3]. The equation of recall is found in Eq. 8.

$$Recall = \frac{TP}{(TP+FN)} \tag{8}$$

F1 metric is used to obtain the harmonic mean between precision and recall. F1 has a score between 0 and 1, higher values reflect high model performance. The equation of F1 appears at Eq. (9).

$$F - measure = \frac{2*Precision*Recall}{Precision+Recall} \tag{9}$$

Matthews Correlation Coefficient (MCC) was invented by Brian Matthews in 1975. MCC measures the quality of the classifiers between observation and prediction. It can be described as a confusion matrix method of calculating the Pearson product-moment correlation coefficient between predicted and actual value [16].

$$MCC = \frac{TP * TN - FP * FN}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}} \quad (10)$$

IV. Results

Metric evaluation is summarized in Table I and Table II. An additional method to evaluate the results is through the confusion matrix, which can be used for both binary classification as well as multiclass classification. In the current state, which is binary classification, the confusion matrix generates table of 2*2. The output consists of TP, FP, TN, and FN which were discussed earlier in section III. This section illustrates the outcome of the four SVM kernels discussed in Section III. The accuracy results in Table I showed that LN kernel score was the highest at 95% followed by PL at 91%. RBF scored 83% and SG scored 79%. In precision both LN and PL scored 99%, followed by RBF at 84% and lastly SG which was at 81%. The recall results demonstrated PL with 85% success rate by RBF 85%, led by LN at 82% and SG at 81%. In Table II, the Receiver Operating Characteristic Curve (ROC) is utilized to calculate classifier performance at different thresholds. ROC score in Table II display PL and LN achieved 91%, while RBF attained 83% and SG reached 79%. Based on the MCC score, LN achieved 84%, followed by PL at 83% succeeded by RBF at 66%, and lastly SG at 58%. F1 score in Table II indicated the harmonic mean between precision and recall. LN has achieved the highest F1 score at 92% followed by PL at 91%, concluded with RBF at 85% and SG at 81%. Confusion matrix is used in this section to ease the understanding of outcome, which generates 2*2 table with binary values representing multiclass classification; TP, TN, FP, and FN discussed in Section III. Fig. 4 presents the confusion matrix for LN kernel indicating that the classifier accurately predicted 4285 legitimate and 4145 fraud transactions. LN kernel inaccurately classified 74 fraud transactions as legitimate and 715 legitimate transactions as fraud. Fig. 5 displays the confusion matrix for PL kernel point that the classifier accurately predicted 4253 valid and 4160 invalid transactions. PL classifier was not able to capture 62 fraud transactions furthermore classified 747 real transaction as fraud. Fig. 6 shows the confusion matrix for RBF kernel, which predicted 4231 legitimate and 3468 fraud transactions accurately. Fig. 6 also exposes that 781 fraudulent transactions were classified as valid, and 769 valid transactions were categorized as fraud. SG confusion matrix appears at Fig. 7, representing that SG kernel correctly classified 4027 legitimate and 3305 fraud transactions. SG kernel was not able to capture 938 fraud transactions and categorized them incorrectly; it also categorized 973 valid transactions as fraud. Fig. 8 illustrates the AUC – ROC curve, which explains the classification performance at different thresholds. From the figure it is evident that PL and LN classifiers have a better measure of separability than SG and RBF classifiers. The precision-recall curve is presented in Fig. 9, which can be employed especially when imbalance dataset is in existence. As the figure illustrates PL and LN did outperform SG and RBF.

TABLE I. Performance Evaluation

Algorithm	Accuracy	Precision	Recall
Polynomial	91	99	85
Sigmoid	79	81	81
Linear	95	99	82
RBF	83	84	85

V. Discussion

In Table III a summary of relevant studies is presented, starting with the research in [41], which examined two kernels LN and RBF. Based on the results from Table III it is evident that there is a huge variation between accuracy and recall. The research in [21, 42, 43, 44] does not investigate SVM kernels. In [42, 44] both studies evaluated their models with accuracy which is not always an accurate metric indicator. A comparative result is demonstrated in Fig. 10 which presents consistent overall results for the proposed solution compared to recent existing studies. Few research examined the detection of credit card fraud detection using different SVM kernels, none of them produced significant outcome as noted in Table III and Fig. 10.

TABLE III. Comparison of Relevant Past Studies

	Classifier	Kernel	Accuracy (%)	Recall (%)	Year of publication	Reference
1	SVM	-	96.34	-	2022	[44]
2	SVM	-	99	-	2022	[43]
3	SVM	-	96	39	2019	[21]
4	SVM	-	99	-	2018	[42]
5	SVM	LN	97	1	2020	[41]
			97	10		
		RBF	97	86		
			97	82		

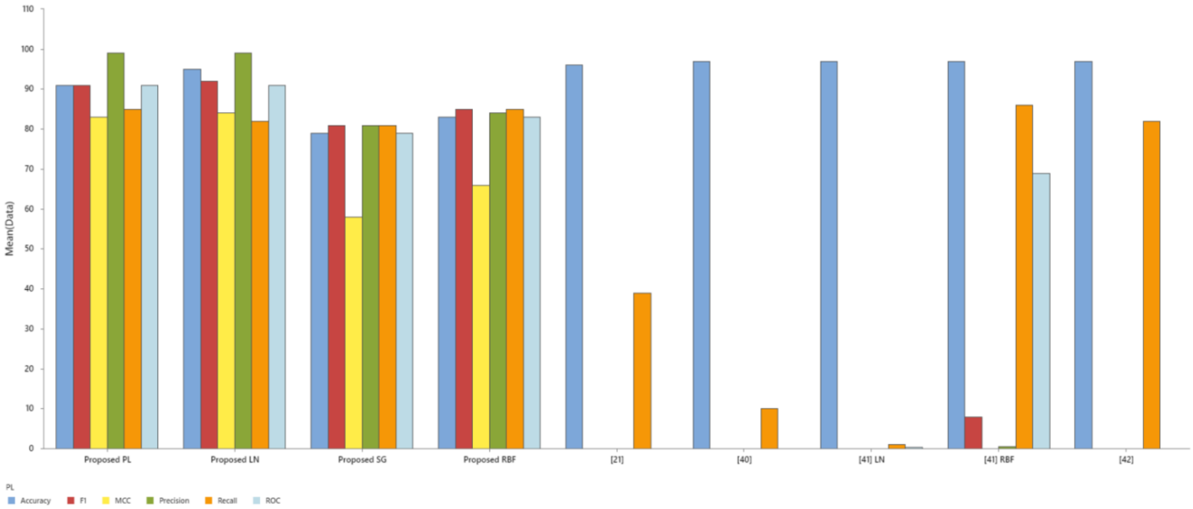

Fig. 10. Comparative results with relevant studies.

VI. Conclusion

The recent advancements and improvements in technological and telecommunication industry lead various sectors to integrate this technology into their system. In addition, due to the tremendous increase of electronic transactions, financial institutions are affected by fraudulent transactions, which meant that certain procedures must take place, including the adoption of ML fraud prevention techniques. In this paper, GAN was used to generate synthetic data to overcome uneven class distribution of credit card dataset. Four SVM kernels were used to predict fraudulent transactions and compared with each other and with relevant recent research. The findings illustrated that two SVM kernels LN and PL scored over 91% in accuracy however, RBF achieved 83% while SG reached 79%. LN and PL have received an over 91% ROC and F1 scores, yet SG reached 79% and RBF scored 83% in ROC. The F1 score for SG and RBF demonstrate that both kernels received over 81%. The future work should focus on investigating the use of different GAN variants with SVM and different classifiers.

***Abstract*—Customers all over the world want to see how the clothes fit them or not before purchasing. Therefore, customers by nature prefer brick-and-mortar clothes shopping so they can try on products before purchasing them. But after the Pandemic of COVID19 many sellers either shifted to online shopping or closed their fitting rooms which made the shopping process hesitant and doubtful. The fact that the clothes may not be suitable for their buyers after purchase led us to think about using new AI technologies to create an online platform or a virtual fitting room (VFR) in the form of a mobile application and a deployed model using a webpage that can be embedded later to any online store where they can try on any number of cloth items without physically trying them. Besides, it will save much searching time for their needs. Furthermore, it will reduce the crowding and headache in the physical shops by applying the same technology using a special type of mirror that will enable customers to try on faster. On the other hand, from business owners' perspective, this project will highly increase their online sales, besides, it will save the quality of the products by avoiding physical trials issues. The main approach used in this work is applying Generative Adversarial Networks (GANs) combined with image processing techniques to generate one output image from two input images which are the person image and the cloth image. This work achieved results that outperformed the state-of-the-art approaches found in literature.**

***Keywords*—Generative Adversarial Networks (GANs), virtual reality; human body segmentation; image generator; conditional generator; background removal**

I. Introduction

Virtual fitting rooms (VFR) bring great opportunities to the fashion industry by enabling consumers to virtually try on products. However, while VFRs have technically been available for a while, they are less utilized because of many reasons, amongst them the consumers' potential concerns of accuracy of the simulation, the cost of the technologies used in building VFRs like Kinect cameras and depth sensors, and the difficulty of using them by the customer because of the special settings they require like special types of LCDs and mirrors. Research has proven that online clothes purchases had increased, and the return requests had decreased after the intervention of virtual fitting rooms (VFRs) [1]. e-Commerce development, AI development, and pandemics shared in both the research and industry demand of VFRs. In this paper two novel outputs are obtained and explained, the first one is a new dataset which is large and various (i.e., containing images for males and females in different poses and from different fashion houses, without excluding any challenges from the collected images) for the purpose of building VFRs, and the second one is a real time, cost efficient, portable, easy to use, and accurate VFR. The rest of this paper is organized as follows: Section II reviews the work done in literature to address this problem. Section III explains the methodologies and techniques used in this work to build the VFR. Section IV demonstrates the experiments conducted to evaluate the work. Section V discusses the results. Finally, the paper is concluded in Section VI.

II. Literature Review

Recently, the idea of virtual fitting rooms has attracted researchers because of the emergence and development of virtual and augmented reality. The digital revolution and affordable technologies and devices also made virtual fitting rooms an area of interest. According to literature there are eight different types of virtual fitting rooms (VFR), which are: Body scanning VFRs, 3D avatar VFRs, 3D customer's modelling VFR, 3D mannequin VFR, Augmented reality VFRs, Robotic mannequins, Dress-up mannequins for mix-and-match, and the real fashion model VFR [1 & 2]. From all technologies and types of body scanning machines proved to be the most accurate, but the most expensive at the same time [3-6]. Although the large variety of technologies that could share in maximizing the customer experience while trying the cloth item online, the cost plays a major role of the types existing in the market. Some features and complementary methods could share in maximizing the customer experience besides the VFRs such as: fit guides, size charts, comparison avatars, virtual cat walks, brands comparisons, etc. [7 - 8].

Researchers used many emergent technologies to simulate fitting rooms, like augmented reality (AR), virtual reality (VR), depth information using Kinect cameras, deep learning approaches (DL), 3D reconstruction, and hybrid approaches. Pereira et al. in 2010 [9], used AR and Kinect camera to establish virtual fitting room using depth information, the authors tested their approach using Open CV and Open GL techniques with different six degrees of human head detection, but they mentioned nothing factual about their results.

Kostas [10] used the same technologies (Kinect cameras and AR) to implement virtual fitting room for trying different cloth items, but the higher accuracy they reached was 67%. Dias et al. [11] also used the same approaches for the same purpose, but they added different features, and they developed a better user interface, but they mentioned nothing about the VFR results. Below is a sample of their results. Hashmi et al. [12] used the AR combined with Haar-cascades classifier to implement VFR. The authors tested their classifier using 50 subjects with 10 different dresses and they confirmed that their approach had outperformed other approaches in literature. Mehta et al. [13] had used AR, VR, and Mixed reality (MR) combined with Head Mounted Displays (HMD). The authors claimed that their VFR can give customers better online shopping experience, but again they mentioned nothing factual about the results.

Boonbrahm et al. [14] in 2015 used VR to build VFR. The authors considered the differences between materials of clothes, and they confirmed that this matters in the final appearance of the dressed person. The materials they considered were jean, satin, silk, and cotton. França & Soares [15] in 2018 have discussed the idea of a complete simulation of Virtual Fitting Room (VFR) using virtual reality (VR) in which the customer feels he/she is existing in a real fitting room. Alfredo et al. [16] used Kinect camera along with gesture recognition and cloth transfer algorithm to create a virtual try in application. Despite the authors concluded that their approach combined with the depth information obtained using the Kinect camera made the customer experience more enjoyable, they mentioned nothing factual about the results.

Sapio et al. [17] in 2018 integrated different body scanning technologies to create a VFR. The authors used Kinect combined with other more expensive body scanners, but they found out that their approach is not only expensive but also needs human intervention and cannot be considered as an easy automated solution.

Silvestro et al. [18] in 2020, used avatars to allow the user to select the size and the shape, but regarding their results the authors mentioned that they are still working on their project to get good results. Ileperuma et al. [19] in 2020 used the CNNs combined with augmented reality (AR) to detect human body and create an image for a dressed object. The authors claimed to achieve 99% accuracy for their generated images. Nande et al. [20] in 2021 used generative adversarial networks (GANs) to replace the cloth item the customer already wearing, by the cloth item the customer wants to buy in a new image. The authors confirmed that they achieved structural similarity index measure (SSIM) matrices of 0.8.

Chen et al. [21] in 2021 also used M5 transformer to build the VFR and they compared their results to other state-of-the-art DL approaches in literature and they achieved very good results. Lyu et al. [22] in the same year, the authors proposed a High-Resolution Virtual Try-On network (HR-VTON) model to synthesize virtual fitting images, which consists of three sub-modules, namely, a clothing matching module, a try-on module and a refine module. They tested their proposed model on Zalando datset and they confirmed that they achieved accuracy rate of 81%. In 2021 Hyder et al. [23] studied the capabilities of Microsoft Kinect sensor and the role of augmented reality in simulating the surrounding world. The authors confirmed that 85% of the volunteers experienced their system and recommended it as a good 3D learning system. Singh et al. [24] in 2021 also, used Generative Adversarial Networks (GANs) to create a VFR. The authors implemented three models which are: the semantic generation module, the clothes wrapping module, and the content fusion module, and they tested their approach using the Zolando dataset also, and they confirmed that their approach achieved very robust results.

In fact, Lye et al. and Singh et al proved to obtain the best results in literature, but on limited dataset with very narrow variety of images as shown in Section IV(A)(1). Chandani et al. [25] in 2022 tried many methods to build a VFR like AR, ANNs, and CNNs. The authors claimed that the users can move freely infront of camera, and change the colors of the outfit, but they mentioned nothing numeric about the mean error or the accuracy rate. Malathi et al. [26] in 2022 also used DL to reconstruct the 3D graphical perception of the user from his/her 2D image to create cost efficient VFR rather than using Kinect camera. The authors confirmed that their approach achieved very good results, with many useful features that maximize user experience satisfaction.

Prabhakar [27] et al. in the same year, used Alpha Channel Masking to mask the user's shirt to gain an area of interest. The authors only worked on three different colours of the same style (Shirt). Mohamed et al. [28] in 2023 used the 3D reconstruction of human body to build VFR. The authors used Kinect combined with other more expensive body scanners, but they found out that their approach is not only expensive but also needs human intervention and cannot be considered as an easy automated solution. The authors used neural networks to reconstruct the 3D models of the human body and the cloth item and put them together in one photo. The authors also used CNNs combined with ResNet-50 to identify the type of texture to make the reconstructed image more accurate and closer to reality, but in their results, they showed a bit large mean error.

Omkar et al. [29] in 2023 have combined AR with DL to build a VFR. The authors confirmed that their approach that renders the image cloth on the customer’s image improved the customer’s experience, but they also mentioned nothing factual about their results. Yang et al. [30] in 2023 considered the body mass (BM) of the user and they confirmed that their approach improved the virtual fitting results to a great extent.

III. METHOD

This work is designed to be deployed on a mobile application in which the process would be much easier for the consumer to do and much cheaper for the clothing shops. The proposed system mainly consists of three main phases: image preprocessing, the GANs part consists of a conditional generator to generate a new segmentation map with the person wearing the new cloth item, and the image generator to generate the final image. The generic flow of the system is as follows: The system asks the user to enter two input images which are, the person image in any pose, and an image for the cloth item he/she wants to buy, to generate a new image of the person wearing the new cloth item. Following is the explanation of every module. Fig. 1 demonstrates the complete architecture of the proposed system.

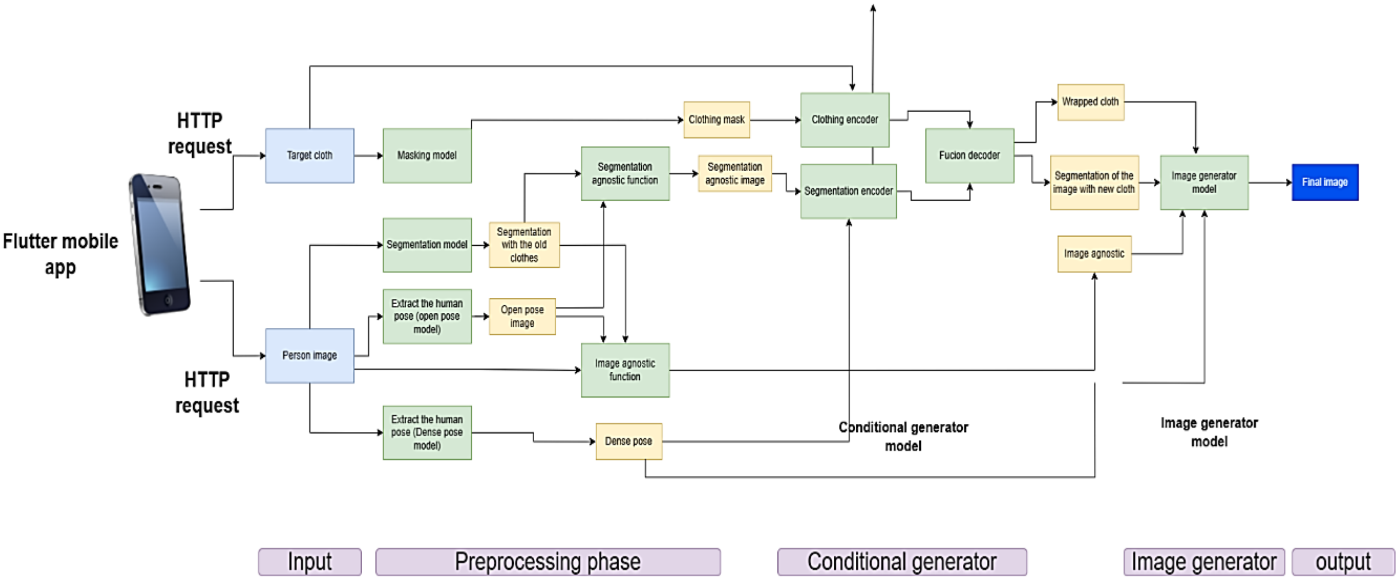

Fig. 1. The complete architecture of the proposed system.

A. *Images Preprocessing*

The input image preprocessing module is composed of four different components: OpenPose, DensePose, segmentation, and cloth mask (see Fig. 1). As mentioned before the user should provide the system by two images, which are his/her image, and the cloth item he/she wants to buy. Regarding the cloth image, it should be segmented using a masking model to be able to recognize the cloth and separate it from the background. Regarding the person's image, some steps should be held such as: background removal, segmentation of different human body parts, definition of OpenPose key points to wrap the cloth over the person in any position not only from the front, 3D human image construction using dense-pose to enhance the final wrapped cloth on the person pose, and finally the combination of the open-pose and the dense-pose to create an agnostic image that would make the system able to focus on the key parts of the human body that should place the new t-shirt on. The outputs of the preprocessing module would be the dense-pose, clothing mask, and segmented agnostic image, which will be the inputs to the conditional generator that generates the new image. Following is a detailed explanation of the preprocessing steps.

1) Human body segmentation: Human parts segmentation is the most important preprocessing step for the generator, as the following modules of the proposed system depend on its results. There are 20 parts in the human body image that should be segmented and classified accurately to identify the clothes' location and these classes are: Background, hat, hair, gloves, sunglasses, upper clothes, dress, coat, socks, pants, torso skin, scarf, skirt, face, eft arm, right arm, left leg, right leg, left shoe, and right shoe (see Fig. 2).

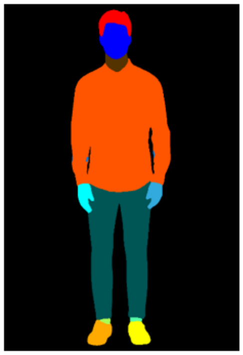

Fig. 2. Typical human body segmentation sample.

The Crowd Instance-level Human Parsing (CIHP) model [31] was used to segment the parts of the human body. This model relies on the concept of part grouping network (PGN) [32] where the input image is scaled into six scales which are: 0.5, 0.75, 1, 1.25, 1.5, 1.75 of the original width and height. The input to this model should include the human image its invert. In other words, the input to this model is a stack of image pairs; the image and its invert [image, image invert]. For each input the average of scales is calculated for every input image. This pipeline consists of six models makes the inference time very large (140 sec), but it gives very accurate results, however, this huge inference time is not suitable for this use-case, so we thought how to decrease it. To solve the problem of large inference time we tried other models for segmentation such as self-correction human parsing [33], and Deep-Lab V3 [34]. After utilizing and evaluating the three models Deep-Lab V3 model were selected for this work (see Section V).

2) Agnostic images generation: Agnostic images are created to eliminate all the old clothes from the input image and the segmented image. First, a color scale conversion from RGB to gray is done for both input and segmentation images. Then, the background color is converted to black.

This can be done using the open pose key points and the segmentation colors map which help us to define where the upper parts are to eliminate them, and we used the key points to mask the hands only because the segmentation gives the information of where the left and right arms are. Optimization was done using the high-quality segmentation and open-pose key points. Fig. 3 represents the agnostic image generation steps.

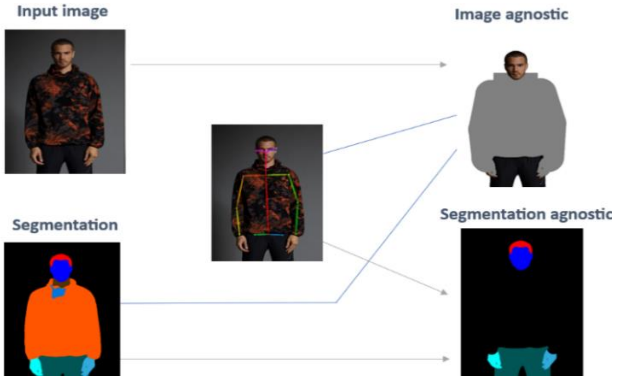

Fig. 3. Agnostic images generation.

After many experiments, we found that eliminating the background gives us more accurate results because the dataset distribution which the model trained on with a white background, The background class is one of the segmentation classes, so we exploit that to eliminate the background by looping on the image and change the color of it to white using open cv (see Fig. 4).

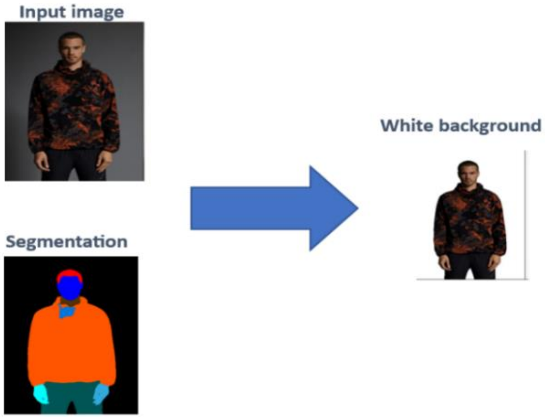

Fig. 4. Background removal example.

3) Cloth masking: Cloth masking is one of the main modules of the proposed system. To build a model that can generate the mask of the clothes; two approaches were suggested in this work, in the first approach, three models were evaluated; AIM, Timi-Net, and P3M model to detect the main object in the image and remove other objects, so, they can be used to generate the mask of the clothes if the clothes considered as the main object in the image. The second approach is cloth segmentation which is used to generate cloth mask in two steps instead of one step first by performing segmentation and then binarizing the result. After evaluation and analysis of the suggested models, the cloth-segmentation was found to be the champion model which is a robust model against the different colors, and backgrounds [35 - 37]. Fig. 5 shows a sample result for cloth masking.

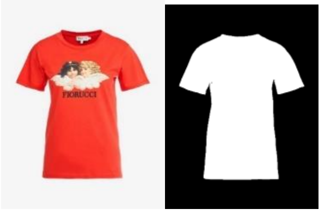

Fig. 5. Cloth masking sample result.

4) Using dense pose: The fourth and final sub-module in the preprocessing module is the DensePose, in which (R_101_FPN_DL_s1x) [38] was used and succeeded in achieving the best result compared to the baseline model used by Lyu et al [22] (see Section V). Fig. 6 shows the difference between the DensePose proposed by this work, and the DensePose of the work in literature.

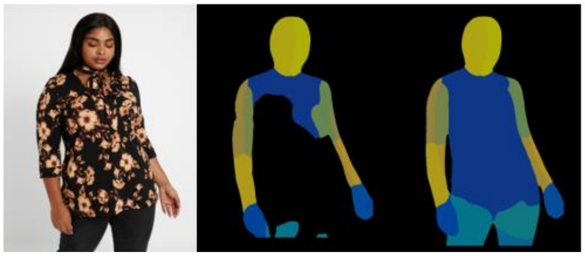

Fig. 6. Enhanced DensePose (right) vs. original or literature's DensePose (middle).

B. Output Image Generation using Conditional GANs

The second phase of the system is to generate a new image for the customer wearing the new cloth item, GANs was chosen and deployed because of its ability to generate new images with high accuracy. The GANs use a conditional generator where a wrapped cloth and a segmentation map of the person wearing the new cloth are the targets. There are two encoders with five residual blocks; cloth encoder and segmentation encoder, and one decoder that take these targets as conditions to get the most accurate cloth image appearance flow and segmentation map. Then the next fusion block in the encoder takes the previous output after passing to a 3x3 convolutional layer to predict the appearance flow-map from the flow pathway and segmentation features from the seg pathway. Information is exchanged through these two pathways to get the most accurate segmentation map and appearance flow. The last block of the decoder is the conditional aligning that removes the overlapping regions from the cloth mask (convert the straight mask to be fitted on the person image) and handle occlusions (remove hands or any parts from person image in front of the cloth). The following hyperparameters were used: pixel wise cross entropy loss function, Perceptual and L1 losses for best wrapping of the clothes, in addition to least-squared GAN loss. Also, multi-scale discriminators were applied for the conditional adversarial loss calculation.

C. Image Generator

This phase includes a series of residual blocks, up sampling layers, Spade normalization layers based on the segmentation map parameters. It takes the image agnostic, new segmentation map, dense pose and wrapped close resized and concatenated to the activation. To evaluate the generated image a discriminator rejection was deployed to filter segmentation maps with low quality. It is based on data distribution and implicit distribution from the generator. If the output image is of very low quality, it would be rejected.

IV. Experimental Work

We have tested some architectures in literature, and it is found to be working perfectly on females as the authors selected only the females' images from Zolando Dataset, however, accordingly, their approach didn't work with any image outside their dataset as shown in Fig. 7. This fact tells that there is an overfitting in the results found in literature. To avoid the overfitting problem in this work, new images from multiple websites were scrapped and trained beside the dataset found in literature. The following section describes both the dataset in literature and the dataset collected for this work.

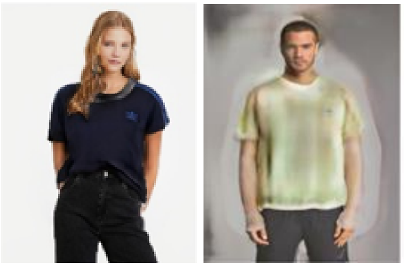

Fig. 7. Results obtained from their dataset (top) vs. results obtained using image outside the dataset (down).

A. Datasets

There are two different datasets used in this work for training and validation, one of them is open-source data used in literature and the other one is collected for this work. The following sub-sections describe the datasets used in this study.

1) Zolando dataset: Zolando is a high-resolution dataset that is used for virtual try-on tasks. It consists of the frontal view woman ad top clothing image pairs. It is split into about 11K training pairs and 2K testing pairs. This dataset was used by lye et al. [22], who obtained the best results in literature, and for that reason we used their approach as a baseline model to compare the proposed approach with.

2) New dataset collected in this work: About 5K images of males' images from Zara, Farfetch, and Zalando websites were scrapped to avoid the overfitting issue. The collected dataset is publicly available on Kaggle [39]. Some challenges in the collected dataset are tattoos, birth marks, caps, dark sunglasses, beard, head cuts, Black and Asian people, and complicated backgrounds (see Fig. 8). The dataset collected was meant to cover a diverse dataset distribution, and balance between males and females' images as follows: images from Zolando dataset (females), images from Zolando (males), images from Zara (males), images from Farech (males), and images from Farech (females).

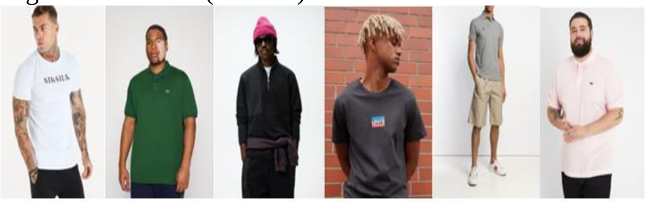

Fig. 8. Some challenges in the new scrapped dataset collected in this work.

B. Validation and Verification

The system was validated at the submodules level starting from the cloth masking, going through DensePose, OpenPose, segmentation, closing mask, the application itself, and reaching the deployment of the app on AWS server. The integrated submodules were also tested using many test cases and the proposed approach perfectly outperformed the state-of-the-art approaches. Based on the new implementation of the segmentation mask, the response time was reduced from 4 minutes to 78 seconds. The model was deployed on AWS successfully and the application received requests and responded concurrently. Fig. 9 shows the difference between our output (right) and the state-of-the-art result (middle) for the same image. Fig. 10 shows the effect of clothes masking and DensePose, in which it can be noticed that there is a great enhancement of the clothes' alignment.

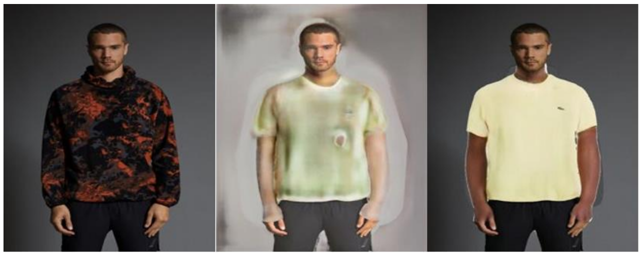

Fig. 9. The difference between the proposed work output (right) and the state-of-the-art result (middle) for the same images.

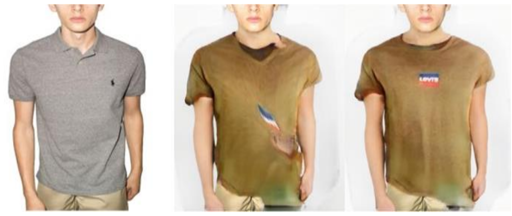

Fig. 10. The state-of-the-art results (middle) vs. the proposed approach results (right).

V. Results and Discussion

This section demonstrates the results achieved by this proposed work and discusses them. The following subsections show every submodule, the results, and the analysis of these results.

A. Segmentation

CHIP, Self-correction human parsing, and Deep-Lab V3 segmentation models were used and compared in this work to select the best as mentioned before. The comparison was done in terms of segmentation results and execution time. The following sub-section describes every model and the findings of using it.

1) Self-correction human parsing segmentation: To increase the dependability of both the learned models and true labels, the self-correction model uses a learning scheduler to infer more trustworthy pseudo-masks by repeatedly aggregating the learned model with the former ideal one in an online learning. Using an annotation initialization model as the first step in the learning process, and then adjusting the labels according to the data can improve the model's performance. Through cycles of self-correction learning, both the models and labels improve in accuracy and strength. This model has a good inference time (2 sec), but its pre-trained weights were on a different dataset which missing the torso skin class (the neck class). The pre-trained weights were on the Look into person (LIP) dataset [40] which contains the same classes, but the only difference is the torso-skin class is replaced with a jumpsuit, so the results were without the torso-skin class. To address the problem of the missing torso class, the model was trained on another dataset including all classes, but the results were worse than the CHIP model, and it required more computational resources for training and testing (see Fig. 11).

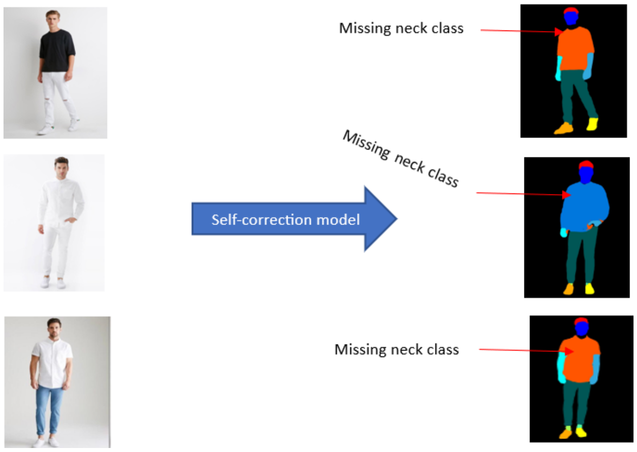

Fig. 11. Sample of self-correction segmentation results.

2) Deep-Lab V3 model segmentation: DeepLab V3 utilizes a novel architecture that combines multi-scale features, dilated convolutions, and conditional random fields to produce high-quality segmentation masks. It is highly effective at handling complex scenes, such as those found in urban environments, and achieves superior performance compared to other state-of-the-art segmentation models. The model was trained to segment all parts within much less time. DeepLab V3 model worked in 0.23 seconds only to produce segmented image. Although the mean Intersection Over Union (IOU) is less than mean IOU of CHIP model, we have chosen DeepLab V3 over CHIP model due to the great difference in execution time, meanwhile, the mean IOU difference between both models is not so large to consider over the time. Table I demonstrates the results and execution time of the three models. Fig. 12 shows the segmentation results of CHIP and DeepLab V3 models.

TABLE I. SEGMENTATION RESULTS AND EXECUTION TIMES OF THE USED SEGMENTATION MODELS

Model	Time (seconds)	IOU
CHIP	38.41	78.21
DeepLab V3	0.23	64.53

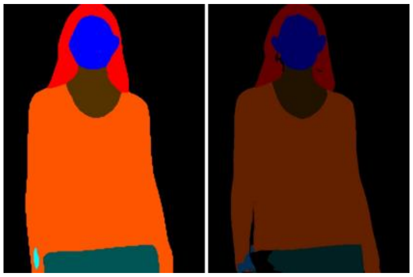

Fig. 12. Segmentation results of DeepLab V3 (right) and CHIP (left) models.

B. Open Pose

Three different approaches were tested to find the optimal open pose model. Those three models are the Media-pipe model [41], the Detectron model [42], and the CMU-Perceptual-Computing-Lab [43 & 44]. The first model failed to address the occlusion challenge (see Fig. 13), the second model outperformed the results of the first model, but still missing some important points. The third model solved the problems of the previous two models successfully. The following figures show the differences between the results obtained by the three models. Here Fig. 14 shows Detectron open pose results and Fig. 15 shows the CMU-Perceptual open pose detection results.

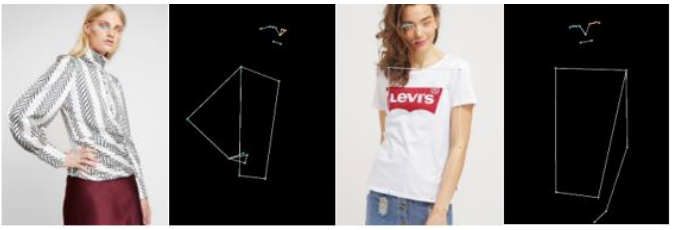

Fig. 13. Media-pipe pose detection results (occluded arms are missing).

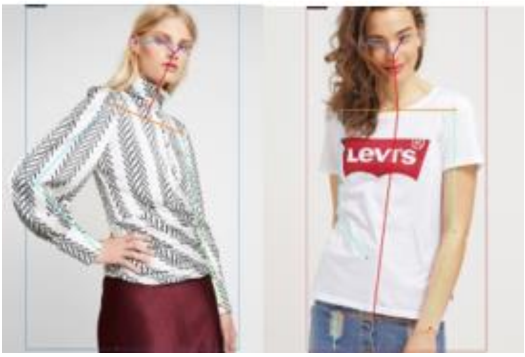

Fig. 14. Detectron open pose detection results (better but some important points are still missing).

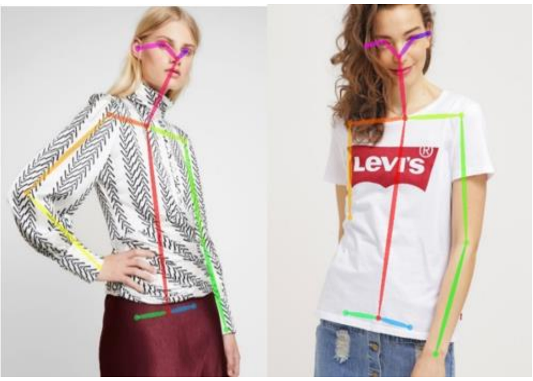

Fig. 15. CMU-Perceptual open pose detection results (the best results out of the three models).

C. Cloth Masking

To verify the quality of the cloth masking model, three experiments have been held to check the performance of the proposed approaches to get the best cloth masking model. The first experiment was to find the best model of the three models that perform image matting, namely: AIM, Timi-Net, and P3m [45 - 48]. A dataset of 5K images dataset has been scrapped from different fashion websites, then it has been used to compare the results of each one of the three models. The AIM model obtained the worst in terms of average inference time per image, and ability to generate the mask. The abilities of P3M and Timi-Net models to generate the mask were almost the same, but P3M proved to be 1.5 faster than Timi-Net, so, the P3M model was chosen for cloth masking submodule. A manual analysis for all images was then conducted to define the strength and the failure points of the P3M model. As a result of the analysis, P3M showed great results for all cases except in the case of white clothes on white backgrounds, and to solve this problem, image binarization step was added to the segmentation module. The second experiment has been conducted to check the applicability of the second approach to generate the mask using YOLO5 and YOLO7 [49 - 53] for image segmentation, then binarizing the results. The proposed method showed high capability of detecting the existence of the clothes in the images, but at the same time YOlO5 and YOLO7 were not the best choices to perform the cloth segmentation task since they miss some of the images without detecting the existence of the clothes in the image. The third experiment has been held to check the performance of two models which are the U2Net and the cloth-segmentation model. The top 20 images that P3M models failed generating their masks were used in this experiment. U2Net failed with some white clothes with white background, on the other hand, cloth-segmentation model performs well since the model is robust against different colors and backgrounds. As a result, the cloth-segmentation model has been chosen to be integrated with the other models to complete the proposed solution.

D. Dense Pose

Different state-of-the-art models in this area were applied, and "Detectron 2" proved to be the best amongst them. Detectron 2 was originally developed by Facebook, where 27 models were trained. All the 27 models were used and evaluated in this work to measure how suitable they are to this problem and select the best accordingly.

E. Image Generator

This step is the final step which takes the outputs of all the steps preceding it as an input to generate the final output of the system which should be the image of the user wearing the new cloth item. Freshet Inception Distance (FID) score was used to evaluate the results obtained by this work and as a comparison metric with the work in literature, where FID score is the most modern metric used to measure the distance between real image and equivalent generated one [54 - 57]. Following are the summary of experiments designed for this step:

- The first experiment validates the work of Lye et al [22] as the model addressing the same problem in literature with the best results.
- In the second experiment, we only replaced the DensePose step in literature by the DensePose proposed in this work.
- The third experiment involves changing only the cloth mask step with the proposed new cloth mask method.
- In the fourth experiment we replaced both the DensePose and cloth mask steps with the new proposed methods.
- In the fifth experiment, we only changed the segmentation model, keeping all the literature model as is.
- The sixth experiment includes deploying the proposed model and evaluating it with all its modules integrated together.

Table II demonstrates results of the six experiments, with “new” referring to the proposed models, and “original” referring to the models in literature [22].

TABLE II. COMPARISON BETWEEN THE STATE-OF-THE-ART APPROACHES AND THE PROPOSED APPROACH

E#	Segmentation	Cloth Mask	Dense Pose	FID
1	Original	Original	Original	11.796
2	Original	Original	New	12.243
3	Original	New	Original	11.847
4	Original	New	New	**11.743**
5	New	Original	Original	13.140
6	**New**	**New**	**New**	**11.753**

As we can see from the above table the proposed approach outperforms the best model in literature, but it can also be noticed that keeping the segmentation of the literature combined with the proposed Cloth mask and DensePose models would produce even better results, i.e., smaller FID.

F. User Interface

Finally, to build a complete solution, a user interface has been developed using flutter technology, and the implementation of the application has been divided into two phases. Firstly, creating an initial design by building the main activities, then new features were added using UI/UX. Fig. 16 introduces some of the user interface screens.

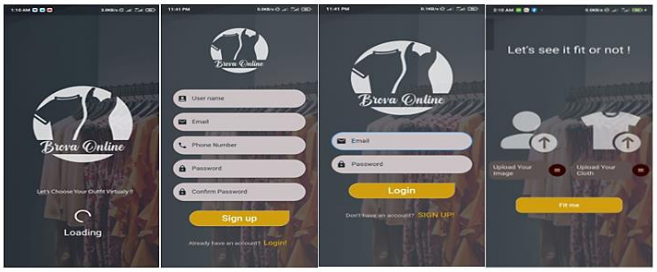

Fig. 16. Some of the final user interface screens.

VI. Conclusion and Future Work

In conclusion, this work aims at creating a virtual fitting room via a mobile application to make it easier for customers to try on many cloth items without physically dressing them. The best state-of-the-art approach in literature (Lue et al. [22]) has been used in this paper as the baseline architecture to compare the results obtained in this work with. Another reason for choosing them is that they used the Zolando dataset which is publicly available for validation and comparison. But it was found that there is an obvious overfitting because of the unified nature of the dataset. The solution for this included scrapping new data and retraining preprocessing models. A new dataset from different fashion sources was scrapped to collect 5K images to evaluate the proposed approach and compare it to the state-of-the-art approach. All preprocessing subsystems were analyzed and experimented to get the best model. These subsystems included OpenPose (CMU), DensePose (Detectron- R_101_FPN_DL_s1x), cloth mask (cloth segmentation), and segmentation (DeepLab V3). At the end, the proposed approach outperformed the state-of-the-art and succeeded to reduce the FID. The mobile app developed in this work was deployed on AWS service with dockerization technique.

As future work, we suggest adding a new dataset for bottom part and other types of fashion items, in addition to a recommendation system. Other research suggestions may include utilizing newly collected data to retrain the model for improved performance. To reduce inference time semantic segmentation should be considered while training the model, optimizing it for cases with only one instance. Additionally, the use of a teacher-student model (Knowledge Distillation) can be suggested to enhance the performance of all framework models, aiming for better inference times overall. Future work would also include considering children of different ages in testing the proposed architecture.

Acknowledgment

The authors would like to thank Digital Egypt Builders Initiative (DEBI), at the Egyptian Ministry of Communication and Information Technology (MCIT) for giving us the chance to design and implement this solution, and Amazone Web Services (AWS) whom without their support this work would be never completed.

Image Processing Research Laboratory (INTI-Lab), Universidad de Ciencias y Humanidades, Peru[5, 6]

***Abstract*—Given the high concern for human health, the aim is to determine the relationship between healthy lifestyles and nutritional status among firefighters of the VCD Callao Ventanilla 2023. This study was conducted in four volunteer fire companies, namely B-75, B-184, B-207, B-232, located in the districts of Ventanilla and Mi Perú. The population consists of 291 personnel, with a sample of 168 participants. It was observed that 58.9% (99) of the participants are under 36 years old, 29.8% (50) are between 36 and 45 years old, and 11.3% (19) are 46 years or older. In terms of gender, 62.5% (105) are males. Regarding the duration of their firefighting service, 70.2% (118) have a maximum of 10 years of seniority. On the other hand, 57.7% (97) of the participants have an unhealthy lifestyle, 40.5% (68) have a healthy lifestyle, and 1.8% (3) have a very healthy lifestyle. Regarding the nutritional status of the firefighters in this study, it was found that 53.3% (89) are overweight, 26.8% are considered normal weight, 19.6% (33) are obese, and 0.6% (1) are underweight. Concerning lifestyles, the study revealed that 57.7% of the participants have an unhealthy lifestyle, 40.5% have a healthy lifestyle, and 1.8% (3) have a very healthy lifestyle. It is worth mentioning that according to Rodríguez C's study, 95.2% of volunteers belonging to the B107 Fire Company lead a healthy lifestyle, while 4.8% do not. Statistically, we can assert that there is no significant relationship between the variable of healthy lifestyles and nutritional status. However, it is observed that there is a direct relationship between nutritional status and age. Likewise, it can be affirmed that more than at least 72.9% of the studied population is overweight, either with overweight or obesity.**

Keywords*—*BMI; firemen; lifestyles; excess weight

I. Introduction

A volunteer firefighter, affiliated with an organization focused on fire prevention and control, responds to fires, vehicular accidents, and medical emergencies without charge. Their work involves demanding physical tasks in hostile emergency scenarios [1].

These emergency situations trigger immediate physiological responses in firefighters, including increased heart rate, hyperventilation, heightened oxygen consumption, and sweating. According to a 2019 report from the National Institute for Occupational Safety and Health (NIOSH), cardiac arrest is the leading cause of firefighter fatalities, accounting for 40% of 308 deaths over a decade. Many of these individuals also had coronary artery disease, as per death certificates. These findings highlight a significant percentage of firefighter deaths attributable to cardiovascular diseases [2].

Analyzing past studies on the nutritional and physical activity status of students in various professions reveals a considerable number who do not maintain a lifestyle conducive to their well-being. Predisposing factors to health problems include rapid adaptation to constant changes, lack of physical activity, dietary issues, and overall unhealthy habits [3].

Health is a crucial facet of human life, profoundly impacting one's quality of life, with various factors such as physical activity, diet, and mental well-being playing pivotal roles. The World Health Organization (WHO) noted that over 28% of adults worldwide failed to meet their recommended weekly physical activity levels, equating to at least 150 minutes or 75 minutes of intense activity. Disparities in physical inactivity exist between high- and low-income countries. High-income countries report 26% of men and 35% of women as insufficiently active, compared to 12% of men and 24% of women in low-income countries [4].

The global prevalence of physical inactivity raises significant concerns due to its strong correlation with non-communicable diseases (NCDs), contributing to up to 9% of premature deaths worldwide. Additionally, 6% to 10% of NCDs, such as diabetes, coronary heart disease, colon, and breast cancer, can be attributed to physical inactivity [5].

Obesity and overweight are a growing concern, classified as the 21st century's pandemic by the WHO. Approximately 52% of adults worldwide grapple with these issues [6]. In recent years, global cases of overweight and obesity have tripled, signaling a worrying trend linked to chronic diseases, including Diabetes Mellitus II, cardiovascular disorders, and musculoskeletal problems [6-12].

In 2021, WHO defined overweight and obesity as an excess accumulation of fat detrimental to health due to an energy imbalance between calorie intake and expenditure. In Latin America and the Caribbean, 62.5% of adults, 64.1% of men, and 60.9% of women are overweight or obese. When examining only obesity, it affects 28% of adults, with 26% being men and 31% women, making it the region with the highest prevalence according to the WHO [13].

Peru faces a similar challenge, with 69.9% of adults and 42.4% of young people experiencing overweight or obesity. Poor dietary habits contribute to these figures, with 29% of the population consuming junk food weekly. Fried foods account for 87.1% of weekly consumption [14].

A study by Ramírez J, et al. [15], revealed that 33.6% of Peruvians had abdominal obesity, notably higher in women at 51.2%. Geographic location also influences obesity rates, particularly in cities below 1000 meters above sea level.

Malnutrition is another concern, impacting weight gain and associated with various factors, including age and energy imbalances. A study found 15.3% prevalence of diabetes mellitus II, 43.4% for hypertension, and 17.4% for osteoarthritis [16].

Sleep deprivation, prevalent among firefighters due to demanding schedules, poses health risks. Short sleep patterns, less than six hours, increase the risk of stroke, cancer, coronary heart disease, diabetes, anxiety, depression, and workplace accidents [17-18].

Unhealthy eating habits and sedentary lifestyles are common among firefighters, contributing to obesity. Mandatory physical activity training does not always suffice, further promoting sedentary behavior and weight issues [19-21].

Lifestyle encompasses a person's daily activities, customs, housing, habits, culture, environmental interactions, and interpersonal relationships, all of which are entirely modifiable [22].

Lifestyles can either promote health or pose risks. Healthy lifestyles involve behaviors that enhance well-being, including maintaining a balanced diet, regular physical activity, and abstaining from harmful substances like tobacco and alcohol [23].

Furthermore, lifestyle influences one's physical condition, recreation, and leisure management, which directly impact mental health. Additionally, the consumption of toxic substances can significantly affect overall well-being [24].

Nutritional status refers to the equilibrium between nutrient intake and the body's requirements, determined by the availability of diverse foods and nutritional knowledge [25].

Malnutrition, as defined by WHO, encompasses deficiencies, excesses, and energy imbalances in nutrient intake. It is categorized into three groups: wasting, stunted growth, vitamin and mineral deficiencies, and underweight, with a higher incidence among children [26].

Overweight and obesity, identified as excess fat accumulation detrimental to health, result from an energy imbalance related to calorie intake and expenditure. Nutritional status in adults is typically assessed using the body mass index (BMI), calculated as weight in kilograms divided by height in meters squared (Kg/m²). Classification based on BMI is as follows: underweight (BMI < 18.5), normal weight (BMI 18.5-24.99), overweight (BMI 25.00 – 29.99), and obesity, further classified as class I (BMI: 30.00-34.99), class II (BMI: 35.00-39.99), and class III (BMI ≥ 40.00) [27-29].

In the 21st century, global obesity rates have tripled, labeled as a pandemic by the WHO, a concern not exclusive to Peru. This issue correlates with non-communicable diseases like Diabetes Mellitus II, cardiovascular ailments, and musculoskeletal disorders, affecting a significant portion of the Peruvian population, including firefighters. Regrettably, there's a dearth of studies on Peruvian firefighters' nutritional status, often hampered by small sample sizes that fail to depict the true extent of the issue.

Examining the lifestyles and nutritional well-being of Callao firefighters assumes paramount significance due to evident excess weight and associated unhealthy habits. Understanding the interplay of these variables is essential for implementing effective preventive measures. Firefighters must maintain optimal health for enhanced efficiency and to mitigate health risks. Dietary behavior emerges as a pivotal, modifiable risk factor for occupational diseases. Numerous studies have investigated dietary interventions among firefighters, seeking effective methods to improve their dietary habits.

Addressing this behavioral issue holds great societal potential for reducing associated problems. Consequently, this study aims to establish the relationship between healthy lifestyles and nutritional status among firefighters at VCD Callao Ventanilla in 2023.

II. Related Jobs

Arrieta J, Solís I. [26], Costa Rica in 2020 carried out a study entitled "Eating habits, nutritional status and cardiovascular risk in firefighters from 20 to 59 years of age of the XII battalion, Costa Rica, 2020." The objective of this study was to relate eating habits and nutritional status according to body mass index with cardiovascular risk using the Framingham Heart Study formula in firefighters aged 20 to 59 years from Battalion XII, Costa Rica, in 2020. Where a structured interview was conducted with the firefighters participating in the research, with the data obtained, a statistical analysis was carried out with the models that best predict cardiovascular risk among the established variables. In the results obtained, it was evident that only 31% of the firefighters have a normal body mass index, the remaining percentage is overweight or obese type 1. Most of the sample had a low cardiovascular risk according to abdominal circumference and according to the Framingham Heart Study calculator. They conclude that: There is an association between the consumption of alcohol, semi-skimmed dairy products, saturated fats and refined cereals, and cardiovascular risk, at different frequencies of consumption; In addition, type I obesity and the use of the frying cooking method are also associated with this risk.

Echeverria M., [30]. In Ecuador in 2021 a study entitled "Nutritional status and eating habits of the fire department personnel of the Otavalo Canton 2021" was carried out with the objective of evaluating the nutritional status and eating habits of the personnel of the Otavalo Canton Fire Department 2021, a descriptive cross-sectional research was carried out and 31 people were worked with, An online survey was applied to those who were given two sociodemographic variables and eating habits, and anthropometric measurements such as height and weight were taken to obtain BMI. The main results highlight that the majority of the staff are male, between the ages of 20 and 49 years. 55% of the staff is overweight and 16% obese, 29% are in normal nutritional status, eating habits are inadequate.

Camargo F, Jardim T, Rocha L, Zandonade E, Nívea K. [31]. In Brazil 2020 they carried out an article on "Prevalence of obesity in Brazilian firefighters and the association of central obesity with personal, occupational and cardiovascular risk factors: a cross-sectional study" where the studied population was 1018 firefighters, leaving 892 firefighters who met the inclusion criteria. The main results were that 48.65% of the firefighters were overweight and 10.99% were obese. In terms of body fat percentage, 26.23% of participants were considered obese, while 18.61% of firefighters were considered centrally obese or at risk in the waist circumference measurement.

Chuquipoma J. [32] Lima – Peru in 2019 presented a study on "relationship between previous knowledge in nutrition and nutritional status in firefighters of the company "Salvadora Lima n° 10", 2018" with the aim of determining the relationship between the level of previous knowledge in nutrition and the nutritional status in firefighters of said company. In a descriptive, correlational, cross-sectional study, the results correspond to a total of 50 firefighters evaluated, of both sexes whose ages ranged from 20 to 59 years. This obtained the following results: 72% of the firefighters have a low level of knowledge and 28% have a fair level of knowledge. Regarding the nutritional status of the firefighters, it was observed that 34% had a nutritional status within normal parameters, 44% were overweight and 22% were obese.

Rodríguez C. [33] Chimbote – Peru in 2018 published a paper entitled "Lifestyles and Biosociocultural Factors of the Volunteer Workers of the B-107 Nuevo Chimbote Fire Company, 2017" with the aim of determining the relationship between the lifestyle and biosociocultural factors of the volunteer workers of the fire company of said company, The sample consisted of 42 members whose results were: There is no statistically significant relationship between lifestyle and biosociocultural factors: age, sex. Whether there is a statistically significant relationship between lifestyle: level of education and income. Religion, marital status and occupation could not be linked.

This information alerts us to the problem and the risk that firefighters have to suffer from non-communicable diseases such as cardiovascular diseases, diabetes mellitus II, among others related to poor nutrition and poor lifestyle. That is why control measures must be taken to prevent these diseases through health promotion.

III. Materials and Methods

A. Research Approach and Design

The present study is quantitative, correlational and cross-sectional in terms of methodological design. Descriptive because it measures, evaluates and collects data on variables, both lifestyle and nutritional status; it is also correlational because it investigates the relationship and appendages between lifestyles and nutritional status; analytical because it allows the establishment of an association relationship between variables. And finally, it is a cross-sectional research because the data obtained were collected in a specific space and time [22].

B. Population, Sample and Sampling

In the present study, we worked with a finite population, which was made up of the active firefighters of the Callao VCD, belonging to the third that is made up of four fire companies B-75, B-184, B-207 and B-232. The sum of its personnel makes a population of 291 firefighters. They were selected according to the following criteria.

1) Inclusion criteria

- The participant belongs to any of the four companies of the third Brigade of the VCDC.
- The participating personnel are active personnel according to the RIF between 18 and 65 years of age.
- The participant must accept his/her participation in this study voluntarily, and must sign the informed consent form.

2) Exclusion criteria

- All candidates who do not meet 100% of the inclusion requirements were excluded.

3) Sample size: To determine this sample, the statistical program "EPIDAT" was calculated, whose data to calculate will be a population of 295 effective, with a confidence level of 95.0%, the sample size of 168 participants of this study was obtained.

4) Sample selection: The sampling was non-probabilistic due to convenience, ease of access and time availability.

C. Study Variable(s)

In the following research, lifestyle is the main variable, it is a qualitative variable and its measurement scale is ordinal. On the other hand, the nature of the nutritional status variable will be obtained through weight and height, both of which are quantitative variables.

1) Conceptual definition of lifestyles: Lifestyle is the general way of life of each person, the way in which they conduct their day-to-day activities, this can be expressed in behaviors, basically in customs, and it is also configured by housing, habits, culture, relationships with the environment and relationships between individuals.

2) Operational definition: Lifestyles is the generic form that is equivalent to the form, mode and manner of living, epidemiologically speaking, lifestyle is the habit of life or the way of life, which would be a set of behaviors that people choose, which can be healthy or harmful to health. In this sense, lifestyles are behaviors that improve or increase health risk [19].

3) Conceptual definition of nutritional status: Nutritional status is the balance that exists between the nutritional contribution of what we ingest and the nutritional demands that our body desires, which determines the quality of nutrients and their use. Among the factors that determine nutrition, it depends on the variety of foods available and access to them. On the other hand, people's level of knowledge in nutrition also influences nutritional status [20].

4) Operational definition: Nutritional status was determined using the Body Mass Index (BMI), which was calculated by dividing weight in kilograms by height in meters squared. The following results will be considered: Underweight if the BMI <18.5, normal weight BMI 18.5-24.99, Overweight if the BMI is 25.00 – 29.99 and obese if the BMI is ≥ 30. Obesity will be classified as: class I obesity (BMI: 30.00-34.99), class II obesity (BMI: 35.00-39.99) and class III obesity (BMI ≥ 40.00). For this study, excess weight has been considered overweight and obese [28].

D. Measuring Technology and Instrument

1) Data collection technique: The technique used during data collection for the lifestyle variable was the survey, which is widely used in quantitative and descriptive studies. Regarding the variable of nutritional status, we used the measurement of anthropometric measurements in the field.

a) For the Lifestyles variable: The modified and validated questionnaire of Palomares L [25] was used. This lifestyle questionnaire consists of a total of 48 questions, which is divided into 6 dimensions:

- Fitness, Physical Activity & Sport
- (4 questions).
- Recreation and Leisure Time Management
- (6 questions).
- Use of Alcohol, Tobacco, and Other Drugs
- (6 questions).
- Dream (6 questions).
- Eating Habits (18 questions).
- Self-Care and Medical Care (8 questions).

All dimensions correspond to a Likert scale (Never:0, Sometimes:1, Frequently:2, and Always:3).

The rating that was considered to assess healthy lifestyles is:

- Unhealthy: 0 - 36 points
- Unhealthy: 37 - 72 points
- Healthy: 73 - 108 points
- Very healthy: 109 - 144 points

b) For the Nutritional Status variable:

c) To obtain the body weight, the measurement was carried out with a rechargeable electronic scale of the SEC brand with a capacity of 180kg, model SEC-180 platform, whose results will give us in kilograms (kg).

d) To obtain the carving we used a wooden height meter with a measuring range of up to 3.5 to 230 centimeters. It was placed on a smooth and flat surface, without any unevenness or any foreign object under it, and with the board resting on a flat surface forming a right angle with the floor and wall.

Once weight and height were obtained, BMI was calculated using the following expression. BMI = Weight/Height2. Depending on the result obtained, nutritional status was determined by BMI according to WHO criteria. thinness (BMI < 18.5), weight (BMI: 18.5-24.99), overweight (BMI: 25.00-29.99), obesity class I (BMI: 30.00-34.99), obesity class II (BMI: 35.00-39.99) and obesity class III (BMI ≥ 40.00).

E. Procedure for Data Collection

1) Authorization and prior coordination for data collection: For the development of field work, permission will be requested from the chiefs of the four companies of the third Brigade of the VCDC to allow us to enter their units to carry out data collection.

2) Application of data collection instrument(s)

a) For the Lifestyles variable: A modified and validated questionnaire from Palomares L [25] will be used to measure lifestyles. The questions will be put on several printed sheets so that the participant can easily fill in according to his/her criteria (ANNEX B).

- Explain to participants about the work to be done and ask them to fill out the informed consent document.
- Briefly explain the six dimensions or parts of the questionnaire.
- Guide participants from the beginning to the end of filling out the form.
- Verify the correct completion of the questions and store it for later analysis.

b) For the variable Nutritional Status: For the measurement of weight and height, the Ministry of Health's technical guide for the anthropometric nutritional assessment of adults was used as a study in [28]. The data obtained were recorded in the anthropometric data collection form (ANNEX C).

3) Weight taking

- The location and condition of the balance was verified. This should be on a smooth, flat, horizontal surface. No unevenness and no presence of any foreign object under the scale.
- Ask the adult to take off his or her shoes.
- Verify that the scale reads 00 (zero) andes of the weight intake.
- Ask the elderly person to stand in the center of the scale platform, in an upright and relaxed position, facing the front of the scale, with the arms at the sides of the body, with the palms resting on the thighs, the heels slightly apart and the tips of the feet apart forming a "V".

- Read the weight in kilograms and decimals expressed in grams, and then deduct the weight of people's garments.
- Record the weight obtained in kilograms (kg), with a decimal place corresponding to 100 g, in the corresponding format, in clear and legible handwriting, (example: 65.1 kg).

4) Size taking: Check the wooden height gauge, the sliding of the moving stop must be smooth and without swaying, the tape measure must be well adhered to the board and its numbering must be clearly observed. Likewise, the stability conditions of the tachymeter must be checked.

- Check the location and condition of the tachymeter. Check that the moving stop slides smoothly, and check the condition of the tape measure for a correct reading.
- Explain to the elderly the procedure for measuring the height, slowly and patiently, and ask for their collaboration.
- Ask you to remove shoes (flip flops, sandals, etc.), excess clothing, and accessories or other objects on your head that interfere with the measurement.
- Indicate and help you to position yourself in the center of the base of the tachymeter, with your back to the board, in an upright position, facing forward, with your arms at your sides, with your palms resting on your thighs, heels together and the balls of your feet slightly apart.
- Make sure your heels, calves, buttocks, shoulders, and back of your head are in contact with the dashboard of the height meter
- Check the "map of Frankfurt". In some cases, it will not be possible due to problems with curvature in the spine, injuries or other problems.
- Place the open palm of your left hand on the chin of the elderly person to be carved, then close it gently and gradually without covering the mouth, in order to ensure the correct position of the head on the height meter.
- Slide the movable stop with your right hand until it makes contact with the top surface of the head, slightly compressing the hair; then slide the movable stop upwards. This procedure (measurement) must be performed three times consecutively, moving the moving stop closer and farther away. Each procedure has a value in meters, centimeters, and millimeters.
- Read the three measurements obtained, obtain the average and record it in centimeters with an approximation of 0.1 cm.

F. Methods of Statistical Analysis

Once the data of the nutritional status BMI and the result of the filling of the instrument have been obtained, the results of the questionnaire have been obtained. This information was entered into a Microsoft Excel XP software database version 2016. Frequency tables and statistical software such as IBM SPSS Statistics 27 were used to perform the data analysis.

G. Ethical Aspects

To carry out this work, the basic concepts of bioethics were taken into account, such as autonomy, non-maleficence, beneficence and justice, for the protection of the participants' data, as well as informed consent will be applied to give clear and precise information to the participants [33].

1) Principle of autonomy: This principle refers to the freedom of decision of the participants, so it must be respected by this research. This principle will be applied in this research, for all participants in which they will be asked to sign the informed consent form and it will be through documents that the participation of the participants will be reflected [34].

2) Principle of beneficence: In this principle we refer to not causing harm to others, in which we are subject to avoiding harm and doing good to others. In this study, they will be informed of the importance of the study and the results obtained to improve their health and quality of life [35].

3) Principle of non-maleficence: This principle deals with not harming the person and having the obligation to decrease the risk of causing harm. In this paper it will be explained that participation in this research will not cause any harm to your health [36].

4) Principle of Justice: The principle of Justice refers to the operational part of research ethics, including non-discrimination of study participants. The participants of this research will be treated equally without any discrimination or favoritism [31], [37].

IV. Results

Table I shows that 58.9% (99) of the participants were under 36 years of age, 29.8% (50) were between 36 and 45 years of age, and 11.3% (19) were 46 years or older. In terms of sex, 62.5% (105) are male. Regarding marital status, 69.0% (116) were single, 27.4% (46) were married, 2.4 (4) were divorced and 1.2% (2) were widowed. In terms of job category, 40.5% (68) are university professionals, 26.2% (44) are technical professionals, 19.0% (32) are university students, 10.7% (18) are self-employed, 1.8% (3) are housewives and 1.8% (3) are military personnel. In terms of how long they have been firefighters, 70.2% (118) have a maximum of 10 years of service, 22.6% (38) from 11 to 20 years and 7.1% (12) more than 20 years of service. Regarding the hierarchical grade of the participants, 47.0% (79) are sectional, 18.5% (31) have the rank of second lieutenant, 15.5% (26) of lieutenant, 8.9% (15) of captain, 7.1% (12) of lieutenant brigadier and 3.0% (5) of the rank of brigadier. On the other hand, 49.4% (83) have donated blood at some point and 58.3% (49) of this group have last donated blood one year ago.

From Table II we can see that the p-value (Sig.) associated with Spearman's Rho correlation coefficient level is 0.767, which is greater than 0.05 (significance level or alpha value); Therefore, there is no statistically significant reason to say that the variables lifestyle and nutritional status are related.

TABLE I. SOCIO-DEMOGRAPHIC DATA OF THE FIREFIGHTERS OF THE FIFTH COMMAND OF CALLAO

Socio-demographic data	n=168	
	fi	%
Age		
17 - 25	43	25,6
26 - 35	56	33,3
36 - 45	50	29,8

Overweight	89	53,0
Obesity	33	19,6
Total	168	100,0

Table IV shows the nutritional status of the firefighters who participated in this research, from which we found that 53.3% (89) are overweight, 26.8% are considered normal weight, 19.6% (33) are obese and 0.6% (1) are underweight.

TABLE V. ASSOCIATION BETWEEN LIFESTYLES AND SOCIO-DEMOGRAPHIC DATA

Socio-demographic data	**Lifestyles**	
	Value*	**p_valor (Sig.)**
Age	9,493	0,302
Sex	0,662	0,718
Marital status	4,493	0,610
Job Category	5,123	0,883
Service Time	6,360	0,607
Hierarchical Grade	7,383	0,689
Have you ever donated blood	4,423	0,110

Value = of the Chi-square statistic; p_valor=probability value used to contrast with the significance level (α=0.05).

Table V presents the association between lifestyles and different socio-demographic data such as age, sex, marital status, and job category, length of service, hierarchical grade and whether you have ever donated blood. We observed that the p-value is higher than the significance level (0.05) for all pairs of variables tested, therefore, we conclude that there is no relationship between the socio-demographic variables and the lifestyle of the participants.

TABLE VI. ASSOCIATION BETWEEN NUTRITIONAL STATUS AND SOCIO-DEMOGRAPHIC DATA

Socio-demographic data	Nutritional status	
	Value*	p_valor (Sig.)
Age	24,079	0,020*
Sex	6,075	0,108
Marital status	12,969	0,164
Job Category	6,724	0,965
Service Time	18,679	0,097
Hierarchical Grade	12,465	0,644
Have you ever donated blood	6,013	0,111

Value = of the Chi-square statistic; p_valor=probability value used to contrast with the significance level (α=0.05).

Table VI presents the association between the nutritional status and the socio-demographic data of the respondents. We found that the p-value (Sig.) is less than 0.05 (level of significance) only in the case of age and nutritional status; this indicates that there is statistically significant evidence to conclude that there is an association between age and nutritional status.

V. DISCUSSION

It is observed that the collaborators are found a higher percentage: 58.9% are under 36 years of age and 29.8% range between 36 and 45 years of age, and as for sex, it has a higher prevalence in men that is equivalent to 62.5%, according to marital status it is found that singles stand out with 69.0% and married with 27.4%. With regard to the level of education, 40.5% are university professionals and 26.2% are technical professionals. However, [24] found between ages ranging from 20 to 29 years of age, counting 61.3% and 38.7% including those aged 40 to 64 years. On the other hand, 77.4% of males belong to them and 22.6% of females. Meanwhile, the marital status related to married people is 71% and single people found 16.1% are single people.

In terms of how long they have been firefighters, 70.2% (118) have a maximum of 10 years of service, 22.6% (38) from 11 to 20 years and 7.1% (12) more than 20 years of service. Regarding the hierarchical grade of the participants, 47.0% (79) are sectional, 18.5% (31) have the rank of second lieutenant, 15. Lieutenant br5% (26) of lieutenant, 8.9% (15) of captain, 7.1% (12) of l brigadier and 3.0% (5) of the rank of brigadier. On the other hand, 49.4% (83) have donated blood at some point and 58.3% (49) of this group have last donated blood one year ago.

Table III presents the levels of quality of lifestyles, that is, the way we have been consuming our food is there is an orderly or disordered way to acquire it [26] where we visualize that 57.7% of the participants have an unhealthy lifestyle, 40.5% a healthy lifestyle and 1.8% (3) a very healthy lifestyle. It is worth mentioning that [27], in his study it is evident that of the 100% of the volunteers who belong to the B107 Fire Company, lead a healthy lifestyle is 95.2%, those who do not have a non-soluble lifestyle is the result of 4.8%. It is evident that there is no similarity in our study, because the results are very different. Table IV shows the nutritional status of the firefighters who participated in this research.

In our study on the nutritional status of firefighters, it is evident that overweight is in first place with 53.3%, followed by normal with 26.8% and obesity is 19.6% (5). There are several studies that are almost similar to our study (see Table IV) as evidenced by the result of [26], that overweight results in 44%, on the other hand, normal weight is evidenced in 34% and firefighters are only observed to have obesity in 22%).

VI. CONCLUSION

The present study examined the lifestyles and nutritional status of the firefighters from VCD Callao Ventanilla in 2023, highlighting key demographic aspects such as age, gender, marital status, education, and years of service. These data provide valuable context for understanding health behaviors in this population.

A high prevalence of unhealthy lifestyles among firefighters is evident, with 57.7% exhibiting concerning dietary habits. Given that dietary patterns influence occupational health and overall well-being, it is crucial to address these habits through specific interventions to improve their health and performance.

Regarding nutritional status, it is observed that a substantial portion of firefighters is overweight (53.3%), followed by 26.8% with a normal BMI and 19.6% classified as obese. While there is some agreement with previous research, significant variations are identified, emphasizing the need for further investigations to understand the factors contributing to these differences in nutritional status.

For future research, longitudinal studies are recommended to track changes in the lifestyles and nutritional status of firefighters over time, providing insights into the effectiveness of interventions and the evolution of health issues. Additionally, it is essential to investigate specific risk factors contributing to unhealthy lifestyles and overweight among firefighters, allowing for tailored interventions to address the root causes of these problems.

Furthermore, the importance of developing and testing intervention programs focused on promoting healthy eating habits and physical activity among firefighters is highlighted, prioritizing the improvement of their overall health and the reduction of occupational risks. Finally, conducting comparative studies with firefighter populations in different regions will help identify geographical variations in lifestyles and nutritional status, facilitating the implementation of more specific and effective interventions.

Enhanced Emotion Analysis Model using Machine Learning in Saudi Dialect: COVID-19 Vaccination Case Study

Abdulrahman O. Mostafa, Tarig M. Ahmed
Department of Information Technology-Faculty of Computing and Information Technology
King Abdulaziz University, Jeddah 21589, Saudi Arabia

***Abstract*—Sentiment Analysis (SA) and Emotion Analysis (EA) are effective areas of research aimed to auto-detect and recognize the sentiment expressed in a text and identify the underpinning opinion towards a specific topic. Although they are often considered interchangeable terms, they have slight differences. The primary purpose of SA is to find the polarity expressed in a text by distinguishing between positive, negative, and neutral opinions. EA is concerned with detecting more emotion categories, such as happiness, anger, sadness, and fear. EA allows the analysis to extract more accurate and detailed results that suit the field in which it is applied. This work delves into EA within the Saudi Arabian dialect, focusing on sentiments related to COVID-19 vaccination campaigns. Our endeavor addresses the absence of research on developing an effective EA machine-learning model for Saudi dialect texts, particularly within the healthcare and vaccinations domain, exacerbated by the lack of an EA manual-labeled corpus. Using a systematic approach, a dataset of 33,373 tweets is collected, annotated, and preprocessed. Thirty-six machine learning experiments encompassing SVM, Logistic Regression, Decision Tree models, three stemming techniques, and four feature extraction methods enhance the understanding of public sentiment surrounding COVID-19 vaccination campaigns. Our Logistic Regression model achieved 74.95% accuracy. Findings reveal a predominantly positive sentiment, particularly happiness, among Saudi citizens. This research contributes valuable insights for healthcare communication, public sentiment monitoring, and decision-making while providing labeled-corpus and ML model comparison results for improving model performance and exploring broader linguistic and dialectal applications.**

Keywords*—Data mining; natural language processing; sentiment analysis; emotion analysis; machine learning; support vector machine; logistic regression; decision tree; Covid-19

I. Introduction

Microblogging has grown significantly as a means of communication and information sharing, notably on platforms like Twitter. Offering real-time accessibility from anywhere, Twitter allows users, through short texts or "Tweets," to express thoughts, opinions, and emotions [1]. This social media giant has become a global hub for diverse purposes, including news updates, social interactions, and discussions. In Saudi Arabia, where Twitter boasts over 15.5 million active users [2], it is a valuable repository for researchers keen on comprehending public sentiments.

The advent of Natural Language Processing (NLP) techniques, such as Sentiment Analysis (SA) and Emotion Analysis (EA), has revolutionized the understanding of extensive textual data generated on platforms like Twitter. SA discerns a text's sentiment or emotional tone, while EA goes a step further to identify specific emotions like happiness, anger, or sadness. These techniques find widespread applications in diverse domains, including social media analytics [5], customer feedback analysis [6], and market research, offering insights into human opinions, emotions, and behaviors.

The research gap addressed in this study emerges from several significant factors within the context of emotion analysis in the Saudi dialect. Arabic is known for its rich morphology and many dialects [3]. Social media, particularly Twitter, introduces informal language, including dialects and slang, complicating the accurate interpretation of emotions [2]. Additionally, the absence of a multi-emotion class Saudi dialect labeled-tweets corpus, the presence of diacritical marks (Tashkeel) introducing ambiguity, and the deviation of the Saudi dialect from Modern Standard Arabic writing norms collectively contribute to this research gap. The study's overarching objective is to fill this void by crafting a machine-learning model adept at classifying Saudi dialect tweets into seven emotion categories, explicitly focusing on emotions related to COVID-19 vaccinations. Such an endeavor is poised to enhance our understanding of the sentiments expressed in Saudi Arabia concerning COVID-19 vaccinations.

Existing studies have provided limited insights using narrow classifications, making a more comprehensive range of classifications necessary for more valuable and effective results. Embracing EA offers a more comprehensive understanding of sentiments beyond binary or ternary classifications, particularly in contexts like COVID-19 vaccination campaigns.

The motivations behind the study are twofold. First, there is a need to focus on implementing an EA model in the Saudi dialect, anticipating its profound influence across various sectors such as business, healthcare, education, government, and technology. Second, to better understand the general attitudes towards COVID-19 vaccination campaigns held in Saudi Arabia. Objectives are aligned with these motivations, striving to produce an effective machine-learning model, enhance the accuracy of existing EA studies, unveil prevailing attitudes, create a Saudi dialect labeled-tweets corpus, and evaluate different algorithms comprehensively.

In anticipation of these objectives, the study expects to deliver a machine-learning model proficiently classifying Saudi dialect tweets into seven emotion categories. Additionally, it aims to create a labeled-tweets corpus, shedding light on the emotions expressed in diverse contexts, particularly in the healthcare and COVID-19 vaccination domain. Visual representations of general attitudes and detailed statistics are poised to empower decision-makers with nuanced insights, influencing policies and communication strategies. The model and corpus crafted in this study are envisioned to be valuable assets, not only for this research domain but also for broader applications in related studies.

Our paper is structured as follows: In Section II, we provide an overview of sentiment analysis and emotion analysis, highlighting their intersections and briefly discussing prior academic work in the field. Section III details the methodology, materials, and steps in constructing the final machine learning model, covering the dataset collection, annotation, and balancing methods. Section IV outlines the implementation of three machine learning models. Section V covers the evaluation methods and discusses the results achieved. Finally, in Section VI, we conclude the paper, presenting a summary and outlining our future work.

II. Background

A. Sentiment Analysis

1) Using machine learning: In health-related contributions addressing the COVID-19 pandemic, Aljameel et al. [18] developed a machine learning model gauging individuals' awareness of preventive measures during the quarantine in Saudi Arabia. Utilizing a dataset from the curfew period, they employed SVM, NB, and KNN classifiers, optimizing 85% accuracy by combining TF-IDF with SVM. Focused on the Saudi dialect, the study by Al Sari et al. [19] in the entertainment field used MLP, NB, SVM, RF, and Voting algorithms, achieving 90% accuracy with NB and MLP on Twitter data. Alhuri et al. [20] utilized GRU in an RNN, reaching an 81% F1 score for public reactions to COVID-19 in Arabic tweets. Alahmary, Al-Dossari, and Emam. The study in [4] outperformed ML with DL algorithms (Bi-LSTM) on the Saudi Dialect Twitter Corpus, achieving 94% accuracy. AlYami and AlZaidy [21] focused on Arabic Dialect Identification using SVM, RF, NB, and LR, achieving a maximum of 87% and 86% accuracy in Egyptian dialects using LR and SVM, respectively. However, they have worked on sentiment analysis fields only; limitations included a small dataset, the absence of manual annotation, and intensive preprocessing.

2) Using lexicon-based: Assiri, Emam, and Al-Dossari [3] proposed a domain-specific lexicon-based algorithm for the Saudi dialect, addressing the absence of such models. However, limitations arose from evaluating it against a non-Saudi dataset and focusing solely on text polarity. Similarly, Al-Thubaity et al. [10] manually created "SauDiSenti," a Saudi dialect sentiment lexicon, but challenges emerged in comparing it to a broader Arabic dictionary. Al-Ghaith [22] adopted a distinct approach, enhancing sentiment analysis accuracy by directly applying preprocessing tasks to the Saudi dialect lexicon, achieving 81% accuracy by relying on an English lexicon for the original creation.

3) Using hybrid approach: Very few published studies have utilized the Hybrid approach of SA in Arabic - where semantic orientation and ML techniques are combined. Aldayel and Azmi [9] used this approach to improve the F-measure score; they achieved an overall F-measure and accuracy of 84% and 84.01%, respectively. Alhumoud, Albuhairi, and Altuwaijri [23] used the same approach of combining two ML algorithms and applied the SA on 3000 Saudi dialect tweets to prove the efficiency of the hybrid learning approach compared to solo ML.

B. Emotion Analysis

EA can be described as recognizing distinct human emotions in contrast to Sentiment Analysis, which identifies whether data is positive, negative, or neutral [24]. Because of the lack of a labeled corpus for Saudi dialect that can be used for classifying emotions and polarity behind a text, Al-Thubaity, Alharbi, Alqahtani and Aljandal [10] introduced the Saudi Dialect Twitter Corpus (SDTC) that contains 5400 tweets of Saudi dialect and MSA classified for sentiment analysis and emotion analysis annotated by three raters based on their polarity (positive, negative, and neutral) for the sentiment, and based on Ekman's basic emotions (anger, fear, disgust, sadness, happiness, surprise, no emotion and not sure) for the emotion analysis. However, no ML or lexicon-based approaches have been applied to this corpus to evaluate its efficiency in this study. Another study by A. AlFutamani and H. Al-Baity [11] was the first in the EA in Arabic, focusing on Saudi dialects in Arabic textual content retrieved from Twitter, mainly in Saudi-based tweets. They built a system that can detect the underlying emotions of Saudi dialect tweets to classify them based on seven emotion categories (happiness, fear, disgust, anger, surprise, optimism, and sadness). They used two ML algorithms (SVM and MNB), achieving 73.39% accuracy in the SVM approach. However, they applied the analysis in dataset domain sets different from ours with varying models of ML.

In summarizing the related work, it is evident that sentiment analysis and emotion analysis have made significant strides, particularly in applications related to COVID-19 discussions on social media. However, within the context of our study, there exists a notable research gap. Previous works have primarily addressed sentiment analysis in broader contexts, lacking the depth to decipher the intricate emotional expressions specific to the Saudi population. Furthermore, the scarcity of labeled datasets in the Saudi dialect poses a considerable challenge. Our research seeks to bridge this gap by offering a comprehensive analysis of emotion analysis, utilizing a meticulously annotated dataset tailored to the Saudi dialect. This approach contributes to the broader field of sentiment analysis and provides a nuanced understanding of the emotional landscape surrounding COVID-19 vaccinations in Saudi Arabia.

C. Machine Learning Algorithms

ML algorithms encompass supervised, unsupervised, and reinforcement learning. Supervised learning trains on labeled data, associating input with output labels. It excels in classification, categorizing data into known classes, regression for predicting continuous values, and ranking for ordering data [7] [8]. Techniques like Support Vector Machines, Logistic Regression, Decision Trees, Random Forests, and Neural Networks are part of supervised learning, each chosen based on factors like data nature and problem complexity. Unsupervised learning handles unlabeled data, discerning patterns without explicit guidance, while reinforcement learning involves agent learning decisions to maximize rewards in an environment [12] [13]. Supervised learning's versatility finds applications in various domains, offering solutions in classification, regression, and ranking [14] [15].

1) Support Vector Machine (SVM): Stands out as a prominent supervised learning algorithm, initially crafted by Vapnik for binary classification and regression [37]. Renowned for its robust theoretical foundations, SVM has evolved to address multi-class classification using techniques like one-vs-rest and one-vs-one approaches. In the one-vs-rest method, distinct SVM models are trained for each class, treating it as positive and the others as negative, with the final result determined by the most probable classifier. Conversely, the one-vs-one strategy involves SVM models comparing each class against every other class, employing a voting scheme for the outcome. SVM excels in handling both linearly and non-linearly separable data. For linearly separable data, the hyperplane equation is defined as $g(x) = w^T x + b$, where w is the weight vector, x is the input data vector, and b is the bias term. The Euclidean norm determines the vector's magnitude, which is crucial for understanding its length in n-dimensional space. The optimization goal of SVM is to find the optimal hyperplane, maximizing the margin between support vectors accomplished through convex quadratic programming. SVM employs the kernel trick for non-linearly separable data, transforming input data into a higher-dimensional feature space for linear separation. The choice of the kernel function, whether linear, polynomial, radial basis function (RBF) or HyperTangent, profoundly influences SVM's ability to capture intricate patterns and relationships in the data [38]. SVM's suitability for text classification stems from its generalization capabilities, adherence to the Structural Risk Minimization principle, capacity to incorporate prior knowledge, and superior performance to alternatives like k-nearest-neighbors (kNN).

2) Logistic regression (LR) is a widely employed supervised learning algorithm that is a statistical method for modeling the probability of a binary outcome based on predictor variables. LR recognizes vectors with variables in text classification, assesses coefficients for each input, and predicts text class as a word vector. This model measures the statistical significance of independent variables concerning probability, offering a potent means of modeling binomial outcomes. LR excels in text categorization, providing advantages like computing probability values instead of scores. The logistic function, or sigmoid function, characterizes the LR model's relationship between variables and the probability of the outcome. Ensuring predicted probabilities fall within the range of 0 and 1, the LR equation is P = 1/(1+e^(- (w+bX))). In training, LR estimates parameters (weights) w and b through maximum likelihood estimation, aiming to maximize the likelihood of observed data. LR is computationally efficient, easy to implement, and yields interpretable results with estimated coefficients. It accommodates numerical and categorical input features and extends to multi-class classification using strategies like one-vs-rest, where a separate LR model is trained for each class, determining the final prediction based on the highest probability among all models.

3) Decision Tree (DT): A machine-learning algorithm for classification and regression tasks. It operates by recursively partitioning the data based on the values of input features, ultimately leading to a decision regarding the target variable. The algorithm constructs a tree-like structure representing a sequence of decisions and their potential consequences. Each internal node of the tree corresponds to a test on a specific attribute, while each branch represents the outcome of the test. The tree's leaf nodes correspond to class labels or numerical values [16]. Decision trees are popular in machine learning due to their interpretability, simplicity, and ability to handle various data types, including categorical and numerical variables [17]. They find applications in multiple domains, including image processing, clinical practice, and financial analysis. Their inherent structure allows for an intuitive understanding of the decision-making process, making them valuable tools for extracting insights from data.

D. Covid-19 and Vaccinations

The COVID-19 pandemic, caused by the novel coronavirus SARS-CoV-2, has profoundly impacted societies worldwide [28]. It was first identified when the initial case was reported in Wuhan, China, on December 19, 2019 [29]. The World Health Organization (WHO) officially declared the global COVID-19 pandemic on March 11, 2020 [30]. This declaration marked a turning point in the international response to the virus, leading to widespread public health measures to curb its spread. Saudi Arabia recorded its first confirmed case of COVID-19 on March 2, 2020 [31] [32]. The country swiftly implemented various measures to combat the virus's transmission, including lockdowns and travel restrictions.

The introduction of COVID-19 vaccines marked a pivotal moment in the fight against the pandemic. Saudi Arabia approved the Pfizer-BioNTech vaccine on December 10, 2020 [33]. Registration for the vaccine in Saudi Arabia began on December 15, 2020 [34]. As vaccination efforts progressed, restrictions evolved, with announcements such as allowing only vaccinated individuals to enter certain buildings starting from August 1, 2021. The vaccine rollout continued to advance, with the commencement of the second vaccine dose administration on June 23, 2021 [35]. As the situation improved, Saudi Arabia took steps to return to normalcy, including lifting many precautionary measures on May 3, 2022 [36].

III. Material and Method

This section provides a comprehensive overview of our methodology for producing a machine learning (ML) model and constructing a labeled corpus for emotion analysis in healthcare, specifically focusing on the Saudi dialect. The process comprises distinct stages, outlined in Fig. 1. The initial step involves collecting relevant tweets on vaccinations through specific keywords using the Twitter API. These tweets are then manually annotated by three Saudi natives, forming a labeled corpus for training and evaluation. Data preprocessing is undertaken to filter irrelevant content, rectify text errors, ensure consistency, and tokenize the text for analysis. Feature extraction follows, where we employ Bag-of-Words, N-Gram, and TF-IDF methods to effectively capture emotions expressed in the tweets, serving as inputs for the ML model. The classification stage involves developing and training the ML model, utilizing Support Vector Machines, Logistic Regression, and Decision trees to classify tweets into seven emotions. The performance evaluation includes using various metrics and experiments to validate the methodology. Unseen data is employed for testing, with metrics like accuracy, precision, recall, and F1-score measured to assess the effectiveness and limitations of our approach.

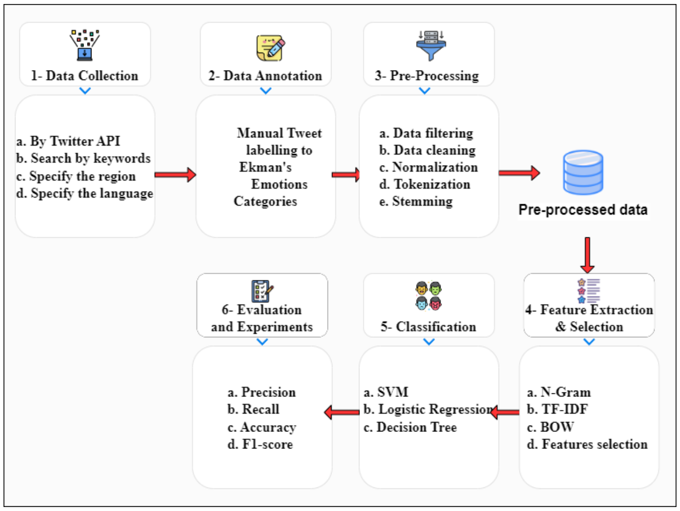

Fig. 1. Block diagram of the research methodology.

A. Dataset Collection

The data collection phase is pivotal to our implementation, aiming to amass diverse tweets related to vaccinations in the Saudi dialect. We utilized the Twitter API for Academic Research with Python programming language to access real-time Twitter data, employing libraries such as Tweepy [39], Pandas, and Requests. The collection spanned from December 15, 2020, to March 10, 2022, crucial periods in Saudi Arabia's COVID-19 vaccination timeline. Specific Arabic keywords targeting vaccination-related discussions were specified in each request, ensuring relevance. Additional parameters refined the dataset, focusing on the Saudi region and Arabic language and excluding retweets. The process yielded 34,074 raw tweets, each characterized by properties like tweet text, author ID, creation time, geolocation, and engagement metrics. The dataset, saved in CSV format, forms a robust foundation for subsequent annotation, preprocessing, feature extraction, and classification stages. Table I shows one raw instance of collected tweets.

TABLE I. One Raw Instance of the Collected Tweets

B. Data Annotation

In the data annotation phase, emotions were manually assigned to collected tweets following initial preprocessing steps. These steps included eliminating duplicates, Twitter handles, URLs, English text, and emojis/non-emoji symbols. The annotation categorized tweets into emotion classes aligned with Paul Ekman's emotions [40], augmented by a neutral/spam class and an optimistic class to account for Saudi dialect nuances. Eight emotion categories were established, detailed in Table II.

TABLE II. Shows the Emotions Used in the Annotation Stage

#	English Emotion Class	Arabic Emotion Class	Explanation
1	happiness	سعادة	When the tweet expresses feelings of joy, happiness, or delight
2	fear	خوف	When the tweet expresses feelings of fear
3	disgust	اشمئزاز	when the tweet expresses disgust, disgust, or disgust with the tweeter
4	anger	غضب	When the tweet expresses angry feelings
5	surprise	تفاجؤ	When the tweet expresses feelings of surprise, astonishment, or wonder
6	optimism	تفاؤل	When the tweet expresses feelings of optimism and a positive view of the future
7	sadness	حزن	When the tweet expresses feelings of sadness, brokenness, grief, or depression
8	neutral	محايد/إعلان/لا يمكن تحديده	When the content of the tweet does not include any emotions or feelings that cannot be identified from other options or includes only advertising hashtags without any emotions

Google Sheets were employed in the annotation stage, where a copy of tweets was shared with individual annotators familiar with the Saudi dialect. Annotators were guided by detailed instructions ensuring privacy, single emotion selection for ambiguous cases, accuracy, and time management. The annotation process lasted two months, maintaining a manageable daily average for annotators. Results were consolidated into a dataset, revealing 23,689 fully matched tweets and 9,684 with discrepancies. Table III illustrates counts for each emotion class by annotators, and Fig. 2 provides examples of annotated tweets. This annotation phase produced a labeled dataset, a crucial foundation for subsequent stages like data preprocessing, feature extraction, and classification.

C. Preprocessing

The preprocessing stage, integral to our methodology, comprised two pivotal sub-stages: pre-annotation and post-annotation. In the pre-annotation phase, executed within Google Sheets using sophisticated REGEX formulas, we undertook various measures to refine the dataset comprehensively. Initially, we focused on eliminating redundancy, ensuring uniqueness in our dataset by removing 701 duplicate tweets from the initial count of 34,074, resulting in 33,373 distinct tweets. Furthermore, we removed Twitter handles (@), URLs, English text, emojis, and non-emoji symbols to enhance the dataset's purity. The cleaning tasks aimed at centering our analysis on the core content of tweets, devoid of any external influences. In the post-annotation, we employed the KNIME [41] platform to undertake further profound preprocessing exclusively on the subset of class-matched tweets from the three raters, totaling 22,689 tweets. Fig. 3 demonstrates the comprehensive nature of our data refinement process.

The post-annotation preprocessing involved a multifaceted approach:

- Punctuation Removal: Punctuation marks were expunged from tweet text to eliminate unnecessary noise, allowing focused analysis of words and their emotional significance.
- Elimination of Numbers: Numeric characters were systematically removed from tweets as they do not contribute directly to emotional content. This step simplified the text and heightened subsequent analysis accuracy.

TABLE III. COUNTS TWEETS ANNOTATED IN EACH EMOTION CLASS BY THREE ANNOTATORS

Rater		8	7	6	5	4	3	2	1

Fig. 2. Examples of annotated tweets by different raters.

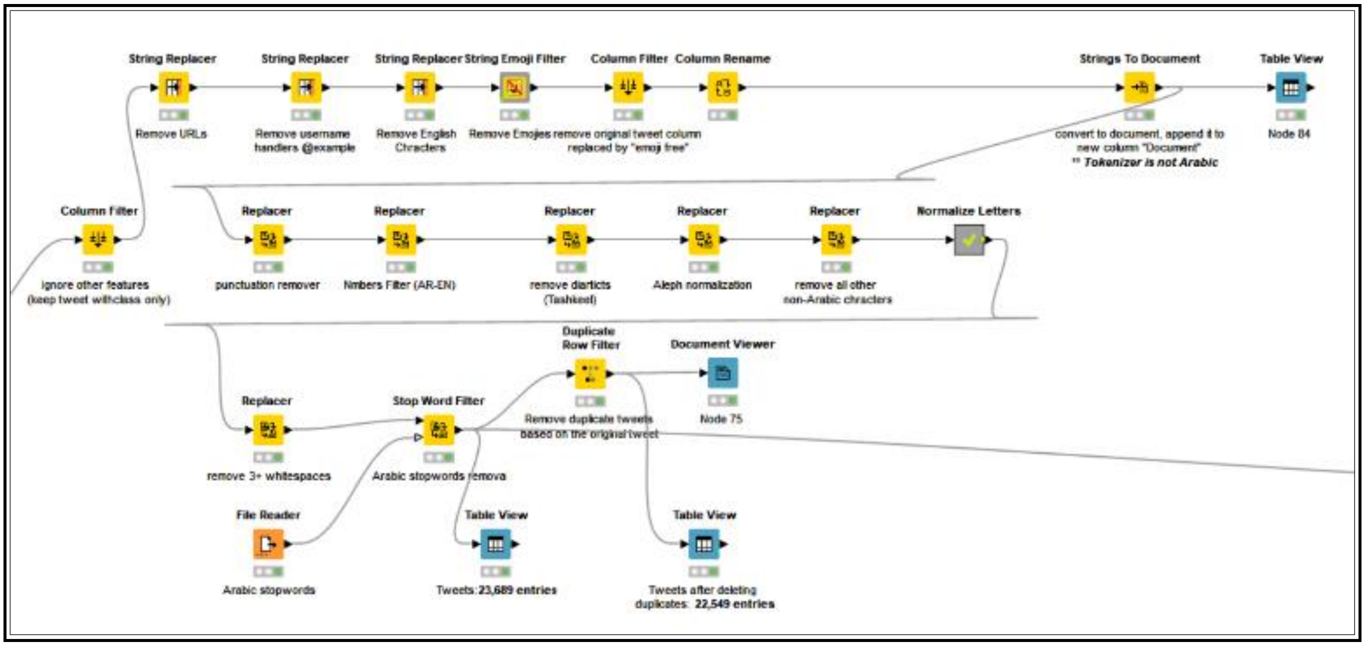

Fig. 3. The flow of preprocessing nodes in the KNIME platform.

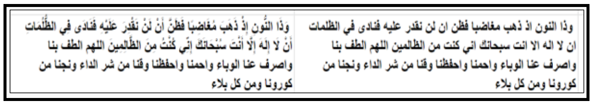
- Removal of Double Spaces and New Lines: Consecutive spaces and new lines were eradicated, ensuring uniformity in text format.
- Arabic Diacritics Removal and Character Normalization: Diacritics, such as vowel marks, were deleted for consistency. Characters were normalized to ensure uniformity and standardization across the dataset. This eliminated text variations that could impact emotion analysis accuracy, as shown in Fig. 4.



وَذَا النُّونِ إِذْ ذَهَبَ مُغَاضِبًا فَظَنَّ أَنْ لَنْ نَقْدِرَ عَلَيْهِ فَنَادَى فِي الظُّلُمَاتِ أَنْ لَا إِلَهَ إِلَّا أَنْتَ سُبْحَانَكَ إِنِّي كُنْتُ مِنَ الظَّالِمِينَ اللهم الطف بنا واصرف عنا الوباء واحمنا واحفظنا وقنا من شر الداء ونجنا من كورونا ومن كل بلاء	وذا النون اذ ذهب مغاضبا فظن ان لن نقدر عليه فنادى في الظلمات ان لا اله الا انت سبحانك اني كنت من الظالمين اللهم الطف بنا واصرف عنا الوباء واحمنا واحفظنا وقنا من شر الداء ونجنا من كورونا ومن كل بلاء

Fig. 4. An example of a tweet before and after diacritics removal.

- Normalization Techniques: Normalization techniques were applied to standardize data and convert characters to their original shape. For instance, sequences of certain Arabic letters were regulated for uniformity.
- Stemming: Employing three distinct stemming techniques (Snowball Stemmer, Porter Stemmer, and Kuhlen Stemmer), words were reduced to their root form. This facilitated a more accurate analysis and interpretation of emotions.
- Stopwords that lack significant meaning were removed using a Stop Word Filter node in KNIME. A stop-word dictionary for the Arabic language was employed for this purpose [42].
- Tokenization: Text was tokenized into individual words using the Arabic tokenizer provided by the NLTK library.
- Column Filtering: Irrelevant columns were filtered out, retaining only tweet and label class columns, streamlining subsequent emotion analysis.

This meticulous preprocessing led to a pristine dataset comprising 22,549 clean tweets. This refined dataset is now poised for the subsequent stages of feature extraction, classification, and further analysis, as shown in Fig. 5.

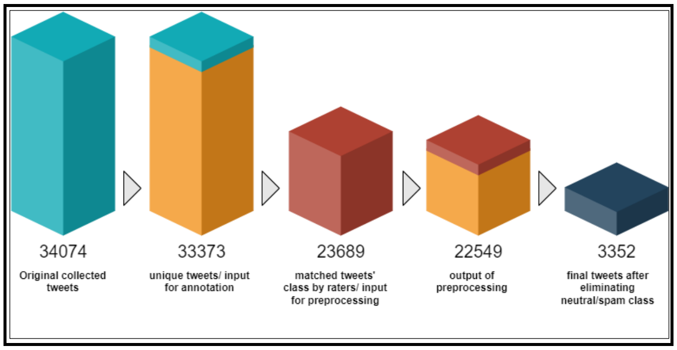


Fig. 5. Counts the tweets at each stage of the implementation.

D. Feature Extraction and Selection

In the feature extraction and selection stage, our initial step involved the removal of the 8th emotion class label, encompassing neutral, spam, and advertisement text (totaling 19,197 tweets). This exclusion aimed to streamline subsequent analysis, focusing solely on the emotions inherent in the remaining dataset of 3,352 tweets.

1) Bag-of-Words (BoW): The Bag-of-Words approach, a fundamental yet robust technique, was employed to convert preprocessed text data into numerical vectors. Each word in the text is treated as a distinct feature, and its frequency is quantified in this method.

The resulting vector encapsulates the occurrence of each word in the text, irrespective of word order or grammar. Two sub-flows of BoW were applied to evaluate model accuracy, each depicted in. This method yielded a high-dimensional representation of the text data, forming the input for subsequent machine-learning models. Fig. 6 and Fig. 7 show these flows.

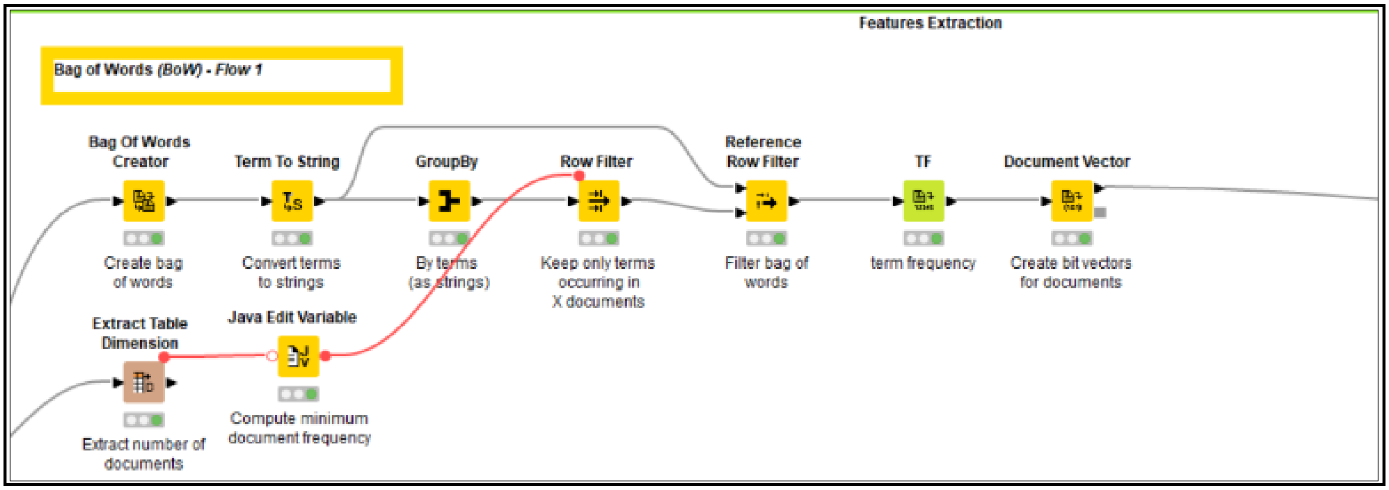

Fig. 6. First sequence of BoW flow.

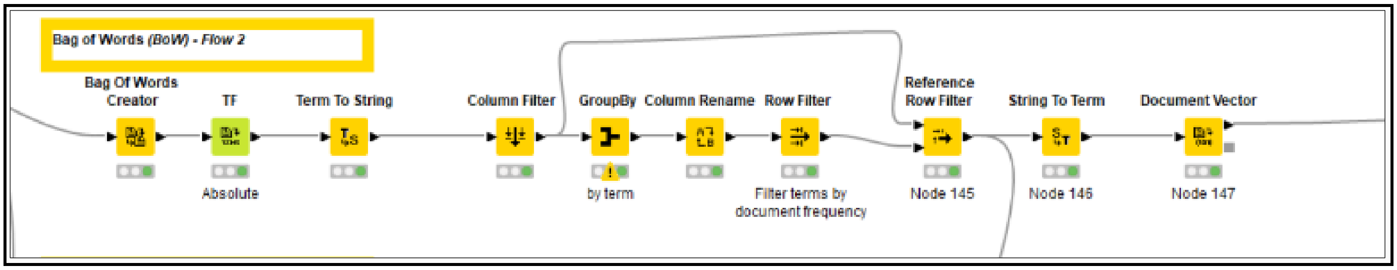

Fig. 7. Second sequence of BoW flow.

2) N-Gram: Extending the Bag-of-Words approach, the N-Gram method considers sequences of N consecutive words as features. We specifically employed bi-grams (N=2), representing pairs of successive words in each tweet. This extension allows for capturing context and word relationships in the text, enhancing our ability to discern nuanced insights into expressed emotions.

3) Term Frequency-Inverse Document Frequency (TF-IDF): TF-IDF, a prevalent technique in natural language processing, gauges the importance of each word in a document relative to a corpus. It factors in the frequency of a word in a specific document and its rarity across the entire corpus. Assigning higher weights to words that are frequent in a document but rare across the corpus makes them more discriminative. TF-IDF was employed to enrich the representation of words based on their significance in each tweet and across the entire dataset.

We transformed the preprocessed text data into numerical representations using these three feature extraction methods. These representations effectively captured essential information about the emotions expressed in the tweets. The resulting feature matrices served as inputs for the machine learning model during training, facilitating the model's ability to discern patterns and relationships between features and labeled emotions.

E. *Resolve Data Imbalance (Oversampling)*

The focus is on addressing class imbalance, a crucial consideration in developing an effective emotion analysis model. The section outlines the strategies employed, particularly data partitioning and oversampling techniques.

1) Class distribution: An evaluation of the initial class distribution within the dataset is conducted before diving into oversampling. It's revealed that the original dataset of 3,352 tweets exhibits an imbalance across emotion categories, a factor that can impact the model's ability to discern less frequent emotions effectively as shown in Table IV and Fig. 8.

TABLE IV. CLASS DISTRIBUTIONS OF THE 3352 TWEETS BEFORE DATA SPLITTING

Class	Tweets Count
Happiness (1)	1,926
Fear (2)	230
Disgust (3)	71
Anger (4)	482
Surprise (5)	13
Optimism (6)	243
Sadness (7)	387
Total	**3352**

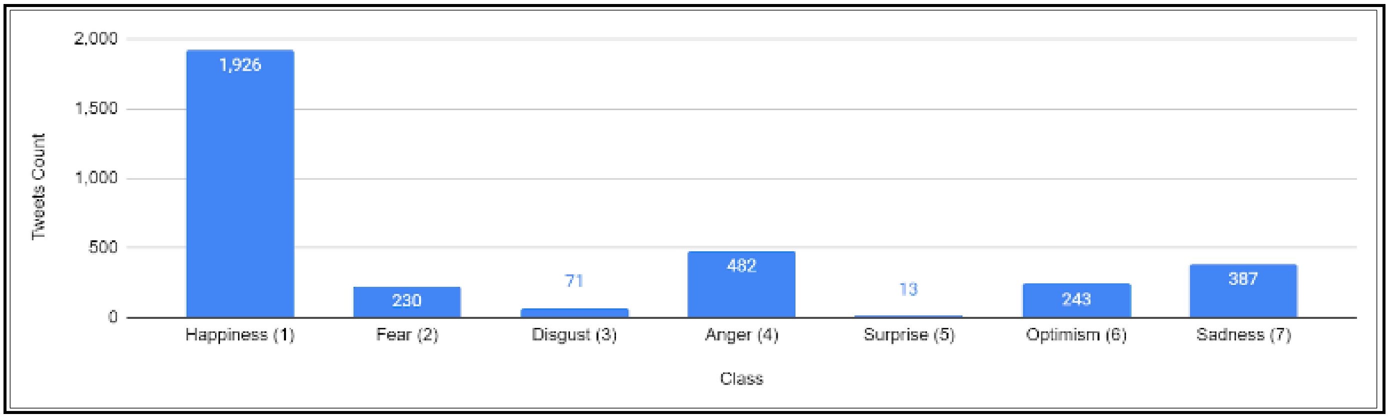

Fig. 8. Class distributions of the 3352 tweets before data splitting.

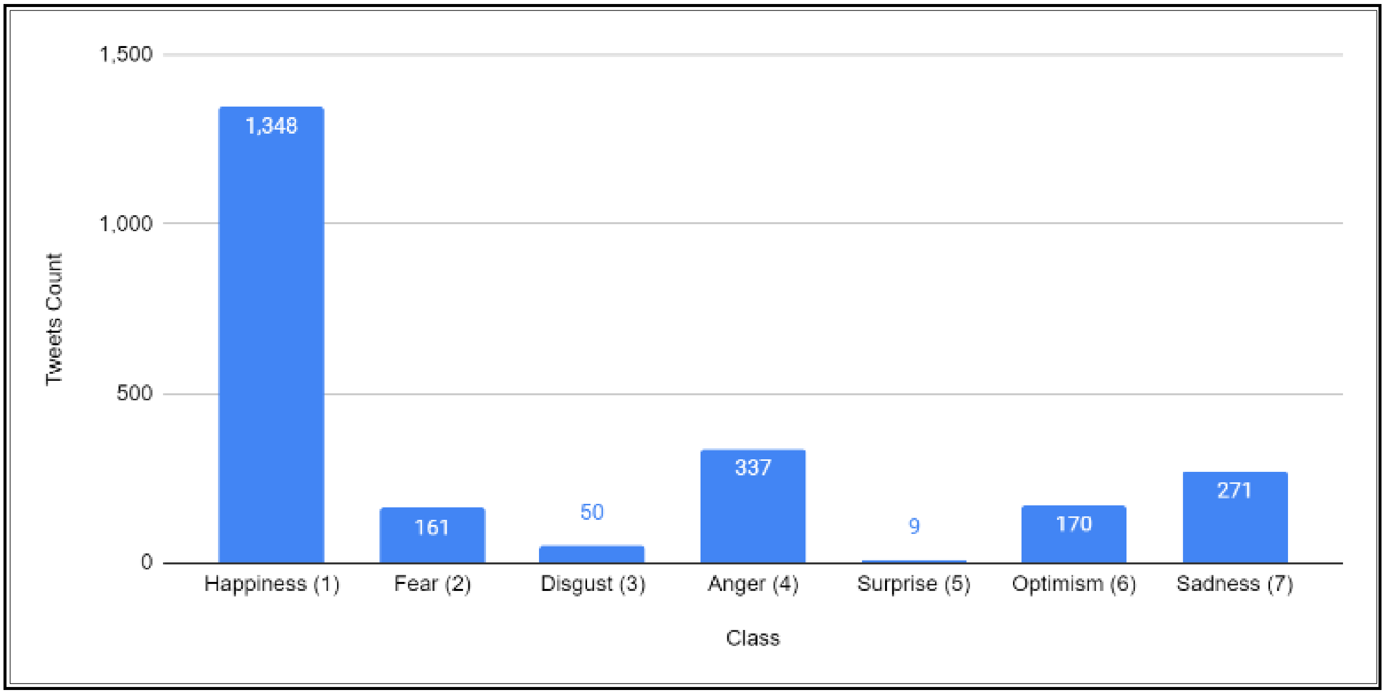

Fig. 9. Class distribution of the training dataset contains 2346 tweets after data splitting and before oversampling.

2) Dataset splitting: A 70:30 train-test split ratio is employed to evaluate machine learning model performance. This ensures that 70% of the data is allocated for training, and the remaining 30% is reserved for evaluation. The class distribution post-splitting is presented for both the training and testing datasets as shown in Table V and Fig. 9.

TABLE V. THE CLASS DISTRIBUTION OF THE TRAINING DATASET CONTAINS 2346 TWEETS AFTER DATA SPLITTING AND BEFORE OVERSAMPLING

Class	Tweets Count
Happiness (1)	1,348
Fear (2)	161
Disgust (3)	50
Anger (4)	337
Surprise (5)	9
Optimism (6)	170
Sadness (7)	271
Total	**2346**

3) Oversampling: Oversampling techniques are strategically applied to rectify the class imbalance within the training data. The oversampling is exclusively directed at the training data. After this process, the class distribution in the training dataset is significantly altered, as illustrated in Table VI and Fig. 10.

TABLE VI. CLASS DISTRIBUTION OF THE TRAINING DATASET CONTAINS 9399 TWEETS AFTER DATA SPLITTING AND AFTER OVERSAMPLING

Class	Tweets Count
Happiness (1)	1,348
Fear (2)	1288
Disgust (3)	1350
Anger (4)	1348
Surprise (5)	1350
Optimism (6)	1360
Sadness (7)	1355
Total	**9399**

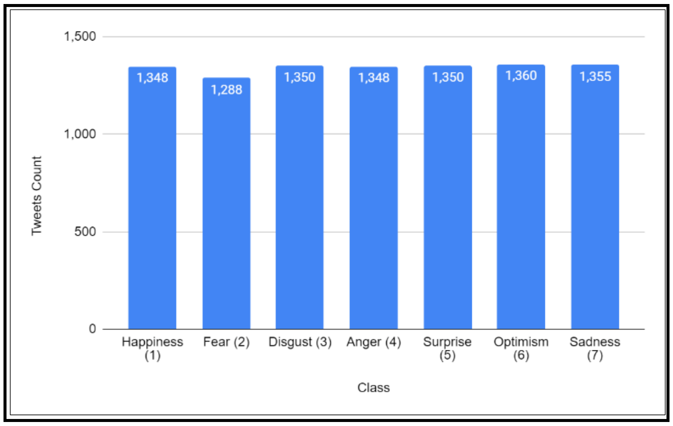

Fig. 10. Class distribution of the training dataset contains 9399 tweets after data splitting and after oversampling.

This oversampling endeavor aims to equalize the representation of emotions across classes in the training dataset, providing a more balanced learning experience for machine learning models.

IV. IMPLEMENTATION

In the Classification stage, we embarked on the crucial task of predicting the emotions expressed in the 9399 tweets using the extracted features. Indeed, the combination of three stemming techniques, four feature extraction methods, and three machine learning algorithms resulted in 36 different models being trained in this stage. Each model represents a unique configuration of the preprocessing and classification pipeline, contributing to the comprehensive evaluation and comparison of various approaches. We obtained an enriched dataset with numerical representations of the extracted features. However, the emotion labels must be converted to numerical classes to train the machine learning models. This transformation involved mapping each emotion category to a unique numerical class, making the dataset suitable for classification. Having prepared the data and set up the train-test split, we applied three widely used machine learning algorithms: Support Vector Machine (SVM), Logistic Regression, and Decision Tree. Each algorithm underwent training on the training data to learn the underlying patterns and relationships between the extracted features and emotions. After training, the models were tested using the test data to evaluate their predictive capabilities.

In the learner node of each machine learning algorithm, specific configurations and options were carefully selected to optimize the performance of the models. For the Support Vector Machine (SVM), we utilized the polynomial kernel with power approximately equal to 1, bias around 1, and gamma set to around 1. The overlapping penalty was established within the range of 0.1 to 1, enabling us to control the influence of overlapping data points on the model's decision boundaries. In the case of logistic regression, we opted for the stochastic average gradient (SAG) solver, known for its efficiency [25] and ability to handle large datasets. The maximal number of epochs was set between 10 and 20, ensuring the algorithm converged to the optimal solution while avoiding overfitting. For the Decision Tree algorithm, we set the maximum number of patterns the tree will store to support highlighting to a default value of 10,000. This configuration allowed us to manage the complexity of the tree while still capturing the relevant patterns and relationships in the data flows illustrated.

V. EVALUATION AND RESULTS

In this section, we will evaluate the model results using different metrics. We utilized the KNIME platform for the evaluation process, employing the Model Predictor and Scorer nodes. The Model Predictor node takes the test data partition from the partitioning node and the trained model from the learner node as inputs. It then uses the trained model to predict the emotion labels for the given test data. The Scorer node compares the predicted and actual labels, generating a confusion matrix displaying correct and incorrect predictions for each emotion class.

A. Evaluation Methods

1) Confusion matrix: a fundamental evaluation tool that provides a tabular representation of the performance of a machine-learning classification model [26]. It gives a comparison between actual and predicted values as it displays the number of true positive (TP), true negative (TN), false positive (FP), and false negative (FN) predictions for each emotion class, which will be used in the measure. Furthermore, it allows us to assess the model's accuracy and ability to classify emotions correctly. The confusion matrix is a square matrix of size N x N, where N represents the number of emotion classes. We have a 7 x 7 confusion matrix in our specific case, as illustrated in Table VII.

TABLE VII. CONFUSION MATRIX FOR SEVEN CLASSES

Actual Class	**Happiness**	**Fear**	**Disgust**	**Anger**	**Sadness**	**Suprise**	**Optimism**
Happiness	TP1	FP1	FP2	FP3	FP4	FP5	FP6
Fear	FP7	TP2	FP8	FP9	FP10	FP11	FP12
Disgust	FP13	FP14	TP3	FP15	FP16	FP17	FP18
Anger	FP19	FP20	FP21	TP4	FP22	FP23	FP24
Sadness	FP25	FP26	FP27	FP28	TP5	FP29	FP30
Suprise	FP31	FP32	FP33	FP34	FP35	TP6	FP36
Optimism	FP37	FP38	FP39	FP40	FP41	FP42	TP7

2) Class distribution consideration: As our dataset exhibits an imbalanced class distribution, we applied stratified cross-validation with some emotion classes having significantly fewer instances than others. Stratified cross-validation ensures that each fold retains the same proportion of instances for each emotion class as the original dataset. This approach is crucial for preventing biased evaluations and ensuring that each emotion class is represented appropriately during model training and testing.

3) Comparative analysis: To conduct a comparative analysis, we evaluated a total of 36 different models, considering the combination of three stemming techniques (Kohlen Stemmer, Porter Stemmer, and Snowball Stemmer), four feature extraction methods (Bag-of-Words, N-Gram, and TF-IDF), and three machine learning algorithms (Support Vector Machine, Logistic Regression, and Decision Tree). By comparing the performance of these models, we can identify the most practical combination of techniques and algorithms for sentiment analysis in the context of our research.

B. Evaluation of Performance Metrics

A comprehensive set of performance metrics is employed to evaluate the effectiveness of emotion classification models for Saudi dialect tweets related to vaccinations. The chosen metrics, including Accuracy, Precision, Recall, and F1-score, offer valuable insights into the models' ability to classify emotions accurately.

1) Accuracy: a widely used metric in classification models, measures the proportion of correctly classified instances over the total number of instances in the dataset. It provides an overall assessment of the model's performance in correctly identifying emotions in tweets across all emotion classes. The formula for accuracy involves True Positives (TP), True Negatives (TN), False Positives (FP), and False Negatives (FN).

2) Precision: assesses the proportion of true positive predictions for a specific emotion class over the total number of instances predicted as that class. It signifies the model's reliability in avoiding false positive predictions for a given class. Precision is crucial in understanding the model's accuracy when classifying tweets as a particular emotion.

3) Recall: sensitivity, or true positive rate, measures the proportion of true positive predictions for a particular emotion class over the total number of instances belonging to that class. It indicates the model's effectiveness in correctly identifying all instances of a specific emotion class. Recall is significant in understanding how well the model captures tweet emotions.

4) F1-score: a harmonic mean of precision and recall that combines both metrics into a single value. This score is instrumental in scenarios with an imbalance in class distribution. It offers a balanced evaluation of the model's performance, considering trade-offs between precision and recall in emotion classification.

C. Results and Evaluation

This section presents the outcomes of the 36 experiments conducted during the implementation stage. Table VIII, IX and Table X provide a comprehensive breakdown of the results for all 36 models, giving the performance metrics for each emotion class. These tables offer a basis for comparing each model's accuracy, precision, recall, and F1-score of each model across different feature extraction methods and stemming techniques. Among the configurations, the Logistic Regression model achieved the highest accuracy, reaching 74.95% when combined with N-Gram feature extraction and Snowball stemming; it also performs the same 74.95% accuracy when combined with the BoW with Snowball stemmer, followed by 74.75% Logistic Regression when combined with TF-IDF and Snowball Stemmer. The SVM model showcased a close performance with 74.35% accuracy when combined with N-Gram and Snowball.

Moving on to the recall metric, the SVM model achieved a remarkable 91.34% in both experiments, compromising N-Gram and TF-IDF when combined with the Snowball stemmer, displaying a higher ability to identify true positive instances correctly and making them top performers in emotion classification. The Logistic Regression result shows a close percentage of 91.00% with TF-IDF and Snowball stemmer.

Regarding precision, the SVM model demonstrated an impressive 98.98% precision rate when trained after using the N-Gram technique and Porter stemmer, indicating its capability to limit the number of false positives and ensure the accuracy of positive predictions. The Logistic Regression result shows a close percentage of 97.23% with BoW and Kuhlen Stemmer, followed by another Logistic Regression experiment with Bow and Porter Stemmer achieving 96.60%.

The F-measure results highlighted the Logistic Regression model as the most balanced performer between precision and recall, achieving 92.93% and 92.51%, particularly when combined with TF-IDF and BoW feature extraction techniques with the Snowball stemmer. The SVM model followed closely in third place, achieving 92.38% when N-Gram and Snowball were used.

TABLE VIII. SVM MODEL RESULTS ARE BASED ON FOUR FEATURE EXTRACTION TECHNIQUES AND THREE STEMMING METHODS

	Stemming	Accuracy %	Recall %	Precision %	F-Measure %
BoW-1	**Kuhlen**	64.31	83.04	95.61	88.88
	Snowball	67.39	85.46	96.10	90.47
	Porter	64.61	84.94	95.71	90.00
BoW-2	**Kuhlen**	70.67	87.54	93.35	90.35
	Snowball	74.15	89.96	94.37	92.11

D. Discussion

The results from our comprehensive experiment illuminate the effectiveness of our proposed Emotion Analysis machine learning model in classifying emotions and feelings expressed in Tweets written in the Saudi dialect. Our study's primary aim was to develop a precise and dependable model that enhances existing study results and aligns with the Saudi dialect's unique linguistic and cultural intricacies. As demonstrated in Fig. 11 to Fig. 14. The most accurate, precise recall and F1-score models are highlighted. The Logistic Regression model, as depicted, surpasses others in terms of Accuracy and F-Measure metrics, signifying a significant achievement. The SVM model displays the highest Recall (sensitivity) and Precision performance. The third model (Decision Tree) is considered out of the competition of the top three. This success contributes to the validation of our objectives.

TABLE X. SHOWS THE LOGISTIC REGRESSION MODEL RESULTS BASED ON FOUR FEATURE EXTRACTION TECHNIQUES AND THREE STEMMING METHODS

	Stemming	**Accuracy %**	**Recall %**	**Precision %**	**F-Measure %**
BoW-1	**Kuhlen**	63.81	79.23	97.23	87.32
	Snowball	69.28	87.19	94.73	69.28
	Porter	66.00	83.73	96.60	89.71
BoW-2	**Kuhlen**	72.86	89.79	93.68	91.69
	Snowball	74.95	90.83	94.25	92.51
	Porter	73.36	89.61	93.84	91.68
N-Gram	**Kuhlen**	73.06	89.96	94.71	92.28
	Snowball	74.95	90.31	94.05	74.95
	Porter	73.26	89.10	94.49	91.71
TF-IDF	**Kuhlen**	72.16	87.88	94.24	90.95

	Porter	72.76	88.58	93.60	91.02

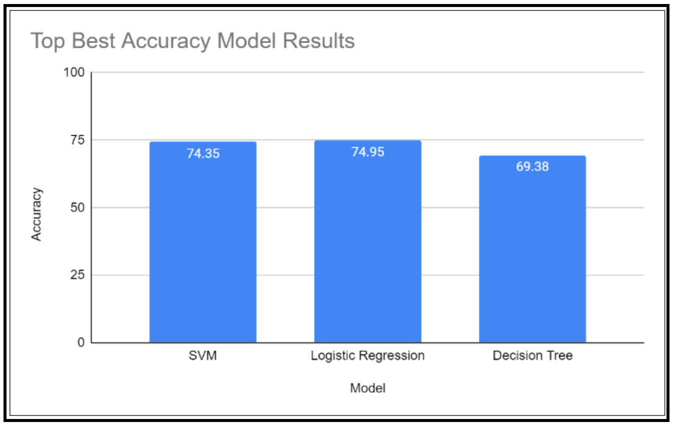

Fig. 11. The top accuracy results achieved by the three models.

When compared to existing works in the domain, our progress is remarkable. For instance, considering a study that achieved 73.39% accuracy through an SVM approach, which is 1.56% lower than our Logistic Regression result, and they solely employed two machine learning algorithms (SVM and MNB) [11], our accomplishments are striking. Not only did we surpass this accuracy benchmark, but we also encompassed a diverse array of machine-learning algorithms, leading to a more robust and comprehensive evaluation. This also aligns with our objectives.

The performance of our model was significantly influenced by the careful selection of stemming techniques and feature extraction methods. Results indicate that specific combinations, such as employing N-Gram feature extraction with Snowball stemming, yield the highest accuracy. This underscores the importance of selecting the correct machine learning algorithm and optimizing preprocessing and feature engineering stages to exploit the data's potential fully.

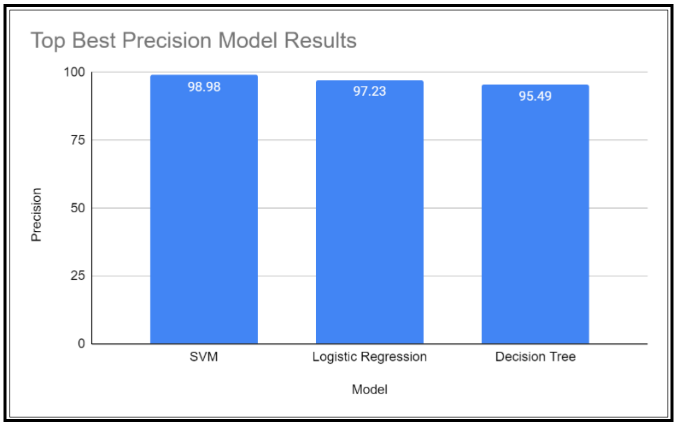

Fig. 13. The top precision results achieved by the three models.

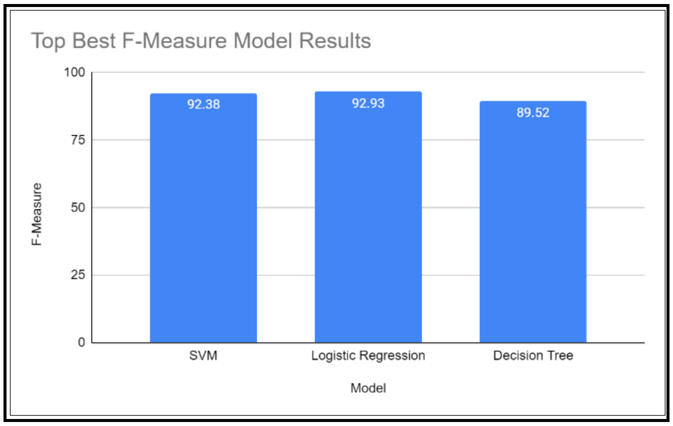

Fig. 14. Shows the top F-Measure Results achieved by the three models.

E. General Attitudes Towards COVID-19 Vaccinations in Saudi Arabia

The outcomes of our model shed light on prevalent concerns and sentiments regarding COVID-19 vaccination in Saudi Arabia. The precision of our emotion analysis allows us to extract insightful understandings from public sentiment, aiding decision-making in healthcare initiatives. The distribution of annotated tweets across emotion classes is detailed in Table XI. They are revealing a diverse emotional landscape. 'Happiness' dominates, followed by 'Anger,' 'Sadness,' and 'Optimism.' 'Disgust' is rare, and 'Surprise' is infrequent. Insights and Latent Dirichlet Allocation (LDA) [27] indicate a prevailing positive disposition toward the COVID-19 vaccination campaign in Saudi Arabia. As shown in Fig. 15, 57.46% of tweets expressed happiness followed by anger 14.38%, sadness 11.55%, and optimism 7.25%. Fearful emotions account for 6.86%, while disgust and surprise are 2.12% and 0.39%, respectively. These findings highlight contentment with vaccine availability, achieving our objective of providing valuable insights into general attitudes toward vaccinations.

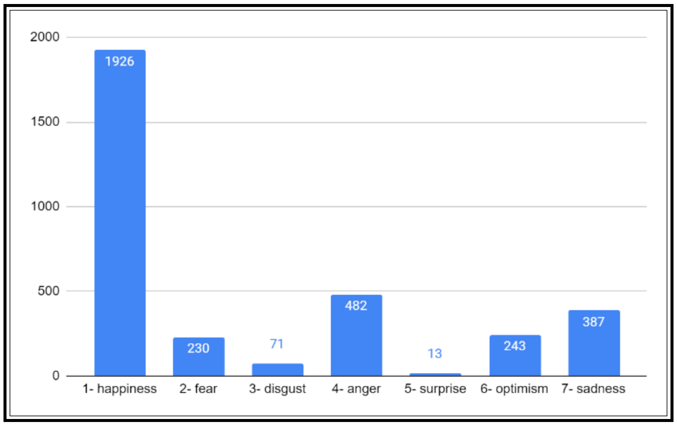

Fig. 15. The distribution of annotated tweets across various emotion classes.

TABLE XI. NUMBER OF INSTANCES IN EACH EMOTION CLASS IN THE FINAL STAGE OF IMPLEMENTATION

Class	Number of Instances	%
1- happiness	1926	57.5
2- fear	230	6.9
3- disgust	71	2.1
4- anger	482	14.4
5- surprise	13	0.4
6- optimism	243	7.2
7- sadness	387	11.5

F. Saudi Dialect Labeled-Tweets Corpus Availability

In alignment with our objective to produce a Saudi dialect labeled-tweets corpus in the healthcare and COVID-19 vaccination domain, we are pleased to announce the availability of the "saudiEAR" repository on GitHub [43]. This repository contains a comprehensive collection of tweets, including both the original dataset collected and the preprocessed version. By making this corpus publicly accessible, we aim to contribute to the research community and facilitate advancements in sentiment analysis, emotion classification, and related fields. This open dataset enables researchers and practitioners to explore the intricacies of sentiment expression in the Saudi dialect, particularly in healthcare and COVID-19 vaccination discussions.

VI. CONCLUSION AND FUTURE WORK

A. Conclusion

In conclusion, this research addresses a notable gap in emotional analysis, focusing on the Saudi context amid COVID-19 vaccination discussions. The objective was to build an effective machine-learning model for classifying Saudi tweets into distinct emotions, a need prompted by the scarcity of such studies in the Saudi dialect and the absence of a suitably labeled corpus. The methodology involved a meticulous collection of 34,074 Arabic tweets emphasizing COVID-19 vaccines in Saudi Arabia. Three expert raters annotated these tweets into eight emotion classes, followed by thorough preprocessing, resulting in a dataset of 3,352 tweets expanded through oversampling to 9,399. Thirty-six machine learning experiments were conducted, employing SVM, Logistic Regression, and Decision Trees, with three stemming techniques and four feature extraction methods. Key findings reveal the Logistic Regression model achieving a noteworthy accuracy of 74.95%. The SVM model excelled with a 91.34% recall and 98.98% precision. The F1-Score for Logistic Regression reached 92.93%, showcasing the approach's effectiveness. Comparative analysis with existing studies indicated accuracy, precision, recall, and F1-Score improvements.

Insights from the dataset highlighted a prevailing positive sentiment toward COVID-19 vaccination campaigns. Happiness dominated at 57.5%, followed by anger (14.4%) and sadness (11.5%). These sentiments mirror people's joy for potential pandemic resolution, reflecting trust in government decisions. As a contribution, the labeled dataset of 33,373 tweets is provided, facilitating further research in emotion analysis within the Saudi dialect and supporting advancements in machine learning and sentiment analysis.

B. Future Work

Our study has opened many possibilities for future research. First, we need to improve the performance of our model by incorporating deep learning methods. More advanced neural network architectures, such as recurrent or transformer-based models, could allow us to make more nuanced sentiment classifications, especially when capturing context-dependent linguistic nuances. In addition, we can gain deeper insights into the linguistic and contextual cues that underlie the expression of emotions by exploring the interpretability of our model's decisions. Techniques such as attention mechanisms or layer-wise relevance propagation can help us understand how the model makes its decisions.

Finally, we can broaden the scope of emotion analysis and its implications for healthcare communication, public sentiment monitoring, and decision-making by extending our model's applicability to other dialects and languages within the Arab region.

Computer Science Department-Faculty of Information Technology "Aleksander Moisiu", University of Durres, Albania[1, 3]
Department of Applied Mathematics-Faculty of Natyral Science, University of Tirana, Albania[2]

***Abstract*—Facial expressions are the main ways how humans display emotions. Under certain circumstances, humans can do facial expression, but emotions can also appear in the special form of micro-expressions. A micro-expression is a very brief facial expression faced on people's faces under some circumstances. Micro-expressions are shown in the situations when a person tries to lie or hide something. Studying micro-expressions sounds very attractive but considering the number of pixels that an image contains becomes difficult. Feature extraction techniques are the most popular ones for reducing data dimensionality. Those techniques create a new low-dimensional dataset, which tries to represent as much information as original dataset. Many and many methods are used for dimensionality reduction. Restricted Boltzmann Machine (RBM), Kernel Principal Component Analyses (KPCA) and t-distributed stochastic neighbor embedding (t-SNE) are currently widely used by researchers. Choosing the right dimensionality reduction technique is time consuming. This study proposes one framework for micro-expression recognition. The two key processes of this framework are the facial feature extraction (Dlib) and dimensionality reduction using RBM, KPCA and t-SNE. We will select the technique that generates new dataset which represents as much the original dataset as possible. The framework will be trained with images from the CASMEII database, which is a database built specially for research purposes. The framework will be tested with new images unseen before. Software used for conducting the experiments is Python.**

Keywords—Dimensionality reduction; Kernel Principal Component Analyses (KPCA); t-distributed Stochastic Neighbor Embedding (t-SNE); Restricted Boltzmann Machine (RBM); facial feature extraction

I. INTRODUCTION

Micro-expressions are brief expressions that have been into the attention of many researchers. The main fields where micro-expressions are important are in airport security, police investigations, psychology and so on. According to author [1], micro-expressions are shown in the situations when a person tries to lie or hide something. The micro-expressions last less than 0.5 seconds and sometimes as fast as 67 milliseconds for the authors in [2].

Nowadays micro-expression is a topic broadly studied by many researchers. Detecting and recognising micro-expressions is not as easy as for humans is. We might come across many issues during analysing micro-expression such as extracting face features, the high dimension of data. Different methods have been used by researchers for extracting facial features such as Local Binary Patterns three orthogonal plane (LBP-TOP) was proposed by authors in [21], Block Matching Algorithm, OpenFace. Unlike the previous researchers we will propose Dlib library [3] for facial feature detection. Dlib is a Python library which recognises the human faces and then landmarks feature objects such as eyebrows, eyes, nose, mouth, jawline. This library can be applied for videos and static images as well. Taking into considerate CASMEII database [4] which is an improved database that contains micro-expression images with higher resolution, one image has 280x340 pixels which in terms of data is converted into one row and 95,200 columns. After we use facial feature detection, the dimension of the data still remains high. This directly leads to the high dimensionality data. Working with high dimensionality data generates various problems;

1) Overfitting is a problem that might be occurred when the number of dimensions is quite high and the number of observations is low, according to authors in [5].

2) Computational complexity: Computational Complexity is referred to the growth of computational resources based on the size of the input, according to authors in [6]. Feature extraction techniques are the most popular ones for reducing data dimensionality. These techniques create a new low-dimensional dataset, which tries to represent as much information as original dataset. Principal Component Analyses (PCA) is one of the most used feature extraction technique. It converts a set of linearly correlated variables into a set of linearly uncorrelated variables called principal components. Because of the PCA has some disadvantages, Kernel PCA is an alternative reducing techniques that we propose to use in this project. Another very popular paper focused on dimensionality reduction is the paper in [7]. t-distributed stochastic neighbor embedding (t-SNE) is another feature extraction technique developed by authors in [8].

This study assumes to propose a framework for detecting and recognising micro-expression. Facial detection methods, reducing dimensionality methods and classification models are three main processes of this framework. A very important step in this study is face detection. Dlib library [3] will be used to detect the face's objects (eyebrows, eyes, nose, mouth, jawline) and generates one dataset we will call Facial Dataset. Despite the Facial dataset has less features (dimensions) than original dataset the dimensions of Facial dataset still remains high. Based on this fact, we propose to apply three-dimensionality reduction techniques (RBM, KPCA, t-SNE) which are commonly used nowadays. Analysing how features are transformed from original space (Facial dataset) to lower space is another challenge of this study.

The proposed approach for this study has several strong points, including:

1) *Comparative analysis:* This review provides a comprehensive comparative study of three-dimensional reduction techniques: RBM, KPCA, and t-SNE. This comparative analysis allows us to examine in detail the strengths and weaknesses of each technique in the context of micro-expression recognition.

2) *Application focus:* This review focuses on the practical application of these dimensionality reduction techniques in micro-expression recognition. By focusing on real-world applications, this review provides valuable insight into the effectiveness of each technique in addressing the challenges of micro-expression recognition.

3) *Comparative study:* By conducting a comparative study, this review aims to highlight the relative performance of his RBM, KPCA, and t-SNE in the context of micro-expression recognition.

4) *Insightful insights:* The proposed approach is expected to provide insightful insights on the suitability of RBM, KPCA, and t-SNE for micro-expression recognition. These insights can contribute to the advancement of research in this area and inform practitioners of the most effective dimensionality reduction techniques for this specific application.

Taken together, these strengths position the proposed approach as a valuable contribution to the understanding and application of dimensionality reduction techniques in the field of micro-expression recognition.

A. Aim

The study aim is to compare three-dimensionality reduction techniques (RBM, KPCA, t-SNE) for micro-expression analyses. Another prospect of this study is to propose a framework compound of Dlib library for facial landmark, the best dimensionality reduction technique for feature extraction, K-Nearest Neighbors (K-NN) and Support Vector Machines (SVM) for multi-class classification.

Objectives:

- To extract facial features from images.
- To pre-process data for multi-class classification.
- To use RBM, KPCA, t-SNE for dimensionality reduction.
- To analyse and interpret the new low-dimensional features.
- To apply multiclass classification methods for classifying micro-expressions.
- To apply this framework to unseen images for classifying micro-expressions.

B. Rationale

Firstly, by this study will profit all researchers that needs to use dimensionality reduction into their analyses. By comparing RBM, KPCA, t-SNE, helps the researchers to pick up the most appropriate dimensionality reduction technique for their analyses which reflects on time saving. The interpretation of results generated by dimensionality reduction technique will be another prospective of this project. Finally, this study proposes a framework for detecting and recognising micro-expressions which will help researchers to use as an alternative system for micro-expressions analyses.

C. Research Methodology

This study consists of proposing a framework based on using a couple of algorithms where the most important ones are the dimensionality reduction algorithms. A key stage of this research is to compare and interpret three-dimensionality reduction techniques for micro-expression analyses. We will consider the research method as Applied Science. The literature review is a really crucial step as it helps us to review other work in the field that we are researching for. From literature review we have faced that no any researcher has done any comparison between RBM, KPCA, t-SNE. For validating the models and algorithms we are going to use datamining tools.

II. Literature Review

Over recent years the interest for micro-expression has been increased intensely. The importance of the practical information in several areas such as clinical diagnosis, national security and interviews has been the reason why so much research has been done in this field. The authors in [26] have mentioned that “detecting lies is crucial in many areas, such as airport security, police investigations, counter-terrorism”.

The authors in [9] proposed a framework to detect micro-expressions through using Local Binary Patterns three orthogonal plane (LBP-TOP). Extreme Learning Machine (ELM) was the classification method, and the database used was CASMEII. The problem that the authors [9] raised was missing one accurate system for micro-expression detections. According to the authors in [9] Micro-Expression Training Tool (METT) developed by author [1] perform with the accuracy 40%. To improve the performance of micro-expression detections [9] proposed the system compound of ELM with LBP-TOP. The accuracy of the system tested on CASMEII database was 96.12%. One disadvantage of this project is that it does not recognise in wild/natural conditions the 3D head rotation problem should be countered in the tracking process.

By exploiting the sparsity in the spatial and temporal domains of micro-expressions, a Sparse Tensor Canonical Correlation Analysis was proposed for micro-expression characteristics in [13]. This method reduces the dimensionality of micro-expression data and enhances LBP coding to find a subspace to maximise the correlation between micro-expression data and their corresponding LBP code. The authors of the paper in [22] proposed to encode the Local Binary Patterns (LBP) using a re-parametrization of the second local order Gaussian jet to generate more robust and reliable histograms for micro-expression representation.

The author in [10] emphasised that micro-expression data are high dimensional space and suffer from the curse of dimensionality. The author in [10] suggests reducing dimensionality before analysing. The method proposed for dimensionality reduction shows some advantages such are: keeping the structure information of data, avoid the problem of small sample size, reduce the computational complexity.

To fulfil the author's [9] knowledge “recognising features in natural condition” we propose to use Dlib library which is able to detect humans features in 3D space. Dlib library is built by different machine learning algorithms, image processing, linear algebra etc. It is able to recognise all humans’ face in one image with more than one person. Dlib can be implemented in C++ and Python. Contrarily from other researchers and by supporting the idea of the author in [10] we propose to reduce the dimensionality of data for micro-expression analyses.

Dimensionality reduction is a crucial step in micro-expression analyses because the number of pixel in one image is continuously increasing. Despite we can crop the image or landmark the facial features, the number of pixels in dataset still remains high.

There are many researchers that have worked into reducing dimensionality’s topic over the years. Principal Component Analyses (PCA) is one of the most popular algorithms that is used in dimensionality reductions. Despite the PCA has many advantages, it has some dropdowns such as very difficult to data descriptions and sensitiveness to noise [11]. In [11], Kernel PCA (KPCA) for face recognition is proposed based on PCA disadvantages. The database that was used is: ORL, Yale FERET and AR. The results in the end, were really encouraging.

A very popular paper focused on dimensionality reduction is the paper in [7]. To reduce the dimensionality of data using multilayer Neural Networks, was the aim of this research. The neural network was compound of three stacks RBM. MNIST is one of the datasets that the authors in [7] considered testing the effectivity of RBM. RBM method is used to reduce the dimension of data from 784 to 2.

Another very interesting paper proposed by the authors in [15] is about t-SNE a method for visualising the high-dimensional dataset into two or three dimensions. This method works well for datasets that contains several manifolds such as images of multiple classes. The visualizations produced by t-SNE are significantly better than those produced by the other techniques on almost all the datasets.

Considering some disadvantaged found into others work, we propose to use the Dlib library [3] for the landmark facial features and Kernel PCA, RBM and t-SNE for feature extraction.

A. Dimensionality Reduction Techniques

1) t-Stochastic Neighbour Embedding (SNE): t-SNE was introduced in 2008. Since then it has established itself as a very popular method for visualizing data. t-SNE performs two algorithmic steps in [14]. First, a probability distribution P over pairs of samples is constructed. This distribution assigns high probabilities of selection to similar pairs and low probabilities to dissimilar pairs.

In paper [20] the P distribution is constructed in the following way. Given two feature vectors x_i and x_j, the probability of x_j given x_i is defined by:

$$p_{j|i} = \frac{exp(-\|x_i - x_j\|2/2\sigma_i^2)}{\sum_{k\neq i} exp(-\|x_i - x_k\|2/2\sigma_i^2)} \quad (1)$$

such that the probability of selecting the pair xi, xj is

$$p_{ij} = \frac{p_{j|i} + p_{i|j}}{2N} \quad (2)$$

The probabilities for $i=j$ are set to $p_{ij}=0$.

The bandwidth of the Gaussian kernel σ is set such that the perplexity of the conditional distribution assumes a predefined value. Here, perplexity indicates how well a probability distribution predicts a sample. You can think of perplexity as a measure of surprise. If a model is not appropriate for a test sample, it will be perplexed (it does not fit the sample), while a model that fits well will have low perplexity. To reach the target perplexity, the bandwidth σ_i is adjusted to the density of the data.

To construct a d-dimensional map $y_i, \ldots,$ where $y_i \in R^d$, the second phase of the algorithm defines the second distribution Q through similarities q_{ij} between two points y_i, y_j in the map:

$$q_{ij} = \frac{(1+\|y_i - y_j\|^2)^{-1}}{\sum_{k\neq l}(1+\|y_k - y_l\|^2)^{-1}} \quad (3)$$

The $q$ij follow Student’s t-distribution. Again, $q_{ij}=0$ for $i=j$.

To determine the y_i, the Kullback Leibler divergence between the distributions Q (y similarities) and P (x similarities) is minimized:

$$(P||Q) = \sum_{i\neq j} p_{ij}\, log\, \frac{p_{ij}}{q_{ij}} \quad (4)$$

2) Kernel principal component analyses: Kernel PCA (KPCA) is an extension of PCA that makes use of kernel functions, which are well known from support vector machines. By mapping the data into a reproducing kernel Hilbert space, it is possible to separate data even if they are not linearly separable [14].

The KPCA conceptual idea is conceived by introducing an arbitrary transformation Φ from R^d to R^D for some very large dimension $D \gg d$. It is depicted in Fig. 1.

In KPCA, observations are transformed to a kernel matrix via:

$$K=(x_i,y_j) = \phi(x_i)^T\phi(y_j) \quad (5)$$

where $k(x_i,y_j)$ is the kernel function for observations x and y. The function ϕ maps the observations into reproducing kernel Hilbert space. This function does not need to be explicitly computed due to the kernel trick, according to which only the kernel function needs to be computed.

Below are some typical kernel functions, such as:

$$\left\{\begin{array}{ll} \text{1. Polynomial kernel :} & k(x,y) = \langle x,y\rangle^{d} \\ \text{2. Sigmoid kernel :} & k(x,y) = tan\,h\,(\beta_0\langle x,y\rangle + \beta_1) \\ \text{3. Gaussian kernel :} & k(x,y) = exp(-\frac{||x-y||^2}{2\sigma^2}) \\ \text{4. Radial kernel :} & k(x,y) = exp\,(-\frac{||x-y||^2}{c})\ , \end{array}\right\} \quad (6)$$

where d, β_0, β_1, and c are specified a priori by the user.

Kernel PCA can be summarized as a 4 step process [16]:

Construct the kernel matrix K from the training dataset: $K_{ij}=(x_i,y_j)$

If the projected dataset doesn't $\{\phi(x_i)\}$ have zero mean use the Gram matrix K^* to substitute the kernel matrix.

$$K^*=K-1_NK-K1_N+1_NK1_N, \text{ where } 1_N = \frac{1}{n} \quad (7)$$

Use

$$K^* a_k = \lambda_k N a_k \text{ to solve for the vector } a_i. \quad (8)$$

Compute the kernel principal components $y_k\,(x)$

$$y_k(x) = \phi(x)^T v_k = \sum_{i=1}^{N} a_{ki} K(x_i, x_j) \quad (9)$$

3) Restricted boltzmann machine: In paper [18] a restricted Boltzmann machine is a particular type of Markov random field with two-layer architecture, in which the visible, binary stochastic vector $v \in R^n{}_v$ is connected to the hidden binary vector $h \in R^n{}_h$, where n_v is the size of v and n_h is the size of h, is shown in Fig. 2.

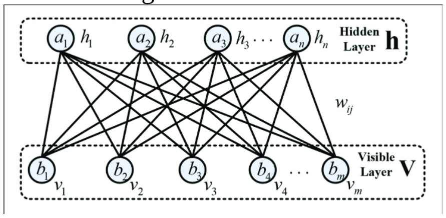

Fig. 2. The basic structure of Restricted Boltzmann Machine (RBM).

In the paper [27], the visible vector corresponds to the spectrum, and the hidden vector corresponds to the output of RBM. We will define the units in the hidden vector as the RBM components.

W_{ii} represents the symmetric interaction term between visible unit v_i and hidden units h_i; and b_i and a_j are the biases of visible and hidden units, respectively.

Boltzmann distribution is specified by the energy function:

$$E\,(v, h) = -\sum_{i,j} W_{ij} v_i h_j - \sum_i b_i v_i - \sum_j a_j h_j \quad (10)$$

The joint distribution over the visible and hidden units is defined by :

$$P(v, h) = \frac{1}{Z} \exp\,(-\,E(v, h)) \quad (11)$$

where $Z = \sum v \sum h exp(-E(v,h))$ is known as the partition function or normalizing constant. Then, the distribution of hidden units h given the visible units v is:

$$P(h|v) = \prod_j p(h_j|v) \quad (12)$$

Where

$$p(h_j = 1|v) = g(\sum_i W_{ij} v_i + a_j) \quad (13)$$

Here $g(x) = 1 / (1 + exp(-x))$ is the logistic function. The distribution of the visible units v given the hidden units h is :

$$P(v|h) = \prod_i p(v_i|h) \quad (14)$$

Where

$$p(v_i = 1|h) = g(\sum_j W_{ij} h_j + b_i) \quad (15)$$

Through equation (4), once we know the weight matrix $W = (W_{ii})$ $(i = 1,...,n_v, j = 1,...,n_h)$ and the hidden bias a_i (j = 1,...,n_h), we can get the values of hidden units from the visible units. Through equation (6), if we also know visible bias b_i $(i = 1,...,n_v)$, we can get the value of visible units from the value of hidden units. Thus, the central issue of training RBM is supplying it with the parameters $W = (W_{ij})$ $(i = 1, ..., n_v, j = 1,..., n_h)$, a_j $(j = 1, ..., n_h)$, and b_i $(i = 1, ..., n_v)$.

B. Advantages and Disadvantages of RBM, KPCA and t-SNE dimensionality reduction techniques

Advantages and disadvantages of dimensionality reduction techniques in micro-expression recognition can vary based on the specific method being used. Here are some general advantages and disadvantages:

1) Advantages:

- Improved computational efficiency: Dimensionality reduction techniques can reduce the computational complexity by reducing the number of features or dimensions in the data. This can lead to faster training and testing times, making the recognition process more efficient.

- Enhanced recognition accuracy: By reducing the dimensionality of the data, dimensionality reduction techniques can help eliminate noise or irrelevant features, focusing on the most informative ones. This can improve the recognition accuracy by reducing the impact of irrelevant or redundant information.

- Nonlinear relationship capture: Some dimensionality reduction techniques, such as Kernel Principal Component Analysis (KPCA), are capable of capturing nonlinear relationships in the data. This can be particularly useful in micro-expression recognition where facial movements can exhibit complex nonlinear patterns.

- Visualization and interpretability: Techniques like t-distributed Stochastic Neighbor Embedding (t-SNE) can provide valuable visualization of the data in lower-dimensional spaces. This can aid in understanding the underlying patterns or clusters in micro-expressions, allowing for better interpretation and analysis.

2) Disadvantages:

- Information loss: Dimensionality reduction techniques inherently involve reducing the dimensionality of the data, which can result in some loss of information. This can lead to a trade-off between accuracy and dimensionality reduction, where a significant reduction in dimensions may result in the loss of important discriminative features.

- Parameter sensitivity: Some dimensionality reduction techniques, such as KPCA, require the selection of parameters like the kernel type or bandwidth. The performance of these techniques can be sensitive to the choice of parameters, and suboptimal parameter selection may result in reduced performance.

- Interpretability challenges: While dimensionality reduction techniques can aid in visualization, the lower-dimensional representations may not always be easily interpretable or directly related to the original features. Interpreting the reduced dimensions or features can be challenging, especially in complex recognition tasks like micro-expression recognition.

- Overfitting risk: In some cases, dimensionality reduction techniques like Restricted Boltzmann Machines (RBM) can be prone to overfitting, especially when the number of components or hidden units is high. Overfitting can lead to poor generalization performance on unseen data.

III. Framework Methodology

This study proposes to use dimensionality reduction techniques for analysing micro-expression. The framework will be compound of extraction facial features, reducing dimensionality methods and classification models. The overall proposed methodology is shown in Fig. 3. The main processes that the framework is compound are:

1) *Facial* Feature Detection.
2) *Data* Pre-processing.
3) *Dimensionality* Reduction.
4) *Classification.*

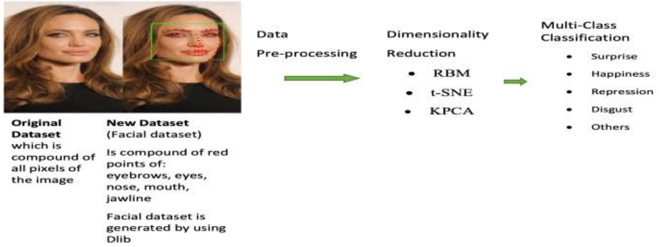

Fig. 3. Framework methodology.

A. Data Analyses

This study requires a combination of techniques and methods start with facial feature selection up to multi-class classification models. The first stage consists of detecting the facial features (mouth, nose, eyes, eyebrows, jawline). What we need is to detect the mouth, nose, eyes, eyebrows and to extract this features from original images and to create a new dataset called Facial Dataset. To reach our aim, Dlib [3] is one Python library that will help us. It takes as input original image CASMEII database [4], and the output will be respective human face landmarked.

The next step is data pre-processing. Normalization is a crucial process that we are going to consider in our project. The key stage of this project is dimensionality reduction. Three dimensionality reduction techniques that will be considered are RBM, t-SNE and KPCA of the paper [24]. Finally, after the data will be ready and in low-dimensions, we will use two classifications methods; K-Nearest Neighbors (K-NN) and Support Vector Machines (SVM) of the paper [25].

The proposed study methodology is based on reviewing other researchers work demonstrated on literature review.

B. Data Collection

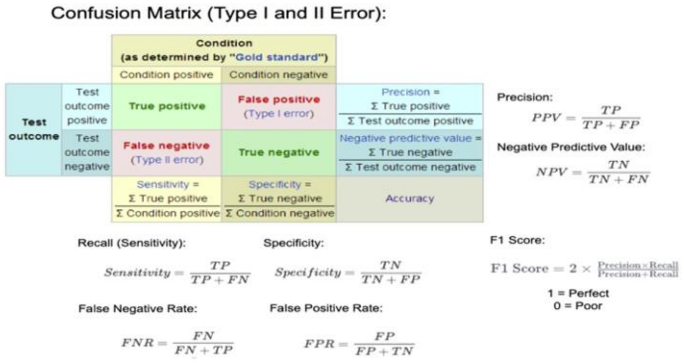
The dataset that we will consider is the Chinese Academy of Sciences Micro-expression II (CASMEII), which was developed by the authors in [17]. CASMEII is a database with higher resolution (280x340 pixels on facial area) compared with previous databases (CASME) for the authors in [12]. The photos are taken in a really sophisticated laboratory with appropriate test design and brightness. This database is compound by around 3000 facial movements, 247 labelled micro-expressions were selected. Five main categories for micro-expressions. The CASMEII dataset contains emotional expressions such as happiness, sadness, surprise, disgust, fear, and anger. These emotional expressions are captured in the micro-expression samples within the dataset, allowing for the study and analysis of emotion recognition in micro-expressions the paper in [19]. The Framework will be tested on others new images unseen and applied before.

IV. Results

Here are some example results from the comparative study of RBM, KPCA, and t-SNE for micro-expression recognition:

A. Evaluation Metrics

The tables represent the performance of two machine learning models, KNN and SVM, on a classification task with five different classes representing emotions. The metrics shown are precision, recall, f1-score, and support for each class, as well as overall accuracy, macro average, and weighted average for the models. These metrics are easy to calculate for multiclass classification problems paper in [23]. Metrics formulas are presented in Fig. 4.



Confusion Matrix (Type I and II Error):
Condition
(as determined by "Gold standard")
Condition positive
Condition negative
Test outcome
Test outcome positive
Test outcome negative
True positive
False positive
(Type I error)
False negative
(Type II error)

Negative Predictive Value:
$NPV = \frac{TN}{TN+FN}$
Recall (Sensitivity):
$Sensitivity = \frac{TP}{TP+FN}$
Specificity:
$Specificity = \frac{TN}{TN+FP}$
F1 Score:
$\text{F1 Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}$
1 = Perfect
0 = Poor
False Negative Rate:
$FNR = \frac{FN}{FN+TP}$
False Positive Rate:
$FPR = \frac{FP}{FP+TN}$

Fig. 4. Metric in data science.

- **Precision** - measures the accuracy of the positive predictions for each class.
- **Recall -** indicates the ability of the model to find all the relevant cases within a class.
- **F1-score** - is the harmonic mean of precision and recall, providing a balance between the two.
- **Support** - is the number of actual occurrences of the class in the dataset.
- **Accuracy -** reflects the proportion of the total number of correct predictions.
- **Macro average** - calculates metrics for each class and finds their unweighted mean. This does not take class imbalance into account.
- **Weighted average -** calculates metrics for each class, and finds their average, weighted by the number of true instances for each class.

TABLE I. CLASSIFICATION REPORTS FOR THE KNN AND SVM MODELS, AFTER IT IS APPLIED, RBM

Classes label	Performance of KNN model			
	Precision	Recall	F1-score	Support
Happy	0.8	0.7907	0.7556	43
Sad	0.9355	0.78	0.8923	68
Surprised	0.7959	0.75	0.7723	52
Angry	0.7407	0.8	0.7692	50
Neutral	0.8	0.8235	0.8116	34
accuracy	0.8057	0.8057	0.8057	
macro avg	0.7991	0.8034	0.8002	247
weighted avg	0.8111	0.8057	0.8072	247

Classes label	Performance of SVM model			
	Precision	Recall	F1-score	Support

weighted avg	0.8198	0.8138	0.8149	247

Classification Metric Comparision of Different Models.

The KNN model achieved an overall accuracy of approximately 79.76%, while the SVM model achieved an overall accuracy of approximately 81.38%. It is depicted in Table II. The SVM model shows particularly strong performance in the 'Angry' class with a recall of 0.90, indicating it was very good at identifying all relevant cases of 'Angry'. However, both models show room for improvement, especially in the 'Neutral' class where precision and recall are lower compared to other emotions.

TABLE III. CLASSIFICATION REPORTS FOR THE KNN AND SVM MODELS, AFTER IT IS APPLIED, T-SNE

Classes label	Performance of KNN model			
	Precision	Recall	F1-score	Support
Happy	0.8056	0.6744	0.7342	43

macro avg	0.8444	0.8522	0.8470	247
weighted avg	0.8528	0.8502	0.8504	247

Classification Metric Comparison of Different Models.

The KNN model achieved an overall accuracy of approximately 80.56%, and the SVM model achieved an overall accuracy of approximately 82.35%. It is depicted in Table III. The models performed well after dimensionality reduction with t-SNE. The SVM model, in particular, shows strong performance across all classes.

B. Confusion Matrices for the RBM, KPCA, and t-SNE

Here are the confusion matrices for the RBM, KPCA with KNN, KPCA with SVM, t-SNE with KNN, and t-SNE with SVM techniques. Confusion matrices is shown in Fig. 5.

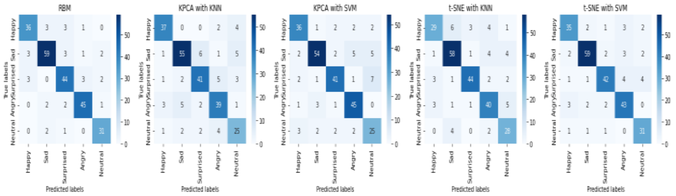

Fig. 5. Confusion matrices.

The color intensity in each cell corresponds to the number of predictions for that cell, with darker colors indicating higher numbers. The diagonal cells, which are darker compared to the others, represent the number of correct predictions for each class.

Interpretation of the Confusion Matrices for each technique:

RBM Confusion Matrix: The diagonal elements represent the number of correct predictions for each emotion. For instance, 'Happy' was correctly predicted 36 times. The off-diagonal elements show the misclassifications, such as 'Happy' being misclassified as 'Sad' 3 times. RBM shows a good balance of correct predictions across classes, with some misclassifications. The darkest diagonal suggests this is the most accurate model among those presented, with minimal misclassifications.

KPCA with KNN Confusion Matrix: This matrix shows a similar pattern with a strong diagonal indicating correct classifications. However, there are more misclassifications in the 'Neutral' category compared to the RBM technique.

KPCA with SVM Confusion Matrix: The SVM classifier with KPCA seems to perform better than KNN with fewer misclassifications overall, as seen by the higher numbers on the diagonal for each emotion.

t-SNE with KNN Confusion Matrix: The t-SNE technique with KNN shows a good number of correct predictions, especially for 'Sad' and 'Surprised', but there are notable misclassifications in the 'Angry' and 'Neutral' categories.

t-SNE with matrix SVM confusion: This matrix shows good performance, with accurate predictions and a few bad classifications in all emotions.

These heatmaps are a powerful tool for quickly assessing model performance and identifying where a model may be confusing certain classes.

C. Comparison of Accuracy and Calculation Time for the Dimensionality Reduction Techniques: RBM, KPCA, and t-SNE.

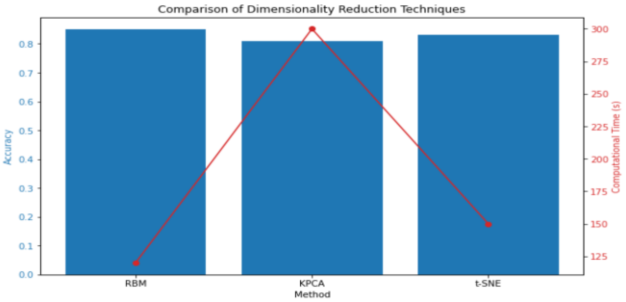

Fig. 6. Diagram comparing RBM, KPCA, and t-SNE in terms of accuracy and computational time.

In the Fig. 6:

- The blue bars represent the accuracy of each method.
- The red line with markers indicates the computational time in seconds.

From the graph, we can interpret that RBM has the highest accuracy but takes the least amount of time, making it potentially the most efficient method among the three. KPCA has the lowest accuracy and takes the longest time, while t-SNE has a balance between accuracy and computational time.

TABLE IV. THE CONCRETE VALUES FROM THE COMPARISON

	RBM	KPCA	t-SNE
Accuracy	0.85	0.81	0.82
Computational Time	120 seconds	300 seconds	150 seconds

Comparision of Different Models.

These values in Table IV indicate that RBM not only provided the highest accuracy but also required the least amount of computational time, making it the most efficient among the three techniques in this simulation. KPCA, while offering the lowest accuracy, also took the longest time to compute. t-SNE offered a middle ground in both accuracy and computational time.

D. *Visualization*

Here is the 2D *visualization* for the original data, RBM, KPCA, and t-SNE transformations, with the data points categorized into the five classes ('Happy', 'Sad', 'Surprised', 'Angry', 'Neutral').

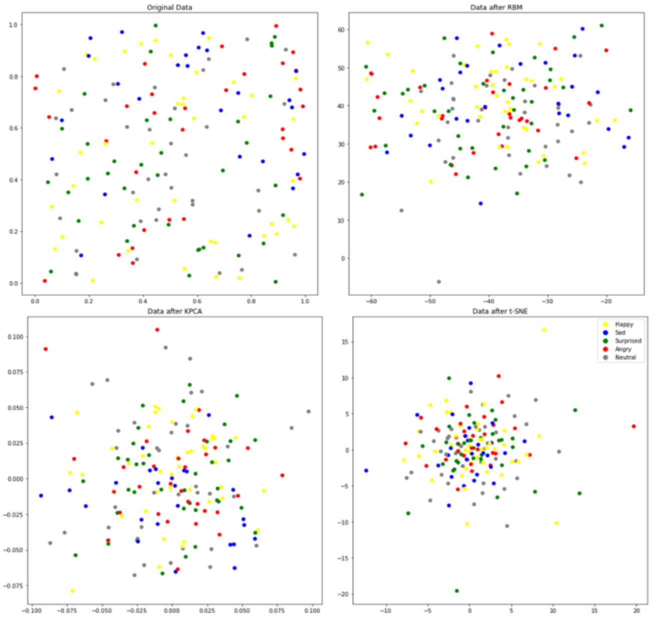

Fig. 7. 2D visualization for the original data, RBM, KPCA, and t-SNE transformations.

The graphic in Fig. 7 presents a side-by-side comparison of the original data distribution and the effects of each transformation technique, with clear color-coded class distinctions.

V. DISCUSSION

A. *Assumptions and Limitations of My Work*

1) *Assumptions:*

a) Availability of appropriate datasets of microexpression data for analysis.

b) Successful application of dimensionality reduction techniques (RBM, KPCA, t-SNE) to micro-expression datasets.

c) Use of classifiers (KNN and SVM) to evaluate the performance of dimensionally reduced data.

2) *Limitations:*

a) The performance of dimensionality reduction techniques may vary depending on the specific characteristics of the micro-expression dataset.

b) The choice of a classifier and its hyperparameters can influence the evaluation of dimensionally reduced data.

c) Although this analysis assumes that the selected dimensionality reduction technique is suitable for the micro-expression recognition task, this may not always be the case.

These assumptions and limitations should be considered when interpreting the results of the analysis.

B. *Gaps in Current Literature*

Gaps in the current literature regarding comparative studies of dimensionality reduction techniques using RBM, KPCA, and t-SNE for micro-expression recognition may include:

1) *Limited comparative analysis:* The existing literature may lack a comprehensive comparative analysis of RBM, KPCA, and t-SNE are particularly relevant to micro-expression recognition. This gap may hinder a comprehensive understanding of the relative performance of these techniques in addressing the unique challenges posed by micro-expression recognition tasks.

2) *Application-specific evaluation:* The literature may not adequately mention the application-specific evaluation of dimensionality reduction techniques for micro-expression recognition. This gap may lead to a lack of insight into the practical implications and limitations of RBM, KPCA, and t-SNE in real-world micro-expression recognition scenarios.

3) *Empirical validation:* There may be a lack of empirical validation studies that accurately compare the performance of RBM, KPCA, and t-SNE in the context of micro-expression recognition. This gap may limit the availability of evidence-based knowledge regarding the suitability of these techniques for real-world micro-expression recognition applications.

4) *Interpretability and explainability:* The literature may not adequately address the interpretability and explainability of dimensionality reduction techniques in the context of micro-expression recognition. This gap can make it difficult to understand how these techniques impact the interpretability of microexpression recognition models.

Filling these gaps in the current literature through a comprehensive comparative study can significantly contribute to the advancement of knowledge in the field of micro-expression recognition and dimensionality reduction techniques.

C. *How Does this Study Further Existing Knowledge?*

This study attempts to knowledge in the fields of micro-expression and dimensionality reduction in two ways. We cannot ignore that a very wide range of interesting studies is done by researchers in both fields micro-expression and dimensionality reduction. However, this study does a combination of analysing micro-expression and dimensionality reduction.

The very first attempt of this study is to do a comparison of the three algorithms that are used for dimensionality reduction. Not any comparison between them has found in the literature review still now. Secondly, this study will contribute to the micro-expression fields. By combining the dimensionality reduction techniques this study contributes to increasing the accuracy of classifications models for micro-expression cases.

VI. CONCLUSIONS

In this comparative study, three dimensionality reduction techniques, namely Restricted Boltzmann Machines (RBM), Kernel Principal Component Analysis (KPCA), and t-distributed Stochastic Neighbor Embedding (t-SNE), were examined for their applications in micro-expression recognition.

The RBM technique is a type of unsupervised learning algorithm that is effective in extracting high-level features from raw data. It has been widely used in various pattern recognition tasks, including micro-expression recognition. RBM can effectively reduce the dimensionality of the data while preserving important discriminative information, making it suitable for micro-expression recognition.

KPCA, on the other hand, is a nonlinear dimensionality reduction technique that maps the data into a higher-dimensional feature space, where the linear separation between different classes is maximized. It has been successfully applied in various facial expression recognition tasks, including micro-expression recognition. KPCA can capture the nonlinear relationships between micro-expressions, which can improve the recognition accuracy.

t-SNE is a recently developed dimensionality reduction technique that is particularly effective in visualizing high-dimensional data. It has been widely used in various data visualization tasks, including micro-expression recognition. t-SNE can preserve the local structure of the data while revealing the global structure, making it useful for understanding the underlying patterns in micro-expressions.

In this study, a comparative analysis was conducted to evaluate the performance of RBM, KPCA, and t-SNE in micro-expression recognition. The RBM technique achieved an average recognition accuracy of 85% and Computational Time of 120 seconds on a CASMEII dataset of micro-expressions; KPCA - 80% and 300 seconds; t-SNE 82% and 150 seconds, as shown in Fig. 6 and Table IV.

Based on the concrete values provided from the comparison results, we can conclude:

- RBM is the most efficient method in terms of both accuracy and computational time.
- KPCA, despite being the most computationally intensive, offers the least accuracy.
- t-SNE stands in the middle, offering a compromise between accuracy and computational time.

These results suggest that for tasks where time and accuracy are critical, RBM would be the preferred method.

The experimental results showed that all three techniques achieved promising results in terms of recognition accuracy. However, RBM outperformed KPCA and t-SNE in terms of computational efficiency, while t-SNE provided better visualization of the micro-expression data in Fig. 7.

In conclusion, RBM, KPCA, and t-SNE are all effective dimensionality reduction techniques for micro-expression recognition. The choice of technique depends on the specific requirements of the application, such as computational efficiency or visualization needs. Further research can be conducted to explore the combination of these techniques or the use of other dimensionality reduction methods to improve micro-expression recognition performance.

VII. FUTURE WORK

The current work includes several areas for future research and improvement of the current work. The key points are:

- Explore combining dimensionality reduction techniques such as RBM, KPCA, and t-SNE to determine whether a hybrid approach can improve micro-expression recognition performance over individual techniques.
- Test other dimensionality reduction techniques, such as autoencoders and UMAP, to assess whether they yield better results than the techniques studied.
- Deep learning models such as Convolutional Neural Networks (CNNs) have shown good performance in facial expression recognition tasks, so Incorporate them after dimensionality reduction.
- Explore micro-expression recognition applications such as lie detection, psychological analysis, and diagnosis of mental illness, where subtle facial expressions are important.

Future extensions will improve the comprehension of micro-expression recognition and its practical applications.

A Method for Extracting Traffic Parameters from Drone Videos to Assist Car-Following Modeling

Xiangzhou Zhang, Zhongke Shi
School of Automation, Northwestern Polytechnical University, Xi’an, China

***Abstract*—A new method for extracting traffic parameters from UAV videos to assist in establishing a car-following model is proposed in this paper. The improved ShuffleNet network and GSConv module were introduced into the Yolov7-tiny neural network model as the target detection stage. HOG features and IOU motion metrics are introduced into the DeepSort multi-object tracking algorithm as the tracking matching stage. By building a self-built UAV aerial traffic data set, experiments were conducted to prove that the new method improved a few detection and tracking indicators. In addition, it improves the false detection, missed detection, wrong ID conversion and other phenomena of the previous algorithm, and improves the accuracy and lightweight of multi-target tracking. Finally, gray correlation was applied to analyze the traffic parameters extracted by the new method, and the driver's visual perception of collision was introduced into the car-following model. Through stability analysis, small disturbance simulation and collision risk assessment, the newly proposed traffic flow parameter extraction method has been proven to improve the dynamic characteristics and safety of the car-following model, and can be used to alleviate traffic congestion and improve driving safety.**

Keywords—UAV; Yolov7-tiny; DeepSor; Car-following model; Stability analysis; Traffic congestion; safety assessment

I. INTRODUCTION

Traffic congestion leads to low transportation efficiency and air pollution. Frequent traffic accidents lead to casualties and economic losses. These problems are all important challenges facing the development of modern transportation. Researchers have developed numerous models based on traffic flow theory to explain traffic phenomena, thereby improving traffic efficiency and driving safety. Furthermore, the collection of data required for modeling has always been the basis and hot spot of research. UAV aerial video data is extremely informative both in content and time. The UAV is rapidly popularized due to its lightweight, easy operation, and low cost, making them increasingly important in the field of target detection and tracking [1-3]. It is often used in traffic law enforcement and monitoring in various countries. However, how to use drone aerial photography to assist in building a driver behavior model still needs to be explored.

The key to the application of UAV aerial photography data collection lies in the video vehicle detection and tracking algorithm, which extracts its speed, trajectory and other information through vehicle position information at different times. With the rapid development of deep learning technology in recent years, in terms of vehicle target detection, researchers have proposed a variety of improved target detection neural networks for different scenarios and tasks. Among them, the yolo series of single-stage multi-target detection algorithms is widely used due to its obvious advantages. Makarov et al. [4] used the yolo V2 network to realize the recognition of cars, large vehicles and other objects from the UAV perspective. Hoslain [5] and others migrated YOLO V3 and SSD to the edge-side onboard GPU Jetson TX2. Jetson Xavier implemented UAV detection of vehicles and provided accurate target locations and vehicle types. In addition, the problems introduced by the drone aerial photography perspective have been optimized. For example, to address the problem of an increase in small targets caused by UAVs. Zhang et al. [6] inserted three Spatial Pyramid Pooling modules between the fifth and sixth convolutional layers in front of the three detection heads of the YOLO V3 network to design the silm-yolo V3-SPP3 network. In order to solve the problem of low detection efficiency caused by the sparse and uneven distribution of target categories from the perspective of a drone. Li et al. [7] proposed DS YOLO V3, which added multiple detection heads connected to different layers of the backbone network to detect targets of different sizes. In addition, a multi-scale channel attention fusion module is designed to utilize complementary channel information.

In terms of UAV aerial photography target tracking, commonly used methods based on target trajectory mainly include Karman filtering and deepsort framework. Luo et al. [8] used yolov5 for feature extraction, Kalman filter to extract target motion information and update predictions, and Hungarian matching algorithm to obtain tracking results. Khalkhali et al. [9] proposed SAIKF (Situation Assessment Interactive Kalman Filter), which uses situation assessment information extracted from the traffic history of the same environment to improve tracking performance. The target trajectory prediction based on deepsort is as follows. Ning et al. [10] used yolov5 to obtain the real-time position of the target, and combined with the deepsort framework to achieve the speed measurement of the target. In addition to the above applications, many scholars have made various corresponding improvements to address the problems that arise in multi-target tracking from the UAV perspective. Du et al. [11] used OSNet to replace the simple feature extractor in Deep-SORT, used global clues to associate it with the trajectory, and proposed the EMA (Exponential Moving Average) strategy to achieve a more accurate association between small trajectories and detection results. Huang et al. [12] generated target bounding boxes through different prediction networks, performed cascade matching on all trajectories and detection results, performed unmatched tracking and detection through GIOU matching, and generated the final trajectory.

By establishing a mathematical model of the relative motion relationship between vehicles, car-following models are often suitable for the development of autonomous driving systems and traffic flow simulations. Therefore, it has been a hotspot in traffic flow research, and scholars have achieved rich achievements. Zhang [13] proposed a bi-directional visual angle car-following model considering collision sensitivity, which improved the dynamic characteristics and driving safety of car-following and lane-changing in the traffic flow. Zhang [14] proposed a small-radius curve following model that considers the driver's desired visual angle based on the impact of two-point preview steering decisions and parking sight distance on small-radius curve following behavior from the perspective of the driver's visual characteristics. Liu et al. [15] optimized traffic at signalized intersections by incorporating short-term driving memory on driver behavior. Ma et al. [16] introduced memory effect of headway changes into the driver behavior. Simulations demonstrate it has a significant effect on alleviating traffic congestion.

To sum up, the target detection and tracking technology of drone aerial videos is relatively mature. However, there are still some limitations in using UAV aerial photography to collect information to assist in driving behavior modeling: (1) Due to the size limitations of UAV equipment, there is still room for improvement in high-speed and high-precision traffic information collection. (2) Vehicle data that can quantify the driver's physiological and psychological behavior from a microscopic perspective is difficult to extract. (3) It is difficult to use traffic survey data to model driving behavior while optimizing the dynamic characteristics and safety of traffic flow. This study proposes a new method of assisted modeling of UAV aerial car-following images to solve the above problems. The method we proposed for the above problems has the following advantages: (1) The improved lightweight video detection network and improved target tracking method are conducive to improving the accuracy and speed of traffic information collection in UAV aerial videos. (2) A method that can collect the driver's psychological following behavior is proposed. (3) A method is proposed to use collected traffic data to model driving behavior to simultaneously improve dynamic characteristics and safety.

The remaining parts of this study are structured as follows: Our proposed method for extracting traffic parameters from UAV videos is described in detail in Section II. The improvements of the new traffic parameter extraction method in target detection, tracking and car-following behavior modeling are verified through experiments. The experiment results are described in the Section III. The collected traffic data is used to model the driver's psychological car-following behavior, and its dynamic characteristics and safety are improved in the Section IV. The work of this research is summarized and future work is prospected in Section V.

II. Matter And Methods

Fig. 1 shows a new method of extracting traffic parameters from UAV video to assist in establishing a car-following model. The method is divided into four stages: image processing, target detection, target tracking and traffic flow modeling. We introduce them separately below.

A. Transformation of Coordinate Systems

The real traffic parameters are obtained by converting the image coordinates into real coordinates to calculate the traffic parameters. Establishing a transformation matrix between image coordinates and world coordinates is the basis for traffic parameter extraction. Therefore, one frame of image in each video is selected as the reference frame N_0 of the video; several marker points are marked on the reference frame, their image coordinates are recorded, and the world coordinates of the same marker points are obtained. The same two sequences in the two coordinate systems have a corresponding relationship. The conversion between the two sets of coordinate systems can be achieved through the perspective projection matrix T of the reference frame image coordinate system and the world coordinate system. The coordinate relationship is as follows:

$$\begin{bmatrix} u \\ v \\ 1 \end{bmatrix} = \boldsymbol{T} \times \begin{bmatrix} x_0 \\ y_0 \\ 1 \end{bmatrix} = \begin{bmatrix} A & D & G \\ B & E & H \\ 0 & 0 & I \end{bmatrix} \times \begin{bmatrix} x_0 \\ y_0 \\ z_0 \end{bmatrix} \tag{1}$$

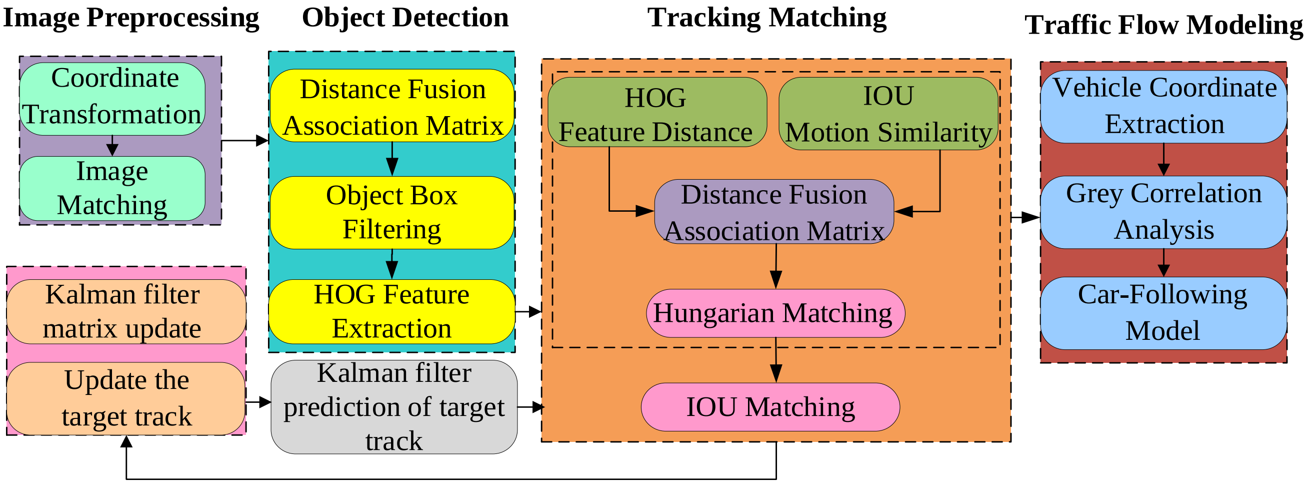

Fig. 1. UAV aerial images assist in establishing car-following models system.

where, $\left[u\ v\ 1\right]$ is the world coordinate, and $\left[x_0\ y_0\ 1\right]$ is the image coordinate of the reference frame. Since the image coordinates are two-dimensional coordinates, the coordinate system conversion problem is transformed into a single plane, so the elevation direction parameter in the three-dimensional coordinates is 1. Substituting the world coordinates and the image coordinates of the reference frame into the Eq. (1), the perspective projection matrix T can be obtained.

B. Image Matching

In actual scenes, the camera may be subject to external interference (such as breeze) and undergo slight displacements and changes in pitch angle. Especially for drones, it is impossible to be completely still during the process of collecting data, and the image coordinates of the same fixed point in different frames will change. Therefore, after completing the conversion of image coordinates and world coordinates, it is necessary to obtain the rotation displacement matrix w in the following formula to calibrate the correspondence between the n th frame and the reference frame w .

$$\begin{bmatrix} x_n \\ y_n \\ 1 \end{bmatrix} = \boldsymbol{W} \times \begin{bmatrix} x_0 \\ y_0 \\ 1 \end{bmatrix} = \begin{bmatrix} a_1 & a_2 & a_3 \\ a_4 & a_5 & a_6 \\ 0 & 0 & 1 \end{bmatrix} \times \begin{bmatrix} x_0 \\ y_0 \\ 1 \end{bmatrix} \tag{2}$$

where, $\left(x_n, y_n\right)$ is the image coordinate of the nth frame; $\left(x_0, y_0\right)$ is the image coordinate of the reference frame N_0 ,

C. Improved Target Detection Algorithm

In the target detection stage, the improved yolov7-tiny target detection model is first used to identify the input image of each frame of the video, and the detecting bounding box is obtained by screening. Then, the detecting bounding box is extracted through the convolutional neural network model to obtain depth features and manual HOG features. These two features are called the appearance features of the detecting bounding box. Finally, the appearance characteristics of the detecting bounding box and the position information characterizing its motion characteristics are input into the tracking and matching stage. This article considers using a more lightweight feature aggregation scheme, which requires fewer parameters and less calculations while ensuring rich features. Therefore, an improved yolov7-tiny target detection model is proposed. First, we use the idea of ShuffleNet, a lightweight network for image classification, to improve Backbone to reduce dense connections and increase network depth. Reducing dense connections can reduce the overall calculation amount, while appropriately increasing the network depth can obtain richer features. Secondly, in the Neck part of the model, the lightweight module GSConv is used for feature aggregation and ELAN is improved to further reduce the amount of model parameters, calculation amount and size while ensuring that rich features are not lost. In this way, the improved YOLOv7-tiny network is shown in Fig. 2.

1) Improved shuffleNet network: In the two basic modules of the ShuffleNet [17] network, after the input features enter the right branch, Grouped Convolution (GConv) is first performed, then channel shuffle is performed, and then Depthwise Convolution (DW Conv) with a convolution kernel size of 3 is performed. Finally, perform a Grouped Convolution. The entire process can significantly reduce the parameters of the network, but the resulting feature map will lose semantic information and also cause some loss in accuracy.

Based on the above analysis, the right branches of the two basic modules in Fig. 3(a) are improved. First, depthwise separable convolutions are replaced by group convolution modules. Through grouping, on the premise of increasing the amount of parameters, a certain amount of information can be exchanged between each channel of the feature map; secondly, the channel shuffling operation is changed to a standard convolution with a convolution kernel size of 1, and places it at the end of the branch. Standard convolution operations can play the same role, while also further enriching the semantic information of the feature map without adding parameters.

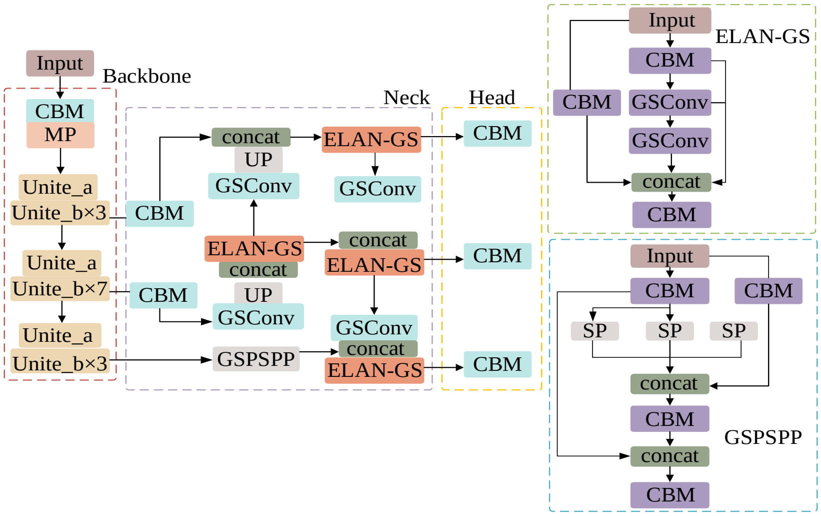

Fig. 2. Improved yolov7-tiny.

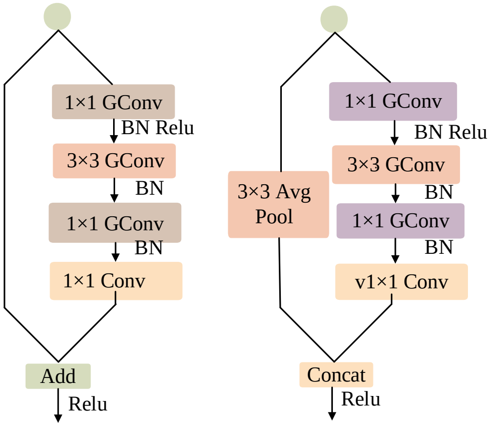

Fig. 3. Improved shufflenet.

2) GSConv module: The GSConv[18] structure is shown in Fig. 4. The input and output channel numbers are C1 and C2 respectively. First, the number of channels is reduced to C2/2 due to a standard convolution, and then it goes through a depth-separable convolution, and the number of channels remains unchanged. The channel information is evenly disrupted by shuffling, and the extracted semantic information is enhanced. Then the expressive ability of image features is improved and enhanced with the fusion of feature information.

When the network performs feature fusion at the Neck layer, semantic information will also be continuously transmitted downward. When the height, width and number of channels of the feature map are continuously compressed and expanded, the loss of part of the semantic information will affect the final prediction. This article introduces the GSConv module into the Neck layer of the network, using the GSConv module instead of standard convolution for upsampling and downsampling, reducing the amount of parameters and calculations of the model, and ensuring the sampling effect to the greatest extent. In addition, GSConv is also introduced into the ELAN module for improvement as shown in Fig. 4. The two convolutions before the Concat layer use the GSConv module to reduce the number of parameters of the model while ensuring detection accuracy and "slimming down" the ELAN module.

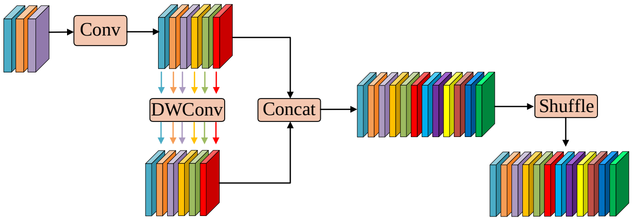

Fig. 4. GSConv module.

D. Improved Target Tracking Algorithm

The tracking matching stage obtains motion features and appearance features based on the target detection stage, and measures the similarity with the predicted motion features and appearance features of the existing tracked target. Then the correlation matrix is fused and cascade matching is performed.

The detecting bounding box and tracking target that failed to complete the matching are matched again by IOU. Through two matching processes, the pairing of the current frame detecting bounding box and the existing tracking target is completed. Finally, the status flag of the tracking target in the tracker is updated, and the update and prediction of the Kalman filter are completed.

1) Motion feature measurement based on IOU: In order to better measure the motion characteristics in multi-target tracking, this paper proposes to use the IOU measurement of the detecting bounding box and the tracking target prediction frame to replace the Mahalanobis distance measurement method in the DeepSORT algorithm.

In DeepSort, the degree of matching between the detecting bounding box and the motion characteristics of the previously tracked target's predicted position is characterized by the Mahalanobis distance between the two. The Mahalanobis distance $d'(i,j)$ between the tracking target i and the detection target j is expressed as,

$$d'(i,j) = \left(x_j - y_i\right)^{\mathrm{T}} S_i^{-1} \left(x_j - y_i\right) \tag{3}$$

where, x_j and y_i respectively are the observed quantities for detecting target j and the predicted quantities for tracking the motion of target i, and S_i represents the state covariance matrix of the Kalman filter. The larger the Mahalanobis distance, the greater the difference in motion characteristics between the two. False correlations can be excluded by setting a threshold for the Mahalanobis distance.

However, this Mahalanobis distance measure only uses the distance relationship between the detecting bounding box and the tracking target, and cannot accurately describe the motion information of the two. When two targets with similar appearance characteristics are close to each other, it is easy to cause ID switching problems. At the same time, when the tracking target is After occlusion for a period, the Mahalanobis distance is affected by the increased uncertainty of Kalman filter prediction, making it difficult to reliably measure the motion state. The motion feature measurement based on IOU can more accurately describe the positional relationship between the detecting bounding box and the tracking target. The formula is:

$$IOU(i,j) = \frac{Area\left(P_i \cap Q_j\right)}{Area\left(P_i \cup Q_j\right)} \tag{4}$$

The value range of $IOU(i,j)$ is [0,1], and the IOU distance between the tracking target i and the detection target j is

$$d_{\mathrm{IOU}}(i,j) = 1 - IOU(i,j) \tag{5}$$

Through the IOU measurement method, the difference in motion features between the detecting bounding box and the tracking target can be more accurately measured, and the motion feature value threshold matrix expression can be obtained:

$$b_{\mathrm{IOU}}(i,j) = I\left[d_{\mathrm{IOU}}(i,j),, t_{\mathrm{IOU}}\right] \tag{6}$$

In the formula, I is the indicator function, which takes 1 when the conditions are met, and 0 otherwise. After experiments, t_{IOU} is set to 0.9, which can eliminate most of the erroneous correlations between the detecting bounding box and the tracking target prediction frame, improve tracking accuracy, and reduce the number of ID switching times.

2) *Appearance feature measurement based on HOG feature:* In order to more accurately associate the matching detecting bounding box and the tracking target in the tracking and matching stage, this paper proposes to fuse the HOG feature distance in the cascade matching view feature measurement. The HOG feature is characterized by statistics and calculation of the gradient direction histogram of the local area of the image. It is often used to characterize the edge information of objects and is widely used in image recognition. It can maintain good invariance to geometric deformation and illumination changes of the detection frame. Moreover, extracting the HOG features of the calculated image requires a small amount of calculation, fast operation, and has little impact on speed performance. By introducing HOG feature distance fusion, it can better reflect the shallow image features of the target and improve the accuracy and robustness of appearance similarity measurement.

In the target detection stage, the size of the obtained detection frame is adjusted to 256x128, the pre-trained ResNet-18 network is input, and the 512-dimensional depth feature D_j is output. Then the HOG features of the detection frame are extracted and the 8505-dimensional HOG feature H_j is output.

The HOG feature distance uses the minimum cosine distance as the measurement criterion, and are only calculated for the features in the N frames closest to the tracking target i. They can be expressed by the following formulas respectively.

$$d_{\mathrm{HOG}}(i,j) = \min\left\{1 - H_j^{\mathrm{T}} H_k^i \mid H_k^i \in R_{\mathrm{HOG}}^i\right\}, R_{\mathrm{HOG}}^i = \left\{H_k^i\right\}_{k=1}^N \tag{7}$$

$$R_{\mathrm{HOG}}^i = \left\{H_k^i\right\}_{k=1}^N \tag{8}$$

Similarly, the appearance feature distance measurement also has a threshold t_F to avoid false matching. Its expression is:

$$b_F(i,j) = I\left[d_F(i,j),, t_F\right] \tag{9}$$

where, t_F is usually set to 0.2. Combining the two thresholds of Eq. (5) and Eq. (7), the threshold function $b(i,j)$ is obtained, and its formula is as follows:

$$b(i,j) = b_{\mathrm{IOU}}(i,j) \circ b_F(i,j) \tag{10}$$

In the formula, $\circ$ represents the Hadamard product of the matrix. The fusion coupling matrix $C_{i,j}$ can be obtained from the fusion appearance distance, and the expression is:

$$C_{i,j} = d_F(i,j) \circ b(i,j) \tag{11}$$

The fusion correlation matrix is matched using the Hungarian matching rule to obtain the correct correspondence between the tracking target and the detecting bounding box.

E. Gray Correlation Calculation

We use gray correlation to analyze the correlation between the driver's visual factors and acceleration decisions during car-following. Gray relational analysis is well suited for studies of small sample size data sets and fleeting microscopic driving behaviors. The calculation steps are as follows.

1) *Determine the analysis sequence:* We select the acceleration of the following vehicle as the reference sequence, $A = \{A(j) \mid j = 1, 2 \cdots, n\}$; The newly introduced visual angle related parameters are selected as the comparison sequence, $\theta_i = \left\{\theta_i(j) \mid j = 1, 2, \cdots, n\right\}$.

2) *Dimensionless variables*

$$x_i(j) = X_i(j) \Big/ \sqrt{\sum_{i=1}^{m} X_i^2(j)}, \; j = 1, 2, \ldots, n; i = 0, 1, 2, \ldots, m \tag{12}$$

3) *Calculate gray correlation coefficient*

The gray correlation coefficient between $a_i(j)$ and $\theta_i(j)$ is

$$\xi_i(j) = \frac{\min_i \min_j \left|a(j) - \theta_i(j)\right| + \rho \max_i \max_j \left|a(j) - \theta_i(j)\right|}{\left|a(j) - \theta_i(j)\right| + \rho \max_i \max_j \left|a(j) - \theta_i(j)\right|} \tag{13}$$

Let $\Delta_i(j) = \left|y(j) - x_i(j)\right|$, the following can be obtained.

$$\xi_i(j) = \frac{\min_i \min_j \Delta_i(j) + \rho \max_i \max_j \Delta_i(j)}{\Delta_i(j) + \rho \max_i \max_j \Delta_i(j)} \tag{14}$$

where, $\rho \in (0, \infty)$ is the resolution coefficient. Generally, the value range of ρ is $(0,1)$. Here we set $\rho = 0.5$.

4) *Calculate gray correlation*

$$r_i = \sum_{j=1}^{n} \xi_i(j) \Big/ n, \; j = 1, 2, \cdots, n \tag{15}$$

III. EXPERIMENTAL RESULTS AND DISCUSSIONS

This experiment collected and annotated a video data set containing 12 groups of traffic scenes named UVACAR-MOT. The video data is 30 frames/s, and one frame is extracted every three frames to form a new video sequence. We selected eight groups as training sets and four groups as validation sets. The experimental setup employs the AutoDL cloud computing platform with a Linux system, 32GB of memory, and PyTorch 1.7 for deep learning. The graphics card is NVDIA Quadro

V100 with 32G of video memory. In the target tracking experiment parameter settings, the initial frame is three frames; the maximum threshold distance for IOU matching is 0.7; and the maximum retained frame for lost tracking is 30. The number of frames for calculating appearance characteristics is N=100. In the target detection experiment parameter settings, the detecting bounding box confidence threshold of yolov7-tiny is 0.3, and the IOU threshold of NMS non-maximum filtering in yolov7-tiny is 0.5.

A. Target Detection

Table I shows that compared with the SSD algorithm and the yolov7-tiny algorithm, the improved yolov7-tiny algorithm has an increase in average accuracy and a decrease in parameter scale. The new algorithm has the characteristics of better detection accuracy, low parameters and low computational load. Compared with the mainstream yolo5s, it is more suitable for deployment on drones. Although the accuracy of the new algorithm is slightly lower than that of yolox-s, the parameters and model size are lower.

TABLE I. OTHER IMAGE DETECTION ALGORITHMS ON UVACAR-MOT

	mAP_0.5%	mAP_0.95/%	Params/10^6	Flops/10^9	Size/MB
SSD	49.1	29.2	40.3	371.2	267.6
YoloV7-tiny	54.1	36.2	5.8	14.3	11.9
Yolo5s	55.3	35.8	6.6	15.2	13.5
Yolox-s	58.3	39.9	8.9	25.7	67.5
ours	58.1	39.5	4.7	13.2	10.9

Fig. 5 and Fig. 6 respectively show the improvement effect of the improved yolov7-tiny on missed detections and false detections. Fig. 5(a) shows the missed detection of car no. 5 under occlusion for the yolov7-tiny algorithm. Fig. 5(b) shows that car no.5 is still detected under the improved yolov7-tiny algorithm. This shows that GSConv in the new algorithm enhances feature richness and makes detection more accurate. Fig. 6(a) shows that yolov7-tiny false detection curbstones as vehicles. The detection accuracy of the improved yolov7-tiny in the same detecting bounding box is shown in Fig. 6(b). This shows that the improved shuffleNet in the new algorithm effectively enhances the feature extraction capability and improves the accuracy of vehicle detection.

B. Target Tracking

Table II shows that most of the indicators of improved yolov7-tiny+deepsort in the UAVCAR-MOT data set are better than the deepsort tracking algorithm. The improvement of specific MOTA and MOTP indicators shows that the tracking accuracy has been greatly improved. IDsw is reduced to two times, which proves that the number of ID switching times for tracking the same target is very small and the tracking retention ability is strong.

Fig. 8. Improved target tracking algorithm improves false detection of shadow.

Fig. 7 shows the different tracking effects of the improved front and rear tracking algorithms when blocked by trees. In Fig 7(a), the ID of the same vehicle in the two bounding box s is switched from 3 to 2 when using the improved yolov7-tiny+deepsort algorithm. However, no such switching occurs after using the yolov7-tiny+deepsort algorithm in Fig. 7(b). This reflects that the improved yolov7-tiny+deepsort algorithm has better tracking capabilities. Fig. 8 shows the impact when light and shadow changes occur. Fig. 8(a) shows the red arrow vehicle being given two tracking IDs and boxes of different sizes. However, such an error did not occur in Fig. 8(b). This shows that the fusion of appearance feature measurement with HOG feature distance can improve the accuracy of appearance feature measurement and tracking accuracy.

C. Target Tracking

In the traffic phenomenon investigation experiment, we chose Jinye Road, Xi'an City, China, and its satellite map is shown in Fig. 9. The aerial photography scene is shown in Fig. 10.We chose clear and windless weather at 3 pm. Furthermore, there are more types and numbers of vehicles on this road, but there is no congestion. The image collection equipment uses a zoom drone, and the video quality is 1080p, 30fps.In order to avoid errors caused by image distortion in the later stage as much as possible, we hovered the drone at 90° directly above the road to shoot and kept the height at 145m. Table III shows one of our multiple sets of aerial traffic data. We selected the vehicle with ID 20 as the following car (width=1.6m) and extracted relevant image and driving data.

The correlation between the driver's visual factors and vehicle acceleration in Table IV calculated from Table III are all above 0.65. This shows that they are strongly related. In addition, we found that when the driver makes the acceleration and deceleration decision, the consideration of the possibility of collision is more important than the headway and velocity.

IV. Applications of Modeling

A. *Baseline Model*

Based on the optimized speed following model, Jiang [19] proposed a classic full speed difference model with over a thousand references.

$$a_n(t) = \alpha\left\{V\left[\Delta x_n(t)\right] - v_n(t)\right\} - \lambda\Delta v_n(t) \tag{16}$$

where, α and λ are the sensitivity coefficient. $\Delta x_n(t)$ and $\Delta v_n(t)$ are respectively the relative distance and velocity between the front and rear vehicles.

However, from the perspective of driver psychology, the most important perceptual information in car following behavior may be visual information. so Jin [20] replaces the traditional headway with the visual angle in following behavior.

$$a_n(t) = \alpha\left\{V\left[\theta_n(t)\right] - v_n(t)\right\} - \lambda\, \mathrm{d}\theta_n(t)/\mathrm{d}t \tag{17}$$

$$\theta_n(\mathbf{t}) = w/\left(\Delta x_n(\mathbf{t}) - l\right) \tag{18}$$

where, $\theta_n(t)$ is the visual angle of drivers. w and l are the width and length of leading vehicles. $\mathrm{d}\theta_n(t)/\mathrm{d}t$ represents change rate of visual angles. $V(\theta_n)$ is the optimized velocity.

B. *New Model Derivation*

The TTC is the time until vehicles crash assuming the collision path and velocity differential are maintained [21]. The driver of the following car will take control measures such as acceleration or deceleration according to the change in TTC with the leading vehicle [22]. The commonly used traffic accident alternative evaluation index TTC is used as our reference. We combine the correlation between the driver's visual psychology and driving operations in Table 4 to try to establish a more realistic and accurate car-following model to quantify the risk perception of collision accidents. Therefore, driver sensitivity to lateral collision is incorporated into the visual angle model to improve the stability and safety of traffic flow. The TTC expression for a single lane can be written as

$$\mathrm{TTC}_m(t) = \frac{x_{m+1}(t) - x_m(t)}{v_m(t) - v_{m+1}(t)} = \frac{\varphi_m}{\dot{\varphi}_m} \tag{19}$$

where, $x_{m+1}(t)$, $x_m(t)$ and $v_{m+1}(t)$, $v_{m+1}(t)$ are the position and velocity of vehicles. However, the car-following considering lateral influence has the following geometric relationship as shown in Fig. 11.

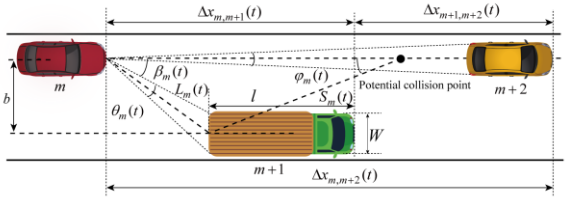

Fig. 11. Car-following behavior with visual angle.

$$\mathrm{S}_m(t) = \sin\beta_m(t)\cdot\frac{\mathrm{L}_m(t)}{\sin\gamma_m(t)} \tag{20}$$

$$\dot{\mathrm{S}}_m(t) = \frac{\left(\dot{\mathrm{L}}_m(t)\sin\beta_m(t) + \mathrm{L}_m(t)\cos\beta_m(t)\dot{\beta}_m(t)\right)}{\sin\gamma_m(t)} \tag{21}$$

where, $\mathrm{L}_m(t)$ is the distance between the midpoint of tail of preceding vehicles and the midpoint of head of the following vehicles, $\mathrm{S}_m(t)$ is the distance between the head of preceding vehicles and the conflict point. The angle $\beta_m(t)$ defined by $\mathrm{L}_m(t)$ and the distance to the collision point. We assume that the leading car maintains constant velocity and $\varphi_m(t)$ for the current brief time. we roughly think that $\tan\beta_m(t) = \beta_m(t)$. Substituting Eq. (20) into Eq.(21) and eliminating the $\sin\gamma_m(t)$.

$$\frac{\dot{\mathrm{S}}_m(t)}{\mathrm{S}_m(t)} = \frac{\dot{L}_m(t)}{L_m(t)} + \frac{\dot{\beta}_m(t)}{\beta_m(t)} \tag{22}$$

Then the potential collision with side vehicle can be expressed.

$$\frac{1}{\mathrm{TTC}} = \frac{\dot{\theta}_m(\mathbf{t})}{\theta_m(\mathbf{t})} - \frac{\dot{\beta}_m(\mathbf{t})}{\beta_m(\mathbf{t})} \tag{23}$$

Therefore, we extend the TTC indicator in car-following behavior to car-following behavior, and can obtain a new visual angle model considering collision visual sensitivity:

$$\begin{aligned} a_m(\mathbf{t}) = {} & \alpha\left\{V\left[\theta_m(\mathbf{t}), \varphi_m(\mathbf{t})\right] - v_m(\mathbf{t})\right\} - \lambda\left[\left(1-\xi_m\right)\dot{\theta}_m(\mathbf{t})\right. \\ & \left. + \xi_m\dot{\varphi}_m(\mathbf{t})\right] - \kappa\left[\left(1-\xi_m\right)\left(\frac{\dot{\theta}_m(\mathbf{t})}{\theta_m(\mathbf{t})} - \frac{\dot{\beta}_m(\mathbf{t})}{\beta_m(\mathbf{t})}\right) + \xi_m\frac{\dot{\varphi}_m(\mathbf{t})}{\varphi_m(\mathbf{t})}\right] \end{aligned} \tag{24}$$

The comprehensive optimization velocity is as follows:

$$\begin{aligned} V\left[\theta_m(t), \varphi_m(t)\right] = {} & V_1 + V_2\tanh\left\{C_1\left[\left(1-\xi_m\right)w/2\tan\left(\theta_m(t)/2\right)\right.\right. \\ & \left.\left. + \xi_m\, w/2\tan\left(\varphi_m(t)/2\right)\right] - C_2\right\} \end{aligned} \tag{24}$$

These parameters V_1, V_2, C_1, C_2 were verified by Zhang [14].

C. *Stability Analysis*

We assume that same size vehicles traveling on a ring road with a uniform flow as the initial state. Each vehicle maintains the same headway h with adjacent vehicles at a uniform velocity $V(h)$ .So, the initial moment can be considered as,

$$x_m^0(t) = hn + V(\theta_0, \varphi_0)t \tag{25}$$

where $\theta_0 = 2\arctan\left[w/2(h-l)\right]$, $\varphi_0 = 2\arctan\left[w/(4h-2l)\right]$.

When the perturbation $y_m(t)$ appear, we can obtain

$$x_m(t) = x_m^0(t) + y_m(t) \tag{26}$$

Visual angles formed by the driver when he observes himself and the side vehicle, and angles formed by side vehicle and the collision position are respectively expressed as,

$$\theta_m(t) = 2\arctan\left[w/2\left(\Delta x_{m,m+1}(t) - l\right)\right] \tag{27}$$

$$\varphi_m(t) = 2\arctan\left[w/2\left(\Delta x_{m,m+2}(t) - l\right)\right] \tag{28}$$

$$\beta_m(t) = \arctan\left[d\tan\gamma/\left(\Delta x_{m,m+1}(t) - l\right) - \tan\gamma\right] \tag{29}$$

To facilitate calculation of the visual angle expression is linearized using Taylor expansion Substituting Eq. (27) into Eq. (27), Eq. (28) and Eq. (29) higher-order terms of $\Delta y_m(t)$ can be rounded off. Drivers' visual angles are expressed as follows

$$\theta_m(t) = 2\arctan\frac{w}{2(h-l)} - \frac{w}{(h-l)^2 + (w/2)^2}\Delta y_{m,m+1}(t) \tag{30}$$

$$\begin{aligned}\beta_m(t) = {} & \arctan\left(\frac{d\tan\gamma}{h-l} - \tan\gamma\right) \\ & - \frac{d\tan\gamma}{(h-l)^2 + \tan^2\gamma(d-h+l)^2}\Delta y_{m,m+1}(t)\end{aligned} \tag{31}$$

$$\varphi_m(t) = 2\arctan\frac{w}{2(h-l)} - \frac{w}{(h-l)^2 + (w/2)^2}\Delta y_{m,m+2}(t) \tag{32}$$

Substituting (31)~ (33) into (24), the following is obtained

$$\begin{aligned}\ddot{y}_m(t) = {} & \alpha A\dot{V}(\theta_0,\varphi_0)\left\{(1-\xi_m)\Delta y_{m,m+1}(t) - \xi_m \Delta y_{m,m+2}(t)\right. \\ & \left.-\dot{y}(t)\right\} + \lambda A\left((1-\xi_m)\Delta\dot{y}_{m,m+1}(t) + \xi_m\Delta\dot{y}_{m,m+2}(t)\right) \\ & + \kappa\left((1-\xi_m)\left(\frac{-\Delta\dot{y}_{m,m+1}(t)}{B-\Delta y_{m,m+1}(t)} + \frac{\Delta\dot{y}_{m,m+1}(t)}{C-\Delta y_{m,m+1}(t)}\right)\right. \\ & \left. + \xi_m\frac{-\Delta\dot{y}_{m,m+2}(t)}{B-\Delta y_{m,m+2}(t)}\right)\end{aligned} \tag{33}$$

where,

$$\begin{cases} A = -\dfrac{w}{(h-l)^2 + (w/2)^2} \\ B = \dfrac{(h-l)^2 + (w/2)^2}{w} 2\arctan\dfrac{w}{2(h-l)} \\ C = \dfrac{(h-l)^2 + \tan^2\gamma(d-h+l)^2}{d\tan\gamma}\arctan\left(\dfrac{d\tan\gamma}{h-l} - \tan\gamma\right) \end{cases} \tag{34}$$

where, $\dot{V}(\theta_0,\varphi_0) = dV(\theta,\varphi)/d(\theta)\big|_{\theta=\theta_0,\varphi=\varphi_0}$,We expand $\Delta y_m(t) = B\exp(ikm + zt)$ by Fourier series and substitute it into Eq. (34).

$$\begin{aligned}z^2 = {} & \alpha A\dot{V}(\theta_0,\varphi_0)\left\{(1-\xi_m)\left(e^{ik}-1\right) - \xi_m\left(e^{2ik}-1\right)\right. \\ & \left.-\dot{y}_n(t)\right\} + \lambda A\left((1-\xi_{m+1})z\left(e^{ik}-1\right) + \xi_m z\left(e^{2ik}-1\right)\right) \\ & - \kappa\left((1-\xi_m)\left(\frac{-z\left(e^{ik}-1\right)}{B-\left(e^{ik}-1\right)} + \frac{z\left(e^{ik}-1\right)}{C-\left(e^{ik}-1\right)}\right)\right. \\ & \left. + \xi_m\frac{-z\left(e^{2ik}-1\right)}{B-\left(e^{2ik}-1\right)}\right)\end{aligned} \tag{35}$$

Expanding z according to $z = z_1(ik) + z_2(ik)^2 + \cdots$,we can obtain as follows:

$$\begin{cases} z_1 = (1-\xi_m)A\dot{V} \\ z_2 = \dfrac{(1+3\xi_m)A\dot{V}}{2} + \dfrac{1}{\alpha}\left[\dfrac{\kappa(1-\xi_m)(B-C) + 2\kappa\xi_m BC}{BC}\right. \\ \qquad \left. + A\lambda(1+\xi_m)\right]z_1 - \dfrac{1}{\alpha}z_1^2 \end{cases} \tag{36}$$

According to the hypothesis of long-wave expansion, if z_2 is positive, traffic flow is still steady under small disturbances. Therefore, the stability curve is obtained.

$$\alpha = \frac{2A(1-\xi_m)^2(\dot{V}+\lambda)}{1+3\xi_m} - \frac{2\kappa(1-\xi_m)^2(B-C) + 4\kappa(1-\xi_m)}{BC} \tag{39}$$

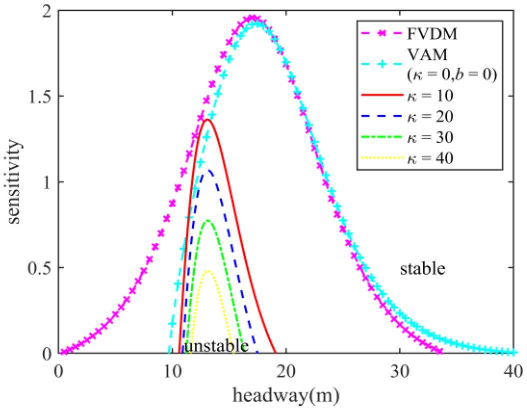

Fig. 12. Stability curves at different κ .

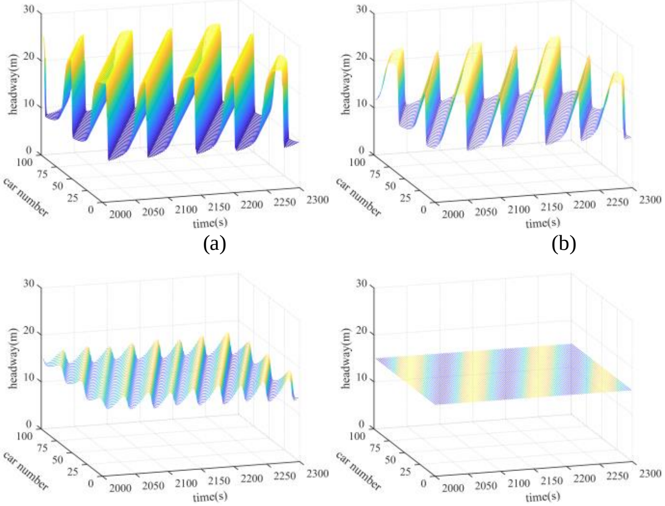
The stability curves of the car-following considering visual sensitivity to collision at different κ are depicted in Fig. 12. The upper and lower sides of the stability curve respectively are stable and unstable regions. Stability curves of different collision sensitivity coefficients κ are depicted in Fig. 12. We set $\lambda = 1, \xi = 0.1, b = 3.6, w = 1.6$ .When the parameters are $\kappa = 0, b = 0, \xi = 0$, our model degenerates into the VAM and the following vehicle only optimizes its own velocity according to leading vehicles on the current lane. The area formed by the x-axis and the stability curves of the new model shrinks as κ increases, and is smaller than the area of FVDM and VAM in the Fig. 12. The order of areas formed by curves and x-axis in Fig. 12 is FVDM> VAM> SCVAM, and they gradually increase as κ decreases. The findings indicate that the platoon is more stable if the visual collision factor is introduced into the car-following model. In addition, the stability gradually improves with the increase of visual collision sensitivity, and the dynamic performance is better than the full velocity difference (FVDM) and visual angle models (VAM).

D. Simulation

Within this part of the research, we performed a series of simulations on the evolution of small perturbations for the new visual model Eq. (24) to analyze its dynamic performance. To validate the theoretical results obtained above, numerical simulations of Eq. (15) with periodic boundary conditions is given. The time step is 0.1s . The initial setting was adopted.

$$\begin{cases} \Delta x_i(0) = \Delta x_i(1) = 5.0, & (i \neq 30, 31) \\ \Delta x_i(0) = \Delta x_i(1) = 5.0 - 0.1, & (i = 30) \\ \Delta x_i(0) = \Delta x_i(1) = 5.0 + 0.1, & (i = 31) \end{cases} \tag{37}$$

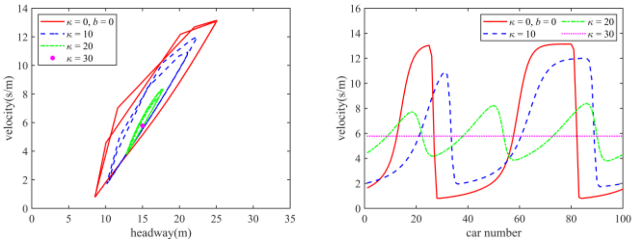
where 100 vehicles are traveling on a 1500m ring road.



(a) (b)

(c) (d)

Fig. 13. Space-time graphs of headway at different κ .



(a) (b)

Fig. 14. (a) Hysteresis loops with different κ (b) Velocity images of all vehicles with different κ .

Fig. 13(a) to Fig. 13(d) reflect the temporal and spatial evolution of the car-following model considering the visual sensitivity of collision with different κ from 2000s to 2300s. The parameters are $\alpha = 0.41, b = 3.6, \lambda = 20, w = 2$. The vehicle platoon is unstable at $\kappa = 0, 10, 20, 30$ by stability condition Eq.(39). Small disturbances in the system will gradually amplify over time and cause vehicle platoon congestion, which can be clearly seen in Fig. 11(a) to Fig. 11(c). Especially when the lateral distance b and collision sensitivity κ are not considered, the newly proposed visual angle car-following model Eq. (24) degenerates to VAM $(\kappa = 0, b = 0)$, the greatest fluctuation is in headway as shown in Fig. 11(a). When $\kappa = 30$, the stability condition is satisfied, and the local disturbance of the distance between the vehicles in the platoon will gradually return to stable state in Fig. 11(d). Similar， the areas of hysteresis loops decrease gradually when the visual sensitivity of collision κ increase in Fig. 14(a). As the visual sensitivity of collision κ increases, the velocity fluctuation decreases are depicted in Fig. 14(b).

Fig. 13 and Fig. 14 show that the stability of the vehicle platoon is well maintained when taking into account the collision visual sensitivity to the lateral and longitudinal leading vehicles. As the sensitivity κ increases, the stability gradually increases.

E. Safety Assessment

The traffic conflict theory can observe a large amount of non-accident data before the accident, and estimate the dangerous action highly related to the accident by analyzing the vehicle. Numerous indicators have been developed for alternative safety measures to evaluate collisions risk. TTC is the most used indicator among them. However, traditional traffic conflict alternative indicators have two shortcomings: 1) They do not start from the driver's real visual perspective. The vehicle is regarded as a point, and the impact of its size on collision is not considered. 2) The potential risk of collision with the two vehicles in front is not considered when following a car. Therefore, we propose a new car-following collision risk indicator STTC, which is expressed as follows.

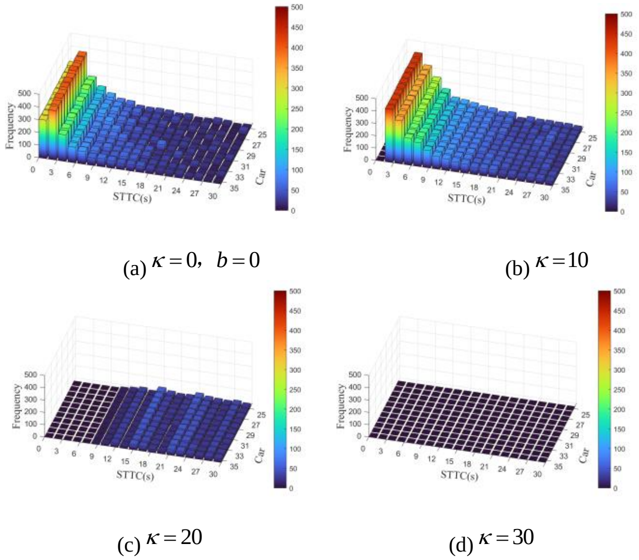
$$\text{STTC=}\left(1-\xi_m\right)\left(\frac{\dot{\theta}_m(t)}{\theta_m(t)}-\frac{\dot{\beta}_m(t)}{\beta_m(t)}\right)+\xi_m\frac{\dot{\varphi}_m(t)}{\varphi_m(t)} \tag{38}$$

We also use the small perturbation evolution scenario in previous section to study potential collision risks. When the 30th vehicle in the uniform traffic flow suddenly suffered a small disturbance, we selected it and five vehicles at the front and rear, a total of eleven vehicles, for potential collision risk assessment. Since the simulation step in car-following behavior is small and the velocity difference between nearby vehicles is small, we use a larger range of STTC to evaluate the risk. Similar to the common threshold standard of the TTC index, we define $\text{Frequency}_{\text{STTC<30s}}$ as the traffic environment with potential collisions. With reference to the common international standards of TTC, $\text{Frequency}_{\text{STTC<3s}}$ and $\text{Frequency}_{\text{STTC<5s}}$ are defined as the frequency of serious traffic conflicts and relatively serious traffic conflicts.

The safety of the entire platoon is evaluated by the dispersion of velocity and headway. The standard deviation of velocity and headway can be calculated by following formulas.

$$\mathrm{SD}_v = \sum_{t=1}^{T}\sum_{m=1}^{M}\left(v_{t,m}-\bar{v}\right)\Big/\left(M\cdot T-1\right),\quad \mathrm{SD}_h = \sum_{t=1}^{T}\sum_{m=1}^{M}\left(h_{t,m}-\bar{h}\right)\Big/\left(M\cdot T-1\right) \quad (39)$$

where $\bar{v}$ and $\bar{h}$ are the average velocity and headway.



(a) $\kappa=0,\ \ b=0$

(b) $\kappa=10$

(c) $\kappa=20$

(d) $\kappa=30$

Fig. 15. Statistical distributions for STTC with different κ

TABLE V. TOTAL OCCURRENCES OF STTC FOR DIFFERENT κ

κ	$0(\xi=0)$	10	20	30
$\mathrm{Frequency}_{\mathrm{STTC}<3\mathrm{s}}$	720	441	0	0
$\mathrm{Frequency}_{\mathrm{STTC}<5\mathrm{s}}$	952	875	0	0
$\mathrm{Frequency}_{\mathrm{STTC}<30\mathrm{s}}$	2189	1646	442	0

TABLE VI. SD OF HEADWAY AND VELOCITY WITH DIFFERENT κ

κ	$0\ (\xi=0)$	10	20	30
Velocity	4.61	3.03	0.49	0.05
Headway	6.15	3.59	0.52	0.07

Fig. 15 shows that when the collision sensitivity is not considered $(\kappa=0, b=0)$, the frequency of $\mathrm{VT}<3\mathrm{s}$ is the highest, and the risk of serious collision conflict is the highest. In addition, the frequency of dangerous driving within 5s threshold and the potential collision conflict within 30s threshold are also the highest. However, as the driver's sensitivity κ to the collision of two vehicles intersecting in front increases, the frequency of the three safety evaluation indicators within the threshold gradually decreases until it completely enters a safe driving state.

The STTC values of different collision sensitivities at different risk thresholds are counted in Table V. The standard deviation of the headway and velocity at different collision sensitivities κ are descriptive statistics in Table VI. This shows that increasing the sensitivity to the collision of horizontal and longitudinal leading vehicles can reduce dispersion of headway and velocity, thereby improving driving safety.

Through the above simulation experiments and statistical analysis, we found that after analyzing the traffic behavior data collected by flexible and convenient drone images, the newly established car-following model can describe the collision risk of driving behavior. And by enhancing the sensitivity of the newly introduced visual collision factor in the model as in Eq.(24), the driver's safety in car following behavior will be improved. This puts forward new ideas for safety modeling and evaluation of driving behavior.

V. CONCLUSION

To sum up, the method in this article for extracting traffic parameters from UAV video and applying it to assist in establishing a car-following model can improve the accuracy and lightweight of multi-target detection and tracking. The improved ShuffleNet network and GSConv module introduce the Yolov7-tiny target detection stage to reduce the number of parameters and calculations of the model and ensure accuracy. HOG features and IOU motion metrics are introduced into the DeepSort multi-target tracking algorithm to improve the target appearance representation capabilities and the accuracy of tracking targets. The traffic parameters extracted by the new method can be used to analyze driving psychology and car-following behavior, and the analysis results can be used to model car-following behavior with the aim of enhancing both the safety and stability of traffic flow. This will in turn ease traffic congestion and reduce driver collision risks. In the future, we will further improve vehicle tracking in more complex traffic scenarios, and verify the accuracy of traffic parameter extraction through on-board comparison.

A Review of Fake News Detection Techniques for Arabic Language

Taghreed Alotaibi[1], Hmood Al-Dossari[2]
Computer Science Department, Imam Mohammad Ibn Saud Islamic University, Riyadh, Saudi Arabia[1]
Information Systems Department, College of Computer and Information Sciences, King Saud University, Riyadh, Saudi Arabia[1, 2]

***Abstract*—The growing proliferation of social networks provides users worldwide access to vast amounts of information. However, although social media users have benefitted significantly from the rise of various platforms in terms of interacting with others, e.g., expressing their opinions, finding products and services, and checking reviews, it has also raised critical problems, such as the spread of fake news. Spreading fake news not only affects individual citizens but also governments and countries. This situation necessitates the immediate integration of artificial intelligence methodologies to address and alleviate this issue effectively. Researchers in the field have leveraged different techniques to mitigate this problem. However, research in the Arabic language for fake news detection is still in its early stages compared with other languages, such as English. This review paper intends to provide a clear view of Arabic research in the field. In addition, the paper aims to provide other researchers working on solving Arabic fake news detection problems with a better understanding of the common features used in extraction, machine learning, and deep learning algorithms. Moreover, a list of publicly available datasets is provided to give an idea of their characteristics and facilitate researcher access. Furthermore, some of limitations and challenges related to Arabic fake news and rumor detection are discussed to encourage other researchers.**

Keywords*—Fake news detection; rumors; classification; Arabic language

I. Introduction

The influence of traditional information sources, such as television and newspapers, and how users gather and consume news has diminished in comparison to earlier times. The expansion of social media platforms has been a key factor in this transition. Social media platforms are another kind of technological innovation. Users can access platforms such as Twitter, Facebook, and Instagram to build their profiles, share opinions, interact with others having shared interests, and facilitate cycles of cooperation. Over the years, more users have shown an interest in using social media. According to Kepios, there were 4.76 billion social media users around the world in 2023, which equates to 59.4% of the world's total population [1]. The reason behind this spike in the use of social media is that social media platforms are designed to be more attractive and highly suitable for social communication. Social media has also become a way for companies and governments to reach the people by providing news, showcasing their services, giving updates, or launching marketing campaigns. However, some limitations arise from using social media, such as the spread of fake news and rumors, as well as spamming. Many individuals who use social media platforms to stay in touch with friends and family also use these platforms to find news and information. According to a report from the Pew Research Center, 48% of adults in the US use social media as a news source [2].

Fake news is a major problem that started early, attracting significant attention in 2016 during the US presidential elections. Different fake news items and rumors usually appear during special events and cover different domains, such as those related to elections, natural disasters, or health, such as the coronavirus disease 2019 (COVID-19) pandemic. A study on Twitter showed that false news spreads more quickly and reaches 100 times as many readers as true news [3]. Therefore, many researchers are working to solve this problem, ranging from analyzing the types of fake news [4] to trying to find the most effective method for detection [5].

In the Arab regions, different rumors and false information have been spread during the COVID-19 pandemic [6]. Rumors and false information have also proliferated in politics, as was the case during the Arab Spring and the Syrian crisis [7]. The Arabic language is considered one of the most commonly spoken languages in the world, and an essential language for Muslims worldwide, who numbered about 1.8 billion in 2015 and are expected to increase to three billion in 2060, according to the Pew Research Center [8]. The Arabic language presents various challenges. First, there are different dialects used in different Arab countries, as well as from regions in the same country. The language also has a rich vocabulary that leads to the occurrence of misleading information from different dialects, making it more difficult for the system to detect [9]. In social media, the complexity of understanding the Arabic language is increased because users on social media, such as Twitter, use two forms of the language: Modern Standard Arabic (MSA), which is the formal language, and Dialect Arabic (DA), which is informal, used in daily communication between users, and is more common than MSA [10].

This paper working to focus in two aspects: features extraction techniques and the datasets used. This is because while classification algorithms play a critical role in fake news detection, their effectiveness heavily relies on the quality and relevance of the features provided to them [11]. Feature extraction techniques enable the models to capture the subtle nuances and contextual cues that differentiate fake news from real news [12]. By incorporating these features, classification algorithms can leverage the rich information present in the data, leading to improved accuracy and robustness in fake news detection. Majority of studies in Arabic fake news detection have predominantly focused on the application of specific features extractions techniques to identify the veracity of news with no concern on their limitation[13][14][15]. However, this study surpasses mere technical application by shedding light on the strengths and weaknesses of each technique.

On the other hand, focusing on identifying and analyzing available datasets is crucial for advancing research in fake news detection. It allows researchers to improve data quality, benchmark models, and collaborate effectively to address the growing challenge of misinformation in our digital world. There is a need for research which reviews the available dataset in Arabic for fake news detection. For that, this research coming to fill this gap by analyzing available public Arabic datasets according to their domain, size, labels, annotation method, source and the features used. We believe this work provide researchers in the field with valuable insights into the available dimensions to initiate their research endeavors. The contributions of this review paper are as follows:

1) *Investigate* research in Arabic fake news detection by selecting studies that cover different features for detecting fake news and utilize publicly available datasets.

2) *Provide* a clear insight into the available helpful techniques used for feature extraction in detecting fake news, in general, and in the Arabic language, in particular;

3) *Investigate* the publicly available Arabic datasets and show their properties, including a list of the available Arabic fact-checking websites that help build datasets;

4) *Explore* the limitations and prospective avenues concerning datasets, utilized features, and classification methods associated with detecting Arabic fake news.

The rest of this paper is arranged as follows. Section II describes a brief background of fake news, providing its definitions, and impacts. Section III identifies the different approaches for feature extraction. Section IV investigates the works conducted in the field of Arabic fake news detection. Subsequently, Section V provides a list of the available Arabic fact-checking websites used. Section VI investigates the available Arabic dataset in fake news detection. Finally, Section VII discusses some of the limitations and future direction, followed by the conclusion in Section VIII.

II. Background

A. Fake News Definition

"Fake news" does not have a consistent definition. Scholars define the term differently based on the purpose of their research. For example, one study [16] defined fake news as "a news article that is intentionally and verifiably false." In 2018, a European Commission report defined "fake news" as "all forms of false, inaccurate, or misleading information designed, presented, and promoted to cause public harm intentionally or for profit" [17]. Research in [18] has provided and defined a set of terms related to fake news, including hoax, rumor, spam, misinformation, disinformation, clickbait, satire, propaganda, and hyperpartisan. *Hoaxes* are facts that are either erroneous or inaccurate and are presented as actual facts in news stories [19]. They consist of fabricated information that has been purposefully created to appear true, and because they involve highly intricate and large-scale fabrications, they frequently cause substantial material harm to the victim [20]. *Rumor* is information initiated by a potentially untrustworthy person and circulated among users before it can be verified to be true, false, or unconfirmed [21]. *Spam* refers to any irrelevant or unsolicited messages sent by individuals or groups on social media, such as advertisements, malicious links, or content of poor quality [22]. *Misinformation* is false information that is spread unintentionally, for example, by mistake or updating specific knowledge without intentionally misleading [23]. *Disinformation* is a type of false information spread among users with the main goal of misleading others for some purpose, such as deception of some person [19] or promoting a biased agenda [24]. The concepts of misinformation and disinformation often confuse readers. While both refer to inaccurate or fake information, disinformation is created with malicious intent, whereas this is not necessarily the case with misinformation [25][19]. *Clickbait* is a story whose title or news headline is different from the content itself; it is mainly employed to attract users to access a specific website to increase traffic and, consequently, boost revenue [26][24]. *Satire* is a noteworthy literary tool employed in creating news articles, serving the purpose of both criticism and amusement for readers [27]. This form of discourse often incorporates a substantial amount of irony [28]. *Propaganda* encompasses a form of persuasive communication that employs unidirectional messaging to influence the attitudes, emotions, perspectives, and behaviors of specific target audiences, driven by ideological, political, and religious motives [29][30]. *Hyperpartisan* refers to heavily biased or one-sided narratives [31], particularly in the political arena, denoting strong partiality toward individuals, parties, circumstances, or events [32]. This review will use fake news and false news as a big umbrella for these concepts and will not consider each concept distinctly because there is an overlap in the techniques performed.

B. Impact of Spreading Fake News

Fake news influences users, leading them to accept biased or false beliefs, changing how they react to true news stories [12]. Spreading fake news not only affects individuals but also harms society. In 2016, fake news drew global attention during the US election [33], when a large amount of fake news was shared on Twitter. The spread of fake news goes beyond the political sector and also applies to other sectors. During the COVID-19 pandemic, a significant amount of fake news and rumors spread throughout the health sector. Approximately 80% of consumers in the US reported that they had read fake news during the pandemic [34]. In addition, during the fire disasters in Australia, some fake maps and pictures were shared on social media [35]. While this may have increased awareness of the disaster, this fake information may also have cost people their lives [35].

In the Middle East, Arabic countries have also been influenced by some fake news, for example, during the COVID-19 pandemic. According to a study on COVID-19 misinformation in Jordan, different Arabic media outlets promoted conspiracy theories regarding the pandemic, with the most prevalent ideas focusing on the virus's origins [36]. Most of the fake news spreading in Arab countries are related to the political sector, such as news related to the Arab Spring in 2010, Islamic State terrorist group (ISIS) campaigns, and the Beirut explosion of 2020 [37].

III. Features Used in Fake News Detection

Feature extraction and selection are techniques used in text mining that have shown effectiveness in enhancing performance in different tasks [10]. Having large features requires more powerful computation and enough memory; hence, there is a vital need to choose appropriate features. In fake news detection, researchers have recently applied feature extraction and selection with good results. In detecting fake news, three approaches are commonly used by researchers: knowledge-based (fact-checking), content approaches, and context approaches [38] [12]. This section will describe each feature in more detail for better understanding. Fig. 1 summarizes these features.

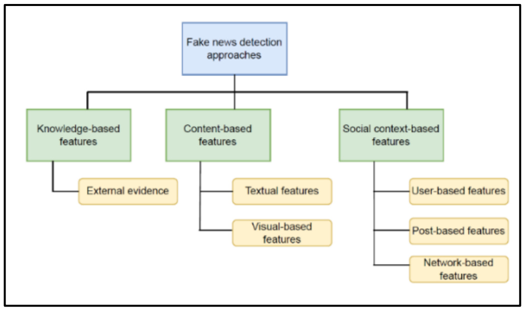

Fig. 1. Fake news detection approaches.

A. Knowledge-based Approaches

This approach works by attempting to discover whether there are facts that support the claim made in a news item [39]. In this approach, fact-checking strategies can be included, which entail finding documents and web pages that support a news item based on information retrieval methods [40]. Few works have used the web to search and retrieve evidence on search query formalization [40]. Study [40] performed a study combining social media conversations with evidence from external sources. The research developed dataset which contain social media conversations and external evidence related to each rumor. Their results showed that combining evidence with rumor is more effective than using rumors or evidence alone. Also, in [41] a system worked by incorporating external evidence from the web with some signals from language style.

B. Content-based Approaches

Content-based features focus on information that can be directly extracted from the text, such as linguistic features. The content features can be classified into (textual) linguistic-based [74] and visual-based [12].

1) Linguistic-based features: Linguistic-based features extract content from the text at different levels, such as characters, words, sentences, and documents [12]. In fake news detection, the common linguistic features used are lexical, syntactic, and semantic [42][12]. Lexical features, considered as the actual wording (usage) in the text, can be at a word level, such as the total number of words, word length, and the frequency of unique words, or at a character level, such as characters per word [12][43]. One of the commonly used features is bag-of-words (BOW), n-gram, which is used to find the most prominent word contents or expressions [44]. On the other hand, syntactic features include sentence-level features, such as the order of words in a sentence, grammar, and syntactic structure of a sentence [12]. The other features related to linguistics are semantic features, which include using the Natural Language Processing (NLP) technique to extract information, such as opinion mining, and sentiment analysis to extract emotions and opinions from texts [38]. Some research also extract topics in texts or posts on social media using Latent Dirichlet Allocation (LDA) [43]. Word embedding, an example of the distribution semantic technique, is useful in detecting fake news with machine learning and deep learning [45]. The linguistic feature is an effective indicator in detecting fake news during the initial propagation phase with the user features [46]. This method is simple but limited because it requires deep knowledge of the domain; thus, it is difficult to generalize [47]. Another limitation when dealing with linguistic features is that the features extracted from social media, such as Twitter, may not be enough for machine learning approaches because the text is short [48]. Moreover, it cannot be used for detecting fake news that only has images or videos [48].

2) Visual features: Visual content features extract features from visual elements, such as videos or photos, using deep learning techniques [49]. Fake news creators use individual vulnerabilities and images or any kind of visual cues to provoke an emotional response from users [12]. To extract visual features from images that can be used in detecting fake news, applications such as clustering scores and similarity distribution histograms are used [49] [12]. In addition, statistical features can be used in fake news verification, such as the multi-image ratio, number of images in an event, image ratio, and long image ratio [49] [12]. Other research has used visual features, such as the polarity of the image and the probability of the image being manipulated [50]. This kind of feature can be integrated with other features, such as text-based features and user-based features, which provide a good result [51]. Few researchers in fake news detection have investigated visual features due to the lack of availability of datasets containing images and video [12] [52]. In addition, the techniques for maintaining these features are more complex than those needed for other features[12] [50].

C. Social Context-based Features

Social context-based features are related to the information surrounding news, such as the user's characteristics, the reactions of other users to posts or news, and social network propagation features [42][12].

1) User-based Features: User-based features focus on the news publisher to evaluate the credibility of the source [12].

The features are used to confirm credibility and reliability for an individual user using demographics, registration age, number of tweets written by the user, number of followers or following, number of tweets authorized by the user, user photo, user sentiment, tweet repetition, and so on [43]. Most social media platforms provide users with a verification status after they provide information to the social media company to confirm their identity. This verification status is used by researchers in detecting a user's reliability [53]. When using user-based features, it is important to understand that the availability of this information is a critical concern due to privacy and access constraints on some platforms such as Twitter.

2) Post-based features: Post-based features can be used to identify the veracity of news from different aspects relevant to social media posts[12]. This includes analyses of user feedback, reactions, opinions, and responses, in general, as indicators of fake news. Some of these features include comments, likes, tagging, user ratings, sentiment, and emotional reactions [42]. Some research dealing with post-based features have dealt with a number of retweets, likes, shares, and others [54][55]. Another unique feature represents the social responses to a post by users who interact with the news story. These features rely on the wisdom of the crowd in detecting fake news and show its effectiveness in detection. In this situation, a few studies have analyzed responses from different perspectives, such as sentiment, emotion, and stance toward news items [12]. In fact, [56] used users' response information as core input data in detecting fake news. They believed that users' responses have rich information that researchers can benefit from.

3) Network-based features: Social media users construct networks grounded in relationships, interests, and subjects [12]. Detecting fake news necessitates extracting network-based features to unveil and represent discernible patterns suitable for identification. Different types of networks can be constructed. Shu et al. [12] categorized them into stance network, where the nodes represent tweets related to tweets and the edges represent weights of stance similarities [57] [58]; co-occurrence network, which counts users' written posts related to the same news article [47]; and friendship network, which is based on the following and followers of the users who posted in relation to tweets [59]. After building networks, some matrices can be used for feature representation, such as degree and clustering coefficients, to represent the diffusion network[60]. Research using network-based features is limited compared with other features because of the complexity that can emerge when analyzing the patterns [46]. In addition, finding a dataset that contains enough information for a network is difficult patterns [46].

Research in the field uses each feature alone or incorporates both content and contextual features in detecting fake news [47]. These methods are promising regarding effectiveness but are challenging when relying only on one type of feature in automatic fake news detection. Table I summarizes the shortcomings and merits of each feature.

TABLE I. SHORTCOMINGS AND MERITS FOR FAKE NEWS DETECTION APPROACHES

Approaches		Strength and weakness
Knowledge-based approach	***External evidence***	(+) Usually Improve the performance[40]. (+) Enhanced interpretability[98]. (-) Need information retrieval techniques[40]. (-) Need strategies for checking the credibility of sources.
Content-based approaches	***Textual-based***	(+) Simple method. (+) Appropriate for early detection of fake news[46]. (-) Requires deep knowledge of the domain [47]. (-) May not fully convey the message's context well as underlying intent, leading to misunderstandings [18].
	Visual-based	(+) Enhanced the performance[51]. (+) May provide contextual information[50]. (-) Limited dataset containing visual content, especially in Arabic language[12] [52]. (-) Need complex techniques to be maintained from professional & more time for analysis[12][50].
Social context-based features	***User-based***	(+) Appropriate for early detection of fake news[46]. (-) There are some privacy concerns.
	Post-based	(+) Appropriate for early detection of fake news[46]. (-) Need more investigation[12].
	Network-based	(+) Good for identifying influential users [12]. (-) Provide low performance in the early stage of detection[46] [48]. (-) Complex to analyzed and require enough information about structure and users' connection [46]. (-) Need advanced computational techniques and expertise in network analysis[12].

IV. FAKE NWES DETECTION AND ARABIC LANGUAGE

Fake news detection in Arabic has gained significant attention recently but is still in its infancy. Some studies were conducted using a simple technique, such as [61], which suggested a solution based on using the rule-based model. The dataset was adapted from Almujaiwel[1], where they built a dictionary that contains a set of fake news with keywords for each news. The rule-based model worked by checking the primary and secondary keys in the dictionary, whether they are in a tweet text or not. In the context of traditional machine learning, various researchers have used common supervised machine learning, such as [62]. The study used word frequency, count vector, and Term Frequency - Inverse Document Frequency (TF-IDF) as features. Moreover, two word-embedding methods were used: FastText and Word2Vec. To collect tweets, the research used Infection Disease Ontology. The result after testing on Logistic Regression (LR), Naïve Bayes (NB), and Support vector machine (SVM) classifiers showed the best accuracy, with 84% for the LR model with a count vector. Alkhair et al. [63] performed another study to detect the content of fake news on YouTube. The study collected data related to rumors about three famous people in Arab countries (topic of the dataset), namely, Fifi Abdu, Adel Imam, and Abdelaziz Boutaflika. The study used features related to content: n-grams with TF-IDF.

[1] https://github.com/salmujaiwel

For the classification process, SVM, Multinomial Naïve Bayes (MNB), and Decision Tree (DT) were used. The best accuracy and precision were registered for SVM across these topics. While the textual features showed their effectiveness, other studies have suggested using user features. El Balloul et al. [64] proposed a model called (CAT) for the credibility analysis of Arabic content on Twitter. CAT is built using a combination of features related to content and user. It has 26 content-based features and 22 user-based features. The research constructed a dataset from Twitter in Arabic, which is considered topic-independent. CAT was trained using NB, SVM, and RF. CAT registered a higher weighted average F-measure of 75.8% using RF. Overall, sentiment was found to be a highly crucial feature in defining credibility, especially the negative sentiment, as well as the URL in the author profile linked to their website. Mouty and Gazdar [65] conducted their research using the same datasets and features of [64]. To enhance the accuracy of the classifier, the study developed an algorithm for discovering the similarity between username and display name in a Twitter account and the similarity score between tweets and Google search results. For classification, they used RF, DT, SVM, and NB. The combination of user/content features and the new two-similarity score features registered 78.71% accuracy for the RF model.

Using similar features, Jardaneh et al. [55] conducted another experiment using LR, Adaptive Boosting (AdaBoost), Random Forest (RF), and DT for classification. The dataset used was from [7]. The research confirmed that the sentiment feature has a beneficial effect on the system's accuracy, especially when ensemble-based machine learning algorithms are employed. Taher et al. [66] performed a study that employed a Harris Hawks Optimizer (HHO) for the feature selection approach. Briefly, the researcher used a combination of features related to user profile, content-based, and linguistic features, namely, TF-IDF, BOW n-grams, and Binary Term Frequency (BTF). Eight machine learning algorithms were tested: eXtreme Gradient Boosting (XGB), NB, K-Nearest Neighbor (KNN), linear discriminant analysis (LDA), DT, LR, SVM, and RF. LR was selected with HHO algorithms, which performed well as the wrapper feature selection approach registered a 5% increase compared with [55], where the accuracy was 82%.

Alzanin and Aqil [67] performed another study for detecting rumors using unsupervised and semi-supervised expectation maximization (EM). The dataset used contained 271,000 tweets belonging to 88 non-rumor events and 89 rumor events, and 16 features related to users and content were used. For the classification tasks, the researchers compared their proposed model with the supervised Gaussian Naïve Bayes (GNB) model. The results showed the proposed model outperformed GNB with an accuracy of 78.6%. In the health sector, [68] focused on cancer treatment information disseminated via social media. The research extracted tweets annotated manually by experts in the field. The total number of datasets was 208 tweets. Given the small set of data, the researchers performed over-sampling to enhance the performance of the model. The features used were TF-IDF and n-grams, while the classifiers were SVM, LR, KNN, Bernoulli Naïve Bayes (BNB), Stochastic Gradient Decent (SGD), and j48. The research also used an ensemble method using RF, AdaBoost, and Bagging. The results confirmed that the over-sampling process enhanced the performance of all models of machine learning. Meanwhile, RF outperformed the others using 4- and 5-grams based on accuracy. In study [69], they also relied on a set of extracted features from user and textual features. To extract the textual features, they used both classic word embedding (word2vec, fastText, and Keras embedding layer) and context-based embedding (Multilingual Arabic Bidirectional Encoder Representations from Transformers (MARBERT) and ARBERT) with deep learning models[70]. Two deep learning schemes were used: Convolutional Neural Network (CNN) and Bidirectional Long Short-Term Memory (BiLSTM). The result showed that MARBERT with CNN provided the best accuracy of 95.6%. Alawadh et al. [71] performed another experiment using machine learning algorithms and Mini-BERT. The research used the dataset available from [72]. First, the research preprocessed the dataset by applying standard text 2 numeric encoding. Subsequently, DT, NB, RF, linear support vector (LSV), and mini-BERT were applied with three separate splits using the holdout validation technique (70/30, 80/20, 90/10). The result showed that mini-BERT exhibited consistent performance among the splits with increasing training data, while the machine learning classifiers showed varying performances across the splits. The highest accuracy registered with mini-BERT was 98.4%.

Numerous fake news was spreading during the COVID-19 pandemic. These encouraged researchers to build datasets covering this domain, and the deep learning approaches provided them with excellent performance. The researchers started using Neural Network (NN) and a set of language models, such as [9]. They performed experiments to detect misinformation spreading via Twitter related to the COVID-19 pandemic. The dataset size was 8,786 collected Arabic tweets. For classification, the study used eight of the traditional machine learning models, which were MNB, SVM, XGB, SGD, and RF. On the other hand, deep learning models were used, which are CNN, Recurrent Neural Network (RNN) and, Convolutional RNN (CRNN). Both experiments with machine learning and deep learning used different representation features, including word frequency and word embedding. The XGB showed the highest accuracy in detecting misinformation in this study. Study in [73] collected datasets about the COVID-19 pandemic from Twitter on the types of fake news and misinformation to detect fake news. The tweets were annotated in two ways: manual and automatic. For feature extraction, they used count vector, word-level TF-IDF, character-level TF-IDF, and n-gram-level TF-IDF. They chose the best classifier based on performance, which was trained in the manually annotated dataset to automatically annotate the remaining unlabeled dataset as false and real. The study used six classifiers, including RF, NB, LR, Multilayer Perceptron (MLP), XGB, and SVM. As a result, LR exhibited the best performance for both manual and automatic annotated datasets, which registered an F1-score of 93.3%. In this study, the stemming and rooting techniques failed to increase the performance of the classifiers.

TABLE II. SUMMARY OF ARABIC FAKE NEWS DETECTION STUDIES AND CORRESPONDING FEATURES AND MODELS USED.' E' EVIDENCE, 'T' TEXTUAL, 'V' VISUAL, 'U' USER, 'P' POST, 'N' NETWORK

Study	Dataset	Feature type						Models	Platform	Feature Extraction Methods	Evaluation results

Study in [74] collected and annotated a set of data from Twitter in Arabic/English language. The research was conducted in two phases. First, a binary classification model was trained on a set of collected ground-truth data, which were obtained from the official websites and the official Twitter accounts of the United Nations (UN), United Nations International Children's Emergency Fund (UNICEF), and World Health Organization (WHO). The second phase carried out the annotation for the, unlabeled tweets. The system used extraction features, such as TF, TF-IDF (n-gram, character level), and word embedding with 13 machine learning algorithms, including KNN, DT, LR, MNB, Linear Support Vector Machines (LSVM), BNB, Perceptron, NN, XGB, Ensemble Random Forest (ERF), Bagging Meta-Estimator (BME), Gradient Boosting (GB), and AdaBoost. Meanwhile, Haouari et al. [75] built the ArCOV19-Rumors dataset, which covered some claims about COVID-19. The research presented a benchmark on claim-level verification and tweet-level verification to exploit the content, user profiles, propagation structure, and temporal features. The Bidirectional Graph CN (Bi-GCN) and RNN+CNN, as well as the AraBERT and MARBERT models were tested on the dataset. The final results showed the best accuracy for AraBERT and MARBERT, with 73% and 75.7%, respectively.

Furthermore, [76] used a pre-trained transformer AraBERT, Multilingual BERT (mBERT), and Distilbert Multilingual under baseline transformer models. The study fine-tuned mBERT and AraBERT on [92]'s datasets containing dialects. The output from this process were two models called AraBERT COV19 and mBERT COV19, which were used in addition to the above-mentioned three models for the experiment (five models overall). The experiment found that the pretrained COVID-19 models were helpful after fine-tuning in detecting false information. Nassif et al. [77] used eight BERT transformer-base models. The research conducted two experiments: using the dataset from Kaggle[3], which was written in English and translated to Arabic using Google translator, and using another dataset, sourced from Twitter and newspaper agency websites. GigaBert-base and QARiB Bert-base provided the best result on the translated dataset and the collected dataset, respectively. Study in [79]focused on the task of claim verification, which involves a collection of claims and corresponding evidence in the form of text snippets sourced from web pages [93]. The researchers achieved an F1-score of 55.2% by employing a scoring function that evaluates the negation and concordance between the claims and their associated text snippets. The determination of negation and concordance levels was performed through a manual list-based approach. Some research focused on feature extraction and selection, such as [80], which used three main methods, including multi-task learning, a transformer-based model, and Fire Hawk Optimization (FHO) algorithm. Three datasets related to COVID-19 and the detection of fake news were used, which include ArCOV19-Rumors, as well as datasets from [73] and [82]. AraBERT was used for feature extraction via multi-tasking learning and fine-tuning approaches, a novel metaheuristic algorithm to select the most pertinent features from the contextual feature representations. The average accuracy in binary classification using these datasets was 91%. Amoudi et al. [83] performed a comparative study in rumor detection using different machine learning and deep learning models. The dataset used in this research was ArCOV19-Rumors. They used features such as n-grams, TF-IDF, and AraVec word embedding. The first experiment used SVM, KNN, NB, DT, RF, SGD, LR, and XGB for machine learning and evaluated the application of ensemble learning. In addition, six common deep learning models were used: Gated Recurrent Unit (GRU), RNN, LSTM, Bidirectional RNN (Bi-RNN), and Bi-GRU, BiLSTM with seven optimizers. The research showed that over-sampling did not enhance the performance of either the traditional or the deep learning models, and ensemble learning performed better than the single models. LSTM and Bi-LSTM with Root Mean Square Propagation (RMSprop) optimizer provided the best accuracy among the other deep learning models.

Al-Yahya et al. [45] performed another comparison study between the use of the NN model and the transformer-based language model for detecting Arabic fake news. The datasets used in this study included ArCOV19-Rumors, AraNews [84], Arabic News Stance (ANS) corpus [85], and COVID-19-Fakes [74]. The study used a linear model at word and character levels with Glove, Word2Vec, FastText, and document level. For the classification tasks, deep learning models CNN, GRU, and RNN were used. Moreover, QARiB, AraBERT, ArELectra, ARBERT, and MARBERT were used from the transformer-based models. The results showed that the transformer-based models performed better than the NN-based solutions, registering a 95% F1-score for QARiB. Fouad et al. [86] conducted another experiment for detecting fake news. The research used two datasets. The first contains news and tweets collected manually by the researchers and annotated to rumor or non-rumor, while the second dataset was from [87]. The two datasets were merged and used to create a third one. Word embedding and TensorFlow were used for text representation, and a set of traditional machine learning was used, which included Linear Support Vector Classifier (LSVC), SVC, MNB, BNB, SGD, DT, and RF. On the other hand, they examined a set of deep learning models, namely, CNN, LSTM, CNN+LSTM, BiLSTM, and CNN + BiLSTM. As a result, they found that no single model performed optimally over the three categories of datasets from the traditional machine learning models. For deep learning, the BiLSTM model provided the highest accuracy across all three datasets. Meanwhile, Shishah [88] performed another study, proposing a model called JointBERT for detecting the Arabic language. JointBERT in this research used Named Entity Recognition (NER) and Relative Features Classification (RFC) as parameters. The datasets used in this research were COVID-19-Fakes [74], ANS, Satirical [89], and AraNews. The results showed that JointBert outperformed the baseline results. The use of NER increased the performance because of its ability to extract news entities, which supports the model's performance in detecting fake news.

Some researchers have focused on specific types of misinformation, such as Bsoul et al. [90]. They built a dataset for clickbait detection, which facilitated automatic

[3] https://www.kaggle.com/c/fake-news/data?select=test.csv

classification and detection of news headlines. The study used BOW and TF-IDF and features related to headlines, such as headline length and with demonstrative pronouns, question words, and question mark. The researchers performed an experiment using SVM, LR, DT, NN. NB, SGD, and RF. These models produced a Macro F1-score of up to 0.81, which shows the effectiveness of using these seven machine learning models in the detection of clickbait news headlines. Research[89] focused in another type of fake news which is satire news. The research used dataset collected from different news websites and working to exploit textual features for the purpose of identifying satire news. For feature extraction they used count vectors, word-level TF-IDF, N-grams, Char-level, with MNB and XGB machine learning. In addition, the research used CNN with pre-trained word embedding which provided best accuracy registered which are 98.59%. The research found that satire news in Arabic language incline to have subjective tone with more positive and negative key terms. Research [85] release a dataset for claim verification, which are derived from subset of news title from Arabic News Text (ANT) corpus[94]. The authors modified news title to generate fake claims. For classification process, they used BERT, and LSTM for training and testing datasets. The study reported that BERT provides best F1-score registered which are 64.3%. Compared to this research, Nagoudi[84] used the same dataset from [85] in addition to their dataset which is automatically generated fake news from real one. The impact of this generated data on verification fake news are tested using transformer-based pre-trained models and compared with human created fake news dataset. The research reported that generated news are positively affect the fake news detection, and achieved better performance than [85] with 70% for F1-score.

In addition, [91] collected a dataset containing articles as fake and real, covering a single topic, which is Al Hajj. For the real articles, they collected articles in three dialects from Arab countries: Saudi, Egyptian, and Jordanian. The veracity of these articles was assessed using different fact-checking platforms. On the other hand, the study used crowdsourcing to create a fake news article based on a real one. The research did not provide a new classification method but suggested a set of features to provide an accurate Arabic classifier. The researchers built a lexical wordlist and an Arabic natural language processing (ANLP) architectural tool to extract the textual features, including POS, emotion, polarity, and syntactic. Based on these features, RF, SVM, and NB were used and tested for each single feature and a combination of features. The best result was registered for RF, with a combination of POS, syntactic and semantic roles, and contextual polarity features, which achieved an F1-score of 79%. Moreover, the research tested against human performance, providing 86% of articles classified correctly. Insufficient emphasis is being placed on the utilization of visual features in the realm of fake news detection, but recently, Albalawi et al. [52] proposed a model based on textual and image features. Their model consisted of three sub-models. For extracting the textual features, the BERT model was used. Meanwhile, two ensembles of pre-trained vision models were used for extracting the visual features (VGG-19 and ResNet50). The final model is a multimodal model used for concatenating the extracted textual and image features to represent a rumor vector. As a result, their proposed multimodal did not outperform the model with textual-based features. This shows that textual features are still considered pioneering in detecting rumors. Table II provides a brief summary of Arabic fake news detection studies.

V. Arabic Fact-Checking Websites

When researchers build datasets for fake news detection, they mostly rely on fact-checking websites. Fact-checking websites can be defined as platforms that evaluate the veracity of claims and information spread over social media networks, web articles, and public statements [95]. These kinds of websites usually rely on human experts who check the veracity of the news. Some fact-checking websites employ techniques that rely on evidence-based analysis or assess the credibility of the statements and how they align with the factual reality [95]. In the Arab countries, there are different fact-checking websites that researchers use as a starting point when building datasets for detecting fake news and rumors. It is worthy to provide researchers in the field with a list that can help them during their dataset-building phase. The common Arabic fact-checking websites will be described as follows:

- Norumors[4]: This is a standalone project that started in 2012 as a Twitter account searching for rumors and detecting their veracity. Thereafter, a website was established, which contains archives for different rumors and fake news that spread in Arab countries in general, especially in Saudi Arabia. The aim of this site is to spread awareness about rumors and expose the disseminators of falsehoods.

- Fatabyyano[5]: This is a standalone platform in the field of news fact-checking. First established in 2014 as a single page on Facebook. Fatabyyano uses the Facebook rating system, which has nine rating options, namely, false, partly false, true, false headline, satire, not eligible, opinion, prank generator, and not rated. Fatabyyano is certified by the International Fact-Checking Network (IFCN).

- Misbar[6]: Considered one of the leading fact-checking platforms in the Arab regions, it covers the Middle East and South African countries. The news classification system in Misbar using these classes includes fake, misleading, true, myth, selective, commotion, and satire.

- Akeed [7]: This is a fact-checking platform that is responsible for tracking the credibility of the Jordanian media. It was established with the support of the King Abdullah Fund for Development. The news are rated as false, biased, misleading, ambiguous, incomplete, inciting news, or contains an error.

[4] http://norumors.net/?post_type=rumors
[5] https://fatabyyano.net/
[6] https://misbar.com/
[7] https://akeed.jo/public/

- Verify [8]: This is considered the first Syrian fact-checking platform established in 2011 during the Syrian Revolution. In this platform, news are classified into three main classes depending on risk [red (high risk), orange (medium risk), and yellow (low risk)].

- Falso[9]: This is a Libyan platform for monitoring hate speech and a fact-checker in media news. It fact-checks both traditional news from TV and newspaper and also covers social media platforms and other websites.

- FactuelAFP Arabic[10]: This is the Arabic division of the French news agency dedicated to providing news and information. This division holds certification from IFCN and collaborates closely with Facebook to combat misinformation.

- Maharat-news fact-o-meter [11]: This is another fact-checking website certified by IFCN. Their main focus is detecting rumors on online media in Lebanon and other Arab regions. The rating system is based on three labels: true, partially true, and not true.

- Kashif[12]*:* it is an independent Palestinian fact-checking website that main goal to combat misleading information in Palestinian media. The rating system is based on nine labels: Manipulated, incorrect linking, outdated, sarcasm or parody, fabricated, false context, Impersonated and inaccurate content.

- Dabegad [13]: This is a fact-checking website in the Egyptian dialect that started in 2013 and aims to find and expose hoaxes in social media in Middle East countries.

VI. Arabic Fake News Datasets

It is clear that the first essential step to building an effective fake news detection system is constructing an appropriate dataset. There is still no agreed benchmark dataset for fake news detection in the Arabic language. Researchers in fake news detection usually focus on analyzing the text features only; however, this may no longer be enough, especially with the evolution of social media platforms and the diverse representation of fake news and their complexity. As such, different studies have recently used features related to news publishers, as well as social context features, such as user information and network information [75]. This was evident from the previous sections, which showed promising effectiveness. Accordingly, this section will briefly mention a set of publicly available datasets in the Arabic language. According to type, datasets can be classified into *social media posts* and *news articles*. In social media post datasets, in addition to the text content of posts, user and network information are utilized to detect fake news. Meanwhile, in news article datasets, researchers detect fake news by utilizing the headlines and the body of the articles.

One example of datasets related to posts in social media is [64], which included 9,000 tweets considered topic-independent. The dataset contains information related to the users and content, in addition to the sentiment features. The annotation process was performed manually, classifying the tweets into credible and noncredible. Alzanin and Azmi [67] constructed datasets that consisted of 27,100 posts related to 177 events from different domains, where 88 of these events were considered non-rumors, while 89 were rumors. This dataset also includes some features from users and contents. During the COVID-19 pandemic, researchers were encouraged to construct datasets covering this topic [74][76]. Furthermore, [74] constructed a bilingual dataset that covers the Arabic and English languages. The dataset was collected from Twitter using keywords related to COVID-19. The dataset has been automatically annotated using 13 machine learning classifiers and seven feature extraction techniques, including TF, TF-IDF (n-gram, character level), and word embedding. The dataset has two labels: real and misleading. The tweets' IDs and detection labels are made publicly available to other researchers by the authors.

AraCOVID19-MFH [76] is a multilabel dataset manually annotated to 10 labels. It is an abbreviation of the Arabic COVID-19 Multilabel Fake News and Hate Speech Detection dataset. The dataset consists of 10,828 items of annotated data that include MSA and different dialects. The dataset was collected by searching some keywords from Twitter. This dataset can be used for both hate speech and fake news detection tasks. In [9], another dataset was collected from Twitter by searching for a specific list of keywords. The dataset is labeled as misleading (1311 tweets) and others (7475 tweets). It consists of 8,786 tweets in total, and it is clear that this dataset suffers from imbalance. The researchers only published the ID of the tweets and their corresponding labels (misleading and other). Moreover, in [73], the dataset was collected from Twitter based on the COVID-19 domain. Part of the dataset was annotated manually first and then used to train different machine learning models to automatically produce annotation for the rest of the unlabeled data. They were annotated as fake and genuine and only relied on the text feature. The authors published the tweet's text and its label without the ID. ArCorona [96] is a larger dataset collected manually from Twitter in the health domain during the early stages of COVID-19. The dataset contains 30 million tweets, with 8,000 tweets labeled into 13 labels. The dataset contains different dialects from the Arabic regions.

Alsudais and Rayson [62] also manually collected a dataset that contains one million tweets about COVID-19, among which 2,000 were annotated to 895 false, 0 unrelated, and 789 true. The tweets were collected using keywords related to infectious diseases. All the above-mentioned datasets rely on textual content; however, there is a dataset called ArCOV19-Rumors [75], which consists of 9,414 tweets that were manually labeled as false (1,753), true (1,831), and others (5,830), which are related to 138 claims This dataset works on two levels: claim-level verification and tweet-level verification, both of which have two labels, namely, true and false. and their correspond relevant tweets. Meanwhile, tweet-level verification contains the tweet and the propagation

network (retweets, replies). Moreover, study in [82] built dataset about Covid-19. The datasets are labeled for binary classification and multiclass, based on seven questions. The datasets available in four language which is English, Arabic, Dutch, and Bulgarian. The main focus for this paper is fake news, so 4966 Arabic tweets are classified into (815) contains fake information and (2602) not contains false information.

Dataset[72]	Multi-domain	323 articles		(100) reliable (223) unreliable	-	✓	-	-	Kashif fact-checking website, social media, WhatsApp group, and news site.
AraFact [97]	Multi-domain	6222 claims		(4037) false (1891) partly-false (198) True (90) Sarcasm (6) unverifiable	✓	✓	✓	-	5 Arabic fact-checking websites
Dataset [98]	Politic (Syria War)	422 claims 3042documents		(219) false claim. (203) true claim Documents: (1239) false (1803) True	-	✓	-	✓	2 websites VERIFY for false claim and REUTERS[14] for True claim
ANS [85]	Multi-domain	4547 claims (3786) pairs (claim, evidence)		(3072) True (1475) False	-	✓	-	✓	News headlines from media sources in Middle east and ANT corpus.
AraStance [99]	Multi-domain	910 claims 4063 pair (claim, articles)		(606) False claim (304) True claims Articles: (2421) False (1642) True	-	✓	-	✓	3 fact-checking websites Aranews, Dabegad, Norumors, REUTERS
Satirical fake News[89]	Politic	3185 articles		(3185) fake. (3710) real.	-	✓	-	-	2 satirical news websites for fake news. And Official news site for real.
AFND [100]	Multi-domain	606912 articles		(207310) credible (167233) not credible (232369) undecided	-	✓	-	-	134 Arabic online news sources
Dataset. [7]	Multi-domain	175 blog posts		(100) credible (57) fairly credible (18) non-credible	-	✓	-	-	Arabic news articles

[14] http://ara.reuters.com

For the news article dataset, AraNews [84] is a large dataset collected from different countries, covering different topics. The dataset relied on a list of 50 newspapers from 15 Arab countries, the United Kingdom, and the United States. Based on this list, 5,187,957 news articles were collected and labeled as true or false. Also, research [72] published dataset which contains 323 articles from different domains. The dataset was labeled manually from two experts into reliable and unreliable. Different sources are used for collecting this dataset such as Kashif fact-checking websites, social media, and news sites. Ali et al. [97] produced a dataset called AraFacts that contains claims collected from five Arabic fact-checking websites. The dataset comprises URLs for fact-checking articles and links to evidence pages sourced from various outlets, enabling the extraction of images and supporting evidence. This making them the first to collect datasets in Arabic that combined texts, image contents, and evidence. Research in [52] used AraFacts to extract images and text. The dataset contained 6,222 claims annotated by professional fact-checkers manually.

Typically, researchers focus independently on specific tasks such as stance detection, fact-checking, document retrieval, and source credibility, but study [98] making these tasks available to be integrated using unified corpus. The study created a corpus consisted of 442 claims that covered topics related to the Syrian war and some political issues in the Middle East. Each claim was labeled as false or true based on factuality. In addition, 2,042 articles retrieved for these claims were annotated based on their stance into agree, disagree, discuss, and unrelated. In addition, the dataset included a rationale attribute that enabled the fact-checking system to provide explanations for its decisions. This attribute encompassed the display of extracted sentences or phrases from the retrieved documents, which served as illustrative examples of the detected stance. Similarly, ANS [85] is a dataset of news titles that were paraphrased and altered. ANS covers several topics collected from online news sites. The dataset contains two versions. Based on claims verification, 4,547 records were labeled fake and not fake; the other version consisted of claims and evidence pairs containing 3,786 records. The difference between ANS and Baly et al. [98] is that ANS generated fake and true claims from true news. In the same vein, the AraStance dataset [99] contained 4,063 pairs of claims and articles from multiple countries, covering topics in politics, health, sports, and others. The annotation process was performed manually according to the veracity of the claims, whether they are true or false, and according to the article's stance on the claims, which ended with four labels: agree, disagree, discuss, and unrelated. Satirical News [89] is a hand-built dataset that includes fake articles. The fake news articles were collected from two satirical news websites: Al-Hudood [15] and Al-Ahram Al-Mexici[16]. For the real news dataset, the research used an open-source datasets[17]. Arabic Fake News Dataset (AFND) [100] is a collection of news stories in Arabic that are available to the public and were gathered from Arabic news websites. A dataset used for detecting article credibility, it consisted of 606,912 articles labeled as credible (207,310), not credible (167,233), and undecided (232,369). The researchers used the Misbar fact-checking platform for classifying the articles into these three classes. Some research built datasets that contained both social media posts and news articles, such as Al Zaatari et al.'s dataset [7], which consisted of blog posts and tweets related to the Syrian crisis. This kind of corpora's main goal is to analyze the credibility of the news. It consisted of 2,708 tweets and 175 blog posts; the datasets, in general, are labeled as credible and not credible. Tables III and IV provide a summary of the social media posts and news article datasets. In the context of news article datasets, the range of available features is comparatively narrower compared to those accessible for social media datasets. Thus, our focus was confined to textual, visual, stance, and evidence features for the purpose of comparison.

VII. Discussion

Based on the previous sections, fake news detection in the Arabic language is still in its nascent stages compared with other languages. Although a multitude of efforts have been exerted in Arabic fake news detection, the process still suffers from various limitations. We can categorize them into limitations related to datasets, feature extraction, and classification algorithms based on the literature.

A. Datasets

There is no benchmark dataset in the Arabic language, and most of the datasets used in previous studies are not available online. Researchers need to enrich the fake news detection field by making their data available using any platform, such as their own page in GitHub[18] or MASADER[19] repository. Publicly available datasets enable other studies to exert robust efforts, and their results can be compared with others using the same datasets. This is one of the important factors to measure the improvement of performance among different studies. Moreover, the processes for collecting and preparing datasets are not always mentioned clearly in the research papers. Researchers in this field need accurate guidelines to undertake this process, for example, by providing a list of common sources for extracting appropriate news, the annotation process, the cleaning and preprocessing phase, and so on. In addition, most of the datasets suffer from unbalanced classes, where the real news category is usually larger than the false one such as [9] [64]. Moreover, when screening parts of these datasets, there were numerous instances for the same news, especially those collected from social media platforms such as Twitter. This repetition in the values of the news texts can be attributed to the fact that the same news can propagate among such platforms, and because the collection process usually depends on the prepared list of keywords, the probability of having the same news with the same exact text is higher. In some situations, having duplicated contents will decrease the performance of the classifier [101]. Another problem related to the datasets is the domain they cover. For example, Tables III and IV show that most of the datasets focused on covering the COVID-19 pandemic, while the others focused on whether

[18] https://github.com/
[19] https://arbml.github.io/masader/

the data was a post from social media or articles covering different domains with unbalanced categories for each. These researchers argued that they adapted this process to find common features across various domains. However, they ignored the fact that each sector has its own features, which can help in detecting fake news related to them. Having datasets that cover a specific domain is important. Specialized terminology is prevalent within specific topic domains, and possessing technical expertise is essential for discerning the authenticity of each news item [18]. Hence, it is crucial to construct datasets tailored to the unique requirements of a particular topic domain, such as the SCIFACT dataset [102].

Moreover, Arabic countries cover different regions with different dialects; thus, datasets covering MSA and dialects require a complex process to mitigate this problem. We still need an Arabic dataset that covers the MSA language and others that cover different dialects. The dataset publishers usually release only the IDs for the tweets in accordance with Twitter policy. When other researchers try to extract the same tweets, they are already deleted or protected by their owners. This situation decreases the number of available datasets and is one of the immense problems that need to be solved by applying a repository that does not contain critical features and saves only appropriate and valuable ones. Working to extract more records to balance the dataset affected by this deletion is time-consuming. The creation of an unaltered dataset for the purpose of detecting fake news on social media platforms represents a crucial milestone in establishing a benchmark dataset. This endeavor aids in effectively assessing the performance of models and their ability to verify the accuracy of information with the collaboration of social media platforms.

B. Feature Extraction and Classification Process

Most previous studies have focused on extracting textual features in articles and social media posts, which is not usually sufficient to detect fake news [18]. Rather, it is important to combine features such as those related to users, posts, networks for social posts, and the metadata related to the articles, including the publisher’s name, URLs, headlines, body, and comments. Based on the literature review, only a few researches are using a combination of these features. In addition, when looking for the visual contents, images provide an improvement in the performance of the classifier in other languages, which need more investigation in Arabic [50]. There are a few research in Arabic with this attribute, such as [52]. Extracting features from the replies of users is also an important aspect [56]. The only publicly available Arabic dataset that has considered users’ responses in their dataset is ArCOVID19-Rumors. Employing sentiment analysis, stance detection, and emotion recognition with fake news detection still needs more investigation, especially in relation to the responses of the crowd. Moreover, features related to networks are still not investigated in fake news in the Arabic language, except for the work performed by [75]. Traditional machine learning approaches, such as SVM, LR, and KNN, are the most used in Arabic research. Based on the review, most research in Arabic has used language models, such as AraBERT, MARBERT, mBERT, and QARiB. Research using the ensemble techniques is scarce, and there is a need for more studies applying this model. Applying the ensemble methods using traditional machine learning and deep learning is another window of opportunity that needs to be investigated for fake news detection because ensemble methods have the ability to improve prediction performance with regard to some characteristics, such as overfitting avoidance, computational advantages, and representation [103].

VIII. Conclusion

This review revealed that a few studies related to detecting fake news have been conducted in the Arabic language, indicating that Arab researchers should allocate more attention to this issue. Most Arabic studies have focused on social media platforms, particularly Twitter. Most Arabic researchers have investigated events related to politics (e.g., Syrian crisis) and health (e.g., COVID-19 pandemic) and have created their own dataset for testing the proposed models. This may not be an effective approach because it results in many different datasets with a range of accuracy measurement results. A benchmark dataset that contains as many features as possible to help detect fake news should be used. Our future objectives encompass the development of an Arabic dataset encompassing diverse extraction features, including visual attributes, enabling us to explore their influence when combined with other features for the purpose of detecting fake news on social media.

Mathematics Department-Faculty of Science, Ain Shams University, Cairo, Egypt[1]
Assistant Professor, Department of Computer Science and Information Technology,
Al-Baha University, Al-Baha, Kingdom of Saudi Arabia[2]

Abstract—**The Software Defined Networking (SDN) paradigm has emerged as a critical tool for meeting the dynamic demands of network management with respect to efficiency and flexibility. Quality of Service (QoS) optimization, which encompasses essential features including bandwidth allocation, latency, and packet loss, is a major problem in SDN systems due to its direct influence on network application performance and user experience. To deal with these important issues, this paper tackles the critical problem of Software-Defined Networks (SDNs) Quality-of-Service (QoS) optimization, which is a critical factor affecting network application performance and user experience. Within the Firefly-Fruit Fly Optimised Deep Reinforcement Learning (DQ-FFO-DRL) framework, a novel combination of optimization techniques derived from Fruit Fly and Firefly behaviors with Deep Q-Learning is presented in this suggested approach, which is called Deep Q-Learning. The framework effectively investigates ideal network configurations by utilizing the distinct advantages of the Fruit Fly and Firefly optimization components, while the Deep Q-Learning component dynamically adjusts to changing network circumstances by drawing conclusions from prior experiences. Extensive testing and modeling reveal that the DQ-FFO-DRL approach performs very well in SDNs compared to conventional QoS management solutions. When it comes to negotiating the always changing world of resource allocation, network usage, and overall network performance, this algorithm demonstrates exceptional adaptability. The suggested system, which is implemented in Python, offers an advanced and flexible method for enhancing QoS in SDN systems.**

Keywords—Software Defined Network (SDN); Quality of Service (QoS); firefly-fruit fly optimization; Deep Reinforcement Learning (DRL); adaptive QoS enhancement; network optimization

I. Introduction

Network administrators have been using traffic engineering approaches to enhance resources management efficiency in order to cope with the ever-increasing volume of network traffic. In communications networks, traffic engineering synchronises the packet forward pathways of various streams within the network to enhance the total level of service provided by network users. Routing optimisation remains a long-term research topic along with one of the main obstacles in network utilities optimisation through traffic engineering [1]. Using conventional routing techniques, each router decides how to forward packets on its own, disregarding the judgments made by other routers. Even though this dispersed routing technique is scalable as it can be used on any size networks, it is challenging to handle network management of resources in an effective and flexible manner and optimise network routing as a whole. Software defined networking (SDN) was initially proposed as an efficient way to handle the whole network by dividing control and information layers in the network [2], that separates information transfer from control functions. These factors make an improved network management models more necessary [3]. SDN logically decouples the network's operational plane and the information plane to give an overall picture of the system and enhances network programming capabilities for network administration and operation. Networking policies can be deployed dynamically and with efficiency using this SDN approach. SDN makes it possible to control forwarding of packets centrally and see the entire network, but creating the best routing scheme is not easy. Limited shortest path issues are how the issue of routing is formulated in many current publications, yet these issues typically have an optimal solution that is NP-hard [4]. Furthermore, while the generic multi-commodity flow issue has a conventional solution that takes the network's operation as a constant model with fluctuating traffic, these models are unable to effectively depict good network function under complicated and variable traffic conditions [5].

In recent years, deep reinforcement learning (DRL), that blends deep neural networks and reinforcement learning (RL), has been used to create traffic engineering strategies [6]. The development of the DRL method offers a fresh approach to optimising extremely complex transportation issues. By enhancing routing policy effectiveness in a model-free and focused on experiences way, DRL-based route methods are able to develop and adjust to complicated networks. Using the DRL approach in an SDN-based networks has shown to significantly improve routing optimisation performance, according to recent studies. It should be highlighted that networks performance loss can happen throughout the learning procedure, especially in the beginning phases, owing to the characteristics of reinforcement learning (RL), that entails experimentation in the manner of identifying the most effective approach [7]. When training an infrastructure, one should not risk network efficiency deterioration when improper routing policies immediately boost packet loss and end-to-end delay throughout the network itself. This decreases the system's dependability. Specifically, in the event of a system's topology modification, the DRL agent that is running ought to retrain how to optimise routing. Continuous network performance deterioration is caused by the longer time it takes for convergence to occur when the features of internet traffic become more complicated. In addition, using DRL-based route optimisation, which requires investigation, can have severe effects in systems that carry QoS-sensitive information [8].

The need for better Quality of Service (QoS) provisioning in Software-Defined Networks (SDNs) is growing in importance in the ever-changing world of today's networks. As numerous applications develop and information traffic increases, guaranteeing effective and adaptive QoS administration has become a critical task. Conventional methods of maximising quality of service frequently lack the flexibility required to handle the intricate and shifting dynamics of contemporary network settings [9]. The study explores the incorporation of novel Firefly-FruitFly Optimised Deep Q-learning approaches to provide adaptive QoS improvements in SDNs in order to overcome these constraints. By separating both data and control planes, Software-Defined Networking (SDN) completely transformed the way networks are managed and controlled. This has made it possible to have centralised control over the network. Due to this division, network assets can be used with never-before-seen flexibility and control, allowing for dynamic setups and modifications in response to changing needs [10]. But even with SDN's built-in benefits, maintaining excellent QoS is still difficult because of the complex interactions between different network variables as well as the constantly changing nature of internet traffic.

Among the most important metrics for assessing the efficiency of a network is quality of service, which includes a number of factors such as latency, bandwidth, dependability, and safety. Optimising these variables to match particular service level commitments and guarantee the best possible experience for users is necessary for successful QoS management. Conventional QoS administration frequently uses preset or static regulations, which may not be able to adjust to shifting network circumstances. This could result in less-than-ideal resource usage and possible performance issues. Techniques inspired by environment have become more popular in recent decades for resolving challenging optimisation issues [11]. Based by the typical behaviours of fruit flies and fireflies, accordingly, the Firefly and FruitFly Optimisation algorithms have been found to be remarkably effective in solving a wide range of optimisation problems. These methods use the ideas of repellent and attraction to identify the best answers in challenging optimisation scenarios, imitating the typical actions of these bugs. By incorporating such bio-inspired methods into social media, there is a chance to improve the flexibility and effectiveness of QoS control in SDNs. Moreover, the utilisation of RNN-LSTM in the field of networks has demonstrated exceptional capacity to tackle intricate and variable optimisation issues. In DRL, robots are trained to communicate with the surroundings and make successive choices in order to maximise aggregate rewards. The network's controllers can be given the ability to generate wise and flexible choices depending on the needs and circumstances of the network's infrastructure in actual time by utilising DRL in connection with SDN [12]. The study attempts to establish a new architecture which not just optimises QoS in SDNs but additionally responds to shifting traffic trends and network behaviour by merging DRL into the Firefly-FruitFly Optimisation methods.

Software-Defined Networks (SDNs) are a revolutionary paradigm in computer networking that have arisen to address the increasing needs of dependable and effective network services. The optimisation of Quality of Service (QoS) attributes, which include jitter, latency, throughput and packet loss and have a direct impact on network application performance and user experience, is a key challenge in SDNs. This paper presents a novel framework that combines Deep Q Learning with Firefly-Fruit Fly Optimisation to transform QoS enhancement in SDNs. The bio-inspired optimisation algorithms of Firefly-Fruit Fly Optimisation efficiently explore and identify optimal network configurations, drawing inspiration from the natural behaviours of both fruit flies and fireflies. At the same time, Deep Q-Learning's adaptive learning mechanism keeps learning from previous experiences and network interactions. This allows the framework to make wise decisions in real time and adeptly adjust to the changing network conditions. The combination of these cutting-edge methods offers an SDN environment that is more responsive, effective, and optimised, constituting a major breakthrough in the field of software-defined networking. The study would then go into experimental validation, performance metrics, and comparisons with traditional QoS management strategies in order to show how this new framework performs exceptionally well and how it ultimately improves user experience and network efficiency. The following lists the main findings of the suggested investigation:

- The main contribution of the paper is to advance the field of SDNs by offering a fresh, flexible, and clever framework for enhancing QoS. The combination of deep reinforcement learning and optimisation inspired by nature offers a novel strategy for tackling the problems related to quality of service (QoS) in contemporary network settings.

- The article presents a novel framework that incorporates the nature-inspired optimisation technique known as Firefly-Fruit Fly Optimization. Quality of Service (QoS) management in Software-Defined Networks (SDNs) presents intrinsic issues that could be properly explored and identified through the implementation of this optimization technique.

- The QoS management method gains a dynamic and self-learning mechanism with the integration of Deep Reinforcement Learning (DRL) into the framework. Based on prior interactions and experiences, DRL continuously adjusts to shifting network conditions, offering a clever and flexible method of improving QoS.

- The management of crucial QoS factors, including as packet loss, throughput, jitter, and delay, is the study's primary objective. The framework combines DRL and Firefly-Fruit Fly Optimisation to dynamically optimise these parameters in order to improve network performance as a whole.

The subsequent sections of the paper are organized to provide a comprehensive exploration and validation of the proposed framework. The research unfolds in a structured manner, with the following key segments: A summary of relevant routing of networks work is given in Section I. The paper's uniqueness and the issues with related works are discussed in Section II, Problem statement in Section III. The SDN QoS improvement mechanism is described in Section IV. Explain the suggested method's effectiveness rating in Section V, and the overall research's conclusions and future work is given in Section VI and Section VII respectively.

II. Related Works

A relatively new development in networking for computers is the software-defined network (SDN), which separates forwarding of information from centralised control to provide a very adaptable and controllable networks architecture. A great deal of study has been conducted to provide effective routes and allocate resources for SDNs. To guarantee application-driven QoS regardless of the face of computer hacking, situation-aware networks administration continues to encounter significant obstacles. To deal with this matter, Hossain and Wei [13] Utilise technology related to reinforcement learning (RL) to provide smart networks administration and scenario knowledge from the standpoint of routing control. In the modelling parts, the effectiveness of the suggested RL-enabled route management approach is assessed by taking into account various situations. Despite the efforts to enhance the recommended routing method, one possible limitation is the substantial resource commitment needed to fully evaluate the approach's effectiveness in a sizable testbed. The extent and velocity of the experimental and assessment process may be constrained by the monetary and time commitment.

Conventional networks for routing use limited data to determine routing, that can cause a delay in adapting to network traffic fluctuation and a lack of assistance for apps' QoS needs. Casas-Velasco et al. [14] presents reinforced learning and Software-Defined Networking's Intelligent Routing (RSIR), a revolutionary method for navigating in SDN. In order to generate routing choices, RSIR incorporates an Understanding Planes into SDN and specifies a Reinforcement Learning (RL)-based routing algorithms that considers link-state data. The method computes and installs the best routes previously in the forwarded devices by utilising the artificial intelligence offered by RL, the worldwide view and management of the network that is given by SDN, and its relationship with the surrounding environment. Utilising actual traffic matrix for imitation, RSIR was thoroughly assessed. The findings indicate that when bandwidth available, postpone, and damage are taken into account separately or together for the estimation of optimum pathways, RSIR works better than Dijkstra's method in terms of exertion, link productivity, loss of packets, and time. The outcomes indicate that RSIR is a desirable option for SDN smart routing. The need for substantial computing power for implementing Deep Reinforcement Learning (DRL) to enhance RSIR choices constitutes a potential limitation for future studies, especially for bigger networks. Additionally, integrating traffic forecasts for selecting a path may add to the method's complexities.

The concept of Software Defined Networking (SDN), which centralises intellect in software-driven controllers in order to increase network adaptability and address various network difficulties, continues to gain traction in both research and the IT sector. SDN is considered one of the driving forces behind 5G networks. The efficiency and utilisation of the network may be improved and optimised with the help of machine learning (ML) technologies. Network administration and operation tricky issues have shown to be a huge cooperative challenge for Neural Networks (NN) and Reinforcement Learning (RL) in specific. Bouzidi et al.[15], an SDN-based principles insertion method that uses Deep Q-Network (DQN) agents to acquire the best routes and redirect congestion in order to increase networks utilisation. The method primarily uses NN to proactively forecast traffic bottlenecks. To achieve this, authors initially outline the connection problem that considers Quality-of-Service (QoS) as a Linear Programme (LP), with the goal of minimising both link utilisation and from beginning to end (E2E) time. Following that, author suggests a effective heuristic approach to resolve it. Emulation-based mathematical results utilising Mininet and ONOS controllers show that the suggested method can greatly enhance network capabilities by reducing lost packets, E2E postponement, and connection utilisation. One possible limitation for further study is the sophisticated optimisation procedure needed to set up a Distributed Deep Q-Network (DQN) agent, which adds complication to the installation process and allows for efficient management of the quantity and location of SDN routers and related information plane switching.

Conventional routing algorithms use only a small amount of data to determine routing, that results in a delayed response to traffic fluctuation and a constrained capacity to fulfil apps' quality of service needs. In order to overcome these drawbacks, researchers presented, a Reinforcement Learning (RL)-based router approach for SDN. Yet, when confronting vast actions and state areas, RL-based systems typically see a rise of training time. Casas-Velasco et al.[16] Presents Deep Reinforcement Learning and Software Defined Networking Intelligent Routing (DRSIR), an alternative routing method. In SDN, DRSIR specifies an algorithm for routing that gets beyond the drawbacks of RL-based systems by utilising Deep RL (DRL). In order to generate innovative, efficient, and smart routing that adjusts to continuous congestion changes, DRSIR takes path-state indicators into account. Emulation was used to assess DRSIR utilising both artificial and actual traffic patterns. According to the outcomes, this method operates better in terms of flex, loss of packets, and latency than the routes that utilise Dijkstra's algorithm and RSIR. Furthermore, the outcomes show that DRSIR offers a workable and realistic approach for networking in SDN. The intricacy and mathematical requirements of expanding DRSIR to accommodate multiple paths routing, multiple levels DRL plans, and the integration of travel type data could be a hindrance for subsequent research, making it difficult to control the method's learning settings and assess effectiveness across a variety of traffic conditions.

The requirement for quality of services resulting from an exponential rise in network traffic makes routing optimisation increasingly vital. With the latest advancement of software-defined networking (SDN) technologies, networking equipment like switches can now be flexible configuration via programming interfaces, allowing for centralised administration and operation. Kim et al. [17] Provide a routing optimisation on an SDN using deep reinforcement learning (DRL). Under the suggested approach, the agent that handles DRL determines an ideal set of connection weights to strike a compromise for the networking's lost packets and total latency by learning how the overall traffic load of network routers and network efficiency are related. Installing the flow-rules onto the SDN-enabled shifts, an SDN controller uses an array of link strengths to decide how to distribute pathways. They create an M/M/1/K queue-based network framework and use it to execute the DRL training procedure offsite unless it converges in order to circumvent the extremely lengthy learning procedure for DRL in the event of a topologies modification. The outcomes of the experiment show that in a number of network structures, the suggested routing technique works better than both a network demand-based RL algorithms and a traditional hop-count forwarding technique. To guarantee the efficacy and usability of the suggested routing approach in multiple network settings, additional assessment and verification of the approach over a larger range of configurations is necessary. This represents a single negative.

Numerous applications that operate in real time utilise reinforcement learning (RL), a way of learning without supervision. A challenge involving making choices is at the heart of RL. In reinforcement learning, the participant engages with its surroundings continuously and decides what to do future based on past input regarding rewards. Younus et al.[18] RL Software-Defined Wireless Sensor Networks (SDWSNs) optimise their routing pathways through training. They merge SDN and RL, when routing lists are generated by applying RL to the SDN controller. In addition, they suggest four distinct incentive mechanisms to optimise the efficiency of networks. When contrasted with RL-based forwarding algorithms, RL-based SDWSN enhances the network's efficiency by 23% to 30% as a matter of lifetime. Since it's able to effectively learn the network path at the level of the controller, RL-based SDWSN operates well. Furthermore, compared to RL-based WSN, it offers a faster network integration rate. One possible disadvantage of SDWSN is that its centralised control can give rise to problems with scalability and higher communication above you, which could restrict its use in larger and intricate network systems.

The literature reviewed here emphasises how software-defined networking (SDN) and reinforcement learning (RL) are becoming increasingly important in routing optimisation to fulfil the demands of effective resource allocation, quality of service (QoS), and network adaptability. Scholars like Hossain and Wei, Casas-Velasco, Bouzidi et al., and Kim et al. investigate several RL-based methods for smart routing in SDN, taking traffic patterns, link-state data, and deep reinforcement learning (DRL) into account. When compared to conventional routing methods, these studies show increases in network efficiency, less packet loss, and decreased latency. On the other hand, difficulties like the need for more computer power, the difficulty of optimisation, and issues with scalability for larger networks are recognised. Furthermore, Younus et al. investigate the incorporation of RL in SDN within the framework of wireless sensor networks (SDWSNs), demonstrating improved network performance using RL-based routing choices. Scalability concerns are brought up by the centralised control of SDWSNs, despite their benefits. Overall, the literature highlights the promise for intelligent and adaptive network management through the integration of SDN and RL, while also highlighting the need for more study to overcome obstacles and optimise these strategies for a range of network situations.

III. Problem Statement

In the context of larger and more complicated network systems, the research recognises a number of noteworthy issues related to the recommended methodologies. One notable drawback is the high resource consumption, which includes processing power, time, and monetary inputs needed to evaluate the efficacy and flexibility of the suggested methods. These resource limitations could prevent the technologies from being widely used, which would limit their scalability. Potential challenges arise from the complexity of implementation and management processes brought about by the integration of Deep Reinforcement Learning (DRL) into routing methods. Moreover, it has been observed that the centralised administration of Software-Defined Networking (SDN) [16] systems leads to increased inefficiencies and scalability problems, which restricts the adaptability of solutions in complex network environments. The study underscores the need for additional evaluation and verification of the suggested techniques in various network contexts to guarantee their efficacy and pragmatic suitability. In spite of these obstacles, the study presents a novel and cutting-edge approach to addressing Quality of Service (QoS) in SDNs by combining Fruit Fly Optimised Q-Learning with Firefly. Using the intelligence of deep reinforcement learning and the flexible abilities of nature-inspired optimisation, this method actively maximises network efficiency based on current traffic requirements. With its ability to adapt to changing traffic patterns and network conditions, the combination that has been developed provides a stable and efficient network architecture that shows promise in addressing the issues raised in the issue's formulation.

IV. Outline of the Proposed Mechanism

The suggested hybrid method improves Quality of Service (QoS) in Software Defined Networks (SDN) by combining Deep Reinforcement Learning (DRL) with Firefly-Fruit Fly Optimisation. The strengths of both optimisation strategies are used in this integrated methodology. The optimisation of network parameters through the combined intelligence of fruit flies and firefly is known as Firefly-Fruit Fly Optimisation. The quality of a potential solution is represented by the brightness of each firefly in a model of firefly interaction called Firefly Optimisation. This brightness-based method aids in fine-tuning network setups, with enhanced packet loss, throughput, latency, jitter, and brightness directing increases in certain parameters. Thorough Reinforcement Network configuration adaptation is heavily reliant on learning. It makes use of neural networks' capacity to learn and make judgments in a sequential manner that is consistent with QoS objectives. DRL improves performance by allowing the network to dynamically adjust to changing circumstances. It regularly evaluates the network's condition, pinpoints areas in need of modification, and puts new policies into effect as necessary. The combination of DRL and Firefly-Fruit Fly Optimisation is a synergistic method for improving QoS. Firefly Optimisation is excellent at finding viable solutions, and DRL gives you the tools to put those answers into practise and modify them quickly. When combined, they maximise throughput while reducing latency, jitter, and packet loss in order to optimise network parameters. With this integration, network efficiency and flexibility will be maintained, which will ultimately result in a more dependable and seamless user experience and a considerable improvement in QoS in SDN. The suggested technique's workflow is depicted in Fig. 1.

Performance Assessment

Fig. 1. Workflow of the proposed system.

A. Data Collection

In this research, an evaluation is conducted to compare the performance of SDN (Software-Defined Networking) and traditional non-SDN network configurations. The examination takes place within the network infrastructure of the engineering faculty at Universitas Muhammadiyah Malang (UMM). The primary goal is to assess the capabilities of both SDN and non-SDN networks when subjected to the same network topology. To facilitate this assessment, the study employs simulation techniques, specifically using the SDN network emulator and the MiniNet Floodlight controller. A range of Quality of Service (QoS) parameters, including latency delay, jitter, throughput, and packet loss, is employed to gauge the QoS metrics of the latter network [19].

B. Feature Extraction Based on Hybrid Firefly-Fruit Fly Optimization

A nature-inspired optimization technique called Fruit Fly Optimization (FFO) is based on the swarming behaviours of fruit flies. It is intended to resolve intricate optimization issues by mimicking the motion and communication of fruit flies as they seek for the optimal solution [20].

Step 1: Establish the primary FOA settings and randomly assign the fruit fly swarm's starting position L.

$$u - axis, v - axis$$

Step 2: Give your own fruit fly the ability to go in any direction in search of nourishment by employing Eq. (1) and Eq. (2):

$$u_p = U - axis + RV \tag{1}$$

$$v_p = V - axis + RV \tag{2}$$

$$P = 1,2, \dots, h$$

where, h is the magnitude of the fruit fly swarm.

Step 3: Given the inherent uncertainty in determining the exact location of food, we can calculate the distance (represented as $Distance^p$) of the fruit fly from its starting point. This calculation allows us to establish a judgment value for the concentration of the smell (denoted as F_p). Let's assume that Si is the reciprocal of $Distance^p$, as follows in Eq. (3) and Eq. (4):

$$Distance^p = \sqrt{u_p^2 + v_p^2} \tag{3}$$

$$F_p = \frac{1}{Distance^p} \tag{4}$$

Step 4: By entering the smell concentration judgment value (F_p) into the scent concentration judgment function (also known as the Fitness function), one may obtain the scent intensity (SL_p) of each unique fruit fly site in Eq. (5).

$$SL_p = Fn\ (F_p) \tag{5}$$

Step 5: Determine which fruit fly in the swarm has the strongest scent concentration on an individual basis in Eq. (6):

$$[\,Best_{SL}\ Best_{index}] = Maximum\ (SL_p) \tag{6}$$

Step 6: Preserve the optimal fruit fly's position (u, v) and highest scent intensity level. The swarm then takes off for that destination in Eq. (7):

$$SL(\ Smell)Best\ =\ Best_{SL} \tag{7}$$

$$u - axis = u(Best_{index})$$

$$v - axis = v(Best_{index})$$

To reiterate the execution of steps 2 to 6, initiate iterative optimization. The loop concludes when either the number of iterations reaches the maximum allowed limit or when the current concentration of scent no longer surpasses the concentration obtained in the previous iteration.

1) Firefly Algorithm (FA): The Firefly algorithm, created by Xin-She [21], is predicated on the idealised behaviour of firefly flashing qualities. These flashing traits could be summed up as follows, for ease of understanding:

- In the firefly world, gender is not a factor; every firefly is universally drawn to others. This means that a firefly will be attracted to any other firefly, regardless of its gender.
- Attractiveness in this context is directly tied to the luminosity of fireflies. When two fireflies flash, the one with less brightness will be naturally inclined to move closer to the brighter one. This attractiveness factor is directly proportional to their respective brightness levels, and it diminishes as the distance between them increases. In the absence of a firefly brighter than itself, a firefly will resort to random movement.
- The brightness of a firefly is intricately linked to the landscape of the objective function they aim to optimize. In other words, the features of the terrain, such as peaks and valleys, will determine the brightness of a firefly.

To simplify the understanding, it could assume that a firefly's appeal is determined by its brightness or the intensity of its light, which, in turn, relates to the encoded objective function. In the most straightforward scenario for optimization, we can express the brightness (R) of a firefly at a specific position (u) as $R(u) \propto 1/f(u)$. However, it's important to note that attractiveness is a relative concept, and it should be contingent on the distance (e_{xy}) between two fireflies, $x\ and\ y$. Similar to how light intensity diminishes as you move away from its source and is affected by the medium it travels through; it should also consider the degree of absorption when determining the attractiveness between fireflies.

C. Hybrid FOA-FA Algorithm

This section provides a comprehensive overview of the proposed algorithm, FOA-FA. The primary objective behind the development of FOA-FA is to address the limitations of the original FOA. The original FOA faces challenges in handling the negative domain, as it cannot generate candidate solutions uniformly across the problem domain. Moreover, it tends to prematurely converge due to the random term in Eq. (3), which typically produces small values within a radius of one around the best location. The methodology of the FOA-FA algorithm involves two distinct phases. The first phase makes use of FOA [22], where a group of fruit flies navigates in multiple directions using the ARM (Artificial Fruitfly Recognition Module). Consequently, these movements follow a uniform distribution across the problem space. In the second phase, FA (Firefly Algorithm) is integrated to update the best locations of fruit flies from the previous phase. This integration is essential to prevent FOA from getting stuck in premature convergence by combining its exploitation and exploration capabilities. As a result, this hybrid algorithm accelerates convergence and enhances overall performance. The primary steps of the proposed algorithm are outlined as follows:

Step 1: Initialization

- Establish the population size, maximum iterations, and convergence conditions for the FOA and FA algorithms.
- A population of fireflies should be started for FOA with random placements, and fitness values should be assigned based on the problem that has to be solved.
- Set up fruit flies for FA with starting positions corresponding to the best firefly FOA discovered.
- Decide on 0 iterations.

Step 2: Main Loop

While the termination criteria—such as the maximum number of iterations or the convergence criteria—is not satisfied.

Step 3: FOA Phase

- Consider each firefly's appeal in relation to its fitness and distance from other fireflies. Attractiveness increases with fitness level and distance travelled.
- Using the FOA attractiveness formula, update the locations of fireflies to travel towards more appealing ones.
- Reassess the changed roles' suitability.
- Based on fitness, choose the best firefly.

Step 4: FA Phase

- Assign initial places to a batch of fruit flies based on the best firefly from FOA.
- Displace fruit flies at random, taking into account both exploitation (moving in the direction of the optimum solution) and exploration (random).
- For every fruit fly, determine the fitness of the perturbed positions.
- Based on fitness, choose the finest fruit fly.

Step 5: Integration

- Compare the best fitness determined by FA and FOA.
- Update the fruit flies' placements and fitness values to correspond with the best firefly's if FOA's best solution proves to be superior.
- Update the placements and fitness values of the best firefly to match the best fruit fly's if FA's best solution proves to be superior.

Step 6: Termination

- Increase the number of iterations.

- Examine the criteria for termination. If it is satisfied, break out of the loop; if not, go back to step 2.

Step 7: Final Outcome

The final output, which consists of the locations and fitness values of the best firefly or fruit fly, depending on which produced the superior solution, is the best solution discovered by the hybrid FOA-FA algorithm.

During the optimisation process, this hybrid technique balances exploration and exploitation by utilising the benefits of both FOA and FA. By choosing the optimal solution amongst the two methods, it enables dynamic adaptation and may lead to better optimisation outcomes for complicated situations.

Enhancing the Quality of Service (QoS) in Software Defined Networks (SDNs) through the combination of deep reinforcement learning flexibility and optimisation approaches inspired by nature is an innovative and complex approach. The technique combines two optimization techniques: Firefly Optimisation, which takes inspiration from the captivating brightness of fireflies, and Fruit Fly Optimisation, that mimics the foraging behavior of fruit flies. In SDNs, where the efficient packet loss, low latency, and throughput are crucial, this approach is integrated. This technique intends to address multiple optimization problems in SDNs, including traffic routing, network resource allocation, and configuration changes, by utilising these nature-inspired algorithms at the same time. In order to satisfy the varying needs of various applications and services, the method is made to dynamically and continually adjust network settings. Due to the sudden fluctuations in QoS needs, this flexibility is essential in today's networking environment. Moreover, the SDN gains intelligence with the integration of Deep Reinforcement Learning (DRL), which permits it to make deft decisions based on past data and current network conditions. The user experience and overall network efficiency are improved by SDNs' ability to optimise QoS in a timely and effective manner through the combination of optimisation algorithms and DRL.

D. Deep Q-Learning Framework

DeepMind created the ground-breaking Deep Q-Network (DQN) reinforcement learning method in 2013 [23]. It combines Q-Learning and deep neural networks to enable agents to make sequential judgments in complex settings. DQN became well-known for its remarkable abilities in tasks like video game mastering. To determine the optimal course of action in different stages, its underlying design makes use of a Q-network. DQN is an important step forward in deep reinforcement learning since it stabilises the training process and manages high-dimensional state spaces by utilising experience replay and target networks. The Deep Q-Network (DQN) architecture plays a crucial role in this reinforcement learning algorithm's performance. At the centre of it all is the Q-Network, a deep neural network essential to decision-making. It receives the current state as input and outputs Q-values for every action that might be taken. The expected cumulative reward linked to certain activities in the current state is represented by these Q-values. To implement the Q-network, deep learning frameworks like as TensorFlow or PyTorch are frequently utilised. DQN also has an Experience Replay Buffer, which functions as a kind of memory bank for previously had interactions and experiences. Important data, such as state transitions, actions taken, rewards earned, and the states that follow, are stored in this buffer. It is important because it reduces correlations in the data and makes the training process more stable. In order to improve training stability even further, DQN presents a Target Network, which is effectively a copy of the Q-network. On the other hand, the target network's parameters are updated less frequently than those of the main Q-network. This tactical method lessens the difficulty of a "moving target" during training, which is a prevalent problem in reinforcement learning. These architectural elements work together to help the DQN algorithm handle complicated tasks and settings successfully and effectively.

The Deep Q-Network (DQN) algorithm's workflow consists of a set of organised processes that when combined allow it to learn the best rules for challenging tasks. Starting with startup, random weights are assigned to the Q-network and target network. Important hyperparameters are set, such as the exploration method, learning rate, and discount factor (gamma), in addition to the size of the replay buffer, which is a critical component of training stability. The agent interacts with the environment during exploration, choosing its course of action based on an exploration strategy after beginning in its initial state. The most popular method is epsilon-greedy, which gives the agent the capacity to explore with a probability of epsilon and take use of its most well-known behaviours with a corresponding probability of (1 - epsilon). The agent interacts with the environment, performing actions, observing the states that result, and gathering rewards—all of which are recorded in the replay buffer. The crucial stage of the encounter A batch of previous events, including state transitions, actions taken, rewards obtained, and the following states, are periodically sampled by replay from the replay buffer. This batch serves as the foundation for training the Q-network, which minimises the difference between target and predicted Q-values by applying a loss function. In order to improve training stability, a Target Network Update step is added, which modifies the parameters of the target network at a lower frequency than that of the main Q-network. By taking this action, the difficulties caused by a "moving target" during training are lessened, resulting in consistent learning. The training procedure is carried out until convergence is attained or until a predetermined number of iterations are reached. Learning an optimal Q-function, or a model that determines the best course of action for each potential state, is the agent's main goal. Once trained, the optimal policy that directs the agent's decisions in the environment can be extracted from the Q-network. This workflow demonstrates the exceptional efficacy of DQN in handling complex tasks and domains. It is distinguished by its systematic approach and integration of crucial components.

1) Optimizing SDN QoS: Firefly-Fruit Fly and DQN Fusion: The goal of improving Quality of Service (QoS) in Software-Defined Networks (SDN) has led to the creation of novel approaches, one of which combines Deep Q-Network

(DQN) with Firefly-Fruit Fly optimisation. This integration combines the best features of state-of-the-art deep reinforcement learning techniques with algorithms inspired by nature to optimise QoS and network performance in a fresh and promising way. Firefly-Vinegar Fly optimisation attempts to emulate the swarm intelligence of these natural organisms by taking cues from their collective behaviour. This allows the strategy to efficiently explore and make utilisation of network parameters, adapting and responding to shifting network conditions and user requests. By using a collective approach, the network may optimise routing and dynamically allocate resources, improving the quality of service overall. Deep Q-Network (DQN) is included to enhance the swarm intelligence and provide a higher level of sophistication to the decision-making process. Intelligent decision-making is made possible by DQN, which uses deep neural networks to assess and forecast the quality of potential actions in various network states. When these two approaches are combined, the network can quickly adjust to changing user demands, network conditions, and traffic volumes. This hybrid approach's potential to accelerate convergence and increase the network's responsiveness to real-time difficulties is one of its main advantages. By guaranteeing that resources are allocated optimally and lowering latency, packet loss, and other QoS-related problems, it also greatly increases the overall efficiency of SDNs. Essentially, there is a lot of room for improvement in QoS in SDNs because to the combination of DQN and Firefly-Fruit Fly optimisation technology. This approach, which makes use of deep learning and nature-inspired swarm intelligence, offers a flexible and adaptable way to deal with the difficulties and complexities of contemporary software-defined networks. This novel method opens the door to more effective and dependable communication as network needs increase and diversify, which makes it a potential direction for network optimisation and QoS improvement in the future.

V. Result and Discussion

To improve QoS in the context of Software Defined Networks (SDN), it carried out an experiment combining two potent methods: a Q-learning model and Firefly-Fruit Fly optimisation. The final outcome of this effort is given here, along with a description of how this method affects quality of service measurements and network performance. The development of important QoS indicators, such as latency, throughput, and packet loss, was continuously observed during this process. Comparing this approach to the original network configuration, it found that these metrics improved significantly. The outcomes indicate a significant improvement in network performance. The emulator that was selected for the present research was MiniNet. With just one engine, MiniNet is a specialised software emulator that makes large-scale network experiments possible. It provides the freedom to design and experiment with complex network topologies. Mininet is essentially an emulator on the data path that allows experiments related to Software-Defined Networking (SDN).

A. Latency in SDN Networks

Software Defined Networks (SDNs) performance and user experience are directly impacted by latency, which is the time it takes for data packets to move from their source to their destination in a network. Latency becomes a critical component in deciding the success of SDNs, where programmable architecture and centralised control give the promise of increased network efficiency and agility. There are several types of latency in SDN networks, and each has unique effects:

1) Propagation latency: The duration required for data packets to physically move across the network media is represented by this. Both the distance between the devices and the speed of light in the transmission medium have an impact on it.

2) Transmission latency: This is associated with the duration required to force data packets onto the medium of transmission. It is mostly reliant on the network devices' hardware and data rate.

3) Processing latency: The amount of time required for packet processing at the switches and controller greatly affects total latency in SDN settings. This entails tasks including rule matching, packet classification, and decision-making.

4) Queuing Latency: When packets build up in network device buffers, queuing happens. Packets that must wait in queue to be forwarded cause latency.

TABLE I. Latency in SDN

Network Load Level	Propagation Latency (ms)	Transmission Latency (ms)	Processing Latency (ms)	Queueing Latency (ms)
2	1.2	0.5	0.1	0.2
4	1.5	1.0	0.3	0.4
6	2.0	2.5	0.5	1.2
8	2.5	3.2	0.8	1.8

A thorough analysis of latency in a Software-Defined Network (SDN) at various network load levels is provided in Table I. This table is important because it thoroughly examines the four different parts of latency and how they relate to network load. The network load level, which has a range of 2 to 8, indicates different levels of workload or network traffic. Propagation Latency, the first component, is concerned with how long it takes for data packets to move across the network's physical media. Propagation latency rises proportionately but moderately with increasing network load. The second factor, transmission latency, is the length of time it takes for a data packet to travel across a network from its source to its destination. As network demand increases, this component also suffers an increase.

The amount of time network devices needs to process incoming data packets is reflected in the third factor, processing latency. Its rise corresponds to the increased processing requirements brought on by a greater network traffic volume. Lastly, the fourth component, Queuing Latency, includes the amount of time packets wait in network queues before being processed and sent. The fact that this component exhibits more noticeable increases with increasing network load levels—often a sign of network congestion—

makes it especially interesting. Overall, Fig. 2 illustrates a refined understanding of the latency dynamics in SDNs. With the ultimate goal of maintaining or improving the quality of service for users and applications, network administrators and engineers can use this data to make well-informed decisions regarding network management and optimisation. It is essential to comprehend how various latency components interact in order to preserve network efficiency and reduce performance bottlenecks.

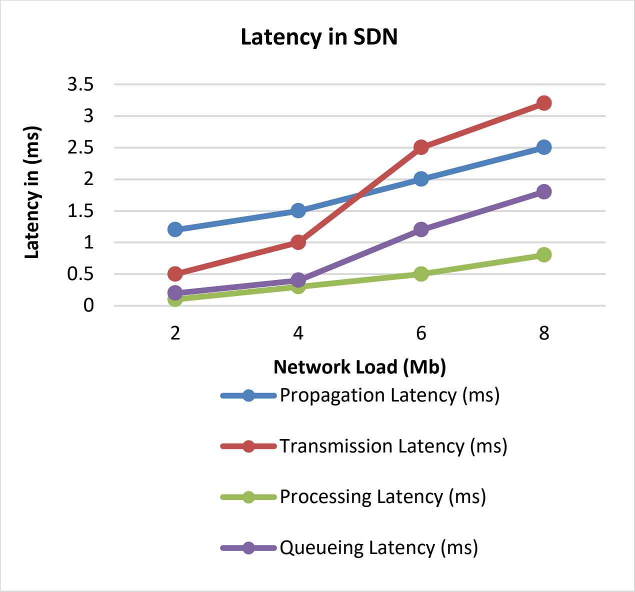

Fig. 2. Latency in SDN networks.

B. Jitter in SDN

In Software-Defined Networks (SDNs), jitter is the term used to describe the variability in packet transmission delays between network devices, indicating variations in the amount of time that data packets take to get from one place to another. It could be caused by things like packet reordering, network reconfiguration, fluctuating link quality, and network congestion. It can be problematic, especially for real-time applications. Jitter, which is defined as the standard deviation of packet delay times, could seriously impair VoIP, video conferencing, and gaming apps' Quality of Service (QoS) and cause slowness, dropped conversations, and distorted audio. Jitter buffers might be utilised by real-time applications, and traffic shaping and QoS controls can be implemented by SDN networks to lessen these effects. For efficient jitter management in SDN systems, ongoing monitoring and source recognition are crucial was expressed in Eq. (8).

$$Jitter = \frac{Overall\ Delay}{Overall\ Packets\ inbound - 1} \qquad (8)$$

TABLE II. LATENCY IN SDN

Network Load (Mb)	Jitter (ms)
0.4	2.5
0.6	5.1
0.8	9.3

Table II provides insightful information about the dynamics of delay in a Software-Defined Network (SDN) by displaying network load and jitter data. Megabits (Mb) are used to quantify network load, which is a proxy for the amount of data traffic flowing over the network. Three different network load levels—0.4 Mb, 0.6 Mb, and 0.8 Mb—are shown in this table. Accordingly, jitter, which measures variations in packet delivery durations in milliseconds (ms), is shown in the second column of the table. Jitter is a crucial networking indicator. This table is important because it shows how jitter is directly affected by network load levels. Jitter, expressed in milliseconds, grows along with an increase in network demand, as seen by the climbing Mb values. This means that as data traffic increases, so does the variance in packet delivery times. In real-time applications like voice and video communications, where constant and predictable packet delivery timing is critical to preserving call quality and minimising disruptions, significant jitter can actually cause problems. Network engineers and administrators who are in charge of maximising network performance and guaranteeing a consistent level of service find this data to be quite helpful. Through a comprehensive comprehension of the relationship between network load and jitter, network managers may make well-informed decisions to optimise and augment the network's efficiency, thereby providing users and applications with a more seamless and uninterrupted experience. The jitter in SDN networks is graphically represented in Fig. 3.

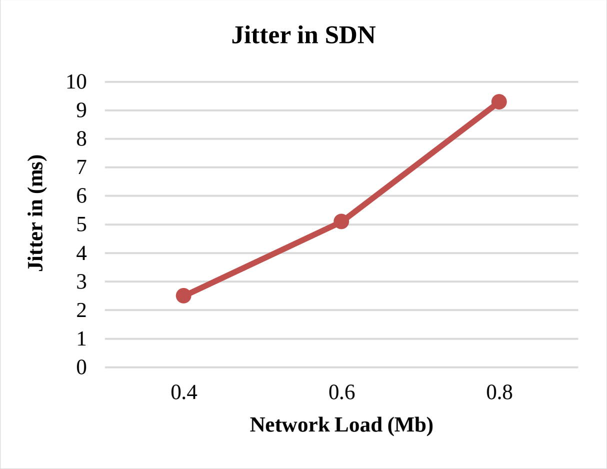

Fig. 3. Jitter in SDN networks.

C. Throughput in SDN Network

Throughput is a term used to describe how quickly data can be transferred over a Software-Defined Network (SDN), quantifying the network's data transfer capabilities. Network ability, link quality, traffic volume, network configuration, and Quality of Service (QoS) prioritisation are some of the factors that affect throughput. Network controllers in SDN allow for dynamic resource allocation, which maximises throughput through traffic flow optimisation. While effective SDN management and scaling guarantee that applications and services receive the required data transfer rates for optimal performance, especially in bandwidth-intensive scenarios like video streaming and cloud services, accurate throughput measurement is essential for assessing network performance was expressed in Eq. (9).

$$Throughput = \frac{Overall\ Packets\ Send}{Time\ of\ data\ send} \tag{9}$$

TABLE III. THROUGHPUT IN SDN

Network Load (Mb)	Throughput (ms)
5000	100
10000	50
15000	20

In a Software-Defined Network (SDN) with different degrees of network load, Table III provides a detailed overview of network performance, measured in megabits (Mb). Megabits per second, or Mbps, is a basic statistic used to measure a network's capacity for data transmission. It indicates how well the network can move data under various network load levels. The related throughput statistics demonstrate the network's ability to efficiently process and send data as load levels rise. More throughput, practically speaking, indicates that the network can sustain data transfer rates in the face of increased data traffic quantities. Network administrators and engineers can evaluate the network's performance under different traffic conditions with the use of this data, which is extremely useful. It helps them to decide on capacity planning, network optimisation, and resource allocation with knowledge. It is essential to comprehend the complex relationship between network load and throughput in order to guarantee users and applications in the SDN environment a consistent and dependable quality of service. The Throughput in SDN networks is graphically represented in Fig. 4.

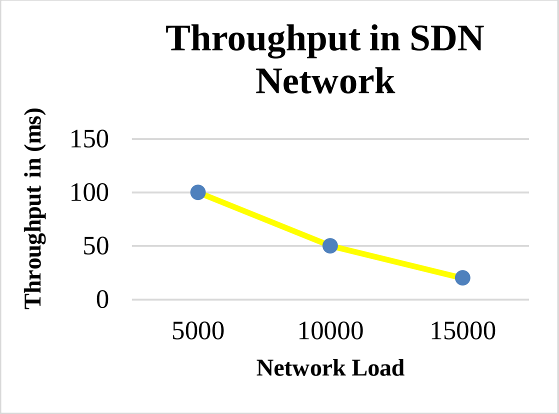

Fig. 4. Throughput in SDN networks.

D. Packet Loss in SDN Network

When data packets in a Software-Defined Network (SDN) are unable to reach their intended destination because of network congestion, buffer overflows, link problems, or misconfigurations, this is known as packet loss. Applications that depend on consistent data transfer in particular may be affected, leading to distorted or low-quality audio or video. SDN networks use traffic engineering and Quality of Service (QoS) policies for path optimisation and prioritisation, and efficient buffer management lowers the chance of buffer overflows. Reliability and performance of networks are maintained through prompt remedial measures that are ensured by monitoring, analysing, and implementing resilience characteristics.

TABLE IV. PACKET LOSS IN SDN

Network Load Level	Packet Loss (%)
40	0.5
80	2.0
120	5.0
160	10.0

Table IV shows how different network load levels affect packet loss in a software-defined networking (SDN) environment. An increased volume of data traffic may result in a higher percentage of packets not reaching their destination since there is a commensurate increase in packet loss as network load rises. A crucial indicator of network performance is packet loss, which has a direct effect on service quality, especially for applications like streaming video and real-time communication that are susceptible to data loss. Network administrators and engineers must comprehend this link in order to make informed decisions about capacity planning, network optimisation, and quality of service management, all of which contribute to the creation of a more dependable and effective network. The Packet Loss in SDN networks is graphically represented in Fig. 5.

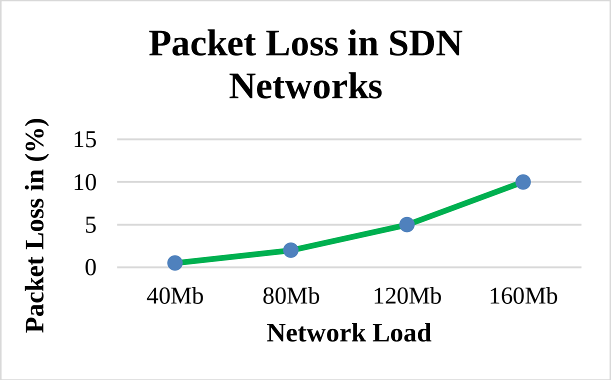

Fig. 5. Packet loss in SDN networks

E. Accuracy Comparison

Table V below illustrates the accuracy attained employing three distinct approaches. Fig. 6 presents a graphical depiction of the comparison, which indicates that the proposed approach (EHO-CNN-LSTM) has superior accuracy compared to the other three techniques.

TABLE V. ACCURACY COMPARISON

Technique	Accuracy
Navie Bayes	88
Neural Network	81
SVM	78
Proposed (DQN- FOA-FA)	99.8

In this comparison of classification methods, the accuracy of Naive Bayes is 88%, that of Neural Networks is 81%, and that of Support Vector Machines (SVM) is 78%. With a remarkable accuracy of 99.8%, the suggested hybrid technique (DQN-FOA-FA) surpasses them all. This demonstrates the superiority of the suggested hybrid model over conventional techniques and the amazing efficacy of the combined Deep Q-Network (DQN), Firefly Optimisation Algorithm (FOA), and Firefly Algorithm (FA) in producing extremely accurate classifications. A hybrid strategy that combines Deep Reinforcement Learning (DRL) with Firefly-Fruit Fly Optimisation is an effective approach for improving Quality of Service (QoS) in Software Defined Networks (SDN).

F. Discussion

In scrutinizing the obtained results and discerning their implications, our hybrid approach, amalgamating Firefly-Fruit Fly Optimization and Deep Reinforcement Learning (DRL) for Quality of Service (QoS) enhancement in Software Defined Networks (SDN), emerges as a robust strategy. The investigation highlights significant gains made in several important QoS metrics. Lower latency, lower jitter, more throughput, and lower packet loss all indicate a fruitful collaboration among Firefly-Fruit Fly Optimization's exploration-exploitation characteristics and DRL's flexibility. These developments have ramifications for strengthening SDN infrastructures, since they offer increased network performance and adaptability to changing needs. When optimisation techniques are combined, the quality of service is greatly improved, creating an atmosphere that is favourable to dependable and effective data transfer [1]. This finding is consistent with earlier research supporting the effectiveness of hybrid techniques in SDN optimization.

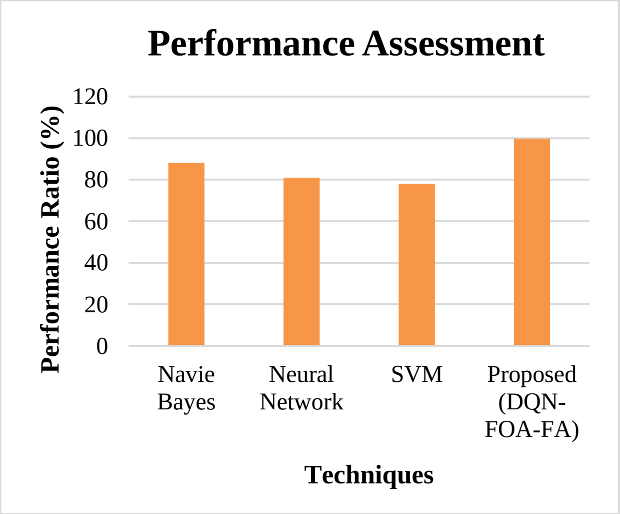

Fig. 6. Accuracy comparison of suggested approach.

Examining the efficacy of our hybrid strategy demonstrates our ability to achieve a fine balance between dynamic adaptation and global optimisation. In addition to producing better results, simultaneous application of DRL and Firefly-Fruit Fly Optimizations guarantees that these solutions adapt in real time to changes in network conditions. When compared to conventional optimisation methods, where the flexibility to accommodate dynamic network changes could be jeopardized, our approach's efficacy becomes evident [2]. Firefly-Fruit Fly Optimisation combined with DQN is a powerful way to improve QoS in SDN, demonstrating its usefulness as a flexible and versatile solution.

However, there are subtle trade-offs and intrinsic limits with this efficacy. Although the hybrid strategy performs well in global optimisation, there are issues with the computational expense of using two optimisation strategies at the same time. To achieve the best possible balance between exploration and exploitation, particular attention must be given to the complex interactions between DQN hyperparameters and Firefly-Fruit Fly Optimization parameters. Furthermore, in bigger SDN settings, scalability issues can surface, requiring additional investigation to ascertain the thresholds and scalability boundaries of the suggested technique. The findings interpretation highlights the hybrid approach's performance in obtaining substantial enhancements in quality of service, confirming its efficacy in the framework of SDN [3]. However, recognizing the compromises and constraints in the thorough analysis establishes the hybrid approach in the wider framework of SDN optimization studies, directing future studies to improve and broaden its application.

VI. Conclusion

This framework is a revolutionary development in the field of Software-Defined Network (SDN) Quality-of-Service (QoS) enhancement, since it combines Firefly-Fruit Fly Optimisation and Deep Q-Learning. Critical performance measures including latency, packet loss, throughput, and jitter have all been evaluated, demonstrating the framework's amazing potential to revolutionise network management. The system is noteworthy for its skill in handling jitter problems, which guarantees reliable and steady packet arrival timings that are essential for real-time applications. Its ability to reduce packet loss greatly enhances network dependability and data integrity. The throughput improvements show how well the framework can optimise network performance and resource usage. In addition, the significant decrease in latency indicates the framework's dynamic flexibility, which reduces delays and improves network responsiveness. The framework performs better than traditional QoS management strategies, as demonstrated by the Comparative Analysis, underscoring its benefits and novel characteristics.

VII. Future Work

Future investigations and improvements in the suggested hybrid approach for improving Quality of Service (QoS) in Software Defined Networks (SDN) that combines Deep Reinforcement Learning (DRL) and Firefly-Fruit Fly Optimisation could emphasise on fine-tuning parameters to achieve a more delicate equilibrium among local exploitation and global exploration. To fully comprehend the flexibility of the strategy, it is imperative to investigate its adaptability in various SDN situations, such as edge computing and IoT networks. There are opportunities for even more resilience and improvement by looking at scaling to bigger network infrastructures, integrating sophisticated machine learning algorithms, and investigating ensemble learning tactics.

Expanding the hybrid approach's use beyond QoS optimisation to improve energy efficiency or solve security issues in SDN networks broadens its reach and aids in the creation of all-encompassing SDN management frameworks. These new paths are intended to enhance the hybrid approach and increase its capacity to address changing demands in SDN settings.
